> Wound will heal by May 1, as evidenced by a progressive decrease in the size of the wound, a decrease in drainage from the wound, improvement in the condition of the surrounding skin, and no evidence of infection (erythema, purulent drainage, or odor).

PLANNING INTERVENTIONS/IMPLEMENTATION

For NIC standardized interventions for skin and tissue integrity problems,

Go to Chapter 35, **Standardized Language, Selected Standardized Outcomes and Interventions for Skin and Wound Diagnoses,** in Volume 2.

Specific nursing activities directed at maintaining skin integrity or healing wounds focus on preventing and treating pressure ulcers and other chronic wounds, providing wound care, and applying heat and cold therapies. In the next section, we discuss these nursing therapeutic measures.

Interventions for Example Problem: Pressure Ulcers?

Pressure ulcers are extremely difficult and time-consuming to treat. As a result, prevention is the most important nursing intervention. Healthy People 2020 proposed two public health objectives focused on pressure-related skin injury: 1) to reduce the proportion of nursing home residents with a current diagnosis of pressure ulcers, and 2) to reduce the rate of pressure ulcer-related hospitalizations among older adults (U.S. Department of Health and Human Services, 2010, updated 2013). The ICSI (2012) has made preventing pressure ulcers one of 12 goals in its 5 Million Lives Campaign. Institute for Healthcare Improvement (IHI) recommended the six crucial elements in preventing pressure ulcers discussed in the following sections (IHI, 2011).

Conduct a Pressure Ulcer Admission Assessment for All Patients

Most agencies use a standardized risk assessment, such as the Braden and Norton scales, to assess the risk of pressure ulcers (see the previous section, Assessment).

You should use these scales to assess every patient on admission to any type of facility (hospital, nursing home, or with home health care). Risk factors found in addition those on the scales will place your patient at even higher risk. Examples include age, fever, incontinence, immobility, hypotension, and poor dietary intake, edema.

Reassess Risk for All Patients Daily

Reassess your hospitalized patient for risk daily because his condition can change frequently and rapidly. Any time your patient's condition changes or he is transferred to another unit, reassess his risk. Monitor a nursing home resident weekly for the first 4 weeks, then quarterly or whenever the patient's condition changes or deteriorates. Reassess home patients at every visit (WOCNS, 2007, revised 2011).

Once a patient is identified as being at risk for developing pressure ulcers, prevention strategies can be implemented. Inform all members of the healthcare team (i.e., physical therapists, transporters, physicians, dietitians) of at-risk patients. Using visual cues, such as stickers on charts or dots on ID bands, can help remind staff.

Inspect Skin Daily

Skin care begins with regular inspection of the skin—at least daily for patients at risk—and usually every 8 to 12 hours for institutionalized patients. You must have adequate light to detect subtle, early skin changes. Use a penlight to inspect bony prominences if direct sunlight is not available. Be sure to check pressure points for erythema, tenderness, or edema. Instruct family members and caregivers about the importance of early detection of skin problems. In obese patients, skin damage can occur under breasts, under abdominal folds, between thighs, or anywhere skin is in contact with skin.

Manage Moisture

Excess moisture creates a risk for skin breakdown. Use the following nursing actions to help you manage moisture:

Incontinence Care Check the patient at regular intervals (e.g., when turned) and provide skin care as soon as possible after each incontinent episode. Apply incontinence or moisture barrier creams to protect perineal skin from urine and stool (WOCNS, 2010). Wipes and spray skin protectant products are comparable in preventing moisture-related skin breakdown. Wipes are more cost effective during hospitalization; however, the spray product preserves skin integrity over a longer period of time, beyond average hospitalization duration (Brunner, Droegemueller, Rivers, et al., 2012). Use undergarments or products that wick moisture away from the skin. For persistent bowel incontinence, consider using a pouching system or fecal containment device to contain protect the skin from the effluent (National Guideline Clearinghouse [NGC], 2006, revised 2014).

Bathing Soaps and bathing techniques can contribute to skin breakdown, so be careful to keep the skin clean and intact. Diaphoretic (sweaty) patients may need frequent bathing, as sweat can be irritating to sensitive or injury-prone skin. Older adults most likely will not need daily bathing because they experience decreased oil and sweat production. Use warm, distilled or filtered water—not hot. Hot water dries the skin, especially for older adults. Gently bathe fragile skin, using a minimum of force and friction; washcloths can be abrasive. Use a mild, emollient cleansing soap only if needed and not routinely. Be sure to rinse thoroughly and gently pat the skin dry. Soaps are drying to the skin because they remove skin oils and may interfere with the ability of the skin to hold water (Ayello & Sibbald, 2012, updated; Joanna Briggs Institute, 2007).

Lotion and Massage If the patient's skin is dry, apply a moisturizing lotion using a gentle massaging motion to promote circulation and wound healing.

Do not massage over bony prominences, as this can irritate the area and lead to tissue injury (NPUAP, 2007; National Guideline Clearinghouse [NGC], 2006, revised 2014).

Linens Keep the linens soft, clean, dry, and free from wrinkles by changing or straightening them frequently. Moisture and wrinkles in the sheets can damage skin integrity.

Optimize Nutrition and Hydration

Nutrition is vital to skin integrity. Patients with rapid weight loss, high metabolic demands, limited intake, or decreased serum albumin levels are particularly at risk for pressure ulcer development. Monitor hydration status and offer water (if appropriate) whenever you reposition the patient. Patients at risk and those with pressure ulcers should take 1 mL of fluid with every kcal consumed per day (National Guideline Clearinghouse [NGC], 2006, revised 2014).

Carefully review the diet ordered for at-risk patients, and assess what the patient is eating. The diet may need to be modified to achieve adequate calorie and protein intake. Protein requirements are 1.25 to 1.5 grams per kilogram of body weight per day (National Guideline Clearinghouse [NGC], 2006, revised 2014) or may be as high as 2 g/kg/day for deeper pressure ulcers or multiple wound sites, so high-protein supplements are often prescribed (Collins & Schnitzer, 2013). Individuals with nutritional and pressure ulcer risks require 30 to 35 kcal per kilogram of body weight per day (NGC, 2006, revised 2011).

Consider the consistency of the diet as well. A soft diet may be helpful for a patient who is frail or is missing teeth. Tube feeding or parenteral nutrition may be prescribed to supplement oral intake if the patient is unable to consume adequate quantities of calories and protein. You may need to make a dietary referral.

Minimize Pressure

Most patients who are at risk for pressure ulcers have mobility problems. As a result, you must provide frequent position changes. This is one of the most important interventions for preventing pressure ulcers. You may delegate turning and position changes to the NAP. Turning and movement prevent tissue damage from ischemia, thereby preventing pressure ulcers (Joanna Briggs Institute, 2008a, 2008b).

Turning and Repositioning Reposition the patient at least every 2 hours (Armstrong, Ayello, Capitulo, et al., 2008; Bergstrom, Bennett, Carlson, et al., 1994; NPUAP, 2007; WOCNS, 2010). However, patients with very fragile skin or little subcutaneous tissue might need to be repositioned more frequently. At-risk individuals who are chair bound should be repositioned every hour or taught to shift their weight every 15 minutes. Place a turning schedule at the bedside so that all caregivers can participate in the prevention strategy. For an example of a patient turning schedule,

Go to Chapter 35, **Tables, Boxes, Figures: ESG Box 35-2, Scheduled Position Changes,** on Davis*Plus*.

Use the Rule of 30 to guide your positioning: Elevate the head of the bed 30° or less, and when the patient is on her side, position the patient at a 30° angle to avoid direct pressure on the trochanter. If the head of the bed is elevated more than 30°, limit the time in this position to minimize pressure and shear (NPUAP, 2007).

To protect skin during turning or repositioning, use lift devices or draw sheets, heel and elbow protectors, or sleeves and stockings. Never drag a patient when pulling her up in bed. Use a minimum of two people when moving patients in bed National Guideline Clearinghouse [NGC], 2006, revised 2014).

Support Surfaces Various support surfaces are available for preventing and treating pressure ulcers. They do so by redistributing pressure and controlling moisture to prevent bacterial growth on the skin (microclimate between the skin and the surface of the bed). Support surfaces for redistributing pressure include specialty mattresses, and alternating and dynamic bed systems. These products may consist of static air, alternating air, gel, foam, or fluid, and are available in several sizes and shapes for beds, chairs, exam tables, and operating room tables (Fig. 35-10). Limit the number of linen layers between the treatment support surface and patient (ICSI, 2012).

Any patient at risk should be placed on a pressure-redistributing device. People lying on ordinary foam mattresses are more likely to get pressure ulcers than those lying on a higher-specification foam mattress (McInnes, Jammali-Blasi, Bell-Sye, et al., 2011). Support surfaces alone will not prevent skin breakdown but should be coupled with effective turning and positioning schedules (NPUAP, EPUAP, 2009).

Protect heels by using products that completely raise the heels off the bed (ICSI, 2012). Pillows may not be enough to redistribute the weight of your patient's foot. Pressure redistributing devices are also made for chairs and wheelchairs. Donut-type devices, bunny boots, rigid splint, IV bags, rolled towels or sheet, and sheepskin should not be used (NPUAP, 2007; WOCNS, 2010; National Guideline Clearinghouse [NGC], 2006, revised 2014).

To see a decision-making tree developed by the AHRQ to guide selection of appropriate support surfaces,

Go to Chapter 35, **Tables, Boxes, Figures: ESG Figure 35-2: Decision Tree Guiding Selection of Appropriate Support Surfaces,** on Davis*Plus*.

What Are Adjunctive Wound Care Therapies?

The use of adjunctive therapies is the fastest growing area in pressure-related wound management. Nurses apply adjunctive therapies that include negative pressure wound therapy, electrical stimulation, hyperbaric oxygen, radiant heat, tissue growth factors, ultrasound, bioengineered skin equivalents, and surgical options.

- **Negative Pressure Wound Therapy.** Negative pressure wound therapy (NPWT) promotes healing by secondary and tertiary intention. Using a specialized pump, negative pressure is placed on a wound packed with foam or gauze dressings to create a vacuum. The subatmospheric pressure improves wound healing by reducing the edema in swollen tissues; promoting granulation tissue formation; and removing exudate and infectious material. Negative pressure promotes granulation tissue formation by "stretching" cells and stimulating blood vessel growth and wound perfusion. The Highlights of Procedures box summarizes this procedure. For complete guidelines,

Go to Chapter 35, **Procedure 35-6: Applying a Negative Pressure Wound Therapy (NPWT) Device,** in Volume 2.

- **Silver Dressing.** Silver-coated dressings or silver-based cream may act as a barrier to bacterial penetration in the wound bed. Silver may eradicate biofilms of colonized bacteria.

Go to Chapter 35, **Tables, Boxes, Figures: ESG Table 35-1: Silver Dressings Used in Chronic Wound Management,** on Davis*Plus*.

- **Electrical Stimulation.** Electrical currents are transferred across tissues to aid in chronic wound healing.

Electrodes are placed around the wound bed and connected to a machine that produces an electrical impulse. This therapy stimulates cellular growth through development of fibroblasts, new collagen, and increased blood flow and tissue oxygenation.

- **Hyperbaric Oxygen Therapy.** Hyperbaric oxygen therapy (HBOT) is the administration of 100% oxygen under pressure. HBOT increases oxygen concentration in the tissue, stimulates the growth of new blood vessels, and enhances white blood cell (WBC) action.
- **Tissue Growth Factors.** Tissue growth factors are proteins that occur naturally in the body and cause specific cells to grow and replicate. Platelet-derived growth factor has been used in chronic wound healing. It is indicated for diabetic and other nonhealing wounds that are free of necrotic tissue and have good vascularity.
- **Ultrasound.** Another adjunctive therapy used in chronic wound healing is ultrasound. Sound waves are emitted by a control unit and handheld sound head or transducer. Vibrations from the transducer create sound waves that pass into the tissue, causing it to vibrate and heat up. This stimulates movement of fluid within and between cells and aids in debridement and increased cell metabolism.
- **Bioengineered Skin Substitutes.** This is a group of substances that aids in the temporary or permanent closure of wounds. Substitutes may be actual human epidermis or dermis from organ donation, animal cells, or synthetic material. They can be used to treat partial- and full-thickness wounds.
- **Surgical Options.** Complicated wounds require the use of surgical options, such as extensive debridement, skin grafts, secondary closure of the wound, and **flap techniques** (partially detached and rotated tissue placed over a wound to fill in the deficit).

- What nursing diagnosis is most appropriate for a patient at risk for pressure ulcer development?

What Patient and Family Teaching Do I Need to Do?

Teaching the at-risk patient and family about pressure ulcer prevention is a key prevention strategy. Include the following topics in your teaching:

- Characteristics of healthy skin
- Appearance of skin that has experienced unrelieved pressure
- Skin care and hygiene
- Protection of the skin and prevention of pressure ulcers
- Importance of adequate nutrition
- Techniques for turning and positioning
- Importance of frequent position changes
- Use of pressure-redistributing devices
- Skin changes that should be reported to healthcare professionals

The following are some simple tips for taking care of wounds at home that you can teach families (ICSI, 2012). If the wound is:

Wet → dry it
Open → cover it
Unclean → clean it
Necrotic → don't scrub it
Dry → moisten it

What Wound Care Competencies Do I Need?

Care planning to meet the complex, individualized needs of a patient with a chronic wound involves the entire multidisciplinary team (e.g., physical therapists, dietitians, infection control specialist, wound specialist). Your wound assessment will guide your choice of interventions, which depend on the nature of the wound. Consider these two examples:

- A patient with a diabetic foot ulcer must have all the pressure taken off that area because every step traumatizes healing tissues. The appropriate dressing must be selected; in addition, this patient will need to wear a special shoe that is specially made for patients with neuropathy.
- Patients with a venous stasis ulcer commonly wear compression garments (e.g., elastic hose, stocking, or multilayer compression wrap). These provide continuous pressure to the veins, which improves venous return and helps the ulcer to heal (O'Meara, Cullum, Nelson, et al., 2012). Before applying elastic compression, be sure the limb is not increasing in edema. Lower extremity arterial disease must be ruled out before applying compression as it can compromise arterial circulation. Avoid thigh-high elastic stockings because they tend to roll and cause a tourniquet effect (ICSI, 2012). See Chapter 32 if you need more information about compression stockings.

Wound care is more than placing a dressing into a wound. It incorporates all of the strategies for preventing that wound, as well as treating it. ESG Box 35-1 lists RN competencies for treating pressure ulcers (NPUAP, 2010). These interventions can also be used in treating other types of acute and chronic wounds.

Go to Chapter 35, **Tables, Boxes, Figures: ESG Box 35-1, Competencies of Registered Nurses for Treating Pressure Ulcers,** on Davis*Plus*.

Cleansing Wounds

Cleansing removes exudate, slough, foreign materials, and microorganisms from the wound. This helps promote healthy tissue healing. Always clean a wound initially and with each dressing change. To cleanse a wound, gently pat the surface with gauze soaked with saline or other prescribed wound cleanser. If there is granulation tissue, be careful not to disrupt it.

Historically, antiseptic solutions, such as Dakin's, acetic acid, hydrogen peroxide, povidone-iodine, chlorhexidine, and alcohol, were used to cleanse all types of wounds. However, antiseptic solutions can damage granulating tissue and should not be used on healing tissue (AHRQ, 2005, updated 2010). Recent clinical evidence suggests that polyhexanide/betaine may be nontoxic and effective in enhancing wound healing (Wilkins & Unverdorben, 2013). Antiseptic solutions should be reserved for new wounds, those that won't heal, or wounds in which the bacterial burden is more harmful than the solution itself.

Because normal saline is physiological, it is safe and it will not harm injured or healing tissue. It will adequately cleanse most wounds if a sufficient amount is used to thoroughly flush the wound. Drinkable tap water can also be used to cleanse wounds (WOCNS, 2010) and is as effective as saline (Fernandez & Griffith, 2008, 2012). However, the decision to use tap water should be based on the nature and complexity of the wound and the patient's general condition, including the presence of comorbid conditions (e.g., diabetes) and immunological status (Watret & McLean, 2013). Additionally, there is some concern over biofilm in hospital water delivery systems (Christina, Spagnola, Casini, et al., 2014). To reduce this risk of microbial contamination, purified water instead of tap should be used for cleansing wounds.

Liquid or foam skin cleansers that are pH balanced may be used to cleanse periwound skin or incontinence effluent. They are not for use in wounds. **Key Point:** ***The most important thing to remember is to use universal precautions to minimize the risk of cross-contamination when cleansing periwound or other non-wound skin.***

Irrigating Wounds

Nurses commonly use irrigation (**lavage**) to cleanse wounds by flushing. To remove debris from a wound, introduce the irrigation solution with a gentle amount of force. Ideal irrigation pressures range from 4 pounds per square inch (psi) to 15 psi. To remove material adhering to the wound bed use a 35-mL syringe attached to a 19-gauge angiocatheter to deliver the solution at approximately 8 psi (ICSI, 2012). Pressures above 15 psi increase the risk of driving bacteria into the tissues, as well as causing mechanical damage.

Some agencies use a piston syringe for irrigation. Do not use a bulb syringe as it increases the risk of aspirating the drainage. Commercial irrigation systems are also available, such as whirlpool agitators, whirlpool hose sprayers, pressurized canisters, and pulsed lavages. Closely evaluate the amount of pressure they deliver before you use these devices. High-pressure irrigation systems (35–70 psi) may dislodge healing granulation tissue, especially in chronic wounds. High pressure can cause pain and also drive bacteria deeper into the wound compartment, leading to increased risk of infection (Gabriel & Schraga, 2013, updated).

There is a risk of splattering when irrigating, so you need to use gowns, masks, and goggles. Sterile technique is used for acute surgical wounds, wounds that have recently undergone sharp debridement, or when prescribed by the provider. The majority of wound irrigations use clean technique. The Highlights of Procedures box provides a summary of the procedure. For the complete steps,

Go to Chapter 35, **Procedure 35-2: Performing a Sterile Wound Irrigation,** in Volume 2.

Caring for Wounds With Drainage Devices

A variety of drains may be inserted into wounds to allow fluid and exudate to exit. Drains prevent excessive pressure from building up in the tissues. Drains are usually

Toward Evidence-Based Practice

Fernandez, R., & Griffiths, R. (2012). The effects of water compared with other solutions for wound cleansing. *Cochrane Database of Systematic Reviews*, 2; Art. No.: CD003861. doi:10.1002/14651858.CD003861.pub3. Retrieved from http://summaries.cochrane.org/CD003861/the-effects-of-water-compared-with-other-solutions-for-wound-cleansing

Use of saline versus tap water for cleansing wounds is debated. Normal saline is traditionally preferred because it cleanses without interfering with the normal healing process. However, tap water is used commonly in the community for cleaning wounds and for care of chronic wounds because it is generally free of pathogens, while easily accessible and inexpensive. Analysis of findings from 24 clinical studies showed no differences in the rates of infections among acute and chronic wounds in adults and children cleansed with tap water compared with those washed with saline.

1. What trend in the research about cleansing wounds do you see compared with previous times?
2. If study findings indicate little difference in wound infection when tap water is used for cleansing, then what would you recommend to those using tap water in the community?
3. What implications does using tap water for cleaning wounds have when sending patients home after surgery?

Go to Chapter 35, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

placed during a surgical procedure. Some are sutured into place, whereas others are simply placed into the cavity.

Types of Drains

A *Penrose drain* is a flexible, flat latex tube that is placed in the wound bed but usually not sutured into place. A clip or pin may be attached to the drain at the insertion site to keep it from slipping into the wound. You may be asked to advance the drain by gradually removing it from the wound bed. For example, the surgeon may prescribe, "Advance the Penrose drain 6 mm (1/4 in.) per day." Each day you will pull the drain out of the wound 6 mm (1/4 in.) until the drain is finally removed. The Highlights of Procedures box summarizes this procedure. For complete guidelines,

Go to Chapter 35, **Procedure 35-13: Shortening a Wound Drain,** in Volume 2.

Some drains are attached to a collection device. Examples include Hemovac and Jackson-Pratt and drains (Fig. 35-11). The provider may order a device to be "placed to suction." This means you will compress the device to create suction and facilitate removal of drainage (Fig. 35-12). The Highlights of Procedures box summarizes this procedure. For complete guidelines,

Go to Chapter 35, **Procedure 35-14: Emptying a Closed-Wound Drainage System,** in Volume 2.

If a specific pressure is to be applied, some drains can be connected to wall suction. The provider will prescribe the amount of suction. For example: "Place Hemovac to 20 mm Hg suction at all times."

Nursing Activities for Maintaining Drains

As a nurse you are responsible for monitoring wound drains. The provider will describe the number and type of drains present. Describe drain placement according to the position on the clock face. Consider the patient's head to be at the 12 o'clock position. Some patients have more than

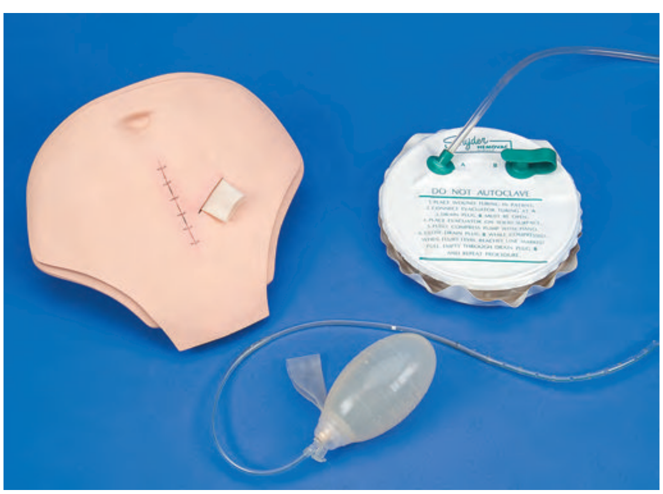

FIGURE 35-11 *Left*, Penrose drain. *Center*, Jackson-Pratt device. *Right*, Hemovac drainage system.

FIGURE 35-12 Compress the bulb of the Jackson-Pratt drain to create suction and remove wound drainage.

one drainage device in a wound. Label the drains numerically with a marker or by placing tape on the collection apparatus so that each caregiver provides consistent care.

When removing dressings or irrigating wounds, be very careful to avoid dislodging the drain. Remember, many drains are not sutured in place. Monitor the amount and character of the drainage and record this information in your nursing notes as well as on the intake and output (I&O) record.

Report to the provider any significant change in the amount or character of the drainage. If you suspect a drain is occluded, check the drain line from the insertion site to the collection device. Remove any kinks in the tubing. If this does not correct the problem, notify the provider of the blockage.

You need to empty the collection apparatus at a designated volume to maintain suction. As the device fills, suction pressure decreases. If there is significant drainage, you may need to empty the device several times during your shift.

Debriding a Wound

Debridement is the removal of devitalized tissue or foreign material from a wound. It also helps remove cells that are alive but not functioning (**senescent**) from the wound bed and edges. Removal of necrotic tissue, exudate, and infective material helps stimulate wound healing and prepare the wound bed for advanced therapies or biological agents. There are five types of debridement: sharp or surgical, mechanical, enzymatic, autolytic, and biotherapy or maggot therapy.

Sharp Debridement

Sharp debridement is the use of a sharp instrument, such as scalpel or scissors, to remove devitalized tissue. This method provides an immediate improvement of the wound bed and preserves granulation tissue. A physician, nurse, or physical therapist may perform this procedure at the bedside if they have received specialized training. If a wound requires extensive debridement, it may be performed in the operating room. Many stage IV ulcers extend into the bone, so a bone biopsy is often performed at the same time. The biopsy will detect **osteomyelitis**, extension of the infection into the bone.

Mechanical Debridement

Mechanical debridement may be performed via lavage (discussed in a preceding section), the use of wet-to-dry dressings, or hydrotherapy (whirlpool).

- **Wet-to-Dry Dressings.** Coarse gauze moistened with normal saline is packed into the wound, allowed to dry, and then removed, perhaps several times a day. This form of debridement was common once, but has declined in use because it causes pain and provides only **nonselective debridement**. That is, it removes not only debris but also granulation tissue. If you must use this method, medicate the patient beforehand with opioid analgesics. Rewetting the gauze aids in its removal and decreases the pain, but it may eliminate the debriding action of the dressing change.
- **Hydrotherapy or Whirlpool Treatments.** Hydrotherapy or whirlpool treatments also provide nonselective debridement. This is a vigorous form of debridement reserved for wounds with a large amount of nonviable tissue, such as burns. Hydrotherapy is usually performed in the physical therapy department once or twice per day. The wound is placed in a whirlpool containing tepid water for a prescribed amount of time (perhaps 5 to 15 minutes). Do not expose the wound directly to the water jets.

  Whirlpool treatments increase the risk for periwound maceration, contamination by waterborne infections, and cross-contamination. Therefore, strict adherence to infection control measures is essential. Use hydrotherapy with caution in patients with venous stasis ulcers because it leads to vasodilation, which may increase edema and congestion. Persons with diabetic neuropathies are at increased risk for burns because of a decrease in sensory abilities.

Enzymatic Debridement

Enzymatic debridement uses proteolytic agents to break down necrotic tissue without affecting viable tissue in the wound. To use an enzymatic product, clean the wound with normal saline, apply a thin layer of the cream, and cover with a moisture-retaining dressing. This may be done once or twice daily, depending on the product. Apply the product only to devitalized tissue because it might cause some local irritation.

Autolysis

Autolysis is the use of an occlusive, moisture-retaining dressing and the body's own enzymes and defense mechanisms to break down necrotic tissue. This process takes more time than the other techniques, but it is tolerated better. The procedure involves applying the dressing and observing the fluid that collects under it (wound fluid may be tan in color). The dressing is normally changed every 72 hours, or sooner if drainage breakthrough occurs. At that time, the wound is cleansed before a new dressing is applied. Observe the wound closely and regularly for signs of infection, such as an increase in pain or a foul odor. Autolysis is contraindicated in the presence of infection or immunosuppression.

Biotherapy or Maggot Debridement Therapy

Maggot debridement therapy is the use of medical-grade larvae of the greenbottle fly to dissolve dead and infected tissue from wounds. The larvae secrete enzymes that liquefy dead tissue and create an alkaline environment. The enzymes are neutralized when they come in contact with normal tissue, so healthy tissue is unharmed. The larvae also digest bacteria from the wound. This therapy is effective and simple to use, though containing the larvae within the dressing can be problematic (Opletalova, Blaizot, Mourgeon, et al., 2012). Larvae are usually changed every 48 to 72 hours and disposed of as biohazardous medical waste. The use of maggots can be emotionally disturbing to both patients and nurses, so take this into consideration and discuss it with the patient.

Providing Moist Wound Healing

A physiological wound environment is one that maintains the right amount of moisture for cells to flourish. More than 65% of the human body is composed of water. The skin maintains this level of moisture by allowing water vapor to escape into the air around us in small amounts. With damage to the skin, body cells can dehydrate and die, so wound dressings must function as a barrier to water vapor loss.

Primary **dressings** are ones that are placed in the wound bed and actually touch the wound. A **secondary dressing** is one that covers or holds a primary dressing in place. Many dressings can act as both, touching the wound bed and securing themselves to the wound with some type of adhesive. Figure 35-13 shows various sizes of gauze dressings.

The type of dressing used on a wound depends on the characteristics of the wound and the goals of treatment. The dressing of choice should:

- Prevent drying of the wound bed.
- Absorb drainage.
- Keep the surrounding tissue dry and intact.

FIGURE 35-13 Gauze dressings are available in a variety of shapes and forms.

- Protect from contamination and infection.
- Aid in hemostasis.
- Debride the wound.
- Eliminate dead space.
- Prevent heat loss.
- Splint the wound site.
- Provide comfort to the patient.
- Control odor.
- Minimize scarring.

Choosing the Dressing

When choosing a dressing, ask yourself whether it will achieve the purposes listed above. Also consider how long the dressing should stay in place, how often it needs to be changed, and whether it can it be removed without damaging fragile skin or the wound itself (Table 35-5).

Ideally, the dressing will facilitate the goals of moist wound healing (preceding). There is no single "recipe" for healing a wound. Each wound must be treated and dressed individually based on the patient history and assessment. Many wound materials are available, and new products are continually introduced. The "newest" dressing is not necessarily the best for the wound. Many products carry hefty price tags, so it must be determined that the benefit achieved is worth the extra cost. Choose the dressing based on what the wound needs and not the manufacturer's brand name. Perform ongoing reassessment of your dressing choice every time you assess the wound, modifying dressings and treatments as the wound evolves.

The Highlights of Procedures box summarizes procedures for applying dry, wet-to-damp (moist-to-moist), transparent film, and hydrocolloid dressings. For complete steps,

Go to Chapter 35, **Procedure 35-4: Removing and Applying Dry Dressings; Procedure 35-5: Removing and Applying Wet-to-Damp Dressings; Procedure 35-7: Applying and Removing a Transparent Film Dressing,** and **Procedure 35-8: Applying a Hydrating Dressing (Hydrocolloid or Hydrogel),** respectively, in Volume 2.

KnowledgeCheck 35-10

- What should you consider when choosing a dressing?
- Describe the five types of wound debridement.
- Identify the purposes of a wound dressing.
- Differentiate among the different categories of dressings.
- What types of dressings may be used for wounds with a large amount of exudate?
- What form of dressing is appropriate for a wound with an eschar that needs to be eliminated?

Securing Dressings

What you will use to secure a dressing depends on wound size, location, amount of drainage, frequency of dressing changes, patient's activity level, and type of dressings used. Tape, ties, bandages, secondary dressings, and binders are among the choices. Tape is most commonly used. It is available in several forms:

- **Adhesive tape** provides stability to a dressing. It is tough and durable and can be used if you need to apply pressure to a wound. It leaves a residue on the skin and can cause trauma to surrounding intact skin when it is removed. However, commercial adhesive removers are available to remove the residue and can be used to loosen tape as it is removed.
- **Foam tape** readily molds to the contours of the body and is ideal for dressings over joints.
- **Nonallergenic tape and paper tape** are best for sensitive skin. Ask patients whether they have any history of tape allergies or irritation, and use a tape that the patient has tolerated well in the past.

To tape a dressing, place strips of tape at the ends of the dressing, and space them evenly over the remainder of the dressing. The Highlights of Procedures box summarizes a procedure for taping dressings. To see the complete procedure,

Go to Chapter 35, **Procedure 35-3: Taping a Dressing,** in Volume 2.

If a dressing requires frequent changes, you can use **Montgomery straps** with ties to secure the dressing (Fig. 35-15). Montgomery straps decrease the amount of pulling and irritation of skin around a wound. Apply the adhesive part of the straps to the skin at the ends of the dressing and at evenly spaced intervals. Lace the cloth ties between the straps to secure the dressing. Change the ties whenever they become soiled. Keep the straps in place until they begin to loosen from the skin.

Consider using thin hydrocolloids, low-adhesion foam dressings, or skin sealants under tape to also help prevent skin tears. For the fragile skin of older adults or infants, use porous tapes and avoid unnecessary tape use.

Controlling Infection

A wound provides a portal of entry or exit for microorganisms. When caring for patients with closed wounds, follow CDC Standard Precautions. For patients with

(text continued on page 928)

Table 35-5 ➤ Types of Wound Dressings

DRESSING TYPE AND DESCRIPTION	USE	CAUTIONS	WOUND SIZE
Absorbent dressings ▪ Made from highly absorptive layers of fibers such as cellulose, cotton, or rayon ▪ May or may not have an adhesive border. Procedure 35-4: Removing and Applying Dry Dressings Procedure 35-5: Removing and Applying Wet-to-Damp Dressings	▪ Can be used as a primary or secondary dressing to manage drainage from partial- or full-thickness wounds. ▪ Highly absorptive. Used for wounds with moderate to large amounts of drainage.	▪ Do not use to pack undermining wounds. ▪ Do not use if the wound is not draining. This can dry out the wound bed and damage tissue.	Moderate to large
Alginates ▪ Fibers derived from brown seaweed and kelp. ▪ Available in pad or rope form.	▪ Very high absorbency (20 to 40 times their weight). ▪ Promote a moist environment. ▪ Facilitate autolytic debridement. ▪ Ideal for wounds that have depth, tracts, tunneling, or undermining.	▪ Will adhere to the wound bed if there is no drainage. ▪ When the alginate comes in contact with exudate, a nonadhesive gel is created. Must irrigate this gel from the wound before placing the next dressing. ▪ Allergy to antibiotic components, or to seaweed or kelp.	Large
Antimicrobials (Antibiotic & Antifungal) ▪ Available as ointments, impregnated gauzes, pads, gels, foams, hydrocolloids, and alginates. ▪ Commonly contain silver and cadexomer iodine.	▪ Reduce exudate and prevent infection by reducing bacteria in the wound. ▪ Promote collagen deposition. ▪ Can be used on partial- or full-thickness wounds, malodorous wounds with little to large amounts of drainage, or highly contaminated or infected wounds.	▪ Allergy to iodine or silver	Large
Collagens ▪ Made from bovine (cow) or porcine (pig) sources and made into sheets, pads, powders, and gels.	▪ Use with partial- and full-thickness and contaminated or infected wounds. ▪ Absorb exudate. ▪ Promote a moist wound bed for healing. ▪ Stimulate wounds to produce collagen fibers and granulation tissue in the wound bed. ▪ Do not stick to the wound bed and are easy to apply and remove.	**Key Point:** *If using porcine dressings, check that your patient has no religious practices that would forbid this use. In particular, check with your Jewish and Muslim patients.*	Minimal to large

Continued

Table 35-5 ➤ Types of Wound Dressings—cont'd

DRESSING TYPE AND DESCRIPTION	USE	CAUTIONS	WOUND SIZE
Foams ▪ Made from semipermeable hydrophilic foam that forms an impermeable barrier over the wound. ▪ Made into wafers, rolls, and pillows; have film coverings; and are adhesive or nonadhesive.	▪ Absorbent; for wounds with moderate to heavy exudates. ▪ Thermal insulation ▪ Promote a moist environment. ▪ Do not stick to wound bed. ▪ Used under compression. ▪ Protect friable periwound skin. ▪ Can be shaped around body contours. ▪ May be used in combination with alginates or films.	▪ Do not use with wounds that have tunneling or tracts. ▪ Not recommended for dry, desiccated wounds. ▪ May macerate periwound skin, if dressing becomes oversaturated.	Minimal to large
Gauze ▪ Simplest and most widely used dressings. ▪ Made of woven and nonwoven fibers of cotton, rayon, polyester, or a combination of these. ▪ Some are impregnated with antimicrobial agents, medications, or moisture, and others contain petrolatum to keep the wound moist.	▪ Cleansing ▪ Protection ▪ Used for packing large wounds, cavities, or tracts, deep or dirty wounds, or heavily draining wounds. ▪ Used in combination with amorphous hydrogels, saline, or medications. ▪ May be packed as sterile or nonsterile, in bulk or in smaller packages.	▪ Labor intensive ▪ Can stick to wound tissue and damage new, regenerated cells with gauze removal. ▪ Does not ensure a moist wound environment, as they allow for fluid evaporation. ▪ May be applied incorrectly, as it must be fluffed to avoid pressure or overpacking of a wound. ▪ Dressing change interval is dependent on the amount of fluid saturation of the gauze. Frequent dressing changes disrupt the wound bed and cause the wound to become hypothermic (cold), which physiologically impairs cell growth for healing.	Large
Hydrocolloids ▪ Wafers, pastes, or powders that contain hydrophilic (water-loving) particles. Procedure 35-8: Applying a Hydrating Dressing (Hydrocolloid or Hydrogel)	▪ Hydrophylic particles interact with water to form a gel that keeps the wound moist. ▪ Provide a protective layer against friction/caustic agents and bacteria. Also reduce pain. ▪ Ideal for wounds with minimal exudates (e.g., partial thickness wounds, stage II pressure ulcers). ▪ Promote autolysis.	▪ Not the dressing of choice for wounds that require frequent dressing changes. ▪ Opaque. Do not allow the wound to be visualized. ▪ Not recommended for wounds surrounded by friable or sensitive skin (difficult to remove). ▪ Should not be used on infected wounds because they are impermeable to oxygen, moisture, and bacteria.	Light to moderate

Table 35-5 ➤ Types of Wound Dressings—cont'd

DRESSING TYPE AND DESCRIPTION	USE	CAUTIONS	WOUND SIZE
	▪ Used under compression. ▪ Mold to the shape of the body, making them useful for difficult areas, such as heels or between buttocks. ▪ Use around stomas to create an even surface on which to place the ostomy appliance. ▪ Do not require a secondary dressing.	▪ When an exudate comes in contact with the hydrocolloid material, it can produce an odor that might be confused with a malodorous wound. Clean the wound bed first before determining if it is malodorous. ▪ May facilitate the growth of anaerobic bacteria. ▪ Should not be used on wounds with tunneling or tracts because these wounds must be packed and allowed to drain. Wound should be shallow enough that the hydrocolloid touches the wound bed.	
Hydrogels ▪ Sheets, granules, or gels with a high water content, creating a jelly-like consistency that does not adhere to the wound bed. Procedure 35-8: Applying a Hydrating Dressing (Hydrocolloid or Hydrogel)	▪ Enhance epithelialization to promote a moist environment. ▪ Rehydrate the wound bed. ▪ Promote autolysis. ▪ Soft, cooling texture promotes comfort. ▪ Soften slough or eschar in necrotic wounds.	▪ Have limited absorptive capabilities (not practical for wounds with significant exudate). Require a secondary dressing. ▪ Easily macerate periwound skin due to high moisture content.	Minimal
Skin sealants and moisture barriers ▪ Skin sealants—made from liquid transparent copolymer. ▪ Moisture barrier ointments—petrolatum, dimethicone, or zinc-based products that can be applied to skin to protect it from exudate, moisture, urine, and feces.	▪ Simple and fast to use, and if needed, should be used with each dressing change. ▪ Can be wiped or sprayed on skin to protect it from wound exudate and moisture, friction, and skin stripping from adhesives ▪ Provide a barrier of protection over vulnerable skin from the effects of moisture and mechanical and chemical skin injury.	▪ Ointments impair the adhesion of wound dressings or tapes.	Any
Transparent films (See Fig. 35-14) ▪ Clear and semipermeable. Procedure 35-7: Applying and Removing a Transparent Film Dressing	▪ Promote a moist environment. ▪ Occlusive with oxygen permeability. ▪ Promote autolysis. ▪ Often used to dress IV sites. ▪ Prevent external bacterial contamination. ▪ Allow wound assessment without removing or disturbing the dressing. ▪ Can be placed over joints without inhibiting movement.	▪ If used over wounds that are draining, the tissues will become macerated. ▪ Adhere to the skin, so do not use them on friable skin.	Minimal to none

FIGURE 35-14 IV sites are commonly dressed with transparent film dressings.

open or draining wounds, follow CDC Tier Two: Contact Level Precautions in addition to Standard Precautions. See Chapter 23, and also,

Go to Chapter 23, **Clinical Insight 23-4: Following Transmission-Based Precautions,** in Volume 2.

The following nursing activities will also aid in preventing and controlling wound infections:

Asepsis Measures

If the patient has an infection, place her in a private room or in a room with a patient who has an active infection caused by the same organism and no other infections. Follow any additional specific precautions for the microorganism identified. Most important, wash your hands frequently.

Use clean gloves when caring for the patient with a wound. Remove gloves and wash your hands before coming in contact with another patient. Change your gloves after removing a soiled dressing and before applying a clean dressing.

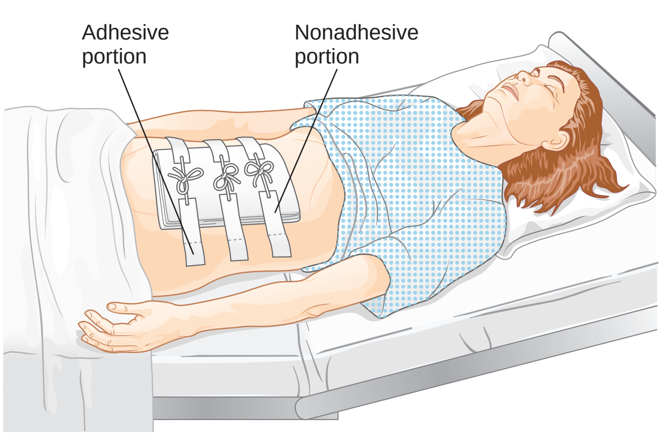

FIGURE 35-15 Montgomery straps with ties may be used to secure a dressing that requires frequent changing.

If a patient has multiple wounds, treat the least contaminated wound first, then progress to the most contaminated. Wash your hands and change gloves between each wound.

Sharp Debridement Use sterile instruments for sharp debridement. Monitor the patient for signs and symptoms of sepsis (fever, tachycardia, hypotension, altered level of consciousness) after sharp debridement. Remember, only specially trained providers can do sharp debridement. **Key Point:** ***Keep in mind there are reasons not to debride a wound. It is imperative not to remove eschar if the wound has poor circulation at the ulcer site. You would also leave alone a stable heel eschar. Additionally, debridement would not benefit the patient who is critically unstable or with a grave prognosis (Association for the Advancement of Wound Care [AAWC], 2005, revised 2010).***

Dressings and Supplies Acute wounds may require sterile dressings. Use clean dressings for chronic wounds. However, even a chronic wound may require sterile dressings if the patient is immunocompromised. Carefully dispose of contaminated dressings in biohazard waste receptacles. Discard unused dressings if they become contaminated.

Store patient dressing supplies in a clean and dry area. Do not share supplies among patients. Access only the number of supplies you need for the dressing change. Do not touch the supply of dressings with gloves that have come in contact with the wound. Discard unused dressings if they have become contaminated.

Think**Like a Nurse** 35-6

What would be the best method to secure dressings for Mr. Harmon (Meet Your Patient)?

Supporting and Immobilizing Wounds

Binders and bandages are used to hold a dressing in place, apply pressure to a wound to impede hemorrhage, and support and immobilize an injured area, thereby promoting healing and comfort. Before applying a bandage or binder, determine the purpose of the application and assess the part being bandaged.

Binders

Binders may be used to keep a wound closed when there is danger of dehiscence, or to immobilize a body part to aid in the healing process. They are typically used on large areas of the body and are designed for a specific body part. They may be made of cloth or elasticized material and fasten with straps, pins, or Velcro. The most common binders are the following:

- *A **triangular arm binder or sling*** is used to support the upper extremities. Because commercial slings are readily available, you will rarely use a triangular sling.

- *A **T-binder*** is used to secure dressings or pads in the perineal area.
- *An **abdominal binder*** is used to provide support to the abdomen, for example, when there is an abdominal incision or an open abdominal wound healing by secondary intention. The binder decreases the risk of dehiscence.

To learn a procedure for applying binders, see the Highlights of Procedures box, and

Go to Chapter 35, **Procedure 35-10: Applying Binders,** in Volume 2.

Bandages

A bandage is a cloth, gauze, or elastic covering that is wrapped in place. With the exception of a sling, most bandages come in rolls and in various widths, commonly 1.5 to 7.5 cm (0.5 to 3 in.). Use a narrow width on small body parts, such as a finger, and wider bandages on arms and legs.

- **Cloth bandages** are most commonly used as slings to immobilize an upper extremity or to hold large abdominal dressings in place.
- **Gauze** is the most frequently used type of bandage. It is available in many sizes and forms and readily

(text continued on page 931)

Highlights of Procedures 35-1 Through 35-15

For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the procedure steps. Use these procedure highlights later to help you review key points.

Procedure 35-1: Obtaining a Wound Culture by Swab

- Position the patient for easy access to the wound and in a manner that will allow the irrigation solution to flow freely from the wound with the assistance of gravity.
- Don clean nonsterile gloves.
- Remove the soiled dressing, and dispose of gloves and dressing.
- Don clean gloves and fill a 35-mL syringe with an attached 19-gauge angiocatheter, with 0.9% (normal) saline solution; open the culturette package.
- Holding the angiocatheter tip 2 cm from the wound bed, gently irrigate the wound (superior to inferior).
- If using Levine's technique, press the culture swab against an area of red granulating tissue, and rotate.
- Or if using the Z-stroke technique, swab the wound from margin to margin in a 10-point, zigzag pattern, avoiding contact with the wound edge.
- Reinsert the swab into the culturette tube (aerobic or anaerobic culture, depending on the type of wound and type of organism); label the tube; and have the specimen transported to the lab.

Procedure 35-2: Performing a Sterile Wound Irrigation

- Administer pain medication 30 minutes before the procedure, if necessary.
- Position the patient for easy access to the wound and in a manner that will allow the irrigation solution to flow freely from the wound with the assistance of gravity.
- Don protective equipment: gown, face shield, and clean gloves.
- Remove the soiled dressing, and dispose of gloves.
- Set up a sterile field with a sterile irrigation kit or a 35-mL syringe and a 19-gauge angiocatheter with needle removed, dressing supplies, and irrigation solution.
- Wearing sterile gloves, fill either the syringe and angiocatheter or the piston-tip syringe with irrigation solution.
- Holding the syringe 2 cm (3/4 to 1 in.) from the wound bed, gently irrigate the wound with a back-and-forth motion, moving from the superior aspect to the inferior aspect.
- Dry the tissue surrounding the wound with sterile gauze.
- Apply a new dressing. Consider applying a waterproof skin protectant if the wound drainage is heavy.
- Dispose of used equipment and soiled dressings in a biohazard container.
- Reposition the patient and change any linens that got wet.

Procedure 35-3: Taping a Dressing

- Place the patient in a comfortable position that provides easy access to the wound.
- Ensure the skin surrounding the dressing is clean and dry.
- Choose a tape that is appropriate for the dressing.
- Place the tape parallel to the incision.
- Tear strips that extend 1–1 1/2 inches beyond the dressing edge.
- Apply tape without pulling or stretching.
- Smooth tape with your fingertips.

Procedure 35-4: Removing and Applying Dry Dressings

- Administer pain medication 30 minutes before the procedure, if necessary.
- Place the patient in a comfortable position that provides easy access to the wound.
- Wearing clean (nonsterile) gloves, gently loosen the edges of the tape to remove the soiled dressing and discard it in a biohazard receptacle.
- Change gloves and cleanse the wound gently with saline-moistened gauze.
- Assess the wound for location, appearance, odor, and drainage.
- Apply a dry dressing.
- Secure the dressing with tape.

Continued

Procedure 35-5: Removing and Applying Wet-to-Damp Dressings

- Assess for pain, and medicate 30 minutes before the procedure, if necessary taping dressing wound
- Place the patient in a comfortable position that provides easy access to the wound.
- Wearing clean nonsterile gloves, gently loosen the edges of the tape to remove the soiled dressing and discard in a biohazard receptacle.
- Change gloves and cleanse the wound gently with saline-moistened gauze.
- Assess the wound for location, appearance, odor, and drainage.
- Don clean nonsterile gloves and apply a single fluffed layer of moist, fine-mesh gauze to the wound. Be sure to place gauze in all depressions of the wound.
- Apply a second moist, fluffed layer over the first layer. Repeat this process until the wound is filled with moistened sterile gauze.
- Cover the moistened gauze with an absorbent, surgical pad.
- Secure the dressing with tape or Montgomery straps. Perform hand hygiene and date and time the dressing.

Procedure 35-6: Applying a Negative Pressure Wound Therapy (NPWT) Device

- Administer an analgesic if needed.
- Select an appropriate dressing, per NPWT unit directions, to fill the entire wound cavity.
- Obtain and set up the NPWT unit.
- Don clean gloves and remove the old dressing and discard in biohazard receptacle.
- Prepare a sterile field for supplies.
- Don sterile gloves for new surgical wounds; or clean gloves for chronic wounds.
- Irrigate/cleanse the wound.
- Apply appropriate dressing per NPWT unit protocol.

Procedure 35-6A: Open Pore Reticulated Polyurethane Foam (i.e., Vacuum Assisted Closure Therapy [V.A.C.])

- Cut the foam to fill the wound cavity.
- Do not place foam into blind/unexplored tunnels.
- Do not allow the foam dressing to overlap onto healthy skin.

Procedure 35-6B: Gauze Dressing Application (i.e., Chariker–Jeter Method)

- Measure the length of the drain.
- Moisten the gauze.
- “Sandwich” the drain in the moistened gauze and place in the wound base.
- Tuck the gauze into any undermining areas to ensure contact with the wound bed.
- Apply a strip or dollop of ostomy paste 1 cm from wound edge and secure the drain as needed.

For Both Types of Dressing

- Connect tubing attached to the dressing to the evacuation tubing going to the collection system.
- Position the tubing and connector away from bony prominences and skin creases.
- Ensure the clamps are open on all tubing.
- Turn on the pump and set to prescribed settings.
- Listen for audible leaks and observe for dressing collapse.
- Change the canister once a week or sooner if it fills.

Procedure 35-7: Applying and Removing a Transparent Film Dressing

- Place the patient in a comfortable position that provides easy access to the wound.
- Remove the soiled dressing, if necessary.
- Cleanse the surrounding skin and wound.
- Assess the condition of the wound.
- Apply the transparent film dressing to the wound by removing the center backing and holding the dressing firmly by the edges.
- Place over the wound and press out wrinkles and air.

Procedure 35-8: Applying a Hydrating Dressing (Hydrocolloid or Hydrogel)

- Place the patient in a comfortable position.
- Remove the soiled dressing, if necessary.
- Cleanse the wound, if necessary.
- Assess the wound, or other area where the hydrocolloid dressing will be applied, for size, location, appearance, exudate, odor, and signs and symptoms of infection.
- Apply the hydrating dressing.

Procedure 35-9: Placing Skin Closures

- Place the patient in a comfortable position that provides easy access to the wound.
- Cleanse the surrounding skin and wound.
- Assess the wound and determine the size and type of skin closure needed.
- Peel the skin closure from the card at a 90° angle.
- Place closures across the wound without tension starting at the middle of the wound.
- Place closures $^{1}/_{8}$ in. (3 mm) apart along the entire wound.

Procedure 35-10: Applying Binders

- Choose a binder of the correct type and size for the intended purpose.
- Make sure the binder is positioned properly to provide support but not compromise circulation or impair breathing.
- Pad any pressure areas or skin abrasions.
- *Abdominal binder:* Assess the patient every 2 to 3 hours to assure that the binder has not slipped up or down or is creating pain. Fasten from the bottom up.

Highlights of Procedures 35-1 Through 35-15

- *Triangular strap binder:* Position the patient's arm across the chest with elbow flexed slightly. Place one end of the triangle over the shoulder of the uninjured arm, and allow the triangle to fall open so that the elbow of the injured arm is at the apex of the triangle.
- *T-binders:* They come in two basic types—those for females have a perineal strap; those for males have a split in the perineal strap.

Procedure 35-11: Applying Bandages

- Bandage the body part in its natural position.
- Work from distal to proximal position.
- Choose a bandage of the proper width.
- Clean the wound (if present).
- Apply primary dressing as prescribed.
- Apply the bandage as needed to secure the primary dressing.

Procedure 35-12: Removing Sutures and Staples

Procedure 35-12A: Removing Sutures

- Place the patient in a comfortable position that provides easy access to the wound.
- Use the forceps to pick up one end of the suture. Slide the small scissors around the suture, and cut near the skin.
- With the forceps, gently pull the suture in the direction of the knotted side to remove it.

Procedure 35-12B: Removing Staples

- Position the staple remover so that the lower jaw is on the bottom.
- Place both tips of the lower jaw of the staple remover underneath the staple.
- Lift slightly on the staple, ensuring that it stays perpendicular to the skin.
- Gently squeeze the handles together and lift the staple straight up.
- Place the removed staples on a piece of gauze.
- Dispose of the removed staples in the sharps container.
- Apply dressing or Steri-Strips if needed.

Procedure 35-13: Shortening a Wound Drain

- Before shortening a wound drain, make sure it is secured tightly.
- Firmly grasp the full width of the drain at the level of the skin and pull it out by the prescribed amount (e.g., 5 mm, [1 in.]).
- Insert a sterile safety pin through the drain at the level of the skin.
- Hold the drain tightly, and insert another pin above your fingers.
- Using sterile scissors, cut the drain a little above the safety pin closest to the skin.

Procedure 35-14: Emptying a Closed-Wound Drainage System

- Don personal protective equipment as needed, including nonsterile procedure gloves, gown, and eyewear.
- Properly dispose of contaminated items into designated biohazard waste receptacles.
- Measure drainage.
- Document on I&O sheet.
- Report excess volume to the primary healthcare provider.

conforms to the shape of the body. It may also be impregnated with medications for application to the skin or with plaster of Paris, which, when dried, hardens to form a cast.

- **Elastic** bandages are used to apply pressure and give support (e.g., to improve venous circulation in the legs). Ace bandages are the most common form of elasticized bandage.
- **A rolled bandage** is a continuous strip of material (gauze, stretchable gauze, or elastic webbing) that you unroll as you apply it to a body part. To apply a roller bandage, hold the free end in place with one hand, and use the other hand to pass the roll around the body part. Start at the distal end and move toward the body. This will prevent the bandage from trapping blood in the distal end. Exert equal tension on each pass (or turn).

Go to Chapter 35, **Procedure 35-11: Applying Bandages,** in Volume 2.

Using Heat and Cold Therapy

Local application of heat or cold has been used for therapeutic purposes for centuries. Temperature-sensitive nerve endings respond readily to temperatures between 59°F and 113°F (15°C and 45°C). Response to heat or cold depends on the area being treated, the nature of the injury, duration of the treatment, patient age, physical condition, and the condition of the skin.

Monitor the patient especially carefully in the following situations:

- **Extremes of Age.** The very young and the very old are the least tolerant of heat and cold therapies.
- **Sensory Impairment.** Patients with sensory impairment are at increased risk for injury related to use of heat and cold therapy because they may not perceive temperature changes, burns, or ischemia.
- **Highly Vascular Areas.** Highly vascular areas, such as the fingers, hand, face, and perineum, are very sensitive to

temperature changes and thus are at high risk for injury from heat and cold.

- **Application to a Large Area.** Application of cold or heat to a large body surface area decreases the patient's tolerance of the treatment. Application to a small area is best tolerated.
- **Injured Skin or Wounds.** Intact skin tolerates heat and cold therapy better than skin that has been injured or has open wounds.

Safety Measures

For patient safety, observe the following precautions when applying heat and cold:

- Avoid direct contact with the heating or cooling device. Cover the hot or cold pack with a washcloth, towel, or fitted sleeve.
- Apply hot or cold intermittently, leaving it on for no more than 15 minutes at a time in any one area. This precaution helps prevent tissue injury (e.g., burns, impaired circulation). It also makes the therapy more effective by preventing ***rebound phenomenon***: At the time the heat or cold reaches maximum therapeutic effect, the opposite effect begins.
- Check the skin frequently for extreme redness, blistering, cyanosis (blueness), or blanching. When heat or cold is first applied, the thermal receptors react strongly, and the person feels the temperature intensely. Over about 15 minutes, the receptors adapt to the new temperature, and the person notices it less. Caution clients not to change the temperature when this occurs because doing so can cause tissue injury.

Applying Heat Therapy

Local application of heat is used to relieve stiffness and discomfort associated with musculoskeletal problems. It may also be used for patients with wounds. Heat increases blood flow to an area through the mechanisms of vasodilatation, increased capillary permeability, and reduced blood viscosity. Increased blood flow brings oxygen and white blood cells to the wound and aids in the healing process. Heat promotes the delivery of nutrients and removal of waste products from the tissue, promotes relaxation, and decreases stiffness and muscle tension.

When heat is applied to a large area of the body, vasodilatation may cause a drop in blood pressure and a feeling of faintness. Warn patients to be alert for this effect if they will be administering heat at home.

Moist Heat Adding moisture to heat amplifies the intensity of the treatment. Moist heat can be applied in several forms, depending on the skin condition.

- *Washcloth or towel.* If heat is being applied for relaxation and the skin is intact, you can soak a washcloth or towel in warm water and wring out the excess moisture before applying to the skin.
- *Gauze compress.* If there are any open areas, you will need to use a sterile gauze compress.
- *Soaks and baths* also provide moist heat. A **soak** involves immersion of the affected area. Soaking helps cleanse a wound and remove encrusted material. A **bath** is a modification of a soak in which a special tub or chair may be used. The most commonly used bath is a sitz bath (Fig. 35-16). A **sitz bath** soaks the patient's perineal area. Disposable sitz baths are often used to help prevent infection.

Dry Heat Dry heat may be applied with electric heating pads, disposable hot packs, or hot water bags. Caution patients to place the heating pad or device over the body area and never to lie on it. The pad or bag should be covered with its own cover or a towel.

- *Electric heating pads* have the advantage of providing a constant temperature, but the risk of burns is high.
- *Aquathermia pads* (Fig. 35-17) may also be used for dry heat application. Aquapads are plastic or vinyl pads that circulate water in the interior of the pad to create a constant temperature.
- *Disposable hot packs and hot water bags or bottles* are also available. Hot water bags are common in home use, but not in healthcare agencies because of the danger of burns from improper use.

For guidelines (including water temperatures) for applying moist and dry heat,

Go to Chapter 35, **Clinical Insight 35-1: Applying Local Heat Therapy,** in Volume 2.

Applying Cold Therapy

The application of moist or dry cold causes vasoconstriction and decreases capillary permeability. It produces local anesthesia, reduces cell metabolism, increases blood viscosity, and decreases muscle tension. It also slows bacterial growth. Applications of cold are used to prevent or limit edema and reduce inflammation, pain, oxygen requirements, and bleeding. Cold therapy is often used to treat fevers and sports injuries (e.g., sprains, strains, fractures, and contusions), and to

FIGURE 35-16 A Sitz bath soaks the patient's perineal area.

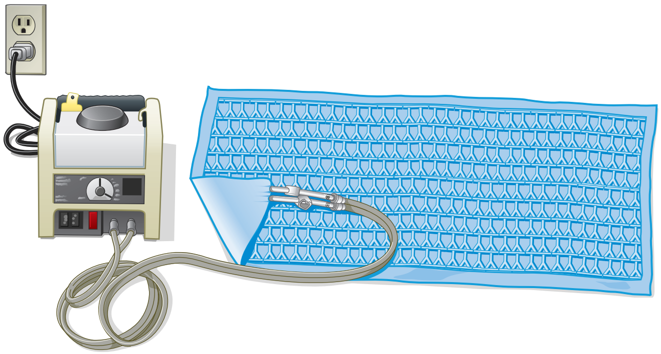

FIGURE 35-17 Aquapads circulate water in the interior of the pad to create a constant temperature.

prevent swelling after surgery (e.g., an ice bag may be applied to the perineum after childbirth; an ice collar may be applied to the throat after a tonsillectomy). Cold applications have the following side effects:

- *Elevated blood pressure.* Because cold causes vasoconstriction, it may increase the patient's blood pressure.
- *Shivering.* Prolonged cold may cause shivering, a normal response as the body attempts to produce heat.
- *Tissue damage.* Prolonged exposure to cold may cause tissue damage from impaired circulation.

For guidelines in applying cold therapy,

Go to Chapter 35, **Clinical Insight 35-2: Applying Local Cold Therapy,** in Volume 2.

KnowledgeCheck 35-11

- What is the effect of adding moisture to heat or cold treatments?
- How long should heat or cold be applied to an area?
- What precautions should you take before using heat or cold therapy?

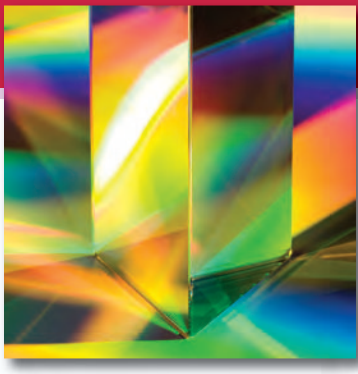
CHAPTER 36



Oxygenation

Learning Outcomes

After completing this chapter, you should be able to:

- Describe the structure and function of the respiratory systems.
- Identify individual, environmental, and pathological factors that influence oxygenation.
- Assess oxygenation, breathing, and gas exchange.
- Interpret diagnostic testing related to oxygenation, breathing, and gas exchange.
- Develop nursing diagnoses related to oxygenation, breathing, and gas exchange.
- Plan outcomes and interventions for maintaining and improving oxygenation.
- Safely and correctly perform common nursing procedures related to oxygenation, breathing, and gas exchange.
- Evaluate adequacy of oxygenation, breathing, and gas exchange, and modify nursing activities appropriately based on outcomes.
- Describe a procedure for safe oxygen administration.
- Describe measures for mobilizing airway secretions.
- Implement measures for promoting optimal respiratory function (e.g., positioning).
- Explain how to suction the upper and lower airways.
- Provide care for patients requiring artificial airways.
- Provide care for patients requiring mechanical ventilation.
- Provide care for patients requiring chest tubes.
- Provide measures to promote oxygenation.
- Recognize medications used to enhance pulmonary function.
- Use identified outcomes to evaluate care for patients with oxygenation problems.

Key Concepts

Oxygenation
Respiration
Ventilation

Related Concepts

Pneumonia

Meet Your Patients

In a pulmonary clinic, your student assignment is to (1) perform a focused assessment related to breathing and oxygenation, (2) perform common therapeutic interventions related to breathing and oxygenation, (3) identify desired outcomes and evaluate achievement of those outcomes, and (4) plan for follow-up and home care needs. In the course of your clinical day, you care for the following clients:

- Mary is a 4-year-old girl with a history of asthma. Her mother, Ms. Green, has brought her in because of an "asthma attack." Mary is sitting on her mother's lap and breathing rapidly through an open mouth. Her cough sounds congested and wheezy. The nurse practitioner has prescribed a nebulized treatment containing albuterol (Proventil) and ipratropium bromide (Atrovent).
- Mr. Chu is a 78-year-old man complaining of cough, sore throat, fatigue, and weakness. His temperature is

Meet Your Patients (continued)

100.4°F (38°C), pulse is 90 beats/min, respirations are 26 breaths/min, and blood pressure (BP) is 166/82 mm Hg.

- William is a 19-year-old male who has had a sudden onset of right-sided chest pain and shortness of breath. His chest x-ray revealed a right pneumothorax, and he is currently receiving 35% oxygen by face mask while waiting for an ambulance to transport him to the hospital for further evaluation.

Each of these patients is experiencing an oxygenation problem. In this chapter you will learn a variety of assessment techniques and interventions to support breathing, oxygenation, and gas exchange for patients such as these.

Theoretical Knowledge knowing **why**

The pulmonary, cardiovascular, musculoskeletal, and neurological systems work together to achieve oxygenation. The musculoskeletal and neurological systems regulate the movement of air into and out of the lungs. The lungs oxygenate the blood, and the heart circulates the blood throughout the body and back to the lungs. In this chapter, we focus on the pulmonary system; Chapter 37 presents the cardiovascular system. Remember, however, that the two systems work together. Changes in one system create changes in the other.

ABOUT THE KEY CONCEPTS

The concept **oxygenation** refers to how well the cells, tissues, and organs of the body are supplied with oxygen. The concepts of **respiration** and **ventilation** are the two major processes that occur in the pulmonary system to oxygenate the blood. All of the problems and interventions in this chapter relate in some way to oxygenation, respiration, or ventilation. Knowledge of these concepts will help you to understand the rationale for interventions such as airway suctioning, oxygen, mechanical ventilation, and chest tubes.

THE PULMONARY SYSTEM

The pulmonary system has two major components: the *airway* and the *lungs.* The following presents a brief review of the anatomy and physiology of the pulmonary system and explains how breathing is controlled. For more in-depth information, consult anatomy and physiology texts, or

Go to Chapter 36, **Supplemental Materials: Structures of the Pulmonary System,** on Davis*Plus.*

The Airway

The airway consists of the nasal passages, mouth, pharynx, larynx, trachea, bronchi, and bronchioles (Fig. 36-1). Air flows through these structures into and out of the lungs. In addition, the airway structures do the following:

- *Moisten the air*—A moist mucous membrane lining adds water to inhaled air.
- *Warm the air*—Blood flowing through the vascular airway walls transfers body heat to the inhaled air.
- *Filter the air*—(1) Specialized cells in the lining of the airways secrete sticky mucus to trap foreign particles. (2) **Cilia,** tiny hair-like projections from the walls of the airways, move rhythmically to sweep trapped debris up and out of the airway.

Upper Airway Located above the larynx, the upper airway includes the nasal passages, mouth, and pharynx. The *pharynx* (throat) contains the openings to the esophagus and trachea. The *trachea* lies just in front of the esophagus. The *epiglottis,* a small flap of tissue superior to the larynx, closes off the trachea during swallowing so that food and fluids do not enter the lower airway. The epiglottis opens during breathing to allow air to move through the airway.

Lower Airway Located below the larynx, the lower airway includes the trachea, bronchi, and bronchioles. The lower airway is considered sterile. The **trachea**, sometimes called the "windpipe," extends from the larynx to the point at which it divides to form the right and left mainstem bronchi. As the airways branch and become smaller, they have progressively thinner and less cartilage, until it disappears completely in the smaller bronchioles. The walls of the bronchi and bronchioles contain layers of smooth muscles. Spasm of these muscles (**bronchospasm**) narrows the airway and obstructs airflow.

The Lungs

The *lungs* are soft, spongy, cone-shaped organs. They are separated by the **mediastinum**, which contains the heart and great vessels. The right lung has three lobes; the left lung has two lobes. The upper portion of each lung, the *apex,* extends upward above the clavicle. The lower portion of each lung, the *base*, rests on the diaphragm. Knowing the location of lung tissue beneath the chest wall helps you to perform a complete and accurate assessment of the lungs.

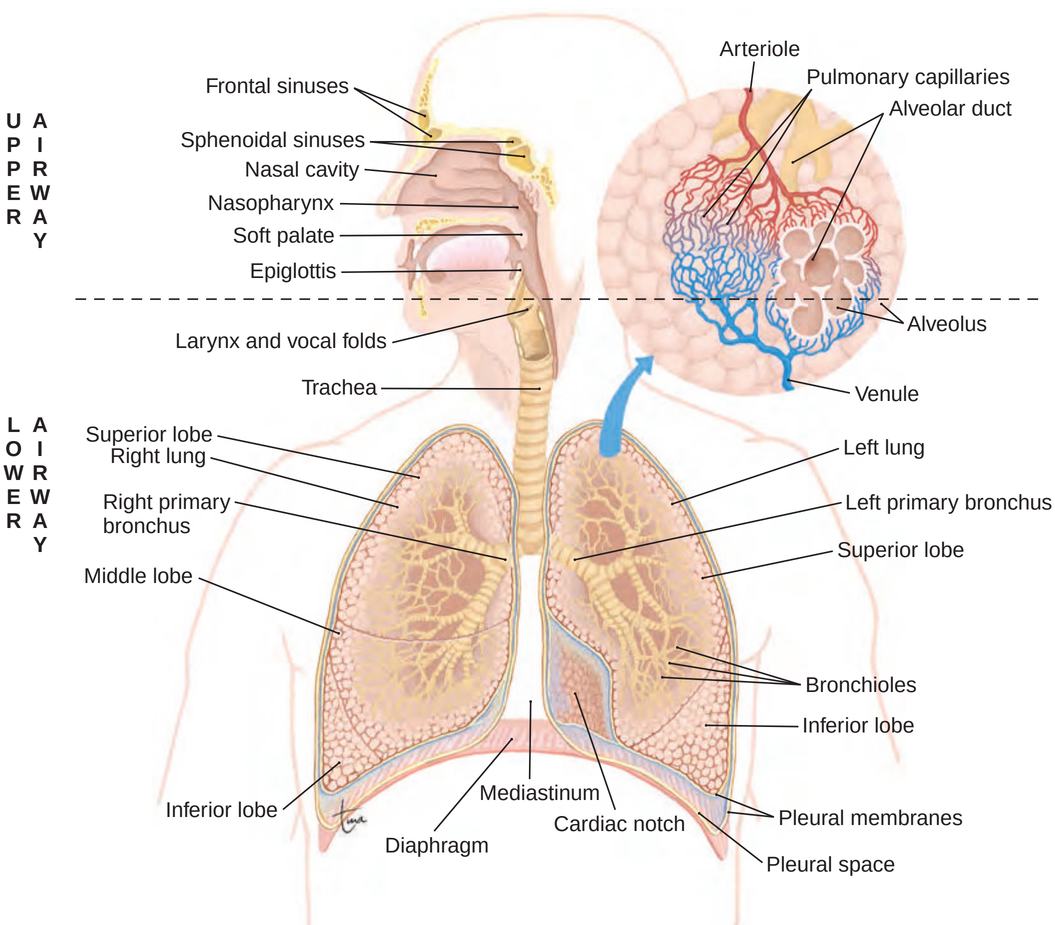

FIGURE 36-1 An anterior view of the respiratory system. The upper airway lies above the larynx. The lower airway, located below the larynx, is considered sterile.

The lungs are composed of millions of **alveoli**—tiny air sacs with thin walls surrounded by a fine network of capillaries. Gases (oxygen and carbon dioxide) easily pass back and forth between the alveoli and capillaries. Alveoli are composed of two types of cells (Fig. 36-2).

- *Type I alveolar cells* are the gas exchange cells.
- *Type II alveolar cells* produce **surfactant**, a lipoprotein that lowers the surface tension within alveoli to allow them to inflate during breathing.

KnowledgeCheck 36-1

- What happens to inhaled air in the airways? How does this occur?
- In which structures of the lung does gas exchange take place?
- What does surfactant do for alveoli?

ThinkLike a Nurse 36-1

You are assigned to care for an adult patient who has a medical condition with which you are not familiar. You look it up and find that the condition causes a dramatic loss of surfactant. Based on your knowledge of the function of surfactant, what problems is this patient at high risk for developing?

WHAT ARE THE FUNCTIONS OF THE PULMONARY SYSTEM?

Two of the key concepts in this chapter are major processes that occur in the pulmonary system: ventilation and respiration. **Ventilation** is the movement of air into and out of the lungs through the act of breathing. **Respiration** is the exchange of the gases oxygen and carbon dioxide in the lungs.

Pulmonary Ventilation

Oxygenation of the blood, and ultimately of organs and tissues, depends on adequate ventilation. Ventilation must move enough air through the lungs to make adequate oxygen available to the alveoli. Ventilation is accomplished through cycles of inhalation and exhalation. To see an animated demonstration of the physiology of ventilation,

Go to **Cardiovascular/Pulmonary Animations: Pulmonary Ventilation,** on Davis*Plus*.

Inhalation Expansion of the chest cavity and lungs creates negative pressure inside the lungs, causing air to

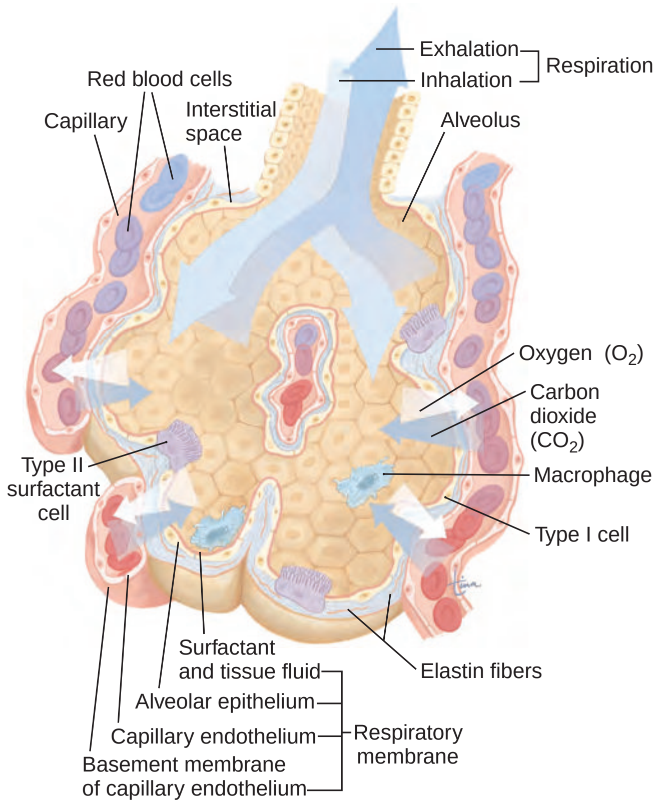

FIGURE 36-2 Alveolar structure showing type I and type II cells. Type I alveolar cells are the gas exchange cells. Type II alveolar cells produce surfactant.

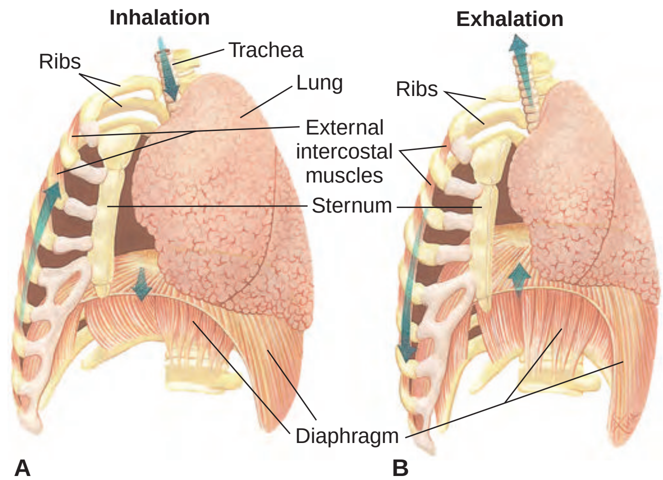

FIGURE 36-3 *A*, During inhalation, the diaphragm contracts, pulling the chest cavity and lung bases downward; the intercostal muscles pull the rib cage up and outward. *B*, In exhalation, the diaphragm relaxes, the lung bases move upward, and the ribs and intercostal muscles move down and in, resulting in lung compression.

be drawn in through the nose or mouth and airways. This is **inhalation**. The *diaphragm* is the major muscle of breathing. When it contracts with each inhalation, the chest cavity is pulled downward, pulling the lung bases downward with it. *Intercostal muscles*, the small muscles around the ribs, also contract on inhalation and pull the ribs outward, slightly expanding the chest cavity and lungs. The pleural membrane covering the lungs adheres ("sticks") to the pleural membrane lining the chest cavity, so the lungs expand. Lung expansion creates negative pressure and draws air in through the only opening to the outside, the trachea (Fig. 36-3A).

Exhalation When the diaphragm and intercostal muscles relax, **exhalation** allows the chest and lungs to return to their normal resting size (Fig. 36-3B). The reduction in size causes the pressure inside the chest and lungs to rise above atmospheric pressure, so air flows out of the lungs. Exhalation requires no energy or effort.

What Factors Affect Ventilation?

The adequacy of ventilation is affected by the rate and depth of respirations, lung compliance and elasticity, and airway resistance.

- **Respiratory rate and depth** are almost self-explanatory. **Rate** is how fast you breathe, and **depth** is how much your lungs expand to take in air. These processes affect oxygen and carbon dioxide levels in the blood.
- **Hyperventilation** occurs when a person breathes fast and deeply to move a large amount of air through the lungs, causing too much carbon dioxide to be removed by the alveoli. Mild hyperventilation can occur in response to **hypoxemia** (a low level of oxygen in the blood). When blood oxygen is low, ventilation increases to draw additional air (and oxygen) into the lungs. However, as ventilation increases, carbon dioxide levels fall. Severe hyperventilation is usually triggered by medication, central nervous system abnormalities, high altitude, heat, exercise, panic, fear, or anxiety.
- **Hypoventilation** occurs when a decreased rate or shallow breathing moves only a small amount of air into and out of the lungs. Hypoventilation can lead to hypoxemia because less air (carrying oxygen) reaches the alveoli. The concern is that hypoxemia will progress to **hypoxia** (an oxygen deficiency in the body tissues).
- **Lung elasticity** (or elastic recoil) refers to the tendency of the elastin fibers to return to their original position away from the chest wall after being stretched (think of stretching a rubber band, then letting go of it). Alveoli that have been overstretched, as with emphysema, lose their elastic recoil over time. This loss of elasticity allows the lungs to inflate easily but inhibits deflation, leaving stale air trapped in the alveoli.
- **Lung compliance** refers to the ease of lung inflation. Normally the lungs inflate easily. Lung compliance is reduced by increased lung water (edema), loss of surfactant, or conditions that cause elastin fibers in the lungs to be replaced with scar tissue (collagen).

- **Airway resistance** is the resistance to airflow within the airways. The larger the diameter of the airway, the more easily air moves through it. Normally, airway resistance is very low, so it takes little effort to move large volumes of air into and out of the lungs. However, even small decreases in airway diameter (as might occur with secretions in the airway or mild bronchospasm) markedly increase airway resistance. Mary, the little girl with asthma in the Meet Your Patients scenario, is undoubtedly experiencing airway resistance.

To see an animated demonstration of the physiology of ventilation,

Go to **Animations: Cardiovascular/Pulmonary Animations: Physiology of Ventilation,** on Davis*Plus*.

KnowledgeCheck 36-2

- What is the difference between ventilation and respiration?
- Describe how the diaphragm, accessory muscles, and pressure changes within the lungs create inhalation and exhalation.
- How does hypoventilation affect risk for hypoxemia and hypoxia?

Respiration (Gas Exchange)

Respiration refers to gas exchange, that is, the oxygenation of blood and elimination of carbon dioxide in the lungs. Although nurses commonly use the term *respirations* to mean “breaths” in an assessment of vital signs, strictly speaking this is not accurate: You cannot measure gas exchange by counting breaths per minute. Gas exchange occurs at two equally essential levels: external (in the lungs) or internal (in other body tissues).

External Respiration **Alveolar–capillary gas exchange** (or **external respiration)** occurs in the alveoli of the lungs. Oxygen (O_2) diffuses across the alveolar–capillary membrane into the blood of the pulmonary capillaries; carbon dioxide (CO_2) diffuses out of the blood and into the alveoli to be exhaled (Fig. 36-4). The rate of diffusion depends on the thickness of the membrane and the total surface of lung tissue available for gas exchange. Examples of conditions that slow diffusion are pleural effusion (fluid around the lungs), pneumothorax (lung collapse), and asthma (bronchospasms). If blood is not adequately oxygenated in the alveoli, hypoxemia (low blood-oxygen levels) occurs. Getting oxygen into the blood as it flows through the lungs is only the first step in oxygenation.

Internal Respiration **Capillary–tissue gas exchange** (or **internal respiration**) occurs in body organs and tissues. Oxygen diffuses from the blood through the capillary–cellular membrane into the tissue cells, where it is used for metabolism. From the cells, CO_2, a waste product of cellular metabolism, diffuses through the capillary–cellular membrane into the blood, and then is transported to the lungs and exhaled. Tissue oxygenation requires both adequate external respiration and adequate

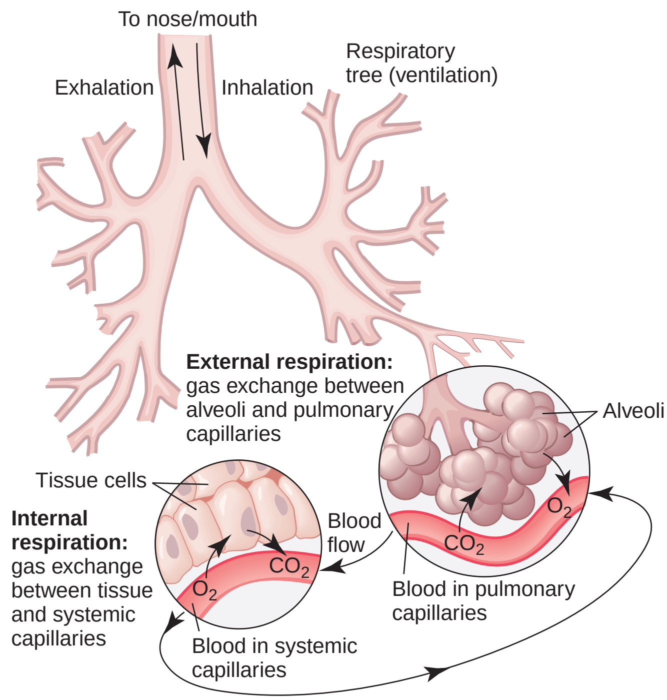

FIGURE 36-4 External respiration occurs at the alveolar–capillary membrane. Internal respiration occurs at the tissue–capillary membrane.

peripheral circulation. Limitations in either function may lead to hypoxia (oxygen deficiency in body tissues). In addition, if tissue cells are using more oxygen for metabolism than normal (e.g., during a high fever), hypoxia will occur unless more oxygen is made available to the tissues.

ThinkLike a Nurse 36-2

William (Meet Your Patients) has a right pneumothorax. Which of the two factors affecting the rate of gas diffusion is causing William to be hypoxemic? If you do not know what a pneumothorax is, look it up.

How Is Breathing Controlled?

The respiratory centers in the brainstem control breathing using feedback from chemoreceptors and lung receptors. Voluntary control from the **motor cortex** can override the involuntary respiratory centers, but only temporarily. This allows a person to continue breathing while doing activities such as talking, singing, swallowing, whistling, and blowing.

- **Chemoreceptors**, located in the medulla of the brainstem, the carotid arteries, and the aorta, detect changes in blood pH, O_2, and CO_2 levels and send messages back to the central respiratory center in the brainstem. In response, the respiratory center increases or decreases ventilation to maintain normal blood levels of pH, O_2 (PO_2), and CO_2 (PCO_2). Normally the blood CO_2 level provides the primary stimulus to breathe. High CO_2 levels stimulate breathing to eliminate the excess CO_2. A secondary, though important, drive to breathe is hypoxemia. Low blood O_2 levels stimulate breathing to get more oxygen into the lungs.

- **Lung receptors**, located in the lung and chest wall, are sensitive to breathing patterns, lung expansion, lung compliance, airway resistance, and respiratory irritants. The respiratory center uses feedback from the lung receptors to adjust ventilation. For example, if the lung receptors sense respiratory irritants such as dust, cold air, or tobacco smoke, the respiratory center triggers airway constriction and a more rapid, shallow pattern of breathing.

For a brief overview of the nervous system,

Go to Chapter 36, **Supplemental Materials: The Nervous System,** on Davis*Plus*.

KnowledgeCheck 36-3

- Describe two ways in which breathing is controlled.
- The level of which gas (oxygen or carbon dioxide) is the primary stimulant for breathing?

ThinkLike a Nurse 36-3

A patient has adequate blood oxygen levels based on a pulse oximeter reading of 98%. Can you conclude that organ and tissue oxygenations are adequate? Explain your thinking.

WHAT FACTORS INFLUENCE PULMONARY FUNCTION?

Factors that influence pulmonary function include developmental stage, the environment, individual and lifestyle factors, medications, and pathophysiological states.

Developmental Stage

Normal development influences lung, heart, and circulatory function, all of which affect oxygenation. Developmental factors have less effect on function in young and middle adults than in older adults.

Infants

Premature infants (less than 35 weeks' gestation) do not have a fully developed alveolar surfactant system. Surfactant is the substance that keeps air sacs inflated for effective respiration. Therefore, premature infants are at high risk for **respiratory distress syndrome (RDS).** RDS is characterized by widespread **atelectasis** (collapse of alveoli). The premature infant also has immature pulmonary circulation. Together with hypoventilation, this leads to hypercarbia (high CO_2 blood levels) and hypoxemia.

Infants born at term are also at risk for oxygenation problems (e.g., infection and airway obstruction) for the following reasons:

- Because the newborn's lower airway structures are immature and small, an infectious agent can spread rapidly.
- The infant's airways are quite narrow in diameter and, therefore, easily obstructed by edema, mucus, or a foreign body, such as meconium passed at birth.
- The central nervous system for preterm, and even some term, infants is immature, leading to periodic breathing patterns and apnea.
- The immune system of infants in the first few months of life is immature. Although at birth infants enjoy the benefit of some maternal immunoglobulin circulating in their system, this protection is limited and not sufficient for fighting certain infections.
- By age 6 months, infants can grasp small objects and put them in their mouth. This new skill, combined with small airway diameter, puts them at risk for choking on small objects.

Toddlers

As the toddler's respiratory and immune systems mature, the risk for frequent and serious infections diminishes. However, *upper respiratory infections* (URIs) remain common because (1) the tonsils and adenoids are relatively large, predisposing to tonsillitis, and (2) many children are exposed to new infectious agents in preschool and day care. Most children recover from URIs without difficulty.

Toddlers actively explore the environment and often put objects in their mouth, which puts them at risk for other respiratory problems, for example:

- *Acquiring and transmitting infections* through toys and other objects
- *Airway obstruction* from aspiration of small objects (e.g., candy, buttons, coins, peanuts, grapes, and so on). The toddler's airway is still relatively short and small and may be easily obstructed.
- *Drowning* in very small amounts of water around the home (e.g., in a bucket of water or toilet bowl)

Preschool and School-Age Children

Preschool and school-age children have developed mature lungs, heart, and circulatory system that can adapt to moderate stress and change. Healthy children typically have bouts of tonsillitis or URIs, which usually resolve without difficulty. Viral infections, such as croup and pneumonia, are common, especially in preschoolers and younger school-age children. Exercise-induced (and other) asthma is also a problem. Unfortunately, as early as middle school children may begin social habits such as tobacco use that can have long-term adverse effects on oxygenation in both the pulmonary and cardiovascular systems.

Adolescents

In adolescence, the lungs develop adult characteristics. The average adolescent is developmentally at little risk for lung diseases. Some may, however, be developing behaviors and habits, such as tobacco use, that can create risk throughout life.

- As do adults, young people often begin smoking for social reasons (e.g., peer pressure, advertising, desire to feel cool), but nicotine addiction perpetuates the habit.
- The use of e-cigarettes is becoming more common. Recent studies indicate that they do not deter smoking and actually contribute to nicotine addiction.
- Adolescents make fewer routine healthcare visits than do younger children, and as a result may not receive the recommended influenza vaccines.
- And finally, exercise-induced asthma is still a problem in this age group.

Young, Middle, and Older Adults

Unhealthy practices (e.g., smoking and a lack of aerobic exercise) of adolescence often continue into adulthood. About 1 in 5 U.S. adults is a cigarette smoker (*Vital Signs*, 2011). Half the adults who smoke were regular smokers by their 18th birthday (American Lung Association, 2011; Schiller, Lucas, & Peregoy, 2012).

Changes in the respiratory system that begin in middle age and increase in older adulthood may become significant when the person experiences stressors such as infection, surgery, anesthesia, and emotional problems. The number of cells and the efficiency of the organs decline in a subtle and progressive way as a person ages. Keep in mind, though, that endurance training and regular exercise minimize the rate of these changes. In fact, an older person who is physically conditioned by regular exercise may have better lung function than will a younger adult who is not well conditioned.

Older adults tend to experience the following changes:

- *Reduced lung expansion and less alveolar inflation*, especially in the bases of the lungs. This is because (1) costal cartilage begins to calcify, reducing chest wall movement during breathing; (2) the lungs have less recoil ability; and (3) the alveoli lose elasticity.
- *Difficulty expelling mucus or foreign material* due to a less effective cough reflex, drier mucus, and fewer cilia in the airways.
- *Diminished ability to increase ventilation* when oxygenation demands increase (e.g., with exercise). As diaphragm strength decreases, vital capacity is reduced; therefore, exhalation becomes less efficient, causing progressive air-trapping.
- *Declining immune response,* especially cell-mediated immunity, T-cell activity, and the inflammatory response
- *Gastroesophageal reflux disease* is more common in older adults, creating a risk for aspirating stomach contents into the lungs. This may result in an inflammatory response.
- *Chemoreceptors* that control breathing respond more slowly to increased O_2 demand or rising levels of CO_2, making hypoxemia more likely when respiratory problems occur.

All of these changes put older adults at risk for respiratory infections. URIs that would be mild and short lived in a younger person may quickly lead to pneumonia in an older adult.

Environment

Environmental factors, such as the following (stress, allergic reactions, air quality, altitude, and temperature and humidity), affect oxygenation.

Stress

The stress response stimulates the release of catecholamines from the sympathetic nervous system resulting, which (1) increases the tendency of blood to clot (e.g., as in pulmonary embolus), and (2) suppresses the immune system and inflammatory response. A chronically suppressed immune and inflammatory response increases the risk for all infections, including respiratory. For additional information on the effects of stress, see Chapter 12.

Allergic Reactions

An **allergy** is a hypersensitivity, or overresponse, to an antigen. Pulmonary allergens include such things as dust, dust mites, cockroach particles, pollen, molds, newsprint, tobacco smoke, animal dander, and sometimes foods.

Hay Fever Hay fever is an allergic reaction affecting the eyes, nose, and/or sinuses. It causes the release of *histamine*, which is largely responsible for accumulation of nasal fluid, swollen nasal membranes, nasal congestion, and itchy, swollen, watery eyes. Antihistamines are effective in combating hay fever.

Asthma Asthma is an allergic reaction occurring in the bronchioles of the lungs. *Slow-reacting substance of anaphylaxis* (SRS-A) is released, which causes bronchoconstriction and lower airway edema and spasms, making breathing difficult and ineffective. Because histamine is not a major factor in causing the asthmatic reaction, antihistamines have little effect in the treatment of asthma. Asthma is the most common serious chronic disease of childhood, and it can be life threatening. In adults, a significant amount of asthma is caused or made worse by their workplace environment, especially among adults ages 45 to 64 years, African Americans, and other minorities (Centers for Disease Control and Prevention [CDC], 2012a).

Air Quality

Air pollution triggers respiratory problems (e.g., lung cancer, carbon monoxide poisoning) that interfere with oxygenation. Even healthy people may experience headache, coughing, and other symptoms when exposed to air pollution. People with existing respiratory disease may become unable to function. Some sources of air pollution are natural (e.g., forest fires), but the most common and damaging sources result from human activities (e.g., automobile exhaust emissions). Indoor air pollutants include carbon monoxide, nitrogen oxides, radon, and suspended particles (e.g., dust, mold spores, aerosols, and tobacco smoke). Pollutants are most harmful to infants, toddlers, older adults, and people with heart or lung disease. For more information about air quality,

Go to Chapter 36, **Supplemental Materials: Air Quality Affects Oxygenation,** on Davis*Plus*.

Altitude

Atmospheric pressure falls from 760 mm Hg at sea level to 523 mm Hg at 10,000 feet. Oxygen pressure falls proportionally, leading to decreased oxygen diffusion from alveoli into capillaries (impaired gas exchange). Low oxygen levels at high altitudes can cause hypoxemia and hypoxia. If a person is suddenly exposed to low oxygen levels, arterial chemoreceptors stimulate ventilation, making more oxygen available in the alveoli and at the tissue level. Over the long term, people who live at high altitudes undergo physiological changes that facilitate oxygenation, including an increase in the following:

- Ventilation, which brings more oxygen into the lungs
- Production of red blood cells (RBCs), which aids in the transport of oxygen to organs and tissues
- Lung volume and pulmonary vasculature, which results in increased surface area for alveolar–capillary gas exchange
- Vascularity of body tissues, which allows for improved oxygen delivery to the tissues
- Production of hemoglobin, which readily binds with oxygen so that the tissue cells can use oxygen even when oxygen pressure is low in the environment.

Temperature and Humidity

When it is very hot or very cold, the body must expend additional energy to main a constant body temperature (e.g., 98.6°F). The additional energy increases the amount of oxygen the body is using. Breathing hot or cold air can also dry and irritate the airway, causing bronchospasm. This decreases the size of the airway and makes it more difficult to move air in and out of the lungs, causing shortness of breath, especially in those with respiratory conditions such as asthma or chronic obstructive pulmonary disease (COPD). High humidity also contributes to shortness of breath.

Lifestyle

Lifestyle factors that affect oxygenation include pregnancy, occupational exposure to hazards, nutrition, obesity, exercise, smoking, and substance abuse.

Pregnancy During pregnancy, oxygen demand increases dramatically. Maternal metabolism increases by approximately 15% during the last half of pregnancy, increasing the demand for O_2. At the same time, the enlarging uterus pushes upward against the diaphragm, limiting its downward movement. In response, the maternal respiratory rate increases in order to increase *minute ventilation* (amount of air moved into and out of the lungs in 1 minute) (Hall, 2011).

Occupational Hazards Occupational hazards may affect pulmonary function by irritating airways or causing cancer. Toxic agents may be categorized as follows:

- *Chemicals and their fumes* irritate the sensitive membranous lining of the lungs and airways and may lead to lung cancer or leukemia. Even common household cleaners can emit toxic fumes.
- *Products of combustion* (e.g., carbon monoxide) are known causes of lung cancer and chronic lung disease.
- *Microorganisms*, such as viruses, fungi, and mold, may lead to infections and precipitate asthma.
- *Fine particles* (e.g., coal dust and asbestos) suspended in the air can be inhaled into the smallest airways, causing irritation and toxic reactions, including cancer.

Nutrition The body needs an appropriate balance of proteins, carbohydrates, fats, and other nutrients for proper immune function. A healthy diet builds resistance to disease and infection, promotes normal cellular function and tissue repair, and maintains a healthy weight. Poor nutrition, especially in those with pulmonary disorders, can lead to loss of ventilatory muscle strength, making breathing more difficult.

Obesity is defined as a body mass index (BMI) above 30. Obesity causes multiple health problems, many of which affect pulmonary function. The following are two examples:

- ***Respiratory infections.*** Excess abdominal fat presses upward on the diaphragm, preventing full chest expansion, leading to hypoventilation and dyspnea on exertion. The risk for respiratory infection then increases because lower lung lobes are poorly ventilated and secretions not removed effectively.
- ***Sleep apnea.*** When the person lies down, chest expansion is limited even more. Excess neck girth and fat deposits in the upper airway often lead to obstructive sleep apnea, a condition characterized by daytime sleepiness, loud snoring, and periods of apnea lasting 10 to 120 seconds (Porth & Matfin, 2010).

Exercise Exercise increases metabolic demands. The body responds by increasing the heart rate and the rate and depth of breathing. Lack of exercise has the opposite effect. A sedentary lifestyle reduces the capacity to increase ventilation in response to exercise.

Substance Abuse People abuse various kinds of substances, including prescription medications. Excess use or overdose of respiratory depressants such as opioids, sedatives, anti-anxiety agents, and hypnotics can cause hypoventilation, apnea, and respiratory failure, in some instances resulting in death. Over-the-counter (OTC) medications and other legally available products, such as alcohol, caffeine, glue, and aerosols and other inhalants, also have abuse potential and can be lethal. A large amount of alcohol, for example, depresses respiratory and vasomotor centers of the brain. Illicit drugs, including stimulants (e.g., amphetamines, cocaine), hallucinogens (e.g., LSD, PCP), marijuana, and in some states "bath salts," also have adverse effects on the respiratory system. And of course, an overdose of these substances can depress respirations and increase the risk for aspiration.

Smoking

Tobacco smoke contains tiny particles of tar and approximately 200 known toxic chemicals, more than 60 of which are known to cause cancer. Tobacco smoke constricts bronchioles, increases fluid secretion into the airways, causes inflammation and swelling of the bronchial lining, and paralyzes cilia. These effects lead to reduced airflow and increased production of secretions that are not easily removed from the airways. Lung inflammation stimulates the release of enzymes that break down elastin and other alveolar wall components. Continued smoking leads to chronic bronchitis, obstruction of bronchioles and alveolar walls, and emphysema. Cigarette smoking is estimated to be the cause of more than 80% of cases of lung cancer. The longer a person smokes and the more cigarettes he smokes, the greater the risk for cancer and other chronic lung diseases (American Lung Association, 2010; MedlinePlus, n.d., last updated 2009).

Roughly 1 in every 5 American adults smokes. However, once a person stops smoking, the body begins to repair the damage. In the first few days, the person will cough more as the cilia begin to clear the airways. Then the coughing subsides, and breathing becomes easier. Even long-time smokers can benefit from smoking cessation (Box 36-1).

BOX 36-1 ■ Benefits of Smoking Cessation

- Life expectancy increases.
- Blood pressure and heart rate decrease.
- Circulation to the extremities improves within 2 hours.
- Carbon dioxide levels in the blood begin to drop within 4 hours.
- Oxygen levels in the blood begin to improve within 8 hours.
- Digestion improves.
- Coughing, congestion, and shortness of breath decrease.
- Overall energy increases.
- Lungs increase ability to clean themselves, thereby reducing the risk of infection.
- Risk of heart attack decreases and returns to that of a nonsmoker in 1 year.
- Risk of lung and other cancers, stroke, and chronic obstructive lung disease decreases.

Secondhand Smoke Also known as **environmental tobacco smoke** (ETS), **second-hand smoke** is a general term for any smoke that non-smokers are exposed to. There are two types of second-hand smoke:

- **Mainstream smoke** refers to the smoke that a smoker inhales and then exhales.
- **Side-stream smoke** refers to the smoke released from the end of a lit cigarette, cigar, or pipe. Side-stream smoke accounts for 85% of the ETS in a smoky room, so although it is no worse for you than mainstream smoke, it makes up the bulk of smoke that non-smokers may encounter.

The Environmental Protection Agency (EPA) classifies secondhand smoke as a Group A carcinogen, meaning it is a substance known to cause cancer in humans. There is no safe level of exposure to secondhand smoke. Even short exposure can make blood platelets stickier, causing damage to blood vessel lining and disturbing the heart rate. Secondhand smoke is the third leading cause of preventable death in the United States (EPA, 2011). Children younger than 18 months are especially vulnerable to lower respiratory tract infections related to secondhand smoke (American Lung Association, n.d.).

The Healthy People 2020 (Healthypeople.gov, 2010) identified the goal of reducing illness, disability, and death related to tobacco use and secondhand smoke exposure by establishing policies to reduce exposure to secondhand smoke, increase the cost of tobacco, restrict tobacco advertising, and reduce illegal sales to minors.

KnowledgeCheck 36-4

- What are the major risks to oxygenation related to developmental factors?
- What environmental and lifestyle factors that influence ventilation can be avoided or minimized?

ThinkLike a Nurse 36-4

Review the Meet Your Patients scenario at the beginning of this chapter.

- Which patient(s) may be experiencing developmental, environmental, or lifestyle-related problems with oxygenation?
- Identify any additional information you need to know to answer this question.

Medications

Many drugs can interfere with pulmonary function by depressing respirations. Respiratory depressants generally act by depressing central nervous system (CNS) control of breathing or by weakening the muscles of breathing. They include general anesthetics, opioids (e.g., morphine), anti-anxiety drugs (e.g., diazepam [Valium]), sedative-hypnotics (e.g., barbiturates), neuromuscular blocking agents, and magnesium sulfate. Drugs that block beta-2 adrenergic receptors (e.g., used to lower the blood pressure) have little effect on healthy lungs but can lead to serious bronchiole constriction in people with asthma.

Medications are also used to improve respiratory function. A few examples include bronchodilators, anti-inflammatory agents such as corticosteroids, cough suppressants, expectorants, and decongestants.

For a more extensive discussion of individual medications that either interfere with or improve respiratory function,

Go to Chapter 36, **Supplemental Materials: Medications That Can Interfere With Oxygenation** and **Medications Used to Improve Oxygenation,** on Davis*Plus*.

Pathophysiological Conditions

Poor exchange of oxygen and carbon dioxide at the alveolar–capillary membrane or the tissue level alters the levels of O_2 and CO_2 in the blood. Unchecked, it affects oxygenation in tissues and organs and can be life threatening. Box 36-2 describes some alterations in gas exchange.

Alterations in gas exchange are caused by a number of disorders that affect the structure, function, and regulation of the pulmonary and cardiovascular systems. Because it is difficult to separate pulmonary and cardiovascular causes and effects, both are included in the discussion of pulmonary disorders that follows. For a thorough description of these diseases and pathological conditions, consult a medical-surgical nursing text, or

Go to Chapter 36, **Supplemental Materials: Pathophysiological Conditions That Influence Gas Exchange,** on Davis*Plus*.

KnowledgeCheck 36-5

- What are some indirect indicators of tissue oxygenation?
- How are hyperventilation and hypoventilation related to carbon dioxide levels?
- What are the effects of carbon dioxide levels on the nervous system?

ThinkLike a Nurse 36-5

You are assessing a very anxious young man who looks frightened and is complaining of trouble breathing. His respiratory rate is 32 and deep. He states his fingers and hands are numb.

- What is the most likely cause?
- What blood levels would help you clarify what is going on?

Example Problem: Respiratory Infections (URIs, Influenza, and Pneumonia)

Respiratory infections interfere with gas exchange. They are among the most common causes of short-term disability in the United States. It is important to distinguish among respiratory infections because antiviral medications are effective for some conditions, but not others. Diagnosis can be difficult because many conditions start with cold-like symptoms (e.g., whooping cough, croup, allergies, measles, influenza, and pneumonia).

BOX 36-2 ■ Alterations in Gas Exchange

Hypoxemia—Low arterial blood oxygen levels

Etiology: Poor oxygen diffusion across the alveolar–capillary membrane into the blood (ineffective external respiration) due to lung or pulmonary circulation disorders. Hypoventilation predisposes to the development of hypoxemia and may lead to hypoxia.

Comments: Even if the blood is adequately oxygenated, hypoxia may still occur in the organs and tissues because of poor circulation.

Hypoxia—Inadequate oxygenation of organs and tissues

Etiology: Either hypoxemia or circulatory disorders

Comments: The effects of hypoxia depend on the organs affected. For example, hypoxic central nervous system tissue causes abnormal brain functioning (e.g., altered level of consciousness), whereas hypoxic renal tissue causes abnormal kidney functioning (e.g., poor urine output), and hypoxic limb tissue results in abnormal muscle functioning (e.g., muscle weakness and pain with exercise).

Hypercarbia (hypercapnia)—An excess of dissolved CO_2 in the blood

Etiology: Hypoventilation is caused by abnormalities affecting the lungs or chest cavity or by neuromuscular abnormalities that interfere with normal breathing. Hypercarbia can occur suddenly, as in acute airway obstruction or drug overdose, or chronically, as in chronic lung disease.

Comments: Very high blood levels of CO_2 have an anesthetic effect on the nervous system and can lead to somnolence progressing to coma and death, a syndrome known as carbon dioxide narcosis.

Hypocarbia (hypocapnia)—A low level of dissolved CO_2 in the blood

In most cases (except high altitude), blood O_2 levels remain normal.

Etiology: Hyperventilation

Comments: Severe hypocarbia stimulates the nervous system, leading to muscle twitching or spasm (especially in the hands and feet) and numbness and tingling in the face and lips.

URIs Most URIs, including the common cold, are caused by viruses. Symptoms of URIs include stuffy nose, sore throat, cough, sneezing, tearing, and a mild fever. Colds are more common in children, and tend to decline with age. They are rarely dangerous to healthy adults and children. There is no "cure" for the common cold.

Influenza Influenza (flu) is a highly infectious viral disease, usually more severe than the common cold, and may involve the lower airways. Most flu fatalities occur in children younger than age 2 years and in older adults, especially the frail elderly. In addition to cold symptoms, the patient may experience high fever, headache, myalgia (muscle pain or tenderness), weakness, exhaustion, nasal inflammation and discharge, sore throat, and cough. New strains of the virus continually emerge, so it is difficult to develop immunity to the disease. Influenza immunizations are manufactured for each season in an attempt to keep pace with the changing virus.

Lower Respiratory Tract Infections Pneumonia, acute bronchitis, respiratory syncytial virus (RSV), and tuberculosis are examples of lower respiratory tract infections. They occur more often and are more severe and more likely to be life threatening in children, older adults, and people with impaired immunity or lung function.

Pneumonia is an infection of the lungs caused by bacteria, fungi, or viruses. It occurs more often during winter months and often follows a recent URI or influenza. Pneumonia-causing organisms gain entry into the lungs from being released into the air with coughing, sneezing, or talking; from contaminated respiratory therapy equipment; transported from the blood to the lung; or from the nose and throat. The invading pathogen releases toxins that damage bronchial and alveolar–capillary membranes. A full-scale inflammatory response triggers edema in the small airways and deposits debris and exudate in the alveoli. Some toxins even cause lung tissue necrosis. The area of the lung affected becomes *consolidated* (solid rather than air filled).

Symptoms of pneumonia include cough, malaise, pleural pain from coughing, discolored sputum, fever, chills, dyspnea, and elevated WBC counts. Treatment includes antipyretics for fever, expectorants to enhance mobilization of secretions, humidity to moisten inhaled air, hydration to thin secretions, *pulmonary hygiene* (deep breathing, coughing, and chest percussion and vibration) to move secretions out of the airways, rest to conserve body energy stores, and, if needed, oxygen therapy. Curative therapy includes specific anti-infective agents to kill the causative organisms. Immunizations are available and are discussed in your textbook.

Pulmonary System Abnormalities

The following is a brief discussion of various pulmonary abnormalities that can lead to alterations in gas exchange.

Structural Abnormalities Structural abnormalities include anything that restricts or limits the free movement of the chest wall (e.g., fractured ribs, kyphosis), interruptions in the chest cavity that inhibit inflation of the lungs (e.g., pneumothorax), or a collection of fluid (blood, lymph, pus) in the pleural space that inhibits lung expansion.

Airway Inflammation and Obstruction Allergic reactions (e.g., asthma) or irritation from smoke or other irritants may cause airway inflammation. Obstruction may be mechanical, as with a foreign object or bolus of food, or due to spasm (e.g., laryngospasm). Swollen tonsils and a swollen epiglottis may also cause obstruction.

Alveolar–Capillary Membrane Disorders These disorders are characterized by a change in the consistency of the lung tissue, especially at the alveolar level. The alveoli become stiff and difficult to ventilate, and gas exchange is impaired. Pulmonary edema, acute respiratory distress syndrome (ARDS), and pulmonary fibrosis are examples.

Atelectasis Anything that reduces ventilation (e.g., tumor, obstructed airway) can cause **atelectasis**, or alveolar collapse.

Pulmonary Circulation Abnormalities

For gas exchange to occur in the alveoli, there must be adequate blood flow through the pulmonary circulation. The most common causes of impaired pulmonary circulation are pulmonary embolus and pulmonary hypertension. A **pulmonary embolus** is obstruction of pulmonary arterial circulation by a foreign substance (e.g., a blood clot, air, or fat).

Pulmonary hypertension is elevated pressure within the pulmonary arterial system. High pressure in the pulmonary circulation increases the workload of the heart. Over time, this causes right-sided heart failure, with a reduced amount of blood pumped into the pulmonary circulation. You will learn about the difference between right-sided and left-sided heart failure in a medical-surgical nursing course. However, if you need some information about it now,

Go to Chapter 37, **Tables, Boxes, Figures: ESG Table 37-1,** on Davis*Plus*.

If you would like to see an animation demonstrating how blood is oxygenated in the heart and lungs,

Go to **Cardiovascular/Pulmonary Animations: Blood Flow and Carbon Dioxide/Oxygen Transport,** on Davis*Plus*.

Central Nervous System Abnormalities

Any condition that injures or alters the function of the CNS can interfere with the regulation of breathing and, therefore, gas exchange. Trauma and stroke (cerebrovascular accident) are the most commonly seen CNS problems in adults. Spinal cord injuries interfere with nerve transmission between the brain and the area below the level of the injury and may, for example, limit diaphragm function. Immature breathing patterns, such as apnea or periodic breathing, are common in preterm and term infants.

Neuromuscular Abnormalities

Neuromuscular abnormalities can affect gas exchange by interfering with the regulation of breathing or by limiting movement of the muscles involved with breathing. Any condition that alters CNS function can interfere with the regulation of breathing. Trauma, stroke, and medications are the most common causes. Neuromuscular disorders that affect the nerves involved in breathing can also depress respiratory function (e.g., Guillain-Barré syndrome, amyotrophic lateral sclerosis, and myasthenia gravis).

KnowledgeCheck 36-6

- Identify four pathophysiological conditions that affect pulmonary function. How are they similar? How are they different?
- What types of injuries are most likely to cause oxygenation problems?

ThinkLike a Nurse 36-6

You are the nursing supervisor on the night shift in a small community hospital. At the beginning of the shift, you have only one critical care bed available. During your shift, you receive calls for assistance on the following patients:

- Patient A has burns on her face, scalp, and chest and is coughing up sputum with black streaks.
- Patient B has pneumonia but has suddenly become confused.
- Patient C is short of breath and complaining that he can't breathe. His skin is cool and moist, and he is coughing up clear sputum with small bubbles in it.

Which patient would you admit to the critical care bed? Why?

Practical Knowledge knowing how

In the remainder of the chapter, we discuss focused respiratory assessment and the nursing activities to maximize ventilation and gas exchange. In Chapter 20, the section Respiration provides more information about assessing respirations. Also,

Go to Chapter 20, **Procedure 20-5: Assessing Respirations,** in Volume 2.

ASSESSMENT

Although this section focuses on respiratory assessments, recall that the pulmonary system is only a part of the concept of oxygenation. An evaluation of overall oxygenation includes a history and physical examination to assess lung, heart, and circulatory function. The order of data collection and the priorities of assessment vary with the patient's condition and the purpose of the assessment. For example, for someone in obvious respiratory distress, the immediate assessment focus is to ask simple questions about current symptoms while performing a quick examination to determine adequacy of breathing, circulation, and oxygenation. In contrast, assessment for risk of respiratory disease in a healthy person might include more extensive questions about occupation, smoking habits, and living environment; a medical history; and an extensive physical examination. For a respiratory assessment that is focused but thorough, you will need to identify risk factors, perform a physical examination, and be familiar with certain diagnostic tests.

Assessing for Risk Factors

A health history related to pulmonary function includes questions about the presence of risk factors that affect lung and airway function. Topics to assess include demographic data, health history, respiratory history, cardiovascular history, environmental history, and lifestyle. For a detailed list of interview questions for each of these topics,

Go to Chapter 36, **Assessment Guidelines and Tools, Focused Assessment: Oxygenation,** in Volume 2.

Key Point: ***All patients, not just those with oxygenation problems, should be asked whether they use tobacco and should have their tobacco-use status documented on a regular basis.***

Physical Examination

You will use all four examination techniques to assess respiratory function:

- *Inspect* to observe respiratory patterns, signs of respiratory distress, chest structures and movement, skin and mucous membrane color, presence or absence of edema, sputum characteristics, and overall general appearance. Refer to Chapter 22 to review the details of inspecting the skin and mucous membranes. Also

Go to **Procedure 22-2: Assessing the Skin,** and **Procedure 22-12: Assessing the Chest and Lungs,** in Volume 2.

- *Palpate* pulses, skin temperature, heart pulsations through the chest wall, and areas of tenderness.
- *Percuss* over the lung fields to screen for areas of consolidation or excess air pockets in the lungs.
- *Auscultate* breath sounds, heart sounds, and vascular sounds. For a step-by-step discussion of how to assess the chest and lungs,

Go to Chapter 22, **Procedure 22-12: Assessing the Chest and Lungs,** in Volume 2.

Assess breathing patterns, cough and associated symptoms, and respiratory effort, as follows. You may also need to monitor oxygenation and ventilation with pulse oximetry and capnography.

Poor peripheral circulation is characterized by weak or absent pulses; mottling (skin marbling); pale, ashen, or cyanotic skin and mucous membranes; and cool skin temperature. You can assess tissue oxygenation indirectly by determining whether organs are functioning normally. You will learn more about this in Chapter 37.

Assessing Breathing Patterns

Assess for normal and altered breathing patterns. They include the following: eupnea, bradypnea, tachypnea, apnea or periodic breathing, Kussmaul's breathing, Biot's breathing, and Cheyne-Stokes respirations. You can see a description of these patterns in Table 20-4. Most irregular breathing patterns result from brain injury or the effects of drugs on the brain.

- **Eupnea**—Normal breathing; rate about 12 to 20 breaths/min

- **Tachypnea—**Fast, shallow breathing; more than 24 breaths/min. Generally caused by hypoxemia or increased oxygen demand (e.g., exercise). Rapid, shallow respirations draw limited air into the alveoli and may result in hypoventilation.
- **Bradypnea—**Slow respirations; Fewer than 10 breaths/min. Bradypnea may cause poor gas exchange. Causes include sedative and opioid medications and neuromuscular dysfunction.
- **Kussmaul's respirations—**Regular but increased in rate and abnormally deep respirations. These may be a compensatory mechanism for metabolic disorders that lower blood pH, as well as a form of hyperventilation caused by fear, anxiety, or panic.
- **Biot's respirations—**Irregular respirations of variable depth (usually shallow), alternating with periods of apnea. This pattern is often associated with damage to the medullary respiratory center or high intracranial pressure due to brain injury.
- **Cheyne-Stokes respirations—**Gradual increase in depth of respirations, followed by a gradual decrease in depth, than a period of apnea. This pattern often results from damage to the medullary respiratory center or high intracranial pressure due to brain injury.
- **Apnea—**Absence of breathing. Respiratory arrest requires immediate cardiopulmonary resuscitation.

Recall that pain alters the rate and depth of respirations. Often patients in pain breathe shallowly and are at risk for atelectasis. Regularly assess all patients for pain. Once you have medicated the patient, reassess breath sounds, and encourage the patient to breathe deeply and cough.

Assessing Respiratory Effort/Dyspnea

A healthy person breathes effortlessly. A patient experiencing shortness of breath or dyspnea requires a thorough assessment. However, you must take care not to increase his respiratory effort. Use closed questions that the patient can answer with yes, no, or only a few words. Ask whether the shortness of breath began suddenly or gradually, how severe it is right now, and whether it is getting better or worse. At the same time, observe for or ask about the signs of increased respiratory effort discussed below. Note that these signs are most easily visible in infants and small children.

- **Nasal flaring—**The visible enlargement of the nostrils with inhalation. It helps reduce resistance to airflow in the nose and keep the nasal passages open to take in more air.
- **Retractions—**The visible "pulling in" of intercostal, supraclavicular, and subcostal tissue, caused by excessive negative pressures generated in the chest to try to increase the depth of inhalation.
- **Use of accessory muscles** during inspiration—The patient may use the intercostals, abdominal muscles, and muscles of the neck and shoulders when there is an increased demand for oxygen or problems with ventilation.
- **Grunting—**Noisy, difficult breathing. It is caused by forced expiration against a closed glottis, and by involuntary muscle contraction during expiration to help keep alveoli open and enhance gas exchange.
- **Body positioning** to facilitate respirations—The patient usually finds an upright posture the most comfortable. In the upright position, gravity pulls the abdominal organs down and allows the diaphragm more room to contract. Most patients with dyspnea cannot tolerate lying down. **Orthopnea** is the term used to describe difficulty breathing when lying down. Ask how the patient usually sleeps. Some patients may report sleeping in a recliner or chair.
- **Paroxysmal nocturnal dyspnea—**Sudden awakening due to shortness of breath that begins during sleep. The patient feels panic and extreme dyspnea and must sit upright to ease breathing.
- **Conversational dyspnea—**The inability to speak complete sentences without stopping to breathe. The more frequently the patient pauses when speaking, the more severe the dyspnea.
- **Stridor—**A high-pitched, harsh, crowing, inspiratory sound caused by partial obstruction of the larynx or trachea. You can hear it without a stethoscope. Partial airway obstruction can easily become complete airway obstruction. Therefore, the patient with stridor needs immediate care.
- **Wheezing—**A musical sound produced by air passing through partially obstructed small airways. It is often heard in patients with asthma and lung congestion.
- **Diminished or absent breath sounds—**In a patient experiencing dyspnea these are signs of worsening ventilation and oxygenation. Oxygen therapy and measures to restore adequate ventilation may be required.

Assessing Cough

Everyone coughs from time to time to remove small amounts of mucus and debris from the airways. Coughing is a normal protective response to known respiratory irritants (e.g., cigarette smoke, irritating fumes, dust particles) or when food or fluid accidentally gets into the airways. A cough becomes significant if it persists, is recurring, or is productive. A persistent or recurring cough may indicate ongoing or recurring airway irritation. Advise patients to obtain medical evaluation for a cough that lasts more than 3 weeks and cannot be explained.

Assess the Type of Cough Is it dry, productive, or hacking? When does the cough occur and how long has the patient been coughing? What makes it worse? What seems to help it? What has been used to treat the cough, and what were the effects?

Assess for Other Clinical Findings Associated With a Cough This helps determine its cause. A cough associated with nasal congestion, sneezing, or watery eyes or nose discharge is most likely due to allergies and may be successfully treated with OTC remedies. A cough occurring with fever, chest congestion, noisy breath sounds, and sputum production is more likely to be due to a URI, which may require antibiotics. A cough associated with dyspnea, chest tightness, and wheezing may be due to an airway obstruction disorder such as asthma, which requires corticosteroids and bronchodilating medications.

Assess the Sputum A cough is described as **productive** if it raises sputum (mucus and debris) up from the airways.

- **Sputum Appearance and Odor.** Sputum appearance and odor provide valuable *clues* about the cause and significance of a cough (see Box 36-3).
- **Sputum Amount.** The amount of sputum can vary from a teaspoon to pints. In general, sputum production increases with the severity of the underlying condition. However, limited sputum production does not always indicate that the problem is minor, because excess mucus and debris may be trapped in the airways and the patient is unable to cough it up and out of the body.
- **Sputum Timing.** Sputum production ranges from constant to once per day. Tobacco smokers often have a "morning cough," which helps clear their airways of mucus and debris accumulated overnight. In contrast, someone with a URI is more likely to produce sputum throughout the day.

BOX 36-3 ■ Significance of Sputum Appearance and Odor

Color/Appearance	Significance
White or clear	Usually present in viral infections (e.g., common cold, viral bronchitis), often requiring only supportive care
Yellow or green	A sign of infection
Black	Caused by coal dust, smoke, or soot inhalation
Rust colored	Associated with pneumococcal pneumonia, tuberculosis, and possibly the presence of blood
Hemoptysis	The coughing up of blood or bloody sputum. It may range from small streaks of blood to large amounts of frank blood.
Pink and frothy	Associated with pulmonary edema

Foul-smelling sputum usually indicates bacterial infection (e.g., pneumonia, lung abscess).

KnowledgeCheck 36-7

- What areas should you include in a nursing history for a patient with oxygenation concerns who is undergoing a comprehensive assessment?
- When is a cough significant? What aspects of a cough should be assessed?
- Identify at least five signs that you may observe in a patient experiencing dyspnea.
- A patient has a respiratory rate of 30 breaths/min that is rhythmic and moderate in depth. What term would you use to describe this breathing pattern?

ThinkLike a Nurse 36-7

Review the patients presented in the Meet Your Patients scenario.

- Which patients are experiencing respiratory distress? Identify the signs of distress in these patients.
- Which patients require a comprehensive assessment, and which patients will need a rapid assessment and immediate treatment because of the severity of their symptoms?

Diagnostic Testing

Diagnostic testing helps clinicians identify the causes of impaired oxygenation and monitor patient responses to treatment. You will need to assist with and be familiar with the results of the tests of respiratory function. We discuss several of these tests in the next sections. For others,

Go to Chapter 36, **Diagnostic Testing: Tests Related to Oxygenation,** in Volume 2.

Obtaining Sputum Samples

You may need to collect sputum samples. Sputum samples are examined microscopically and cultured in the lab to identify organisms and test for sensitivity to different anti-infective agents. For a summary of this procedure, see the Highlights of Procedures box. For the complete steps,

Go to Chapter 36, **Procedure 36-1: Collecting a Sputum Specimen,** in Volume 2.

Skin Testing

To review a procedure for administering intradermal injections,

Go to Chapter 26, **Procedure 26-11: Administering Intradermal Medications,** in Volume 2.

- **Tuberculin skin testing** is widely used to detect exposure and antibody formation to the tubercle bacillus. Annual screening is recommended for low-income populations, residents in congregate living conditions (e.g., dormitories, correctional facilities), immigrants from countries with a high prevalence of tuberculosis (TB), and healthcare workers. For the skin test to be effective, you must administer the antigen intradermally, not subcutaneously. Read the test site 48 to 72 hours after administration.

A positive skin test is defined as an area of induration (hardness) at the test site. The size of the induration that indicates a positive result depends on risk factors. Patients with positive TB skin tests must undergo further testing (chest x-ray study and sputum cultures) to determine whether they have merely been exposed to disease or whether they have active disease. For guidelines for interpreting test results,

Go to Chapter 36, **Diagnostic Testing: Reading a Tuberculin Skin Result,** in Volume 2.

- **Allergy testing** uses skin testing to identify antigens that may cause hypersensitivity reactions in susceptible individuals. Testing is performed by scratching antigen samples onto the skin. The area is then observed for allergic skin reactions. Skin testing is performed in facilities with resuscitation equipment and personnel trained in its use, because life-threatening airway obstruction sometimes occurs in response to the allergens.

Pulse Oximetry

Pulse oximetry is a noninvasive estimate of arterial blood oxygen saturation (SaO_2). **SaO_2** reflects the percentage of hemoglobin molecules carrying oxygen. The normal value is 95% to 100%. Values below 94% are considered abnormal in healthy people and should be investigated to determine the cause. Well-oxygenated hemoglobin and deoxygenated hemoglobin absorb light differently. Using a light-emitting diode (LED), the oximeter is able to detect this difference and calculate the percentage of oxygenated hemoglobin.

Pulse oximetry is simple to perform, provides a rapid reading, and can be used intermittently or continuously (Fig. 36-5). Frequency of measurement depends on the clinical condition of the patient. Recent recommendations are that pulse oximetery can be used to screen newborns for critical congenital heart disease (American Academy of Pediatrics, 2011b).

Such factors as movement, acrylic fingernails, nail polish, or cold extremities can interfere with the accuracy of the readings. For the complete procedure,

Go to Chapter 36, **Procedure 36-2: Monitoring Pulse Oximetry (Arterial Oxygen Saturation),** in Volume 2. Also, go to Chapter 36, **Clinical Insight 36-1: Tips for Obtaining Accurate Pulse Oximetry Readings,** in Volume 2.

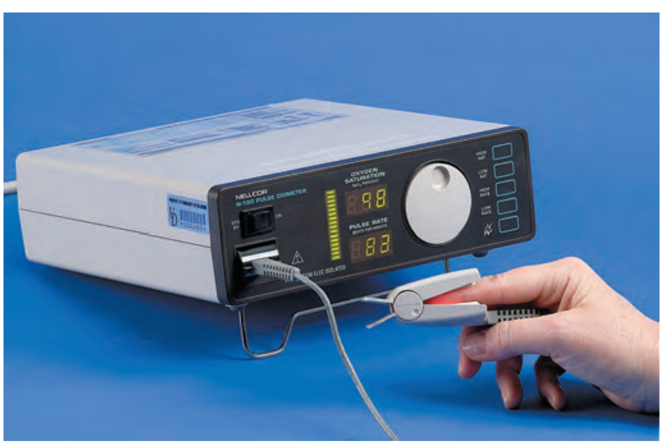

FIGURE 36-5 Pulse oximetry is a noninvasive estimate of arterial blood oxygen saturation (SaO_2). It uses a light-emitting diode (LED) probe to measure light absorption by hemoglobin in the circulating red blood cells.

Capnography

Capnography measures the carbon dioxide (CO_2) in inhaled and exhaled air. As a beam of infrared light passes through a sample of respiratory gases, more or less of it is absorbed depending on the amount of CO_2 that is present. The device displays the results digitally and prints out a graph showing CO_2 at various times in the breathing cycle. Capnography directly measures ventilation, and indirectly measures the partial pressure of CO_2 in the arterial blood. Normally the difference between arterial blood and expired CO_2 is very small.

Capnography is often used with pulse oximetry because (1) it provides information about ventilation because it shows accumulation or depletion of CO_2, whereas pulse oximetry reflects only oxygenation of the blood; and (2) capnography is a more reliable indicator of respiratory depression than is pulse oximetry. Examples of the situations in which capnography is used include the following: when a patient is receiving opioids, during general anesthesia, and for adjusting parameter settings in mechanically ventilated patients.

Although they do measure carbon dioxide, **CO_2 detectors** are different from capnography. They use chemically treated paper that changes color when exposed to CO_2. They do not give exact readings, but can measure only a range of values.

Spirometry

Spirometry is a measure of air that moves into and out of the lungs. To describe the events of pulmonary ventilation, the air in the lungs is divided into four volumes and four capacities. Normal lung volumes and capacities vary with body size, age, and exercise. Men, large people, and athletes have greater lung volume and capacity for ventilation. For a summary of this information,

Go to Chapter 36, **Diagnostic Testing: Lung Volumes and Capacities,** in Volume 2.

Think**Like a Nurse** 36-8

You hear a pulse oximeter alarm sound in a nearby patient room and find it reading 75%.

- What observations should you make?
- What actions should you take?

Arterial Blood Gases

Arterial blood gas (ABG) analysis measures the levels of oxygen and carbon dioxide in arterial blood. A blood sample is obtained from an artery (usually the brachial, radial, or femoral), either by arterial puncture or by withdrawal from an existing arterial line. Arteries are located deep under the skin and alongside nerves, making needle insertion painful. Nurses in critical care units routinely draw ABGs and monitor patients with invasive arterial monitoring; however, you may care for patients on medical-surgical units, or even outpatients, who will undergo periodic ABG evaluation. ABG analysis measures pH, partial pressure of oxygen (PO_2), partial pressure of carbon dioxide (PCO_2), saturation of oxygen (SaO_2), and bicarbonate (HCO_3) level. Here, we discuss only PO_2 and PCO_2. For a more thorough discussion of arterial blood gas values, see the discussion, Interpreting ABGs, and Table 38-6 in Chapter 38.

Measuring Arterial Blood Oxygen

Three values are important when assessing the degree to which the tissues are receiving oxygen:

- **Hemoglobin** is the iron-containing pigment of red blood cells that as *oxyhemoglobin* carries oxygen in the blood.
- **PO_2 (partial pressure of oxygen)** is the amount of oxygen available to combine with hemoglobin to make oxyhemoglobin.
- **SaO_2 (saturation of oxygen)** reflects oxygen that is actually bound to hemoglobin.

At sea level, the normal PO_2 range in arterial blood is 80 to 100 mm Hg. After tissues have extracted oxygen from arterial blood and the blood enters the veins to return to the heart, the venous blood PO_2 has fallen to around 40 mm Hg. The SaO_2, along with the PO_2 and hemoglobin level, indicates the degree to which the tissues are receiving oxygen. Small changes in SaO_2 are associated with large changes in PO_2. For blood gas values,

Go to Chapter 38, **Diagnostic Testing: Assessing Fluid, Electrolyte, and Acid–Base Balance,** in Volume 2.

To fully interpret PO_2 and SaO_2 values, you need to know the percentage of oxygen in the air the patient is inhaling. This is known as the **fraction of inspired oxygen**, or **FIO_2**. At sea level, atmospheric air (commonly known as *room air*) is 21% oxygen (FIO_2 = 21%). The norms quoted for PO_2 and SaO_2 are based on an FIO_2 of 21%. If a healthy patient receives 100% oxygen for a few minutes, the arterial PO_2 would rise to 500 to 600 mm Hg, and the SaO_2 would remain at 100%. The reason is that the SaO_2 measures the oxygen *bound to hemoglobin*—and of course the hemoglobin cannot be "filled" with oxygen to more than 100% capacity. When gas exchange is impaired as a result of disease or injury, PO_2 and SaO_2 levels fall. However, they can be kept at normal levels if supplemental oxygen is given.

Measuring Arterial Blood Carbon Dioxide

The **partial pressure of carbon dioxide (PCO_2)** is a measure of the CO_2 dissolved in the blood. Normal arterial PCO_2 is 35 to 45 mm Hg. Carbon dioxide readily diffuses across the alveolar–capillary membrane in the lungs even when there are obstacles such as alveolar fluid or thickened membranes. As a result, PCO_2 levels remain normal until a severe disorder interferes with all gas exchange. Once in the alveoli, the amount of carbon dioxide exhaled from the lungs is directly influenced by how well air is moving into and out of the lungs (ventilation).

- **Hypocarbia.** When a person hyperventilates, he exhales large amounts of CO_2, causing arterial PCO_2 values to fall. Hyperventilation brings more oxygen into the lungs, so unless it is triggered by hypoxemia, oxygen levels (PO_2) usually remain normal.
- **Hypercarbia.** Conversely, in hypoventilation less CO_2 moves into the alveoli for exhalation, leaving more CO_2 in the arterial blood. This causes PCO_2 values to rise. High PCO_2 levels (hypercarbia) suppress the respiratory drive, have an anesthetic effect on the nervous system, and can be toxic. Hypoventilation severe enough to cause hypercarbia is usually associated with hypoxemia because not enough oxygen is inhaled.

KnowledgeCheck 36-8

- What does a pulse oximetry reading tell you?
- What is the relationship between arterial PO_2 and SaO_2 levels?
- Identify normal PO_2, SaO_2, and PCO_2 levels.
- What effect does ventilation have on arterial PCO_2?
- How is PCO_2 related to oxygenation?

ThinkLike a Nurse 36-9

You are caring for two patients, both of whom have a PO_2 of 95 mm Hg and SaO_2 of 99%. Do they have similar lung function? Explain your answer.

Peak Flow Monitoring

Peak expiratory flow rate (PEFR) measures the amount of air that can be exhaled with forcible effort. Patients with asthma use PEFR monitoring to detect subtle changes in their condition, often before symptoms occur. A peak flow meter is used to monitor these changes (Fig. 36-6). Peak flow is expressed in liters per minute. Patients with asthma are often asked to measure their peak flow daily and with the onset of any symptoms. Treatment protocols describe the use and frequency of medications based on individualized peak flow rates. The Home Care box Home Use of a Peak Flow Meter describes self-monitoring.

ANALYSIS/NURSING DIAGNOSIS

Alterations in pulmonary function may be nursing diagnoses, etiologies of other problems, or merely symptoms of other problems. In analyzing the assessment data, you must determine which. For example, suppose

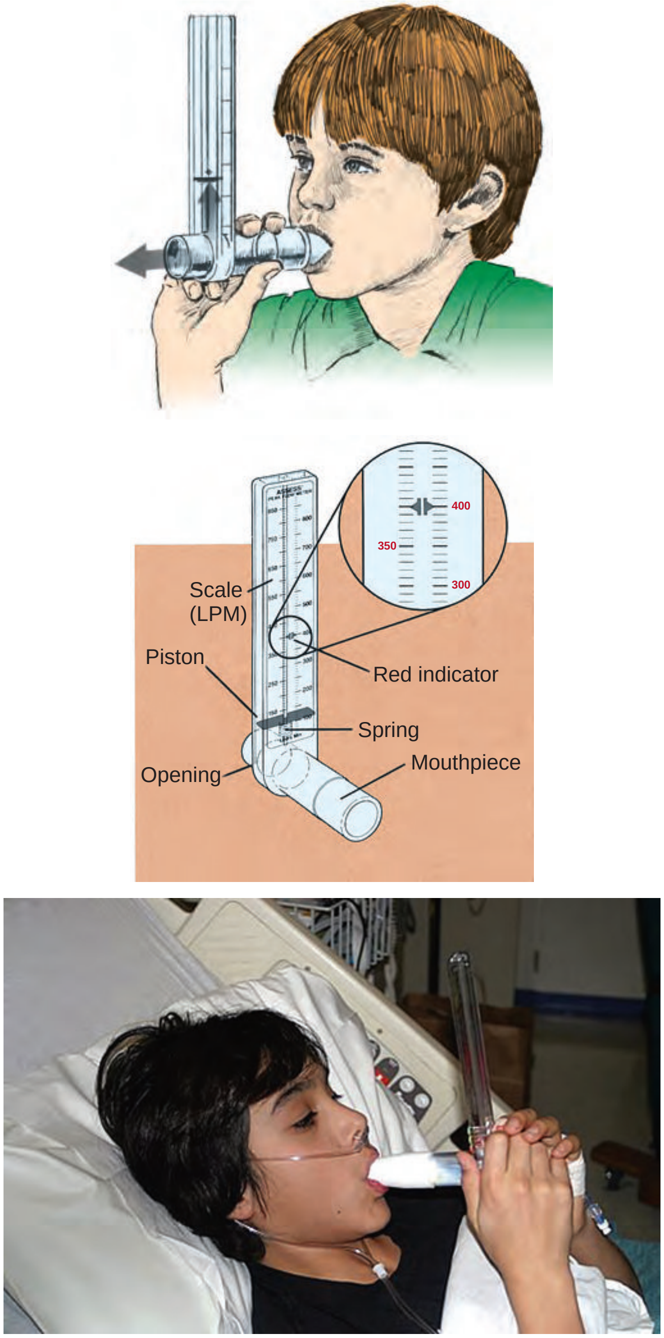

FIGURE 36-6 A patient with asthma using a peak flow meter to monitor peak expiratory flow rate (PEFR).

a patient is breathing shallowly and slowly. The pulmonary problem might be one of the following:

- **A nursing diagnosis:** *Ineffective Breathing Pattern (hypoventilation)* r/t pain secondary to rib fractures. In this case, you would provide pain relief; the desired outcome is that the patient will have effective (normal) ventilation. To sees a nursing care plan and care map for Ineffective Breathing Pattern,

Go to Chapter 36, **Care Plan and Care Map,** on Davis*Plus*.

Home Care

Home Use of a Peak Flow Meter

People with asthma are often asked to monitor their peak flow readings at home and to compare their current readings with their baseline "personal best."

- Teach patients that to get an accurate reading, they need to take a deep breath and forcefully exhale.
- Teach patients to take a series of three readings and record the highest reading.
- Teach patients to maintain or adjust their medication according to their highest reading. They should follow the color-coded treatment protocols prescribed by their physician. These are individualized for each patient. Notice that these correspond to the color-coded markers on their peak flow meter.

Green = ***All clear: Baseline peak flow***—*Peak flow is within 80% to 100% of personal best baseline.*

Treatment protocol calls for routine medication use.

Yellow = ***Caution: Peak flow is 50% to 80% of usual or "normal" rate.*** *Said another way, there is a 20% to 50% reduction in peak flow—This reading signals the onset of airway changes.*

Treatment protocols usually specify an increase in the dosage of maintenance medications, use of rescue therapies (e.g., fast-acting bronchodilators), or a call to the healthcare provider. These measures are designed to reverse acute exacerbations before they become severe.

Red = ***Medical alert: Peak flow is less than 50% of personal best baseline.*** *Severe reduction in peak flow.*

Treatment protocols usually specify immediate treatment with rescue medications and to seek emergency treatment if symptoms do not improve.

Source: Adapted from American Lung Association. (2013). *Six steps.* Retrieved from http://www.lungusa.org/lung-disease/asthma/living-with-asthma/take-control-of-your-asthma/AsthmaActionPlan-JUL2008-high-res.pdf

- **An etiology:** Risk for ineffective Cerebral Tissue Perfusion (Cerebral) *r/t Ineffective Breathing Pattern (hypoventilation).* In this case, you might address the etiology by administering oxygen; the desired outcome would be effective cerebral perfusion, evidenced by normal speech and alertness.
- **A symptom:** Decreased Intracranial Adaptive capacity r/t brain injury, *as manifested by Ineffective Breathing Pattern (hypoventilation), and baseline ICP ≥10 mm Hg.* In this situation, you would, of course, support ventilation (the symptom) until the problem subsides. However, the primary interventions would be directed toward the head trauma and increased intracranial pressure (ICP). Once these etiologies were corrected, the hypoventilation would disappear. The goal would be normal intracranial pressure, evidenced in part by a normal breathing pattern.

Problems of Ventilation and Gas Exchange Five NANDA International (NANDA-I) diagnoses directly describe problems with ventilation and gas exchange. Use these diagnoses when they are the central problem and you intend to use interventions to eliminate the cause of the problem.

- *Ineffective Airway Clearance* is the inability to maintain a clear airway.
- *Ineffective Breathing Pattern* is used to describe inadequate ventilation, such as hypoventilation, hyperventilation, tachypnea, or bradypnea.
- *Impaired Gas Exchange* is the appropriate diagnosis if the patient is ventilating adequately but diffusion of gases across the alveolar–capillary membrane is impaired.
- *Impaired Spontaneous Ventilation* describes a condition in which a patient, as a result of decreased energy reserves, is unable to maintain breathing adequate to support life.
- *Dysfunctional Ventilatory Weaning Response* represents a specific situation in which a patient who is being mechanically ventilated cannot adjust to lower levels of ventilator support, prolonging the ventilatory weaning process.
- *Risk for Aspiration* should be used when there is a risk for secretions, solids, or fluids entering into tracheobronchial passages (e.g., for patients who have had head or neck surgery or who have a reduced level of consciousness).

For further discussion of these diagnoses,

Go to Chapter 36, **Standardized Language, Nursing Diagnoses Associated With Impaired Ventilation and Gas Exchange,** on Davis*Plus*.

PLANNING OUTCOMES/EVALUATION

NOC standardized outcomes appropriate for patients with pulmonary function problems include, for example, Mechanical Ventilation Weaning Response: Adult; Respiratory Status: Airway Patency; and Respiratory Status: Gas Exchange. For examples of other NOC outcomes and NIC interventions for selected oxygenation nursing diagnoses,

Go to Chapter 36, **Standardized Language, Examples of NOC Outcomes and NIC Interventions Linked to Oxygenation Diagnoses,** on Davis*Plus*.

These provide a general care planning guide. Depending on individual patient needs, other NOC outcomes or NIC interventions may also be appropriate.

Individualized goals/outcome statements depend on the nursing diagnosis you identify. For diagnoses related to gas exchange, the following are examples of goals you might write:

Expectorates secretions effectively
No dyspnea or shortness of breath
Lungs clear; no adventitious sounds present

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC standardized interventions related to oxygenation are found in the Respiratory Management category. They focus on maintaining a patent airway and promoting gas exchange, and include Airway Management, Airway Suction, Cough Enhancement, Oxygen Therapy, and Respiratory Monitoring.

Specific nursing interventions for patients with oxygenation problems include health promotion, prevention, and treatment activities. They are discussed in the sections that follow.

Administering Respiratory Medications

Respiratory medications promote ventilation and oxygenation by their effects on the respiratory system itself. Some need a prescription; others do not. Medications used to improve respiratory function include bronchodilators and anti-inflammatory agents such as corticosteroids, cough suppressants, expectorants, and decongestants.

See the accompanying Self-Care box Cough and Cold Medicines: Tips for Parents for assistance in administering such medications to children. Also refer to the accompanying CAM box for some common alternative cold remedies. For an extensive discussion of individual medications that either interfere with or improve respiratory function,

Go to Chapter 36, **Supplemental Materials: Medications That Can Interfere With Oxygenation and Medications Used to Improve Oxygenation,** on Davis*Plus*.

Promoting Optimal Respiratory Function

Deep, regular breathing promotes ventilation and optimizes gas exchange. Other interventions to promote optimal function include preventing and treating URIs, influenza, and pneumonia (including immunizations); supporting smoking cessation; positioning; incentive spirometry; and preventing aspiration.

Example Problem: Upper Respiratory Infections (Prevention Interventions)

URIs may be viral or bacterial. Viral infections usually last about 10 to 21 days and are self-limiting. URIs may, however, lead to other respiratory diseases and seriously compromised oxygenation in children, older adults, and people who have other illnesses. Therefore, it is important to teach clients the importance of hand washing and other measures for preventing URIs. For teaching tips, see the Self-Care box Teaching Clients How to Prevent URIs, in Chapter 42.

Overuse of antibiotics to treat URIs has contributed to the current crisis of antimicrobial resistance. Teach clients that antibiotics should be used only as prescribed for diagnosed bacterial infections. This includes taking

Self-Care

Cough and Cold Medicines: Tips for Parents

- Do not give children medicines labeled for adults only.
- Do not give over-the-counter (OTC) cough and cold remedies to children younger than age 4 years. There is a risk of serious and even life-threatening side effects.
- Read labels! Some labels are marked "Do not use for children under age 4."
- The safety and effectiveness of OTC cough and cold remedies for children ages 2 through 11 years is still in question. It is not certain they are safe, and they may not be effective.
- Choose medications with safety caps. Close caps tightly and store out of sight and reach of children.
- Do not give more than one medicine with the same active ingredient. Check the "active ingredients" on the label. Your child could be harmed by getting too much of the ingredient.
- Carefully follow the directions on the label for how to use the medicine. Overuse or misuse can cause serious side effects (e.g., drowsiness, breathing problems, and seizures).
- Measure carefully. Do not use household spoons because they come in different sizes.
- Understand that OTC medicines do not cure the cold or cough. They only treat symptoms such as runny nose, congestion, fever, and aches. They do not shorten the length of time your child is sick.

Source: CDC (2009); U.S. Food and Drug Administration (2013).

Complementary & Alternative Modalities (CAM)

Common Cold Remedies

- Cold care products containing *Pelargonium sidoides*, an extract of the South African geranium, may reduce the intensity of the common cold. However, more evidence is needed (Ross, 2012). In the United States, Zucol products are one example.
- Honey is more effective than dextromethorphan in children with nocturnal cough (Cohen, Rozen, Kristal, et al., 2012). However, avoid giving honey to children younger than the age of 1 year because it is a reservoir of *Clostridium botulinum* spores, and may cause botulism in infants.
- Vitamin C in daily doses of 200 mg or more has not been found to prevent colds, but it did reduce the length and severity of symptoms. Be aware that in amounts of 2,000 mg, it may cause diarrhea and gas (Hemilä & Chalker, 2013).
- A systematic review of research studies found there is no evidence that Echinacea preparations are effective for preventing and treating the common cold (Thomas, 2012).
- Although lab studies are preliminary, elderberry (*Sambucus nigra*), an herb, has been found to help combat viruses, specifically influenza. It is thought to strengthen the immune system and keep the flu virus from adhering to cells (Kinoshita, Hayashi, Katayama, et al., 2012).

the full course of prescribed antibiotics, even if symptoms are no longer present. Antibiotics are not without risks, and they are not effective for treating the common cold. Advise clients not to pressure clinicians for a prescription, nor to take any antibiotics left over from previous prescriptions or from others who might offer to share antibiotics.

Example Problem: Influenza (Prevention Interventions)

The most effective strategy for preventing influenza is annual vaccination. Vaccines are developed annually to closely match the major known strains of the virus that have evolved. Immunizations given to healthy young adults are 70% to 90% effective. Though less effective in preventing the disease in older adults, immunization decreases the severity of the disease, the development of secondary complications, and the incidence of death (American Academy of Pedriatics, 2011a; Fiore, Uyeki, Broder, et al., 2010).

Another prevention measure is to avoid exposure to the virus. That is, avoid being around people who are sick, if possible; and use recommended hand hygiene measures.

Infection rates are highest among children. Rates of serious illness and death are highest among older adults, children younger than age 2 years, and people with certain medical conditions. However, the CDC continues to recommend universal vaccination—that is, all people age 6 months and older receive annual influenza vaccination (CDC, 2013).

Example Problem: Pneumonia (Prevention Interventions)

Pneumonia is a leading cause of infectious death in the United States, with a mortality rate of approximately 50% in people older than age 65. Therefore, people who are most susceptible should be immunized against pneumonia. Historically this vaccine was thought to convey lifetime immunity, but recent data illustrate that this may not be so. As a result, the vaccine is recommended annually for high-risk groups, including the following (CDC, 2012b):

- Adults age 65 years or older
- Children younger than age 5 years
- Children age 6 through 18 years who have certain medical conditions
- People age 2 through 64 years who have chronic illnesses (e.g., those with heart disease, diabetes, pulmonary disease, alcoholism, HIV infection) or lowered resistance to infection
- Adults age 19 through 64 years who have asthma or are smokers

CDC recommended immunization schedules change periodically. To be certain you have the most current information, always check the CDC Web site at

www.cdc.gov/vaccines/schedules/index.html

Healthcare-Associated Pneumonia Healthcare-associated pneumonia tends to be more complicated and to have a higher mortality rate than community-acquired pneumonia. Guidelines for preventing healthcare-associated pneumonia include following standard precautions for hand hygiene and gloving.

- Wear gloves when handling respiratory secretions or objects contaminated with respiratory secretions of all patients.
- Change gloves and decontaminate hands:
  - Between contacts with different patients
  - After handling respiratory secretions or contaminated objects and before contact with another patient, object, or environmental surface
  - Between contacts with a contaminated body site and the respiratory tract or respiratory device on the same patient (Allegranzi & Pittet, 2009)

Support Smoking Cessation

Smoking cessation is important in preventing and treating all respiratory problems, including the example problems (URIs, influenza, and pneumonia). Nurses can provide effective support to patients who want to quit smoking. When nurses offer smoking cessation advice, smokers are more likely to quit as compared with smokers who do not receive such advice from nurses (Rice & Stead, 2008; Rigotti, Clair, Munafò, et al., 2012). *All* patients, including school-age and adolescent children, should be asked whether they use tobacco. Furthermore, a systematic review of evidence indicates that their tobacco-use status should be documented regularly (e.g., by chart stickers or computer prompts) (Coffin, Klompas, Classen, et al. 2008). The U.S. Public Health Service guidelines suggest the "5A's" model for treating tobacco dependence (Box 36-4) (Fiore, Jaén, Baker, et al., 2008).

Motivational counseling includes discussion about the connection between tobacco use and current health status, the risks of continued tobacco use, the rewards of quitting, anticipated barriers to quitting, and strategies for addressing barriers. It may also be important to refer the person to a tobacco cessation program. Most smokers are not able to quit "cold turkey."

Combining medication and counseling is more effective than either used alone. Encourage patients to contact their primary care provider for nicotine replacement therapy (e.g., nicotine patch) or other medications (e.g., antidepressants, clonidine) to treat tobacco dependence. A recent study indicates that electronic cigarettes have been used as successfully as nicotine patches for smoking cessation (Bullen, Howe, Laugesen, et al., 2013). However, others (e.g., Grana, 2014) have found that e-cigarettes are not associated with higher rates of smoking cessation. For pregnant women, smokeless tobacco users, light smokers, and adolescents, medications may be contraindicated or may lack evidence of effectiveness (National Guideline Clearinghouse, 2013; Stead & Lancaster, 2012).

Box 36-1 highlights some of the benefits of smoking cessation. Share these and smoking cessation tips with patients (Self-Care: Smoking Cessation Tips).

BOX 36-4 ■ The 5A's for Treating Tobacco Dependence

Ask about tobacco use and document tobacco use status for every patient at every visit.

Advise to quit. Use a clear, strong, personalized approach to urge the patient to quit.

Assess willingness to make a quit attempt at this time.

Assist in a quit attempt. If the patient is willing, refer for counseling and medication. If the patient is not willing to quit at this time, provide interventions designed to increase future quit attempts.

Arrange follow-up. If the patient is willing to quit, make follow-up contacts beginning the first week after the quit date. If the patient is not willing to quit at this time, address tobacco dependence and willingness to quit at the next clinic (or other) visit.

Source: Adapted from Fiore, M., Jaén, C., Baker, T., et al. (2008). *Treating tobacco use and dependence: 2008 update.* Clinical Practice Guideline. Rockville, MD: U.S. Department of Health and Human Services. Public Health Service.

Position for Maximum Ventilation

Position affects ventilation. An upright or elevated position pulls abdominal organs down, allowing maximum diaphragm excursion and lung expansion. Therefore, this intervention is applicable to almost all respiratory problems, including the example problems, URI, influenza, and pneumonia.

- If the patient is short of breath, provide an overbed table to lean forward on. Patients with impaired respiratory function adopt a tripod position to allow maximum expansion. They may need to rest their arms on an overbed table.
- When the patient is lying on her side, provide pillows to support the upper arm.
- Assist with frequent position changes to keep all areas of the lungs well ventilated, and ambulate as often as possible without creating fatigue.

Assist With Incentive Spirometry

Incentive spirometers are designed to encourage patients to take deep breaths by reaching a goal-directed volume of air. Incentive spirometry is usually reserved for patients at risk for developing atelectasis or pneumonia, for

Self-Care

Smoking Cessation Tips

- Identify several personal reasons to quit smoking, such as: "I'll live longer and be able to spend more time with my children and grandchildren," or "My father died of lung cancer. He really suffered. I have no desire to experience that."
- Plan a time to quit. Choose a time that will not require many additional demands on you.
- Talk with friends and coworkers who have successfully quit smoking.
- Tell several supportive people of your plan to quit. Ask them to help you be successful.
- Identify friends who do not smoke, and plan to spend time with them.
- Participate in a structured smoking cessation program, if possible.
- Tell your healthcare providers that you would like to quit smoking.
- Consider asking your healthcare provider about nicotine-replacement therapy, for instance, gum or patches.
- Before smoking, ask yourself, "What can I do instead of smoking this cigarette?"
- Have carrot sticks, celery, gum, or sunflower seeds available to chew instead of smoking a cigarette. These also help you cope with the increased hunger you may feel.
- Learn several relaxation techniques, such as meditation or visualization, to help you through the stress of quitting.
- Use positive affirmations daily. "I can successfully quit smoking. I am no longer a smoker."
- When you feel a craving to smoke, breathe deeply, find something to distract yourself, or call a supportive person.
- To help cope with irritability, use relaxation exercises or deep breathing; take a hot bath; or do something else you enjoy.
- Make a list of things you enjoy doing. Choose one of these items as a reward for not smoking.
- Save the money you would have spent on cigarettes. Treat yourself to an activity or event with the money you have saved.

example, patients who have had abdominal, chest, or pelvic surgery, patients on prolonged bedrest, or patients with a history of respiratory problems. Incentive spirometers offer various visual cues (such as elevation of a ball or piston) to show patients whether they are inhaling deeply enough. As a registered nurse (RN), you can delegate incentive spirometry coaching to licensed practical nurses (LPNs) and qualified nursing assistive personnel (NAPs). However, you are responsible for ensuring that incentive spirometry is carried out correctly and at required frequencies. You must also evaluate patient responses, airway clearance, and ventilation. See Figure 39-6 and Self-Care: Teaching Your Patient About Incentive Spirometry, in Chapter 39.

Take Aspiration Precautions

Aspiration is a risk for patients with a decreased level of consciousness, diminished gag or cough reflex, or difficulty with swallowing. Preventing aspiration requires you to have practical knowledge about positioning, enteral and oral feedings, and administering medications. For guidelines to use with at-risk patients,

Go to Chapter 36, **Clinical Insight 36-2: Guidelines for Preventing Aspiration,** in Volume 2.

Many of the guidelines involve basic care and can be delegated to qualified LPNs and NAP. The RN is responsible for monitoring for aspiration. Record in the nursing notes any preventive measures taken.

KnowledgeCheck 36-9

Identify at least three nursing interventions to promote optimal respiratory function in a hospitalized patient with chronic lung disease.

ThinkLike a Nurse 36-10

- Review the Meet Your Patients scenario. For which of these patients should you recommend annual flu or pneumonia immunizations? Why?
- A 24-year-old nursing student has no previous hospitalizations or known chronic health problems, takes no medications, and has no current respiratory symptoms. On routine purified protein derivative, or PPD, testing (tuberculin skin testing), the student has an area of induration measuring 5 mm. How would you interpret these results?

Mobilizing Secretions

Coughing promotes deep inhalation and forceful expulsion of secretions. Interventions that help enhance coughing and mobilize secretions include deep breathing, coughing exercises, and hydration. Mobilizing secretions is useful for many respiratory conditions, including the example problems, UTI, influenza, and pneumonia.

Teach Deep Breathing and Coughing

Deep breathing promotes ventilation and gas exchange. Coughing after deep breathing mobilizes secretions, which keeps airways and alveoli open and provides greater surface area for gas exchange. This intervention is important, for example, in treating pneumonia and preventing stasis pneumonia postoperatively. For information about teaching patients to deep-breathe,

Go to Chapter 36, **Procedure 36-1A: Collecting an Expectorated Sputum Specimen,** in Volume 2.

Alter this procedure for patients with chronic lung disease. Have the patient exhale through pursed lips and cough throughout expiration in several short bursts to avoid high expiratory pressures, which collapse diseased airways.

Maintain Hydration

The following activities are important to keep pulmonary secretions thin and mobile. (e.g., in infections such as influenza and pneumonia):

- *Maintain systemic hydration.* Encourage oral fluid intake as much as possible. Supplement oral intake by intravenous fluid administration if the patient cannot ingest adequate amounts of fluid. For guidelines to use in teaching patients to maintain hydration, refer to the Self-Care box Teaching Patients to Prevent Fluid and Electrolyte Imbalances in Chapter 38.
- *Humidify inhaled air.* You can accomplish this with humidification devices or nebulizers. A **humidifier** is a device that delivers small water droplets from a reservoir. Small humidifiers filled with sterile distilled water are attached to oxygen delivery systems to moisten the dry oxygen and keep secretions thin and mobile. A **nebulizer** is a device that turns liquids into an aerosol mist that can be inhaled directly into the lungs. Nebulizers are often used to deliver medications to the lungs, but they can also be used to deliver moisture to the airways and lungs. See Administering Respiratory Inhalations in Chapter 26, and Figures 26-11 and 26-12. Also,

Go to **Clinical Insight 36-3: Oxygen Therapy Safety Precautions,** in Volume 2.

Perform Chest Physiotherapy

Chest physiotherapy moves secretions to the large, central airways for expectoration or suctioning (Fig. 36-7). It involves postural drainage, chest percussion, and chest vibration. In many institutions, respiratory therapists routinely perform chest physiotherapy. However, these procedures are briefly discussed below and in the Highlights of Procedures box. For detailed discussion,

Go to Chapter 36, **Procedure 36-3: Performing Percussion, Vibration, and Postural Drainage,** in Volume 2.

- *Postural drainage* is the use of positioning to promote drainage from the lungs. Check chest x-ray results to see what segments of the lungs are affected. With this information, you can plan how to position your patient. Postural drainage uses gravity to drain the lungs, so you will position the affected area uppermost so that secretions will drain down toward the large, central airways. For example, if the patient has pneumonia of the right lower lobe, you would place her on her left side and elevate the foot of the bed to allow the right lower lobe to drain.

FIGURE 36-7 Patient receiving chest physiotherapy.

- *Chest percussion and chest vibration* are used in conjunction with postural drainage to loosen and mobilize secretions. **Chest percussion** is the rhythmic clapping of the chest wall using cupped hands. **Chest vibration** is the vibration of the chest wall with the palms of the hands. Vibration is a gentle procedure, so you can use it in frail patients who cannot tolerate percussion. You can use a vibrating machine, if one is available, instead of the palms of your hands. Have the patient assume the desired position for 10 to 15 minutes before percussing and vibrating.

ThinkLike a Nurse 36-11

Your patient has pneumonia in the right lower lobe. She is mildly dyspneic with any activity. Plan how you would perform chest physiotherapy on this patient. What activities would you consider to make this procedure more tolerable for the patient?

Providing Oxygen Therapy

Oxygen therapy provides oxygen at concentrations greater than the level found in room air, which contains only about 21% oxygen. Because oxygen is a medication, it requires a medical prescription for dosage (concentration) and route. Many agencies have protocols with standing orders for oxygen administration in an emergency. (Note that oxygen therapy may be needed for the example problem, pneumonia.) Oxygen is supplied in several different ways.

- *Wall outlets* connected to a large central tank of oxygen are usually provided in healthcare facilities (Fig. 36-8).
- *Compressed O_2 in portable tanks* may also be available (Fig. 36-9).
- *Liquid oxygen units* are often used for home oxygen therapy (Fig. 36-10).

FIGURE 36-8 Healthcare facilities usually have oxygen available through wall outlets connected to a large central tank of oxygen.

FIGURE 36-9 Portable oxygen tanks come in a variety of sizes.

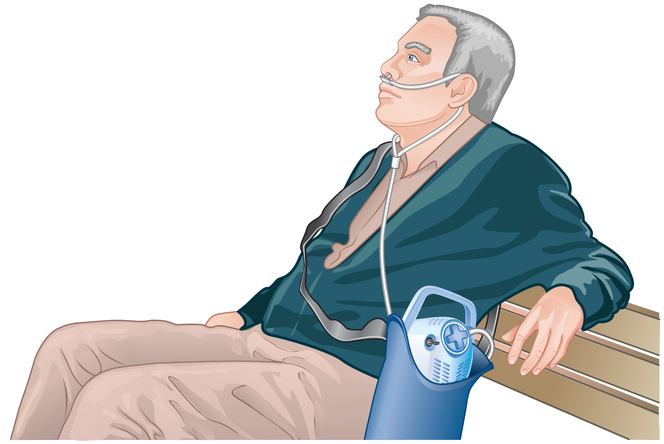

FIGURE 36-10 Liquid oxygen units are small and portable. They are ideal for home use.

- An *oxygen concentrator* removes nitrogen from room air and concentrates O_2. It requires a battery pack or electrical outlet for power. Oxygen concentrators can deliver flow up to 4 liters per minute (L/min) to create an FIO_2 of approximately 36%. Concentrations are higher at lower flow rates (e.g., an FIO_2 of 95% at 1 L/min). These devices eliminate the need for buying oxygen cylinders, relieving clients' anxiety about running out of oxygen. However, they are expensive, noisy, and not portable; moreover, the client must still have backup oxygen in case of a power failure.

An oxygen flow meter must be connected to the oxygen source to control the flow rate of oxygen from its source to the patient. Flow meters are set in liters per minute.

Various devices (e.g., mask, cannula) are used to deliver oxygen to a patient. They differ in the amount of oxygen they can deliver and the degree to which they enclose the patient. Low-flow devices are the nasal cannula, simple face masks, and rebreather masks. High-flow devices include Venturi masks, aerosol face masks, face tents, and tracheostomy collars—all capable of reaching up to 100% oxygen concentration (Stich & Cassella, 2009).

The Highlights of Procedures box summarizes how to set up and apply oxygen therapy. For the complete procedure and to see the various types of masks,

Go to Chapter 36, **Procedure 36-4: Administering Oxygen,** in Volume 2.

Oxygen administration is a nursing responsibility. NAP may assist in maintaining oxygen use (e.g., adjusting the face mask), but you are responsible for monitoring the patient's response to therapy.

Oxygen Hazards

The following risks are associated with oxygen therapy. For guidelines,

Go to Chapter 36, **Clinical Insight 36-3: Oxygen Therapy Safety Precautions,** and **Procedure 36-4,** in Volume 2.

- *Oxygen toxicity can develop* when O_2 concentrations of more than 50% are administered for longer than 48 to 72 hours. Prolonged use of high O_2 concentrations reduces surfactant production, which leads to alveolar collapse and reduced lung elasticity.
- *Oxygen supports combustion*, although it does not burn. High concentrations of oxygen will turn a small spark or fire into a large fire. Fire prevention precautions must be used near oxygen delivery systems.
- *Oxygen tanks contain oxygen under pressure*. If the tank ruptures or falls, compressed oxygen shoots forcefully from the tank, turning it into an unguided missile. Oxygen tanks have been known to hurtle through walls when ruptured.

Transtracheal Oxygen Delivery

A **tracheostomy** is a surgical opening into the trachea through the neck. It may be permanent or temporary. When a patient has a tracheostomy, inhaled air bypasses the upper airway, which normally warms and moistens air before it reaches the lower airway. Oxygen may be delivered through the tracheostomy via a collar or an adapter. A **transtracheal catheter** is a catheter placed into the tracheostomy to deliver O_2 directly into the trachea. Because oxygen cannot be humidified through this device, it is rarely used.

KnowledgeCheck 36-10

- Why is oxygen humidified?
- Which oxygen delivery method is appropriate for the following patients?
  - A patient prescribed to receive 2 L/min of oxygen
  - A patient who complains of being claustrophobic and requires low-flow humidified oxygen
  - A patient with chronic obstructive pulmonary disease (COPD) with an order for oxygen at an FIO_2 of 24%
  - A patient who wants to avoid intubation but requires an FIO_2 of 100%

Using Artificial Airways

Artificial airways provide an open airway for patients who have or who are at risk for airway obstruction. Airways may be placed into the pharynx or deeper, into the trachea.

Pharyngeal Airways

Pharyngeal airways provide an open air passage by holding the tongue away from the back of the pharynx. When artificial airways are properly placed, air can flow around and through them, and suction catheters can be passed through them. Pharyngeal airways may be placed through the mouth or the nose.

- **Oropharyngeal airways** are C-shaped, hard plastic devices inserted through the mouth into the pharynx. To select the appropriate size, hold the airway next to the patient's face. The length of the airway should extend from the front of the teeth to the end of the jawline (Fig. 36-11). If it is *too short,* it will not keep the tongue pulled forward; if it is *too long,* it may push the epiglottis against the laryngeal opening and completely obstruct the airway. To learn how to insert an oropharyngeal airway,

Go to Chapter 36, **Procedure 36-12: Inserting an Oropharyngeal Airway,** in Volume 2.

- **Nasopharyngeal airways** are flexible rubber tubes that are inserted through a nostril into the pharynx. Patients who are semiconscious can tolerate nasal airways because they do not stimulate the gag reflex. Nasopharyngeal airways are available in a variety of pediatric and adult sizes. Generally, the larger the internal diameter is, the longer the tube will be. To select the appropriate size, hold the airway next to the patient's face. The length of the airway should extend from the nares to the end of the jawline (Fig. 36-12). To learn about inserting a nasopharyngeal airway,

Go to Chapter 36, **Procedure 36-13: Inserting a Nasopharyngeal Airway,** in Volume 2.

Endotracheal Airways

Patients who cannot breathe effectively because of airway obstruction or respiratory or cardiac failure need an airway inserted directly into the trachea. **Endotracheal**

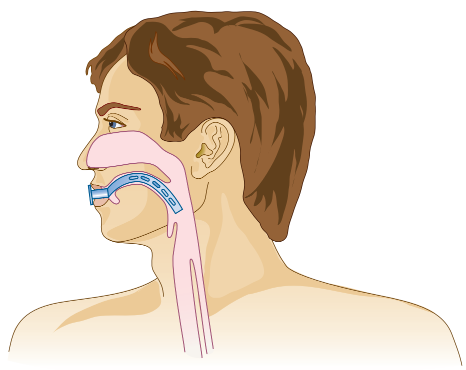

FIGURE 36-11 Oropharyngeal airway in place.

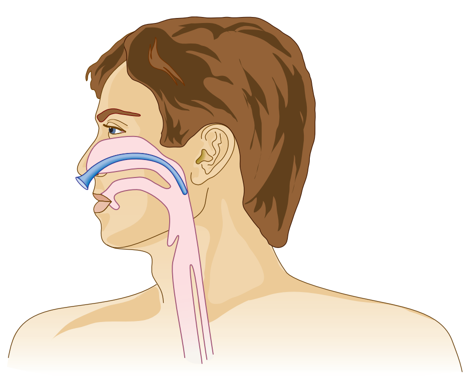

FIGURE 36-12 A nasopharyngeal airway in proper position.

airways are pliable tubes inserted into the trachea through the following routes:

Orotracheal tube—the mouth
Nasotracheal tube—the nose
Tracheostomy tube—an opening directly into the trachea

There are several types of tracheostomy tubes, made of various materials. They may be cuffed or uncuffed and may have a single or double lumen. A cuffed tube is used for patients who are being ventilated or who have difficulty swallowing. For self-care at home, a tube with an inner cannula is preferred because the inner tube can be removed and cleaned to avoid tube occlusion, primarily due to accumulation of secretions in the airway.

Because tracheostomy tubes bypass the upper airway, the patient inhales air directly into the lower airway without humidification, filtering, or warming. For this reason, devices that warm and humidify inhaled air are used with endotracheal airways. Figure 36-13A illustrates the parts of an endotracheal airway. Figure 36-13B shows the placement of an orotracheal tube. Nursing responsibilities related to endotracheal airways are to assist in their insertion, maintain stabilization, and provide routine suctioning and management.

Assisting With Endotracheal Airway Insertion

Insertion of endotracheal airways is within the scope of practice of certain specially trained nurses (e.g., nurse anesthetist). As a general-practice nurse, you will assist with insertion by gathering equipment and preparing the patient. On most units, you will find intubation equipment in the resuscitation cart. Intubation must often be done quickly, in response to a temporary decline in the patient's respiratory function during a procedure. For more information about assisting with and managing endotracheal airways,

Go to Chapter 36, **Clinical Insight 36-4: Caring for Patients With Endotracheal Airways,** in Volume 2.

Managing Endotracheal and Tracheostomy Tubes

Managing endotracheal and tracheostomy tubes generally requires the expertise of a respiratory therapist or an RN, but you can delegate this activity to specially trained and skilled LPNs, especially in critical care areas. Once the ostomy is well healed, the airway will not collapse if the tracheostomy tube is dislodged; so a NAP, or even the patient, can reinsert it if necessary. Many patients with permanent tracheostomies perform self-care at home.

Evidence is still mixed about whether to use sterile or clean gloves when performing endotracheal care. The following are the different levels of asepsis currently in use for tracheostomy care:

- **Sterile technique** is the use of a sterile suction catheter and other supplies with sterile gloves. For new tracheostomies, most facilities use sterile technique. However, some use sterile technique only for patients who have increased susceptibility to infection.
- **Modified sterile technique** is use of a sterile suction catheter and supplies, but with nonsterile procedure gloves. For healed tracheostomies, and in many institutions for all tracheostomies, the trend is toward a modified sterile technique.
- **Clean technique** is use of a clean catheter and clean hands or nonsterile gloves. The portion of the catheter that will be inserted in the tracheostomy tube is protected to avoid contact with unclean surfaces. Clean technique is the usual method in the home setting. Anyone who is not a family member and anyone concerned about acquiring an infection should wear nonsterile procedure gloves, even in the home setting.

You should follow the technique used in your healthcare facility or school. To learn a procedure and guidelines for tracheostomy care, respectively,

Go to **Procedure 36-5: Performing Tracheostomy Care Using Sterile Technique** and **Clinical Insight 36-4: Caring for Patients With Endotracheal Airways,** in Volume 2.

KnowledgeCheck 36-11

- In what circumstances would you use an oropharyngeal airway? A nasopharyngeal airway?
- What facts should you record if a patient is intubated?
- Describe seven interventions associated with caring for a patient with an endotracheal tube.

Quality and Safety Education for Nurses

Removing Barriers to Patient and Family Involvement in Care

Chapter Key Concepts: *Oxygenation, Ventilation*

Competency: *Patient-Centered Care (Knowledge, Skills, Attitudes); Teamwork (Knowledge)**

Scenario: Mrs. Yablonski, a 66-year-old former smoker, has a permanent tracheostomy but can speak using an electromechanical device. The nurses want her to learn how to suction herself and change the tracheotomy dressing. For 3 days in a row, different nurses have tried to explain how to perform the care. Each time Mrs. Yablonski became tearful and frustrated. The nurse manager speaks with her to identify problems that may be occurring. Mrs. Yablonski cites several issues:

"Sometimes it's me. I may just feel too overwhelmed or I may just not have any energy. But the nurses don't always ask me if I feel well enough to learn. None of them really know me, and they don't take enough time with me. And sometimes my nurse doesn't want me to help; she would rather just do it herself and get it over with.

"There are too many nurses trying to teach me. They tell me different ways to do it or make me go over what I already know, so I get confused. I try to tell them what I already know, but they don't seem to listen. They want to do it their way. They should have this all written down somewhere.

"I want my husband to learn how to do the trach care, but he can't be here during the day, and that's the only time anyone tries to show me how to do it. I asked the doctor about learning about it later on in his office but he didn't even want to talk about it. He said the nurses here would teach me."

Think about it: Including patients or their significant others as equal partners in care is the foundation of patient-centered care. Think about the following questions:

- What barriers to participating in her own care does Mrs. Yablonski identify?
- Are the barriers you identified applicable to other patient care scenarios?
- How is team communication affecting this situation?
- Does Mrs. Yablonski see herself as a valuable partner in her care?
- What might the effects be if Mrs. Yablonski felt more empowered?
- What are the potential negative outcomes if Mrs. Yablonski goes home before she masters her tracheostomy care?
- What can the nurse manager do to make Mrs. Yablonski's care more patient-centered?

*For specific Knowledge, Skills, and Attitudes,

Suctioning Airways

Airways are suctioned to remove secretions and maintain patency. Signs that indicate the need for suctioning include agitation, gurgling sounds during respiration, restlessness, labored respirations, decreased oxygen saturation (SaO_2), increased heart and respiratory rates, and adventitious breath sounds on auscultation. Although suctioning helps remove secretions, it also removes air from the airways and causes the patient's O_2 levels to fall. Therefore, suctioning must be done quickly and is often accompanied by supplemental oxygen. Suctioning can also irritate mucous membranes if done too frequently.

Suction catheters may be open tipped or "whistle tipped" (Fig. 36-14A and B). Most suction catheters have a port on the side, over which you place your thumb to control the suction. A Yankauer tube (Fig. 36-14C) is a rigid device for suctioning the oral cavity.

Both respiratory therapists and nurses are responsible for suctioning and tracheostomy care. The respiratory therapist and the nurse should keep each other informed of changes in the patient's condition. Airway suctioning is usually performed by RNs and LPNs, but not by NAPs. NAPs may use a Yankauer tube to suction the oral cavity as part of maintaining hygiene and preventing aspiration of oral secretions.

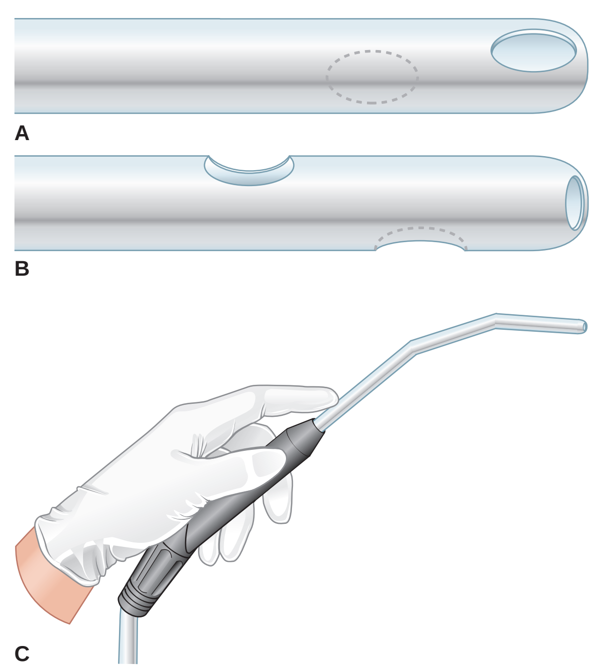

FIGURE 36-14 *A*, Whistle-tipped suction catheter. *B*, Open-tipped suction catheter. *C*, Yankauer (oral) suction tube.

Suctioning the Upper Airway

Pharyngeal suctioning is performed to prevent oral and nasal secretions from entering the lower airway when the patient is too weak to cough them up. Suctioning the pharynx triggers a cough, which helps loosen and mobilize secretions. The patient's condition determines whether you suction the pharynx through the mouth or nose. Most patients find oropharyngeal suctioning more comfortable than the nasal approach. However, if the patient is unable to cooperate and automatically bites down when anything is placed in his mouth, or if the jaw is wired, use a nasal approach. To learn how to suction the pharynx, see the summary in the Highlights of Procedures box. For the complete steps,

Go to Chapter 36, **Procedure 36-9: Performing Upper Airway Suctioning,** in Volume 2.

Suctioning the Lower Airway

In tracheal suctioning, a catheter is passed beyond the pharynx into the trachea to remove secretions from the lower airways. The trachea may be suctioned through the mouth, nose, or an endotracheal airway. In the healthcare setting, deep tracheal suctioning is a sterile procedure.

Orotracheal or Nasotracheal (NT) Approach When suctioning through the nose or mouth, insert the catheter into the pharynx, and advance it into the trachea during inspiration. This prevents the catheter from entering the esophagus and causing the patient to gag or vomit. When the suction catheter enters the trachea, it will stimulate coughing. Except in an emergency, NT suctioning should be done through a nasopharyngeal airway. The Highlights of Procedures box provides a summary of this procedure. For the complete steps,

Go to Chapter 36, **Procedure 36-8: Performing Orotracheal and Nasotracheal Suctioning (Open System),** in Volume 2.

Endotracheal or Tracheostomy Approach An endotracheal or tracheostomy tube provides a direct path into the trachea. To suction, insert the catheter through the artificial airway into the trachea. You do not need to insert the catheter as far into a tracheostomy tube, because you are bypassing the long upper airway. Before suctioning, make sure the airway is secured so it is not dislodged by coughing or suctioning. The Highlights of Procedures box summarizes this procedure. For the complete steps,

Go to Chapter 36, **Procedure 36-6: Performing Tracheostomy Suctioning (Open System),** in Volume 2.

KnowledgeCheck 36-12

- Describe the difference between pharyngeal and tracheal suctioning.
- How can you ensure that the suction catheter enters the trachea and not the esophagus?

Caring for a Patient Requiring Mechanical Ventilation

A **mechanical ventilator** is a machine that assists a patient to breathe. The patient is intubated before he is connected to the ventilator. An endotracheal tube or a tracheostomy tube is connected by oxygen tubing to the ventilator. Before initiating ventilation, be certain that the healthcare team is aware of advance directives and consults with family members. Many patients do not wish to be mechanically ventilated if it might be a permanent intervention. Mechanical ventilation is indicated for acute or chronic respiratory failure, and may be a short- or long-term therapy.

Negative pressure ventilators consist of shells that fit externally around the chest. Negative pressure generated inside the shell pulls the chest outward and forces the patient to inhale air, similar to normal breathing. These ventilators are rarely used for acutely ill patients, but they are occasionally used for chronic conditions, for example, in patients with muscle weakness from neuromuscular disease.

Positive pressure ventilators (also called mechanical ventilation) are the most widely used type. They require the patient to have an artificial airway (Fig. 36-15). Positive pressure ventilation carries risks, including *barotrauma* (injury to the airways as a result of pressure changes) and drop in cardiac output as the positive pressure in the chest decreases venous return to the heart.

To care for a patient receiving mechanical ventilation you will need to be familiar with the types of ventilators in use. You need a thorough understanding of the ventilator you are using, its settings, and how to troubleshoot problems. In the event of a malfunction, if the repair is not readily obvious, manually ventilate the patient with an Ambu bag (resuscitation bag) connected to supplemental oxygen while a colleague troubleshoots the problem. The Highlights of Procedures box describes the care of a patient on a mechanical ventilator. For the

FIGURE 36-15 A patient being mechanically ventilated.

Toward Evidence-Based Practic

Rello, J., Afonso, E., Lisboa, T., et al. (2012). A care bundle approach for prevention of ventilator-associated pneumonia. *Clinical Microbiology and Infection, 19*(4), 363–369.

This was a study of patients in three adult intensive care units who were intubated and mechanically ventilated. Nurses implemented ventilator-associated pneumonia (VAP) bundle (which includes elevating the head of the bed to 30° and other interventions). There was a significant reduction in VAP related to hand hygiene, intra-cuff pressure control, oral hygiene, and sedation. In addition there was a reduction of ICU length of stay (from 10 to 6 days) and duration of mechanical ventilation (from 8 to 4 days).

Kelly, D. M. (2012). The organization of critical care nursing and outcomes of mechanically ventilated older adults. Scholarly Commons Repository. University of Pennsylvania. Paper AAI3542907. http://repository.upenn.edu/dissertations/AAI3542907

This was a multi-state analysis that examined the organization of critical care nursing and outcomes of 56,826 mechanically ventilated ICU patients cared for in 303 hospitals. Critical care nurse staffing, the practice environment, and hospital proportion of bachelor's prepared (BSN) nurses and specialty certified nurses were measured. Healthcare-associated infections were less likely to occur when staffing and resources in the critical care unit were higher, with greater proportion of BSN prepared nurses, and better practice environment.

Mateoso, J., Gonzalez, N., Sadaba, M., et al. (2011). Nursing care in the prevention of ventilator-associated pneumonia. *Enferm Intensive, 22*(1), 22–30.

Researchers observed and described the care of 26 patients with more than 24 hours of invasive mechanical ventilation. They reported good nursing compliance with established protocols for oral hygiene, oropharyngeal suction, and turning of patients, and of patient tolerance of enteral nutrition. Incidence of VAP was low and well within internationally established ranges. They concluded, nevertheless, that incidence of VAP could be further reduced with better control of endotracheal tube cuff pressures and by elevating the head of the bed to between 30° and 45°.

1. Based on these study findings, list two interventions a staff nurse could do to help prevent VAP.

2. Which study might you use to convince a hospital administrator to hire more nurses?

Go to Chapter 36, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

complete procedure, including ventilator terminology you will hear,

Go to Chapter 36, **Procedure 36-10: Caring for Patients Requiring Mechanical Ventilation,** in Volume 2

Patients being mechanically ventilated, even for a short period, are at high risk for developing *ventilator-associated pneumonia (VAP).* VAP is associated with high mortality rates. Procedure 36-10 includes guidelines for nursing interventions to help prevent VAP.

Caring for a Patient Requiring Chest Tubes

Normally there is negative pressure in the pleural space and only a thin layer of fluid between the membranes. Accumulation of fluid and blood in the pleural space (**hemothorax**) interferes with lung expansion, ventilation, and gas exchange. Air in the pleural space (**pneumothorax**) creates positive pressure, causing lung tissue to collapse. To see diagrams of different types of pneumothorax,

Go to Chapter 36, **Tables, Boxes, Figures: ESG Figure 36-1, ESG Figure 36-2,** and **ESG Figure 36-3,** on Davis*Plus*.

The purpose of a chest-drainage system is to make room for the lungs to fully expand. This is done by removing air and fluid from the pleural space. A valve in the line or a water-sealed compartment prevents reentry of air and fluid. A chest-drainage system is composed of a chest tube inserted into the pleural space and a drainage collection system. The system usually is attached to some form of suction.

Flow of air and fluid must be in one direction: from the patient to the collection system. Think of the chest tube as an extension of the pleural space. To provide negative pressure within the chest tube, the open end of the tube is placed under water. With each exhalation, air is expelled through the chest tube into the water, but no air is drawn in during inhalation (Fig. 36-16). Once all air is expelled from the pleural space, negative pressure is reestablished and the lung can fully expand. When the lung tissue is reexpanded, the chest tube can be safely removed.

Types of Drainage Systems

Various chest drainage systems are available, including the older, reusable glass, three-bottle, water-seal system. However, you will most often use a disposable system. These are more compact and lightweight. Disposable systems may be water-seal or dry-seal, and may or may

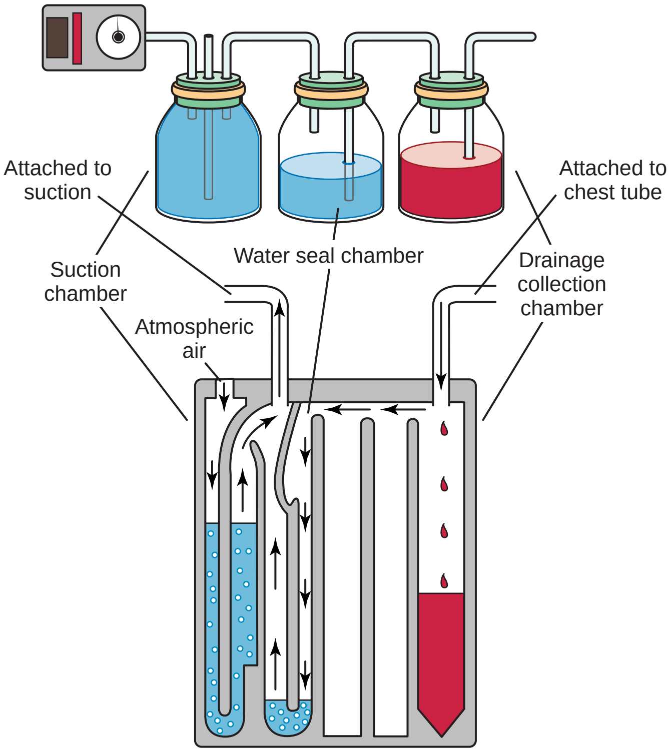

FIGURE 36-16 A disposable chest drainage system.

not use suction. To learn how to set up disposable chest drainage systems

Go to **Procedure 36-11: Setting Up Disposable Chest Drainage Systems**, in Volume 2.

Water-Seal Systems

Water-seal systems can consist of one, two, or three chambers (or bottles, in the traditional glass bottle system).

- **One-Chamber Device.** A one-chamber device is the simplest chest drainage system. The chest tube connects to one drainage chamber, which serves as both a collector and a water seal. This system can handle only small volumes of fluid or air. As fluid drains through the chest tube, it raises the fluid level in the chamber, making it harder for the patient to exhale. It is important that the device not be tipped over because the vent tube would no longer be below water and air would enter the pleural space.
- **Two-Chamber System.** A two-chamber system has one chamber that connects directly with the chest tube and serves as a collection bottle. The second chamber serves as the water seal; it maintains negative pressure as air flows through it. Because the chest drainage never enters the water-seal chamber, you can measure the amount of drainage more accurately. The two-chamber system can handle large amounts of fluid drainage, but its design can still contribute to labored breathing.
- **Three-Chamber System.** This system adds a third chamber, which connects to the water-seal chamber and placed to suction (see Fig. 36-16). This creates controlled negative pressure within the system. The suction control chamber has three vent tubes: one connected to suction, one connected to the water seal chamber, and a long middle tube with one end open to air at the top. The amount of sterile water in the suction chamber determines the maximum suction possible within the system. Suction pressure is expressed in centimeters of water.

Adjusting the suction regulator does not increase the amount of suction. Instead, it simply draws more air in from the atmosphere and causes more bubbling within the bottle. This is a safety feature that prevents excessive negative pressure from being created in the system. For proper functioning, adjust the suction regulator to create gentle bubbling in the suction control bottle.

Dry-Seal Systems

Dry-seal systems are fairly new. They are a one-piece device with three chambers: fluid collection, dry seal, and dry suction control. They do not use water in the suction chamber, relying instead on a mechanical automatic control valve (ACV) and an air leak monitor. The valve allows air to pass out of the patient and prevents it from returning to the patient—even if the system is knocked over. Pressure is set by adjusting the rotary suction dial. The ACV keeps the pressure constant by adjusting to changes in air leaks and fluctuations in the suction source.

Portable Systems

Portable or mobile systems consist of a single, dry-seal chamber attached to the patient's chest tube (Fig. 36-17). It drains by gravity, but can be connected to wall suction. Portable systems improve ambulation and reduce the

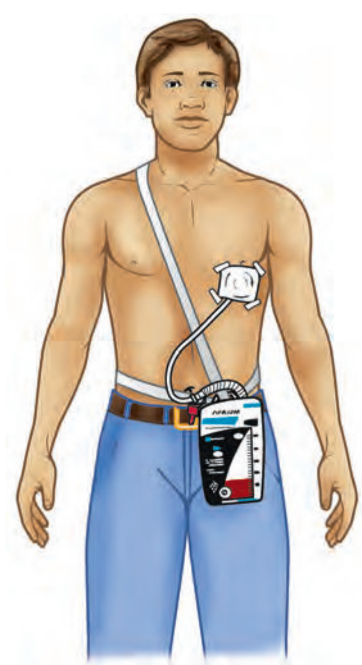

FIGURE 36-17 A one-chamber, dry-seal, portable chest drainage system.

risk of deep vein thrombosis and pulmonary embolism. They are thought to decrease the length of time a patient must stay in the hospital. The collection chamber holds a maximum of 500 mL, so portable systems are not practical for patients whose drainage is more than 500 mL daily.

For more information on how to set up disposable chest drainage system, see the Highlights of Procedures box, and

Go to Chapter 36, **Procedure 36-11: Setting Disposable Chest Drainage Systems,** in Volume 2.

Preventing Complications of Chest Drainage

Drainage is usually greatest when the chest tube is initially inserted and decreases as the lung reexpands. Care of a patient with a chest drainage system involves four broad nursing interventions: monitoring, maintaining a properly functioning drainage system, promoting lung reexpansion, and recognizing and intervening promptly should complications develop. For guidelines to help you manage care for patients with chest tubes,

Go to Chapter 36, **Clinical Insight 36-5: Managing Chest Tubes,** in Volume 2.

KnowledgeCheck 36-13

- What is the purpose of mechanical ventilation?
- Why is a chest tube inserted?
- What is the advantage of a three-chamber system (compared with a one-chamber or two-chamber system)?
- How does a portable chest drainage system compare to a water-seal drainage system?

Highlights of Procedures 36-1 Through 36-13

For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the procedure steps. Use these procedure highlights later to help you review key points.

Procedure 36-1: Collecting a Sputum Specimen

Procedure 36-1A: Collecting an Expectorated Sputum Specimen

- Use a high- or semi-Fowler's position.
- Caution the patient not to touch the inside of the sterile container or lid.
- Instruct the patient to breathe deeply for three or four breaths, cough forcefully, then expectorate in the container.
- Label the specimen container with the patient's name, test name, and collection date and time.
- Place the specimen in a plastic bag with a biohazard label. Follow agency policy.
- Send the specimen to the laboratory immediately. If specimen transport is delayed, consult the lab; refrigeration may be required.

Procedure 36-1B: Collecting a Suctioned Sputum Specimen

- Position patient in a high- or semi-Fowler's position.
- Don protective eyewear.
- Attach the suction tubing to the male adapter of the inline sputum specimen container.
- Don sterile gloves.
- Attach the sterile suction catheter to the rubber tubing on the inline sputum specimen container.
- Lubricate the suction catheter with sterile saline solution.
- Insert the tip of the suction catheter through the nasopharynx, endotracheal tube, or tracheostomy tube. Advance into the trachea.
- When the patient begins coughing, apply suction for 5 to 10 seconds to collect the specimen.
- If an adequate specimen is not obtained, allow the patient to rest for 1 minute, and then repeat the procedure. Administer oxygen at this time, if indicated.
- When an adequate specimen is collected, discontinue suction, and gently remove the suction catheter.
- Label the specimen container.
- Place the specimen in a plastic bag with a biohazard label.
- Send the specimen to the laboratory immediately. If specimen transport is delayed, consult the lab; refrigeration may be required.

Procedure 36-2: Monitoring Pulse Oximetry (Arterial Oxygen Saturation)

- Choose a sensor that is appropriate for the patient's age, size, and weight and for the desired location.
- Attach the probe sensor to the site, with photodetector and light-emitting diodes facing each other.
- Connect the sensor probe to the oximeter, and turn it on.
- Read the SaO_2 measurement on the digital display when it reaches a constant value.
- If continuous monitoring is necessary, set and turn on the alarm limits for SaO_2 and pulse rate, according to the manufacturer's instructions, patient condition, and agency policy.
- When monitoring is no longer needed, remove the probe sensor, and turn off the oximeter.

Procedure 36-3: Performing Percussion, Vibration, and Postural Drainage

- Help the patient assume the appropriate position based on the lung field that requires drainage.

Continued

- Keep the patient in the desired position for 10 to 15 minutes.
- Using cupped hands, perform percussion over the affected lung area for 1 to 3 minutes while the patient is in the desired drainage position.
- Next, perform vibration.
- Assist the patient to sit up. Ask him to cough at the end of a deep inspiration to clear the airway of secretions.
- Repeat postural drainage, percussion, and vibration for each lung field that requires treatment. The entire treatment should not exceed 60 minutes.
- Provide mouth care.

Procedure 36-4: Administering Oxygen

- Attach the flow meter to the oxygen source.
- Assemble and apply the oxygen equipment according to the device prescribed (nasal cannula, face mask, or face tent).
- Turn on the oxygen using the flow meter, and adjust according to the prescribed flow rate.
- Double check that the oxygen equipment is set up correctly and functioning properly.
- Assess the patient's respiratory status before you leave the bedside.

Procedure 36-5: Performing Tracheostomy Care Using Sterile Technique

- Position the patient in a semi-Fowler's position.
- Don gown, eye protection, and sterile gloves.
- Suction the tracheostomy.
- Remove soiled dressing; remove gloves; wash hands.
- Set up sterile field and prepare the equipment, keeping supplies sterile.
- Don sterile gloves (procedure gloves for modified sterile technique).
- Remove the oxygen source, if the patient is receiving supplemental oxygen, and attach to outer cannula if possible. If not possible, clean and return the inner cannula before proceeding.
- Remove the inner cannula with your nondominant hand, and dispose of it (if it is a disposable cannula) or clean it (if it is a reusable cannula).
- Clean the stoma under the faceplate with the cotton-tip applicators.
- Clean the top surface of the faceplate and the skin around it with the gauze pads and cotton-tip applicators
- Dry the skin around the faceplate and stoma with dry sterile gauze.
- With the help of an assistant, remove soiled tracheostomy ties.
- Ask the patient to flex his neck, and apply new tracheostomy ties.
- Insert a precut, sterile tracheostomy dressing under the faceplate and new ties.

Procedure 36-6: Performing Tracheostomy Suctioning (Open System)

- Suction only when necessary.
- Use a suction catheter that is no more than half the internal diameter of the airway tube.
- Position the patient in a semi-Fowler's position.
- Adjust the suction regulator according to agency policy, using the lowest possible suction pressure.

  Adults: 100 to 150 mm Hg

  Children: 100 to 120 mm Hg

  Infants: 50 to 95 mm Hg
- Don sterile gloves. (Dominant hand is sterile; nondominant is unsterile.)
- Using your dominant hand, attach the suction catheter to the connecting tubing.
- Hyperoxygenate the patient.
- Insert the catheter gently, without suction.
- Advance the suction catheter, gently aiming downward, no further than the carina tracheae (or a maximum of 6 inches).

  Do not force the catheter.

  Do not apply suction as you enter the airway.
- Apply continuous suction as you withdraw the catheter. Apply suction for no longer than 15 seconds.
- Avoid saline lavage during suctioning.
- Repeat suctioning as needed, allowing intervals of at least 30 seconds between suctioning. Hyperoxygenate the patient between each pass.
- Replace the oxygen source when finished.
- Provide mouth care and reposition the patient.

Procedure 36-7: Performing Tracheostomy or Endotracheal Suctioning (Inline Closed System)

- Position the patient in a semi-Fowler's position unless contraindicated.
- Adjust the suction regulator according to guidelines or agency policy.
- Hyperoxygenate the patient according to agency policy.
- Insert the suction catheter gently, with suction off.
- Advance the suction catheter gently, aiming downward, no farther than the carina trachea (premeasure). Do not force the catheter.
- Do not apply suction as you enter the airway.
- Apply continuous suction as you withdraw the catheter, but for no longer than 15 seconds.
- Avoid saline lavage during suctioning.
- Repeat suctioning as needed, allowing at least 30 seconds between each suctioning. Hyperoxygenate the patient between each pass.
- Withdraw suction catheter completely into the sleeve, until you see the indicator line.
- Use normal saline to clear secretions from the catheter.

- Lock the suction regulator port.
- Provide mouth care and reposition the patient.

Procedure 36-8: Performing Orotracheal and Nasotracheal Suctioning (Open System)

- Position the patient in a semi-Fowler's position.
- Adjust suction pressure according to guidelines or agency policy (typically 100 to 150 mm Hg for adults, 100 to 120 mm Hg for children, and 80 to 100 mm Hg for infants, and 60 to 80 mm Hg for neonates).
- Prepare the suction equipment. For the nasotracheal (NT) approach open the water-soluble lubricant.
- Don sterile glove(s), protective eye equipment, and gown.
- Holding the suction catheter in your dominant hand, attach it to the connection tubing.
- Approximate the depth to which the suction catheter should be inserted.
- Preoxygenate the patient, if indicated.
- Lubricate (for NT approach) and insert the catheter, and advance it to the pharynx as the patient inhales.
- Advance the catheter to the predetermined distance as the patient inhales.
- Apply suction (no longer than 15 seconds) while you withdraw the catheter, using a continuous rotating motion.
- Withdraw the catheter and clear it with sterile saline.
- Repeat lubrication and suctioning as needed, allowing intervals of at least 30 seconds between suctioning.
- Replace the oxygen source.
- Coil the suction catheter in your dominant hand. Pull the sterile glove off over the coiled catheter. Discard in a biohazard receptacle.
- Make sure new suction supplies are readily available for future suctioning.
- Provide mouth care.

Procedure 36-9: Performing Upper Airway Suctioning

- Position the patient in a semi-Fowler's position.

  Oropharyngeal: Patient's face turned toward you

  Nasopharyngeal: Neck hyperextended
- Adjust suction regulator according to agency policy (typically 100 to 120 mm Hg for adults, 95 to 110 mm Hg for children, and 50 to 95 mm Hg for infants).
- If using the nasal approach, open the water-soluble lubricant.
- Don procedure gloves.
- Using your dominant hand, attach the suction catheter to the connection tubing.
- Approximate the depth the suction catheter should be inserted.
- Remove the oxygen delivery device, if necessary.
- If the oxygen saturation is <94%, or if the patient is in distress, administer supplemental oxygen before, during, and after suctioning.
- Lubricate and insert the suction catheter.
- Gently advance the catheter the premeasured distance into the pharynx.
- Engage the suction and apply it while you withdraw the catheter, using a continuous rotating motion.
- Clear the catheter with sterile saline.
- Lubricate the catheter, and repeat suctioning as needed, allowing 20-second intervals between suctioning.

Procedure 36-10: Caring for Patients Requiring Mechanical Ventilation

- Prepare the resuscitation bag; keep it at the bedside.
- Wear protective eye covering and gown.
- Respiratory therapists are responsible for setting up mechanical ventilation in most agencies. If you must assume the responsibility, refer to the manufacturer's instructions and:
  - Verify ventilator settings with the medical prescription.
  - Make sure the ventilator alarm limits are set appropriately.
  - Don gloves.
  - Attach the ventilator tubing to the endotracheal tube or tracheostomy tube, and secure the ventilator tubing.
  - Attach capnography device, if available.
  - Prepare the inline suctioning equipment.

After the initial ventilator setup:

- Check arterial blood gases and assess respiratory status about 30 minutes after setup.
- Maintain the patient in a semirecumbent position (head of bed at 30° to 45°).
- Check the ventilator tubing frequently for condensation.

  Drain the condensate into a collection device, or briefly disconnect the patient from the ventilator and empty the tubing into a waste receptacle, according to agency policy.

  Never drain the condensate into the humidifier.
- Provide the patient with an alternative form of communication.
- Check ventilator and humidifier settings regularly.
- Check the inline thermometer.
- Give sedatives or anti-anxiety drugs as needed.
- Reposition the patient regularly (every 1 to 2 hours).
- Moisten the lips with a cool, damp cloth and water-based lubricant. Provide frequent antiseptic oral care.
- Ensure the call light is within reach; answer the call light and respond to ventilator alarms promptly.
- Monitor tracheostomy tube for proper cuff inflation.
- Monitor for gastric distention.

Procedure 36-11: Setting Up Disposable Chest Drainage Systems

- Position the patient according to the indicated insertion site.
- Set up the sterile field and supplies you will need for dressing the insertion site.

Continued

Highlights of Procedures 36-1 Through 36-13

- Don mask, gown, and sterile gloves.
- As soon as the chest tube is inserted, attach it to the drainage system.
- Turn on the suction source (usually –80 mm Hg).
- Set the prescribed suction level on the chest drainage unit (CDU).
- Don a clean pair of sterile gloves.
- Using sterile technique, wrap petroleum gauze around the chest tube at the insertion site, and dress the site with two precut sterile drain dressings covered by a large drainage dressing.
- Apply an occlusive dressing over the insertion site (cover the dressing completely). Date, time, and initial the dressing.
- Using the spiral taping technique, wrap 1-inch silk tape around the connections. Wrap from top to bottom and bottom to top. (Or use locking connections, if available.)
- With an 8-inch-long piece of 2-inch tape, secure the top end of the drainage tube to the chest tube dressing.
- Make sure the tubing lies with no kinks and no dependent areas, in a straight line to the CDU.
- Prepare the patient for a portable chest x-ray exam.
- Keep emergency supplies at the bedside in the event of tube dislodgement or system failure.
- Maintenance: Prevent tubing kinks, ensure patency of the air vent, and keep the system below the level of the chest tube.
- Keep the head of the bed always elevated to at least 30°.

Procedure 36-12: Inserting an Oropharyngeal Airway

- You will need a variety of sizes of airway, procedure gloves, tongue blade, suction equipment, and possibly a handheld resuscitation bag and oxygen source.
- Measured on the outside of the cheek, the airway should extend from the front teeth to the end of the jaw line.
- Clear the mouth of debris and secretions. Suction if needed.
- Position patient in supine or semi-Fowler's position, neck hyperextended.
- Hold the tongue down with a tongue blade, as needed, and insert the airway in the upside-down position.
- Rotate the airway 180° and continue inserting until the front flange is flush with the lips.
- Keep the patient's head slightly tilted and chin elevated.
- Verify airway patency by auscultating breath sounds.
- Do not tape the airway in place.
- Keep suction available at the bedside.
- Suction the oropharynx as needed.

Procedure 36-13: Inserting a Nasopharyngeal Airway

- You will need a correctly sized nasopharyngeal airway, procedure gloves, tongue blade, water-soluble lubricant, suction equipment, and possibly a handheld resuscitation bag and oxygen source.
- Measured on the outside of the cheek, the airway should extend from the tip of the nose to the earlobe. It should be slightly smaller than the nares.
- Position patient in a supine or semi-Fowler's position, neck hyperextended.
- Lubricate the airway with water-soluble lubricant.
- Advance the airway through the naris until the outer flange rests on the nostril. Do not force.
- Visually inspect the top of the posterior pharynx; only the tip of the tube should be visible.
- Use your finger to check for air exchange at the naris.
- Auscultate the lungs bilaterally.
- Keep suction available at the bedside.
- Suction as needed.

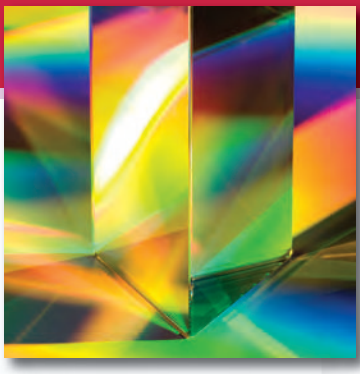
CHAPTER 37



Circulation

Learning Outcomes

After completing this chapter, you should be able to:

- Describe the structure and function of the cardiovascular system.
- Identify individual, environmental, and pathological factors that influence circulation and perfusion.
- Assess circulation and perfusion.
- Interpret diagnostic testing related to circulation and perfusion.
- Develop nursing diagnoses related to circulation and perfusion.
- Safely and correctly perform common nursing procedures related to circulation and perfusion.
- Evaluate adequacy of circulation and perfusion, and modify nursing activities appropriately based on outcomes.
- Provide measures to promote peripheral circulation.
- Recognize medications used to enhance cardiovascular function.

Key Concepts

Circulation

Perfusion

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patients

You are scheduled for a clinical placement in urgent care clinic. Your assignment is to (1) perform a focused assessment related to circulation, (2) perform common therapeutic interventions related to circulation, (3) identify desired outcomes and evaluate achievement of those outcomes, and (4) plan for follow-up and home care needs. One of your clients is Ms. Saunders, a 55-year-old accountant. She says she has been extremely tired, easily becomes short of breath, and is unable to complete her chores without frequent rest breaks. She is pale and moves slowly. Her vital signs are as follows: temperature, 98.4°F (36.7°C); pulse, 86 beats/min; respirations, 24 breaths/min and unlabored; BP, 136/78 mm Hg; and pulse oximetry, 98% on room air. She is now waiting for her lab results, which include a complete blood count (CBC).

Theoretical Knowledge knowing why

As you have you learned in Chapter 36, the pulmonary, cardiovascular, musculoskeletal, and neurological systems work together to achieve oxygenation. The lungs oxygenate the blood, and the heart circulates the blood throughout the body and back to the lungs. The circulatory system transports oxygenated blood throughout the body to meet the needs. Changes in one system create changes in the other. Theoretical knowledge in this chapter consists of the structures, functions, regulation, and factors affecting the cardiovascular system, as well as factors that affect cardiovascular function.

ABOUT THE KEY CONCEPTS

The concept of **circulation** refers to flow of blood throughout the heart and blood vessels. **Perfusion** describes blood flow to a capillary bed to provide nutrients and oxygen to tissues and organs. Although the distinction between these two concepts is subtle, they go hand in hand in explaining how a healthy circulatory system contributes to healthy functioning of every organ in the body.

WHAT ARE THE STRUCTURES OF THE CARDIOVASCULAR SYSTEM?

The structures of the cardiovascular system are the heart, the systemic and pulmonary blood vessels, and the coronary arteries.

The Heart

The heart is a four-chambered muscular organ encased in the **pericardium** (a sac of connective tissue) located inside the chest cavity. The two thin-walled **atria** receive blood into the heart, and the two thick-walled **ventricles** pump blood out of the heart. Valves between the heart chambers open widely to allow blood to flow easily and without turbulence from one chamber to another, and the valves close tightly to prevent backflow of blood. The **base**, or broadest side of the heart, which houses the atria, faces upward. The **apex**, or tip of the heart, which houses the ventricles, faces downward (Fig. 37-1).

A strong, efficient heartbeat keeps blood flowing through the vascular system. Deoxygenated blood from organs and tissues flows through the venous system into the right side of the heart and then into the pulmonary circulation. At the alveolar–capillary membrane, external gas exchange occurs. The newly oxygenated blood then flows from the lungs into the left side of the heart and out into the arterial circulation.

The Cardiac Cycle

The **cardiac cycle** is the sequence of mechanical events that occurs during a single heartbeat. Very simply, it is the simultaneous contraction of the two atria, followed a fraction of a second later by the simultaneous contraction of the ventricles—one cycle of diastole and systole. The electrical activity of the myocardium regulates the cardiac cycle (Fig. 37-2).

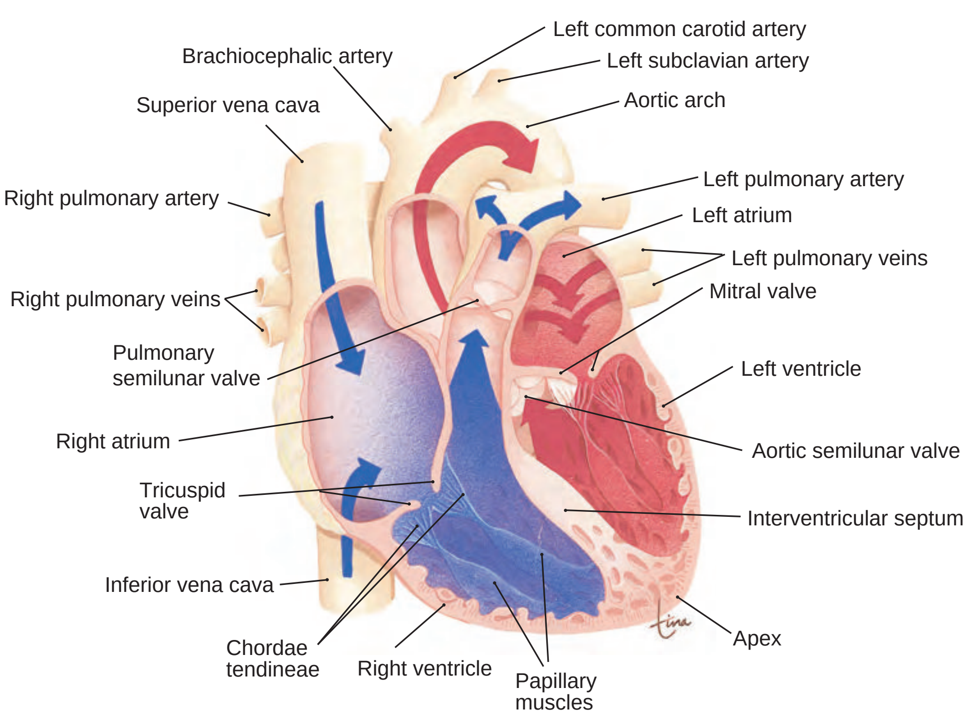


FIGURE 37-1 The atria receive blood into the heart; the ventricles pump blood out of the heart. Valves between the chambers allow blood to flow in one direction from one chamber to another without backflow.

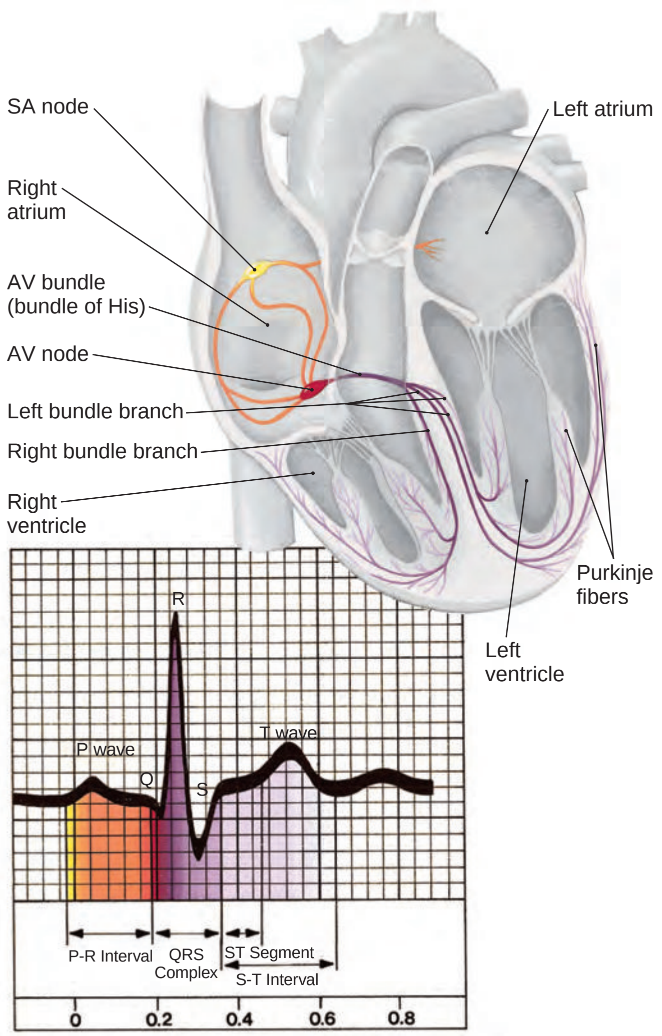

FIGURE 37-2 Conduction pathway of the heart. Anterior view of the interior of the heart. The electrocardiogram tracing is one of a normal heartbeat. See text for description.

Electrical Conduction

The heart contains specialized areas of nerve tissue that initiate electrical impulses without external nervous system stimulation

- The **sinoatrial (SA) node** acts as the pacemaker. Located in the right atrium, it initiates an impulse that triggers each heartbeat. The impulse travels rapidly down the atrial conduction system so that both atria contract as a unit.
- At the **atrioventricular (AV) node**, there is a slight delay. From the AV node, impulses pass into the left and right *bundles of His* and into the *Purkinje fibers* to the ventricles.

In this way, myocardial fibers are electrically stimulated almost simultaneously to create a unified cardiac muscle contraction strong enough to pump blood out of a heart chamber. This spontaneous rhythm of the heart is called **automaticity**. If there are defects in this electrical system, impulses travel more slowly through the heart and some areas contract before others. This can lead to ineffective heart pumping and decreased cardiac output.

Normally, the SA node is in charge and initiates a rate of 60 to 100 beats/min, depending on the body's oxygen needs. If the SA node fails, the AV node can take over as the pacemaker, but it generally triggers a slower heart rate. If both the SA and AV nodes fail, the conduction fibers can initiate impulses. Ventricular conduction generates a very slow rate, usually less than 40 beats/min; however, this can be lifesaving if no other node or fiber is initiating an impulse.

Systemic and Pulmonary Blood Vessels

The vascular system is composed of three types of vessels: arteries, veins, and capillaries. All vessels are lined with a smooth endothelial layer that promotes nonturbulent blood flow and prevents platelets from sticking to the sides of the walls and beginning a clot.

- **Arteries** have thick, elastic walls that allow them to stretch during cardiac contraction (**systole**) and to recoil when the heart relaxes (**diastole**).
- **Arterioles** are smaller branches of arteries. They are primarily smooth muscle and thinner than arteries. Under the control of the sympathetic nervous system, the arterioles constrict or dilate to vary the amount of blood flowing into capillaries and help maintain blood pressure.
- **Capillaries** are microscopic vessels, created as arterioles branch into smaller and smaller vessels. Capillaries connect the arterial and venous systems and carry blood from arterioles to venules. Because they are only one cell thick, capillaries facilitate the exchange of gases, nutrients, and wastes between the tissue cells and the blood. Billions of capillaries provide blood flow to every cell in the body.
- The **venous system** returns the deoxygenated blood to the heart. **Veins** and **venules** have thin, muscular, but inelastic walls that collapse easily. These walls contract or relax in response to feedback from the sympathetic nervous system: When blood volume is low, the veins contract to provide a smaller space for smaller volume of blood; when blood volume is high, veins relax and enlarge to accommodate increased volume of blood. Think of the venous system as a holding tank for fluctuations in blood volume.

For illustrations of the systemic arteries and veins,

Go to Chapter 37, **Tables, Boxes, Figures: ESG Figure 37-1** and **ESG Figure 37-2,** on Davis*Plus*.

To see an animated illustration of the circulatory system,

Go to **Animations, Cardiovascular/Pulmonary Animations: Blood Flow,** on Davis*Plus*.

The Coronary Arteries

The heart has its own blood supply through the coronary arteries (Fig. 37-3). The coronary sinus (not shown), located just above the aortic valve, fills with blood during diastole. From the coronary sinus, blood flows into the two main coronary arteries, which branch into several sections to supply the heart muscle with blood. The coronary arteries are the only arteries in the body that fill during diastole. To see an animated illustration of the coronary circulation,

Go to **Animations, Cardiovascular/Pulmonary Animations: Blood Flow Through the Heart,** on Davis*Plus*.

KnowledgeCheck 37-1

- Describe oxygenation and perfusion.
- Trace the path of normal electrical impulses in the heart.
- How do the walls of arteries, veins, and capillaries differ?
- What is the importance of diastole to perfusion of the heart?

ThinkLike a Nurse 37-1

Your patient has a condition that has caused the mitral valve to become stiff with only a narrow opening for blood flow. What type of problems related to oxygenation would you anticipate in this patient?

HOW ARE OXYGEN AND CARBON DIOXIDE TRANSPORTED?

The cardiovascular system circulates oxygenated blood to organs and tissues and returns deoxygenated blood to the heart. Maintaining this blood flow requires adequate circulation and effective regulation of cardiovascular function.

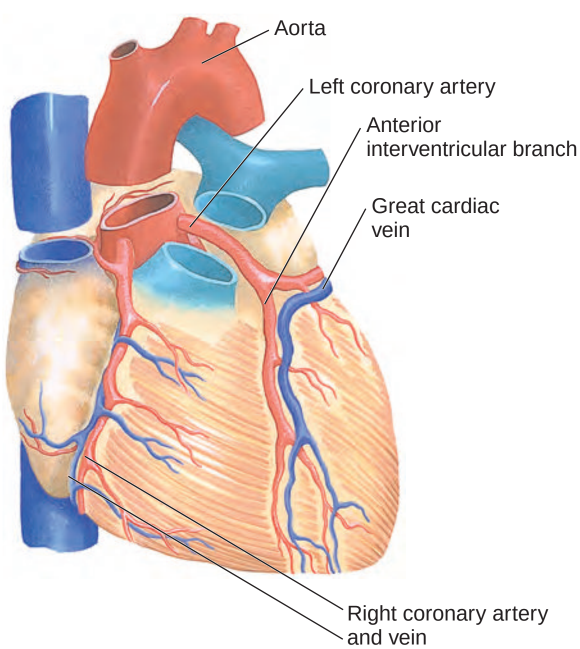

FIGURE 37-3 Coronary vessels in anterior view. The pulmonary artery has been cut to show the left coronary artery emerging from the ascending aorta.

A full 97% of blood oxygen is bound to hemoglobin, the iron-containing protein in red blood cells; only 3% is in a dissolved state. At the tissue level, O_2 leaves the hemoglobin, becomes dissolved in the blood, and passes through the capillary membrane into the tissues. Only the dissolved form of O_2 can pass through capillary membranes. Hemoglobin thereby serves as a reservoir for oxygen until it is needed in the dissolved state.

Carbon dioxide is a waste product of normal aerobic tissue metabolism. Carbon dioxide can be carried in the blood in three ways: About 7% of CO_2 is dissolved in plasma, 23% attaches to hemoglobin, and 70% is converted into bicarbonate ions. However, CO_2 diffuses through cellular and alveolar–capillary membranes only in its dissolved state. The CO_2 bound to hemoglobin eventually detaches and becomes dissolved in the plasma for diffusion into the alveoli of the lungs. The bicarbonate ions in the plasma are converted back to CO_2, which becomes dissolved, diffuses into the alveoli, and is exhaled.

To see an animated explanation of CO_2 and O_2 transport,

Go to **Animations, Cardiovascular/Pulmonary Animations: Carbon Dioxide/Oxygen Transport,** on Davis*Plus*.

HOW IS CARDIOVASCULAR FUNCTION REGULATED?

Cardiovascular function is regulated by the autonomic nervous system (ANS) and by control centers in the brainstem.

Autonomic Nervous System

The autonomic nervous system regulates cardiovascular function through its influence on cardiac rate and muscle contractility, as well as vascular tone.

Heart Through branches at the thoracic level of the spinal cord, *sympathetic fibers* stimulate the heart to beat faster and contract more strongly. *Parasympathetic fibers* innervate the heart through the vagus nerve. Parasympathetic stimulation results in a slowed heart rate, but it does not influence myocardial contractility.

Vascular System All blood vessels are innervated by *sympathetic fibers* that maintain them in a constant baseline state of partial contraction (**tone**). Vascular tone maintains blood pressure and blood flow even when a person is resting or asleep. Sympathetic stimulation above and beyond baseline tone varies in response to body needs. Increased sympathetic stimulation causes constriction of some vessels (e.g., skin, gastrointestinal tract, and kidneys) and dilation of other vessels (skeletal muscle). This shunts blood flow to the skeletal muscles for a fight-or-flight response. The *parasympathetic nervous system* has no significant control over blood vessels.

For more complete information, consult an anatomy and physiology text. For a brief overview of the nervous system,

Go to Chapter 36, **Oxygenation, Supplemental Materials: The Nervous System,** on Davis*Plus*.

Brainstem Centers

The brainstem centers integrate feedback from baroreceptors and chemoreceptors in the body to regulate cardiac function and blood pressure. The *vasomotor center* controls sympathetic stimulation of the heart and vascular system. The *cardioinhibitory center* controls parasympathetic slowing of the heart rate.

Baroreceptors Baroreceptors located in the walls of the heart and blood vessels are sensitive to pressure changes. The aortic arch and carotid artery baroreceptors are particularly important in the regulation of heart rate and vascular tone. When baroreceptors sense even a small drop in pressure, they send messages to the brainstem centers to stimulate the sympathetic nervous system to increase heart rate and induce vasoconstriction. This mechanism allows us to change positions and maintain blood pressure.

Chemoreceptors Chemoreceptors located in the aortic arch and the carotid arteries are sensitive to changes in blood pH, oxygen levels, and carbon dioxide levels. Their main function is to regulate ventilation, but they also send information to the vasomotor center in response to lack of oxygen. The vasomotor center responds by activating sympathetic stimulation.

If you would like further review of nervous regulation of the heart,

Go to Chapter 37, **Tables, Boxes, Figures: ESG Figure 37-3,** on Davis*Plus*.

KnowledgeCheck 37-2

- How are oxygen and carbon dioxide transported in the blood?
- How is the cardiovascular system regulated?
- Does poor peripheral perfusion increase the risk for hypoxemia (a low level of oxygen in the blood)?

ThinkLike a Nurse 37-2

You are assigned the care of a 4-year-old girl with a history of asthma. She is receiving a nebulized treatment containing Proventil (albuterol) and Atrovent (ipratropium bromide). These medications stimulate the sympathetic nervous system.

- What cardiovascular side effects can you anticipate?
- How might these side effects affect oxygenation?
- What do you need to know about the patient's history to safely administer the drugs?

WHAT FACTORS INFLUENCE CARDIOVASCULAR FUNCTION?

Similar to respiratory function, cardiovascular function is influenced by developmental stage, environment, lifestyle, substance abuse, medications, and pathophysiological conditions.

Developmental Stage

Normal development influences heart and circulatory function. Developmental factors exert more of an influence on older adults than on young and middle adults.

Infants

Successful transition from life inside the uterus to the extrauterine environment depends on critical physiological changes that occur at birth. Prior to delivery, the fetus uses the placenta for gas and nutrient exchange. Fetal circulation bypasses the lungs. When the umbilical cord is clamped and the newborn takes the first breath, the resistance in the pulmonary vessels then markedly decreases. The lungs inflate, and blood circulates without shunting as it did during fetal life.

Preschool and School-Age Children

Preschool and school-age children have body systems mature enough to adapt to moderate stress and change, including the heart and circulatory systems. However, children as young as school age sometimes begin social habits, such as tobacco use, that can have long-term adverse effects on the cardiovascular system. A diet high in fats and sugars contributes to hyperlipidemia and the beginning of plaque lining the walls of blood vessels. Processed foods contain a great deal of salt and fat, which can contribute to high blood pressure and high cholesterol, even in children.

Adolescents

In adolescence, the heart and blood components develop adult characteristics. The average adolescent is developmentally at little risk for heart or circulatory disorders, although some athletes can be at risk for collapse and sudden cardiac dysrhythmia that is familial. New guidelines for health professionals performing sports assessments call for thorough investigation of the family history for fainting, collapse, or sudden death.

Some adolescents adopt behaviors and habits that can create risk throughout life. For instance, about half the adults who use tobacco were regular smokers by their 18th birthdays, and 20% of students in high schools report they have smoked cigarettes on one or more of the 30 days preceding the survey (American Lung Association, 2011; Centers for Disease Control and Prevention [CDC], 2012). Although obesity rates have fallen among preschoolers, the overall incidence of childhood obesity in the United States has risen to epidemic incidence. As a result, some adolescents exhibit signs of cardiovascular disease (e.g., high blood levels of lipids and cholesterol, a known factor in the development of high blood pressure, heart disease, and blockages in the arteries of the heart).

Young and Middle Adults

Lifestyle in young and middle adulthood can create cardiac risk factors. Some adults become "too busy" to prepare and eat nourishing foods, or more often simply prefer the taste of high-fat, high-sugar foods. A sedentary lifestyle, lack of aerobic exercise, and tobacco use also contribute to cardiovascular disorders in this group. Crack cocaine and methamphetamine abuse can lead to sudden cardiac failure. Family history of cardiovascular disease is yet another risk factor for this age group.

Older Adults

Cardiac efficiency gradually declines as the heart muscle loses contractile strength and heart valves become thicker and more rigid. The peripheral vessels become less elastic, which creates more resistance to ejection of blood from the heart. As a result of these changes, the heart becomes less able to respond to increased oxygen demands, and it needs longer recovery times after responding. For example, in response to exercise, an older adult's heart rate does not increase as much as a younger person's, but it does remain elevated longer. Thus, older adults have lower exercise tolerance, need more rest after exercise, and are more prone to orthostatic hypotension. Keep in mind, though, that endurance training and regular exercise slow the rate of these changes. In fact, an older person who is physically conditioned by regular exercise may have better heart and circulatory function than a younger adult who is not well conditioned.

Environment

Environmental factors, such as stress, allergic reactions, altitude, and temperature, affect cardiovascular function.

Stress

The stress response stimulates the release of catecholamines from the sympathetic nervous system. This results in increased heart rate and contractility, vasoconstriction, and increased tendency of blood to clot. Sustained stimulation of the sympathetic nervous system can lead to cardiovascular disease. In addition, a chronically suppressed immune and inflammatory response increases the risk for all infections. For additional information on the effects of stress, see Chapter 12.

Allergic Reactions and Air Quality

An **allergy** is a hypersensitivity, or overresponse, to an antigen. Inflammatory substances released during an allergic response (e.g., histamine, protease) cause the following cardiovascular events:

- Blood vessels dilate in areas affected (which increases blood flow to the areas).
- Eosinophils and neutrophils are attracted to the reaction site.
- Local tissues are damaged by protease.
- Capillaries become more permeable, resulting in fluid leak into tissues.
- Local (e.g., vascular) smooth muscle cells contract.

Altitude

Oxygen pressure falls proportionally with increased altitude (to review, refer to Chapter 36) making more oxygen available in the alveoli and at the tissue level. Over the long term, people who live at high altitudes undergo physiological changes that facilitate oxygenation. Among the cardiopulmonary changes are the following:

- Increased production of red blood cells (RBCs)
- Increased vascularity of body tissues
- Increased ability of tissue cells to use oxygen even when atmospheric oxygen pressure is low

Heat and Cold

Heat generally causes vasodilation, which increases cardiac output and oxygenation. However, heat also increases metabolism. As a result, people are naturally more sedentary in hot weather.

Cold slows cell metabolism, reducing O_2 demand. It also causes vasoconstriction, and slows the heart rate. Induced hypothermia is used in some medical and surgical procedures. As another example, victims of cold-water near-drowning have been revived after long periods of time, in part because of the reduced O_2 demands associated with hypothermia. Prolonged exposure to cold causes frostbite, loss of hypothalamic temperature regulation, and death.

Lifestyle

Lifestyle factors that affect cardiovascular function include pregnancy, nutrition, obesity, exercise, tobacco use, and substance abuse.

Pregnancy

During pregnancy, oxygen demand increases dramatically because of the needs of the fetus. Therefore, there is an approximate 15% increase in maternal metabolism during the last half of pregnancy. To compensate, the mother's blood volume increases by 30%. The woman requires additional iron to produce this blood as well as to meet fetal requirements. Failure to meet these iron demands can result in maternal anemia, reducing tissue oxygenation to the mother and fetus.

Nutrition

The body needs an appropriate balance of proteins, carbohydrates, fats, and other nutrients for proper immune function, resistance to disease and infection, normal cellular function and tissue repair, and maintenance of a healthy weight. A diet high in saturated fat predisposes to the development of atherosclerosis, coronary artery disease, and hypertension, all of which can compromise circulation and oxygenation. A low-fat, low-cholesterol, low-sodium diet is considered "heart healthy." Vitamins, minerals (especially iron), and protein are important to prevent anemia, which reduces blood-oxygen–carrying capacity. Green tea consumption has been associated with reduced mortality due to cardiovascular disease (Kokubo, Iso, Saito, et al., 2013).

Recent studies have demonstrated the relationship between the consumption of sugar-sweetened beverages and adverse changes in lipids, inflammatory factors, and increased waist circumference in both adults and children (deKoning, Malik, Kellog, et al., 2012; Kosova, Auinger, & Bremer, 2013). Consuming sugar-sweetened beverages such as cola has been associated with an increased risk for weight gain and type 2 diabetes, which are risk factors for coronary heart disease (CHD) (Sugiri, Hisatome, & Bahrudin, 2012).

Obesity

Obesity is a body mass index (BMI) above 30 (see Chapter 27). Obesity causes multiple health problems, many of which affect the heart and circulation. Obesity increases the risk of developing atherosclerosis and hypertension. Excess fat stores in and around the heart itself reduce its effectiveness as a pump. At the same time, the workload of the heart is increased by the need to perfuse the excess body tissues.

Exercise

Exercise improves blood circulation and delivery of oxygen to tissues and cells. It also increases metabolic demands. The body responds by increasing the heart rate and the rate and depth of breathing. Like skeletal muscles, the heart muscle is strengthened with regular aerobic exercise. As the heart becomes stronger, it becomes a more efficient pump. As a result, resting heart rate is slower because a higher heart rate is not required to maintain cardiac output. Lack of exercise has the opposite effect. A sedentary lifestyle reduces the efficiency of the heart and the capacity to increase ventilation in response to exercise.

Tobacco Use

Tobacco use is a major risk factor in several chronic cardiovascular conditions: stroke, peripheral arterial disease, aortic aneurysm, and heart disease. Smoking has been shown to cause atherosclerosis (fatty buildups in the arteries), hypertension, and decreased HDL (good) cholesterol—all of which lead to coronary heart disease and heart attack. The risk of coronary artery disease is four times higher in cigarette smokers than it is in nonsmokers. Cigarette smoking doubles a person's risk for stroke. Older adults who smoke have a 73% higher chance of developing heart failure than non-smokers. Former smokers' risks are related to how long they have smoked. Even light smoking increases the risk of sudden cardiac death. Cigar and pipe smoking are also implicated, but not to the extent of cigarettes (American Heart Association, 2011a).

Substance Abuse

Substances that people abuse include over-the-counter (OTC) and prescription medications, commonly available commercial products, and illegal substances. Large amounts of alcohol depress respiratory, cardiac, and vasomotor centers of the brain. Chronic alcohol abuse causes fatty infiltration of the heart muscle, thrombi in the coronary arteries, heart enlargement, and dysrhythmias, all of which can ultimately lead to heart failure. Illicit drugs, including stimulants (e.g., methamphetamine, cocaine), hallucinogens (e.g., LSD [acid], mescaline [buttons]), and cannabinoids (e.g., marijuana), also have adverse effects on the cardiovascular system. For example, cocaine has been linked to myocardial dysfunction, dysrhythmias, endocarditis, and aortic dissection.

Medications

The U.S. Preventive Services Task Force (USPSTF) (Agency for Healthcare Research and Quality [AHRQ], 2009) recommends the use of aspirin for the primary prevention of cardiovascular disease (CVD). Aspirin fights pain and inflammation associated with heart disease by blocking the production of prostaglandin, a chemical that signals an injury and triggers pain. Prostaglandins also trigger clumping of platelets to form blood clots. Thus, when aspirin inhibits prostaglandins, it inhibits the formation of blood clots. Blood clots are harmful because they can clog the arteries supplying the heart muscle and brain, increasing the risk of heart attack and stroke. Aspirin has been shown to reduce the risk of heart attack and stroke and reduce the short-term risk of death among people suffering from heart attacks. Aspirin is recommended for men ages 45 to 79 years to reduce risk of myocardial infarction (MI) and for women ages 55 to 79 years to reduce risk of ischemic stroke.

Various other types of medication are used to improve cardiac output and tissue oxygenation. They act to slow the heart rate or reduce the force of myocardial contraction; ease the workload of the heart; dilate blood vessels and reduce blood pressure in the pulmonary circulation and systemically; rid the body of excess fluid accumulation; and block abnormal heart rhythms (American Heart Association, 2011b). See Table 37-1.

Go to Chapter 37, **Supplemental Materials: Cardiovascular Medications,** on Davis*Plus*.

KnowledgeCheck 37-3

- What changes occur in the cardiovascular system with aging?
- How does smoking affect the cardiovascular system?

Table 37-1 ➤ Medications That Promote Circulation

CLASS	ACTION	EXAMPLES AND COMMENTS
Vasodilators	■ Enhance cardiac output, providing increased blood flow and oxygenation to organs and tissues. ■ Cause vessel dilation, which eases workload of the heart. ■ Control blood pressure. ■ Treat heart failure.	Angiotensin-converting enzyme (ACE) inhibitors Angiotensin II receptor blockers Nitrates
Beta-Adrenergic Blockers	■ Block norepinephrine and epinephrine (adrenaline) ■ Reduce the workload of the heart and oxygen consumption. ■ Control abnormal heart rhythms (dysrhythmias) by slowing conduction through the AV node. ■ Control blood pressure.	$Beta_1$-Selective: atenolol, metoprolol Nonselective: carvedilol, metoprolol, propranolol
Calcium-Channel Blockers	■ Block the flow of calcium into the cells of the heart and blood vessels. ■ Decrease blood pressure. ■ Reduce the strength of myocardial contraction; slow heart rate. ■ Dilate the arteries and arterioles.	Nifedipine
Positive Inotropic Agents	■ Improve the effectiveness of the heart's pumping action without creating excess cardiac workload and oxygen demand. ■ Reduce the heart muscle cells' ability to trigger their own contraction (automaticity). ■ Dilate blood vessels.	Cardiac glycosides: digoxin Phosphodiesterase (PSE) inhibitors: PDE3 inhibitors (congestive heart failure) PDE5 inhibitors (erectile dysfunction)
Diuretics	■ Remove sodium and water from the body through urine. ■ Reduce the volume of circulating blood. ■ Prevent accumulation of fluid in the pulmonary circulation and body tissues.	Thiazide diuretics: hydrochlorothiazide (HCTZ), metolazone Loop diuretics: furosemide Potassium-sparing diuretics: spironolactone Bumetanide Metolazone Triamterene

Pathophysiological Conditions

Alterations in circulation and perfusion at the tissue or cellular level may be life threatening, particularly when hypoxemia and acidosis occur. Refer to Chapter 36 to review the effect of poor oxygenation on body systems.

Cardiovascular Abnormalities

Alterations in gas exchange are caused by a number of disorders that affect the structure, function, and regulation of the cardiovascular system. Cardiovascular abnormalities interfere with the flow of oxygenated blood to organs and tissues, and continue to be the number one cause of death for adults in the United States (CDC, 2011). Major abnormalities are as follows:

- **Heart failure** occurs when the heart becomes an inefficient pump and is unable to meet the body's demands. Blood is oxygenated when it passes through the lungs, but it is not well circulated to the organs and tissues. Impaired circulation leads to systemic and pulmonary edema, which further impairs gas exchange.
- **Cardiomyopathy** is a heart muscle disorder that results in heart enlargement and impaired cardiac contractility.
- **Cardiac ischemia** occurs when oxygen requirements of the heart are unmet. Prolonged ischemia leads to

Toward Evidence-Based Practice

Mizuno, J., & Monteiro, H. L. (2012). An assessment of a sequence of yoga exercises to patients with arterial hypertension. *Journal of Bodywork and Movement Therapies, 17*(1), 35–41.

This study describes the effects of a yoga sequence on patients with hypertension. Thirty-three volunteers participated in the study (control = 16 and yoga = 17) for 4 months. Blood pressure measurements and cardiac and respiratory rates were collected monthly. The yoga group showed a significant reduction of systolic blood pressure and heart and respiratory rates (p <0.05). The authors concluded that yoga exercises should be implemented as a means of complementary non-pharmacological control of blood pressure in patients with hypertension.

Begum, M. N. (2013). To evaluate the effect of yoga on moderate degree hypertension and lipid profile. *National Journal of Integrated Research in Medicine, 4*(3), 109–114.

Sixty patients (30 females and 30 males) aged 40 years to 60 years with moderate degree hypertension were trained in asanas (postures), pranayama (breathing exercise), and relaxation techniques for 6 months. Blood pressure; serum total cholesterol; LDL, VLDL, HDL cholesterol; and total triglycerides were measured at the beginning and at the end of the study. The results demonstrated that yoga practice in patients with moderate degree hypertension leads to a decrease in blood pressure and lipid profile within the period of 6 months.

Deepa, T., Sethu, G., & Thirrunavukkarasu, N. (2012). Effect of yoga and meditation on mild to moderate essential hypertensives. *Journal of Clinical and Diagnostic Research, 6*(1), 21–26.

This study evaluated the effect of yoga and meditation on mild to moderate essential hypertensive patients. Patients were divided in to two groups: (a) 15 patients treated with antihypertensive drugs along with yoga, (b) 15 patients with antihypertensive drugs alone. Yoga was practiced for 45 minutes daily in the morning and again in the evening. The study showed a significant fall of mean blood pressure after 3 months of yoga, suggesting that yoga can be used as adjunctive treatment with drug therapy for those with mild and moderate hypertension.

These three studies demonstrate that yoga may be a complementary therapy for use in patients with hypertension. Using what you know about yoga,

1. What may be some reasons for patients not participating in this type of exercise?
2. What strategies can you use to motivate patients to practice yoga?

Go to Chapter 37, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

MI as parts of the heart *necrose* (die) from inadequate oxygen. **Angina pectoris** is transient chest pain due to myocardial ischemia. The tissue becomes injured but does not necrose.

- **Coronary artery disease**, a leading cause of cardiac ischemia, is a condition in which plaque builds up inside the coronary arteries. Plaque narrows the arteries, reducing blood flow to the heart muscle and making it more likely that clots will form and block the arteries. If you are interested in seeing animated explanations of plaque buildup and coronary artery disease, respectively,

Go to **Animations: Atherosclerosis** and **Coronary Artery Disease,** on Davis*Plus*.

- **Dysrhythmias** (alterations in heart rate or rhythm) can lower cardiac output, decrease tissue oxygenation, and increase the risk of stroke
- **Heart valve abnormalities** create turbulent flow, leading to a decrease in cardiac output and compromised tissue oxygenation. Often there is an audible murmur. The valves most commonly affected are the mitral and aortic valves.

If you are interested in a more extensive discussion of cardiovascular abnormalities,

Go to Chapter 37, **Supplemental Materials, Cardiovascular Abnormalities,** on Davis*Plus*.

Peripheral Vascular Abnormalities

Disorders of peripheral blood vessels impair blood flow to and from organs and tissues. Arterial abnormalities disrupt flow of oxygenated blood to tissues. When arterial blood flow is compromised, signs and symptoms include pallor, pain, weak or absent pulses, poor capillary refill, cool skin, and tissue dysfunction. Venous abnormalities disrupt blood return to the heart. Clinical signs of compromised venous blood flow include edema, brown skin discoloration, and tissue dysfunction (e.g., stasis ulcers). If you are interested in a more extensive discussion of peripheral vascular abnormalities,

Go to Chapter 37, **Supplemental Materials, Peripheral Vascular Abnormalities,** on Davis*Plus*.

Oxygen Transport Abnormalities

Even if the heart is functioning well and arterial blood flow is intact, tissues can become hypoxic if the blood is unable to carry adequate amounts of oxygen. The most common causes are anemia and carbon monoxide poisoning. **Anemia** is an abnormally low level of red blood cells, hemoglobin, or both. **Carbon monoxide** is a colorless, odorless gas produced by the combustion of flammable materials and fuels. When inhaled, carbon monoxide binds tightly to hemoglobin at the oxygen receptor sites, making it impossible for hemoglobin to carry oxygen. If you are interested in a more extensive discussion of oxygen transport abnormalities,

Go to Chapter 37, **Supplemental Materials, Oxygen Transport Abnormalities,** on Davis*Plus*.

PracticalKnowledge knowing how

Nursing care for patients with cardiovascular problems is directed at assessing for and maximizing the effectiveness of the heart and circulatory system.

ASSESSMENT

Although this section focuses on cardiovascular assessments, evaluation of overall oxygenation status includes a history and examination that gathers information about lung, heart, and circulatory function. **Key Point:** ***The patient's condition and the purpose of the assessment determine your priorities for assessment and the order in which you gather information.*** For example, for someone with a cardiac emergency, the immediate assessment focus would be to ask simple questions about current symptoms while performing a quick examination to determine adequacy of breathing, circulation, and oxygenation. In contrast, the assessment for risk of coronary artery disease in a healthy individual might include more extensive questions about occupation and smoking habits, a medical history, and an extensive physical examination.

You will need information about the patient's past and present cardiovascular signs and symptoms, risk factors, medications, activity level, tolerance of activity, and lifestyle factors that affect cardiovascular functioning.

Assessing for Risk Factors

One aspect of improving cardiovascular health and quality of life is prevention, detection, and treatment of risk factors for heart attack and stroke (Healthy People 2020, 2010). A health history related to cardiovascular functioning includes questions about the presence of risk factors that affect the heart, and peripheral vascular function. Topics to assess include the following:

- Demographic data
- Health history
- Family history
- Respiratory history
- Cardiovascular history
- Environmental history
- Lifestyle

You should also assess the patient's anxiety level. Patients with cardiac or respiratory problems are almost certain to be anxious, and anxiety interferes with achieving good outcomes for these patients. Pay close attention to verbal cues because heart rate and blood pressure changes may not be useful in assessing acutely ill patients for anxiety (Van Beek, Mingels, Voshaar, et al., 2012). For a detailed list of interview questions for each of these topics,

Go to Chapter 37, **Assessment Guidelines and Tools, Focused Assessment: Assessing Circulation,** in Volume 2.

Physical Examination

Start the physical exam by obtaining the patient's height and weight. BMI and waist circumference indicate obesity, which is a major risk factor for cardiovascular disease. Assessment of heart and peripheral vessels includes inspection, palpation, and auscultation (and occasionally percussion). Use inspection to observe for signs of distress (e.g., chest pain), skin and mucous membrane color, presence or absence of edema, and overall general appearance. Palpate pulses, skin temperature, edema, heart pulsations through the chest wall, and areas of tenderness. Auscultate heart sounds, vascular sounds, and blood pressure. Auscultate the lungs because adventitious sounds, such as rales, may signal decreased cardiac output. For a step-by-step discussion of how to assess the heart and vascular system,

Go to Chapter 22, **Procedure 22-13: Assessing the Heart and Vascular System,** in Volume 2.

Assess Pain

If a patient has chest pain, evaluate it immediately because chest pain is the most common heart attack symptom. Ask the patient to describe the pain, its location, duration, frequency, and radiation. Chest pain may also be caused by musculoskeletal or respiratory conditions, for example, a fractured rib or pleuritis (inflammation in the pleural space). **Key Point:** ***You can differentiate cardiac pain because it is usually in the center or on the left side of the chest and radiates to the left arm (most often in men). The pain typically lasts several minutes; it may go away and come back. Some women have milder chest pain, sometimes none at all. They are thought to be***

more likely than men are to experience other symptoms, such as jaw or back pain, nausea, fatigue, and shortness of breath. Cardiac pain typically does not change with inhalation or exhalation. Ask the client to rate the pain on a scale of 0 to 10, with 0 representing no pain and 10 representing the worst possible pain. See Chapter 31 for pain assessment, as needed.

Patients experiencing chest pain are likely to be fearful—most people are aware that chest pain may signal a heart attack. You need to work quickly but calmly to instill confidence in the patient. If the person is experiencing a cardiac event, anxiety and stress can make it worse by increasing oxygen consumption, thereby extending hypoxic damage to the heart.

When assessing for a clot in the veins (deep vein thrombosis [DVT]), deep under the muscles of the leg, you will assess for pain, warmth, redness, and swelling of the leg. **Homan's sign** (pulling toes forward) and **Pratt's sign** (squeezing calf to trigger pain) have not been found to be reliable in diagnosing DVT. However, these signs may help confirm DVT when also considering the clinical signs of DVT, as well as the results of more accurate and specific diagnostic tests, such as ultrasound or venography (Naib & Salih, 2013).

Assess Fatigue

Fatigue is a subjective experience. The patient feels tired and lacks endurance. Fatigue is a common symptom of various oxygenation problems, including anemia and heart failure. Ask your patient to rate his fatigue on a 0 to 10 scale, as you do for pain.

Assess Dyspnea

Dyspnea (shortness of breath) is discussed in Chapter 36 in relation to respiratory conditions. Recall that dyspnea is a sign of hypoxia, which can be associated with cardiovascular diseases and anemia, as well as with respiratory problems. As with pain, dyspnea provokes anxiety.

Assess Peripheral Circulation

Even if the lungs and heart are functioning well, pathology in the arteries and veins can interfere with tissue perfusion. Palpate the peripheral pulses, assess skin color and temperature, and note the distribution of hair on the extremities. Weak pulses, cool feet, lack of hair, and shiny skin on lower legs and feet usually accompany peripheral vascular disease. Look for skin ulcers that often accompany severe venous or arterial disease. Check for edema of the feet and ankles; this is one symptom of heart failure.

KnowledgeCheck 37-4

Why would you auscultate the lungs as a part of your assessment of cardiac function?

ThinkLike a Nurse 37-3

Why might it be more difficult to recognize a heart attack in a woman than in a man?

Diagnostic Testing

Diagnostic testing helps clinicians identify the causes of cardiovascular symptoms and monitor patient responses to treatment. We discuss several of these tests in the next sections. For others,

Go to Chapter 37, **Diagnostic Testing: Tests Related to Circulation,** in Volume 2.

Tests of Blood Oxygenation

Pulse oximetry, capnography, and arterial blood gases were discussed in the Diagnostic Testing section of this chapter. You should understand, though, that results from all of those tests are pertinent to cardiac conditions. **Key Point:** *Remember: The heart and lungs work together to provide oxygenation; a problem in one creates a problem in the other.* For the complete procedure,

Go to Chapter 36, **Procedure 36-2: Monitoring Pulse Oximetry (Arterial Oxygen Saturation),** in Volume 2.

To review (and use in clinical assignments) arterial blood gas values, see the section Interpreting ABGs, and Table 38-6 in Chapter 38.

Laboratory Testing

Cholesterol, lipid panel, C-reactive protein (CRP), and glucose testing are a valuable part of cardiovascular risk assessment. The National Heart, Lung, and Blood Institute (NHLBI) (2002, updated 2012) recommend testing total cholesterol, HDL and LDL, triglyceride levels every 5 years for adults over age 20. For adults with total cholesterol >200 mg/dL, a fasting measurement is recommended. The maximum LDL cholesterol would be 176 mg/dL. Glucose testing is indicated, particularly those at risk for metabolic syndrome, which includes heart disease. The CRP appears to be the most reliable marker for arterial inflammation currently available.

An Expert Panel appointed by the NHLBI (2011) is recommending aggressive cholesterol screening for all children, regardless of family history. The panel recommends that children undergo select lipid screening between the ages of 9 and 11 years age followed by another full lipid screening test between 18 and 21 years of age. The panel also recommends measuring fasting glucose levels to test for diabetes in children 10 years of age (or at the onset of puberty) who are overweight with other risk factors, including a family history, for type 2 diabetes mellitus.

Cardiac Monitoring

Cardiac monitoring is the continuous monitoring of the **electrocardiogram (ECG)**, a rendering of the electrical activity of the heart. Three to five electrodes placed on the skin of the chest display a waveform on a monitor screen or printout (Fig. 37-4). The ECG illustrates electrical activity, but not mechanical activity. In other words, the ECG reflects what the nerves are telling the heart muscle to do, but *not* what the heart muscle is actually doing in response.

The USPSTF (2012) recommends against screening with resting or exercise ECG for the prediction of CHD events in asymptomatic adults at low risk for CHD events. The current evidence is insufficient to balance the benefits and harms of screening for the prediction of CHD events.

The purposes of cardiac monitoring are to:

- Identify the patient's baseline rhythm and rate.
- Recognize significant changes in the baseline rhythm and rate.
- Recognize lethal dysrhythmias that require immediate intervention.

The ECG reading illustrates the complete cardiac cycle. Each part of the ECG complex has been given a letter to identify it: **P, Q, R, S,** and **T** (see Fig. 37-4).

- The **P wave** represents the firing of the SA node and conduction of the impulse through the atria. In the healthy heart, this leads to atrial contraction.
- The **QRS complex** represents *ventricular depolarization* and leads to ventricular contraction.
- The **T wave** represents the return of the ventricles to an electrical resting state so they can be stimulated again (*ventricular repolarization*). The atria also repolarize, but they do so during the time of ventricular depolarization; thus, they are obscured by the QRS complex and cannot be seen on the ECG complex.
- The **U wave** is not always seen on the ECG, but may be detected with electrolyte imbalance, such as hypokalemia or hypercalcemia. U waves sometimes occur in response to certain medication (e.g., digitalis, epinephrine). Inverted U wave may occur with ischemia to the cardiac muscle.

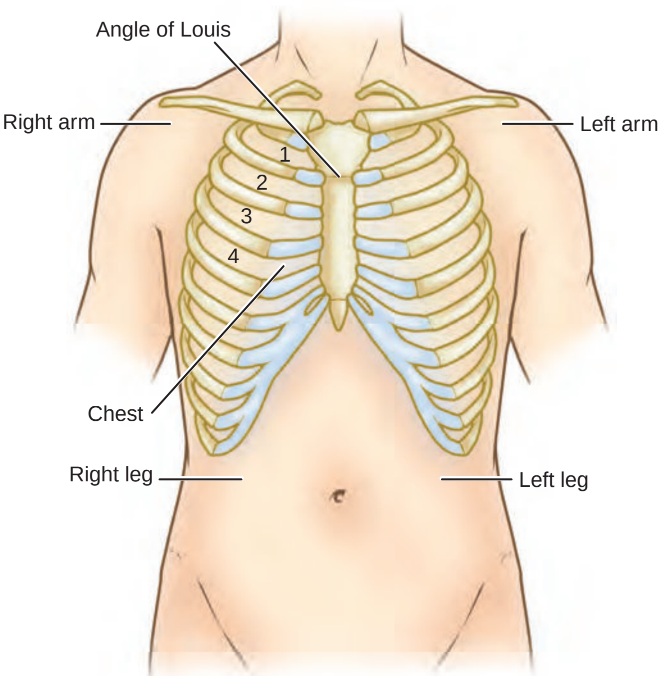

FIGURE 37-4 Electrodes placed for continuous cardiac monitoring.

Dysrhythmias are abnormal heart rhythms. Dysrhythmias can be broadly categorized according to rhythm as follows:

Tachydysrhythmias—Rates >100 beats/min
Bradydysrhythmias—Rates <60 beats/min
Ectopy—extra beats

Within each or those categories, dysrhythmias can be further classified by their site of origin:

Supraventricular—Above the ventricles
Junctional—Within the AV node
Ventricular—In the ventricles

Note that a tachy- or bradydysrhythmia depends on the patient's baseline heart rate. Some people have a low resting heart rate (fewer than 60 beats/min) without distress. Keep this in mind before assuming that the heart rate is abnormal.

All dysrhythmias have the potential to decrease cardiac output, resulting in hypotension and tissue hypoxia. Skill in identifying cardiac rhythms (both normal and abnormal) requires study and experience and is beyond the scope of this chapter. The Highlights of Procedure 37-1 box summarizes the activities involved in the care of a patient requiring a cardiac monitor. For the complete procedure,

Go to Chapter 37, **Procedure 37-1: Performing Cardiac Monitoring,** in Volume 2.

In contrast to cardiac monitoring, *electrocardiography* uses 12 "leads" (views of the heart). These are done by specially trained nurses or technicians. If you are interested in reading more about 12-lead ECGs,

Go to Chapter 37, **Supplemental Materials, 12-Lead Electrocardiography,** and **Tables, Boxes, Figures: ESG Figure 37-4** and **Figure 37-5,** on Davis*Plus*.

KnowledgeCheck 37-5

- What do the P wave, QRS complex, and T wave of an ECG complex represent?
- What kind of dysrhythmia would describe a heart rate of 140 beats per minute that originates in the ventricles?

ANALYSIS/NURSING DIAGNOSIS

Several nursing diagnoses address impaired circulation and tissue or organ hypoxia. They are briefly discussed below. For additional information,

Go to Chapter 37, **Standardized Language, Nursing Diagnoses Associated With Impaired Circulation,** on Davis*Plus*.

- *Decreased Cardiac Output* is the appropriate diagnosis when the heart is unable to pump adequate amounts of blood to meet the metabolic demands of the body. Definitive interventions for this problem are collaborative.

Highlights of Procedure 37-1

Procedure 37-1: Performing Cardiac Monitoring

- Identify electrode sites based on the monitoring system and the patient's anatomy.
- With an alcohol pad, clean the areas for electrode placement; allow to dry.
- Connect lead wires to electrodes.
- Apply the electrodes, pressing firmly.
- If the patient's chest is very hairy, shave the small areas for the electrodes.
- Check the ECG tracing on the monitor. If necessary, adjust the gain (sometimes called sensitivity) to increase the waveform size.
- Set the upper and lower heart rate alarm limits and turn them on.
- Obtain a rhythm strip by pressing the "record" button.

- *Risk for Decreased Cardiac Tissue Perfusion* is appropriate for a patient who has no symptoms of decreased cardiac perfusion, but has risk factors such elevated C-reactive protein, cardiac surgery, taking birth control pills, hyperlipidemia, or substance abuse.
- *Risk for Ineffective Cerebral, Gastrointestinal, or Renal Tissue Perfusion* is appropriate for a patient who is at risk for experiencing poor perfusion to those systems (e.g., a patient with a brain tumor, certain heart problems, embolism, substance abuse).
- *Ineffective Peripheral Tissue Perfusion* is appropriate for a patient experiencing poor perfusion to the periphery that compromises health.
- *Risk for Shock* should be used for patients who have inadequate blood flow to body tissues that may lead to life-threatening cellular dysfunction (e.g., patients with sepsis and hypovolemia).

Cardiovascular functioning can also be the etiology of other nursing diagnoses, such as the following examples:

- Risk for Activity Intolerance related to decreased oxygen-carrying capacity of the blood secondary to anemia
- Acute Pain secondary to myocardial ischemia
- Anxiety related to shortness of breath
- Death Anxiety related to diagnosis of myocardial infarction (heart attack)
- Ineffective Coping related to hospitalization for oxygenation impairment

PLANNING OUTCOMES/EVALUATION

NOC standardized outcomes and evaluation criteria related to cardiovascular status are included in the Cardiopulmonary class of NOC Domain II: Physiologic Health. They include the following: Blood Loss Severity, Cardiac Pump Effectiveness, Circulation Status, Tissue Perfusion (Abdominal Organs, Cardiac, Peripheral, Pulmonary), and Vital Signs.

Individualized goals/outcome statements depend on the nursing diagnosis you identify. For diagnoses related to cardiac function or circulation, the following are examples of goals you might write:

- No dyspnea or shortness of breath
- Heart rate in expected range
- Peripheral pulses strong and equal bilaterally
- Brisk capillary refill
- Normal skin color (no pallor or cyanosis)

For examples of NOC outcomes and NIC interventions for selected oxygenation nursing diagnoses,

Go to Chapter 37 **Standardized Language, Examples of NOC Outcomes and NIC Interventions Linked to Circulation Diagnoses,** on Davis*Plus*.

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC standardized interventions related to the cardiovascular system are found in NIC Domain 2: Physiological Interventions: Complex, in the subcategory of Tissue Perfusion Management. Tissue Perfusion Management focuses on optimizing circulation. These provide a general care planning guide. Depending on individual patient needs, other NOC outcomes or NIC interventions may also be appropriate.

Specific nursing interventions for patients with cardiovascular problems focus on relieving anxiety, promoting circulation, administering medications, and performing cardiopulmonary resuscitation (CPR).

Manage Anxiety

Almost everyone who experiences dyspnea or chest pain becomes anxious—some, extremely so. It is important to reduce anxiety because anxiety activates the sympathetic nervous system and triggers the stress response. Hormone changes occur, including the release of aldosterone, which promotes fluid retention and increases blood pressure. The heart rate and contraction force increase; peripheral and visceral vessels constrict; and the blood clots more readily. All of these make a cardiac or vascular condition more serious.

Prioritize your interventions. You will need to intervene first to prevent life-threatening situations. But try not to appear rushed, and speak calmly and quietly to the patient and to those around you. Do not leave the patient alone. Provide clear factual information and keep the patient and family informed about treatments being given. Many patients are reassured by the presence of a family member. If you need a review of detailed information about assessments and interventions for anxious patients, go to Chapter 13.

Promote Circulation

Adequate circulation ensures that oxygenated blood reaches tissues and organs and that venous blood returns to the heart. Two important nursing interventions are to promote venous return and prevent clot formation.

Promote Venous Return

Measures that promote venous return increase the flow of blood back to the vena cava and the right side of the heart.

- Elevate the patient's legs above the level of the heart. Gravity promotes venous return from the feet and legs.
- If a recliner is available, have the patient sit in one that elevates the legs rather than sitting upright in a chair with legs elevated on a stool. Flexion of the hips, legs, and knees constricts the veins and slows venous blood flow.
- Teach patients to avoid sitting with the legs crossed; this interferes with blood flow.
- Encourage and support early and frequent ambulation (e.g., after surgery). Contraction of the muscles in the legs moves blood upward against gravity.
- Encourage or provide range-of-motion (ROM) exercises, which increase venous blood flow through rhythmic massaging of the veins by the active muscles (see Chapter 32 to review ROM).
- Apply compression devices. **Antiembolism stockings (TED hose)** are elastic stockings that compress superficial leg veins and promote venous return. **Sequential compression devices (SCDs)**, also called *pneumatic compression devices*, are cuffs that surround the legs and alternately inflate and deflate to promote venous return to the heart. Antiembolism stockings and SCDs are frequently used in perioperative patients to promote venous return and prevent clot formation (Woo & Cowie, 2013). See Chapter 39 for further discussion and instructions on how to apply these stockings and appropriate follow-up care.

Go to Chapter 39, **Procedure 39-2: Applying Antiembolism Stockings,** in Volume 2.

Promote Peripheral Arterial Circulation

Peripheral artery disease, usually found in the legs and feet, occurs when tissues do not receive enough blood flow to keep up with the demand for oxygen. It is caused by the buildup of fatty deposits and plaque within the arteries (atherosclerosis). When arteries that supply blood to the legs are narrowed, leg pain occurs, especially with walking. This is called **intermittent claudication**. As the blood flow becomes more restricted, pain occurs at rest, as well as numbness or a cold feeling to the leg or foot, especially on one side, weak pulse, change in color, hair loss or shiny skin on the legs, sores that won't heal, and erectile dysfunction in men. Teach the patient and family the following:

- Patients with poor peripheral circulation need to quit using tobacco because smoking restricts blood flow.
- When circulation is poor, healing is slower. It is especially important to take good care of feet and prevent injury to the feet. Even dry, cracked skin can result in a sore and become infected. Patients need to wear well-fitting shoes with smooth, dry socks.
- Regular exercise improves circulation and oxygen delivery to body tissue.
- Medication might be needed to control blood pressure, control pain, lower cholesterol, prevent clots, and control blood sugar if the patient has diabetes.
- Angioplasty using a mesh stent or graft bypass surgery might be necessary to create a new path for blood flow to go around the damaged area of the blood vessel.

When peripheral artery disease is treated properly, new, collateral blood vessels can form, allowing blood to circulate around the damaged area.

Prevent Clot Formation

A **thrombus** is a stationary clot adhering to the wall of a vessel. Clots can form after injury to vessels or in response to hypercoagulability. An **embolus** is a clot that travels in the bloodstream.

- Patients at high risk for thrombus formation may be prescribed anticoagulant mediations to help prevent abnormal clot formation. Anticoagulant medications include heparin and warfarin sodium (e.g., Coumadin). Newer anticoagulants (e.g., dabigatran, apixaban, and rivaroxaban) work by inhibiting thrombin or factor X in the clotting chain. They have the advantage of not requiring tests of blood levels. However, unlike heparin and warfarin, they have no specific antidote.
- Hospitalized patients are at particularly high risk for clot formation and may develop an asymptomatic DVT and die from pulmonary embolism (PE) even before the diagnosis is suspected. For this reason, The Joint Commission (TJC) (2013) identified thromboprophylaxis (anticoagulant therapy) against VTE as the "number one patient safety practice" for hospitalized patients. Of course, all the strategies to promote venous return also help prevent clot formation.
- Turn patients frequently; teach patients to change positions frequently. This prevents vessel injury from prolonged pressure in one position.
- Use scrupulous sterile technique when inserting or handling intravenous lines. This prevents infection that can damage the vessel lumens.
- Be sure intravenous medications are adequately diluted. This prevents chemical irritation of veins during IV medication therapy.
- Promote adequate hydration (i.e., monitor intake and output, assess hydration, manage fluid intake, teach patients to drink plenty of fluids). Unless contraindicated, adult fluid intake should be approximately 2,000 mL per day to keep urine output around 1,500 mL per day. Adequate hydration keeps respiratory secretions thin but also keeps the blood from becoming viscous ("thick"). Viscous blood clots more readily.
- Promote smoking cessation. Nicotine increases the risk for thrombus formation because of its constricting effects on vessel walls.

Administer Medications

Cardiovascular medications are used to prevent atherosclerosis and to enhance cardiac output, thus providing increased blood flow and oxygenation to organs and tissues. They include vasodilators, beta-adrenergic blocking agents, diuretics, positive inotropes, and anti-cholesterol medications.

- ***Vasodilators*** cause vessel dilation, which eases the work of the heart. Drugs that dilate arterioles decrease the resistance against which the heart pumps (afterload). Drugs that dilate veins decrease venous return to the heart (preload). Vasodilating agents include angiotensin-converting enzyme (ACE) inhibitors, angiotensin II receptor blockers, and nitrates.

  Vasodilators can cause hypotension, especially when the person rises from a sitting or lying position. Patients should be warned of this effect. You will need to monitor the patient's blood pressure and observe for symptoms of hypotension.

- ***Beta-adrenergic agents*** block stimulation of beta receptors, which are located primarily in the heart, lungs, and blood vessels. Beta-1 selective agents are used to treat angina, acute myocardial infarction, and congestive heart failure (CHF). They decrease heart rate, slow conduction through the AV node, and decrease myocardial oxygen demand by reducing myocardial contractility.
- ***Diuretics*** increase removal of sodium and water from the body by increasing urine output. In patients with CHF, diuretics are used to reduce the volume of circulating blood and prevent accumulation of fluid in the pulmonary circulation.
- ***Positive inotropes*** increase cardiac contractility. They are used therapeutically to make the heart a more effective pump. The goal is to improve pumping effectiveness without creating excess heart work and oxygen demand. The two main classes of positive inotropes are cardiac glycosides and phosphodiesterase inhibitors.
- ***Anticholesterol medications (statins)*** are a class of drugs that protect against coronary artery disease by lowering the level of triglycerides and reduce the production of cholesterol by the liver. Statins block the liver enzyme that is responsible for making cholesterol. Statins are used for those who have an elevated LDL cholesterol level. For primary prevention recent guidelines recommend their use for all persons, even with a normal level, if they have diabetes or a high risk of cardiovascular disease (Ray, Kastelein, Boekholdt, et al., 2014; Stone, Robinson, Lichtenstein, et al., 2013.)

Performing Cardiopulmonary Resuscitation

All of the previously discussed interventions are designed to promote circulation and perfusion. However, the patient's condition can rapidly deteriorate. You must be prepared to perform *cardiopulmonary resuscitation (CPR)* in the event your patient experiences a respiratory, cardiac, or cardiopulmonary arrest. **Cardiac arrest** is the cessation of heart function. Signs of cardiac arrest are pale, cool, grayish skin; absence of femoral or carotid pulses; apnea; and pupil dilation. In the event of cardiac arrest, you have only 4 to 6 minutes before the brain is damaged by lack of oxygen. **Respiratory (pulmonary) arrest** is cessation of breathing. It can be caused by a blocked airway or occur after a cardiac arrest; it may be sudden or preceded by increasingly labored breathing.

CPR procedures are regularly updated as new knowledge is gained. The American Heart Association provides training sessions for healthcare professionals to become certified in CPR. This is a prerequisite for employment and clinical practice. **Key Point:** ***We recommend you obtain CPR training from certified professionals.*** However, if you are already trained and just want to review the procedure,

Go to Chapter 37, **ESG Procedure 37-1: Performing Basic Life Support for Healthcare Providers,** on Davis*Plus*.

Key points of the most recent guidelines *for trained professionals* include the following:

- Focus on effective, uninterrupted chest compressions.
- Push hard, push fast in the center of the chest.
- About 100 compressions per minute
- 30 compressions to 2 breaths—for all victims except newborns
- Give breaths over 1 second and make the chest rise visibly (Dumas, Rea, Fahrenbruch, et al., 2013; Sayre, Berg, Cave, et al., 2008).

In-Hospital Arrests

All agencies have procedures (called a "Code Blue" in many agencies) for announcing cardiac or respiratory arrest, and there is usually an emergency alert system in the patient rooms in acute care facilities. Activating the alert system (e.g., by pulling down a handle) summons a code team trained in CPR. However, you will probably need to begin CPR before they arrive. Begin CPR immediately after activating the alert, and use an automatic external defibrillator (AED) or manual defibrillator as soon as one is available. For a manual defibrillator, use a dose of 2 J/kg for the first shock and a dose of 4 J/kg for the second and subsequent shocks. Before beginning CPR, you are responsible for knowing whether your patient has an advance directive stating whether or not he would want CPR.

"Hands-Only" CPR

The American Heart Association (2011c) recommends different responses for laypersons, first responders, and CPR-trained professionals. The goal of these changes is to make it easier to learn, remember, and perform CPR. Referred to as "Hands-Only" CPR, the method is recommended for people who see an adult collapse suddenly in the community. It has only two steps:

1. Call 911, or send someone to make the call.
2. Push hard and fast in the center of the victim's chest.

See Self-Care: Teaching Your Client Hands-Only CPR for a more detailed description of CPR that you can teach to lay persons.

Rescuers should use Hands-Only CPR only for adults they observe to suddenly collapse. They should use CPR that combines breaths and compressions for:

Adults found already unconscious and not breathing normally
Victims of drowning or collapse due to breathing problems
All infants and children

Self-Care

Teaching Your Client Hands-Only CPR, for a Single Rescuer, Adult Victim

Witnessed Collapse

If you see an adult suddenly collapse in an "out-of-hospital" setting:

1. Call 911 (or send someone to do that).
2. Push hard and fast in the center of the chest (100 pumps per minute)
3. Continue until help arrives.

Unwitnessed Collapse

For an unwitnessed collapse of an adult victim:

1. Establish unresponsiveness (ask, "Are you okay?")
2. Call 911 (or send someone to do it).
3. Obtain an AED, if possible.
4. Start traditional CPR, if you know how, while waiting for the AED.

Traditional CPR

1. When the AED arrives, turn it on for rhythm analysis.
2. After turning on the AED, apply pads and await directions from AED.
3. Administer one shock and wait for the AED to tell you what to do next.
4. When the AED says to continue CPR, start alternating 30 compressions with 2 breaths. Continue until help arrives. Stop only to check the AED for rhythm.

Key point: *Remember: The most important action is to deliver uninterrupted, hard and fast chest compressions.*

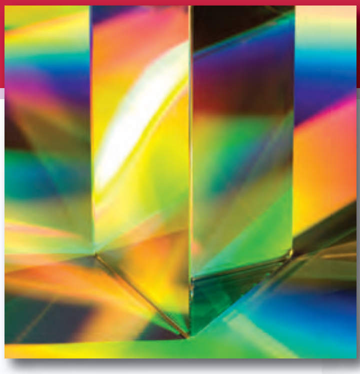
CHAPTER 38



Fluids, Electrolytes, & Acid–Base Balance

Learning Outcomes

After completing this chapter, you should be able to:

- Identify the fluid compartments within the body.
- Describe the location and function of the major electrolytes of the body.
- Differentiate among active and passive transport, osmosis, diffusion, and filtration.
- Describe the body mechanisms for maintaining fluid and electrolyte balance.
- Summarize the major fluid and electrolyte balance disorders.
- Compare and contrast respiratory and metabolic acidosis and alkalosis.
- Describe compensatory mechanisms for acid–base imbalances.
- Provide nursing interventions for clients with fluid, electrolyte, and acid–base imbalances.

Key Concepts

Acid–base balance
Electrolyte balance
Fluid balance

Related Concepts

See the Concept Map on Davis*Plus*.

Example Problem

Fluids, electrolytes, and acid–base imbalance

Meet Your Patients

Your instructor has assigned you to care for Jackson LaGuardia, a 60-year-old man with end-stage renal disease. You arrive at the hospital to review his chart so you can provide care the following day. When you arrive on the unit, the charge nurse informs you that Mr. LaGuardia is still in the emergency department (ED) waiting to be admitted to the medical-surgical unit. You go to the ED to review his chart and gather data.

In the ED, you introduce yourself and explain your purpose. The charge nurse tells you that five members of the LaGuardia family have all come to the ED complaining of nausea, vomiting, and diarrhea related to severe gastroenteritis, a viral intestinal disorder. The family members include the following:

8-month-old Jason, grandson of Jackson
26-year-old Susanna, Jackson's daughter and Jason's mother
58-year-old Gemma, Jackson's wife
60-year-old Jackson
82-year-old Martha, Jackson's mother

Jason, Jackson, and Martha are being admitted to the hospital. However, Susanna and Gemma have been asked to follow up tomorrow in the urgent care clinic. As you prepare for your clinical day, you think, "If they all have the same disorder, why are only three family members being admitted? What makes these patients different?" In this chapter, we follow the LaGuardias and answer these questions.

Theoretical Knowledge knowing why

When we are healthy, the fluid and chemical state of our bodies is in balance. However, illness can disturb this balance and threaten our existence. In this chapter, we examine how fluid, electrolyte, and acid–base balances are maintained, as well as what happens when there are disturbances in each of these areas.

ABOUT THE KEY CONCEPTS

The concepts of **fluid balance** and **electrolyte balance** are intricately related. Usually, when one electrolyte changes, so does another; and often fluids shift with the electrolyte. Tipping the delicate balance among fluids and electrolytes leads to dysfunction and disease.

Likewise, the status of **acid–base balance** is a reflection of the overall body functioning. Disruption of the balance in pH (acidity and alkalinity) and other body chemicals has a profound effect on overall health. By the end of this chapter, you will become familiar with the various balances and imbalances among fluids, electrolytes, acids, and bases.

BODY FLUIDS AND SOLUTES

Body fluid is primarily water and is essential for proper functioning of the body organs. It contains gases (e.g., carbon dioxide and oxygen) and solid substances, called **solutes**, that dissolve in body fluids. Many solutes are **electrolytes**—substances (e.g., sodium, potassium) that develop an electrical charge when dissolved in water. Other solutes are nonelectrolytes. **Nonelectrolytes** (e.g., glucose, urea) do not conduct electricity. Body fluids perform several important functions:

- Maintain blood volume.
- Regulate body temperature.
- Transport material to and from cells.
- Serve as a medium for cellular metabolism.
- Assist with digestion of food.
- Serve as a medium for excreting waste.

Fluid makes up approximately 60% of an average adult's body weight. However, total body water content varies with the number of fat cells, age, and sex. Infants have very high body water content (70%–80%), and the percentage progressively decreases with age. Women have less body fluid than men because they have proportionately more body fat. An obese person has less fluid than a person of lean build. Table 38-1 presents the distribution of fluid based on age and gender.

Table 38-1 ➤ Total Body Fluid in Relation to Sex and Age

AGE	TOTAL BODY FLUID (% OF BODY WEIGHT)
Full-term newborn	70%–80%
1 year old	64%
Young adult	Men: 60% Women: 50%–55%
Middle adult	Men: 55% Women: 45%–50%
Older adult	Men: 50% Women: 45%

What Are the Body Fluids Compartments?

Most body fluid is contained within two compartments. **Intracellular fluid (ICF)** is contained within the cells. It accounts for approximately 40% of body weight and is essential for cell function and metabolism. **Extracellular fluid (ECF)** is outside the cells. It carries water, electrolytes, nutrients, and oxygen to the cells and removes the waste products of cellular metabolism. ECF accounts for 20% of body weight and exists in three main locations in the body:

- *Interstitial fluid* lies in the spaces between the body cells. Excess fluid within the interstitial space is called edema.
- *Intravascular fluid* is the plasma within the blood. Its main function is to transport blood cells.
- *Transcellular fluid* includes specialized fluids that are contained in body spaces (e.g., cerebrospinal, pleural, peritoneal, and synovial fluid); and digestive juices.

Figure 38-1 illustrates the distribution of body fluids. In times of illness, fluid may move into an area that makes it physiologically unavailable, such as the peritoneal space (a condition called *ascites*), the pericardial space (a condition called *pericardial effusion*), or the *vesicles* (blisters) produced by a burn wound. This type of fluid movement is known as **third spacing** because fluid is literally trapped in a third compartment—not within interstitial (cells) or the intravascular spaces (blood vessels).

What Electrolytes Are Present in Body Fluids?

In addition to water, body fluid is composed of oxygen, carbon dioxide, dissolved nutrients, metabolic waste products, and electrolytes. Electrolytes that carry a positive charge are called **cations**. Electrolytes that carry a negative charge are called **anions**. Electrolytes are measured in milliequivalents per liter (mEq/L) of water or milligrams per 100 mL (mg/100 mL or mg/dL). Note that 1 dL, or deciliter, equals 100 mL. *Milliequivalent* is a measure of chemical combining power, whereas *milligram* is a weight measure.

The composition of body fluids varies between compartments:

- **In the ICF**, the major cations are potassium and magnesium. The major anion is phosphate. Other electrolytes are present, but to a lesser degree.

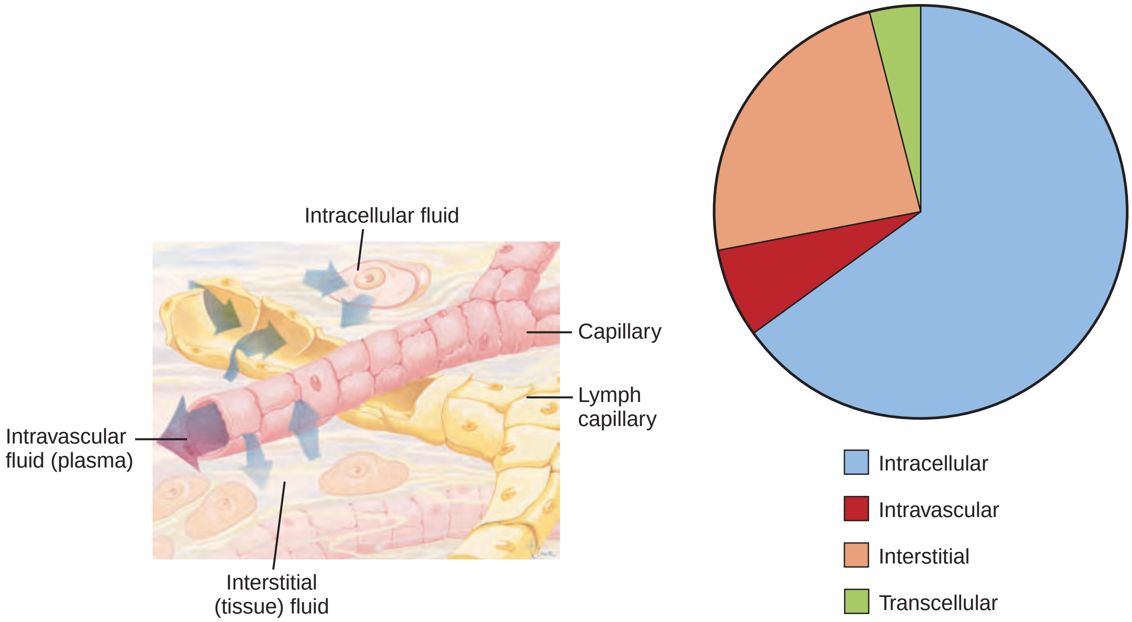


FIGURE 38-1 Normal distribution of body fluids. Transcellular fluid includes specialized fluids such as cerebrospinal and peritoneal fluid and digestive juices.

- **In the ECF**, the major electrolytes are sodium, chloride, and bicarbonate. Albumin is also present in the ECF, mostly in the intravascular fluid. Gastric and intestinal secretions (transcellular fluids) also contain electrolytes.

Severe electrolyte imbalances can occur if electrolytes move into a compartment they do not normally occupy or if they are lost in excess amounts from the body through perspiration, wounds, injury, or illness.

KnowledgeCheck 38-1

- Define *solute, electrolyte, intracellular fluid, extracellular fluid, cation*, and *anion*.
- Identify the major electrolytes in the ICF and ECF.

ThinkLike a Nurse 38-1

- Based on the information presented in the Meet Your Patients scenario, rank the members of the LaGuardia family based on total body water content.
- Does this information help you understand which family members were admitted to the hospital?

How Do Fluids and Electrolytes Move in the Body?

The selectively permeable membranes of cells and capillaries separate ICF and ECF (see Fig. 38-1). Fluid and electrolytes move across these membranes by passive and active mechanisms. In **active transport**, movement of fluid and solutes requires energy. **Passive transport** requires no energy. The three passive transport systems are osmosis, diffusion, and filtration. To see an animated illustration of these three systems,

Go to **Animations: Osmosis, Diffusion, Filtration, and Active Transport,** on Davis*Plus*.

Osmosis

Osmosis involves movement of water (or other pure solute) across a membrane from an area of a less concentrated solution to an area of more concentrated solution. Water moves across the membrane to dilute the higher concentration of solutes (Fig. 38-2). Recall that a solute is a substance dissolved in body fluid. Solutes may be crystalloids or colloids. **Crystalloids** are solutes that readily dissolve (e.g., electrolytes). **Colloids** are larger molecules that do not dissolve readily (e.g., proteins).

The concentration of solutes creating pressure in body fluid is called **osmolality**. **Osmols** refers to the number of particles of solute per kilogram of water and is expressed as milliosmoles per kilogram (mOsm/kg). Sodium is the greatest determinant of serum osmolality, and potassium is the greatest determinant of intracellular osmolality. Glucose and urea also contribute to osmolality in the ICF and ECF.

Another term for osmolality is **tonicity**.

- **An isotonic solution** is of the same osmolality as blood**.** An isotonic solution is often given by intravenous (IV)

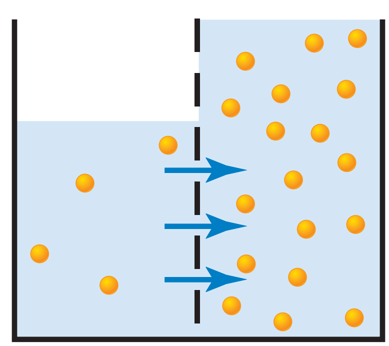

FIGURE 38-2 Osmosis is the movement of water across a membrane from a less concentrated solution to a more concentrated solution.

infusion if blood volume is low. Because the solution is the same concentration as blood, the fluid will remain in the vascular space, and no osmosis will occur.

- **A hypotonic solution** is of lower osmolality than blood. When a hypotonic solution is infused, water moves by osmosis from the vascular system into the cells.
- A **hypertonic solution** contains a higher concentration of solutes than does blood. When a hypertonic solution is given to a patient, water moves by osmosis from the cells into the ECF.

Diffusion

Diffusion is a passive process by which molecules of a solute move through a cell membrane from an area of higher concentration to an area of lower concentration. Movement occurs (Fig. 38-3) until the concentrations are equivalent on both sides of the membrane. For an example of diffusion, pour yourself a cup of coffee. Now add cream to the coffee. Initially, the cream is concentrated in the area where you have poured it. However, within a short time the cream is evenly dispersed throughout the coffee. If you stir the coffee, the cream disperses even more quickly. Fluids within the human body work on a similar principle; movement of the body speeds the diffusion of molecules.

The rate of diffusion varies according to the size of the molecules, the concentration of the solution, and the temperature of the solution. Small molecules move more rapidly than larger molecules. Large differences in concentration require a longer period of time to reach equilibration. Higher temperatures cause molecules to move faster, so that diffusion occurs more rapidly.

Filtration

Filtration is the movement of both water and smaller particles from an area of high pressure to one of low pressure (Fig. 38-4). **Hydrostatic pressure** is the force created by fluid within a closed system; it is responsible for normal circulation of blood. In other words, blood flows from the high-pressure arterial system to the lower pressure capillaries and veins. As fluid (plasma)

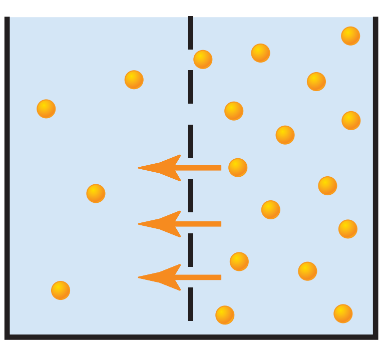

FIGURE 38-3 Diffusion is the movement of molecules of a solute through a cell membrane from an area of higher concentration to an area of lower concentration.

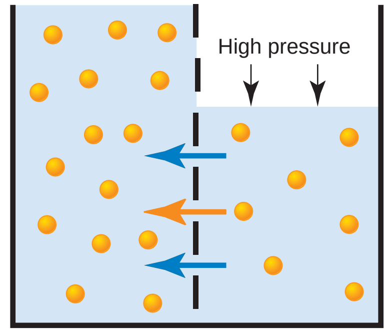

FIGURE 38-4 Filtration is the movement of water and smaller particles from an area of high pressure to an area of low pressure.

moves through the capillary membrane, only solutes of a certain size can flow with it. For example, the membrane pores of Bowman's capsule in the kidneys are very small, and only albumin, the smallest of the proteins, can be filtered through the membrane. By contrast, the membrane pores of liver cells are extremely large, so a variety of solutes can pass through and be metabolized.

Osmotic pressure is the power of a solution to draw water. A highly concentrated solution (with many molecules in solution) draws water and has a high osmotic pressure. The plasma proteins in the blood exert osmotic, or colloidal, pressure to help maintain fluid in the vascular space. However, when hydrostatic pressure exceeds osmotic pressure, fluid leaves the vessels. This difference, known as the **filtration pressure**, represents the net pressures that move fluid and solutes. The hydrostatic pressure is higher at the arteriole end of the capillary and lower at the venous end; thus, blood is forced out at the arteriole in and returned at the venule side.

Active Transport

Active transport occurs when molecules (e.g., electrolytes) move across cell membranes against a concentration gradient (from an area of low concentration to an area of high concentration). Active transport requires energy expenditure (Fig. 38-5). Adenosine triphosphate (ATP) is released from the cell to enable certain substances to acquire the energy needed to pass through the cell membrane. For example, sodium concentration is greater in ECF; therefore, sodium tends to enter by diffusion into the intracellular compartment. This tendency is offset by the sodium-potassium pump, which consists, in part, of transport proteins located on the cell membrane. In the presence of ATP, the sodium-potassium pump actively moves sodium from the cell into the ECF and potassium from the ECF into the cell. Active transport is vital for maintaining the unique composition of both the extracellular and intracellular compartments.

Table 38-2 summarizes the processes of fluid and electrolyte movement.

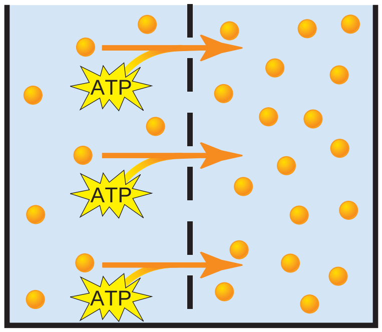

FIGURE 38-5 Active transport is the movement of electrolytes against a concentration gradient. For the movement to occur, active transport requires energy expenditure.

KnowledgeCheck 38-2

Identify the appropriate mechanism: osmosis, diffusion, filtration, or active transport:

- Molecules move across a membrane to equalize concentration.
- Fluid moves across a membrane to equalize concentration.
- Molecules move against a concentration gradient.
- Molecules move to equalize pressure.

How Does the Body Regulate Fluids?

A balance between fluid intake and output is essential to maintain homeostasis. Excesses or deficits of intake or output can lead to severe disorders.

Fluid Intake

You have undoubtedly been told to drink eight to ten glasses of water per day. Did you ever wonder where that recommendation came from or why that volume is important? Eight to ten 8-ounce glasses of water provide 1,920 to 2,400 mL of fluid. The Institute of Medicine (IOM) (2004), however, recommends a total fluid intake of 2,700 mL per day for women and 3,700 mL per day for men. The IOM states that we should obtain 80% of our intake from drinking fluids and the remaining 20% from food and cellular metabolism of foods. Prolonged exercise and heat exposure increase the requirements. The IOM did not set an upper limit on fluid intake.

A daily intake of 1,500 to 2,000 mL of noncaffeinated fluids will maintain hydration in older adults (Miller, 2012).

Thirst is the major regulator of fluid intake. Changes in plasma osmolality signal the thirst center in the hypothalamus, which leads to the urge to drink. Situations that increase plasma osmolality (and promote thirst) include excessive fluid loss, excessive sodium intake, and decreased fluid intake. Situations that inhibit the thirst mechanism include a high intake of fluids, fluid retention, excessive IV infusion of hypotonic solutions, and low sodium intake.

Fluid Output

Fluid loss occurs throughout the day, creating a constant need to replenish fluid. In a healthy state, fluid losses are equivalent to fluid intake. **Sensible fluid loss** is measurable and perceived (e.g., urine, diarrhea, ostomy, and gastric drainage). **Insensible fluid loss** is loss that we do not perceive, is not easily measured, but accounts for about 900 mL per day. It occurs primarily by diffusion and evaporation through the skin, but also from the lungs. Insensible loss increases with open wounds, burns, or other breaks in the protective layer of the skin. The following are common sources of fluid loss:

- *Urine* (1,500 mL/day). Urine accounts for the greatest amount of fluid loss. Urine output varies according to intake and activity, but should remain at least 30 to 50 mL/hour. The volume of urine increases as intake increases, and it decreases to compensate for other fluid losses (e.g., vomiting and excessive perspiration).
- *Feces* (100 to 200 mL/day). Soft stools contain more water than hard stools. As stool frequency increases, water loss also increases.
- *Skin* (about 600 mL/day). **Sensible (perceived) fluid loss** through the skin occurs through perspiration, at 300 to 600 mL/day. Perspiration varies based on temperature, skeletal muscle activity, and metabolic activity. Fever, exercise, and some disease processes increase metabolic activity and heat production, leading to increased fluid loss.
- *Lungs* (about 300 mL/day). Insensible loss occurs through the lungs as water is exhaled with each breath. An increase in respiratory rate increases the amount of fluid lost.

Hormonal Regulation

The kidneys are the principal regulator of fluid and electrolyte balance. The following hormones are involved:

Table 38-2 ➤ Processes of Fluid and Electrolyte Movement

PROCESS	WHAT MOVES	FROM AREA OF	TO AREA OF
Diffusion	Molecules (solute)	High concentration	Low concentration
Active transport	Molecules (solute)	Low concentration	High concentration
Osmosis	Water	Low concentration	High concentration
Filtration	Water and small particles	High pressure	Low pressure

Antidiuretic Hormone Pressure sensors in the vascular system stimulate or inhibit the release of **antidiuretic hormone (ADH)** from the pituitary gland. ADH causes the kidneys to retain fluid. If fluid volume within the vascular system is low, fluid pressures within the system decrease, and more ADH is released. If fluid volume (and therefore pressure) increases, less ADH is released, and the kidneys eliminate more fluid. ADH is also produced in response to a rise in serum osmolality, fever, pain, stress, and some opioids.

Renin–Angiotensin System When extracellular (i.e., intravascular) fluid volume is decreased, receptors in the glomeruli respond to the decreased perfusion of the kidneys by releasing renin. **Renin** is an enzyme responsible for the chain of reactions that converts angiotensinogen to angiotensin II. **Angiotensin II** acts on the nephrons to retain sodium and water and directs the adrenal cortex to release aldosterone.

Aldosterone When aldosterone is released, it stimulates the distal tubules of the kidneys to reabsorb sodium and excrete potassium. Sodium reabsorption results in passive reabsorption of water, thereby increasing plasma volume and improving kidney perfusion. When fluid excess is present, renin is not released, and this process stops.

Other Hormones Other hormones affect fluid and electrolyte balance by their effect on certain organs of the body:

- *Thyroid hormone* affects fluid volume by influencing cardiac output. An increase in thyroid hormone causes an increase in cardiac output, thereby increasing glomerular filtration rate and urine output. A decrease has the opposite effect.
- *Atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP)*, and *C-type natriuretic peptide (CNP)* are important in renal and cardiovascular regulation of fluid maintenance. **Natriuresis** (natriuretic) is the discharge of sodium through urine. BNP is actually released from both the brain and the right atrium. In clinical practice, BNP can be measured in the serum to help determine presence of heart failure with fluid excess and to distinguish heart failure from pulmonary edema. The test can be performed at the bedside.

ThinkLike a Nurse 38-2

Apply the information on fluid balance to the LaGuardia family (Meet Your Patients). What have you learned that helps you explain why some family members require hospitalization? What additional information do you need to be able to predict each person's fluid balance?

How Does the Body Regulate Electrolytes?

To maintain health, the body must balance electrolyte losses and intake. For example, potassium lost through diarrhea and vomiting must be replaced by dietary potassium or potassium supplements. Table 38-3 provides information about the function, regulation, and food sources of major electrolytes in the body. Maintenance of normal serum levels also depends on dietary intake and various other mechanisms, which are discussed in the remainder of this section.

Sodium (Na^+)

Sodium is the major cation in the ECF. Its primary function is to regulate fluid volume. When sodium is reabsorbed in the kidney, water and potassium are also reabsorbed, thereby maintaining ECF volume. According to the *2010 Dietary Guidelines for Americans*, adults should limit the intake of salt to 2,300 mg/day. People (including children) with chronic diseases (e.g., hypertension, diabetes, chronic kidney disease), African Americans, and people older than age 51 are especially sensitive to the blood-pressuring raising effects of salt. They are advised to limit salt intake to 1,500 mg/day. This applies to nearly 50% of the U.S. population (U.S. Department of Agriculture [USDA], 2011).

Potassium (K^+)

Potassium is the major cation of the ICF; it is a key electrolyte in cellular metabolism. Only 2% of body potassium is found in the extracellular fluid. The *2010 Dietary Guidelines for Americans* recommends that adults consume at least 4,700 mg/day. However, most people do not consume enough potassium. Most American women age 31 to 50 consume less than half this amount and intake is only moderately higher for men. Moderate potassium deficiency is associated with increases in blood pressure, salt sensitivity, risk of kidney stones, and risk of bone turnover (USDA, 2011). Because of its effect on blood pressure, low intake of dietary potassium is associated with increased risk of stroke.

The Dietary Reference Intakes (DRIs) do not specify an upper limit of potassium intake because there is no evidence of problems associated with higher potassium intake (IOM, 2004). In a healthy person, a high potassium intake does not result in a high serum potassium level (hyperkalemia) because the kidneys efficiently eliminate excess dietary potassium.

Calcium (Ca^{2+})

Calcium is responsible for bone health and neuromuscular and cardiac function. It is also an essential factor in blood clotting. About 99% of body calcium is located in the bones and teeth. The remaining 1% circulates in the blood and affects system functions. Because calcium is so vital for cardiac and muscle function, serum levels are tightly regulated. As serum levels drop, calcium leaches from the bones into the blood to compensate.

Prolonged insufficient dietary intake can cause bone loss that leads to osteoporosis. Half the women older than age 50, 90% of women older than age 75, and about 30% of men older than age 50 have osteoporosis. About half of all Caucasian women will suffer an osteoporosis-related fracture at some point in life, as will approximately 1 in 5 men. Because most Americans do not include the recommended amount of calcium in their diets, the chances of bone loss increase with age. Most calcium should be obtained from naturally calcium-rich foods, such as dairy products. Calcium-fortified foods and calcium supplements can be used as a secondary source.

Calcium requirements are highest during childhood, adolescence, pregnancy, and breastfeeding. People who are immobile are at increased risk for reduced bone density.

Older adults are at risk for calcium deficiencies because of reduced absorption that occurs with aging and chronic medical conditions (National Osteoporosis Foundation, n.d.).

For recommended calcium intake by age group, see Table 38-4.

Magnesium (Mg^{2+})

Magnesium is a mineral used in more than 300 biochemical reactions in the body. Like calcium, only about 1% of magnesium is found in the blood. The remaining 99% is divided between the ICF and bone (in combination with calcium and phosphorus). Although magnesium deficiency is rare, you may find low levels in individuals who have a high alcohol intake. Some malabsorption disorders may also cause magnesium depletion (Crawford & Harris, 2011a).

Chloride (Cl^-)

Chloride is the most abundant anion in the extracellular fluid. It is usually bound with other ions, especially sodium or potassium (e.g., as sodium chloride, or salt). A healthy adult between the ages of 19 and 50 should consume 2.3 grams of chloride each day along with 1.5 grams of sodium to replace daily losses and maintain serum blood levels (IOM, 2004).

Phosphorus (Phosphate [PO_4^-])

Most phosphorus in the body is combined with oxygen, forming phosphate—mostly bound with calcium in teeth and bones as calcium phosphate. Phosphate is the most abundant intracellular anion. Phosphate and calcium exist in an inverse relationship; as one increases, the other one decreases. As a result, high blood phosphate levels decrease the movement of calcium from the bones. Phosphate in the ECF is known as **phosphorus**.

Bicarbonate (HCO_3^-)

Bicarbonate is present in both ICF and ECF. The kidneys regulate extracellular bicarbonate to maintain acid–base balance. When serum levels rise, the kidneys excrete excess bicarbonate. If serum levels are low, the kidneys conserve bicarbonate. Bicarbonate is not consumed in the diet but is produced by the body to meet current needs.

KnowledgeCheck 38-3

- Identify the major functions of sodium, potassium, calcium, magnesium, chloride, phosphate, and bicarbonate.
- What are the major concerns associated with sodium and potassium intake?
- Identify at least five potassium-rich foods.
- Identify the ideal calcium intakes for each member of the LaGuardia family (Meet Your Patients).

ThinkLike a Nurse 38-3

Based on the information you have learned about the major electrolytes of the body, which electrolytes are most likely to be out of balance in members of the LaGuardia family? Explain your answer.

How Is Acid–Base Balance Regulated?

Acids and bases are formed in the body as part of normal metabolic processes. An **acid** is any compound that contains hydrogen ions (H^+) that can be released. For this reason, acids are referred to as cation donors. A common strong acid is hydrochloric acid (HCl), which is present in gastric secretions. A **base** or **alkali** is a compound that combines with (accepts) hydrogen ions in solution. Therefore, bases are referred to as cation (a positively charged particle) acceptors. A strong base has a tendency to bind hydrogen ions, whereas a weak base binds only a small portion of the available hydrogen ions.

The amount of acid or base present in a solution is measured as **pH**. The pH is reported on a scale of 1 to 14: 1 to 6.9 is acidic, 7 is neutral, and 7.1 to 14 is basic, or alkaline. The stronger an acid, the lower the pH. In contrast, a strong base has a high pH. The pH is a *logarithmic* scale. For example, a pH of 4 is 10 times more acidic than a pH of 5. The body functions normally within a narrow range of pH values. Arterial blood and tissue fluid normally have a pH of 7.35 to 7.45; therefore, they are slightly alkaline. A serum pH below 7.30 or above 7.52 alters enzymatic activity and creates myocardial irritability. A serum pH below 6.9 or above 7.8 is usually fatal. Three complex mechanisms maintain acid–base balance: (1) buffers, (2) respiratory control of carbon dioxide, and (3) renal regulation of bicarbonate (HCO_3^-).

Buffers

Buffer systems prevent wide swings in pH. A buffer system consists of a weak acid and a weak base. Buffer molecules keep strong acids or bases from altering the pH either by absorbing or releasing free hydrogen ions.

Carbonic Acid–Sodium Bicarbonate System Carbonic acid (H_2CO_3) and sodium bicarbonate ($NaHCO_3$) buffer almost 90% of metabolic processes in the ECF. Blood and tissue fluid depend on this buffer system to maintain a relatively constant pH. During normal metabolism, blood and tissue fluids tend to become acidic; therefore, more sodium bicarbonate is required than carbonic acid. The usual ratio of $NaHCO_3$ to H_2CO_3 is 20:1.

Table 38-3 ➤ Major Electrolytes

ELECTROLYTE	FUNCTION	REGULATION	SOURCES
Sodium (Na^+) Major cation in the ECF *Normal serum level is 135–145 mEq/L	Regulates fluid volume. Helps maintain blood volume. Interacts with calcium to maintain muscle contraction. Stimulates conduction of nerve impulses.	Moves by active transport across cell membranes. Regulated by aldosterone and ADH levels Reabsorbed and excreted through the kidneys Minimal loss through perspiration and feces Low sodium may be caused by excess water intake.	Table salt, soy sauce, cured pork, cheese, milk, processed foods, canned products, and foods preserved with salt
Potassium (K^+) Major cation in the ICF Normal serum level is 3.5–5.0 mEq/L	Maintains ICF osmolality. Regulates conduction of cardiac rhythm. Transmits electrical impulses in multiple body systems. Assists with acid–base balance.	Regulated by aldosterone Excreted and conserved through the kidneys Lost through vomiting and diarrhea Loss triggered by many diuretics	Common food sources include bananas, oranges, apricots, figs, dates, carrots, potatoes, tomatoes, spinach, dairy products, and meats.
Calcium (Ca^{2+}) Most abundant electrolyte in the body Normal serum level is 8.5–10.5 mg/dL	Promotes transmission of nerve impulses. Major component of bone and teeth Regulates muscle contractions. Maintains cardiac automaticity. Essential factor in the formation of blood clots Catalyst for many cellular activities	Combines with phosphorus to form the mineral salts of the teeth and bones. Calcium and phosphorus levels are inversely proportional Parathyroid hormone (PTH) stimulates release of calcium from bones and reabsorption from kidneys and intestines. Calcitonin (from the thyroid) blocks bone breakdown and lowers calcium levels. Absorption stimulated by vitamin D	See Table 38-4 for average daily requirements. Common food sources include milk, milk products, dark green, leafy vegetables, and salmon, as well as calcium-fortified foods such as breads and cereals.
Magnesium (Mg^{2+}) Present in skeleton and ICF; second most abundant cation in ICF Normal serum level is 1.6–2.6 mEq/L	Involved in protein and carbohydrate metabolism Necessary for protein and DNA synthesis within the cell Maintains normal intracellular levels of potassium. Involved in electrical activity in nerve and muscle membranes, including the heart	Ingested in the diet and absorbed through the small intestine Excreted by kidneys Loss may be triggered by diuretics, poorly controlled diabetes mellitus, and excess alcohol intake.	Average daily requirement is 18–30 mEq. Found in most foods, but high levels are present in green vegetables, cereal grains, and nuts.

Table 38-3 ➤ Major Electrolytes—cont'd

ELECTROLYTE	FUNCTION	REGULATION	SOURCES
	May have a role in regulating blood pressure and may influence the release and activity of insulin (Crawford & Harris, 2011a; IOM, 2004).		
Chloride (Cl^-) Major anion in the ECF Normal serum level is 95–105 mEq/L	Works with Na^+ to maintain osmotic pressure between fluid compartments. Essential for production of HCl for gastric secretions Functions as buffer in oxygen–carbon dioxide exchange in RBCs. Assists with acid–base balance.	Reabsorbed and excreted through the kidneys along with sodium Regulated by aldosterone and ADH levels Deficits lead to potassium deficits; potassium deficits lead to chloride deficits.	Found in foods high in sodium
Phosphate (PO_4^-) Major anion in the ICF Normal serum level is 1.7–2.6 mEq/L	Serves as a catalyst for many intracellular activities Promotes muscle and nerve action Assists with acid–base balance Important for cell division and transmission of hereditary traits	Combines with calcium to form the mineral salts of the teeth and bones Calcium and phosphorus levels are inversely proportional Regulated by PTH; has inverse response to calcium Excreted and reabsorbed by the kidneys	Foods high in phosphorus are meat, fish, poultry, milk products, carbonated beverages, and legumes. Readily available in body as a result of metabolism
Bicarbonate (HCO_3^-) Major buffer in the body In ECF and ICF Normal serum level is 22–26 mEq/L	Maintains acid–base balance by functioning as the primary buffer in the body	Lost through diarrhea, diuretics, renal insufficiency Excess possible if person ingests quantities of acid neutralizers	Present in acid neutralizers (e.g., sodium bicarbonate)

**Note that normal ranges may differ among references and in different laboratories.*
ADH = antidiuretic hormone; ECF = extracellular fluid; ICF = intracellular fluid; PTH = parathyroid hormone; RBC = red blood cell.

As long as this ratio is maintained, the pH remains within its normal range. If bicarbonate is depleted while neutralizing a strong acid, the pH may drop below 7.35, resulting in a condition called **acidosis**. If a strong base is added to extracellular fluid and depletes carbonic acid, the pH may rise above 7.45, resulting in a condition called **alkalosis**.

Phosphate System The phosphate system helps regulate acid–base balance in intracellular fluids. The phosphate system works in the same way as the bicarbonate system but converts alkaline sodium phosphate (Na_2HPO_4) to acid sodium phosphate (NaH_2PO_4).

Protein System Plasma proteins and the globin portion of hemoglobin (in red blood cells) contain chemical groups that can either combine with or free up hydrogen ions. This system helps buffer intracellular fluid and plasma to maintain pH balance.

Respiratory Mechanisms

The lungs are the second line of defense to restore normal pH. They control the body's carbonic acid supply via carbon dioxide retention or removal to maintain the 20:1 ratio of base to acid. When the serum pH is too acidic (pH is low), the lungs remove carbon dioxide

Table 38-4 ➤ Recommended Daily Allowances (RDA) for Calcium and Vitamin D*

AGE	CALCIUM (MILLIGRAMS)	VITAMIN D* (INTERNATIONAL UNITS)
Birth to 6 months	200	400
6–12 months	260	400
1–3 years	700	600
4–8 years	1,000	600
9–13 years	1,300	600
14–18 years	1,300	600
19–30 years	1,000	600
31–50 years	1,000	600
51–70 years, males	1,000	600
51–70 years, females	1,200	600
Older than 70 years	1,200	800
Pregnant or Lactating Women		
18 years or younger pregnant or lactating	1,300	600
19–50 years	1,000	600

*Adequate intake of Vitamin D is necessary for absorption of calcium.

through rapid, deep breathing. This reduces the amount of carbon dioxide available to make carbonic acid. If the serum pH is too alkaline (pH is high), the lungs try to conserve carbon dioxide through shallow respirations.

Renal Mechanisms

The last line of defense is the kidneys, which regulate the concentration of plasma bicarbonate. They can neutralize more acid or base than either the respiratory system or the chemical buffers. If the serum pH is too acidic, the kidneys conserve additional bicarbonate to neutralize the acid. If the serum pH is too alkaline, the kidneys excrete additional bicarbonate to lower the amount of base and thereby decrease the pH. The kidneys also buffer pH by forming acids and ammonium (a base).

Although the renal system is very effective at altering pH, it is slow. It may take up to 3 days to return the pH to normal limits. This process is known as *compensation*. The pH returns to normal, but the carbon dioxide or bicarbonate level is abnormal. Over time, or when the original problem is corrected, these levels also return to normal.

KnowledgeCheck 38-4

- Briefly describe the three mechanisms used to maintain pH.
- Rank in order the acid–base balance mechanisms from the most rapidly acting to the slowest acting.

Example Problem: Fluid, Electrolyte, and Acid–Base Imbalances

Illness or disease may lead to imbalances of fluid, electrolytes, or pH. These are discussed in the next sections. The Practical Knowledge section, later in this chapter, presents some interventions to correct these imbalances.

Fluid Imbalances

Fluid imbalances involve a deficit or excess in fluid volume or an alteration in distribution among the fluid compartments. Fluid deficit, regardless of the cause, is referred to as *hypovolemia*, whereas fluid excess, usually not blood, is referred to as *hypervolemia.*

Deficient Fluid Volume

Deficient fluid volume (hypovolemia) occurs when there is a proportional loss of fluid and electrolytes from the ECF. Loss of blood volume is called hypovolemia (*hypo* = low, *vol* = volume, *emia* pertains to blood). Hypovolemia may occur with surgery, trauma, or uterine rupture.

Dehydration

Dehydration describes a state of negative fluid balance in which there is a loss of water (*hydro* = water) from the intracellular, extracellular or intravascular spaces. Dehydration can be categorized by three causes:

- Insufficient intake of fluids (e.g., as may occur with depression, sedation, or alcohol abuse)
- Excessive fluid loss (e.g., bleeding, vomiting, diarrhea, nasogastric [NG] suction)
- Fluid shifts (e.g., intravascular fluid may leak into body tissues, burns).

When dehydration occurs from the loss of body fluids, electrolytes may also be lost. Fluid loss can also lead to an increase is serum osmolarity.

Early Symptoms of Dehydration The first symptom of volume loss is thirst. If the patient is able to recognize thirst and respond by drinking liquid, no further treatment may be required. If fluid is not available or the patient is unable to drink, or if blood loss continues faster than fluid is replaced (e.g., hemorrhage), fluid becomes deficient. Initially as fluid volume decreases, the heart rate increases and the blood vessels constrict. This increases the blood pressure, in order to continue to circulate the remaining fluid to meet the body's fluid demands.

Continuing Fluid Loss (Hypovolemic Shock)

If volume continues to be lost, the heart pumps faster but not as powerfully, resulting in a rapid, weak pulse, and orthostatic hypotension. This is known as **hypovolemic shock**. Orthostatic blood pressure is measured when the patient is lying, sitting, and standing. A drop in the systolic blood pressure (from lying or sitting to standing) greater or equal to 20 mm Hg is called **orthostatic hypotension**. Low fluid volume is just one of its causes.

As fluid loss continues, water is pulled from the interstitial spaces and the ICF into the vascular system, resulting in dry skin and mucous membranes, decreased skin and tongue turgor, decreased urine output, and flat neck veins. Patients complain of muscle weakness, fatigue, and feeling warm. Temperature increases because the body is less able to cool itself through perspiration. In an older adult, temperature will rise but may not be elevated above normal body temperature.

Assessing for and Preventing Deficient Fluid Volume

Weight is a sensitive measure of fluid loss. A sudden 5% loss of body weight is considered clinically significant. When loss approaches 8%, fluid loss is severe. A sudden loss of 15% of body weight due to fluid loss is usually fatal. The patient with fluid volume deficit usually has elevated blood urea nitrogen (BUN)–to-creatinine ratio and elevated hematocrit. Both values increase because there is less water in proportion to the solid substances being measured. Specific gravity of the urine increases as the kidneys attempt to conserve water, resulting in more concentrated urine.

You can help prevent fluid volume deficit by identifying patients who have the highest risk for developing this condition: older adults, infants, children, and any patients with conditions associated with fluid loss (e.g., diabetes insipidus, vomiting, diarrhea, fever). You will learn how to facilitate fluid intake and provide parenteral fluid replacement in the Planning Interventions/Implementation section, to follow.

Excess Fluid Volume

Excess fluid volume (hypervolemia) involves excessive retention of sodium and water in the ECF. Fluid volume excess can result from excessive salt intake, disease affecting kidney or liver function, or poor pumping action of the heart. The retained sodium increases osmotic pressure in the ECF. This pressure pulls fluid from the cells into the ECF.

Signs of Fluid Overload The vital sign changes in a patient with hypervolemia are the opposite of those seen in hypovolemia. The blood pressure is elevated, pulse is bounding, and respirations are increased and shallow. The neck veins may become distended. Along with increased intravascular volume, excess ECF may accumulate in the tissues, especially in dependent areas, as *edema*. The skin is pale and cool. Urine output becomes dilute, and volume increases. The patient rapidly gains weight. In severe fluid overload, the patient develops moist crackles in the lungs, dyspnea, and ascites (excess peritoneal fluid). Hemodilution causes BUN, hematocrit, and specific gravity of the urine to decrease.

Preventing Fluid Overload You can help prevent fluid overload by monitoring intake and output and carefully regulating intravenous infusions. The use of electronic infusion pumps controls the rate of infusion of intravenous fluid, thereby minimizing the risk of fluid overload (see Planning Interventions/Implementation).

KnowledgeCheck 38-5

- Define *deficient fluid volume* and *excess fluid volume*.
- Identify the signs and symptoms of deficient fluid volume and excess fluid volume.
- Describe dehydration and hypervolemia.

Electrolyte Imbalances

Any electrolyte may become imbalanced. Table 38-5 discusses the common causes; signs and symptoms; and treatment of sodium, potassium, calcium, magnesium,

Table 38-5 ➤ Electrolyte Imbalances

DISORDER	COMMON CAUSES	SIGNS AND SYMPTOMS	TREATMENT
Hyponatremia Na^+ <135 mEq/L	Diuretics GI fluid loss Adrenal insufficiency Excessive intake of hypotonic solutions, such as water or D_5W IV fluids Syndrome of inappropriate ADH	Anorexia, nausea, and vomiting Weakness Lethargy Confusion Muscle cramps or twitching Seizures	Monitor I&O. Monitor sodium level. Increase oral sodium intake. Administer IV saline infusion and take seizure precautions, if severe.
Hypernatremia Na^+ >145 mEq/L	Excessive sodium intake Water deprivation Increased water loss through profuse sweating, heat stroke, or diabetes insipidus Administration of hypertonic tube feeding	Thirst Elevated temperature Dry mouth and sticky mucous membranes If severe: Hallucinations Irritability Lethargy Seizures	Monitor I&O. Monitor sodium level. Monitor vital signs and level of consciousness. Restrict sodium in the diet. Beware of hidden sodium in foods and medications. Increase water intake. Administer IV solutions that do not contain sodium.
Hypokalemia K^+ <3.5 mEq/L	Diuretics GI fluid loss through vomiting, gastric suction, or diarrhea Steroid administration Hyperaldosteronism Anorexia or bulimia	Fatigue Anorexia, nausea, and vomiting Muscle weakness Decreased GI motility Dysrhythmias Paresthesia Flat T wave on ECG Increased sensitivity to digitalis	Monitor I&O. Monitor potassium level. If the client is taking digoxin, monitor pulse and observe for toxicity. Encourage intake of foods rich in potassium. Administer potassium supplements (*Note:* IV potassium must be well diluted and administered into a central vein slowly.)
Hyperkalemia K^+ >5.0 mEq/L	Renal failure Potassium-sparing diuretics Hypoaldosteronism High potassium intake coupled with renal insufficiency Acidosis Major trauma Hemolyzed serum sample produces pseudohyperkalemia	Muscle weakness Dysrhythmias Flaccid paralysis Intestinal colic Tall T waves on ECG	Monitor I&O. Monitor potassium level. Caution about potassium-rich food intake in patients with elevated creatinine levels.
Hypocalcemia Ca^{2+} <8.5 mq/dL	Hypoparathyroidism Malabsorption Pancreatitis	Diarrhea Numbness and tingling of extremities	Monitor I&O. Monitor serum calcium. Encourage increased

Table 38-5 ➤ Electrolyte Imbalances—cont'd

DISORDER	COMMON CAUSES	SIGNS AND SYMPTOMS	TREATMENT
	Alkalosis Vitamin D deficiency	Muscle cramps Tetany Convulsions Laryngeal spasms Cardiac irritability *Positive Trousseau's and Chvostek's signs	calcium intake. Administer calcium supplements. If severe, monitor patency of airway, institute seizure and safety precautions, and administer parenteral calcium.
Hypercalcemia Ca^{2+} >10.5 mq/dL	Hyperparathyroidism Malignant bone disease Prolonged immobilization Excess calcium supplementation Thiazide diuretics	Muscle weakness Constipation Anorexia, nausea, and vomiting Polyuria and polydipsia Kidney stones Bizarre behavior Bradycardia	Monitor I&O. Encourage fluid intake to prevent stone formation. Encourage fiber to prevent constipation. Eliminate calcium supplements and limit calcium-rich foods. Avoid calcium-based antacids. Renal dialysis may be required.
Hypomagnesemia Mg^{2+} <1.3 mEq/L	Chronic alcoholism Malabsorption Diabetic ketoacidosis Prolonged gastric suction	Neuromuscular irritability Disorientation Mood changes Dysrhythmias Increased sensitivity to digitalis	Monitor I&O. Encourage foods high in magnesium. Avoid alcohol intake. If the client is taking digoxin, monitor pulse and observe for toxicity.
Hypermagnesemia Mg^{2+} >2.1 mEq/L	Renal failure Adrenal insufficiency Excess replacement	Flushing and warmth of skin Hypotension Drowsiness, lethargy Hypoactive reflexes Depressed respirations Bradycardia	Monitor vital signs and airway. Monitor reflexes. Avoid magnesium-based antacids and laxatives. Restrict dietary intake of foods high in magnesium.
Hypophosphatemia PO_4^- <2.5 mg/dL	Refeeding after starvation Alcohol withdrawal Diabetic ketoacidosis Respiratory acidosis	Paresthesia Joint stiffness Seizures Cardiomyopathy Impaired tissue oxygenation	Monitor serum phosphorus level. Monitor calcium levels as phosphate is replaced. Start TPN slowly to avoid drops in phosphate.
Hyperphosphatemia PO_4^- >4.5 mg/dL	Renal failure Hyperthyroidism Chemotherapy Excess use of phosphate-based laxative	Short term: tetany symptoms—tingling of extremities and cramping Long term: Calcification in soft tissue	Monitor serum phosphorus level. Monitor for tetany. If severe, administer aluminum hydroxide with meals to bind phosphorus.

*See Clinical Insight 38-1: Assessing for Trousseau's and Chvostek's Signs
ADH = antidiuretic hormone; ECG = electrocardiogram; GI = gastrointestinal; I&O = intake and output; TPN = total parenteral nutrition
Source. Van Leeuwen, A., Poelhuis-Leth, D., & Bladh, M. (2011). *Davis's comprehensive handbook of laboratory and diagnostic tests with nursing implications* (4th ed.). Philadelphia: F.A. Davis.

and phosphate imbalances. Disorders affecting chloride ions occur along with sodium disorders. As sodium levels rise, chloride levels also rise. Decreases also occur simultaneously. Clinical signs and treatments are identical to sodium imbalances. Because of the role of bicarbonate as a buffer, bicarbonate levels rise and fall to maintain pH. You will find further discussion of abnormal bicarbonate levels in the section Acid–Base Imbalances, which follows.

We can apply the information in Table 38-5 to the LaGuardia family (Meet Your Patients). Jackson LaGuardia has end-stage renal disease (ESRD), or renal failure. As a result, he is at risk for imbalances in all of his electrolytes. Now he is experiencing nausea, vomiting, and diarrhea. This will further aggravate the imbalance of potassium and sodium. Because of his complex imbalances, he is a candidate for admission to the hospital. He will need careful rehydration and monitoring of his electrolytes. The remaining family members are likely to be experiencing sodium, potassium, and fluid deficits.

Think Like a Nurse 38-4

Martha LaGuardia is taking the following medications: atenolol (Tenormin) 50 mg daily at bedtime, alendronate sodium (Fosamax) 10 mg daily, furosemide (Lasix) 20 mg every morning, and calcium carbonate 500 mg three times per day. She takes her medications regularly and sees her primary care provider monthly. Using your reference books, look up her prescribed medications. Given that Ms. LaGuardia is now experiencing nausea and vomiting, she may be at risk for developing problems and side effects related to her medications. Which medications may cause problems and what problems might they cause? Explain your rationale.

Acid–Base Imbalances

The two broad types of acid–base imbalance are acidosis and alkalosis. **Acidosis** occurs when the serum pH falls below 7.35. **Alkalosis** occurs when the serum pH increases above 7.45 (Fig. 38-6). Arterial blood gases (ABGs) are used to monitor acid–base balance. **ABG analysis** measures pH, partial pressure of oxygen (Po_2), partial pressure of carbon dioxide (Pco_2), saturation of oxygen (Sao_2), and bicarbonate (HCO_3^-) level. Acid–base balance is reflected by the pH, Pco_2, and HCO_3 values.

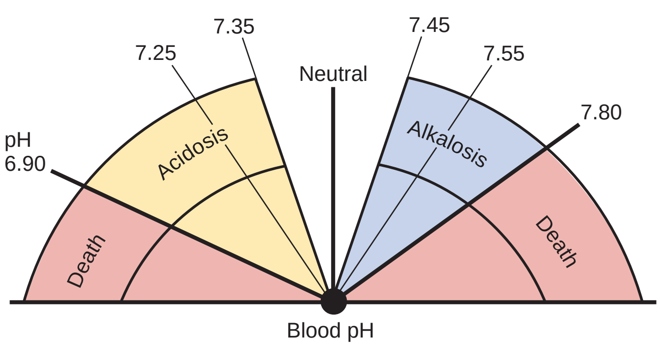

FIGURE 38-6 The pH scale ranges from 1 to 14. Normal blood pH is 7.35 to 7.45.

A respiratory disturbance alters the carbonic acid portion of the buffering system, and the resulting imbalance is labeled **respiratory acidosis** or **respiratory alkalosis**. A metabolic disturbance alters the bicarbonate portion of the buffering system, so the resulting imbalance would be labeled as **metabolic acidosis** or **metabolic alkalosis**. Metabolic and respiratory problems can coexist, resulting in disturbances of both sides of the buffering system. Compensatory mechanisms may also produce both bicarbonate and carbon dioxide abnormalities.

Interpreting ABGs

To determine acid–base balance, you must examine the ABG results. The pH, Pco_2, and HCO_3^- values are of primary importance (Table 38-6). The partial pressure of oxygen (Po_2) and saturation of oxygen (Sao_2) are also part of the ABG result, but they do not affect acid–base balance. Instead, they affect tissue oxygenation. For further discussion on those two measures, see Chapter 36. Table 38-7 describes the causes, manifestations, ABG results, and treatments of acid–base imbalances. Use the following steps to interpret acid–base balance of blood.

Step 1: Examine the pH. ***Is it acidotic, alkalotic, or normal?***

- If the pH is low (<7.35), then the blood is *acidic*.
- If the pH is high (>7.45), then it is *alkalotic*.
- If the pH is between 7.35 and 7.45, then it is *normal*

Key Point: ***Don't forget that the neutral pH is 7.4, which will be very important when we discuss compensation.***

Step 2: Check the amount of carbon dioxide in the blood (Pco_2). ***Is there too little or too much?***

- If Pco_2 is <35 mm Hg, that means there is too little acid in the blood (respiratory alkalosis).
- If Pco_2 is >45 mm Hg, then there too much acid in the blood (respiratory acidosis).
- If Pco_2 is 35 to 45 mm Hg, then the cause for the abnormal pH is not respiratory.

Step 3: Think about the bicarbonate level (HCO_3). ***Is there too little or too much?***

- If HCO_3 is <22 mEq/L, that means there is too little base in the blood (metabolic acidosis).
- If HCO_3 is >26 mEq/L, then there too much base in the blood (metabolic alkalosis).
- If HCO_3 is 22 to 26 mEq/L, then the cause for the abnormal pH is not metabolic.

Table 38-6 ➤ Using ABGs To Assess Acid–Base Balance

EXPLANATION OF CHANGES	ABG COMPONENT	NORMAL RANGE	ACIDOSIS	ALKALOSIS
Indicates acidosis, alkalosis, or normal acid–base balance	pH	7.35–7.45 (7.4 is "neutral")	Low	High
Carbon dioxide ("acid"). Signals respiratory cause	PCO_2	35–45 mm Hg	High	Low
Sodium bicarbonate ("base"). Signals metabolic cause	HCO_3^-	22–26 mEq/L	Low	High

Table 38-7 ➤ Acid–Base Imbalances

DISORDER	CLINICAL MANIFESTATIONS	INTERVENTIONS
Respiratory Acidosis May be caused by conditions or medications that impair gas exchange at the alveolar–capillary membrane, depressed respiratory rate and depth, or injury to the respiratory center in the brain.	***Acute:*** Increased pulse and respiratory rate Headache, dizziness Confusion, decreased level of consciousness (LOC) Muscle twitching ***Chronic:*** Weakness Headache	Provide pulmonary hygiene. Institute measures to improve gas exchange, such as chest physiotherapy, bronchodilators, antibiotics possible. Provide supplemental oxygen. Maintain hydration.
Respiratory Alkalosis May be caused by hyperventilation resulting from anxiety, fever, sepsis, thyrotoxicosis, lesion in the respiratory center in the brain, or excessive ventilation with a mechanical ventilator.	Confusion, difficulty focusing Headache Tingling Palpitations Tremors	If caused by anxiety, encourage the patient to relax and breathe slowly. For other causes: Identify and treat the underlying disorder.
Metabolic Acidosis May be caused by retained acids in the blood resulting from renal impairment, poorly controlled diabetes mellitus, or starvation. Conditions that decrease bicarbonate, such as excessive GI loss, will also trigger metabolic acidosis. May be caused by excessive intake of acids, which may occur with aspirin poisoning, or by prolonged infusion of chloride-containing IV fluids.	Headache Confusion, drowsiness Weakness Peripheral vasodilatation Nausea and vomiting Kussmaul's breathing (rapid and deep) Frequently associated with hyperkalemia	Treatment is directed at correcting the underlying problem. Bicarbonate may be ordered.
Metabolic Alkalosis May be caused by excessive acid loss due to vomiting or gastric suction, use of potassium-wasting diuretics, hypokalemia, excess bicarbonate intake, or hyperaldosteronism.	Dizziness Tingling of extremities Hypertonic muscles Decreased respiratory rate and depth	Treatment is directed at correcting the underlying problem. Treatment often includes administration of NaCl-rich fluids.

UNCOMPENSATED ABG	pH	$PaCO_2$	HCO_3
Respiratory Acidosis	↓	↑	normal
Respiratory Alkalosis	↑	↓	normal
Metabolic Acidosis	↓	normal	↓
Metabolic Alkalosis	↑	normal	↑

Step 4: Is there compensation? ***If so, is it partially or fully?***

Now let's look at what happens when the acid–base imbalance continues for a period of time.

Key Point: ***The body will naturally try to correct the unhealthy situation by using the lungs and kidneys to buffer the abnormality and return the pH into a normal range. If breathing is the reason for the abnormal pH, then the kidneys will pick up the slack and try to improve the situation. But if the problem is metabolic, then breathing (either faster and deeper or slower and more shallow) is the answer.***

- **No compensation.** If the pH is abnormal, no compensation has occurred. The following example shows low pH levels and high levels of carbon dioxide. This is respiratory acidosis with no compensation.

  pH = 7.30, $P\text{CO}_2$ = 50 mm Hg, HCO_3^- = 24 mEq/L

- **Partial compensation.** Again, the pH will be abnormal unless it is fully compensated. If the *pH and one ABG component are abnormal*, with the second ABG value starting to change and the pH beginning to move toward normal, partial compensation is taking place. Compare the uncompensated blood gas (above) with the partially compensated blood gas below. Although below, the pH is increasing, it is still acidotic, while the $P\text{CO}_2$ remains high. Note that the HCO_3 is increasing to alkalosis to bring the pH closer to normal. This is partially compensated respiratory acidosis. In this same respiratory acidosis example the pH and $P\text{CO}_2$ are still abnormal in the ABG below. However, the HCO_3 has also become abnormal (high) and is pulling the pH toward normal. This example is *partially compensated respiratory acidosis.*

  pH = 7.32, $P\text{CO}_2$ = 50 mm Hg, HCO_3^- = 28 mEq/L

PARTIAL COMPENSATION	pH	$Paco_2$	HCO_3
Respiratory Acidosis	↓	↑	↑
Respiratory Alkalosis	↑	↓	↓
Metabolic Acidosis	↓	↓	↓
Metabolic Alkalosis	↑	↑	↑

- **Full compensation.** Full compensation occurs when the *pH returns to normal range* and both other ABG components are abnormal. The initial causal component is still abnormal, and the second ABG component (that had the normal values) has changed enough to return the pH to normal. Note in the blood gas below, the pH is now in the normal range and the $P\text{CO}_2$ is still high. But the HCO_3 is now also high; it has moved enough to raise the pH into the normal range. The problem is now *fully compensated respiratory acidosis.*

  pH = 7.35, $P\text{CO}_2$ = 50 mm Hg, HCO_3^- = 30 mEq/L

FULL COMPENSATION	pH	$PaCO_2$	HCO_3
Respiratory Acidosis	Normal, but <7.35	↑	↑
Respiratory Alkalosis	Normal, but >7.35	↓	↓
Metabolic Acidosis	Normal, but <7.35	↓	↓
Metabolic Alkalosis	Normal, but >7.35	↑	↑

KnowledgeCheck 38-6

Interpret the following ABG results:

pH = 7.53 $P\text{CO}_2$ = 26 mm Hg HCO_3^- = 22 mEq/L
pH = 7.40 $P\text{CO}_2$ = 39 mm Hg HCO_3^- = 25 mEq/L
pH = 7.30 $P\text{CO}_2$ = 70 mm Hg HCO_3^- = 30 mEq/L
pH = 7.48 $P\text{CO}_2$ = 46 mm Hg HCO_3^- = 30 mEq/L

PracticalKnowledge knowing how

In the remainder of this chapter, you will learn to apply theoretical knowledge of fluids, electrolytes, and acid–base balance to patient care.

ASSESSMENT

The purposes of a focused assessment of fluids, electrolytes, and acid–base status are to identify clients at risk for or already experiencing imbalances, to identify the nature of the disorder, and to evaluate responses to treatments.

Assessing for Example Problem: Fluids, Electrolytes, and Acid–Base Imbalances

Assessment for fluid, electrolyte, and acid–base imbalances includes collecting a focused nursing history, performing a physical assessment, and reviewing pertinent

PICOT

Early Treatment of Metabolic Acidosis

Situation: Several family members are being seen in the emergency department for suspected food poisoning. The grandfather, who has chronic kidney disease (CKD), is diagnosed with metabolic acidosis and admitted for treatment. The nurse wonders about the rationale for the treatments the patient receives.

PICOT Components:

P	Population/client	=	Patients with CKD
I	Intervention/indicator	=	Early metabolic acidosis treatment
C	Comparator/control	=	Late or no treatment for metabolic acidosis
O	Outcome	=	Reduced muscle wasting
T	Time	=	The course of the disease

Searchable Question: Do _________(P) who receive/are exposed to __________(I), as compared to __________(C), demonstrate __________(O) during __________(T)?

Example of Evidence: The kidneys regulate fluid, electrolyte, and acid–base homeostasis. When these balances are altered, a client with CKD commonly develops chronic metabolic acidosis. This can lead to acceleration of the CKD, muscle wasting, development of bone disease, resistance to insulin, and increased mortality. Metabolic acidosis can be treated early in renal disease, with oral medications or the addition of bases to dialysate. This helps maintain a normal plasma bicarbonate level and prevent chronic CKD.

Practice Change: The nurse acquired new knowledge of the importance of early treatment of CKD and its potential for preventing muscle wasting and other CKD complications.

Source: Kraut, J., & Madias, N. (2011). Consequences and therapy of the metabolic acidosis of chronic kidney disease. *Pediatric Nephrology, 26*(1), 19–28.

laboratory tests. The purpose of the focused assessment is to identify clients at risk for or already experiencing imbalances, to identify the nature of the disorder, and to evaluate responses to treatments.

Focused Nursing History

A focused nursing history for fluids, electrolytes, and acid–base balance includes questions about demographic data, past medical history, current health concerns, food and fluid intake, fluid elimination, medications, and lifestyle. For questions to use in obtaining this focused nursing history,

Go to Chapter 38, **Assessment Guidelines and Tools, Focused Assessment for Fluid, Electrolyte, and Acid–Base Balance, Nursing History,** in Volume 2.

Focused Physical Assessment

Correlate physical assessment data with the nursing history and laboratory studies. You will need to assess the following:

- *Skin*. Assess for color, temperature, moisture content, continuity, turgor, and edema. To describe edema, see Chapter 22, Procedure 22-2, Assessing the Skin.
- *Mucous membranes.* Inspect the tongue and buccal mucosa; assess the color, moisture, and continuity of the mucous membranes. Also assess tongue turgor in all age groups, since it is not affected by age.
- *Cardiovascular system*. Pulse and blood pressure are affected by fluid and electrolyte status. Also assess for orthostatic hypotension, capillary refill, jugular venous distension, and peripheral edema.
- *Respiratory system*. Assess respiratory rate, depth, and pattern, and breath sounds.
- *Neurological system.* As described in Tables 38-5 and 38-7, neurological status (e.g., level of consciousness) provides cues to fluid, electrolyte, and acid–base imbalance.

In addition to the above assessments, you will track vital sign changes, monitor daily weights, and record intake and output. These are independent nursing assessments. They do not require a medical prescription. You may delegate these tasks to assistive personnel, but you remain responsible for evaluating the data. For complete guidelines for focused physical assessments and clinical observations,

Go to Chapter 38, **Assessment Guidelines and Tools, Focused Assessment for Fluid, Electrolyte, and Acid–base Balance, Physical Assessments,** in Volume 2.

Vital Signs

All of the vital signs reflect information about fluid, electrolyte, and acid–base balance. These effects are briefly summarized below.

- *Temperature*. An elevated body temperature increases the loss of body fluids. In hypernatremia, body temperature rises because the fluid available for sweating decreases. In uncomplicated fluid volume deficit, body temperature decreases.
- *Pulse*. Tachycardia is an early sign of fluid volume deficit. Dysrhythmias can result from potassium, calcium, and magnesium imbalances. Fluid status directly affects the pulse volume: As fluid volume increases, the pulse volume also increases; similarly, a drop in fluid volume leads to a drop in pulse volume.
- *Respiratory rate*. Alterations in respiratory rate may cause acid–base imbalances or be associated with compensation for a metabolic disorder.
- *Blood pressure*. Blood pressure rises and falls with fluid volume. Postural hypotension occurs with dehydration. Blood pressure is also affected by electrolytes.

High sodium intake is a factor in hypertension, whereas high potassium and magnesium intake may lower blood pressure.

Daily Weights

Monitoring daily weight change is an accurate method of assessing fluid status. Weight changes over time are usually related to diet and exercise. In contrast, short-term changes usually indicate changes in fluid status. Each kilogram (2.2 lb) of weight is equivalent to 1 liter (1,000 mL) of fluid. Thus, in a client with diarrhea, a sudden drop in weight of 5 pounds is equivalent to a fluid loss of almost 2,300 mL.

Key Point: ***For weight to accurately reflect fluid status, you must use the same balanced scale each time. Weigh the client at the same time each day, making sure that he is wearing the same amount of clothing.***

Clients undergoing hemodialysis (blood cleansing through an artificial kidney) are usually weighed before and after dialysis treatments. Many lose 3 to 4 kg (6.6 to 8.8 lb) over the course of several hours of dialysis. As a result, hypotension, tachycardia, and feelings of lightheadedness are common after a dialysis treatment.

Weight monitoring is especially valuable data when it is impractical or impossible to measure intake and output. For example, it is not easy to know for sure how much fluid a breastfed infant receives with each feeding nor how much fluid is lost in urine and stools. Incontinence, draining wounds, and limited resources may also make it difficult to monitor intake and output. Weight monitoring is a practical solution that may be initiated as a nursing order.

Fluid Intake and Output

Intake and output (I&O) are monitored to assess fluid status. I&O are usually tallied at the end of each shift, as well as for each 24-hour period. In intensive care units, I&O are measured at least hourly. To monitor I&O, measure all fluids the client consumes or excretes. You must correlate I&O with daily weights to accurately determine overall fluid status (Ladeserto, Chohan, Kasa, et al., 2009; Shepherd, 2011).

- **Output.** Fluid output includes urine, liquid stools, emesis, gastrointestinal fluids (e.g., from suction devices), and drainage (e.g., from wounds and pressure ulcers). Output also includes insensible losses through perspiration and respiration, but these are not usually measured. For more information about I&O, refer to the section Measuring Intake and Output in Chapter 28. For procedure steps,

Go to Chapter 28, **Procedure 28-1: Measuring Urine,** in Volume 2.

- **Intake.** Measuring fluid intake includes a variety of sources (e.g., oral fluids, semiliquid foods, ice chips, parenteral fluids, enteral feedings, and irrigations instilled and not withdrawn immediately). For more information about measuring intake,

Go to Chapter 38, **Clinical Insight 38-2: Guidelines for Measuring Intake and Output (I&O),** in Volume 2.

Most healthcare facilities have standardized I&O forms for recording at the bedside and as a permanent part of the patient record (either paper or electronic). To see an electronic I&O record, see Figure 18-2 in Chapter 18. For an example of a paper I&O flow sheet,

Go to Chapter 18, **Charting Forms: Intake and Output Sheet,** in Volume 2.

KnowledgeCheck 38-7

- Identify 10 physical assessment components that can be used to monitor fluid, electrolyte, and acid–base balance.
- What aspects should be evaluated in a nursing history focused on fluid, electrolyte, and acid–base balance?

ThinkLike a Nurse 38-5

What vital sign changes would you expect to find when assessing Jackson LaGuardia (Meet Your Patients)?

Laboratory Studies

Several laboratory tests are performed to evaluate fluid, electrolyte, and acid–base status.

Complete Blood Count Fluid status is reflected in a **complete blood count (CBC)**, which is a measure of red blood cells (RBCs), white blood cells (WBCs), and platelets. Included in the CBC is the hematocrit, a measure of the percentage of RBCs in whole blood. As fluid levels decrease, the percentage of blood made up by cells increases, and the hematocrit rises. Conversely, as fluid levels increase, the hematocrit falls.

Serum Electrolytes Venous blood samples are taken commonly to measure sodium, potassium, chloride, and bicarbonate levels. In many labs, a basic metabolic panel also includes calcium, BUN/creatinine ratio and glucose. BUN and creatinine are sensitive measures of fluid status and kidney function. Physical assessment can also reveal hypocalcemia; for information,

Go to **Clinical Insight 38-1: Assessing for Trousseau's and Chvostek's Signs,** in Volume 2.

Serum Osmolality A measure of the solute concentration of the blood is **serum osmolality**. It is expressed as milliosmoles per kilogram (mOsm/kg). Sodium is the greatest determinant of serum osmolality. Glucose and urea also contribute to serum osmolality. Serum osmolality may be directly measured with venous blood or estimated by doubling the serum sodium level. A rise in serum osmolality indicates fluid volume deficit; a decrease indicates fluid volume excess. Changes in serum osmolality usually indicate alterations in sodium levels.

Urine Osmolality The solute concentration of urine is measured by **urine osmolality**. The body excretes nitrogenous wastes as well as electrolytes. As a result, urine osmolality is substantially higher than serum levels. Fluid volume deficit increases urine osmolality; fluid volume excess decreases urine osmolality. This test may call for a 24-hour urine specimen, or for discarding the first morning specimen and collecting a clean-catch specimen 2 hours later.

Urinalysis The routine screening test **urinalysis** includes a measure of urine pH and specific gravity. Urine pH normally ranges from 5.0 to 9.0, with an average of 6.0.

- *pH.* Urine becomes more acidic in respiratory or metabolic acidosis, starvation, or fluid volume deficit. Alkaline urine is associated with an alkaline state in the blood.
- *Specific gravity.* Specific gravity rises and falls in opposition to fluid status. A normal range is 1.001 to 1.029. A low specific gravity occurs when fluid is plentiful. When fluid levels decrease, urine becomes more concentrated, and specific gravity increases. For a procedure for testing specific gravity of urine,

Go to Chapter 28, **Procedure 28-3B: Measuring Specific Gravity of Urine,** in Volume 2.

- ABGs. Interpretation of ABGs was discussed earlier in this chapter. For a list of these values, along with other lab studies discussed earlier,

Go to Chapter 38, **Diagnostic Testing: Assessing Fluid, Electrolyte, and Acid–Base Balance,** in Volume 2.

ANALYSIS/NURSING DIAGNOSIS

Nursing diagnoses directly related to fluid, electrolyte, and acid–base balance include: Deficient Fluid Volume, Excess Fluid Volume, Readiness for Enhanced Fluid Volume, Risk for Deficient Fluid Volume, Risk for Electrolyte Imbalance, Risk for Imbalanced Fluid Volume, and Risk for Vascular Trauma. For other defining characteristics and etiologies of these NANDA International (NANDA-I) diagnoses,

Standardized Language, NANDA-I Diagnoses Related to Fluid, Electrolyte, and Acid–Base Balance, on Davis*Plus*.

Diagnoses for Example Problem: Fluid, Electrolyte, and Acid–Base Imbalances

Impaired Gas Exchange is appropriate for a client with a disorder affecting gas exchange at the alveolar–capillary membrane in the lungs (see Chapter 36). This condition limits the effectiveness of the carbonic acid–bicarbonate buffer system and alters serum pH, predisposing the patient to acid–base imbalances.

Fluid, electrolyte, acid–base imbalances (e.g., dehydration, metabolic acidosis, respiratory alkalosis), and treatment imbalances may be etiologies of other nursing diagnoses. Below are a few examples:

- Activity Intolerance related to excess fluid and electrolyte loss through Diarrhea
- Impaired Oral Mucous Membrane related to Deficient Fluid Volume
- Decreased Cardiac Output related to Hypovolemia
- Risk for Vascular Trauma (from insertion of an IV catheter)

PLANNING OUTCOMES/EVALUATION

The overall goal for a client experiencing fluid, electrolytes, or acid–base imbalance is to restore balance.

Outcomes for Example Problem: Fluids, Electrolytes, and Acid–Base Imbalances

NOC standardized outcomes for describing fluid and electrolyte status include: Electrolyte & Acid/Base Balance, Fluid Balance, Fluid Overload Severity, and Hydration. For selected indicators for these outcomes,

Go to Chapter 38, **Standardized Language, Selected NOC Outcomes and NIC Interventions for Fluid and Electrolyte Problems,** on Davis*Plus*.

Individualized goals/outcome statements you might write for a client include the following examples:

- Maintains fluid balance, as evidenced by balanced 24-hour intake and output; good skin and tongue turgor; blood pressure and heart rate within normal limits; and no adventitious breath sounds.
- Electrolyte balance restored, as evidenced by alertness and cognitive orientation and no muscle cramping, seizures, or electrocardiogram changes.
- Drinks at least 2,500 mL in 24 hours.
- Urine specific gravity within normal limits.

PLANNING INTERVENTIONS/IMPLEMENTATION

The following sections describe nursing interventions and activities for preventing and treating fluid, electrolyte, and acid–base problems.

Interventions for Example Problem: Fluid, Electrolyte, and Acid–Base Imbalances

NIC standardized interventions related to fluid, electrolyte, and acid–base balance include Acid–Base Management, Electrolyte Management, and Fluid Management. For a listing of other interventions, Go to Chapter 38, **Standardized Language, Selected NOC Outcomes and NIC Interventions for Fluid and Electrolyte Problems,** on Davis*Plus*.

Individualized interventions are aimed at correcting the underlying disorder that led to imbalance. Nursing care focuses on preventing imbalances, modifying oral intake, providing parenteral fluids, and transfusing blood products, all of which are discussed in the rest of this chapter.

Preventing Fluid and Electrolyte Imbalances

It is better to prevent imbalances than to treat them. Use the data obtained from your assessment to plan how to help your client avoid imbalances. Common strategies are listed in the accompanying Self-Care box Teaching Patients to Prevent Fluid and Electrolyte Imbalances.

Dietary Changes

To promote fluid and electrolyte balance, most people need to limit their sodium intake and increase their intake of dietary potassium and calcium. Some may need oral electrolytes supplements as well (see the Self-Care box Taking Oral Electrolyte Supplements). As previously discussed, most North Americans consume more sodium than they should and not enough potassium and calcium. Teach clients to eat foods rich in potassium and calcium every day and to avoid sodium-rich foods (e.g., processed foods) (see Chapter 27 to review foods, as needed). For example, instruct clients to read food labels, particularly when trying to limit sodium intake.

Self-Care

Teaching Patients to Prevent Fluid and Electrolyte Imbalances

- Teach the client about usual fluid needs and circumstances that increase fluid needs, such as high environmental temperature, fever, gastrointestinal (GI) fluid loss, or draining wounds. Base your teaching on the client's current intake and the changes required to meet fluid goals.
- Identify medications or conditions that place the client at risk for imbalances. For example, if the client is receiving a potassium-wasting diuretic, she will need to increase potassium intake, either by taking a supplement or by altering the diet.

Also teach clients to do the following:

- Drink at least eight to ten 8-ounce glasses of water per day unless your healthcare provider has told you to limit fluids.
- Healthy adults use thirst as a guide to fluid intake. However, adults older than age 50 may have diminished thirst sensation and cannot depend solely on thirst for fluid replacement.
- Colorless urine is also a guide to adequate hydration, whereas darker urine is associated with dehydration. You can also use a urine color chart to monitor hydration.
- Limit consumption of fluids high in salt, sugar, caffeine, or alcohol.
- Vigorous exercise may delay the thirst mechanism. Athletes should become accustomed to consuming fluids at regular intervals during training sessions and competition so that they do not experience dehydration.
- Drink water before, during, and after strenuous exercise.
- Avoid routine use of laxatives, antacids, weight-loss products, or enemas. These products may cause imbalances of fluids and electrolytes such as sodium and potassium.
- Weigh yourself daily if fluid balance is critical or if you are experiencing excessive loss or gain.
- Contact a health professional if there is a sudden change of weight, decreased urine output, swelling in dependent areas (e.g., hands and feet), shortness of breath, or dizziness.
- Contact a healthcare provider if you experience prolonged vomiting, diarrhea, or inability to tolerate liquids or food.
- Eat a well-balanced diet, including dairy products rich in calcium.

Self-Care

Taking Oral Electrolyte Supplements

- Encourage clients to take potassium supplements with juice to mask the taste.
- Teach clients to take supplements as prescribed to maintain electrolyte balance.
- Remind clients that supplements are medications and should be viewed as part of the treatment plan.
- If the client's medications are altered, review the continued need for supplements.
- Caution clients that salt substitutes contain potassium. If the client has been advised to use salt substitutes, evaluate the need for potassium supplements.
- Encourage clients who take calcium supplements to consume at least 2,500 mL of fluid per day to avoid constipation and reduce the risk of kidney stone formation.

Oral Electrolyte Supplements

Many clients are unable to correct electrolyte disturbances with dietary changes alone. This is especially true for clients who have food intolerances, who rely on prepared meals, or who live in group settings. Such clients may need oral supplements to meet their dietary requirements. Potassium and calcium are among the most common supplements.

Most adults, especially older adults, consume less dietary calcium per day than the 1,200 mg recommended amount. This further increases their risk for osteoporosis and fractures.

Calcium supplements come in many forms, including tablet, liquid, and chewable form. Potassium supplements are available in pill and liquid form. Many have an unpleasant taste. See the Self-Care box Taking Oral Electrolyte Supplements for suggested nursing activities to help improve your client's compliance.

KnowledgeCheck 38-8

- Identify laboratory tests that monitor fluid, electrolyte, and acid–base balance.
- Give at least five strategies to prevent fluid and electrolyte imbalance.

Modifying Oral Fluid Intake

Clients experiencing fluid imbalances may need to restrict or increase their daily oral intake to correct the underlying disorder.

Facilitating Fluid Intake

Clients with actual or potential fluid volume deficit may need to increase their fluid intake. Whenever possible, clients should take fluids by mouth. You may provide replacement through a nasogastric or feeding tube if the client is unable to meet his needs independently, but can tolerate fluids in the gastrointestinal tract. Parenteral fluid replacement is used only when enteral replacement cannot meet the client's fluid needs (for review, see Chapter 27).

To increase fluid intake successfully, you must first establish the desired amount of fluid intake for the client. The daily fluid goal reflects the client's current fluid balance and underlying condition. For example, if a client is dehydrated, an order might read: "Force fluids: 2,500 mL oral fluids per 24 hours." You can develop a plan to increase fluids from this order. Typically people drink more fluid during the day and early evening, when they are more likely to be active. A large volume of fluid late in the evening may interrupt sleep because it may prompt the need to urinate. Therefore, you should distribute fluids to reflect the time of day, for example:

0700 to 1500—1,300 mL
1500 to 2300—1,000 mL
2300 to 0700—200 mL

Strategies to increase fluid intake include the following:

- Assess the client's fluid preferences.
- Offer a variety of fluids throughout the day on a regular schedule. Vary hot and cold liquids, and offer a choice of juices and other drinks.
- Instruct nursing assistive personnel to make "fluids rounds" to offer and help with oral fluids.
- Each time you are at the bedside, remind the patient to drink.
- Break daily goals into hourly amounts. For example, in the preceding example, in the 8 hours between 0700 and 1500 have the patient drink 150 mL of fluid every hour. Give him a written schedule.
- Provide a glass or cup with milliliter markings on it so that the patient will know how much he is drinking.
- Always have fluid readily available to the patient. For example, keep a pitcher of water at the bedside.
- When possible, have the patient and family members participate in offering fluids and tracking fluid intake.
- Schedule diagnostic and surgical procedures to minimize the length of time the patient must be NPO.
- For ambulatory patients (e.g., residents in long-term care facilities) schedule "tea time" or "happy hour" to promote increased intake.

Facilitating Fluid Restriction

Patients may need to limit fluids for a variety of reasons (e.g., cardiovascular, liver, or renal impairment). To facilitate fluid restrictions effectively, teach patients and caregivers the reason for the restriction and the amount of fluid allowed. Typically, fluid volume is divided into amounts allotted per shift. However, fluid restrictions usually include *all* forms of intake, not only oral. For example, a prescription might read: "Limit total fluid intake to 1,500 mL per 24 hours." If the patient is receiving IV antibiotics four times per day, you must include that volume as a part of the total fluids. If 75 mL is infused with each administration, total IV fluids equal 300 mL. So, the oral intake must be limited to 1,200 mL per day. This amount may be distributed as 700 mL on the day shift, 400 mL on the evening shift, and 100 mL at night. Strategies to restrict fluid intake include the following:

- Do not offer liquids with meals. Reserve liquids for between meals.
- Limit intake of foods that increase thirst (e.g., dry, salty, or spicy foods).
- Offer ice chips to help quench thirst.
- Provide frequent oral hygiene.
- Keep liquids away from the bedside.
- Provide diversional activities for the patient.

Parenteral Replacement of Fluids and Electrolytes

When fluid loss is severe or the client cannot tolerate oral or tube feedings, fluid volume is replaced parenterally. The word *parenteral* refers to any route other than through the alimentary canal (passage from the mouth to the anus). **Intravenous (IV) therapy** is the administration of fluids, electrolytes, medications, or nutrients by the venous route. IV fluids are used to:

- Expand intravascular volume.
- Correct an underlying imbalance in fluids or electrolytes.
- Compensate for an ongoing problem that is affecting either fluid or electrolytes.

For instance, Martha LaGuardia (Meet Your Patients) is being treated in the emergency department (ED) for gastroenteritis. She is experiencing fluid loss from vomiting and diarrhea, complicated by her use of a diuretic. IV therapy will allow her to receive fluid to expand her intravascular volume and to maintain her hydration until the vomiting and diarrhea subside. It will also provide electrolyte replacement based on her laboratory results. Mrs. LaGuardia will continue to receive IV fluids until she can meet her fluid and electrolyte needs orally. All of the members of the LaGuardia family are experiencing fluid losses and would benefit from increasing their fluid intake. When fluid balance is fragile, or when the client cannot tolerate oral fluids, replacement may be supervised in an inpatient setting.

When initiating and maintaining intravenous infusions, always use careful aseptic technique. Remember that the IV catheter provides a portal of entry for pathogens directly into the bloodstream. You should know that Medicare will not reimburse a hospital for the expenses (e.g., antibiotics, extra hospital days) caused by catheter-related infections that occur during hospitalization. Excellent nursing technique can reduce IV catheter-associated infections.

Types of Intravenous Solutions

Solutions, including IV fluids, are classified according to how they compare to the osmolality of blood serum: IV fluids are classified as isotonic, hypotonic, and hypertonic solutions (Crawford & Harris, 2011b). To help you remember, here is a somewhat oversimplified summary. When infused:

- *Isotonic* fluids remain *in* the intravascular compartment.
- *Hypotonic* fluids pull body water *out* of the intravascular compartment.
- *Hypertonic* fluids pull body water *into* the intravascular compartment.

Isotonic Fluids Normal blood serum osmolality is 275 to 295 mOsm/kg. Isotonic solutions have similar tonicity (250 to 375 mOsm/L). Therefore, when infused, they remain inside the blood vessels. As a result, isotonic fluids are useful for clients with hypotension or hypovolemia. Commonly prescribed isotonic fluids are the following:

- 0.9% sodium chloride (0.9% NaCl), also called *normal saline* (*NS*)
- Lactated Ringer's (LR)

The solution, 5% dextrose in water (D_5W) may be classified as both isotonic and hypotonic. It is isotonic in the bag, but is not prescribed for isotonic use because after (rapid) metabolism, it is hypotonic in the body.

Clients who have congestive heart failure (CHF) must be closely monitored when they receive isotonic fluid replacement, because they may easily develop fluid overload.

Hypotonic Fluids The osmolality of a hypotonic solution is less than that of serum (less than 250 mOsm/L). Therefore, when infused, these solutions pull body water from the intravascular compartment into the interstitial fluid compartment. As the interstitial fluid is diluted, its osmolarity decreases, drawing water into the adjacent cells. Hypotonic fluid is used for hyperglycemic conditions, such as diabetic ketoacidosis, in which high serum glucose draws fluid out of the cells and into the vascular and interstitial compartments. Examples of hypotonic fluids include:

- 5% dextrose in water (D_5W). Recall that D_5W is isotonic in the bag, with an osmolality of 253 mOsm/L, but becomes hypotonic in the body.
- 0.45% NaCl (½ normal saline)
- 0.33% NaCl
- 0.2% NaCl

Administer hypotonic fluids carefully to prevent a sudden fluid shift from the intravascular space to the cells. Never give hypotonic solutions to patients at risk for increased intracranial pressure because they can cause or worsen cerebral edema.

Hypertonic Fluids The osmolality of hypertonic fluids is higher than that of serum. When administered, they pull fluids and electrolytes from the intracellular and interstitial compartments into the intravascular compartment. Hypertonic fluids can help stabilize blood pressure, increase urine output, and reduce edema. Volume expanders (e.g., dextran and serum albumin) are hypertonic, and used to increase blood volume following severe loss of blood or plasma, such as in major burns or hemorrhage. Following are examples of hypertonic fluids:

- D_5 0.9% NaCl (D_5 NS)
- D_5 0.45% NaCl (D_5 ½ NS)
- D_5 lactated Ringer's
- 3% NaCl and 5% NaCl—highly hypertonic; used only in critical situations.
- 10% dextrose in water ($D_{10}W$)
- $D_{20}W$—used as an osmotic diuretic to promote diuresis

For more information about these types of IV solutions,

Go to Chapter 38, **Supplemental Materials: Types of IV Fluids,** on Davis*Plus*.

Peripheral Vascular Access Devices

Intravenous therapy requires placement of a vascular access device (VAD). You will choose the type of device on the basis of the client's condition, type of fluid that will be infused, and the anticipated length of treatment.

Key Point: ***IV catheters (and needles) are sized by their diameter, which is called the* gauge*. The smaller the diameter is, the larger the gauge will be (e.g., a 16-gauge catheter is larger than a 21-gauge catheter).***

Therefore, the smaller the gauge, the more rapidly fluid can be delivered. Various types of catheters are used to access peripheral veins, including the following:

Over-the-Needle Catheters These are also called **angiocaths**, short for angiocatheter (Fig. 38-7A). A polyurethane or Teflon catheter is threaded over a metal stylet (needle). You pierce the skin and vein with the needle, advance the catheter into the vein, and remove (or retract) the metal needle. In most cases, the plastic catheter is less than 7.5 cm (3 in.) in length. This type of access device is ideal for brief therapy. However, you cannot give highly irritating or hyperosmolar solutions through this type of catheter because it may cause severe damage to the vein. For an animated illustration of an over-the-needle IV catheter,

Go to **Animations: Insertion of an Over-the-Needle IV Catheter,** on Davis*Plus*.

Inside-the-Needle Catheters This type of catheter is similar to the over-the-needle catheter; however, the polyurethane or Teflon catheter lies inside the metal needle (Fig. 38-7B). After you advance the catheter into the vein, you withdraw the needle.

Butterfly Needle Also called a *scalp vein needle* or *wing-tipped catheter*, a **butterfly needle** is a short, beveled metal needle with flexible plastic flaps attached to the shaft (Fig. 38-8). You can pinch the flaps and hold them tightly together to facilitate insertion. After insertion, flatten them out and tape them against the skin to prevent dislodgement during the infusion process. These needles are commonly used for intermittent or short-term therapy for children and infants or for single-dose medications and drawing blood. Because the inflexible metal needle remains in the vein, a butterfly needle is more likely to **infiltrate** (damage the vein and allow fluid to leak into the interstitial spaces) than a flexible plastic catheter.

Midline Peripheral Catheter A **midline peripheral catheter** (midline VAD) is a peripherally inserted flexible IV catheter typically inserted into the antecubital fossa and then advanced into the larger vessels of the upper arm for greater hemodilution. It is 15 cm (6 in.) long, so it can be used for a longer period of time than a shorter, over-the-needle catheter—typically 1 to 4 weeks. A midline peripheral catheter should be changed only when there is a specific indicator (CDC, 2011a) (e.g., swelling, pain). A midline catheter is still considered a peripheral line, so you cannot administer highly osmolar and irritating solutions through it.

It is essential to distinguish a midline VAD from a peripherally placed central line (PICC). Because visual identification is not sufficient for identification, the type of VAD must be marked on the dressing label. If you are uncertain about the catheter type, consult the patient's health record.

In response to the Needlestick Safety and Prevention Act passed by Congress in 2000, the Occupational Safety and Health Administration (OSHA) requires the use of "needleless" systems (OSHA, 2011). Therefore, you will usually have available access devices with safety features to prevent accidental "sticks." But if you find you must use an older, nonsafety device, do not attempt to recap the needle after removing it from the vein.

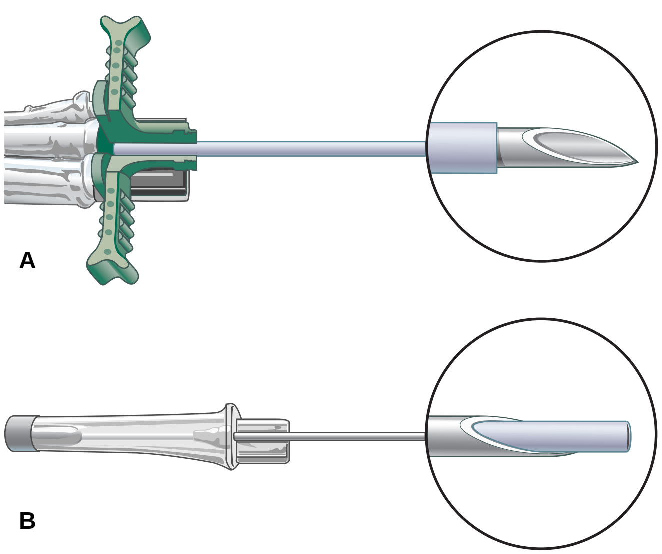

FIGURE 38-7 Typical IV access devices. *A*, An over-the-needle catheter. *B*, An inside-the-needle catheter.

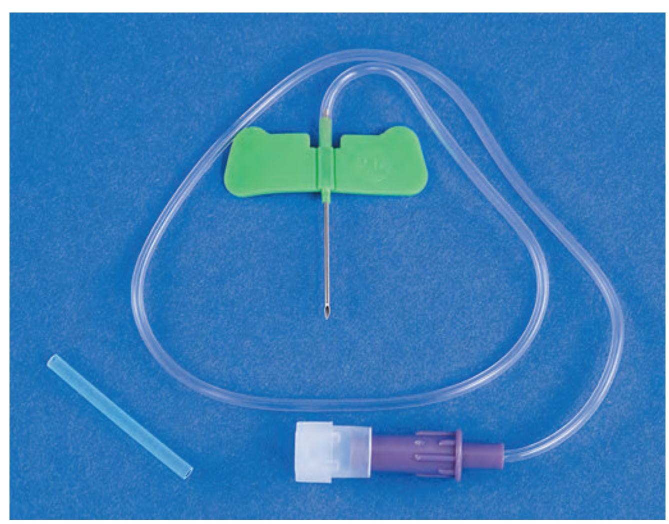

FIGURE 38-8 The butterfly, or scalp vein, needle is commonly used for intermittent or short-term therapy for children and infants.

Peripheral Intravenous Lock

A **peripheral intravenous lock** (also called a saline lock, a prn adapter, and sometimes a heparin lock) establishes a venous route as a precautionary measure for clients whose condition may change rapidly or who may require intermittent infusion therapy. A peripheral IV catheter or butterfly wing–tipped catheter is inserted into a vein, and cap the hub with a lock port (Fig. 38-9). Patency of the lock is maintained by injecting normal saline or a dilute heparin solution, depending on agency policy.

Central Venous Access Devices

A **central venous access device (CVAD)** is an intravenous line inserted into a major vein. Typically, the subclavian or internal jugular vein is used. Using surgical asepsis, a catheter is advanced from the insertion site into the superior vena cava. CVADs are used to administer large volumes of fluid or highly irritating medications, when peripheral sites are unavailable, for monitoring central venous pressure, and for frequent blood draws. You will likely care for patients with central lines, and you may need to assist with inserting them. To learn how to care for patients with central lines, see the Highlights of Procedures box for a summary, and

Go to Chapter 38, **Clinical Insight 38-4: Caring for Patients With a Central Venous Access Device, Procedure 38-5B: Central Line Dressings,** and **Procedure 38-9: Assisting With Percutaneous Central Venous Catheter Placement,** in Volume 2.

Advantages of Central Lines A central line offers several advantages:

- A central vein can accommodate highly irritating and hyperosmolar solutions because the blood and solution mix rapidly at the infusion site.
- Central veins are accessible even if the patient is experiencing severe fluid depletion.
- Some types of central lines may also be used to monitor central venous pressure.
- Central lines can be left in longer than peripheral IVs, ranging from a week to long term, depending on the type of central line used.
- Nutrition can be given parenterally.
- Phlebitis, extravasation, and infiltration are less likely to occur with central lines.
- Central lines with extra ports allow you to withdraw blood from a port to use for laboratory tests.

FIGURE 38-9 A peripheral intravenous lock establishes a venous route as a precautionary measure for clients whose condition may change rapidly or who may require intermittent infusion therapy.

Disadvantages of Central Lines Drawbacks to central lines include:

- Practitioners must have specialized training to insert the catheter.
- You must obtain patient consent.
- Placement must be confirmed by radiography.
- Placement is treated as a minor surgical procedure, requiring strict sterility.
- Dressing changes require strict sterile technique.
- When placed via the neck, especially though the subclavian vein, there is a risk of pneumothorax.
- There is a risk that the catheter will float into the right side of the heart, where it may cause ventricular dysrhythmias.
- There is a greater risk of air embolus and infection when compared to peripheral IVs.
- Associated costs are greater than with peripheral lines.
- The risk for sepsis is much higher than for peripheral sites. CVCs account for about 90% of catheter-related bloodstream infections.

Preventing Central Line–Associated Bloodstream Infections This is one of The Joint Commission's national patient safety goals for 2013, and is likely to be a continuing goal.

Key Point: ***To help prevent CVC catheter-related infections, The Joint Commission recommends the following set of measures:***

- **Education and training**—regarding proper infection control measures to prevent intravascular catheter-related infections. Encourage patients to report any changes or new discomfort in their catheter site.
- **Hand hygiene**—Wearing gloves does not make hand-washing unnecessary.
- **Maximal barrier precautions for insertion**—Includes sterile drape for patient, hat, mask, and sterile gown and gloves.
- **Chlorhexidine skin antisepsis**—Use 2% chlorhexidine gluconate in 70% isopropyl alcohol to prep the insertion site.
- **Optimal catheter site selection**—The subclavian vein has the lowest rate of infection. The femoral vein should be avoided if possible.
- **Type of catheter**—To reduce the risk of catheter-related infection, the catheter with the fewest number of ports or lumens needed to manage the patient is best.

- **Daily review of lines**—The CVC should be removed as soon as it is no longer necessary. Risk of infection is closely related to the length of time the CVC is in place (Institute for Healthcare Improvement [IHI], 2012; O'Grady, Alexander, Burns, et al., 2011)

Types of Central Venous Catheters

There are four types of CVADs: peripherally inserted central catheters, nontunneled CVCs, tunneled CVCs, and implanted ports.

Peripherally Inserted Central Catheters (PICC lines)

PICCs are long, soft, flexible catheters inserted at the antecubital fossa through the basilic or cephalic vein of the arm. The catheter is then advanced into the superior vena cava (Fig. 38-10). A physician or specially trained registered nurse performs the insertion. PICC lines are most commonly used for prolonged IV antibiotic therapy, parenteral nutrition, and chemotherapy. A PICC line is intended for intermediate to long-term use and does not need to be replaced unless the site appears infected or the catheter is no longer patent.

Nontunneled Central Venous Catheters

Nontunneled CVCs are inserted by a physician, specially trained nurse practitioner, or physician assistant through the skin into the jugular, subclavian, and, occasionally, femoral veins. They are sutured in place. Often these are referred to as single-, double-, triple-, or quadruple-lumen catheters, depending on the number of ports in the line (Fig. 38-11). These CVADs are intended for shorter use than a PICC line (less than 6 weeks); however, guidelines advise that nontunneled CVADs not be routinely replaced (CDC, 2011). They can be used to measure central venous pressure (CVP) to obtain information on blood volume. A low reading indicates hypovolemia and a high reading, hypervolemia.

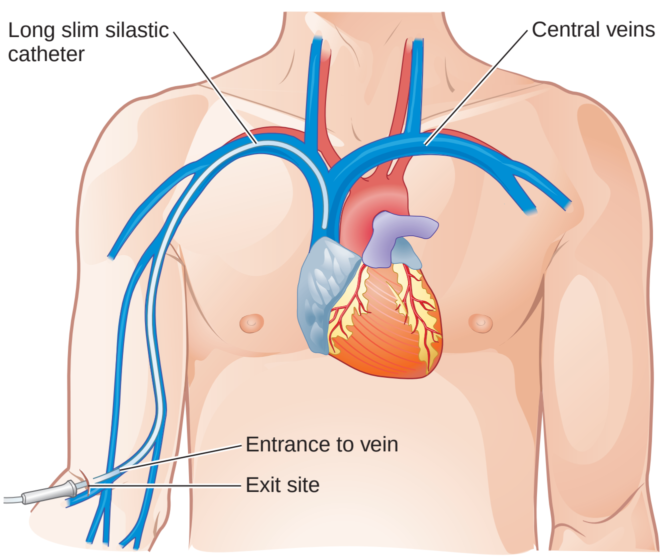

FIGURE 38-10 A PICC line is a long, soft, flexible catheter inserted through a vein in the arm and threaded into a central vessel.

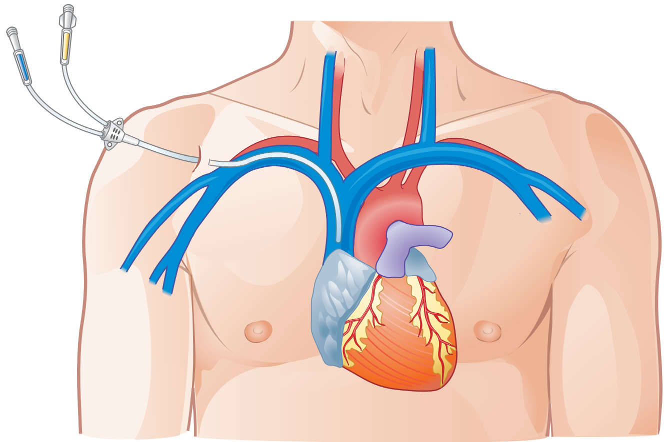

FIGURE 38-11 Nontunneled central venous catheters are inserted into the jugular, subclavian, and, occasionally, femoral veins.

Blood can also be drawn from a nontunneled CVAD for other diagnostic studies. However, if parenteral nutrition or blood is running in a port, you cannot use that same port for blood draws.

Example: Imagine that you have a frail elderly patient who needs two different kinds of IV fluid, parenteral nutrition, and frequent blood draws for lab tests. This patient has fragile peripheral veins and is also at high risk for infection and other complications. With a multiple-lumen central catheter, the patient needs only one insertion site. You can run both fluids and the parenteral nutrition fluids, and still reserve one port for drawing blood. The patient has less risk for the catheter to become dislodged or infiltrate, or for phlebitis to develop.

Tunneled Central Venous Catheters

Tunneled CVCs are intended for long-term use. The catheter is inserted by a surgeon through a 7.5- to 15-cm (3- to 6-in.) subcutaneous tunnel in the chest wall and then into the jugular or subclavian vein (Fig. 38-12). The catheter can be sutured in place, with the sutures removed when fibrosis has developed around the catheter, or it can be secured with an IV securing device. Because CVCs are tunneled through the skin rather than through a vein, the risk of infection is less with their use than it is with PICCs or nontunneled central lines.

Implanted Ports

Implanted ports are devices made of a radiopaque silicone catheter and a plastic or stainless steel injection port with a self-sealing silicone-rubber septum. The catheter enters the internal jugular vein in the neck, and it may be tunneled or untunneled to a completely implanted subcutaneous reservoir (port) in the upper chest (Fig. 38-13). Implanted ports are placed by surgeons and only specially trained nurses are allowed to access an implanted port because of the risk of infiltration into the tissue if the needle placement is not correct. Implanted ports are intended for long-term use.

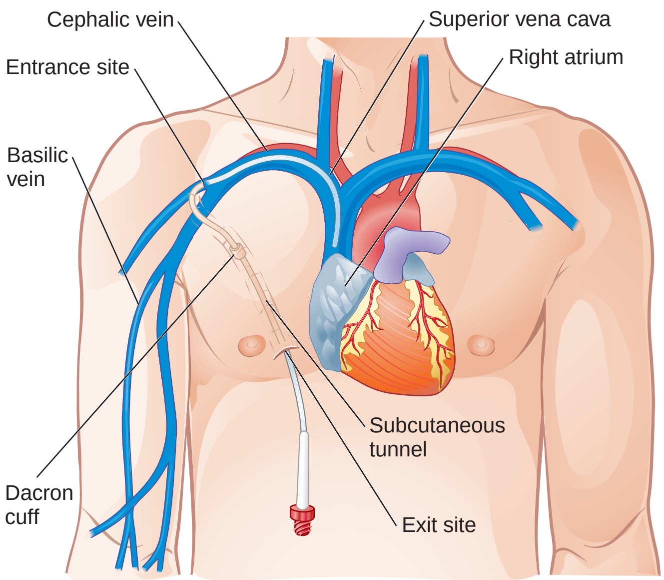

FIGURE 38-12 A tunneled central venous catheter is inserted through subcutaneous tissue in the chest wall into the jugular or subclavian vein.

Avoid taking blood pressures or drawing blood in the extremity on the side of the chest where the implanted port has been placed.

The Highlights of Procedures box summarizes steps. For a procedure, for assisting with placement of a central venous catheter,

Go to Chapter 38, **Procedure 38-9: Assisting With Percutaneous Central Venous Catheter Placement,** in Volume 2.

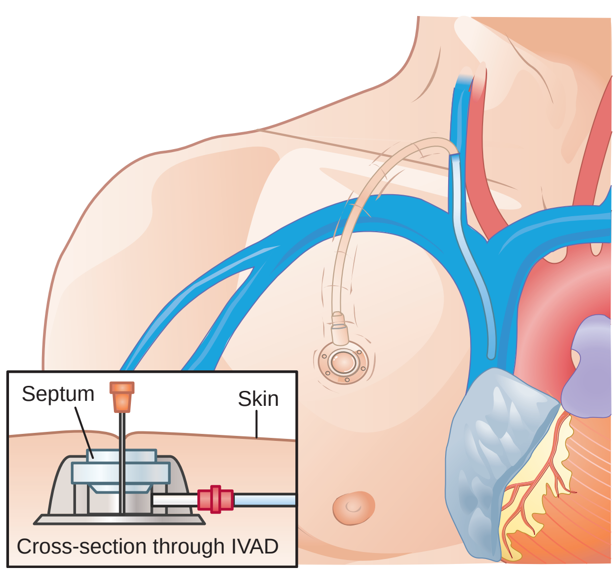

FIGURE 38-13 An implanted venous access port (IVAD) is a CVAD that enters the internal jugular vein in the neck but is tunneled to a completely implanted subcutaneous reservoir (port) in the upper chest.

Intraosseous Devices

Designed for immediate access (within seconds) and short-term use (less than 24 hours), intraosseous (IO) access devices are used to administer fluids when a peripheral catheter cannot be inserted or when a central line insertion is not advisable, but especially in emergency situations. IOs are placed into the matrix of a bone. The venous sinusoids in the matrix can quickly absorb fluids to send to the central circulation. The most common access site is the proximal tibia in both children and adults. The sternum and the head of the humerus can also be used in adults. Osteomyelitis is a rare complication, occurring in fewer than 1% of cases. Contraindications for IO use include obesity, fracture, recent surgery, infection, or evidence of poor circulation at the proposed insertion site.

KnowledgeCheck 38-9

- What is the purpose of intravenous fluids?
- Describe the functions of the three types of IV solutions—isotonic, hypotonic, and hypertonic—and identify two commonly prescribed fluids in each category.
- Under what conditions would a central venous access device be preferable to a peripheral device?

ThinkLike a Nurse 38-6

What type of venous access device would you expect Martha LaGuardia (Meet Your Patients) to receive in the hospital? Why?

Starting an Intravenous Infusion

To start an IV infusion, you will need to gather equipment and supplies, set up the solution and administration set, select a venipuncture site, and perform venipuncture.

Obtain Equipment and Supplies

Venipuncture supplies and IV infusion equipment are sterile, prepackaged, and disposable. They vary based on manufacturers, so familiarize yourself with what is available in your facility. Set up the solution and administration set before performing the venipuncture.

- ***IV Catheter.*** Select the smallest diameter and the shortest length catheter that will accommodate the prescribed therapy. Catheter sizes range from 16- to 24-gauge, depending on patient, type of fluid, and infusion rate. Nurses commonly use a 20- or 22-gauge catheter for adult peripheral infusions. A 20-gauge needle will accommodate adult blood transfusions. You will need the larger 16- or 18-gauge needle for rapid infusions, viscous (thick) fluids, or surgical or trauma patients. The smaller 24-gauge needle is used in geriatric and neonates. The following are infusion rates catheters of different gauges are expected to deliver (Masoorli, 2012):

18 gauge	4,000 mL/hr
20 gauge	3,500 mL/hr
22 gauge	2,000 mL/hr
24 gauge	1,500 mL/hr

- ***Administration Set (Infusion Kit).*** The administration set connects the fluid container to the catheter inserted in the patient. The set consists of tubing with a plastic insertion spike, a drip chamber, a roller clamp to regulate the flow, an injection port, and a catheter adapter (hub) (Fig. 38-14). Both ends of the infusion set (the spike and the hub) are sterile and must remain sterile. You should remove the protective caps just before use and avoid touching the spike and hub when connecting the tubing to the solution container and the IV catheter in the patient's vein.

  The drip chamber is calibrated to allow a predictable amount of fluid to be delivered in each drop. The drop factor is indicated on the package. A roller clamp on the tubing controls the rate of flow.
  - A *macrodrip* delivers 10 to 20 drops per milliliter of solution, depending on the manufacturer; select a macrodrip for most adult infusions.
  - A *microdrip* delivers 60 drops per milliliter; use a microdrip for very slow infusion rates or for infants and children.
- ***Extension Tubing and Filters.*** The end of the IV tubing contains an adapter that attaches to the inserted sterile IV catheter. This should be a locking or screw-on connection, if one is available. You may use extension tubing to lengthen the primary tubing (e.g., for active patients) or to provide additional Y-injection ports for administration of multiple IV solutions or medications.

  Particulate matter may be generated when glass ampules are opened, or from additives or medications that have a tendency to clump. Occasionally, a filter will be used to remove particulate matter from the solution or to filter microorganisms. Some administration sets have built-in filters, or you may attach one to the end of the tubing. The finer the filter size is, the smaller the particles that are removed from the solution. Research on the use of IV filters to reduce the rate of phlebitis and bacteremia is inconclusive and at present, guidelines do not recommend using filters routinely for infection-control purposes (Niel-Neise, Stijnen, & van den Broek, 2010).

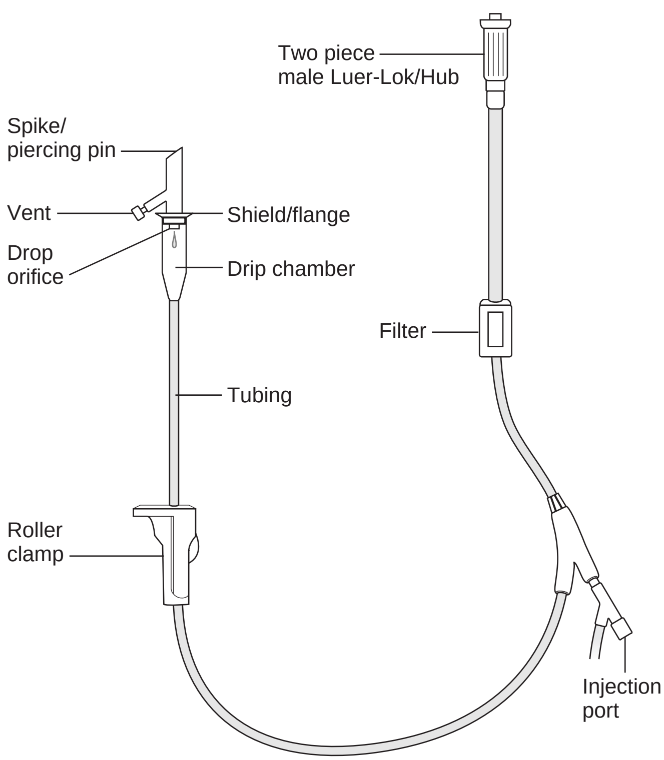

FIGURE 38-14 A basic administration set, or infusion kit.

- ***Injection Port.*** Use the injection port to administer a secondary IV fluid or medication (see Chapter 26).
- ***Solutions***. Inspect the solution container to be certain that it contains the desired fluid, the fluid is clear, the bag is intact, and the solution has not expired. Glass containers were the first containers for IV fluids, but today most IV fluids are packaged in plastic. Fluids for continuous infusions are packed in 1-liter or 500-mL bags. Smaller solution bags (50 mL, 100 mL, and 250 mL) are used for intermittent infusions, such as antibiotics or other medications. Plastic containers collapse as fluid infuses, so you can use a nonvented administration set. Glass bottles do not collapse and therefore require a vented administration set.

Select a Peripheral Intravenous Site

To select a venipuncture site, consider the following factors:

- ***Age.*** For adults, you will usually use veins in the hand or arm (Fig. 38-15); for infants, veins in the scalp or dorsum of the foot.
- ***Type of solution.*** For hypertonic solutions, viscous solutions, or irritating medications, use a large vein to cause the least amount of trauma.
- ***Speed of infusion.*** The faster the rate is, the larger the vein and the larger the IV catheter you will need. Use the largest vein available, keeping other selection criteria in mind.
- ***Duration of infusion therapy.*** To prevent bacterial colonization and phlebitis, some guidelines recommend changing short peripheral IV catheters every 72 to 96 hours (CDC, 2011a; while others recommend changing it as clinically indicated (Infusion Nurses Society [INS], 2011a).
- ***Presence of disease or previous surgery.*** For example, avoid areas with scarring or impaired circulation.

For more detailed guidelines for selecting an insertion site,

Go to Chapter 38, **Clinical Insight 38-3: Guidelines for Selecting a Peripheral Venipuncture Site,** in Volume 2.

Perform Venipuncture

For a successful venipuncture, you need to be able to visualize or palpate the vein before attempting to insert the catheter. Use a vein viewer, if available, to aid in locating the vein. These instruments use infrared light and camera technology to project the patient's superficial

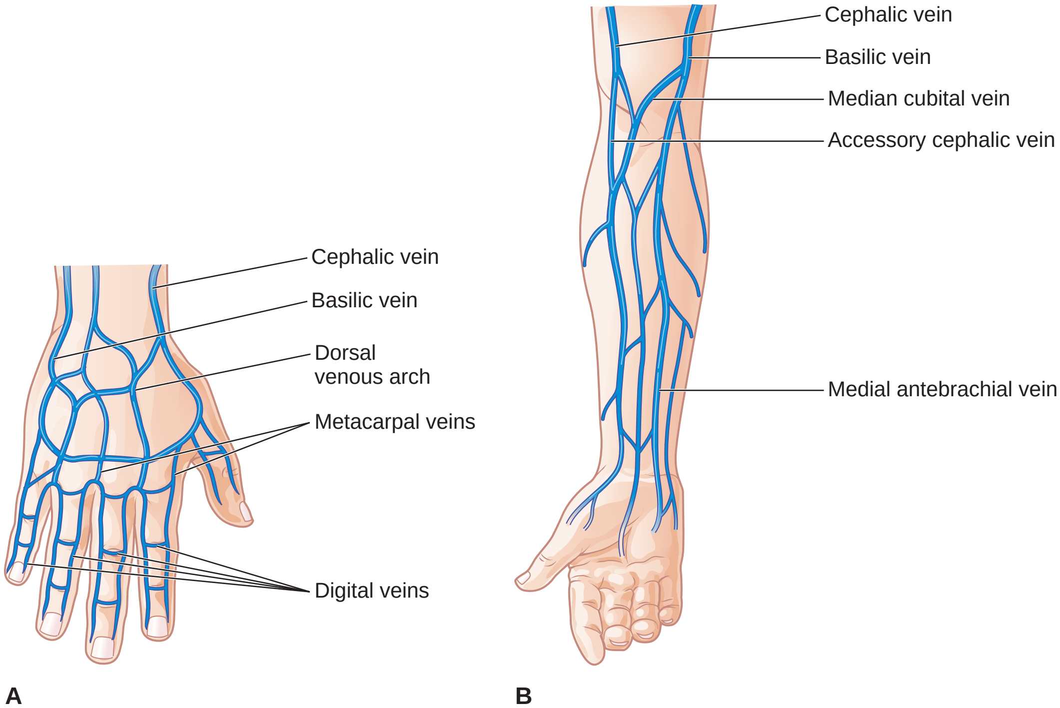

FIGURE 38-15 *A*, Superficial veins of the hand. *B*, Superficial veins of the forearm.

veins on to the skin surface. The Highlights of Procedures box summarizes the procedure for venipuncture. For other fine points of venipuncture (e.g., stabilizing the vein, angle of insertion, other techniques),

Go to Chapter 38, **Procedure 38-1: Initiating a Peripheral Intravenous Infusion,** in Volume 2.

Key Point: ***If you are not successful with the venipuncture, you can make a second attempt above the initial site or in the opposite extremity. But do not make more than two attempts to start an IV on a patient. Get help from a more experienced colleague.***

Regulating and Maintaining an Intravenous Infusion

Intravenous fluids can flow by gravity or be regulated by an electronic infusion-control device (pump). You are responsible for maintaining the correct rate of flow and for monitoring the client's response to the infusion. Many factors can influence the flow rate of an IV solution, especially when using gravity flow.

- ***The height of the solution container.*** The greater the distance between the height of the container and the patient's heart, the faster the flow will be. Check the flow rate each time the client or IV solution is repositioned to ensure that it is correct.
- ***Client position.*** Pressure on the IV site decreases flow. If an IV is infusing in the right arm and the patient is positioned on his right side, the pressure on the right arm will be greater than if the client were positioned supine or on the left.
- ***Blood pressure.*** As blood pressure rises, more force is required to infuse into the vein.
- ***The internal diameter of the IV catheter.*** The smaller the diameter (that is, the higher the gauge), the more you must open the roller clamp to achieve the flow rate desired.
- ***Condition of the catheter and tubing.*** If the catheter is dislodged from the vein, flow may stop entirely or continue at a slowed rate. A knot or kink at any point in the tubing will slow flow.

Gravity Flow

Most IV fluids are administered by a volume-control pump. However, you may still encounter instances when you will need to regulate the rate with the roller clamp on the tubing. You should check gravity infusion rates hourly and adjust the flow as needed. If the fluid is running too slowly, do not attempt to catch up by administering extra fluid rapidly. If the fluid is running too fast, slow the rate, and assess the client for signs of fluid volume excess.

If the client is ambulatory, attach the fluid container to a pole with wheels. Instruct the client to keep the solution container above the infusion site and to avoid pulling on the tubing or the infusion site. The Highlights of Procedures box summarizes how to regulate a gravity-flow IV. For the complete procedure,

Go to Chapter 38, **Procedure 38-2: Regulating the IV Flow Rate,** Volume 2.

Volume-Control Set

A volume-control set (e.g., Buretrol, Soluset, Volutrol) is another method for regulating an IV infusion (see Fig. 26–35). You will drain a small amount of fluid from the larger IV solution container into the volume-control container. Typically, the volume placed in the volume-control container is equal to the prescribed hourly infusion rate. The rate is regulated in the same way as other administration sets (the drip factor is usually 60 gtts/mL [60 drops/mL]); however, the maximum amount of fluid that can enter a patient is limited to the volume in the volume-control set. You may use this type of equipment when the client is at risk for fluid volume excess and for infants and children, who require close supervision of fluid intake. However, more often, the policy will be to use an infusion pump for continuous infusions for such patients. An advantage of this system is that medications can be added to the volume-control set and diluted with IV fluid for intermittent administration.

Infusion Pump

If you are using an electronic volume-control device (pump), the machine will maintain the infusion rate after you program it. Most infusion pumps sound an alarm when the fluid bag is almost empty, when air is in the line, or when there is resistance to flow. Infusion-control devices save time and prevent accidental delivery of large amounts of fluid. They do not, however, excuse you from regularly monitoring the flow rate and assessing the needle insertion site.

You should know that absence of an alarm does not mean there is no problem. For example, if the IV is infiltrated, the pump may keep infusing fluid into the tissues.

To learn more about how to regulate an IV using an infusion pump, see the Highlights of Procedures box and,

Go to Chapter 38, **Procedure 38-3: Setting Up and Using Volume-Control Pumps,** in Volume 2.

KnowledgeCheck 38-10

- What factors should you consider when selecting an insertion site for a peripheral IV line?
- What are the preferred locations for peripheral IV lines?
- What equipment is needed when inserting an IV and starting an IV infusion?
- Identify three ways to regulate the flow rate of IV fluid.

Calculating Flow Rates

As you already know, intravenous administration sets are sized as microdrips or macrodrips. Microdrips deliver fluid at a rate of 60 drops/mL. Macrodrips deliver fluid at a rate of 10 to 20 drops/mL (depending on the manufacturer). To begin, you need to know the ordered infusion rate and the flow rate of the administration set in drops per minute. See Box 38-1 to learn how to calculate flow rates.

Managing Multiple Lines

When a patient has multiple IV solutions and multiple lines, you must label each line to identify what is infusing in it. Label the IV tubing close to the catheter so that it is easy to see which fluid is infusing in the line.

BOX 38-1 ■ Calculating IV Flow Rates

Microdrips = 60 drops/mL

Macrodrips = 10 to 20 drops/mL

You need to know drops per minute: the prescribed infusion rate and the flow rate of the administration set.

1. Multiply the hourly rate (number of mL to be infused in 60 minutes) by the drop factor (in drops per milliliter) to obtain the total drops per hour.
2. Then divide by 60 to get the drip rate in drops per minute. For example, an hourly rate of 100 mL multiplied by 15 drops per milliliter and divided by 60 equals the drip rate. Therefore, the drip rate equals 25 drops per minute.

Use this formula to calculate flow:

$$\frac{\text{Hourly rate in mL} \times \text{drop factor (drops/mL)}}{60\text{ minutes}} = \text{drip rate}$$

Example: gtts/min

$$\frac{100\text{ (mL per hour)} \times 15\text{ (gtts/mL)}}{60\text{ minutes}} = 25\text{ gtts/min}$$

This is especially true when using double- and triple-lumen catheters. Multiple lines are often used because solutions are not compatible with each other (e.g., you can never infuse blood, parenteral nutrition, or lipids through a line with anything else; and you can never draw blood samples from these lines).

- ***Record the name of each line in your nursing notes and the intake form.*** For peripheral IVs, use RA for right arm, LA for left arm, and so on; and designate a number for each site because there may be more than one line or site in each arm (e.g., RA-1, RA-2, LA-1). If the lines are in separate arms, it may seem unnecessary to give each one a number; however, over the course of therapy, some lines may need to be discontinued and new ones started.
- ***For multiport central lines, label each port, in addition to recording in nursing notes.*** For example, with a triple-lumen central catheter, you might have named each lumen as proximal, mid, and distal, or CVAD-1, CVAD-2, CVAD-3. The finished labeling and nursing record may indicate "CVAD-1—TPN; CVAD-2—$D_5$1/2 NS; CVAD-3—insulin."
- Always keep the lines untangled and know where your main IV fluid is (e.g., the D_5-½ NS), so that if a crisis occurs or intermittent infusions are needed, you can quickly identify the correct solution and tubing for use.

Complications of Intravenous Therapy

Complications at the IV site include infiltration, extravasation, infection, thrombus, and thrombophlebitis. Inserting an IV catheter breaks the body's first line of defense (the skin) and provides a portal of entry for microorganisms.

In addition, trauma roughens the vein wall and predisposes the person to platelet clumping and thrombus formation. Minimize this effect by swiftly piercing the skin and anchoring the catheter and tubing to reduce tissue trauma. Systemic complications occur less frequently than do local complications but may be life threatening. They include fluid volume excess, sepsis, and embolus. Table 38-8 describes potential complications of IV therapy. For more information on managing infiltration and extravasation,

Go to **Clinical Insight 38-5: Managing Infiltration and Extravasation,** in Volume 2.

Changing Intravenous Solutions, Tubing, and Dressings

Follow practice guidelines and agency policies for changing IV solutions, tubing, and dressings. As with IV insertion, use meticulous aseptic technique.

Changing IV Solutions Hang a new container of fluid when the present container is nearly empty, but fluid still remains at the appropriate level in the drip chamber. The infusion rate dictates how often you need to change the IV solution. For example, a liter of IV fluid infusing at 125 mL/hr must be changed every 8 hours; a liter infusing at 50 mL/hr will hang for 20 hours. Evidence-based practice does not provide an exact length of time that an IV solution can hang before it has to be changed (CDC, 2011a); therefore, you should follow your agency's policy. For full instructions on the procedure for changing solutions, tubing, and dressings,

Go to Chapter 38, **Procedure 38-4A: Changing the IV Solution, Procedure 38-4B: Changing the IV Administration Tubing and Solution,** and **Procedure 38-5: Changing IV Dressings,** in Volume 2.

Changing Administration Sets The INS (2011a) and the CDC (2011b) recommend that primary and secondary administration sets be changed no more frequently than 96 hours, but at least every 7 days; primary intermittent administration sets should be changed every 24 hours. This guideline applies to administration sets that are continuously used and the patient is not receiving blood, blood products, or fat emulsions. Administration sets used for parenteral nutrition are exposed to intravenous fat emulsions and should be changed every 24 hours and every 96 hours for non-lipid-containing parenteral nutrition solutions (INS, 2011).

Key Point: ***As a rule, if you start an IV at a new site, use a new administration set. Reusing a set from a previous site increases the risk of contamination.***

Changing IV Dressings Change peripheral IV dressings routinely when the catheter is replaced, or as clinically indicated (e.g., when the dressing becomes damp, soiled, or loose) (CDC, 2011). For central venous catheters (CVCs), The Infusion Nurses Society (INS, 2011a) recommends the following:

- For short-term CVCs, the dressing at the site must be changed every 2 days for gauze dressings and every 7 days for transparent dressing. In pediatric patients, if the risk of dislodging the catheter is high, the dressing can be left in place.
- For tunneled or implanted sites, unless soiled or loose, a transparent dressing is changed no more than once a week until the insertion site has healed.
- For long-term cuffed and tunneled CVS with well-healed sites, no recommendations are made. You should follow your agency's policy for dressing changes on these sites. In home care, the dressing may be left in place for 1 week. Change any dressing, regardless of site, when it becomes soiled, damp, or loosened.

Key Point. ***It is best to dress both central and peripheral lines with transparent, semipermeable dressings.*** These dressings allow direct visualization of the site between dressing changes, permit evaporation of moisture, and provide a secure anchor for the catheter. You may still sometimes see tape securing a catheter at the insertion site; however, the use of a catheter stabilization device is preferred over tape or sutures (INS, 2011a).

Converting to a Peripheral Intravenous Lock

The terms *peripheral lock, saline lock,* or *prn adapter* are used interchangeably. Recall that you may need a peripheral IV lock (PIV) for intermittent infusions or for venous access for emergencies. Also, when clients do not need the additional fluids provided by a constant infusion of solution, a peripheral infusion can be easily converted to a peripheral lock. To do this, you simply remove the tubing from the IV catheter and replace it with a sterile injection cap (see Fig. 38-9). Some IV locks also contain a short segment of tubing.

Each time you give a medication through the lock, you will need to disinfect and flush the lock before and after you administer the medication. The INS (2011a) recommends that 0.9% sodium chloride (USP) be used to flush the peripheral IV lock. A PIV should also be flushed and locked at least every 12 hours when not in use. The Highlights of Procedures box summarizes the procedure for converting to a PIV. For complete instructions,

Go to Chapter 38, **Procedure 38-6: Converting a Primary Line to a Peripheral IV Lock,** in Volume 2.

Discontinuing an Intravenous Line

Discontinue the IV line and IV catheter when IV fluids and medications are no longer needed or if the integrity of the line is compromised. Inspect the catheter to ensure that it is intact when you remove it. The Highlights of Procedures box summarizes removal of an IV catheter. For the complete procedure,

Table 38-8 ➤ Complications of Intravenous Therapy

COMPLICATION	CAUSES	SIGNS AND SYMPTOMS	NURSING RESPONSE
Local Complications			
Hematoma—a localized mass of blood outside the blood vessel	Nicking the vein during an unsuccessful insertion, discontinuing an IV line without holding pressure over the site, or applying a tourniquet too tightly above a previously attempted venipuncture site	Ecchymosis, localized mass, discomfort	Be gentle with venipuncture technique. Apply pressure when discontinuing an IV.
***Infiltration**—the seepage of nonvesicant solution or medication into surrounding tissues	IV catheter dislodges or the tip penetrates the vessel wall.	Slowed or stopped flow Swelling, tenderness, pallor, hardness and coolness at the site The patient may report a burning sensation in the area.	Stop the infusion immediately. Restart the IV infusion in a different vein, higher in the extremity or in another extremity. Elevate the affected arm on a pillow to promote absorption of excess fluid.
***Extravasation**—seepage of a vesicant substance into the tissues. (A *vesicant* is a solution that causes the formation of blisters and subsequent tissue sloughing and necrosis.)	IV catheter dislodges, or the tip penetrates the vessel wall.	Slowed or stopped flow Pain, burning, and swelling at IV site, blanching and coolness of the surrounding skin Blistering is a late sign. If extravasation resulted from vasoconstricting medication may see necrosis (death) of dermis.	Treatment depends on the severity of the infiltration. Stop the IV infusion immediately. Administer an antidote, if one is available. (Antidotes alter the pH, alter DNA binding, neutralize the drug, or dilute the extravasated drug.) Apply cold compresses, and elevate the extremity.
Phlebitis—inflammation of the vein	May be due to mechanical irritation, infusion of solutions that are irritating to the vessel, or sepsis. Dextrose solutions, potassium chloride, antibiotics, and vitamin C are associated with a higher risk of phlebitis. Trauma to the vessel, compression of the line by client movement, or a low flow rate	Redness, pain, and warmth at the site, local swelling, palpable cord along the vein, sluggish infusion rate, and elevated temperature Slowed or stopped infusion, localized warmth at the site, inability to restart flow of IV	Discontinue the IV infusion and restart in a new location. Initially, apply cold compresses to the site if the site is warm and tender. Thereafter, use warm compresses. Assess for circulatory impairment. Consult the primary care provider if there is streaking or erythema along the vein or a palpable cord. *Prevention measures*: Use the smallest catheter practical (usually 22-gauge or 24-gauge thin-walled catheter). Use polyurethane catheters instead of Teflon.

Continued

Table 38-8 ➤ Complications of Intravenous Therapy—cont'd

COMPLICATION	CAUSES	SIGNS AND SYMPTOMS	NURSING RESPONSE
			Stabilize and secure the catheter to minimize movement in the vein. Rotate the site at least every 96 hours.
Thrombophlebitis—thrombosis and inflammation	Use of veins in the legs for infusion, use of a hypertonic or highly acidic solution; can be a result of untreated phlebitis	Sluggish flow rate, edema, tender and cord-like veins, warmth, and erythema at site	Discontinue the IV infusion, and restart in the opposite extremity, using all new equipment. Apply warm, moist compresses. Consult the primary care provider.
Local infection—mic-robial contamination of the cannula or IV site	Using poor technique when inserting the catheter, leaving the catheter in place for longer than 96 hours, or direct contamination	Redness, swelling, exudate, elevated temperature	Remove the IV line. Apply a sterile dressing over the site. Administer antibiotics, if necessary.
Nerve injury—a nerve is inadvertently injured during venipuncture (direct) or is compressed	Using veins on inner surface of the wrist and forearm; not anchoring the vein for puncture; using a large needle; advancing the needle across instead of with the vein; "probing" (excessive redirection of the needle at insertion); inserting too deeply and through the back wall of the vein; too many venipuncture attempts; infiltration, extravasation, tourniquet too tight or left on too long	*Direct injury*—sharp acute pain at the site or up and down the arm; pins and needles or electric shock sensation; pain, numbness, or tingling in fingers; pain that persists after the needle is removed *Compression injury*—pain and tingling typically appear 24 to 96 hours after venipuncture.	Do not make more than 2 venipuncture attempts. *If patient complains of symptoms:* Stop the procedure and withdraw the catheter. Apply pressure to prevent hematoma. Report to supervisor and physician. Do not start a new IV in the affected arm. Treat infiltration if it occurs. **Fasciotomy** (incisions around the area to let blood or fluid seep out) is the usual treatment; or fluid may be expressed.
Systemic Complications			
Septicemia—the presence of microorganisms or their toxic products in the circulatory system	A break in aseptic technique, or contaminated IV solution	Fluctuating fever, chills, tachycardia, confusion, hypotension, altered mental status, elevated WBC count	Discontinue the IV infusion immediately. Consult the primary care provider. Treatment often involves antibiotics, fluids, and medications to support vital signs.

Table 38-8 ➤ Complications of Intravenous Therapy—cont'd

COMPLICATION	CAUSES	SIGNS AND SYMPTOMS	NURSING RESPONSE
Fluid overload	Infusing excessive amounts of IV fluids or administering fluid too rapidly.	Weight gain, edema, hypertension, shortness of breath, crackles, distended neck veins	Slow the IV flow rate. Place the client in high-Fowler's position. Monitor vital signs. Administer oxygen, if needed. If severe, diuretics may be ordered.
Air embolus—a rare complication involving the introduction of air into the vascular system	Loose connections, adding a new IV bag to a line that has run dry without clearing the line of air, air in tubing cassette of infusion pump	Palpitations, chest pain, light-headedness, dyspnea, cough, hypotension, tachycardia, sudden change in mental status	Call for help. Place client in Trendelenburg's position on the left side. Administer oxygen. Have emergency equipment available.
Catheter embolus—a piece of catheter breaks off and travels through the vascular system	Reinserting a catheter used in an unsuccessful insertion; removing and reinserting a stylet, causing shearing of the catheter; placing the catheter in a joint flexion	Sharp, sudden pain at IV site, jagged catheter end on removal, dyspnea, chest pain, tachycardia, hypotension	Apply a tourniquet above the site. Notify the physician and radiologist. Start a new IV line. Prepare the patient for radiographic examination.

Source: Phillips, L. D. (2010). *Manual of I.V. therapeutics* (5th ed.). Philadelphia: F.A. Davis.

Go to Chapter 38, **Procedure 38-7: Discontinuing a Peripheral IV,** in Volume 2.

KnowledgeCheck 38-11

- The prescription reads, "5% dextrose in water/0.45% saline solution ($D_5\frac{1}{2}$ NS) with 20 mEq KCl; infuse 1 liter in 5 hours." Calculate the hourly rate and the drip rate using (1) a macrodrip administration set with 15 gtts/mL and (2) a microdrip set.
- Describe the difference between infiltration and extravasation as a complication of IV therapy.
- In general, how often are administration sets changed on peripheral IV lines? How often are administration sets changed when total parenteral nutrition (TPN) is being infused?

Replacement of Blood and Blood Products

Intravenous fluids can replace fluid volume, but they do not restore oxygen-carrying capacity or replace clotting factors. Blood products are infused when the patient has experienced significant blood loss, diminished oxygen-carrying capacity, or a deficiency in one of the blood components. The American Association of Blood Banks (AABB) estimates that 9.2 million volunteers donate blood each year; a total of 15.7 million units of whole blood and red blood cells was donated in 2011 (AABB, n.d.).

Each unit of donated blood is separated into multiple components, such as red blood cells, plasma, platelets, and clotting factors. Thus, one unit of donated blood may be used in the care of four clients. Unfortunately, fewer than 10% of eligible persons donate blood each year. To

For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the procedure steps. Use these procedural highlights later to help you review key points.

For all intravenous procedures, maintain scrupulous aseptic technique to prevent infection and possible sepsis.

Procedure 38-1: Initiating a Peripheral Intravenous Infusion

- Prepare the IV solution and administration set, including extension tubing and volume-control device if used. Prime the tubing.
- Label the IV solution container and place a time-tape on it with the infusion rate. Label the tubing with the date and time.
- Apply the tourniquet.
- Locate a vein. Then loosen the tourniquet. (As a rule, select the most distal vein in an upper extremity.)
- Don clean nonsterile gloves and open the catheter package. Keep the catheter sterile.
- Reapply the tourniquet and cleanse the site. Allow the antiseptic to dry on the skin.
- Inform the patient that you are about to insert the catheter.
- Stabilize the vein with your nondominant hand.
- Hold the catheter, bevel up, at a 30° to 45° angle and pierce the skin.
- Look for a flashback of blood. Lower the catheter so it is parallel to the skin, and advance into the vein.
- When the needle is at least halfway into the vein or when a steady backflow of blood occurs, gradually withdraw the needle while advancing the catheter fully into the vein.
- While holding the catheter in place with one hand, release the tourniquet with your other hand.
- Connect the IV administration set to the IV catheter.
- While stabilizing the catheter with your hand, adjust the flow rate according to the prescriber's order.
- Secure the connection; stabilize the catheter; and dress the IV insertion site.
- Label the dressing.
- Loop and tape the tubing to the skin.
- Place an arm board as needed.

Procedure 38-2: Regulating the IV Flow Rate

- Follow all "checks" and "rights" of medication administration, including:

  Verify the prescription

  Check the solution to make sure that you have the proper IV fluid with the prescribed additives.

  Apply a time tape to the solution container. Mark the time the infusion was started.

  Open the roller clamp so that the IV fluid begins to flow.
- Calculate the hourly rate and the drip rate; verify your calculations.
- Hold a watch beside the drip chamber; count the number of drops for 1 minute.
- Adjust the roller clamp, increasing or decreasing the flow until you achieve the prescribed drip rate.
- Monitor manually regulated infusion rates closely for the first 15 minutes after you begin the infusion; then monitor the rate hourly.

Procedure 38-3: Setting Up and Using Volume-Control Pumps

- Calculate and verify the infusion rate.
- Attach the volume-control pump to the IV pole, and plug it into the nearest electrical outlet.
- Close the clamp on the administration set and spike the port of the solution container. Attach a filter if one is needed.
- Label the tubing and solution container.
- Hang the solution container on the IV pole.
- Fill the drip chamber halfway.
- Place the electronic sensor on the drip chamber, if there is one. If not, consult the manufacturer's instructions.
- Prime the administration tubing, then close the clamp.
- Turn on the pump, and load the administration tubing into the pump.
- Program the pump with the hourly infusion rate, total hours, and the volume to be infused.
- Don clean nonsterile gloves and check the IV site for patency.
- Scrub the injection port; allow to dry.
- Connect the tubing adapter to the injection port.
- Unclamp the administration set tubing, and press the start button.
- Make sure that the alarms are turned on and audible.
- Check the pump regularly to make sure that the correct volume is infusing.
- At the end of your shift (or at the specified time), clear the pump of the volume infused and record the volume.

Procedure 38-4: Changing IV Solutions and Tubing

Procedure 38-4A: Changing the IV Solution

- Prepare and label your next container of IV solution at least1 hour before the present infusion is scheduled to finish.
- Close the roller clamp on the infusing (empty) administration set.
- Wearing nonsterile gloves, remove the old IV solution container from the IV pole. Remove the spike from the bag, keeping the spike sterile.

- Spike the new IV solution container.
- Hang the new IV solution, and inspect the tubing for air.
- Adjust the drip rate.
- Place the time tape on the new IV solution container. Mark the times.

Procedure 38-4B: Changing the IV Administration Solution and Tubing

- Prepare and hang the new IV solution and tubing.
- Close the roller clamp on the old administration set.
- Wearing clean nonsterile gloves, stabilize the IV catheter while applying pressure over the vein just above the insertion site.
- Remove the protective cover from the distal end of the new administration set and connect the new tubing.
- Adjust the drip rate.
- Cleanse the IV site.
- Resecure the IV catheter and tubing connection; loop and tape the tubing.
- Label tubing and solution with date, initials, rate, and time tape.

Procedure 38-5: Changing IV Dressings

Procedure 38-5A: Peripheral IV Dressings

- Wearing clean procedure gloves, stabilize the catheter with your nondominant hand, and carefully remove the dressing.
- Inspect the insertion site.
- Don clean gloves. Cleanse the insertion site, following manufacturer's guidelines for product use
- Allow the antiseptic to dry on the skin.
- Perform hand hygiene and don nonsterile gloves.
- Apply a new sterile catheter stabilization device and dressing.
- Secure the connection between the catheter and the tubing.
- Loop and tape the tubing to the patient's skin.
- Label the dressing with the date and time of insertion, catheter size, the date the dressing was changed, and your initials.

Procedure 38-5B: Central Line Dressings

- Obtain sterile central line dressing kit (or equivalent supplies if there is no kit) and a mask for the patient, if one is needed.
- Place the patient in a semi-Fowler's position, if tolerated.
- Ask the patient to turn his head to the opposite side of the insertion site; if unable, place a mask on the patient.
- Don mask and clean nonsterile gloves.
- Carefully remove the old dressing and stabilization device.
- Inspect the site for signs of complications.
- Remove gloves and perform hand hygiene
- Set up a sterile field, open dressing change kit, and don sterile gloves.
- Arrange sterile supplies as needed.
- Scrub the insertion site with gentle friction for at least 30 seconds, using the antiseptic swabs contained in kit.
- Scrub the sutures (if any) and the catheter from insertion site to the hub or bifurcation with an antiseptic swab for at least 15 seconds.
- Allow the site to dry completely; do not fan.
- Apply the transparent dressing that comes in the kit.
- Apply the new catheter stabilization device, if one is used.
- Remove drape, if one was used.
- Loop the catheter gently and secure it with tape to the skin (do not tape it to the dressing).
- Label the dressing with the date changed, time, and your initials.

Procedure 38-5C: PICC Line Dressings

- Obtain sterile central line dressing kit (or equivalent supplies if there is no kit) and mask for the patient, if one is needed.
- Place the patient in a comfortable semi-Fowler's position.
- Explain the procedure to the patient
- Ask the patient to turn his head to the opposite side of the insertion site; if unable, place a mask on the patient, if consistent with agency policy.
- Inspect the site for signs and symptoms of infection.
- Don mask and nonsterile gloves
- Remove and discard your gloves along with the old dressing.
- Perform hand hygiene.
- Set up a sterile field, open dressing change kit, and don sterile gloves.
- Arrange sterile supplies, as needed.
- Use sterile tape, measure the external length of PICC to compare to base insertion length, if consistent with agency's policy.
- Scrub the catheter's insertion site and the surrounding skin that will be covered by the dressing for 30 seconds.
- Allow to air dry completely.
- Apply the stabilization device, if one is used.
- Apply the transparent dressing. Loop the catheter and injection camp so that it is pointing up.
- Label the dressing with the date, time, and your initials.
- Loop and anchor the catheter; secure with tape.

Procedure 38-6: Converting a Primary Line to a Peripheral IV Lock

- Maintain sterility of equipment throughout.
- Don clean nonsterile gloves.
- Remove the IV lock from the package, and flush the adapter, according to agency policy. Do not contaminate the lock.

Continued

- Remove the IV dressing and the tape that is securing the tubing.
- Close the roller clamp on the administration set.
- With your nondominant hand, apply pressure over the vein just above the insertion site; stabilize the catheter hub with your thumb and forefinger.
- Disengage the used tubing from the IV catheter.
- Quickly insert the lock adapter into the IV catheter and turn it to lock it in place.
- Scrub the adapter injection port and flush the lock again with the second syringe.
- Apply a sterile transparent semipermeable dressing; do not cover the catheter-tubing connection.
- Label the dressing with date and initials.
- Discard used supplies.

Procedure 38-7: Discontinuing a Peripheral IV

- Place a linen-saver pad under the extremity with the IV catheter.
- Don clean nonsterile gloves, and close the roller clamp on the administration set.
- Remove the dressing; scrub the catheter-skin junction with an antiseptic pad for 15 seconds.
- Place a sterile 2 in. × 2 in. gauze pad above the IV insertion site and gently remove the catheter.
- Apply firm pressure with the gauze pad; hold pressure for 1 to 3 minutes, or longer if bleeding persists.
- Replace the soiled 2 in. × 2 in. gauze pad with a new sterile one. Secure it with tape or use a transparent dressing.

Procedure 38-8: Administering a Blood Transfusion

Procedure 38-8A: Administering Blood and Blood Products

- Verify that informed consent has been obtained.
- Verify the physician's prescription, noting the indication, and rate of infusion.
- Administer any prescribed pretransfusion medications.
- Obtain a blood administration set and 250 mL of IV normal saline solution.
- Obtain infusion pump, if possible and blood warmer, if necessary.
- Obtain the blood product from the blood bank according to your institution's policy. Verify that the blood matches the prescription. Inspect it for abnormalities.
- With another qualified staff member (per agency policy) verify the patient and blood product identification (e.g., date of birth, hospital identification number, blood type). If all verifications are in agreement, both staff members should sign the blood bank form. Contact the blood bank immediately if there are discrepancies, and do not administer the blood product.
- Document on the blood bank form the date and time the transfusion is begun.
- Close all clamps on the blood administration set. Label the tubing.
- Hang the normal saline and prime the tubing.
- Gently invert the blood product container several times.
- Spike the blood product and hang the blood on the IV pole.
- Obtain a set of vital signs.
- Scrub the port with an alcohol swab or chlorhexidine/alcohol antiseptic product for at least 15 seconds before connecting to an existing line.
- Attach the administration set tubing to the IV catheter.
- Slowly open the roller clamp closest to the blood product. Infuse the first 50 mL slowly; if no reaction, set to the prescribed rate.
- Remain with the patient for the first 5 minutes. Measure vital signs in 5 minutes, 15 minutes, and 30 minutes; then hourly.
- Observe for and ask the patient to immediately report symptoms of transfusion reaction.
- When the blood has transfused, flush the line with the normal saline solution.
- Disconnect the tubing from the IV catheter, and dispose of the blood product container and tubing per agency policy.
- If a second unit of blood is to be transfused, the same administration set may be used.
- Administer any post-transfusion medications prescribed.

Procedure 38-8B: Managing a Transfusion Reaction

- If there are signs or symptoms of transfusion reaction, stop the transfusion immediately. Do not flush the tubing.
- Disconnect the administration set from the IV catheter.
- Call for help and prepare for emergency care.
- Obtain vital signs, and auscultate heart and breath sounds.
- Maintain patency of the IV catheter by hanging a new infusion of normal saline solution, using new tubing.
- Notify the primary care provider.
- Place the administration set and blood product container, with the blood bank form attached, inside a biohazard bag. Send the bag to the blood bank immediately.
- Obtain blood (in the extremity opposite the transfusion site) and urine specimens according to your institution's policy.
- Continue to monitor vital signs frequently.
- Administer medications, as prescribed.

Procedure 38-9: Assisting With Percutaneous Central Venous Catheter Placement

- Explain procedure to the patient and verify informed consent.
- Obtain vital signs
- Gather supplies and perform meticulous hand hygiene.

Highlights of Procedures 38-1 Through 38-9

- Position the table so it is easily accessible by the provider.
- Prepare sterile field and add supplies.
- Position the patient (Trendelenburg with a rolled towel between the shoulders).
- After the physician or advanced practice nurse performs hand hygiene, offer mask, gown, and sterile gloves (and possibly hat, depending on agency policy).
- Don mask and then sterile gloves.
- Prep an 8 in. × 10 in. area around the site, using applicators of 2% chlorhexidine gluconate in 70% alcohol, per agency guidelines.
- Place the large sterile drape to cover patient's head and chest.
- Have the patient turn his head opposite the direction of insertion.
- Observe while the physician inserts and sutures the catheter.
- Apply sterile transparent dressing, close any lumen clamps, and place tape across the lumens near the injection caps.
- Monitor for complications (especially respiratory distress).
- Obtain a chest x-ray.

be eligible to donate blood, a person must be in good health (no cold or flu, uncontrolled hypertension, anemia, or diabetes), at least 16 years of age (although some states permit younger people, with parental consent, to donate), have a hemoglobin of at least 12.5 gm/dL, and weigh at least 110 pounds. In addition, each potential donor is screened for travel to certain countries and for a variety of disorders, such as hepatitis, HIV, and Creutzfeldt-Jakob disease (the human form of mad cow disease).

Blood Groups

Human blood is classified into four main groups (A, B, AB, and O) based on the presence or absence of certain antigens and antibodies. You inherit the blood group you belong to from your parents.

If you belong to blood group A, you have A antigens on the surface of your red blood cells (RBCs), and B antibodies in your plasma. The opposite is true for persons with blood group B. Blood group AB has both antigens on the surface of the red blood cells and no antibodies at all in the plasma. In contrast, blood group O has neither A nor B antigens on the surface of the red blood cells but both A and B antibodies in the blood plasma (Table 38-9). Patients must receive only blood that is compatible with their own blood group to prevent a hemolytic reaction (see Table 38-10).

An additional antigen, known as Rh factor, is also important with blood typing. If the antigen is present, you are referred to as Rh positive (Rh^+). If it is absent, you are Rh negative (Rh^-). Thus, you can belong to one of the following eight groups:

A Rh^+	B Rh^+	AB Rh^+	O Rh^+
A Rh^-	B Rh^-	AB Rh^-	O Rh^-

Blood Typing and Crossmatching

Once blood is donated, several tests are performed on the sample. First, the sample is tested for ABO group (blood type) and Rh type (positive or negative), as well as for any unexpected red blood cell antibodies that may cause problems in a recipient. Screening tests assess for evidence of donor infection with hepatitis B and C viruses, HIV, human T-lymphotropic viruses, West Nile virus, and syphilis. If all disease screens are negative, the blood is acceptable for transfusion and is placed in the pool of available products.

When a potential donor is identified, crossmatching is performed. **Crossmatching** identifies possible minor antigens that will affect the compatibility of the donor blood in the recipient. RBCs from the donor blood are

Table 38-9 ➤ Blood Transfusions

BLOOD GROUP	ANTIGENS	ANTIBODIES	CAN GIVE BLOOD TO	CAN RECEIVE BLOOD FROM
AB	A and B	None	AB	AB, A, B, and O
A	A	B	A and AB	A and O
B	B	A	B and AB	B and O
O	None	A and B	AB, A, B, and O	O

mixed with plasma from the potential recipient. A reagent is added, and the sample is observed for clumping or agglutination. If no clumping is observed, the risk of transfusion reaction is low, and it is considered safe to transfuse the sample of blood. Table 38-9 summarizes blood group matching.

Key Point: ***People with blood group O are considered universal donors, because of the absence of antigens, whereas people with blood group AB are considered universal recipients because of the absence of plasma antibodies.***

In regard to Rh factor, people who are Rh^+ may receive blood with or without Rh factor. However, people who are Rh^- may receive only Rh^- blood.

When possible, **autologous** (self-donated) units of blood are given instead of blood from a donor. This negates the risk of a mismatch or exposure to undetected disease. The patient's blood is usually collected in the preoperative weeks for possible transfusion during elective surgery. Autologous donation is most often done with orthopedic, cardiac, and vascular surgery. The process of donating autologous blood stimulates the bone marrow to produce new blood cells. Given adequate time for recovery, the collected cells may be wholly or partially replaced prior to surgery.

Blood Products

Several blood products are available for transfusion:

- *Whole blood* contains RBCs, WBCs, and platelets suspended in plasma.
- *Red blood cells* are prepared from whole blood by removing the plasma. RBCs can raise the client's hematocrit and hemoglobin levels while minimizing an increase in volume. RBCs are available for transfusion as packed RBCs (PRBCs).
- *Plasma* is the liquid portion of the blood. It is 90% water and makes up about 55% of blood volume. Plasma may be transfused whole or may be separated into specific products, such as albumin, clotting factor concentrates, and immune globulins.
- *Platelets* help the clotting process by sticking to the lining of blood vessels. Units of platelets are prepared by using a centrifuge to separate the platelet-rich plasma from the donated unit of whole blood. The platelet-rich plasma is then centrifuged again to concentrate the platelets further. Platelets are used to treat clients who have a shortage of platelets or have abnormal platelet function.
- *White blood cells (WBCs)*, specifically granulocytes, can be collected by centrifugation of whole blood. They are transfused within 24 hours after collection and are used for infections that are unresponsive to antibiotic therapy. The effectiveness of WBC transfusion is still being investigated.
- *Plasma derivatives* are concentrates of specific plasma proteins prepared from many units of plasma. Plasma derivatives include a variety of clotting factors, immune globulins, and albumin.

Initiating a Transfusion

It is critical to identify the patient and the blood product when transfusing blood. Before beginning a transfusion, verify the written prescription for the blood product.

Obtain a set of vital signs 5 to 15 minutes before initiating the infusion. If the patient's temperature is elevated, inform the primary care provider before hanging the transfusion. Most patients experience a minor temperature elevation after a transfusion is given. A preexisting elevated temperature may exacerbate this response. Some patients will refuse a blood transfusion because of cultural, religious, or other beliefs. Be ready to discuss with them any available alternatives to whole blood administration.

Also inspect the IV site to be sure it is patent before hanging the blood product. Nurses commonly use a 20-gauge catheter to infuse blood and a larger size for rapid flow rates. There is evidence that a 22-gauge catheter can be used in adults without damage to the red blood cells (INS, 2011a). Certainly, for children and the frail elderly you will need a smaller, 22- or 24-gauge catheter. The Highlights of Procedures box summarizes the procedure for initiating and monitoring a blood transfusion. For the complete procedure,

Go to Chapter 38, **Procedure 38-8A: Administering Blood and Blood Products,** and **Procedure 38-8B: Managing a Transfusion Reaction,** in Volume 2.

Transfusion Reactions

Even though you use perfect technique, transfusion reactions can and do occur. Five types of reaction are possible: allergic, bacterial, febrile, or hemolytic reactions; and circulatory overload. Table 38-10 describes each of these reactions. To help prevent transfusion reactions, be extremely careful in identifying the patient and the blood, start the transfusion slowly, remain with the patient for the first 5 minutes of the transfusion, and assess again at 15 minutes (see Procedure 38-8, in Volume 2). Many physicians routinely prescribe acetaminophen (e.g., Tylenol) or diphenhydramine (e.g., Benadryl) before transfusions, with the goal of preventing febrile and minor allergic reactions. However, some question whether the risks of routine medication outweigh the benefits and suggest that more research is needed in this area (Geiger & Howard, 2007).

KnowledgeCheck 38-12

- Identify eight potential blood types.
- Describe the types of blood products that are available for transfusion.
- Identify and describe types of transfusion reactions.

Table 38-10 ➤ Transfusion Reactions

TYPE OF REACTION	SIGNS AND SYMPTOMS	NURSING RESPONSIBILITIES
Allergic—allergy to blood being transfused	Flushing, itching, wheezing, urticaria (hives); anaphylaxis, if severe	Stop the transfusion. Replace with a saline infusion. Notify the physician immediately. Administer prescribed antihistamine.
Bacterial—contamination of the blood	Fever, chills, vomiting, diarrhea, hypertension	Stop the transfusion. Replace with a saline infusion. Notify the physician. Administer antibiotics as ordered. Treat symptoms.
Febrile—temperature elevation due to sensitivity to WBCs, plasma proteins, or platelets	Fever, chills, warm, flushed skin, aches	Stop the transfusion. Replace with a saline infusion. Notify the physician. Treat symptoms.
Hemolytic reactions—destruction of RBCs as a result of infusing incompatible blood; occurs in 1 in 600,000 transfusions	Fever, chills, dyspnea, chest pain, tachycardia, hypotension; can be fatal	Stop the transfusion immediately. Replace with a saline infusion. Notify the physician immediately. Send the remaining blood, including tubing and filter; a sample of venous blood; and the first voided urine to the lab for analysis. Treat shock.
Circulatory overload—administering too great a volume or too rapidly	Persistent cough, crackles, hypertension, distended neck veins	Slow or stop the transfusion. Monitor vital signs. Place the client upright. Notify the physician.

Toward Evidence-Based Practice

Houck, D., & Whiteford, J. (2007). Transfusion with infusion pump for peripherally inserted central catheters and other vascular access devices. *Journal of Infusion Nursing, 30*(6), 341–344.

In a 500-bed community hospital, policy required that blood transfusions be infused by gravity flow using a peripheral IV (PIV). Nurses sought to show that using a peripherally inserted central catheter (PICC) line with an infusion pump was safe and efficient. A literature review showed no increased risk of hemolysis of red blood cells when given via pump as compared with gravity. A total of 169 units of blood products were infused via various types of PICCs and infusion ports, some using a pump and some using gravity flow. All PICC lines remained patent during transfusion and no problems with using a pump were identified. An overall reduction in cost was identified based on a 30-minute decrease in nursing time (starting and maintaining a PIV). Based on the study, the policy for blood administration via PICC lines was changed.

Galvey, J., Ibey, A., McConnell, G., et al. (2011). Infusion pumps for blood and blood products transfusions and administration. Retrieved from http://resna.org/conference/proceedings/2011/CMBEC34/galvey-69501.pdf

Based on evidence-based research and preferences by nurses, various regulatory and coordinating agencies investigated and developed standards for changing practice from blood transfusions using gravity sets to using infusion pumps. The change required reviewing manufacturers' research on infusing blood and blood products with various pumps, establishing preventive maintenance schedules, developing operating policies and procedures, and cost analysis. The average cost increase per infusion based on equipment and supplies was less than $20.

1. Based on these studies, how do you see that nurses can affect institution policy and procedure?

2. Are there any other concerns related to infusing blood via an infusion pump that you might have, and why?

3. What factors must be considered when implementing new changes in practice?

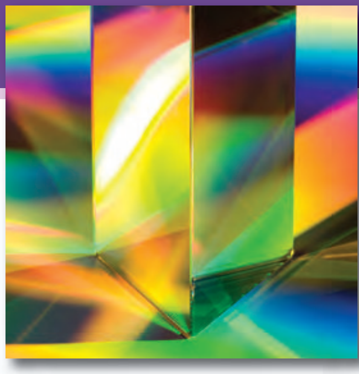
Nursing Functions

CHAPTER 39



Perioperative Care

Learning Outcomes

After completing this chapter, you should be able to:

- Discuss the importance of perioperative safety.
- Name and differentiate the three phases of the perioperative period.
- Describe the ways in which surgeries can be classified.
- Discuss factors that affect the degree of risk of surgery.
- Describe nursing actions associated with the preoperative phase, including physical preparations for surgery, preoperative teaching, and surgical consent forms.
- Compare and contrast the roles of the circulating and scrub nurse.
- Compare and contrast general anesthesia, local anesthesia, regional anesthesia, and conscious sedation.
- Discuss common nursing interventions during the intraoperative phase, including skin preparation, positioning for surgery, and intraoperative safety measures.
- Describe nursing assessments appropriate for surgical clients on admission to the nursing unit.
- Provide nursing care to prevent postoperative complications, including application of elastic and sequential compression devices, use of incentive spirometry, and management of gastric suction.
- Use nursing diagnoses appropriately to describe a patient's unique needs during the preoperative, intraoperative, and postoperative periods.

Key Concepts

Perioperative nursing
Preoperative care
Intraoperative care
Postoperative care

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patient

Nishad Singh is a 68-year-old man who came to the emergency department (ED) with sudden onset of rectal bleeding. He tells the ED nurse, "I've been real tired and dragging for several months. This morning I felt a little worse than usual. When I went to the bathroom, there was a lot of blood. I've never had that before, and it scared me. I've had to go to the bathroom a couple times this morning, and it's all blood." The ED nurse collects the following data:

BP: 138/88 mm Hg
Pulse: 104 beats/min and regular
Respiratory rate: 20 breaths/min
Temperature: 36.7°C (98.0°F)
Oxygen saturation: 98%

The ED nurse assesses that Mr. Singh is mildly anxious. His breath sounds are clear, but his abdomen is tender in the left lower quadrant (LLQ). The nurse draws blood to be sent to the lab. While they are waiting for the lab results, Mr. Singh tells the nurse, "My stomach is cramping down low, and I need to go to the bathroom." She provides him with a bedpan. He passes approximately 200 mL of bright red blood with a small amount of fecal material. He becomes sweaty and lightheaded after the BM. The nurse rechecks his vital signs and

(Continued)

Meet Your Patient (continued)

notes that his BP is now 120/76 mm Hg and that his pulse is up to 120 beats/min. The nurse shows the ED physician the bloody bowel movement and updates him on the change in vital signs. When the ED physician examines Mr. Singh, he tells Mr. Singh that he will need to be admitted to the hospital for further evaluation of the bleeding.

You are the nurse assigned to care for Mr. Singh on the medical-surgical unit. Mr. Singh has been sent from the ED directly to radiology for a computed tomography (CT) scan of his abdomen. The scan reveals a tumor in the sigmoid colon. Since leaving the ED, Mr. Singh has had three more bloody bowel movements. His blood pressure is 100/72 mm Hg, and his pulse rate is now 134 beats/min. The physician prescribes a bolus of 1,000 mL of lactated Ringer's solution and a unit of packed red blood cells as soon as it is available. Mr. Singh is scheduled for colon resection surgery, which will occur as soon as the surgical team can be assembled and the room prepared.

ABOUT THE KEY CONCEPTS

The overarching concept for this chapter is **perioperative nursing**, which includes the key concepts of **preoperative**, **intraoperative**, and **postoperative care**. To help you understand and remember those concepts, we discuss in this chapter how to prepare a client for surgery and the activities that occur before, during, and after surgery, as we follow Mr. Singh (Meet Your Patient) through his perioperative experience. We will present definitions and examples of the key concepts as well as numerous sub-concepts that relate to each other in various ways. We begin with perioperative nursing.

PERIOPERATIVE NURSING

Perioperative nursing involves the care of clients before, during, and after surgery and some other invasive procedures. Historically, perioperative nursing practice was called "operating room nursing" and was limited to transferring patients into and out of operating rooms and handing instruments to surgeons during surgical procedures. Now nurses in all phases of the operative experience actively provide and manage care, teach, and study the care of perioperative patients.

The Association of periOperative Registered Nurses (AORN) is one of the most highly organized and influential specialty organizations within the nursing profession. AORN *Standards and Recommended Practices* (2009, updated 2011) keep perioperative nurses up to date on current practice. For additional information about AORN,

Go to the **AORN Web site,** at http://www.aorn.org

Perioperative Safety

An important aspect of the perioperative nursing role is to help prevent complications of surgery. Hand hygiene is an important component of prevention (Box 39-1). Preventable perioperative errors cause 10% of surgery-related deaths, have an unfavorable financial impact on healthcare institutions, and result in physical and emotional harm to patients (Agency for Healthcare Research and Quality [AHRQ], 2008). Various government and private organizations stress the importance of patient safety:

- ***The Association of periOperative Registered Nurses (AORN, 2009, updated 2011).*** Perioperative Safety is one of the four domains under which AORN organizes its perioperative patient outcomes (the others are Physiological Responses, Family and Individual

BOX 39-1 ■ Recommended Practices for Hand Hygiene

- Perform hand hygiene:
  - Immediately before and after each patient contact
  - After removing gloves. Wearing gloves does not substitute for hand hygiene.
  - Anytime you may have come in contact with blood or potentially infectious substances
  - Before and after eating
  - After using the restroom
- Remove rings, watches, and bracelets before performing hand hygiene.
- Preferably, do not wear rings. They have been associated with a significant increase in skin microorganism count.
- Keep fingernails short and clean. They should not extend beyond the fingertips.
- Replace nail polish when it is chipped or at least every 4 days.
- Do not wear artificial nails. Fungal growth often occurs under them.
- Be certain there are no lesions or breaks in skin integrity on your hands.
- For handwashing and handrub procedures,

Go to Chapter 23, **Procedure 23-1: Hand Hygiene,** in Volume 2.

Sources: Adapted from AORN (2009, updated 2011); Boyce & Pittet (2002); Siegel, Rhinehart, Jackson, et al. (2007).

Behavioral Responses, and Health System). Specific safety outcomes include prevention of injury and freedom from infection.

- ***The Joint Commission (2012).*** The Joint Commission National Patient Safety Goals for 2012 applicable to surgery include preventing infection, improving the accuracy of patient identification, using medication safely, and performing a time-out immediately before starting procedures to prevent mistakes in surgery (right surgery on right site on right patient).
- ***The National Priorities Partnership (NPP) (2011).*** The NPP National Quality Forum established a national priority that includes the aims of achieving better care, providing improved health for people and communities, and making quality care more affordable. One of its six national priorities and goals is making care safer by reducing harm caused in the delivery of care.
- ***The Institute for Healthcare Improvement (IHI) (n.d., 2011).*** This is an independent, not-for-profit organization that works to reduce morbidity and death in American healthcare, including perioperative care. One goal of its 100,000 Lives Campaign and its 5 Million Lives Campaign was to reduce surgical complications and specifically surgical infections. To see the entire list of IHI recommendations,

Go to Chapter 23, **Tables, Boxes, Figures: ESG Box 23-1, The 100,000 Lives Campaign,** on Davis*Plus*.

"Never Events"

"Never events" are serious and costly errors resulting in severe consequences for the patient, and that are mostly preventable. Believing these events are reasonably preventable and should never happen in a hospital, Medicare will no longer reimburse institutions for care related to such complications (Centers for Medicare & Medicaid Services, 2006, updated 2008, 2011). Several of the never events (also called serious reportable events) are also targeted by the national organizations listed earlier. Among the never events important to perioperative care are

- Surgery on the wrong body part
- Surgery on the wrong patient
- Wrong surgery on a patient
- Deep vein thrombosis (DVT) or pulmonary embolism (PE) after total knee or hip replacement
- Foreign body left in a patient after surgery (e.g., sponge, clip for draping)
- Surgical site infections after certain elective procedures (e.g., bariatric surgery for obesity). AORN, The Joint Commission, NPP, and IHI extend that to include all infections. The Centers for Disease Control and Prevention (CDC) targeted certain antimicrobial-resistant bacterial infections.

You will see those themes recur in the theoretical and practical knowledge in the remainder of this chapter and in Volume 2.

PREOPERATIVE CARE

The **preoperative phase** begins with the client's decision to have surgery and ends when he enters the operating room.

Theoretical Knowledge knowing why

Nursing care during the preoperative phase focuses on identifying existing health concerns, planning for intraoperative and postoperative needs, and providing preoperative teaching. Preoperative nursing care is delivered in a variety of settings. More than two-thirds of surgeries in the United States are performed in outpatient settings, such as endoscopy suites, physicians' offices, and ambulatory surgery centers (Cullen, Hall, & Golosinskiy, 2009). The length of the preoperative period and the extent of the patient teaching depend on the type of surgery to be done and the patient's overall health status.

How Are Surgeries Classified?

Knowing the type of surgery helps you identify the patient's perioperative needs and plan patient care. Surgeries can be classified by body system, purpose, level of urgency, and acuity. The classifications often overlap.

By Body System

The body system classification is useful for determining the postoperative risk of infection. For example, surgical incisions that enter the gastrointestinal, respiratory, or genitourinary tract have a higher risk for infection than does surgery of other body systems. However, if an organ ruptures or surgery is required to repair a penetrating injury, the risk of infection is very high regardless of the body system involved. Mr. Singh (Meet Your Patient) will have surgery of the gastrointestinal system.

By Purpose

See whether you can identify the purpose that describes Mr. Singh's (Meet Your Patient) surgery.

- **Ablative surgery** involves removal of a diseased body part. For example, a cholecystectomy removes a diseased gallbladder.
- **Diagnostic (exploratory) surgery** is done to confirm or rule out a diagnosis. Examples include a biopsy, a fine-needle aspiration, or invasive testing, such as a cardiac catheterization.
- **Palliative surgery** is performed to relieve discomfort or other disease symptoms without producing a cure. Examples include nerve root destruction for chronic pain.
- **Reconstructive surgery** is performed to restore function, for example, rotator cuff repair (repair of a torn ligament).

- **Cosmetic surgery** is done to improve appearance (e.g., a face-lift).
- **Transplant surgery** replaces a malfunctioning body part, tissue, or organ. Joint replacements and organ replacement procedures are included in this category.
- **Procurement surgery** is related to transplant surgery. An organ or tissue is harvested from someone pronounced brain dead for transplantation into another person.

By Degree of Urgency

Based on the following definitions, how would you describe the degree of urgency for Mr. Singh's surgery?

- **Emergency surgery** requires transport to the operating suite as soon as possible to preserve the patient's life or function. The surgical team is summoned and preparations are made rapidly. Internal hemorrhage, rupture of an organ, and trauma are common causes of emergency surgery.
- **Urgent surgery** is scheduled within 24 to 48 hours to alleviate symptoms, repair a body part, or restore function. Removal of a cancerous breast and internal fixation of a fracture are examples.
- **Elective surgery** is performed when surgery is the recommended course of action, but the condition is not time sensitive. The client may delay surgery to gather information, consider options, or organize care for the family. Examples include repair of a torn ligament, removal of rectal polyps, or a rhinoplasty (repair of the nose).

By Degree of Risk

There is an old adage that "the only minor surgery is someone else's surgery." This statement reflects the anxiety that often accompanies surgery. Nevertheless, surgery is defined as major or minor based on the degree of seriousness or risk associated with the procedure. The degree of risk varies with the condition of the client as well as with the type of surgery.

Major surgery is associated with a high degree of risk. For example, it may be associated with the potential for significant blood loss, involve vital organs, be a prolonged or complicated procedure, or have significant potential for postoperative complications. Some examples of major procedures are coronary artery bypass graft (CABG), organ transplantation, nephrectomy (removal of a kidney), and colon resection. **Minor surgery**, often performed on an outpatient basis, involves little risk and usually has few complications. Examples include arthroscopy, breast biopsy, and inguinal hernia repair.

What Factors Affect Surgical Risk?

The patient's age, general health, and personal habits can contribute to increased risk during any surgical procedure.

Age The very young and very old are at greatest risk during surgical procedures. *Infants* have limited ability to regulate temperature and have immature immune, cardiovascular, liver, and renal systems. They are also at greater risk for infection, excess fluid volume, and deficient fluid volume. Even minor blood loss may represent a substantial portion of the infant's blood. In addition, infants may have difficulty calming. They are unable to understand what is happening, so you cannot use verbal reassurance and explanations to comfort them.

Toddlers understand simple explanations but may be anxious about separation from parents or caregivers. Many have fear of the dark. *Preschoolers* fear damage to body parts. Fear of pain or of needles is common for children of any age. *Teens* might fear disfigurement resulting from scars. *Young adults* commonly are anxious about the cost associated with hospitalization or surgery.

Older adults are at increased risk because they have less physiological reserve and often have comorbid conditions (other illness not related to the surgery). Many of the physiological changes of aging predispose older adults to increased risk. Among these changes are decreased kidney function, diminished immune function, decreased bone and lean body mass, increased peripheral vascular resistance, decreased cardiac output, decreased cough reflex, and increased time required for wound healing.

Type of Wound Both preexisting wounds (e.g., from trauma) and the wounds (incisions) created by the surgical procedure can pose a risk for infection (Table 39-1). Risk to the patient increases along with the risk for or presence of infection. Which type of wound will Mr. Singh have immediately after surgery?

Preexisting Conditions The ideal surgical candidate is a healthy young adult who takes no medications. Unfortunately, many surgical clients have underlying acute or chronic disorders that increase surgical risk (Box 39-2). Also see the accompanying PICOT box.

Mental Status Patients with altered cognition, from either physical or mental illness, may be unable to comprehend preoperative instructions or give informed consent for surgical procedures. They may also require medications (e.g., antipsychotic agents) that interact with anesthetics and analgesics given in the perioperative period. Surgery and anesthesia may aggravate preexisting dementia, confusion, and disorientation.

Medications Both prescribed and over-the-counter medications may increase surgical risk (Box 39-3). For example, patients who self-prescribe vitamin E may be at increased risk for bleeding. Certain herbal and alternative medications can:

- Increase the risk for cardiac dysrhythmias secondary to potassium loss.
- Interfere with metabolism of anesthetics because of their effects on the liver.

Table 39-1 ➤ Wound Type and Potential for Infection

WOUND TYPE	WOUND CHARACTERISTICS	EXAMPLES OF SURGERY ASSOCIATED WITH THE WOUND
Clean Wounds	Uninfected; minimal inflammation; little risk of infection AND Surgery does not involve the gastrointestinal, respiratory, or genitourinary tract.	Face-lift, cataract surgery, joint replacement, breast biopsy, tonsillectomy
Clean-Contaminated Wounds	Not infected, but carry increased risk for infection	Surgical incisions that enter the gastrointestinal, respiratory, or genitourinary tracts
Contaminated Wounds	Not infected, but carry high risk for infection	Surgery to repair trauma to open wounds, such as compound fractures; surgery in which a major break in surgical asepsis occurred
Infected Wounds	Evidence of infection, such as purulent drainage, necrotic tissue, or bacterial counts above 100,000 organisms per gram of tissue	A postoperative surgical incision of any type that has evidence of infection

BOX 39-2 ■ Preexisting Conditions That Increase Surgical Risk

Chronic Conditions

Cardiovascular diseases (such as hypertension, congestive heart failure, and myocardial infarction) affect the ability of the heart to work as an efficient pump. If these disorders are well controlled (e.g., with blood pressure medications or cardiotonic medications), risk is limited.

Coagulation disorders delay clotting and increase blood loss, placing the patient at risk for hemorrhage and hypovolemic shock. In contrast, a hypercoagulation state increases the risk of stroke, embolism, or intravascular clotting.

Chronic respiratory disorders (such as emphysema, asthma, or bronchitis) decrease pulmonary function, increase the risk of respiratory infection, and may be exacerbated (made worse) by general anesthesia.

Renal disease affects the patient's ability to excrete many medications, including anesthetic agents. It also affects the ability to regulate fluid and electrolytes.

Diabetes mellitus delays wound healing and increases the risk of infection and cardiovascular disorders associated with diabetes.

Liver disease affects the body's ability to metabolize amino acids, carbohydrates, and fat; to manufacture prothrombin for clotting; and to detoxify medications. Therefore, the patient is at increased risk for poor wound healing, hemorrhage, and toxic reactions to anesthetics and medications.

Neurological disorders (such as paralysis or spinal cord injury) increase the risk for vasomotor instability and thus create the potential for wide swings in blood pressure. In addition, patients with seizure disorders are more likely to have a seizure in the perioperative period.

Nutritional disorders can affect surgical outcomes. Patients who are malnourished or obese are at risk for delayed wound healing, infection, and fatigue. Obese clients are also more prone to cardiovascular disorders and impaired pulmonary function.

Acute Conditions

Upper respiratory tract infections are associated with increased risk of postoperative pneumonia, especially if the patient receives a general anesthetic.

Acute infections tax the patient's energy and physiological reserves, increasing the risk for various postoperative complications.

- Increase the potential for excessive bleeding.
- Decrease cerebral blood flow.
- Cause hypertension.
- Increase the effects of opioids and sympathetic nervous system stimulants.

For a list of herbal products and associated surgical risks,

Go to Chapter 39, **ESG Box 39-1,** on Davis*Plus*.

Personal Habits Substance abuse can increase surgical risk. Smoking affects pulmonary function; long-term alcohol use contributes to liver disease, predisposing the patient to bleeding. Alcohol and drugs interact with anesthetic agents and medications to create adverse effects. Also, habitual substance abusers may have a cross-tolerance to anesthetic and analgesic agents, causing them to need higher than normal doses.

Allergies Patients may be allergic to medications (e.g., antibiotics, such as penicillins or cephalosporins), analgesics (e.g., codeine), tape, latex, and solutions used in surgery. Reactions range from unpleasant to life-threatening.

BOX 39-3 ■ Medications That Increase Surgical Risk

Antibiotics	May potentiate the action of anesthetic agents.
Anticoagulants	Increase risk for bleeding.
Antidysrhythmics	May impair cardiac function during anesthesia.
Antihypertensives	Increase the risk for hypotension during surgery; may interact with anesthetic agents to cause bradycardia and impaired circulation.
Aspirin	Increases risk for bleeding.
Corticosteroids	Delay wound healing and increase risk for infection.
Diuretics	Alter fluid and electrolyte balance (especially potassium balance).
Opioids	Increase the risk of respiratory depression.
NSAIDs	Inhibit platelet aggregation, increasing the risk for bleeding.
Tranquilizers	Increase the risk of respiratory depression.

KnowledgeCheck 39-1

- Define *preoperative phase*.
- What are four ways surgery can be classified?
- What factors affect surgical risk?

ThinkLike a Nurse 39-1

How would you evaluate Mr. Singh's (Meet Your Patient) surgical risk? What additional information do you need to answer this question?

PracticalKnowledge knowing how

The nursing focus in the preoperative phase is to prepare the patient for surgery. You will use the nursing process to identify any unique nursing diagnoses a patient might have. However, many perioperative nursing interventions are routine preventive measures that you will use for *all* surgical patients.

Perioperative Nursing Data Set

The Perioperative Nursing Data Set (PNDS) is a standardized vocabulary specifically designed to describe the care of perioperative patients. It is the first nursing language developed by a specialty organization that has been recognized by the American Nurses Association (ANA). The latest update of PNDS reflects the nursing process including nursing assessment, diagnoses, identified nursing-sensitive outcomes, nursing interventions, and implementation and evaluation. The PDNS promotes better communication among nurses and other healthcare providers, increases visibility of

PICOT

Older Adults, Comorbidity, and Risk for Surgical Site Infection

Situation: The student is caring for an elderly patient who is four days postoperative after a colon resection. The abdominal incision is reddened, with purulent yellow drainage on the dressing. The patient has a history of chronic obstructive pulmonary disease (COPD), and obesity (BMI of 31).

PICOT Components

P	Population/patient	=	Older adults
I	Intervention/indicator	=	Chronic disease and comorbidity
C	Comparator/control	=	No health problems
O	Outcome	=	Increased risk of incision infection
T	Time	=	After surgery

Searchable Question

Do ________ (P) who receive/are exposed to ________ (I), as compared to ________ (C), demonstrate ________ (O) during ________ (T)?

Example of Evidence: Surgical site infections (SSIs) account for roughly 11% of hospital-acquired infections in patients age 65 and older. Older people who experience SSIs tend to have a worse clinical outcome than do younger adults. Researchers evaluated cases of elderly patients with SSIs, and identified several independent predictors of surgical site infections. These include obesity, COPD, congestive heart failure, American Society of Anesthesiologists grade of ≥3, wound class >2, and socioeconomic factors.

Application to Practice: Patients with these risk factors can be identified preoperatively, and nursing care adjusted to decrease the potential for SSIs.

Source: Kaye, K., Sloane, R., Sexton, D., et al. (2006). Risk factors for surgical site infections in older people. *Journal of the American Geriatrics Society, 54*(3), 391–396. doi:http://dx.doi.org/10.1111

nursing interventions, improves patient care, and standardizes a way to evaluate nursing care outcomes (Peterson & Kleiner, 2011).

In this chapter, we continue to use the NANDA-I, NOC, and NIC standardized languages, to which you have already been introduced in previous chapters.

Perioperative Patient-Focused Model The PNDS is derived from the Perioperative Patient-Focused Model. The patient is at the center of the model and the focus of care. The perioperative nurse intervenes within the context of the healthcare system to assist the patient throughout the perioperative experience to achieve outcomes in the Health System domain and the Patient-Centered domains (which include Safety, Physiological Responses to Surgery, and Behavioral Responses to Surgery).

The Health System domain refers to the system in which perioperative care is given. It involves administrative and structural elements necessary for successful surgical outcomes—for example, equipment, supplies, staff, and policies (AORN, 2009, updated 2011).

ASSESSMENT

For patient safety, patient data must be correct and complete. To prevent omission of important information, many organizations have developed a preoperative checklist. Although the forms may vary at each institution, the areas for assessment are the same and are discussed in the sections that follow.

Focused Nursing History

It is essential to determine whether the client is physiologically, cognitively, and psychologically prepared for the intraoperative and postoperative phases of surgery. For an accurate nursing history, collect assessment data from the client, significant others, medical records, and other members of the healthcare team. Include the following topics in your preoperative assessment: health history, physical status, allergies, medications (including herbal products and over-the-counter medications), mental status, knowledge and understanding of the surgery and anesthesia, cultural and spiritual factors, access to social resources, coping strategies, and use of alcohol and drugs. It is also important to elicit patients' values and expressed needs (see the accompanying Quality and Safety Education for Nurses box).

To see an example of a preoperative assessment form developed by the AORN,

Go to Chapter 39, **Assessment Guidelines and Tools, Example of a Preoperative Checklist,** in Volume 2.

Additional assessments may be needed if the client is undergoing outpatient surgery or has a planned short stay after surgery (see the Home Care box Preoperative Assessment for the Surgical Client Who Will Be Discharged to Home).

Quality and Safety Education for Nurses

Quality and Safety for Perioperative Patients

Chapter Key Concepts: *Perioperative Nursing, Preoperative Care, Intraoperative Care, Postoperative Care*

Competency: *Patient-Centered Care*

Eliciting each patient's values, preferences, and expressed needs as part of the focused nursing history will assist you in meeting the QSEN (2012) competency of patient-centered care. You can then communicate patient values, preferences, and expressed needs to other members of the healthcare team to assure patient-centered care with sensitivity and respect for the diversity of individual patients.

Competency: Teamwork and Collaboration

To provide for effective participation within nursing and inter-professional teams, nurses must foster open communication, mutual respect, and shared decision making with the goal of quality patient care (Cronenwett, Sherwood, Pohl, et al., 2007).

Surgical briefings encourage team members to talk when there is no problem, so they are more likely to speak up when they have misgivings when problems occur (Hendrickson, Wadhera, & El Bardissi, 2008). Two-minute briefings led by the attending surgeon, using a standardized format, just before surgery have been found to improve communication and reduce delays and wrong-site surgery (Makary, Mukherjee, Sexton, et al., 2007).

To see a description of the knowledge, skills, and attitudes you need for achieving this competency,

Go to the QSEN Web site, at www.qsen.org/ksas_prelicensure.php

Home Care

Preoperative Assessment for the Surgical Client Who Will Be Discharged to Home

The type of surgery, the client's condition, and the support system determine whether it is safe to discharge a client to home after surgery. Your assessment for home care should focus on these questions:

- What kind of care will be needed?
- Is the client able to take care of himself? If not, who is available to assist with care?
- Does the caregiver have the necessary skills to provide care?
- If not, can these skills be taught before the client is discharged?
- What features in the home environment will facilitate the client's progress? What features will inhibit progress? For example, can the client get to the bathroom? Can the client negotiate the stairs in the house?
- How will the client be followed after discharge? That is, how soon should he visit his physician? Will he receive home nursing care?

Focused Physical Assessment

If you identify risk factors from the nursing history, focus on these aspects during your brief head-to-toe physical assessment. For example, if the patient states she had a cough last week, perform a focused assessment of the ear, nose, throat, and lungs to determine how the cough may affect the patient's risk. If the patient has lower airway congestion, as evidenced by rhonchi and productive cough, communicate these findings to the surgeon and the anesthesia team; if a general anesthetic is planned, it may be necessary to delay the surgery. For all patients, assess risk factors for thrombophlebitis, as venous thrombus is one of the never events that can lead to potentially life-threatening pulmonary emboli. For additional details on a brief (bedside) physical assessment, see Chapter 22.

Recent guidelines state that optimal preoperative assessment of older adults include:

- cognitive ability
- capacity to understand the surgery
- nutritional status
- risk factors for postoperative delirium and pulmonary complications
- patient's treatment goals and expectations
- family and social support system
- depression
- cardiac status
- functional status
- history of falls
- detailed medication history, including polypharmacy
- baseline frailty score
- diagnostic tests specific to elderly patients (Chow, Ko, Rosenthal, et al., n.d.)

Diagnostic Testing

Preoperative screening tests are usually prescribed before surgical procedures. The type of testing depends on the patient's age, health history, and facility policies. For example, most institutions require a complete blood count and urinalysis before surgery, as well as an electrocardiogram for patients older than age 50. Routine chest radiology (x-ray) is not recommended for all patients prior to surgery. Chest x-ray incurs extra costs to the healthcare system and exposes patients to small risks from radiation exposure (National Guideline Clearinghouse [NGC], 2011). Patients with chronic health problems, including cardiopulmonary disease, may require additional testing.

Age alone is not a risk factor for postoperative complications, but older adults with multiple comorbidities (other medical conditions), such as cardiovascular or pulmonary disease, may be at risk for postoperative complications. Further preoperative screening may be ordered for older adults to identify risk factors for perioperative and postoperative complications and to optimize patient condition prior to surgery.

Go to Chapter 39, **Diagnostic Testing: Common Preoperative Screening Tests,** in Volume 2.

KnowledgeCheck 39-2

- List the information you should gather in the preoperative nursing history.
- What type of physical assessment is performed as part of the preoperative assessment?
- What laboratory tests are most commonly prescribed before surgery?

ThinkLike a Nurse 39-2

- What factors will affect your preoperative assessment of Mr. Singh (Meet Your Patient)?
- Describe how you might perform the assessment as well as provide physical care. What modifications, if any, should you make in his assessment?

ANALYSIS/NURSING DIAGNOSIS

As you learned in Chapter 4, nursing diagnoses describe the individualized needs of patients. However, preoperative patients share a common set of needs, regardless of their individual differences and the type of surgery they are to have. Consider the following examples:

- All preoperative patients need preoperative teaching, so it's not necessary to write a nursing diagnosis of Deficient Knowledge for every patient. Agency protocols or critical pathways will almost certainly mandate teaching.
- Almost all surgical patients have at least mild anxiety, and many of your routine actions will help to relieve anxiety, so there is no need to always include a diagnosis of Anxiety.

Key Point: ***Do not put any nursing diagnosis on the care plan unless you plan to address it with something other than the routine preoperative interventions.***

Individualized Nursing Diagnoses

Individualized nursing diagnoses for the preoperative patient evolve from your assessment. You should identify an actual nursing diagnosis only if the patient has the defining characteristics for it. Identify risk (potential) diagnoses only if the patient has an underlying condition that places him at higher risk than the average surgical patient. The following NANDA-I nursing diagnoses may be useful for certain preoperative patients:

- ***Anxiety*** may be mild, moderate, severe, or at panic level. In the preoperative client, anxiety may be related to the current change in health status or due to concerns about being unable to provide care for loved ones. Make this diagnosis only if the client has symptoms such as restlessness, trembling, increased pulse, and other defining characteristics.
- ***Fear*** is a common reaction to surgery. Fear may be related to the unknown outcome of the surgery, to learning the diagnosis after a diagnostic procedure, and to the prospect of pain during and after surgery. Fear

and Anxiety share several defining characteristics. Many of the routine preoperative interventions help to address Fear.

- ***Ineffective airway clearance*** may be used for patients who have a preexisting health problem, such as bronchitis or emphysema.
- ***Disturbed Sleep Pattern*** often results from anxiety about the upcoming surgery.
- ***Ineffective Coping*** may be appropriate for a patient with extreme anxiety and concerns about the outcomes of the surgery.
- ***Latex Allergy Response*** is appropriate for patients who have a known allergy to latex.
- ***Risk for Latex Allergy Response*** is appropriate for patients who have had multiple surgeries or urinary catheterizations; are in professions with daily exposure to latex; have a history of asthma; or are allergic to bananas, avocados, kiwi, chestnuts, or poinsettia plants. Do not use it routinely for all patients.
- ***Deficient Knowledge.*** As you know, you do not usually need a Deficient Knowledge diagnosis. If you believe the patient may not learn, or that the information is too complex to remember, then identify the problem likely to result from the Deficient Knowledge. For example:

  Ineffective Management of Therapeutic Regimen related to Deficient Knowledge of postoperative medications and office visits

  Risk for Infection related to Deficient Knowledge of wound care and asepsis

Special Risks for Older Adults

Older adults, especially those older than age 70 and the frail elderly, are likely to need some individualized nursing diagnoses. They present unique risks not only because they often have other illnesses, but also because of certain physiological changes of aging. For example, older adults metabolize anesthetic agents differently from younger adults (see Table 39-2)

ThinkLike a Nurse 39-3

Which, if any, of the preceding nursing diagnoses would be most appropriate for Mr. Singh (Meet Your Patient)? Do not use the potential complications in Table 39-2. Explain your reasoning.

Table 39-2 ➤ Special Risks for Older Adults

RISK FACTORS	POTENTIAL COMPLICATIONS (PC) AND NURSING DIAGNOSES
Most older adults have at least some degree of coronary artery disease.	▪ PC: Hypotension ▪ Risk for Falls secondary to orthostatic hypotension
Delirium is one of the most common surgical complications in older adults. Predisposing factors include being older than 75 years, preoperative hyperglycemia or hypoglycemia, psychological distress, preoperative cognitive impairment, inadequate nutrition, and functional impairment (Brooks, 2012)	▪ PC: Delirium
Age-related respiratory changes, such as decreased chest wall compliance, forced vital capacity, and diaphragmatic strength	▪ PC: Pneumonia ▪ PC: Atelectasis
Age-related skin changes: Dry, fragile skin; decreased turgor and elasticity	▪ Risk for Impaired Skin Integrity ▪ Risk for Impaired Tissue Integrity
Age-related musculoskeletal changes: Decreased bone mass and muscle fiber mass	▪ Risk for Impaired Mobility ▪ Risk for Falls
Comorbidities of the central nervous system are more common in older adults. Some conditions may be aggravated by surgery and anesthesia.	▪ PC: Dementia ▪ Risk for Acute Confusion
Age-related decrease in gastrointestinal motility	▪ PC: Ileus ▪ Risk for Aspiration secondary to vomiting
Age-related decreases in genitourinary function: decreased bladder tone, elasticity, and tone; decreased renal function	▪ PC: Side effects of medications ▪ PC: Renal complications ▪ PC: Urinary tract infection ▪ Risk for Impaired Skin Integrity r/t urinary incontinence

PLANNING OUTCOMES/EVALUATION

The overall nursing goal in the preoperative phase is to prepare the patient adequately for surgery and to deliver him to the operating suite in the best condition possible. Outcomes that provide evidence of achieving this goal, and that are appropriate for nearly all preoperative patients, are that the patient:

- Is able to describe his surgical procedure in a basic manner.
- Provides informed consent.
- When asked, states what he can expect in the postoperative period.
- States he has very little anxiety.

Associated NOC outcomes for the preoperative nursing client depend, of course, on the nursing diagnoses you identify. For outcomes and goals using NOC terminology for the diagnoses Anxiety, Fear, Deficient Knowledge, and Disturbed Sleep Pattern, and for *individualized goals/outcome statements* you might write for those diagnoses,

Go to Chapter 39, **Standardized Language, Preoperative Patients—Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

PLANNING INTERVENTIONS/IMPLEMENTATION

For *NIC standardized interventions* designed to achieve the expected outcomes for the nursing diagnoses of Anxiety, Fear, Deficient Knowledge, and Disturbed Sleep Pattern,

Go to Chapter 39, **Standardized Language, Preoperative Patients—Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

Many preoperative nursing activities are routine interventions to be used for *all* preoperative patients, regardless of their nursing diagnoses. NIC has a special Perioperative Care domain (category) for such interventions. The following are the preoperative NIC interventions in that domain:

- ***Preoperative Coordination:*** Facilitating preadmission diagnostic testing and preparation of the surgical patient. (Activity example: Notify the physician of abnormal diagnostic test results.)
- ***Surgical Preparation:*** Providing care to a patient immediately before surgery and verifying required procedures/tests and documentation in the clinical record. (Activity example: Complete the preoperative checklist.)
- ***Teaching: Preoperative:*** Assisting a patient to understand and mentally prepare for surgery and the postoperative recovery period. (Activity example: Correct unrealistic expectations of the surgery, as appropriate.)

The following sections explain in more detail how to carry out routine interventions such as obtaining informed consent for the surgery, providing preoperative teaching, communicating with the surgical team, preparing the client physically, and transferring to the operating suite. Be sure to include parents and caregivers in your plan of care.

Confirm That Surgical Consent Has Been Obtained

Before a surgical procedure is performed, professional standards and the law require the surgeon to obtain the patient's informed consent. The signed consent form verifies that the surgeon and patient have communicated adequately about the surgery (Dale, Rothrock, & McEwen, 2011). Once signed and witnessed, the consent form is part of the patient's record and accompanies him to the operating room.

Key Point: ***The surgeon is responsible for (1) giving the patient the necessary information and (2) determining the patient's competence to make an informed decision about the surgery. You are responsible for verifying that the surgical consent form is signed and witnessed.***

Often you will obtain the signature and document on the preoperative checklist that you have done so. As a patient advocate, you should first verify with the patient that the physician has explained the procedure and answered all his questions: Ask the patient to state what he was told during the consent process. If the patient has questions or if you have any questions about the patient's competence, notify the surgeon, and delay sending the patient to surgery. Be sure to document these conversations, and document in the nursing notes that the surgeon was notified of any additional questions or concerns.

The surgical consent form includes the following information (The Joint Commission, 2010):

- The type of surgery being performed
- The name and qualifications of the person performing the surgery (e.g., Jason Esmar, MD) and the primary practitioner for the patient's care and treatment
- A statement that the risks and benefits of surgery, as well as reasonable alternatives, have been explained to the patient
- A statement of the relevant risks, benefits, and side effects of the alternatives
- The likelihood of achieving goals
- A statement that the patient has the right to refuse surgery or withdraw consent at any time
- When indicated, any limitations on the confidentiality of information about the patient

Informed consent requires that the patient understood the communication and was not coerced (pressured) to consent. The patient must be alert, rational, mentally competent, and not sedated when he signs; and the information must be given to him in a language and vocabulary that he can understand. Patients who are unconscious or have a mental disability; who have been judged insane; who cannot read, write, or hear; and those under the influence of sedative drugs or alcohol are generally not competent to give consent (Buppert, 2012). In most states a family member, conservator, or legal guardian may give consent for the procedure. If you would like more information on informed consent, see Chapters 44 and 45.

Informed consent helps protect patients from having a surgery they do not understand or want, and the signed document protects the healthcare agency and workers from later claims that the patient did not consent to have the procedure.

KnowledgeCheck 39-3

- Who is responsible for obtaining informed consent for the surgical procedure?
- What are the nursing responsibilities related to informed consent?

Provide Preoperative Teaching

Preoperative teaching prepares the patient for the surgical experience, allays fears, and decreases the risks of postoperative complications. See Chapter 19 as needed to review patient teaching.

What to Teach

The content of the teaching plan should focus on:

- What will happen before, during, and after surgery
- How the patient or caregiver can participate in the care
- Common feelings and concerns that patients have about surgery. This helps the patient feel supported and less anxious.
- What patients and families can do to prevent surgical site infection (The Joint Commission, 2012). Teach patients the content in the Self-Care box Teaching Patients How to Help Prevent Surgical Site Infections.

The type of surgery influences the content of your teaching. For example, if the patient is scheduled for an outpatient knee arthroscopy (visualization of the joint) under spinal anesthesia, the teaching plan needs to describe the procedure and the anticipated discharge of the patient within hours after surgery. This is different from the teaching for a patient who will have cardiac surgery and spend a number of days in the hospital. You will find specific teaching content in the teaching interventions for the Deficient Knowledge diagnosis, in the Standardized Language table in Volume 2. Also refer to Clinical Insight 39-1, in Volume 2.

Go to Chapter 39, **Standardized Language, Preoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

Go to Chapter 39, **Clinical Insight 39-1: Preoperative Teaching,** in Volume 2.

Self-Care

Teaching Patients How to Help Prevent Surgical Site Infections

Before Surgery

- If you smoke, stop. Those who smoke are more likely to get infections.
- Discuss your health problems with your surgeon (e.g., diabetes, allergies). These can affect incision healing.
- Ask your surgeon whether you should have antibiotics before surgery.
- Don't shave near where you will have surgery. Not all procedures require hair removal, but if they do, it should be done with electric clippers. If someone starts to use a razor to shave you, speak up.

After Surgery

- Be sure family and friends wash their hands or use alcohol-based handrub before and after they visit you.
- When anyone examines you or checks your incision ask them if they have washed their hands (or used alcohol-based handrub).
- Wash your hands before and after caring for your own incision.
- Do not allow family and friends to touch your incision or the surgical dressing.
- Be sure you know how to care for your incision before you go home.
- If you have fever or redness, pain, or drainage at the surgery site, call your physician right away.

Source: Adapted from Centers for Disease Control and Prevention. (n.d., updated 2011). Having surgery? What you should know before you go. Retrieved from http://www.cdc.gov/features/SafeSurgery/

For the complete steps of deep breathing, coughing, moving in bed, and leg exercises,

Go to Chapter 39, **Procedure 39-1: Teaching a Patient to Deep-Breathe, Cough, Move in Bed, and Perform Leg Exercises,** in Volume 2.

How to Teach

You can use written instructions, video presentations, phone contact, or face-to-face discussion to provide preoperative teaching. Teach in a language the patient understands and at a level that is easily understood. Use terms the patient understands clearly—that is, avoid medical jargon. See Chapter 19 if you need to review patient teaching techniques and information about health literacy.

Obtain an interpreter for translation if the patient speaks a language that you do not speak. When possible, avoid using family members as translators to protect the patient's privacy or avoid a bias in translation (see Chapter 15 if you need more information about language differences).

Include family members in the teaching as much as possible and as much as desired by the patient, especially if the patient is a child or dependent adult. So that the child better understands what will happen before, during, and after surgery, you might teach using dolls or age-appropriate toys. Play is an effective way for children to learn (e.g., have the child give medicine to her doll with an empty syringe or listen to its "heart" with your stethoscope). Simple language is a must! For example, you'd say to a young child, "Lie on your tummy, please."

Older adults may experience physical, psychological, and/or psychosocial issues that impair their ability to learn. Decreased hearing, vision, and sense of touch may interfere with their ability understand and remember information. To increase understanding, provide an environment conducive to learning, allow for more time for the patient to process information, and provide written material that clearly conveys the essentials.

When to Teach

For elective surgery, many patients have a scheduled preoperative assessment about a week before the surgery. The session may include preoperative testing, an appointment with the anesthesia staff, signing the consent form, and planned preoperative teaching.

Patients undergoing emergency surgery usually require extensive physical care preoperatively. You may need to give IV fluids, transfuse blood, treat for pain, and administer many medications, as in the case of Mr. Singh (Meet Your Patient). Because of the urgency of some surgeries, you may have limited time for preoperative teaching. However, you should always teach the patient as much as possible to prepare him for the surgical experience.

Prepare the Patient Physically for Surgery

Physical preparation of the patient for surgery involves several nursing concerns.

Maintaining Normothermia Recent evidence-based guidelines stress that maintaining a normal body temperature helps produce good surgical outcomes (Hooper, Chard, Clifford, et al., 2010; Joanna Briggs Institute, 2010). In addition to monitoring temperature, you can provide passive thermal care measures, such as providing blankets, socks, and head coverings; and keeping the room temperature at or above 75°F (24°C). If the patient is hypothermic you can use forced-air warming gowns or mattresses to pre-warm patients before surgery as well as in the intraoperative and postoperative periods.

Nutritional Status Anxiety and anesthesia reduce gastrointestinal motility. To decrease the risk of nausea and vomiting, patients usually fast, taking no food or liquids (NPO) for 8 hours before surgery. Stress to patients and family the importance of fasting (for the prescribed length of time) to avoid the danger of aspiration. You should know, though, that years of evidence support shorter fasting times than you will see used in most institutions. The American Society of Anesthesiologists preoperative fasting guidelines for healthy patients recommends ingesting clear liquids up to 2 hours before surgery—and even a light meal up to 6 hours before surgery (Crenshaw, 2011; "Practice Guidelines for Preoperative Fasting," 2011).

Skin Preparation Depending on the surgery and facility, patients may be asked to shower or scrub the surgical site with soap or an antibacterial solution (e.g., 4% chlorhexadine gluconate, Betadine) the evening before surgery and the morning of the surgery. Studies demonstrate that this reduces bacterial colonization on the skin, but do not clearly prove that it reduces surgical infection (National Guideline Clearinghouse [NGC], 2008a; National Institute for Health and Clinical Excellence [NICE], 2008). Final skin preparation and hair removal, if done, should be completed before taking the patient into the surgical suite.

Bowel Preparation Enemas are now used primarily for surgical procedures of the colon, not for all surgeries. To empty the colon of feces, patients are asked to consume a low-residue diet for several days before surgery and are given a regimen of medications and/or enemas to clear the bowel. Stress the importance of adhering to the regimen to limit the risk of contaminating the operative site with feces.

Urinary Elimination Indwelling catheters are not routinely inserted for surgery. Catheterization may be prescribed if it is important to keep the bladder empty during surgery, if fluid status is being carefully monitored, or if surgery is expected to last for a prolonged period of time.

If a catheter is not prescribed, have the patient void before receiving preoperative medications. The patient could fall if he gets out of bed to use the bathroom after being sedated or given opioids for pain.

Preoperative Medications The anesthesiologist may prescribe preoperative medications to relax the patient, reduce respiratory secretions, or reduce the risk of vomiting and aspiration (Table 39-3). If the surgery time is known, the medication is prescribed at a prearranged time (e.g., at 0615). If not, it may be prescribed to give "on call." You will give the on-call medication when the surgical suite staff notifies you it is time to do so.

Antibiotics are often administered prophylactically to help prevent postoperative infections in patients before:

- clean surgery involving the placement of a prosthesis or implant
- clean-contaminated surgery
- contaminated surgery

Table 39-3 ➤ Preoperative Medications

TYPE OF MEDICATION	USE	EXAMPLES
Antibiotics	Reduce the microbial burden of intraoperative contamination to a level that cannot overwhelm host defenses	Cephalosporins (e.g., cefazolin, cefoxitin), clindamycin, vancomycin
Anticholinergics (e.g., phenothiazines)	Reduce oral and pulmonary secretions, prevent laryngospasms, prevent bradycardia	Atropine (Atropisol), chlorpromazine (Thorazine), scopolamine (Hyoscine), glycopyrrolate (Robinul)
Anxiolytics (e.g., benzodiazepines)	Control anxiety, calming	Alprazolam (Xanax), clonazepam (Klonopin), diazepam (Valium), lorazepam (Ativan), midazolam (Versed)
Antihistamines	Provide sedation and antiemetic effects	Hydroxyzine (Vistaril), diphenhydramine (Benadryl)
Barbiturates	Provide sedation without significant cardiopulmonary depression	Secobarbital (Seconal), pentobarbital (Nembutal)
H_2 receptor antagonists	Reduce gastric acidity	Cimetidine (Tagamet), ranitidine (Zantac)
Hypnotics	Provide sedation and increase the duration of sleep	Temazepam (Restoril)
Neuroleptics	Provide sedative, antiemetic, and anticonvulsant effects	Droperidol (Inapsine), Innovar (fentanyl and droperidol)
Opioid analgesics	Provide pain relief and sedation; induce anesthesia	Fentanyl (Sublimaze), meperidine (Demerol), morphine (Duramorph)

You will usually administer the antibiotic intravenously timed so that a bactericidal concentration of the drug will be present in the serum and tissues by the time the incision is made (usually within the hour preceding incision, just as the patient is going to the surgical suite (NGC, 2008a; NICE, 2008). Antibiotics may, instead, be given at the start of anesthesia and repeated if the surgery is longer than the duration of the antibiotic.

Routine Medications Many routine medications are held (not administered) on the day of surgery. For example, an insulin-dependent diabetic patient may be instructed to hold her morning injection or administer half of the normal dose. The patient needs less insulin because her NPO status will keep her blood sugar lower than usual. The anesthesiologist will monitor the blood sugar in the operating room and give additional insulin if needed. Some patients may be instructed to stop routine medications several days before surgery. For example, a client receiving warfarin for anticoagulation may need to stop the medication 7 days before surgery.

Prostheses Before being transported to the operating suite, the patient must remove all artificial body parts, such as dentures, artificial limbs, or contact lenses. Wigs, eyeglasses, makeup, and jewelry must also be removed.

Antiembolism Stockings Also referred to as thromboembolic disorder hose (or "TED hose"), **antiembolism stockings** are elastic stockings that compress the veins of the legs and increase venous return to the heart (Fig. 39-1). They may be applied preoperatively to prevent venous pooling during surgery and decrease the risk of thrombus formation. Along with prophylactic medications (antithrombotics), antiembolism stockings aid in the prevention of DVT and PE (*Morbidity and Mortality Weekly Report*, June 8, 2012). However, hospitals are increasingly using sequential compression devices and anticoagulation therapy, instead of elastic stockings, to prevent DVT (Perry, Borchert, Burke, et al., 2012).

FIGURE 39-1 Antiembolism stockings compress the veins of the legs and increase venous return to the heart.

Older adults and those with risk factors for venous thromboembolism are most in need of antiembolism stockings (Bartley, 2006). Risk factors include the following conditions (AORN, 2009, updated 2011):

- Venous stasis (such as occurs with bedrest, lengthy surgery, varicose veins, and heart failure)
- Vascular wall injury, which initiates clotting (e.g., surgery, IV catheter, irritating IV drugs, prior DVT, smoking).
- Hypercoagulability (e.g., estrogen therapy, oral contraceptive use, cancer, dehydration, pregnancy)

Older adults may be at higher risk for DVT because they have more than one of these risk factors. Safety measures to prevent DVT in older adults include range-of-motion (ROM) exercises and applying antiembolism stockings to prevent pooling of blood in the extremities (Bashaw & Scott, 2012)

Antiembolism stockings may extend from foot to knee, or foot to thigh, although the Institute for Clinical Systems Improvement (ICSI) suggests that thigh-high stockings be avoided because of their tendency to roll and restrict circulation (Perry, Borchert, Burke, et al., 2012). Some stockings have an opening at the toes that allows you to assess circulation in the feet.

Stockings must be sized and applied correctly to be effective. Stockings are contraindicated for some patients (e.g., those with peripheral arterial disease) (The Joanna Briggs Institute, 2008b; Winslow & Brosz, 2008).

The procedure for applying antiembolism stockings is summarized in the Highlights of Procedures box. For complete steps,

Go to Chapter 39, **Procedure 39-2: Applying Antiembolism Stockings,** in Volume 2.

Take Measures to Prevent Wrong Patient, Wrong Site, Wrong Surgery

The following safety measures will help prevent patient misidentification and wrong-site surgery (The Joint Commission, 2012; Reid, 2011):

- Use a preoperative checklist to confirm that appropriate documents are available and the appropriate activities have been performed.
- Verify the patient's identity before the patient leaves the preoperative area.
- Mark the surgical site before surgery. Use a permanent marker that will not be removed by the surgical skin prep, and involve the patient in the marking process.
- Take a time-out with all team members before starting the procedure (see Perioperative Safety, near the beginning of this chapter).

Communicate With the Surgical Team

The most common root cause of medical errors is communication failure (AHRQ, 2003). For this reason, good communication is essential for patient safety in perioperative care. The following are elements of successful communication among the surgical team. Team members:

- Receive a summary of the plan of care (e.g., a short briefing by the surgeon) and develop a shared understanding of the plan.
- Speak up and are assertive with concerns about the procedure or decisions.
- Ask questions to clarify confusion.
- Acknowledge that they have heard and understood.
- Ask for and provide feedback (e.g., read back) on critical information.
- Use standard terminology (e.g., checklists). In one large, long-term study, use of surgical checklists was found to reduce the number of deaths from surgery by more than 40% (Haynes, Weiser, Berry, et al., 2009).

Two-minute briefings just before surgery, led by the attending surgeon using a standardized format, have been found to improve communication and reduce delays and wrong-site surgery (Makary, Mukherjee, Sexton, et al., 2007). Surgical briefings encourage team members to talk when there is no problem, so they are more likely to speak up when they have misgivings or when problems occur (Hendrickson, Wadhera, & El Bardissi, 2008).

Also see the preceding Quality and Safety Education for Nurses box.

KnowledgeCheck 39-4

- Identify topics that should be discussed in preoperative teaching.
- Describe the typical physical preparation of a client undergoing surgery.

ThinkLike a Nurse 39-4

- What aspects of preoperative teaching should you stress when caring for Mr. Singh (Meet Your Patient)?
- A bowel preparation is typically part of preoperative preparation for a client having colon surgery. Do you think this will be part of Mr. Singh's physical preparation? Why or why not?

Transfer Patient to the Operative Suite

Once you have completed your preoperative care, the patient is ready for transport by stretcher to the operative area, usually to the surgical holding area (Fig. 39-2). The completed preoperative checklist and the patient's chart must accompany the patient. Lock up valuables according to agency policy, or have the patient's family keep them. Occasionally, especially if the patient has a significant sensory deficit, the patient can wear his hearing aid or glasses to the surgical suite. You will need to arrange this in advance with the surgical staff or anesthesia team.

Often children are permitted to bring a favorite toy with them to the operating room (OR) to provide comfort.

FIGURE 39-2 Surgical holding area.

Children may fear being separated from their parents, so arrange for parents to spend time with the child immediately before the surgery and as soon as possible after the surgery. Keep the parents informed, and let them know what to expect.

Prepare the Postoperative Room

If you transfer the patient to the surgical suite from a nursing unit in the hospital, you should prepare the room for the patient's return after surgery. Put clean linens on the bed and arrange the supplies and equipment you will need. For an illustration and complete instructions;

Go to Chapter 39, **Clinical Insight 39-2: Preparing a Room for a Patient's Return From Surgery,** and Chapter 11, **Clinical Insight 11-1, Preparing the Room for a Newly Admitted Patient,** in Volume 2.

INTRAOPERATIVE CARE

The **intraoperative phase** begins when the patient enters the operating suite and ends when she is admitted to the postanesthesia care unit.

TheoreticalKnowledge knowing **why**

To provide intraoperative care, you will need theoretical knowledge of the roles of the various members of the intraoperative team and of the different types of anesthesia that are used.

Operative Personnel

The personnel who attend the client during the surgical procedure are called the *intraoperative team*. The team is divided into members who must use sterile technique and those who use clean technique (see Chapter 23 if you need to review medical and surgical asepsis). During the intraoperative phase, a registered nurse can function as the scrub nurse, circulating nurse, or registered nurse first assistant. Each of these roles contributes to the safe care of surgical clients.

Sterile Team Members of the sterile intraoperative team include the surgeon, surgical assistant, and scrub person. Before beginning the surgery, they perform a surgical scrub of the hands and arms, dry with sterile towels, and don sterile gowns and gloves. To review these procedures, see Chapter 23.

The **scrub nurse** can be an RN, LVN/LPN, or a surgical technician. The scrub nurse sets up the sterile field, prepares the surgical instruments, assists with the sterile draping of the patient, anticipates and responds to the surgeon's needs, and maintains the integrity of the sterile field. The **registered nurse first assistant (RNFA)** is an RN with additional education and training in surgical technique and is also part of the sterile team. The RNFA serves as an assistant to the surgeon, a role that has historically been filled by physicians. The RNFA may be employed by the surgeon or the hospital.

Sterile team members are the only persons allowed to enter the sterile field. The sterile field encompasses the client and the area immediately surrounding the client. Creation of the operative field is explained in:

Chapter 39, **Clinical Insight 39-3: Creating an Operative Field,** in Volume 2.

Clean Team Team members who abide by clean technique (medical asepsis) include the anesthesiologist or nurse anesthetist, the circulating RN, biomedical technicians, and radiology technicians. These personnel never enter the sterile field, but instead function around and beyond it.

An **anesthesiologist** or a **nurse anesthetist (CRNA)** induces amnesia, analgesia, and muscle relaxation or paralysis with anesthesia. His role is to continuously monitor and evaluate the patient's responses to the anesthetic agent and the surgical procedure. CRNAs administer more than half of all anesthetics in the United States.

The **circulating nurse** is a registered nurse who applies the nursing process to coordinate all activities in the operating room. She is a strong client advocate who continuously monitors the client and the sterile field. The circulating nurse maintains a safe, comfortable environment, communicates with appropriate personnel outside the operating room, manages care of the intraoperative client, and responds to emergencies. An important aspect of the circulating nurse's role is to attend to the patient during the induction of anesthesia.

KnowledgeCheck 39-5

- Identify the intraoperative nursing roles that are part of the sterile intraoperative team and those that are part of the clean intraoperative team.
- Which nursing roles are always held by a registered nurse?

Toward Evidence-Based Practice

White, J., Khan, W., & Smitham, P. (2011) Perioperative implications of surgery in elderly patients with hip fractures: An evidence-based review. *Journal of Perioperative Practice, 21*(6), 192–197.

Older adults are at higher risk for complications following surgery owing to many factors including comorbidities and a depressed physiological state. Older adults are also more likely to experience poor postoperative pain management, pressure ulcer development, venous thromboembolism, and postoperative confusion/dementia. The authors reviewed current research studies to develop an evidence-based approach to decrease complications in the postoperative period. To improve outcomes for older adults, the authors recommend that they are put in the best physiological state prior to having surgery, are cared for by a multidisciplinary team approach, and experience careful and frequent assessment to identify risks factors and changes in their condition. Evidence-based management of patient complications is essential to assure the best outcomes possible.

Egol, K. A., & Strauss, E. J. (2009). Perioperative considerations in geriatric patients with hip fracture: What is the evidence? *Journal of Orthopedic Trauma, 23*(6), 386–394.

Managing the care of geriatric patients with hip fractures is complex. Based on the findings from a review of current research studies from the American Association of Orthopedic Surgeons' Task Force on Serving the Elderly Orthopedic Patient, the authors recommend a collaborative approach to care including the orthopedic surgeon, the geriatrician, the nursing staff, therapists, pharmacists, nutritionists, and pain management specialists. A collaborative approach has been shown to decrease the rate of perioperative complications, including deep vein thrombosis, uncontrolled pain, pressure ulcer development, malnutrition, and surgical site infection. The authors identified the goal of care of early mobilization as a way to minimize complications and help the patient attain the highest functional status possible.

1. As a nurse caring for older adults on your surgical unit, what could you include in your preoperative assessment that may help you to identify older adults at risk for postoperative complications?

2. Based on the information in the research articles and the Quality and Safety Education for Nurses (QSEN) project, identify ways you could address the QSEN competency of *Teamwork and Collaboration*.

Go to Chapter 39, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

Types of Anesthesia

During surgery, anesthesia is used to obtain analgesia (control of pain), muscle relaxation or paralysis, and amnesia (memory loss). Anesthesia is classified as general, conscious sedation, or regional.

General Anesthesia

General anesthesia produces rapid unconsciousness and loss of sensation. The anesthesiologist or nurse anesthetist administers inhaled and intravenous medications that depress the patient's central nervous system (CNS) and relax the musculature. Muscle relaxants, paralyzing agents, narcotics, barbiturates, and inhaled gases are some of the agents used during general anesthesia.

Advantages of General Anesthesia

- The patient is unconscious, so she experiences no anxiety that might affect cardiac and respiratory functioning.
- The muscles are relaxed, so the patient remains completely motionless during the surgical procedure.
- Anesthesia can be adjusted to accommodate the length of the procedure and the patient's age and physical condition. For example, an older adult may require less anesthetic than anticipated; if so, the anesthetist can decrease the dosage without interrupting the procedure.

Also, if complications occur, the anesthesia can be continued for longer than originally planned.

Disadvantages of General Anesthesia

- The respiratory and circulatory muscles are depressed, so mechanical ventilation is needed while the patient is under the effects of the anesthetic agent(s). These effects predispose the patient to pneumonia and thrombophlebitis in the postoperative period.
- General anesthesia creates a risk for death, heart attack, stroke, and malignant hyperthermia. **Malignant hyperthermia** is a rare, often fatal, metabolic condition that can occur during the use of muscle relaxants and inhalation anesthesia. Metabolism increases in the skeletal muscles, and they become rigid. The temperature rises rapidly. Predisposition to this condition is inherited.
- Frequent minor complaints after general anesthesia include sore throat (from intubation), nausea and vomiting (from relaxation of gastrointestinal smooth muscle), headache, uncontrollable shivering, and confusion.

Conscious Sedation

Conscious sedation is an alternative form of anesthesia that provides intravenous sedation and analgesia without producing unconsciousness. During conscious sedation, the patient may feel sleepy but is aware of his surroundings, can be easily aroused by touch or speech, and can talk with the surgical team. Nevertheless, blood pressure, heart rate, respiratory rate, and oxygen saturation are monitored, and the patient usually receives oxygen via nasal cannula during the procedure. Because of the amnesic effect of many of the medications, the patient may not recall aspects of the procedure afterward. Advantages are that (1) pain and anxiety are adequately controlled without the risks of general anesthesia, and (2) recovery is rapid. Conscious sedation is used for procedures such as bronchoscopy and cosmetic surgery, but it is not practical for highly anxious patients.

Regional Anesthesia

Regional anesthesia prevents pain by interrupting nerve impulses to and from the area of the procedure. The patient remains alert but is numb in the involved area. Regional anesthesia may be administered by infiltration of the surgical site and surrounding tissue with local anesthetics, such as lidocaine (Xylocaine) or bupivacaine (Marcaine). These medications may also be injected into and around specific nerves to depress the sensory, motor, and/or sympathetic impulses of a limited area of the body.

Regional anesthesia is low in cost, is simple to administer, and requires a minimal recovery period. It is especially suitable for minor ambulatory procedures. However, many patients are apprehensive about being able to see and hear the procedure. Regional anesthesia may not be practical if the patient is highly anxious or if adequate pain control cannot be achieved. Techniques for achieving regional anesthesia include the following.

Peripheral Nerve Block

A **nerve block** is the injection of an anesthetic into and around a nerve or group of nerves (e.g., the facial nerve, the brachial plexus). A **Bier (intravenous) block** is a nerve block technique in which the anesthetist places a tourniquet on an arm or leg, and then injects a local anesthetic agent intravenously below the level of the tourniquet. The tourniquet is maintained at a pressure that limits venous return but continues to allow arterial circulation. The patient feels no pain in the extremity as long as the tourniquet is in place. Advantages of the Bier block are its rapid onset and recovery time. Also, the tourniquet decreases bleeding during the surgical procedure and prevents systemic absorption of the local anesthetic. However, when the procedure is finished, the tourniquet is deflated, and there is potential for systemic absorption of the anesthetic. To prevent tissue damage, the tourniquet must not be left in place for more than 2 hours.

Spinal Anesthesia

Spinal anesthesia is the injection of an anesthetic into the cerebrospinal fluid (CSF) in the subarachnoid space (Fig. 39-3A). This injection blocks sensation and movement below the level of the injection. Spinal anesthesia is often used for surgical procedures in the lower abdomen, pelvis, and lower extremities. This technique allows the patient to remain conscious during the procedure and usually does not depress respirations. Occasionally a higher level of spinal anesthesia is achieved than intended—that is, the medication may migrate upward in the spinal fluid. This can depress respirations and cardiac rate. Placing the patient in Fowler's position may prevent respiratory paralysis.

Side effects of spinal anesthesia include hypotension, nausea, vomiting, urinary retention, or a headache from leakage of CSF. A headache after spinal anesthesia must be closely monitored and may require additional treatment by the anesthesia staff.

The blood pressure may also decrease suddenly due to pervasive vasodilatation—the anesthesia blocks the sympathetic vasomotor nerves, which normally maintain muscle tone in peripheral blood vessels. Patients with these complications often require ventilation and support of blood pressure during surgery, so they must be carefully monitored during surgery and in the recovery period.

Epidural Anesthesia

Epidural anesthesia requires insertion of a thin catheter into the epidural space (Fig. 39-3B). Anesthetic agents are infused through the catheter to produce loss of sensation. Epidural anesthesia can be used as a surgical anesthetic and to provide postoperative analgesia. Advantages and disadvantages of epidural anesthesia are similar to those of spinal anesthesia. Epidural anesthesia is safer than spinal anesthesia because the anesthetic does not enter the subarachnoid space and the depth of anesthesia is not as great. However, drugs intended for epidural administration are of a higher concentration than those for spinal administration; so if the medication is inadvertently injected too deeply (into the subarachnoid space), hypotension and respiratory paralysis occur, and temporary mechanical ventilation is necessary.

Epidural anesthesia is ideal for obstetrics procedures (e.g., cesarean birth or pain control with vaginal birth) because the mother is awake to bond with the newborn, and her mobility is limited for only a short time.

Local Anesthesia

Local anesthesia produces loss of pain sensation at the desired site (e.g., a wound to be sutured, a skin growth to be removed). It is typically used for minor procedures. However, after finishing a major surgery, the surgeon may infiltrate the operative area with local anesthetics to provide postoperative pain relief. Local anesthetics may be applied topically or injected. A **topical anesthetic** is applied directly to the skin and mucous membranes. Lidocaine (Xylocaine) and benzocaine (Orajel, T-caine) are commonly used because they are rapidly absorbed and rapid-acting.

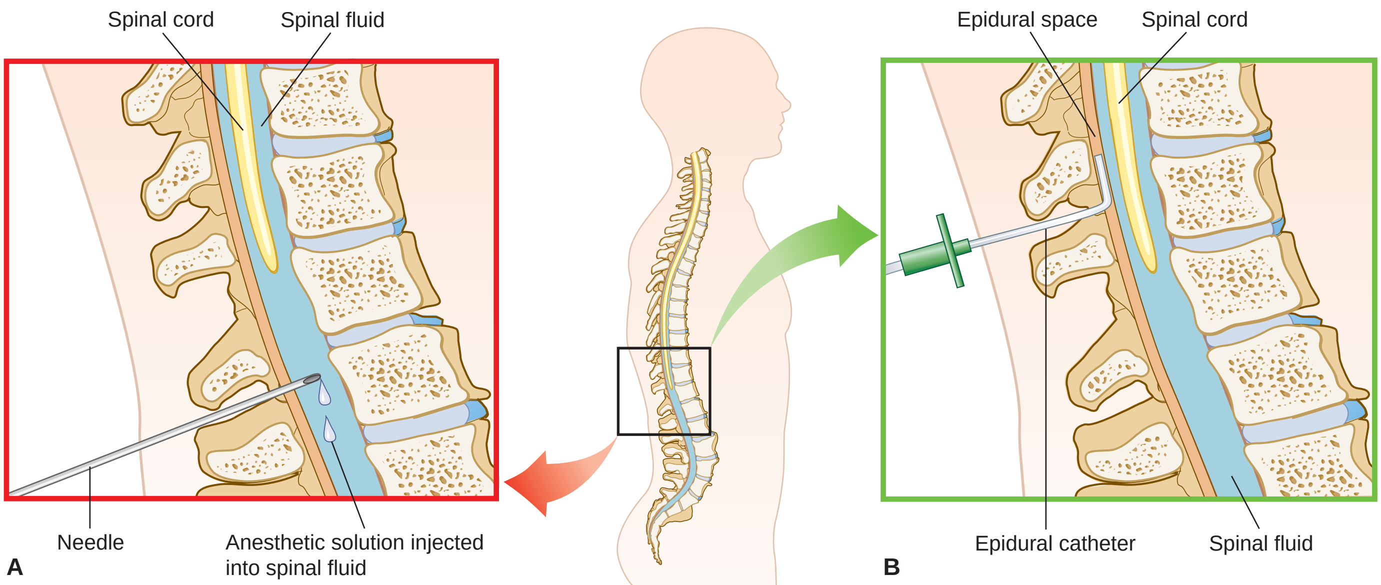


FIGURE 39-3 *A*, Spinal anesthesia is the injection of a local anesthetic into the subarachnoid space to block sensation and movement. *B*, Epidural anesthesia can also be used to provide continuous postoperative analgesia.

KnowledgeCheck 39-6

- What is the purpose of anesthesia?
- Under what type(s) of anesthesia does the client remain conscious?

ThinkLike a Nurse 39-5

What form of anesthesia is Mr. Singh (Meet Your Patient) most likely to receive? Why?

PracticalKnowledge knowing how

When a patient arrives in the surgical suite, the nurse verifies the information on the preoperative checklist and assesses the patient. The nursing focus is on safe and successful completion of the surgery.

ASSESSMENT

The circulating nurse greets the client in the preoperative holding area and performs a brief assessment. The nurse first verifies that the surgical consent has been signed and witnessed and that the preoperative checklist is complete. The nurse then assesses the client's anxiety level and physical condition. The next steps are to measure the vital signs; examine the surgical site; and inspect IV lines, drainage tubes, and catheters. Often the circulating nurse or the anesthetist starts an IV line in the holding area if one is not already present. A preoperative medication may be given in the holding area. Vital signs are monitored often, or even continuously, during the intraoperative period.

For common interview questions to use in the intraoperative period,

Go to Chapter 39, **Assessment Guidelines and Tools, Intraoperative Care Questionnaire,** in Volume 2.

In addition to the checklist completed in the preoperative period, the surgery team will also complete a checklist, with one staff member functioning as the checklist coordinator. The World Health Organization (WHO, 2009) checklist covers three phases of a surgical procedure:

- Before Induction of Anesthesia
- Before Skin Incision
- Before Patient Leaves the Operating Room

Commonly referred to as "sign in," "time out," and "sign out," the three phases of the surgical checklist are reviewed by the checklist coordinator, who verbally checks that each element was done. The goal of using a surgical checklist is to enhance communication, teamwork, and safety by addressing key activities that occur as part of the perioperative process.

To see the complete WHO checklist,

Go to Chapter 39, **Assessment Guidelines and Tools, Example of a Surgical Safety Checklist,** in Volume 2.

ANALYSIS/NURSING DIAGNOSIS

As in the preoperative phase, most intraoperative nursing care consists of standard activities to be used for all patients. Most intraoperative patients, regardless of the surgery, have the following potential complications (collaborative problems) of surgery and anesthesia:

- Potential complications of surgery:
  Hypothermia
  Fluid and electrolyte imbalance
  Excessive bleeding or hemorrhage
  Musculoskeletal injury secondary to positioning
- Potential complications of anesthesia:
  Aspiration
  Vasomotor instability (and resultant hypotension and diminished peripheral perfusion)

Respiratory depression
Cardiovascular compromise

Except in unusual circumstances (e.g., a patient in poor nutritional status, a frail elderly patient), you may not need to identify nursing diagnoses for a patient because the standardized care addresses all the potential complications. However, for nurses who prefer to organize care according to nursing diagnoses, the following potential diagnoses apply to most patients having major surgery:

- *Risk for Imbalanced Body Temperature* related to exposure in cool environment and administration of cool IV fluids. This applies especially to very young, very old, and very thin patients.
- *Risk for Aspiration* related to depressed respirations and reflexes. For patients who have weak muscles for coughing or a poor gag reflex, this diagnosis is especially relevant.
- *Risk for Imbalanced Fluid Volume* related to NPO status and blood loss from surgery. Some patients are at higher than normal risk, for example, patients with renal or cardiac problems.
- *Risk for Perioperative Positioning Injury* related to patient factors such as edema, emaciation, obesity, and sensory perceptual disturbances secondary to anesthesia.

Use the following nursing diagnoses only if the patient has the necessary defining characteristics or risk factors. Do not use them for all patients.

- *Risk for Latex Allergy Response* related to multiple exposures (e.g., multiple surgeries, catheterizations) or history of related allergies
- *Latex Allergy Response* (needs no etiology)

PLANNING OUTCOMES/EVALUATION

The overarching goals in the intraoperative phase are that the patient will:

Be free from injury
Remain physiologically stable
Experience optimal surgical outcomes

For *associated NOC standardized outcomes* for intraoperative patients, along with examples of goals created with NOC indicators and scales,

Go to Chapter 39, **Standardized Language, Intraoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

Notice that the goals are appropriate for nearly all surgical patients.

Individualized goals/outcome statements are formulated from the patient's nursing diagnoses. The following are examples:

- Maintains body temperature within the normal range.
- Has clear lung sounds and patent airway.
- Has urine output of at least 30 mL/hr.
- Will have no skin, tissue, or neuromuscular injury as a result of positioning.
- Will not acquire healthcare-related infection.

PLANNING INTERVENTIONS/IMPLEMENTATION

Intraoperative care focuses on maintaining a safe environment and assisting the surgery team to provide appropriate care for the client. The nurse anesthetist manages the interventions for most of the patient's potential problems, for example, fluid volume status, airway protection, and vital signs monitoring.

NIC standardized interventions for the intraoperative period come from the domain of Perioperative Care. They include interventions for all intraoperative patients, regardless of their individual nursing diagnoses. One intervention, Anesthesia Administration, must be performed by an anesthesiologist or nurse anesthetist. The nurse assists in implementing a number of interventions:

- Anesthesia Administration
- Autotransfusion
- Infection Control: Intraoperative
- Positioning: Intraoperative
- Surgical Assistance
- Surgical Precautions
- Surgical Preparation
- Temperature Regulation: Intraoperative

For NIC *standardized interventions for specific intraoperative nursing diagnoses*,

Go to Chapter 39, **Standardized Language, Introperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

Notice, however, that most of the interventions apply to all surgical patients and are subsumed by (or fall under) the preceding NIC Perioperative Care interventions. As in all patient care, you should be always mindful of using hand hygiene. Sterile asepsis is an important focus in the intraoperative period; you can review that in Chapter 23.

The following sections explain in more detail how to carry out "routine" interventions, such as providing skin preparation, positioning, and intraoperative safety measures. **Key Point:** ***Note that "routine" in this context means that the activities are planned and performed for all patients. Nursing interventions are* never *routine in the general sense; they must always be performed with thought and skill.***

Skin Preparation

Surgical skin preparation reduces the risk of postoperative wound infection by reducing the microbial count at the operative site. Skin preparation may begin in the preoperative phase, when the client cleanses the skin with an antimicrobial solution the evening before and the morning of surgery. The intraoperative nurse provides additional skin preparation as follows:

Assess the Skin Assess skin for signs of infection, rash, or other forms of skin irritation. Document the condition of the skin on the intraoperative record.

Remove Hair From the Site Only If Necessary Historically, the surgical site was always shaved. Now, however, you will remove hair only if there is a large amount of it in the area of the surgery or if the surgeon specifies a preference for hair removal. Hair removal increases the risk of abrasions or nicks in the skin, which can provide a portal of entry for bacteria. If you do remove hair, you will likely do it in the preoperative holding area immediately before surgery to reduce the time for bacterial growth. Use clippers or depilatory cream to trim hair because they are less likely than a razor to cause skin irritation (The Joanna Briggs Institute, 2007).

Cleanse the Surgical Site In the operative suite, skin preparation precedes draping of the client. Using sterile technique, cleanse the surgical site and a generous part of surrounding area with the recommended anti-infective solution. Povidone-iodine (Betadine) is commonly used for the scrub; then the skin is painted with Betadine solution. If the client is allergic to iodine, use an alternative preparation solution.

Positioning

The position of the patient in the OR is determined by the surgical site, access to the patient's airway, the need to monitor vital signs, comfort, and safety. A position that is ideal for accessing the surgical site may not be used if any of the other factors are compromised. If the patient has preexisting injuries or discomfort, factor this information into the decision about how to position. For example, a patient with chronic cervical spine pain may be positioned using a neck roll.

The patient is usually positioned after anesthesia has begun. Use straps, wedges, pillows, and surgical table attachments to maintain the position during the surgery. To prevent shearing, lift—do not slide—the patient into position. In many cases, the surgical team assists with positioning.

The circulating nurse is responsible for preventing positioning injuries. Surgical patients often spend 3 to 4 hours, or even longer, in the same position. This places them at risk for pressure ulcer formation. Some anesthetic agents decrease tissue perfusion, further increasing the patient's risk for sustaining positioning injuries. Padding the bony prominences is one measure to protect the client during surgery. For nursing interventions to address the NANDA-I diagnosis Risk for Perioperative Positioning Injury,

Go to Chapter 39, **Standardized Language, Intraoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

Intraoperative Safety Measures

Just before starting any surgical or invasive procedure, you should conduct a final verification process to confirm the correct patient, procedure, and site (The Joint Commission, 2012). The circulating nurse is responsible for a variety of other measures that protect the patient in the intraoperative phase. These measures are briefly explained here.

Assist the Scrub Nurse to Prepare and Maintain the Sterile Field The circulating nurse gathers surgical supplies and equipment for use during surgery. She then works with the scrub nurse to transfer the supplies to the sterile field.

Provide Supplies and Materials During Surgery If additional supplies are needed during surgery, the circulating nurse obtains them and opens them on the sterile field. Supplies may include dressings, surgical equipment, medications, irrigating solutions, or sutures.

Monitor Intake and Output of the Client Together with the anesthetist, the circulating nurse monitors the fluid infused, urine output, drainage, and blood loss.

Handle Specimens The circulating nurse handles specimens and sends them to the lab or pathology for evaluation after the surgery is complete. The surgeon may sometimes obtain a tissue sample that must be analyzed during the operative procedure. The circulator receives the specimen, coordinates with the pathologist to review the sample, and reports the pathology findings to the surgeon.

Perform Sponge, Sharps, and Instrument Counts

The circulating nurse and the scrub nurse count the material that is added to the sterile field. As the surgery comes to an end, a repeat count is performed to ensure that no instruments, sponges, or sharps are left inside the client. A retained sponge can lead to infection and additional surgeries. A major surgery, such as a heart surgery, can use several hundred sponges. Once soaked in blood, sponges can blend in with the body cavity and be difficult to see. Some agencies are now using sponges with barcodes, which the nurse scans before and after use. The system alerts the surgical team if they are left behind. In another system, chip-embedded sponges rely on radiofrequency identification technology to count sponges and locate any that are left behind.

Document Record the care provided and the client's response to care on the surgical record. Usually you will use a graphic or a checklist form, perhaps with some space for narrative notes about anything the form does not address.

KnowledgeCheck 39-7

- For what activities is the circulating nurse responsible in the surgical suite prior to the skin incision?
- Describe six intraoperative safety measures performed by the circulating nurse.

ThinkLike a Nurse 39-6

What special concerns, if any, do you have about Mr. Singh (Meet Your Patient) during the intraoperative phase of care?

POSTOPERATIVE CARE

The postoperative phase begins when the client enters the postanesthesia care unit and ends when he has healed from the surgical procedure. This phase consists of two parts: recovery from anesthesia and recovery from surgery.

TheoreticalKnowledge knowing why

When the surgical procedure is complete, members of the surgical team prepare the client for transfer to the postanesthesia care unit (PACU), also called the recovery room (Fig. 39-4).

Recovery From Anesthesia

The first postoperative phase is often known as the *postanesthesia phase* or the *immediate postoperative phase*. This phase begins when the client is transferred from the operating table to a bed (or gurney) for transport to the PACU. During this phase, the client is at high risk for respiratory and cardiovascular compromise. As a precaution, the anesthetist and the circulating nurse accompany the client and attend to her needs during transport to the PACU. They are also responsible for giving a comprehensive report to the PACU nurse.

The PACU, located near the OR, is typically an open unit that allows nurses to observe clients easily. PACU nurses have specialized education and experience in caring for postoperative clients. Commonly, nurses working in the PACU have experience in critical care. The PACU nurse receives a comprehensive report from the anesthesia provider and circulating nurse (see Box 39-4):

FIGURE 39-4 Postanesthesia care unit.

Recovery From Surgery

The second phase of postoperative care begins when the patient is discharged from the PACU and admitted to the surgical nursing unit. The patient is transported to the surgical unit only after he has recovered from anesthesia and his condition is stable. The goal of this phase is to facilitate healing and prevent postoperative complications.

PracticalKnowledge knowing how

In the next sections we discuss nursing care associated with both phases of postoperative care.

Nursing Care in the Postanesthesia Care Unit

The PACU nurse performs a quick, focused initial assessment of the surgical patient in the presence of the anesthesia provider and circulating nurse. After that, she assesses the patient every 5 to 15 minutes. AORN (2009, updated 2011) has identified the essential elements of assessment in the PACU.

For that information

Go to Chapter 39, **Assessment Guidelines and Tools, Postanesthesia Assessment: Essential Elements**, in Volume 2.

BOX 39-4 ■ Information Contained in the Report From the Surgical Suite

- Procedure performed
- Type of anesthesia
- Medications administered in the surgical suite
- Duration of the procedure and anesthesia
- Postoperative vital signs
- Pulse oximetery values
- Allergies
- Lab values
- Estimated blood loss
- Fluid intake and output, including urine, stool, gastric losses
- Preoperative mobility status, skin integrity, and sensory perception abilities
- Surgical complications
- Presence of tubes, drains, catheters
- Existing IV lines
- Postoperative prescriptions

An unconscious client is usually positioned on his side to help maintain an open airway. This decreases the likelihood of aspirating mucus or saliva by allowing it to drain out instead of back into the throat. Elevating the superior arm on a pillow allows for good chest expansion so the patient can breathe deeply and expand the lungs fully.

NIC: Postanesthesia Care. The only postoperative intervention from NIC's Perioperative Care category is Postanesthesia Care. Postanesthesia Care encompasses the preceding assessments and adds measures such as providing for safety and administering oxygen. Many patients arrive in the PACU with an artificial airway or endotracheal tube in place. The client remains in the PACU until the PACU nurse determines that he has recovered from the effects of anesthesia (Box 39-5) and is able to maintain his own airway. She then removes the airway and transfers the patient to the surgical unit.

For *NIC interventions* for other postoperative nursing diagnoses:

Go to Chapter 39, **Standardized Language, Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

BOX 39-5 ■ Evidence of Recovery From Anesthesia

Airway—The patient is able to maintain a patent airway independently and to deep-breathe, cough, and expectorate secretions.

Level of consciousness—The patient is conscious and easily reoriented. Often patients will drift off to sleep between arousals; however, they easily reorient and are generally aware of circumstances and surroundings.

Vital signs—Vital signs are stable and within an acceptable range. The blood pressure may be markedly different from that taken during the immediate preoperative measures, because BP is often elevated preoperatively. This can also be caused by anxiety, pain, and not administering routine BP medications because of NPO status. The patient may require medication to control pain or BP before he can be discharged from the PACU.

Mobility and sensation—The patient is able to move all extremities that he could move preoperatively. The patient regains movement and sensation once spinal or epidural anesthesia has worn off.

Fluid balance (I&O)—The patient is urinating at least 30 mL/hr and is in relative fluid balance. Consider blood loss, urine output, gastric drainage, and emesis when calculating fluid balance.

Dressings and drains—Dressings are dry and intact, or wound drainage is considered appropriate for the procedure. The patient should have no overt signs of excessive blood or fluid loss before he is transferred to the surgical unit.

Postoperative Nursing Care on the Surgical Unit

The assigned nurse admits the patient to the surgical unit. If the patient is transported by gurney, assist him to the bed. As soon as the patient has arrived, perform an assessment, and listen to a summary report from the PACU nurse (Box 39-4).

ASSESSMENT

The initial postoperative assessment is identical to the assessment performed by the PACU nurse. However, the patient has undergone a period of stabilization since surgery, so assessments can be less frequent than in the PACU, where the patient was assessed every 5 to 15 minutes. You may increase the frequency if the patient's condition changes. Of course agency protocols vary, but a common pattern is to assess the patient:

On arrival to the nursing unt
Every 15 minutes for the first hour
Every 30 minutes for the next 2 hours
Every hour for the next 4 hours
Then every 4 hours

KnowledgeCheck 39-8

- What are the two phases of the postoperative phase of care?
- How often is a patient typically assessed after surgery?
- What assessments are made?

ANALYSIS/NURSING DIAGNOSIS

If healing proceeds normally and no complications develop, most postoperative patients have a common set of collaborative problems (Table 39-4), regardless of the type of surgery they underwent. You will not need to write potential ("risk for") nursing diagnoses, except in special situations (e.g., patients with comorbid conditions, such as diabetes or asthma).

Potential Nursing Diagnoses Write potential nursing diagnoses (instead of collaborative problems) only if a patient has a higher risk for the problem than the average surgical patient. For example, you might use:

- *Risk for Ineffective Peripheral Tissue Perfusion* for patients who have a history of peripheral arterial disease or cardiac insufficiency.
- *Risk for Deficient Fluid Volume* for patients who have lost a large amount of blood in surgery or who are dehydrated on admission.
- *Risk for Ineffective Breathing Pattern* for patients with weak accessory muscles for breathing, with a decreased level of consciousness, or with a respiratory condition such as emphysema.
- *Risk for Infection* for patients who have compromised immune status or who may not be capable of managing their own wound care at home.

Actual Nursing Diagnoses Of course, you will use a nursing diagnosis whenever a problem becomes actual instead of merely potential. Nursing diagnoses will vary based on the surgical procedure and the client situation. There is no need for a *Deficient Knowledge* diagnosis because patient teaching is a routine intervention for all postoperative patients. Two common postoperative nursing diagnoses are:

- *Delayed Surgical Recovery*. This is appropriate when the patient requires more days to recover than the anticipated length of stay for the surgery.
- *Acute Pain.* There are independent nursing interventions to relieve pain (e.g., teaching the patient to splint the incision). However, they do not usually provide adequate relief in the early post-op period. You will nearly always need to administer analgesics, which require a medical prescription.

For other frequently used diagnoses,

Go to Chapter 39, **Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

PLANNING OUTCOMES/EVALUATION

A comprehensive plan of care for common postoperative nursing diagnoses includes NOC standardized outcomes as well as individualized goals. Because of shortened hospital stays, the postoperative period now extends well past the patient's discharge from the hospital. Often, especially for those who have had major or complex procedures, a home health nurse continues to follow the patient at home to facilitate a smoother transition through the postoperative process.

For postoperative *NOC standardized outcomes and individualized goals*,

Go to Chapter 39, **Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

PLANNING INTERVENTIONS/IMPLEMENTATION

Most postoperative interventions focus on prevention and early detection of potential complications (collaborative problems). Many such interventions are done as a part of the preoperative teaching. Others are described in Table 39-4. These are routines that are followed for all postoperative patients, regardless of type of surgery.

For *NIC interventions for postoperative nursing diagnoses*,

Go to Chapter 39, **Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions,** in Volume 2.

Specific nursing activities should be designed to relieve identified nursing diagnoses. In the next sections, we discuss pain management, routine postoperative teaching, and the use of sequential compression devices.

Pain Management

One systematic evidence synthesis has found that there is no strong evidence to support that any particular nursing intervention for relief of postoperative pain is better than any other. Interventions included medication administration, preoperative education, regular assessment and documentation of pain intensity, use of protocols and flowsheets, and nonpharmacological interventions (e.g., massage) in relieving postoperative pain (Crowe, Chang, Fraser, et al., 2008). Therefore, when interventions seem to be equally effective, you will need to weigh the potential benefits, possible adverse events, and patient preferences to decide which to use.

Postoperatively, a patient usually receives analgesics by more than one route. For example, in the immediate postoperative period, the patient may receive intravenous or epidural medications, progress to oral opioids in a day or two, and then move to nonopioid analgesics (e.g., acetaminophen).

Providing sufficient pain control for older adults can be a challenge. Because of concerns about impaired cognition, medical comorbidities, drug interactions, and problems with appropriate dosing many older adults may be undermedicated and experience unnecessary pain (Egol & Strauss, 2009).

For a complete discussion of types of pain relief, refer to the section Routes of Administration for Opioid Analgesics in Chapter 31, and

Go to Chapter 31, **Procedure 31-1: Setting Up and Managing Patient-Controlled Analgesia by Pump,** and **Clinical Insight 31-1: Nursing Care of the Patient with an Epidural Catheter,** in Volume 2.

Key Point: ***Keep in mind that no one drug is likely to work with every person with pain.***

One recent development is a single-use pain relief pump that administers a continuous, regulated flow of local anesthetic through a thin catheter directly into the patient's surgical site. A dressing holds the tubing in

(text continues on page 1052)

CAM for Pain, Anxiety, and Tension

Massage Therapy for Postoperative Pain, Anxiety, and Tension

Cutshall, Wentworth, Engall, et al. (2010) collected data from 58 postoperative cardiovascular patients. Twenty-eight of the patients received 20 minutes of massage therapy in addition to the usual pain management during postoperative days 2 to 5. Statistically and clinically significant decreases in pain, anxiety, and tension were reported compared to the group of patient who did not receive massage therapy.

Table 39-4 ➤ Potential Postoperative Complications (Collaborative Problems)

POTENTIAL COMPLICATION	DESCRIPTION	CLINICAL SIGNS	INTERVENTIONS FOR PREVENTION AND EARLY DETECTION
Respiratory System			
Aspiration Pneumonia	Airway inflammation caused by inhaling gastric secretions (especially hydrochloric acid from the stomach) because of absent gag reflex secondary to anesthesia	Cough, fever, elevated WBC, decreased or absent breath sounds, decreased oxygen saturation (SaO_2), tachypnea, dyspnea, blood-tinged sputum	*Preoperative:* Institute NPO for at least 8 hours prior to surgery. *Postoperative:* Continue NPO until intestinal motility returns; carefully monitor sedated patient and place in side-lying position.
Atelectasis	Collapse of alveoli due to hypoventilation, airways blocked by mucous plugs, opioid analgesics, immobility	Decreased or absent breath sounds, noisy respirations, decreased O_2 saturation (SaO_2), chest asymmetry, sternal retractions, accessory muscle use, trachea deviated from midline, fever, tachypnea, dyspnea, tachycardia, diaphoresis, pleural pain, increased restlessness, anxiety	■ Monitor for clinical signs (Column 3) ■ Monitor rate, rhythm, depth, and effort of respirations. ■ Monitor ability to cough effectively. ■ Determine need for suctioning by listening for crackles and rhonchi over major airways. ■ Suction, as needed. Auscultate lung sounds after suctioning, and other respiratory treatments to determine effectiveness. ■ Encourage deep breathing, coughing, moving in bed, ambulation, use of incentive spirometry. ■ See interventions for NIC category Respiratory Monitoring.
Pneumonia	Inflammation of the alveoli due to infection with bacteria or viruses, toxins, or irritants. Caused by hypoventilation secondary to anesthesia and opioid analgesics, and by poor cough effort as a result of aging or weakness.	Productive cough with blood-tinged or purulent sputum, fever, elevated WBC, decreased or absent breath sounds, decreased SaO_2, chest pain, tachypnea, dyspnea	■ Monitor for clinical signs. ■ Encourage and assist with deep breathing, coughing, moving in bed, ambulation, use of incentive spirometry.
Pulmonary Embolus	A clot that occludes blood flow to a portion of the lungs; usually a result of clot formation in the lower extremities, which breaks loose and migrates to the lungs. May also be due to venous injuries, hypercoagulable state, use of high-dose estrogen, preexisting circulatory disorders.	Sudden onset of dyspnea, shortness of breath, chest pain, hypotension, tachycardia, decreased SaO_2, cyanosis	■ Prevent thrombophlebitis: Encourage and assist with leg exercises, early ambulation, antiembolism stockings, sequential compression devices, hydration. Go to Chapter 39, **Procedure 39-2: Applying Antiembolism Stockings,** and **Procedure 39-3: Applying Sequential Compression Devices,** in Volume 2. ■ If thrombophlebitis occurs, position and immobilize the limb; do not massage calves.

Table 39-4 ➤ Potential Postoperative Complications (Collaborative Problems)—cont'd

POTENTIAL COMPLICATION	DESCRIPTION	CLINICAL SIGNS	INTERVENTIONS FOR PREVENTION AND EARLY DETECTION
Cardiovascular System			
Thrombophlebitis	Blood clot and inflammation of a vein or artery, usually in the legs. Results from increased coagulability and venous stasis resulting from immobility during and after surgery.	*Superficial:* Vein is red, hard, and hot to touch. *Deep:* Limb is pale and edematous; aching, cramping in limb; Homans' sign (pain in calf when foot is dorsiflexed).	Refer to Pulmonary Embolism actions, above.
Embolus	▪ Movement of a thrombus or foreign body from its original location. ▪ Movement in the arterial system results in symptoms in the area affected (e.g., cerebrovascular accident, myocardial infarction, or loss of circulation to an area). ▪ In the venous system, often results in pulmonary embolus (see Pulmonary Embolus, preceding).	See Pulmonary Embolus. For arterial emboli, symptoms depend on the location.	▪ Monitor for clinical signs. ▪ Prevent thrombophlebitis. If thrombophlebitis occurs, position and immobilize the limb. ▪ Do not massage calves.
Hemorrhage	Bleeding may be internal or external. May be caused by slipped ligature, uncontrolled bleeder, or infection.	*If external:* Dressings saturated with bright red blood; increased output in drains or chest tubes *If internal:* Increased pain, increasing abdominal girth, ecchymosis or swelling around incision, tachycardia, hypotension	Frequently monitor vital signs, dressings, and wound drainage.
Hypovolemia	Decreased blood volume; may be due to blood loss during and after surgery, dehydration, or excess loss through vomiting, diarrhea, or drains	Hypotension, tachycardia, decreased urine output, fatigue, thirst, dehydration	▪ Monitor vital signs and I&O. ▪ Insert urinary catheter, if appropriate. ▪ Monitor skin color, temperature, and moistness; central and peripheral cyanosis. ▪ Identify possible causes of changes in vital signs. ▪ Administer IV therapy as prescribed. ▪ Promote oral intake when tolerated. ▪ Prepare to administer blood or blood products, as prescribed.

Table 39-4 ➤ Potential Postoperative Complications (Collaborative Problems)—cont'd

POTENTIAL COMPLICATION	DESCRIPTION	CLINICAL SIGNS	INTERVENTIONS FOR PREVENTION AND EARLY DETECTION
Gastrointestinal System			
Nausea and Vomiting	Stomach upset or vomiting related to pain, anxiety, anesthesia, medications, or oral intake before peristalsis returns	Vomiting, retching, stated nausea	▪ Have patient remain NPO until return of bowel sounds. ▪ Advance diet slowly. ▪ Treat pain.
Abdominal Distention (Tympanites)	Excess gas within the intestines; may be the result of a slow return of peristalsis or from handling of the intestines during surgery	Abdominal discomfort, bloating, hypoactive or absent bowel sounds	▪ Encourage and assist to move in bed and ambulate. ▪ Maintain NPO until return of bowel sounds; avoid drinking with a straw. ▪ Provide fluids at room temperature.
Constipation	A decrease in the frequency of bowel movements, resulting in the passage of hard stool. Usually related to use of opioids, immobility, inadequate fluid intake, or low-fiber diet.	Abdominal discomfort, bloating, hypoactive or absent bowel sounds	Encourage and assist the patient to move in bed, ambulate, and increase fluid and fiber intake after bowel sounds return.
Ileus	Loss of the forward flow of intestinal contents because of decreased peristalsis secondary to anesthesia, handling of the intestines during surgery, electrolyte imbalances, infection, or ischemic bowel	Abdominal pain, distention, absent bowel sounds, vomiting	There are few independent preventive measures. Observe for symptoms; notify the surgeon.
Genitourinary System			
Renal Failure	Decreased or absent urine output owing to hypovolemia, shock, or toxic reaction to medications.	Urine output <30 mL/hr; rising BUN and creatinine levels	Carefully monitor I&O and lab values.
Urinary Retention	Accumulation of urine in the bladder. May result from poor muscle tone as a result of anesthesia and anticholinergic medications, handling of tissues during surgery, or inflammation in the pelvic region.	Bladder distention, suprapubic pain, diminished urine output or output less than fluid intake, inability to void or small frequent voidings, hypertension, restlessness	▪ Monitor for clinical signs. ▪ Provide privacy and adequate time to urinate. ▪ Catheterize if needed.
Urinary Tract Infection	Infection in the urinary tract related to catheterization, stagnant urine in the bladder secondary to immobility or anticholinergic medications, or instrumentation of the urinary tract	Urinary frequency, suprapubic discomfort, burning on urination, cloudy urine	▪ Monitor for clinical signs. ▪ Monitor I&O. ▪ Use aseptic technique with catheterization and perineal care. ▪ Provide adequate IV and oral fluids.

Table 39-4 ➤ Potential Postoperative Complications (Collaborative Problems)—cont'd

POTENTIAL COMPLICATION	DESCRIPTION	CLINICAL SIGNS	INTERVENTIONS FOR PREVENTION AND EARLY DETECTION
Surgical Incision			
Dehiscence	Separation of one or more layers of the wound as a result of poor nutritional status, obesity, or other strain on suture line, inadequate closure of the muscles, or wound infection	A pop or tearing sensation, especially with sudden straining from coughing, vomiting, or changing positions in bed. Usually an immediate increase in serosanguinous drainage occurs.	▪ Provide adequate nutrition. ▪ Use binders to support the incision. ▪ Have client avoid strain. ▪ Monitor for infection.
Evisceration	Protrusion of organs or tissues through the separated incision. For causes, see Dehiscence.	Visible protrusion of organs through incision	Same as for Dehiscence
Wound Infection	Inflammation or drainage from a wound as a result of growth of microorganisms secondary to poor aseptic technique or pathogens already present in surgical area	Localized swelling, redness, heat, pain, fever (>100.4°F or 38°C), foul-smelling drainage, or a change in the color of the drainage.	▪ Effective skin prep in preoperative period ▪ Surgical scrub according to guidelines in the intraoperative period ▪ Monitor for systemic and localized signs and symptoms of infection. ▪ Inspect incision and drain areas for redness and extreme warmth. ▪ Inspect surgical dressings for drainage and odor. ▪ Monitor vital signs, especially temperature. ▪ Assess vulnerability to infection. ▪ Maintain aseptic nontouch technique with surgical dressing changes. ▪ Use and teach good hand hygiene. ▪ Use sterile saline for wound cleansing up to 48 hours post-op (NICE, 2008). ▪ See interventions for NIC category Infection Protection. ▪ Limit the number of visitors, as appropriate. ▪ Obtain cultures as needed. ▪ Encourage sufficient nutritional and fluid intake. ▪ Teach client about signs of infection.

place, and the pump can be carried in a small bag and used after the patient returns home. It reduces the need for opioids, thus reducing complications, such as nausea, vomiting, and respiratory depression. It is said to hasten ambulation and the return to normal activities. Depending on the type of pump, it is filled with 65 to 750 mL of medication and can remain in place for up to 5 days, depending on the amount of anesthetic included (Fig. 39-5).

Postoperative Teaching

Teaching is especially important postoperatively because most patients must perform quite a bit of self-care. Postoperative teaching should reinforce content taught preoperatively. In addition, you should teach the patient about the topics in the Self-Care box Postoperative Patient Teaching. To use time efficiently, try to do some teaching each time you are at the bedside for other care. Be sure the patient is comfortable but alert. Do not attempt teaching when the patient is in pain, needs to void, or is drowsy from opioid analgesics.

Incentive Spirometry

Incentive spirometry may be prescribed for patients who are at high risk for atelectasis and pneumonia (e.g., the patient has a history of lung problems or smoking or will experience a prolonged period of inactivity). Incentive spirometry facilitates deep breathing, increases lung volume, and promotes coughing to clear mucus from the respiratory tree. The equipment varies in appearance, but all devices include a gauge to monitor the patient's progress visibly (Fig. 39-6).

If incentive spirometry is prescribed postoperatively, explain its use to the patient (see the Self-Care box Teaching Your Patient About Incentive Spirometry). If you know in advance that the patient will be using an incentive spirometer postoperatively, include its use in your preoperative teaching.

Self-Care

Postoperative Patient Teaching Topics

- Postoperative treatment regimen (e.g., dressing changes, exercises), including rationale for the treatments
- Self-management of the treatment regimen
- Expected results and effects of the surgery
- The prescribed diet, and how to select foods on the diet
- Prescribed activity
- Signs and symptoms of complications that require the patient to notify the surgeon or primary care provider
- Return office or clinic visits
- Lifestyle changes that may be needed
- Community resources available (e.g., Reach for Recovery)

See also the Complementary & Alternative Modalities box Massage Therapy on Pain, Anxiety, and Tension for an alternative approach to pain management.

Antiembolism Stockings and Sequential Compression Devices

More than half of all hospitalized patients are at risk for venous thromboembolism, and surgical patients seem to be at higher risk than medical patients (Cohen, Tapson, Bergman, et al., 2008). Preventive measures include anticoagulant medications (blood thinners),

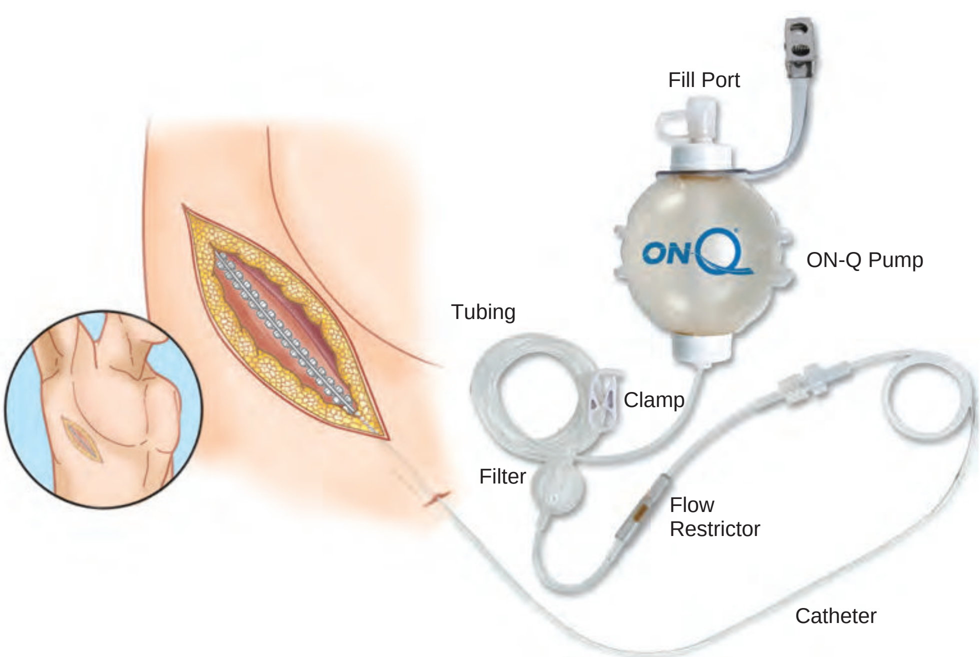

FIGURE 39-5 A single-use pain relief pump delivers a local anesthetic directly into the patient's surgical site.

FIGURE 39-6 Incentive spirometry facilitates lung expansion and coughing to clear mucus from airways.

Self-Care

Teaching Your Patient About Incentive Spirometry

- Explain to the patient that the machine will enable him to monitor the depth of his breathing.
- Patients with abdominal or chest incisions may require pain medication to use the incentive spirometer.
- Assist the patient to an upright position in the bed or chair.
- Instruct the patient to do the following:

1. Breathe out normally.
2. Place the mouthpiece in the mouth and create a seal.
3. Breathe in slowly and as deeply as possible through the mouthpiece. Monitor the depth of inspiration by viewing the gauge. (Establish goals for the patient so that progress can be monitored.)
4. Hold your breath as long as possible, at least to a slow count of 3.
5. Remove the mouthpiece from your mouth, and exhale.
6. Rest for a few seconds
7. Repeat this process 10 times every hour while awake, if possible.
8. After each set of 10 deep breaths, cough to be sure lungs are clear. Support any incision when coughing by holding a pillow firmly against it.

postoperative exercises, and antiembolism stockings ("TED hose").

Antiembolism Stockings Antiembolism stockings were discussed previously as a preoperative care intervention in the Preoperative Care section Prepare the Patient Physically for Surgery. Encourage postoperative patients to ambulate as soon and as much as possible to promote peripheral circulation and prevent thrombophlebitis. **Key Point:** ***Antiembolism stockings are not a substitute for activity. Early ambulation is essential to prevent postoperative complications.***

To learn how to apply antiembolism stockings,

Go to Chapter 39, **Procedure 39-2: Applying Antiembolism Stockings,** in Volume 2.

Sequential Compression Devices (SCDs) In addition to antiembolism stockings, a sequential compression device (SCD) may be prescribed for patients at high risk for thrombophlebitis. The SCD is a plastic sleeve with chambers (Fig. 39-7). The sleeve is wrapped around the patient's legs and connected to an air pump that provides sequential pressure to the chambers of the plastic sleeve. Starting at the ankle, the first chamber is inflated. When the second chamber inflates, the first chamber deflates, and so on. SCDs apply brief pressure to each segment of the leg. This compresses the veins and promotes venous return to the heart. SCDs may extend from ankles to knees or up to the top of the thighs. To learn how to apply SCDs,

Go to Chapter 39, **Procedure 39-3: Applying Sequential Compression Devices,** in Volume 2.

FIGURE 39-7 Sequential compression devices may be prescribed for clients at high risk for thrombophlebitis.

Gastrointestinal Suction

Patients having certain surgeries, such as a laparotomy to close a bowel perforation or surgery to relieve a bowel obstruction, are at high risk for abdominal distention. In addition to causing pain, distention can increase postoperative respiratory problems, place a strain on suture lines, and interfere with wound closure. Such patients will return from surgery with a nasogastric (NG) or nasointestinal tube in place for gastric or intestinal decompression. If prolonged intestinal decompression is anticipated, a gastrostomy may be performed instead of using a nasogastric tube.

Decompression tubes are typically connected to either intermittent or continuous suction to collect excess fluid and gas. Suction is continued until peristalsis resumes, bowel sounds are audible, and the patient is passing flatus. While suction is in place, the patient remains NPO. To review insertion and care of NG and nasoenteric tubes, see Chapter 27. To learn how to manage gastrointestinal suction, see the summary in the Highlights of Procedures box, and

Go to Chapter 39, **Procedure 39-4: Managing Gastric Suction,** in Volume 2.

KnowledgeCheck 39-9

- Identify six potential postoperative complications.
- Why are sequential compression devices used?

CarePlanning & MappingPractice

For Care Planning/Care Mapping practice,

Go to Student Resources, **Care Planning & Care Mapping Practice,** on Davis*Plus*.

Highlights of Procedures 39-1 through 39-4

For steps to follow in *all* procedures, refer to the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the procedure steps. Use these procedure highlights later to help you review key points.

Procedure 39-1: Teaching a Patient to Deep-Breathe, Cough, Move in Bed, and Perform Leg Exercises

- Assess the patient's readiness to learn.
- Ensure that the patient is clear about the difference between coughing and merely clearing the throat.
- Demonstrate how to splint a potential chest or abdominal incision.
- Make sure the patient flexes her knees prior to turning on her side in bed.
- Support the patient who is unable to maintain a side-lying position with pillows.
- Teach the patient to alternately flex and extend the knees.
- Teach the patient to alternately dorsiflex and plantar flex the foot.
- Teach the patient to rotate her ankles in a complete circle.

Procedure 39-2: Applying Antiembolism Stockings

- Measure the patient's leg to ensure that you select stockings of the correct size.
- Inspect the legs and feet for edema, abrasions, lesions, open areas, and circulatory changes.
- Elevate the patient's legs for at least 15 minutes prior to applying stockings.
- Insert your hand and turn the stocking inside out to the level of the heel.
- Insert patient's foot into stocking. Gradually pull the remaining portion of the stocking up and over the leg.

  Keep knee-high stockings 2.5 to 5 cm (1 to 2 in.) below the joint.

  Do not apply thigh-high stockings if the thigh circumference is greater than 82 cm (32 in.).
- Make sure the stocking is free of wrinkles and is not rolled at the top or bunched.

Procedure 39-3: Applying Sequential Compression Devices

- Determine whether elastic stockings are to be used concurrently with the sequential device. If so, apply them (see Procedure 39–2).
- Place the regulating pump for the sequential compression in a location that will ensure patient safety.
- Place the patient in a supine position.
- If you are using SCD and PAS brand thigh-high compression sleeves, measure the thigh.
- Place the lower extremity on the open sleeve, ensuring that the compression chambers are located over the correct anatomical structure (e.g., knee opening is at the level of the joint).
- Leave one to two fingerbreadths between the sleeve and the extremity.
- Set the regulating pump to the correct pressure, as ordered.
- Instruct the patient to call for assistance in disconnecting the tubing from the sleeve.

Procedure 39-4: Managing Gastric Suction

Procedure 39-4A: Initial Equipment Setup

- Connect and secure the suction source, collection container, and drainage tubing.
- Don nonsterile gloves.
- Connect suction drainage tubing to nasogastric tubing.
- Secure the NG tube to the patient's nose and gown (if not already done).
- Turn on the suction.

Procedure 39-4B: Emptying the Suction Container

- Don nonsterile gloves.
- Turn off the suction; close the stopcock (or clamp the tubing).

Highlights of Procedures 39-1 through 39-4

- Empty the suction container and measure the contents.
- Empty and wash the graduated measuring container.
- Cleanse the suction container port and close the stopper; place the container back in the holder.
- Turn on the suction.
- Observe for proper functioning and tubing patency.

Procedure 39-4C: Irrigating the Nasogastric Tubing

- Prepare the irrigation set.
- Don nonsterile gloves.
- Place patient at a 30° to 45° degree elevation
- Check for NG tube placement.
- Fill the syringe with 10 to 30 mL of saline.
- Turn off the stopcock or clamp the NG tube.
- Disconnect the NG tube from drainage.
- Drain the suction tubing and turn off the suction source.
- Turn on the stopcock or unclamp the NG tube.
- Slowly instill and withdraw irrigant into the NG tube until fluid flows freely.
- Turn off the stopcock or reclamp the NG tube.
- Reconnect the NG tube.
- Turn on the stopcock or release the clamp.

Procedure 39-4D: Providing Comfort Measures

- Don nonsterile gloves.
- Provide mouth care.
- Remove nasal secretions.
- Apply water soluble lubricant to nostrils.
- Check that tape or tube fixation device is secure.

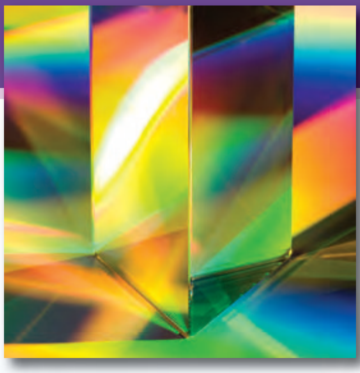
CHAPTER 40



Leading & Managing

Learning Outcomes

After completing this chapter, you should be able to:

- Distinguish leadership, followership, and management.
- Compare and contrast authoritarian, democratic, and laissez-faire leadership styles.
- Explain the differences between transactional and transformational theories.
- Discuss the qualities and behaviors that contribute to effective leadership and followership.
- Discuss the qualities and activities that contribute to effective management.
- Explain how a SWOT analysis or a SOAR analysis can help you prepare to become a leader and manager.
- Discuss the qualities of preceptors and mentors.
- Present strategies for effective followership.
- Describe the challenges presented to nurse managers by the economy and the nursing labor market.
- Define power and empowerment.
- Describe several ways in which nurses can be empowered.
- Explain why communication skills are important to nurse leaders and managers.
- Describe the change process.
- Identify methods of dealing with change.
- Describe the major concepts of conflict, conflict resolution, and informal negotiation.
- Describe the major concepts of safe and effective delegation.
- Establish short- and long-term personal and career goals.
- Develop effective time management strategies.

Key Concepts

Leadership
Management
Followership
Change

Related Concepts

See the Concept Map on Davis*Plus*.

Portions of this chapter were taken from D. K. Whitehead, S. A. Weiss, & R. M. Tappen (2010). *Essentials of nursing leadership and management* (5th ed.). Philadelphia: F. A. Davis. Used with permission.

Meet Your Peer

Mary is a student in a nursing program. She considers herself a "pretty good test-taker" and has a GPA of 3.4. She received her first test grade in the Nursing Fundamentals class, and it was a C. Mary is sure that she will never pass this course and that her dream of becoming a nurse will vanish. When discussing the test with her classmates, she realized there are several other disappointed students who have been used to making As and Bs on exams. The nursing exams seem different because they do not only ask students to recall memorized material but also apply what they have learned. Mary decides to get the group together and plan some strategies for study groups. She asks the instructor whether she will meet with them and go over their plan to make sure they are on the right track. Mary has exhibited some leadership qualities.

Theoretical Knowledge knowing why

In this chapter, we discuss the challenges to nurses as they lead and manage others, and deal with change in organizations and the healthcare environment.

ABOUT THE KEY CONCEPTS

Have you ever heard the phrase, "Not every good leader can manage, and not every good manager can lead"? This chapter defines and differentiates between the key concepts of leadership and management. To lead and manage effectively, you will also need to grasp and apply the key concepts of **leadership**, **management**, **followership**, and **change**, as well as subconcepts such as power, empowerment, conflict resolution, delegation, and time management. As you study each of those concepts, try to grasp how they relate to leadership and management.

WHAT IS LEADERSHIP?

You may be thinking, "I just started in my nursing program. How can you expect me to be a leader now?" As a student, you do need time to learn how nurses function in a work environment. However, you can begin to assume some leadership skills as a new student. The essence of **leadership** is the ability to influence other people. Effective leaders enable people to move "in the same direction, toward the same destination, at the same speed, not because they have been forced to, but because they want to" (Lansdale, 2002, p. 63; Gonzalez, 2012). A leader in healthcare has three primary tasks:

- Set direction (i.e., help people develop vision, a mission, goals, and purpose).
- Build commitment (i.e., help people develop motivation, team spirit, and teamwork).
- Confront challenges that arise from innovation, change, and turbulence (Porter-O'Grady, 2011).

ThinkLike a Nurse 40-1

1. Think of a goal your class might have. Obviously, each student wants to develop the skills necessary to provide excellent patient care and learn the theory content to pass the course and continue in the program. What other goals might you have, as a group? As a leader, how might you help the group members meet their goals?
2. Brainstorm with your peers to identify some shared goals of professional nurses.

Leadership Theories

How does a person become a leader? What type of leader is most effective? Although much research has been done to study these questions, no theory has yet emerged as the clear answer. The reason may be that different situations require different qualities and behaviors. In nursing, for example, some situations require quick thinking and fast action. Others require time to reflect on the best solution to a complicated problem. Let's look now at some of the best-known leadership theories, beginning with some of the older ones.

Trait Theories

Have you ever heard someone say, "Leaders are born, not made"? That implies some of us are natural leaders, but others of us are not. Much of the early leadership research was done in an attempt to identify the qualities, or **traits**, that distinguish a leader from a nonleader. The traits most often identified are intelligence and initiative. Other qualities that were found to be associated with leadership are excellent interpersonal skills, high self-esteem, creativity, willingness to take risks, and ability to tolerate the consequences of taking risks (Northouse, 2013; White & Lippitt, 1960). Leadership may come more easily to some than to others, but everyone can be a leader, at least in certain areas, if she develops the necessary knowledge and skills.

Behavioral Theories

The trait theories were concerned with what a leader *is*, whereas the behavior theories are concerned with what the leader *does*. One of the most influential of these behavioral theories is concerned with leadership style. Three styles have been identified (Northouse, 2012; White & Lippitt, 1960). Pavitt summed up the difference between these three leadership styles:

- A democratic leader tries to move the group *toward its goals*.
- An autocratic leader tries to move the group *toward the leader's goals*.
- A laissez-faire leader makes *little or no attempt* to move the group (Pavitt, 1999, p. 330; Zineldin & Hytter, 2012).

Authoritarian Leadership

This is also called *autocratic, directive, controlling*. The **authoritarian leader** gives orders, makes decisions for the group as a whole, and bears most of the responsibility for the outcomes. For example, when a decision needs to be made, an authoritarian leader would say, "I've given this a great deal of thought and decided this is the way we're going to solve our problem." Authoritarian leadership may be either punitive or kind and compassionate. This type of leadership can be an efficient way to run things when a group needs lots of direction in achieving high-quality and high-quantity outputs (Marquis & Huston, 2012). However when used long term, it tends to inhibit creativity and motivation.

Democratic Leadership

Democratic leadership is also called *participative leadership*. In contrast to the authoritarian leader, a democratic leader shares the planning, decision making, and responsibility for outcomes with members of the group. This type of leader tends to provide guidance rather than control. Although this is often a less efficient way to run things, it is more flexible and more likely to foster motivation and creativity. Group output tends to be of high quality.

Laissez-Faire Leadership

Also called *permissive or nondirective,* the **laissez-faire** ("let it alone") leader has a relatively inactive style and intervenes only when goals have not been met or a problem arises (Zineldin & Hytter, 2012). Laissez-faire leadership gives followers the majority of control in the decision-making process. Some mature individuals thrive under laissez-faire leadership because they need little guidance. However, in most instances, followers look to the leader for direction and may become confused and frustrated with no goal, guidance, or direction. The laissez-faire leader offers little feedback and support to the followers, postpones decision making, or never makes it at all, which leads to poor quality and inefficient work output.

KnowledgeCheck 40-1

- Identify the three common styles of leadership in the behavioral theories of leadership.
- Discuss the type of follower that would benefit from each style of leadership.

Task Versus Relationship Theories

Another important distinction in leadership style is that between a *task* focus and a *relationship* focus (Blake, Mouton, & Tapper, 1981; Havig, Skogstad, Kjekshus, et al., 2011). Some leaders emphasize the tasks (e.g., keeping the nursing station neat, getting charting done) and fail to realize that interpersonal relationships (e.g., attitude of physicians toward nursing staff, treating housekeeping staff with respect) have considerable impact on employee morale and productivity. Others focus on the interpersonal aspects and ignore the quality of job performance. The most effective leader is able to balance the two, attending to both the task and the relationship aspects of working together.

Emotional Intelligence Theory

Emotional intelligence (EI) theory focuses on the relationship aspects of leadership. In part, what sets leadership "stars" apart from ordinary leaders is that they consciously address the effect of people's feelings on the team. This is done by leaders who:

- Learn how to recognize, understand, and manage their own emotions; and how to stay clearheaded and suspend judgment until all the facts are in (Feather, 2009).
- Listen attentively, perceive and accurately interpret unspoken emotions, and acknowledge others' perspectives.
- Bring people together in an environment of respect and cooperation so they can direct their energies toward achieving team goals.

The emotionally intelligent leader's enthusiasm, caring, and support inspires the same feelings throughout the team (Feather, 2009; Sadri, 2012; Whitehead, Weiss, & Tappen, 2010).

Situational Theories

We know now that people and leadership situations are far more complex than the early theories recognized. Furthermore, situations may change rapidly, requiring even more complex theories to explain people's responses. Thus, less simplistic theories have evolved to replace the trait and behavioral theories.

Adaptability is the key to the situational approach (Flackman, Hansebo, & Kihlgren, 2009; Furtado, Batista, & Silva, 2011). Instead of assuming that one particular approach works in all situations, situational theories recognize the complexity of work situations and encourage the leader to consider a number of factors when deciding what action to take. Every situation is different. Situational theories emphasize that it is important to (1) understand all of the factors that affect a particular group of people in a particular environment, and (2) vary the type of leadership to meet the needs of the situation.

Transformational Theories

Although situational theories were an improvement over earlier theories in recognizing how complex the process of influencing others really is, they were still missing something. They did not address meaning, inspiration, and vision, which are the distinguishing features of transformational leadership theory. According to transformational theory, people need a sense of mission that goes beyond good interpersonal relationships or the reward for a job well done (Bass & Avolio, 1993; Salanova, Lorente, Chambel, et al., 2011). This is especially true in nursing. Caring for people, sick or well, is the goal of our profession. Most of us chose nursing for our vision: to do something for the good of humankind. One goal of nursing leadership is to guide us toward achieving that vision.

Transformational leadership involves the ability to inspire and motivate followers. The transformational leader creates a supportive climate, listens to followers, and acts as a coach and mentor. Transformational leaders communicate their vision in a way that is so meaningful and exciting that it reduces negativity and inspires commitment in the people with whom they work (Leach, 2005; Salanova, Lorente, Chambel, et al., 2011). Followers become motivated to go beyond their own self-interests for the good of the group or organization, often accomplishing more than what would normally be expected of them (Doody & Doody, 2012).

The American Nurses Credentialing Centers (ANCC) (2013) Magnet Recognition Program was developed to recognize healthcare organizations that provide the very best in nursing care. The ANCC expects leaders in Magnet organizations to demonstrate the transformational qualities listed in Table 40-1.

Transactional Theories

Whereas transformational leadership uses more of a “selling” style, transactional leadership uses more of a “telling” style. Transactional theory assumes that people are motivated by reward and punishment and that they work best within a clear chain of command. The leader creates structures to make clear what is required of subordinates and what the rewards are. The structure usually includes formal systems of discipline. These leaders monitor behaviors closely to point out errors and make corrective criticisms. They enforce rules to avoid mistakes (Jones & Rudd, 2007; Sabir, Sohail, & Khan, 2011). Transactional leadership is commonly used by managers, and in an organization, the “rewards” are salary and benefits (e.g., healthcare insurance). However, when the demand for a skill—or for workers of a particular type—is greater than the supply, the usual rewards may not be sufficient, and other types of leadership are more effective. Table 40-1 compares the traits of transactional and transformational leadership.

Table 40-1 ➤ Contrast of Traits in Transactional and Transformational Leadership

TRANSACTIONAL LEADERSHIP	TRANSFORMATIONAL LEADERSHIP
Directive	Participative
Top down	Bottom up
Information	Conversation
Hierarchical communication	Matrix communication
Event oriented	Future oriented
Task focused	Overall experience focused
Directed	Facilitated
Rigid	Flexible
Here and now	Visions for the future
Traditional	Contemporary
Rules	Risk taking
Control	Creativity
Individual performance	Team and relationships
Responsibility	Accountability

ThinkLike a Nurse 40-2

Observe a nurse in one of the healthcare agencies at which you are doing a clinical rotation. What leadership qualities and behaviors do you see the nurse exhibiting? How do these behaviors help in planning nursing care?

WHAT IS MANAGEMENT?

Whereas leaders may or may not have official appointments to the position, managers are usually officially appointed. A **manager** is an employee of an organization who has the power, authority, and responsibility for enforcing decisions and for planning, organizing, coordinating, and directing the work of others. Every nurse should be a good leader and a good follower; however, not everyone can or should be a manager. You may notice the following discussion of management overlaps a great deal with the content on leadership you have just read. That is because managers must be leaders, and they have varying styles of leadership.

Key Point: ***Not all leaders should be managers, but all managers should be leaders.***

You may be saying to yourself, "I don't want to be a manager. I just want to take care of patients." However, as a registered nurse, you will manage groups of patients, and you will be responsible for supervising nursing assistants, licensed practical nurses, and other ancillary staff. Even as a staff nurse, you will be a manager of care. You may be interested to know that the NCLEX-RN Testing Plan has an entire section devoted to management of care, which is not necessarily about managing the nurses or the nursing unit but rather organizing and delivering (i.e., managing) care to the patient. Questions address nursing activities, such as assessing clients to prioritize care, making appropriate referrals to the community, and acting as a client advocate.

Management Theories

Although there are many management theories, there are two major schools of thought in management: (1) scientific management and (2) the human relations approach to management. As you will see, the first emphasizes the task aspects of managing people, and the second emphasizes the relationship aspects.

Scientific Management

Almost 100 years ago, Frederick Taylor argued that most jobs could be done more efficiently if they were thoroughly analyzed (Lykins, 2011; Taylor, 1911/2011). Given a properly designed task and sufficient incentive to get the work done, workers would be more productive. For example, Taylor encouraged paying people "by the piece," that is, by the number of "widgets" made rather than by the number of hours worked. This encourages workers to get the most work done in the least amount of time. In healthcare, the equivalent of paying "by the piece" would be to pay for the number of clients bathed or monitored. In scientific management, the fastest way to do a job is usually thought to be the best way (Taylor, 1911/2011).

Which do you think would take the least amount of time and worker power: bringing patients to the radiology department or bringing a portable x-ray machine to the bedside? What about physical therapy: taking patients to the physical therapy department or having the therapist come to the patient's room? In healthcare, there has been much discussion about these kinds of questions. This type of thinking is the basis for the emphasis on eliminating excess staff and increasing the productivity of remaining employees.

Human Relations–Based Management

McGregor's (1960) Theory X and Theory Y are good examples of the difference between scientific management and human relations–oriented management (O'Leary, 2010).

Theory X managers believe that most people really do not want to work very hard and that the manager's job is to make sure that they do work hard. According to Theory X, a manager needs to use strict rules, constant supervision, and the threat of punishment (e.g., reprimands, withheld raises, and threats of job loss) to create industrious, conscientious workers. Theory X is similar to scientific management.

Theory Y managers believe that work itself can be motivating, that people want to do their jobs well, and that they will work hard if their managers provide a supportive atmosphere. Theory Y, a human relations–oriented theory, is the opposite viewpoint of Theory X. A Theory Y manager emphasizes guidance rather than control, development rather than close supervision, and reward rather than punishment.

A Theory Y nurse manager is concerned with keeping staff morale as high as possible, assuming that satisfied, motivated staff will do the best work. Employees' attitudes, opinions, hopes, and fears are important to this type of leader. Such a manager would make an effort to work out conflicts and promote mutual understanding among the staff to provide an atmosphere in which people can do their best work.

Servant Leadership

Despite its name, servant leadership applies more to supervisors and administrators than to nurses in staff positions. This type of management emphasizes interpersonal relationships, but goes one step further. The servant leadership manager believes people have value as people, not just as workers (O'Brien, 2011). The manager's attitude is employee first, and the manager is committed to improving the way each employee is treated at work. The servant-leader manager is there to remove barriers, make the work easier, and provide employees with whatever they need to provide the best patient care possible.

Qualities of an Effective Manager

Two-thirds of people who leave their jobs say the main reason was an ineffective or incompetent manager (Ripper, 2013). Given the high costs associated with orientation of new employees, nurse managers are challenged to retain staff nurses. A review of the nursing administration literature indicates that effective leadership styles of nurse managers and administrators enhance staff nurse retention (Duffield, Roche, Blay, et al., 2010). An effective nurse manager has the qualities of leadership, clinical expertise, and business sense. None of these alone is enough; it is the combination that prepares a person for the complex task of managing a group of healthcare providers. Let's look at each quality:

Leadership **Leadership** is the core of skills (e.g. people, leadership, influence) the nurse needs to function as an effective manager.

Clinical Expertise A nurse manager's role is to help others develop their skills and evaluate how well they have done; therefore, she needs a certain amount of clinical expertise. It is not necessary (or even possible) to know everything that every professional on the team knows, but it is important to be able to assess the effectiveness of the team's work in terms of client outcomes.

Business Sense Nurse managers need to be concerned with the "bottom line," that is, the cost of providing care, especially in comparison with the benefit received from that care. In other words, nurse managers need to be able to analyze how much time is spent to provide a given amount of client care, how effective that client care has been, how much will be paid to the institution for the care delivered, and who will pay for it (e.g., private insurance, government insurance, or the client). These are complex tasks that require knowledge of budgeting, staffing, and measuring patient outcomes, most of which are beyond the scope of this textbook.

Activities of an Effective Manager

Mintzberg (1989) divides the manager's activities into three categories: interpersonal, decisional, and informational. Whitehead, Weiss, and Tappen (2010) build on that work:

Interpersonal Activities

Interpersonal activities are important to both leaders and managers. In fact, one might say that interpersonal skills are important to everyone! From the beginning of your career in nursing school, you will have many opportunities to develop positive working relationships with members of other disciplines, departments, and units within the organization. Can you see how Mary (Meet Your Peer) would need interpersonal skills to accomplish her goals?

Interpersonal activities of managers include the following:

- *Networking*. Managers must clearly articulate nurses' roles in and value to the institution.
- *Conflict negotiation and resolution.* For example, conflict may arise on a unit over work schedules, especially on holidays.
- *Employee development.* This includes providing for continuing learning and upgrading employees' skills.
- *Rewards and punishments*. Examples include salary increases, time off, and praise.
- *Coaching*. The goal is to help the employee do a better job through learning. Some managers use a directive approach ("Let me show you how to do this"). Others use a nondirective approach ("How do you think we can improve our outcomes?").

Decisional Activities

From the very beginning of your career, you will be expected to develop critical-thinking, prioritizing, and decision-making skills in your clinical experiences. Even as a student, you will need to know what information to report to your instructor and when to provide it. Nurse managers' decisions include:

- *Employee evaluation* (e.g., conducting formal performance appraisals)
- *Resource allocation* (e.g., budgeting and how to use available funds wisely)
- *Personnel action* (e.g., hiring and terminating employees)
- *Planning for future changes* (e.g., in budgets or client populations)
- *Job analysis and redesign* (e.g., to make the units run as efficiently as possible)
- *Unit-based decisions* (e.g., staffing policies, space utilization)

What decisions did Mary (Meet Your Peer) make?

Informational Responsibilities

Side by side with decisional responsibilities are the informational responsibilities of a manager.

- *Spokesperson*. The manager relays information from administration to staff members, and speaks to administration on behalf of staff members.
- *Monitoring*. Managers monitor the activities of their units or departments (e.g., the number of clients seen, length of stay), as well as the staff (e.g., absenteeism) and the budget (e.g., money spent).
- *Public Relations*. Nurse managers share information with clients, staff members, and employers, for example, regarding new developments in healthcare and policy changes.

What kinds of information would Mary (Meet Your Peer) need to communicate to the students interested in forming a study group?

KnowledgeCheck 40-2

- How is transformational leadership different from the other theories of leadership?
- Define *manager*.
- In McGregor's management theory, which is more like scientific management: Theory X or Theory Y?

HOW CAN I PREPARE TO BECOME A LEADER AND MANAGER?

You may still be asking yourself, "What does all this leadership and management stuff have to do with me?" Besides learning the role of the registered nurse, you should begin right now to look at the skills employers think you need to be ready to work for them. Along with passing the NCLEX-RN examination to obtain nursing licensure, employers cite the skills listed in Box 40-1 as

BOX 40-1 ■ Desirable Job Candidate Skills

- Ability to assume responsibility
- Computer knowledge
- Critical-thinking and analytical skills
- Interpersonal skills
- Leadership abilities
- Motivation, initiative, and flexibility
- Oral and written communication skills
- Organizational skills
- Problem-solving and decision-making abilities
- Proficiency in field of study or technical competence
- Self-discipline
- Teamwork ability
- Willingness to work hard
- Ability to teach others
- Ability to adapt equipment to serve user needs
- Flexibility to adjust action in relation to others

desirable in job candidates (Ghannadian, 2013; Shingleton, 1994; Villarreal, 2002). Many of these skills have been identified in our discussion of leading and managing. It is not too early to begin to develop your abilities in these areas. These skills will assist you as you go through your nursing program, and will also make your adjustment to the RN role much easier.

One of the first steps in identifying what skills you already possess and which you need to develop is to do a brief SWOT analysis. A SWOT (strengths, weaknesses, opportunities, threats) analysis plan, borrowed from the corporate world, can guide you through an analysis of your own internal strengths and weaknesses and reveal external opportunities and threats that may help or hinder your leadership and management skills (Orr, 2013). Your SWOT analysis may include the factors listed as examples in Table 40-2, but certainly you will have others.

You might prefer to use the SOAR strategic planning model to help you prepare to become a leader and manager (Table 40-3). This model can be used to analyze any type of situation and create a plan to achieve personal and professional goals. With this model, you would use inquiry, imagination, innovation, and aspiration, and also focus on strengths, opportunities, aspirations, and results (Sprangel, 2011; Stavros, Cooperrider, & Kelly, 2007).

Think Like a Nurse 40-3

Stop and think! Take some time to personalize the SWOT analysis in Table 40-2. What weaknesses do you need to minimize, or which strengths do you need to develop as you begin to develop your leadership and management skills?

How Can Mentors and Preceptors Help Me?

There are two aspects to consider as you get ready to become a leader and manager. The first, discussed earlier, consists of developing self. The second is really a combination of developing self and developing others: mentorship and preceptorship. A **mentor** is someone more experienced who provides career development assistance, such as coaching, sponsoring advancement, providing challenging assignments, protecting protégés from adversity, and promoting positive visibility. Mentors provide guidance to new students or recent graduates as they continue in the profession. They offer a constructive example as a role model to novices. Mentors can also fulfill psychosocial roles, such as personal support, friendship, acceptance, role modeling, and counseling.

Table 40-2 ➤ SWOT Analysis Plan—Examples

STRENGTHS	WEAKNESSES	OPPORTUNITIES	THREATS
Relevant work experience	Poor communication and people skills	Changes in healthcare	Changes in healthcare
Advanced education	Inflexibility	Availability of mentors and preceptors	Lack of time
Good communication and people skills	Lack of interest in self-learning	Variety of experiences in clinical rotations	Competition from other students and other nursing programs
Computer skills	Difficulty adapting to change	Many leadership and management books and self-learning programs available	

SWOT = strengths, weaknesses, opportunities, threats

Table 40-3 ➤ SOAR Strategic Planning

THE PROCESS: HOW TO SOAR	THE SOAR REPORT OR SUMMARY
To SOAR: Inquire, imagine, innovate, and inspire.	Use SOAR to report or tell your story.
Inquiry: Internal analysis of strengths and external analysis of opportunities	**Strengths.** My (or the group's) strengths are . . . (Examples of strengths may be a supportive environment, individual strengths, a product that others need, and so on.)
Imagination: Co-create vision, values, and mission. Imagine desired outcomes. Imagine the best pathway to achieve the outcomes.	**Opportunities.** My values are . . . (e.g., dedication, quality). As I imagine the future, my vision (for myself, for our group) is . . . (e.g., to become a transformational manager on a nursing unit).
Innovation: Create initiatives, strategies, structures, and systems. Create plans for tactics.	**Aspirations.** Here is how I believe I (or we) can achieve the desired outcomes.
Inspiration: Inspire action-oriented activities that achieve results. Implement a plan for continuous improvement.	**Results.** To achieve your desired outcomes, you must be motivated (and possibly need to inspire others) to take the necessary actions.

SOAR = strengths, opportunities, aspirations, results

You should always use sound judgment when following the advice of others. Do not blindly engage in behaviors or actions because others do them.

Many organizations have preceptors for new employees. A preceptor is someone with more experience who provides practical teaching and guidance for a student or new employee. As a student, you may be assigned an RN preceptor in your clinical rotations. You may work side by side with a preceptor to provide patient care as a student nurse and as a new graduate nurse (Fig. 40-1). In many instances, the preceptor will become your mentor. However, the mentor role is much more encompassing than the preceptor role. The mentor relationship is a voluntary one and is built on mutual respect and development of the mentee. Box 40-2 identifies responsibilities of the mentor and mentee in this relationship.

You should look for a mentor in the nursing program right now—someone to guide you as you grow into your professional role. A student who has already completed several semesters and appears to be a leader is a good choice. In some programs, you may be assigned a student preceptor while you are in the program. Although this student may or may not become your mentor, you will need to have leadership and management skills to work side by side effectively.

Will you assume the role of preceptor or mentor while you are still in school? We hope your response is yes. As you progress in the program, remember the feelings of uncertainty and anxiety that you may now have, and volunteer to mentor another new student. Through the mentoring process, you can continue to develop yourself as a leader. Mentoring and precepting are part of your professional responsibilities, as the American Nurses Association (ANA, 2010) Standard of Professional Performance 10 states:

> *Collegiality.* The registered nurse interacts with and contributes to the professional development of peers and colleagues.

FIGURE 40-1 Nurse precepting a new graduate.

BOX 40-2 ■ Mentor and Mentee Responsibilities

Mentor Responsibilities

- Demonstrate excellent communication and listening skills.
- Be sensitive to the needs of nurses, patients, and the workplace.
- Encourage excellence in others.
- Share and provide counsel.
- Exhibit good decision-making skills.
- Demonstrate an understanding of power and politics.
- Demonstrate trustworthiness.

Mentee Responsibilities

- Demonstrate eagerness to learn.
- Participate actively in the relationship by keeping all appointments and commitments.
- Seek feedback, and use it to modify behaviors.
- Demonstrate flexibility and an ability to change.
- Be open in the relationship with the mentor.
- Demonstrate an ability to move toward independence.
- Evaluate choices and outcomes.

How Will Leadership Grow in My Nursing Career?

As you begin your nursing clinical experiences, your nursing instructor will supervise most of your decisions. As you continue to develop your knowledge and skills, you will begin working more as a member of the team. You will be expected to prioritize patient care, work with a variety of team members and families, and provide care for groups of clients. You may go to community agencies and network with community groups. To be successful in your continued role development as a nurse, you must work on perfecting the skills discussed in this chapter.

KnowledgeCheck 40-3

- Identify four skills that employers cite as desirable in job candidates.
- Identify three responsibilities of a mentor and three responsibilities of a mentee.

ThinkLike a Nurse 40-4

Think about how you are working with your peers at this time. What mentor responsibilities are you exhibiting? Is there someone who is already mentoring you? If so, what qualities does this person exhibit?

WHAT IS FOLLOWERSHIP?

Leadership and followership are two separate concepts and two separate roles that are complementary, not competitive. Great leaders can create successful followers, and great followers create successful leaders. No one person can have the best strategy, the clearest vision, or identify the most effective approaches to solve problems. All participants need to be recognized as full partners in the organizational venture. If we define **followers** as individuals who take another person as a role model and who act in accordance with, imitate, support, and advocate the ideas and opinions of another (Grossman & Valiga, 2012), then we can define **followership** as the willingness to work with others toward accomplishing the group mission. This term also refers to those who show a high degree of teamwork and build cohesion among the group (Ricketts, 2010).

An organization is a community of many leaders and many followers, frequently changing places depending on the particular activity that is occurring. Blindly following a leader without question or taking a passive role in one's work or professional organization will do little to advance the profession, promote individual growth, or achieve quality patient care. To participate fully and provide significant feedback, followers need to demonstrate a number of important qualities and behaviors (Grossman & Valiga, 2012; Kean, Haycock-Stuart, Baggaley, et al., 2011; Whitehead, Weiss, & Tappen, 2010):

- Suggest ways to improve client care.
- If you discover a problem, inform your team leader right away. Include a suggestion for solving the problem. If it is not accepted, your job is then to support—not undermine—the leader.
- Listen carefully and reflect on what the leader or manager says.
- Be truthful. Give honest feedback and constructive criticism, even if it means politely challenging the leader's ideas. Suggest alternative courses of action.
- If you feel you must have a "heated" discussion with the leader, do so privately. When you disagree, explain why.
- Freely invest your interest and energy in your work and in finding best solutions for the group.
- Function independently; be a self-starter; take on extra tasks without being asked.
- Be innovative, creative, and actively involved.
- Be responsible and hold up your end of the bargain; accept responsibility when it is offered.
- Be supportive of new ideas and directions suggested by others, but think critically about ideas that are proposed. Seek information so you can see the larger picture.
- Don't gossip.

- Think and act as a team; be cooperative and collaborative.
- Draw on and complement one another's and the leader's specialties, strengths, and areas of expertise.
- Work on behalf of the organization and the mutually agreed-on vision and goals.
- Continue to learn as much as you can about your specialty area; share what you learn with others.
- Know your own strengths and what your unique contributions to the effort can be.
- Know how to assume the role of the leader when necessary.
- Have a positive sense of self-worth and a "can do" attitude.
- Take care of yourself and your family. If you and they are unhappy, your job performance will suffer.

To find more suggestions for developing your skills as a follower,

Go to Chapter 40, **Tables, Boxes, Figures: ESG Box 40-1, Developing Effective Follower Skills,** on Davis*Plus*.

WHAT ARE THE CHALLENGES TO BEING AN EFFECTIVE LEADER AND MANAGER?

Even after you have developed the skills necessary to become an effective leader or manager, challenges exist in the healthcare environment. These challenges include the economic climate of healthcare and the nursing labor market.

Economic Climate of Healthcare

For many years, decisions about care were based primarily on providing the best quality care, whatever the cost. More recently healthcare providers are pressured to seek methods of care delivery that achieve quality outcomes at lower costs. This economic perspective is rooted in three fundamental observations:

1. *Resources are scarce*. The scarcity of resources means that three decisions must be made:
   - How much do we spend on healthcare services, and what do those services consist of?
   - How will those healthcare services be produced?
   - How should, or can, we distribute healthcare? In other words, how are services apportioned within the population? For example, it is hard to believe that the healthcare needs of more than 47 million uninsured individuals in America are not being met because these people cannot afford to pay insurance premiums. How will this change with the Affordable Care Act?
2. *Resources have alternative uses.* Because resources are limited, a choice to spend resources in one area eliminates the allocation of those same resources for another use. If we wish to build more nursing homes, for example, we must be willing to accept fewer hospitals or less housing, education, or other uses of those same resources. In healthcare, an expanded program of immunization may mean limiting care for certain chronic illnesses or for certain age groups.
3. *Individuals want different things or have different preferences.* Some people choose alternative treatment modalities, such as acupuncture, herbal therapy, or massage therapy, rather than traditional healthcare. The assumption exists that preferences for products and services can be influenced—hence, the extensive marketing of healthcare services.

Nursing Labor Market

The number of registered nurses employed in the nurse workforce in the United States is at 2.6 million, and continues to grow. There are 62.2% registered nurses employed in hospitals (ANA, 2011). More than half of RNs work at least 40 hours a week in their principal position, and another 24% work 32 to 39 hours per week (U.S. Department of Health and Human Services [USDHSS], 2013).

The Bureau of Labor Statistics predicted there would be more than 1 million vacant positions for registered nurses by 2020 (Robert Wood Johnson Foundation, 2013). The need for nurses is expected to increase even more dramatically as the baby boomers reach their 60s, 70s, and beyond. From now until 2030, the population aged 65 and older will double. The questions are (1) whether there will be enough nurses available to fill those jobs, and (2) even if nurses are available, whether it will be economically feasible for organizations to hire as many as they need. The Affordable Care Act will present changes in the healthcare system in the United States. It is certain that the future supply and demand of nurses will be affected by this (Poghosyan, Lucero, Rauch, et al., 2012).

As in the past, cost control and demand for nursing services will most likely involve changing nurse staffing patterns, the model of care, or professional nursing practice (Douglas, 2009). All of these changes will affect you. Regardless, healthcare system changes will likely demand that the RN lead and manage personnel delivering patient care while maintaining fiscal responsibility. Healthcare is big business, even though it is heavily regulated by government and other agencies. You must juggle the needs of your patients with the needs of the organization. From time to time, think about how you might do that.

ThinkLike a Nurse 40-5

Identify changes in your community that will affect you as you embark upon your nursing career. What will you do to prepare for these changes?

WHAT ARE POWER AND EMPOWERMENT?

The leadership and management techniques discussed so far will help you to achieve your goals. However, there are times when your attempts to influence others are overwhelmed by other forces or individuals. Where does this power come from? Who has it? Who does not?

Although people at the top of an organization have most of the *authority* in the organization, they do not have all of the *power*. In fact, the people at the bottom of the hierarchy also have some power. **Power** is the ability to influence other people despite resistance from them. In other words, one person or group can impose its will on another person or group (Haslam, Reicher, & Platow, 2011). Power may be actual or potential, intended or unintended. It may also be used for good or for evil, for serious purposes or for selfish ones.

Sources of Power

The sources of power vary from one situation to another. Some of these sources may be available to nurses (Kelly, 2012).

- **Authority:** The power granted to an individual or a group by virtue of position (within the organizational hierarchy, for example)
- **Reward:** The promise of money, goods, services, recognition, or other benefits to an individual or group to influence them to change.
- **Expert:** The power derived from knowledge and skills an individual is believed to possess. As Sir Francis Bacon said long ago, "Knowledge is power" (Bacon, 1597, quoted in Fitton, 1997, p. 150; Bacon, 2011).
- **Coercion:** The threat of pain or of harm, which may be physical, economic, or psychological

Let's look at various groups of people in a healthcare organization in terms of the types of power that may be available to them.

Managers are able to reward people with salary increases, promotions, and recognition. They can also use coercion—cause economic or psychological pain for the people who work for them, particularly through their authority to evaluate and fire people.

Patients at first appear to be relatively powerless in a healthcare organization. However, if patients refused to use the services of a particular organization, that organization would eventually cease to exist. Patients reward healthcare workers by praising them to their supervisors. They can also cause discomfort by complaining about them.

Registered nurses have expertise power, as well as authority to delegate appropriately to licensed practical nurses, nursing assistive personnel (NAPs), and other personnel by virtue of their position in the hierarchy and the state's nurse practice act. Nurses are essential to the operation of most healthcare organizations and could cause considerable disruption if they refused to work. These actions are another source of power (coercion) for nurses (Weydt, 2010).

Nurses have always had the power of information, or expertise. For example, Florence Nightingale showed very graphically in the 1800s that wherever her nurses were, far fewer patients died; and wherever they were not, far more died. Think of the power of that information. Immediately people were saying, "What would you like, Miss Nightingale? Would you like more money? Would you like a school of nursing? What else can we do for you?" (Fralic, 2000, p. 340). She had solid data, she knew how to collect, interpret and distribute the data in terms of things that people valued (Stanley & Sherratt, 2010).

Assistants and technicians may appear to have less power because of their position in an organization's "top-down" hierarchy. Imagine, though, how the work of the organization (e.g., hospital, nursing home) would grind to a halt if all the nursing assistants failed to appear one morning. Therefore, they have both expertise and coercive power.

KnowledgeCheck 40-4

What are the sources of power available to nurses?

Sources of Empowerment

How can nurses, either individually or collectively, maximize their power and increase their feelings of empowerment? To answer this question, you should first distinguish between the concepts of power and empowerment. Recall that power is the ability to influence other people despite resistance from them. **Empowerment** is a psychological state, a feeling of competence, control, and entitlement that a person experiences.

Key Point: ***Given these definitions, it is possible to be powerful and yet not feel empowered. Power refers to action, and empowerment refers to feelings. Both are of interest to nursing leaders and managers.***

Feeling empowered includes the following:

- **Self-determination:** Feeling free to decide how to do your work
- **Meaning:** Caring about your work, enjoying it, and taking it seriously
- **Competence:** Confidence in your ability to do your work well
- **Impact:** Feeling that people listen to your ideas, that you can make a difference

Nurses, like most people, want to have some power and to feel empowered. You want to be heard, recognized, valued, and respected. You do not want to feel unimportant or insignificant to society or to the organization in which you work. The following contribute to your empowerment: (a) manageable, reasonable work assignments; (b) reward, recognition, and appreciation for a job well done; and (c) fair, consistent treatment of all staff.

Not all empowerment comes from others. You can become empowered by actively participating in professional nursing organizations, joining a collective bargaining unit, and seeking opportunities to be involved in decision making in your organization. Two other ways of empowering yourself are by enhancing and sharing expertise.

Enhancing Expertise

Nurses and other healthcare professionals are empowered to some degree by their own professional knowledge and competence. Following are some ways in which you can enhance your competence, thereby increasing your own sense of empowerment:

- Actively participate in interdisciplinary team conferences and patient-centered conferences on your unit.
- Attend continuing education activities to enhance your expertise. This might include local, regional, national, and international conferences sponsored by nursing organizations.
- Use evidence-based practice guidelines, current nursing journals, and books to make decisions regarding your nursing practice.
- Participate in nursing research projects related to your clinical area.
- Discuss with colleagues in nursing and other disciplines how to handle a difficult clinical situation.
- Observe the practice of experienced nurses.
- Continue education by earning additional degrees and certifications in nursing.

Although you have just begun your nursing career, it is not too early to begin thinking of ways to become empowered.

Sharing Expertise

The second part, becoming empowered through expertise, is to share with others the knowledge and experience you have. This means not only using your knowledge to improve your own practice, but also communicating what you have learned to other students and, later, to your colleagues in nursing. It also means letting your instructors and supervisors know that you have enhanced your professional competence. You can share your knowledge with your clients, empowering them as well. In the future, you may even reach the point at which you have learned more about a particular subject than most nurses have and want to write about it for publication.

PracticalKnowledge knowing**how**

As a leader or manager, you will need to get people to work together to make things happen. To do so, you will need to effectively communicate, delegate, deal with conflict and change, and manage your time appropriately. All of these can be thought of as skills or processes (practical knowledge).

COMMUNICATING

Leadership arises through relationships with other people, and leaders use communication to engage and support these relationships. Some view communication as a circular process that is affected by many factors. Thus, communication has both content and a relationship context. This means the activity is continuous, mutually interdependent, and influenced by the behaviors of each communicator. You need to use active listening to pick up all levels of meaning in a communication. Surface listening, or inattention, often causes a misinterpretation of the message. Your attitude also influences what you hear and how you interpret the message. Communication skills are taught extensively in Chapter 21, if you need to review them now.

To effectively manage client care, it is important to keep the lines of communication open on all levels. As a professional nurse, you will need to communicate client information to members of the nursing team, members of other disciplines, families, and individual clients. Trust and sincerity enhance communication among team members. Congruence (agreement) between your words and your deeds promotes trust. If team members feel that you are trustworthy and sincere, they will be more likely to ask questions and seek clarification when they are uncertain of something.

A leader is responsible for providing frequent evaluative feedback. Done poorly, evaluation can be stressful, even injurious. Done well, it promotes growth and employee satisfaction. Evaluative feedback is important because it:

- ***Reinforces constructive behavior.*** Positive feedback lets people know which behaviors are most productive and encourages them to continue the behaviors.
- ***Discourages unproductive behavior.*** Negative feedback prompts the person to correct inappropriate behavior.
- ***Provides recognition.*** Praise is an excellent motivator.

DELEGATING

An important aspect of leadership and management is learning how to delegate. You can apply the nursing process to delegating to safely provide client care.

- ***Assess and diagnose.*** Before deciding who should care for a particular client, you must assess each client's particular needs.
- ***Plan goals and interventions.*** Set client-specific goals, and identify the interventions required to achieve these goals. Mentally identify which staff member is best suited for the task or activities before delegating helps prevent problems later.
- ***Implement.*** Next, determine which personnel have the knowledge and skills to care for the client, and assign the tasks to the appropriate person.
- ***Evaluate.*** You must still oversee care and determine whether client care needs have been met. Be sure to

Quality and Safety Education for Nurses

The Effect of Authority Gradients on Teamwork and Patient Safety

Chapter Key Concept: *Management, (Subconcept) Followership*

Competencies: *Teamwork and Collaboration (Knowledge, Skills, Attitudes); Patient-Centered Care (Skills)**

Teamwork and collaboration are influenced by the psychological distance a team member feels between him and others higher up in the team structure. This is called the *authority gradient*. The greater the authority gradient, the less likely a person is to feel part of a team, question those in authority, or communicate concerns. Minimizing the authority gradient has been shown to improve communication, which reduces errors.

The authority gradient between physicians and nurses is very steep and is reinforced by tradition, individual personalities, physicians' attitudes, and, at times, nurses' fears of being incorrect. What are the authority gradients between nurses and other members of the healthcare team, including nursing assistants and others over whom nurses have authority?

Education and Team Building. To flatten these gradients, facilities need to provide education and team-building activities to all staff, including physicians.

Team Briefings. Another strategy is to establish team briefings as an expected routine. Briefings promote clear, effective communication and include introductions all around, review of the patient's problems and the treatment plan, and specific requests by the physician (or other person with the most authority and accountability) for input. Briefings create a shared understanding and foster an environment in which team members can and do speak up about any concerns.

Individual Skills. Individually, you can develop your communication skills, adopt an attitude of collaboration, and learn more about how to become a capable team member. To begin this process, consider the following:

- What are your strengths or weaknesses as a team member? What Knowledge, Skills, and Attitudes can you acquire to become more effective?
- How can you gain the confidence to question a doctor's order or assert your perspective on a patient's treatment plan? Have you practiced assertive communication?
- Are you succinct when you communicate? What structured communication style can you adopt to keep your comments and requests clear?
- Do you consistently show respect for other team members and what they contribute to the patient's care?
- Can you communicate the patient's values, preferences, and expressed needs to the healthcare team?

Sources: Hamman, Beaudin-Seiler & Beaubien. (2010); The Joint Commission (2011); Magrane, Khan, Pigeon, et al. (2010); Manser, T. (2009).

*For specific Knowledge, Skills, and Attitudes,

Go to the QSEN Web site, at http://qsen.org/competencies/pre-licensure-ksas/

allow time for feedback during the day. This enables all personnel to see how they are doing and what they still need to do. If you must give negative feedback, do so privately.

You will find an extended discussion of delegation in Chapter 7. You might also find helpful the American Nurses Association and National Council of the State Boards of Nursing (NCSBN) (n.d.) joint statement on delegation and a decision tree to promote proper delegation. For the NCSBN (2009) checklist using the *Five Rights of Delegation*,

Go to Chapter 7, **Implementation and Evaluation Tools, The Five Rights of Delegation-Checklist,** in Volume 2.

A manager must first determine the mix of personnel (RN, LVN/LPN, or NAP) required to deliver care on a unit before being able to delegate tasks to individuals. By looking at the needs of each client, you can make an educated decision about which staff members have the appropriate education and skill to deliver safe, quality care.

What If I Lack the Experience to Delegate?

The added responsibility of delegation often causes discomfort for new graduates. You may be used to providing total patient care for one or more clients, but lack the experience of organizing care for groups of clients with other team members. To overcome your discomfort, you need to observe how more experienced nurses delegate to others. Working with a preceptor will also give you experience in delegation.

Become familiar with nursing professional organization guidelines. The ANA has specified that RNs may not delegate the following tasks (Neumann, 2010):

- Initial nursing assessment; follow-up assessments if nursing judgment is indicated
- Nursing diagnosis
- Decisions and judgments about outcomes
- Formulation and approval of a patient plan of care
- Interventions that require professional nursing knowledge, decisions, or skills
- Decisions and judgments necessary for the evaluation of patient care

The ANA (2002, 2007) has issued a Position Statement on use of nursing assistive personnel (Plawecki & Amrhein, 2010). The list includes direct and indirect client care that may be delegated to NAPs (Fig. 40-2). Various other nursing personnel can also be used to meet patient care needs (Box 40-3).

What Are the Concerns About Delegating?

Today's healthcare environment requires nurses to delegate. Many nurses voice concerns about the personal

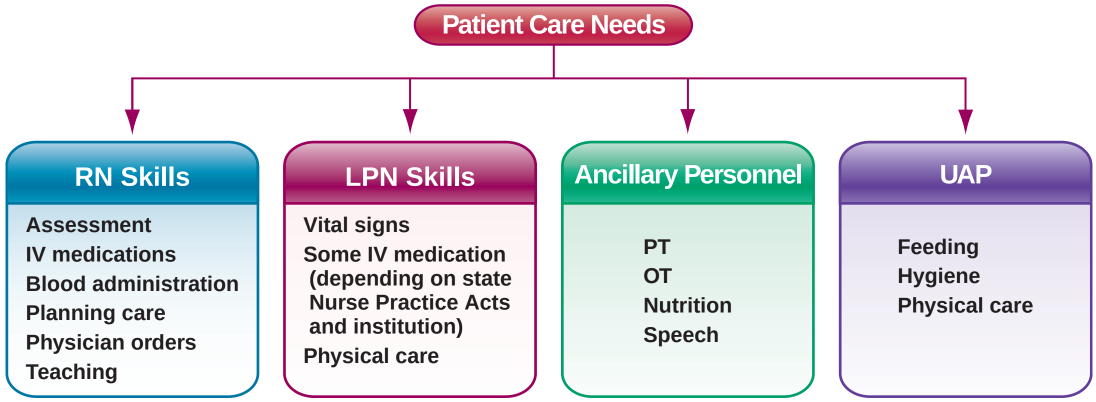

FIGURE 40-2 Patient care needs.

BOX 40-3 ■ Examples of Care That May Be Delegated to Nursing Assistive Personnel

Direct Client Care Activities

- Assisting with activities of daily living: feeding, drinking, ambulation, grooming, toileting, dressing
- Assisting with socializing
- Taking vital signs

Indirect Client Care Activities

- Providing a clean, safe environment
- Providing transport for noncritical clients
- Assisting with stocking nursing units
- Providing messenger and delivery services
- Making beds
- Ordering supplies

risk to their licensure if they delegate inappropriately. The courts have usually ruled that nurses are not liable for the negligence of other workers, provided that the nurse delegated appropriately. Delegation is within the scope of nursing practice, according to the ANA. Refer to Chapter 45 for further discussion on the legal aspects of delegation.

Nurses have also expressed concern over the effects of delegation on the quality of client care. When you delegate, you control the delegation. You decide to whom and what you will delegate. Remember that there are levels of acceptable performance and that not every task needs to be done perfectly.

KnowledgeCheck 40-5

Explain the relationship of delegation and the nursing process.

MANAGING CHANGE

Change is a naturally occurring phenomenon, a part of everyone's life. Every day, we have new experiences, meet new people, and learn something new. We grow up, leave home, graduate from college, and begin a new career, and perhaps a new family as well. Some of these changes are milestones in our lives, ones we have prepared for and anticipated for some time. Others are entirely unexpected—sometimes welcome and sometimes not. Many are exciting, leading us to new opportunities and challenges. When change occurs too rapidly or with high demands, it can make us very uncomfortable.

The Comfort Zone

The basic stages of Lewin's change process are unfreezing, change, and refreezing (Doolin, Quinn, Bryant, et al., 2011; Lewin, 1951). Figure 40-3 shows the relationship among those stages and the concepts of comfort zone, discomfort zone, and a new comfort zone.

Let's assume that your daily routine was basically stable before you started nursing school. You took care of the family or worked during the day and took a class or two each term. You knew what to expect and how to deal with whatever problems arose in the course of a day. In other words, you were operating within your "comfort zone" (Farrell & Broude, 1987; Lapp, 2002; Ryder, 2013). A big change is likely to move you out of this comfort zone into disequilibrium, possibly into discomfort. Now you are most likely attending a full-time nursing program and juggling changes in finances, child-care arrangements, and planning options. This first stage in the change process is called *unfreezing*. You are moving out of your comfort zone.

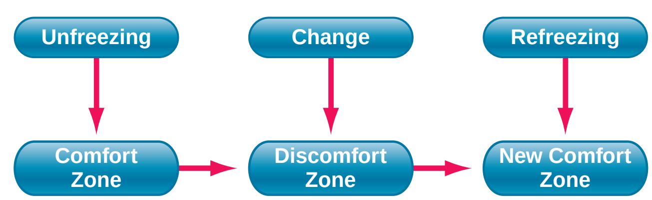

FIGURE 40-3 The change process. (Based on Doolin, C., Quinn, L., Bryant, L., et al., 2011; Farrell, K., & Broude, C., 1987; Lewin, K., 1951; Ryder, J., 2013.)

Resistance to Change

People resist change for a variety of reasons. For example, you may find that you can manage the change in class schedule, but that the child-care arrangements are more difficult. Resistance to change (and unfreezing) comes from three major sources: technical concerns, psychosocial needs, and threats to a person's position and power. For a student, so-called technical concerns may involve practical issues related to transportation to school or work, getting children to school, or managing household responsibilities.

Recall Maslow's (1970) Hierarchy of Needs, discussed in various chapters in this book. Maslow observed that the more basic needs (e.g., physiological and safety needs) must be at least partially met before a person is motivated to seek fulfillment of the higher-order needs. Change can make it more difficult for a person to meet any or all of these physiological and psychosocial needs (Cannon, 2013). Once status, power, and influence are gained within families and organizations, they are hard to give up. You may be the one in charge in the family and in the office, yet be a novice in the nursing program.

Recognizing Resistance

It is easy to recognize resistance to a change when it is expressed directly. When a person says to you, "That's not a very good idea," "I am going to quit if I can't get better grades," or "There's no way I'm going to do that," there is no doubt that you are meeting resistance. When resistance is less direct, however, you may not recognize it unless you know what to look for. Resistance may be active or passive.

- **Active resistance** can take the form of aggressive actions or outright refusals to comply (such as the statements in the previous paragraph), writing negative e-mails that attack and destroy the idea or the person who suggested it, quoting existing rules that make the change difficult or impossible to implement, or organizing resistance to the change (encouraging others to resist).
- **Passive approaches** involve avoidance: canceling appointments to discuss implementing the change; being "too busy" to make the change; agreeing to the change but doing nothing to effect it; and simply ignoring the entire process as much as possible.

ThinkLike a Nurse 40-6

Recall one change that you have experienced that was put into effect by a command (or a new rule, policy, or law).

- What effects did this change have on your life (e.g., work, school, home)?
- How did the command make you feel?
- What would have made this change easier for you?

Lowering Resistance

Key Point: ***A change that is welcomed by one group may be strongly resisted by another group. Resistance to change is affected by the leadership approach and the type of organizational structure.***

You can use various approaches to lower people's resistance to change. Strategies fall into four categories: commanding, disseminating information, refuting currently held beliefs, and providing psychological safety (Whitehead, Weiss, & Tappen, 2010).

Commanding Change Obviously, the quickest way to implement change, if you have the authority to do so, is to issue a command. Dictating change is not necessarily the best strategy, but it is sometimes necessary when the change must be made quickly. Commanding a change may not be effective if there are ways for people to resist, for example, when:

- Passive resistance can undermine the change
- High motivational levels are necessary to make the change successful
- People can refuse to obey the order without negative consequences

Sharing Information Much resistance is simply the result of misunderstandings about a proposed change. Sharing information is usually an effective way to reduce uncertainty and ease transition. Information about the change can be shared on a one-to-one basis, in group meetings, or through written materials distributed by print or electronic means. For you as a student, it is important that any changes in the program are communicated to you without delay. You should also communicate any changes in your plans to the appropriate people, such as other students, your nurse team leader, or your instructor. As a student nurse or staff member, you should treat client resistance to change in the same manner. The more information that you give the client, the more likely she will be to cooperate with the change.

Refuting Currently Held Beliefs You can sometimes increase a person's willingness to change by simply providing evidence that his actions or beliefs are inadequate, incorrect, or inefficient. For example, a patient may enter the hospital recalling horror stories from friends and family, but may then find that there was no basis for the stories. Consider the fact that your ideas about the nursing program have changed since you first began. What happened, or what information did you receive, that caused you to change your beliefs?

Providing Psychological Safety When a proposed change threatens basic human needs in some way, reducing that threat can lower resistance. This leaves people feeling more comfortable about the change. Although each situation poses different kinds of threats and requires different actions to reduce them, Box 40-4 identifies common strategies that help increase psychological safety and reduce resistance to change.

BOX 40-4 ■ Common Strategies to Increase Psychological Safety and Reduce Resistance to Change

- Point out similarities between old and new procedures.
- Suggest ways in which the change can provide new opportunities and challenges.
- Allow time for learning and practice of any new procedures, if possible, before a change is implemented.
- Recognize the competence and skill of the people involved.
- Involve as many people as possible in both the design and implementation of the change.
- Express approval of people's concern for providing the best care possible.
- Express the value of each individual's and group's contributions in general and to the proposed change.
- Provide a climate of trust and acceptance in which mistakes can be made without negative consequences for individuals.
- If possible, provide assurance that no one will lose his or her position because of the change.
- Provide opportunities for people to express their feelings and ask questions about the proposed change.

Implementing the Change

In planning for change, you will already have asked yourself these questions:

What is the purpose of this change? What are we trying to accomplish?
Is the change necessary?
Is the change technically correct?
Will the change work?
Is there a better way to do this?

After employing some unfreezing strategies, you are ready to make the change that has been so carefully planned. In addition to employing strategies to lower resistance, increase motivation, and help people work well together, you will want to consider the following characteristics of the change:

- **Magnitude of the Change.** Is this a major change that affects almost everything people do, or is it a minor one with little impact on what people do every day?
- **Complexity of the Change.** Is this a difficult change to make? Does it require much new knowledge or skills, or both? How long will it take for people to acquire the necessary knowledge and skills?
- **Pace of the Change.** How urgent is this change? Can it be done gradually, or must it be implemented all at once?
- **Stress Level of Those Involved.** What is the current stress level of the people involved in this change? Is this the only change that is taking place, or is it just one of many changes taking place? How stressful are these changes? How can I help people keep their stress levels within tolerable bounds?

As indicated earlier, some discomfort is likely to occur with almost any change, but it is important to keep it within tolerable limits. You need enough pressure to get people to pay attention to the change process, but not so much that they are overstressed by it. In other words, you want to raise the heat enough to get them moving, but not so high that they boil over (Battilana & Casciaro, 2013).

Integrating the Change

Integrating the change is the last step. After the change has been made, it is important to make sure that everyone has moved into a new comfort zone. Ask yourself:

- Is the change well integrated into everyday operations?
- Are people comfortable with it now?
- Is it well accepted and perceived as valuable? If not, why not? What can be done to increase acceptance?
- Is there any residual resistance that could still undermine full integration of the change? If there is, how can this resistance be overcome?

Change "sticks" when, instead of being the new way to do something, it has become "the way we always do things around here" (Kotter, 1999, p. 18; see also Dean, 2013).

Change is an inevitable part of living and working. Your leadership can influence how people respond to change, the amount of stress it causes, and the amount of resistance it provokes. Handled well, most changes can become opportunities for professional growth and development rather than just additional stressors for students, nurses, and their clients.

CONFLICT

Nursing education and healthcare settings bring together people of different ages, genders, income levels, statuses, ethnic groups, educational levels, lifestyles, and professions. They share the goal of maintaining people's health. Differences of opinion over how to best accomplish goals are a normal part of working with people of various skill levels and different segments of society. Each unique individual brings different experiences, beliefs, values, and habits to interactions with others. Various pressures and demands in the classroom, clinical setting, and workplace can also generate problems and conflicts. Any or all of these can interfere with your ability to work together.

Conflicts Occur at All Levels

Conflicts can occur at any level and involve any number of people, including your boss, subordinates, peers, patients, or families.

- **On the *individual level***, they can occur between two people working together on a classroom or clinical project, between two people in different departments,

Toward Evidence-Based Practice

The Center for Health Design. (2009). Pebble Project data summary. Retrieved from http://www.healthdesign.org/pebble

Preliminary data from the Pebble Project include the following studies:

Weill Cornell Medical College, New York, New York. Conducted studies at six ambulatory sites to examine how wait times affect perceived quality and anxiety. Key findings include the following:

- The more attractive the environment is, the higher the perceived quality and the lower the anxiety will be.
- There was no significant relationship between *actual* wait times and perceived quality or anxiety.
- There was a significant relationship between *perceived* wait times and perceived quality and anxiety.

Paoli Hospital, Paoli, Pennsylvania. Results collected on a new patient pavilion found (Nash & Taylor, 2011):

- That patients feel the design features (e.g., private rooms, décor, increased room size, larger windows and natural light, and rooms with window views) positively affect their hospital experience. As a result patient satisfaction scores increased significantly.
- That staff feel the design features (e.g., materials, temperature, and noise) provide patient privacy and improve everyday work tasks except access to staff break rooms.
- That the rate of patient falls per 1,000 patient days was reduced by nearly 10% in the new pavilion, with an 86% reduction in the rate of falls with injury. Key features of the redesign included location of nurses work areas and visibility of the patient by the staff.
- That medication errors decreased by 19%. Design strategies included placing medications in a box outside each patient room with a closed door to minimize distractions during medication preparation.

Lake Health TriPoint Medical Center, Concord Township, Ohio. Results and data collected on new acute care hospital using state-of-the-art digital hospital design include the following (Gardiner, 2012):

- A 20% to 30% reduction in operating costs as a result of custom air-handling units and integrated controls solutions that delivered the desired temperature and humidity to both critical and non-critical spaces. The sustainable design also increased additional usable floor space.
- A long-term contingency emergency preparedness plan was developed that would minimize the amount of time the hospital would be out of service and would quickly restore productivity in operating rooms.

1. Imagine you are a nurse manager about to present at a budget meeting your ideas for why it would be cost effective to remodel the clinic lobby, including addition of skylights, plants, and a small fountain. List your rationale and state which of the healthcare agency studies supports each item. Be sure to tie your rationale to cost-effectiveness.

or even between a staff member and a client or family member.

- **On the** ***group level***, conflict can occur between two or more teams, departments, or professional groups (e.g., nurses and social workers may conflict over who is responsible for discharge planning).
- **On the** ***organizational level***, conflicts can occur between two or more hospitals, health agencies, or community organizations. *Gender-based* conflicts may involve equal pay for women and sexual harassment issues.

"Win–Win" Resolutions

Some people think about problems and conflicts in the same way as they think about a football game or tennis match: Someone has to win, and someone has to lose. There are some problems with this comparison to sports competition:

- In healthcare, our aim should be to work together more effectively, not to defeat the other party.
- The people who lose are likely to feel bad about losing. As a result, they may spend their time and energy preparing to win the next round, rather than on their work.
- A tie (neither side wins or loses) may be just a stalemate; no one has won or lost, but the problem is also still there and no gain is achieved.

So the answer to the question, "Win, lose, or draw?" is, "None of the above." Instead, a win-win result, in which both sides gain some benefit, is the best resolution (Haslam, Reicher, & Platow, 2011). People address conflict in various ways. Some avoid it, some make immediate decisions, others use an analysis approach.

When compared with their younger counterparts, older adults were more likely to choose the deferral option when presented with low and high conflict scenarios. Both groups were more likely to defer decisions in high conflict scenarios (Pethtel & Chen, 2013). You should accept that not everyone will address conflict.

Conflict Resolution

When differences and disagreements first arise, problem-solving may be sufficient. If the situation has already developed into a full-blown conflict, however, formal or informal negotiation of a settlement may be necessary. Using a problem-solving process, the goal is to find a solution that satisfies everyone involved.

Step 1 ***Identify the problem or issue.*** Ask people what they want (Hagemann & Stroope, 2012). Sometimes, if the issue is not a highly charged or highly political one, it is easy to identify the real issue or problem. At other times, however, some discussion and exploration of the issues are necessary before the real problem emerges. "It would be relaxing if what other people were really saying was always obvious, if all their essential thoughts were clearly labeled for us . . . and if all knowledgeable people agreed about answers to important questions" (Browne & Kelley, 2010, p. 6). Even though this is ideal, it may not happen. People are often vague about their real concern; sometimes they are genuinely uncertain about what the real problem is. Emotional involvement may further cloud the issue. All of this must be sorted out so that the problem is clearly identified and a solution can be sought.

Step 2 ***Generate possible solutions.*** Here creativity is especially important. As a leader, begin the process of trying to find new, creative solutions. It is natural for people to try to repeat something that worked well for them in the past, but solutions that were previously successful may not work in the future. Instead, encourage people to spend some time searching for innovative solutions. Think outside the box for new and better ways to handle things.

Step 3 ***Evaluate suggested solutions.*** An open-minded, objective evaluation of each suggestion is needed, but you may find that this is not always easy to accomplish. When a group engages in problem-solving, it is sometimes difficult to separate the suggestion from its source. For example, on a team, the status of the person who made the suggestion may influence whether the suggestion is judged to be useful. Judge the suggestion on its merits, not its source.

Step 4 ***Choose the best solution.*** Choose the solution that is most likely to work—one that will give you the best results with the fewest negative effects. A combination of suggestions is often the best solution.

Step 5 ***Implement the solution chosen.*** The true test of any solution is how well it actually works. Once a solution has been implemented, it is important to give it time to work. Impatience may lead you to abandon a good solution prematurely.

Step 6 ***Evaluate—Is the problem resolved?*** Not every problem is resolved successfully on the first attempt. If the problem has not been resolved, you need to resume the process with even greater attention to identifying the real problem and how it can be successfully resolved.

Informal Negotiation

If problem-solving does not resolve the conflict, you may have to move on to the next step—informal negotiation. The following steps may prove useful.

1. **Clarify the situation in your own mind.**
   What am I trying to achieve?
   What is the environment in which I am operating?
   What problems am I likely to encounter?
   What do both sides want?
2. **Set the stage.**
   This may involve confronting the two parties or groups with their behavior toward one another, making direct statements designed to open communication and challenge them to seek resolution of the situation.
3. **Conduct the negotiation.**
   Manage the emotions.
   Set the ground rules.
   Clarify the problem.
   Make your opening move.
4. **Continue with offers and counteroffers.**
5. **Agree on the resolution of the conflict.**

Conflict is inevitable within any large or diverse group of people who are trying to work together over an extended period of time. However, it does not have to be destructive, and it does not even have to be a negative experience if everyone handles it skillfully. In fact, conflict can stimulate people to learn more about each other and how to work together in more effective ways. Resolution of a conflict, when it is done well, can lead to improved relationships, more creative methods of problem-solving, and higher productivity.

TIME MANAGEMENT

Many of the personal management and workplace organizational skills focus on time management and scheduling. Although new nurses may have the required job skills, many lack personal management skills, specifically, time management. You might be able to handle conflict and change, delegate appropriately, and be a strong leader among your peers, your faculty, and staff. But if you can't organize and manage your time, you will never gain your full potential.

Many nurses "punch a time clock" that records the minute they enter and leave work, and management accepts very few excuses for being late. Timesheets and schedules are part of most healthcare workers' lives. We are expected to follow precisely set schedules and meet deadlines for virtually everything we do, from distributing medications to getting reports done on time. Many agencies analyze computer-generated data to determine the amount of time spent on various activities. Consider how you can use the following suggestions to improve your time management.

Setting Your Own Goals

It is difficult to decide how to spend your time, because there are so many things that need time. A good first step is to get an overview of the situation. Then ask yourself, "What are my goals?" Goals help clarify what you want and give you energy, direction, and focus. Once you know where you want to go, set priorities. This is not an easy task. In Lewis Carroll's (1865/2010) *Alice's Adventures in Wonderland*, the child heroine, Alice, becomes lost and asks for help from a fantasy creature, the Cheshire Cat. They have this conversation:

> *"Would you tell me please, which way I ought to go from here?" asked Alice.*
> *"That depends a good deal on where you want to go to," said the Cat.*
> *"I don't care where," said Alice.*
> *"Then it doesn't matter which way you go," said the Cat.*

How can you get somewhere if you do not know where you want to go? It is important to explore your personal and career goals. This can help you make decisions about the future. You can apply these ideas to daily activities as well as to career decisions. Spend some time thinking about what you want to accomplish over a particular time period.

To help organize your time, you need to set both short- and long-term goals. **Short-term goals** are goals that you wish to accomplish within the near future. Setting up your day in an organized fashion is a short-term goal, and so is scheduling a time to study. **Long-term goals** are goals you wish to complete over a long period of time. Advanced education and career goals are examples. A good question to ask yourself is, "What do I see myself doing 5 years from now?" Every choice you make requires a different allocation of time.

Organizing Your Work

Many healthcare professionals are linear, fast-tempo, achievement-oriented people. However, working at a rapid pace is not necessarily the same as accomplishing a great deal. You can use much energy in rushing around and stirring things up while actually achieving very little. Fast does not necessarily mean efficient or effective.

To "manage" time, you need to handle time with a measure of skill. Therefore, time management includes efficiently meeting client care needs during a nursing shift. Organizing your work can eliminate extra steps or serious delays in finishing. It can also reduce the amount of time you spend doing things that are neither productive nor satisfying. As you begin your nursing program, you may care for only one or two patients. However, as you develop time management skills, you will be able to handle a workload of care for seven or eight inpatients. The following are some suggestions:

Time Inventory To begin managing your time, you need to develop a clearer understanding of how you use your time. A personal time inventory helps you estimate how much time you spend in typical activities. Keeping the inventory for a week gives a fairly accurate estimate of how you spend your time. It also helps identify "time wasters." Set up a time log and enter your activities every half hour. Keep this record for about 3 days so you can see a pattern emerging. You may be interested to know that one study of 36 hospitals found that medical-surgical nurses spend their time in the following ways (Hendrich, Chow, Sklerczynski, et al., 2008; Robert Wood Johnson Foundation, 2009):

Documentation	27.5%
Care coordination	16.0%
Patient care activities	15.1%
Medication administration	13.4%
Assessments/vital signs	5.8%
Nonclinical	12.6%
Waste [of time]	6.8%
Unit-related functions	2.8%

Key Point: ***Promoting the efficient use of nurses time is a top concern in unit redesigns.***

Energy Use Work on the most difficult tasks when you have the most energy. This decreases frustration later in the day, when you may be more tired and less efficient. Also consider your energy levels when beginning a big task. Start when levels are high and not at, say, 4 p.m., if that is when you find yourself winding down. For example, if you are a "morning person," plan your demanding work in the morning. If you get energy spurts later in the morning or early afternoon, plan to work on larger or heavier tasks at that time. Of course, this choice is not always within your control. Many nursing tasks are based on a schedule. If the wound care is due at 1 p.m., you must carry out the task then, even if you would prefer to eat lunch and rest. Analyze your work to determine which tasks are fixed and what you can manipulate to match your energy.

Lists and Schedules Make a "to do" list and prioritize the tasks in order of importance. Determine how much time each task will require, and when each must be completed. If you find yourself postponing an item for several days, decide whether to give it top priority the next day or drop it from the list altogether.

Daily Worksheet To help organize your day, provide yourself with reminders of various tasks and when they need to be done. Without some type of schedule, you are more likely to drift through a day or shift from one activity to another in a disorganized fashion. The risk in using schedules, however, is that the more they divide the day into discrete segments, the more they fragment the work and discourage a holistic approach. Use the schedule as an organizational tool, but focus on your clients. For a worksheet you can use,

Go to Chapter 7, **Tables, Boxes, Figures: ESG Figure 7-1, Worksheet for Organizing Nursing Care,** on Davis*Plus*.

Say "No" Take control to avoid time wasters. It is important to prevent endless activities and other people controlling you. Learn when to say no. Learn to say, "I would really like to help you; can it wait until I finish this?" Or, "I am sorry, I won't be able to help you with that."

Delegate See previous discussions about delegation.

Do Not Multitask Studies show that people who do many things at once do none of them well, even though they believe they do. Do not check your voicemail while documenting in the patient record, for example. Finish one task, then move on to the next one.

Streamline Your Work Many tasks cannot be eliminated or delegated, but they can be done more efficiently. Here are three wise sayings in time management:

- "Work smarter, not harder." This should appeal to nurses facing increasing demands on time (Box 40-5).
- "Never handle a piece of paper more than once." This philosophy can be used for patient care, as well as office work and schoolwork. Handle an issue now rather than putting it off until later.
- "A stitch in time saves nine." Preventive action saves time in the long run.

Plan the Night Before Take a few minutes before bedtime to lay out your clothing for the next day, set up the coffee pot, or whatever you need to do to avoid last-minute chaos in the morning.

BOX 40-5 ■ Work Smarter, Not Harder

- Gather materials, such as bed linens, for all of your clients at one time. As you go to each room, leave the linen so that it will be there when you need it.
- While giving a bed bath or providing other personal care, perform some of the aspects of the physical assessment, such as taking vital signs, skin assessment, and parts of the neurological and musculoskeletal assessment.
- If a client does not "look right," do not ignore your instincts. The client is probably having a problem.
- Prevention is always a good idea. If you are not sure about a treatment or medication, ask before you proceed. It is usually less time consuming to prevent a problem than it is to resolve one.
- When you set aside time to do a specific task that has a high priority, stick to your schedule and complete it.
- Do not allow interruptions while you are completing any tasks (e.g., paperwork, medication administration). Focus on the task at hand.

Components of Time Management

Time can be your best friend or your worst enemy. It is important to identify how you feel about time and to assess your own time management skills. Nursing requires that you perform numerous activities within what often seems a very short period of time, so learn how to make the most of your day. Finally, remember that you should set aside 8 hours for sleep and a few more for personal or leisure time ("time off"). Use Table 40-4 to help you to review the necessary components of time management.

Table 40-4 ➤ Components of Time Management

ACTION	EXAMPLES
Prioritize	List tasks in order of importance. Remember that some tasks must be done at specific times, whereas others can be done at any time. Emergencies take precedence. Identify events you control and events others control. Use critical-thinking skills to assign priorities.
Question	
■ Effectiveness	■ Did the task produce the desired outcome?
■ Efficiency	■ How can I accomplish the plan with the least expenditure of time? Is there a way to break this down into simpler tasks?
■ Efficacy	■ Do I have the skill and ability to obtain the desired effect?
Recheck	Mentally and physically recheck an unfinished or delegated task.
Practice Self-Reliance	Identify tasks that are within your control and those that are not. Use critical-thinking skills and adaptability to revise priorities "Go with the flow."
Treat	Treat yourself to a break when you can. Treat yourself to time off. Treat yourself to an educational experience: Commit yourself to excellence. Treat others with courtesy and respect.

KnowledgeCheck 40-6

- List the steps of conflict resolution.
- List several suggestions for organizing your work.
- State one "wise saying" to guide you in streamlining your work.

PUTTING IT ALL TOGETHER

You are just beginning your journey toward becoming a nurse. Undoubtedly you will want to function well within your organization and deliver high-quality patient care. Begin now to examine and work on your own strengths and weaknesses. As you work with your classmates, your instructors, and the clinical facilities, focus on developing the traits of a good leader. You will soon recognize that conflict and change are a normal part of life and your clinical practice, so learn to become proactive as issues arise. You will observe how "real" nurses delegate and manage their time. Take what is useful, and learn from their examples. There will be opportunities to be mentored; watch for those and make time to mentor others. Above all, remember that you may be the most important person in the life of your client during the time you are with him or her—a very big responsibility, but one you will meet with honor and courage.

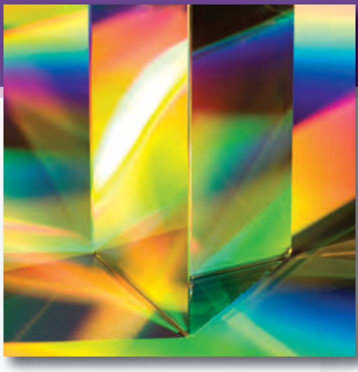
CHAPTER 41



Nursing Informatics

Learning Outcomes

After completing this chapter, you should be able to:

- Define informatics and its four components.
- Describe the importance of computers in evidence-based nursing practice.
- Explain the role of interoperability and standardized languages within the electronic health record system for exchanging health information.
- Discuss the benefits of the electronic health record.
- Discuss the impact of legislative efforts to encourage electronic health record adoption.
- Describe the importance of protecting personal health information.
- Explain the relationship between computers and standardized nursing languages.
- Identify at least two ways that automation decreases error in healthcare.
- Explain how computers can reduce some of the barriers to evidence-based practice.
- Identify at least four online sources of nursing research.
- Describe the process of literature database searching.
- Outline a process for evaluating evidence and determining a solution.

Meet Your Nurse Role Model

Six weeks ago, Ted Samuels, 67, a business executive, began experiencing headaches, occasional palpitations, blurred vision, and increased thirst. Mr. Samuels accesses the **patient web portal** of his **personal health record (PHR)** and sends an e-mail to his physician's scheduling service requesting an appointment. Within an hour, an appointment is confirmed with the family nurse practitioner (FNP) the next day.

The physician's office has just installed an **electronic health record system (EHR)** that is **integrated** with the hospital record for seamless communication among Mr. Samuel's caregivers. At his appointment, the FNP enters his insurance and personal contact information into the system, and explains that the system is **encrypted** (special security coding) to protect his privacy. In the exam room, the medical assistant weighs Mr. Samuels, takes his vital signs, and enters the information in the EHR. Next, Karen Shock, FNP, arrives. As she takes Mr. Samuels's history and completes a physical examination, she updates the information in the computer. Noting his family history of diabetes, the increased thirst, and slight weight gain, she checks a random glucose via the office glucometer and finds a blood sugar level of 300 mg/dL. The **decision support algorithms** built into the software alert her that Mr. Samuels's blood pressure was also elevated at 170/98. The software suggests

(Continued)

Meet Your Nurse Role Model (continued)

possible medical diagnoses of hyperglycemia and hypertension. Following the evidence-based care guidelines in the computer, Ms. Shock uses **computerized provider order entry (CPOE)** to enter requests for a basic metabolic profile, lipid profile, electrocardiogram (ECG), blood urea nitrogen (BUN), creatinine, and Hgb A_{1c}. She asks that Mr. Samuels be fasting for the blood work, and prints patient education instructions. Ms. Shock instructs Mr. Samuels to check his blood pressure two to three times daily for 1 week and to enter the results in the online log in his PHR. She asks Mr. Samuels to grant viewing rights to the log for her and Dr. Gregg.

The next morning Mr. Samuels arrives at the hospital for his lab work and ECG. His registration information is automatically updated from the information provided with a previous health visit. The **online order requisitions** Ms. Shock entered yesterday provide the technicians with the information needed, the tests are completed, and Mr. Samuels is quickly on the way back to his office. At the end of the day, he receives an e-mail notification that his lab results are available for review. He logs into the PHR portal to view the results. He also finds a message from Ms. Shock confirming the preliminary diagnosis of type 2 diabetes. The office is scheduling diabetic instruction, and they have e-mailed a prescription to Mr. Samuels's pharmacy for metformin, an antidiabetes drug. An education leaflet explaining the medication and potential side effects is attached to the message. Mr. Samuels notices that metformin is now showing on his **medication list** in his PHR.

During the course of the week, Ms. Shock monitors Mr. Samuels's blood pressure log entries. A **trending graph** shows consistently high blood pressure readings. She orders Lisinopril, an antihypertensive, 5 mg daily, and requests that he continue to check his blood pressure frequently. A follow-up appointment is scheduled for 6 weeks.

A few weeks later, Mr. Samuels wakes up with severe chest pain and calls 911. En route to the emergency department (ED), the paramedic transmits an ECG tracing via satellite to the ED physician. Using telehealth technology, the physician interprets the ECG, determines that Mr. Samuels is having a myocardial infarction (MI), and notifies the cardiac catheterization team to be on standby. The ED physician sees that Mr. Samuels has recently completed tests at the hospital, and reviews his medication list, allergies, and medical history online. Within 30 minutes Mr. Samuels is sent to the cath lab for percutaneous transluminal coronary angioplasty.

Four hours later, Mr. Samuels is resting comfortably in the progressive care unit. Throughout the next 48 hours, the bedside nurse monitors Mr. Samuels's vital signs and cardiac rhythm. An **interface** allows the nurse to directly import vital signs data from the cardiac monitor directly into his electronic health record. Caregivers document electronically at the bedside, and the physician uses CPOE to manage Mr. Samuels's prescriptions. At discharge, the nurse gives Mr. Samuels a printed copy of his medication list, discharge instructions, and follow-up appointments are made with Dr. Gregg and the cardiologist.

ThinkLike a Nurse 41-1

Reflect on this Meet Your Nurse Role Model scenario. Identify how information was managed and processed.

- What mechanisms for gathering and disseminating information were used?
- How did automation assist decision making?
- How was evidence used in decision making?
- What characteristics make it more likely for patients to use personal health records?

TheoreticalKnowledge knowingwhy

Computers have become as much of a diagnostic tool as stethoscopes have been for the past century. The Meet Your Nurse Role Model scenario is an example of how healthcare professionals use these tools to make decisions in practice. This chapter gives you an overview of how this works.

ABOUT THE KEY CONCEPTS

You may already feel the push and pull on your time and knowledge. And why work harder, when you can work smarter using technology-based tools? In today's increasingly complex and ever-changing environment, healthcare professionals must be competent in the use of information technology to communicate effectively with the healthcare team, patients, and families; manage information; support clinical decision making; and reduce the risk of medical error.

Nursing informatics and **healthcare technology** (e.g., mechanical ventilators, implantable insulin pumps) support your passion for nursing and innovation, leading to improved patient outcomes and higher quality care. **Electronic communication** (e.g., electronic health records and telehealth) is also an important part of this equation.

WHAT IS NURSING INFORMATICS?

Whether you become a staff nurse, an administrator, a researcher, primary healthcare provider, or an educator, you will need current, accurate, and "best available" information to do your job well. The good news is that plenty of information is available. MEDLINE, a vast medical literature database supported through the National Institutes of Health (NIH), currently contains more than 18 million citations and is growing at the rate of more than 1.4 million new entries per year (NIH, 2013). If you read two new articles every day, by the end of the year you would be 918 years behind in keeping up with the literature. The bad news (if you want to call it that) is that we are drowning in information while still lacking in knowledge. Do you ever feel that way as a student?

It is not possible to keep all the necessary information in your head. No one can. We need critical thinking and tools to make it useful to us. No one can learn and retain all the information, so you must know how to find, process, and manage it to arrive at the best decisions for your practice. In essence, this is the definition of **informatics**: the managing and processing of information necessary to make decisions**. Nursing informatics** is informatics applied to nursing practice, education, and research. The first conceptual framework for informatics envisioned the elements ("stuff") of informatics as *data, information,* and *knowledge* (Graves & Corcoran, 1989). Full-spectrum nurses interact with all three of these elements in daily practice, so you need to understand how they interrelate.

Nursing informatics specialists (NIS) work with informatics technicians and others to provide clinical information and data analysis for effective patient care. In addition, they work with computers, data analysis systems, and nursing knowledge and experience to be sure the best possible care is provided. This role involves good understanding of basic nursing techniques and standards. Data collection, analysis of different types of data, information sharing, and research dissemination are functions of the NIS. The NIS also acts as a manager or team leader to bring together all aspects of treatment options and best practice research. In sum, the NIS uses nursing science, computer science, and information science to manage and communicate data, information, knowledge, and wisdom in nursing practice. The sections that follow describe these four elements of informatics.

Data

Data are "discrete entities that are described objectively without interpretation" (American Nurses Association [ANA], 2008). In other words, data are raw, unprocessed numbers, symbols, or words that have no meaning by themselves. For example, what does 101 mean? It could indicate the college course English 101; a piece of programming language; or someone's body temperature, pulse rate, weight, or age. Without a context, data are meaningless.

In nursing, we speak of data as the primary facts and observations acquired when providing services, such as the numerical value of a blood pressure measurement, or facts such as, "Father died of prostate cancer." Notice that even this information has no meaning until the nurse interprets it: The meaning of "Father died of prostate cancer" changes if the client is a healthy 24-year-old female sharing this information versus a 74-year-old male experiencing blood in his urine.

Information

Information consists of groupings of data processed into a meaningful, structured form (ANA, 2008). If you combine 300 with a unit of measure, you know that the number represents a blood sugar result. If other data—gender (male), age (67), and family history—are grouped together, information is formed. You now know that this man has most likely developed type 2 diabetes.

Data:	300 mg/dL glucose, male, 67, thirst
Grouped data:	Male gender, age 67, family history of diabetes
Information:	Man with probable new onset of diabetes

In the opening scenario, what information did the FNP receive that triggered an alert?

Knowledge

In the Meet Your Nurse Role Model scenario, what *information* did the FNP use to create knowledge of Mr. Samuels's condition? Take a minute to write your answer.

The answer to the question is that the FNP received information on the blood sugar (300 mg/dL) and blood pressure (170/98 mm Hg). Grouping this with other information (e.g., the history of headaches, blurred vision, palpitations, family history of diabetes), the FNP created *knowledge* of the potential for a diagnosis of type 2 diabetes and hypertension.

Knowledge is formed when data are grouped, creating meaningful information and relationships, which are then added to other structured information (ANA, 2008). The knowledge can either be previously known or new. In the preceding scenario of the 67-year-old man with the blood sugar of 300 mg/dL, we can add information about pathophysiology, pharmacokinetics (how medications work), patient history, and physical assessment, providing the knowledge to make an informed decision about the patient's current condition and further treatment.

Figure 41-1 depicts the transformation of data into knowledge. We have come to realize that the gathering

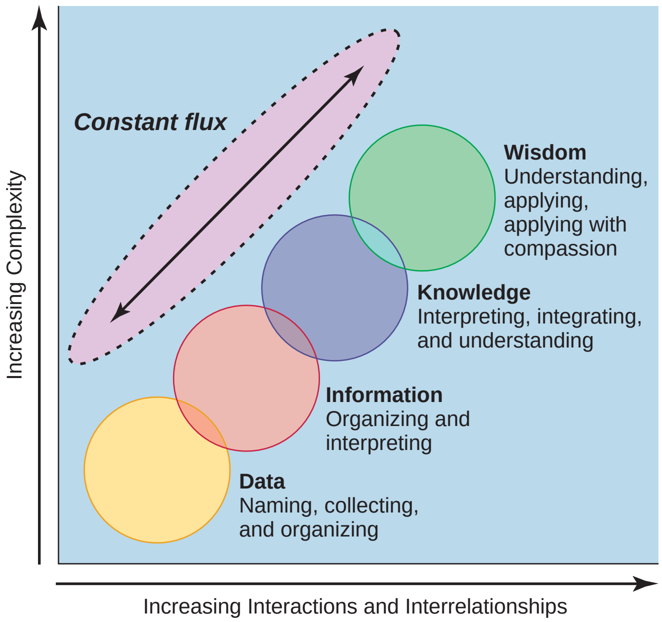

FIGURE 41-1 The relationship of data, information, knowledge, and wisdom. Each level increases in complexity. (Reprinted from Englebardt, S., & Nelson, R. *Health care informatics: An interdisciplinary approach.* Copyright 2002. With permission from Elsevier.)

of data and information to make decisions is never ending. Notice that the model shows overlapping circles and both forward and backward movement.

Wisdom

Nelson and Joos (1989) added *wisdom* to the Graves and Corcoran model. **Wisdom** is defined as the *appropriate use* of knowledge in managing or solving human problems. Wisdom develops as an outcome of your clinical experience, theoretical knowledge, critical thinking, and intuition—as you progress from novice to expert in the practice of full-spectrum nursing.

KnowledgeCheck 41-1

- What is the difference between knowledge and wisdom?
- Define the following: *data, information, knowledge.*
- Give an example of each: data, information, knowledge.

HOW DO NURSES USE INFORMATICS AT WORK?

Because computers are essential in healthcare, it is important that nurses develop a set of core computer competencies or skills (Hart, 2008; TIGER, 2009). These include a basic understanding of computer logic, data entry, data retrieval, information literacy, and troubleshooting basic hardware and software issues. In your work as a nurse, you will use computers not only to communicate, but also to provide and document patient care, seek information, examine evidence-based practice resources, and possibly conduct or participate in clinical research.

UNDERSTANDING COMPUTER BASICS

Computers are vital to the functioning in our daily lives. We rely on them for communication (e.g., e-mail, texting, blogs, social networking), access to information (e.g., personal and business contacts, education, general information), and business operations (e.g., scheduling, purchasing), to name but a few. By definition, a **computer** is an electronic device with four main functions: input, processing, output, and storage. Collectively, these operations are known as **information processing** (or *data processing*).

Key Point: ***The power of a computer is based on the speed, accuracy, and reliability with which it operates, as well as the enormous amounts of data it can store and keep readily available for processing.***

Computers consist of hardware (machines and monitors), memory (data storage), processors (translators), and software (coded programs or applications that support specific functions). They can exist as a stand-alone device, or as part of a network of computers that share a common purpose. Power in computing is enhanced by the ability to connect to other computers. Devices can be either *wired* (connected with physical wires) or *wireless* (connected through electromagnetic waves). *Connectivity* is a term referring to the ways in which computers and other hardware communicate and share information.

Data are stored either internally (in the memory) or externally on some form of storage media (disc, flash drive, external hard drive, network drive, the Cloud). If you are a savvy computer user, you probably already know how a computer functions. See if you can answer questions about computer basics.

Go to Chapter 41, **Supplemental Materials: Pretest Questions and Pretest Answer Key,** Davis*Plus.*

If you had difficulty answering the questions,

Go to Chapter 41, **Supplemental Materials: How Does a Computer Work?** on Davis*Plus.*

Electronic Communication

Electronic communication, whether simple (e.g., text messaging), or complex (e.g., telehealth), can be a timesaver, but does reduce face-to-face interaction between people.

Electronic Mail and Text Messaging

In many facilities electronic mail (e-mail) is now a primary method for managers to communicate with staff. E-mail and text messaging allow for rapid, simultaneous distribution of information and messaging to individuals or a large number of recipients. Nurses and other healthcare providers can use e-mail to interact with patients; consult with colleagues; and communicate with insurance industry representatives, pharmacies, and hospitals. E-mail and text offer convenient, up-to-the-minute patient updates among nurses, other providers, and patients and their families; plus, it can be used to document communications between people or groups.

Key Point: ***Protected information includes any individually identifiable health information; current, past, or potential physical or mental conditions; and any payment information. These transmissions occur only on secure or encrypted sites if personal patient information is involved, not in an e-mail.***

Be aware that privacy is not protected with electronic messaging. For example, it is entirely legal and not uncommon for employers to read incoming and outgoing employee messages when they are transmitted on company equipment. In addition, once a message has been sent, you have no control over who may read it or to whom it might be forwarded. You also don't know whether other people receive a blind copy of the message without your knowledge.

Key Point: ***Most facilities have policies governing use of company e-mail for personal use. Always check facility policies before sharing e-mail addresses with persons outside of the organization.***

How was e-mail used to facilitate communication between the patient and providers in the Meet Your Nurse Role Model situation?

Web Conferencing and Webinars

Web conferencing is used to conduct or participate in live or synchronous meetings or presentations via the Internet. Attendees download a Internet-based application onto their local computers. These interactions are most often two-way communication. To access the meeting, an e-mail is distributed to the attendee(s) that contains a link to enter the conference at the arranged time. A **webinar,** or **webcast**, is a specific type of Web conference that is conducted in a one- way manner, from the speaker to the audience. These tools can be useful in helping staff obtain updated clinical information (e.g., continuing education, inservice) for patient care.

Electronic Mailing List

An electronic mailing list, often called a *listserv*, is essentially a large, undisclosed distribution list whose members share a specialty interest. The names and addresses of the people on the mailing list, called **subscribers**, are stored on a single server. A single address is then designated for the group to use. When a message is sent to that address, it is delivered to the mailing list server, which then distributes the message via e-mail to all subscribers.

Electronic mailing lists are a powerful communication tool. Communication is global and almost instantaneous. Ideas and protocols can be shared, questions asked and answered, and surveys taken. Everyone on the list has an opportunity to share in the discussion.

Key Point: ***If you use an electronic mailing list, be aware that any message you send through the mailing list goes to everyone on the distribution list. So be careful when you hit the "Reply All" command!***

Numerous nursing mailing lists are available representing a wide variety of topics and health specialty areas. Use your favorite Internet search engine and search using the key words "nursing listservs." Look for a site that interests you. What kind of information do you see? Visit one of the sites. What kind of information do you see?

Social Networking

Social networking tools allow people to connect interactively with others who have similar interests. This can be done through **blogging** (posting open messages that can be read by anyone with permissions to access the site), sharing pictures, videos, or **texts**. Sites generally require you to register for the site, create a profile, and be granted access privileges by the Internet page administrator. Twitter, FaceBook, YouTube, CaringBridge, PatientsLikeMe, CureTogether, are examples of popular social networking sites. For instance, you can go to YouTube to view video demonstrations showing nursing skills. You will need to be cautious about whether the source of information is expert and reliable; for example, some of the YouTube skills videos have errors in the demonstrations. To find nursing videos, often it's easiest to search the specific topic, not simply "nursing videos."

As with many Internet-based tools, social networking sites are searchable by anyone with access. Many employers now regularly include searching these sites as part of their applicant verification process.

Key Point: ***Never post anything on these sites that you would not want an employer to view. In addition, posting pictures or descriptions of patient information represents significant risk of violating federal privacy laws.***

Wikis are an increasingly popular way to exchange information. These are Internet pages that can either be public or limited to specific groups through user name and passwords. Many schools have created Wikis to support communication among student groups. Support group Wikis are becoming common for use by patients with chronic health conditions, such as diabetes and congestive heart failure.

It is important to note that anyone with access can add information to these sites, creating the potential for you to find inaccurate information. It is useful to know whether support groups are being facilitated or at least monitored by a professional before recommending them to patients.

Interactive Gaming and Virtual Learning

As we are shifting from the Information Age to the Interaction Age, educators are adopting new, more engaging and collaborative methods for teaching and learning. One example is a Internet-based, three-dimensional virtual world called Second Life that digitally simulates the human experience. Residents, or participants in Second Life, also called **avatars**, can interact with one another in a social networking–type community that the residents refer to as the Grid. Educators use this game-like environment to simulate a nurse–patient experience and clinical care as well as to evaluate a variety of nursing skills.

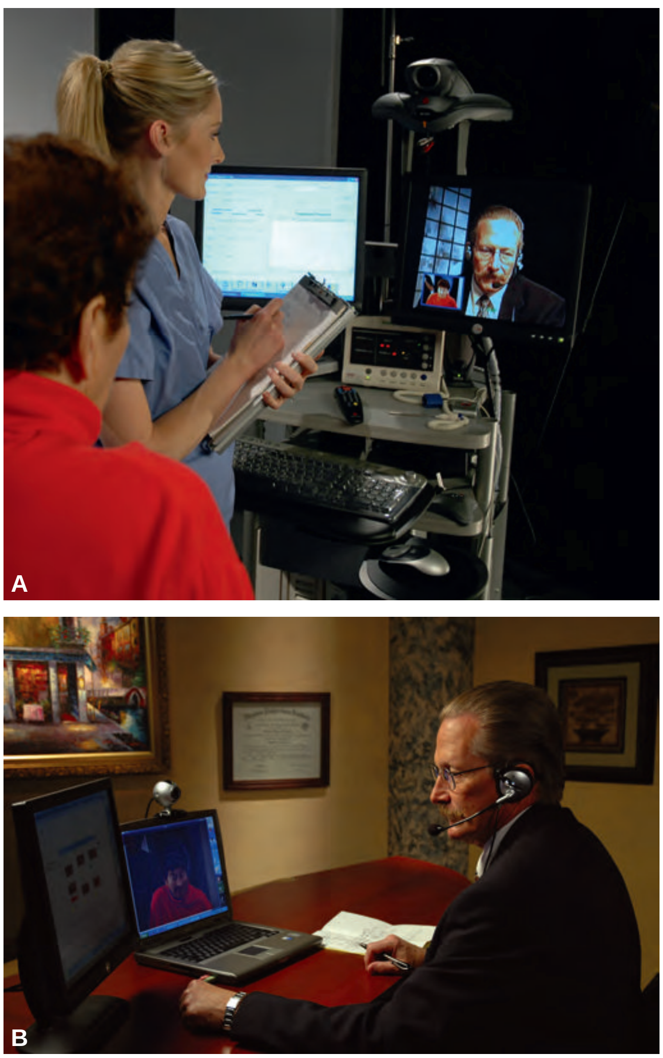
Telehealth

Telehealth is the use of telecommunication to send healthcare information between patients and professionals at different locations (Fig. 41-2). It improves access to healthcare by providing long-distance clinical healthcare, patient and professional education, and health administration. For instance, the U.S. Department of Defense pioneered telehealth technology and now uses it to provide healthcare services to soldiers in combat and dependent families in outlying posts. The following are other examples of the use of telehealth.

- **Rural Healthcare.** In rural healthcare sites there may not be a specialist located in the area. Telecommunications equipment at the rural site and the specialist's site allow the specialist and patient to see and talk to each other. The specialist can also view the health records, x-ray films, lab results, and so on. This reduces the cost of traveling to a distant site, and the stress on a patient who may not feel well enough to travel.
- **Home Health Monitoring.** A more common use of telehealth is the use of home health monitoring devices. These devices allow the healthcare professional to monitor vital signs and other indicators without physically entering a home or requiring a patient to make a clinic trip. Therefore, patients can be monitored more frequently, providing better follow-up care, and earlier discharge from the hospital. See the Home Care box Use of Informatics in Home Care.
- **Compensating for Shortage of Healthcare Providers.** In the hospital, critically ill patients can be remotely monitored by a hospital **intensivist** (physician employed by the hospital to provide healthcare to patients in intensive care) and critical care nurses from a central location. These systems enhance patient safety and provide an extra set of eyes for a busy nurse who cannot remain constantly at a patient's bedside.
- **Emergency Care Triage.** Some cities have incorporated telehealth nurse triage into their emergency 911 call system. Telenurses use a set of protocols to manage patient calls. These cities report a significant decrease in the need for ambulance services and emergency room visits (Enrado, 2009).

Despite barriers such as cost and issues surrounding licensing and reimbursement, telehealth applications will continue to expand in the future. For information about barriers that slow the growth of telehealth,

Go to Chapter 41, **Supplemental Materials: Barriers to Telehealth,** Davis*Plus.*



A
B

FIGURE 41-2 *A*, *B*, Telehealth improves access among healthcare providers at remote and central sites.

Home Care

Use of Informatics in Home Care

A telephone application for documentation has been developed for home health aides. It reduces the amount of time the aide must spend in recording care, improves accuracy, and prevents lost documentation.

- **When arriving at a patient's home**, the aide uses the patient's phone to dial in to a central number and keys in her identification. The time of the call, telephone number from which it came, and identification of the worker are automatically recorded.
- **At the end of the visit**, the aide again calls from the patient's phone. Again, the location, time, and identification of the caller are recorded. Using the telephone keypad, the aide then keys in codes indicating the tasks accomplished. She never has to physically write a documentation record; it is accomplished using the telephone.

ThinkLike a Nurse 41-2

- As a patient, would you prefer a telehealth or a face-to-face consultation? Why?
- Now imagine that you are an accident victim brought to a rural clinic staffed only with paraprofessionals. Does your answer change? If so, why?

KnowledgeCheck 41-2

- What is personal health information, and why is it important to protect it?
- How is a listserv different from regular e-mail?

Computer-Based Tools for Providing and Managing Care

As a nurse, you will be called on to use a wide variety of computerized devices in the workplace such as digital thermometers, cardiorespiratory monitors, glucometers, smart IV pumps, barcode scanners, and electronic bedscales.

Tracking Patients and Equipment

Global positioning systems (GPS) allow real-time tracking, which can be used in select clinical situations in which wandering is a patient safety concern. The Alzheimer's Association promotes use of electronic tracking for some patients with dementia as a way to postpone the need for a more secure environment (McShane, 2013).

Some agencies are using Real Time Location Systems (RTLS) or Radio Frequency Identification Detectors (RFID) to assist in locating patient care equipment that may be dispersed throughout a building. These systems save nurses time, deter staff from storing equipment on a particular unit rather than a centrally accessible location, and decrease costs of lost equipment (Turisco & Rhoads, 2008). Other efficiency-enhancing devices include hands-free communication badges and wireless smart phones, which may be interfaced with alerts from bedside equipment.

Managing Workflow

Internet-based tools for staff scheduling, patient flow, access to evidence-based references, policy and procedures, and staff education are used for their efficiency and convenience. Many hospitals have developed internal resources, special intranet pages with references specific to nursing. Mobile digital devices, including tablet computers and personal digital assistants (PDAs), are efficient for bedside retrieval of patients' health information, prescribed medications and interventions, and test results in the electronic health record. They also are convenient for charting at the bedside or other locations (Prgomet, Georgiou, & Westbrook, 2009).

Reducing Error With Automation

As healthcare becomes more complex, the opportunities for error increase significantly. A hospital stay can be prolonged or injury and even death can result from a seemingly simple mistake such as administering incompatible medications, or erroneously transcribing a medication order. There are two types of errors:

- *Errors of commission*— when the wrong action occurs (e.g., giving an incorrect drug)
- *Errors of omission*—when the correct action does not occur (e.g., overlooking a serious medication allergy or failing to put up the bed rails for a confused patient)

Another way to look at errors is by asking whether the error was in planning or execution:

- *An error in planning* occurs when the original intended action or plan was not correct.
- An *error of execution* occurs when the correct action is taken but does not proceed as intended.

Toward Evidence-Based Practice

Duffy, M. (2012). Tablet technology for nurses. *American Journal of Nursing, 112*(9), 59–64.

This article explores the advantages and potential barriers for nurses' use of tablets in the clinical setting. Advantages include portability, the potential to teach patients at the patient bedside, and EHR documentation at the point of care. Barriers include cost, availability of wireless connectivity, and concerns about compromising HIPPA/patient confidentiality.

Mitchell, M. (2012). Nursing informatics. How mobile is your technology? *Nursing Management, 43*(9), 26–30.

This article examines the use of mobile technology (tablets and smart phones) by patients and healthcare providers. Patients use mobile technology, with a hospital-provided access code, to go to the portal for patient education and information about when medications are scheduled to be taken and what procedures are scheduled. Nurses use mobile technology to access healthcare references, including drug guides, and secure text-messaging capabilities between the nurse and the physician.

According to both Duffy and Mitchell,

1. What are the advantages of using tablets?
2. What barriers exist to the use of tablets in the healthcare setting?
3. How can the nurse assure that patient confidentiality is protected when using tablets and smart phones?

Go to Chapter 41, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

Automation (e.g., EHR) provides a secure way to integrate all patient information, including allergy history, laboratory values, and other prescriptions. It improves communication among those who prescribe, dispense, and administer medication to patients. For example, new prescriptions are automatically checked for potential errors or problems. The system can detect dosing errors by flagging medication dilution or dosages that fall outside normal standards and alert providers of the possibility of a drug interaction, allergy, or incorrect dose. In addition, some drug names sound like other drugs, the EHR can notify prescribers and help avoid a serious drug error.

Following are three examples of error-prevention technologies:

- ***Computerized physician order entry (CPOE)*** helps prevent errors in reading and transcribing orders.
- ***Bar-coding medications at the unit-dose level*** helps to prevent nurses from selecting an incorrect medication (Bell, 2009; Fowler, Sohler, & Zarillo, 2009).
- ***Use of smart technologies (e.g., infusion devices) at the point of care*** helps to ensure that the correct dose is delivered to the patient.

To read more about ways to decrease medication error,

Go to Chapter 41, **Supplemental Materials: How Does Automation Decrease Medication Error?** on Davis*Plus*.

Aiding Patients in Self-Care

The convergence of personal health records with mobile communication devices (e.g., smart phones, mobile tablet personal computers) boosts patients' ability for self-care. Internet-based programs and applications (apps) for mobile devices provide patients with patient education (e.g., disease-specific information, or healthy habit tips, including nutritional information, meal planning, dietary tracking), patient-specific medication dose reminders (Fig. 41-3), and even medical bill-paying reminders, for instance.

The Pew Research Center (2013) found that roughly one-third of American adults have gone online to find healthcare-related information and figure out what medical condition they have. Patients who look for this information may be seeking information about conventional, alternative, or complementary therapies and treatments, or looking for shared experiences of others with similar conditions. Patients may not always share their findings from online searches with their healthcare providers, which can lead to confusion or adverse reactions to prescribed treatment.

You can help guide your patients in their searches by educating them about how to use online sources and choose reputable, trustworthy sites. You may also need to help them interpret information that they find. Many hospitals have patient education materials on their Internet sites that provide links to reputable sources

Quality and Safety Education for Nurses

Are Information Technologies Living Up to Their Promise?

Chapter Key Concept: *Informatics*

Competency: *Informatics (Knowledge, Skills, Attitudes); Safety (Knowledge, Skills, Attitudes)*

Billions of dollars have been allocated for the development of electronic information systems (which are made up of electronic health records, digitized images, decision-support systems, computerized provider order entry, communication systems, and more). The electronic health information system has been promised to enhance the quality and safety of healthcare and provide information for clinical research. But is it really possible to develop a reliable, error-proof system that everyone understands and uses correctly?

A recent article (Black, Car, Pagliari, et al., 2011) questions whether we should automatically assume the usefulness of an all-electronic information system. Using 53 high-quality studies, researchers evaluated the evidence to support the use of information technologies to improve the quality and safety of healthcare. They concluded that existing evidence was weak and inconsistent. Not only did very few of the promised benefits materialize, but also new sources of errors were created. They found one particularly troubling effect: the tendency for prescribing errors to occur, which resulted when prescribers overestimated the capabilities of clinical decision-support systems.

Think about it: The informatics competency stresses the need for nurses to understand the time, effort, and skill required for information technologies to become reliable, effective tools for patient care system. What do you see as the nurse's role in developing and evaluating the electronic health record?

Consider the following questions to help develop your knowledge and skills and shape your attitudes about informatics and safety:

- What thinking skills will be necessary for nurses and other providers to respond appropriately to decision supports and alerts?
- How will nurses in particular use an electronic health record?
- How might electronic health records be used to improve care?
- How might the electronic health record improve the safety of an individual patient's care?
- What information should be included in an electronic database to make it useful for clinical research?

Source: Black, A. D., Car, J., Pagliari, C., et al. (2011).

To learn about specific Knowledge, Skills, and Attitudes,

Go to the QSEN Internet site at http://qsen.org/competencies/pre-licensure-ksas/

FIGURE 41-3 Nurse and senior client using a digital tablet for medication reminder and dose tracking.

FIGURE 41-4 Human patient simulator offers practical experience before caring for patients or training special skills.

(Gee, Greenwood, Kim, et al., 2012). In addition, customizable digital products (e.g., ebooks, apps, games, Web worlds) provide patients with interactive ways to engage in their medical care. Gaming applications are available to motivate patients in taking medication doses and manage dietary intake, weight, activity, and other prescribed health habits.

Educating Nurses

The electronic learning environment continues to expand in nursing education. A few of the many ways that computers assist nursing students in learning include:

- *Communicating* with faculty, peers, and patients through text messaging, synchronous and asynchronous text-based discussions, Web logs (blogs), social media, and other social sources
- *Searching online databases and the Internet* for evidence-based support of clinical practice and other sources of health information
- *Performing and documenting course assignments, clinical tasks, and self-evaluation tasks* using learning management systems
- *Using clinical simulation mannequins* (Fig. 41-4) and other interactive gaming tools to emulate an authentic clinical environment prior to performing skills using live patients. You may have already been using clinical simulation mannequins in your nursing program. Would it surprise you to know that practicing nurses also use them in continuing education provided in their workplaces? What kind of computer programs and devices are available in your clinical setting?

ELECTRONIC HEALTH RECORDS

You have been introduced to several ways in which computer information systems are used in nursing care. In addition, this section discusses EHRs and the barriers to and benefits of their adoption. Table 41-1 summarizes the use of information systems in practice, education, administration, and research.

EHRs are a system for exchange of healthcare information. As a part of networked information systems software, EHRs allow clinicians to create, store, edit, and retrieve patient charts via the Internet or local intranet software. Patient demographics, progress notes, problems, medications, vital signs, past medical history, immunizations, laboratory data, and radiology reports are important components of the patient health record.

Figure 41-5 is an example of a computer screen using EHR software. Notice the electronic view uses combinations of tabs and icons to support logical navigation through the patient chart. These tabs are often named and arranged to match tabs in a traditional paper chart, including patients' clinical and personal data. A successful EHR project allows an organization to replace paper charts and care plans with electronic records.

Interoperability and Standardized Nursing Languages

In this section, we describe the role of informatics and standardized nursing languages in communicating health information in EHRs, nursing education, and evidence-based practice.

EHRs are a system for exchanging health information. **Interoperability** refers to the ability of many different kinds of computers and operating systems to talk with each other through standard languages or formats without losing the meaning of the information. For that to happen, consistent languages are needed—languages that all computers can understand. If information about heart rate is to be exchanged, consistent languages are needed. For example the EHR system in Hospital A might refer to "heart rate," while the EHR system in a physician's office might refer to "pulse rate." This could interfere with clear communication of meaning. Standardized nursing language facilitates communication among organizations and between nurses and the healthcare team.

Table 41-1 ➤ Use of Computer Information Systems in Nursing

NURSING PRACTICE	NURSING EDUCATION	NURSING ADMINISTRATION	NURSING RESEARCH
Literature access and retrieval (e.g., for evidence-based practice)	Literature access and retrieval	Quality assurance and utilization review	Literature review
Care planning	Computer-assisted instruction (CAI) programs	Employee records (e.g., to track licenses, immunizations)	Data collection
Client records (e.g., documenting, order entry, retrieving lab results)	Classroom technology	Staffing patterns, hiring	Data analysis (both qualitative and quantitative)
Telenursing (e.g., in home health)	Distance learning	Buildings and facilities management	Research dissemination
Case management	Testing and grading	Finance and budgets	Applying for grants
Documenting medications	Student records	Accreditation reviews (e.g., monitoring quality indicators for The Joint Commission)	
Transcribing orders	Development of electronic and learning communities using the World Wide Web		
Reordering medications			
Identifying drug interactions			
Warning practitioners about drug incompatibilities			

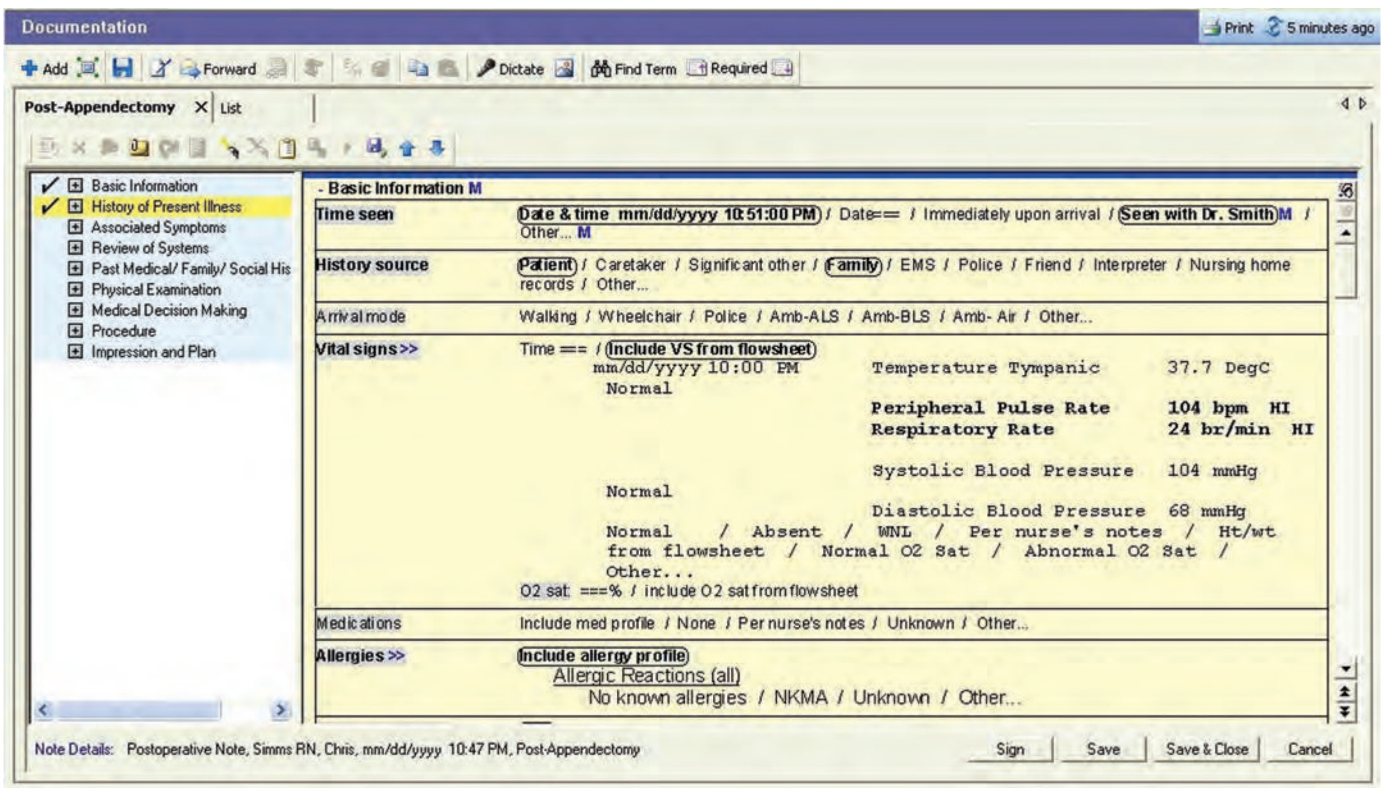


FIGURE 41-5 Computer screen from an electronic health record (Courtesy of Cerner Corporation, Kansas City, MO)

Standardized languages also support evidence-based practice. Suppose you wanted to find out how many patients on your hospital unit had a nursing diagnosis of Impaired Skin Integrity during the past year. If the hospital uses paper medical records, how could you find out? If patient records are computerized, would that make a difference?

You may have thought about pulling all patient charts within a select time period, and examined the nursing notes. Or perhaps you might search for the words *Impaired Skin Integrity* in the computerized records. That's a beginning—but this task would have been difficult because nurses use a variety of terms to describe the same data. For example, in some charts you would find the term *skin breakdown*; in others, *a reddened area*, *bedsore*, or a *stage III pressure ulcer*. Would you count all of these as Impaired Skin Integrity? What if the nurses used some terms you didn't think to search for?

Do you see how the lack of a standardized way to describe patient problems can hamper efforts to create and retrieve nursing data from automated documentation systems? Recall the goal for interoperability among EHR systems discussed above. **Standardized language**—using the same terms to describe a clinical condition in all EHRs—helps to achieve that goal. For more discussion about standardized language,

Go to Chapter 41, **Standardized Language, American Nurses Association Recognized Languages for Nursing,** in Volume 2.

Electronic Health Record (EHR) Adoption

EHR usage among healthcare providers and hospitals has sharply increased since passage of the Health Information Technology for Economic and Clinical Health (HITECH) Act in 2009. The HITECH Act focuses on improving healthcare quality and efficiency. Approximately 80% of all eligible hospitals and more than half of physicians and other eligible healthcare professionals in the United States have received an incentive payment for adopting, implementing, upgrading, or meaningfully using an EHR (U.S. Department of Health and Human Services [USDHHS], 2013). The rationales for federal-funding support for a nationwide, interoperable system of health records are that EHRs are expected to provide higher-quality, patient-focused healthcare by improving care provider access to patients' health information; to improve population health by facilitating research and wider use of patient information; and to facilitate billing and record keeping.

Benefits of an Electronic Health Record

EHR systems improve the quality of care and reduce healthcare costs with technology-based tools for the exchange of health information exchange, computerized physician order entry (CPOE) systems, and clinical decision support (CDS) tools (Menachimi & Collum, 2011). These are discussed later in this section. Other benefits of EHRs include being able to easily access computerized records and to eliminate poor handwriting, which has historically been a potential source of error within the healthcare delivery system.

Improved Efficiency Improved access to patient health information can increase efficiency, productivity, and continuity of care. A paperless health record conveniently stores all patient information in one location rather than in bits and pieces in many different files and locations. Some EHR systems are designed for planning as well as for documenting care. Standardized care plans are typically incorporated in EHR systems. Other applications are designed to support efficient patient care workflow. Standardized coding for patient diagnoses and interventions allows for more accurate, convenient, and uniform billing.

Reduced Redundancy Allowing for the secure and potentially real-time sharing of patient information can reduce costly redundant tests. For example, diagnostic testing is often ordered because one provider (e.g., a family physician) does not have access to the clinical information stored at another provider's location (e.g., a cardiac specialist). Historically, providers relied on faxing or mailing each other pertinent information, which makes it difficult to access on site when and where it is needed.

Accessibility Have you ever needed to write your nursing notes before leaving the clinical setting, only to discover that the chart was in the x-ray department with the patient? Or that the physician was making rounds with it in her hands? In contrast to a paper record, any number of people in different locations can access a computerized record—and all at the same time. A physician can view lab results from the office at the same time a nurse views them in the hospital and a lab technician adds more data. Various types of hardware support access patient health information, from stationary bedside terminals, wireless laptops mounted on mobile carts, and handheld devices (Fig. 41-6).

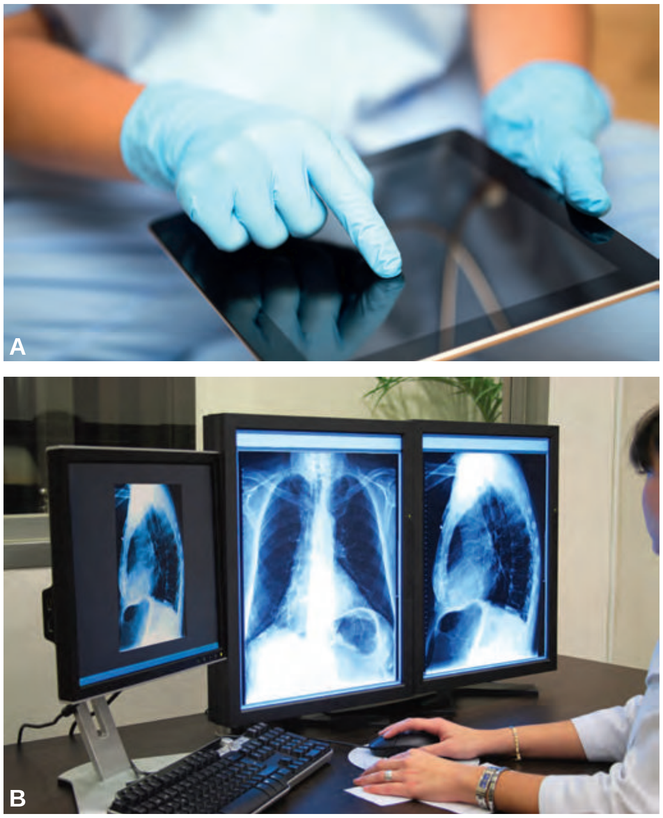

FIGURE 41-6 Point-of-access computing. *A*, Handheld device. *B*, Terminal unit for accessing patient data.

Clinical Support Tools (CST) EHRs equip providers with clinical support tools to conveniently access information to assist with clinical decision making. For example, a CST may offer current drug information; cross-reference a patient allergy to prescribed medication; and alerts prescribers and nurses to potential drug interactions and other patient risks.

Reduced Errors **Computer physician order entry (CPOE)** allows healthcare providers to enter orders via a computer instead of handwriting them, thus reducing errors resulting from illegible handwriting. It also makes the prescription process more efficient for nursing and pharmacy staffs by saving time in soliciting information missing from illegible or incomplete orders.

Privacy Access to sensitive patient information can be limited only to individuals with proper authorization, and each retrieval of data can be logged electronically—a vast improvement over the folders and charts that can pass through many hands without a record of who examines them.

Research and Public Health Benefits Computerized records place data in repositories (storage areas) so that the information can be sorted and analyzed to create the information and knowledge necessary to aid research to support decision making. For example, state health departments can access population-based medical information to track communicable diseases, possibly preventing epidemics. Health researchers and analysts can also use aggregate health information to judge which treatment is most effective for a disease. One possible outcome might be fewer prescriptions for unnecessary antibiotics (Hebert, Beaumont, Schwartz, et al., 2012). To protect patient privacy and promote ethical practice of research, review boards govern access to population data.

Barriers to EHR Adoption

There are numerous reasons why some providers and hospitals resist using an EHR. Some providers resist using an EHR because they fear of loss of autonomy. Some claim moving to an EHR will cause disruption in workflow or lead to errors, as some EHR products are hard to use and not well engineered for clinical workflow (Ford, Menachemi, Peterson, et al., 2009). Others object to EHRs because of the purchase and installation costs. The most prevalent reason, though, is computer illiteracy and discomfort with technology. User adoption and systems training are expensive, time consuming, and frustrating. This can be problematic in a demanding clinical environment.

Although the intent of computerization is to decrease cost by improving efficiency and communication, there may be unintended consequences of EHR implementation, such as diminished face-to-face communication among the healthcare team. Software upgrade and periodic new releases are inevitable, some of which may require more robust hardware than previous editions. New, expensive equipment to replace perfectly serviceable hardware, which has been rendered obsolete by the EHR, is a factor when considering the cost of an EHR.

The nurse informatics specialist, a nurse with additional education and experience in informatics, provides guidance for clinicians in identifying gaps between how the EHR system functions and how clinical processes work. Successful changes from paper to electronic systems are those that provide opportunities for nurses to have a voice in choosing systems and planning the change. Some people adopt change readily and some are more resistant. For more discussion about how people tend to respond to innovation,

Go to **Chapter 41, Tables, Boxes, Figures: ESG Box 41-1, Adopters of Innovation,** on Davis*Plus*.

KnowledgeCheck 41-3

- What are some of the benefits of EHR implementation?
- List at least three ways in which computers can help reduce medication errors.

Ethical Use of Electronic Health Records

Medical records contain highly sensitive information. Patients confide in nurses and physicians, trusting that their information will remain private. Most facilities have disciplinary policies in place to manage security breaches and assign fines or prosecution when patient privacy is violated. Personal integrity and adherence to nursing and other codes of ethics are necessary to protect patient privacy within healthcare organizations.

With an automated record, many people can view the information at the same time, and they can be in many different locations. Nevertheless, in some ways the automated record is more secure than the paper record. Almost anyone in the clinical unit can view the paper record. There is no record to show who has seen the information. In contrast, several measures protect the confidentiality of the electronic health record.

Passwords

Passwords for all users are probably the most obvious protection. In most institutions, exposure to protected patient information is tied to the responsibilities of the job description. For example, as a rule, the business office does not see day-to-day clinical information; and nurses do not see any special arrangements a patient has made to pay a bill.

Although it is important to protect the privacy of healthcare records from outside observers, professionals who have password access but are not assigned to the patient to provide care make most breaches of confidentiality.

BOX 41-1 ■ Some Simple Rules for Password Management

- Never share passwords with others.
- The more complex the password is, the harder it is for hackers to break it. Use combinations of letters, numbers, and symbols for maximum protection.
- Don't use words or numbers that are easy to guess (e.g., pet names, birthdays).
- Change passwords frequently.
- Do not record passwords in easily accessible places.

Audit Trails

Organizations are required to have software that tracks each person who accesses information. This is called an **audit trail**. Anything a person adds to or changes in the record is recorded automatically on the audit trail and can be investigated.

HIPAA Regulations

Most health insurance plans and care providers must comply with the Department of Health and Human Services (HHS) Privacy Rule (also referred to as "the HIPAA regulations"). The Privacy Rule was mandated in response to the Health Insurance Portability and Accountability Act (HIPAA) of 1996. It was the first comprehensive federal protection for the privacy of individually identifiable health information. The two important requirements are that health plans and providers must:

- Obtain consent before disclosing health information used for treatment or payment options.
- Limit disclosure of information to the minimum necessary to accomplish intended purposes.

These rules were extended as part of the HITECH Act discussed earlier. New rules increase fines levied on organizations for each reported breach of personal health information, and give authority to individual states to monitor compliance with the rules. They apply to all forms of communication: electronic, written, and oral. For full information,

Go to the **U.S. Department of Health and Human Services** Internet site at http://www.hhs.gov/ocr/hipaa/

If you would like further discussion of EHR privacy issues, review the section How Do I Maintain Confidentiality and Data Security? in Chapter 18.

KnowledgeCheck 41-4

- Discuss at least three measures to protect the confidentiality of patients' electronic health records.

Think**Like a Nurse** 41-3

- How does automation contribute to or decrease errors in healthcare?

PracticalKnowledge knowing **how**

Professional standards require accountable practitioners to keep up to date with research and new knowledge. For example, criteria in the ANA Professional Standard 8 state the nurse should demonstrate a commitment to lifelong learning and seek experiences that reflect current practice to maintain skills and competence (ANA, 2010). You can accomplish this by knowing how to search literature databases efficiently and use Internet resources discriminatingly to complement your use of the EHR in providing quality patient care.

USING INFORMATICS TO SUPPORT EVIDENCE-BASED PRACTICE

The ***traditional model of healthcare decision making*** relies on each practitioner's personal experience and judgment. But healthcare is now so complex that problems routinely exceed the clinical decision-making capacity and reliability of individual practitioners. A better model of decision making is ***evidence-based practice***. As you have learned in previous chapters, evidence-based practice involves (1) identifying a clinical question or need for change; (2) searching the literature for "best evidence," which can change quickly and continuously; (3) evaluating evidence; and (4) translating the results into practice (Majid, Foo, Luty, et al., 2011; Sackett, Rosenberg, Gray, et al., 1996).

Nurses require the most current, best-quality information for making decisions in their practice. It is not enough to find one journal article in support of an intervention, but rather to search broadly for high-quality, scientific evidence. Managing and processing information are essential for these tasks. Nurses need information on a wide variety of topics including clinical nursing issues, drug therapy, improving patient outcomes, innovative practice changes, and leadership skills. To find the current *best* evidence, you must be skilled in computer use and in searching relevant literature. These skills partially describe an information-literate person. Other qualities of an information-literate person are found in Box 41-2.

Think**Like a Nurse** 41-4

Analyze the Meet Your Nurse Role Model scenario. What example of evidence-based practice do you find in it?

Computers for Evidence-Based Practice

Most nurses are action oriented, preferring to learn by looking, listening, and talking. It may seem easier to seek information from colleagues, rely on past experience, draw on knowledge of pathophysiology, and read whatever references are closest at hand. However, in the clinical setting, the closest reference book may not

BOX 41-2 ■ Profile of an Information-Literate Person

An information-literate person *accesses* information:

- Recognizes the need for information
- Understands accurate and complete information is the basis for intelligent decision making
- Formulates questions based on information needs
- Identifies potential sources of information and selects those with credibility
- Accesses print and technology-based sources of information

An information-literate person *evaluates* information:

- Accepts authoritative, current reliable information
- Sorts information based on accuracy and relevance
- Distinguishes opinion from factual knowledge
- Rejects inaccurate and misleading information
- Rejects biased information
- Creates new information to replace inaccurate or missing information as needed

An information-literate person *manages* information:

- Develops successful search strategies
- Organizes information so the most important points are clear
- Breaks complex information into understandable chunks
- Sorts out language and technical points into meaningful terms
- Tracks sources of information responsibly and credits appropriately

An information-literate person *uses* information:

- Organizes information for practical application
- Integrates new information into an existing body of knowledge
- Applies information in critical thinking and problem-solving

Other characteristics:

- A resourceful and independent learner
- Competent reader
- Confident in his ability to solve problems
- Able to function independently and work well in groups
- Creative and able to adapt to change

Source: Adapted from: Association of College & Research Libraries. (2000). Information literacy competency standards for higher education. Retrieved from http://www.ala.org/acrl/standards/informationliteracycompetency; U.S. Department of Health and Human Services. (n.d.). *Quick guide to health literacy*. Retrieved from http://www.health.gov/communication/literacy/quickguide/quickguide.pdf

contain the most current information or the best possible evidence. Computers at the workplace help overcome this barrier to evidence-based practice by providing fast, easy access, 24 hours a day, to current practice information from around the world. For example, you could quickly use a computer to look up the latest tested interventions for a patient who is incontinent of urine.

How Do I Use Computers to Search the Literature?

Lack of literature-searching skills is another reason many nurses fail to take advantage of automated information available to enrich their practice. There are several steps to conducting an automated search of the literature:

- **Identify the information.** When you clearly define the information you want to gather and how it will be used, it is easier and more efficient to search, locate, evaluate, retrieve, organize, and manage the resources required to answer your question.
- **Formulate a precise definition of the problem.** This is usually in the form of a question, for example, "What are the leading causes of falls in older adults?" This question guides your search for information.
- **Conduct a search** of the most recent literature and most relevant studies. To learn about or review the PICOT method of defining and stating questions, go to the section Formulate a Searchable Question and Box 8-4, in Chapter 8.

ThinkLike a Nurse 41-5

Before reading the next section, see whether you can puzzle out the answers to the following two questions. Consult with your classmates and instructors, if necessary, after finishing the chapter.

- Why must a question be formed before initiating the search?
- The suggested question in the preceding section was "What are the leading causes of falls in older adults?" Why can't you use a general topic such as "falls" for your search topic?

Sources of Nursing Research Literature

You must evaluate the type of literature you need to answer the question. For instance, a research report provides better support for an intervention than does an opinion article. Although some information is classic and timeless, it is usually best to find the most current studies from reliable sources, such as government agencies, clinical organizations, or professional, refereed, peer-reviewed sources.

Textbooks Textbooks are good for general information. However, they are not the most current source of information because of the time it takes to prepare them for publication.

Printed Journal Articles Printed journal articles are more current, but the information may still be 6 months to 2 years old by the time the article is published. Journals come in varying degrees of academic rigor. You must discriminate among scholarly, general interest, and popular periodical literature.

- ***Scholarly Journals.*** Scholarly journals contain tables and graphs, but are not as colorfully illustrated as general interest periodicals. A scholar, clinical expert, or scientific researcher in the field submits topical articles that adhere to professional standards, carefully footnoting and citing references. Articles submitted to scholarly journals are reviewed by a group of experts to determine whether they are suitable for publication. This process is known as a peer review. The main purpose of a scholarly journal is to report on original research to make the information available to others. Examples of scholarly journals include *Journal of Nursing Scholarship*, *Journal of Nursing Administration*, *Nursing Research*, and *International Journal of Nursing Terminologies and Classifications.*
- ***General interest periodicals.*** General interest periodicals are usually attractive. Articles tend to be heavily illustrated, commonly with photographs. News and general interest periodicals sometimes cite sources, but not always. Articles may be written by a member of the editorial staff, a scholar, or a freelance writer and are often peer reviewed. The language is geared to any educated audience. A specialty is not assumed. Some examples of general interest nursing periodicals include the *American Journal of Nursing*, *RN*, and *Nursing* [current year].
- ***Popular periodicals.*** Popular periodicals are usually slick and attractive in appearance. They include many graphics and photographs. These publications rarely, if ever, cite sources. Information in such journals is often second- or thirdhand, and the original source is sometimes obscure. Articles are usually short, lack depth, and are written in simple language and designed to meet a minimal education level. The main purpose is to promote a product or viewpoint. Examples include *Women's Health* and *Modern Healthcare*.

The World Wide Web The World Wide Web contains the most current information, from such sources as professional organizations (e.g., American Heart Association), government sources (e.g., Centers for Disease Control and Prevention), sites publishing clinical guidelines (e.g., Joanna Briggs Institute; National Guideline Clearinghouse), and various online nursing journals. New health information can be uploaded immediately on the Web for the entire world to see without the delay of print publishing.

Literature Databases

Literature databases are a powerful tool for finding information. Literature databases are catalogues of articles, usually sorted by discipline. Databases exist for engineering, education, law, medicine, nursing, and other disciplines. For example:

- MEDLINE is the largest medical database and lists internationally published articles from journals in all areas of biomedicine.
- The Cumulative Index for Nursing and Allied Health Literature (CINAHL) is a smaller database covering nursing, allied health, biomedical, and consumer health journal articles.

These databases often overlap—what is found in one database might also be found in another. Most of the articles in CINAHL are also listed in MEDLINE. If, however, you are looking for a nursing-focused article, it is more efficient to use CINAHL because the search is already narrowed to nursing and allied health.

Each entry in a database contains an article citation, subject headings describing the article, and a text summary of the article called an **abstract**. Other information about the article may also be included, such as the name of the author(s), the name of the institution at which the research was done, and the language in which the article was published (Box 41-3). Many full-text journal articles are available online, some free and some for a fee. Some are available in the school or hospital's library for nurses to access. Table 41-2 includes descriptions of some commonly used databases in healthcare. Do not limit your search to a single database. You will find valuable information in the databases of other disciplines (e.g., psychology, education, business, law).

How Do I Evaluate Evidence and Determine a Solution?

Evaluating the evidence is sometimes as simple as reading a descriptive research study and applying the results to your current situation. For example, when searching for information about falls in older adults, you may find research to indicate a number of safety measures that can be easily implemented to create a safer environment for your patients. At other times, evaluating evidence can be very complicated, requiring an understanding of statistics and research methodologies. Just because one study indicates that sugar causes cancer does not mean that the study was valid or reliable; therefore, you must not base conclusions on the results of only one study. Experience and further study about research will increase your ability to evaluate your findings in the literature.

Key Point: ***Although an article you find on the Internet may be current, it is not necessarily complete, accurate, valid, or reliable.***

Many sites are created by individuals with questionable credentials or by companies attempting to sell their product or service. Such sites may not provide the best information to support your research; even

The search results may also contain an abstract of the article and in some instances the full-text article is available either for a fee or at no charge.

Table 41-2 ➤ Selected Databases for Health Literature

DATABASE	DESCRIPTION
CINAHL (Cumulative Index for Nursing and Allied Health Literature)	Covers nursing, allied health, biomedical, and consumer health journals; publications of the American Nursing Association; and the National League for Nursing. Coverage with abstracts is from January 1986 to the present. Coverage with indexing is from 1982 to the present. Updated monthly.
Cochrane Library	A regularly updated collection of evidence-based medicine databases, including systematic reviews, reviews of effectiveness, and a controlled-trials register. This is a source of reliable evidence about the effects of healthcare.
Health and Wellness Resource Center	Provides integrated access to medical, health, and wellness information from reference sources, magazine and journal articles, pamphlets, and some Internet resources. Quick Start links include a medical encyclopedia, dictionary, drug and herb finder, health organization directory, health assessment links, health news, and a few select medical Internet sites.
MEDLINE	Produced by the U.S. National Library of Medicine, MEDLINE is the world's largest medical library in all areas of biomedicine and healthcare.
PsycINFO 1887	Covers worldwide literature in psychology and related disciplines, such as psychiatry, sociology, anthropology, education, linguistics, and pharmacology. Journal articles, technical reports, and dissertations are included. Coverage is from 1887 to the present. Updated weekly.

worse, their information may be incomplete, inaccurate, biased, or unreliable. See Table 41-3 for suggestions on evaluating materials obtained from a Internet site. For ethical principles to guide health information Internet sites,

Go to **Chapter 41, Tables, Boxes, Figures: ESG Box 41-2, Guiding Ethical Principles for Health Information Internet Sites,** on Davis*Plus*.

If you would like to review the process for evaluating the quality of research articles you find in your searches, or for a process to find the best evidence for a nursing intervention, refer to the section How Can I Base My Practice on the Best Evidence? in Chapter 8.

ThinkLike a Nurse 41-6

What factors can make the Internet an unreliable source of information? What factors can help you find reliable information?

Table 41-3 ➤ How to Evaluate a Health Information Web Site

Remember, anyone can publish anything on the Web. The information you obtain may have been created by an expert, but most World Wide Web sites are authored by nonexperts. They may contain fact or opinion. Do not believe everything you read on the Web! Use the following questions to guide your evaluation.

EVALUATE FOR	QUESTIONS TO ASK
Authority	■ *Who is the author?* What are his credentials and qualifications to speak on this topic? Are the sources of information stated? Don't confuse the author with the webmaster. ■ *Check the URL domain* (e.g., *www.nih.gov*). What institution published the document? The Web address provides clues to this: .com—a company. .mil—the U.S. military .edu—a school or university .net—a network of computers .gov—the U.S. government .org—a nonprofit organization ■ The domain symbols ~ or % or a name (e.g., jsmith), "users," or "members" indicate a personal web page. ■ *Who is the sponsor?* The name right after "www" will provide a clue (e.g., see "nih"), but the full name (e.g., National Institutes of Health) should be on the page. ■ *Can you contact the author* for clarification or more information?
Currency	■ *When was it produced?* For some topics, you need current information. ■ *When was it updated?* Note that the fact that the Web page was "updated" may not mean that the information was updated at the same time. It may simply mean that the physical file was changed in some way (e.g., a misspelled word corrected) ■ *Are the links up to date?* Check the links to see whether they work.
Purpose	■ *Why was the page put on the Web?* Remember that many sites are designed to promote a product or an idea. Other purposes may be to entertain, to give facts, to share humor, or to provide a forum for ideas and opinions. ■ *Look for words such as "about our company," "mission," "philosophy," "who am I," and so on.* ■ *Who are the intended users* of the page? Students, experts, patients? ■ *Are there advertisements* on the page? This may be a clue.
Availability	■ *Can you view or download the information* without a special browser or special software? ■ *Are there fees* for viewing the full content?
Content quality (accuracy, objectivity, coverage)	■ *Are the sources documented* with footnotes or links? Are they scholarly links or information sources? ■ *Is the information provided by the site, or is it reproduced* from another source? ■ *Are there links to the original sources* (if they are online)? Or a reason for not providing a link? Do they work? ■ *Look for bias* (e.g., political or ideological), especially when you agree with it! Are there links to opposing views if it is an opinion page? ■ *Is the information reliable and error free?* Is there someone who verifies or checks the information? ■ *How in-depth* is the material? ■ *What does the page offer* that you can't find elsewhere? ■ *Look up the page* in a directory that evaluates the website contents. For example: ■ *www.ipl.org (the Librarians' Internet Index)* ■ *http://www.lib.umd.edu/guides/webcheck.html*
Usability	■ *Is it easy to read and navigate?* ■ *Are HELP screens available?* ■ *Is there a search engine on the site?* ■ *Is it frequently offline or slow to load?*

CHAPTER 42

Promoting Health

Learning Outcomes

After completing this chapter, you should be able to:

- Define *health*, *health promotion*, and *health protection*.
- Identify health prevention activities and categorize them as primary, secondary, or tertiary levels of prevention.
- Discuss the *Healthy People 2020* report in relation to leading causes of death and to health promotion strategies: nutrition, exercise, lifestyle, and environment.
- Apply Pender's Health Promotion Model to plan activities designed to change unhealthy behavior.
- Identify Prochaska and DiClemente's four stages of change.
- Identify specific health promotion strategies (including immunizations and screenings) across the life span.
- Discuss nurses' roles in health promotion, and list health promotion activities that a nurse may conduct in acute care facilities, in the workplace, in local communities, and in schools.
- Identify the areas of assessment in relation to developing a health promotion plan.
- Assess a client's cardiorespiratory function, muscle strength and endurance, joint flexibility, and nutrition (body mass index or body fat percentage).
- Construct a health promotion plan of care using the nursing process, NANDA-I taxonomy, Nursing Outcomes Classifications, and Nursing Interventions Classifications.

Key Concepts

Health promotion
Health protection
Illness prevention
Wellness

Meet Your Peer

You have completed all your prerequisites and are now enrolled in your first nursing course. Aside from classroom work, you have a skills course and clinical rotation. You spend a lot of time reading, studying, preparing for clinical work, writing care plans, and completing follow-up assignments from your clinical rotation. You have other non-nursing course work and family responsibilities as well. Often, you stay up late and get up early, usually getting about 5 or 6 hours of sleep. By the end of the week, you're exhausted. You don't have time to cook so you pick up fast food several times a week. Even though it is not the healthiest choice, at least this way you can get something to eat. You have little time to exercise, and when you do have time, you feel too tired and uninterested. You use cigarettes to relax and help cope with stress. On the weekends, you let loose with friends, drinking beer and having a good time.

You spend most of your time learning about health and illness. Given your current lifestyle, do you consider yourself healthy? How did you make that decision? Your answer is based on your personal beliefs about health and what you have learned in your nursing course work. In this chapter, we explore health promotion. As you learn more about this topic, you may develop a plan to promote your own health as well as the health of clients.

Theoretical Knowledge knowing why

To begin, we explore what others have written about the concepts. Various descriptions and definitions use the concepts health and wellness interchangeably, and we do the same in this chapter.

ABOUT THE KEY CONCEPTS

In Chapter 11, we considered the concepts of health, wellness, and illness. In this chapter, the emphasis is on strategies to support those concepts: **health promotion**, **health protection**, **illness prevention**, and **wellness**. As you study various concepts, such as health screening, role modeling, and health behaviors (to name a few examples), try to understand how they relate to the key concepts.

WHAT IS HEALTH PROMOTION?

To promote health, we must first identify what we mean by *health* and *wellness*. We will use the following definitions to synthesize a meaning.

World Health Organization The World Health Organization (WHO) defines health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1948). At the first conference for health promotion, WHO defined **health promotion** as the process of equipping people to have control over, and to improve, physical, emotional, and social health (WHO, 1986).

Jean Watson This nursing theorist proposed that health consists of three elements: (1) a high level of overall physical, mental, and social functioning; (2) a general adaptive-maintenance level of daily functioning; and (3) the absence of illness (or the presence of efforts that lead to its absence). She also refers to health as being a state of mind, the perception of the individual. A person may have a terminal illness and yet consider himself healthy (Watson, 1979).

Betty Neuman This nursing theorist describes health as an expression of living energy available to an individual. The energy is displayed as a continuum, with high energy (wellness) at one end and low energy (illness) at the opposite end. Individuals have varying levels of energy at various stages of life. When more energy is generated than expended, there is wellness. When more energy is expended than is generated, there is illness, possibly death (Neuman, 1995).

Myers, Sweeney, and Witmer In 2000 these theorists defined wellness as "a way of life oriented toward optimal health and well-being in which body, mind, and spirit are integrated by the individual to live more fully within the human and natural community" (p. 252). This definition includes lifestyles and habits as components of health and permits people who have been diagnosed with disease to be considered healthy.

Synthesis Applying aspects of these reflections on health, **health promotion** means finding ways to help individuals develop a state of physical, spiritual, and mental well-being. Health promotion activities are useful to all individuals, whether well or sick, because they encourage optimal function. How does this compare with the WHO definition of health promotion you read earlier?

Health Promotion Versus Health Protection

For the most part, the activities that promote health also protect health. Nevertheless, the ideas behind health promotion and health protection differ subtly but significantly. Pender, Murdaugh, and Parsons (2010) explain that motivation is what distinguishes the two activities.

- Health promotion is motivated by the desire to increase well-being.
- Health protection is motivated by a desire to avoid illness.

For instance the 40-year-old who begins an exercise program to improve strength and endurance is motivated by the benefits of health promotion. If he starts exercising because his father died of a heart attack at age 50, he may be motivated by the need to protect his health.

Levels of Prevention

Leavell and Clark (1965) identified three levels of activities for health protection (illness prevention): primary, secondary, and tertiary. Interventions are classified according to their purpose in different stages of the disease process. This timing directs the types of interventions needed.

- **Primary prevention** activities are designed to prevent or slow the onset of disease. Examples include eating healthy foods, exercising, wearing sunscreen, obeying seat belt laws, and keeping up with immunizations.
- **Secondary prevention** involves screening activities and education for detecting illnesses in the early stages. Examples are breast self-examination, testicular exams, regular physical examinations, blood pressure and diabetes screenings, and tuberculosis skin tests.
- **Tertiary prevention** focuses on stopping the disease from progressing and returning the individual to the pre-illness phase. Rehabilitation is the main intervention during this level.

Patients and health providers move among these levels of prevention. For example, a patient hospitalized for a total hip replacement would receive tertiary prevention—care focused on helping her recover from surgery, preventing complications of surgery, and, later on, helping her regain her strength and learn to walk again. Secondary prevention strategies may have been used previously, for example, to screen for osteoporosis that leads to bone fragility and fractures. When she goes home, if she decides to limit her salt intake and eat a balanced diet that is low in fat and refined sugar, these activities would be primary prevention strategies.

Health Behaviors

For the population overall, life expectancy (at birth) reached a record high of 78.7 years, up from 75.4 years in 1990. The gap between men and women has narrowed from 7.0 years in 1990 to 4.8 years in 2010 (Centers for Disease Control and Prevention [CDC], 2013). Health status is affected by health behavior, such as weight management, increasing the amount of physical activity, safer sex, moderate alcohol use, and avoidance of tobacco and drugs.

Teen Pregnancy

Pregnant teenagers are less likely to receive early prenatal care. They are more likely to drop out of school and to live in poverty than are older pregnant women. The birth rate for teenagers aged 15 to 19 years dropped 8% from 2010 to 2011, to 31.3%, a historic low for the United States. Rates fell for all races including in those of Hispanic origin (CDC, 2013).

Abuse of Alcohol and Illicit Drugs

The risk of disease, injuries, and intentional death (suicide and homicide) increases with substance abuse.

- An estimated 30% of the U.S. population is affected by alcohol misuse; most of the 30% engage in risky use. More than 85,000 deaths per year are attributable to alcohol misuse, which is the estimated third leading cause of preventable deaths in the United States. The U.S. Preventive Service Task Force (USPSTF) (2013) recommends that clinicians screen adults aged 18 years or older for alcohol misuse and provide persons engaged in risky or hazardous drinking with brief behavioral counseling interventions to reduce alcohol misuse.
- In 2011, 8.1% of students reported having tried marijuana before the age of 13 years, and 20.7% reported nonmedical use of prescription drugs. (*Morbidity and Mortality Weekly Report*, 2012).

Substance abuse in adolescents is associated with a greater frequency of suicide attempts, more lethal (successful) attempts, an increased seriousness of intent, and greater suicidal ideation.

Tobacco Use

Cigarette smoking increases the risk of lung cancer, tuberculosis, heart disease, emphysema, and other diseases.

- The percentage of middle and high school students who reported smoking cigarettes in the past month was 7.1% and 23.2%, respectively (CDC, 2012).
- "Ever use" of electronic cigarettes among students in grades 6 to 12 increased from 3.3% to 6.8% during 2011–2012. Those who said they are "currently using" them increased from 1.1% to 2.1% (*Morbidity & Mortality Weekly Report*, 2013).
- Overall the percentage of high school students and adults who reported smoking cigarettes remained stable at 20% to 23%, after declining from 36% in the previous decade.
- Men were more likely to be current cigarette smokers than were women (24% compared with 18%) (CDC, 2010).
- The highest percentage of tobacco users are in the South (CDC, 2009a).
- Smoking as few as three cigarettes a day can increase the risk for cardiovascular disease by more than 60% (Pope, Burnett, Krewski, et al., 2009). The risk of active tuberculosis is nearly doubled with tobacco use (Linn, Ezzati, Chang, et al., 2009).

Obesity

The risk of heart disease, diabetes, and stroke increases with obesity.

- In 2009–2010, more than 16% of U.S. children and adolescents were obese. The prevalence of obesity was higher among adolescents than among preschool-aged children and higher among boys (18.6%) than girls (15%) (CDC, 2012).
- More than 35% of U.S. men and women were obese in 2009–2010. There was no significant difference in prevalence between men and women at any age. Overall, adults aged 60 years and over were more likely to be obese than younger adults (CDC, 2012).
- With the U.S. obesity trend, only 7.5% of Americans now have five low-risk factors for cardiovascular disease—no tobacco use, normal blood pressure, normal weight, low blood cholesterol, no diabetes, and age younger than 75 years (Ford, van Dam, & Fonarow, 2009).

Sedentary Lifestyle

Exercise reduces the risk of disease and enhances mental and physical health. American adults have made no substantial progress toward achieving recommended levels of physical activity or strength training. Between 1995 and 2006, the percentage of adults 18 years of age and older engaged in regular leisure-time physical activity or strength-training activities remained level.

KnowledgeCheck 42-1

- How does health promotion differ from health protection?
- Which level of prevention is represented by the following activities?
  Mumps, measles, rubella (MMR) vaccination
  Tuberculosis (TB) skin test
  Physical therapy after repair of a hip fracture

Health Promotion Models

A model illustrates a system or framework to help explain what you see in clinical practice. The most common frameworks used for designing health promotion programs are described next.

Pender's Health Promotion Model

Pender's Health Promotion Model (HPM) (Fig. 42-1) identifies three groups of variables that affect health promotion: (1) individual characteristics and experiences, (2) behavior-specific cognitions and affect, and (3) behavioral outcome. The HPM is based on seven assumptions that reflect both nursing and behavioral science perspectives (Pender, Murdaugh, & Parsons, 2010). Two general assumptions are about the interpersonal environment:

1. Health professionals constitute a part of the interpersonal environment, which exerts influence on persons throughout their life span.
2. Self-initiated reconfiguration of person–environment interactive patterns is essential to behavior change.

The other five assumptions are characteristics of people, who the theorists assume:

1. Seek to create conditions of living through which they can express their unique human health potential.
2. Have the capacity for reflective self-awareness, including assessment of their own competencies.
3. Value growth in directions viewed as positive and attempt to achieve a personally acceptable balance between change and stability.
4. Seek to actively regulate their own behavior.
5. In all their biopsychosocial complexity interact with the environment, progressively transforming the environment and being transformed over time.

Pender's model has been used extensively in several disciplines in research and professional practice focused on health promotion. As a nurse, you should find Pender's focus applicable to your work.

Think**Like a Nurse** 42-1

- How might peers influence health behaviors? At what age might peers have more influence?
- Apply Pender's model to a person trying to lose weight. What might be some perceived barriers (see Fig. 42-1)?

Wheel of Wellness

Several authors have likened the different facets of health to the spokes of a wheel (Hettler, 1984; Myers, Sweeney, & Witmer, 2000; Witmer & Sweeney, 1992). If one of the spokes is weak, the whole wheel is weak. The "spokes" of the health wheel represent the dimensions of health: emotional, intellectual, physical, spiritual, social/family, and occupational (Fig. 42-2). The level of

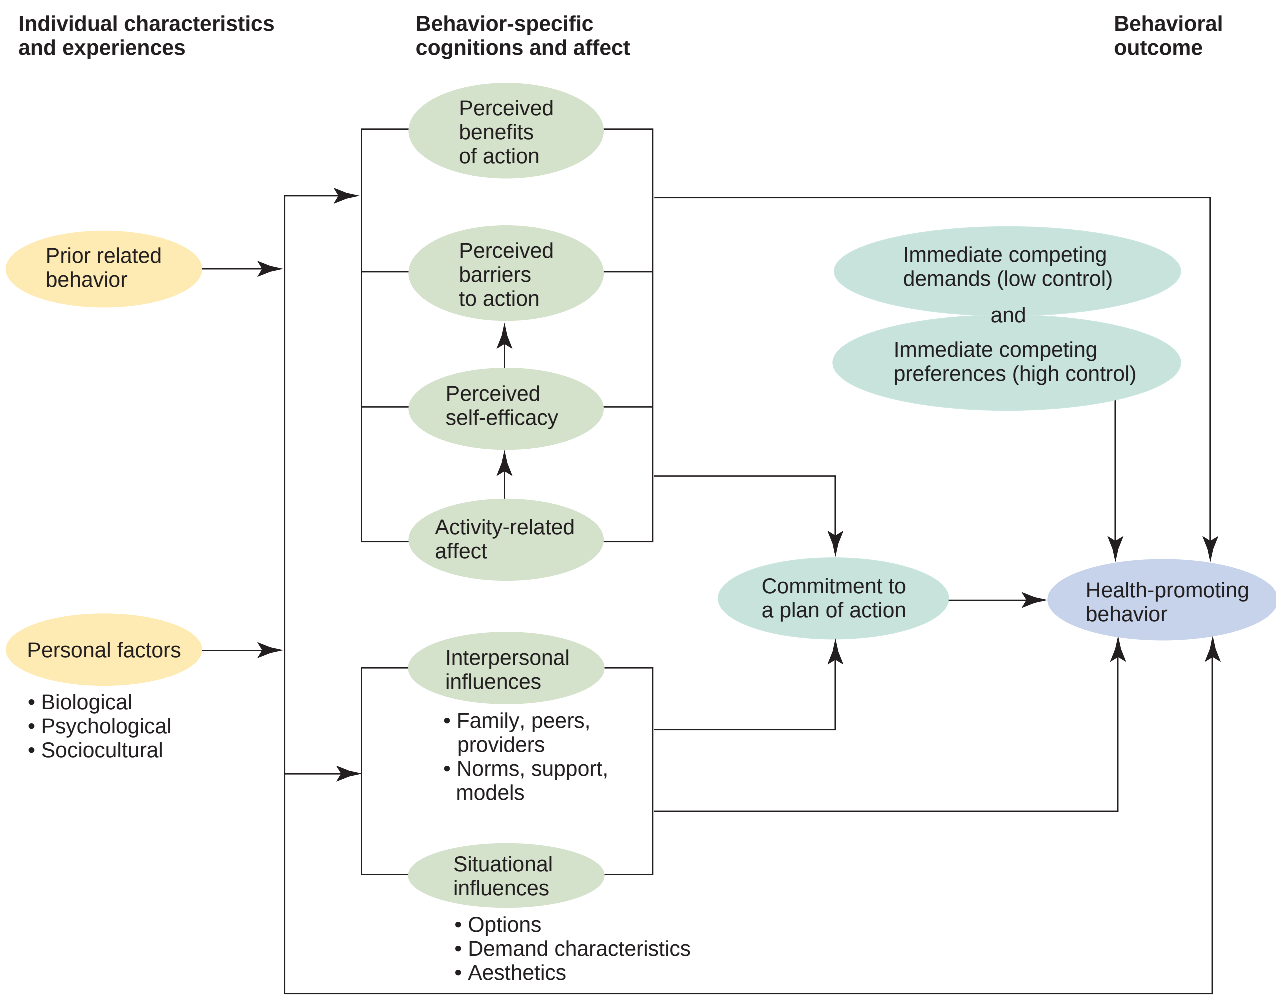

FIGURE 42-1 Pender's Health Promotion Model.

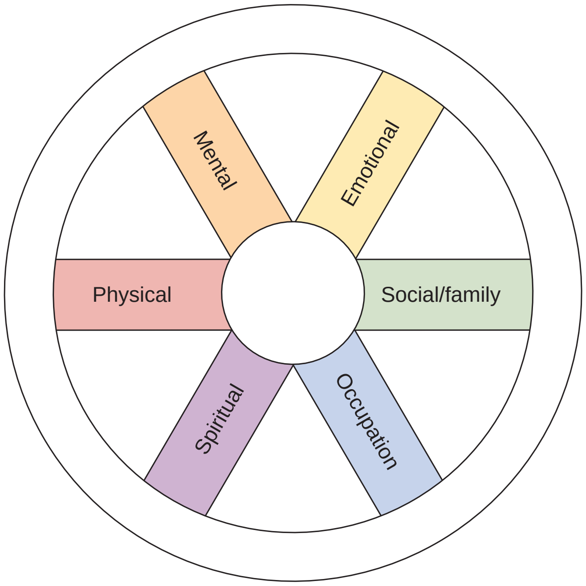

FIGURE 42-2 Wheel of Wellness.

wellness progresses from the center to the outer part of the wheel. The center represents the least amount of wellness, and the outer part represents optimal wellness. If one area of a person's life is not functioning at optimal level, life will not be as fulfilling as it could be. As a nurse, you should assess each dimension for strengths and weaknesses.

Transtheoretical Model of Change

The transtheoretical model of change (Prochaska & DiClemente, 1982) may serve as a means to alter unhealthy behaviors. Health promotion and protection involve either changing the individual's response to the illness-producing stimuli or changing the environment so that the person will be less likely to encounter illness-producing stimuli. Either idea involves change. In this model, change occurs in five stages (six, if you do not include termination in the maintenance stage):

Stage 1 **Precontemplation** is the stage in which there is no intention to change behavior in the foreseeable future, because patients are unaware or underaware of their problems.

Stage 2 **Contemplation** is the stage in which patients are seriously thinking about overcoming a problem but have not yet made a commitment to take action.

Stage 3 **Preparation** is the stage in which individ uals are intending to take action in the next month and are reporting some small behavioral changes (''baby steps'').

Stage 4 **The action stage** is the implementation of the plan and requires considerable commitment of time and energy.

Stage 5 **The maintenance stage** allows the changed behavior to be reinforced.

Stage 6 **The termination stage** completes the maintenance. A person who enters the termination stage has changed the behavior and is not in danger of relapse.

Ideally, the stages would progress in this order. Realistically, a person may progress and regress in any of the stages. The change process in persons with some unhealthy habits (e.g., cigarette smoking, substance abuse, and excessive eating) may best be described as a revolving door. An individual may exit at any point as the door goes around. If the exit occurs during or at the end of the maintenance period, the behavioral change is successful. If the exit occurs before the end of the maintenance period, relapse will occur, and the individual will return to the previous lifestyle.

Health Promotion Programs

Health promotion programs help a person advance toward optimal health. In the sections that follow we discuss several types. For further discussion of individual activities that promote health,

Go to Chapter 42, **Supplemental Materials: Individual Health Promotion Activities,** on Davis*Plus.*

Disseminating Information To recognize a problem and understand the options for change, people need information. Information may be disseminated at three levels, as illustrated in the following examples:

- Individual level—Teaching a client how to modify his personal dietary intake
- Group level—Classes offered at the local hospital, prenatal education programs, and worksite programs
- Community level—A billboard that presents the dangers of smoking, health blogs on the Internet, and health fairs

Changing Lifestyle and Behavior These are group-level programs. They focus on activities such as weight loss, smoking cessation, exercise, nutrition, and stress management. These programs usually provide information and offer support. Many times, they include a maintenance program to help solidify the change.

Protecting the Environment The term *environment* refers to air, water, and soil as well as social and political surroundings. Environmental control programs promote health by working to create a healthy environment. Programs focus on air and water quality, toxic waste, healthy homes and communities, infrastructure and surveillance, and global environmental health.

Assessing Wellness and Appraising Health Risk These programs focus on identifying behaviors that promote health and create the risk for disease. A wellness assessment tends to focus on the healthy behaviors. It supports positive change to improve health. A health risk appraisal identifies risky behaviors that promote disease. These programs are readily available on the Internet, in magazines, and at fitness centers.

KnowledgeCheck 42-2

- What are the six dimensions of health represented by the spokes on the wellness wheel?
- Identify the stages of change identified by Prochaska and DiClemente.
- Describe the four main types of health promotion programs.

ThinkLike a Nurse 42-2

J.T. drinks a vodka and tonic while eating lunch with his coworkers. He keeps a bottle of vodka in his office desk for use during the day. Later, he stops at a local bar for a drink on the way home. At home, he drinks a six-pack of beer while watching the game. What information do you need to determine which of Prochaska and DiClemente's stages of change he is experiencing? How would you get this information?

Settings for Health Promotion Programs

The most common sites for health promotion programs are health facilities, worksites, and schools. Healthcare settings, such as clinics, physician offices, or hospitals, are natural settings for health promotion. Remember, each interaction between patient and healthcare provider is an opportunity for health promotion. Unfortunately, most interactions focus on the disease process and compliance with treatments. You will need to make a conscious effort to help clients focus on behaviors that prevent illness and promote health.

Nurses work in health clinics within large companies or may be contracted to provide specific health promotion programs, such as smoking cessation, stress management, weight reduction, and fitness training. Employers have found that health programs decrease work-related injuries and sick leave. For instance, one study demonstrated that employees classified as high risk (according to body fat, blood pressure, anxiety, and other measures) who received cardiac rehabilitation and exercise training from an expert team were converted to low-risk status by the end of a 6-month program. Furthermore, medical claims costs had declined by more than $1,000 per participant, compared with those from the previous year. A control group showed no such improvements (Berry, Mirabito, & Baun, 2010).

Another setting for community health promotion is the local school district. Health teaching can begin at an early age, and nurses and teachers can regularly reinforce healthy behaviors and redirect unhealthy behaviors. The school setting allows for continued exposure to information. Interventions may be directed at general health promotion issues, such as physical activity, or they may focus on specific health risks, such as tobacco and alcohol use. Ideally, parents and families are included in the learning. School nurses work closely with teachers and parents to provide health promotion services in the schools.

Health Promotion Throughout the Life Span

Health promotion is a lifelong process that begins at conception. Table 42-1 describes the focus of health promotion programs at each developmental stage, as well as the types of screenings recommended for each age group.

PracticalKnowledge knowing how

Pender, Murdaugh, and Parsons (2010) summarized the health promotion process as a series of nine steps that involve the client and the nurse. Notice that many steps of this process are similar to the nursing process:

1. Review and summarize data from assessment.
2. Reinforce the client's strengths and abilities.

Table 42-1 ➤ Health Promotion Throughout the Life Span

HEALTH PROMOTION FOCUS	HEALTH SCREENINGS	HEALTH PROMOTION FOCUS	HEALTH SCREENINGS
Conception to Birth		**Infancy**	
Education about pregnancy Abstinence from alcohol, cigarettes, and illicit drugs Nutrition, including folic acid and iron requirements Exercise to maintain strength and muscle tone and to control weight gain Parenting education	Alpha-fetoprotein level Screening for gestational diabetes Prenatal care Abuse Additional screenings that may be offered: ▪ Ultrasound ▪ Amniocentesis ▪ Chorionic villus sampling	Nutrition (breast versus bottle) Introduction of solid foods Placing the infant on her back for sleep without a pillow to reduce the risk of sudden infant death syndrome (SIDS) Sensory stimulation Safety Motor vehicle safety Oral health	Hearing evaluation Screening for birth defects Blood work to rule out certain metabolic conditions Monthly examinations until at least 6 months of age After age 6 months, visits every 2 or 3 months Growth and development Abuse

Table 42-1 ➤ Health Promotion Throughout the Life Span—cont'd

HEALTH PROMOTION FOCUS	HEALTH SCREENINGS
Toddler and Preschool	
Adequate supervision Safety, including storage of poisons Toilet training Motor vehicle safety Nutrition Immunizations Oral health Sleep and rest	Annual examinations Growth and development Cognitive skills Abuse Kindergarten readiness

Nutrition Physical activity Safety Sexuality Stranger danger Oral health	Annual examinations Growth and development Cognitive skills Abuse
Adolescence	
Peer pressure Motor vehicle safety Safety Self-esteem Physical activity Suicide and depression Firearm safety Violence Sexuality Substance use and abuse Limiting sun exposure Update of immunizations Oral health	Growth and development Sexually transmitted infection (STI) screening Breast self-exam Testicular self-exam Mental health Stress Alcohol and drug use Abuse
Young Adult	
Physical activity Motor vehicle safety Safety Violence Sexuality Substance use and abuse Limiting sun exposure Update immunizations Oral health	Comprehensive exam at least every 3 years Lifestyle Pap smear STI screening Breast self-exam monthly Testicular self-exam monthly Mental health Stress Alcohol and drug use Abuse
Middle Adult	
Physical activity Safety Obesity Sexuality Lifestyle Update of immunizations Oral health Substance use and abuse	Comprehensive exam at least every 3 years to age 40, yearly after age 40 BP screening Lipid panel Blood glucose Stress Mammograms yearly and clinical breast exam for women over age 40 Digital rectal exam for prostate evaluation in men PSA for men yearly over age 50 (as decided with provider) Annual eye exam Sigmoidoscopy or colonoscopy Stool for occult blood with comprehensive exam Bone density Abuse
Older Adult	
Physical activity Nutrition Safety Obesity Sexuality Lifestyle Update of immunizations Oral health Changes associated with aging	Functional skills (ADLs and IADLs) Hearing Falls risk Stress Annual eye exam BP screening Lipid panel Blood glucose Mammograms and clinical breast exam (as decided by provider and patient) Digital rectal exam for prostate evaluation in men PSA for men (as decided with provider) Stool for occult blood Bone density Follow-up sigmoidoscopy or colonoscopy Mental health Abuse

3. Identify health goals and related behavioral change options.
4. Identify behavioral or health outcomes that will indicate that the plan has been successful from the client's perspective.
5. Develop a behavior change plan based on the client's preferences, on the stages of change, and on "state-of-the-science" knowledge about effective interventions.
6. Reiterate benefits of change, and identify incentives for change from the client's perspective.
7. Address environmental and interpersonal facilitators and barriers to behavior change.
8. Determine a time frame for implementation.
9. Commit to behavior-change goals, and structure the support needed to accomplish them.

ASSESSMENT

A health promotion assessment involves obtaining a health history, physical examination, fitness assessment, lifestyle and risk appraisal, life stress review, analysis of health beliefs, nutritional assessment, and screening activities.

History and Physical Examination

Assessment should begin with a thorough health history, review of body systems, and a physical examination. Ask the client about family history of various health disorders and cause of death of family members. Keep in mind the accuracy of reporting is higher for relatives without, rather than those affected by, a given disease (Qureshi, Wilson, Santaguida, et al., 2009). Gather the history directly from the client. As always, provide privacy and comfort while conducting the history and exam.

The level of detail of the physical examination depends on the health history. At a minimum, the exam should include vital signs, weight, body mass index (BMI) or waist circumference, auscultation and palpation of the chest and abdomen, inspection of the skin, and palpation of peripheral pulses. The exam may be accompanied by laboratory studies. Recommended lab work depends on the history and exam findings. For most adult clients, a screening lab consists of a complete blood count, comprehensive metabolic panel (also known as a chem 20 panel), lipid panel, thyroid function panel, and urinalysis (American College of Sports Medicine [ACSM], 2013). In clients with known cardiac or pulmonary disease, additional disease-specific studies may be performed (e.g., electrocardiogram [ECG], carotid ultrasound, or pulmonary function tests).

Physical Fitness Assessment

Regular physical activity each week, sustained for months and years, can produce long-term health benefits. Regular physical activity is linked with a lower risk for heart disease, stroke, type 2 diabetes, hypertension, high cholesterol, metabolic syndrome, certain types of cancer, and depression. Regular physical activity also prevents weight gain; improves cardiorespiratory and muscular fitness; prevents falls by increasing muscle tone, strength, and balance; and promotes better memory and cognition in older adults (ACSM, 2013). A physical fitness assessment includes the following:

- *Cardiorespiratory fitness* is reflected in the ability to perform large-muscle, moderate- to high-intensity exercise for prolonged periods of time (ACSM, 2013). There are many different modes of testing, such as field tests (walking or running), treadmills, stationary bicycles, and step testing. Results depend on age and gender.
- *Muscular fitness* refers to both muscle strength and endurance. Muscle strength is a measure of the amount of weight a muscle (or group of muscles) can move at one time. Muscle endurance refers to the ability of a muscle to perform repeated movements.
- *Flexibility* is the ability to move a joint through its range of motion. The most common assessment is to evaluate low back and hip (trunk) flexion.

For information and guidelines for assessing physical fitness,

Go to Chapter 42, **Assessment Guidelines and Tools, Focused Assessment—Cardiorespiratory Fitness, Muscular Fitness Assessment, and Flexibility Assessment** in Volume 2.

Lifestyle and Risk Appraisal

Lifestyle refers to the manner in which a person conducts his life: physically, emotionally, spiritually, and mentally. Personal habits, recreation, and occupation are part of one's lifestyle. In the context of health and wellness, lifestyle includes all of the activities that promote optimal living, such as taking responsibility for one's health, physical activity, nutrition, interpersonal relations, spiritual growth, and stress management. You can gather this information by interview or by using a variety of questionnaires. A **health risk appraisal (HRA)** is a questionnaire that evaluates risk for disease based on current demographic data, lifestyle, and health behaviors. There are many HRA tools available; many are online. For one example of an HRA,

Go to Chapter 42, **Assessment Guidelines and Tools, Focused Assessment: Lifestyle and Risk Assessment,** in Volume 2.

ThinkLike a Nurse 42-3

- Evaluate your own compliance with recommended health screenings for your age group. What activities should you incorporate into your own health promotion plan?
- Answer the questions in the Lifestyle and Risk Assessment in Volume 2. How did you score? What additional activities should be added to your health promotion plan?

Life Stress Review

In 1976, Hans Selye proposed that stress triggers physiological responses that may, over time, induce illness. Likewise, Richard Rahe (1974) identified some stress-inducing life change events and researched their possible effects on health. He attached numeric values for each change based on the degree of disruption or stress produced by the event. Rahe discovered that a high score on a life-change event scale is associated with a greater likelihood of a negative health change. To see and use a life-change event scale,

Go to Chapter 12, **Assessment Guidelines and Tools, The Holmes-Rahe Social Readjustment Scale,** in Volume 2.

Other researchers have focused on daily stresses and their effects on actual health or on one's perception of health. Daily stresses involve travel to and from work, taking children to activities, daily chores, waiting in lines at shops, raising teenagers, and traffic jams. Researchers have found these stresses may gradually erode one's coping mechanisms, producing an inability to cope with daily events and an increased likelihood of illness.

Hardiness Research has also demonstrated that in the face of life events, some people develop hardiness rather than vulnerability (Maddi, Koshaba, Fazel, et al., 2009). Kobasa (1979) identified hardiness as a quality in which an individual experiences high levels of stress yet does not fall ill. There are three general characteristics of the hardy person:

- **Control**—belief in the ability to control the experience
- **Commitment**—feeling deeply involved in the activity producing stress
- **Challenge**—the ability to view the change as a challenge to grow

These traits are associated with a strong resistance to negative feelings that occur under adverse circumstances (Escolas, Pitts, Safer, et al., 2013). If you need additional information on hardiness, review Chapter 11.

ThinkLike a Nurse 42-4

- Undoubtedly you are experiencing stress as a student in a nursing program. How would you rate your level of hardiness?
- What statements would demonstrate a hardy personality in each area (commitment, control, challenge)?

Health Beliefs

A health promotion assessment would not be complete without investigating an individual's health beliefs. Health beliefs are embedded in one's culture and personal experiences. Culture consists of characteristics, beliefs, and behaviors of an individual or group (Chapter 15)—all the experiences, biases, beliefs, and rituals. Culture influences beliefs and practices affecting wellness and disease prevention. For example, some people may use certain foods (e.g., garlic to prevent heart disease, orange juice to prevent a cold) or herbs to protect or restore health. Why do you think it is important for you to respect cultural and religious views regarding health while working with clients to adopt personal health goals?

It will be helpful to know whether health outcomes are a result of actions the person takes, actions of powerful others, or chance. The Multidimensional Health Locus of Control scale (MHLC), developed by Wallston, Wallston, and DeVellis (1978), helps you obtain this information. The MHLC measures the person's perception of the extent of control from each source. The person rates her level of agreement with statements such as "I am in control of my health," "No matter what I do, if I am going to get sick, I will get sick," and "Regarding my health, I can only do what my doctor tells me to do." Identifying a patient's locus of control is of practical importance for several reasons:

- People who feel powerless about preventing illness are least likely to engage in health promotion activities.
- People who respond to direction from respected authorities often prefer a health promotion program that is supervised by a healthcare provider.
- Clients who feel in charge of their own health are the easiest to motivate toward positive change.

For a copy of the MHLC you can print out and use with your patients,

Go to Chapter 42, **Resources for Caregivers and Health Professionals, Vanderbilt University Web Site,** on Davis*Plus*.

Nutritional Assessment

A nutritional assessment is a key component of an overall wellness assessment. Unhealthy eating habits occur across all ages, ethnicities, and socioeconomic classes. The assessment involves an evaluation of typical eating patterns correlated with physical examination findings and BMI. Body composition is important in identifying health risks. The usual methods for determining body fat composition clinically are by measuring height, weight, circumferences, and skinfolds (see Chapter 27 to review these).

The pattern of body fat distribution is an important predictor of health risks. People with fat stored around the trunk and abdominal area have a higher incidence of metabolic syndrome, hypertension, hyperlipidemia, heart disease, type 2 diabetes, and premature death than those who have the fat stored in the extremities (Ashwell, Gunn, & Gibson, 2012). Traditionally, the waist-to-height ratio has been used as a method for determining fat patterns in the body. More recently, the focus has shifted to waist circumference alone.

Health Screening Activities

Health screening activities are secondary prevention activities designed to diagnose specific diseases at an early stage so that treatment can begin before there is an opportunity for the disease to spread or become debilitating. Many of these screening activities are part of your usual care. For example, each time you check a client's blood pressure, you are performing a screen for hypertension. Table 42-1 identifies the typical health screening activities with each developmental stage. For further information about selected health screening activities.

Go to **Assessment Guidelines and Tools: Selected Health Screening Activities,** in Volume 2.

Screening for Breast Cancer Currently, there is some controversy about whether we should encourage breast self-examination (BSE) (American Academy of Family Physicians [AAFP], 2012; Tria, 2013). In studies around the world, BSE was found not to reduce mortality resulting from breast cancer, and may even cause false security and delayed diagnosis when lumps that are present are not detected. Because of the ongoing uncertainty raised by such studies and the fact some women do self-detect lumps that signal cancer, the American Cancer Society continues to advise women that BSE is an optional screening tool but plays only a small role in finding breast cancer (American Cancer Society, 2012). However, BSE can be a useful screening strategy when used in combination with regular physical exams and mammography. So until evidence is conclusive, it seems reasonable to continue to encourage and teach BSE.

Screening for Prostate Cancer The issue of whether to perform mass prostate-specific antigen (PSA) and digital rectal exam screening for prostate cancer is also unsettled. The U.S. Preventive Services Task Force (USPSTF) (2012) recommends against PSA-based screening for prostate cancer but understands that some patients may request testing. PSA screening should be done only if it includes shared decision making that enables an informed choice by patients.

For points to include when teaching breast and testicular self-examination,

Go to **Assessment Guidelines and Tools: Breast Self-Exam** and **Testicular Self-Exam,** in Chapter 9.

KnowledgeCheck 42-3

- Identify at least three common sites for health promotion activities.
- What assessments are parts of a health promotion assessment?
- What role does stress play in health promotion?

ThinkLike a Nurse 42-5

Your 55-year-old aunt tells you she hasn't had a physical examination in 20 years. She is a registered nurse. "I don't need one because I feel fine and I can take care of myself." How would you respond?

ANALYSIS/NURSING DIAGNOSIS

"Health promotion diagnoses describe clinical judgment about a person's, family's, group's, or community's motivation and desire to increase well-being and actualize human health potential" (NANDA International, 2012, p. 96). Health promotion diagnoses can be used in any health status and do not require a current level of wellness. NANDA-I health promotion labels are specific behaviors preceded by the phrase *Readiness for Enhanced*, and will be one-part statements with no etiology (e.g., Readiness for Enhanced Parenting, and Readiness for Enhanced Nutrition). For specific NANDA-I labels you can use to describe health promotion diagnoses,

Go to Chapter 42, **Standardized Language, Examples of NANDA-I Health Promotion Diagnoses,** in Volume 2.

PLANNING OUTCOMES/EVALUATION

NOC standardized outcomes related to health promotion vary depending on the focus area. For example, if the nursing diagnosis is Readiness for Enhanced Nutrition, a NOC outcome might be Nutritional Status. For examples of other NOC health promotion outcomes,

Go to Chapter 42, **Standardized Language, Examples of NOC Standardized Health Promotion Outcomes,** on Davis*Plus*.

Individualized goals and outcomes might include losing 20 pounds or exercising for 30 minutes five times per week. The nurse's role in health promotion primarily is to motivate clients and facilitate change. Clients are independently responsible for most of their health promotion activities. You may need to help them identify goals, but it is essential that the goals be the clients', not yours.

Healthy People 2020 Goals. You may need aggregate wellness goals for groups as well as individualized goals. The following are four broad goals for the U.S. population set by the *Healthy People 2020* initiative (U.S. Department of Health and Human Services [USDHHS], 2009, p. 2):

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors all life stages.

Interventions to achieve these goals are targeted at the 37 focus areas shown in Box 42-1.

Public health agencies at the local, state, and federal levels use these focus areas as a blueprint to design programs aimed at improving the health status of the community (USDHHS, 2009). To view those objectives,

Go to the ***Healthy People 2020* Web site,** at http://www.healthypeople.gov/Search/objectives.htm

BOX 42-1 ■ Focus Areas of *Healthy People 2020*

Source: U.S. Department of Health and Human Services, Office of Disease Prevention & Health Promotion and Human Services. (2009, October 30, revised). *Healthy People 2020* topics and objectives. Retrieved from http://www.healthypeople.gov/hp2020/Objectives/TopicAreas.aspx

Whether standardized or individualized, expected outcomes for wellness diagnoses describe behaviors or responses that demonstrate health maintenance or achievement of an even higher level of health. For example:

During the next year, Mr. Needham will continue to eat a balanced diet, with more emphasis on including whole grains and fiber.

By using the highest number (5) on the rating scale, you can use the NOC to write wellness outcomes. For example:

Nursing diagnosis: Readiness for Enhanced Nutrition
Expected outcome: Nutritional Status: (5) Not compromised

PLANNING INTERVENTIONS/IMPLEMENTATION

Community and public health nurses focus on the problems contributing to disease, such as poor housing conditions, poor sanitation, poor nutrition, poverty, and substance abuse. The wellness focus in acute care is to educate patients about health and disease.

Once the client identifies his goals, help him to identify the steps that he must take to reach the goals. Change occurs in stages. To create positive change, the client will need to understand the benefits of change, overcome the barriers to change, and make a commitment to follow through on the plan.

For *NIC standardized interventions* and activities for health promotion,

Go to Chapter 42, **Standardized Language, Selected NIC Health Promotion Interventions,** in Volume 2.

NIC does not have a special domain, or grouping, for wellness interventions. Instead, they are found throughout all areas of the taxonomy, particularly in the Behavioral, Safety, Family, Health System, and Community domains. Specific NIC nursing activities for health promotion include those in the following four subsections. The remainder of the chapter provides some strategies to promote their use (see the accompanying PICOT box).

Nutrition To guide people in making nutritional choices that promote health and prevent disease, the U.S. Department of Agriculture (USDA) and the USDHHS revised the *Dietary Guidelines for Americans* (you will find these in Chapter 27) to include My Plate, a symbol of a plate that is divided into four sections—fruits, vegetables, grains, and protein. It replaces the familiar pyramid image, which was first introduced in 1992 and revised in 2005 but had become too complicated for people to understand easily. Instead, My Plate is a quick, simple reminder to people to be more mindful of the foods they eat. The symbol is part of a healthy eating initiative that conveys seven key messages: Enjoy food but eat less; avoid oversized portions; make half of the plate fruits and vegetables; drink water instead of sugary drinks; switch to fat-free or low-fat (1%) milk; compare sodium in foods; and make at least half your grains whole grains. From a practical point of

PICOT

Health Promotion

Situation: The student has noticed that many of his classmates have gained significant amounts of weight as the program has advance. In addition, it seems as though there is always someone who is sick in class. Students are complaining about the cost of co-payments and over-the-counter medications. The student wonders whether there are practical ways to improve this situation at his school.

PICOT Components

P	Population/client	= Young adult students
I	Intervention/indicator	= Health promotion information
C	Comparator/control	= None
O	Outcome	= Decreased risk of health problems
T	Time	= None

Searchable Question

Do ________ (P) who receive/are exposed to ________ (I) demonstrate ________ (O) as compared to ________ (C) during ________ (T)?

Example of Evidence: The World Health Organization defined health promotion as the process that enables people to improve their own health by improving control over the determinants of health. Health promotion is an important nursing activity. Healthcare spending in the United States exceeded $2 trillion in 2006. America's worsening health habits, particularly obesity, are contributing to this massive growth in spending. Cost-effective health promotion measures include educating people about preventable health problems such as obesity, diabetes, hypertension, and other chronic diseases. Nursing educators will be at the forefront in evaluating nursing programs and teaching future nurses according to the needs of global health.

Practice Changes: The student talks to his professor about organizing a wellness group to share health promotion ideas.

Source: Jadelhack, R. (2012). Health promotion in nursing and cost-effectiveness, *Journal of Cultural Diversity, 19*(2), 65–68.

view, the plate image will help people make better food choices.

Exercise Encourage the development of physical fitness lifestyle habits in people of all ages and abilities. Most health benefits occur with at least 150 minutes (2 hours and 30 minutes) a week of moderate-intensity physical activity, such as brisk walking. Additional benefits occur with more physical activity (USDHHS, 2008). Children and teens should engage in at least 1 hour of age-appropriate, physical activity daily. Activity should be vigorous in intensity and varied in type, not only to prevent boredom but also to promote muscle and bone strengthening as well as flexibility (Fig. 42-3). For more information,

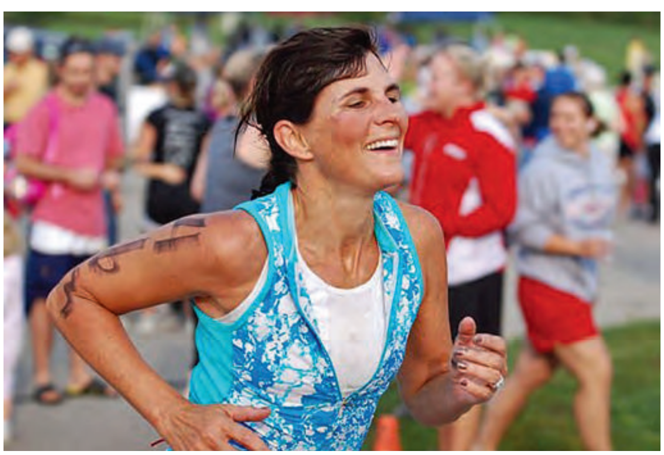

FIGURE 42-3 Vigorous-intensity exercise promotes muscle and bone strength and improves cardiovascular health.

Go to the **President's Challenge Web site,** at http://www.presidentschallenge.org

Lifestyle Changes For healthy living, adults and teens choose a lifestyle without drugs, including tobacco, and little alcohol. Getting enough sleep, and managing stress are also important.

Sleep In general, adults need 6 to 9 hours of sleep a night. Children need more sleep (see Chapter 34). Inadequate sleep is linked to weight gain and obesity.

For an expanded discussion of these areas for health promotion,

Go to Chapter 42, **Supplemental Materials: Individual Health Promotion Activities,** on Davis*Plus*.

Role Modeling

A role model teaches by example, demonstrating the behaviors and/or attitudes to be learned. Models provide inspiration and strategies for health promotion behavior. Clients select their own role models, often without making a conscious decision to do so. For example, a morbidly obese female joins a weight loss group led by a woman who has lost nearly 100 pounds. She admires the leader for her determination and success and selects her as a role model.

It may sometimes be helpful for you to facilitate the client's choice. When suggesting a model, consider the client's age, culture, values, and preferred activities. The model should be someone with whom the client identifies. Ideally, the role model should be someone accessible to the client during the early stages of change.

This allows for interacting and for exchanging information. Nurses also serve as role models. As a result, we should provide an example of healthy behaviors. It is difficult to advocate for healthy behavior if you do not follow the behavior you recommend to clients. Imagine the trust a client loses when he finds out that the nurse who tells him not to smoke cigarettes has a two-pack per day habit. To what extent do you role model healthy behaviors?

Providing Counseling

Counseling is an interpersonal communication process that helps a client to identify problems and make changes. In the context of health promotion, counseling promotes personal growth and helps clients change their lifestyle. Counseling may be formal one-to-one or small-group discussion, or it may be informal discussion with the client at a healthcare encounter. Each meeting with a client is a potential counseling session. In addition to face-to-face contact, counseling may be offered via telephone or even by e-mail.

Individual Counseling

Face-to-face interaction may be helpful when clients are attempting major lifestyle change. In an individual session, you can customize and map out the steps required to meet the client's goals. This may include writing a contract detailing the client's expected behaviors. Print the contract, and have the client sign it to reinforce his commitment. Suggest the client post the plan in a location he sees often so that it serves as a frequent reminder.

During counseling sessions, remember to reinforce health-promoting behaviors that have already been established. For example, the client who uses tobacco may eat a balanced diet; reinforce the healthy habit to boost self-esteem. Stress to the client that although the behavior to be changed may be unhealthy, you believe the client can succeed in making the change.

Telephone Counseling

Telephone counseling may be used as a primary counseling approach or as follow-up. Many clients with hectic schedules find it easier to arrange telephone counseling than to schedule a face-to-face interaction. The disadvantage is that telephone counseling does not allow you to observe nonverbal communication.

When using telephone counseling, you will set goals and map out the strategy for change just as you would in face-to-face counseling. Let the client know how

Toward Evidence-Based Practice

Cooley, M. E., Finn, K. T., Wang, Q., et al. (2013). Health behaviors, readiness to change, and interest in health promotion programs among smokers with lung cancer and their family members: A pilot study. *Cancer Nursing*, *36*(2), 145–154

Data were collected once from 37 lung cancer patient–family member dyads. Lung cancer patients and their family members had high rates of continued smoking, low intake of fruits and vegetables, and high rates of physical inactivity. Patients and family members indicated readiness to change behaviors within the next 6 months and interest in participating in a behavioral risk reduction program.

Hoffman, A. J., Brintnall, R. A., Brown, J. K., et al. (2013). Too sick not to exercise: Using a 6-week, home-based exercise intervention for cancer-related fatigue self-management for postsurgical non-small cell lung cancer patients. *Cancer Nursing*, *36*(3), 175–188.

Seven participants with early-stage lung cancer performed light-intensity walking and balance exercises using the Nintendo Wii Fit Plus. Exercise started the first week after hospitalization for surgical removal of the tumor and continued for 6 weeks. The intervention positively impacted cancer-related fatigue severity; fatigue self-management, walking, and balance; fatigue self-management behaviors; and functional performance (number of steps taken per day). Researchers concluded that a home-based, light-intensity exercise intervention for patients after surgery for lung cancer is feasible, safe, well tolerated, and highly acceptable, showing positive changes in cancer-related fatigue self-management.

Cooley, M. E., Emmons, K. M., Haddad, R., et al. (2011). Patient-reported receipt of and interest in smoking cessation interventions after a diagnosis of cancer. *Cancer*, *117*(13), 2961–2969.

Data were collected from questionnaires and medical records from 160 smokers or recent quitters with lung or head and neck cancer. Eighty-six percent of smokers and 75% of recent quitters reported that healthcare providers gave advice to quit smoking. Fifty-one percent of smokers and 20% of recent quitters expressed an interest in a smoking-cessation program. An individualized smoking-cessation program was the preferred type of program. Among smokers, younger patients with early stage disease and those with partners who were smokers were more interested in programs.

1. Based on these studies, why is it important to assess a patient's interest in smoking-cessation programs?

2. Why do you think a patient's diagnosis of lung cancer might influence his willingness to participate in healthy activities?

3. In light of the research, what might you do to facilitate health promotion in your patient with a lung cancer diagnosis?

and when you can be reached if questions arise. If you are using the telephone for follow-up counseling, it is best to schedule a time to speak. Having an appointment helps keep the client accountable to the expected behavior and to reinforce the information.

Providing Health Education

Health education may focus on self-care strategies, caregiver concerns, or how to be an effective healthcare consumer. Self-care programs typically cover nutrition, exercise, stress management, or disease prevention. Programs may consist of lectures, printed material, billboards, or posters. For example, the accompanying Self-Care box Teaching Clients How to Prevent Upper Respiratory Infections might be reproduced and posted in the lounge, rest rooms, or locker areas of a worksite during cold and flu season to decrease absenteeism. Caregiver education programs may teach caregivers how to perform nursing tasks or prevent injuries, or they may provide a list of community resources for respite care. Nurses can teach clients how to be effective healthcare consumers, how to interact with healthcare providers, and how to maneuver through the healthcare system. For a review of teaching and learning, see Chapter 19.

Providing and Facilitating Support for Lifestyle Change

Changing one's lifestyle is difficult. Most clients need support to make the change. You can provide support during your interactions and counseling sessions. You can also help the client to identify available support and resources within the community as well as from family, friends, coworkers, and others.

Group support exists for a variety of lifestyle changes. For example, Weight Watchers is a group support program for clients who want to lose weight; Alcoholics Anonymous is a group support program for clients who want to become and stay sober; various cancer support groups help clients deal with the common issues and fears associated with dealing with a potentially life-threatening disease. Group support provides clients with a chance to meet people experiencing the same difficulties and perhaps to find a role model. As a nurse, you should be familiar with various programs available in your community and refer clients to them.

Self-Care

Teaching Clients How to Prevent Upper Respiratory Infections

- **Maintain a healthy lifestyle.** That means get adequate sleep, ensure good nutrition, and engage in physical exercise. A balanced diet and physical fitness can boost your immune system to fight infection if it occurs.
- **Wash your hands often, and teach children to do so.** This helps prevent spread of infection. When using public restrooms, wash your hands. Then turn off the faucet with a paper towel. Also use a paper towel to open the door as you leave the room.
- **Avoid touching your eyes, nose, and mouth**, because doing so spreads any virus your hands have contacted (e.g., on doorknobs).
- **Avoid crowds when there is a cold or influenza epidemic.**
- **Throw away tissues as soon as you use them.**
- **When someone in the family has a cold**, keep bathrooms and the kitchen very clean and do not drink from the same glass or use the same utensils.
- **When someone at home or at work has a cold**, wipe telephone receivers with soap and water or an antibacterial solution.
- **If a child has a cold**, wash his toys and commonly used items well.
- **When choosing childcare**, look for a clean environment; ask what rules the facility or individual has about keeping the children clean (e.g., washing hands before snack time).
- **Don't smoke.** Cigarette smoke can irritate the respiratory tract, making you more susceptible to colds and illness.
- **Control stress.** People experiencing emotional stress tend to have weakened immunity to fight infection.
- **Consider taking echinacea**, although conclusive evidence of its effectiveness does not exist at this time. Consult your primary healthcare provider.

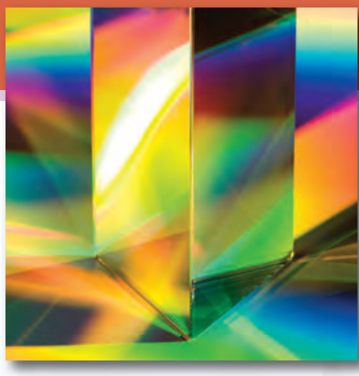
The Context for Nurses' Work

CHAPTER 43



Community & Home Health Nursing

Learning Outcomes

After completing this chapter, you should be able to:

- Define the meaning of community.
- Identify at least four factors by which you can recognize a healthy community.
- Discuss factors that create vulnerability for a population.
- Compare and contrast community-based care, community health nursing, public health nursing, and community-oriented nursing.
- Distinguish primary, secondary, and tertiary interventions in regard to a community health scenario.
- Discuss at least three strategies that nurses use to gather community data.
- Describe the roles of nurses in the community setting.
- Use standardized nursing language taxonomies (NANDA-I, NOC, NIC, Omaha, and CCC) to describe care planning in community and home care.
- Identify the primary goal of home care.
- Describe ways in which home healthcare differs from hospital nursing.
- Categorize the various agencies that deliver home healthcare according to purpose, client served, and funding source.
- Describe how the nurse's emphasis differs in hospice nursing as compared to home health nursing.
- List at least four criteria clients must meet for home care to be reimbursed by Medicare.
- Outline the steps required to prepare for a home visit, including considerations for the nurse's safety.
- Discuss ways in which the assessment process is unique in home care.
- Explain the role of the nurse in helping clients and families manage medications and treatments in the home setting.
- Describe how infection control measures differ in the home and in the hospital.
- State two important safety concerns in home care that arise out of The Joint Commission 2014 home care safety goals.
- Describe the nurse's role in treating caregiver strain.

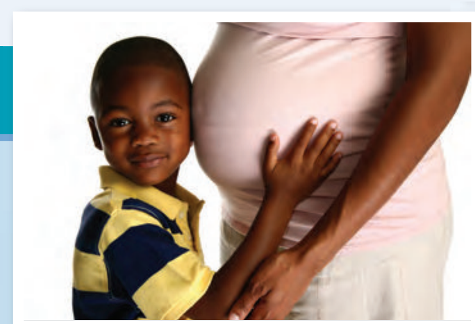
Meet Your Patients



Your Neighbor, Tanya

You are nearing completion of your fundamentals course. One night while you are preparing for your next clinical, the telephone rings. It is your neighbor, Tanya. Her 5-year-old son, Jacob, came home from kindergarten with a letter from the school nurse stating that a classmate was ill with H1N1 influenza and that all the students in the class had been exposed to the disease.

Tanya is concerned about the risks to Jacob and the rest of the family. Tanya is 8 months pregnant, and the family has no health insurance. She says, "You are a nursing student; do you know what I should do or where I might go for assistance?"

Although you are flattered that Tanya has consulted you, you need to consider whether you have the expertise to answer her questions. This situation requires knowledge

(Continued)

Meet Your Patients (continued)

from many aspects of nursing (e.g., immunizations, pregnancy, microbiology, pathophysiology). Though you may not have all of the information you need to answer her questions, you should be able to help your neighbor resolve her concerns. You will need to consider the following questions:

- What is going on in the situation that may influence the outcome?
- Who should be involved to improve the outcome?
- What theoretical knowledge do I need to answer my neighbor's questions? Where would I find this information?
- What additional data do I need to collect from my neighbor?
- What suggestions and/or referrals should I offer to my neighbor?

Your Patients, the Escobars

Flora Escobar is 78 years old. She lives at home with her husband, Roland, age 78. Both enjoyed good health until Roland was hospitalized for a cerebrovascular accident (CVA, or stroke) 3 weeks ago. He then spent 2 weeks in a skilled nursing facility (SNF). He returned home yesterday and will be followed by the local home health agency for physical therapy and nursing care.

At your initial visit, Mrs. Escobar greets you at the door. She is a petite woman who looks exhausted. Her apron pockets are stuffed with pill bottles. The hallway is partially blocked with a bedside commode, walker, and tray table. Mr. Escobar, wearing pajamas and a robe, is in a hospital bed in the living room. He is a tall, stocky man who is sitting up in bed but is slumped and leaning to the left.

After introducing yourself, you ask an open-ended question to build rapport: "How have things been going since you came home yesterday?" Mrs. Escobar sighs, and says, "I'm worried that I'm doing things wrong. I have a hard time helping him move. He is so much bigger than me, and I don't want to hurt him. He is frustrated with me, but he has difficulty talking and can't tell me what he needs." Tears fill Mrs. Escobar's eyes. Her husband turns away to avoid eye contact with you. To refocus their attention, you suggest that you go over some information and then begin to look at what additional services might be helpful.

Imagine how stressed Mrs. Escobar must feel. How do you think you could best help this family? In this chapter, as you read the section on home health nursing, you should find it easier to answer those questions.

Theoretical Knowledge knowing **why**

In the past couple of decades, the population has aged and hospital stays have become shorter in an effort to reduce costs. As a result, community-based healthcare, including home nursing care, has grown rapidly. Community and public health nurses regularly deal with such concerns as health screening and preventing disease. Home-care nurses provide care to clients with complex, chronic, or terminal illness in the home. They promote self-care and independence with activities of daily living, regardless of the level of functioning. In this chapter, we discuss communities and community and home nursing care. We also explore the roles, interventions, and career opportunities for nurses who work in communities.

ABOUT THE KEY CONCEPTS

Perhaps your career path will lead you to caring for clients in one of the many community healthcare settings, including clients' own homes. In this chapter, you will learn about the concepts of **community health** and **home health** and how different **populations** have unique healthcare needs. You will learn how these concepts are related to each other and to subconcepts, such as public health nursing, vulnerable populations, and home visits.

UNDERSTANDING THE CONCEPT OF COMMUNITY

The word **community** comes from the Latin term *communis*, meaning the "gift or fellowship of common relations and feelings." Historically, it meant a body of like-minded people or the inhabitants of a town. Then and now, the term suggests a general sense of selflessness, sharing, relationship, and doing good that comes from working together. Most members of a community share a common language, certain rituals, and special customs.

In contrast to community, we tend to think of a **population** as a certain geographic region. But the term *population* has other meanings, as well.

- It can mean the group of people of a particular race or class in a specified place (e.g., "There are 1,500 Latino people living in Edwards County").
- It can also mean *any* group of people subject to statistical or other study (e.g., all the homeless people in Edwards County, or all the pregnant adolescents living in Edwards County).

The U.S. Bureau of the Census conducts a survey and count of the American people (the population of the

United States) every 10 years. The most recent census is the one conducted in the year 2010. For results,

Go to the **U.S. Census Bureau Web site,** at www.census.gov/2010census/

When the census is completed, the U.S. Census Bureau groups the data into sections of 1,500 to 8,000 people, known as **census tracts**. The area of individual census tracts varies according to the density of the population. In urban centers, a census tract covers a small area. Rural census tracts are large. Census tracts are useful to public officials, market analysts, and anyone—including community nurses who study the characteristics and concerns of smaller sections of people.

Maps and census tracts show the *geopolitical* boundaries of a community. But as we noted earlier, a community can also be a group of people with a common purpose. They may live in different geographical areas, but they have a "sense of belonging" to their group (community). For a comparison of geopolitical boundaries and census tracts,

Go to Chapter 43, **Tables, Boxes, Figures: ESG Figure 43-1,** Geopolitical Boundaries and Census Tract Data on Davis*Plus*.

An **aggregate** is a group of individuals with at least one shared characteristic, either personal or environmental. For example, a community health nurse may work with a class of high school girls to reduce the incidence of adolescent pregnancy. The shared characteristics of this aggregate are that they are female, of childbearing age, and attend a particular school. As another example, the nursing students in your school are an aggregate. What characteristics and goals do you share?

KnowledgeCheck 43-1

- Give several examples of a community.
- How is a population different from a community?

ThinkLike a Nurse 43-1

- Why might the boundaries of a census tract change every 10 years?
- How could you figure out what census tract you live or go to school in?

What Are the Components of a Community?

To understand a particular community and its needs, you will need information about its three components: the concepts of structure, status, and process.

- **Structure** refers to the general characteristics of a community. These include demographic data, such as gender, age, ethnicity, and educational and income levels, as well as data about healthcare services, such as the number of primary care providers or emergency care facilities in the area.
- **Status** describes the biological, emotional, and social outcome components of a community. ***Biological*** data include morbidity (illness) and mortality (death) rates, life expectancy ratios, and risk factor profiles for the respective age groups within a community. ***Emotional*** data include general indications of mental health and consumer satisfaction survey results about various aspects of the community as compared to other locales. ***Social*** data include crime rates, citizenship involvement in community-wide activities, and general functioning levels of the community members.
- **Process** describes the overall effectiveness level of the community. For example, do the members of the community perceive that they are part of a group with common purpose, values, or interests? What is the extent of interaction among community members? Does the community have an established forum for conflict resolution?

What Makes a Community Healthy?

As with individuals, the meaning and perception of health varies among aggregates. For nurses, it is important to understand what a particular community defines (and values) as health rather than relying on personal definitions.

When determining what makes a community healthy from a traditional biomedical perspective, the national consensus paper *Healthy People 2020* provides useful guidelines. That document is based on the understanding that many of the health problems of Americans were preventable. *Healthy People 2020* identifies leading indicators for measuring the health of our nation (U.S. Department of Health and Human Services [USDHHS], 2008). Some examples affecting community health include:

- Physical activity
- Overweight and obesity
- Tobacco use
- Substance abuse
- Sexual behavior
- Mental health
- Injury and violence
- Environmental quality
- Immunizations
- Access to healthcare

For the complete list of indicators, see Box 42-1, Focus Areas of *Healthy People 2020.*

The four overarching goals of the *Healthy People 2020* initiative are to (1) attain high-quality, longer lives free of preventable disease, disability, injury, and premature death; (2) achieve health equity, eliminate health disparities, and improve the health of all groups; (3) create social and physical environments that promote good health for all; and (4) promote quality of life, healthy development, and healthy behaviors across all life stages. These aggregate goals are to be achieved through promoting healthy behaviors, increasing access to quality healthcare, and strengthening community health resources. For more information,

Go to the ***Healthy People 2020*** **Web site,** *at* http://www.healthypeople.gov

KnowledgeCheck 43-2

- What makes up the "structure" of a community?
- What is community "status"?
- What is community "process"?
- Use the guidelines from *Healthy People 2020* to compile a list of several characteristics that make a community healthy.

What Makes a Population Vulnerable?

The concept of **vulnerable population** is defined as an aggregate that is at increased risk of adverse health outcomes. Members of vulnerable populations have a higher probability of developing illness than do members of the general population. Because of their increased risk for developing health problems, vulnerable populations are a major focus of community health efforts. Vulnerability involves multiple factors:

Limited Economic Resources Income is a major predictor of health risk. People with higher incomes typically have greater access to health services and greater selection of providers, treatment options, and location of health services. In contrast, the more limited a person's income is, the more limited her healthcare options will be. Many persons with low income forgo preventive care and seek healthcare only when they are quite ill.

Limited Social Resources Friends and family are valuable resources to help a person deal with day-to-day stress and demands of an illness. They can provide feedback, listen to concerns, and offer emotional and physical assistance. Unfortunately, not everyone has social resources. Older adults who live alone and people with mental illness are examples of groups at increased risk because of social isolation.

Age The very young and the very old are less able to adapt to physiological stress and are at increased risk of disease. They are more prone to infections and may not be able to protect themselves against environmental hazards, such as cold or heat. These age groups are also more often living in poverty.

Chronic Disease and Obesity People who have chronic diseases are at greater risk of health problems. For example, people with obesity are at increased risk of heart disease, diabetes, impaired mobility, joint pain, and other complications. People with diabetes are at risk of blindness, impaired wound healing, kidney failure, poor peripheral circulation, heart disease, and other complications.

History of Abuse or Trauma People who have experienced abuse or traumatic events often feel they have limited control over their health and circumstances. They may feel powerless or hopeless, and be unable to take actions that promote health or lead to early treatment of illness. Abuse and trauma also tax a person's reserves, placing them at risk of mental health problems.

Other Factors Other vulnerable populations include people who are poor or homeless, migrant workers, people with disabilities, premature infants, women with a high-risk pregnancy and pregnant adolescents, people with communicable disease, people who abuse substances, members of certain ethnic/racial groups, and the untreated mentally ill.

UNDERSTANDING THE CONCEPT OF COMMUNITY-BASED NURSING

A community can be either a ***site*** for healthcare delivery or a ***recipient*** of healthcare services. In fact, the first hospitals in the United States were established only in the late 1860s to protect society from contagious disease. Several decades passed before hospitals and other freestanding clinics became the predominant settings for providing healthcare. However, as the technological advances of the past 30 years have escalated the costs of delivering health services, efforts to lower costs have resulted in a move back to more community-based care, including complementary and alternative care.

Community-based care refers to healthcare or rehabilitative services performed in clinics, offices, mobile care units, and other facilities in the community—rather than in acute care settings, such as hospitals (although acute care settings also exist within the community). For example, many surgeries and diagnostic procedures are now performed in privately owned surgical centers, health clinics, and physicians' offices rather than in hospitals. People also receive mental, physical, cardiac, and pulmonary rehabilitation services in outpatient settings. Extended care facilities, or nursing homes, commonly provide rehabilitative care for patients after acute traumatic injuries as well as continuous skilled care for older adults and people with chronic illness. The following sections describe three approaches to community-based nursing care: community health nursing, public health nursing, and community-oriented nursing.

Community Health Nursing

Although many people use the terms *community health nursing* and *public health nursing* interchangeably, the two are not identical. **Community health nursing** focuses on how the health of individuals, families, and groups affects the community as a whole. Community health nurses strive to promote, protect, preserve, and maintain the health of the population through the delivery of personal health services to individuals, families, and groups. For example, a community health nurse may work in a prenatal clinic providing free services for low-income women. The nurse provides a direct service

Complementary & Alternative Modalities (CAM)

Using CAM for Preventing Illness

Barrett, B., Muller, H. M, Ward, A, et al. (2012). Meditation or exercise for preventing acute respiratory infection: A randomized controlled trial. *Annals of Family Medicine, 10*(4), 337–463.

In a study designed to evaluate the potential preventive effects of meditation or exercise, 154 adults 50 years and older were recruited from the community and randomized into one of three groups: (1) those who received 8 weeks of training in mindful meditation, (2) a matched group involved in 8 weeks of training in moderate-intensity and sustained exercise, and (3) an observational group.

Researchers found fewer episodes and reduced severity of acute respiratory infection (ARI) in the meditation and exercise groups.

to each pregnant woman, yet she is doing so to improve the general health of the entire community. By encouraging the mother to eat balanced meals, exercise, and avoid harmful substances, the nurse improves the health of both mother and baby—who are members of the community—and therefore improves the overall health of the community.

Public Health Nursing

Public health nursing focuses on the community as a whole and the eventual effect of the community's health status on the health of individuals, families, and groups. The goal of public health is to prevent individual disease and disability, in addition to promoting and protecting the overall health of the community. Today's public health nurses functioning in a health promotion role must process important skills, such as community assessment, cultural competence, program planning, communication, financial planning and management, leadership and systems thinking, and policy development, for example (Quad Council of Public Health Nursing Organizations, 2011).

For example, a public health nurse may be employed by a county health department to provide surveillance services to monitor for tuberculosis (TB). The nurse helps to protect the entire community by screening for TB at the local school, by testing high-risk individuals for TB, and by identifying and tracking clients with active disease to ensure that they complete the prescribed 6- to 9-month medication regimen.

Because public health focuses on large-scale programs for the entire community, government-based agencies often provide these services. The U.S. Public Health Service (USPHS) is an example of a public health agency within the federal government. Some examples of successful public health programs are human papillomavirus (HPV) immunizations for adolescents, smoking cessation for healthcare workers, motor vehicle and infant car-seat safety, and obesity prevention programs for children. For additional information on the USPHS,

Go to Chapter 43, **Supplemental Materials: United States Public Health Service,** on Davis*Plus*.

Community-Oriented Nursing

Community-oriented nursing combines components of community and public health. It focuses on health promotion, illness prevention, early detection, and treatment provided within the community setting. The practice is evidence-based and collaborative with other community health disciplines. The approach is a comprehensive look at the individual, family, group, and community at large. For example, a nurse with a community-oriented approach might work in an adolescent prenatal program. The nurse provides individual care at the local clinic 2 days per week. While at the clinic, she gathers data from adolescent clients about the schools they attend; their knowledge of birth control, pregnancy, and childbirth; and the issues these girls face with pregnancy. On the remaining 3 days, she meets with school officials to identify pregnant teens who need prenatal care; teaches a class about sexuality in the local high school; works with teachers to identify strategies to keep pregnant teens in school; provides parenting education to adolescents who have children; and advocates changing a bus route so that teens can easily get to the local clinic. Each aspect of care allows the nurse to gather more data about the needs of the individuals and the community as a whole. Figure 43-1 provides a schematic of the relationship of the various community-based nursing approaches identified in this section.

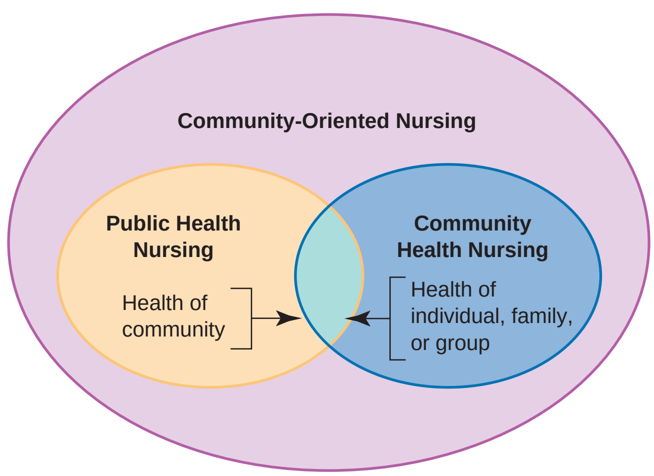


FIGURE 43-1 Schematic relationship of community nursing approaches.

KnowledgeCheck 43-3

- What is the distinction between an aggregate population and a vulnerable population?
- Identify practice differences between a community-based nurse and an acute care nurse.
- How is public health nursing different from community health nursing? How is it the same?
- How is community-oriented nursing related to community health nursing and public health nursing?

ThinkLike a Nurse 43-2

Review the scenario of Tanya and Jacob (Meet Your Patients). Which form of community-based nursing would be most appropriate to address their concerns?

Who Were Some Pioneers of Community Nursing?

The following are some of the most notable people who have contributed to the development of community-based nursing care.

- ***Florence Nightingale***—Established the importance of promoting health by manipulating the environment (e.g., light, warmth, sanitation, cleanliness) and nursing the whole person.
- ***Lillian Wald***—Known as the first community health nurse; founded the first visiting nurses association in New York.
- ***Clara Barton***—Founder of the American Red Cross.
- ***Margaret Sanger***—Founded the International Planned Parenthood Federation. Pioneered the use of family planning and birth control education.

If you would like to learn more about the achievements of these community health pioneers,

Go to Chapter 43, **Supplemental Materials: Pioneers of Community-Based Nursing,** on Davis*Plus*.

WORKING WITHIN COMMUNITIES

Community nurses' roles vary depending on the community and its identified needs. Community nursing care is by nature holistic, and it serves a large client population. Therefore, one of the most effective nursing interventions is **empowerment**. This means assisting the client (individual or community) to recognize and use available resources to achieve or maintain the desired level of health, achieve autonomy, and maintain positive self-esteem.

What Are the Roles of Community Nurses?

Community health nurses function as client advocates, educators, collaborators, counselors, and case managers. All of these roles require excellent written and oral communication skills. Although the widespread use of electronic health records, e-mail, text messaging, and other forms of electronic communication have made it possible to communicate efficiently with large numbers of people, computer or Internet access might be a problem in some areas. In addition, there are still some people with limited or no computer skills.

Client Advocate The effective community health nurse consistently supports the identified or expressed concerns of the client and/or community. Advocating for a community often requires political involvement at the local, state, or national level. The challenge is in knowing whom to approach for political support and how to gain their support. As a community health nurse you can effect change by getting involved in your local student nurses association, professional nursing organizations, school board, and citizen committees, or by attending council meetings.

Educator Because community nursing focuses on wellness and disease prevention, much of what the nurse does involves client education—of individuals, aggregates at risk of disease, politicians, or a community. It is difficult to evaluate the effect of the health education because people may not act on the knowledge for months or years after the teaching moment. When planning teaching, you must be aware of the stage of development, educational level, and learning style of the community group you intend to educate. The best learning programs are short; provide relevant, practical information; and can be easily incorporated into the learner's daily routine. For more information about teaching clients, see Chapter 19.

Collaborator A primary role of a community health nurse is to serve as a collaborator Consider the following example: A community health nurse is concerned about poor compliance with recommended immunization schedules for 2-year-olds in a particular community. After surveying some of the parents, the nurse discovers that the clinic's operating hours are limited and the automated call routing system is frustrating for people trying to set an appointment; and the clinic does not offer online scheduling. The nurse also discovers that some offices do not send reminders to clients, nor follow up to reschedule missed appointments. The nurse schedules a meeting of clinic staff, practice managers, and patients to resolve these issues. At the meeting, some larger issues are revealed, such as the insufficient number of Medicaid providers to serve the community, and the failure of state Medicaid agencies to reimburse the providers adequately and in a timely manner. Partnerships and coalitions can effectively address common concerns among different communities, as well as those within a single community.

Counselor Once you have established rapport with a group, members may consult you about a variety of health- and non–health-related concerns. Be careful to offer counsel only in areas within your scope of practice and make recommendations that are practical yet meet the needs of the community. Often, you may need only to serve as a witness to the group's concerns. Letting clients discuss or work through issues empowers them and fosters self-reliance.

Case Manager Community nurses commonly make referrals to or collaborate with various health and social agencies. Be aware when referring clients to these resources that agency policies and financing change frequently. Also, because community agencies often operate on grants and time-limited funding, a program that is available at one time may be dissolved at another. As a community health nurse, you will need to remain informed about the community services in your area. For example, a local group has established a healthcare program at a minimal charge for low-income families. Providers and nurses volunteer their time to provide the care. Pharmaceutical representatives donate the medical supplies and routine medications. Local specialists (e.g., surgeons) provide services to those with complex or specialized needs. However, in such a clinic the appointment times fill up quickly, and often clients have to wait more than a month or two for an appointment. Before enrolling families in the program, you would need to be aware of these limitations and share this information with clients.

KnowledgeCheck 43-4

Give an example of a nursing activity involved in each of the following community health roles: educator, advocate, case manager, counselor, and collaborator.

How Are Community Nursing Interventions Classified?

There are three basic levels of care in which nursing interventions can be classified: primary, secondary, and tertiary. Most community-oriented nursing practices are aimed at the primary (prevention) level.

Primary Interventions

The goal of **primary (first-level) interventions** is to promote health and prevent disease. Educating susceptible individuals with no known disease process is a routine, primary intervention that community health nurses practice. For example, a nurse may educate ninth-grade students about the risk of hepatitis B and HPV, the benefits of vaccination, and strategies to reduce the likelihood of exposure to contaminated body fluids. Other examples include collaborating with local agencies to provide clean and secure temporary housing for migrant farm workers, or lobbying elected representatives for a ban on smoking in restaurants and other public places.

Secondary Interventions

Secondary (second-level) interventions aim to reduce the impact of the disease process by early detection and treatment. For example, a community health nurse may screen a sexually active adolescent girl for hepatitis B and/or HPV. She has known risk factors for sexually transmitted infection (STI) but no apparent disease symptoms. The nurse will also teach the client how to protect herself from STIs, hepatitis B, and HIV in the future. Other examples of secondary interventions include providing outreach screening programs offering mammography, scoliosis screening, lipid testing, or prostate-specific antigen (PSA) testing for prostate cancer (Fig. 43-2).

Quality and Safety Education for Nurses

Promoting Patient-Centered Care in Community Health

Chapter Key Concept: *Community Nursing*
Competency: *Patient-Centered Care (Knowledge, Skills, Attitudes)**

Scenario: Nurses at a public clinic note an increased number of Hispanic clients seeking services. To best serve this growing community, one of the nurses researches healthcare issues affecting urban Hispanic populations. Latino men are more likely to be diagnosed with late-stage prostate cancer and to die from the disease than non-Latino men. Clinic staff plan to develop a flyer about prostate cancer screening, directed at Hispanic men aged 50 and older. The nurse asks a coworker, Mr. Sanchez, what cultural norms might influence health behaviors. He says that many Latino men view seeking healthcare as a sign of weakness. He explains "machismo" and "caballerismo," concepts of manliness in the Latino culture that value courage, honor, and dignity. This means that for many Latino men, a digital rectal exam would be emasculating, embarrassing, and an affront to dignity.

The nurse searches the literature for more information and learns that many Hispanic men feel healthcare providers do not understand their culture and do not take time to develop a relationship with them. After synthesizing the literature, the nurses decided to adopt the following strategies:

- They will create educational materials, which will be available in Spanish.
- Educational materials will specifically address culture-based fears that the exam is a threat to manliness.
- To reach the men (who tend to avoid healthcare), nurses will educate the women in the family. They believe the women will then encourage their men to get screened.
- The nurses will use community leaders, public service announcements, and churches to spread information.

Think about it:

- In what ways did the nurses make the planned educational materials patient-centered?
- How could the nurses evaluate the patient-centeredness of the educational materials? What information would they need? Where might they obtain the information?
- Patient-centered care often correlates to improvements in care. How can the clinic staff evaluate improvements in the healthcare of Latino men in their community after the educational campaign?

  What goals are reasonable for this educational effort?

  What assessments would be used to determine effectiveness?

Source: Agency for Healthcare Research and Quality (2010); Center for Research Strategies (2002); Rivera-Ramos & Buki (2011).

*For specific Knowledge, Skills, and Attitudes,

Go to the QSEN Web site at **http://qsen.org/competencies/pre-licensure-ksas/**

FIGURE 43-2 Secondary interventions. Early detection of heart disease with lipid screening.

Tertiary Interventions

The goal of **tertiary (third-level) intervention** is to halt disease progression and/or restore client functioning to the pre-disease state. The disease process is clinically apparent and client debilitation, including death, is likely without intervention. Tertiary-level interventions require the nurse to collaborate with members of other healthcare providers to provide treatment. For example, a student may report to a school nurse that she has been involved in unprotected sexual activities. The school nurse may refer the student to the public health clinic for a pelvic exam and lab testing to detect STI, and hepatitis B, HPV, and HIV screening. The student has an abnormal Pap smear, showing cells suggestive of HPV exposure. The clinic nurse, in collaboration with the provider, administers medical treatment. There is no cure for HPV, so the teen also needs to learn how to prevent the spread of the disease to others, get immunized with the HPV vaccine, and obtain regular Pap and pelvic exams to detect cervical cancer and other STIs.

Think**Like a Nurse** 43-3

What level of intervention is required to address the concerns of Tanya and Jacob (Meet Your Patients)? Discuss your response.

KnowledgeCheck 43-5

For each of the nursing actions listed, identify the level of the nursing intervention as primary, secondary, or tertiary.

- Taking a client's blood pressure at a health fair
- Administering insulin to an elderly person at an extended care facility
- Teaching second-grade students to wash their hands correctly

Toward Evidence-Based Practice

Jones-Cooper, S. N., & Walton-Moss, B. (2012). Using reminder/recall systems to improve influenza immunization rates in children with asthma. *Journal of Pediatric Health Care*, 27(5), 327–333. doi:org/10.1016/j.pedhc.2011.11.005

This literature review examined the effectiveness of reminder systems in improving immunization rates in children with asthma. Healthcare providers provided verbal and mailed reminders, electronically generated alerts, and year-round scheduling of flu vaccination appointments. Although the reminder methods improved vaccination, the gain was only modest using these traditional strategies. More effective alert systems are needed.

Abbas, A. H. (2011, November 23). Children vaccination reminder via SMS alert. *International Conference on Research and Innovation in Information Systems*, 1–5. doi:10.1109/ICRIIS.2011.612575

This study presents a reminder system for parents of children due for vaccination using short message service (SMS). The existing practice for notifying the vaccination schedule was via written appointment. Results show the benefit of having reminders sent via SMS in improving vaccination compliance and reducing missed appointments.

Pereira, J. A., Quach, S., Heidebrecht, C. L., et al. (2012). Barriers to the use of reminder/recall interventions for immunizations: A systematic review. *BMC Medical Informatics and Decision-Making, 12,* 145. doi:10.1186/1472-6947-12-145

Researchers conducted a systematic review of 10 evidence-based articles examining healthcare providers' perceptions of the barriers in implementing electronic reminder systems to improve vaccination. The most reported barriers were limited staffing (time and willingness to implement vaccination reminders) and the expense of electronic software. The accuracy of patient immunization records was questionable given the lack of data sharing among numerous immunization providers.

1. In spite of reminders, what would you anticipate to be patient-related obstacles to optimal vaccine coverage?

2. What would you anticipate to be some other factors in the medical clinic or office practice that could contribute to a less-effective immunization program?

3. What are some ideas you have to improve the effectiveness of an immunization program in the setting in which you might work?

What Career Opportunities Are Available for Community-Based Nurses?

The following are only a few of the many career opportunities for those who want to practice community-based nursing.

School Nursing

Nursing practice in the school setting began when educators realized that children with health problems had more difficulty learning. School nurses provide direct care for children with chronic health conditions such as asthma, attention deficit disorder, and diabetes. They also help children who need routine procedures, such as catheterization, during the school day. School nurses perform vision and hearing screenings. They also administer prescribed medication and ensure that age-appropriate immunizations are documented. Some school nurses offer health education on topics such as nutrition, physical activity, and sexual and reproductive health. The nurse may also serve as a role model for students who lack parental support or who are struggling with peer pressure. For the most part, a school nurse is autonomous and must be capable of prioritizing and making decisions (American Nurses Association [ANA] and the National Association of School Nurses [NASN], 2011).

Occupational Health

Occupational health nurses work primarily in industrial or corporate settings. They provide health promotion programs for employees and their families in an effort to reduce absentee hours, increase productivity, and reduce illness and complications. Occupational health nurses also complete required medical documentation for disability claims or occupational hazardous events. They conduct new-hire and annual screenings, provide care to injured or ill workers, obtain random drug testing, and file worker's compensation claims. To reduce costs, some industries contract a staffing agency to provide trained occupational health nurses. Nursing autonomy and responsibility vary with the employer and the negotiated contract.

Parish Nursing

Parish nursing is a specialized area of nursing practice that focuses on the promotion of health within the context of the values and beliefs, and practices of a faith community. Integrating faith with health, parish nurses act as educators of holistic health (e.g., parenting issues, use of medications, choosing healthcare providers). In the role as personal health counselor, parish nurses increase awareness of the interrelationship between lifestyle, personal habits, attitudes, and faith (Fig. 43-3). Parish nurses develop support groups, provide information through seminars and printed or electronic materials, train volunteers, and act as a liaison to community services as needed (Health Ministry Association/American Nurses Association, 1998). The level of autonomy and responsibility of parish nurses varies, depending on the faith community setting.

FIGURE 43-3 Parish nursing. Caring for an elderly woman in her home.

Nursing in Correctional Facilities

Corrections nurses deliver healthcare within the criminal justice system, for example, in juvenile detention, substance abuse treatment facilities, and prisons. The nurse provides primary care services to people of all ages in an unbiased and nonjudgmental manner (ANA, 2013a). Nurses have a high level of autonomy in most correctional or substance rehabilitation facilities. Correctional facilities employ providers who conduct routine examinations and acute and chronic healthcare on a scheduled or as-needed basis. The nurse also commonly performs occupational health duties for facility staff. For personal safety, nurses must meet certain physical requirements and complete special weapons training before working in most correctional facilities.

Public Health Clinics

Many community nurses practice within local and state departments of health, including public health clinics. Services offered by health departments can range from basic to comprehensive, based on the needs of the community and funding. Large cities tend to have many nurses who may specialize in an area, such as immunizations, prenatal health, school health, or epidemiological survey. Smaller communities may have only one nurse (or full-time equivalent) providing all services. The autonomy and scope of practice of public health nurses are often limited by the philosophy of the political administration and availability of funding.

Disaster Services Nursing

A disaster is any event or catastrophe inflicting widespread loss of life, health, and destruction of property. Features characterizing a disaster typically involve unpredictability, urgency, threat, speed, and uncertainty. They may develop as sudden-onset or slow-onset. *Human-generated disasters* might be the result of acts such as a terrorist attack, war, or use of nuclear energy to cause harm or fear. *Technological disasters* cause damage or disruption on a large scale (e.g., computer systems failure, mass power outage, explosion, or hazardous substance exposure). Examples of *natural or ecological disasters* include hurricanes, earthquakes, tsunamis, and floods, or even environmental degradation, such as deforestation. *Biological disaster* may involve exposure to pathogenic microorganism, toxin, or other bioactive substance, for instance an outbreak of endemic disease or plant contagion.

Community-oriented nursing emphasizes community assessment and education to reduce the number of casualties when disasters occur and to achieve the best possible level of health for the people and community involved in a disaster.

Disasters affect the health status of a community in the following ways:

- Lead to premature death, illness, or injury.
- Disrupt healthcare services offered within the community.
- Cause environmental issues, such as outbreaks of communicable disease or food/water-borne illness.
- Cause shortages of safe food and drinking water.
- Burden other healthcare systems when displaced populations shift to a host community for basic needs (Veenema, 2013).

In large-scale disasters, nurses practicing in special circumstances and disaster conditions are typically needed to:

- Rapidly assess the overall situation and that of individual victims.
- Triage care and initiate life-saving measures first.
- Adapt nursing skills to the disaster situation, considering available equipment, supplies, and personnel.
- Evaluate the safety of the environment and remove health hazards.
- Provide leadership in coordinating care, assigning priorities for care, and transporting victims.
- Prevent further injury or illness.
- Provide compassionate support to victims and their families.

Good Samaritan laws protect nurses when volunteering—in any state—as long as actions are reasonable.

For additional information on disaster preparedness and preparation for terrorist attacks,

Go to Student Resources, Chapter 43, **Supplemental Materials: Disaster Preparedness,** on Davis*Plus*.

International Nursing

Nurses working internationally commonly provide relief services after a natural or man-made disaster. They may also offer health or human aid services through a medical clinic, faith-based mission, orphanage, or other international relief program. International nursing requires a high level of autonomy, flexibility, and ingenuity, depending on community needs and available resources. Common problems affecting the health of international communities are poor sanitation, contaminated food and water, waste management, limited or dangerous transportation, communicable disease, parasitic infections, cultural practices, and limited education. Nurses working globally commonly treat people with malnutrition, dehydration, mosquito and other insect-related illnesses, parasitic infestation, hepatitis and HIV, to name a few (Fig. 43-4). Because of poor access to healthcare and limited or no resources to pay for medication, many people do not receive adequate healthcare.

BOX 43-1 ■ What You Should Do During a Disaster Event

- Remain calm and be patient.
- Follow the advice of local emergency officials.
- Listen to your radio or television for news and instructions.
- If the disaster occurs near you, check for injuries. Give first aid, and get help for seriously injured people.
- If the disaster occurs near your home while you are there, check for damage using a flashlight. Do not light matches or candles or turn on electrical switches. Check for fires, fire hazards, and other household hazards. Sniff for gas leaks, starting at the water heater. If you smell gas or suspect a leak, turn off the main gas valve, open windows, and get everyone outside quickly.
- Shut off any other damaged utilities.
- Confine or secure your pets.
- Call your family contact—do not use the telephone again unless it is a life-threatening emergency.
- Check on your neighbors, especially those who are older or disabled.

FIGURE 43-4 International nursing. Health and nutrition program for women and children at an African health clinic.

ThinkLike a Nurse 43-4

Increase your self-knowledge: Assume you are going to be a community-based nurse. Of the many career opportunities available, which work do you think you would rather do? Explain why.

PracticalKnowledge knowing how

The American Nurses Association, in the *Standards for Community Health Nursing* (1986), describes the goal of community health nursing as the promotion and preservation of the health of the community population as a whole, defined groups, families, and individuals. Community nursing care should be delivered in a practical, culturally sensitive manner (Kulbok, Thatcher, Park, et al., 2012).

For more information about community health nursing standards,

Go to Chapter 43, Student Resources, **Supplemental Materials, American Nurses Association Standards of Community Health Nursing Practice,** on Davis*Plus*.

ASSESSMENT

The nursing process follows the same steps you have studied in the previous chapters but uses different forms and different language when your client is a community. Community assessment is usually ongoing and requires the nurse to collaborate with and compile information from a variety of sources. The assessment approach is based on the type of community, the purpose of the assessment, and personal preference. Most beginning students elect to assess a geopolitical community because the data are more readily available than data from aggregate groups. Therefore, we focus on the geopolitical community assessment procedure.

Windshield Survey Community assessment usually begins with a windshield survey. A **windshield survey** is performed by observing the community through your automobile window, while walking, or otherwise being physically present in the area. It is similar to general observation of the individual client in that it provides an overview and allows you to see the community in its natural state. As you observe, make note of the condition of buildings and public facilities, residences, religious facilities, streets and sewers, modes of transportation, lighting, outward signs of crime or violence, pollution, waste disposal, and other signs of the well-being of the community. Protective services, such as police and fire services, should be included. You may need to repeat the survey over a period of time at different times of the day, month, or year to get an accurate picture of the community. For more reliable survey results, observers should be trained.

- Begin by describing the neighborhood and the people you see in the community.
- Strive to remain objective in your observations; avoid using personal opinions and biases
- Route your course prior to conducting the visit.
- Record your findings as soon as possible after your survey.
- Document the observation with photographs and videography when possible.

Databases and Public Records You can also obtain data from publicly available resources, such as birth records, marriage licenses, local news publications, and community Internet sites. Internet search engines can help you obtain demographic information, morbidity and mortality data, vital statistics, educational levels, criminal activity, political leadership issues, and/or information about community resources.

Client Perceptions You will also gather information about how individuals in the community perceive the community and its state of health. Through community gatherings and informal conversations, you can assess a cross section of the population. This is not only an important part of your assessment, but also an excellent way to establish rapport, convey your concerns, and develop a working relationship with key community members.

ANALYSIS/NURSING DIAGNOSIS

After a thorough assessment, you will analyze the complete set of data and compile a list of community strengths and limitations. Work with the community to develop a list of their priorities, considering needs identified by the client, and based on availability of funding and political feasibility.

The NANDA-International Taxonomy

In community practice, you need nursing diagnoses that describe the health status of individuals, families, groups, and entire communities. Recall from Chapter 4 that the NANDA-I taxonomy of nursing diagnoses can be used in any nursing setting or specialty. You would simply add the term *community* to other NANDA-I labels when creating a community-based diagnosis: for example, Decisional Conflict (Community) related to safety needs of the homeless population. In addition, the NANDA-I taxonomy includes four diagnoses that specifically describe the health status of a community:

- Deficient Community Health
- Ineffective Community Coping
- Readiness for Enhanced Community Coping
- Ineffective Management of Community Therapeutic Regimen

The Omaha Problem Classification System

The Omaha system was developed specifically for use in community settings (Martin & Norris, 1996). In addition to nursing diagnoses, it contains standardized terminology for outcomes and interventions. For a thorough overview,

Go to the **Omaha System Web site,** at http://www.omahasystem.org/

For an expanded discussion of the Omaha problem classification scheme and for examples of diagnosis (problem) labels, and problem modifiers, and examples of creating a diagnostic statement,

Go to **Standardized Language, Omaha Problem Classification Scheme,** in Volume 2.

PLANNING OUTCOMES/EVALUATION

In the community you will need to write goals and outcomes for aggregates. The *Healthy People 2020* goals are aggregate goals. The NOC and Omaha taxonomies provide standardized terms for stating community goals. For guidelines in using these two taxonomies,

Go to Chapter 43, **Standardized Language, Using the NOC and Omaha Systems to Write Aggregate Goals,** in Volume 2.

PLANNING INTERVENTIONS/IMPLEMENTATION

As a community health nurse, you will need interventions to promote and preserve the health of individuals, aggregates, and communities. Both NIC and the Omaha system provide standardized vocabularies for aggregate interventions.

The NIC taxonomy includes 18 interventions specifically designed for community health. The Omaha taxonomy provides four intervention categories that can be used in community-oriented nursing practice. For guidelines,

Go to Chapter 43, **Standardized Language, Using the NIC and Omaha Interventions Labels,** in Volume 2.

APPLYING THE NURSING PROCESS IN COMMUNITY-BASED CARE

Community assessment and care planning may at first seem different from what you have been doing for individual patients. But it does follow the same problem-solving process, as illustrated following:

Scenario: As a nurse employed by a local immunization clinic, you have been hired into a new position created by federal and state grant monies to investigate why immunization levels are low among 2-year-olds in Census Tract 15. You would begin with an assessment.

1. **Gather data about the community.**
   - *Define the community*. For instance, determine the physical boundaries of Census Tract 15, a geopolitical community.
   - *Learn the community*. Start interacting with the community to build rapport. Begin the ongoing assessment by conducting windshield surveys, searching for information through reputable databases, and talking with community members.
   - *Focus the data collection*. Focus on the information that will help you determine possible causes of low immunization rates. In this case, the priority problem has already been defined by the financing agency.

ThinkLike a Nurse 43-5

What data would you want to look at? What are possible reasons for low immunization rates?

2. **Analyze the Data.** Next, examine the characteristics of the families failing to provide immediate immunization for children, including:
   - Family demographics
   - Age of children
   - Number of immunizations needed and the cost
   - Beliefs about negative effects of vaccines
   - Availability of transportation
   - Public sites providing vaccinations
   - Overall continuity of general healthcare for children

   Assume that after working with the community for 6 months, you have spoken at parenting classes about the need to vaccinate children. Several community members have told you they thought their child had already received all necessary immunizations or that their healthcare provider had said to wait until they have better insurance. You will need to arrange a meeting with the local providers to discuss low immunization status. They explain that many vaccinations are too expensive to provide based on the reimbursement they receive from government funding sources.
3. **Plan care.** Your next move is to do some planning. Using the Omaha system you could generate a care plan to address some of the issues raised by community members and physicians.

4. **Evaluate results and follow up.** Community assessment is never complete because the community is constantly changing. However, you need to define the identified needs and desired outcomes during a given period of time, based on best data available at the time of collection. In this case, you would share with local healthcare providers, the health department, and local health policy committee your approach to addressing the factors suspected of contributing to poor immunization compliance. An important part of your role as a community health nurse is to continue to monitor and evaluate the data and provide updates to the appropriate groups.

Now that you have some understanding of community healthcare, the rest of the chapter focuses on a specific type of community nursing: delivering healthcare in the patient's home.

Theoretical Knowledge knowing why

UNDERSTANDING THE CONCEPT OF HOME HEALTHCARE

Recall that community-based healthcare refers to services performed outside of acute care settings. Home healthcare is one such service. **Home healthcare** is the delivery of health-related services in the client's home. Home healthcare is appropriate when a client needs ongoing care that exceeds the abilities of friends and family, as in the following situations:

- To supplement the skills a family member is providing
- To serve as a backup for safety or additional assessment
- For older adults who need ongoing care but want to avoid moving to a skilled nursing facility
- For people of any age who require home-care service when they are recovering from illness or surgery or when they are terminally ill
- For ongoing care of chronically ill adults and children to avoid hospitalization

Goals of Home Healthcare

Nurses provide home care to clients with complex, chronic, or terminal illness. The primary goals in home healthcare are that (1) the client's self-care ability and Independence will improve and (2) caregivers gain the ability to assist the client with ongoing health needs.

This approach may be very different from what you have experienced in other clinical settings. For example, as the nurse in the Meet Your Patients scenario, you would help the couple manage Mr. Escobar's care independently at home. Initially you might show Mrs. Escobar how to administer medications and explain their function, and demonstrate strategies for moving and turning Mr. Escobar. However, your goal would be for her to progress to handling these tasks independently.

Distinctive Features of Home Healthcare

Home health nursing differs from hospital nursing in several ways. The hospital environment is controlled. Surfaces are regularly disinfected; supplies are stocked; and foods, medications, and other therapies are readily available. Computers are conveniently located with information easily accessible about the patient. In addition, the hospital-based nurse can consult almost immediately with a team of healthcare providers (i.e., other nurses, the primary care provider, various therapists, social workers, a pastoral care provider, and even a business office staff to ensure that reimbursement will be forthcoming).

In contrast, when you are in a patient's home, surprisingly little is within your control. The home may be spotless or filthy, food plentiful or scarce, and supplies readily available or unreliable. The television or music may be loud; a dog may bark continually; or several young children may be playing nearby and repeatedly interrupting your interactions with the client or caregiver. You will find nursing care in the home environment to be different from inpatient settings in the following ways:

- You are a guest in the client's home. The client and family determine whether they are willing to let you enter the home to deliver care.
- You are responsible for making the assessments and determining whether to advise the primary care provider of client changes.
- You must bring all necessary supplies or arrange to have them delivered ahead of time.
- You must be able to distinguish between skilled services, which are eligible for reimbursement from Medicare, and homemaker services. **Skilled services** are services that must be performed or supervised by a licensed healthcare professional (Box 43-2). **Homemaker services** (e.g., cleaning, meal preparation) are reimbursed to clients only if the principal reason for home care is a skilled service. These services are provided by home health aides.
- You must be more self-sufficient and function more independently. Often there are no other team members immediately available for support, assistance, or consultation.
- You must be aware of and comfortable with the family observing you as you provide care.
- You will need to adapt to varying family relationships and some home environments that are difficult or even dysfunctional.
- You will need to encourage the family to help in providing care and in taking over care when you leave the home. Be aware that overburdened caregivers may need your help as much as does the client.

BOX 43-2 ■ Skilled Nursing Services

Medicare defines *skilled nursing care* as services and care that can be done safely and correctly only by a licensed registered or practical nurse. The services must be reasonable and necessary for the treatment of the illness or injury.

- Patient assessment
- Ongoing monitoring of patient status
- Management and coordination of the patient's plan of care
- Evaluation of response to medications or treatment
- Medication instruction
- Teaching patients or caregivers to provide care or therapies
- Disease-related teaching (e.g., diabetes education)
- Complex tasks, such as injections, insertion of urinary catheters, infusion therapy, wound care, tube feedings, or ventilator management

- You must preplan your visit by figuring out the directions to sites in advance and arranging appointments efficiently.
- Your personal safety may be more of a concern when making home visits. You must always be aware of the environment around you and alert to possible dangers.
- As things do not always go as planned in a less controlled home environment, you will need to be flexible and learn to modify your plan.

One advantage of home healthcare is that it allows you to expand your understanding of the concept of *client*. The home is a window into the client's life, through which you can see his personal environment: how he lives, eats, and negotiates his world (Fig. 43-5). The photos, mementos, personal belongings, and other things the client values and cherishes make cultural beliefs and practices more visible. These things provide clues to his lifestyle, strengths, resources, and motivation.

Home health nursing also differs from community healthcare. Community health nurses provide care for individuals, families, and groups with an emphasis on population-based care. In contrast, home health nursing focuses on the individual and his support system.

FIGURE 43-5 The home is a window into the client's life.

KnowledgeCheck 43-6

Identify at least four skilled services that may be provided in the home.

WHO PROVIDES HOME HEALTHCARE?

Home healthcare is provided by a variety of healthcare professionals employed by or working in cooperation with home healthcare agencies.

Home Health Agencies

Home health agencies coordinate the services of various professionals and paraprofessionals. They may be categorized by purpose, by type of client served, or by funding source.

Purpose In this category, **direct care agencies** are the most common. They focus on direct client interaction by providing skilled care, associated therapies and health services, home health aides, chore workers, and delivery of **respite care** (relief for family caregivers). **Indirect service agencies** also play a vital role in home healthcare. Examples of indirect home services include pharmaceutical and infusion companies and suppliers of durable medical equipment. **Durable medical equipment (DME)** is reusable equipment (e.g., walkers, wheelchairs, apnea monitors). Medicare pays for some, but not all, such devices. It is expensive, so before ordering it, be sure the DME is covered or the client is able to pay for it.

Type of Client Served An important specialty home service agency is hospice care. This may be a separate agency or a division of a home health agency. Still other agencies specialize in caring for patients with complex diseases, such as AIDS, or ventilator-dependent clients, or patients of a certain age group (services for older adults or chronically ill children).

Funding Source Agencies may take on many forms based on funding source, profit or nonprofit status, and relationship with other healthcare organizations.

- **Public agencies** are official or governmental agencies organized at the city, county, state, or national level. They are usually funded by taxes, along with reimbursement from insurance companies. The local health department is a good example of a public agency. Health departments focus chiefly on community needs, although they often also offer some home health services, especially when tracking clients in some of their disease management programs.
- **Voluntary agencies** are prominent in the delivery of home healthcare. These agencies are normally governed by a board of directors and funded by donations,

endowments, and third-party (insurance) reimbursement. Many **hospice organizations** (groups that provide care for people who are frail, terminally ill, dying, or not expected to improve) are voluntary organizations.

- **Proprietary organizations** are corporate or privately owned businesses that aim to make a profit. These agencies receive payment from insurance companies but also accept private-pay clients. Proprietary organizations may provide traditional home health services as well as private-duty care and other services that assist individuals to remain independent.
- **Hospital-based agencies** are an extension of the services provided by a hospital. Clients who no longer meet the criteria for continued hospitalization may be transferred to home care for continued services. A benefit of this type of home health agency is in the ease of transition between hospital and home.

The Home Health Team

In home healthcare, the registered nurse serves as the coordinator of health services, but other members of the healthcare team may also provide care. The team varies according to the needs of the client but is usually multidisciplinary. It may include physicians; nurse practitioners; registered nurses; licensed practical (vocational) nurses; home health aides; physical, speech, occupational, or respiratory therapists; nutritionists; social workers; pharmacists; podiatrists; dentists; chaplains; and family members.

Home Health Nurses

To succeed in home healthcare, you must have the ability to work independently and collaboratively, be flexible and resourceful, and adapt to different home environments and family interactions. The ANA asserts that because of the level of independence, knowledge, and expertise required to meet the demands of home care, baccalaureate nurses are better prepared for that role. However, it also says that the necessary knowledge and skills can be developed through formal orientation programs, structured preceptor programs, and guided clinical experiences (ANA, 2008, p. 8).

Home health nurses provide a broad range of services to clients of all ages. Your principal roles as a home health nurse (also called visiting nurse) are discussed in this section. Each role requires you to function as a skillful communicator. Communication is crucial in home care because of the need to establish good rapport with the client and family and to communicate frequently with other members of the healthcare team.

Direct Care Provider As a direct care provider, you may administer medications, dress wounds, or perform other skilled, complex tasks.

Client and Family Educator Recall that the goal of home healthcare is to promote self-care. Instead of focusing on performing the procedures, you will be helping the client or family take over the care. You can easily see the need to communicate skillfully in this role. You must be able to clearly explain the care required, the rationale for it, and how to safely perform the care. This requires patience, skill, and repetition.

Client Advocate In home care, the client and family are directly in charge of the plan of care. As client advocate, you support the client's right to make healthcare decisions yet protect the client from harm if he is unable to make decisions. In the event family members disagree, remember that as the client's advocate, you must try to see that his choices are respected and his rights upheld. You must also advocate for services the client needs. This may mean trying to secure additional home health support to avoid hospitalization, or it may mean advocating for another level of service, such as referral to hospice or placement in the hospital, based on your assessment of the client and discussion with the client and family.

Care Coordinator Home health nurses must manage and coordinate care among an array of healthcare providers. Therefore, as the case manager, you will need to gather data at an initial visit and develop a plan of care that addresses the client's needs. Your plan may require you to make additional visits as well as specify and perhaps arrange delivery of therapies and services by other professionals in the home.

KnowledgeCheck 43-7

What roles does the nurse assume in home care? List and describe them.

Hospice Nurses

As you learned in Chapter 17, **hospice nursing** focuses on care of patients who are dying or whose condition is not expected to improve. Hospice services are provided in the home, in the hospital, in nursing homes, and in homes specifically designed as hospices. The goal of hospice care is to promote comfort and quality of life. For these reasons, most hospice services are provided in the client's home. Because the client is not expected to recover, the focus of home hospice care is quite different from traditional home care. More than promoting self-care and independence, hospice care focuses on providing comfort and managing symptoms (Table 43-1).

The roles of hospice nurse and home health nurse differ mainly in their emphasis. As a direct care provider, the hospice nurse assesses the client's condition and monitors responses to interventions aimed at relieving distress. As an educator, the hospice nurse teaches the client and family how to adjust medications and care to control pain and other symptoms. The roles of communicator and client advocate assume prime importance as the client's condition deteriorates. The nurse shares these roles with the family and other home caregivers. Generally, there is less coordination of multiple services

Table 43-1 ➤ Home Healthcare and Home Hospice Care

	HOME HEALTHCARE	HOME HOSPICE CARE
Purpose	Promote self-care and independence.	Promote comfort and quality of life.
Focus of Nursing Interventions	Teach the family or other caregivers to assist the client with ongoing health needs and activities of daily living.	Provide comfort and manage symptoms.

in home hospice care. Instead, there may be greater emphasis on pain management. If you need more information on hospice care, see Chapter 17.

WHO PAYS FOR HOME HEALTHCARE?

Medicare, Medicaid, other government funded or mandated coverage, private insurance, and individual payments (private pay) help pay for home-care services. Medicare and Medicaid are the largest payors for home healthcare. Keep in mind the federal healthcare act passed in 2010 will likely change reimbursement in a variety of ways over the coming years (111th Congress, 1st session, 2010).

Medicare is a federally funded healthcare system designed to provide health coverage for persons who are older than 65 years and younger people who are disabled or diagnosed with end-stage renal disease or amyotrophic lateral sclerosis.

Medicare Reimbursement

Reimbursement by Medicare for home care depends on the following, strictly applied criteria:

- ***The client must need skilled care.*** See Box 43-2. Other services may also be provided, but the primary purpose for establishing care must be based on a skilled care need. This means that Medicare will not pay for personal care such as bathing and dressing when this is the only care the client needs.
- ***The client must be homebound.*** This means (1) the client must have a condition that restricts the ability to leave the home; and (2) leaving the home requires special assistance, transportation, supportive devices, or an escort.
- ***The client must require nursing care that is part-time and intermittent.*** This means Medicare will pay for a limited number of hours per day or days per week that the client can get skilled nursing care or home health aide services.
- ***The plan of care must be authorized by the physician and recertified every 62 days.*** For the client to continue to receive care, there must be evidence of continued need that remains acute.
- ***The care must be medically necessary and reasonable.*** The plan of care must address the client's health concerns and have clearly delineated outcomes. The expectations of the patient must be reasonable.
- ***Medicare will pay only for interventions identified on the treatment plan.*** The payer may periodically request patient health records to verify that the care was given.
- ***The home health agency must be approved by Medicare.*** An agency must show that it meets the Medicare definitions and requirements to become Medicare certified.

Medicaid is a program sponsored jointly by the federal government and the states to provide services to people whose income is below a mandated level. In many states, the criteria for reimbursement are the same as those required by Medicare. However, each state at present determines what services will be part of its medical assistance plan.

Private Insurance and Self-Payment

Private insurance companies may also offer home health services. The type and extent of covered services are specified in each separate insurance group and plan.

Many people require assistance in the home but do not meet criteria for reimbursement from Medicare, Medicaid, or their private insurer. Others simply do not have health insurance. (This was true when this book was published, but it is likely to change during the next few years as the new federal healthcare regulations are gradually put into effect.) Frequently, older clients require home health assistance but may not need skilled services. For example, they may need assistance with grocery shopping, meal planning and preparation, or transportation. The client or family may contact an agency to provide assistance for these services. Services are billed directly to the client.

ThinkLike a Nurse 43-6

Review the scenario focused on Mr. Escobar (Meet Your Patients). What members of the home health team may be required to provide care? Why?

HOW ARE CLIENTS REFERRED TO HOME HEALTHCARE?

Referrals to home healthcare come from a variety of sources. However, for home care to begin, there must be a medical prescription and a physician-approved treatment plan.

Hospital-based agencies have a built-in referral base. If the primary provider or nursing staff determine that the client would benefit from home health services, they refer the patient to the agency for evaluation while he is still hospitalized. Many agencies have *intake coordinators* who work in the hospital and review clients for suitability of services, gathering information from the chart, the client, the family, and the hospital team. Home services are arranged before discharge from an inpatient facility. Ideally, a discharge planner gathers information, secures the prescription from the provider, and makes arrangements. In some smaller hospitals, this task falls to the staff nurse providing predischarge care.

Referrals may also come from doctors, nurses, primary care offices and clinics, mental health workers, and other healthcare providers in the community, as well as directly from families and clients. Most home health agencies evaluate clients to determine whether they are eligible for services that are reimbursable by insurance. They may also offer services that the client may pay for independently.

WHAT IS THE FUTURE OF HOME HEALTHCARE?

Healthcare analysts have predicted several changes in home care during the next few decades:

- **Increased need for home healthcare.** During the next several decades, the demand for home care is expected to rise. Considering the growing number of older adults in the United States, it is more cost effective to provide healthcare in the home than in an inpatient setting.
- **Increased use of the home for hospice care.** Public acceptance of the home as a place of comfort and care, as well as concerns about the cost of inpatient care, has increased the number of persons who choose this compassionate option for end-of-life and palliative care.
- **Increased technology.** Technological advances, such as online resources or telemedicine consultation, make it safer and more affordable to deliver complex care in the home and allow home health nurses to deliver information and provide support (Bradford, Armfield, Young, et al., 2013). Computerized monitoring and documentation allow home health agencies to better coordinate care, receive needed supplies, and manage costs.
- **Continued research.** Research is needed in the area of strategies to improve the effectiveness of care, identify predictors of need for rehospitalization, and integrate home care into overall community-based services.

PracticalKnowledge knowing how

As a home healthcare nurse, your days will vary. Normally your caseload will be contained within a limited geographic boundary, so that you can schedule your visits efficiently, spending less time driving to visits, and have more time for delivering care. If you want to envision what it would be like to be a home health nurse, you need only to look at the list of services Medicare recognizes as skilled, in Box 43-2.

HOW DO I MAKE A HOME VISIT?

The home visit has three phases: preparation before the visit, nursing care during the visit, and evaluation after the visit.

Before the Visit

First review the client's chart and referral form to determine why you are making the visit. You may also need to review material about the client's health problem, medications, or treatment plan. Then you can begin to plan for the visit. What supplies will you need? What teaching materials will you need? What are the goals of the visit? Does the agency require additional client information, such as insurance data, to provide care? The agency will probably have a set of forms (e.g., HIPAA privacy forms, billing information) for you to complete during the first visit. Be sure you have those with you.

Before the visit you will need to find the address, get directions to the home, and determine whether there are safety concerns. Contact the client to notify him of the planned date and time of the visit and to determine whether his health status has changed since the referral was made. This will allow you to bring additional equipment or personnel along if needed.

Prepare Supplies

Home health nurses usually carry a nursing bag (Fig. 43-6). The nursing bag is often customized to the needs of the

FIGURE 43-6 The home health nursing bag contains some standard items but is usually customized according to the requirements of the clients in the nurse's caseload.

clients in the nurse's caseload, and normally contains the following:

- Handwashing supplies (e.g., soap or antibacterial handrub, paper towels)
- Stethoscope
- Sphygmomanometers (with cuffs in a variety of sizes)
- Thermometers (oral and rectal)
- Small equipment (scissors, forceps, penlight, staple remover)
- Tape measure (with plastic coating that can be cleaned, or several disposable ones)
- Plastic apron
- Gloves, sterile and clean
- An assortment of gauze dressings, tape, and cotton balls
- Occupational Safety and Health Administration (OSHA) supplies: mask, protective eyewear, disinfectant spray, disposable gowns to protect clothing
- A variety of syringes and safety needles (this varies widely among agencies)
- Venipuncture supplies
- Airway and resuscitation mask
- Miscellaneous supplies (e.g., specimen cups, sealable bag to transport specimen, agency forms, business cards)

You may need other supplies, such as medications, a scale, and a transfer belt, depending on the requirements of the clients in your caseload. If the client needs frequent dressing changes or supplies for treatments (e.g., tube feedings), it is best to have the supplies delivered directly to the client's house to reduce the number of materials you must carry. Note that in some states nurses are not permitted to carry medications because of safety concerns. You will need to check on the rules that apply to your state.

Provide for Your Safety

As you drive to the home, begin to make your assessment. Locate the stores, hospital, and community resources. What is the overall character of the neighborhood? Does this appear to be a safe neighborhood? What are the conditions of the approach to the home?

Safety for yourself and the client is an essential consideration in home healthcare. Bring your impressions about neighborhood safety and home safety with you into the home. You should evaluate whether the environment contributes to the client's health problems. In addition, you must also assess the implications for your own safety. You should provide your agency with your patient care schedule for the day. For suggestions about the safe delivery of home healthcare,

Go to **Clinical Insight 43-1: Safety Considerations in Home Care,** in Volume 2.

KnowledgeCheck 43-8

What are the major tasks that must be completed before making a home visit?

At the Visit

When you arrive at the home, you must remember this is the client's domain. Knock or ring the doorbell, and wait to be invited in. Introduce yourself to the client and family. Be respectful of their home, as well as their beliefs, values, practices, and cultural preferences.

The first few minutes of the initial visit set the tone for the relationship among client, family, nurse, and agency. This is your opportunity to develop rapport and trust. Introducing yourself, waiting for permission to enter, and treating the client and family members with respect are ways to help to establish rapport (Fig. 43-7).

You should also offer your card to identify yourself, and provide contact information for the home health agency. Generally, agencies have information packets that include the client's bill of rights, client responsibilities, billing information, information on the frequency and duration of services, how to reach the agency, and the date and time of the next visit.

As you do all this, you also gather data. Who answered your questions? What is the relationship between the caregiver and the client? How do they interact? What other people live there? What is the condition of the home? If this is an initial visit, you may need to verify or complete client data on the referral form. In the hospital, admissions personnel usually gather admitting data and obtain consent for treatment. In home care you need to collect and document this information.

FIGURE 43-7 The first few minutes of the initial visit set the tone for the relationship among client, family, nurse, and agency.

At a home visit, you might do a variety of things, such as performing physical care; drawing blood sample for lab work; checking weight; administering medication, IV fluid, or tube feedings; providing wound or ostomy care; or whatever is needed.

ThinkLike a Nurse 43-7

Review the case of Mr. Escobar (Meet Your Patients). What information did you gain from the first few minutes of the visit?

- Both Mr. and Mrs. Escobar are in need of nursing interventions. However, this is your agency's first home visit to them, and you have other clients you must visit today, so you will need to prioritize. What must the home health nurse do during the initial visit to a client?
- In addition to completing your assessment and talking about a plan of care with the Escobars, what do you think is the single most important thing you can do for them today? Explain your thinking.
- When Mrs. Escobar meets you at the door and brings you into the living room, you notice a large German shepherd dog lying beside Mr. Escobar's bed. Mrs. Escobar says, "Stay, King"; and then to you, "Roland likes having him nearby." What should you do?

After the Visit

After you leave the home, there is still a lot of work for you to do. Often you will need to complete the documentation for the visit. In Chapter 18, you learned about documentation techniques, various forms of charting, and legal aspects of documentation. In home care all of these rules apply; however, some aspects of home-care documentation are unique.

Home health agencies use Medicare's Outcome and Assessment Information Set (OASIS) to record initial assessment data. To continue to provide needed services to the client, you must include in your documentation: (1) evidence of homebound status, and (2) evidence of continued need for skilled care.

Other post-visit activities include ordering supplies needed for the next visit, making referrals to additional services (e.g., occupational therapy), coordinating care among the various services, and scheduling the next visit.

NURSING PROCESS IN HOME CARE

The nursing process moves through the same phases in all patient care settings. The difference in home care is that you must use forms structured to satisfy Medicare and other insurance requirements. Nevertheless, you need to assess the client, the family, the home, and the community to identify nursing diagnoses and other health problems. You will work from a plan of care prescribed by a medical provider, but individualize it with suitable nursing diagnoses and interventions. Periodically, you must evaluate the client's continued homebound status and ongoing need for medical treatment and skilled nursing care.

ASSESSMENT

On the initial visit, you need to perform an assessment to establish a baseline and determine the type of care required. This assessment includes a health history, review of all medications—prescribed, over-the-counter, and alternative—pertinent family and social history, mental status, functional ability, availability of family and informal support and caregivers, nutritional status, and assessment of the home environment. Typically a full assessment requires multiple visits.

Medicare requires home health agencies to collect specific information for all Medicare clients they serve. The OASIS data must be collected at the start of care, with each recertification (every 60 days), and at the termination of care. Medicare uses these data to determine the effectiveness of care and to monitor client outcomes. In addition to the required OASIS information, many agencies use other assessment tools created specifically for their needs. For an example of the OASIS form,

Go to Student Resources, Chapter 18, **Tables, Boxes, Figures: ESG Figure 18-3, Outcome and Assessment Information Set (OASIS),** on Davis*Plus*.

It is also important to assess the needs of the caregivers—the family members, friends, and support system in the home. To be successful in home care, you must work *with* the caregivers. Take time at each visit to speak with them, making sure to include them in your assessment, plan of care, and teaching. Assessment of the caregivers often allows you to determine what services are needed in the home. Caregivers may have health problems of their own that affect their ability to provide care for another. This is common among older couples.

ANALYSIS/NURSING DIAGNOSIS

As in any setting, the nursing diagnoses are based on the client's responses to illness and care. As a home healthcare nurse, you will work with clients with numerous medical and nursing diagnoses. Two frequently used nursing diagnoses, Caregiver Role Strain and Deficient Knowledge, are discussed below. Safety and Risk for Infection, also key concerns in the home, are thoroughly discussed in Chapters 24 and 23, respectively. Infection control measures in the home are also presented in a following section, Infection Control in the Home.

Caregiver Role Strain Providing care to a loved one at home can be a challenge, especially when finances don't allow a family to hire home health aides. Around-the-clock caregiving duties can lead to physical exhaustion, social isolation, resentment, sadness, or depression. In addition, family members themselves may become seriously ill and no longer be able to function as caregiver. These role changes may be difficult for both the ill person and the caregiver. For example, imagine that your mother suddenly became very ill and you became her primary caregiver. This would be a reversal of the roles you both are used to, and it would be emotionally taxing, especially if you are already exhausted and isolated from your friends and other support. In addition, a primary caregiver may worry that caring for the client interferes with other responsibilities (e.g., as a parent, spouse, friend, student, worker).

Given these factors, it is not surprising that the two nursing diagnoses most commonly applicable to loved ones providing care at home are Caregiver Role Strain and Risk for Caregiver Role Strain. These diagnoses identify those for whom the burden of delivering care has become—or is at risk of becoming—overwhelming. Common signs of caregiver role strain include difficulty adjusting to role changes, fatigue, isolation, depression, and difficulty in performing routine care for the client.

Deficient Knowledge Client and family teaching is especially important in home care because most of the caregiving is performed by the client and significant others. You will spend much of your time teaching them the skills necessary for self-care (e.g., how to administer insulin, how to manage the oxygen equipment). Recall that to be eligible for home nursing care, clients must require skilled nursing care. Client education is a service for which Medicare and other insurers will reimburse. You must be certain to include a Deficient Knowledge diagnosis on the care plan to ensure the client's continued eligibility and reimbursement for the service.

Key Point: ***In other chapters we caution against indiscriminate use of the Deficient Knowledge diagnosis. However, an exception must be made for home care because of Medicare regulations.***

KnowledgeCheck 43-9

- Why are the first few minutes of the initial visit so important?
- Identify five things that should be assessed at an initial home visit.

ThinkLike a Nurse 43-8

- Based on the information in the scenario, what nursing diagnoses might Mr. Escobar (Meet Your Patients) have? There may not be enough data to make definite diagnoses, but what probable diagnoses are there for which you would want to gather confirming data? Do not include potential diagnoses, such as Risk for Imbalanced Nutrition.
- Mr. Escobar has a potential problem, Risk for Falls. What are two interventions you would probably be able to do today to reduce his falls risk?
- What, if any, evidence of caregiver strain does Mrs. Escobar exhibit?

Standardized Terminology for Home Health Nursing Diagnoses

Recall from the nursing process chapters that various disciplines, including nursing, have developed classifications of standardized terminology (also called taxonomies, vocabularies, and standardized languages) for describing their work and for planning and documenting care. You are familiar with the NANDA-I taxonomy of nursing diagnoses; however, home-care nurses more commonly use the Clinical Care Classification (CCC) because it is closely related to the OASIS reporting forms required by Medicare. If you need to review the concept of standardized nursing language, see Chapters 4, 5, and 6.

The CCC also contains 176 diagnostic concepts—60 major categories and/or 116 subcategories—that describe nursing diagnoses and patient problems (Saba, 2012). Approximately 50 labels are also NANDA-I diagnostic categories that are especially applicable to home healthcare. Common CCC nursing diagnoses used in the home include:

Activities of Daily Living (ADLs) Alteration
Caregiver Role Strain
Family Processes Alteration
Home Maintenance Alteration
Knowledge Deficit
Physical Mobility Impairment
Self-Care Deficit

The CCC system consists of 21 care components to classify diagnoses and interventions. An accompanying coding structure and framework parallel the steps of the nursing process and link the CCC diagnoses to interventions and outcomes. To see the CCC Care Components and an example of a CCC nursing diagnosis with interventions, respectively,

Go to **Standardized Language, Clinical Care Classification System for Home Healthcare,** and **An Example of a CCC Nursing Diagnosis and Interventions,** in Volume 2.

For complete information on the CCC and complete lists of diagnoses, outcomes, and interventions,

Go to the **Clinical Care Classification Web site,** at http://www.sabacare.com

PLANNING OUTCOMES/EVALUATION

Each Nursing Diagnosis requires an Expected Outcome, which is the anticipated goal of the nursing actions planned to care for the patient's condition (Saba, 2012). To formulate a goal/outcome in the CCC system, attach one of the three CCC "modifiers" (*improve, stabilize, deteriorate*) to the diagnosis. The outcome describes the *desired* client health status. To evaluate client progress, you again use one of the three modifiers to describe the client's *actual* health status. The following is an example:

CCC nursing diagnosis:	Knowledge Deficit
Goal/expected outcome:	Knowledge Deficit, Improve
Actual status on evaluation:	Knowledge Deficit, Stabilized

Medicare requires that the client's status be evaluated and coded as improved, stabilized, or deteriorated, the same as the CCC system. In your nursing notes, you would include additional narrative to support your evaluation.

The Nursing Outcomes Classification (NOC) can also be used in home health nursing (Moorhead, Johnson, Maas, et al., 2013). A few of the outcomes that pertain to home and families are Caregiver Home Care Readiness, Caregiver Performance: Direct Care, Caregiver Stressors, Family Coping, and Family Functioning.

To prepare the client and family for self-care, inform them of the needs you have identified, and involve them in setting goals and planning care. They may be able to identify strategies to solve problems or to help you identify needs that are not readily apparent.

PLANNING INTERVENTIONS/IMPLEMENTATION

Medicare requires that the physician-prescribed plan of care include the following, as applicable:

- Parameters for notifying the primary provider of changes in vital signs and other clinical findings
- Diabetic foot care, including education
- Falls prevention interventions
- Depression interventions
- Interventions to monitor and treat pain
- Interventions to prevent pressure ulcers
- Pressure ulcer treatments

Once the plan of care has been agreed on, you will document it and forward it to the client's physician for certification. At the first visit, you will determine the specific skilled care required and make referrals to other required services such as physical, occupational, or speech therapy, social services, nutritional support, or home health aide services.

Standardized Nursing Interventions

The CCC system is commonly used in planning and recording home care, but the NIC taxonomy is also an option.

CCC Nursing Interventions The CCC contains 201 nursing interventions organized according to the care components. For an example,

Go to Chapter 43, **Standardized Language, An Example of CCC Nursing Diagnoses and Interventions,** in Volume 2.

An intervention consists of a label (e.g., Activity Care) and a definition (e.g., Actions performed to carry out physiological or psychological daily activities). In addition to the label, you must specify the type of intervention action from among four qualifiers:

Assess/Monitor/Evaluate/Observe
Care/Perform/Provide/Assist
Teach/Educate/Instruct/Supervise
Manage/Refer/Contact/Notify

The CCC nursing interventions include only skilled services because this type of service is the only type of care reimbursed by Medicare and most insurers in home health. In the Meet Your Patients scenario, Mrs. Escobar is clearly experiencing Caregiver Strain. This is a nursing diagnosis under the Care Component of Coping. Several interventions are possible:

Coping Support: Actions to sustain a person dealing with responsibilities, problems, or difficulties
Assess for Caregiver Strain.
Provide (perform) emotional support.
Refer to community services: caregiver support groups, Meals on Wheels, and respite care services.

NIC Interventions for Home Health The Nursing Interventions Classification (NIC) may also be used in home health nursing (Bulechek, Butcher, & Dochterman, 2012). A few of the interventions that pertain to home and families are Caregiver Support, Family Integrity Promotion, Home Maintenance Assistance, and Respite Care.

Assisting With Medication Management

One of The Joint Commission 2014 safety goals for home care is to use medications safely. This includes preventing errors with look-alike and sound-alike medications, educating patients about anticoagulant therapy, and keeping a current list and reconciling medications when a client transfers from one agency to another. Nurses in the home setting must be careful to avoid error when recording and communicating information about patients' medications. The Joint Commission also advises nurses to diligently compare those medications the patient is already taking with new ones to be given in the home. Make sure your patients know about medications they take at home and that they should bring a complete and updated list every time they visit a healthcare provider.

Some patients, particularly older adults, have visual and motor deficits that limit their ability to read labels and manipulate bottle caps, syringes, and so on. Other reasons for noncompliance include lack of outward symptoms, inability to tolerate side effects, pain, forgetfulness, low motivation, and impaired mental capacity. Always investigate the patient's reasons for nonadherence so that you can take appropriate actions.

You may need to teach clients and caregivers skills, such as measuring dosages, giving injections, and managing intravenous therapy. Or they may need tips on how to help clients with difficulty swallowing take oral medications. For example, for some clients, pills may be crushed and mixed in a small amount of applesauce or pudding.

Involve family members in the care of the older adult as needed, including giving medication. Older adults and caregivers may have difficulty remembering when to take their pills, which ones to take, and even whether they have already taken them. Suggest they use a medication organizer with a compartment for each day of the week. You may need to prepare a week's worth of oral medications for them during your visits. To help them remember which drug is used for each of their illnesses or symptoms, write the medical condition, names of medication, and doses, and how and when to take the medication on a large card. Then use clear tape to attach a sample of each drug next to its name on the card.

Because improperly disposed medication may end up in the water supply, it is important to inform clients about how to safely dispose of medications in the home. Teach them to return unwanted or expired prescription and over-the-counter drugs to a drug take-back program. Some counties offer household hazardous waste collection sites where drugs are accepted. Expired or unused prescription and over-the-counter drugs should never be flushed down the toilet or poured into a drain unless the label or accompanying patient information specifies that it is safe to do so (Environmental Protection Agency, 2011).

For more information about ways to properly discard medication,

Go to Chapter 24, **Home Care: Preventing Poisoning in the Home**

Controlling Infection in the Home

The Joint Commission (2014) safety goals for home care include reducing the risk of healthcare-associated infections. In the hospital, you have ready access to supplies that facilitate infection control. The home presents unique challenges.

Hand hygiene is one of the most important home interventions to prevent the transmission of infection. You will need to follow Standard Precautions but recognize how to modify infection control techniques for the home environment. For suggestions to help you maintain infection control during a home visit,

Go to **Clinical Insight 43-2, Infection Control in the Home,** in Volume 2.

Homes and conditions vary widely. Do not assume that a client lives in clean surroundings or that running water and electricity are readily available. Some people with limited financial resources, especially in urban environments, live in single-room occupancy hotels (SROs). Residents of SROs live in a small room with shared bath and shower areas. To provide optimal care, you need to bring infection control supplies and personal protective equipment to the visit or order them to be delivered to the home.

Barrier Precautions

The reason you implement barrier precautions in the home setting differs from use in hospital practice. As a rule, you will use gowns, gloves, and masks in home care to protect yourself, rather than the patient. You will need to use standard precautions, but will usually need a mask only when caring for clients who have pulmonary tuberculosis, airborne pathogens, or multidrug-resistant infections. Such organisms may be transmitted to other home-care patients through inanimate objects or hands, so use appropriate barrier precautions (Lescure, Locher, Eveillard, et al., 2009). See Chapter 23 if you need to review infection control.

Clean and Sterile Technique

Infection control in home care is different in many ways from that in acute care. In acute care, the patient is exposed to invasive interventions and environmental risks, including other patients and contaminated inanimate objects. Generally, patients have developed some resistance to the microorganisms in their own homes and are less likely to acquire infections there than in the hospital environment. You may find differences in how you handle home infusion therapy, urinary tract care, respiratory care, wound care, and enteral therapy. It is safe, in many instances, to replace sterile with clean technique, as in some of the following examples:

- **Intravenous therapy.** Sterile practices should be the same at home as in the hospital because the associated risk of sepsis is so high.
- **Insulin injections.** Many people (e.g., those who have diabetes) must give themselves repeated injections, perhaps several each day. Supplies for home use are expensive. Insurance may or may not cover the cost, or the person may not have insurance. Therefore, manufacturers recommend that disposable syringes and needles be used only once and discarded in a puncture-proof container, and it is safest to do that. Nevertheless, some people find it practical to reuse needles and syringes. For guidelines for teaching patients about this,

Go to **Clinical Insight 26-1, Reusing Needles and Syringes: Home Care,** in Volume 2.

- **Urinary catheters.** Clients and family typically use clean, rather than sterile, gloves to perform catheterization. In the home, clients frequently interrupt the drainage system to empty a leg bag, or to change or disinfect the drainage bag. They may also disinfect and reuse urinary catheters.
- **Respiratory care.** As an example, tracheostomy care in the home is nearly always performed using clean, not sterile, technique.
- **Wound care.** Procedures for wound care should be based on the potential for contamination and infection. Usually clean technique is adequate. For example, a surgical site that is primarily closed and has no drains should be low risk for home-care-acquired infection. However, if the incision has drains or is open, the risk for infection increases, and your wound-care procedures must address the risk. Also, you do not need to arbitrarily "always" discard irrigation fluids at set intervals (e.g., every 24 hours). Order for them, or guide caregivers to buy, small containers (e.g., no more than 500 mL) that can be used up in two or three visits. Teach them how to avoid contaminating the fluids (e.g., how to handle the cap, always recap the bottle, and store the bottle away from children and pets).
- **Enteral therapy.** Emphasize the need to refrigerate the feedings after opening and store solutions until expiration. Teach caregivers to keep the kitchen appliances (e.g., blenders) and tools used in preparation meticulously clean. Sterilization of blender parts, measuring cups, and spoons is probably not necessary, but they should be washed in a hot water dishwasher after use.

KnowledgeCheck 43-10

Identify three infection control supplies that you should bring in your nursing bag on a home health visit.

Promoting Home Safety

The following two The Joint Commission 2014 home-care safety goals are important to keep in mind.

- ***Reduce the risk of client harm resulting from falls.*** Assess the client and the home for risk factors (e.g., dimly lit stairs, clutter on the floors) and teach caregivers falls reduction measures. Educate the patient concerning the potential for their medications to make them feel weak, dizzy, or sleepy. You will find extensive discussion of falls prevention in Chapter 24 if you need more information about that.
- ***Identify risks associated with oxygen therapy*** *(e.g., fire)*. Be certain the home has working smoke detectors, fire extinguishers, and a fire safety plan. Assess the client and family's ability to understand and comply with fire prevention activities, and report any concerns to the physician.

If you need a checklist to use in assessing for safety hazards in the home,

Go to Chapter 24, **Tables, Boxes, and Figures: ESG Figure 24-2, Home Safety Checklist,** on Davis*Plus*.

Supporting Caregivers

Even when the client is receiving in-home care from an agency, it is not usually around-the-clock care. If the client cannot perform self-care, most of the duties fall to family members. One study found that even with short-term formal services, family caregivers provided three-fourths of the care of homebound patients. Half of the caregivers said they were not adequately prepared when it was time for their home health services to be discontinued. And at all stages, they expressed significant isolation, anxiety, and depression (Levine, Albert, Hokenstad, et al., 2006).

Unrelieved caregiving duties are physically and emotionally taxing. Caregivers may become depressed, physically exhausted, isolated from friends, and neglectful of their own health. If the primary caregiver becomes unable to function, the client must be institutionalized. Clearly, it is important to provide caregiver support.

There is some evidence to indicate that caregiver support and training workshops can relieve depression, reduce the perceived burden of caregiving, and better prepare the caregivers for their role. However, the most improvement in adaptation to the caregiver role was shown by those with more independent lives and social support (Huynh-Hohnbaum, Villa, Aranda, et al., 2008). See Box 43-3 for suggestions to help caregivers.

BOX 43-3 ■ Ways to Help Caregivers

Provide a listening ear. Encourage caregivers to talk about what they do and how they feel, and listen actively to their concerns. Find time to focus on the caregiver's needs, rather than on those of the care recipient.

Give positive feedback and validate their importance to the client's health.

Help the caregiver identify people who may be able to help, for example, family members living outside the home, neighbors, church members, community support groups.

Talk with family and friends, if the caregiver wishes. Teach them how to support the caregiver, for example, by telephoning regularly, visiting, sending cards, or staying with the client a few hours (or days) so the caregiver can rest or take a vacation. Encourage them to listen to the caregiver without giving advice, and to help her feel appreciated (e.g., "I really appreciate all you do for Dad.")

Arrange for a home health aide, if possible. This relieves the caregiver of housekeeping and grocery shopping.

Remind family members and significant others to take care of themselves. Explain that their health is important to both them and the patient. Even the most devoted and self-sacrificing person may understand when you explain, "You must take care of yourself so that you are able to take care of your loved one."

- Stress the need for the person to eat nutritious meals. Arrange for meals to be delivered to the home, if needed.
- Encourage the caregiver to rest as much as possible, perhaps while the home health aide is there; or ask family members and acquaintances to take turns staying an hour or two with the patient while the caregiver rests or "gets away." Help contact those offering respite care and make a schedule, if needed.
- Stress the need for the caregivers to take some time for themselves, even if it is just an hour alone, or coffee with a neighbor.
- Encourage caregivers to take a vacation, if they can afford it, even if the getaway is close to home or for a short time. Reassure them that competent help can be obtained and that it is okay to delegate caregiving to others for a while.
- Some agencies have a weekend respite program for caregivers. The client is admitted to a skilled care unit for 2 or 3 days so the caregiver can have a break.

Encourage the caregiver to maintain spiritual connections, for example, to take time to go to church; or ask the spiritual adviser to visit the home.

Communicate medical updates about the client—lab results, new treatment plans, and so on.

Help the family understand the goals of care and solve problems when needed.

Teach the family what to expect with regard to medications, treatments, and signs of approaching death. If family members know what is normal, they will be less likely to panic or fear the inevitable.

Follow up with other healthcare team members promptly if the family has questions that are outside your scope of practice.

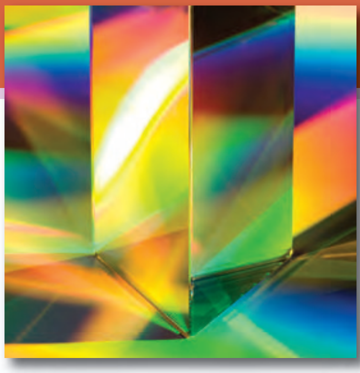
CHAPTER 44



Ethics & Values

Learning Outcomes

After completing this chapter, you should be able to:

- Define *morals*, *ethics*, *bioethics*, and *nursing ethics*.
- Discuss what is meant by *ethical agency*.
- Identify at least four factors that contribute to the frequency of nurses' moral problems.
- Differentiate personal values and morality from professional values.
- Explain how developmental stages, values, moral frameworks, professional guidelines, and moral principles affect moral decisions.
- Describe five major ethical principles that are used in reasoning about healthcare.
- Compare and contrast four ethical frameworks: consequentialism (e.g., utilitarianism), deontology, an ethics of care, and feminist ethics.
- Identify the ethical issues and principles involved in a given ethical situation.
- Describe a systematic approach for resolving ethical dilemmas.
- Discuss the concept of an integrity-producing compromise.
- Describe the nurse's obligations in ethical decisions.
- Discuss the role of the nurse as client advocate in the delivery of ethical nursing care.
- Apply the steps identified in the MORAL model to make ethical decisions in patient care.

Whistleblowing

Meet Your Patients

Angie and Edward Frese are a couple with two teenage children. They are a close and loving family with a large network of family and friends. Alan, 15 years old, has just been severely injured in a high school soccer game. At the hospital, Angie and Edward are told that Alan has multiple bone fractures and active internal bleeding.

The surgeon informs the distressed parents that Alan will need a blood transfusion to survive. Although genuinely devastated, the parents adamantly refuse to consent to a lifesaving blood transfusion, stating they are Jehovah's Witnesses and that receiving blood is against their religious beliefs. The surgeon asks you, Alan's nurse, to get the parents to change their minds right away. You talk with the couple, but they continue to refuse a blood transfusion. You immediately contact your charge nurse. Try to answer the following critical-thinking questions about Alan and his parents. You may not have the experience or theoretical knowledge to answer them all—you will acquire that in this and the following chapter—but do your best based on the background you have.

ThinkLike a Nurse 44-1

- Do Alan's parents have the right to refuse a blood transfusion based on their religious beliefs?
- Do you think the fact that Alan is a minor (age less than 18 years) may make a difference in this situation?
- What actions do you think the charge nurse should take?
- Can an ethical conflict such as this be resolved to everyone's satisfaction?

TheoreticalKnowledge knowing why

The theoretical knowledge you will need to begin professional practice includes an understanding of the nature of morals and ethics (and especially nursing ethics) and basic information about factors that affect moral decisions (i.e., values, moral frameworks, professional guidelines, and ethical principles).

ABOUT THE KEY CONCEPTS

Nursing ethics, **morals**, and **values** are key concepts in this chapter because everything in the chapter is related to those concepts in some way—as you will discover. The subconcepts of *advocacy* and *compromise*, for example, are intimately integrated in the implementation of nursing ethics in clinical practice. Remember to use the key concepts to help you organize chapter content in your mind. As you read, try to understand how each subconcept you encounter relates to nursing ethics, morals, and values.

ETHICS AND MORALS

To understand ethics, we must first understand the broader meaning of ethics. Although the terms *ethics* and *morals* have similar meanings, in modern theory **morals** refers to private, personal, or group standards that consider in a broad, general manner what is good or bad, right or wrong (e.g., "In general, it is wrong to steal"). Ethics answers the question "What should I do in a given situation?" (e.g., "Is it wrong to steal if you have to do it to feed your children?").

Morals are learned from external influences and communicated through various systems (e.g., religious, political, educational, societal). **Moral behavior** is that which is consistent with customs or traditions based on the external influence (such as religious beliefs). A person whose behavior is inconsistent with traditional notions of right and wrong is labeled as immoral. Consider the conversation between two nurses discussing a teenager who assaulted and robbed a wheelchair-bound 92-year-old woman.

Nurse A: "I cannot believe someone would be so heartless as to attack an innocent, helpless elderly woman."

Nurse B: "I agree—that person is immoral. Absolutely no morals."

You may agree with this, because you have been taught to respect and protect older adults. Morals are linked to a person's character and often determine how we treat others. Another example is the "Golden Rule," which states that you should treat others as you wish to be treated.

Can you think of another example of moral behavior that you may have learned as a child?

Can you identify any morals that are evident in the scenario about Alan at the beginning of the chapter?

How do his parents' morals influence Alan's care?

Ethics, in contrast, is the study of a system of moral principles and standards, or the process of using them to decide your conduct and actions. Ethics helps us to decide what is right or wrong and what actions should be taken in certain circumstances. While a nurse's moral code would find the act of driving under the influence thoughtless and reprehensible, his ethics as a nurse would require him to provide care to the driver for the injuries received in the motor vehicle accident. In the case of Alan and his family (Meet Your Patients), the ethical decision making is quite different from the moral perspective of Alan's parents. The parents believe a blood transfusion is morally wrong; this fits with their religious beliefs. The surgeon and the nurse, however, believe withholding blood from Alan would be unethical.

Ethics and Law How are laws related to ethics and morals? In some situations, there is a fine line between law and ethics. Think about the following:

- *Law:* It is illegal to drive faster than the speed limit.
  Situation: A child is bleeding profusely and may have cut an artery. The driver drives very fast and even drives through a red light.
  Question: Was that illegal? Was it immoral?
- *Law:* In the United States, it is legal in certain situations to have an abortion.
  Fact: Although everyone would have to agree that the act is legal, people are about evenly divided about whether they believe it is moral.

The adage "Courts are ill equipped to deal with ethical issues" reflects the difficulty of trying to decide a case on a continuum of right and wrong (ethics) versus applying strict legal principles (law). Although ethics is rooted in the religious, political, customs, and other values of a society, you should be able to see now that ethics is not the same as law, religion, institutional practices, or customs. An action that is legal or customary may not be morally right or ethically justifiable. The same holds true of religion. You cannot assume that an accepted practice of a certain religion is an ethical practice in every situation.

What Is Nursing Ethics?

Bioethics refers to the application of ethical principles to healthcare. Bioethics is concerned with every area of healthcare, including direct care of patients, allocation of resources, utilization of staff, and medical and nursing research. **Nursing ethics** is a subset of bioethics. It refers to ethical questions that arise out of nursing practice. The first things to come to your mind may be the dramatic questions such as, "Should we turn off the ventilator and allow this patient to die? Should this baby have surgery even though his quality of life will probably never be good?" "Is abortion moral?" In reality, you may have some input, but the patient, physician, and family will make the final decision in such situations. As a nurse, you are responsible for deciding the nature and extent of your own participation in each situation, and you must support patients who are making ethical decisions or perhaps coping with the results of decisions made by others. Consider the following true story paraphrased from Curtin and Flaherty (1982, pp. 3–4):

> *A woman took her 6-year-old son to the emergency department (ED) to have a scalp laceration sutured. She tried to calm him by telling him that the doctors would "numb" him and no one would hurt him "on purpose." On arrival, they were placed in a cubicle next to another little boy who was awaiting treatment for a similar laceration. His father was also trying to reassure his son.*
>
> *In the cubicle of the father and son, a nurse roughly cleansed the cut with no explanation or words of comfort. The physician came and sewed the laceration without a word and without waiting for the local anesthetic to take effect. The boy screamed in pain and terror the whole time. The woman was horrified, and her son was scared. But when the same nurse approached the woman and her son, she was kind and gentle. The same physician carefully injected a local anesthetic and waited for it to take effect before suturing.*

Can you think of reasons for the stark differences in the treatment? Was it because the man and boy appeared to be of lower socioeconomic status? Was it the presence of a father rather than a mother? Was it because the father and son were from a minority group and the woman and son were not? It may have been all of these reasons or none of them. Regardless of why it happened, what makes this case important? After all, both boys received medical treatment; both incisions will heal; no one's life or health was threatened; no life-and-death decisions were made. But notice that the first child's humanity and dignity were violated, and the actions were not fair.

Key Point: ***This case is a perfect example of nursing ethics: questions that have to do with the nurse's actions, not the actions of others. The nurse did not need a medical prescription or permission from hospital administration to act ethically.***

In the Meet Your Patients scenario, you, as the nurse, are not responsible for deciding the broad questions: "Is blood transfusion right or wrong?" "Do the parents have a right to refuse blood transfusion?" *Your* decision is "What should *I* do? Should I try to persuade the parents to change their minds, as the surgeon directs, or not?" That is the *nursing ethics* question. And in that scenario, you will need to deal with the effects of the final decision on Alan. He may be frightened; he may be angry; he may die. The nurse is there for patients' most human and vulnerable moments.

Why Should Nurses Study Ethics?

Nurses should study ethics for a variety of reasons. This section will help you understand those reasons.

- ***You will encounter ethical problems frequently in your work.*** A consciously made, informed decision must surely be better than one made without awareness of the ethical issues involved. The most difficult questions you will face as a nurse will not be "How do I do this?" but "Should I do this?"
- ***Ethics is central to nursing.*** Commitment to caring for other human beings supports the claim that nursing is a moral art (Butts & Rich, 2012). Caring for the sick, promoting health, and practicing with care and compassion are central values in nursing.
- ***Multidisciplinary input is important.*** No one profession is responsible for an ethical decision. As situations become more complex, multidisciplinary input becomes increasingly important. For example, surgeons are responsible for knowing what surgery to perform and obtaining consent, but the nurse has a part in being sure the patient is adequately informed so that true consent is obtained.
- ***Ethical knowledge is necessary for professional competence.*** Being a professional includes being accountable to others in the profession for the ethical conduct of your work. Using professional expertise for social good is one hallmark of a profession. Therefore, to conduct our work well and have it stand the test of public scrutiny, we need to be clear about the ethics of our work.
- ***Ethical reasoning is necessary for nursing credibility among other disciplines.*** For your opinion to be valued by others, you must be able to clearly express your moral position in a logical way. To be a truly accountable practitioner, you must be able to (1) understand your own values as they relate to basic morality and (2) use ethical reasoning to articulate your moral position.
- ***Ethical proficiency is essential for providing holistic care.*** Nurses deal with the whole person—that includes providing support for spiritual and moral concerns.
- ***Nurses have a responsibility to be advocates for patients.*** **Advocacy** is the communication and defense of the rights and interests of another. Since the 1960s, schools have socialized nurses to include patient advocacy in their role conceptions. Currently, the American Nurses Association (ANA) Code of Ethics for Nurses

(2001), provision 3, states: "The nurse promotes, advocates for and strives to protect the health, safety and rights of the patient."

Advocacy includes protecting patients' legal or moral rights (e.g., taking appropriate action when the actions of a healthcare team member jeopardize the patient's rights or best interests). However, you can advocate for patients in everyday practice, for example, by contacting a primary provider to request a new prescription when a pain medication is not effective. To advocate for patients in ethical situations, you must be able to identify the ethical issues, know your resources, and communicate the patient's wishes.

- ***Studying ethics will help you to make better decisions.*** The study of ethics prepares you to analyze moral problems from multiple perspectives rather than relying entirely on your personal values, intuition, and emotions. Practice in analyzing ethical dilemmas will help you to become an informed decision maker, capable of understanding the perspectives of all the people in each situation—to understand, for example, why the Freses (Meet Your Patients) are refusing a blood transfusion.

Most nursing problems have more than one acceptable answer. This is especially true of ethical problems. Each situation is unique in its details—for example, the people are different in how they evaluate what is and is not beneficial for themselves. By thinking it through critically from several different perspectives, you will be assured that you have done all that you can to provide your client with the highest quality of ethical care.

KnowledgeCheck 44-1

- Define *morals*, and give an example that is not in the text.
- Define *ethics*, and give an example that is not in the text.
- How is bioethics different from ethics?
- Why do nurses need to study ethics?

What Is Ethical Agency?

Moral agency or **ethical agency** for nurses is the ability to base their practice on professional standards of ethical conduct and to participate in ethical decision making. Simply stated, it means that nurses have choices and are responsible for their actions. An ethical agent must be able to:

- Perceive the difference between right and wrong.
- Understand abstract moral principles.
- Reason and apply moral principles to make decisions, weigh alternatives, and plan sound ways to achieve goals.
- Decide and choose freely.
- Act according to choice (this assumes both the power and the capability to act).

For a more expanded discussion of ethical agency,

Go to Chapter 44, **Supplemental Materials: Elements of Ethical Agency,** on Davis*Plus*.

ThinkLike a Nurse 44-2

Consider the five components of ethical agency. To what extent do you believe nurses possess those abilities? Explain your thinking.

Example Problem: Moral Distress

In practice, nurses may find themselves in situations in which they feel morally responsible and have identified an ethically acceptable course of action, but are unable to implement their moral decisions. A seminal study by Wilkinson (1987/1988) identified this as **moral distress**. Situational pressures (constraints) influence nurses' moral decisions as well as their ability to carry out their decisions. These constraints can be internal (e.g., relationships with physicians, power of nurse administrators, support from other nurses, perception or impact on the patient and family members, or threat of lawsuits) or external (e.g., being socialized to follow orders or policies, doubting their own knowledge, lack of courage, concern of other's opinions, or hope for miracles). Whether these constraints are real or merely perceived, nurses in various studies have named these factors as obstacles to carrying out their moral decisions (Burston & Tuckett, 2012; Jameton, 1984; Varcoe, Pauly, Storch, et al., 2012; Villers & DeVon, 2012; Wiegand & Funk, 2012).

The fact is that even if you make a logical, carefully considered moral decision, you may not be able to do what you believe to be right. This problem is not unique to nurses, and recent studies describe moral distress among other healthcare professionals (e.g., Allen, Judkins-Cohn, deValasco, et al., 2013; Milton, Peacock, Storch, et al., 2010). No one is 100% "free" to choose and act. Actions always have consequences: for you and for others. Nevertheless, if you are confident you have made a good decision and can express it logically and clearly to others, you can at least enter into a conversation with nurse administrators, physicians, and families about what ought to be done.

You should clearly identify the source of your moral distress and initiate actions based on reasoned choices and not emotions. In addition to discussing your concerns with those who can address the issues or provide solutions, you should develop a network of supportive colleagues. Because many sources of moral distress are not limited to nursing, you should involve members from other disciplines to can speak on work environmental issues (Epstein & Delgado, 2010). These approaches should give you a sense of comfort knowing that you have done all you could do, even if it is not all you wished to do.

If you would like an optional, expanded discussion of moral distress,

Go to Chapter 44, **Supplemental Materials: Moral Distress,** on Davis*Plus*.

Example Problem: Whistleblowing

Nurses experience **moral outrage** when they perceive that others are behaving immorally (Wilkinson, 1987/1988).

FIGURE 44-1 Ethical problems can create moral distress.

Moral outrage is similar to moral distress, except that in cases of moral outrage, nurses do not participate in the act. Therefore, they do not believe that they are responsible for doing wrong, but that they are powerless to prevent it (Burkhardt & Nathaniel, 2014; O'Mara, Jackson, Batson, et al., 2011). A nurse may respond to moral outrage by "blowing the whistle."

A **whistleblower** is person who reveals information about the practices of others that he reasonably believes is corruption; mismanagement; fraud; abuse; illegal; or harmful to the health, safety, and welfare of the general public. The "others" in question may be an individual or an entire organization. When the wrongdoing involves an organization, the whistleblower must hold the situation up to public scrutiny, for example, by going to the news media or pursuing legal recourse.

At some point in your nursing career, you may become aware that a team member is doing something illegal, unethical, or incompetent. It is difficult to know what to do. You will need to consider the nature of the action, the likelihood of immediate harm, and the accuracy and completeness of your data. If it involves an immediate threat to the health, safety, and well-being of others, you should report it immediately. In other situations, you should follow **THINK**:

Talk with an attorney or other legal representative.
Have concrete and credible evidence of the violation or wrongdoing.
Institute a survival plan, if your job is put in jeopardy or you are fired.
Note the nature and consequences of the problem—its type, severity, and potential impact. Weigh the risks against the benefits.
Know your reporting options and support systems. The systems involve that can correct the problems.

Impaired Nursing Practice Whistleblowing is difficult in the case of an impaired colleague. **Impaired nursing practice** occurs when the nurse's ability to perform the essential functions of nursing is diminished by chemical dependence on drugs or alcohol or by mental illness. Impairment is a threat to patients, and the impaired nurse may have difficulty being accountable to herself or in assessing her self-competence. The Code of Ethics for Nurses guides that as a compassionate colleague, you must ensure that an impaired nurse receives assistance in regaining optimal function by reporting the behaviors to the appropriate entity within the employment setting (ANA, 2001)

Toward Evidence-Based Practice

Attree, M. (2007). Factors influencing nurses' decisions to raise concerns about care quality. *Journal of Nursing Management, 15*(4), 392–402.

Professional ethics require nurses to raise concerns about standards of practice; however, underreporting is the norm. This qualitative study analyzed data from interviews with 142 nurses and found that nurses perceived reporting concerns to be a high-risk, low-benefit action. They lacked confidence in reporting systems. Nurses named fear of repercussions, retribution, labeling, and blame as reasons for not raising concerns, as well as the belief that nothing would be done about the concerns.

Peters, K., Luck, L., Hutchinson, M., et al. (2011). The emotional sequelae of whistleblowing: Findings from a qualitative study. *Journal of Clinical Nursing, 20* (19/20), 2907–2014.

Fourteen nurses who were either whistleblowers or the subject of a whistleblowing episode identify persistent, severe emotional distress after the incident due to a lack of social support and an unwelcoming work environment. Three major themes emerged from their interviews: (1) feelings of overwhelming distress, sadness, and depression; (2) physical symptoms associated with anxiety, insomnia, and hypervigilance; and (3) constant thoughts about the situation, resulting in nightmares and constant stress. While moral distress may cause nurses to become whistleblowers, the act itself can create long lasting emotional distress.

1. What type of moral situation (for the nurse) is best illustrated by the Peters study: moral distress or whistleblowing? Explain your reasoning.

2. How does the Peters study impact your thoughts of becoming a whistleblower?

KnowledgeCheck 44-2

- Define *ethical agency*.
- What five abilities must be present for ethical agency to exist?
- List at least three constraints that can keep nurses from carrying out their moral decisions.

What Are Some Sources of Ethical Problems for Nurses?

Several factors contribute to the frequency of nurses' ethical problems, including societal factors, the nature of nursing work, and the nature of the nursing profession itself.

Societal Factors

This section discusses how some ethical problems for nurses are created by the ever-changing nature of our dynamic, multicultural society.

Increased Consumer Awareness Historically, the healthcare system operated in a paternalistic manner. Sick people sought and followed the advice of a physician without question. Now, the Internet has increased consumer awareness and availability of information online, and consumers are more actively involved in healthcare decisions. Providers are now expected to share knowledge with patients, defend treatment choices different from those found on the Internet, and obtain truly informed consent for treatments.

Technological Advances New technology brings new ethical issues. For example, in vitro fertilization and embryo transfer methods raise questions about the disposal of embryos that are not implanted into a uterus: Who owns them? If implanted, child support issues may arise. Other ethical questions surround the topics of late-term abortions when amniocentesis reveals fetal defects, genetic engineering, human embryonic stem cell research, costs versus quality of life for ventilator-dependent patients, and security of electronic healthcare records (EHRs).

Multicultural Population We live in a multicultural, multifaith society. You cannot assume that your values and beliefs are similar to those of your patient, other providers, and your colleagues. You will need to respect a variety of belief systems, and serve as a patient advocate even when the patient's value system is strikingly different from your own. There are nursing theories that can help you recognize various cultural values, for example, Leininger's (2002) theory of Cultural Care Diversity and Universality (for a review, see Chapters 8 and 15).

Cost Containment The emphasis on reducing healthcare costs creates many morally questionable situations. For example, patients are being sent home from the hospital while they still require considerable nursing care. On being discharged, they may discover that insurance payments are limited for services outside the hospital, including specialists, home care, and medical supplies (e.g., bandages, walkers). Cost containment efforts have led healthcare agencies to increase the number of patients each nurse is assigned. You will undoubtedly find yourself in situations in which fewer nurses are available than patient acuity requires. You will have to make personal decisions about how far you will stretch your own resources to maintain patient safety.

The Nature of Nursing Work

Ethical problems exist in all kinds of work. However, the nature of nursing work itself can create unique ethical problems.

Nurses' Moral Problems

Nurses' moral problems are immediate, serious, and frequent. In the classroom, you have the luxury to leave questions unsettled. In the real world, you must always decide: Either you take action or you do not. For a nurse, deciding *not* to act is, in effect, an act. For example, suppose the family wishes a patient to have aggressive resuscitation efforts (code). However, you know the patient does not wish to be "coded." When the patient's heart stops, whether or not you know the "right" thing to do, you must decide immediately to carry out or not carry out the code. If you wait too long to ponder the ethical issues, the patient may die before you decide. If you do not decide, the effect is the same as though you had decided it was wrong to code.

Nurses' Unique Position in Healthcare Organizations

Nurses have multiple obligations and relationships, and sometimes conflicting loyalties. They are employees (with a relationship with the agency) as well as professionals (with a special relationship with patients). In addition, they have peer relationships and a unique relationship with providers. Although nurses are usually not employed by a physician, they are expected to follow physician prescriptions for patient care. In addition, in most organizations, providers are higher on the power and status hierarchy than are nurses. Ethical questions arise when nurses experience conflicts among their loyalties to patients, families, physicians, employers, and other nurses. Consider the following example: A patient wants to know his test results; but the provider is reluctant to tell him. What are the conflicting loyalties? Should the nurse give the patient the information or not? There are two options:

Tell. By providing the test results, the nurse would honor the principle of personal autonomy and her obligation to the patient. But this might harm the patient's relationship with the provider, which is important to the patient's well-being. Furthermore, if the nurse tells the patient his test results, it may create problems between the provider and the employer (e.g., the hospital). In addition, this action may in some instances violate hospital policies, and, therefore, harm the nurse's relationship with the hospital. It will certainly affect her relationship with the provider.

Don't tell. The nurse could preserve the patient–provider relationship by withholding the test results from the patient. This choice does not honor her relationship with the patient. Also, if the nurse does not tell the patient his test results, the patient may find out anyway and be angry with the hospital, the physician, and the nurse.

According to professional ethics, your first allegiance is to the patient. However, the patient's needs often conflict with institutional policies, family desires, or even laws of the state. There may also be conflicts in your relationships with the patient and his family. You can see an example of this in the Meet Your Patients scenario, wherein the nurse finds it impossible to honor the parents' autonomy and at the same time advocate for Alan. You may also encounter this type of conflict when a patient does not want any heroic measures and wishes only to die peacefully, but the family has not yet been able to accept the imminent death and are insisting on full resuscitation.

The Nature of the Nursing Profession

Some ethical problems arise because of value conflicts and a lack of clarity within the nursing profession. We have unresolved questions about the nature, scope, and goals of our practice, as well as our professional values (values are discussed later in the chapter). In most of the following examples, we value both of the opposites. We would not wish to give up either one. But specific situations require us to choose between them, and that is one source of our discomfort.

- ***Caring versus time spent with patients.*** Nursing values caring, humanistic care, and nurse–patient relationships—but nurses now spend less time with the patient than ever before. One reason is understaffing and heavier patient loads, but there are other factors: the use of technology; the need for careful documentation; and the emphasis on leading, managing, and delegating instead of hands-on care.
- ***Autonomy versus escaping hard choices.*** On one hand, we believe nurses should have an equal status with other healthcare professionals—on the other hand, many nurses want to escape hard choices by "letting the provider decide."
- ***Higher pay versus cost-effectiveness.*** Most nurses believe we deserve higher pay—yet, we claim nurses are cost effective because we work less expensively than do physicians and other providers.
- ***Professionalism versus caring.*** On one hand, we claim the nurse is a professional, citing critical thinking, knowledge, and management skills—on the other hand, we emphasize caring, with the nurse at the bedside offering comfort and doing hands-on tasks.

WHAT FACTORS AFFECT MORAL DECISIONS?

By now, you should have an idea of the nature of morals and ethics and of the need to study nursing ethics. We turn our focus now to some basic theoretical knowledge about factors that are involved in making moral decisions: developmental stages, values, moral frameworks, ethical principles, and professional guidelines. As you learn about each of these concepts, consider how it affects moral decision making.

Developmental Stage

A person's stage of moral development affects the way he reasons about moral issues. We learn and internalize our morals throughout the life span, beginning in childhood. Kohlberg's (1968, 1981) research led him to conclude that children go through a sequence of moral reasoning ability, proceeding through several stages. In stage I, they base moral reasoning on avoiding punishment and personal interest; in stage II, principles focus on pleasing others and following rules. In stage III, the final level in adulthood, people base moral principles on universal and impartial principles of justice (see Moral Development Theory: Kohlberg in Chapter 9). If you would like to have an expanded version of that theory and examples of Kohlberg's stages,

Go to Chapter 44, **Tables, Boxes, Figures: ESG Table 44-1, Stages of Moral Development,** on Davis*Plus*.

The stages overlap. Kohlberg found that more than half of a person's thinking always reflects the stage he is in, with the remainder at the stage he is leaving or the stage into which he is moving. Although some people never achieve Kohlberg's highest levels, progression through the stages is always forward—except in extreme trauma, it is never backward—and people do not skip stages.

Gilligan (1993) challenged Kohlberg's perspective of moral development, citing it as male biased. Gilligan found through her research that girls develop morally by paying attention to community and to relationships, whereas boys tend to process dilemmas through more abstract ideals or principles. If you need a review of Gilligan's three stages—caring for oneself, caring for others, and caring for self and others—refer to Chapter 9.

Values, Attitudes, and Beliefs

Your values influence what you think and do. This is important to know because values are entangled in all ethical situations. If asked, could you say what your values are? Could you explain how they affect your decisions about right and wrong in a given situation? If so, that's a great beginning. If not, you will learn more as you move through this section.

What Are Values? A **value** is a belief about the worth of something; it serves as a principle or a standard that influences decision making. Values are ideals, beliefs, customs, modes of conduct, qualities, or goals that are highly prized or preferred by individuals, groups, or society. You can value an idea, a person, a way of doing things, or even an object (e.g., money). People express their values through behaviors, feelings, knowledge, and decisions. For example, the nurse who values compassion will interact with patients in a sensitive, caring manner.

Your **value set** is your "list" of values. It gives direction for your life and forms a basis for behavior. Your **value system** is your value set ranked from the most important value to the least important. Your value system begins to emerge shortly after birth and continues throughout your life, as various sources (parents, teachers, religious figures, peers, and so on) influence your values. The total number of values a person has is rather small. The number of significant ones is even smaller. It is easy enough to identify values—for example, love, freedom, courage, and responsibility—but how many of them have a consistent and predictable impact on your actions? Those are the significant values.

Values are highly individualized. They can vary and change with new experiences. As you progress through your study of nursing, you will incorporate the professional values associated with the practice of a registered nurse (e.g., caring, compassion, human dignity). You will experience role conflict when your values are different from practice expectations.

KnowledgeCheck 44-3

- What are values?
- What are three characteristics of values?

ThinkLike a Nurse 44-3

- Think about what you value personally in your own life. What are the five ideals, principles, or things that are most important to you?
- Now refer to Chapter 15, where you were asked to list five ideals, principles, or things that were most important to you. What did you list then? Is your list any different now that you have gained some clinical experience and theoretical knowledge?

What Are Attitudes? **Attitudes** are mental dispositions or feelings toward a person, object, or idea. They have three components: cognitive (thinking), affective (feeling), and behavioral (doing). These make up our way of responding to situations or things. For example, you might have a positive *attitude* about cleanliness—that is, you may think it is a good thing (e.g., "The floor is clean. That's nice.") But if you *value* cleanliness, you would be willing to scrub the floor. You would also wash your hands at appropriate times, bathe regularly, and teach others about hygiene.

What Are Beliefs? A **belief** is something that one accepts as true (e.g., "I believe that germs cause disease and that by washing my hands I remove germs"). Beliefs are sometimes based on faith and sometimes on facts. A belief may or may not be true.

Our beliefs can be altered by acquiring knowledge and experiences. Research shows that nursing students' attitudes toward and beliefs about older adults changed when they spent quality time with older adults and were given the appropriate geriatric assessment tools. The students' misperceptions were replaced with an understanding of the unique needs, abilities, and desires of geriatric clients (Potter, Clarke, Hackett, et al., 2013).

Beliefs may or may not involve values. Consider the following statements of belief.

"I believe the Earth is round." (Does not involve a value)

"Working hard to achieve goals is important to me; therefore, I believe that I must work during the summer to save money for college." (Involves a value)

From those examples, can you see how values, beliefs, and behaviors are related?

How Are Values and Ethics Related? Values and morals are learned in conscious and unconscious ways and become a part of your makeup. When we evaluate right and wrong, or good and bad, we are using moral judgment. Therefore, our individual preferences (values) of right or wrong become our moral values. Whether or not you are aware of it, your values shape the manner in which you make ethical decisions in your nursing practice (Burkhardt & Nathaniel, 2014; Butts & Rich, 2012).

So, although ethics are based on a structured set of principles and theories, and ethical decisions are publicly stated in terms of possible alternative behaviors, such decisions are always influenced unconsciously by our own personal and moral values.

Key Point: ***It is important to clarify the influence of your values each time you enter into a situation in which you are called on to be objective in your decision making.***

ThinkLike a Nurse 44-4

- Think about Alan and his family (Meet Your Patients). What do you think were the values of Alan's parents that influenced their behavior at the hospital? First, identify their behaviors specifically. Then speculate about the values underlying each behavior.
- How do you think values can influence health?

KnowledgeCheck 44-4

- Define *belief*; give a new example.
- Define *attitude*; give a new example

Professional Versus Personal Values

Your **personal value system** is a set of values that you have reflected on and chosen that will help you to lead a good life (Purtilo, 2010). You have internalized some *societal values* and have come to perceive them as your own (e.g., good manners, such as saying “Please” and “Thank you”). In addition, you probably have some *personal values* (e.g., friendship, fairness, creativity) that are important to you but may or may not be important to society at large.

As you move forward in your profession, you will integrate what you learn and experience and form **professional values** (e.g., caring, autonomy, veracity, competence, justice). Many of these will simply expand your personal values. The American Association of Colleges of Nursing (AACN) has identified six professional values. These are included in Table 44-1, along with other professional values. Personal and professional values are not always congruent, though. Consider the following situation:

Alexandra Jensen is a 17-year-old pregnant girl who comes in to your ambulatory surgical center for a voluntary termination of an early pregnancy. You are assigned to admit her to your unit and get her ready for this procedure. Imagine that your personal value in this situation is that you do not believe in abortion but that your professional value is guided by the ANA standards of professional practice, which state that the nurse “delivers care in a manner that preserves and protects patient autonomy, dignity, rights, values and beliefs” (ANA, 2010, p. 137). It is difficult to hold a personal value in high regard while under pressure to assume a conflicting professional value. How might you feel in the situation just described?

Do you think that your personal and professional values need to be compatible in order for you to be a competent nurse? Do you think that you should have the absolute right to refuse to participate in a situation (such as the one above) that may violate your personal values?

ThinkLike a Nurse 44-5

- Name some other examples of societal values.
- What groups and social experiences have helped to form your values?
- Examine your personal values to see whether they match the AACN’s professional values (see Table 44-1).
  Which of those values, if any, do you not share? Explain your thinking.
  Name a few of your personal values that are not found on this list of professional values.

KnowledgeCheck 44-5

- What is the difference between personal and professional values?
- What is an example of professional values?
- What are some other types of values?

How Are Values Transmitted?

As you have learned, we acquire values from social interaction. So how does that work? How are values transmitted? Table 44-2 outlines the methods of value transmission. Research reports the reciprocal transmission of values between parents and adolescents and that the presence of a receptive and supportive parent makes value transmission more likely (Pinquart & Silbereisen, 2004). Another study found only a marginally positive relationship between maternal and adolescent values. However, when adolescents’ basic needs (i.e., for autonomy, competence, and relatedness) were satisfied within the home, their values were more aligned with maternal values (Lekes, Joussemet, Koestner, et al., 2011).

What Is Value Neutrality?

You have probably been taught that nurses need to be nonjudgmental in working with their clients. As a nurse, you have a duty to provide the best care to clients. You should not assume that your personal values are right, and you should not judge the client’s values as right or wrong on the basis of whether they agree with your value system. Think back to the discussion regarding Alexandra, who was seeking to terminate her pregnancy. A nurse who does not believe in abortion could still provide competent nursing care to Alexandra even though his personal values regarding abortion are different from Alexandra’s. **Value neutrality** means that we attempt to understand our own values regarding an issue and to know when to put them aside, if necessary, to become nonjudgmental when providing care to clients. However, you should know that some healthcare professionals believe value neutrality is not possible to achieve. Further, they say it is not even desirable because it obligates healthcare providers to suppress or modify their own deepest moral and religious beliefs (Balch, 2006; Clark, 2006).

KnowledgeCheck 44-6

- What are some ways that values can be transmitted?
- What is value neutrality?

Ethical Frameworks

Ethics uses specific rules, theories, principles, and perspectives to inquire into the justification of an individual’s actions in a particular situation. **Ethical** (or **moral**) **frameworks** are systems of thought (theories) that are the basis for the differing perspectives people have in ethical situations. Many such philosophical frameworks are rooted in ancient works, for example, of the Greek philosophers Plato and Aristotle. See Chapter 8 if you need to review the purposes and uses of theories.

There is no single “best” theory that will provide the one “true” answer to an ethical problem, as the value of theories is that each one provides a different perspective. Using more than one framework to analyze a situation enables you to perform a more comprehensive analysis of the problem.

Key Point: ***No matter how well you know the theories, they will not provide the “right” answers for what to do in a specific patient situation. They merely offer a lens through which you can examine an ethical problem.***

Table 44-1 ➤ American Association of Colleges of Nursing (AACN) and Other Professional Nursing Values and Behaviors

VALUES	SAMPLE PROFESSIONAL BEHAVIORS
Altruism	
Concern for the welfare and well-being of others. Altruism is reflected by the nurse's concern for the welfare of patients, other nurses, and other healthcare providers. Includes patient advocacy.	■ Demonstrates understanding of cultures, beliefs, and perspectives of others. ■ Advocates for patients, particularly the most vulnerable. ■ Takes risks on behalf of patients and colleagues. ■ Mentors other professionals.
Autonomy	
The right to self-determination—to choose and act on that choice. Every competent person has the right to decide his own course of action.	■ Plans care in partnership with patients. ■ Honors the right of patients and families to make decisions about healthcare. ■ Provides information so that patients can make informed choices. ■ Informs patients about details of their care (e.g., test results).
Human Dignity	
Respect for the inherent worth and uniqueness of individuals and populations.	■ Provides culturally competent and sensitive care. ■ Protects the patient's privacy. ■ Preserves the confidentiality of patients and healthcare providers. ■ Designs care with sensitivity to individual patient needs. ■ Values and respects colleagues and patients.
Integrity	
Acting in accordance with an appropriate code of ethics and accepted standards of practice. Includes honesty.	■ Provides honest information to patients and the public. ■ Documents care accurately and honestly. ■ Seeks to remedy errors made by self or others. ■ Demonstrates accountability for own actions.
Social Justice	
Upholding moral, legal, and humanistic principles. Treating others fairly regardless of race, age, citizenship, economic status, disability, or sexual orientation. This value is reflected in professional practice when the nurse works to ensure equal treatment under the law and equal access to quality healthcare. **Additional professional values frequently cited for nursing** ■ Caring ■ Diversity ■ Equality (having the same rights, privileges, or status) ■ Aesthetics (qualities of objects or people that are pleasing) ■ Freedom (capacity to choose) ■ Truth (faithfulness to fact or reality) ■ Service (commitment to work useful to others)	■ Supports fairness and nondiscrimination in the delivery of care. ■ Promotes universal access to healthcare. ■ Encourages legislation and policy consistent with the advancement of nursing care and healthcare. ■ Works to ensure equal treatment under the law.

Table 44-1 ➤ American Association of Colleges of Nursing (AACN) and Other Professional Nursing Values and Behaviors—cont'd

VALUES	SAMPLE PROFESSIONAL BEHAVIORS
▪ Education (basic and lifelong continuing education for nurses) ▪ Holism ▪ Competence, excellence (skill, knowledge, performance of nursing work) ▪ Loyalty (feeling of duty or attachment to other nurses)

Table 44-2 ➤ Modes of Value Transmission

MODE	DESCRIPTION
Modeling	Children learn values from a variety of role models (parents, peers, rock stars, significant others) by observation. This modeling may lead to socially acceptable or unacceptable behaviors.
Moralizing	"This way is the only way." Children are taught a complete set of values in an authoritarian approach. If the child does not conform, the parent may inflict guilt and fear on him. This approach by parents, teachers, church leaders, and other authorities may make it difficult for young people to make independent choices because they have no experience selecting values that are good for them.
Laissez-faire	"Doing your own thing." Children are allowed to explore differing sets of values on their own with little guidance or discipline. This may lead to conflict and confusion on the part of the child.
Reward and punishment	The child's behavior is controlled by offering rewards for certain valued behaviors and punishing the child who fails to comply. Rewards can strengthen behavior, whereas physical punishment may teach that violence is an acceptable behavior.
Responsible choice	A balance of freedom and restriction allows children to select the values, explore new behaviors, and experience the consequences. This can lead to personal satisfaction and parental support.

What Is Consequentialism?

In **consequentialist** theories, the rightness or wrongness of an action depends on the consequences of the act rather than on the act itself. **Utilitarianism**, the most familiar consequentialist theory, asserts that the value of an action is determined by its usefulness. The *principle of utility* states that an act must result in the greatest good (positive benefit) for the greatest number of people. Any act can then become the ethical choice if it delivers "good" results. In healthcare, the principle of "first, do no harm," is consequentialist in nature. Because of this principle, we are always concerned about weighing the risks and benefits of our care (e.g., a medication may kill cancer cells, but side effects may harm the patient's quality of life).

Using utilitarianism to resolve an ethical problem requires you to engage in a risk-benefit analysis. You evaluate every alternative action for its potential outcomes, both positive (pros) and negative (cons)—similar to a technique you may already use when making other decisions. You would then select the action that results in the most benefits for the greatest number of people involved in the situation. The following is an example of utilitarian reasoning: The practice of triage is used in a disaster when emergency workers sort patients to determine who will be treated first or who will receive limited resources (e.g., oxygen or intravenous therapy). If a victim has little potential for survival, he may not be treated at all, or his treatment may be postponed to allow the healthcare team to treat those victims with the greatest potential to survive. (i.e., "the greatest number")

ThinkLike a Nurse 44-6

- Describe a time in your life when you used consequentialism to resolve a difficult situation.
- What types of clinical dilemmas might be best resolved using this theory?

What Is Deontology?

Deontology is based on rules and principles and uses the language of rights and duties. Unlike the utilitarian theory, deontology considers an action to be right or wrong regardless of its consequences. Such decisions are based on moral rules and unchanging principles. There is a variety of deontological theories, but you will commonly find they make use of the following, or similar, principles:

The Categorical Imperative This principle, established by the philosopher Immanuel Kant (1724–1804), states that one should act only if the action is based on a principle that is universal—or in other words, if you believe that everyone should act in the same way in a similar situation.

Treat People as Ends and Never as Means This means that the person is more important than the goal you may be trying to accomplish. Can you imagine the ethical concerns created if research subjects were exposed to some amount of risk (e.g., a new surgical procedure) to find a drug or treatment that will benefit many other people?

Moral Rules and Principles When using a deontological model, you would critically examine a situation to determine which actions are right or wrong according to moral rules and principles (e.g., justice, autonomy, doing good, and doing no harm). These principles are regarded as unchanging and absolute, and they come from the same universal values that underlie all major religions.

Rights and Duties Deontological frameworks also emphasize rights (e.g., the right to freedom, the right of self-determination) and duties (obligations). For example, you must help someone in need because you have a duty to help others, not because helping will produce good consequences. In fact, you have a duty to help even if your helping may produce some bad consequences.

Additional Considerations The following are two issues that may arise when using a deontology framework:

- **Conflict of Universal Principles.** Sometimes you must choose between conflicting universal principles. It is not always clear which principle to honor. Allowing Alan's parents (Meet Your Patients) to refuse to provide him with blood honors the principle of autonomy, but their decision may interfere with a right: Alan's right to life. Can you see that it might be difficult to decide which is the appropriate principle to honor?
- **Evaluating Motives.** In deontology, it is important to consider motives. It is one thing for Alan's parents to refuse a blood transfusion because they are honoring a religious principle; it would be quite another thing if they refused the transfusion because they stood to inherit a large trust fund left to Alan by his grandfather. Motives may place more weight on one of the conflicting universal principles over the other and make a decision clearer. Unfortunately, it is sometimes hard to recognize your own motives, much less to be sure about the motives of others.

Key Point: ***As a nurse, you will almost never be able to decide only on the basis of principles and rules; you will always need to consider the consequences of your actions.***

KnowledgeCheck 44-7

- Describe utilitarianism.
- Define *deontology*.

What Is Feminist Ethics?

Feminist ethics is based on the belief that traditional ethical models provide a mostly masculine perspective and that they devalue the moral experience of women (Butts & Rich, 2012). Traditional deontological models focus on abstract principles such as fairness, justice, and rights, which are more typical of male reasoning. In contrast, virtues such as love, relationships, caring, nurturing, and sympathy are more relevant to women but are rarely seen in traditional theories (Butts & Rich, 2012). Feminists assert that focusing on deontological principles distracts one from dealing with larger social issues. Feminist ethical reasoning uses relationships and stories rather than universal principles. Feminists argue that it is impossible to avoid being influenced by one's relationships. They see that influence as positive and believe it should not be lessened by an attempt to be objective—and in any case, that objectivity is impossible anyway.

Feminist theories do use principles and consequences, but they also ask you to look at social issues in the ethical situation to ensure that social facts are considered (Tong & Williams, 2009). The point is to address issues of gender inequality within each situation. This means that part of your reasoning would be to think, "How is this decision affecting the woman?" Consider an example of deciding whether to allocate federally funded healthcare resources to younger people or to older adults. Feminist reasoning on this question might say that, all other considerations being equal:

- In the United States older women outnumber older men.
- Older women tend to be poorer and are more likely to be alone than are men.

- Therefore, if healthcare for older adults were to be rationed, it would negatively affect women more than men.
- Thus, more healthcare resources should be allocated to older adults, especially women.

What Is Ethics of Care?

An **ethics-of-care** nursing philosophy directs attention to the specific situations of individual patients, viewed within the context of their life narrative. You would ask: "What is the story of this person's life? What is going on right now in his life? And what does that have to do with the morality of the action I'm considering?" Care theories (which grew out of feminist ethics) integrate the notion that caring is a natural human quality with the commitment and responsibility that you assume by entering into a helping profession (Lachman, 2012). An ethics of care emphasizes the role of feelings, but also includes some of the principles that are part of traditional ethics, such as *autonomy* (self-determination) or *beneficence* (doing good), responsibility, and commitment.

Using an ethics of care, nurses have a responsibility to care as a part of their professional behavior, consistent with the ANA Code of Ethics. Some aspects of care include the ability and duty to appreciate, understand, and even share the patient's pain or condition. Using a caring framework, your ethical analysis would focus on relationships and client stories. The following guidance is derived from an ethics-of-care philosophy (Edwards, 2009, 2011; Lachman, 2012; Vanlaere & Gastman, 2011):

- View caring as the central force in nursing.
- Promote dignity and respect for patients as people.
- Attend to a person's real needs and maintain the competence to fully address those needs.
- Cultivate a habit of care.
- Redefine fundamental moral principles to include virtues such as kindness, attentiveness, empathy, compassion, and reliability.

Using the caring perspective and patient stories tends to focus discussion at the level at which the relationships are located, rather than on an intellectual plane. Critics of the ethics of care suggest that the term *caring* can be misconstrued to become too sentimental and, therefore, ineffective. Further, unless the sentiment of care is associated with a universal principle, such as justice, favoritism or separateness can occur (Vanlaere & Gastman, 2011).

Ethics-of-care models provide a refreshingly new perspective into moral situations. As you gain more clinical experience, revisit these philosophies and reflect on how they apply to your nursing practice.

KnowledgeCheck 44-8

- How does feminist ethics affect ethical decision making?
- What do ethics-of-care philosophies emphasize?

Ethical Concepts and Principles

Remember from Chapter 8 that theories are made up of concepts and principles. The same is true for ethical theories. Although theories differ, they share some of the same principles. Therefore, ethical concepts and principles are useful in patient care discussions because they provide a common language for healthcare professionals to identify the issues. Even if people disagree about which action is right in a situation, they can agree on which principles apply. Agreement "in principle" can provide common ground for a compromise or other resolution of the problem. We will discuss the ethical principles of autonomy, nonmaleficence, beneficence, fidelity, veracity, and justice.

Autonomy

Autonomy refers to a person's right to choose and ability to act on that choice. It is based on respect for human dignity. You demonstrate respect for autonomy when you treat patients with consideration, believe their stories about the course and symptoms of their illnesses, and protect those who are unable to decide for themselves. You honor autonomy when you respect the patient's or surrogate decision maker's right to decide, without judgment, even when you believe those choices are not in the patient's best interest.

In the Meet Your Patients scenario, if you believed autonomy to be the most important principle in the situation, you would respect Alan's parents' decision to refuse blood products for their son. If respect for autonomy was not your dominant ethical principle, you would probably try to persuade them to change their minds.

Informed Consent. The principle of autonomy underlies informed consent—the right of competent patients to decide for themselves whether to agree to a proposed treatment.

Key Point: ***Remember this general nursing principle: "Every competent adult has the right to accept or refuse treatment and should be provided all the information needed to make an informed decision."***

To ensure truly informed consent, patients need to know the diagnosis and related information, the recommended treatment, alternative treatment options, the risks and benefits associated with each, and the providers involved in the treatment regimen. The nurse's role is to verify that the patient understands and to obtain her signature.

Key Point: ***The nurse should notify the provider if the patient does not understand the treatment, before obtaining her signature.***

Advance directives help to ensure that treatment given to an incompetent person is in accordance with his previous wishes. They were created to allow adults while they are competent to make decisions about their healthcare that will guide their care when they are incompetent. You can help support autonomy by informing patients about advance directives: the living will and durable powers of attorney for healthcare.

Privacy and Confidentiality The principles of **privacy** and **confidentiality** are also partly derived from the principle of autonomy. An autonomous person has control over the collection of, use of, and access to her personal information. Many patients share sensitive information with nurses that they would not share with others, and it is important to maintain the patient's trust. This means that you should not discuss patients in the elevator, halls, lunchroom, or anywhere it can be overheard, even if the discussion is relevant to the patient's care. You should communicate to those involved in the patient's care only the information needed to provide healthcare. Share other information only with the patient's consent.

You should also be careful not to post pictures of yourself with patients or post patient information on social media sites. Even inadvertently capturing patients in photographs has led to harsh disciplinary actions against the nurse.

Key Point: ***A person who knowingly violates the privacy and confidentiality requirements of the Health Insurance Portability and Accountability Act (HIPAA) can face imprisonment of 1 to 10 years and a monetary fine of $50,000 to $250,000, depending on motive.***

If you would like more information about privacy and confidentiality, see Chapters 18 and 45; also

Go to Student Resources, Chapter 44, **Supplemental Materials: Confidentiality and Privacy,** on Davis*Plus*.

Nonmaleficence

The principle of **nonmaleficence** is the twofold duty to do no harm and to prevent harm. Nonmaleficence refers to both actual harm and risk of harm, as well as to intentional and unintentional harm. Both the physicians' Hippocratic Oath and the nurses' Nightingale Pledge state that care providers have a duty to cause no harm to patients. When you are careful to prevent medication errors, or a patient fall by providing a walker, or using an ambulation belt for mobility, you honor the nonmaleficence principle. In nursing it is rare to find intentional harm, but unintentional harm does occur as a result of incompetence or failure to adhere to each component of the nursing process (Beauchamp & Childress, 2012).

Nonmaleficence requires that you think critically and identify the potential risks and benefits in the treatment plan. When using nonmaleficence to guide treatment regimens, ask the question, "Does this treatment cause more harm or more good to the patient?"

- **Risk of harm is not always clear.** Suppose you are about to get a patient out of bed for the first time after surgery. The benefit clearly is that this will prevent postoperative complications such as pneumonia and thrombophlebitis; but the risks, in terms of excessive pain or unintentional damage to the operative site, may be less clear.
- **Weighing risks and benefits is a value-laden exercise.** Who is to say what amount of pain is excessive—you or the patient? To honor the principle of nonmaleficence in this situation, you would need to be sure to premedicate the patient and carefully assess his status during ambulation.

Respect for Dignity The value of respect for human dignity derives in part from the duty to do no harm. **Respect for dignity** refers to the nurse's respect for the intrinsic worth of each person, without respect to age, race, religion, medical condition, or any other factors. Respect for dignity recognizes that patients are vulnerable, and that nurses should not abuse their relationships for personal gain or exploit or enter into romantic, sexual, or other relationships with their patients. The nurse should at all times maintain professional boundaries. To read more about professional boundaries,

Student Resources, Chapter 44, **Supplemental Materials: Professional Boundaries,** on Davis*Plus*.

Think**Like a Nurse** 44-7

Think about the Meet Your Patients scenario in terms of nonmaleficence. The parents refuse to allow a blood transfusion. You, the nurse, have tried to persuade them to change their minds. You do not need to decide what you ought to do; just analyze the situation in terms of the risks.

- What is it that creates the risk for harm to Alan?
- What is the risk for harm to Alan's parents because of the nurse's actions?

Beneficence

Beneficence is the duty to do or promote good. You can think of this principle as being on a continuum with nonmaleficence. At one end of the continuum is beneficence, the duty to bring about positive good; at the other end is the duty to do no harm. The following examples illustrate the duties in priority order:

- Do no harm. (Don't push the man into the river.)
- Prevent harm when you can. (If the man is getting dangerously close to the river's edge, warn him that he is about to fall into the river.)

FIGURE 44-2 Nurse involves the patient in her plan of care.

- Remove harm when it is being inflicted. (If you see a struggle and someone is trying to push the man into the river, interfere and try to stop it if you can do so without undue harm to yourself.)
- Bring about positive good. (If the man has fallen in the river, jump in and try to save him, or toss him a lifeline and call 911 if you can't swim.)

When weighing the risks and benefits of an action, you are actually balancing nonmaleficence with beneficence. Keep in mind that patients, family members, and other professionals may identify benefits and harms differently. A benefit to one may represent a burden to another. For example, in Meet Your Patients, you may see a blood transfusion as a benefit to Alan, but to the parents it may represent harm. Doing good very much depends on the context and the rights of the person for whom the action is being taken.

Paternalism Although beneficence seems like such a positive goal, it can have negative consequences. One such outcome is **paternalism** (treating others like children). This would occur, for example, if you think you know what is best for a competent client and then coerce the client to act as you wish rather than to act as she wishes. Saying to a patient, for example, "Trust us; we know what is best for you to do in this situation," may seem to be beneficent because you are trying to support the patient. But it is actually paternalistic behavior that lacks respect for the patient's autonomy (and therefore represents "harm").

Fidelity

Fidelity (faithfulness) is the duty to keep promises. It is a basic part of every patient care situation. Sometimes the promises are of major significance, such as promising not to share certain information with other members of the healthcare team. At other times it may be only a promise to come back to check the effectiveness of a pain medication or to bring a requested item back to the client's room.

In practice, you will often find that competing tasks prevent you from being able to deliver something exactly as you have promised. Instead of "I'll be right back with your medication," you might be a bit more vague and say, "I'll get back with your medication as quickly as I can" or "I must go help another patient for a few minutes, but I'll get here with your medication as quickly as I can."

Key Point: ***The duty to keep a promise is the same regardless of its level of importance. Make promises in a thoughtful, careful manner to maximize the likelihood that you can keep them.***

Veracity

Veracity is the duty to tell the truth. This seems straightforward, but there are times when veracity presents a challenge. For example, should you tell the truth when you know that it might cause harm to the client? Would it be appropriate to tell a lie to relieve extreme patient anxiety? Most nurses would agree that it isn't hard to tell the truth, but at times it may be very hard to determine how *much* of the truth to tell. For example, healthcare professionals may feel uncomfortable giving families "bad news." So instead of saying, "Your father has a fatal illness and is unlikely to live for more than a month," they may say, "Your father is very ill, but we will do everything we possibly can for him." In this, as in most situations, the risk of losing patient trust outweighs any benefit of withholding the truth.

Although you always presume the value of telling the truth, there may be times when you are justified to withhold information. In the United States, we tend to place a high value on autonomy. However, in some cultures, families go to great lengths to protect a dying patient from the harsh truth of his prognosis, and the patient himself may not wish to know. In such a situation, you need to be culturally sensitive so that you may act on the family's values, not on the dominant cultural values. Always consider the context.

Think**Like a Nurse** 44-8

Review the Meet Your Patients scenario. Alan will not survive without a blood transfusion, yet the parents refuse to allow one. He asks the nurse, "Am I going to die?" You do not need to decide which response is best; just write an example that illustrates each of the following. What might the nurse say if she wishes to:

- Tell Alan the truth?
- Withhold or partially disclose the truth?
- Answer with an untruth?

Justice

Justice is the obligation to be fair. It implies equal treatment of all patients. Questions of justice will become a part of your everyday experience in patient care, from deciding how to allocate your time among patients to larger decisions, such as how to allocate limited healthcare resources.

Distributive Justice

Distributive justice requires fair distribution of both benefits and burdens (Butts & Rich, 2012). It is especially relevant to healthcare, as in the following issues.

- ***Allocating resources.*** Distributive justice questions come up when more than one person or group competes for the same resources. For example, consider organ transplantation. Human organs are scarce resources. How do we decide which patient should receive an available organ? Is an 18-year-old more deserving of a kidney than a 75-year-old? Is a person with liver disease due to alcoholism less deserving of a liver than someone with liver disease not caused by alcoholism? The decision of who should live and who may die is never an easy decision. In the United States, a national committee sets criteria for how organs will be distributed so the standard of justice is considered.

- ***Fair access to care.*** Access to care is a specific kind of healthcare resource. The principle of distributive justice holds that we should provide equal access to healthcare for all. As the baby boomer generation ages and these nurses retire, there will be fewer nurses to care for more aging patients at a time when national healthcare dollars are stretched very thin. How will the nation decide where to spend the limited dollars? How will nurse managers decide how to provide adequate care when they do not have enough nurses on their staff? The ability to develop sound criteria on which to base the allocation of resources is the challenge of distributive justice.

Compensatory Justice

Compensatory justice focuses on making amends for wrongs that have been done to individuals or groups. Malpractice lawsuits consider this type of justice when they decide how much money to award a victim who has been harmed. Groups of citizens may also be harmed. For instance, if a company's unintentional pollution of water was proved to cause cancer in members of the community, a monetary settlement might be made.

Procedural Justice

Procedural justice is important in processes that require ranking or ordering (Landwehr, 2013). For example, institutional policies are written to ensure that the same procedures apply to all clients or employees in the same way (e.g., visiting hours, working on holidays, sick leave). Can you think of an example of procedural justice that you have experienced during your nursing education?

ThinkLike a Nurse 44-9

Look again at the emergency department situation described in What Is Nursing Ethics? at the beginning of this chapter. In this scenario, two little boys were treated for lacerations. Which principle of justice was violated: distributive, compensatory, or procedural? Explain your thinking.

KnowledgeCheck 44-9

List the definition of each of the six ethical principles.

Professional Guidelines

You should consult professional guidelines when making ethical decisions. Healthcare professionals have an obligation to society to be competent in their field; to allow only qualified persons entry into the profession; to discipline members of the profession who do not practice at an acceptable level; to do no harm; and to use high moral and ethical standards to resolve dilemmas (Husted & Husted, 2008; Landwehr, 2013). You can find ethical standards for nurses in codes of ethics, standards of practice, statements of patients' rights, and in various laws.

Nursing Codes of Ethics

Professional codes of ethics are formal statements of a group's expectations and standards for professional behavior generally accepted by members of the profession. Codes of ethics set forth ideal behaviors, but they are only as effective as the behaviors of the nurses who live up to the codes. The purposes of a nursing code of ethics are to:

- Inform the public about the profession's minimum standards.
- Demonstrate nursing's commitment to the public it serves.
- Outline major ethical considerations of nursing.
- Provide general guidelines for professional behavior.
- Guide the profession's self-regulating functions.
- Remind us of the special responsibility we assume in caring for the sick.

Nursing codes are not legally binding. However, they often exceed legal obligations. In most states, the state board of nursing uses the nursing code of ethics as the standard against which to evaluate a nurse's ethical behavior. The board has the legal authority to censure or reprimand the nurse who does not practice within the boundaries of ethical practice. The following nursing organizations have had long-standing codes to guide nurses' ethical decision making. The codes differ in specific details, but are based on similar principles.

International Council of Nurses The International Council of Nurses (ICN) first adopted its Code of Ethics for Nurses in 1953 as "a guide for action based on social values and needs" (ICN, revised 2012). The ICN Code has since served as the standard for nurses worldwide. The ICN Code stresses respect for human rights, including cultural rights, the right to life and choice, the right to dignity, and the right to be treated with respect. The code is designed to guide nurses in everyday choices, and supports their refusal to participate in activities that conflict with caring and healing. If you wish to see the revised code,

Go to Student Resources, Chapter 44, **Tables, Boxes, Figures: ESG Box 44-1, ICN Code of Ethics,** on Davis*Plus*.

The American Nurses Association The ANA revised its Code of Ethics for Nurses in 2001 (Box 44-1). The ANA used input from a wide range of nurses and groups to ensure that the revised code would be relevant in many practice settings and reflect current ethical situations. The code has nine provisions, followed by interpretive statements to explain what is meant by each provision. If you would like more information about the ANA Code,

Go to the **ANA Web site,** at http://www.nursingworld.org/MainMenuCategories/EthicsStandards/CodeofEthicsforNurses

BOX 44-1 ■ American Nurses Association Code of Ethics for Nurses

1. The nurse, in all professional relationships, practices with compassion and respect for the inherent dignity, worth, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of health problems.
2. The nurse's primary commitment is to the patient, whether an individual, family, group, or community.
3. The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
4. The nurse is responsible and accountable for individual nursing practice and determines the appropriate delegation of tasks consistent with the nurse's obligation to provide optimum patient care.
5. The nurse owes the same duties to self as to others, including the responsibility to preserve integrity and safety, to maintain competence, and to continue personal and professional growth.
6. The nurse participates in establishing, maintaining, and improving healthcare environments and conditions of employment conducive to the provision of quality healthcare and consistent with the values of the profession through individual and collective action.
7. The nurse participates in the advancement of the profession through contributions to practice, education, administration, and knowledge development.
8. The nurse collaborates with other health professionals and the public in promoting community, national, and international efforts to meet health needs.
9. The profession of nursing, as represented by associations and their members, is responsible for articulating nursing values for maintaining the integrity of the profession and its practice, and for shaping social policy.

BOX 44-2 ■ American Nurses Association Standards of Professional Performance Standard 7. Ethics

Definition: The registered nurse integrates ethical provisions in all areas of practice.

Measurement Criteria

The registered nurse:

- Uses the Code of Ethics for Nurses With Interpretive Statements (ANA, 2001) to guide practice.
- Delivers care in a manner that preserves and protects patient autonomy, dignity, and rights.
- Respects the centrality of the patient/family as core members of any healthcare team.
- Upholds and advocates for patient confidentiality within legal and regulatory parameters.
- Serves as a patient advocate assisting patients in developing skills for self-advocacy and informed decision making.
- Maintains a therapeutic and professional patient–nurse relationship with appropriate professional role boundaries.
- Demonstrates a commitment to practicing self-care, managing stress, and connecting with self and others.
- Contributes to resolving ethical issues of patients, colleagues, community groups, systems, and other stakeholders.
- Takes appropriate action regarding instances of illegal, unethical, or inappropriate behavior that can endanger or jeopardize the best interests of the patient or situation.
- Cooperates in an interprofessional team to make ethical decisions regarding the application of technologies and the acquisition and sharing of data.
- Demonstrates professional comportment (openness, honesty, integrity, and authenticity) (Massachusetts Department of Higher Education, 2010).
- Speaks up when appropriate to question healthcare practice when necessary for safety and quality improvement.

ANA Standards of Care

In addition to its Code of Ethics, the ANA sets standards for all aspects of clinical practice. In *Nursing: Scope and Standards of Practice* (2010), standard 7 focuses on ethical practice. This standard (see Box 44-2) directs nurses to practice within the parameters described in the Code of Ethics for Nurses. Standard 7 speaks to the nurse's responsibilities to patients and directs nurses to manage ethical dilemmas and to report practices that are illegal, incompetent, or impaired.

The Patient Care Partnership

When patients are admitted to hospitals or to extended care facilities, they are entitled to specific rights in terms of their treatment: the right to make their own decisions, to be active partners in the treatment process, and to be treated with dignity and respect. Because rights are rooted in values, and because values are derived from culture, patient rights are different throughout the world. In the United States, the American Hospital Association (AHA) published *Patient Care Partnership* (2003). Instead of using "rights" language, this document is written in terms of patient expectations and responsibilities. The *Patient Care Partnership* encourages healthcare providers to be more aware of the need to treat patients in an ethical manner and to protect their rights (Box 44-3).

BOX 44-3 ■ American Hospital Association: The Patient Care Partnership

Patients, when hospitalized, should expect the following:

- High-quality care, including the right to know the identity of caregivers
- A clean, safe environment, including safety, freedom from abuse and neglect, and discussion of any changes in care
- Respect for healthcare goals, values, and spiritual beliefs
- To be involved in making decisions about their care and treatment. This includes receiving information about:

  Health condition and treatments

  The benefits and risks of treatments, and whether a treatment is experimental or part of a research study

  What the patient and family will need to do regarding treatment follow-up after leaving the hospital
- Information about the right to make decisions and to refuse care, including advance directives and counselors or chaplains available to help with decision making
- Protection of their privacy and confidentiality
- Help reviewing the bill and filing insurance claims
- Preparation and information when leaving the hospital, including:

  Identification of sources for follow-up care and whether the hospital has a financial interest in any of the referrals

  Coordination of hospital activities with caregivers outside the hospital

  Information and training about the self-care the person will need at home

The Joint Commission Accreditation Standards

The Joint Commission standards contain sections on organizational ethics and individual rights. The section on organizational ethics requires ethical behavior in care, treatment, services, and business practices. The patient's values, preferences, need for information, and other factors that promote autonomy must be considered in her plan of care. It includes a statement about the need to provide for meeting patient needs in the event care must be denied in the institution. In meeting the patient's needs, you must also consider the organization's legal responsibility.

KnowledgeCheck 44-10

- How would the nurse use a professional guideline or code of ethics to assist in the ethical decision-making process?
- What are some examples of such resources?

ETHICAL ISSUES IN HEALTHCARE

As a nurse, you are likely to encounter several ethical issues that occur in healthcare. For example, ethical questions arise in the following situations:

Abortion
Acquired immune deficiency syndrome (AIDS)
Advance directives
Allocation of healthcare goods and services
Compelling unwanted treatment
Confidentiality and privacy (e.g., reporting gunshot wounds and child abuse)
Do Not Attempt Resuscitation (DNAR) orders
Euthanasia, assisted suicide, aid in dying, extraordinary (heroic) measures to prolong life
Informed consent
Organ transplantation
Reproductive technology (e.g., in vitro fertilization, surrogate mothering, sex preselection)
Withdrawing or withholding life-sustaining treatments (e.g., ventilators, artificial nutrition, and hydration)

Extended discussion of those specific issues is best addressed in an ethics text or an ethics course. However, if you wish to learn some basic information about these situations and the ethical conflicts surrounding them,

Go to Student Resources, Chapter 44, **Supplemental Materials: Ethical Issues in Healthcare,** on Davis*Plus.*

PracticalKnowledge knowing how

To fulfill your professional obligations for ethical practice, you will need practical knowledge of the processes of values clarification, ethical decision making, patient advocacy, and integrity-producing compromise.

ASSESSMENT/ANALYSIS/DIAGNOSIS

A holistic, comprehensive patient assessment will help you establish the context in which ethical decisions are made. For patients struggling with moral (ethical) issues, the following diagnoses may apply:

- *Decisional Conflict*—Use this label when the patient is uncertain about which course of action to take. The patient may verbalize distress and uncertainty, may delay decision making, may show physical signs of distress (e.g., increased heart rate), and may question moral rules and values and personal beliefs.
- *Moral Distress*—Use this label when the patient has made a moral decision but is unable to carry out the

chosen action. Cues include expressions of powerlessness, guilt, frustration, anxiety, self-doubt, and fear.

NANDA-I also lists other diagnoses in the Value/Belief/Action Congruence class, including Spiritual Distress and Risk for Spiritual Distress.

VALUES CLARIFICATION

Values clarification refers to the process of becoming conscious of and naming one's values (Burkhardt & Nathaniel, 2014). If you are clear about your values, you will be more able to make good decisions and to avoid imposing your values on others. Because each person has his own unique values set, it is important that you appreciate how others' values influence their decisions. Clarifying values should be a positive process of growth that results in more awareness, empathy, and insight (Peate, Watts, & Wakefield, 2013; Roberts, 2012). A values clarification process does not tell you what your values ought to be; it merely helps you discover what they are. Values change over time, so you may need to repeat the process more than once in your lifetime.

How Can I Clarify My Values?

As a nurse, you will need to examine your values regarding life, death, wellness, and illness. A good place to start is to ask yourself questions about situations that you think you may be uncomfortable with, such as caring for a substance abuser seeking drugs in the emergency department, an unwed adolescent mother pregnant for the second time in 11 months, or parents such as the Freses (Meet Your Patients), who refuse treatment for a child because of religious beliefs. Ask yourself questions such as:

- Could I take care of this person?
- Does this bother me?
- What would I do if confronted with such a situation?
- Could I provide the same quality care as for my other patients?

If you would like to use some exercises that can help you begin to clarify your values related to healthcare,

Go to Student Resources, Chapter 44, **Tables, Boxes, Figures: ESG Box 44-2, Rank-Ordering Values** and **ESG Box 44-3, Values Preference Exercise,** on Davis*Plus*.

Remember that there are no right or wrong answers to values clarification exercises. They are designed to assist you to identify your values and examine their relevance in your personal and professional life.

How Can I Help Clients to Clarify Their Values?

Some clients may exhibit behaviors that indicate that their values are not clear. Consider this example:

Jon White is the chief executive officer of a large healthcare facility. Jon has had two myocardial infarctions (heart attacks) in the past 5 years. He also has hypercholesterolemia (high cholesterol) and hypertension (high blood pressure). Jon's physician has prescribed a heart medicine, low-dose aspirin, and medications to control his hypertension and cholesterol. Jon has repeatedly been taught about his diet, medications, and activity. He insists he is compliant. Jon's wife tells you that he has stopped exercising and is eating whatever he wants, including saturated fats. Jon tells her it is okay to eat what he wants because he is taking a "cholesterol-buster" pill.

The following patient behaviors may indicate that a patient needs values clarification:

- Ignoring the advice of a health professional
- Patient's words not consistent with his actions
- Numerous admissions for the same problem
- Uncertainty or confusion about which action to take

Which of those behaviors did Jon exhibit? To help Jon clarify his values, you might ask him to list the three things that are most important to him in life. Or you might help him work through the steps in Table 44-3 (choosing, prizing, and acting).

KnowledgeCheck 44-11

- What is values clarification?
- What are the steps in values clarification?

ETHICAL DECISION MAKING

Decision models used in bioethics do not offer easy decisions, but they do provide a guiding structure to help you arrive at the best answer in specific situations. Decision models can help you decide on a course of action even if they do not tell you absolutely that the action is right or wrong.

How Can I Recognize Ethical Issues? We have said it is important to be aware of the ethical issues in patient care situations, but how will you recognize them? The key is that there is usually a conflict:

- About the right action to take
- Among the duties and obligations of healthcare professionals (or they are unclear)
- Between the needs and interests of an individual and a group of clients
- Between what the family wants and what the client wants or needs
- Between the family and health professionals
- Among ethical principles or values (e.g., autonomy versus nonmaleficence, as in the Meet Your Patients scenario)

Problem or Dilemma?

In the best of all possible worlds, you could easily apply ethical principles and decide what to do. However, often in moral situations one ethical principle is in conflict with another equally important principle. It

Table 44-3 ➤ Values Clarification

STEP AND DESCRIPTION	QUESTIONS TO ASK YOUR PATIENT
Choosing (cognitive)	
Beliefs are chosen: Freely (allows you to cherish your choice) From alternatives After considering all consequences (ensures that the alternative is right for you)	Do (did) you have any choice about what you do? Do you have any control over what happens? What have you decided to do? Can you list some alternative actions? What are your options? What could you do instead of . . . ? What do you think will happen if you do that? What will you gain by doing that? What is the disadvantage of doing that?
Prizing (affective)	
Beliefs and behaviors that are chosen are prized: With pride (feeling good about your choice) With public affirmation	How do you feel about your decision? People sometimes feel good after making such a decision. Others feel pressured. How is it for you? How do you intend to tell your family (friends) about this decision? What will you say to your wife (friends, family)? When will you announce your decision to . . . ?
Acting (behavioral)	
Beliefs are acted on: By incorporating the choice into one's own behavior With consistency and repetition	Try to determine whether the client will act on the decision: ■ How do you think your wife (significant other) will react when you do that? ■ When will you actually carry out this decision? ■ Try to predict consistent behavior by asking: • How many times in the past have you . . . ? • What kind of schedule have you worked out? How often and when will you . . . ?

Source: Adapted from Raths, L. E., Harmin M., & Simon, S. B. (1978). *Values and teaching: Working with values in the classroom.* Columbus, OH: Merrill.

is also possible for a philosophical framework to produce more than one acceptable option. An **ethical dilemma** is a situation in which a choice must be made between two equally undesirable actions. There is no clearly right or wrong option. Such situations are emotionally painful for everyone in the situation, as you can see from the Meet Your Patients scenario at the beginning of this chapter. If you support Alan's parents' right to refuse a blood transfusion, you honor the principle of autonomy, but at the expense of the principle of nonmaleficence, which says we should prevent harm to Alan.

Fortunately, not all moral problems are dilemmas nor are they complex and difficult. In fact, you will confront a true dilemma only occasionally. Some questions are easily answered (e.g., "Should I take the patient's morphine to relieve my back pain?"). It is probably more accurate, then, to talk about "moral questions," "moral problems," or "moral situations" and not use the term *dilemma* loosely. Only problems that pose a question between competing and equally valuable interests are true dilemmas. You may never or only occasionally confront a true emotional dilemma.

Ethical behavior and decision making do not deal only with dilemmas. They really involve choosing to be ethical in the everyday aspects of your practice: for example, treating colleagues and patients with respect, not passing by a room when you see a patient crying, or helping out a new graduate who is frustrated and anxious. The scenario (in What Is Nursing Ethics?) about the two little boys in the emergency department is more representative of everyday ethics than is the Meet Your Patients scenario.

How Do I Work Through an Ethical Problem?

Once you have identified an ethical problem, a decision model can help you logically decide the best action to take. Still, in the case of a true ethical dilemma, you will probably not be comfortable with any course of action, no matter how logically you think it through.

Ethical decision-making models will help you carefully consider several perspectives, guide your reasoning, and explain the reasons for your final action. Each approach may produce a different solution. One of the easiest to remember and use is the MORAL model. This model has been credited to two different authors: Thiroux (1977) and Crisham (in Scott, 1985). The letters MORAL will remind you of the steps in this model, which is described in the following section. To use the model in clinical settings,

Go to **Clinical Insight 44-1: Using the MORAL Model for Ethical Decision Making,** in Volume 2.

First, Use Problem-Solving

As a first step in ethical decision making, use the nursing process approach to describe the problem and alternative approaches:

- ***Assessment—What are the relevant facts?*** Alan needs a blood transfusion to survive. Both you and the surgeon have tried to persuade the parents to consent, but they still refuse. The parents' religion prohibits blood transfusions. Alan is 15 years old (a minor), so you cannot administer a transfusion without his parents' consent.
- ***Analysis/Diagnosis—Identify the problem; state the conflict***. There is a values conflict: The healthcare professionals value preserving physical life; the parents place more value on preserving the soul. There is an ethical dilemma, as well: If no transfusion is given, you violate the principle of nonmaleficence (harm to Alan); if you somehow coerce the parents to consent, you have violated the principle of autonomy (respect for their values and their freedom to choose). So the decision to be made is whether to (a) follow the parents' wishes, (b) find a legal way to transfuse without their consent, or (c) find some compromise that will work.

Next, Use the MORAL Model

Now use the MORAL model to come up with alternative solutions for the Frese family.

M—Massage the Dilemma

1. ***First identify and define the issues in the dilemma, and consider the values and options of all the major players:*** Mr. and Mrs. Frese, Alan, the surgeon, possibly a member of the clergy, and you (the nurse). You have already identified the values in the problem-solving approach: physical life versus spiritual life. You and the surgeon also value the principles of autonomy and nonmaleficence.
2. ***Then identify the information gaps.*** In massaging the situation, you should ask yourself:
   - Do I fully understand the situation that is causing the need for blood?
   - How much time is available to make this decision—do the parents have to decide within a few minutes, or do they have enough time to discuss this with their congregational elders?
   - Does the physician know that the family members are Jehovah's Witnesses?
   - Does the surgeon have any treatment that could be used to stabilize Alan while the parents discuss the situation?
   - Do Alan's parents fully understand the nature of Alan's physical emergency?
   - In the Freses' religious view, what is the consequence of receiving blood?
   - Do they understand what might happen if blood is not administered (i.e., do they understand the consequence of their action or inaction)?
   - Is this what Alan would want? Has Alan discussed in the past how he feels about blood transfusions? Have they ever had family discussions when other young Jehovah's Witnesses have been faced with such a decision? Where did Alan stand in those discussions?
   - How is this situation like other situations they have experienced in their lives?
   - Have they thought about their opposing duties: the duty to uphold their religious values and the duty to protect their son from harm?
   - Has everyone's voice been heard?
   - Have the parents contacted their congregational elders and discussed the situation?
   - What emotions are coming into play in this situation?
   - How is this decision affecting the parents as individuals? Are they in agreement on the issue, or is there dissension? If there is dissension, are both sides being supported fairly?
   - Is there some common ground between what the surgeon wants and what the parents feel they need to do to uphold their religious convictions?

O—Outline the Options

At this step in the MORAL model, you (or the charge nurse or a member of the ethics committee) should outline all of the options to all parties, including those that are less realistic and conflicting. You might ask a member of the ethics committee or the hospital chaplain to help the family and the doctor understand the opposing viewpoints.

The surgeon needs to outline the state of emergency that exists for Alan and to explain what the limited medical options are: to transfuse blood or, if no blood is given, what other treatments are available (e.g., volume enhancers). The surgeon will need to say how soon the decision must be made based on Alan's condition. He should clearly describe the consequences of each action. Carefully, and with as little emotion as possible, explain the consequences of each action to the parents. The physician should state whether one administration of blood will likely fix the situation or whether continued administration may be required.

The family (or the congregational elders) should explain for the doctor and nurse the basis for their refusal to consent and what they believe the consequence would be if blood were given.

R—Resolve the Dilemma

Now carefully review the issues and options. Apply basic ethical principles. If you can, also look at the situation using alternate ethical frameworks.

- **Autonomy.** By their refusing to give consent, the Freses are exercising their autonomy. How far will we go to honor their autonomy?
- **Beneficence and Nonmaleficence.** How are we defining "good" (beneficence) and "harm" (nonmaleficence) in this situation? The physician defines "good" as Alan receiving the needed blood. He defines "harm" as the outcome for Alan without the blood, even if he uses a less effective alternative. Alan's parents would define "good" as following their religious mandates and making sure their son will remain pure in the eyes of God. They might explain that a Jehovah's Witness who willingly accepts a blood transfusion might forfeit his or her eternal life. The Freses might believe the taking of blood to be more harmful than death, because they believe that would affect Alan's eternal life, not just his physical life.
- **Fidelity.** The surgeon is being loyal (exhibiting fidelity) to the principles of medicine and evidence-based practice, which mandate the administration of the blood. To the parents, their loyalty to their religious principles to ensure that Alan has eternal life may be more important than the loss of the physical life itself.
- **Veracity.** The principle of veracity holds that the surgeon should not exaggerate the need for the blood, and he should be honest with the parents in terms of the consequences of the alternative actions. Another question of veracity involves the parents: Are they being honest with each other regarding their feelings?

Your role as a nurse is to be an advocate for the patient and the family. Talk with the family and their religious representative, if available, about what they are thinking about their opposing duties: the duty to uphold their religious values and the duty to protect their son from physical harm. Explain to the surgeon the reasoned position of Alan's parents, if you can do so.

Key Point: ***Ensure that everyone's viewpoint has been respected and considered. This may be as important as the final decision that is reached. In this and other difficult situations, always look for the opportunity for a good compromise (to be discussed later in this chapter).***

A—Act by Applying the Chosen Option

This step is the first one that actually requires action. The hospital is bound to follow the parents' decision because Alan is a minor. However, if there is time, many agencies might refer this situation to the hospital ethics committee. The hospital might also ask a legal court authority to resolve the situation. If an emergency requires an immediate decision, the only *legal* action is to follow the parents' decision, whether or not you consider it the best moral action.

Whatever happens, Alan's parents will need emotional support. If they decide to refuse the blood transfusion, you must remain nonjudgmental in supporting them, even if you do not agree with their decision. If they, or the courts, decide that the blood will be given, they may need even more support. They may feel overwhelming guilt, and they may fear that Alan will be forever burdened with guilt at the realization that they violated church doctrine with the medical care. If their extended family is not present, you could volunteer to call in extended family, friends, and church members if they wish. They will need a quiet, private place to await the outcome of the treatment.

L—Look Back and Evaluate

This phase calls for evaluation of the entire process, not just the consequence of the decided action.

- How well did the process work? Were processes in place for the dilemma to be discussed respectfully without undue delay in treatment?
- Were all parties' expectations realistic?
- How are all of the affected parties feeling now (doctor, parents, family, Alan, you)? Regardless of the outcome of the decision, do all involved feel they had a voice and their views were respected?
- How well did you do in the situation? Did you act as an effective advocate for the rights of Alan and his parents? Did the power and authority of the physician or hospital in the situation unduly influence you?
- Were policies and procedures in place to guide you in the process of working out this situation?
- Has anything changed since the dilemma came to light? Has a greater good been achieved for future situations? Have future situations been made easier as a result of the things learned in this situation? Has any aspect of this ethical decision now become a universal policy at the institution?
- Are further actions required in terms of this or like situations?

For guidelines to help you avoid common errors when making ethical decisions,

Go to Student Resources, Chapter 44, **Supplemental Materials: Common Errors in Decision Making,** on Davis*Plus*.

Look for a Good Compromise

Even if you believe you know the right thing to do, others may not agree with you, or there may be constraints that prevent you from doing it. For example, in the case of Alan, even if you decided the right thing to do is give him a blood transfusion, (1) his parents do not agree with you, and (2) the law says you cannot do so without his parents' consent. This will happen often—much more often than a true dilemma, in which you cannot *decide* the right thing to do. No matter how well we work together, there will always be ethical problems and disagreements. Many cases are full of complexity and uncertainty, and sometimes the price of acting on your beliefs is extremely high. For example, what might have happened if the surgeon had infused blood without the Freses' consent? What might have happened if you had refused to talk to the parents as the surgeon asked you?

Many times, it will be possible to reach a "good" compromise. A **good compromise** is one that preserves the integrity of all parties. This means that:

- **The discussions are carried out in a spirit of mutual respect**—that all viewpoints are respected and considered.
- **The compromise solution itself is ethically sound**; that is, you should be able to provide a principles-based rationale for the compromise, as well as for each of the opposing positions. In the case of Alan and his parents, there probably is no compromise position between "give blood" and "don't give blood." Perhaps the parents would agree to one, but no more than one, transfusion; but that is hard to justify ethically. If one transfusion is acceptable (to honor nonmaleficence), why not two or three? If two transfusions are against their religious beliefs, why would one be acceptable? Nevertheless, in many cases compromise is possible.

So how do you compromise without losing moral integrity? First, realize there is more at stake than the issue itself ("Is a blood transfusion right or wrong?"). There are some things that are inherently good in compromising.

- **First, it is never good to settle things by force** (as you would if you got a court order to transfuse Alan without his parents' consent). You have probably heard the old saying "Might doesn't make right." A compromise can preserve the rights of the less powerful party in a disagreement.
- **Keeping peace on a nursing unit is good for both the nurses and patients.** When there is upheaval and moral suffering, care quality throughout the unit can suffer. A compromise can bring peace.
- **There is intrinsic good in taking part in a process in which we try to see things from others' points of view.** It may make us more open minded, more creative, and less judgmental.
- **Keep in mind that most issues do contain room for reasonable differences of opinion.** In the Meet Your Patients scenario, can you see that both sides are people of good will who have ethical reasons to justify their opinion? Also, there is often room for doubt, on your own part, about the morally best action to take.
- **A compromise may achieve mutual respect.** It is a significant thing to reach a settlement in which each party feels assured of the other's respect for its seriousness and sincerity.

Given all those ideas, a person of good will might want to reexamine and back away from a very strong opinion. Remember, sometimes your position isn't all that strong, and the other position isn't all that weak (as in the case of Alan). There is also always the chance that you may have made an error in your reasoning or have not completely understood some facts of the case. Ethical disputes can be settled only if you are willing to engage in discussion and admit that the other people might have a point! There may be cases in which you cannot compromise (perhaps Alan's case is one), but don't listen to people who say, "You can never reach agreement on ethical issues. They are too complex." It is possible to achieve integrity-producing compromises, and in nursing it is often necessary.

What Are My Obligations in Ethical Situations?

As you can see, in making ethical decisions, nurses rarely act alone. Usually you will be one of several healthcare professionals and family members who will jointly arrive at the best decision. Your role when an ethical decision is needed includes the following:

- ***Be aware of and sensitive to issues*** so you can identify them when they arise. Educate yourself—attend workshops, read, and talk to other nurses.
- ***Assume responsibility for your own moral actions.*** Even if you do not have the "last word" about what happens to a patient or about what others do, you are always responsible for your own actions in every situation.
- ***Function as a team member*** when ethical problems arise. Realize you should have input—no one profession has full moral expertise—and realize that your input can be valuable.
- ***Support the patient and family members*** while they are making the decision and afterward. Listen. Ask questions. Provide unbiased information. Be helpful without being too directive or judgmental.
- ***Support patients who are not being allowed to decide.*** For example, in the Meet Your Patients scenario, you would want to be sure Alan's wishes were considered, if possible. However, if the parents insist on deciding for him, against his wishes, he may need a great deal of emotional support.
- ***Use and participate in institutional ethics committees*** if you are given the opportunity.
- ***Most important, advocate for your client.*** You may need to balance your client's autonomy with the

wishes of family members or the responsibilities of other healthcare professionals to the patient. As an advocate, you may find yourself in conflict with other team members or family members. Frequently you and the others involved will have different ethical perspectives.

- ***Continually strive to improve your ethical decision making.***

Use and Participate in Institutional Ethics Committees

There is no easy way to decide which principle should outrank another principle, or which person's values are best in a given situation. For this reason, many healthcare institutions have ethics committees. These interdisciplinary committees typically include nurses, doctors, clergy, ethicists, and lay representatives. Ethics committees develop guidelines and policies, provide education and counseling, and, in the case of ethical dilemmas, review the case and provide a forum for the expression of the diverse perspectives of those involved. Ethics committees usually follow one of three models when discussing a dilemma: the autonomy model, the patient benefit model, and the social justice model.

Autonomy Model The **autonomy model** is useful when the patient is competent to decide. This model emphasizes patient autonomy and choice as the highest value. For example, if this committee knew Alan's (Meet Your Patients) wishes, they might be inclined to try to persuade his parents to do as Alan wants.

Patient Benefit Model The **patient benefit model** assists in decision making for the incompetent patient by using substituted judgment (i.e., what the patient would want for himself if he were capable of making these issues known). If Alan is unconscious and cannot say what he wants, this committee would probably ask Alan's parents, family, and friends, "What do you think Alan would want? Have you ever heard him talk about a situation such as this?"

Social Justice Model The **social justice model** focuses more on broad social issues involving the entire institution, rather than on a single patient issue (Yoder-Wise, 2010). Such a committee might consider whether, in general, an institution ought ever to seek a legal order to act against the wishes of the parents. Or they might discuss whether supporting parents' religious beliefs in this instance might have implications for supporting other types of religious beliefs in future cases.

- What is an integrity-producing compromise?
- What are the functions of an ethics committee?
- What does the mnemonic MORAL stand for?

Be a Patient Advocate

The role of advocates is to safeguard clients against abuse and violation of their rights. When you think of the rights and values described, for example, in the *Patient Care Partnership* and in nursing codes of ethics, you can see how important this role is. Be aware that advocacy in everyday clinical practice is less about the patient's legal rights and ethical theory, and more about such seemingly "routine" measures as obtaining a new prescription when an analgesic is ineffective, even if it does mean telephoning the prescriber for the third time on your shift. The advocacy role requires you to be respectful, considerate, courageous, persistent, and concerned with justice.

Why do you think advocacy is so important? Why can't patients do these things for themselves? The following are some of the reasons.

You Have Special Knowledge That the Patient Does Not Have Diseases, treatments, and the healthcare system are so complex that when clients become ill, they may not have the energy to deal with the complexity, even if they do have the necessary knowledge. You may need to help them to "jump through the necessary hoops" to get what they need. When patients' rights are denied or when patients do not have the ability to exert their rights, nurses have a responsibility to step in. "Without the advocacy and protection of rights there really are no rights" (Bandman & Bandman, 2002, p. 23).

One Aspect of Your Professional Role Is to Defend Patients' Autonomous Decisions Recall that the ANA Code of Ethics requires you to be a patient advocate (see Boxes 44-1, 44-2, and 44-3). As a nurse, you will be called on to defend your patients' autonomous decisions, even if you do not agree with them and even if they conflict with the opinions of others involved in the patient's care. You may find yourself the sole supporter of a patient's right to choose for himself the direction of his care.

Nurses Have a Special Relationship With Patients You may find that you are able to obtain information about a patient that is not available to professionals of other disciplines. In general, nurses interact with patients over longer time intervals and are involved in very personal activities, especially in inpatient settings. They often become the most trusted caregivers. Details about family life, coping styles, personal preferences, fears, and insecurities are all more likely to be discussed during the time involved in nursing interventions than in the brief minutes of interaction when a physician makes rounds. In addition, patients may perceive less social distance between themselves and the nurse and, therefore, feel freer to confide in them. The nurses' point of view can be a valuable asset to resolving an ethical problem satisfactorily. Of course, many providers have long-standing relationships with their patients; however, this does not negate the importance of the nurse's input, which may provide a different perspective.

Your Role as an Advocate Is to Inform, Support, and Communicate You should inform clients of their rights and provide the information they need to make informed decisions, if they are capable of doing so. Then you must remain objective and support them in the decisions they make, even if (perhaps especially if), you do not agree with the patient's decision. If others are not respecting client choices, you will need to intervene. This may simply be a matter of conveying information and clarifying the client's wishes to family or healthcare professionals (e.g., "I know how hard it is for you to let him go, but your dad says he has made peace and is ready to die. His treatments make him feel even more ill, and he simply does not want to fight anymore."). Advocacy may require you to arrange for the client to consult with a religious leader or an attorney for advice and support, or may require you to consult an institutional ethics committee.

Inform Patients About Advance Directives Data reveal that 28% of home healthcare patients, 65% of nursing home residents, and 88% of discharged hospice patients had at least one advance directive on file (Jones, Moss, & Harris-Kojetin, 2011), so there is work to be done with certain populations. An important advocacy intervention is to ask patients whether they have an advance directive and to inform them about advance directives if they do not. Even people who have an advance directive do not always, or even often, understand the statements they have checked in the boxes on the form. Take the time to go over the form with them if they are able to do so. See Chapters 17 and 45 if you need further discussion of advance directives.

For guidelines that will help you to function effectively as an advocate,

Go to Chapter 44, **Clinical Insight 44-2: Guidelines for Advocacy,** in Volume 2.

Improve Your Ethical Decision Making

By now, you should understand that you cannot avoid making moral decisions in nursing. A recent study pointed out the need to promote nurses' development from the conventional (rules-bound) to the post-conventional (reasoning) stage of moral development. The study found that when nurses were faced with ethical dilemmas they tended to use conventions (e.g., rules, procedures) as criteria for decision making rather than patients' personal needs and well-being (Dierckx de Casterlé, Izumi, Godfrey, et al., 2008). As a full-spectrum nurse, you should use the following suggestions so you will be prepared when ethical issues arise.

- **Use Theoretical Knowledge.** Review nursing and other literature for discussion of cases and experiences of other nurses. This will give you a broader view of the problems you may confront and the strategies for managing them. Become familiar with the various codes of ethics, the *Patient Care Partnership*, and ethical frameworks and principles.
- **Use Self-Knowledge.** Examine your personal value system. Explore the influences of your religion, cultural beliefs, and personal experiences. This will help you to recognize your comfort zone with specific ethical issues.
- **Use Practical Knowledge.** While still a student, you should ask to attend either ethical rounds or an ethics committee meeting. As a graduate nurse, you could volunteer to be a member of your institution's ethics committee or plan to attend nursing ethics rounds to familiarize yourself with the types of ethical problems that occur at your institution.
- **Consult Reliable Sources.** Attend ethics education programs and talk about issues with other healthcare providers. Attorneys, ethicists, and members of the clergy can provide helpful perspectives.
- **Share.** Regularly engage in discussions with the staff on your unit to determine differences in value systems and to collaborate proactively to work out methods that can be used to resolve ethical dilemmas effectively. When you are faced with a difficult moral decision, consult with peers, coworkers, and teachers. Seek guidance and support.
- **Evaluate.** After the situation is resolved, evaluate your decision and the effects of your actions. You should be able to learn from even the worst decision. And when everything goes well, you can file your strategies away to use in future similar situations.

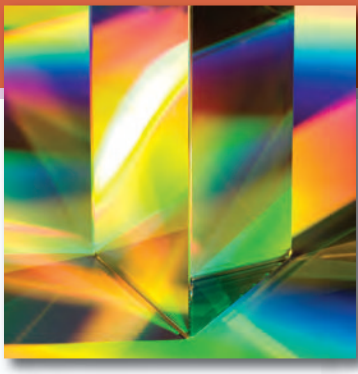
CHAPTER 45



Legal Accountability

Learning Outcomes

After completing this chapter, you should be able to:

- Identify four basic sources of law.
- Discuss direct implications of the Nurses' Bill of Rights to practice.
- Relate the impact of the Health Insurance Portability and Accountability Act (HIPAA) to patient rights and protections.
- Discuss the effects of the Patient Self-Determination Act on healthcare practices.
- Describe accommodations that conform to the Americans With Disability Act (ADA).
- Apply state mandatory reporting laws to patient care situations.
- Apply the concepts of Good Samaritan laws to nurses' actions.
- Identify seven rights of nurses within the healthcare workplace.
- Discuss how nurse practice acts provide the foundation for nursing practice.
- Explain disciplinary actions for unacceptable nursing decisions or actions.
- Discuss basic principles of criminal law that affect nursing practice.
- Compare and contrast intentional and unintentional torts.
- Discuss common causes of malpractice litigation.
- Describe the phases of the litigation process in a nursing malpractice case.
- Identify strategies to minimize liability in nursing practice.

Key Concepts

Law
Liability
Malpractice

Meet Your Nurse Role Model

A nurse with 3 years of experience on a medical-surgical unit arrives at work and discovers that two of her colleagues called in sick, including the charge nurse. The nursing supervisor informs her that she will need to assume the charge nurse role, in addition to assuming care for three patients. Feeling frustrated, the nurse ponders whether she should just quit and find another job, but, nevertheless, decides to accept the assignment. Two hours into the shift, one of her patients begins to experience complications, requiring blood glucose checks every 2 hours and frequent monitoring. In addition, one of the nurses becomes ill and is replaced by a float nurse from the labor and delivery unit. The nurse contacts the nursing supervisor and requests additional assistance, but is told no other nurse is available and that the supervisor is involved with an emergency situation on another unit. The nurse begins to analyze this situation from a legal perspective to determine the best course of action.

- Should the nurse have accepted the assignment? If yes, what factors should the nurse have considered before accepting the assignment?
- If the nurse should not have accepted the assignment, could she have been charged with abandonment?
- How should the nurse handle this situation?

Theoretical Knowledge knowing why

In clinical practice, nurses are often confronted with situations that present legal issues. You must have an understanding of the legal guidelines governing nursing practice to protect yourself, your patients, your colleagues, and your employers. The theoretical knowledge in this chapter, combined with the critical thinking model in Chapter 2, will help you to answer questions related to the Meet Your Nurse Role Model scenario.

ABOUT THE KEY CONCEPTS

The concept of **law** can be described as a binding practice, rule, or code of conduct that guides appropriate actions and defensible decisions of an individual or a group. Laws protect society by establishing acceptable patterns of behaviors and are enforceable by a controlling authority. Nurses are legally responsible for their own actions and this responsibility cannot be delegated—this is the basis for liability in nursing practice. **Liability** means that the person is financially or legally responsible for something. **Malpractice** is one source of legal liability. It means that a professional person has failed to act in a reasonable and prudent manner. If someone is harmed, the professional may be held liable.

WHAT ARE THE SOURCES AND TYPES OF LAW?

The U.S. Constitution establishes three branches of government: executive, legislative, and judicial. Each branch has specified powers that are designed to equalize power among the three and to provide a system of checks and balances. Laws are derived primarily from four sources: (1) the Constitution, (2) statutes, (3) administrative bodies, and (4) the courts (Table 45-1).

Constitutional Law A **constitution** is a system of fundamental laws and principles that prescribes the nature, functions, and limits of a government. The U.S. Constitution is the superior law of the land and applies to all states throughout the United States. Thus, all state and federal laws must be consistent with the U.S. Constitution. The U.S. Constitution limits the powers of the federal government and gives each state the power to govern itself and to pass laws to promote the health, welfare, order, and security of its citizens (police power). Each state has a similar structure that likewise establishes the governing system for the state, its cities, and municipalities. Any law that conflicts with the U.S. Constitution is considered invalid or void. If you would like to see the seven articles of the Constitution,

Go to Chapter 45, **Tables, Boxes, Figures: ESG Box 45-1, Articles of the United States Constitution.**

Statutory Law A **statute** is a law passed by Congress or by a state legislative body. Congress passes laws for the benefit of society as a whole, whereas states use their police power to pass laws to ensure the general health, safety, and welfare of their citizens. Nurse practice acts (NPAs) are examples of statutory law. NPAs, passed by the legislative body of each state, are regulations that govern the profession of nursing.

Administrative Law Formally defined, **administrative law** refers to the laws that govern the activities of administrative agencies. Administrative agencies are created at

Table 45-1. Branches of Government and Sources of Law

	Branches of government	
	EXAMPLES	**DESCRIPTION**
Executive	U.S. president, attorney general, secretary of state, state governors	Authority to execute and enforce laws.
Legislative	Congress (House of Representatives + Senate)	Make or formulate laws.
Judicial	U.S. Supreme Court; state and local courts	Interpret statutory law and decide cases and controversies.
	Type/sources of law	
	EXAMPLE	**QUESTION POSED**
Constitutional Law	Freedom of speech	Can an employer prevent internationally educated nurses from speaking in their native language in the work environment?
Statutory Law	Definition of nursing	What is the nurse's scope of practice (duties and responsibilities)?
Administrative Law	Delegation and supervision	Is the registered nurse legally responsible for tasks or assignments delegated to other nurses?
Common Law	Affirmative duty	Does a registered nurse have a responsibility to exercise an independent judgment to prevent harm to patients?

the federal level by Congress and at the state level by its legislative bodies. As applied to nursing, within each state's nurse practice act, the legislative body created a board of nursing to enforce the NPA. The board creates rules and regulations that define and expand on the provisions in the NPA necessary to ensure compliance with its statutory mission—to regulate the practice of nursing.

Common (Judicial) Law A compilation of laws made by judges or courts is known as **common law**. Also referred to as *case law*, common law is based on common customs and traditions. It comes from legal principles and guidelines that judges use to determine the outcome of legal cases.

WHAT LAWS AND REGULATIONS GUIDE NURSING PRACTICE?

As a professional nurse, you will need to understand the various laws and regulations that guide nursing practice. Laws and regulations at the federal and state levels have a direct impact on the nurse's actions and decisions.

Federal Law

Several federal statutes have direct implications for professional nursing practice. Many NPAs require nurses to have knowledge of such laws. This section presents some federal laws.

Bill of Rights

The first 10 amendments to the U.S. Constitution are known as the *Bill of Rights*. It clearly identifies, and in many ways limits, the role of government in individuals' lives. Many of these rights have direct implications for healthcare, including the rights of nurses and of patients. For example, protecting patients' privacy rights is a fundamental role of the professional nurse that is derived from the Fourth Amendment to the U.S. Constitution. If you would like to review all the amendments in the Bill of Rights,

Go to Chapter 45, **Tables, Boxes, Figures: ESG Box 45-2, The Bill of Rights, Amendments 1–10 of the Constitution,** on Davis*Plus*.

ThinkLike a Nurse 45-1

- Develop a scenario illustrating how a nurse might protect a patient's right to privacy.
- What is one thing a nurse can do to respect a patient's property rights?

Health Insurance Portability and Accountability Act (HIPAA)

The Health Insurance Portability and Accountability Act (HIPAA) was passed by Congress in 1996 to:

- Protect health insurance benefits for workers who lose or change their jobs

- Protect coverage to persons with preexisting medical conditions
- Establish standards to protect the privacy of personal health information

Under HIPAA rules, healthcare agencies and their employees must take steps to ensure the confidentiality of the patient information and medical records. Nurses and other healthcare providers must protect the patient's right to privacy by not sharing patient information with unauthorized individuals. In addition, HIPAA allows patients to see, make corrections to, and obtain copies of their medical records. The cases in the following box highlight the importance of understanding and complying with the safeguards created under HIPAA.

Case: Violation of a Patient's Privacy

- A nursing assistant spent 8 days in jail after being convicted of invasion of personal property for posting graphic photos of elderly and disabled patients on Facebook.
- Several emergency room nurses were fired after painting the face of an unconscious obese patient with charcoal, making unprofessional comments, and taking pictures of him with their cell phones.
- A man who received the registration face sheets of patients admitted to the hospital from the manager of the hospital's trauma unit and provided them to personal injury attorneys was sentenced to 33 months in federal prison for violation of HIPAA.

Emergency Medical Treatment and Active Labor Act (EMTALA)

The Emergency Medical Treatment and Active Labor Act (EMTALA) requires healthcare facilities to provide emergency medical treatment to patients who seek healthcare in the emergency department (ED), regardless of their ability to pay, legal status, or citizenship status. The obligation is for the medical facility to provide medical screening to determine whether an emergency exists and to stabilize the patient before transferring him or her to another healthcare facility.

Case: EMTALA

A patient presented to the ED with complaints of chest pain. Per protocol, the triage nurse obtained information on the onset and severity of the pain and medications taken by the patient. She then completed a focused history and assessment, obtained a pulse oximeter reading, and ordered an electrocardiogram (ECG) and lab work. She reported the results to the ED physician, who consulted a cardiologist. The patient initiated a lawsuit alleging he suffered heart damage because of a delay in treatment. Ruling in favor of the hospital and nurse, the court noted that the care received via protocol was the same as that of any patient with similar complaints (*Byrne v. Chester Co. Hospital*, 2013).

ThinkLike a Nurse 45-2

A 54-year-old uninsured and unemployed woman arrives at the ED of a small private hospital complaining of chest pain and nausea. The triage nurse calls the on-call physician, who instructs the nurse to send the patient to the county hospital several blocks away. The nurse assesses the patient and contacts her supervisor, who tells her to contact the medical chief of staff to inform him that the patient is in need of emergency treatment.

- Discuss whether the nurse's action was appropriate or inappropriate.

Patient Self-Determination Act

The Patient Self-Determination Act (PSDA) of 1991 recognizes the patient's right to make decisions regarding his own healthcare, based on the information provided to him by the healthcare provider, regarding the medical or surgical treatment options available, the benefits, risks, and alternatives. Box 45-1 describes agency and healthcare workers' responsibilities under the PSDA.

There are two types of legal written advance directives: the living will and the durable power of attorney for healthcare.

A **durable power of attorney for healthcare (DPOA)** identifies a person who will make healthcare decisions in the event the patient is unable to do so. The person given the right to make decisions is called the *surrogate decision maker*. The surrogate has the right to make the medical decisions for as long as the person is not able to do so for himself (is incompetent).

Case: Durable Power of Attorney

Mr. Green was in a coma as a result of head trauma experienced in a motor vehicle accident. In his DPOA, he had designated his brother, Joey, as his surrogate. Although Mr. Green is married with two adult children, Joey is the person legally recognized to make decisions regarding Mr. Green's healthcare. Two weeks later, Mr. Green came out of the coma and regained the ability to make decisions. At that point, Mr. Green no longer required Joey as a surrogate.

BOX 45-1 ■ The Patient Self-Determination Act

The Patient Self-Determination Act requires healthcare facilities to:

- Provide written information to each patient regarding the right to make decisions, including the right to accept or to refuse medical treatment and the right to make advance directives.
- Document in the patient's medical record the presence or absence of advance directives.
- Provide education to the staff, healthcare providers, and community on advance directives.
- Follow state law as it relates to advance directives.
- Treat everyone the same regardless of the presence or absence of advance directives. (Facilities may not discriminate.)

A **living will** is prepared by an alert and oriented (competent) individual that gives directions to others about the person's wishes regarding life-prolonging treatments if the person becomes unable to make those decisions. As a legal document, the requirements may vary from state to state. However, language common in the living will gives the person the opportunity to specify treatment in numerous areas (Box 45-2).

The American Nurses Association (ANA, 2010a) highlighted the nurse's role in advance care planning and counseling in a 2010 position statement. As a nurse, you have the following responsibilities:

- Listen to patients to identify their concerns, expectations, and hopes regarding end-of-life care.
- Review patients' documented preferences upon admission to healthcare facilities.
- Recognize that advance care planning is a continual process and not a one-time execution of documents.
- Encourage patient and family participation in healthcare decisions about advance directives and end-of-life decisions.

You might want to ask the following questions about advance directives as a part of your nursing admission assessment:

What is your understanding of an advance directive, including the living will and durable power of attorney for healthcare?
Do you have an advance care directive?
If you have an advance care directive, do you have a copy with you?
Do you wish to initiate an advance care directive?
Who will make your healthcare decisions if you are unable to do so? Have you discussed your end-of-life choices with this person, significant others, and your provider?

BOX 45-2 ■ Sample Living Will Language

If I am in a terminal condition, irreversible coma, or in a persistent vegetative state, my wishes are as follows:

I ✹ **do** ✹ **do not** want to be in or taken to a hospital.

I ✹ **do** ✹ **do not** want pain medications to keep me comfortable.

I ✹ **do** ✹ **do not** want cardiac resuscitation, including drugs and electrical shock.

I ✹ **do** ✹ **do not** want mechanical respiration/artificial respiration.

I ✹ **do** ✹ **do not** want tube feeding or any other artificial or invasive form of nutrition (food).

I ✹ **do** ✹ **do not** want hydration (water), via tube or intravenous.

I ✹ **do** ✹ **do not** want blood or blood products.

I ✹ **do** ✹ **do not** want any form of surgery or invasive diagnostic tests.

I ✹ **do** ✹ **do not** want kidney dialysis.

I ✹ **do** ✹ **do not** want antibiotics.

Case: Durable Power of Attorney

Mrs. Terry Schiavo collapsed in her Florida home in 1990 after a suspected potassium imbalance secondary to bulimia, and was without oxygen for about 5 minutes. She suffered severe brain damage. Terry Schiavo did not have a living will. According to Florida law, her husband became her legal guardian, and thus the decision maker regarding her medical treatments. In November 1992, Mr. Schiavo won a medical malpractice lawsuit for $1 million from her physician on the theory that he failed to diagnose Mrs. Schiavo's bulimia. In 2000, Mr. Schiavo petitioned the court to have her feeding tube removed. Her parents opposed the action. During the next 5 years, extensive legal battles ensued. Finally, the court ruled in favor of removing the feeding tube. Mrs. Schiavo died on March 31, 2005. It was lack of a living will that (1) allowed this situation to go on for so long and (2) made it impossible to know for sure what Terry Schiavo would have wanted. It's all guesswork without a documented living will (Shepard, 2009).

Americans With Disabilities Act

The Americans With Disabilities Act (ADA) of 1990 provides protection against discrimination of individuals with disabilities. A person has a ***disability*** if he has a physical or mental impairment that substantially limits one or more major life activities, has a record of such impairment, or is regarded as having an impairment (ADA Amendments Act of 2008). In general, the ADA says that employers must provide reasonable accommodations within the work setting to allow employees with disabilities to perform their jobs.

Case: ADA Accommodations

- A nurse with a substance abuse addiction was caught using illegal drugs. She was allowed to return to work after rehabilitation. Her employer had a policy that provided employees with a last-chance agreement. When the nurse returned to work, she was reassigned to a job that did not require her to dispense medication. She was given periodic drug tests.
- A nurse with fibromyalgia syndrome was provided accommodations to help her overcome extreme fatigue and pain at work. She switched from evening to day shift to better regulate her sleep pattern, eliminated working two consecutive 12-hour shifts, and changed from full-time to part-time employment status.
- A nurse with insulin-dependent diabetes had difficulty maintaining glucose control. Her employer provided consistent times for breaks and lunch and privacy to check blood sugars and administer insulin as needed (Job Accommodation Network, n.d.).

To read about strategies to accommodate disabilities and follow the Job Accommodation Network link,

Go to Chapter 45, **Resources for Caregivers & Health Professionals,** on Davis*Plus*.

KnowledgeCheck 45-1

- Which federal law requires healthcare agencies to provide patients with information about advance directives?
- Which federal law ensures that patients can receive emergency treatment regardless of their ability to pay?
- What protections are provided to patients by the Department of Health and Human Services "privacy rule" of HIPAA?

State Laws

In addition to federal law, many states have laws that directly impact nurses' actions and behaviors. These include mandatory reporting laws, Good Samaritan laws, nurse practice acts, and medical malpractice statutes.

Mandatory Reporting Laws

The law in various states requires healthcare workers to report communicable diseases. You also have a duty to report physical, sexual, or emotional abuse or neglect of vulnerable individuals (e.g., children, older adults, the mentally ill), whether you suspect it or have actual evidence of it. The intent is to protect people who cannot protect themselves and to protect society against the spread of communicable diseases. Mandatory reporting laws also protect you when reporting abuse. In most instances, the identity of the reporter is kept confidential. If you fail to report certain communicable diseases or child abuse, you can be charged with a criminal misdemeanor or be subject to disciplinary action by the board of nursing.

The duty to report takes priority over the patient's right to privacy. Therefore, if you report abuse or neglect, you cannot be charged with violating a patient's right to privacy (e.g., under HIPAA). Since the mandatory reporting laws vary from state to state, you should be familiar with the law in your state.

Case: Mandatory Reporting

A high school principal and superintendent were arrested and charged with failure to report child abuse for allegedly failing to notify the Department for Children and Families of a student allegation of inappropriate touching by a teacher. State law mandates that allegations of child abuse be reported within 24 hours after allegations are brought (Wellington, 2013).

Good Samaritan Laws

Good Samaritan laws are designed to protect from liability those who provide emergency care to someone who is in need of medical services. To successfully use the Good Samaritan defense, the following elements must be present:

- Care was provided in an emergency situation.
- Person(s) providing the care did not cause the emergency or injury.
- Care was provided in a reasonably competent manner.
- Care provided must be voluntary (not paid or eligible for payment).
- Person receiving care did not object to receiving care.

Additional guidelines nurses should follow to ensure their protection by Good Samaritan laws include the following:

- Call 911, or have someone else call, as soon as you can.
- Do not leave the person unless you transfer care to an equally competent professional.
- Place the person under the care of emergency personnel, physicians, or advanced practice nurses as soon as possible and follow their instructions.
- Do not accept money or any other form of compensation for the services provided.

Good Samaritan laws vary from state to state. You should be familiar with the law in your state. A typical case involving Good Samaritan laws is as follows:

Case: Good Samaritan

A registered nurse is leaving the hospital after working a 12-hour shift, when she witnesses a single-person motor vehicle accident. She calls 911, stops, and approaches the accident scene, where she smells gasoline. Fearing that the car will explode, she pulls the accident victim from the car, places him flat on the ground, and assesses his injuries. She puts pressure on his bleeding femoral artery and stays with him until the ambulance arrives. The victim has spinal cord injuries and sues the nurse for removing him from the car. The nurse is protected from liability by the Good Samaritan law.

Nurses working in healthcare environments may not be protected by Good Samaritan laws if they already have a responsibility to provide care to those in need.

Case: Good Samaritan

The court denied the Good Samaritan defense for two physicians who were sued for malpractice. The physicians were salaried employees of a college of medicine that contracted with a community health clinic to provide backup emergency services for medically complex cases. The college of medicine received a fixed amount of money from the clinic for such services. The two physicians were called to assist with a complicated delivery that resulted in the death of an infant from injuries received during birth. One physician billed the clinic for her services and the

(Continued)

court ruled that, based on the relationship, the physician rendered emergency services for a fee. The other physician deviated from policy and did not submit a bill. However, the court ruled that a provider who is eligible for payment is not protected from liability under the Good Samaritan doctrine simply because he does not bill for his services (Rodas v. Seidlin, 2011).

Nurse Practice Acts

Nurse practice acts (NPAs) are statutory laws passed by each state's legislative body that define the practice of nursing. Nurse practice acts are designed to:

- Regulate nursing practice to protect the health, safety, and welfare of the general public.
- Define the scope of nursing practice.
- Approve programs providing prelicensure nursing education to students.

The components of NPAs are discussed in more detail later in the chapter.

Medical Malpractice Statutes

Medical malpractice refers to a lawsuit brought against a healthcare provider for damages (e.g., money) when there has been death of, injury to, or other loss to the person being treated. Laws governing medical malpractice vary from state to state, primarily regarding the time frame for bringing a lawsuit (statute of limitations) and the amount of monetary compensation allowed. To protect themselves from personal losses, many healthcare providers purchase malpractice insurance, which provides them with an attorney to defend against the claim and pay the damages (money) awarded to the claimant by a judge or jury. Malpractice is discussed in more detail later in this chapter.

Other Guidelines for Practice

In addition to federal and state laws, other practice guidelines may define what constitutes reasonable and prudent nursing care.

Institutional Policies and Procedures

Institutional policies and procedures usually are more specific and detailed than standards set by professional organizations. They describe care that is reasonable, appropriate, and expected in the context of that facility. You must be familiar with these policies and procedures because they can be used as evidence of a violation of a standard of care if you failed to follow them. Healthcare facilities should not have policies and procedures that conflict with the nurse practice act, professional standards of practice, the ANA Code of Ethics for Nurses, and other documents that guide nursing practice. If you encounter conflicts, or if a policy is not working well, you should bring the matter to your supervisor's attention and/or contact the board of nursing in your state for an advisory opinion.

American Nurses Association Code of Ethics

The ANA Code of Ethics (2001) describes the standards of professional responsibility for nurses and provides insight into ethical and acceptable behavior. It describes nurses' obligations for safe, compassionate, nondiscriminatory, and quality care while defining commitments to self, the patient, the employer, and the profession.

The Code of Ethics is not a law, and therefore you would not be charged with criminal offenses for violating the code's provisions. In many situations, there is a fine line between what is legal and what is ethical. When confronted with a situation, to avoid legal jeopardy you should ask yourself, "Is there a law that relates to this situation?" If the answer is yes, you should understand the guidance provided by the law. If you cannot follow the law in good conscience, talk with your supervisor or seek legal advice. If there is no law, or if it seems immoral or unethical to you, ask, "What guidance is provided under the Code of Ethics?" Your action should be consistent with the code, if at all possible. The ANA code guarantees the patient the right to dignity, privacy, and safety. And that the nurse will:

- Be accountable and competent
- Use informed judgment
- Maintain employment conditions conducive to quality patient care
- Protect the client from misinformation and misrepresentation
- Collaborate with other healthcare professions to meet the patient's healthcare needs

A nurse who violates a provision of the Code of Ethics may have to defend her action to the state board of nursing. Also, in a malpractice suit, courts may look to these codes to judge whether the nurse's action was at the level expected by the profession. However, you must understand that the code will not likely protect you if you break a law or fail to follow agency policies, even if you believe the law to be immoral. If you need more information on nursing codes of ethics, see Chapter 44.

Patient Care Partnership

The Patient Care Partnership (PCP) replaced the American Hospital Association's Patient Bill of Rights. The PCP brochure is available in eight languages that explain in detail to patients that during hospitalization, they should expect:

- High-quality care
- A clean and safe environment
- Involvement in care
- Protection of privacy
- Help when leaving the hospital
- Help with billing claims

Like the ANA Code of Ethics, these rights are not necessarily legally binding, but they can provide evidence by which to judge whether the patient's care and environment met reasonable and appropriate standards. For more information on the Patient Care Partnership, see Box 44-3.

American Nurses Association Nurses' Bill of Rights

The Nurses' Bill of Rights is a policy statement adopted by the ANA to identify the seven conditions that nurses should expect from their workplace that are necessary for sound professional practice. It provides a framework for employers to understand what nurses need for a safe work environment and to support nurses as they address such issues as unsafe staffing, workplace violence, and mandatory overtime (ANA, n.d.a). The Nurses' Bill of Rights highlights that nurses have the right to:

- Practice in a manner that fulfills their obligations to society and to those who receive nursing care
- Practice in environments that allow them to act in accordance with professional standards and legally authorized scopes of practice
- A work environment that supports and facilitates ethical practice as defined by the Code of Ethics for Nurses
- Freely and openly advocate for themselves and their patients, without fear of retribution
- Fair compensation for their work, consistent with their knowledge, experience, and professional responsibilities
- A work environment that is safe for themselves and for their patients
- Negotiate the conditions of their employment, either as individuals or collectively, in all practice settings

American Nurses Association Standards of Practice

The ANA (2010b) Standards of Practice have three components:

1. *Professional standards of care* that incorporate the nursing process in the diagnostic, intervention, and evaluation aspect of patient care
2. *Professional performance standards* that identify the various role functions of the nurse in direct patient care, quality of practice, ethics, education, communication, research, leadership, collaboration, resource management, collegiality, and environmental health
3. *Practice guidelines* for the various specialty areas that are developed by professional organizations (e.g., American Association of Critical Care Nurses).

If you need to review the ANA Standards of Clinical Nursing Practice, refer to Chapter 1, Table 1-3. Standards establish the minimum level of competency for nurses. Nurses are expected to follow the standards that apply to their specialty areas. For a list of the Scope and Standards of Practice for the various clinical areas published by ANA,

Go to Chapter 45, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

ThinkLike a Nurse 45-3

Recall the Meet Your Nurse Role Model scenario. Would the nurse have done the right thing if she had decided not to accept the assignment and leave the facility immediately?

- What standards, guidelines, and laws would apply to determine whether the nurse's behavior was in accordance with standards of practice?
- Which statements in the ANA Nurses' Bill of Rights might the nurse use to justify her actions?

Nurse Practice Acts

As you have learned, nurse practice acts (NPAs) contain a provision that creates and empowers a state board of nursing to regulate the practice of nursing in that state. All 50 states, the District of Columbia, and the four U.S. territories have established boards of nursing. Although NPAs can vary from state to state, they all have common components, because states used ANA guidelines in developing their regulations. A state's nurse practice act usually includes the following:

- The authority of the board of nursing, its composition, and powers
- A definition of *nursing* and the boundaries of nursing practice
- Standards for the approval of nursing education programs
- The requirements for licensure of nurses
- Grounds for disciplinary action against a nurse's license

If you would like to see specific standards of care found in a typical nurse practice act,

Go to Chapter 45, **Tables, Boxes, Figures: ESG Box 45-4, Minimum Acceptable Standards of Care Required by a Typical State Nurse Practice Act,** on Davis*Plus*.

Case: Nurse Practice Act

Mejonus X Institute is advertising an associate degree nursing program that can be completed in 12 months at a cost of $45,000. You are interested in the program, but are not sure whether the program is legitimate. Your initial investigation of the program should start with the state board of nursing, which approves nursing education programs. A list of approved nursing programs can usually be found on the state board of nursing Web site in many states.

Requirements for Licensure

Perhaps the most important function of state boards of nursing is establishing and enforcing the requirements for licensure. Unlicensed health providers pose a danger to the health, safety, and welfare of the general public because they have not met the specified standards to ensure a minimum level of competency to enter the nursing profession. In most states, the applicant for licensure must:

- Graduate from an approved or accredited nursing program
- Meet the established character criteria
- Undergo a criminal background check and fingerprinting
- Pass the NCLEX-RN or -PN exam
- Pay an application fee
- Some states, such as Texas, may require applicants to pass a jurisprudence examination before receiving a permanent license.

Case: Applicant for Licensure With a Criminal Conviction

An RN applicant for licensure was convicted 3 years earlier of a misdemeanor theft. He was sentenced to 12 months in jail, with 11 months of the sentence suspended; 2 years of probation; 180 hours of community service, and $1,200 in fines. The board of nursing approved his application for licensure by examination and reprimanded him for the criminal conviction.

Special Cases of Licensure

To protect the public, licensing is meant to ensure that practicing nurses have met the minimum competencies set by the state.

Mutual Recognition Model (MRM)/Nurse Licensure Compact Certain states, through a multistate agreement, allow nurses whose primary state of residency is in a compact state to practice in other compact states without obtaining a new license. You must obtain licensure "by endorsement" if you change your state of residency to another compact state or if your state of residency is not a member of the compact. To be *licensed by endorsement*, you do not have to retake the NCLEX examination, but must apply to the new state and fulfill any of that state's application requirements such as fingerprinting, background check, transcripts, and fees.

Case: Multi-State Compact

Roberto is a clinical nurse residing in Overland Park, Kansas (his primary state of residency), and originally licensed in Kansas after passing the NCLEX-RN exam. He is now employed at the Children's Hospital on the other side of the state line in Missouri. Roberto is required to maintain active licensure in the state where he is employed. He received an RN licensure by endorsement in the state of Missouri by meeting the requirements of the Missouri State Board of Nursing, but did not have to retake the NCLEX-RN.

Government/Military Personnel Another special case of licensure involves nurses employed by the military, Veterans Administration, Public Health Service, or other entities of the federal government. These nurses may practice in other states without obtaining a new license as long as they are practicing within the scope of their employment.

Case: Special Case of Licensure

Jane is a clinical nurse in the U.S. Air Force Reserve. She is licensed in the state of Texas, but is assigned to a military hospital in Nevada for her 2-week annual military tour. Jane will not need to obtain a license in the state of Nevada to practice at the military hospital.

Scope of Practice

The scope of nursing practice is found in the definition of nursing at the various levels. Nurses must be familiar with the definition of *nursing* at their level to plan and implement care that is consistent with their scope of practice. A nurse who practices outside the scope of practice can be charged with violation of the nurse practice act.

Nurse practice acts vary slightly state by state. However, in most states, the licensed practical nurse (LPN) scope of practice is limited in assessment privileges and interpretation of clinical data. Typically, LPN/LVNs do not have authority to alter nursing care plans. You must know the requirements of your state because they determine the legal limits of your practice. The following landmark case should make clear that no one, including an employer or physician, can increase a nurse's legal scope of practice.

Case: Scope of Practice

A physician delegated to an LPN the task of administering a polio booster to a 2-year-old boy. The nurse put the boy over her knee and proceeded to give the injection. The boy moved and the needle broke off in his buttocks, where it remained for 9 months despite attempts to surgically remove it. Since the Washington State Nurse Practice Act at that time did not allow LPNs to give injections, the nurse was in violation of the Nurse Practice Act by performing a task that was outside of her legal limits (Barber v. Reinking, 1966).

For the ANA (n.d.b) model of professional practice regulation,

Go to Chapter 45, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

Disciplinary Actions

The state board of nursing can take disciplinary actions against your license for violation of the NPA.

A disciplinary action usually involves some or all of the following:

- The process begins with a complaint from an individual, employer, or professional organization that the nurse has engaged in unprofessional conduct.
- The complaint is then assigned to an investigator to determine its legitimacy or validity.
  - If the investigator decides the complaint is invalid or does not constitute a violation of the NPA, it will be dismissed.
  - If the complaint may violate the NPA, the investigator gathers additional information by contacting the nurse, interviewing witnesses, and reviewing documents and records.
- The case may be heard by the board of nursing members, who will decide whether the nurse violated the NPA and the appropriate punishment. To fulfill the due process requirements of the Fourteenth Amendment, the board of nursing must provide you with:
  - **Notice** of the charges against you
  - **Evidence** that supports the charges
  - **A hearing** in which you have the opportunity to cross-examine the witnesses and to present your own evidence and witnesses
- If you are not satisfied with the board's actions and punishment, you can appeal your case to the appropriate state court.
- At every stage during the disciplinary process, you have the right to have an attorney present. Questions that you should ask of a potential attorney include the following: (1) How many of your cases were in the area of administrative law and procedures? (2) How many times have you represented clients in front of professional boards, such as the board of nursing?

For examples of nursing actions that constitute unprofessional conduct,

Go to **Tables, Boxes, Figures: ESG Box 45-3, Actions, Behaviors, or Omissions That Constitute Unprofessional Conduct,** on Davis*Plus*.

ThinkLike a Nurse 45-4

A registered nurse was assigned to care for a 76-year-old patient who had a stroke (brain attack). On entering the room, the nurse found the patient surrounded by 10 family members. The nurse requested the family members leave the room so she could conduct her initial assessment and perform any related treatments. They did so. The nurse provided care in a professional, unhurried, and gentle manner. As she was leaving, the patient said, "Thank you. You are a wonderful nurse." Later, the nursing supervisor told her the patient told his family members that the nurse had spoken harshly to him and had yanked his arms. The family stated they would file a complaint with the hospital administrator and the board of nursing.

- Are there grounds for disciplinary actions? What should the nurse do?

KnowledgeCheck 45-2

How does each of the following protect patients?

- The Patient Care Partnership (PCP)
- Nursing codes of ethics
- Mandatory reporting laws

Credentialing

Many healthcare disciplines, including nursing, use a voluntary form of self-regulation called **credentialing**. In the legal sense, credentialing includes accreditation and certification. Having credentials implies that the person or agency has met higher standards than the minimum (e.g., licensure).

Accreditation Most nursing boards establish educational requirements for nursing programs and continuing education courses within a given state. The board usually requires that for a nursing program to be approved, it must meet the requirements for accreditation established by the Accreditation Commission for Education in Nursing or the Commission on Collegiate Nursing Education and by the state NPA. This helps ensure students receive education that meets the minimum standard for quality and that patients are cared for by safe practitioners.

Accreditation also applies to institutions other than educational facilities; for example, hospitals seek accreditation by The Joint Commission. This is intended to ensure a minimum standard quality of care is provided.

Certification Another form of credentialing is **certification**. Through certification and licensing, the board identifies nurses who are qualified for advanced practice (e.g., clinical nurse specialists, midwives, and nurse practitioners) or for certification in a subspecialty, such as emergency nursing or pediatric nursing. In some states, the board establishes the criteria for certification, including (1) educational preparation, (2) clinical experience, and (3) certification by other professional organizations. In other states, the nurse may obtain an advanced practice license only if she is first certified by a national organization, such as the American Nurses Credentialing Corporation or a specialty organization. Not all states require certification for advanced practice nurses.

WHAT IS CRIMINAL LAW?

Criminal law deals with wrongs or offenses against society. It may result in prosecution (legal action) by the state or federal government for engaging in behavior that constitutes a crime. A **crime** is a violation of a law as defined by a legislative body. The legislature also specifies the punishments for the crime. State-level criminal laws vary from state to state.

There are two "levels" of crimes: misdemeanors and felonies. The primary difference is the possible punishment.

- **Felonies** involve crimes punishable by more than 1 year in jail (e.g., murder, assisted suicide, rape/sexual assault, stealing drugs and equipment, felony abuse). A person convicted of a felony loses the right to vote, hold public office, serve on a jury, and possess firearms. The person may also lose any professional license.

- A **misdemeanor**, compared with a felony, is a minor charge. Misdemeanors involve less than a year in jail. They include crimes such as assault, battery, and petty theft. You may also lose your nursing license if you are convicted of a misdemeanor that involves crimes against persons or that can cause harm to others.

An emerging issue in the nursing profession is whether nurses who accidentally cause harm to patients should be charged with criminal offenses (e.g., a nurse accidentally administers the wrong drug to a patient and the patient dies). In the past, these cases have been dealt with under civil law and by the board of nursing. Now state prosecutors are beginning to bring felony and misdemeanor charges against these nurses.

Case: Criminal Law

Several patients complained that their pain medication was not working. A review of the health records of the patients assigned to the nurse revealed that all but one of her patients who received pain medication had similar complaints. When confronted, the nurse admitted to stealing the patients' pain medication and giving them saline. She also admitted to using other nurses' passwords to steal narcotics. The nurse was terminated and reported to the board of nursing. She refused to enter an impaired nurse's program. Her license was revoked after a hearing. She also faced criminal charges for theft of controlled substances.

Case: Criminal Law

Joan, RN, was arrested for stealing computer equipment and wound supplies from the hospital that were valued at $55,000. She was charged with grand larceny, a felony. Two weeks before her trial, she entered into a plea deal that reduced the charge to a misdemeanor with probation for 6 months.

For an expanded discussion of criminal law,

Go to Chapter 45, **Supplemental Materials: Criminal Law,** on Davis*Plus*.

WHAT IS CIVIL LAW?

In contrast to criminal law, in which the state or federal government brings charges against a person, civil law involves a dispute between individuals or entities. A settlement in civil law often results in the guilty party paying monetary damages. The two types of civil law are contract law and tort law.

- **Contract law** involves a written or oral agreement between two parties in which one party accepts an offer made by the other party to perform (or not perform) certain acts in exchange for something of value. A breach of contract occurs if either party does not comply with the terms of the agreement. An example would be an employment contract.
- **Tort law**, in comparison, deals with wrongs done to one person by another person that do not involve contracts. A tort is a civil wrong and there are three types of tort: quasi-intentional torts, intentional torts, and unintentional torts.

What Are Quasi-Intentional Torts?

Quasi-intentional torts involve actions that injure a person's reputation. The overall concept for these torts is defamation of character. All four of the following essential elements of **defamation of character** must be present. The communication (written or oral) about the person:

- Was false
- Was made to another person or persons
- Caused the defamed person to experience shame and ridicule and had a negative impact on the person's reputation
- Was made as a statement of fact rather than as an opinion

Libel is the written or published form of defamation of character. **Slander** is the spoken or verbal form of defamation of character. A person is not guilty of defamation of character if the statement made about the other person is true or if the person has the protection of a "privilege," such as reporting possible child abuse.

Case: Quasi-Intentional Torts

The nursing supervisor calls you into a conference room and states, "I know that you have been stealing (diverting) narcotics from the unit and injecting yourself with it while at work. It shows, because your work is sloppy and you are falsifying your documentation. You are a poor excuse for a nurse." Before you can defend yourself, the supervisor turns and leaves. The statements are not true. Nurses in the conference room try to console you. The supervisor has committed slander.

What Are Intentional Torts?

An **intentional tort** is an action taken by one person with the intent to harm another person. The harm does not have to be violent, hostile, or cause a significant amount of pain or distress to the other person. The person must have merely intended to cause harm or known the action would bring about the harm. Intentional torts may also be prosecuted under criminal law. For example, a nurse who is sued for malpractice in civil court may also be charged with a homicide if a patient died because of the nurse's actions. Intentional torts most commonly encountered in nursing are assault, battery, false imprisonment, and invasion of privacy.

Assault

An assault occurs when a nurse intentionally places a patient in immediate fear of personal violence or offensive contact. An assault must include words expressing an intention to cause harm and some type of action. For example, a nurse has committed an assault if she says to the patient "I will slap you" and raises her hand as if to slap the patient. The combination of the words and action causes the patient to believe the threat will be carried out.

Battery

A **battery** is committed when (1) an offensive or harmful physical contact is made to the patient without his consent, or (2) there is unauthorized touching of a person's body by another person. To avoid charges of battery, always obtain informed consent before providing certain treatments. On admission to healthcare facilities, patients sign a general consent form, which usually covers routine aspects of nursing care, such as vital signs and patient assessments. However, when performing any invasive procedure, such as inserting a catheter or intravenous line, you should always explain the procedure to the patient and obtain his consent before beginning.

Case: Battery—Withdrawal of Consent During the Procedure

A patient having blood drawn experienced severe pain and requested the technician to stop while he was attempting to fill a second vial of blood. The technician continued and filled the second vial. Ruling in favor of the technician, the court noted that the patient did not allege that stopping the treatment was feasible and without harm. No battery is committed if, at the patient's request, the procedure cannot be stopped without creating harm (*Pallacovitch v. Waterbury Hosp.*, 2012).

Assault and Battery

An **assault and battery** occurs when there is the intent to cause a person fear combined with an offensive or harmful contact.

Case: Assault and Battery

A patient admitted for an elective surgical procedure complained that the automatic blood pressure cuff was causing her extreme pain and demanded it be removed. The nurse did not immediately remove the cuff as requested by the patient. The nurse was guilty of a battery, but not assault, because there was no evidence the nurse intended to create or cause fear or pain (*Coulter v. Thomas*, 2000).

False Imprisonment

False imprisonment is the restraining of a person without proper legal authorization. It includes any type of unjustified restriction on a person's freedom of movement—for example, when nurses restrain patients without their permission or when patients are involuntarily committed to mental health units. False imprisonment can involve the use of physical restraints (e.g., vest or wrist restraints) or chemical restraints (e.g., sedatives or opioids). You may restrain patients who pose an immediate threat to themselves or others. However, you must immediately obtain the proper authorization to continue the restraint.

Against Medical Advice If a competent patient wishes to leave the healthcare facility, you should contact the nursing supervisor and the primary care provider. The patient must be informed of the risks associated with leaving, and given the choice to stay and receive treatment or to sign out against medical advice (AMA). You need to be aware of the hospital policy and procedures on AMA discharges.

Invasion of Privacy

Invasion of privacy violates a person's right to be left alone. The law recognizes that a person's personal life should not be opened up for public scrutiny and the person has the right to freedom from unwanted interference in her private affairs. A person has the right to:

- Have her private information protected
- Not be falsely portrayed or intentionally misrepresented in character, beliefs, or actions
- Be free from unwanted intrusion (spying, eavesdropping).

Examples of violating right to privacy include discussing patients in public places (e.g., elevators, cafeterias), photographing patients without their permission, providing information to news media without consent, searching a patient's personal belongings without permission, and releasing medical information without the patient's consent.

Fraud

Fraud is the false representation of significant facts by words or by conduct. It can occur, through making false statements, falsifying documentation, or concealing information that should have been disclosed. It is intentionally misleading or deceiving another person to act (or not act) for the personal gain of the one committing the fraud.

Case: Fraud

A home health nurse was terminated from her salaried position after she refused to falsify Medicare documentation. She was instructed to bill patients for more visits than actually occurred, alter care records to prolong a patient's eligibility for home services, and admit a non-homebound patient to homebound therapy (*Admore v. Nurse Connection, Inc.*, 2009). An award of damages and attorney fees in her favor was upheld by the court of appeals (*Nurse Connection, Inc. v. Admore*, 2010).

What Are Unintentional Torts?

The most common type of unintentional tort involving healthcare professionals is negligence or malpractice. **Negligence** is the failure to use ordinary or reasonable care or the failure to act in a reasonable and prudent (careful) manner. *Malpractice* has a similar definition, but applies only to professionals, such as nurses and physicians. It is defined as the failure of a professional person to act in a reasonable and prudent manner. A malpractice lawsuit may occur when such actions cause injury or death to the patient. The person bringing the lawsuit is the **plaintiff** and the person who must defend against the lawsuit is the **defendant**.

Malpractice/Negligence Liability

To win and recover damages (money) in a malpractice lawsuit, the plaintiff must prove four elements (duty, breach of duty, causation, and damages). The elements must be proved by a "preponderance of the evidence," in other words, with enough evidence to tip the scale in his or her favor.

Duty The nurse–patient relationship creates this legal obligation. A duty forms when the patient is assigned to the nurse or seeks treatment from the nurse, or when the nurse observes another person doing something that could harm the patient.

Breach of Duty A breach of duty occurs when the nurse fails to meet standards of care. Attorneys look to several sources of information to identify the standards of care and to determine what a reasonable and prudent (careful) nurse would have done in the situation. These sources include the NPA, job descriptions, hospital policies and procedures, textbooks, professional standards and guidelines developed by professional organizations, and the nursing code of ethics.

The attorney will usually hire an **expert witness** who is a nurse with advanced education or experience. The purpose of an expert witness is to educate the judge and jury on the local practice of nursing and how the nurse's actions or omissions failed to meet acceptable practice for nurses.

Causation The breach of duty or deviation from acceptable standards of care by the nurse must be the direct and proximate cause of the injury suffered by the patient. Causation is usually established based on the testimony of experts, such as physicians, advanced practice nurses, or other healthcare professionals, who can clearly show the connection between the nurse's action or omission and the resulting injury to the patient.

Case: Causation

A nurse forgot to change the patient's dressing at the scheduled time, but changed it 3 hours later. The hospital policy reads that nurses must administer medications or perform prescribed treatments within 30 minutes before or 30 minutes after the scheduled time. The patient did not experience any harm or infection. In this case, there were both existence of and a breach of duty, but the breach of duty did not cause any harm or injury to the patient. Therefore, if a malpractice action had been brought, the plaintiff would not have received an award. Nurses are encouraged to report medication and treatment errors as promptly as possible so that actions can be taken to prevent and/or minimize injury to the patient.

Damages In civil cases, the remedy for the harm the patient suffered is money. The judge or jury will award the plaintiff money to compensate him for pain and suffering, lost wages, additional medical bills, and other losses. In some cases, the plaintiff may be awarded punitive damages (additional money) for grossly negligent or wrongful behavior by the healthcare provider.

Case: Damages

The plaintiff began to bleed excessively after a nonemergency cesarean section delivery. The nursing staff notified the provider of the bleeding, decreased blood pressure and oxygen level, and increased heart rate. The patient had surgery to repair a uterine laceration and returned to the recovery room, where additional blood products and fundal massage were prescribed. The obstetrician indicated that nurses did not notify him that the patient's pulse rate was high and the blood pressure and blood oxygen content remained low. He admitted that he had not read the monitor. The nurses did not notify the physician because they assumed he reviewed and interpreted the monitor readings each time he visited the patient. Two hours after being admitted to the recovery room, the patient arrested, was resuscitated, but suffered severe brain damage. She died 6 months later when mechanical ventilation was removed.

Analysis of the Case:

Duty: Based on the nurse–patient relationship

Breach of Duty: Failure to communicate to the provider; failure to intervene to counteract the patient's deteriorating condition

Causation: Appropriate medical care was not provided based on the patient's signs and symptoms

Damages: In the above case, a settlement was reached with a present value of about $1.35 million.

(Nurses Service Organization, 2013a)

KnowledgeCheck 45-3

- Distinguish negligence from malpractice.
- Distinguish civil law from criminal law.
- Under which type of law (constitutional, statutory, administrative, or common law) does each of the following fall?
  - A defendant claiming the right not to incriminate himself under the Fifth Amendment
  - A nurse having her license revoked by the state board of nursing
  - The wording of a state nurse practice act
- Define *plaintiff* and *defendant* in the context of civil law.

Toward Evidence-Based Practice

Falls: Care plan not updated, Jury finds negligence (2010). *Legal Eagle Eye Newsletter for the Nursing Profession*. Retrieved from www.nursinglaw.com/fallcareplan4.pdf

A 51-year-old male with a below-the-knee amputation, kidney failure, and liver disease was placed in a nursing facility. He had short-term memory deficit and problems with balance. He was able to ambulate with a prosthesis and cane, but spent most of his time in a wheelchair. After falling on five previous occasions, he fell and broke his hip and died 9 months after the hip repair surgery. The expert witness, testifying about the breaches of duty, indicated that each fall required more than documentation of the fall in the resident's medical record. Likewise, given his short-term memory deficits, reminding him to ring his call bell was not an effective safety measure; he required new safety equipment (e.g., wheelchair tipping guards, bed brakes).

O'Dea v. Cardinal Cook Care Center, 2010 WL 3232844 (Sup. Ct. New York Co., New York, June 20, 2010).

1. Nurses knew the patient suffered from short-term memory deficits. What do you think was the basis for the court decision that the patient's injury was due to negligence of the nurse?

Nurses Service Organization. (2011). August 2011 Legal Case Study. Retrieved from http://www.nso.com/case-studies/article/293.jsp

A 74-year-old female was admitted to the hospital for repair of a T4 fracture from a fall that occurred in her kitchen. She had a rheumatoid arthritis with hand and feet deformities and osteoporosis. After an uncomplicated surgery, the patient was transferred to the orthopedic unit. The next morning, after completing a physical and fall risk assessment, the nurse assisted the patient to the bedside commode. She instructed the patient to call her when finished to be assisted back to bed and left the room. The commode collapsed and came apart, causing the patient to fall and fracture her tibia, which required additional surgery. She was discharged to a skilled nursing facility for 7 weeks and required the assistance of a walker or wheelchair. The patient sued, alleging that the nurse breached the standard of care by not staying with her or providing her with a bedpan. A verdict was returned in favor of the nurse.

2. What factors led to a defense verdict in this case?

Nurses Service Organization. (2013c). Woman falls while home health nurse is weighing her—fractured leg— surgery, rehab and need for continuing care— $791,573 verdict. January 2013 Legal Case Study. Retrieved from http://www.nso.com/case-studies/casestudy-article/315.jsp

A 74-year-old patient was receiving home healthcare services after a total knee replacement. The nurse instructed the patient to stand on a scale in the bathroom to obtain her weight. The patient fell and broke the fibula and tibia in one leg. Her injuries required additional surgery, hospitalizations, and continuing 24-hour home care. She sued the nurse, alleging a breach of duty by not providing her with proper support given her unstable balance and weighing her in a confined space. The jury rejected the nurse's defense that proper support was given and weighing her in the bathroom was reasonable.

3. In this case, what was the basis for the jury's decision that the patient's injury was the result of the nurse's negligence of the nurse?

ThinkLike a Nurse 45-5

- Give one nursing example of each: negligence, malpractice, damages.
- Can you think of one nonfraudulent example of a nurse's being untruthful with a patient? Do you think that the circumstances described in your example make the untruthfulness justifiable?
- Can you think of an example of a nurse's committing assault, other than the one given in the text?

Vicarious Liability

You are legally accountable for your actions or inactions. This is a common legal principle that should guide your behavior. It means that you can be sued for behavior or omissions that deviate from acceptable standards. In certain circumstances, though, the law will assign liability to a person or entity that did not directly cause the injury but with whom you have a special kind of relationship. This type of liability is known as **vicarious** or **substituted liability**. The various types of vicarious liability existing under common law are discussed below.

Captain of the Ship This principle applies to situations in which a physician (e.g., surgeon or obstetrician) is held liable for the negligence of another healthcare provider. *Captain of the ship* usually applies to surgical suite situations. Many states no longer recognize it as protection for the nurse because the nurse is still liable for her own actions.

Borrowed Servant Doctrine This doctrine relieves the primary employer of liability for the actions or omission of its employee when the employee was borrowed by another person. In theory, the borrower becomes liable for the actions of the employee. This would apply, for example, to agency nurses.

Respondeat Superior The Latin term **respondeat superior** means "let the master answer." The employer must answer for the negligent acts or omissions of its employees, who are functioning within the scope of their employment. For example, a nurse working within the scope of her practice as a labor and delivery nurse makes a medication error; the hospital can be sued for the nurse's error.

KnowledgeCheck 45-4

- Define these terms: *assault, battery, fraud, slander, libel, negligence, malpractice*.
- State the four elements of malpractice.

LITIGATION IN CIVIL CLAIMS

Litigation is the formal process wherein the legal issues, rights, and duties between the parties are heard and decided (adjudicated). The litigation process follows several stages: (1) pleading and pretrial motions, (2) discovery, (3) alternative dispute resolution, (4) trial, and (5) appeal.

Pleading and Pretrial Motions

The litigation process starts when the plaintiff files a complaint. A **complaint** is a legal document outlining how the plaintiff has been harmed by another person. Once the case is filed with the court, the complaint is served on (delivered to) the defendant. The complaint identifies the plaintiff, the specific allegations and time frame, the standards allegedly breached (e.g., behavior[s] or omissions), the persons (defendants) involved, and the harm suffered.

If you are served with a complaint, you must immediately notify your employer. In addition, if you have malpractice insurance, you must also notify your insurance company. You will need an attorney to defend you. Your attorney has a specified time within which to file an answer (response) to the complaint. The answer addresses each of the allegations (unproven accusations). As a defendant, you should not contact the plaintiff or the plaintiff's attorney or discuss the case with coworkers or friends. The facility's risk manager and your attorney will advise you. Cooperate fully and be honest in all your answers.

Discovery Phase

The discovery process allows for both parties to gather facts and evidence about the case that can be used at trial. Discovery is designed to make sure there are no "surprises" during the trial. Attorneys may obtain discovery through written questions (*interrogatories*), requests for documents and other evidence, and by *depositions* (attorneys orally question parties to the lawsuit under oath, as though they were testifying in court). You may be deposed (questioned) as either a fact witness, a party to the lawsuit (defendant), or an expert witness. A *fact witness* is someone who was present when the incident occurred, whereas the defendant will testify about the care provided and the actions taken.

Deposition may occur several years after the incident, so you may not remember specific information. You should prepare for the deposition by reviewing the medical records and any other evidence that may exist regarding the lawsuit. During the deposition, listen to your attorney, do not volunteer information, take your time before answering each question, and provide only objective information. Always tell the truth, but base your answers on facts; do not speculate. If your attorney objects to any question, immediately stop and do not provide an answer unless directed by your attorney.

Alternative Dispute Resolution

Lawyers and involved parties usually try to resolve disputes before going to trial. The three most common methods of alternative dispute resolution are as follows:

- **Negotiation** takes place informally between the lawyers for the plaintiff and the defendant in an attempt to settle the case prior to trial.
- **Mediation** is the attempt to resolve the dispute using a neutral third party. The primary role of the mediator is to help the parties focus on the issues and to facilitate communication to identify what is needed to reach a resolution.
- **Arbitration** involves a third party making a decision after hearing the evidence and information from both parties.

Trial Process

If the dispute cannot be resolved and is not dismissed by the court during pretrial motions, the case goes to trial. Malpractice cases are usually heard by a jury. After hearing all the evidence and reviewing submitted documents, the judge or jury makes a decision, which is either dismissal or the award of damages.

Appeal

After the judge or jury has made a decision, either party has the opportunity to present post-trial motions, move for a new trial, or appeal the verdict and/or damages to a court of appeals. The court of appeals will review the transcript and documents from the trial and determine whether errors (e.g., improper evidence allowed, proper evidence denied, improper jury instructions) were made during that trial that resulted in an unfair verdict. The court of appeals can uphold the verdict or dismiss the verdict, in part or in whole, and remand (send back) the case to the trial court with special instructions.

KnowledgeCheck 45-5

- Identify the phases of the trial process.
- How is arbitration different from mediation?

PracticalKnowledge knowing how

To decrease your chances of being involved in a malpractice suit, you should know the most common causes of malpractice claims and some practical preventive actions you can take. Keep in mind that causes are often difficult to categorize because they overlap; an error usually results from interlocking causes.

WHAT ARE THE MOST COMMON MALPRACTICE CLAIMS?

Nurses must use the nursing process to provide safe and efficient care to patients. The most common causes of nursing malpractice claims (Box 45-3) can be categorized according to where they fall in the nursing process: failure to assess and diagnose, failure to plan, failure to implement, and failure to evaluate (O'Keefe, 2001; Reising, 2012).

Failure to Assess and Diagnose

As the first step in the nursing process, the failure to conduct an adequate assessment can lead to numerous breaches of duty. Failure to analyze the data and make correct nursing diagnoses can lead to incorrect actions, no action, or improper delegation.

Case: Failure to Assess and Diagnose

In an actual case, a 67-year-old patient who had a total knee replacement had an epidural catheter inserted for pain management. After successful treatment of an episode of hypotension in the postanesthesia care unit, he was transferred to the medical-surgical unit. The registered nurses assessed the patient and delegated direct care to an LPN, although this was denied by the LPN. Three hours later, the patient experienced nausea and vomiting. The patient was found cyanotic and unresponsive 10 minutes later and subsequently died from anoxic encephalopathy. Many facts were disputed among the numerous codefendants and documentation was poor (Nurses Service Organization, 2012).

Safe and competent assessment and diagnosis practices require the nurse to:

- Perform an admission assessment. This duty cannot be delegated to a nursing assistant.
- Analyze the assessment data to clearly identify problems.
- Apply theoretical knowledge to ensure a correct diagnosis. The presenting signs and symptoms should be consistent with the disease process or medical problem. Remember that the nursing diagnosis consists of Patient Response r/t Etiology. When the assessment reveals adverse symptoms, the nurse must report the symptoms to the appropriate provider and carry out the standard nursing care and prescribed interventions.
- Conduct frequent focused assessments until the end of your shift or until the problem is resolved.

BOX 45-3 ■ Common Causes of Malpractice Litigation

Failure to respond, such as not intervening to care for the patient's specific symptoms or expressed request for care.

Failure to educate, such as not answering questions, not teaching self-care measures, or not explaining procedures or equipment adequately on the patient's discharge.

Failure to follow standards of care and institutional policies and procedures. This most commonly occurs in the form of medication errors and failure to follow a provider's orders. It also frequently occurs from failure to use equipment responsibly. Among other reasons, a nurse may fail to follow standards of care when the unit is understaffed or the nurse is inexperienced.

Failure to communicate often comes up when a nurse fails to seek medical authorization for a treatment or fails to notify a physician in a timely manner when a patient's condition warrants action.

Failure to document the following in the patient's record: assessment data (e.g., drug allergies), patient injuries, medication administration details, patient progress and response to treatment, physicians' orders, and telephone conversations with physicians.

Failure to act as an advocate. Nurses must frequently intervene to prevent harm to the patient by other healthcare providers and by relatives and significant others. The following are examples of advocacy errors:

- ***Medical and discharge orders.*** As an example of failure to advocate, suppose two physicians order the same drug for a patient, but under different brand names. The nurse does not recognize that two drugs are the same, so the patient receives twice the normal amount and has a toxic reaction. Other errors occur when the nurse does not question incomplete or illegible orders or does not question discharge orders when she believes the patient is not well enough to be discharged.
- ***Impaired nurses.*** You have a duty under most state nursing practice acts to report impaired nursing practice (e.g., as a result of alcoholism or mental illness) to the appropriate licensing agency. Failure to do so is a failure to advocate for patients.
- ***Family and significant others.*** Advocacy includes reporting neglect and intentional injuries to children, the elderly, and the disabled. Failure to do so may constitute negligence and/or violation of state statutes.

Failure to Plan

The ANA standards specifically requires nurses to formulate a plan of care. The plan of care may be written or unwritten depending on state regulations. Many agencies require nurses to complete nursing care plans or patient care tools as a means of measuring patient outcomes and progress. The plan of care should be consistent with standards of treatments acceptable for the given diagnosis or problem. Safe and competent practices in this category require the nurse to:

- Know the correct approach to treat patient actual or potential problems.
- Have the theoretical knowledge base to successfully plan nursing care for patients.
- Develop a plan of care that is individualized to the patient.

Failure to Implement a Plan of Care

Implementation is the nursing process step in which the nurse performs the care or nursing interventions. Failure to implement encompasses a variety of actions, shown in Box 45-3, Common Causes of Malpractice Litigation.

Failure to Evaluate

Evaluation is the last step in the nursing process. It requires you to make a decision or judgment about the success of your interventions in addressing the client's problems. The duty to evaluate requires an ongoing cycle of the following:

- ***Observing for changes*** after interventions and treatments. You must know the expected outcomes and side effects of medications and treatments, so you can accurately interpret and document anticipated and adverse responses.
- ***Recognizing significance of the change.*** For example, if Mr. Adkins's blood pressure (BP) is usually 140/88, a change to 150/90 after exercise would not be significant for him. But for Mrs. Jonas, whose BP is usually 100/64, a change to 150/90 would be cause for concern.
- ***Documenting or reporting symptoms*** to the appropriate person. If a change is significant, you have a legal duty to report the change to the appropriate provider and to document this change in the appropriate medical record.
- ***Following up on patient responses*** to nursing interventions requires you to know the expected outcomes and side effects of medications and treatments.

KnowledgeCheck 45-6

- State the four requirements of the nurse's duty to assess.
- State four ways in which the nurse may fail to implement a plan of care.
- Give one example of the duty to advocate for a patient.
- List the four components of the nurse's legal duty to evaluate.

Quality and Safety Education for Nurses

Fall Prevention and the Nurse's Legal Responsibilities

Chapter Key Concepts: *Law, Liability, Malpractice, Negligence*

Competency: *Safety (Knowledge, Skills, Attitudes)**

Background: The beginning nursing student needs to acquire knowledge about the legal implications in nursing and develop the skills "necessary to make critical legal and personal accountability decisions about quality of care and patient safety" (March, Cassandra, Adams, et al., 2011, p. 68). Patient falls are considered a hospital-acquired condition, a priority issue for hospitals, and a threat to patient safety (Spoelstra, Given, & Given, 2012). A fall risk assessment and strategies to reduce falls are required to meet The Joint Commission standard.

Scenario: The student nurse is caring for a patient and leaves the bedside to prepare for medication administration. The student fails to return the bed to low position before leaving. The patient attempts to get out of bed, falls, and sustains a hip fracture.

Think About It: In the scenario, what are the legal responsibilities of the student, the faculty member, and the staff nurse?

- ➤ Using the American Nurses Association's *Scope and Standards of Clinical Nursing Practice*, identify which standard of care has been violated.
- ➤ Does the scenario constitute negligence/malpractice on the part of the student?
- ➤ Make a simple Concept Map showing how the following are related:

  The key concept, Malpractice

  The QSEN competency, Safety

  Fall prevention

Discuss answers to the Think About It questions with your peers—if you have difficulty with any of the questions, consult your instructor.

Go to the QSEN Web site, at **http://qsen.org/competencies/pre-licensure-ksas/**

*As reference for your QSEN log box, the QSEN KSA that is most pertinent is:

Demonstrate effective use of strategies to reduce risk of harm to self or others.

HOW CAN YOU MINIMIZE YOUR MALPRACTICE RISKS?

The best way to minimize your risk of malpractice is to practice in a safe and competent manner. You must have the appropriate body of theoretical knowledge for clinical practice, which you are already beginning to acquire. You should also be familiar with your state's nurse practice act, professional standards of practice, and institutional policies and procedures. These provide the legal framework for your practice and help you to evaluate the quality of the care you deliver. Ignorance of the law and of practice standards is no excuse for failing to comply with the law, and it is no defense in a malpractice suit.

You may significantly reduce your risk exposures when you follow these three guidelines:

- Perform timely patient assessments and document your findings for every patient interaction.
- Communicate all changes in your patient's status to the primary healthcare provider and document those changes.
- Use the proper chain of command to ensure appropriate and timely care when the primary healthcare provider is not available (Banford & Budake, 2012).

You will find discussion of other helpful suggestions in the remainder of this chapter. For more tips,

Go to Chapter 45, **Clinical Insight 45-2: Tips for Avoiding Malpractice,** in Volume 2.

If you would like to see the typical standards of care found in a nurse practice act,

Go to Chapter 45, **Tables, Boxes, Figures: ESG Box 45-4, Minimum Acceptable Standards of Care Required by a Typical State Nurse Practice Act,** on Davis*Plus*.

Use the Nursing Process and Follow Professional Standards of Care

The nursing process provides you with a systematic approach to patient care and is the legally acceptable model of decision making in nursing practice. Your documentation should reveal that you have assessed, diagnosed, planned, implemented, and evaluated care based on current and acceptable standards.

Avoid Medication and Treatment Errors

Medication errors are among the most common healthcare errors. To administer medications accurately, you must know the rationale for administering the drug, safe dosage ranges, side effects of the medications, and relevant information to teach the patient about the medication. To prevent medication errors, you should:

- Follow the "rights of medication administration" (see Chapter 26).
- Investigate any patient concerns before giving the medication (e.g., the patient might say, "Is this a new medication? I have not taken this one before.").
- Question prescriptions that are incomplete or that seem inappropriate.
- Make sure the equipment used to administer drugs is working properly.
- Use the correct technique to provide patient treatment (e.g., maintain a sterile field during wound care to prevent an infection).

For tips to help you use equipment properly and safely,

Go to Chapter 45, **Clinical Insight 45-1: Using Equipment Safely,** in Volume 2.

Report and Document

For every suggestion for minimizing malpractice risk, add the reminder "Document what happened." Remember the old adage "If it isn't documented, it wasn't done." If you are ever required to appear in court, the patient record may be the only proof you have of the care you gave. It is unlawful to make false entries or destroy entries in medical records, but do carefully record in detail all care you provide.

Cases: Documentation Can Make a Difference

In an actual case, the plaintiff alleged that the nurse had violated numerous standards of practice including the failure to properly assess the patient, failure to properly monitor vital signs and intake/output, and failure to recognize and respond to signs and symptoms of sepsis. A settlement was reached for $706,250. Weaknesses in documentation revealed that the patient's blood pressure was not documented until day 14 of home care, and evidence of infection—wound appearance and size, amount and appearance of drainage—was not consistently documented by the nurses caring for the patient (Nurses Service Organization, n.d.)

In another actual case, the nurse was accused of failure to properly assess and monitor an impaired, restrained patient and failure to provide proper care in a safe environment. The patient suffered severe burns over 25 percent of his body when the bed linen ignited as he attempted to burn off the restraints with a lighter. A verdict was rendered in favor of the nurse. Strengths in documentation showed that the nurse performed patient monitoring and assessments every 15 minutes as prescribed, missing one time to care for a critical patient. The assessment findings at each check were fully documented in the patient's medical records (Nurses Service Organization, 2013b)

Charting

Key Point: ***A basic principle of charting is that a third person should be able to read your documentation and form a mental picture of your patient and the care provided during your shift.*** Record all interactions with clients, as well as patients' refusal of or noncompliance with treatment. Document telephone conversations with primary care providers, including time, content of the conversation and the action you took. Document the facts; do not editorialize (e.g., do not write, "I could not check on the patient as often as ordered because we were understaffed"). Refer to Chapter 18 for a review of your documentation responsibilities, and use the letters F-A-C-T-U-A-L as a reminder when charting.

F—Your information must be **factual** and objective. Don't chart your opinions.
A—You must be **accurate**: For example, record the vital signs accurately.
C—Your information must be **complete**: Don't omit any important information.
T—You must be **timely**: Chart care as soon as possible after doing it; don't wait until the end of your shift and then try to remember everything that happened.
U—You must be **diligent**. Always document **unusual occurrences**.
A—You must document your **assessment data** and the plan of care.
L—Remember that the patient's chart is a **legal record** and is subpoenaed in a malpractice case.

Go to Chapter 45, **Clinical Insight 45-3: Guidelines for Documenting Care,** in Volume 2.

Incident Reports

If a standard of care is breached or an unusual incident occurs (e.g., a visitor or patient falls or is injured), you should complete an **incident report** (also called *variance report* or *occurrence report*). These reports are used, in part, for quality improvement in the agency and should not be used to discipline staff members or be placed in employees' files. The goal is to prevent the incident from occurring again. In many states, the incident report is not made available as a part of discovery in litigation. It becomes discoverable (available to the plaintiff) if it is mentioned in the medical records. You can prevent an otherwise confidential report from becoming evidence by not writing "Incident report completed" in the patient record.

When reporting an incident, be sure to clearly identify the patient, date, time, and location. Briefly describe the incident in factual terms. Use the exact words of the patient or persons involved and put the information in quotes. Do not speculate, draw conclusions, or place blame. Identify any witnesses to the event or equipment involved. For example:

1900 Demerol 50 mg given intramuscularly.
    Physician order: Demerol 15 mg.
1930 Patient's respirations: 8 breaths/min;
    BP 100/60; skin pale.
2000 Called Dr. Smith. Prescription for naloxone
    (Narcan) 1 mg IV STAT
2005 Narcan given as prescribed. Resp
    12 breaths/min, BP 118/70

You should be prepared to discuss the 30-minute delay between the patient's findings and contacting the physician. The standard of care would require that the physician be notified immediately. Chapter 18 presents additional information on occurrence (incident) reports.

Obtain Informed Consent

Informed consent is the permission for any and all types of care given by the patient with full knowledge of the risks, benefits, costs, and alternatives. For hospital admission and for invasive or specialized treatments or diagnostic procedures, the consent must be written and signed by the patient or the person legally responsible for the patient. The law provides for implied or assumed consent in emergency situations; therefore, written consent is not necessary in an emergency if experts would agree that there was an immediate threat to life or health.

Elements of Consent

To be legally valid, the informed consent should fulfill the following requirements:

- **Completeness.** Healthcare consumers need adequate information to make educated decisions regarding their treatment. Be sure they get information on the nature of the procedure, risks, benefits, post-procedure care and considerations, and treatment alternatives.
- **Clarity and Comprehension.** Language should be appropriate to the patient's educational level, so the patient (or his surrogate decision maker) can understand the explanation. Always ask the patient to describe in his own words the procedure to which he is consenting. If the patient asks, "What will the doctor do during surgery?" the nurse is aware that the patient does not understand the nature of the surgery. She could contact the surgeon.
- **Voluntariness.** The patient must be free to accept or reject the treatment. He must not be pressured or coerced to give consent. There must be no actual or implied threat by anyone to force the patient into having the surgery (e.g., "Mom, if you don't let them do this, I'm never coming back to see you."). Otherwise, the consent is not valid.
- **Competence.** The person must have the ability to understand the information and make a choice about the particular situation (e.g., the ability to decide what clothing to wear does not necessarily mean that the person is competent to decide whether to have surgery). If the person is confused and disoriented, you should contact the case manager or your supervisor for guidance. State law identifies the order of individuals who can make decisions for individuals who are judged incompetent. It is usually the spouse, then parents, then sisters and brothers, and so on. If the person does not have relatives, the court will appoint a legal guardian to make healthcare decisions.

Generally speaking, a competent adult has the legal right to consent to or refuse any treatment. However, this right does not always extend to situations in which an adult is making the decision for a minor. A court sometimes will authorize treatment of a child against his parents' wishes. In some states, a minor who is married or living independently is considered emancipated and can make his/her own healthcare decisions.

The Nurse's Role

As a nurse, your legal role regarding written consent is to collaborate with the primary provider, usually a physician or advanced practice nurse. You may witness a patient's signature on a consent form, but you are not legally responsible for explaining the treatments and options or for evaluating whether the provider has adequately explained them. You must, however, determine that the elements of a valid informed consent are in place, communicate the patient's needs for more information to the care provider, and provide feedback if the patient wishes to change her consent.

Be sure you have the patient's informal, verbal consent for nursing interventions that you perform (e.g., urinary catheterization). Coming to the agency for healthcare implies that the patient consents to usual treatment, such as injections and vital signs. However, you should explain all procedures to the patient before their implementation. If the patient objects, identify the reasons for the refusal, correct any misinformation, and explain the benefits of the treatment. If the patient still objects or refuses, do not proceed. Contact the primary care provider.

In addition to state statutes, case law, and agency policy, The Joint Commission standards provide valuable guidance regarding informed participation in decision making. See Chapter 44 for discussion of informed consent from an ethical perspective.

Maintain Patient Safety

Falls are by far the most common incident reported in hospitals and long-term care facilities. On admission to the facility, all patients should be assessed for risks of falls and "fall precautions" instituted when needed. Simply raising the siderails on the bed is not enough to prevent falls. You may still be found negligent if the patient falls because he called for help and no one came to assist him out of bed, or if the call device was not placed within the patient's reach and he was unable to call for assistance. Several useful tools have been developed for assessing falls, including the Morse Fall Scale. See Chapter 24 for information about meeting patients' safety needs, including falls and use of restraints. For a falls risk tool,

Go to Chapter 24, **Tables, Boxes, Figures: ESG Figure 24-1, Falls Risk Assessment Using the Morse Scale,** on Davis*Plus*.

Maintain Confidentiality and Privacy

Always maintain patient confidentiality unless directed by law to do otherwise (e.g., when a patient is threatening to harm someone). Family members and significant others do not have an automatic right to information about the patient. For example, parents do not have an automatic right to see the medical records of their adult child or minor child who is married or emancipated. Of course, you need to discuss clients' medical conditions with other health team members, but this does not include chatting about the client's personal life or talking about the patient in the lunchroom. **Key Point:** ***You should discuss the patient's health status with those who have a need to know (those involved in the patient's care).***

Another aspect of privacy is to maintain the confidentiality of patient records (e.g., do not leave a patient's health record in locations that are accessible to visitors or nonauthorized staff). Do not give information about patients over the phone unless the agency has a system that enables you to know that you are speaking to a person authorized by the patient. Refer to Chapter 41 if you require advice about maintaining confidentiality of electronic records. Also,

Go to Chapter 18, **Clinical Insight 18-3: Guidelines for Documenting in the Electronic Health Record,** in Volume 2.

Provide Education and Counseling

Part of your role as a nurse is to provide information to patients and caregivers about their illness, medications, and other treatments. This helps to fulfill informed consent requirements and to involve patients in their own healthcare. Use teaching-learning principles to make sure the patient understands, retains the knowledge, and can demonstrate any skills. Ask the patient to repeat instructions to you or to provide a return demonstration of a skill, such as self-injection of insulin. To reinforce understanding, always review written information with the patient. Refer to Chapter 19 for more information on teaching patients.

Delegate According to Guidelines

As a nurse, you are expected to properly delegate to ensure patients receive timely and quality care. This involves implementing the five rights of delegation: delegating the right task to the right person, under the right circumstances, using the right directions and communication, and practicing the right supervision and evaluation. To do this safely, you (the delegator) must know the education background, knowledge, experience, and physical and emotional capability of those to whom you delegate (delegatee). You must also know the scope of practice of the delegatee as determined by the state board of nursing. In addition, you must consider the condition and requirements of the patient. The registered nurse should not delegate to LPNs or nursing assistive personnel patients whose care is complex, unpredictable, require nursing judgment, or involve a high level of interaction.

When delegating, be sure the delegatee understands the assignment. The Case feature "Failure to Assess and Diagnose" identifies numerous breakdowns in the delegation process. The duty to delegate has a corresponding duty to supervise the care and evaluate the outcome. For example, if you assign an LPN to provide direct care for a new postoperative patient, you should obtain hourly updates on the patient's status. If you need to review specific guidelines for delegating, see

Chapter 7. For the ANA and other relevant Web sites on delegation,

Go to Chapter 45, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

Accept Assignments for Which You Are Qualified

As a nurse, when you accept an assignment, you must consider whether the assignment is within your level of education, experience, and physical and emotional capability. The refusal to accept an assignment does not mean that you have abandoned the patient. Your duty to the patient begins once you accept the assignment. **Key Point:** ***You are legally responsible for the assignment that you accept. If your assignment becomes overwhelming and unmanageable, immediately contact the charge nurse or nursing supervisor for assistance.***

Nursing supervisors have a duty to ensure adequate staffing and patient coverage. This means that you must report to the nurse in charge when leaving the patient care unit. Failure to do this may result in charges of patient abandonment. A nurse should never leave the patient care unit without making certain there is another nurse available to provide care to the patient. This does not mean that you must work overtime (e.g., a double shift), as long as you follow established policies and procedures, which will include giving notice and explaining your reasoning (e.g., that you are too fatigued to provide safe care).

If you work a double shift or if a unit is understaffed, you are still liable for any malpractice that you commit. Unfortunately, being "busy" and overwhelmed is not a defense for error. In addition, you have the duty to tell supervisors that staffing is inadequate; be sure to do it in writing. You should know and follow agency policy on how to address short-staff issues.

Participate in Continuing Education

As a nurse, you have a duty to participate in ongoing education in your area of practice and to keep up with new laws, equipment, treatments, and procedures. Be sure to obtain documentation of your attendance. In some states, continuing education is mandatory for license renewal. In states where it is not mandatory, other standards of care still require that you obtain the education and training necessary to implement current nursing procedures and practices. In malpractice cases, the nurse's competency in providing nursing care is frequently an issue. Continuing education is available "for credit" through colleges and universities, other healthcare agencies, conferences, in some nursing journals (e.g., *The American Journal of Nursing*), and online.

Observe Professional Boundaries

Nurses must be careful to maintain professional boundaries, not only with the patient but also with other healthcare providers. Do not accept gifts from patients or encourage attempts to have close personal relationships outside the healthcare setting. Violations of professional boundaries may be physical, sexual, emotional, or financial in nature. Cues to possible overstepped boundaries are listed in Box 45-4.

If you would like more specific information on professional boundaries,

Go to the **National Council on State Boards of Nursing Web site,** at https://www.ncsbn.org/ProfessionalBoundariesbrochure.pdf

Sexual Harassment Be aware of and report the behaviors of staff members who commit sexual harassment. **Sexual harassment** involves the use of power over people lower in the power structure of the organization. It is defined as "unwelcome sexual advances, requests for sexual favors, and other verbal or physical conduct of a sexual nature" if submission (1) is a condition of employment, (2) interferes with job performance, (3) is the basis for employment decisions, or (4) creates a hostile and intimidating work environment (Equal Employment Opportunity Commission, n.d.).

If you witness or experience sexual harassment, your first step is to consult the agency's sexual harassment policy. Every agency receiving federal funding must have such a policy in place. It will tell you how to file a grievance, what forms you need to use, to whom the incident is reported, and what the procedure is for hearing and resolution.

BOX 45-4 ■ Potential Boundary Violations Between Nurse and Client

Excessive Self-Disclosure—Discussing personal problems or intimate details with the client

Flirtation—Communication that is sexual in nature or reveals personal attraction between client and nurse

Secretive Behavior—When the nurse is defensive or guarded about the interaction between client and nurse

"Super Nurse" Attitude—The nurse who acts as though she is the only one who understands and can meet the client's needs

Excessive Attention to Client—When the nurse spends much more time with a particular client than is required by his needs; personal gifts, off-duty visits, or trading assignments are signs of boundary violation.

Unclear Communication—When only part of the story is told with client care. The client might repeatedly seek out the nurse, even when not assigned to his care.

Observe Mandatory Reporting Regulations

As noted earlier in the chapter, most states have laws requiring the nurse to report communicable diseases, known or suspected abuse of patients, and impaired or unsafe professional practice. When you observe violations of the state's licensing regulations, you have a professional and legal responsibility to report them to the appropriate authority. The "authority" varies among states; it may be your immediate supervisor, the board of nursing, or a peer assistance program, often sponsored by the state nurses association. See the section Mandatory Reporting Laws, earlier in the chapter, and the following discussion of reportable situations.

Impaired Nurses

Nurses who come to work under the influence of alcohol or mind-altering substances pose a danger to the health, safety, and welfare of the patients. You have a legal obligation to protect patients from impaired nurses. Always pay attention to the possibility of a coworker using or stealing narcotics. Impaired nurses account for a major percentage of disciplinary actions against nurses. The board of nursing in many states has programs that provide monitoring and support to nurses with substance addictions who seek help as an alternative to disciplinary actions against their license. See Box 45-5 for signs of chemical dependence in the workplace. To determine the magnitude of the problem in your state, go to the state board of nursing's Web site and click on *disciplinary actions*.

BOX 45-5 ■ Signs of Possible Chemical Dependence in the Workplace

Absenteeism

- Frequent unscheduled absences with improbable excuses
- Frequent late arrivals or early departures
- Absences after payday or days off
- Higher than average absences for cold, flu, and minor illnesses

Absent "On the Job"

- Long shift breaks
- Brief, unexplained absences from the nursing unit
- "Locked door syndrome" (excessively long use of restroom)
- Frequent visits to Occupational Health Services for illness on the job

Difficulty Concentrating

- Errors, particularly involving medication or with taking and transcribing verbal orders
- Omitted, illogical, incomplete, or illegible charting
- Taking more time to carry out assignments than is expected given the nurse's skill and experience
- Deterioration of handwriting during the shift
- Overlooking the signs of patient's deteriorating condition

Inconsistent Work Patterns

- Alternating periods of high and low efficiency
- Minimal or substandard work compared with that of peers
- Frequent requests for help with patient assignments
- Altered judgment in patient care decisions

Physical or Emotional Problems

- Nervousness, excessive sweating, tremors of the hands
- Physical or emotional condition changes during shift
- Deteriorating personal appearance, grooming, and hygiene
- Weight gain or loss

Decreasing Efficiency

- Omitting treatments; making bad decisions; showing poor judgment related to patient care
- Requests to be changed to a less supervised shift

Poor Relationships on the Job

- Mood swings, from isolation to angry outbursts
- Uncooperativeness
- Avoidance of contact with supervisors
- Patient complaints of irritability, roughness, or verbal abuse
- Lethargy and hyperactivity
- Emotional hypersensitivity
- Isolation from others

Medication-Centered Problems

- Excessive use of prn psychoactive medications or narcotics recorded for patients
- Increased waste or breakage of controlled substances
- Missing drugs, unaccounted-for doses
- Omission of dates or times from narcotic sign-out sheets
- Patient complaints about lack of pain relief

Personal Life Interferes With Job

- Frequent or excessively long phone calls
- Visitors or unexplained errands during work shift
- Legal problems
- Increased number of accidents

Unauthorized Practice

Your employer will require you to submit verification of current licensure in the state where you are working. If your license expires and you continue to practice nursing, you can be charged with unauthorized practice of nursing. You must report the unauthorized practice of nursing, which means reporting persons practicing nursing without a proper license. In addition, you must know the scope of practice for yourself, LPNs/LVNs, and nursing assistive personnel to ensure practice within professional boundaries. For example, unlicensed personnel cannot perform the initial patient assessment on a newly admitted patient.

Abuse and Communicable Diseases

State laws also require you to report known or suspected child, elder, and spousal abuse and communicable disease. Since state laws may vary, you need to be familiar with them to know what and to whom to report in your area. If you are working for a healthcare agency when you suspect abuse, always report it to your supervisor. If you need to review signs of abuse,

Go to Chapter 9, **Procedure 9-1: Assessing for Abuse,** in Volume 2.

Other Safeguards for Nurses

In addition to the Good Samaritan laws and the ANA Nurses' Bill of Rights (previously discussed), safe harbor laws and professional liability insurance offer some legal protection for nurses.

Safe Harbor Laws

Safe harbor laws, found in the nurse practice act or other state laws, provide for exceptions to certain laws. They protect you from being suspended, terminated, disciplined, or discriminated against for refusing to do (or not do) something you believe would be harmful to a patient. Under these laws, you also have a right to ask for peer review of either the situation or directives that you believe would violate the nursing practice act. You must follow the guidelines required under the safe harbor provisions.

Case: Prepping a Patient for a Surgical Procedure

The nurse cannot find documentation in the patient's medical record for informed consent. Knowing her legal role in informed consent, she refuses to assist with treatment when a patient has not given informed consent. Safe harbor laws protect her from dismissal for denying the surgeon's request for her to obtain informed consent.

Professional Liability Insurance

If you are sued for malpractice, the insurance company pays for the attorney's fees and for any judgment or settlement, up to the policy limits. You should carefully review your insurance policy because most insurance policies have **exclusions** (items not covered by the policy). If the patient's claim arises out of excluded activities, the insurance company will not pay for the costs of litigation and damages. The following are examples of exclusions:

- Sexual abuse of a patient, assault and battery, and other intentional torts
- Injury caused while the nurse is under the influence of drugs or alcohol
- Criminal activity
- Transmission of acquired immunodeficiency syndrome from the nurse to a patient
- Actions that can lead to an award of punitive damages (damages awarded to punish the defendant for egregious acts or omissions)

Types of Coverage

There are two types of malpractice coverage. **Occurrence-type insurance** is most often recommended for nurses, because this policy covers malpractice claims for any injury or damage that occurred during the time the policy was in force, regardless of when the claim was reported and the lawsuit occurred. In contrast, **claims-made insurance** covers only those claims in which the negligent action or omission occurred and the claim was filed or reported during the policy period. To maintain coverage under a claims-made policy after it has lapsed or been canceled, some insurers will offer "tail" insurance. You should consult an attorney to decide which type of policy is best for you.

As a rule, if you work for a hospital or other institution, you will be covered by the institution's insurance. However, it covers you only while you are working within the scope of your employment. For example, you would not be covered during the one day a week that you volunteer at a free clinic. Some legal experts recommend that you purchase individual liability insurance in addition to the coverage provided by your employer. Again, consult an attorney before making a decision.

ThinkLike a Nurse 45-6

Susan, RN, was employed by Landold Nursing Service and assigned to Alvalup Hospital from June 1, 2012, to May 30, 2013. Susan carried her own professional liability claims-made policy during this time. She decided to attend real estate school and not renew her policy. On August 10, 2013, a medical malpractice claim was filed against Susan. Based on this scenario, would Susan have coverage under her policy? What kind of policy should she have obtained to have coverage for the claim made against her?

Student Responsibilities

As a student, you are held to the same standards of care as are licensed nurses. You must be familiar not only with your state's standards of practice, but also with the policies and procedures in the agency in which you have your clinical experiences. Your instructor is responsible for making assignments that are within your competence and for providing clinical supervision. However, this does not release you from your own legal responsibilities. To help protect yourself and your patients:

- Prepare carefully for each clinical experience.
- Never attempt a procedure or make a judgment about which you feel unsure. If you lack the theoretical or practical knowledge for an assignment, notify your clinical instructor immediately.
- Notify your instructor or a staff nurse if your patient's condition changes significantly.
- Unless otherwise arranged, take instructions only from your clinical instructor.

Your nursing school may require you to carry personal professional liability insurance. The school's policy will cover you only for the nursing care you give in your educational experiences. If you are employed as a nursing assistant, for example, the school's policy will not provide coverage for you at work. Furthermore, you are legally permitted to perform only the procedures contained in your job description. For example, even though you administer injections in your student role, you are not licensed to do so in your role as a nursing assistant.

SUMMARY

Ethical and legal issues are a major source of conflict for nursing practice. This chapter discusses only the legal aspects of the major issues. See Chapter 44 for ethical considerations. It is important to be clear in your mind that what is *legal* and what is *ethical* are not always the same thing. On the one hand, an act may be legal (e.g., abortion), even if you consider it unethical. On the other hand, you may believe an action (e.g., assisted suicide) is ethically necessary, but the law may forbid it. You should be aware of the legal consequences that your ethical decisions may bring about. For a more detailed discussion of some major legal issues in nursing (e.g., stem cell research, cloning, reproductive issues, life-sustaining medical treatment),

Critical-Thinking Model

Thinking Process	Description	Questions for Focusing Thinking
Contextual awareness (deciding what to observe and consider)	An awareness of what's happening in the total situation, including values, cultural issues, interpersonal relationships, and environmental influences	• What is going on in the situation that may influence the outcome? • What factors may influence my behavior and that of others in this situation (e.g., culture, roles, relationships, economic status)? • What about this situation have I seen before? What is different? • Who should be involved in order to improve the outcome? • What else was happening at the same time that affected me in this situation? • What happened just before this incident that made a difference? • What emotional responses influenced how I reacted in this situation? • What changes in behavior alerted me that something was wrong?
Inquiry (based on credible sources)	Applying standards of good reasoning to your thinking when analyzing a situation and evaluating your actions	• How do I go about getting the information I need? • What framework should I use to organize my information? • Do I have enough knowledge to decide? If not, what do I need to know? • Have I used a valid, reliable source of information (e.g., patient, other professionals, references)? • Did I (do I need to) validate the data (e.g., with the client)? • What else do I need to know? What information is missing? • Are the data accurate? Precise? • What's important and what's not important in this situation? • Did I consider professional, ethical, and legal standards? • Have I jumped to conclusions?
Considering alternatives	Exploring and imagining as many alternatives as you can think of for the situation	• What is one possible explanation for what is happening or what happened? • What are other explanations for what is happening? What is one thing I could do in this situation? • What are two more possibilities/alternatives? • Are there others who might help me develop more alternatives? • Of the possible actions I am considering, which one is most reasonable? Why are the others not as reasonable? • Of the possible actions I am considering, which one is most likely to achieve the desired outcomes?
Analyzing assumptions	Recognizing and analyzing assumptions you are making about the situation and examining the beliefs that underlie your choices	• What have I (or others) taken for granted in this situation? • Which beliefs/values are shaping my assumptions? • What assumptions contributed to the problem in this situation? • What rationale supports my assumptions? • How will I know my assumption is correct? • What biases do I have that may affect my thinking and my decisions in this situation?
Reflecting skeptically and deciding what to do	Questioning, analyzing, and reflecting on the rationale for your decisions	• What aspects of this situation require the most careful attention? • What else might work in this situation? • Am I sure of my interpretation of this situation? • Why is (was) it important to intervene? • What rationale do I have for my decisions? • In priority order, what should I do in this situation and why? • Having decided what was wrong/happening, what is the best response? • What might I delegate in this situation? • What got me started taking some action? • What priorities were missed? • What was done? Why was it done? • What would I do differently after reflecting on this situation?

Preface

We chose our book title carefully. We have used the words *theory, concepts, application, thinking, doing,* and *caring* because we believe that excellent nursing requires an equal mix of knowledge, thought, and action. Nurses use all of these to express caring. It is knowledge and its application—not just the tasks nurses do—that delineate the various levels of nursing. Even so, skillful performance of tasks is essential to full attainment of the nursing role.

We present our material in two volumes to enable students to focus on material suitable for use in specific venues. Volume 2 was designed to be a compact, easy-to-carry reference to use in the skills lab and in clinical. This volume contains practical, "how to" information for safely performing nursing actions and interacting with real patients. Rationales for each action explain the "why behind the what" to help you practice nursing based on concepts rather than cookbook-style steps. Volume 2 offers practice-based forms, assessment questionnaires, and other clinical tips, but it is not limited to skills and procedures. It includes both thinking and doing, the same as does Volume 1; however, the emphasis is different in each volume. Volume 2 works seamlessly with Volume 1, the Skills Videos, and Davis*Plus* to provide a user-friendly learning experience that will surely stimulate new enthusiasm for learning. For example, throughout Volume 2, students have access to a simulated experience, known as Caring for the Nguyens, through which they apply our full-spectrum model of nursing to learn about the nursing role, the healthcare system, and the real-world application of the content in Volume 1.

Other features in each chapter of this volume include critical-thinking activities (Critical Thinking and Clinical Reasoning), step-by-step procedures and clinical insights (with rationales); exercises to tie the procedures to the skills videos; assessment guidelines and tools; a summary of the main points that were covered in Volume 1; and a knowledge map of the concepts discussed in the chapter. All of these features will be useful during a student's clinical day.

This volume, like Volume 1, will appeal to nontraditional students of the technological generation, encourage independent learning, promote critical thinking, support a variety of learning styles, and assure students that it is possible to achieve excellent nursing despite today's challenges.

We hope you will read the Preface and other introductory material in the front of Volume 1. It explains the philosophical underpinnings for this text and describes in more detail how to use the various pieces of this highly integrated learning package, which is flexible enough to accommodate a variety of teaching styles and curriculums.

CHAPTER 39

Meet the Nguyens

Throughout this text, you will be applying what you have learned as you care for the Nguyen family. In Chapter 1, you will meet Nam Nguyen, a construction work supervisor, who arrives at the Family Medicine Center for his first physical exam in 10 years. It is Nam's knee pain that causes him to seek help because it affects his work. But as you will see, Nam will discover that he has other serious health problems that require him to be more vigilant about his health. As you read and work through the exercises in Caring for the Nguyens, you will also get to know Nam's wife, Yen Nguyen, his grandchild, Kim Phan, other members of his extended family, and his friends as they deal with health issues and life changes.

Your experience in caring for the Nguyens will show you that patients come to you with symptoms but each person brings unique values, lifestyle, and relationships to the encounter. From the Nguyens, you will learn what it means to care for the whole person and how to be a full-spectrum nurse.

Mr. Nam Nguyen is a new patient at the Family Medicine Center. He arrives at the Center for an appointment for a physical exam and completes the following admission questionnaire.

Name: *Nam Nguyen* DOB: *7 / 12 / 50*

Marital Status S M W D Partnered

If applicable, spouse/partner name: *Yen*

Occupation: *Construction supervisor* Spouse/partner occupation: *Daycare teacher*

Does your spouse or partner have any health care problems? If so, please list:

High blood pressure

Do you have children? *Yes* Ages? *30, 27, 22*

Please circle yes or no if you have had the following:

AIDS/HIV +	YES	NO
Allergies	YES	NO
Anemia	YES	NO
Anorexia	YES	NO
Anxiety	YES	NO
Arthritis	YES	NO
Bleeding Disorder	YES	NO
Breast Problems	YES	NO
Cancer	YES	NO
Chicken Pox	YES	NO
Colon Disorder	YES	NO
COPD/Emphysema	YES	NO
Depression	YES	NO
Diabetes	YES	NO
Epilepsy/Seizures	YES	NO
Eye Problems	YES	NO
Gallbladder Disorder	YES	NO
Stomach Problems/Ulcer	YES	NO
Gout	YES	NO
Gynecological Problems	YES	NO
Sexually Transmitted Disease	YES	NO

Headaches	YES	NO
Heart Disease	YES	NO

Pneumonia	YES	NO
Polio	YES	NO
Prostate Problems	YES	NO
Skin Problems	YES	NO
Stroke	YES	NO
Suicide Attempt	YES	NO
Thyroid Problems	YES	NO
Other	YES	NO

Please list your current medications and dosages. Also list over-the-counter and herbal products you use regularly.

Ibuprofen *Ben-Gay Balm on knees*
MultiVitamin 1 per day
Acetaminophen

The Diagnosis

During the visit, the clinic nurse records the following information in Nam's chart.

Height	5 ft 4 in.
Weight	165 lb
BP	162/94 mm Hg
Pulse	84 beats/min
RR	20 breaths/min
Temp	98.2°F oral

Presenting Complaint: Patient states he is here to become established as a patient at the Center and that he has not had a physical exam in more than 10 years. Wife accompanies. He is currently experiencing bilateral knee pain that is affecting his work performance. "I supervise construction workers. To check on things, I have to climb up and down ladders, lift things, and crawl around a lot." Has not missed any work but has been using increasing amounts of acetaminophen and ibuprofen "to get through the day." The medications provide only limited relief. States pain occurs daily even if not at work. Describes the pain as achy and dull. Feels best when he is off his feet. Desires pain relief and checkup. Explains that both parents had heart disease. Wife expresses worry that he may be developing heart problems "because he's so tired after work and he gets short of breath easy."

The nurse explains to Nam that he will be seen by the nurse practitioner shortly. She asks Mr. Nguyen if he would like his wife to be present for the exam. Mr. Nguyen requests that his wife remain in the room.

Zach Jackson, MSN, FNP-BC, is on duty at the Center today. Zach worked as a registered nurse (RN) for more than 10 years in the local emergency department and urgent care clinic. He has been a family nurse practitioner (FNP-BC) for more than 5 years. Zach enters the room and introduces himself to the Nguyen couple. To begin the exam, Zach reviews the information Mr. Nguyen supplied on the admission form, and then asks Nam about his family history.

Zach: Are your parents still living?

Nam: Yes, they're both alive. My father is 80 years old and my mother is 76.

Zach: I'd like to hear a little more about your family history. Tell me about your father's cancer. How old was he when he was first diagnosed? Has he had treatment?

Nam: He was probably about 60 when he first found out about it. I know he had some kind of surgery and takes medicines but I don't know the details. He seems all right though.

Zach: Your father also has high blood pressure and heart disease. Please tell me a little more about that.

Nam: My father and mother both have high blood pressure and heart disease. They both take medicines for their blood pressure. My father had a small heart attack about 10 years ago. My mother has never had a heart attack that I know of, but she sometimes has chest pain.

Zach: Your mother also has diabetes?

Nam: She's had that for a long time. A lot of people in my family have diabetes, especially on my father's side—but nobody in my mother's family. Yet my mother is the one with the diabetes!

Yen: A lot of people in my family have diabetes too. But so far I'm okay, I think.

Zach: Have you had a health exam lately, Mrs. Nguyen?

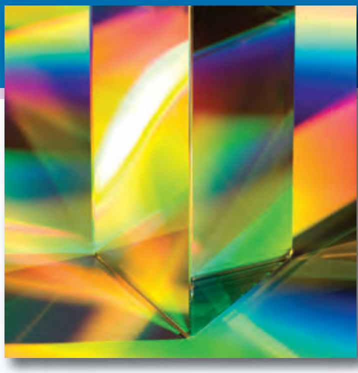
Yen: Not in about a year, but I'm going to schedule an appointment here.

The Nguyen couple and Zach continue to review the health information. After reviewing the history and discussing current complaints, Zach performs a complete physical exam.

unit 1

How Nurses Think

CHAPTER 1



Evolution of Nursing Thought & Action

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 1:
- **Response sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Evolution of Nursing Thought & Action (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 1, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Review the opening scenario in the front of the book. On Nam Nguyen's preliminary visit to the Family Medicine Center, he is examined by Zach Miller, MSN, FNP-BC.

A. How would you respond to Mr. Nguyen's concerns that he was examined by someone who is "just a nurse"?

B. What factors might be causing Mr. Nguyen to question care by "a male nurse"?

Critical Thinking and Clinical Reasoning

1. At a holiday family gathering, you are at the dinner table with your 60-year-old aunt, your 85-year-old grandmother, and your 15-year-old sister-in-law. Your aunt and grandmother are retired RNs. Your sister-in-law aspires to be a nurse, and you are in school studying to be a nurse.
   a. What factors will influence how each of you views nursing?
   b. Your sister-in-law asks you to define nursing. What would you say?
   c. How could you explain to her how a nurse is different from a nurse's aide or a physician?
2. Review the information on educational pathways into nursing.
   a. What do you believe is the minimum level of education that should be required in order to practice nursing?
   b. What reasons can you give to support your opinion?
3. Review the description of the National Student Nurses Association (NSNA). If your program has a local chapter of the NSNA, consider attending a meeting or consulting the association's Web site for more information. Identify at least three potential benefits of joining this organization.
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or the evolution of nursing thought and action. Note that these are *not* to be merely definitions.

   Healthcare delivery system
   The Nightingale era
   ICN and ANA definitions of nursing
   Regulation of nursing practice
   Benner's stages of nursing skill
   Nursing organizations
   The national economy
   Better-informed healthcare consumers
   Use of nursing assistive personnel
   Use of life-extending, high-technology equipment

What Are the Main Points in This Chapter?

- Religious organizations and the military have played a major role in the development of nursing and healthcare organizations.
- Initially the role of the nurse was limited to bathing, feeding, and supporting the patient; keeping the patient environment clean and orderly; and providing support for the physician.
- Contemporary nursing care includes activities that are performed in collaboration with other members of the healthcare team and also independently.
- Licensed practical nurses (LPNs or LVNs) are nurses who have successfully completed a practical nursing program and have passed a licensure exam (NCLEX-PN). They are prepared to give direct patient care.
- Registered nurses (RNs) are nurses who have successfully completed a registered nurse education program and have passed a licensure exam (NCLEX-RN). There are several types of RN education programs.
- Graduate nursing education is designed to prepare the RN for advanced practice, expanded roles, nursing education, or research.
- Benner has identified a five-step progression of skill acquisition in nurses: novice, advanced beginner, competence, proficiency, and expert.
- Nurse practice acts are laws that regulate nursing practice at the state level.
- Nurses engage in health promotion, illness prevention, health restoration, and care of the dying.
- Nurses work in a variety of inpatient and outpatient settings, including hospitals, extended care facilities, ambulatory care, and community or home health settings.
- Nurses provide care using either the case method, functional, team, primary, or differentiated model.
- The economy, technology, an aging population, increased consumer involvement in healthcare, the women's movement, and the change in nursing role are all forces that have strongly affected nursing.
- The healthcare delivery system is complex and involves a multitude of players.
- Managed care models of insurances (HMOs, PPOs, POS, IDNs) reduce cost by reimbursing providers at discounted, predetermined rates and limiting the consumers' choice of providers.
- Government funded programs, such as Medicare, Medicaid, and CHIP, provide health insurance for persons with disabilities, are 65 years of age or older, or have a low income.
- Nurses care for sicker inpatients due to changes in reimbursement rates to hospitals.
- Nurses are essential members of the interdisciplinary healthcare team.
- Nurses must engage in lifelong learning activities to remain knowledgeable of and competent in professional practice.

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 2, **Podcast— Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Review the opening scenario of Nam Nguyen in the front of this book. Imagine that you are the clinic nurse at the Family Medicine Center. Based on the information presented in the scenario, work through the following questions:

Caring for the Nguyens (continued)

A. Patient Situation
- Why is Mr. Nguyen at the clinic?
- What are his wife's concerns?
- Are his wife's concerns similar to or different from his?

B. Critical Thinking
- How do I go about getting the data I need? What sources should I use?
- Are my data congruent?
- What is one possible explanation for what is happening in this situation?

C. Nursing Knowledge
What type of nursing knowledge (theoretical, practical, ethical, or self-knowledge) is needed to answer the following questions?
- What health concerns does Mr. Nguyen have that should be addressed by the healthcare team?
- What is the role of Zach Jackson on the healthcare team?
- What role will you play in the care of Mr. Nguyen?

D. Nursing Process
- In what phase of the nursing process are you engaged when you are asking Mr. Nguyen about the reason for his visit?
- What activities are involved in the diagnosis phase? In planning outcomes? In planning interventions?
- Why would you not, at this point, be using the evaluation phase?

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mrs. Castillo has late-stage cancer and is not expected to live more than a few months. With chemotherapy, she could live perhaps a year or two more. She cannot decide what to do. She knows the chemotherapy will have unpleasant side effects and will be very expensive, and she wants to protect her family from the emotional and financial hardships of a lingering illness. She is showing physical signs of anxiety and distress (e.g., increased heart rate, restlessness, tearfulness). You want to provide support for her decision, whatever it may be.

THINKING

1. *Theoretical Knowledge*: What theoretical knowledge do you need to help Mrs. Castillo?
2. *Critical Thinking (Contextual Awareness)*: What details in the scenario represent *patient situation* or *context*?

DOING

3. *Practical Knowledge*:
   a. What practical knowledge do you need to help Mrs. Castillo?
   b. Which skills are you already competent in, and which ones would you need to learn or review before caring for this patient?

CARING

4. *Ethical Knowledge*: Depending on Mrs. Castillo's decision, can you think of one ethical issue that might arise for you or members of her family later on?

Critical Thinking and Clinical Reasoning

1. At the end of your first nursing class, your instructor gives an overview of a long-term assignment. She informs you that each semester of the program the class is required to complete a project that provides some

type of service to the college community or the local community, and that demonstrates the role or importance of nursing. The instructor asks you to begin discussing potential projects and come to class next week prepared to discuss several proposals for your community and the potential benefits of each option. You and several friends gather to talk about the class. "What an odd assignment!" you tell your friends. "How can we possibly do this now? We aren't nurses. We don't have any skills. What could we possibly do?" Your friends echo similar views.

This exercise is designed to help you actually work through the imaginary assignment you have just read. Use the *critical-thinking model* shown in Figure 2-1 and the sample questions in Table 2-1 of Volume 1 to complete the assignment.

Go to Volume 1, **Chapter 2: Critical Thinking & Nursing Process.**

a. *Contextual awareness* is one concept in the critical-thinking model. Consider the context in which the assignment was given.
- What exactly is this assignment?
- Your instructor is perfectly aware of your knowledge and skill levels. Why do you think she would ask students to complete such an assignment so early in their nursing studies?

To complete this assignment you would need to gather information to find ways to answer the following questions. You would also need to use credible sources (another task of critical thinking) to address these questions.

b. What sources might you use to answer the following two questions?
- What will I learn this semester?
- What skills will I have by the time this assignment is due?

c. What are some ways in which you could answer the following two questions?
- What do nurses do?
- How do nurses interact with the community?

d. What are some ways in which you could obtain information to answer this question: What does my community need?

e. If you had actually gathered the preceding information, you would then need to consider possible solutions. One way would be to develop a list of community needs, a list of activities nurses engage in, and a list of skills and knowledge you will have at the end of the term. Then look at the overlap between the lists. This should help you to get some ideas for projects. Imagine now that you have a list of possible projects similar to the following:
- Take blood pressures at a neighborhood grocery store for a day.
- Hold a health fair at a neighborhood shopping center.
- Create some materials for teaching about a healthy diet; distribute them at a community event.

Now think critically about this list of projects (this involves *reflective skepticism and exploring and imagining alternatives*). What questions could you ask about each project to help you decide which to actually do?

2. Review the following scenarios. Is critical thinking occurring? If so, which part of the critical-thinking model is the student using, or which critical-thinking skill or attitude from Chapter 2 in Volume 1? If there is no evidence of critical thinking, revise the scenario to include it.

a. Juan is a first-year nursing student. His clinical rotation is at a skilled nursing facility (SNF). He arrives at the unit at 0700 for the start of the day shift. After hearing the shift change report, he prepares to give his client a bedbath per unit policy.

b. Lily is teaching her patient, Mr. Johannsen, about the medications he will be taking when he is discharged from the hospital. When Lily reviews the list with him, he says, "That's too many medicines. It's too confusing." Lily devises a schedule and information sheet about the medicines that she gives to her client. She reviews the medications and their schedules with Mr. Johannsen and his wife before discharge.

c. Erin is caring for a young man who has had orthopedic surgery after a skiing accident. She is unable to hear his blood pressure when she attempts to take his vital signs. He is alert and able to converse with her. Since she is unable to hear the blood pressure, she records "0" in the client record.

d. As you are walking down the hall on the hospital unit, you hear a patient call out, "Nurse!" When you enter the room, you notice that the bedside is crowded with equipment. The patient is receiving several fluids intravenously, and a unit of blood is hanging from the IV pole. Since you have limited clinical experience you say to the patient, "I'll get you some help."

3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or critical thinking in the nursing process. Note that these are *not* to be merely definitions.

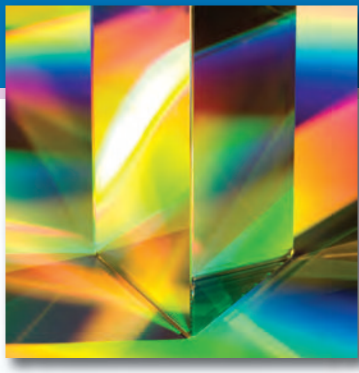
Caring	Planning outcomes phase
Critical-thinking skills	Planning interventions phase
Critical-thinking attitudes	Implementation phase
Exploring alternatives	Evaluation phase
The nursing process	Theoretical knowledge
Assessment phase	

What Are the Main Points in This Chapter?

- Nursing involves thinking, doing, and caring; and all are equally important.
- Critical thinking is a combination of reasoned thinking, openness to alternatives, an ability to reflect, and a desire to seek the truth.
- Critical thinking involves both attitudes and cognitive skills.
- Critical thinking attitudes include independent thinking, intellectual curiosity, intellectual humility, intellectual empathy, intellectual courage, intellectual perseverance, and fair-mindedness.
- Nurses use critical thinking in all aspects of their practice.
- Practical knowledge (knowing what to do and how to do it) and theoretical knowledge (knowing why) are equally important in nursing.
- The nursing process is a systematic problem-solving process that guides all nursing actions.
- The nursing process consists of six overlapping and interdependent phases: assessment, diagnosis, planning outcomes, planning interventions, implementation, and evaluation.
- Critical thinking is used in each phase of the nursing process; it is related to, but not the same as, the nursing process.
- Your ability to think critically depends on your theoretical knowledge about critical thinking, your motivation to practice it, and your fund of nursing knowledge.
- In full-spectrum nursing the nurse applies thinking, doing, and caring to the patient situation to help effect positive patient outcomes.

Knowledge Map

CHAPTER 3



Nursing Process: Assessment

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. Go to Student Resources, Chapter 3, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Review the opening scenario of Nam Nguyen in the front of Volume 2. Imagine that you are the clinic nurse at the Family Medicine Center. Using the information presented in the scenario, work through the following questions:

A. What type of assessment, comprehensive or focused, is being performed at this clinic visit? Explain your thinking.

B. Identify the types of data (e.g., subjective/objective, primary/secondary) that have been gathered so far. Give an example of each type.

(Continued)

Caring for the Nguyens (continued)

C. How might you verify data that Mr. Nguyen provided on the intake sheet?

D. Based on what you know about Mr. Nguyen, what follow-up assessments would provide useful data to help with the care of Mr. Nguyen? Why would you make these assessments?

PracticalKnowledge knowing how

In this chapter, practical knowledge pertains to your skill in applying the concepts of assessment and data, for example, by using structured and unstructured methods of data collection.

CLINICAL INSIGHTS

Clinical Insight 3-1 ➤ Preparing for a Patient Interview

Prepare Yourself

- **Know your purpose.** Be sure you know why you are conducting the interview and how the data will be used. As a student, this may simply mean preparing thoroughly for your clinical assignment.
- **Read the patient's chart.** This will give you an idea of where to start with the interview and keep you from covering topics already assessed by other caregivers. Be careful to keep an open mind, though. If you approach an interview with preconceived ideas, you may overlook important data.
- **Form some goals** for the interview.
- **Think of some opening questions.**
- **Schedule some uninterrupted time** for the interview. Giving the patient your undivided attention builds rapport and helps her to feel freer to share information with you.
- **Gather the necessary assessment forms and equipment.** You will need a stethoscope, pen, pencil, blood pressure cuff, and thermometer.
- **Take a deep breath and compose yourself** just before entering the room.

Prepare the Space

- **Provide privacy** (e.g., ask visitors to wait outside, shut the door). Unless you need information from the visitor (e.g., when the client cannot communicate clearly) you may wish to postpone the interview until it can be done in private. The presence of even a close family member may inhibit the client in some situations. For example, a wife may not want her husband to know that she had a miscarriage before they were married.
- **Keep the focus on the client** as much as possible. If others must be present, sometimes the client's spouse, family, or partner will offer information that may or may not be pertinent. Focus on the client, but do not ignore the information provided by others.
- **Remove distractions** (e.g., turn off the television, arrange for someone to watch the children for a while, if they are present).
- **Sit down. Do not hover over the bed.** Position yourself at the same level as your client, even if the client is in bed.

Prepare the Patient

- **Introduce yourself** to the patient and others in the room.
- **Call the patient by name.** First ask what name the patient prefers. Don't use endearing terms like "grandma," "dear," and "sweetie." You may think you are being friendly or expressing caring, but many people feel belittled by these terms.
- **Tell the patient what you will be doing and why.** Explain that you will be taking notes and that you will keep all information confidential.
- **Assess and provide comfort** (e.g., assess and medicate for pain, offer the bedpan, offer a drink of water).
- **Assess for anxiety.** Be sure the patient is comfortable emotionally as well as physically. A very anxious person cannot provide good information, so you may need to intervene to relieve anxiety before proceeding.
- **Assess readiness to discuss health issues.** If the patient indicates that now is not a good time, reschedule (e.g., if the patient has just received some bad news about his condition, or in his personal life, he may need some time to process that information before he can concentrate on interview questions).
- **Interviews** are recorded only when done during research projects. The researcher must be sure to obtain institutional review board approval and written permission from the patient, using an approved consent form.

Clinical Insight 3-2 ➤ Conducting a Patient Interview

- **Individualize your approach.** Ask yourself, for example, "What approach is best considering the client's age and developmental level?" Respect the generational differences of a person older or younger than you are.
- **Be sensitive to cultural differences** (e.g., comfort with eye contact, the need for space).
- **Begin with neutral topics**, such as the biographical data (e.g., address, contact person, occupation). Ask more personal or sensitive questions after you and the client are more comfortable with each other.
- **Key Point:** *Use active listening. This is the most important interviewing technique. Focus intently on trying to understand what the client is saying, rather than thinking ahead to what your response to the statement will be.*
- **Use the mnemonic FOLK** to remember other active listening behaviors:

  Face the patient (either sitting or standing).
  Open, relaxed posture (arms and legs uncrossed).
  Lean toward the patient.
  Keep eye contact.
- **Do not get caught up in note taking.** Excessive writing interferes with eye contact and may inhibit the client's responses, especially when you are discussing personal issues such as sexuality or drug and alcohol use.
- **Pay attention to nonverbal communication.** Body language may signal that the person is tired or in pain but is too polite to say so. If the person is fatigued, you may need to end the interview and finish it at another time.
- **Use open-ended questions** as much as possible to encourage the client to talk.
- **Avoid asking too many questions.** Asking too many questions may make you seem merely curious instead of genuinely interested in the client.
- **Use neutral statements instead of questions** (e.g., instead of asking, "How many children do you have?" say, "Tell me about your family").
- **Avoid asking "why"** (e.g., "Why have you stopped taking your pills?"). For some people, "why" suggests disapproval and causes them to become defensive. (This may be because parents frequently ask their children, "Why did you do that?")
- **Do not use healthcare jargon** (e.g., say, "I want to take your temperature and blood pressure" instead of "I want to take your vital signs").
- **Do not "talk down" to the client** (e.g., Don't say, "How often do you go potty?" when interviewing an adult).
- **Be sure your client understands what he says.** Confirm that clients actually understand the terminology they use. If a client says, "It's the inflammation that causes me the trouble, you know," you might say, "Tell me where the inflammation is and what happens when you have it." People may repeat words they hear from care providers without really knowing what the words mean.
- **Refocus and redirect the client as needed** (e.g., when a response becomes scattered or does not produce useful information). Encourage the client to talk about the topics of importance to her, but direct her to topics that need to be covered (e.g., "We haven't talked about your surgery. What do you expect to happen?").
- **Curb your curiosity.** Do not get caught up in the details of the client's story. Focus on the information you need to plan care.
- **Do not give advice or voice approval or disapproval.** Even if the advice is good (e.g., "It is good that you take your pills on time"), it may cause the client to be less open because he feels you are judging him. This can interfere with your ability to gather data.

Clinical Insight 3-3 ➤ Closing a Patient Interview

- Prepare the patient for closure. Begin by informing her that the interview is nearly finished.
- Summarize the key points of the interview.
- Be sure you have recorded all the important data. Ask the patient, "Is there anything else you would like to tell me?" or "Is there anything else we should talk about?"
- Thank the patient for answering the questions.
- Encourage the patient to keep you informed. For example, you might say, "Please let us know if you think of anything else we should know."
- Tell the patient what to expect next. Let the patient know when you will be leaving, when you will see him again, and what he can expect for the rest of the day (e.g., tests, treatments).
- And finally, ask, "Is there anything I can do for you before I leave?"

ASSESSMENT GUIDELINES AND TOOLS

You can use the forms in this section to perform a focused assessment of activities of daily living and to perform a comprehensive patient assessment. If you want to use an interactive assessment tool to create your own assessment form,

Go to **Davis's Care Planning & Nursing Diagnosis Resource Center, Interactive Assessment Tool,** at **http://davisplus.fadavis.com/daviscareplans/assessment tool.cfm.**

Patient Assessment Tool—Lawton Instrumental Activities of Daily Living (IADL)

Date: ________________ Name: ______________________________

Please check the box that most applies for each activity:

Activity	Needs no help (2 pts. each)	Needs some help (1 pt. each)	Unable to do at all (0 pts. each)
1. Using the telephone	___	___	___
2. Getting to places beyond walking distance	___	___	___
3. Grocery shopping	___	___	___
4. Preparing meals	___	___	___
5. Doing housework or handyman work	___	___	___
6. Doing laundry	___	___	___
7. Taking medications	___	___	___
8. Managing money	___	___	___
Total score: ___ =	**(___ × 2 =) ___ +**	**(___ × 1 =) ___ +**	**0**

A patient is awarded 2 points for each area in which he/she can function totally without help, 1 point in those areas that they need some help, and 0 points for those activities that somebody else must do completely for them. The maximum score is 16, minimum score is 0.

Like other evaluations, the IADL scale provides a baseline of data that can be compared with the results of future evaluations. (Note that some activities may be gender specific. Omit these items if the patient does not usually perform those tasks.)

Permission obtained from M. Powell Lawton, Ph.D., Philadelphia Geriatric Center, Philadelphia, PA. May be used freely for patient assessment. Formatted and posted May 25, 1996, to www.acsu.buffalo.edu/~drstall/assessmenttools.html by Robert S. Stall, M.D.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

As the intake nurse in a community-based clinic, your role is to complete a comprehensive nursing assessment and initiate a plan of care for the clients. Your first client is a 27-year-old single woman, Sami, who is requesting clinic services for her general healthcare needs. Sami is Cuban American and lives alone in a one-bedroom apartment. She works as a fitness trainer at the local fitness club while attending college part-time. Her family lives in another city about 200 miles away. Sami's earnings place her at the poverty level, but she realizes that she must have healthcare to prevent illness and to detect and receive treatment of illnesses should they arise.

THINKING

1. *Theoretical Knowledge:* To care for Sami, what knowledge would you need that you do not already have? List the URL for at least one reputable online source for this information.
2. *Critical Thinking:* The nurse asks Sami, "If you can't afford healthcare, couldn't you get a roommate to save some money on rent?" What are some critical-thinking questions you should ask yourself when reflecting on this question later?

DOING

3. *Practical Knowledge:* What practical knowledge will you, as the nurse, use in this scenario?
4. *Nursing Process:* What kind of assessment will you perform for Sami (e.g., comprehensive, focused, special needs, discharge, etc.)?

CARING

5. *Self-Knowledge:* In what ways are you similar to Sami? In what ways are you different?

Critical Thinking and Clinical Reasoning

1. Recall the definition of subjective data. Make a list of the kinds of patients from whom you might not be able to get subjective data or who might give unreliable data. One example is a baby who cannot talk yet. How many others can you think of?
2. What are some factors that might make it difficult, but not impossible, for a patient to provide you with subjective data? One example is when the person is severely anxious.
3. For each of the factors in question 2, state what you could do to facilitate collection of reliable subjective data from that person.
4. List your present assessment skills and indicate your comfort level using each skill. Include observation, physical assessment, and interviewing skills. Use a scale of 1–5, with 1 = slightly comfortable; 2 = somewhat comfortable; 3 = moderately comfortable; 4 = fairly comfortable; and 5 = very comfortable.
5. For any skill that you score as 3 or lower, write a plan describing what you need to do to move to the higher comfort level.
6. The following are excerpts from criteria in the American Nurses Association (ANA) (2010) professional practice Standard 1. For each of the criteria, write an example of what would constitute evidence (proof) that the standard is being followed in a healthcare agency. The first one is done for you.
   a. "Collects data . . . in a systematic and ongoing process."
      I would look in the care plan for nursing orders that call for some kind of assessment on a scheduled basis. For example, an order might read, "Temperature q4hr" or "Check dressing for drainage once per shift." I would also look at the nursing notes, especially for flow sheets (e.g., vital sign flow sheets, input and output records, neurological checks) to see whether assessment findings were recorded at regular intervals. I would look for nursing diagnoses or other conclusions they have charted in the nurses' notes (e.g., stating that the medication has effectively relieved pain). Other evidence would be to observe the nurses doing systematic and ongoing data collection.
   b. "Involves the healthcare consumer, family, and other healthcare providers, as appropriate, in holistic data collection."
   c. "Prioritizes data-collection activities based on the healthcare consumer's immediate condition, or the anticipated needs . . ."
   d. "Uses appropriate evidence-based assessment techniques, instruments, and tools."
   e. "Synthesizes available data, information, and knowledge relevant to the situation to identify patterns and variances."
   f. "Documents relevant data in a retrievable format."
7. Your client, Sami (Meet Your Patient, in Volume 1), was born in Cuba. Having worked with many clients of Cuban heritage and being familiar with nursing literature regarding various cultural patterns, you are aware of the following:
   - Many Hispanic people who live in Sami's city are bilingual.
   - When communicating, especially with strangers, it is not unusual for Hispanic women not to maintain eye contact. (During the interview, Sami speaks rapidly and does not maintain eye contact with you.)
   - Many people of Cuban descent are Catholic and consider birth control to be taboo.
   - Many Cuban American women do not obtain annual physical examinations (Purnell & Paulanka, 2008).

   a. Looking at the four points from the literature, how is Sami's cultural background similar to or different from your own? Remember that you are looking at cultural patterns, not Sami's individual and personal values and behaviors.
   b. On the basis of your understanding of your own and Sami's culture, what questions might you want to ask Sami to support her reproductive health?
8. What physical examination techniques would you use to:
   a. Assess for a distended bladder?
   b. Get information about a patient's headache?
   c. Obtain data about a patient's ankle edema?
   d. What subjective data could you obtain by using one of the four physical assessment techniques?

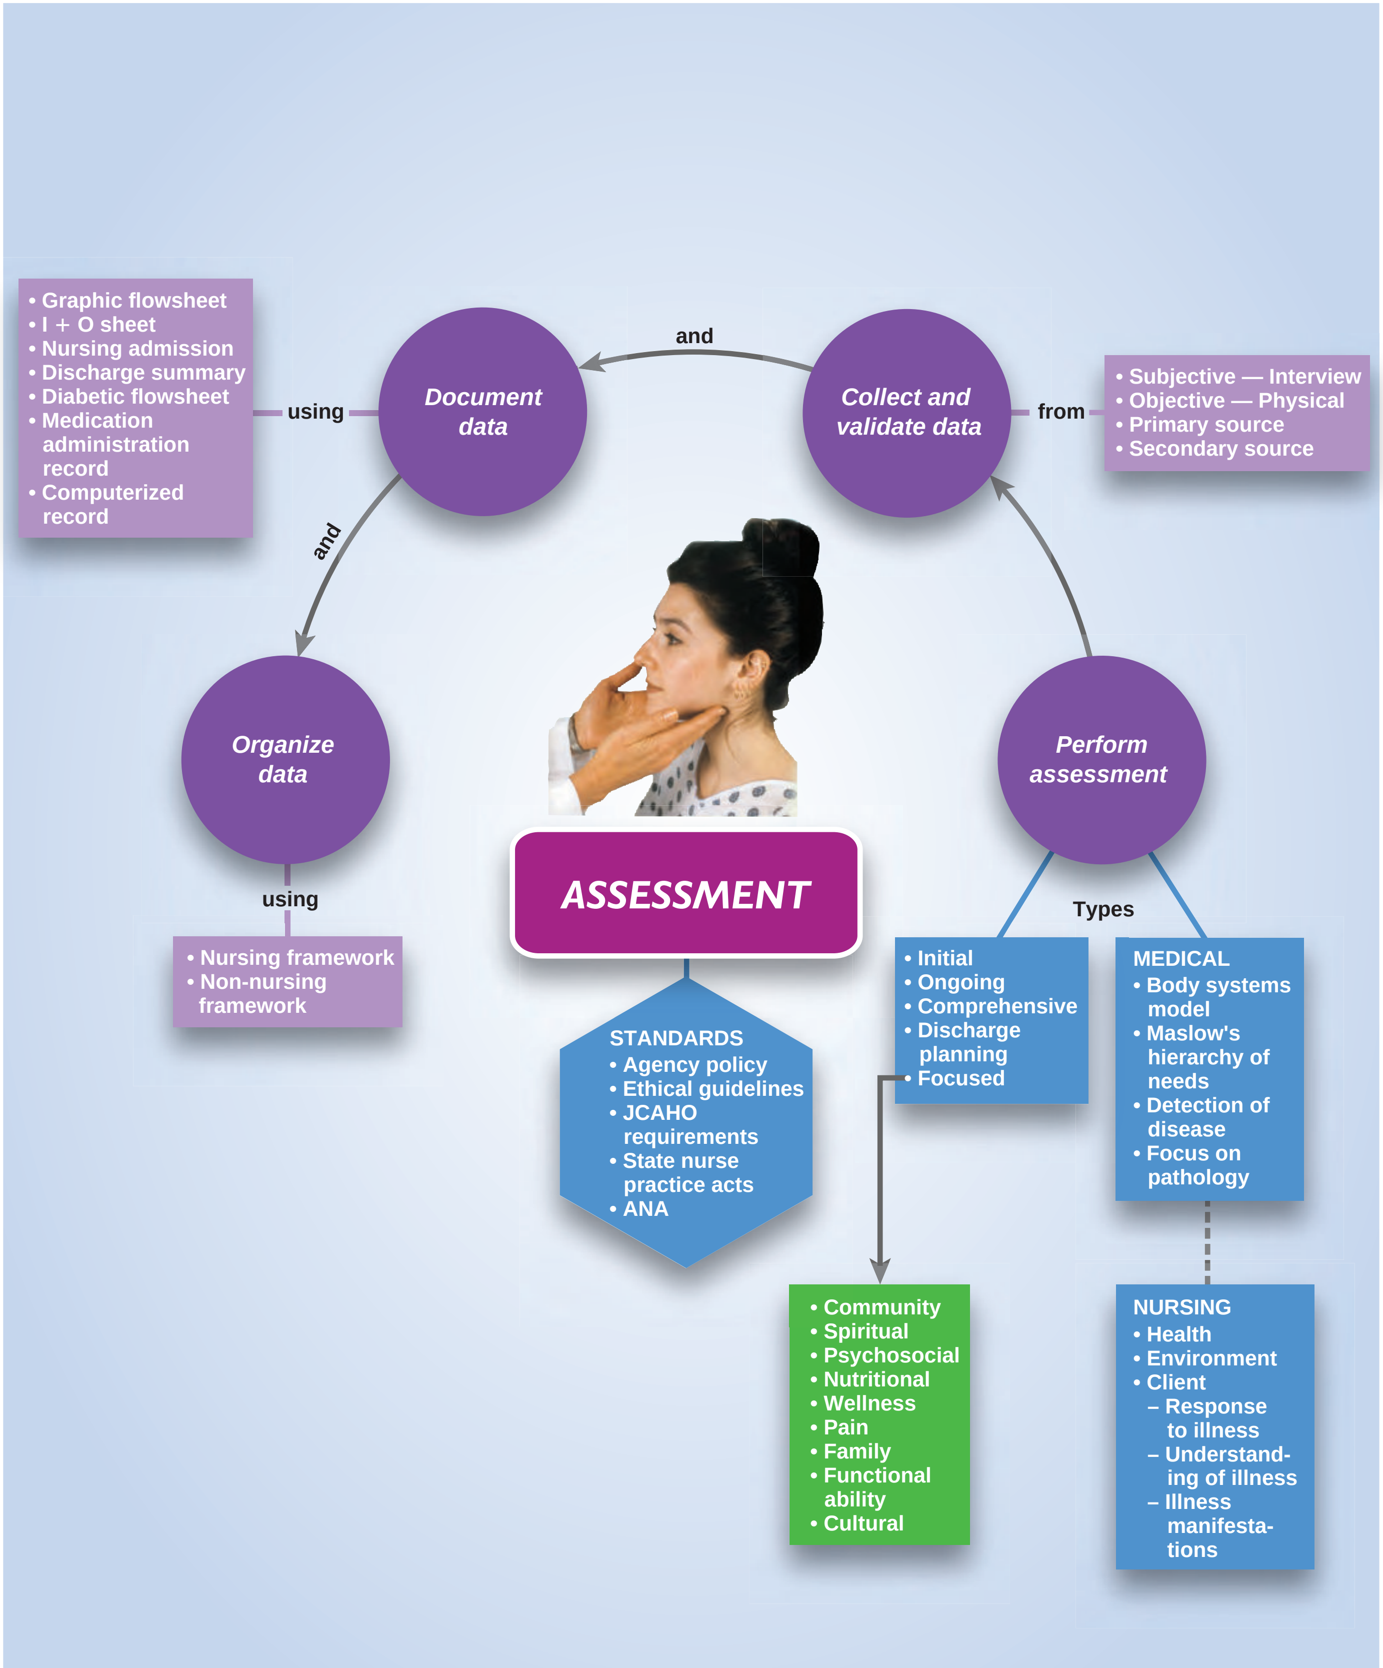
9. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or assessment. Note that these are *not* to be merely definitions.

Active listening	Recording data
Agency policies	Reflecting critically about your assessment
ANA standards of practice	Special needs assessments
Assessment	Spiritual health assessment
Comprehensive assessments	The Joint Commission
Focused assessments	The nursing health history
Nursing frameworks/models	Validating data
Pain assessment	Wellness assessment

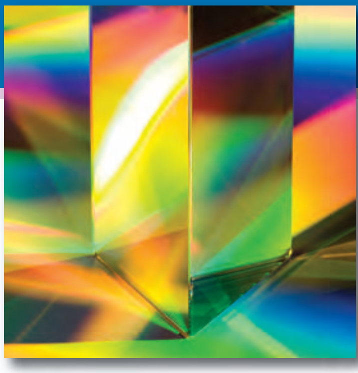
What Are the Main Points in This Chapter?

- Assessment is a systematic, ongoing process of collecting, categorizing, and recording holistic data about client health status.
- Accurate, complete data are essential to effective nursing diagnosis and care planning.
- Nursing assessments focus on client responses to illness and stressors rather than on identifying disease processes.
- ANA standards of practice state that professional nurses are responsible for assessing clients.
- A comprehensive assessment provides information about the client's overall health, whereas a focused assessment provides data about a particular topic, body part, or functional ability.
- Special needs assessments provide in-depth information about a particular area of client functioning (e.g., nutrition, pain, lifestyle).
- Subjective data can be perceived only by the client; objective data are measurable or observable by the nurse or other healthcare providers.
- Nurses obtain data by observing and interviewing patients, and by performing physical assessment.
- The formats and frameworks for the nursing health history vary among agencies; however, all have essentially the same components (e.g., chief complaint, family history, review of body systems).
- Effective interviews require preparation by the nurse and use of both closed and open-ended questions.
- Active listening is one of the most important interviewing techniques.
- Validating data helps to ensure that they are accurate, complete, and factual.
- Documentation of assessment findings is of critical importance and has professional and legal implications.
- When documenting assessments, the nurse should record cues (observations), not inferences (conclusions).

Knowledge Map



CHAPTER 4



Nursing Process: Diagnosis

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 4:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Nursing Process: Diagnosis (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 4, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Review the opening scenario of Nam Nguyen in the front of this book. After the nurse practitioner completed the interview and physical examination of Mr. Nguyen, he listed the following diagnoses on the problem list:

Hypertension
Obesity
Musculoskeletal pain
Tobacco abuse
Family history of prostate cancer
Family history of cardiovascular disease
Family history of diabetes mellitus (DM)

Caring for the Nguyens (continued)

A. What type of problem list does this represent? How is it similar to or different from a problem list that you might generate?

B. Based on the data in the scenario, identify at least one actual, one potential, and one wellness diagnosis for Mr. Nguyen. Identify the NANDA-I labels, and describe the cues that support your choices.

C. The nurse has identified a problem of Imbalanced Nutrition: More Than Body Requirements for Mr. Nguyen.
- What information do you need in order to determine the etiology of this problem?
- Because you do not have that information, write a two-part diagnostic statement describing Mr. Nguyen's nutritional status.

D. Now rewrite the nutrition statement as a three-part statement, including the phrase *"as evidenced by."*

E. The nurse has identified Acute Pain (knees) for Mr. Nguyen. If the pain were caused by a medical condition, osteoarthritis, how would you write a two-part diagnostic statement to describe this health status?

PracticalKnowledge knowing **how**

In this section, you will find a list of descriptors for NANDA-I nursing diagnoses. To see an alphabetical list of NANDA-I nursing diagnoses,

Go to Additional Resources, **NANDA-I Nursing Diagnoses, 2012-2014 Alphabetical List,** on Davis*Plus*.

To see NANDA-I labels organized into taxonomy categories,

Go to Student Resources: Chapter 4, **Standardized Language, NANDA-International Taxonomy II: Domains, Classes, and Diagnoses (Labels),** on Davis*Plus*.

Refer to these lists as you develop nursing diagnoses for your patients.

STANDARDIZED LANGUAGE

Descriptors for NANDA-I Nursing Diagnoses

Axis 1. The Diagnostic Focus This describes the "human response or experience" that is the core of the diagnosis. Examples are activity tolerance, airway clearance, anxiety, and pain

Axis 2. Subject of the Diagnosis This is defined as the person(s) for whom a nursing diagnosis is determined. The values (descriptors) in Axis 2 are:

Descriptor	Definition
Individual	A single human being distinct from others, a person
Family	Two or more people having continuous or sustained relationships, perceiving reciprocal obligations, sensing common meaning, and sharing certain obligations toward others; related by blood or choice
Group	A number of people with shared characteristics
Community	A group of people living in the same locale under the same governance (e.g., neighborhoods, cities)

Axis 3. Judgment A descriptor or modifier that limits or specifies the meaning of the diagnostic focus (or concept). The values (descriptors) in Axis 3 are:

Descriptor	Definition
Complicated	Intricately involved, complex
Compromised	Damaged, made vulnerable
Decreased	Lessened (in size, amount, or degree)
Defensive	Used or intended to defend or protect
Deficient	Insufficient, inadequate
Delayed	Late, slow, or postponed
Disabled	Limited, handicapped
Disorganized	Not properly arranged or controlled

(Continued)

Descriptors for NANDA-I Nursing Diagnoses—cont'd

Disproportionate	Too large or too small in comparison with norm
Disturbed	Agitated; interrupted, interfered with
Dysfunction	Not operating normally
Effective	Producing the intended or desired effect
Enhanced	Improved in quality, value, or extent
Excess	Greater than necessary or desirable
Failure	Cessation of proper functioning or performance
Imbalanced	Out of proportion or balance
Impaired	Damaged, weakened
Ineffective	Not producing the intended or desired effect
Insufficient	Quantity or quality that is not able to fulfill a need or requirement
Interrupted	Having its continuity broken
Low	Below the norm
Organized	Properly arranged or controlled
Perceived	Observed through the senses
Readiness for	In a suitable state for an activity or situation
Situational	Related to a particular circumstance

Axis 4. Location The parts/regions of the body and/or their related functions. The values (descriptors) in Axis 4 are:

Descriptor	Definition
Auditory	Neurovascular
Bladder	Olfactory
Body	Oral
Bowel	Peripheral
Breast	Peripheral neurovascular
Cardiac	Peripheral vascular
Cardiopulmonary	Renal
Cerebral	Skin
Gastrointestinal	Tactile
Gustatory	Tissue
Intracranial	Vascular
Kinesthetic	Verbal
Liver	Visual
Mucous membranes	Urinary

Axis 5. Age Refers to the age of the person who is the subject of the diagnosis. The values (descriptors) in Axis 5 are:

Fetus	School-age child
Neonate	Adolescent
Infant	Adult
Toddler	Older adult
Preschool child	

Axis 6. Time The duration of the diagnostic concept (Axis 1). The values (descriptors) in Axis 6 are:

Descriptor	Definition
Acute	Lasting less than 6 months
Chronic	Lasting more than 6 months
Intermittent	Stopping or starting again at intervals, periodic, cyclic
Continuous	Uninterrupted, going on without stopping

Axis 7. Status of the Diagnosis Refers to the actuality or potentiality of the problem or to its categorization as a wellness/health promotion diagnosis. The values (descriptors) in Axis 7 are:

Descriptor	Definition
Actual	Existing in fact or reality, existing at the present time
Health Promotion	Behavior motivated by the desire to increase well-being and actualize human health potential (Pender, Murdaugh, & Parsons, 2006, cited in *NANDA-I Nursing Diagnoses: Definitions & Classification 2012–2014)*
Risk	Vulnerability, especially as a result of exposure to factors that increase the chance of injury or loss
Syndrome	Clinical judgment describing a specific cluster of nursing diagnoses that occur together, and are best addressed together and through similar interventions

Source: From NANDA International. (2012). *NANDA international nursing diagnoses: Definitions and classification 2012–2014.* Ames, IA: Wiley-Blackwell.

CLINICALREASONING
Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Recall Todd from Volume 1, Meet Your Patient. You have admitted him from the emergency department (ED). His admitting medical diagnosis is chronic renal failure, and that he has a medical history of type 2 diabetes mellitus. Todd is married, 58 years old, and employed. In the past 3 days, he has developed decreased sensation in his bilateral lower extremities with slight mobility impairment.

You will need to ask Todd about his medication regimen, his compliance with his diabetes treatment plan, and the extent to which his family is involved. You will also need to find out what laboratory tests have been completed and how severe his renal dysfunction has become. Your initial impressions about possible problems are the following:

- Because he has chronic renal failure, you can anticipate a problem with fluid balance.
- He has been admitted to the hospital and is acutely ill, so he may be anxious and fearful.
- He has decreased sensation in his lower extremities, so he may have a mobility or a safety problem.
- He has diabetes, so he is at risk for impaired skin and tissue integrity.
- Because diabetes and renal failure require complex regimens and patient self-care, it is possible that Todd may not be managing his therapy effectively, either because he is not motivated to do so or because he lacks the knowledge to do so.

When Todd and his family arrive on your unit, you begin gathering additional data. Armed with comprehensive data, you then make a list of Todd's health problems, in priority order. These actions illustrate the diagnosis phase of the nursing process phase. The purpose of diagnosing is to identify the client's health status, from which you will create your plan of care.

THINKING

1. *Theoretical Knowledge:* What theoretical knowledge will you need to identify the collaborative problems and nursing diagnoses for Todd?
2. *Critical Thinking (Inquiry Based on Credible Sources):*
   a. What resources would you use to find out more about the pathophysiology of renal failure? How do you know the source is credible?
   b. One of your first impressions was that Todd seemed anxious and fearful. What data do you need in order to decide whether to write an Anxiety nursing diagnosis? How will you obtain the data?
   c. When you are making your assessments of Todd, who is your best source of data? Why?

DOING

3. *Nursing Process (Diagnosis):*
   a. Write one collaborative problem for Todd. If you do not know the potential complications of chronic renal failure, look them up in a medical–surgical or pathophysiology textbook. Also explain why you would not use a nursing diagnosis to describe the problem.
   b. After further assessment, you observe that Todd's skin is intact and without redness or lesions. Write a nursing diagnosis (problem and etiology) to describe your concerns about his skin.
   c. Based on Maslow's Hierarchy of Needs, which problem has the highest priority?

CARING

4. *Ethical Knowledge:* The scenario doesn't provide enough information for you to identify the ethical dimensions of Todd's care. However, based on what you already know about him, speculate about some things that might create ethical questions for you.

PATIENT SITUATION

5. *Patient Preferences:* Think critically about the patient's preferences and concerns. Suppose that Todd's main concern is not the same as the high-priority problem you identified. Speculate about some other concerns he might have. What other things might he want to have resolved that could—for him—be more important than his chronic renal failure? Aside from his physical condition, what life concerns do you think Todd might have right now?

Critical Thinking and Clinical Reasoning

1. Sally Jones, a 45-year-old woman, was admitted to your surgical unit directly from the surgical suite. She was in a motorcycle accident this evening. In the emergency department, her blood pressure was falling, and she was bleeding profusely from many sites. She was sent directly to the operating room for a splenectomy, internal fixation of a compound fracture of bilateral femurs, and traumatic amputation of

the right hand. During surgery she lost 2,000 mL of blood and received three units of packed red blood cells (volume = 750 mL) along with 1,000 mL of fluid administered intravenously.

You receive the report on the client at 1900. Sally is receiving IV fluid through several peripheral lines and through a central line (a catheter inserted into a major vein leading to the heart). She has a Foley catheter, which is draining 30 mL of concentrated urine each hour. Sally's vital signs are as follows: temperature, 102.8°F (39.3°C) (rectal); heart rate, 120 beats/min; respirations, 28 breaths/min; and blood pressure, 160/86 mm Hg. Her skin is flushed, dry, and warm to the touch. On assessment, you find the following: skin turgor > 3 seconds, dry mucous membranes, and bloodstained dressing on right upper extremity.

She is complaining of thirst, weakness, and pain at a level of 10 on a scale of 1 to 10 (10 highest). Sally is receiving a continuous infusion of morphine. She refuses to deep-breathe, cough, or attempt to turn. She lies very still and is rigid. Sally drifts in and out of sleep but remains asleep for less than 30 minutes each time. She is irritable and restless. She communicates with one-word answers only. Frequently, she displays facial grimaces and becomes increasingly stiff. Her eyes appear dull. She complains of severe pain with any passive or active movements. In answering the following questions, use a nursing diagnosis handbook to look up the NANDA-I defining characteristics, definitions, and so forth, as needed.

a. Based on the data provided, which of the following NANDA-I labels would you use for Sally? Explain your reasoning.
   Deficient Fluid Volume or Risk for Deficient Fluid Volume
b. For Sally, what cues are present for a diagnosis of Deficient Fluid Volume? What related factors are present?
c. Using your responses to (a) and (b), write a diagnostic statement that includes problem, etiology, defining characteristics (cues), and the medical condition that the problem is "secondary to."
d. Think of other explanations for these cues: temperature, 102.8°F (39.3°C); heart rate, 120 beats/min; respirations, 28 breaths/min; blood pressure, 160/86 mm Hg.
e. Sally certainly has the defining characteristics for the nursing diagnosis Impaired Physical Mobility. If you use this problem label, what would the etiological factors be?
f. Which of those etiological factors could you treat with independent nursing interventions?
g. Sally has the nursing diagnoses (problem labels only are listed) and collaborative problems listed below. Answer the two following questions about that list:
   - From Sally's perspective, which is probably the highest priority problem?
   - Using an urgency (or threat to life) criterion, name Sally's three most important problems and why you consider them most important.

     Problems:
     Deficient Fluid Volume
     Acute Pain (abdominal incision, amputation site, fractures)
     Risk for Disturbed Body Image
     Potential Complication of trauma, surgery, and IV lines: infection
     Risk for Ineffective Airway Clearance
h. Examine your theoretical knowledge. To care for Sally, what additional theoretical knowledge do you need?
i. What practical knowledge will you need to use in her care?

2. You have a homebound client with diabetes who has the beginning of a ressure ulcer. You have been treating the client for Impaired Skin Integrity related to decreased circulation and mobility. However, the client's skin continues to break down.
   a. Your client has diabetes mellitus type 2. What type of problem is that (medical, nursing, or collaborative)?
   b. What is the client's nursing diagnosis?
   c. The client has Impaired Skin Integrity. The break in the body's first line of defense (intact skin) increases the risk for infection. Write a problem statement reflecting that risk nursing diagnosis.
3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or nursing diagnosis. Note that these are *not* to be merely definitions.

   The diagnosis step of the nursing process
   NANDA International
   Patient strengths
   Maslow's hierarchy
   Documenting priorities
   Nursing diagnoses
   Possible nursing diagnoses
   Collaborative problems
   Wellness nursing diagnosis
   Cues
   Diagnostic label definition
   Defining characteristics
   Risk factors
   Etiological factors
   Theoretical knowledge
   Standardized nursing languages

What Are the Main Points in This Chapter?

- Nursing diagnosis is the unique obligation of the professional nurse; it cannot be delegated.
- An accurate nursing diagnosis is the foundation for the plan of care because it directs the choice of client-centered goals and nursing interventions.
- A nursing diagnosis is a statement of health status that nurses can identify, prevent, or treat independently.
- A medical diagnosis describes a disease, illness, or injury. A nursing diagnosis, in contrast, more holistically describes human responses to disease, illness, or injury.
- Collaborative problems are potential physiological complications of diseases, treatments, or diagnostic studies that nurses monitor and help to prevent but that cannot be treated primarily by independent nursing interventions.
- You must determine the "status" of each nursing diagnosis—that is, actual, potential, or possible problem; wellness diagnosis; or syndrome—because each status requires (1) different wording and (2) different nursing interventions.
- Diagnostic reasoning involves analyzing and interpreting data, verifying problems with the patient, and prioritizing the problems.
- You can never be certain that an inference is accurate, but you can have more confidence in an inference that is well supported by data.
- A problem etiology consists of the factors causing or contributing to the problem.
- You should involve patients in verifying and prioritizing their problems.
- Sound diagnostic reasoning is based on critical thinking and good theoretical and self-knowledge.
- A NANDA-I nursing diagnosis consists of a diagnostic label, a definition, defining characteristics, and related or risk factors.
- To choose the correct NANDA-I problem label, match the patient's cue clusters to the NANDA-I definition and defining characteristics.
- A diagnostic statement consists basically of "problem + etiology"; however, a variety of formats is needed to describe client health status.
- In general, the problem side of the diagnostic statement directs the choice of goals; the etiology directs the choice of nursing interventions.
- Diagnostic statements should be descriptive, accurate, clear, concise, and nonjudgmental.
- One criticism of standardized diagnostic language is that it represents a threat to creative, holistic thinking.

Knowledge Map

CHAPTER 5

Nursing Process: Planning Outcomes

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 5, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Review the opening scenario of Nam Nguyen in the first pages of this volume. As the clinic nurse, you have written the following nursing diagnostic statement: Imbalanced Nutrition: More Than Body Requirements related to inappropriate food choices and serving size as evidenced by body mass index (BMI) of 28.5.

Write at least two short-term and two long-term goals for Mr. Nguyen based on this diagnostic statement. Remember that your goals must be realistic and take into account Mr. Nguyen's other health problems.

Practical Knowledge knowing how

Practical knowledge in the planning phase of the nursing process requires you to use a variety of care planning forms and, in some organizations, standardized language. This section includes a discharge planning form, as well as a table of Nursing Outcomes Classification (NOC) measurement scales. The remainder of the chapter consists of activities to help you apply critical thinking and clinical reasoning to the concepts you learned in Volume 1.

ASSESSMENT GUIDELINES & TOOLS

Discharge Planning Form

FOLLOW -UP CARE

When to call the doctor; symptom management (pain, nausea); plan for meeting outcomes not met during hospitalization:

Call your primary physician to find out if an insurance referral form is needed for follow-up appointments.
After discharge, you need to call for an appointment to see physician.

Clinic/Physician	Phone #	Date	Time	
___	___	___	___	or _____days ______weeks _____months
___	___	___	___	or _____days ______weeks _____months
___	___	___	___	or _____days ______weeks _____months

STANDARDIZED LANGUAGE

By combining the following scale with NOC labels and indicators, you can write observable, concrete patient goals to use in evaluating a patient's response to care.

NOC Measurement Scales

SCALE NUMBER	1	2	3	4	5*
01	Severely compromised	Substantially compromised	Moderately compromised	Mildly compromised	Not compromised
02	Severe deviation from normal range	Substantial deviation from normal range	Moderate deviation from normal range	Mild deviation from normal range	No deviation from normal range
06	Not adequate	Slightly adequate	Moderately adequate	Substantially adequate	Totally adequate
07	10 and over	7–9	4–6	1–3	None
09	None	Limited	Moderate	Substantial	Extensive
11	Never positive	Rarely positive	Sometimes positive	Often positive	Consistently positive
12	Very weak	Weak	Moderate	Strong	Very strong
13	Never demonstrated	Rarely demonstrated	Sometimes demonstrated	Often demonstrated	Consistently demonstrated
14	Severe	Substantial	Moderate	Mild	None
17	Poor	Fair	Good	Very good	Excellent
18	Not at all satisfied	Somewhat satisfied	Moderately satisfied	Very satisfied	Completely satisfied
19	Consistently demonstrated	Often demonstrated	Sometimes demonstrated	Rarely demonstrated	Never demonstrated
20	No knowledge	Limited knowledge	Moderate knowledge	Substantial knowledge	Extensive knowledge

Source: Moorhead, S., Johnson, M., Maas, M., & Swanson, E. (2013). *Nursing outcomes classification (NOC)* (5th ed.). St. Louis, MO: C.V. Mosby, pp. 12–17. Used with permission.

*The scores (1 through 5) are constructed so that 5 is usually the most desirable and 1 is the least desirable condition relative to the outcome.

CLINICALREASONING
Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Ivan Benjamin has just been admitted to an orthopedic unit after an automobile accident. He was driving. Mr. Benjamin is 80 years old and has been living at home. His preexisting comorbidities are type 2 diabetes and osteoarthritis. He has casts and traction on both legs and a cast on one arm. He is receiving morphine sulfate intravenously via PCA pump. Imagine that you are an orthopedic nurse and must plan care for Mr. Benjamin. The admitting nurse wrote the following diagnoses and goals on the plan of care:

NURSING DIAGNOSES	GOALS/EXPECTED OUTCOMES
1. Acute Pain secondary to musculoskeletal trauma (arms, legs, body) and muscle spasms	▪ Demonstrates correct use of PCA pump ▪ Rates pain not higher than 4 on a scale of 1 to 10 at all times
2. Risk for Peripheral Neurovascular Dysfunction secondary to casts/traction	▪ Peripheral pulses palpable ▪ Fingers and toes warm ▪ Fingers and toes without pallor or cyanosis ▪ No edema of fingers and toes ▪ Capillary refill less than 3 seconds

THINKING

1. *Theoretical Knowledge:* What general *theoretical knowledge* will you need to care for this patient? Identify just the topics; limit the answer to about 150 words.
2. *Critical Thinking (Considering Alternatives):* Older adults are especially sensitive to certain medications, including morphine sulfate. What is one thing you could do to ensure Mr. Benjamin's safety while managing his acute pain? (There are several; think of just one.)
3. *Critical Thinking (Inquiry):* List at least two more things you need to know about Mr. Benjamin in order to begin his discharge planning.

DOING

4. *Practical Knowledge:* What general practical knowledge will you need? What would you do to obtain this knowledge?
5. *Nursing Process:*
   a. *Diagnosis:* What is another nursing diagnosis you might want to assess for Mr. Benjamin?
   b. *Planning Goals:* On the care plan rewrite the goals/expected outcomes for Acute Pain so that they will have all the required components. Assume that today's date is January 4.

CARING

6. *Self-Knowledge:* What beliefs, values, biases, or emotional responses might interfere with your ability to provide the best care to Mr. Benjamin?

CONTEXT

7. Think critically about the context. Is there anything in this situation that you have seen before? Identify any familiar elements. For example, you may have an elderly male relative, even if you have never cared for an 80-year-old patient before.

Critical Thinking and Clinical Reasoning

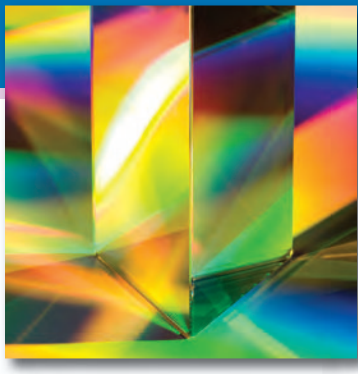
1. Merle Quinn is visiting a family planning clinic where she has just been informed that she is 6 weeks pregnant. She looks worried and makes the following statements: "This is a shock. I've just started a new business, and I need to work 7 days a week to make it go. . . . I don't know if I am ready to be a mother. . . ." Her husband agrees: "I just don't see how we can afford this. We don't even have any insurance now."
   "Still," Mrs. Quinn says, "I don't see how I could deal with having an abortion. My parents would be devastated. I'm sure they'd never speak to me again." Her husband says, "Not to speak of the fact that the Church forbids it. It would be a sin."
   A week later Mrs. Quinn calls the clinic in tears. She says she has not been able to eat or sleep and that she doesn't know what to do about her pregnancy. "I don't want this baby, but I can't bring myself to have an abortion." The nurse diagnoses Decisional Conflict related to unexpected/unwanted pregnancy and possibly assuming that abortion is her only alternative, as evidenced by statements of indecision, tearfulness, and inability to sleep. She makes an appointment to see Mr. and Mrs. Quinn that same day. Imagine that you are the nurse writing the care plan for the Quinns.
   a. Analyze your assumptions. What values and beliefs do you have that may influence the goals you write for the Quinns? Specifically, how could your values affect the goals you write?
   b. Develop a short-term goal to address the problem clause of this nursing diagnosis. The goal should be one you expect the Quinns to be able to achieve during their appointment that same day.
   c. You also write a goal stating: "By the end of this visit, clients will verbalize and demonstrate decreased anxiety and stress." Which part of the nursing diagnosis does this goal address?
   d. The NOC standardized outcomes linked to the NANDA-I diagnosis of Decisional Conflict are the following (definitions are given):
      Decision Making: Ability to choose between two or more alternatives
      Information Processing: Ability to acquire, organize, and use information
      Participation: Health Care Decisions: Personal involvement in selecting and evaluating health care options
      Which of those outcomes is most important for the Quinns to achieve *today*? Why?
   e. Now imagine that you have written the following individualized goals/outcomes for today's visit with the Quinns:
      By the end of this visit, clients will:
      1. Verbalize and demonstrate decreased anxiety and stress.
      2. Verbalize awareness that they have options for coping with whatever decision they make about the pregnancy.
      3. Discuss with the nurse options for continuing or terminating the pregnancy.
      4. Verbalize intent to discuss their feelings with family (i.e., their parents).
      5. Verbalize intent to discuss feelings with a member of the clergy.
      6. Decide whether to continue the pregnancy.
         - Why is outcome 2 so important?
         - What would you have had to assume in order to write outcome 4?
         - What would you have had to assume in order to write outcome 5?
         - Which of the outcomes is/are probably *not* appropriate for today's visit? Why?
2. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or the process of planning care. Note that these are *not* to be merely definitions.
   Discharge planning
   A written, individualized nursing care plan
   Standardized care-planning documents (e.g., protocols)
   Critical pathways
   Computerized care planning
   Goals (expected outcomes)
   Short-term goals
   Long-term goals
   Action verbs (in goals)
   Essential patient goals
   The Nursing Outcomes Classification (NOC)
   Aggregate goals
   Wellness goals
   Concrete, specific goal/outcome statements (as opposed to vague statements)

What Are the Main Points in This Chapter?

- During the planning outcomes phase, you will derive goals/expected outcomes from identified nursing diagnoses.
- Goals/expected outcomes (1) suggest nursing interventions, (2) serve as criteria for use in the evaluation step of the nursing process, and (3) provide motivation for patients and nurses.
- To ensure continuity of care, you should begin discharge planning with the initial patient assessment.
- Discharge planning is especially important for older adults and patients with complex needs.
- A holistic, individualized patient care plan contains information needed to address (1) basic needs and ADLs, (2) medical and collaborative therapies, (3) nursing diagnoses and collaborative problems, and (4) special teaching and/or discharge needs.
- Ideally, a care plan consists of a combination of standardized and individualized goals and interventions.
- Standardized approaches to care planning include institutional policies and procedures, protocols, unit standards of care, standardized care plans, critical pathways, and integrated plans of care (IPOCs).
- Computer-assisted care planning helps ensure that the nurse considers a variety of interventions and does not overlook common and important interventions; it reduces the time spent on paperwork.
- Nursing-sensitive goals (expected outcomes, predicted outcomes, desired outcomes) describe the changes in patient health status that are intended to result from and can be influenced by nursing interventions.
- Goals for collaborative problems are usually not nursing sensitive, and should not be included on a nursing care plan.
- A goal statement should include a subject, an action verb, a performance criterion, a target time, and special conditions if needed.
- For every nursing diagnosis, you must state one "essential" goal—one that, if achieved, would demonstrate problem resolution or improvement.
- Among the ANA-recognized standardized vocabularies/taxonomies for describing patient outcomes are NOC, the Omaha System, and the Clinical Care Classification System.
- Goals should be concrete, specific, and observable; they should be valued by the patient/family; and they should not conflict with the medical treatment plan.

Knowledge Map

CHAPTER 6



Nursing Process: Planning Interventions

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 6, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Recall that you have written the following nursing diagnosis for Mr. Nguyen: Imbalanced Nutrition: More Than Body Requirements related to inappropriate food choices and serving size, as evidenced by body mass index (BMI) of 28.5.

Caring for the Nguyens (continued)

A. Based on the outcomes you wrote in Chapter 5, Nursing Process: Planning Outcomes, identify four possible interventions to address the diagnosis and outcomes.

B. Review the interventions, and identify two that would be most appropriate for Mr. Nguyen given all of the information you have about his health status.

C. Write a nursing order for each of the two interventions you identified above.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mr. Sanborn is a 65-year-old man who has come to the clinic for a complete physical checkup. He has no health complaints and his physical examination is negative except for a few minor changes associated with aging. During the interview, he tells you that he is gay, and that he has had the same partner for 5 years. On further questioning, he reveals that he has had numerous sex partners during his lifetime. He says, "I was wondering if I should be tested for HIV" and "Mike, that's my partner, says I ought to get a flu shot and maybe a hepatitis shot. What do you think?"

THINKING

1. *Theoretical Knowledge:* What principles and concepts do you need to know in order to help Mr. Sanborn today?
2. *Inquiry:* Which of those do you already know enough about, and which ones will you have to study further?

DOING

3. *Practical Knowledge:* What psychomotor and communication skills will you need in order to help Mr. Sanborn?
4. *Nursing Process (Assessment):* What further data do you need about Mr. Sanborn's sexual activity?
5. *Nursing Process (Planning Interventions):* What is one important nursing intervention for today?

CARING

6. *Self-Knowledge:* How do you feel about same-sex relationships? Would you be able to care for Mr. Sanborn effectively?
7. *Ethical Knowledge:* What does the American Nurses Association (ANA) *Nursing Code of Ethics* say about relationships to patients and the nature of patient health problems? To see the *Nursing Code of Ethics,*

Go to http://www.nursingworld.org/MainMenuCategories/EthicsStandards/CodeofEthicsforNurses/Code-of-Ethics.aspx

Critical Thinking and Clinical Reasoning

1. Recall the Quinns from Chapter 5. Merle Quinn is visiting a family planning clinic, where she has just been informed that she is 6 weeks pregnant. She looks worried and makes the following statements: "This is a shock. I've just started a new business and I need to work 7 days a week to make it go. . . . I don't know if I am ready to be a mother. . . ." Her husband agrees: "I just don't see how we can afford this. We don't have any insurance now."

   "Still," Mrs. Quinn says, "I don't see how I could deal with having an abortion. My parents would be devastated. I'm sure they'd never speak to me again." Her husband says, "Not to speak of the fact that the Church forbids it. It would be a mortal sin."

   A week later, Mrs. Quinn calls the clinic in tears. She says she has not been able to eat or sleep and that she doesn't know what to do about her pregnancy. "I don't want this baby, but I can't bring myself to have an abortion." The nurse diagnoses Decisional Conflict related to this unplanned/unwanted pregnancy and inability to accept the only perceived alternative (abortion), as evidenced by statements of indecision, tearfulness, and inability to sleep. The nurse makes an appointment to see Mr. and Mrs. Quinn that same day. Imagine that you are the nurse writing the care plan for the Quinns.

a. *Critical Thinking and Self-Knowledge (Analyzing Assumptions):* To set aside your assumptions and care for the Quinns, you will need to focus on the Quinns' immediate problem, Decisional Conflict, rather than thinking about what they "ought" to do. Remember, the nurse's role is not to make decisions for clients, but to provide information, clarification, and support.
- What questions must you ask in this case to analyze your assumptions?
- What are the answers to those questions?

b. *Critical Thinking (Contextual Awareness) and Knowledge of Patient Situation (Context):*
- What is going on in the Quinns' lives that may affect your choice of interventions?
- What is going on with Mrs. Quinn's health status that may affect your choice of interventions?

Now imagine that the nurse has written the following care plan for today's visit with the Quinns:

OUTCOMES	INTERVENTIONS
NOC Outcomes	**NIC Interventions**
Decision Making	Decision-Making Support
Participation: Health Care Decisions	Family Planning: Contraception
	Family Planning: Unplanned Pregnancy
Individualized Goals	**Computer-Generated Nursing Activities**
By the end of this visit, clients will:	1. Offer emotional support.
1. Verbalize and demonstrate decreased anxiety and stress.	2. Inform client(s) of alternative views or solutions.
2. Verbalize awareness that they have options for coping with whatever decision they make about the pregnancy.	3. Help to identify advantages and disadvantages of each alternative.
3. Discuss with the nurse options for continuing or terminating the pregnancy.	4. Encourage client(s) to explore options, including termination, keeping the infant, or adoption.
4. Verbalize intent to discuss their feelings with family (i.e., their parents).	5. Provide information as requested by client(s).
	6. Serve as liaison between patient and family.
5. Verbalize intent to discuss feelings with a member of the clergy.	7. Assist in identifying support system.
	8. Refer to community agency for counseling, if needed (e.g., family-planning clinic).
	9. Discuss factors related to unplanned pregnancy (e.g., no use or misuse of contraceptives).
	10. Teach and clarify misinformation about contraceptive use.
	11. Teach regarding preparation and procedures.
	12. Monitor for complications of procedure.

c. *Nursing Process:* Which NIC intervention, based on its label alone, does *not* appear to be relevant to producing the stated goals. (Note that it also does not appear that it would relieve the problem, reduce the etiology, or relieve Mrs. Quinn's symptoms of anxiety and distress.)

d. *Nursing Process:* Which of the computer-generated activities is/are *not* appropriate for today's visit with the Quinns?

e. *Nursing Process:* For which individualized outcome is there apparently *not* a computer-generated nursing activity?

f. *Critical Thinking:* Look at intervention 6 ("Serve as liaison between patient and family"). What critical-thinking questions should you ask about that intervention with regard to:
- Contextual awareness?
- Credible sources?
- Reflecting skeptically?

g. *Critical Thinking (Prioritizing):* Which of the computer-generated interventions will you probably need to do first today?
h. *Critical Thinking (Prioritizing):* Look at computer-generated interventions 2, 3, and 4. Which of these is most important to do today? Which one could you encourage the Quinns to do during the next week or so? Why?
i. *Nursing Process (Planning Interventions):* What would you need to do to nursing activity 1 to turn it into a nursing order that another nurse could use to care for the Quinns?
j. *Nursing Process (Assessment):* What questions would you need to ask to individualize activity 1 for the Quinns' care plan?

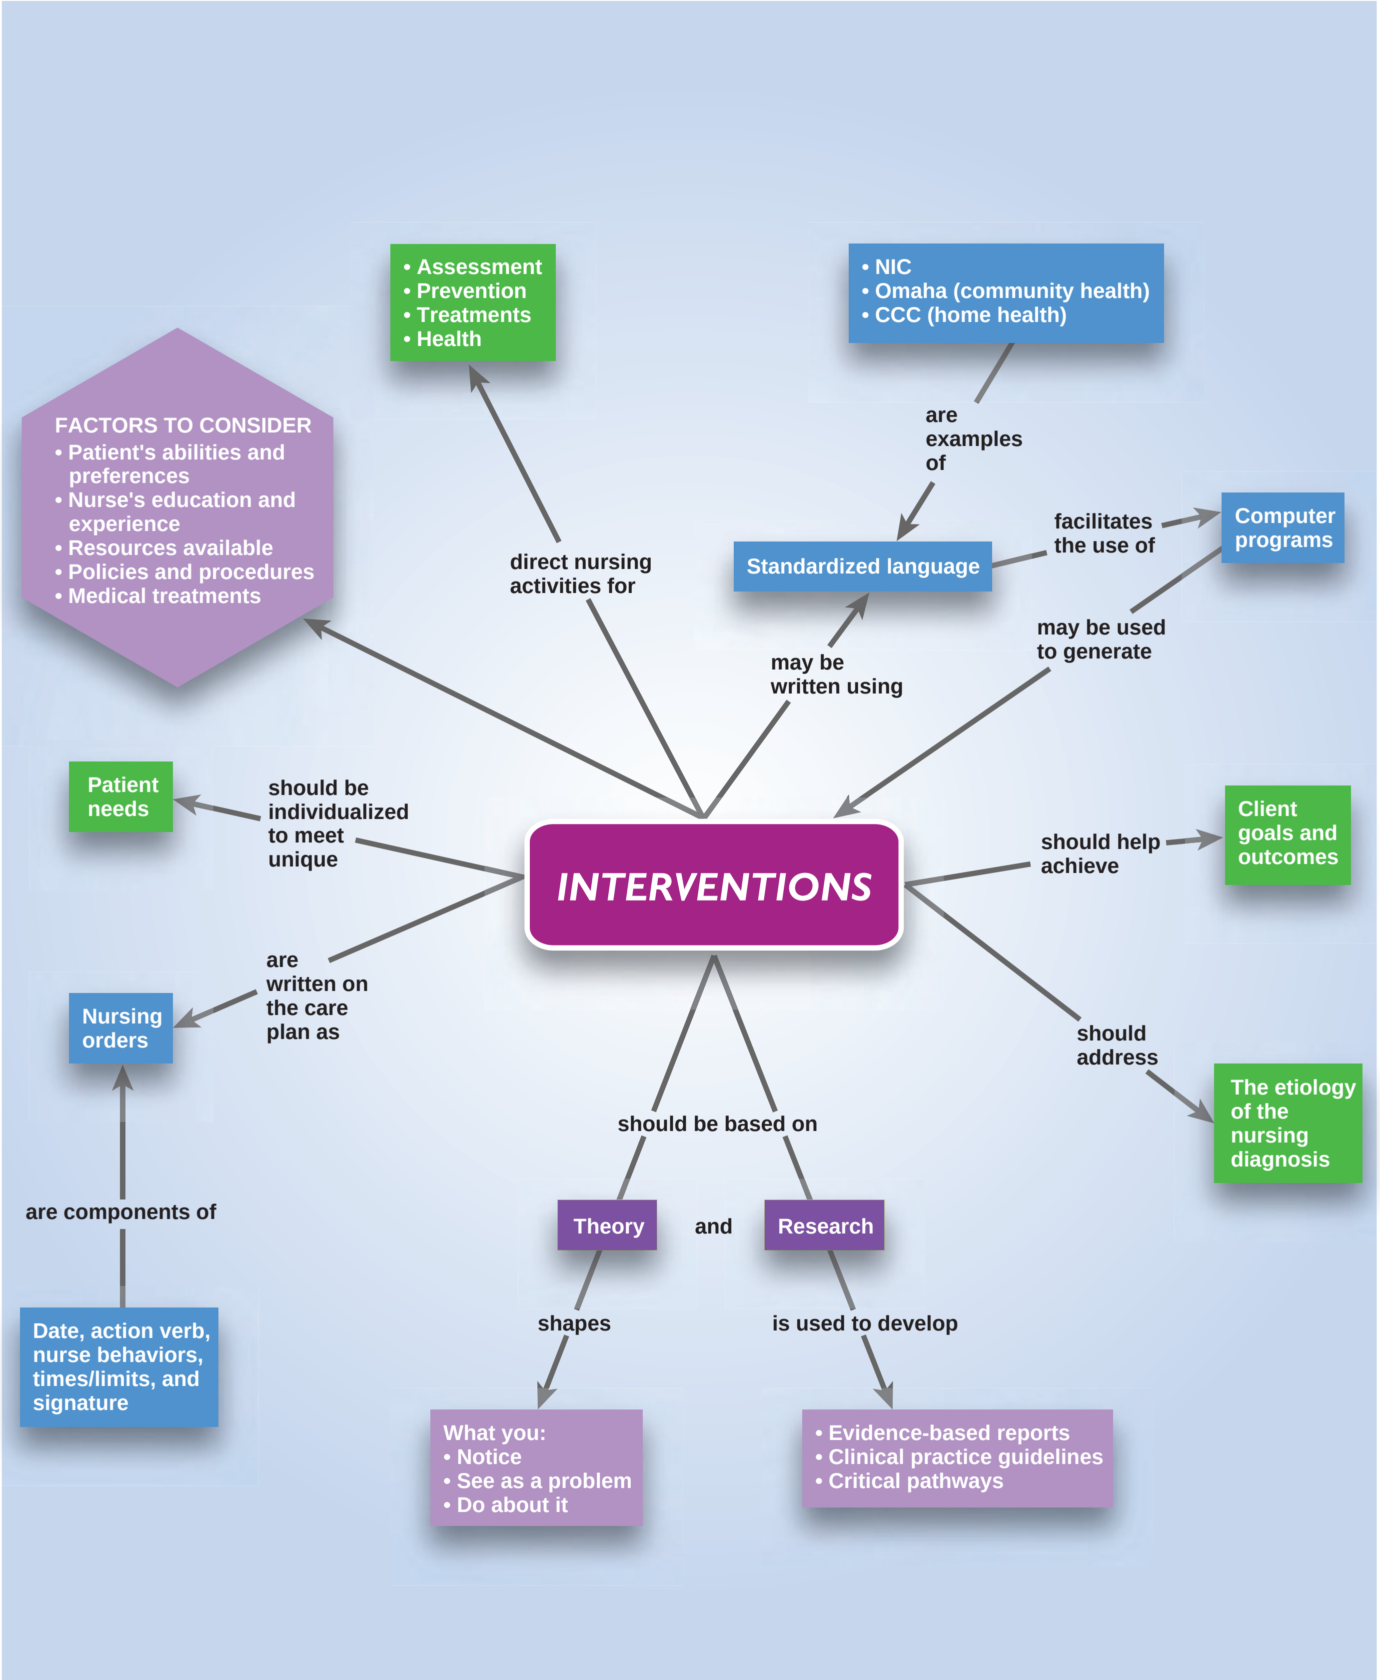
2. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or the process of planning interventions. Note that these are *not* to be merely definitions.

Nursing interventions/strategies/activities/actions
Individualized interventions
Independent interventions
Collaborative interventions
Dependent interventions
Theories
Research
Evidence-based practice
The patient's problem status
The nursing diagnosis etiology
Client outcomes
Critical thinking (e.g., contextual awareness, reflecting skeptically)
Computerized care planning program
Standardized intervention vocabularies
Nursing Interventions Classification (NIC)
Wellness interventions
Spiritual care interventions
Nursing orders

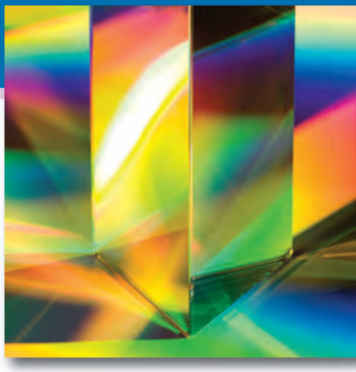
What Are the Main Points in This Chapter?

- Nursing interventions are treatments that nurses perform (1) in response to nursing diagnoses and (2) for the purpose of achieving client outcomes.
- Nursing interventions include such activities as teaching, counseling and emotional support, referral, physical care, and environmental management.
- Independent interventions are nurse-initiated treatments—those that nurses perform or delegate based on their knowledge and skills.
- Nursing interventions are performed for the purpose of assessing health status, preventing and treating disease/illness, and promoting health.
- The RN is responsible for choosing interventions and writing nursing orders; however, the RN can delegate actual performance of some interventions to nursing assistive personnel (NAPs) and LPN/LVNs.
- Theories influence your perspective: What you notice and identify as a problem, as well as how you define a problem, more or less determines your choice of interventions.
- Ideally, a nursing intervention should have a sound basis in research.
- When generating interventions, nurses use critical-thinking skills such as making interdisciplinary connections, predicting, generalizing, explaining, and making therapeutic judgments.
- The American Nurses Association has approved the following three standardized vocabularies for nursing interventions: (1) the Nursing Interventions Classification (NIC), (2) the Omaha System (developed for community health nursing), and (3) the Clinical Care Classification (CCC).
- Standardized vocabularies are especially useful in agencies that have computerized care planning systems.
- Standardized vocabularies include terminology for describing wellness interventions and spiritual interventions.
- Nursing orders, written on the nursing care plan, consist of the detailed instructions for performing nursing interventions.

Knowledge Map



CHAPTER 7



Nursing Process: Implementation & Evaluation

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus*, at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 7:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Nursing Process: Implementation & Evaluation (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 7, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

The following information is recorded on Mr. Nguyen's clinic health record:

9/1/16 Imbalanced Nutrition: More Than Body Requirements related to inappropriate food choices and serving size, as evidenced by BMI of 28.5
Outcome: Will lose 5 lb by 10/15/2016
Interventions:

- Collect 3-day nutrition history 9/2/2016 through 9/4/2016.

(Continued)

Caring for the Nguyens (continued)

- Have patient meet with clinic nurse for diet review and nutrition instruction 9/8/2016.
- Provide sample meal plans at 9/8/2016 instruction.
- Phone patient 9/22/2016 to discuss nutrition questions and review progress.
- Have patient return to clinic 10/15/2016 for follow-up visit.

A. What must you do before implementing each nursing intervention?

B. Identify at least two strategies that will help promote Mr. Nguyen's participation in and adherence to the plan.

C. How will you determine whether Mr. Nguyen has met his goal?

PracticalKnowledge knowing how

When implementing and evaluating care, you will need to make good decisions about administering and delegating care. In this section, you will find forms to help you delegate, implement, and evaluate patient care.

IMPLEMENTATION AND EVALUATION TOOLS

The first tool is a small checklist, followed by a delegation grid (to help you make wise delegation decisions). The final tool is an Evaluation Checklist.

For a worksheet for organizing nursing care that you can print and use in clinical,

Go to Student Resources: Chapter 7, Tables, Boxes, Figures: **ESG Figure 7-1, Worksheet for Organizing Nursing Care,** on Davis*Plus*.

That worksheet allows you to see at a glance the total work you need to accomplish for all your patients. Write on it, in priority order, only the most important things you must accomplish during this one day. Room numbers take up less space than names, but remember to refer to your patients by name, not by number or diagnosis. At first, you may also need to make a time-sequenced list, the size of a 3 × 5 card, to help you organize your day. For example, it might read in part:

0700 – Assessments, all patients, begin with Room 310
0730 – Ambulation: 315, 318
0800 – Change IV, meds 310; check intake
0815 – Meds 315, 318, 319; check intake
0845 – Toilet and bath, 310

and so on for the rest of the day.

The Five Rights of Delegation—Checklist

Right Task *(Can I delegate it?)*

The task is:

—Delegable for a specific patient.

—Within the nurse's scope of practice.

—Permitted by the state's nurse practice act.

—Permitted by the agency's policies.

Right Circumstance *(Should I delegate it?)*

Consider patient safety:

—Is the patient setting appropriate?

—Are adequate resources available?

—Other factors to maintain safety?

Right Person *(Who is best prepared to do it?)*

The right person:

—Is delegating the task (the nurse must be competent to delegate).

—Will be performing the task (the NAP must be competent to do the task).

—Will receive the care (i.e., the severity of the patient's illness is considered).

Right Direction/Communication *(What does the NAP need to know?)*

—The task is described clearly, including its objective, limits, and expectations.

—The delegatee (NAP) understands the communication.

Right Supervision *(How will I follow up?)*

—The nurse monitors, evaluates, and intervenes as needed.

—The nurse obtains feedback from the patient.

—The nurse obtains feedback from the delegatee.

Source: National Council of State Boards of Nursing. (1995). *Delegation: Concepts and decision-making process.* National Council Position Paper. Chicago: Author.

NCSBN Delegation Grid

Elements for review		Client A	Client B	Client C	Client D
Activity/Task Level of client stability	Describe activity/task: Score the client's level of stability: **Client condition:** 0 – Is chronic/stable/predictable 1 – Has minimal potential for change 2 – Has moderate potential for change 3 – Has unstable/acute/strong potential for change				
Level of NAP competence	Score the NAP competence in completing delegated nursing care activities in the defined client population: **NAP is:** 0 – Expert in activities to be delegated, in defined population 1 – Experienced in activities to be delegated, in defined population 2 – Experienced in activities but not in defined population 3 – Novice in performing activities and in defined population				
Level of licensed nurse competence	Score the licensed nurse's competence in relation to both knowledge of providing nursing care to a defined population and competence in implementation of the delegation process: 0 – Expert in the knowledge of nursing needs/activities of defined client population *and* expert in the delegation process 1 – Either expert in knowledge of needs/activities of defined client population and competent in delegation *or* experienced in the needs/activities of defined client population and expert in the delegation process 2 – Experienced in knowledge of needs/activities of defined client population *and* competent in the delegation process 3 – Either experienced in knowledge of needs/activities of defined client population *or* competent in the delegation process 4 – Novice in knowledge of defined population *and* novice in delegation				
Potential for harm	Score the potential level of risk the nursing care activity has for the client *(risk is probability of [the client] suffering harm):* 0 – None 1 – Low 2 – Medium 3 – High				
Frequency	Score based on how often the NAP has performed the specific nursing care activity: 0 – Performed at least daily 1 – Performed at least weekly 2 – Performed at least monthly 3 – Performed less than monthly 4 – Never performed				
Level of decision making	Score the decision-making needed, related to the specific nursing care activity, client (both cognitive and physical status) and client situation: 0 – Does not require decision making 1 – Minimal level of decision making 2 – Moderate level of decision making 3 – High level of decision making				
Ability for self care	Score the client's level of assistance needed for self-care activities: 0 – No assistance 1 – Limited assistance 2 – Extensive assistance 3 – Total care or constant attendance				
Total Score					

Scoring: A low score on the grid suggests that an activity can be safely delegated. For example if a client's stability is ranked 3 (unstable) and the level of NAP competence is also 3 (novice in the activity), then you probably should *not* delegate to that NAP. Each agency should establish a policy regarding the individual and/or total scores to be considered acceptable for delegating.

Evaluation Checklist

Evaluation Checklist

Instructions: Check the appropriate response and follow the associated instructions

Assessment Review

1. Were the assessment data complete and accurate?
   __ YES. No action.
   __ NO. Reassess client. Record the new data. Change care plan as indicated
2. Have all data been validated, as needed?
   __ YES. No action.
   __ NO. Validate with client (by interview and physical examination), significant others, or other professionals. Record validation (or failure to validate). Change care plan as indicated.
3. Have new data become available that require changes in the plan (e.g., a different problem etiology, new goals/ outcomes, new medical orders)?
   __ NO. No action.
   __ YES. Record the new data in the progress notes; redefine problem, goals, nursing orders, as needed.
4. Has the patient's condition changed?
   __ NO. No action.
   __ YES. Record data about present health status. Change care plan as indicated.

Move to a review of the diagnosis step.

Diagnosis Review

1. Is the diagnosis relevant and related to the data?
   __ YES. No action.
   __ NO. Revise the diagnosis.
2. Is the diagnosis well supported by the data?
   __ YES. No action.
   __ NO. Collect more data. Support or revise diagnosis.
3. Has the problem status changed (actual, potential, possible)?
   __ NO. No action.
   __ YES. Restate the problem.
4. Is the diagnosis stated clearly?
   __ YES. No action.
   __ NO. Revise the diagnostic statement.
5. Does the etiology correctly reflect the factors contributing to the problem?
   __ YES. No action.
   __ NO. Revise the etiology.
6. Is the problem one that can be treated primarily by nursing actions?
   __ YES. No action.
   __ NO. Label as collaborative and consult appropriate health professional.
7. Is the diagnosis specific and individualized to the patient?
   __ YES. No action.
   __ NO. Revise diagnosis. Revise outcomes and nursing orders as suggested by the new nursing diagnosis.
8. Does the problem (diagnosis) still exist?
   __ YES. No action.
   __ NO. Delete diagnosis and related outcomes and nursing orders.

Proceed to a review of client goals.

Planning Review: Outcomes

1. Have nursing diagnoses been added or revised?
   __ NO. No action.
   __ YES. Write new outcomes.
2. Are the outcomes realistic in terms of patient abilities and agency resources?
   __ YES. No action.
   __ NO. Revise outcomes.
3. Was sufficient time allowed for outcome achievement?
   __ YES. No action.
   __ NO. Revise time frame.
4. Do the outcomes address all aspects of the client's problem?
   __ YES. No action.
   __ NO. Write additional outcomes.

Evaluation Checklist *(continued)*

5. Do the expected outcomes, as written, demonstrate resolution of the problem specified in the nursing diagnosis?
   __ YES. No action. __ NO. Revise outcomes.
6. Have client priorities changed, or has the focus of care changed?
   __ NO. No action. __ YES. Revise outcomes.
7. Is the client in agreement with the goals?
   __ YES. No action. __ NO. Get client input. Write outcomes valued by the client.

Proceed to a review of nursing orders.

Planning Review: Nursing Orders

1. Have nursing diagnoses or outcomes been added or revised in previous review steps?
   __ NO. No action. __ YES. Write new nursing orders.
2. Are the nursing orders clearly related to the stated patient outcomes?
   __ YES. No action. __ NO. Revise or develop new nursing orders.
3. Is the rationale sufficient to justify the use of the nursing order?
   __ YES. No action. __ NO. Revise or develop new nursing orders.
4. Are the nursing orders unclear or vague, so that other staff may have had questions about how to implement them?
   __ NO. No action. __ YES. Revise nursing orders. Add details to make more specific or individualized to the patient.
5. Do the nursing orders include instructions for timing of the activities?
   __ YES. No action. __ NO. Revise nursing orders: add times, schedules.
6. Was an order clearly and obviously ineffective?
   __ NO. No action. __ YES. Delete it.
7. Are the orders realistic in terms of staff and other resources?
   __ YES. No action. __ NO. Revise orders or obtain resources.
8. Have new resources become available that might enable you to change the goals or nursing orders?
   __ NO. No action. __ YES. Write new goals or nursing orders reflecting the new capabilities.
9. Do the nursing orders address all aspects of the client's health goals?
   __ NO. No action. __ NO. Add new nursing orders.

Proceed to a review of implementation step

Implementation Review

1. Did the nurse [or NAP] get client input at each step in developing and implementing the plan?
   __ YES. No action. __ NO. Obtain client input, revise plan and implementation as needed. [Coach NAP or role model, as needed.]
2. Were the nursing interventions acceptable to the patient?
   __ YES. No action. __ NO. Consult patient; change nursing orders or implementation approach.
3. Did the nurse [NAP] prepare the patient for implementation of the nursing order (e.g., explain what the patient should expect or do)?
   __ YES. No action. __ NO. Continue same plan, but prepare patient before implementing. Reevaluate.
4. Did the nurse [NAP] have adequate knowledge and skills to perform techniques and procedures correctly?
   __ YES. No action. __ NO. Continue same plan. Have someone else implement or help the nurse [or NAP] to acquire the needed knowledge or skills. If neither of these is possible, delete nursing order.

(continued)

5. Did client or family comply with the therapeutic regimen? Were self-care activities performed correctly?
   ___ YES. No action.
   ___ NO. Reassess motivation, knowledge, and resources. Add outcomes and nursing orders aimed at teaching, motivating, and supporting, patient in carrying out the regimen. Set time for reevaluation.
6. Did other staff members follow the nursing orders?
   ___ YES. No action.
   ___ NO. Implement the omitted nursing orders or ensure that others will do so. Set time for reevaluation. Find out why order was not carried out.
7. Was the plan of care implemented in a manner that communicated caring?
   ___ YES. No action.
   ___ NO. This is a problem that must be addressed by personal and staff development.

After making the necessary revisions to the care plan, implement the new plan and begin the nursing cycle again.

Source: Wilkinson, J. (2011). *Nursing process and critical thinking* (5th ed.). Upper Saddle River, NJ: Prentice Hall, pp. 325–327.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Recall Jeannette Wu from Volume 1. Jeannette Wu is a frail 80-year-old woman who is in the hospital after fracturing her hip. Her hip was surgically repaired 4 days ago, but because of her overall fragile health and some postsurgery confusion, her recovery is slower than usual. One of her nursing diagnoses is Self-Care Deficit (Bathing, Dressing, and Toileting) related to weakness, pain, confusion, and decreased mobility. Her nursing orders (NIC) include Bathing and Self-Care: Activities of Daily Living (ADLs). As the nurse is helping a nursing assistive personnel (NAP) with Mrs. Wu's bath, she notices a reddened area on Mrs. Wu's sacrum. Realizing that this may be the beginning of a pressure ulcer, the nurse observes carefully and notes a small skin excoriation (abrasion) in the reddened area. She repositions Mrs. Wu to prevent further pressure on her sacrum. After finishing the bath, the nurse records her findings and enters on Mrs. Wu's care plan a nursing diagnosis of Impaired Skin Integrity related to impaired bed mobility and minimal subcutaneous tissue. She writes nursing orders, including an order to observe skin over bony prominences every 4 hours, and then delegates to the NAP the task of turning and repositioning Mrs. Wu every 2 hours. The nurse also sends a consultation request to a wound care nurse specialist.

THINKING

1. *Theoretical Knowledge:*
   a. What facts and principles do you already know about the causes of pressure ulcers?
   b. Do you have enough information to provide interventions for Mrs. Wu's actual Impaired Skin Integrity? If not, what do you still need to find out?
2. *Critical Thinking (Inquiry):* What resource would be best to use to find out exactly what is meant by Mrs. Wu's diagnosis of Self-Care Deficit? Why?

DOING

3. *Practical Knowledge:* What do you know about positioning patients? How would you explain to the NAP about how to position Mrs. Wu "to prevent further pressure on her sacrum"?
4. *Nursing Process (Evaluation):*
   a. To evaluate Mrs. Wu's Impaired Skin Integrity problem, what reassessments would you make?
   b. To evaluate Mrs. Wu's Self-Care Deficit problem, what reassessments would you make? Who can or should make them? How often, or when, would you reassess?

CARING

5. *Self-Knowledge:* How comfortable would you be in caring for Mrs. Wu, who is a frail older adult? What is one problem that might arise that is not described in the scenario?

Critical Thinking and Clinical Reasoning

1. You are working a 12-hour shift (1900 to 0700) on a medical unit at a local hospital. You will be caring for six adult patients. Make a list of the theoretical and practical knowledge you need about the patients to begin organizing your work for the shift. You may not yet have enough experience to make a complete list, but speculate about the kinds of information you think you might need. For example, to organize your work, you will need to know whether you have an NAP or LVN/LPN to assist you or whether you are providing total care for the patients.
2. Create a form for organizing your work. You will need to use a separate sheet of paper for this. Be sure it has space for at least six patients. You might begin by making a column for each patient's name and age, for example. Be sure to leave enough room to write the necessary information. For example, you will need more room to write the patients' tests and treatments than for writing in age and gender.
3. Alma Newport, who is 80 years old, has diabetes, severe arthritis, and mild dementia secondary to Alzheimer's disease. She lives alone. She refuses to consider an assisted living facility or nursing home, although her primary provider and children, who live out of town, believe it would be safer for her to do so. On more than one occasion, she has forgotten to turn off a stove burner while cooking, burning the contents of the pan and smoking up the house.

   A home health nurse visits Mrs. Newport once a week. The physician wants Mrs. Newport to check and record her blood sugar levels before each meal. When the nurse asks, she says her blood sugar level is "OK" and shows the nurse the record she has kept, on which she has recorded many extremely low readings (e.g., 17, 20, 80, 24, 17 mg/dL). When the nurse checks Mrs. Newport's blood sugar, she obtains a reading of 210 mg/dL. After calibrating the glucose meter, the nurse writes the following care plan:

   Nursing Diagnosis:
   Deficient Knowledge related to cognitive deficits secondary to dementia
   Desired Outcomes:
   Mrs. Newport will demonstrate correct method for checking her blood sugar by next visit.
   Mrs. Newport will obtain correct readings.
   Nursing Orders:
   Teach correct method of fingerstick and checking blood glucose.
   Evaluate patient's technique at each visit.

   Over the next few weeks, the home health nurse checks Mrs. Newport's log and fingerstick method at each visit. The logs continue to show low readings, and Mrs. Newport remains unable to perform a fingerstick blood glucose test correctly in spite of repeated demonstrations.

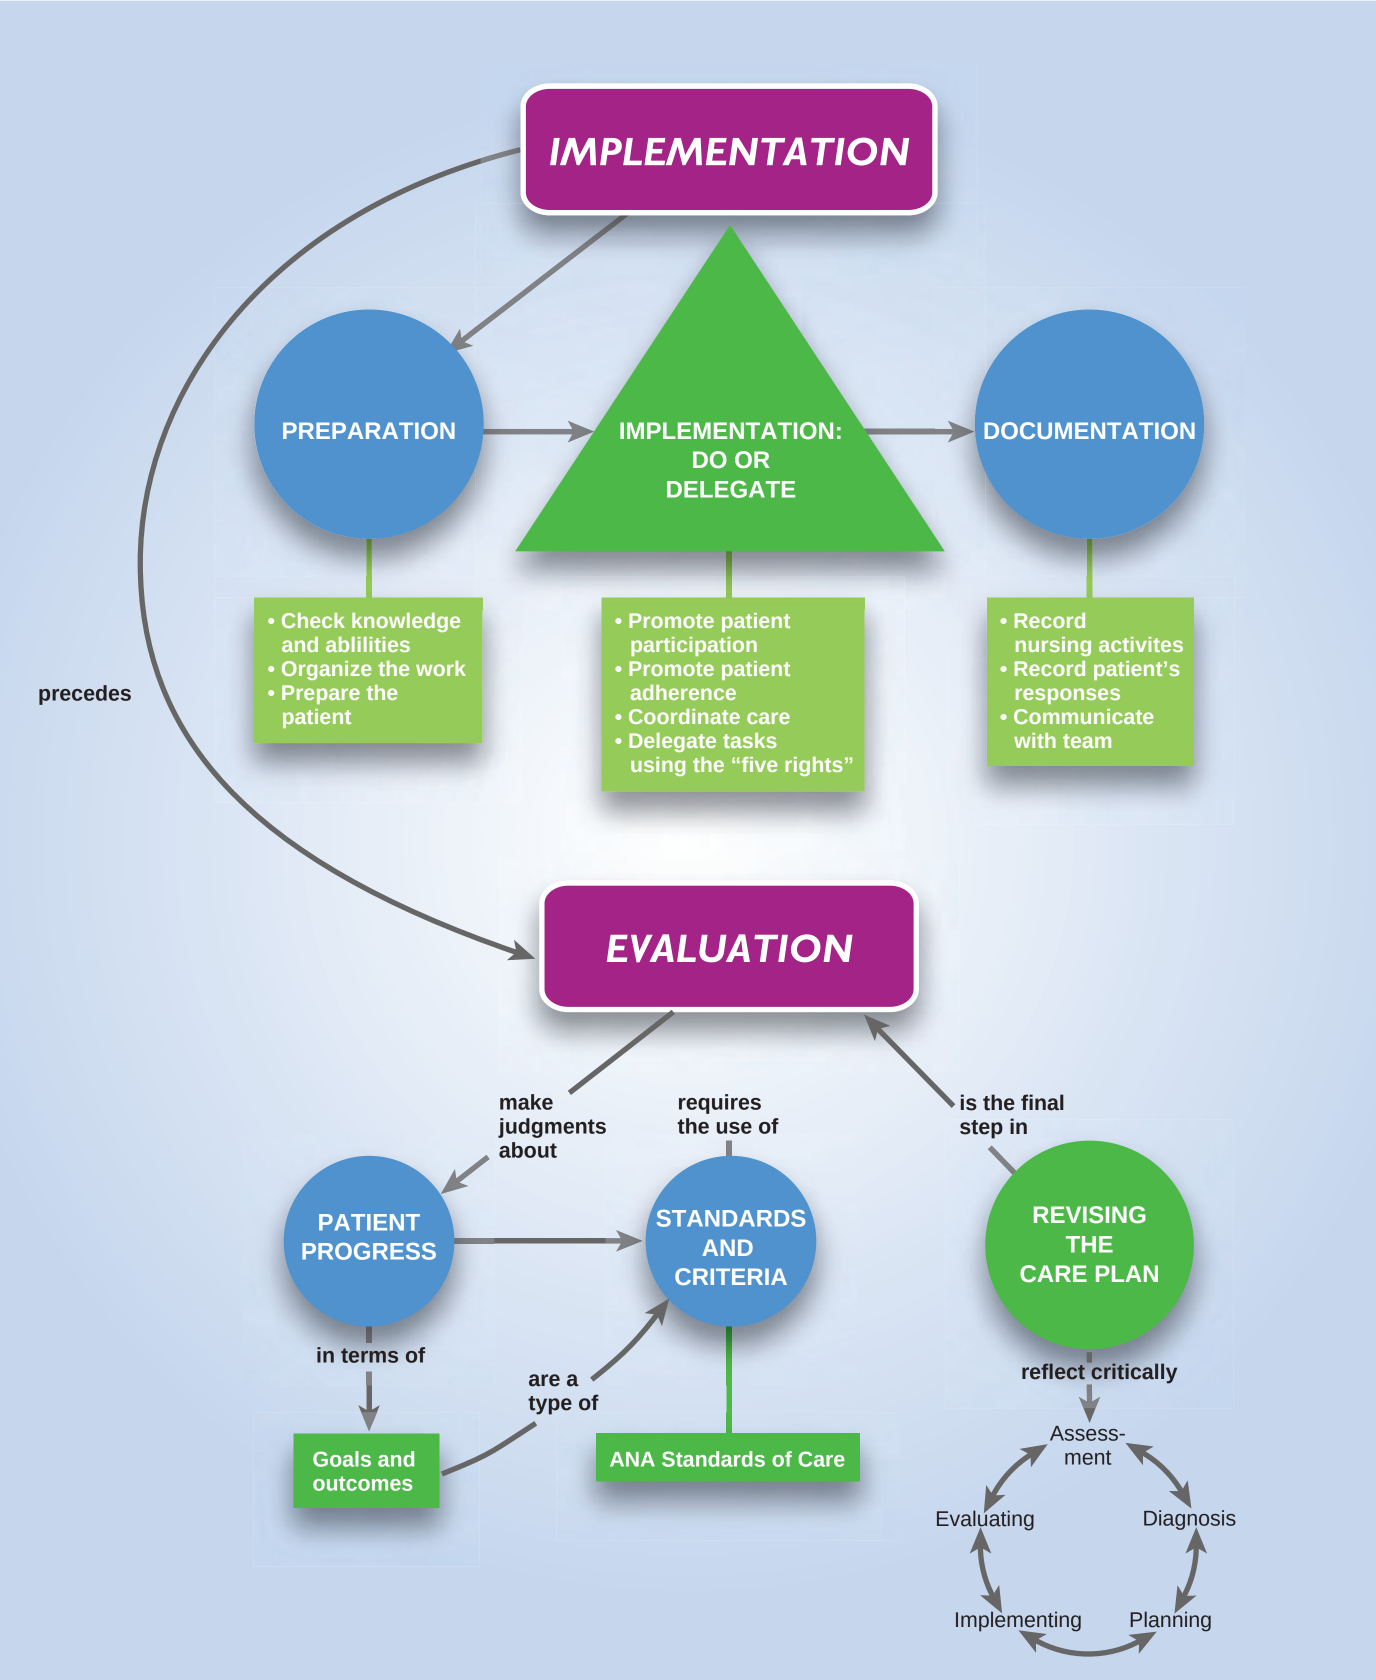
   a. Evaluate Mrs. Newport's progress. Has she met, partially met, or not met the desired outcome?
   b. What possible reasons may account for your evaluation (of Mrs. Newport's outcome status)? Hints:
      (1) Use your theoretical knowledge and personal experience with physical changes that occur with aging.
      (2) Use the data you have about Mrs. Newport.
      (3) Use your practical knowledge about nursing diagnoses.
4. A NAP is helping a patient with a shower when her pager goes off. After ensuring the patient's safety, the NAP goes into the hallway and answers her page. You observe that the NAP is still wearing her gloves. How would you handle this situation?
5. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or the processes of implementing and evaluating. Note that these are *not* to be merely definitions.

   Overlapping (of implementation and other nursing process steps)
   Preparing for implementation
   Client participation and adherence
   Coordination of care
   Delegation of care
   The "five rights" of delegation
   Supervision
   Reflecting critically about implementation
   Evaluation
   Outcomes evaluation
   Evaluative statements
   Quality assurance programs

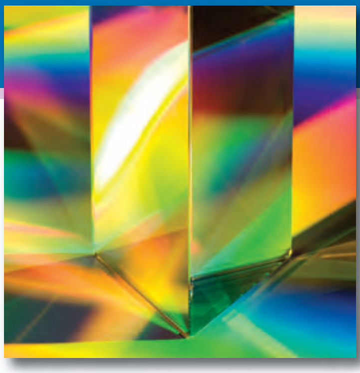
What Are the Main Points in This Chapter?

- Implementation is the nursing process phase in which you perform or delegate the nursing activities that were planned in preceding steps.
- Before performing interventions, you should organize supplies and equipment and ensure the client's readiness.
- While implementing care, you will continue to make assessments and evaluate client responses.
- Collaboration and coordination of care are important nursing functions.
- Delegation is the transfer of responsibility for an action while retaining the accountability for the outcome—this implies that you must supervise those to whom you delegate care.
- The "five rights" of delegation are right task, right circumstance, right person, right direction/communication, and right supervision.
- The final activity in the implementation step is documentation of the care provided. Documenting client responses is actually a part of the evaluation phase; however, you will document both at the same time, often in the same note.
- Evaluation is the final step of the nursing process; it is a planned, ongoing, systematic activity in which you use predetermined standards and criteria to make judgments about: (1) patient progress toward health goals; (2) the effectiveness of the nursing care plan; and (3) the overall quality of care on a unit, in an organization, or in a geographical area.
- When evaluating client health status, you will compare the client's present data/responses to the desired outcomes (goals) set in the planning outcomes phase.
- When evaluating the effectiveness of the nursing care plan, remember that you cannot control all of the variables that influence the success of a nursing activity.
- Quality improvement programs are specially designed to promote excellence in nursing; they include structure, process, and outcomes evaluation.

Knowledge Map



CHAPTER 8



Evidence-Based Practice: Theory & Research

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 8, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Nam Nguyen arrives at the clinic for a follow-up visit. As you may recall, he has been diagnosed with hypertension. At a previous visit, you wrote a nursing diagnosis of Imbalanced Nutrition: More Than Body Requirements related to inappropriate food choices and serving size, as evidenced by a body mass index (BMI) of 28.5.

Today you have gathered the following intake data:

Blood pressure: 174/96 mm Hg
Heart rate: 88 beats/min
Respiratory rate: 18 breaths/min
Temperature: 98.5°F
Weight: 175 lb

Caring for the Nguyens (continued)

A. What observations can you make about today's data in comparison with his initial visit?

B. As part of the treatment plan for Nam Nguyen, you have been asked to educate him about a diet to assist with weight loss and hypertension management. How would you determine the most appropriate diet to include in your treatment plan?

C. A number of sources recommend the DASH (Dietary Approaches to Stop Hypertension) eating plan. Go to the Internet and search for "Dietary Approaches to Stop Hypertension." Is there sufficient research to support incorporating this information into Mr. Nam's treatment plan? If so, describe the research, and summarize the DASH eating plan.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

You are caring for a 90-year-old patient in a long-term care facility. He is completely dependent for activities of daily living (ADLs). In addition, he has been unresponsive, cannot swallow safely, and for many months has been receiving fluids and nutrition through a feeding tube. His adult grandson has recently discovered a living will, in which the patient had stated that he does not wish to be kept alive by "artificial means, including being tube fed." The grandson, John, insists that the patient's wishes be honored, but the patient's son (Mr. Lee) threatens a lawsuit if the caregivers discontinue the feedings. They argue loudly, and Mr. Lee yells to his son, "You just want him gone because you're in a hurry to get his money! You know you're getting the major part of it."

THINKING

1. *Theoretical Knowledge:* What facts are important to know in order to decide whether or not to stop the feedings?
2. *Critical Thinking (Analyzing Assumptions):* Without thinking too carefully about it, what is your first thought about what is causing the disagreement between Mr. Lee and his son, John? Examine your assumption. How certain are you it is true? What else might be going on in their lives to cause father and son to disagree on this issue?

DOING

3. *Nursing Process (Assessment):* In order to provide some information about the patient that might be helpful in restoring peace between Mr. Lee and John, what patient assessments should you make?

CARING

4. *Ethical Knowledge:* State one ethical issue involved in this case—or one moral problem that it would be present for you if you were involved in it.

Critical Thinking and Clinical Reasoning

1. Recall the scenario about Mr. Wilkey (Meet Your Patient) in Volume 1. Imagine you are the charge nurse on the night shift at a long-term care facility. You hear the certified nursing assistant (CNA) and another person talking loudly down the hall. You immediately go to see what has happened. You are surprised and shocked by what you see. An older patient, Mr. Wilkey, is sitting on the bed of another patient, Mrs. Fredrickson, who is crying and shouting, "Get out! Get out!" Mr. Wilkey is tearful and looks frightened. He keeps repeating, "Where is Momma? Where is Momma?" The CNA is visibly upset and is grabbing at Mr. Wilkey in an effort to get him off the bed. Use any nursing theory you wish, or your own idea, and describe each of the following concepts as they apply in this scenario:
   a. Patient (Who is the patient? How do you know?)
   b. Nurse (Who is the nurse? What is she doing that is "nursing"?)
   c. Health (Is the patient healthy? What is the patient's state of health?)
   d. Environment (Where is the nurse–patient encounter occurring?)

2. Recall Maslow's Hierarchy of Needs. Give one example of a specific nursing intervention a nurse could do to meet each of those needs. If you think the nurse cannot address a need, explain.
   a. Physiological
   b. Safety and security (mental and physical protection)
   c. Love and belonging
   d. Self-esteem (achievement, reputation)
   e. Cognitive needs (knowledge, self-awareness)
   f. Aesthetic needs (beauty, balance, form)
   g. Self-actualization (personal growth, fulfillment)
   h. Transcendence (helping others to self-actualize)
3. You are an emergency department nurse taking care of a 4-year-old child who has had a bike accident. The child has an open abrasion and a few cuts that will require some minor care. However, he is frightened and crying.
   a. Using Nightingale's theory, what interventions might you use?
   b. Using Watson's theory, what might you do?
   c. Using Henderson's theory, what would be the focus of your interventions?
   d. Choose one of the following theories: Neuman, Orem, or Rogers. Look it up on the URL listed in Volume 1 or on Davis*Plus*. Describe how that theory would direct you in this case.
4. You are working the night shift, and while making your 0200 rounds, you are surprised. As you look into the room of 22-year-old Angela Kindred, you see her mother sitting at her bedside sobbing. Visits are not encouraged at that time of night, and you didn't know Mrs. Kindred was on the unit. Even though Angela's leukemia prognosis is terminal, you understood from the day nurse that the family, as well as Angela, had accepted the inevitable outcome. Explain how you can demonstrate caring to this mother who will soon lose her beloved daughter. Look at Watson's (1988) 10 caring processes, repeated below from your textbook. How can you use them to demonstrate caring to this mother and daughter? Be specific in your answers.

Watson's Ten Caring Processes:

1. Forming a humanistic–altruistic system of values
2. Instilling faith and hope
3. Cultivating sensitivity to self and others
4. Forming helping and trusting relationships
5. Conveying and accepting the expression of positive and negative feelings
6. Systematic use of the scientific problem-solving method that involves caring process
7. Promoting transpersonal teaching–learning
8. Providing for supportive, protective, and corrective mental, physical, sociocultural, and spiritual environment
9. Assisting with gratification of human needs
10. Sensitivity to existential–phenomenological forces

5. You are an emergency department nurse taking care of a 4-year-old child who has had a bike accident. The child has an open abrasion and a few cuts that will require some minor care. However, he is frightened and crying, even though his mother is sitting in the treatment room with him. You ask the mother to hold the child while he is being treated and restrain him, if necessary. In reflecting on this intervention afterward, you decide to find the best evidence for your intervention to be certain you will want to use it in similar situations in the future. Write a PICO question to guide your literature search. Write each part, then write the full statement. Note that you do not need to add the "Time" element to this statement.
   P—
   I—
   C—
   O—
   Full statement of the question.
6. Read analytically an article in a research journal. Answer the following questions about the article:
   a. What is the article about as a whole? Answer using one sentence.
   b. What are the author's main conclusions?
   c. Do you think these conclusions are true? If not, why not?
   d. Is this article of any significance in nursing? That is, how could it be used to improve patient care or nursing education?

7. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or nursing theory and research. Note that these are *not* to be merely definitions.

Nursing theory	Nursing research
The science of human caring	Institutional review board
From novice to expert	Informed consent
Culturally competent care	Research utilization
Evidence-based practice	Analytical reading

What Are the Main Points in This Chapter?

- According to Florence Nightingale, nursing theories describe "what is" and "what is not" nursing.
- The four basic components of a nursing theory are person, nurse, environment, and health.
- A theory is developed by recognizing a need in nursing or by having an idea, using research to determine whether the idea is effective, and then using the research results to define a theory.
- Theories help nurses (1) find meaning in their experiences of nursing; (2) organize their thinking around pertinent ideas; and (3) develop new, evidence-based ideas and insights into the work they do.
- Nurses use theories as an evidence-based framework for their nursing practice.
- Three leaders in nursing caring theories are Dr. Jean Watson, Dr. Patricia Benner, and Dr. Madeleine Leininger.
- Nursing research is a systematic, objective process of analyzing phenomena of importance in nursing.
- Quantitative research may be generalized to populations similar to the one studied. It has tight controls and large numbers of participants, and the data are statistically analyzed.
- Qualitative research tells the lived experience of a person or group of people. It is analyzed by examining the words and actions of a small number of participants.
- The research process is a systematic way of organizing, preparing, and presenting research.
- Research participants (people in a research study) are protected from harm by specific laws and regulations.
- Research reports are critiqued by reading analytically and using preselected criteria.
- Nursing research evolved slowly. The advanced education currently available to nurses is speeding up the evolution of research.
- Evidence-based nursing requires evaluating research to find the best evidence, and then applying it in practice.
- The process of finding best evidence consists of: identifying a clinical nursing problem, formulating a searchable question, searching the literature, evaluating the quality of the research, and integrating the research into practice.
- The parts of a PICOT question are: **P**atient problem, **I**ntervention, **C**omparison intervention, **O**utcome, and **T**ime.

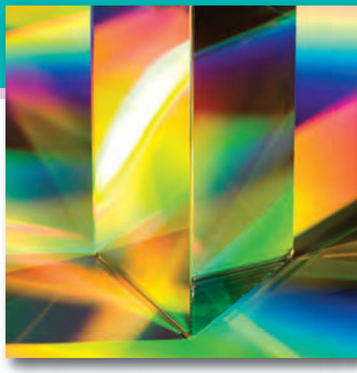
unit 2

Factors Affecting Health

CHAPTER 9



Life Span: Infancy Through Middle Adulthood

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find response sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 9:

- **Response Sheets for all activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Life Span: Infancy Through Middle Age (Suggested Readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

Caring for the Nguyens

Review the scenario of Nam Nguyen, in the Meet the Nguyens section before Chapter 1 in the front of this book. Answer the following questions based on that scenario:

(Continued)

Caring for the Nguyens (continued)

A. Evaluate Mr. Nguyen's physical health status in comparison with what is expected for someone in his age group.

B. Mr. Nguyen and his wife are raising their 3-year-old grandson. What effect might this have on Mr. Nguyen's ability to accomplish his developmental tasks?

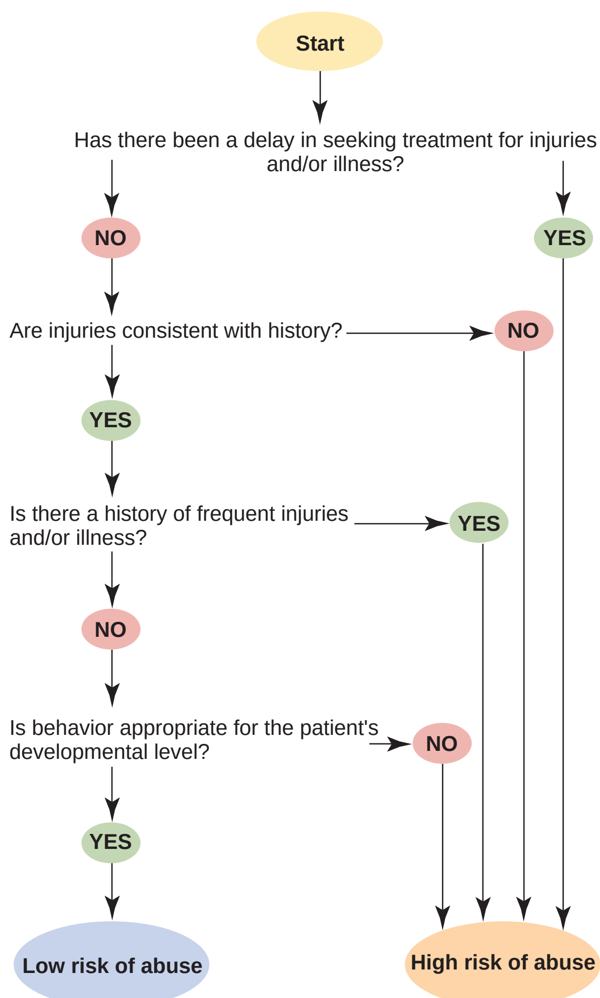
Practical Knowledge knowing how

One important aspect of developmental care across the life span is to identify abuse and intervene with patients who are being abused.

PROCEDURES

You will find information on elder abuse in Chapter 10; however, the following procedure can be used for patients of all ages.

Keep in mind that if there is an injury, there is the possibility that it was inflicted. The following flow chart and Procedure 9-1 will aid you in identifying cases of abuse.



Procedure 9-1 ■ Assessing for Abuse

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2.

Delegation

Key Point: ***Assessment is a nursing responsibility and cannot be delegated.***

Pre-Procedure Assessment

- If you suspect sexual abuse, request a forensic nurse or sexual assault nurse examiner (SANE) be present.
  A forensic nurse and SANE are specially trained to identify findings that indicate abuse, to support the patient, and to handle the evidence to ensure validity in a court of law.
- Assess for abuse routinely in elderly or vulnerable adults and women of childbearing age, and any time a child, dependent person, or spouse has an injury.
  Although there is not a strong base of evidence to support screening, The Joint Commission requires that all patients be screened for abuse and domestic violence.

➤ When performing the procedure, always identify your patient according to agency policy and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ Privacy and confidentiality are extremely important for this procedure.

Procedure Steps

Obtain a Focused Health History.

1. **Interview the patient and family** members or caregivers separately. If more than one caregiver is present, separate them for the interview, as well.
   Allows the patient more freedom to express his concerns. An abused person may be afraid to talk with the abuser present. Victims have often been intimidated and will usually support the abuser's version of events. If two adults accompany a child, it may be that one of them is abusing both the partner and the child. To help rule that out, separate the caregivers to be certain that they tell the same story.

2. **Approach the subject in a nonthreatening and caring manner.** For example, you might say: "The law requires us to ask about certain injuries. We are not accusing you of anything. I know you care about your child/parent/spouse and want to do everything possible for her health."

3. **Consider the patient's developmental and cognitive level** in assessing whether the story of how the injury occurred is consistent with the injuries.
   The patient must be developmentally capable of performing an activity in a situation in which an injury occurred. For example, an infant is not likely to have opened a medication bottle and taken pills; if a child cannot yet walk, it is not likely that he reached up to pull a hot pan off the stove.

4. **Observe the patient's behavior.** Is it inconsistent with his developmental level?
   In the presence of the abuser, it is common for the abuse victim to appear passive and withdrawn and avoid eye contact. The victim may exhibit anxious or fearful behavior; may look to the parent or caregiver before answering questions; may be overly compliant; or may let the abuser answer the questions for him.

5. **Ask about the injury or incident.** Ask detailed questions about how and when the injury occurred or the illness began: "When did this injury happen or when did you first begin to feel ill?" "How did you get this injury?" "What happened to you?" "What have you been doing to treat your symptoms since you first became ill?"
   A delay of treatment of 12 to 18 hours may indicate abuse. If the details of the history of an injury change during the interview, the likelihood of abuse increases.

6. **Ask about past injuries or incidents:** "Have you ever had similar injuries?" "Have you ever required emergency care in the past?"
   Abusive behavior typically occurs over and over. If an injury is due to abuse, the patient would most likely have experienced abuse in the past and would have evidence of old injuries.

7. **Ask about the patient's usual diet:** "What do you usually eat for breakfast? Lunch? Dinner? What kind of snacks do you have during the day?"
   Neglect and/or abuse may be exhibited by an inadequate or inappropriate diet.

Assess for Sexual Abuse.

8. **Ask directly whether the patient has been touched** inappropriately or forced to have sexual relations.
   Whenever possible, question the patient directly so your question will not be misunderstood.

9. **Ask whether the patient has genitourinary symptoms:** "Have you had any burning or itching when you urinate? How about any vaginal discharge?"
   In a child, genitourinary symptoms may indicate sexual abuse or neglect.

10. **Does the child display knowledge or interest in sexual acts** inappropriate to his or her age, or even seductive behavior?

11. **Does the child appear to avoid another person,** or display unusual behavior—either very aggressive or very passive?

12. **Does the victim display destructive behaviors**, such as alcohol or drug abuse, self-mutilation, or suicide attempts?

(continued on next page)

13. Is the victim pregnant, particularly if no intimate relationship is known or the victim is very young?

Assess for Psychological Abuse.

14. Ask parents or caregivers, "Are there family members or friends who help you with problems?"
Isolation is a risk factor for abuse. Parents or caregivers may not have the support they need.

15. Ask the patient, "Whom do you talk to when you are having problems?"
An abuser will try to isolate the victim from family and friends over time. Ask questions to determine what the relationship is between the victim and family and friends.

16. Ask, "Tell me how you feel about yourself."
An abuser demeans and degrades the victim so that the victim has a low self-worth and feels the "punishment" is deserved; conversely, the victim may desire the attention.

17. Observe if the child acts fearful, shies away from touch, or appears to be afraid to go home.

18. Ask, "Who manages the family finances, and how are decisions made regarding spending?"
An abuser frequently controls all the finances, and restricts the resources of the victim. Abusers typically seek control of victims by fostering dependency and powerlessness.

Perform a Focused Physical Assessment.

19. If sexual abuse is suspected from the interview, have a forensic nurse or SANE present if possible.
For any sexual examination, always have a witness in the room to protect the patient and the examiner.

20. Assess the current injury and look for evidence of previous injuries. Look for the following cues:

a. Bruises that form an outline of a hand, cord loop, buckle, or belt

Injuries of different ages and multiple injuries may show a pattern of abuse. Be careful to assess the bruise accurately. Some home treatments may cause what looks like bruising. For example, ***moxibustion*** *(includes such things as firmly rubbing a warm spoon down the affected area) is used in some Asian cultures.*

b. Injuries that are of varying ages (e.g., bruises of different colors, cuts in various stages of healing)

c. Obvious nonaccidental burns, such as burns to both feet and lower legs from immersion in hot water

One method of abuse is to immerse the victim's hands or feet into scalding water. The resulting injury has a well-defined border and usually occurs on both extremities.

d. Circular burns, possibly from cigarettes

Burns at several locations on the body are signs of abuse.

e. Bite marks

f. Oral ecchymosis or injury from forced oral sex

Forced oral sex will cause injuries to the mouth.

g. Bruising at the crease above the eyelids, tense fontanel if the victim is an infant, hyphema, subconjunctival hemorrhage or retinal bleeding, detached retina, ruptured tympanic membrane

Key Point: ***Injuries to the head are common in abuse. Abusive head trauma (AHT, previously referred to as shaken-baby syndrome) is one of the most common and most serious injuries for a young child.***

h. Bleeding or bruising of genitalia, poor sphincter tone, encopresis (poor bowel control) and bruises on inner thighs

i. Positive culture for sexually transmitted infection (STI) or positive pregnancy test

STI, particularly in a child, can indicate sexual abuse.

j. Bruises on wrists and ankles from being restrained

Abused individuals may be tied or locked in a closet or other small space.

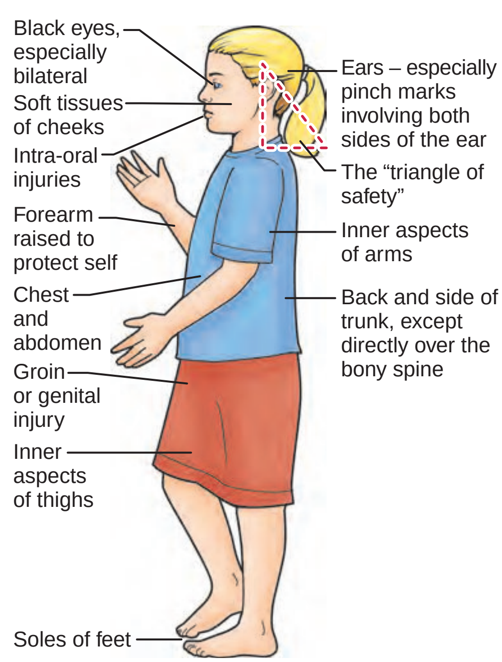
k. Refer to the figure for typical features of injuries that may be nonaccidental:

Injuries to both sides of the body

Injuries to soft tissue

Injuries in the "triangle of safety" (ears, side of face, neck, and top of the shoulders)

Accidental injuries are usually over bony prominences. One suspicious pattern is the "swimsuit zone" on the trunk, breast, abdomen, genitalia, and buttocks.



21. Assess whether injuries are consistent with the history.
If injuries are not consistent with the history, you must assume abuse.

22. Observe for signs of neglect:
- Malnutrition, such as a distended abdomen, or weight markedly below ideal body weight
- Excess body weight for height and age
- Poor hygiene, including oral hygiene
- Ingrown nails
- Untreated sores or pressure sores or other medical conditions
- Matted hair
- Dehydration
- Confusion
- Clothing that is inappropriate for the weather, such as heavy, long-sleeved pants and shirts on hot days
- Periods of time a young child or frail, older adult is left alone without care or supervision

Signs of neglect occur because of long-term starvation or underfeeding, poor personal care, untreated sores or injuries, and inadequate fluid intake. Neglect can also result in childhood obesity as a result of food of poor quality, erratic eating patterns, and poor supervision of the diet.

After The Examination.

23. If the forensic nurse or primary care provider determines that abuse has occurred, follow legal procedures to ensure that all evidence is secured. If possible, have a forensic nurse and social worker work with the patient.
In situations in which violation of the law has occurred, strict procedures are essential to ensure that your findings can be used in a court of law and to protect yourself against legal liability.

24. Provide referrals, if appropriate, for the abused person, partner, family member, or caregiver to obtain assistance in escaping the abusive situation and/or stopping the abuse.
Resources are available to assist the abused individual and to assist the parent or caregiver to stop the abuse. Be aware of local and national resources.

25. Report concerns regarding abuse according to agency and state guidelines.
Key Point: ***Suspected child and elder abuse must be reported to the appropriate agency, according to federal and state laws. Spousal abuse may be mandatory to report, depending on state law. The Joint Commission requires that all cases of possible abuse or neglect are immediately reported in the hospital.***

26. Treat physical injuries or refer to the primary care provider for medical care, as needed.
Detection and prevention of abuse require collaborative efforts of the health-care team.

What if. . .

- **My patient is a child? Are there any special assessments I should make or actions I should take?**

Follow steps 1 through 25 above, with these modifications:

➤ *Note: The interview is important in ruling out sexual abuse in children. Physical findings are often absent, even when the perpetrator admits to penetration of the child's genitalia. Most expert interviewers do not interview children younger than 3 years.*

a. To assess for sexual abuse, ask whether the patient has been touched inappropriately:
   - *Child older than 2:* Ask about being touched in "private parts."
   - *Older child:* Ask a question such as, "Sometimes people you know may touch or kiss you in a way that you feel is strange or wrong. Has this ever happened to you?"
   - *Adolescent*: Ask, "Sometimes people touch you in ways you feel are wrong. This can be frightening, and it is wrong for people to do that to you. Has this ever happened to you?"

b. Ask the parent or caregiver:
   - "Has the child started wetting the bed or soiling himself?"
   - "Does the child have fears that seem unreasonable?"

Abuse may result in regression to former behaviors. Symptoms of sexual abuse in children may be general and nonspecific, such as sleep disturbances, bed-wetting, or excessive fears.
   - "Has the child been masturbating or sexually acting out with other children?"

A child who is sexually abused may exhibit inappropriate sexual behavior.
   - "Has the child ever run away? If she leaves, does she go to somewhere safe?" "Is the child/adolescent sexually active?"

An abused child may have feelings of low self-worth and may demonstrate risk-taking behavior, such as running away to places that are unsafe.

c. To assess for psychological abuse, ask the parent or caregiver:
   - "Was the child a result of a planned pregnancy? What were the pregnancy, birth, and postpartum period like?"

Risk factors for abuse include an unplanned pregnancy, complications during pregnancy, stressors (e.g., moving, illness, loss of job, divorce), a difficult pregnancy or birth, and lengthy stay in the neonatal intensive care unit.
   - "How would you describe the child now?"

An abusive parent may describe the child as a "problem child" who is always doing something wrong. The opposite is sometimes seen, when the child is "perfect."
   - "How does the child's behavior compare with that of others in the family?"

Determine whether the parent sees the child differently from siblings. This is a risk factor for abuse.
   - "Has the child experienced physical or emotional problems in the past?"
   - "What are your expectations of the child's behavior [e.g., school performance, following instructions]?"

The expectations of parents or caregivers who are more at risk to abuse a child may be that the child will "always be a problem" or will be a "perfect" son or daughter.
   - "What form of discipline works best with the child?"

(continued on next page)

Determine whether the parents or caregivers use physical or emotional punishment that may be abusive or disproportionate for the act or situation.

- "Do you have any history of depression, anxiety, difficulty coping with situations or everyday life, or other history of mental health problems?"

Mental health disorders interfere with a person's ability to perceive others and situations in a realistic and appropriate way. When coping is compromised, the risk for abuse escalates.

d. Perform a physical assessment. Signs of physical abuse and neglect in children include the following:

- Bruises on head, face, ears, buttocks, and lower back that are inconsistent with the history of the injury and are of varying stages of healing (different colors)
- Hemorrhage of the eye, detached retina, ruptured ear drum

Bruising may occur in different patterns. One pattern is the "swimsuit zone" on the trunk, breast, abdomen, genitalia, and buttocks. Children often have accidental bruises over bony areas, but usually not on the abdomen. Injuries to the head are common in abuse. The abusive head trauma (AHT) syndrome may cause detached retina(s), hemorrhages, and subdural hematomas.

- Abdominal pain

Abdominal pain may be a symptom of sexual abuse in children. Signs of sexual abuse may be general and nonspecific in children.

What if. . .

- **My patient is an older adult? Are there any special assessments I should make or actions I should take?**

a. Ask the patient and caregiver:

- "Describe the patient's personal support network. Who visits the patient? How often does the patient have visitors?"

As in spousal abuse, people who victimize older people often isolate the person from any support network.

- "Who is the patient's primary healthcare provider?"

Multiple healthcare providers, or lack of a provider, can be an indication of abuse. The caregiver may bring the patient to a different physician with each injury or illness to avoid discovery.

- "Has the patient ever received the wrong dose of medication?"

Getting the wrong medication or dosage of medication (especially oversedation) may indicate abuse or inability to provide safe care.

- "Who manages the patient's finances?"

Financial abuse is a fairly common form of abuse in this population. Determine who has control of the older person's finances and makes the decisions regarding spending.

b. Ask the patient:

- "Do you feel safe in your home?"

The patient who is being abused does not feel safe. Keep in mind that abandonment is a form of abuse.

- "Tell me about your usual day." "Are you able to take care of yourself?" "Who helps you shower and dress?" or "Do you require help with showering or dressing?" "Who is responsible for grocery shopping and cooking in your home?" "How do you get to your appointments or other places you want or need to go?"

To determine the patient's usual level of self-care

c. Observe for signs of self-neglect.

What if . . .

- **You feel that you are or the patient is in immediate danger?**

If the patient's or your safety is at risk, immediate intervention is required. You may need to secure the area (e.g., by closing the door), notify the in-house security officer, and then call the police.

Evaluation

- Determine whether abuse may have occurred.
- Ensure that appropriate agencies have been notified of the possible abuse.
- Evaluate whether it is safe to let the patient leave the facility.

Patient Teaching

- Inform the patient, parent, partner, and/or caregiver of local resources for prevention or intervention in situations of child, spousal, or elder abuse.
- Inform the patient that abuse is suspected. Ask for her perceptions of the situation.
- Emphasize to the patient that her safety is the primary concern.

Home Care

- If potential abuse is identified in the home, follow agency and state legal guidelines.
- If the patient's safety is at risk, immediate intervention is required. You may need to notify the police or call an ambulance. Be sure to carry a fully charged cell phone with you.
- If you believe that you are at risk for harm (common in abusive situations), leave the setting before notifying the police.

Documentation

- Chart all findings factually—do not add any interpretations. For example:

Do Chart:

4-year-old boy admitted with second-degree burns to both feet extending to midpoint of shins. Father says, "I put him in the bathtub and didn't realize how hot the water was."

Do Not Chart:

4-year-old boy admitted with immersion burns to both feet extending to midpoint of shins, such as those found in abuse.

- Follow legal requirements for documenting possible abuse, including disposition of potential evidence.

- If possible, include pictures of the injuries in the charting, using a digital camera. Place a ruler or other common object next to the injury for reference by a third party viewer. *Photos must be saved and stored in-house because of the requirement to protect confidentiality.*

Smith & Segal, 2012; The Joint Commission, 2012; National Guideline Clearinghouse 2004, 2007; U.S. Preventive Services Task Force, 2012a.

ASSESSMENT GUIDELINES & TOOLS

Apgar Scoring

CATEGORY	0	1	2
Breathing effort	Not breathing	Respirations slow (less than 30 breaths/min) or irregular	Infant cries well
Heart rate (by stethoscope)	None	Less than 100 beats/min	Greater than 100 beats/min
Muscle tone	Loose and floppy	Some muscle tone, weak flexion	Active motion, full flexion
Grimace response or Reflex irritability (re-sponse to stimulation such as mild pinch)	No reaction	Grimacing	Grimacing and cough, sneeze, or vigorous cry
Skin color	Pale blue	Pink with blue extremities	Entire body is pink

Source: Medline Plus, U. S. National Library of Medicine, National Institutes of Health. APGAR. (Last updated August 27, 2012). Retrieved August 30,2012 from http://www.nlm.nih.gov/medlineplus/ency/article/003402.htm#top

Focused Assessment

Breast Self-Examination (BSE)

The best time to examine your breasts is when they are not tender or swollen. Have your technique reviewed periodically by your healthcare professional. It is acceptable to choose not to do BSE or to do BSE once in a while. Report any changes to your healthcare provider right away.

1. Lie down. Place a pillow under your right shoulder and place your right arm behind your head. (Lying down spreads the breast tissue evenly over the chest wall, making it easier to feel all the tissue.)
2. Using the finger pads (not the tips) of the three middle fingers of your left hand, feel for lumps in the right breast. Use overlapping dime-sized circular motions of the fingers to feel the breast tissue. Move in an up-and-down pattern (see step 4).

3. Use three different levels of pressure to feel all the breast tissue:
   - Light pressure to feel the tissue closest to the skin
   - Medium pressure to feel a little deeper
   - Firm pressure to feel the tissue closest to the chest and ribs

   Use each pressure level to feel the breast tissue before moving on to the next spot.
4. Start at an imaginary line drawn straight down your side from the underarm. Move across the breast to the middle of the chest bone (sternum), moving in an up-and-down pattern. Check the entire breast area, moving down until

continued

Focused Assessment

Breast Self-Examination (BSE)—cont'd

you feel only ribs, and moving up to the neck or collar bone (clavicle). Evidence suggests that this vertical (up-and-down) pattern is the most effective way to avoid missing any breast tissue.

5. After completely examining your right breast, put the pillow under your left shoulder and examine your left breast using the same methods.
6. Next stand in front of a mirror, arms at your sides, and look at each breast. Note the size, shape, contour, and direction of your breasts and nipples.
7. Press your hands firmly on your hips and look at your breasts for any changes in size, shape, contour, or dimpling, or redness or scaliness of the nipple or skin.
8. While standing (or sitting) with your arm raised slightly, examine each underarm. If you raise your arm straight up, it tightens the tissue and makes it harder to examine.

Source: Adapted from the American Cancer Society (December 31, 2013). How to perform a breast self-exam. Retrieved August 30, 2012, from http://www.cancer.org/docroot/CRI/content/CRI_2_6x_How_to_perform_a_breast_self_exam_5.asp

Focused Assessment

Testicular Self-Examination

Note: The U.S. Preventive Services Task Force (USPSTF) (2011b) recommends against routine screening with testicular self-examination (TSE). However, from the point of view of the individual patient, because there is no harm in self-examination, and because that is the way most testicular cancers are discovered, we see no reason to discourage it. If a patient chooses to perform TSE, you can teach him to use the following method monthly after a warm bath or shower when the scrotal skin is relaxed.

1. Stand in front of the mirror and look for swelling on the skin or scrotum.
2. Using both hands, with the fingers under the scrotum and thumbs on top, gently roll each testicle, feeling for lumps.
3. Palpate the epididymis, a normal cord-like structure on the top and back of each testicle that carries the sperm.

4. Contact your healthcare provider as soon as possible if you palpate a lump or if the area is painful or swollen.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Lani Ettinger is a 30-year-old woman, married, with three school-age children. She has just had a mastectomy (removal of a breast) because her biopsy was positive for cancer. The surgery was uncomplicated, the cancer was removed at an early stage, and she is expected to recover completely. As you are helping her prepare to leave the hospital, she begins crying.

THINKING

1. *Theoretical Knowledge:* What are Havighurst's developmental tasks of young adulthood?
2. *Critical Thinking (Contextual Awareness):* Which of those developmental tasks is/are most likely to be affected by Lani's mastectomy and her emotional reaction to it?

DOING

3. *Nursing Process (Assessment):* When you see that Lani is crying, what do you need to do?

CARING

4. *Self-Knowledge:* Suppose Lani tells you, "My husband has gone to get the car, but when he was here, he didn't want to hug me or kiss me. I asked him if he will still love me and he didn't say anything. He was crying when he left." What would your feelings be about the husband? You do not need to speculate on exactly what he meant; just imagine what your initial feelings would be.

Critical Thinking and Clinical Reasoning

1. Now that you have an understanding of the stages of growth and development, let us return to the three pediatric patients you met in Meet Your Patients, in Volume 1. All three children are diagnosed with pneumonia. You have introduced yourself to Miguel's and Tamika's caregiver and spoken by phone to Carrie's mother. Each is asking you how this hospitalization will affect their child or grandchild.
   - Tamika, a 3-year-old, lives with her grandparents. Her elderly grandmother is present only during afternoon visiting hours because she must care for her husband, who suffers from numerous health problems.
   - Miguel, a 2-month-old, lives with his mother. Since his admission yesterday, his mother has stayed at his bedside and provided most of her son's care. Miguel's mother is 17 years old and is very concerned about her son's condition.
   - Carrie, a 13-year-old, lives with her parents. Both parents are able to visit only during evening visiting hours, when they leave work.
     a. Based on Erikson's stages of development, contrast the developmental stages of Miguel, Tamika, and Carrie.
     b. How will nursing care differ for each child?
     c. Analyze each caregiver's developmental stage, and discuss the impact it may have on health teaching.
     d. Would it be a good idea to have the children's caregivers meet for a group teaching session to provide information about pneumonia? Explain.
2. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or growth and development. Note these are *not* to be merely definitions.

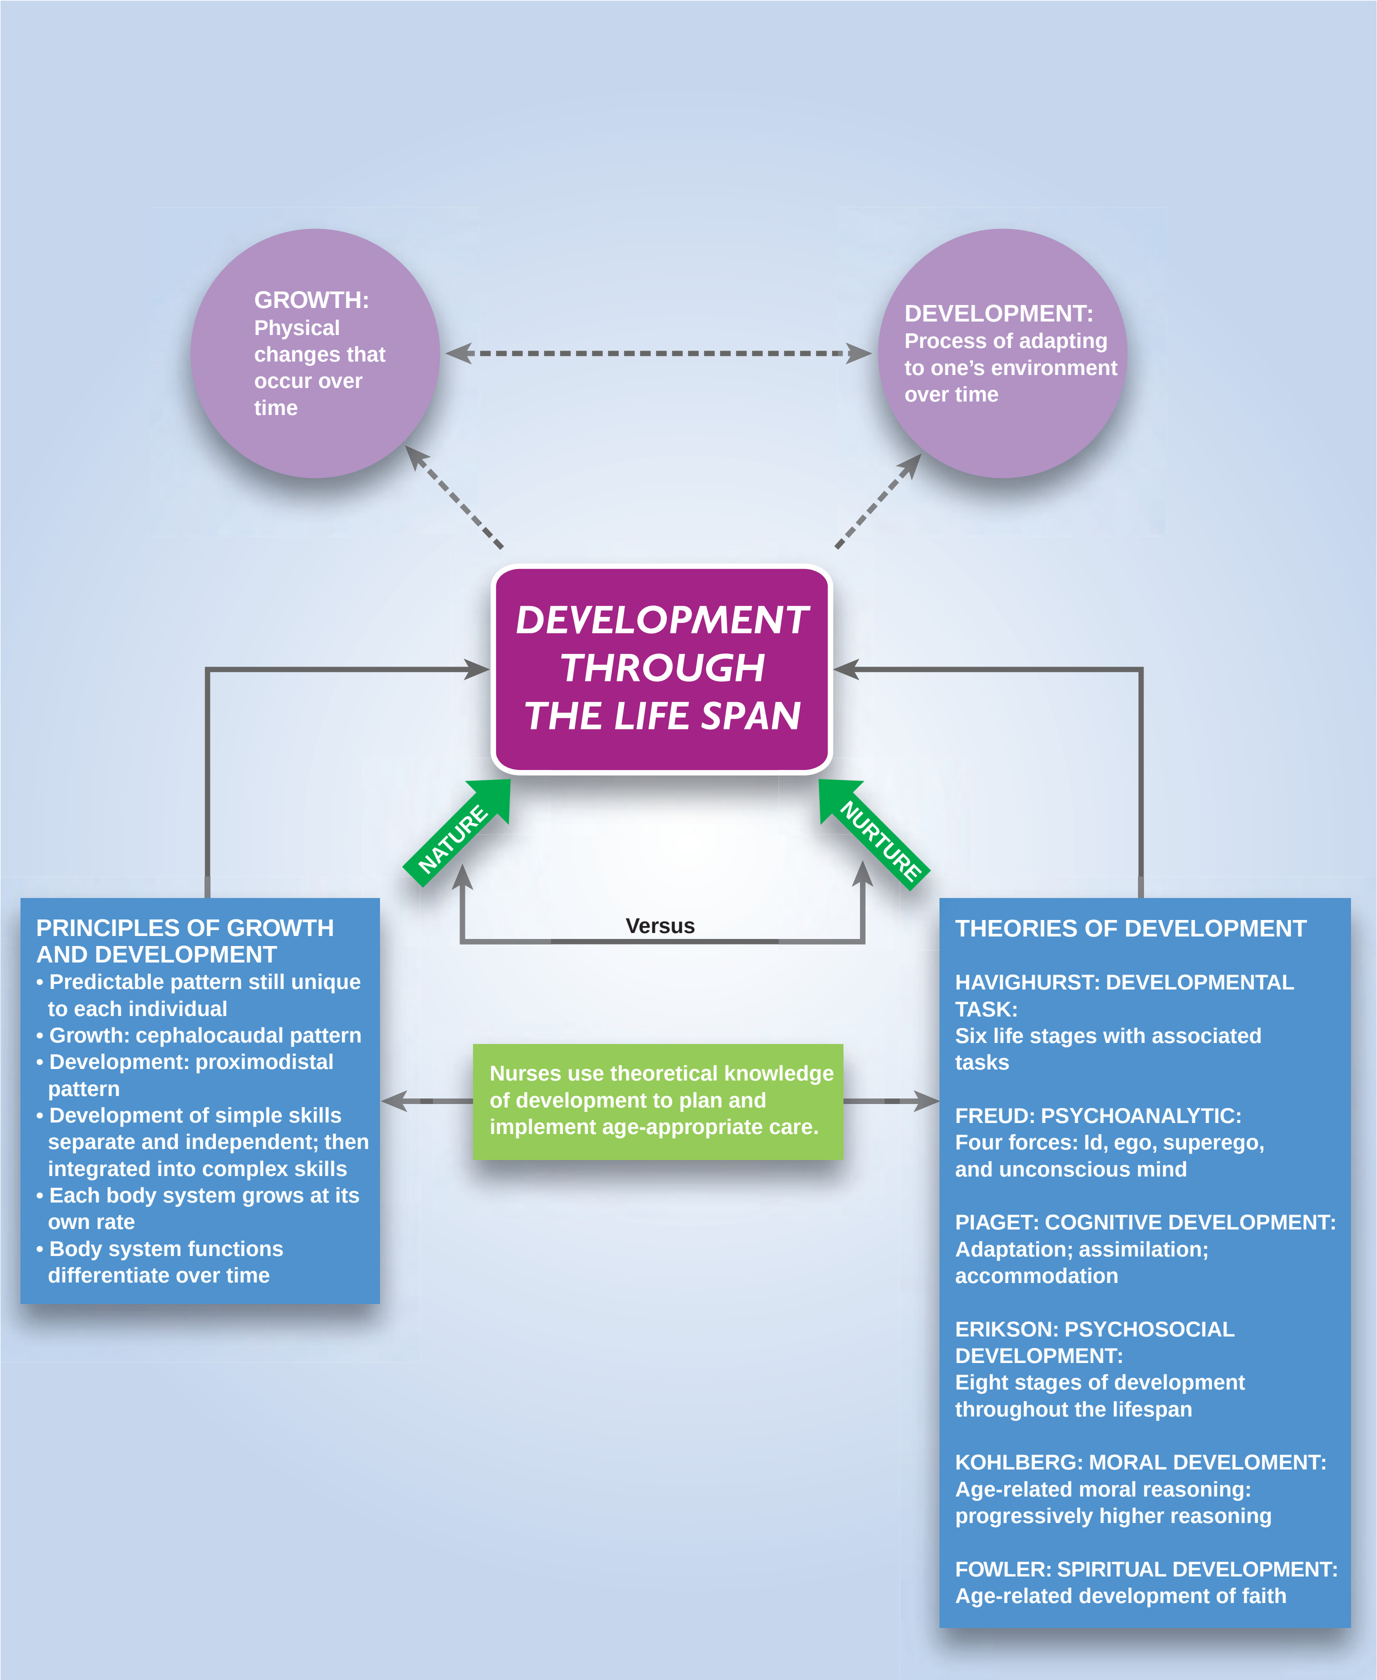
Ego defense mechanisms	Preschooler development
Cognitive development	School-age development
Psychosocial development	Puberty
Fetal development	Adolescent development
Infant development	Young adult development
Reflexes	Middle adult development
Toddler development	Older adult development

What Are the Main Points in This Chapter?

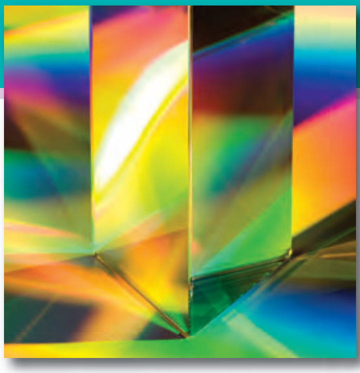
- Growth and development occur across the life span in a predictable pattern.
- Developmental theories help nurses identify what to expect behaviorally, cognitively, socially, and morally from patients at various ages.
- Fetal growth begins at the time of conception and continues for 10 lunar months until birth.
- Critical adaptations at birth include the establishment of respirations and independent circulation, thermoregulation, and the production of urine.
- Between birth and 1 year, infants develop a sense of trust when the caregiver provides the child with love, warmth, and food.
- The toddler period (12 to 36 months) is the time when the child explores the environment and attempts to become autonomous.
- In the preschool period (4 to 5 years) children are able to separate from their parents, communicate needs through language, and control bodily functions.
- The school-age child (6 to 12 years) begins to develop relationships outside the home. This leads to increasing confidence and independence.
- In the adolescent period (12 to 18 years) children establish their own identities and begin to make decisions that will affect their future.
- The young adult (20 to 40 years) leaves home and begins to function as an independent person.
- Middle adulthood (40 to 65 years) is a time when people balance aspirations with reality. It is often a time when the needs of children diminish whereas the needs of aging parents increase.

- Growth and developmental differences result in each age group's having specific health problems requiring specific assessment techniques. Data from these assessments are used to plan and provide care and anticipatory guidance that are developmentally appropriate.
- Abuse of both children and adults is common. Assess all patients for signs of abuse.

Knowledge Map



CHAPTER 10



Life Span: Older Adults

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to DavisPlus, at DavisPl.us/Wilkinson3.

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 10, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Nam Nguyen's father, Binh, is 80 years old and has multiple health problems. He has hypertension and heart disease. Although he had surgery for prostate cancer many years ago, the cancer has now metastasized. Because Binh's health was declining rapidly, Nam and Yen moved him and his wife, Mai, into their home last year. Both Nam and his wife work outside the home, so the elderly Mai cares for her husband as best she can during the day. Binh is too weak to get out of bed without help, and his wife is not strong enough to support him. She cooks for him, but he eats only a few bites, then pushes the plate away. Nam telephones today to say, "We can't take care of him safely at home any longer. Can you tell me how to get him admitted to a hospital or a nursing home?"

Caring for the Nguyens (continued)

A. What other ideas do you have for helping the Nguyens to care or to find care for Binh other than placing him in a hospital or nursing home?

B. Nam's first concern seems to be about getting help for his father. What do you think his next concern will be?

C. What actual data do you have about Binh Nguyen's nutritional status?

D. What else do you need to know to fully assess Binh's nutritional status? If you do not know the answer to this, you will find some information in the Assessment sections of this chapter in Volume 1. For more complete information, refer to Screening for Nutritional Problems and in Focused Nutritional Assessment, in Chapter 27 of this volume. Also

Go to **Assessment,** in Chapter 27 of Volume 1.

E. Would you consider Binh Nguyen to be a frail elderly person? Why or why not?

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Alvin Bell, 82 years old, was just discharged from the hospital following a myocardial infarction (heart attack). On your first home visit to supervise his medication regimen, you notice that the house looks as though it has not been cleaned in weeks. Piled on every flat surface, including the floor, is what appears to be months' accumulations of newspapers, magazines, and other clutter. Dishes are piled in the sink, apparently from before his hospitalization. There is hardly any food in the cupboard. When you weigh Mr. Bell, you see that he has lost 3 lb in the 3 days he has been home. He admits he has not been eating: "I'm not hungry, and it's too much trouble." As you talk with him, you learn that his wife died of cancer 7 months ago. He says, "I don't know what to do without her. I hate living alone. I don't have much reason for going on." Mr. Bell is alert and oriented, but talks and moves very slowly.

THINKING

1. *Theoretical Knowledge:*
   a. What do you know about depression in older adults? Do you have enough knowledge of that topic to be able to assess whether Mr. Bell is depressed? If not, what resources would you use to find out (list specific resources; that is, give the URL, don't just say "the Internet"; give the name or author of the book, not just "my psych-nursing book").
   b. You will also need to know whether it is normal for appetite to decrease in older adults, and what their calorie needs are compared with other age groups. Where can you go to find this information?
2. *Critical Thinking (Considering Alternatives):*
   a. As you survey Mr. Bell's overall situation, what is your first impulse to improve his situation? What questions come to you?
   b. What community services might be helpful for Mr. Bell?
   c. How would you handle referrals? Would you leave a list of telephone numbers? Would you call the agencies yourself? Explain your thinking.

DOING

3. *Practical Knowledge:* In your physical examination of Mr. Bell, you find no old or recent bruises or other injuries. However, because he is depressed and losing weight, you wonder if he is suffering neglect or financial abuse. What questions could you ask to find out?

CARING

4. *Self-Knowledge:* Think of one patient you have cared for who has something in common with Mr. Bell. Describe the way(s) in which they are alike.

Critical Thinking and Clinical Reasoning

1. Margaret O'Malley, age 67, tells you that even though she has new reading glasses, she still cannot see as well as she would like to for reading or sewing. She says, "My eyes often feel dry and scratchy. I wonder if something is wrong."
   a. What would you advise her to do that might improve her reading ability?
   b. What age-related change do you think may be causing Mrs. O'Malley's eyes to feel dry and scratchy?
2. Tony King, age 78, is having difficulty controlling his diabetes. As he leads a sedentary life, his physician has advised him to take daily walks to help regulate his blood sugar. Mr. King says, "Doc, I can't do that. With the arthritis in my back and hips, every step is agony. I walk just enough to take care of myself, get to the store, come here, and do whatever I have to. I'm already taking a lot of drugs for the pain; I can't take more when I walk." What kind of program could the physician recommend to Mr. King?
3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or growth and development. Note that these are *not* to be merely definitions.
   a. Gender disparities in life expectancy
   b. Age distribution in the population (population pyramid)
   c. Aging in place

What Are the Main Points In This Chapter?

- The number of older adults (age 65 and older) has risen significantly because of increasing life expectancy.
- Older adulthood is a time of transition. Most health problems experienced by older adults are chronic in nature and often affect the person's ability to live independently.
- Most older adults live independently.
- Aging can be examined from a life expectancy, percentage of total population, or life-span perspective.
- Aging in place means that as they age, persons live in their own elder-friendly residences and receive supportive services for their changing needs, rather than moving to another location or alternative type of housing.
- Retirement communities are planned and built specifically to provide elder-friendly dwellings and environments for independent living and allow older adults to "downsize" their dwelling.
- Continuing care retirement communities (CCRC) offer a wide range of living accommodations, including residential living, assisted living, skilled nursing care, rehabilitation, and dementia care on a large campus-like setting.
- Assisted-living facilities (ALFs) are congregate residential settings that provide or coordinate personal services, 24-hour supervision and assistance, activities, and health-related services.
- Nursing care facilities, or nursing homes, provide skilled and unskilled nursing care for older adults and adults with disabilities.
- The stages of older adulthood are typically referred to as the *young-old* (age 65 to 74), *middle-old* (age 75 to 84), and *oldest-old* (age 85+).
- The fastest growing segment of older adults is the oldest-old, some of whom are the frail elderly and *centenarians* (people over 100 years old).
- Older adults learn new material more slowly. However, there is no loss of intelligence as a person ages.
- Disengagement theory and activity theory attempt to explain the psychosocial development of older adults.
- **Dementia**, a loss of cognitive ability, is not a normal result of aging. It is important to differentiate dementia from depression, acute confusion, or delirium that may be precipitated by dehydration, infection, or a medication side effect or overdose.
- Developmental differences result in each age group's having specific health problems requiring specific assessment techniques. Data from these assessments are used to plan and provide care and anticipatory guidance that are developmentally appropriate.
- Older adults should have an annual physical examination, including a focused assessment of functional status.
- Frailty is set of characteristics that describe a heightened state of vulnerability for developing adverse health outcomes.
- Abuse of adults is common. Assess all patients for signs of abuse.
- Suspicion of elder abuse must be reported to adult protection services and/or the authority designated by law in each state.

Caring for the Nguyens

Nam Nguyen has recently been diagnosed with hypertension, obesity, and degenerative joint disease (DJD). He is struggling with these diagnoses. He tells his wife, Yen, "I feel so old now. These are the kind of things my parents are dealing with." At a clinic visit Nam tells you, "It's hard to think of myself as sick. I've been depressed ever since Zach told me about his findings. Now he's asked me to get some lab work. I'm afraid he may find even more problems." If you need help answering the following questions,

Go to Chapter 11, The Health-Illness Continuum and Dunn's Health Grid in Volume 1.

Caring for the Nguyens (continued)

A. Identify the disruptions that Mr. Nguyen must deal with based on these diagnoses. Explain your reasons for choosing these disruptions.

B. How would you evaluate Mr. Nguyen health status? To review the concepts of health status,

Go to Chapter 11, **The Health-Illness Continuum and Dunn's Health Grid** in Volume 1.

C. What kinds of activities could you suggest to Nam to improve his health status?

D. What stage of illness behavior is Mr. Nguyen exhibiting in regard to his recent medical diagnoses?

PracticalKnowledge knowing how

Practical knowledge in this chapter means using the nursing process to apply what you have learned about how people experience health, wellness, and illness.

PROCEDURES

The procedures in this chapter are designed to help you admit, transfer, and discharge patients in such a way that you can begin to establish trust at the first patient contact.

Procedure 11-1 ■ Admitting a Patient to a Nursing Unit

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Identifying armband (if this has not been supplied by the admissions department)
- Patient's chart, including physician's orders and nursing admission record
- Thermometer, blood pressure cuff, and stethoscope
- Scales for height and weight
- Gown
- Admission pack (e.g., water pitcher, soap, comb, toothbrush, mouthwash, and facial tissues)
- Nursing care plan or clinical pathway, if one has already been made
- Hospital brochures, Patient Care Partnership, and other forms
- Admission assessment form

Delegation

A registered nurse is responsible for managing medical orders and assessing the patient's need for nursing care in all settings, although this may vary in some specifics according to hospital policy, the law, and regulations. Most other admission activities can be delegated to nursing assistive personnel (NAP) if the patient is stable.

Pre-Procedure Assessments

- Assess for signs of emotional and/or physical distress.
- Assess ability to ambulate and/or move.
- Assess ability to communicate and understand what is occurring.

➤ When performing the procedure, always identify your patient according to agency policy and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Ensure placement of patient labels** (e.g., on the chart, at the bedside, outside the door).
2. **Introduce yourself to the patient and family.** Explain who you are. Don't be afraid to tell a client that you are a nursing student.
   Many clients are aware that students have more time to spend with them. Talking to the patient and family reassures them and provides information about the patient's level of consciousness and awareness, social relationships, and so on.
3. **Assist the patient into a hospital gown.**
   If the patient is able to stand, assist her into a gown before weighing her to obtain the most accurate weight.

(continued on next page)

Procedure 11-1 ■ Admitting a Patient to a Nursing Unit (continued)

4. **Measure height and weight** while the patient stands on a scale, if possible. If she is unable to stand, transfer her into the bed and measure her weight using a bed scale.
Weigh in the same manner each time to ensure accuracy.

5. **Assist the patient into the bed.**
Get the patient comfortable before continuing the admission to prevent overtiring her.

6. **Check the patient's identification band** to ensure the information, including allergies, is correct. Verify this information with the patient or family.
Questioning the patient about allergies and verifying with the family will ensure that the information is accurate and documented on the wristband and the chart.

7. **Measure vital signs.**
Measuring the vital signs before completing the rest of the admission ensures that you will be aware of the patient's status. If the vital signs are abnormal, further assess the patient's condition before continuing. Report your findings to the admitting care provider.

8. **Complete the nursing admission assessment**, including health history and physical assessment. Be sure to include the patient's expectations and concerns. For inpatients, this must be completed within 24 hours after admission. All patients should be screened on admission for risk for pressure ulcers. (Chapter 22 provides a step-by-step approach to physical assessment.)
An admission assessment is needed to identify problems and establish a baseline. The Joint Commission requires that each patient have an admission assessment performed by a registered nurse.

9. **Check the list of the patient's current medications** (created in the admitting department) to be sure it is complete and accurate. Usually the patient's own medications are sent home with the family, or they may be sent to pharmacy for storage.
It is important to know what medications the patient has been taking. The pharmacy will identify medicines from home when necessary. When medications are ordered and given during the patient's stay, they are compared with those on the list so any discrepancies can be resolved.

10. **Orient the client to the room.**
These actions ensure that the patient and family will be able to call for assistance if needed and increase the patient's and family's level of comfort and ability to function in the hospital setting. Remember that one of the disruptions associated with illness is anxiety about the unknown. If you tell your client what to expect, you help to minimize his anxiety.
    a. Make sure the client knows how to use the bed, the call light, and any equipment that you expect him to use.
    b. Point out the location of personal care items.
    c. Show the client the location of the restroom.
    d. If you will be measuring the client's intake and output, tell him so during your orientation.
If the client is alert, he may be able to assist you with these measures.

11. **Explain hospital routines**, including use of side rails, meal times, and so on. Answer the patient's and family's questions.
Hospitalization takes away control of basic decisions. Knowing the routines and available choices increases patient and family comfort.

12. **Verify with the patient all other admission data** on the chart for completeness and accuracy.
Basic data such as name, address, marital status, name of admitting physician, admitting diagnosis, consent to treatment, and so on, will usually be obtained in the admitting office. However, you will need to be sure all the admitting information is complete, and complete it if it is not.

13. **Ask if the patient has an advance directive** (e.g., power of attorney or living will). If so, place a copy in the hospital record. If not, explain the purpose of the document and give the patient a form to fill out if he wishes to do so. (See Chapters 17 and 45, Volume 1, if you need more information about advance directives.)
Advance directives enable patients to indicate their preferences about treatments and prolonging life.

14. **Advise the patient of his privacy rights under HIPAA.** See that he has a written explanation of his privacy rights (see Chapter 45 as needed).

15. **Inventory the patient's belongings.** Encourage the family to take home valuable items and money. If that is not possible, arrange to have valuables placed in the hospital safe. Most agencies require money in excess of $5.00 to be sent home or to the cashier's office.
Patient belongings, including valuables, are frequently lost during hospitalization. Documenting the disposition of everything ensures being able to return the belongings to the patient upon discharge.

16. **Complete all admission orders** or ensure that they have been completed (e.g., laboratory tests, medications, diet and fluid orders).
Unless it is an unscheduled admission, diagnostic tests are usually completed on an outpatient basis before admission to the hospital. However, there may still be some orders that need to be done immediately, while others can be delayed. Make sure the orders are completed in the most appropriate time frame.

17. **Ensure patient comfort** (e.g., positioning, pain, water at bedside).

18. **Make one last safety check** (i.e., call light within reach, bed in low position, siderails up as appropriate, equipment functioning properly).

19. **Before leaving, ask if you can do anything else** for the patient and family.

20. Initiate the care plan or clinical pathway.
Identifying the patient's priority problems enables the nurse to develop the most appropriate nursing orders.

What if. . .

- **The patient may be at risk for falls?**

Perform falls risk assessment as appropriate to the patient, and according to agency policy.
Falls are common in inpatient facilities, especially among older adults. If a patient has falls risk factors, risk reduction measures can be instituted.

- **The patient has special care needs?**

When the patient has special needs, such as allergies, a "nothing by mouth" order or an "intake and output" order, post patient care reminders at the head of the bed or at the door to remind other care providers.

- **The patient needs a more in-depth assessment in some areas?**

Perform special needs assessments as relevant to the care and condition of the patient (social situation, nutrition and hydration status, functional abilities, spiritual and cultural variables). If these are warranted, they must be completed within 24 hours after admission or prior to surgery.
In-depth assessment of these topics is not a part of all admission assessments, but should be done if the patient's condition warrants.

- **The patient has a learning disability?**

If possible, preadmissions should be arranged for the patient and main caregiver. This allows more time to discuss issues of consent, alleviate anxiety, and set up links with a learning disability specialist or social worker. Whether or not this is possible: Allow more time for the admission process.

Use short sentences, with one idea at a time.

Include the caregiver in the admission process, but encourage the patient to participate as much as possible.

Document the main caregiver and contact numbers.

Expect the patient to be anxious.

Include special communication and personal needs in the plan of care.

Give the patient hospital information with pictures, such as those given to children, if appropriate for her developmental level.

- **The patient is an older adult?**

Ask all older adults if they have had any falls in the past year. If they report a fall, observe them as they stand up from a chair without using their arms, walk several paces, and return ("get up and go"). If they are steady, no further assessment is required. If there is unsteadiness or if the person reports more than one fall, further assessment is required.
The incidence and severity of fall-related complications rise steadily after age 60. Fall rates in nursing homes and hospitals are almost three times the rate for those living at home.

- **The patient is a child?**

Use a friendly approach.
The first priority is to establish a trusting relationship with the child and parents to help relieve fears and anxiety. Children younger than 3 years may fear being separated from parents. Older children usually worry more about what is going to happen to them.

Explain the visiting and rooming-in policies to the parents.

Ask about the child's usual routine (e.g., toileting, bedtime rituals, favorite foods).

Speak to the child directly if she is old enough to understand.

Direct the family to the bathroom, playroom, television, and snack room, if those are available.

Encourage the parents to bring toys and other favorite items from home.
It helps the child feel more comfortable in the unfamiliar surroundings.

Documentation

- Document all assessment findings on the admission database provided by the institution. If you need an example, see Chapter 3, Tables, Boxes, Figures, Nursing Admission Data Form, Assessment Forms: Nursing Admission Data Form, in this volume.
- Document an admission note and any teaching or other interventions in the nursing notes or flowsheet (according to agency policy).
- Recall that a discharge plan is created on admission. You will find forms for discharge assessment and teaching under Forms, after the Procedures in this chapter. For another example of a discharge plan, see Chapter 5, Discharge Planning Form, in Volume 2.

Practice Resources

The American Geriatrics Society (n.d.); The Joint Commission (2008, 2012b); Michael, Y., Lin, J., Whitlock, E., et al. (December 2010).

Procedure 11-2 ■ Transferring a Patient to Another Unit in the Agency

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Medical record or chart
- Care plan
- Patient's medications
- Supplies for any ongoing treatments
- Patient's belongings, clothes, and personal care articles
- Standardized handoff form, if available
- A utility cart, if belongings are numerous
- Wheelchair or transfer cart, if bed is not being moved

Delegation

If the patient's condition allows, you can delegate the physical transfer of the patient and have the nursing assistive personnel (NAP) move the patient's belongings to the other room. However, as the nurse, you are responsible for obtaining and completing the necessary records, making the final assessment, and gathering and checking the medications. You must also give the handoff report to another nurse.

Pre-Procedure Assessment

- Make a final, brief focused physical assessment.
- Assess the patient's mobility and ability to assist.
- Assess for emotional and/or physical distress (administer medications, as needed).
- Assess the patient's ability to communicate and understand what is occurring.

➤ When performing the procedure, always identify your patient according to agency policy and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Obtain the number of personnel needed** to make a safe transfer.
   For efficiency and patient and staff safety.

2. **Gather the patient's medications and label them** correctly for the new room.
   Ensures availability of medications when the patient arrives at the new unit; helps prevent medication administration errors.

3. **Notify the receiving unit of the time to expect the transfer**; notify other departments (e.g., dietary, pharmacy, admitting), primary care provider, and family of the transfer.
   You need to schedule the transfer with the receiving nurse so he can plan his work and so you can arrange the transfer time to limit the number of interruptions during the handoff. Limiting interruptions minimizes the possibility of failing to communicate or forgetting information. Other departments must have the transfer data so that services such as meals and physical therapy treatments will not be interrupted. The primary care provider and family, of course, need to know where to find the patient.

4. **Gather the patient's personal belongings and supplies**, including: treatment-related supplies and equipment (e.g., isolation supplies, clean dressings), chart, Kardex, and care plan. Place in a container (e.g., the patient's bath basin) or on a utility cart if necessary.
   Having the supplies and equipment "ready to go" makes the transfer more efficient for you and less stressful for the patient.

5. **Bring the wheelchair or transfer cart to the bedside** and assist the patient to the chair or cart. If using a wheelchair, the patient can hold the pan of supplies; if using a bed or cart, place supplies on the bed.

6. **Take the patient to the new room and give the handoff report.** Follow agency procedure for handoff reports. However, the method chosen should allow both the giver and receiver of patient information the opportunity for questioning.
   a. If you need to review content of an oral handoff report, see Chapter 18. In general, the report should include name, age, sex, physicians, surgical procedures, medical diagnoses, medications, allergies, laboratory data, special equipment (e.g., oxygen, suction), the patient's current health status, and whether there are advance directives and resuscitation status. Identify the nursing diagnoses and priorities for nursing care.
   b. Consistently use a structured framework or memory aid to guide the handoff process and the oral report.
   The objective of a handoff is to provide accurate information about the patient. The information communicated must be accurate in order to ensure patient safety.
   c. Be sure to point out to the nurse if patient is taking corticosteroids, anticoagulants, diabetic medications, antibiotics, or narcotic analgesics.
   These medications can have serious side effects and need careful monitoring.

? What if . . .

- **The patient has intravenous (IV) lines and other equipment that cannot be turned off?**

It is common to transfer patients with IV lines. Some wheelchairs are equipped with an IV pole; for others, you may need to obtain a rolling pole from the unit supply room. The patient may be able to maneuver the rolling pole. Most beds and transfer carts also have portable IV poles, sometimes stored along the underside. Portable oxygen and suction are also available for patients who must have them even during transfer. Be sure to obtain these, set them up, and check their functioning prior to moving the patient from his bed.

- **The patient has too many personal belongings for one person to carry?**
  If the patient's condition requires two staff members to transfer, one person can manage the utility cart while the other manages the patient. If only one person can make the actual move, load a utility cart and move all the supplies and belongings to the new room before transferring the patient.

- **The patient is being transferred to the intensive care unit (ICU)?**
  If this is an urgent transfer, you may need to notify the receiving nurse and move the patient with his records and medications. Later you can make the other notifications, finish the charting, and move belongings and other supplies. In some ICUs, the family may need to take the patient's personal belongings home.

Evaluation

With the receiving nurse, evaluate the patient's response to the move. The receiving nurse will take vital signs and make a preliminary admission assessment.

Documentation

- Just before moving, document as much information as you can, including the patient's status at that time.
- After handoff, document the information reported in the handoff, the name and title of the person who received the patient, and your report.
- Sign the note. Some agencies have a standardized form for the transfer note.

Example documentation

3/13/15, 1615. Client transferred to room 501 by stretcher, with both siderails up, with assistance of one. Temperature 104.8°F, pulse 100 beats/min, BP 138/88, respirations 20 breaths/min and shallow. Drowsy upon arrival. Responds to verbal stimuli with moaning. Last pain medication given at 1515. Denies pain when asked. No urine noted since 12:00 pm; will encourage voiding by offering urinal every 2 hr. #22 IV in RAC and #18 IV in R hand flushed with 3 mL of normal saline; flushes without redness, edema, or induration. Receiving 3 L/min of oxygen during transfer. Placed on 3 L/min in room; will wean oxygen as tolerated. Handoff report given to Linda Hamm, RN.————— Sarah Fields, RN

Practice Resources

The Joint Commission (2012a); McFetridge, B., Gillespie, M., Goode, D., et al. (2007); Riesenberg, L. A., Leisch, J., & Cunningham, J. M. (2010).

Procedure 11-3 ■ Transferring a Patient to a Long-Term Care Facility

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Medical record or chart
- Care plan
- Patient's medications
- Supplies for any ongoing treatments
- Patient's belongings, clothes, and personal care articles
- Standardized transfer form, if available
- A utility cart, if belongings are numerous
- Wheelchair or transfer cart

Delegation

If the patient's condition allows, you can delegate the physical transfer of the patient and have the NAP move the patient's supplies and belongings. However, as the nurse, you are responsible for obtaining and completing the necessary records, making the final assessment, and gathering and checking the medications. You must also give the handoff report to another nurse.

Pre-Procedure Assessment

- Make a final, brief focused physical assessment.
- Assess the patient's mobility and ability to assist.
- Assess for emotional and/or physical distress (administer medications, as needed).
- Assess the patient's ability to communicate and understand what is occurring.

(continued on next page)

Procedure 11-3 ■ Transferring a Patient to a Long-Term Care Facility (continued)

➤ When performing the procedure, always identify your patient according to agency policy and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Notify the patient and family well in advance** of the upcoming transfer to another facility. Include information about the reasons the patient is being transferred, as well as any alternatives to transfer. You will also need to determine which agency is to arrange transportation for the patient.
Allows them time to adjust emotionally and to make any necessary plans.

2. **Prepare the patient's records.** You may need to send a copy of the patient's chart to the receiving facility. The original remains with the hospital. You will usually also send a copy of the comprehensive nursing assessment and a detailed nursing care plan, as well as prescriptions and cards for future appointments (e.g., with physicians or social workers).
Ensures continuity of care, thus minimizing patient stress.

3. **Gather and pack the patient's personal items** and treatment supplies to send to the long-term care facility with the patient.
Having the supplies and equipment "ready to go" makes the transfer more efficient for you.

4. Be certain the medications are labeled correctly.
Ensures availability and correct administration of medications when the patient arrives at the new facility.

5. **Coordinate the transfer.** Notify the receiving facility of the time to expect the transfer and of any special equipment the patient will need (e.g., IV pole, portable oxygen); notify other hospital departments (e.g., dietary, pharmacy, admitting), primary care provider, and family of the transfer.
You need to schedule the transfer with the receiving agency so they can plan their work and so you can arrange the transfer at a time that will limit the number of interruptions during the transfer. Other in-house departments must have the transfer data so that services such as meals and physical therapy treatments will be discontinued. The primary care provider and family, of course, need to know where to find the patient.

6. **Just before transfer, make your final quick assessment and sign off your charting** (usually there is a preprinted, standardized discharge form for this purpose).
It is important to complete documentation in a timely manner, but it is also important to provide the most recent assessment data to the long-term care facility.

7. **Take the patient off the unit and out of the hospital after you are notified** that transportation has arrived (or delegate this task). Alternatively, a transporter may come to your unit to get the patient. (Note: Some agencies ask you to remove the patient's identification band at time of transfer.)
Keeping the patient on the unit as long as practical helps to minimize his anxiety and fatigue that may occur from a long wait in the hospital lobby.

8. **Give an oral report** to the nurse at the long-term care facility. You will usually give a telephone report unless a nurse comes to your hospital to accompany the patient. The report should include, as appropriate for the care, treatment, and services provided, the following:
   a. The reason the patient is being transferred
   b. The patient's physical and psychosocial status
   c. A summary of care, treatment, and services provided and progress toward outcomes
   d. Referrals, community resources provided to the patient

   A report helps ensure continuity of care and provide a baseline for later changes in the patient's health status.

- It is best to consistently use a structured framework or memory aid to guide the handoff process and the oral report.
The objective of a handoff report is to provide accurate information about the patient. The information communicated must be accurate in order to ensure patient safety.
- **Notify the long-term care agency if the patient is colonized or infected with methicillin-resistant *Staphylococcus aureus* (MRSA) or other contagious microorganisms.**
So they can arrange for and communicate any special isolation or care activities to their staff. MRSA is a serious problem for long-term care residents.
- If the patient is taking corticosteroids, anticoagulants, diabetic medications, antibiotics, and/or narcotic analgesics, be sure to point out to the nurse
These medications confer particularly high risk of adverse postdischarge drug events, and the long-term-care nurses will need to continue careful monitoring.

What if. . .

- **The patient has intravenous (IV) lines and other equipment that cannot be turned off?**

It is common to transfer patients with IV lines. Some wheelchairs are equipped with an IV pole, or you may need to hold the IV bag while taking the patient to the transporting vehicle. If so, always hold the bag well above the patient's chest and arm so that blood does not back up in the tubing. Also, you should notify the long-term care facility so they will have the necessary equipment in the transport vehicle. Portable oxygen and suction are also available for patients who must have them. Usually the receiving facility will bring these, but you need to coordinate that in advance.

- **When you are ready to transfer the patient, her condition worsens and she becomes unstable?**

Perform interventions to stabilize the patient, call for help if needed, and notify the medical provider. Notify the transporter and the long-term care center of the change and postpone the transfer until further medical assessment is done.

Evaluation

The receiving nurse at the long-term care facility will evaluate the patient's response to the move.

Documentation

- Just before the transfer, document your final assessment and complete the agency's discharge summary.
- You will probably put your final nursing note on a transfer or discharge summary, similar to the ones shown in the Forms section in this chapter of Volume 2.

Practice Resources

The Joint Commission (2012a); McFetridge, B., Gillespie, M., Goode, D., et al. (2007); Riesenberg, L. A., Leisch, J., & Cunningham, J. M. (2010).

Procedure 11-4 ■ Discharging a Patient From the Healthcare Facility

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Medical record or chart
- Patient's medications
- Supplies for any ongoing treatments
- Patient's belongings, clothes, and personal care articles
- Standardized discharge form, if available, with instructions for patient
- A utility cart, if belongings are numerous
- Wheelchair

Delegation

If the patient's condition allows, you can delegate to the NAP such tasks as packing belongings, helping the patient dress, and taking the patient out of the facility. However, as the nurse, you are responsible for obtaining and completing the necessary records, making the final assessment, gathering and checking the medications, and coordinating care.

Pre-Procedure Assessment

- Make a final, brief focused physical assessment.
- Assess the patient's mobility.
- Assess for emotional and/or physical distress.
- Assess the patient's ability to communicate and understand what is occurring.

➤ When performing the procedure, always identify your patient according to agency policy and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Notify the patient and family** as much in advance of the discharge as possible. This is often done early in the hospital stay.
   Allows them time to adjust emotionally and to make any necessary plans.

A Day or Two Before Discharge (Steps 2 and 3)

2. **Make or confirm necessary arrangements.**
   a. Arrange for or help the family arrange for services (e.g., home healthcare, physical therapy, intravenous therapy, social worker) that will be needed at home.
      NOTE: To reimburse for home care, insurers require a physician's order for all services, and the patient must meet certain eligibility criteria.
   b. Confirm or arrange for equipment needed in the home (e.g., portable oxygen).
   c. Confirm or arrange for transportation.
   d. Make necessary referrals (e.g., medical specialists, physical therapists); book appointments, if necessary and if in line with agency policy.
   Hospital stays are short, and many patients are still ill enough to require complex treatments and care by family members when they go home.

3. Communicate and provide teaching to the patient and caregivers.
   Patients who have a clear understanding of their after-hospital care (e.g., medications, follow-up visits) are 30% less likely to visit the emergency department or be readmitted than patients who lack this information (Agency for Healthcare Research and Quality [AHRQ], 2009).
   a. Discuss the patient's diagnosis, care needs, and functional abilities with the family/caregiver.
   b. Train the patient and caregiver in the use of equipment. Arrange for follow-up evaluation at home to check that equipment is working and being used correctly, and that further training is given if needed.
   In the stress of illness and the disruption of transition home, patients may not retain what they are taught in the hospital. Therapies will be ineffective if equipment

(continued on next page)

Procedure 11-4 ■ Discharging a Patient From the Healthcare Facility (continued)

is used incorrectly, so follow-up is essential to help avoid further illness and hospital readmission.

c. Educate about medication use and side effects.
Medication errors at home are a frequent cause of adverse events and readmissions to the hospital.

d. Ask relatives or the caregiver to bring clothing for the patient to wear home, if needed.
If this was an unplanned admission, the patient may have come in nightwear and a robe.

Day of Discharge (Steps 4 Through 16)

4. **Make and document final assessments.**
   a. Assess that the patient's condition remains as expected.
   b. Confirm that the patient has house keys, heating is turned on, and food is available.
   c. Follow up on diagnostic and laboratory test results.

5. **Bring a wheelchair or other transport** device to the bedside.

6. **Make final notifications.**
   a. Contact the family or guardian; confirm transportation.
   b. Notify community service agencies and home health nursing of the discharge, as needed.

7. **Gather prescriptions and instruction sheets**, including a list of current medications and appointment cards; give to the patient along with the discharge instructions at discharge. **Key Point:** ***Be certain that either the patient or caregiver can read the instructions. Inadequate literacy has been shown to be a risk factor for readmission.***

8. **Gather and pack the patient's personal items** and treatment supplies.
Having the supplies and equipment ready to go makes the transfer more efficient for you and less stressful for the patient and family.

9. **Prepare the patient's medications.** Be certain the medications are labeled correctly; pack them; and record which medications he is taking home.
Ensures availability and correct administration of medications when the patient arrives home. Provides a legal record that the patient left with the medications.

10. **Review discharge instructions** with patient and caregiver (and provide a written copy to take home): Review:
    a. Medication instructions
    b. Symptom management and treatments
    c. When and with which care provider the follow-up appointment(s) takes place
    d. How to obtain further care, treatment, and services, as needed
    e. How and when to call the physician or primary care provider, including signs of a change in condition
    f. Whom to contact in an emergency
    g. Diet restrictions
    h. Maintenance of hydration
    i. Activities of daily living, focusing on safety and mobility

Teaching should occur throughout the hospital stay. However, it is important to reinforce with a last-minute summary and written instructions to take home. With the stress of illness and anticipation of discharge, patients may not retain what they are taught.

11. **Address any questions or concerns** of the patient and caregiver.
To ensure the ability to safely transition to home.

12. **Give new prescriptions and reminder cards** (e.g., for appointments with physicians, social services) to the patient.
Ensures continuity of care, thus minimizing patient stress.

13. **Document your final nursing note and complete the discharge summary** (the patient often receives a copy of the summary). The patient needs a copy of (1) his instructions for care at home, which may be called a discharge plan, and (2) his discharge summary, a summary of the progress of his illness and treatment from admission through discharge. Some agencies combine these into one form.
It is important to document the patient's condition at the time he leaves the unit. This provides a baseline for comparison if his condition should deteriorate after discharge.

14. **Accompany the patient off the unit** and out of the hospital (or delegate this task) when you are notified that transportation has arrived.
Keeping the patient on the unit as long as practical helps to minimize the anxiety and fatigue that may occur from a long wait in the hospital lobby while a family member brings a car to the door.

15. **Notify the admissions department** of the discharge. Depending on agency policy, notify the primary care or admitting physician.
This will stop all scheduled services, such as meals, and notify the housekeeping department that the room needs to be cleaned.

16. **Ensure the patient's records are sent** to the medical records department.
Whether paper or electronic, the chart is a legal document and remains permanently in storage in the medical records department.

What if. . .

- **Near the time of discharge, the patient's condition worsens and he becomes unstable?**
  Perform interventions to stabilize the patient, call for help if needed, and notify the provider. Notify the family that discharge will be delayed.

Communicate with other hospital departments and community agencies as necessary.

- **The patient is an older adult?**
  - Allow for more time to dress and leave the hospital.
  - Allow for more time to communicate, teach, and answer questions.
  - Obtain feedback to be certain the caregivers have heard and understood instructions.
  - Consider having a geriatric nurse specialist make follow-up home visits.

Hearing, visual, and mobility deficits become more common with advanced age.

- **The patient is taking "high-risk" drugs postdischarge?**

Medications with a high risk of postdischarge adverse events include corticosteroids, anticoagulants, diabetic medications, antibiotics, antianxiety agents, sedatives, and narcotic analgesics.

- Provide teaching for patient, family, and other caregivers throughout the hospital stay. A day or two before discharge, review teaching with patient and family; evaluate their understanding.
- On discharge, summarize medication precautions and provide clear written instructions. Be sure the patient and family can read them.

Evaluation

A few weeks after discharge, the facility will contact the patient to evaluate the quality and appropriateness of the discharge process. This may be done by making a home visit, telephoning, or sending a questionnaire. As a nurse, you may or may not be involved in this evaluation. The best evaluation of the multidisciplinary care will be whether the patient must be readmitted to the acute care facility.

Documentation

- For the medical record, the primary provider will write a discharge progress note that contains the following information:

  Reason for hospitalization

  Significant findings during the stay, including significant changes in status since admission

  Procedures performed; care, treatment, and services provided during the stay

  Status of goals for the stay

  Condition at discharge

- Agency policy determines the format and content of nursing documentation. This is often a combination of a structured discharge form or checklist and a narrative progress note. Regardless of format, you should document the following information:
  - Your final assessment of the patient's health status
  - Information and teaching provided to the patient and caregivers
  - Referrals, medications
  - How patient left the unit (e.g., in wheelchair) and who accompanied him (e.g., wife, name of staff member)

The Joint Commission recommends standardized formats for documentation (2008, p. 367).

To see examples of discharge summaries,

Go to Forms, later in this chapter.

CLINICAL INSIGHTS

Clinical Insight 11-1 ➤ Preparing the Room for a Newly Admitted Patient

Delegation

As a general rule, these tasks can be delegated to NAPs. The nurse is responsible for evaluating and supervising, as well as for setting up special equipment (although the NAP may obtain it from storage).

Clean the Room

Agencies differ; however, it is common for the housekeeping department to clean the room and change the bed linens when a patient is discharged, so you should find the room ready for your preparations. The rest of these guidelines assume that fact.

Prepare the Bed

- Position the bed according to patient status. If the patient is ambulatory, put the bed in the lowest position and lock the wheels. If the patient will arrive on a stretcher, place the bed at stretcher height.
- If necessary, rearrange the furniture to allow easy access to the bed.
- Fold back the top linens to "open" the bed (see the figure).
- The patient may need to go to bed immediately, so it should be ready when she arrives.

Prepare Routine Supplies

- Most agencies have an admission pack containing a bath basin, soap, lotion, tissues, water pitcher, and drinking glass. Open it and put it in the room.
- Place a hospital gown on the bed and nonslip footware by the bedside. Patients may choose to wear their own sleep clothing, though.

Prepare Equipment

You will need:

- A stethoscope, thermometer, and blood pressure cuff in the room for taking vital signs
- A scale for measuring and weighing the patient
- Bedpan and urinal if the patient is not ambulatory; possibly a bedside commode
- A clean-catch urine specimen container if laboratory work has not already been done
- Set up and check special equipment (e.g., oxygen, suction, cardiac monitor, pulse oximeter, IV pump).

Prepare the Environment

Turn on the lights, adjust the room temperature. Open or close curtains, as needed.

FORMS

The forms in this section are copies that are put into the patient's permanent record in paper form. Many agencies have computer-based discharge processes, however.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Recall Evelyn (Meet Your Patient). She is 87 years old and has lived in a nursing home for the past 5 years. She suffers from congestive heart failure (CHF), hypertension, diabetes, macular degeneration resulting in near blindness, a severe hearing deficit, urinary incontinence, and immobility resulting from a hip fracture. Despite these limitations, she keeps current in the lives of all of her family members and friends. At the nursing home, staff members confide in Evelyn and she knows about their children, their romances, and the gossip around the nursing home. Whenever there is an election, she makes sure that she gets to vote. She "reads" every audio book she can get her hands on.

Recently Evelyn was admitted to the hospital in severe CHF. When leaving the nursing home, she told her pastor, "I don't want to die yet. I'm having too much fun!" You notice that the papers from the nursing home do not contain an advance directive, and it was not mentioned in their report to you.

THINKING

1. *Critical Thinking (Considering Alternatives):*
   a. What are some possible reasons that there is no advance directive?
   b. Which of those seems most likely to you?
   c. How might you find out about the status of Evelyn's advance directive?

DOING

2. *Nursing Process (Nursing Diagnosis):* On the care plan from the nursing home, there were two nursing diagnoses:
   - Urge Urinary Incontinence related to difficulty ambulating to bathroom
   - Impaired Skin Integrity related to immobility and incontinence

   Which of these can you remove from the care plan for now? Explain your decision.

CARING

3. *Self-Knowledge:* The next day, despite aggressive treatment, Evelyn's condition worsens. She is not responding to verbal stimuli and her oxygen level is decreasing. There is discussion about putting her on a ventilator.
   a. What would you be feeling?
   b. If Evelyn has an advance directive that says "no ventilator," how would that change your feelings?
   c. If there is an advance directive that says "do everything possible to keep me alive," how would that change your feelings?

   Note: We are not asking you what you would do; rather, you should consider how you would feel.

Critical Thinking and Clinical Reasoning

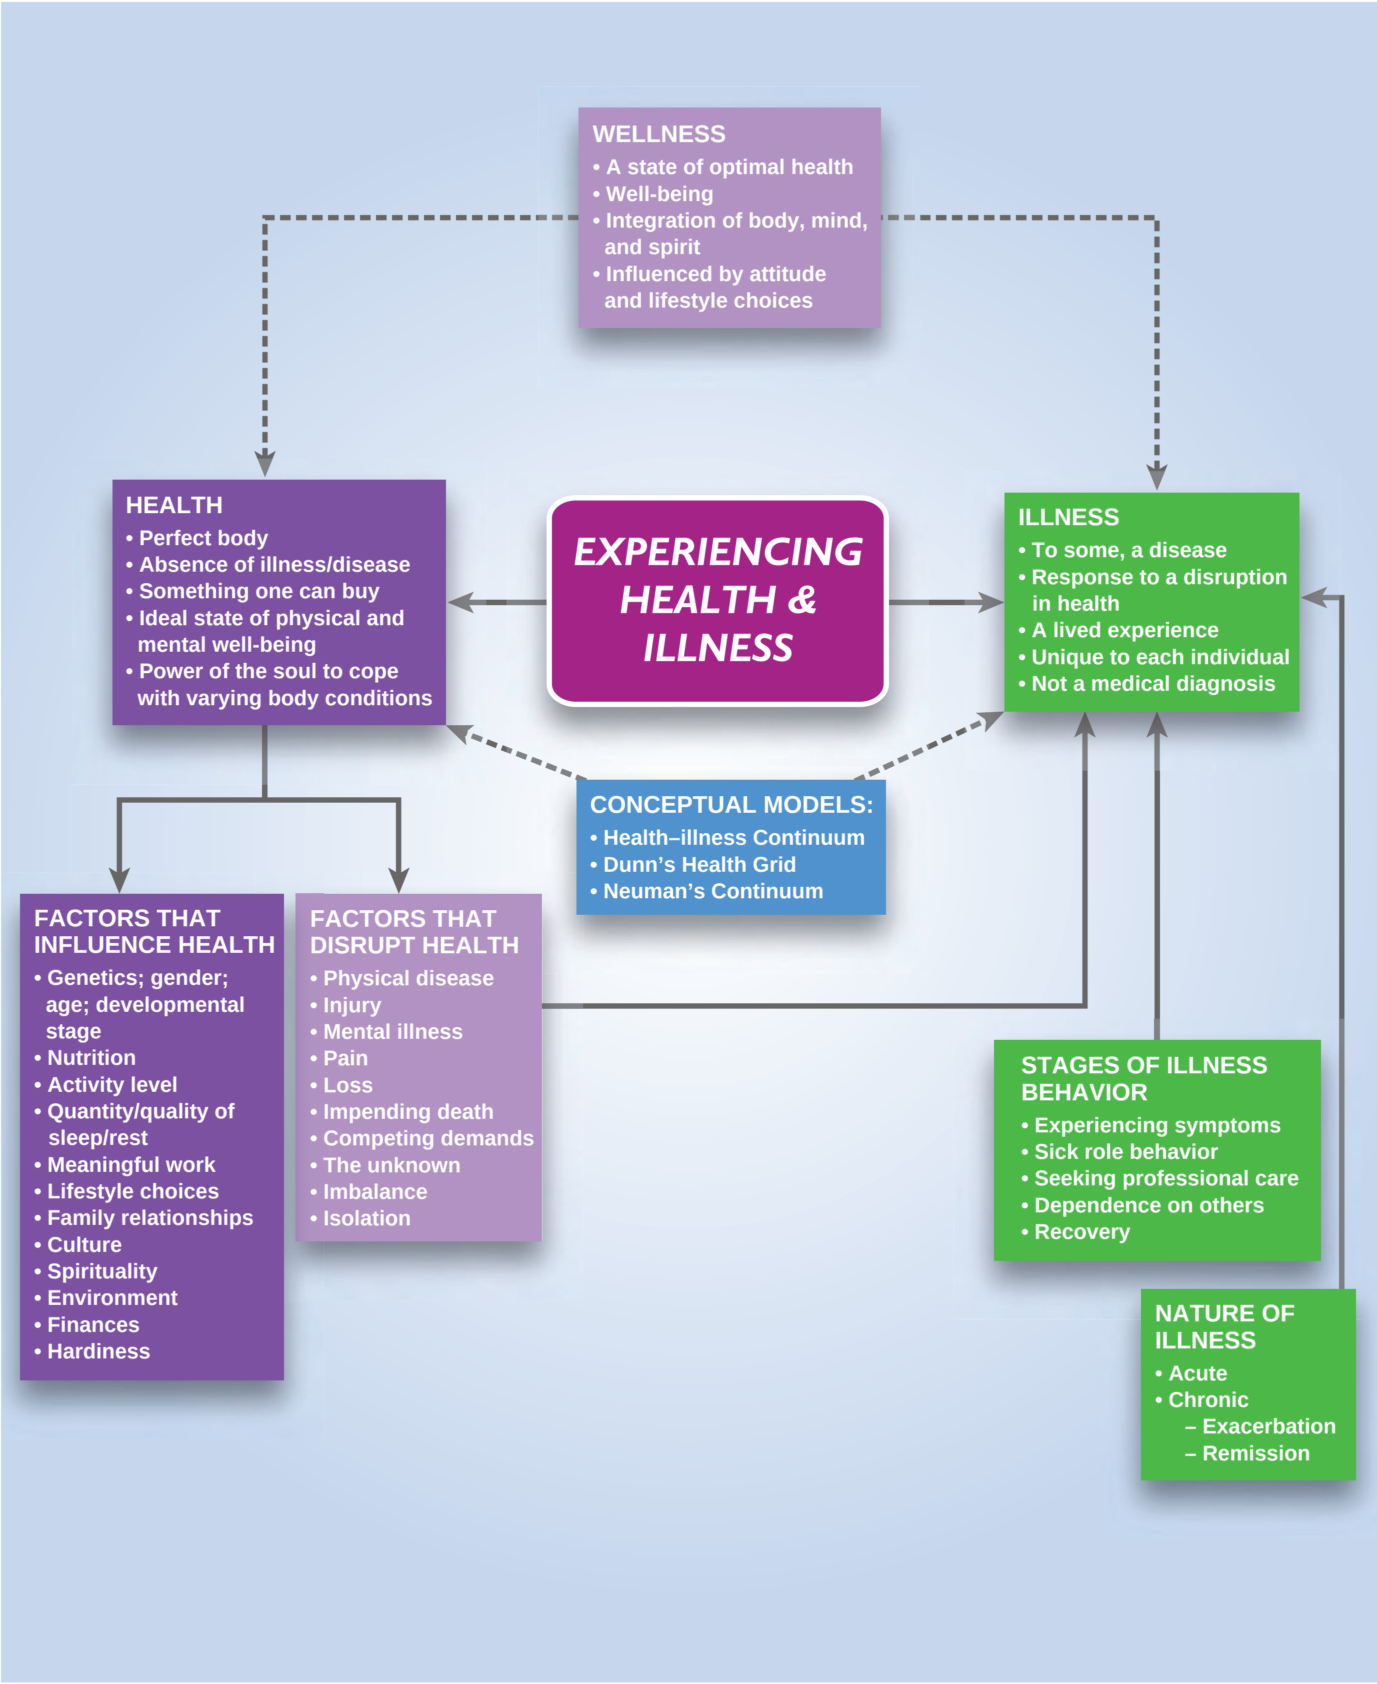
1. Describe your personal view of health.
2. Identify an individual in your life, personally or professionally, who personifies health. What characteristics do you identify in this individual that represent health? What factors do you think contribute to this individual's health status?
3. Use the nursing process to develop a plan to improve your personal health.
4. What attributes, resources, or life experiences do you have as an individual to offer in your role as a nurse?
5. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or experiencing health and illness. Note that these are *not* to be merely definitions.

   Health
   Wellness
   Illness
   Disruptions
   Hardiness
   Responses to illness
   Health–illness continuum

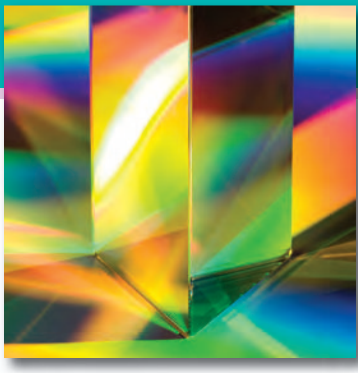
What Are the Main Points in This Chapter?

- Health is a complex phenomenon that involves physical, mental, and spiritual aspects. Having good health is an almost universal desire.
- Wellness is a way of life oriented toward optimal health and well-being.
- Life and wellness require nourishment. Nourishment comes in the form of food, exercise, sleep, relationships, meaningful work, the environment, and memories.
- The person with an illness rarely perceives the experience as a medical diagnosis. Instead, illness is usually described in terms of how it makes the person feel, such as pain, sadness, loss, fatigue, or being overwhelmed.
- People dealing with life-threatening illness have to figure out how to live and still be dying. Dealing with death is one of the most difficult experiences you will face as a nurse.
- One aspect of persevering in illness and life disruption is maintaining as much normalcy as possible. Normalcy helps clients cope with illness.
- Nurses deal with people who have been thrust into new life situations, situations they did not ask for and for which they were not prepared.
- People who are suffering experience loneliness. Part of aloneness can be related to the actual physical separation, part of it from a sense of the world going on without them, and part of it from a sense of no one really being in their world.
- Several factors influence a person's responses to disruptions. These factors include age; family patterns; culture; hardiness; support; access to healthcare resources; the stage and nature of the illness; and the intensity, duration, and multiplicity of the disruption.
- Chronic illnesses are a large and growing healthcare concern, especially among older adults.
- The top three risks for functional decline are cognitive impairment, depression, and disease burden.
- You can ease patients' disruptions experienced during admission, transfers, and discharge from a healthcare setting by discharge planning, communication, coordination, and teaching.
- As a nurse, you will need to cultivate a healing presence. Listening, being attentive, being willing to learn from those in your care, and recognizing and respecting others' ways of coping are behaviors associated with a healing presence.
- Most people experience health, illness, and wellness as an ever-changing continuum on which they move.
- Communicating genuine care, concern, and sensitivity comes from who you are as a person, not from assuming a professional persona that you "put on" to fulfill a role.
- Patients and families may not recognize the strengths and creative abilities that they bring to a situation. Part of the art of nursing is to envision strengths and potential in patients and families who may be too overwhelmed to identify them on their own.
- Your healing presence may be the most memorable aspect of nursing care that you have to offer.

Knowledge Map



CHAPTER 12



Stress & Adaptation

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 12:
- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Stress & Adaptation (suggested readings)**

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 12, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

After having a comprehensive physical exam at the family health center, Yen Nguyen has been scheduled to have a mammogram and screening laboratory work. When she arrives at the clinic for her mammogram, she tells you she is very nervous. "I have a good friend who just found out she has breast cancer. She's very depressed now. Do I really have to do this test?"

A. What kind of stress is Yen experiencing?

B. Three days later, the radiologist contacts Yen requesting that she return to the family health center for additional films of the upper outer quadrant of the right breast. "There are some calcifications I want to check out," explains the radiologist.

- What factors might affect Yen's adaptation to this stress?
- Evaluate what you know about Yen's perception of her stress, her overall health status, her support system, and her coping methods. What more do you need to know about these topics to fully answer this question?

C. Later, Yen calls the office frantically explaining that she is very upset about this recent event. She says, "Not knowing is killing me. I'm so nervous I can't stand it. I can't sleep. I can't eat." She asks how she can handle the stress until she comes in for the additional tests next week. What strategies would you recommend to help Yen deal with the stress?

PracticalKnowledge knowing **how**

CLINICAL INSIGHTS

Clinical Insight 12-1 ➤ Dealing With Angry Patients

- ***Be aware of how you are responding to angry patients.*** Are you relieving your own stress, or are you relieving the client's stress? If you respond angrily to relieve your own stress, you may provoke further anger in the patient and even escalate the situation to the point of violence.
- ***Keep reminding yourself not to take anger personally;*** remind family members of this as well.
- ***Recognize that anger and anxiety are normal feelings*** when facing adversity, such as a life-threatening or debilitating illness. Do not discount feelings by saying something like, "Please, don't be so angry," or "You shouldn't talk like that." Or, "Everything will be OK. Don't worry."
- ***Encourage the client and family to express feelings*** verbally and appropriately.
- ***Listen instead of defending.*** If the patient yells, "Everything about this place stinks," don't respond with something like, "This hospital is highly rated by The Joint Commission," or, "We really are all trying to do the best we can for you." Instead, say something to encourage the person to express his feelings or give you more information: "You seem really angry; what's going on?" or "Maybe I can help. Tell me a little more about what stinks."
- ***Do not take responsibility for the patient's anger.*** It is not your fault, so don't apologize (unless you really *do* have

(Continued)

Clinical Insight 12-1 ➤ Dealing With Angry Patients *(continued)*

something to apologize for). In the preceding example, for instance, it is not your fault that "the place stinks" or that the patient feels that way. So do *not* say, "I'm sorry we haven't been meeting your expectations."

- ***Remain calm;*** this reassures the patient.
- ***Help the patient identify what is causing the anger*** and try to meet those needs.
- ***Be alert to your own and to the patient's safety needs.***
  - If the person seems violent, do not allow him to get between you and the door.
  - Be sure you know how to call for help from staff or security personnel if you think you or someone else is in danger.
  - Do not wear a stethoscope around your neck, dangling jewelry, or anything a patient might use to hurt you.
  - Do not go into a room alone with an angry patient who seems to have a potential for violence.
  - Remain at least an arm's length away from an angry and potentially violent patient.
  - Do not turn your back on an angry patient.
- ***If you believe the patient's anger may escalate to violence, your priority is your own safety and the safety of others in the area***.

In addition to the above, if you want more information,

Go to Chapter 24, **Box 24-8,** in Volume 1.

Also refer to the NIC intervention, Anger Control Assistance (Bulechek, Butcher, & Dochterman, 2013, pp. 81—82).

Clinical Insight 12-2 ➤ Crisis Intervention Guidelines

For nurses who are at an entry level of practice, the goals of crisis intervention include the following (Brammer & MacDonald, 2003; Neeb, 2006):

1. Assess the situation.

What is the nature of the patient's condition and the severity of the crisis?

2. Ensure safety.

- Call for help if you or the patient is in physical danger.
- Do not leave the patient unless you think you are in imminent danger.
- First ensure your own safety; then provide for the patient's safety.

3. Defuse the situation.

- Keep in mind that a person in crisis may not be in control of his actions.
- Try to calm the person verbally.
- Attempt physical restraint only as a last resort and only when there is enough help to do it safely for both the staff and the patient.

4. Decrease the person's anxiety.

- Reassure the person that he is in a safe place and that you are concerned and want to help.
- Explain gently but firmly that you need his help and cooperation.
- Help the person to vent feelings of fear, guilt, and anger.
- Use physical contact very cautiously. The person in turmoil may interpret touch as aggression or a sexual approach.

5. Determine the problem.

- Find out what the patient believes to be the cause of the crisis.
- Remain calm, and do not pressure the patient to give reasons. Any tension on your part will create further panic in the patient.

6. Decide on the type of help needed.

- You may be able to calm the person enough for him to understand what just happened, or you may not. Evaluate your ability to calm the patient based on your assessment of his coping skills and resources.
- Put in place the help needed to restore the person to a minimal level of functioning. This may require long-term treatment. In that case, make the referrals.

7. Return the person to his precrisis level of functioning. This may involve crisis counseling and/or home crisis visits.

- The goal of crisis counseling is to provide immediate relief, solve the most urgent problems, and give long-term counseling if needed. Crisis centers often rely on telephone counseling ("hotlines").
- If telephone counseling is not adequate or if observations of the home environment are needed, home visits may be necessary.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

The Holmes–Rahe Social Readjustment Scale

This is a way to check your stress level, measured in "life change units." Of course it is not possible to score the exact "amount" of stress. However, this will give you a general idea of your stress level and should provide some insight about the sources of your stress. The following are based on the number of life change units over a 1- to 2-year period:

Over 300 points (Major amount of change): 80% chance of major illness

200–299 (Moderate amount of change): 50% chance of major illness

150–199 (Mild amount of change): 33% chance of major illness

0–149 (Insignificant amount of change): Minimal chance of major illness

Of course, your personality and your ability to cope also determine the likelihood of your becoming ill.

Life Event	Life Change Units	Life Event	Life Change Units
Death of spouse	100	Son or daughter leaving home	29
Divorce	73	Trouble with in-laws	29
Marital separation	65	Outstanding personal achievement	28
Imprisonment	63	Spouse begins or stops work	26
Death of a close family member	63	Begin or end school	26
Personal injury or illness	53	Change in living conditions	25
Marriage	50	Revision of personal habits	24
Dismissal from work	47	Trouble with boss	23
Marital reconciliation	45	Change in work hours or conditions	20
Retirement	45	Change in residence	20
Change in health of family member	44	Change in schools	20
Pregnancy	40	Change in recreation	19
Sexual difficulties	39	Change in church activities	19
Gain of new family member	39	Change in social activities	18
Business readjustment	39	Minor mortgage or loan	17
Change in financial state	38	Change in sleeping habits	16
Change in number of arguments with spouse	35	Change in number of family reunions	15
Major mortgage	32	Change in eating habits	15
Foreclosure of mortgage or loan	30	Vacation	13
Change in responsibilities at work	29

Focused Assessment

Assessing for Stress: Questions to Ask

1. **Assess stressors and risk factors.** Ask the client to complete a stress inventory, such as the preceding Holmes-Rahe Social Readjustment Scale. Then ask the client the following questions:
   - ➤ What is causing the most stress in your life?
   - ➤ On a scale of 1 to 10 (where 1 is "not much" and 10 is "extreme"), rate the stress you are experiencing in each of these areas: work or school, finances, community responsibilities, your health, health of a family member, family relationships, family responsibilities, relationships with friends.
   - ➤ How long have you been dealing with the stressful situation(s)?
   - ➤ Can you track the accumulation of stress in your life?
   - ➤ How long have you been under this stress?
   - ➤ Note the client's developmental stage, and determine whether he is functioning as expected for this stage. Review Chapter 9 if you need help to identify developmental milestones. To help you assess for stressors that can be predicted to occur in each stage, you might ask questions such as:

     What challenges do you face as a result of your life and your age?

     Have you had recent life changes?

     Do you anticipate any life changes?

To review developmental stage changes,

Go to **Chapters 9 and 10,** in Volume 1. Also see Chapter 12, **Box 12-1: Stressors Throughout the Life Span,** in Volume 1.

2. **Assess coping methods and adaptation.**
   - ➤ What coping strategies have you used previously? What was successful, and what was not successful?
   - ➤ Tell me about previous experiences you have had with stressful situations in your life.
   - ➤ What do you usually do to handle stressful situations? (If the client needs prompting, you can ask, "Do you cry, get angry, avoid people, talk to family or friends, do physical exercise, pray? Some people laugh or joke, others meditate, others try to control everything, others just work hard and look for a solution. What is your usual response?")
   - ➤ How well do these methods usually work for you?
   - ➤ What have you been doing to cope with the present situation?
   - ➤ How well is that working?
   - ➤ During the interview, you should also observe for the use of psychological defense mechanisms.

To review psychological defense mechanisms,

Go to Chapter 12, **Table 12-1: Psychological Defense Mechanisms,** in Volume 1.

   - ➤ If the patient has not exhibited any defense mechanisms, you could ask about the common ones. For example, "Do you ever cope with a situation by denying it exists or just by trying to put it out of your mind?"
   - ➤ Also ask the client about physiological changes and diseases caused by ongoing stress. Check the client's records for a history of somatoform disorders. Ask the client:

     What physical illnesses do you have? How long have you had them?

     What, if any, physical changes have you noticed?

     Do you have other physical conditions, for example, hypertension, cardiac disease, diabetes, arthritis, joint pains, cancer?

To review findings that might indicate maladaption to stress,

Go to Chapter 12, **Table 12-2, Organic Disorders Brought About by Failure of Adaptive Mechanisms,** in Volume 1.

3. **Assess physiological responses to stress.**

   The following are examples of questions you should ask:
   - ➤ What do you do to stay healthy?
   - ➤ Tell me about your health habits.
   - ➤ How often do you have a checkup?
   - ➤ What are your health concerns?
4. **Assess emotional and behavioral responses to stress.**

Emotional Responses

Observe for:

- ➤ Anger
- ➤ Anxiety
- ➤ Depression
- ➤ Fear
- ➤ Feelings of inadequacy
- ➤ Low self-esteem
- ➤ Irritability
- ➤ Lack of motivation
- ➤ Lethargy

Behavioral Responses

Observe for:

- ➤ Crying, emotional outbursts
- ➤ Dependence
- ➤ Poor job performance
- ➤ Substance use and abuse
- ➤ Sleeplessness (or sleeping too much)
- ➤ Change in eating habits (e.g., loss of appetite, overeating)
- ➤ Decrease in quality of job performance
- ➤ Preoccupation (i.e., daydreaming)
- ➤ Illnesses
- ➤ Increased absenteeism from work or school
- ➤ Increased number of accidents
- ➤ Avoiding social situations or relationships
- ➤ Rebellion, acting out

Examples of Assessment Questions

- ➤ Do you smoke?
- ➤ How much alcohol do you drink every day?
- ➤ What do you eat? What is your typical eating pattern?
- ➤ How much fluid do you drink daily?
- ➤ How many hours do you sleep at night? Do you feel rested when you wake up?

Focused Assessment

Assessing for Stress: Questions to Ask—cont'd

- Do you often wake up very early in the morning and have difficulty getting back to sleep?
- What prescribed medications, vitamins, over-the-counter medications, or herbs do you take?
- What regular physical activity or exercise do you engage in?
- How much time do you spend at work versus at leisure and play?
- Do you constantly take work home with you? Or think about work almost all the time?
- How do you relax?
- Have you given up activities and relationships you previously enjoyed because you "don't have enough time" or are too tired?
- How do you express anger?
- Do you try to be perfect?
- Would you describe yourself as having the stress-filled lifestyle of a type A personality?
- How often do you find yourself feeling hopeless? Sad?

5. **Assess cognitive responses to stress.**

   Observe for the following responses when you assess other functional areas:

   - Difficulty concentrating
   - Poor judgment
   - Decrease in accuracy (e.g., in counting money)
   - Forgetfulness
   - Decreased problem-solving ability
   - Decreased attention to detail
   - Difficulty learning
   - Narrowing of focus
   - Preoccupation, daydreaming

6. **Assess support systems.**

   Ask the following questions:

   - Tell me about your home. Describe your living environment. (Make a home visit if possible, or contact the case manager or social worker to arrange a home evaluation.)
   - Who are the persons who provide the most support for you? In what ways do they support you?
   - What support is available from family, friends, significant others, community agencies, and clergy that you may not have required until now?
   - Do you have or do you seek spiritual support?
   - How has your stress affected the family?
   - What are your financial resources? What are your financial obligations?

STANDARDIZED LANGUAGE

NANDA-I Nursing Diagnoses Associated With Stress

Physical

Constipation
Deficient Fluid Volume
Delayed Growth and Development
Diarrhea
Disturbed Energy Field
Disturbed Sleep Pattern
Fatigue
Imbalanced Nutrition (can be More Than or Less Than Body Requirements)
Nausea
Pain (e.g., backache)
Risk for Injury
Sleep Deprivation

Behavioral

Decisional Conflict
Impaired Home Maintenance
Impaired Verbal Communication
Ineffective Coping
Ineffective Health Maintenance
Ineffective Self-Health Management
Ineffective Therapeutic Regimen Management
Risk-Prone Health Behavior
Self-Neglect

Cognitive

Acute Confusion
Disturbed Thought Processes
Impaired Memory

Emotional

Anxiety
Defensive Coping
Disturbed Body Image
Disturbed Personal Identity
Fear
Grieving, Complicated
Ineffective Coping
Ineffective Denial
Low Self-Esteem (Chronic or Situational)

Interpersonal Relationships

Caregiver Role Strain
Compromised or Disabled Family Coping
Dysfunctional Family Processes
Impaired Parenting
Impaired Social Interaction
Ineffective Community Coping

(Continued)

NANDA-I Nursing Diagnoses Associated With Stress—cont'd

Interrupted Family Processes
Post-Trauma Syndrome
Relocation Stress Syndrome
Risk for Compromised Resilience
Risk for Other-Directed Violence
Risk for Self-Directed Violence
Risk for Suicide
Social Isolation
Stress Overload

Spiritual Domain

Hopelessness
Spiritual Distress
Impaired Religiosity

CLINICALREASONING
Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mrs. Williams is a 76-year-old Indian American woman who was admitted yesterday after suffering a stroke that paralyzed her right side. She has had diabetes and high blood pressure for many years. Since the stroke, she has been unable to speak clearly and becomes frustrated as she attempts to communicate her needs. Her daughter says Mrs. Williams is a proud, independent, and tidy woman who has been living alone since her husband's death last year. Until her stroke, she had been driving her car, cleaning the house, doing her grocery shopping, and maintaining the yard and garden. She wears eyeglasses for reading and driving and has a hearing aid, although she rarely uses it.

THINKING

1. *Theoretical Knowledge:*
   a. What stroke risk factors probably functioned as stressors for Mrs. Williams? (*Hint:* Look up stroke risk factors in a medical-surgical nursing or pathophysiology text, or online.)
   b. What are common stressors for patients who must be hospitalized?
2. *Critical Thinking (Contextual Awareness):*
   c. Now that Mrs. Williams is in the hospital, what new stressors might she have?

DOING

3. *Practical Knowledge:* What might you advise Mrs. Williams's daughter to do to help her mother adapt more comfortably to the stressors in the hospital?
4. *Nursing Process (Diagnosis):* Based on only the data in the scenario, write one actual nursing diagnosis for Mrs. Williams. Do not use potential diagnoses. Remember, the defining characteristics must be present in the scenario. State the data you would need in order to make the diagnosis more descriptive.

CARING

5. *Self-Knowledge:* Imagine yourself in Mrs. Williams's situation.
   a. What is the one thing that would cause you the most stress? Why would that be the most stressful thing?
   b. What is the single most important thing you would want your nurse to do for you?

Go To Chapter 12, **Applying the Full-Spectrum Nursing Model Response Sheet,** on Davis*Plus*.

Critical Thinking and Clinical Reasoning

1. Gloria and her husband, John, (Meet Your Patient, in Volume 1) live in a residential community from which John commutes to work in a nearby city. Gloria runs an accounting business from their home. They have two teenage boys who are active in sports, church activities, Boy Scouts, and the school band. The boys need transportation to activities. Gloria and John teach Sunday school and are Boy Scout leaders. Gloria's mother needs knee replacement surgery and so cannot take care of Gloria's father, who is in the early stage of Alzheimer's disease. In addition to her own home responsibilities, Gloria must go to her parents to prepare meals and to provide care for her parents during the day. Gloria's sister comes at 8:00 p.m. to sleep in the parents' home during the night.
   a. What resources may be available to help Gloria?
   b. What stress-reducing techniques can you suggest to help Gloria?
   c. What may reduce John's stress?
   d. On a scale of 1 to 10 (1 being low and 10 being high), what number will you give to Gloria's stress level?
2. Look again at Gloria and John's situation. Using the following defense mechanisms, create a possible scenario for each. That is, what might Gloria (or John) say and/or do if they use the defense mechanism in this situation? If you need to review ego defense mechanisms,

Go to **Table 12-1,** in Volume 1.

   a. **Avoidance—**unconsciously staying away from events or situations that might open feelings of aggression or anxiety.
   b. **Conversion—**changing emotional conflict into physical symptoms that have no physical basis.
   c. **Denial—**transforming reality by refusing to acknowledge thoughts, feelings, desires, or impulses. This is unconscious; the person is *not* consciously lying.
   d. **Displacement—**"kicking the dog." Transferring emotions, ideas, or wishes from one original object or situation to a substitute inappropriate person or object that is perceived to be less powerful or threatening.
   e. **Reaction formation—**similar to compensation, except the person develops the exact opposite trait. The person is aware of her feelings but acts in ways opposite to what she is really feeling.
3. Mary is a nursing student. She works part-time to maintain health insurance coverage for herself and her children and to earn tuition money for school. She has to do her studying after the children are in bed, so she gets little sleep herself. Her grades are low and do not reflect Mary's true knowledge level. Nursing faculty suggest that Mary seek counseling for exam anxiety and test-taking strategies. Mary realizes she may fail out of nursing school without this counseling, but she does not know how she will fit weekly sessions into her already full schedule.
   a. List Mary's stressors.
   b. *Self-Knowledge*:
      - What life experiences do you have that may help you to understand Mary's situation?
      - How could these same life experiences interfere with your empathy for and understanding of Mary?
      - How much of Mary's story can you identify with as being part of your own experience now?
   c. Which type of intervention do you think would be most helpful to Mary: (1) helping her to change her perception of her stressors, or (2) the health promotion activities discussed in Volume 1? Explain your reasoning.
   d. Before deciding specifically how to help Mary, what data do you still need?
   e. Based on the information you have, what do you think Mary's two most important goals are?
   f. If you discover that Mary's most important goals actually are to (1) provide for her children and (2) succeed in nursing school, how might you use this information to help her?
4. *Self-Knowledge:* In Volume 1, you listed your stressors. Let's assess further.
   a. What are your two (or three) *most* important goals? List them in order of importance.
   b. What support do you have that can help you to achieve each of these goals?

5. *Self-Knowledge and Theoretical Knowledge:* Use the Script for Visualization to lead a partner through a visualization exercise; then reverse roles, and have your partner lead you through it. To see the script,

Go to Chapter 12, **Tables, Boxes, Figures: ESG Box 12-2,** on Davis*Plus*.

   a. Before beginning, what were your thoughts and feelings about the exercise?
   b. After doing the visualization exercise, how did you feel? Did you feel more relaxed?
   c. How do you think your attitudes and perceptions prior to the exercise affected how you felt *after* the exercise?

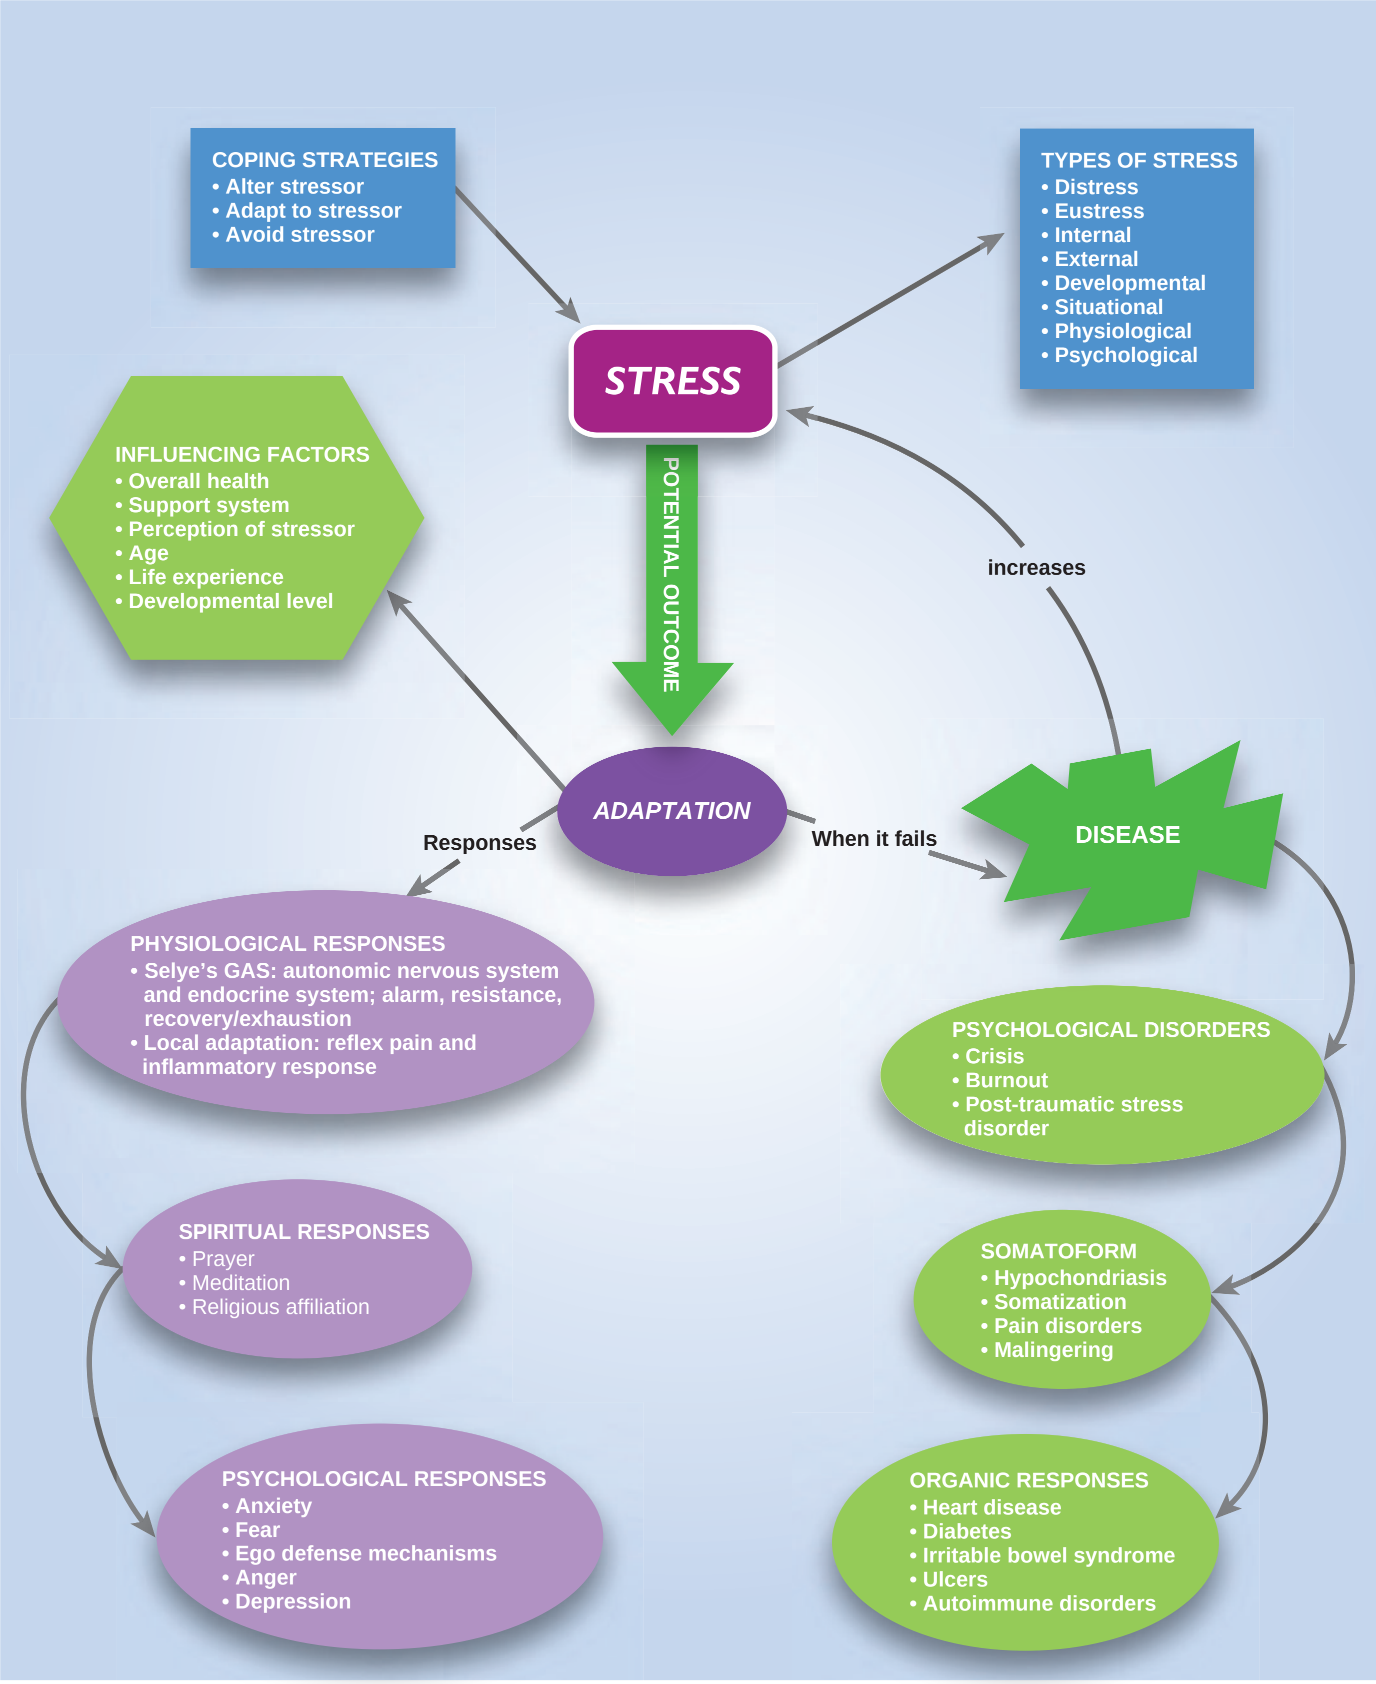
6. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or stress and adaptation. Note that these are *not* to be merely definitions.

   Stress
   Developmental stressors
   Coping strategies
   Ego defense mechanisms
   Inflammatory response
   Somatoform disorders
   Relaxation techniques for stress reduction

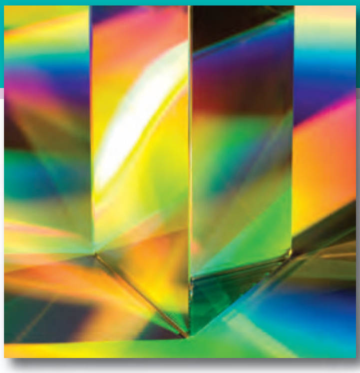
What Are the Main Points in This Chapter?

- Stress is a disturbance in normal homeostasis caused by internal or external stimuli called stressors.
- Adaptive coping techniques are those that offer healthy choices to the person and reduce the negative effects of stress.
- Approaches to coping include altering the stressor, adapting to the stressor, and avoiding the stressor.
- Whether the outcome of stress is positive (adaptation) or negative (disease) depends on the balance between the strength and duration of the stressors and the effectiveness of the person's coping methods.
- The three stages of Selye's general adaptation syndrome (GAS) are alarm, resistance, and exhaustion. Each stage in the GAS produces different physical or psychological responses.
- In the alarm stage of the GAS, responses are produced primarily by adrenal hormones, epinephrine, mineralocorticoids, and the sympathetic nervous system.
- The exhaustion stage can lead to stress-induced illness, burnout, or death.
- The two most common responses of the local adaptation syndrome (LAS) are the reflex pain response and the inflammatory response.
- Examples of psychological responses are anxiety, fear, anger, and ego defense mechanisms.
- Ego defense mechanisms are unconscious mental mechanisms that help to decrease the inner tension associated with stressors; when overused, they are maladaptive.
- Unsuccessful adaptation can lead to crisis, organic disease (e.g., stomach ulcers), somatoform disorders (e.g., hypochondriasis), and psychological disorders (e.g., mental illness).
- Crisis exists when (1) an event in a person's life drastically changes his or her routine and is perceived as a threat to self, and (2) the person's usual coping methods are ineffective, resulting in high anxiety and reduced ability to function.
- Burnout occurs when nurses or other professionals cannot cope effectively with the demands of the workplace.
- You should assess for data about the patient's stressors, risk factors, coping and adaptation, support systems, and psychosocial and physiological responses to stress.
- Interventions for stress must be individualized to the patient. They include (1) health promotion activities for preventing and improving the ability to cope with stressors; (2) managing anxiety, fear, and anger; (3) stress management techniques that focus on discharging tension or producing relaxation; (4) techniques to alter perception (i.e., cognitive restructuring and positive self-talk); (5) identifying and using support systems; (6) reducing the stress of hospitalization; (7) providing spiritual support; (8) crisis intervention; (9) stress management in the workplace; and (10) making referrals.

Knowledge Map



CHAPTER 13



Psychosocial Health & Illness

STUDENT RESOURCES

The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on DavisPlus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 13:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Psychosocial Health & Illness (suggested readings)**
- **Concept Map of chapter content**

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 13, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Recall the case of Nam Nguyen. Mr. Nguyen has been diagnosed with hypertension, obesity, and degenerative joint disease (DJD). At clinic visits he has made the following comments: "Every time I come in here, I get some new diagnosis. I guess it's amazing I'm not dead yet. I thought I had a lot more time left, but I'm not so sure anymore." When you ask him what his main concerns are, he tells you, "Just take a look at me! I'm a mess. Nothing is turning out the way I planned. I might as well just die now. It would save my family a lot of grief."

Caring for the Nguyens (continued)

A. What information do you need in order to respond to Mr. Nguyen?

B. How should you respond to Mr. Nguyen?

C. What actions should you take?

D. What conclusions can you make about Mr. Nguyen's self-concept (body image, role performance, personal identity, and self-esteem)? What additional information do you need about his self-concept?

PracticalKnowledge knowing how

This section provides guidelines and forms for assessing self-concept, self-esteem, anxiety, and depression, which are basic to psychosocial health and illness. In addition, you will find tables of selected standardized outcomes and interventions to consider when planning care for patients with problems related to anxiety and depression.

CLINICAL INSIGHTS

Clinical Insight 13-1 ➤ Assessing Self-Concept Problems

Assessment Category	Examples of Assessment Questions
Body image	■ When you look in the mirror, what do you see? ■ How do you think others see you? ■ How does your current ability to engage in work and leisure activities compare with how you would like to be?
Role performance	■ What are your three or four major roles (e.g., daughter, student)? ■ How successful are you in each of these roles? ■ How important is it to you to be successful in each of these roles? ■ What is interfering with your ability to perform any of these roles? What can you do about it?
Personal identity	■ How did you see yourself before your illness/injury/loss? ■ How do you see yourself now? ■ How would you describe yourself to others? ■ What special abilities do you have? ■ How do you think others see you?
Self-esteem (also refer to the Assessment Box, Performing a Self-Esteem Inventory)	■ How do you feel about yourself? ■ What do you like about yourself? ■ To what extent do you feel you are in control of your life? ■ If you could change one thing about yourself, what would it be? ■ Where would you like to be 5 years from now? ■ How realistic are your expectations of yourself? ■ How do you see your illness/injury/loss in relation to yourself?

Clinical Insight 13-2 ➤ Performing a Self-Esteem Inventory

Place a check mark in the column that most closely describes the client's answer to each statement. Each check is worth the number of points listed.

	3 Often or a great deal	2 Some-times	1 Seldom or occasionally	0 Never or not at all
1. I become angry or hurt when criticized.				
2. I am afraid to try new things.				
3. I feel stupid when I make a mistake.				
4. I have difficulty looking people in the eye.				
5. I have difficulty making small talk.				
6. I feel uncomfortable in the presence of strangers.				
7. I am embarrassed when people compliment me.				
8. I am dissatisfied with the way I look.				
9. I am afraid to express my opinions in a group.				
10. I prefer staying home alone rather than participating in group social situations.				
11. I have trouble accepting teasing.				
12. I feel guilty when I say no to people.				
13. I am afraid to make a commitment to a relationship for fear of rejection.				
14. I believe that most people are more competent than I am.				
15. I feel resentment toward people who are attractive and successful.				
16. I have trouble thinking of any positive aspects about my life.				
17. I feel inadequate in the presence of authority figures.				
18. I have trouble making decisions.				
19. I fear the disapproval of others.				
20. I feel tense, stressed out, or "uptight."				

Problems with low self-esteem are indicated by items scored with a 3 or by a total score higher than 46.

Source: Townsend, M. C. (2010). *Psychiatric mental health nursing: Concepts of care* (5th ed.). Philadelphia: F.A. Davis, p. 248.

Clinical Insight 13-3 ➤ Identifying Depressed Patients Who Should Be Referred for Evaluation

One way to identify depression that is more than simple, situational depression is to ask the following two questions. A Yes answer merits a referral.

1. "Over the past 2 weeks, have you felt down, depressed, or hopeless?"
2. "Over the past 2 weeks, have you felt little interest or pleasure in doing things?"

Source: U.S. Preventive Services Task Force (USPSTF). (2009). Screening for depression in adults. Retrieved January 18, 2013, from http://www.uspreventiveservicestaskforce.org/uspstf/uspsaddepr.htm

---

SIGECAPS

Another method is to use the mnemonic SIGECAPS, a concise version of the *DSM-5* diagnostic criteria. Ask the patient if he has experienced, for 2 or more weeks:

Sleep increase/decrease
Interest in formerly compelling or pleasurable activities diminished
Guilt, low self-esteem
Energy poor
Concentration poor
Appetite increase/decrease
Psychomotor agitation or retardation
Suicidal ideation

Both of the following require referral for evaluation and treatment:

Major depression = depressed mood or interest *plus* 4 SIGECAPS for 2 or more weeks
Mild depression (mood disorder) = depressed mood or interest plus 3 SIGECAPS most days for 2 or more years

Source: Breggin, P. (2009). *Medication madness: The role of psychiatric drugs in cases of violence, suicide, and crime*. New York: St. Martin's Press.

IN SAD CAGES

Some people prefer a mnemonic from an older source, IN SAD CAGES, which you would use in essentially the same way. Ask the patient whether he has experienced, for 2 or more weeks:

Interest reduced
Negative thoughts

Sleep disturbance
Appetite change
Decreased confidence or self-esteem

Concentration reduced
Affect blunt or flat
Guilt
Energy reduced
Suicidal ideas

The original reference does not include a suggested total that requires referral. However, you can assume that the more symptoms there are, the more severe the depression will be. We would suggest the following:

IN (reduced interest and negative thoughts or depressed mood) plus 4 of the other SAD CAGES requires referral.

Do not try to differentiate mild and major depression with this method.

Adapted from Leng, L. B. (2011). Overview of major depressive disorder. *The Singapore Family Physician, 37*(4), 18–21.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Anxiety Assessment Guide

Rating Scale: None = 0, Mild = 1, Moderate = 2, Severe = 3, Disabling (Panic) = 4

PHYSIOLOGICAL EFFECTS	Rating	PSYCHOLOGICAL EFFECTS	Rating
Shortness of breath (dyspnea)	____	Depersonalization (unreal)	____
Choking sensation	____	Feeling "on edge"	____
Dry mouth	____	Poor concentration	____
Pounding heart, increased heart rate	____	Poor memory	____
Chest pain	____	Depressed mood	____
Increased sweating and clamminess	____	Loss of interest	____
Feeling faint, dizzy, unsteady	____	Restlessness	____
Nausea and abdominal upsets	____	Sense of panic	____
Numbness (pins and needles)	____	Worry, anticipation of the worst	____
Hot/cold flashes	____	Irritability	____
Trembling, shaking	____	Nightmares	____
Muscle tension and aches	____	Feeling of fear and foreboding	____
Exaggerated startle response	____	Excessive apprehension	____
Difficulties in falling asleep and staying asleep	____	Feeling lack of control	____

Assessing Overall Scores

0–28	Mild anxiety
29–56	Moderate anxiety
57–84	Severe anxiety
85–112	Disabling anxiety

Creating a total score from this table can help you assess whether overall anxiety is mild, moderate, severe, or disabling. However, individual physiological or psychological symptoms that are rated as severe (3) or disabling (4) may be more important and relevant to your nursing assessment. For example, your patient's overall or total assessment may be 26 (in the mild range, 0–27) but she has rated "Excessive apprehension" as 4 (disabling).

Focused Assessment

Depression Assessment Guide: Patient Health Questionnaire (PHQ-9)

This is a valid and reliable measure of depression developed in 1999 by Pfizer, Inc. It can be self-administered (Kroenke, Spitzer, & Williams, 2001). It may be useful across cultures (Arthurs, Steele, Hudson, et al., 2012; Chen, Huang, Chang, et al., 2006).

Over the past 2 weeks, how often have you been bothered by any of the following problems? (Check or circle your answers.)

	NOT AT ALL	SEVERAL DAYS	MORE THAN HALF THE DAYS	NEARLY EVERY DAY
1. Little interest or pleasure in doing things	0	1	2	2
2. Feeling down, depressed, or hopeless	0	1	2	3
3. Trouble falling or staying asleep, or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself—or that you are a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed. Or the opposite—being so fidgety or restless that you have been moving around a lot more than usual	0	1	2	3
9. Thoughts that you would be better off dead or of hurting yourself in some way	0	1	2	3
ADD COLUMNS		☐	+ ☐	+ ☐

TOTAL: ☐

10. If you checked off any problems, how difficult have these problems made it for you to do your work, take care of things at home, or get along with other people?

Not difficult at all _____

Somewhat difficult _____

Very difficult _____

Extremely difficult _____

(Healthcare professional: For interpretation of TOTAL, please refer to the accompanying score card. *[Note to students: Interpretation requires training. You should report the patient's score to your instructor or your immediate supervising nurse.]*)

Source: Pfizer, Inc. Retrieved January 23, 2013, from http://www.phqscreeners.com/. Used by permission.

Focused Assessment

Differentiating Depression and Dementia

This table may help you to identify older adults who should be referred for further evaluation to determine whether symptoms are related to depression or dementia. To screen for depression,

Go to Chapter 13, **Tables, Boxes, Figures: Geriatric Depression Rating Scale (Short Form),** on Davis*Plus*.

To determine whether the patient should be referred to a mental health professional, refer to Clinical Insight 13-3.

CHARACTERISTIC	DEPRESSION	DEMENTIA
Cause/triggers	Loss (e.g., of spouse, of independence); stress	Physiological causes (e.g., Alzheimer's disease, brain infarcts)
Onset	Acute or chronic; can be related to specific events	Chronic, gradual, and insidious
Course	Varies, depending on cause	Progressive, over a long period of time
Alertness	Usually reduced	Usually normal
Memory	Memory loss and forgetfulness	Recent and remote memory impaired; loss of recent memory is first sign; some loss of common knowledge
Thinking	Inability to concentrate	Difficulty with abstraction and word finding, especially nouns; difficulty with calculations; decreased judgment
Response to questions	Often says, "I don't know."	Answers inappropriately or with "near misses"
Language	Speaks slowly; slow to respond to verbal stimuli	Disoriented, rambling, incoherent; difficulty using nouns
Sleep	Difficulty falling asleep, early morning awakening, much day sleeping	Sleep fragmented; awakens often during night
Reversibility	Potential	Irreversible, progressive

STANDARDIZED NURSING LANGUAGE

You can use the tables in this section when planning care for patients with problems of anxiety, depression. The tables provide standardized wording for nursing diagnoses, outcomes, and interventions. You can use the NOC indicators with the outcomes to write goals. Non-NOC outcomes are also suggested. In addition to the broad NIC interventions, the tables provide specific nursing activities suggested by NIC.

Anxiety-Related Diagnoses: Selected NOC Outcomes and NIC Interventions

CUE CLUSTER	NANDA-I DIAGNOSIS*	NOC OUTCOMES†	SELECTED INDICATORS	NIC INTERVENTIONS AND SPECIFIC ACTIVITIES‡
Susan is pacing the floor and does not make eye contact when she speaks to you. Her hands are shaking. Her BP is 140/88 mm Hg, P is 100 beats/min, and R is 24 breaths/min. She says she is worried.	Anxiety	Anxiety Self-Control ***Other Outcomes*** Anxiety Level Concentration Coping	(Often demonstrated) ▪ Monitors intensity of anxiety. ▪ Maintains concentration.	Anxiety Reduction ▪ Use a calm, reassuring approach. ▪ Explain all procedures, including sensations the patient is likely to experience during the procedure. ▪ Help the patient identify situations that precipitate anxiety. ***Other Interventions*** Anger Control Assistance Anticipatory Guidance Calming Technique Coping Enhancement Emotional Support
Martin has a terminal illness. He looks very sad. He states that he is worried that his dying will be prolonged and difficult for his family and that he is afraid of dying.	Death Anxiety	Acceptance: Health Status ***Other Outcomes*** Anxiety Self-Control Comfortable Death Depression Level Dignified Life Closure Fear Self-Control Hope Spiritual Health	(Often demonstrated) ▪ Appears peaceful. ▪ Reports positive self regard. ▪ Clarifies personal values.	Emotional Support ▪ Listen to and encourage expressions of feelings and beliefs. ▪ Provide support during denial, anger, bargaining, and acceptance phases of grieving. ***Other Interventions*** Anxiety Reduction Coping Enhancement Decision-Making Support Dying Care Hope Instillation Pain Management Presence Religious Ritual Enhancement Spiritual Support
Ms. Eng says, "I just don't know whether to have this chemotherapy or not. I know I could live a little longer, but the side effects . . ." She has decided twice to do it and each time has changed her mind. She says, "I just can't focus on anything else."	Decisional Conflict	Decision Making ***Other Outcomes*** Information Processing Participation: Health Care Decisions Personal Autonomy	(Not compromised) ▪ Identifies alternatives. ▪ Identifies needed resources to support each alternative.	Decision-Making Support ▪ Determine whether there are differences between the patient's view of own condition and the views of healthcare providers. ▪ Serve as a liaison between the patient and family. ▪ Serve as a liaison between patient and other healthcare providers. ***Other Interventions*** Assertiveness Training Health System Guidance Learning Facilitation Mutual Goal Setting

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Matthew has been admitted to the emergency department with extensive wounds to both forearms, including tendon and vascular damage, from a suicide attempt. Matthew seems very quiet, almost withdrawn, and answers most of your questions in monosyllables.

Matthew reports the following: He is the third child in a family of five. Matthew's middle-class parents are now retired, and his brothers and sisters are scattered across the country in various large cities. Although Matthew claims his schooling years were unremarkable, he reminisces about several occasions when he was bullied and physically beaten by gangs of older adolescents.

Matthew further states that he graduated from Harvard Law School and became vice president of an influential law firm. Despite his apparent success in life, he has continued to question his self-worth since childhood. Plagued by worries and depression that have increased over the past few years, he says he wrote a note indicating that he now realizes what a failure he is and proceeded to slash both of his forearms with a sharp razor.

Matthew reports that he has not been eating much, feels tired all the time, and has no interest in going outside the house. He says, "I just don't feel like doing anything; I just want to sleep all the time."

THINKING

1. *Theoretical Knowledge:* Using just the information you have in the Patient Situation, use the SIGECAPS method outlined in Clinical Insight 13-3 to assess Matthew's level of depression. You will need to assume that he is reporting what he has experienced in the past 2 weeks (unless he is obviously referring to the past).
2. *Critical Thinking (Inquiry):* What items of the SIGECAPS cannot be completed with the information in the Patient Situation? What do you need to ask Matthew to complete them?

DOING

3. *Nursing Process (Interventions):* Based on your SIGECAPS data, what do you need to do right away (or be certain it was done in the emergency department)?

CARING

4. *Self-Knowledge:* What do you have in common with Matthew that might help you to empathize with him?
5. *Ethical Knowledge:* Try to put aside your own beliefs now, and answer the following questions from the perspective of (a) Matthew and (b) one of your nursing colleagues on the unit:
   a. Give one reason to support Matthew's claim that he has a right to commit suicide if his despair is too deep to bear.
   b. Give one reason to support a colleague's claim that Matthew does not have a right to commit suicide, no matter how he feels.

Critical Thinking and Clinical Reasoning

1. Review the scenario about Karli (Meet Your Patient from Volume 1):

   You are caring for a 16-year-old patient named Karli who is suffering from fractures to both arms and several ribs, as well as extensive first- and second-degree burns to 30% of her body after a motor vehicle accident. Karli was driving her parents' car home from her part-time job when she lost control of the car and crashed into a wall. The car exploded in flames. A passerby quickly reported the accident, and fast action by the emergency response team saved Karli's life.

   Karli is suffering from a moderate amount of shock and pain. She alternates among outbursts of anger, self-directed sarcasm, and despondence. She tells you that she cannot understand how the accident happened, that one moment she was adjusting the car radio, and the next moment she awoke in the hospital. Then suddenly she explodes. "It's not fair! I just took my eyes off the road for a second; that's all!" She bursts into tears. Picking at her bandages, she sobs, "No one will ever love me the way I'm going to look. My life is over. I hate myself!" You take her hand. "I used to be pretty," she says, "but now I'll look like a freak! What did I do to deserve this? I know plenty of kids who drive drunk or high all the time. I wasn't doing anything wrong! Why did this happen to me?"

a. Now that you have completed Chapter 13 in Volume 1, make a list of the multiple physical, psychological, and social issues that you would need to consider in developing a comprehensive care plan for Karli.
b. Compare your list with the one you made when you first began reading the chapter. How is it different? Or is it the same?

2. In the Meet Your Patient scenario, Karli perceives herself as unlovable "looking this way." Which of the following nursing activities do you think might be helpful in *exploring and changing her perception*? For those you *do not* choose, explain why.

Role Enhancement

- Help the patient distinguish ideal and actual self. Help her describe realistic roles and expectations tailored to specific health changes.
- Compare realistic roles with previous and less functional roles.

Conflict Mediation

- Provide a quiet, private, neutral setting for mediation to take place.
- Maintain your own neutrality in the process; do not "take sides."

Promoting Family Integrity

- Encourage and facilitate communication among family members.
- Encourage family members to care for the patient as much as possible.

Family Mobilization

- Help the family to identify strengths they can use to support the patient.
- Teach family members how to provide home care for the patient.
- Help the family identify community resources and/or support groups.
- With the patient's permission, keep the family informed about the patient's progress.

Enhancing Socialization

- Explore and reinforce the individual's established relationships.
- Provide opportunities to rehearse relationship-building skills.
- Investigate, assist, and promote any developing relationships with persons of similar interests and goals.
- Provide information and links to community activities that relate to the person's past, current, and future interests.
- Promote access to education in social skills development.
- Encourage the patient to communicate and engage in interpersonal relationship activities by providing ongoing positive feedback.
- Organize small, cohesive group activities.
- Provide or act as a role model where appropriate.

3. Mrs. King is being admitted into the orthopedics unit for a scheduled total knee replacement. Even though she appears to be in good health for a 72-year-old woman, you are concerned about her excessive weight, which can be described as moderate to severe obesity. You are troubled by how the obesity may negatively affect postsurgical recovery, wound healing, and mobility.
   a. What theoretical knowledge will you draw on to plan care to meet her biopsychosocial needs?
   b. What assumptions are you making? What stereotypes do you have that might affect your understanding of Mrs. King's situation?
   c. What do you think might be contributing to Mrs. King's obesity?
   d. What facts do you have to support those ideas?
   e. How could you find out for sure what is contributing to Mrs. King's obesity?
4. Day by day, you notice that your patient is eating less and complaining about constipation and tiredness. You carefully review her nutritional requirements against the food menu, as well as check nursing records for bowel movements. You have exhausted your initial search for obvious reasons your patient's appetite has changed. After sitting down next to your patient, you cannot help noticing how tired she looks.
   a. What psychosocial problem do you suspect (low self-esteem, depression, anxiety, or disturbed personal identity)?

b. What data do you have to support your inference in (a)?
c. Objective data in her chart indicate that the patient has been eating very little and that she has been having bowel movements only every 3 or 4 days—and even then only with a laxative or enema. What other symptom do you need to investigate further?
d. How could you obtain more information about that symptom?
e. Think of depressed people you have known or depressed patients you have cared for. What have you found to be difficult about dealing with them?

5. Edna Jackson is 42 years old. She has had a hysterectomy (removal of her uterus). Her surgery was uncomplicated, her overall health is good, and she is expected to make a full and rapid physical recovery. Her husband was not present when she was admitted and has not been to see her since the surgery. He did not want her to have the surgery. He told Edna that he doesn't know whether he will want to have sex with her when she is no longer "a whole woman." He has had casual affairs during their marriage, which Edna has tolerated because she feels that difficulty is balanced by the many positive benefits of their relationship, which include a "good sex life."

   Edna has seven brothers and sisters, and she has five children of her own, ages 23, 21, 18, 6, and 4. She comes from a culture and a religion that value children and motherhood. She believes she is a good mother, although she must work full-time outside the home. Edna is an office manager—respected by her boss and by those who work for her. She has an internal locus of control and evaluates her job performance as "better than most people would do."

   a. Look at the context. What aspects of this situation may negatively impact Mrs. Jackson's recovery?
   b. Based on your answers in (a), what nursing diagnoses might be useful in describing the psychosocial aspects of Mrs. Jackson's health? (State both the problem and the etiology.)
   c. What strengths does Mrs. Jackson have that may help her to avoid and/or overcome those problems?

6. Matthew has been admitted to the emergency department with extensive wounds to both forearms, including tendon and vascular damage, from an attempted suicide. Matthew seems very quiet, almost withdrawn, and answers most of your questions in monosyllables.

   Matthew reports that he is the third child in a family of five. Matthew's middle-class parents are now retired, and his brothers and sisters are scattered across the country in various large cities. Although Matthew claims his schooling years were unremarkable, he reminisces about several occasions when he was bullied and physically beaten by gangs of older adolescents.

   Matthew graduated from Harvard Law School and became vice president of an influential law firm. Despite his apparent success in life, he has continued to question his self-worth from early childhood. Plagued by worries and depression that have increased over the past few years Matthew wrote a note indicating that he now realized what a failure he is and proceeded to slash both his forearms with a sharp razor.

   During the nursing assessment, Matthew reports that he has not been eating much, feels tired all the time, and has no interest in getting outside the house. He says, "I just don't feel like doing anything; I just want to sleep all the time."

   a. After Matthew's tendon and vascular repair, he is admitted to your medical-surgical unit. What, broadly speaking, are your first two priorities for Matthew's care?
   b. Which of these nursing diagnoses— Risk for Suicide or Risk for Self-Mutilation—would you use, and why? (Consult a NANDA-I handbook, if necessary)
   c. Prioritize the following interventions for Matthew. Rank them (1 = highest rank, 4 = lowest rank). Explain your thinking.
      ____ Refer to a mental health professional for help with his depression.
      ____ Examine Matthew's belongings and the room for anything he might use to harm himself.
      ____ Encourage Matthew to tell you if he begins having thoughts of suicide.
      ____ Begin establishing a therapeutic relationship and gaining his trust.
   d. Evaluate your self-knowledge. To plan comprehensive care for Matthew, in what areas do you need to increase your theoretical and practical knowledge? How will you do that?

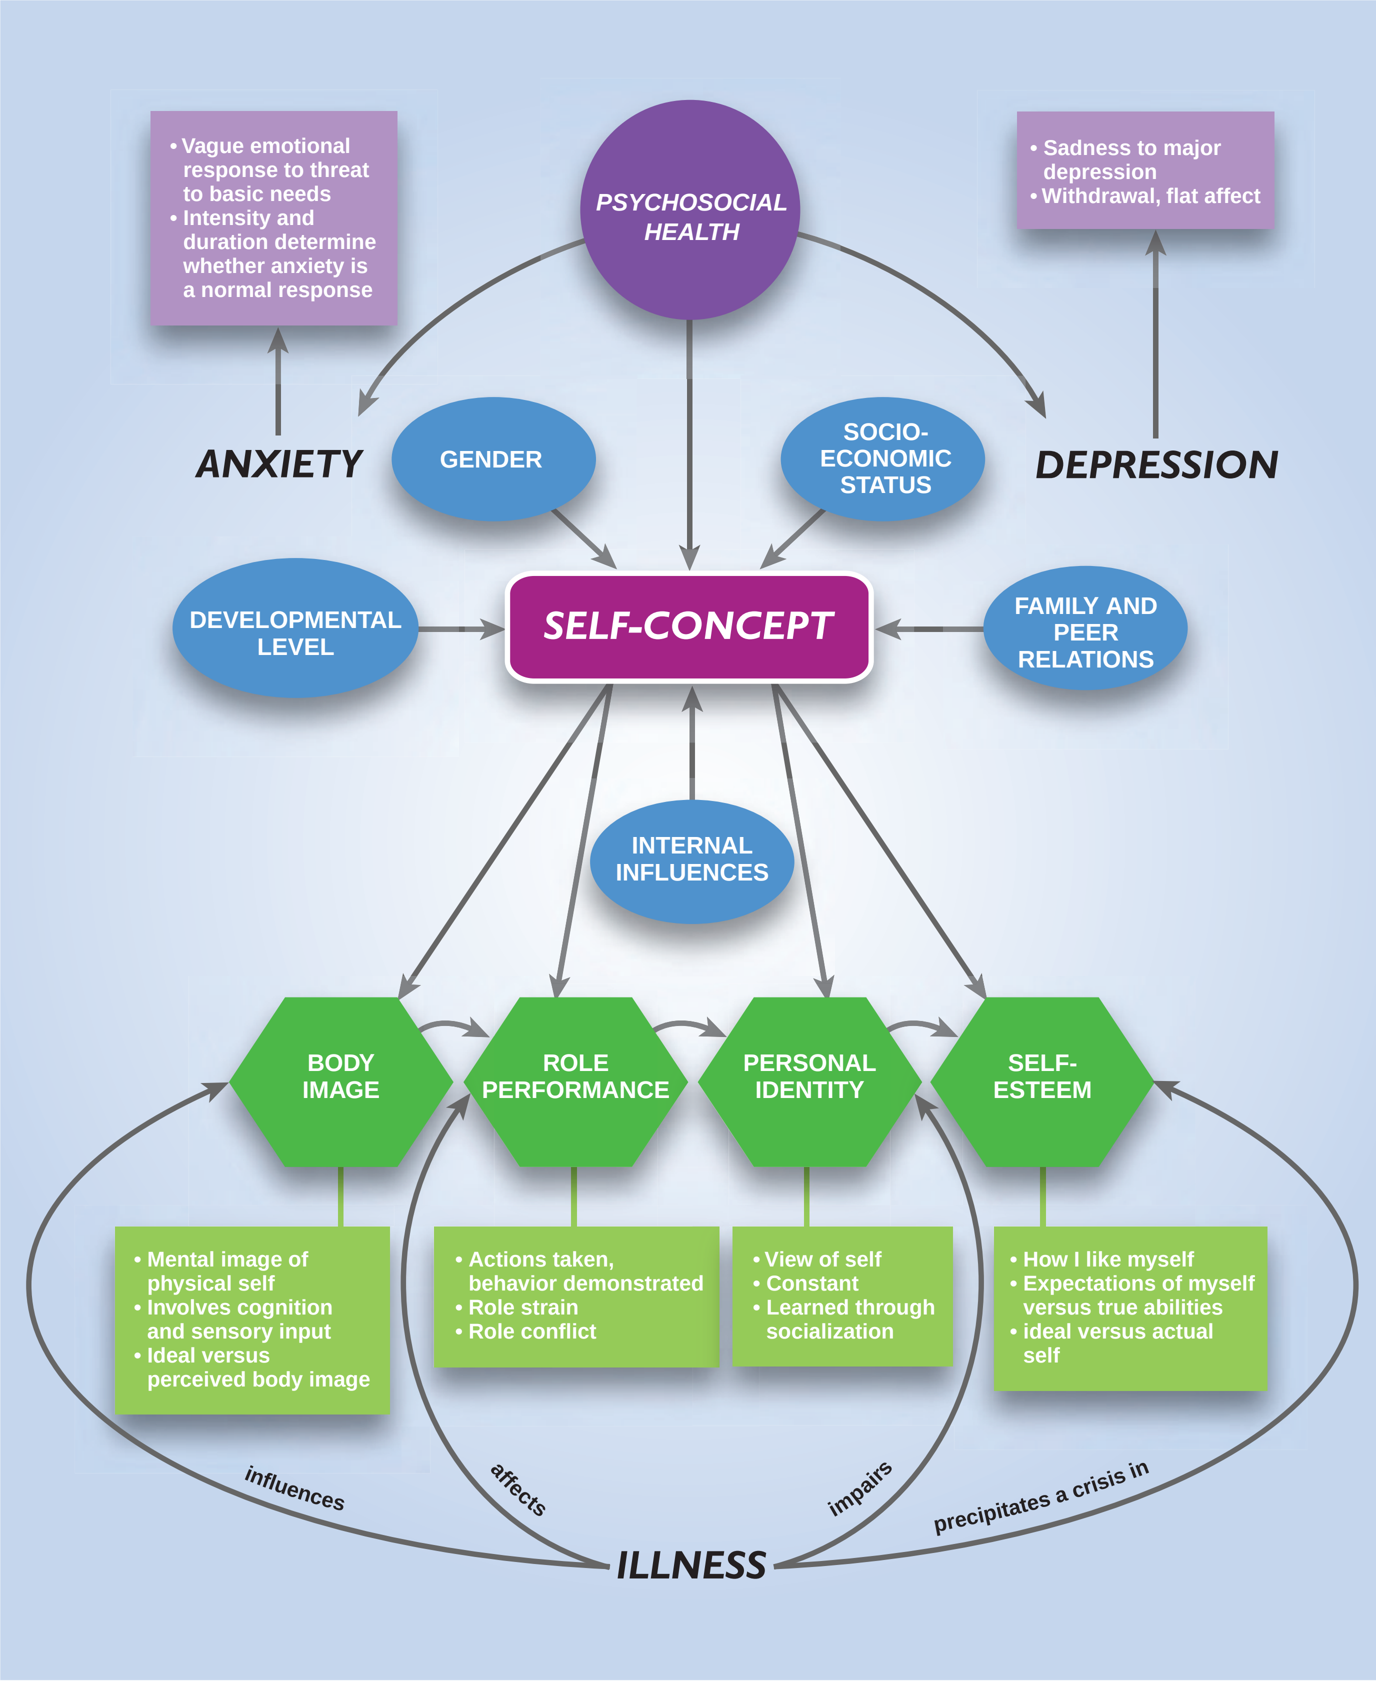
7. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or psychosocial health and illness. Note that these are *not* to be merely definitions.

Self-concept
Self-esteem
Body image
Biopsychosocial well-being
Anxiety
Defense mechanisms
Depression
Therapeutic relationships
Hopelessness

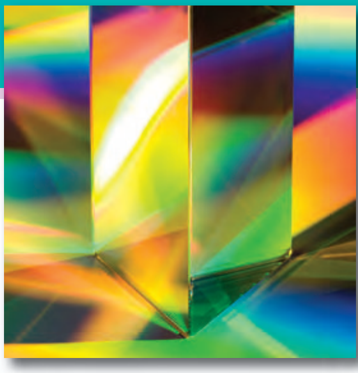
What Are the Main Points in This Chapter?

- Health and well-being are influenced by psychological, social, and spiritual development.
- Psychosocial theory provides a way to understand people as interactions of psychological and social events.
- Self-concept is one's overall view of oneself; it answers the question, "Who do you think you are?"
- Self-concept is developed throughout the life span and is influenced by multiple factors. Four dimensions contribute to self-concept: body image, role performance, personal identity, and self-esteem.
- Body image is a person's mental image of his physical self.
- Role performance consists of the actions a person takes and the behaviors she demonstrates in fulfilling a role, such as the role of a student.
- Personal identity is a person's view of himself as a unique human being, different and separate from all others.
- Self-esteem evaluations arise from the differences between the ideal and the actual self.
- Communication skills are important because psychosocial information is personal and sometimes sensitive.
- When you formulate psychosocial diagnoses it is difficult, but important, to determine what is cause and what is effect.
- Many of the NOC standardized psychosocial outcomes are found in the domains of Psychosocial Health and Family Health.
- Many of the NIC standardized psychosocial interventions are found in the Behavioral and Family domains.
- Anxiety is a common emotional response to a (usually unknown) stressor; it results from psychological conflicts, and it is accompanied by physical symptoms (e.g., trembling).
- Assessment should identify the presence, level, and cause of anxiety.
- Interventions for anxiety should help the patient become aware that he is anxious, identify the source of anxiety, and deal with the symptoms it produces.
- Depression is characterized by diminished interest or pleasure in previously enjoyed activities, sadness, emptiness, a flat or hollow feeling (absence of feeling), tearfulness, difficulty concentrating, feelings of worthlessness, and some physical symptoms (e.g., constipation).
- Assessment of depression includes a comprehensive history of mood, thoughts, behavior, and physical status.
- If you suspect severe depression, you should refer the patient to a mental health specialist; if there is a risk of suicide, referral should be immediate.
- In communicating with depressed persons, it is important not to be overly cheerful and to avoid phrases such as "Cheer up."

Knowledge Map



CHAPTER 14



The Family

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 14:
- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About the Family (suggested readings)**
- **Concept Map of chapter content**

Caring for the Nyugens

Kim Phan, 3 years old, is the first grandchild for Nam and Yen Nguyen. Until recently, Kim lived with his mother, Trinh Phan, the Nguyen's daughter. Trinh was diagnosed with schizophrenia at age 18, and initially was functioning adequately on her medications. However, her condition has been worsening and for the past year she has not been taking her medications. When Trinh became unable to care for Kim, Nam and Yen assumed the child's care. Trinh rarely visits Kim. Nam and Yen convinced Trinh to obtain residential care at a mental health facility. Nam tells you at a clinic visit that he wishes his family were "normal."

A. What do you need to clarify about Nam's statement about his family?

B. What do *you* think Nam means by a "normal" family?

C. How would you respond to Nam's comments?

D. What effect might this new family structure have on Nam's and Yen's health?

E. How might you promote family functioning for the Nguyens? What assessments should you make? What interventions should you consider?

F. What personal values or biases do you have that may affect your ability to care for the Nguyens?

PracticalKnowledge knowing how

Material in this section will help you to assess and plan care for families.

CLINICAL INSIGHTS

Clinical Insight 14-1 ➤ Conducting a Family Assessment

In general, a family assessment should include the following:

Identifying data	Include such information as name, address, phone number, cultural/ethnic background, religious identification, social affiliation.
Family composition	For each member of the family, include gender, age, relationship, date and place of birth, occupation, and education.
Family history and developmental stage	This refers to the stages and developmental tasks in the table Assessing Family Development Tasks.
Environmental data	Include a description of the home, neighborhood, larger community, family's social supports, and their transactions with the community.

(Continued)

Clinical Insight 14-1 ➤ Conducting a Family Assessment—*(continued)*

Family structure	In addition to identifying the structural type (e.g., traditional nuclear, single-parent, etc.), assess: ■ Communication patterns: Functional and dysfunctional patterns; the manner in which emotions are expressed, and contextual variables that affect communication ■ Power and role structures (e.g., How are family decisions made? What are the roles of each member? Have there been changes in these?) ■ Family values (e.g., What are their values? What are their priorities? How do they compare with the values of their cultural group? Are there value conflicts in the family?)
Family functions	Assess the effectiveness of the family's: ■ Nurturing (e.g., Are the members close? Are they separate or connected?) ■ Socialization and child rearing (e.g., Who is the socializing agent(s) for the children? What are their child-rearing practices? Are needs for play being met?)
Health beliefs, values, and behaviors	How do they define health and illness? What are their dietary, sleep, physical, and drug habits? What are their dental and medical health practices, including physicals, eye exams, immunizations, etc.? Do they have access to health services?
Family stressors and coping	What are their stressors (e.g., financial, family communication or relationships, neighbors, holidays, children's behavior)? What successful coping strategies have they used? What dysfunctional strategies?
Abuse and violence within the family	Because of the prevalence of abuse and because families are likely to be ashamed to discuss it, you should assess every family to see if any abuse or neglect is occurring. For detailed guidelines, go to Procedure 9-1, Assessing for Abuse.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Assessing Family Developmental Tasks

STAGES	TASKS	CHILDREN'S AGES (IF ANY) (APPROXIMATE)
Beginning family	■ Relinquishing the family of origin as the major emotional and economic resource ■ Gaining a sense of autonomy and independence ■ Making the relationship/marriage work; investment in spouse as the major emotional resource ■ Finding a place in the kin network of each partner ■ Exploring options for career development ■ Deciding whether to have children	None
Childbearing family	■ Achieving pregnancy and birth ■ Adjusting to life changes after birth and to the infant's needs ■ Determining ways to meet all members' needs ■ Renegotiating marriage ■ Increasing contact with extended family	Newborn to 2 years
"No longer newlyweds" (with no children)	■ Establishing a sense of the permanence of the relationship ■ Establishing long-term residency ■ Being involved in the community/promoting the well-being of the community	Not applicable
Family with preschool children	■ Adjusting to increased costs associated with family life ■ Socializing the preschoolers ■ Coping with loss of parental energy and privacy	3–5 years

Focused Assessment

Assessing Family Developmental Tasks—cont'd

STAGES	TASKS	CHILDREN'S AGES (IF ANY) (APPROXIMATE)
Mature family (with no children)	■ Renegotiating relationship on basis of more maturity ■ Adjusting to changing levels of responsibility in work and community ■ If not done already, achieving financial security	Not applicable
Family with school-age children	■ Adjusting to the needs and demands of growing children ■ Promoting joint decision making among parents and children ■ Encouraging and supporting educational and school-related activities	6–12 years
Family with teenagers and young adults	■ Maintaining open communication among family members ■ Reinforcing ethical and moral values ■ For teens, balancing independence with parental rules	13–20 years
Family launching young adults	■ Maintaining support to young adults as they leave the security of family ■ Rediscovering marriage	18–30 years
Postparental family	■ Preparing for retirement ■ Adjusting to children's moving into new phases of adulthood, marriage or other relationship, and childbearing and to becoming a grandparent	Adult
Middle-aged couple (with no children)	■ Accepting that it may be too late to reconsider childbearing or child rearing ■ Reaching the peak of a career or realizing that the peak may not occur ■ Planning for retirement	*None*
Aging family (applies to family with no children)	■ Adjusting to retirement and changes associated with aging ■ Adjusting to the loss of a spouse and friendships	Adult *(or none)*

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Sandra Jackson is the 22-year-old single mother of an 18-month-old child. She has type 1 diabetes mellitus. Sugar control has been unstable at times, primarily during times of stress and illness. Sandra lives with her mother, two younger sisters, and a brother. At times her boyfriend will stay in the home, depending on the status of their relationship. Sandra works part-time at a retail chain, struggling to meet the financial responsibilities of rearing a child. She is showing physical signs of depression and distress (e.g., apathy, anorexia, excessive sleeping, and episodes of crying). Sandra says to you during your home visit, "Something is really wrong with me. I can't snap out of this feeling of darkness. Life is too hard for me and is nothing but pain. I can't take it anymore and want it to be over." You believe she needs immediate mental health support.

THINKING

1. *Theoretical Knowledge:*
   a. What facts and principles do you already know about stress and depression?
   b. How does the emotional well-being of one family member affect others living in the home and the family as a whole?
2. *Critical Thinking (Inquiry):*
   a. What factors in Sandra's life are possibly contributing to her feelings of hopelessness and thoughts of self-harm?
   b. Name at least three nursing diagnoses that would best suit Sandra's health needs.

DOING

3. *Practical Knowledge:* Based on the knowledge you have about stress and depression, (see #1 above) how would you explain to the family about how best to support Sandra?
4. *Nursing Process (Evaluation):* What measures would you identify to determine whether your nursing plan of care was effective?

CARING

5. *Self-Knowledge:*
   a. How comfortable would you be caring for a patient who is at risk for self- injury?
   b. What is one problem with Sandra and her family, not described in the scenario, that could possibly arise?
6. *Ethical Knowledge:* What ethical concerns might you have for a woman with a young child who is at risk for self-injury, but has no financial resources to cover the expenses of mental health care?

Critical Thinking and Clinical Reasoning

1. You are caring for a 58-year-old woman who was admitted for surgery of the foot. Today is the second day you have cared for the patient. You notice that the family seems quiet and subdued. You ask the client whether something is wrong. She says that her 29-year-old niece just lost her job as a TV programming assistant because her employer found out she is HIV positive. Apparently the diagnosis was revealed on her health insurance claim forms when they were processed.
   a. Name two things in this scenario that you, as a nurse, *cannot* change.
   b. Do the client and family have a problem that you *can* help them with? How could you find out?
   c. Imagine you were your client (the aunt). What concerns would you have?
   d. Try to depict this situation by using systems theory. Draw circles for each system involved and show where they interact.
   e. Use your self-knowledge. What biases or values do you have that might affect your thinking in this case, either positively or negatively?
2. You are the nurse in the intensive care unit (ICU) who is caring for a 45-year-old man who was involved in a serious car accident. He suffered severe head trauma and, if he lives, probably will have serious deficits. He was admitted 24 hours ago and has not made significant improvements. The family is aware of his status and likely outcome.
   a. What are some concerns this family might have?
   b. Using structural-functional theory, describe how this family might be affected.
   c. How could you help this family?

3. You are the nurse in the emergency department caring for a 3-year-old child who experienced a fall. The child will be fine and is being discharged. As you are reviewing the discharge instructions, the mother reveals that she and the child spent the previous night in a hotel because of violence in the home. She tells you that her husband (the child's stepfather) drinks excessively and at times has become violent, hitting her but not the child. She did not call him when they went to the emergency room, and is afraid to go home.
   a. What do you think this woman's main concerns might be?
   b. Do you think this is a common or an unusual problem?
   c. What is the developmental stage of this family?
   d. What theoretical knowledge do you need to help this family?
   e. What kinds of help do you think this woman might need if she decides to escape from her husband?
   f. How could you help her at this moment?
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or the family. Note that these are *not* to be merely definitions.

   Family relationships
   Blended families
   Communication
   Systems theory
   Structural–functional theories
   Developmental theory
   Family interactional theory
   Family as the unit of care
   Family health risk factors
   The national economy
   Health beliefs
   Family coping mechanisms
   Unexpected illness

What Are the Main Points in This Chapter?

- *Family* is not limited to the traditional definition of husband, wife, and their children; defined more broadly, it is a group of individuals who provide physical, emotional, economic, and/or spiritual support while maintaining involvement in each other's lives.
- Families are structured in a variety of ways. Three examples are the traditional nuclear family, dual-earner families, and single-parent families.
- Family nursing views the family from three perspectives: as the context for care of an individual, as the unit of care, and as a system.
- Wellness of each member is critical to the health of the family unit.
- Under general systems theory, the family is viewed as a system in interaction with other systems (e.g., other families, groups, communities, and individuals).
- Under structural–functional theories, families are viewed as social systems with a focus on outcomes.
- Developmental theories focus on family stages: beginning family, childbearing family, family with preschool children, family with school-age children, family with teenagers and young adults, family launching young adults, postparental family, and aging family.
- Family interactional theory views the family as a unit of interacting personalities with a major emphasis on family roles.
- The family teaches health beliefs, values, and behaviors to its individual members.
- Assessment of family communication patterns consists of interviewing the family and the individual seeking care, as well as astute observation by the nurse.
- How families cope with everyday life situations and hospitalization can influence the effectiveness of care rendered.
- Nurses can promote family wellness by addressing both individual and family concerns.
- The family can be a source of support or a source of difficulties for the ill person.

Knowledge Map

FAMILY RISK FACTORS
- Adapting to new roles
- Financial needs
- Adolescent's risk-taking behaviors
- Children leaving home
- Illness
- Sandwich generation

CHALLENGES TO HEALTH

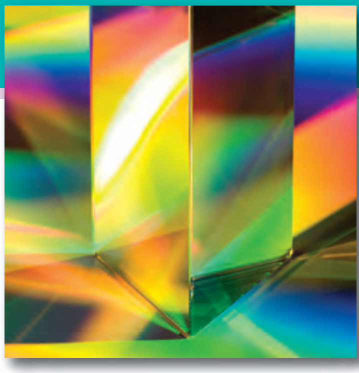
FAMILY COMMUNI-CATION PATTERNS

FAMILY HEALTH

INDICATORS OF FAMILY HEALTH
- State of family well-being
- Sense of belonging and connectedness
- Shared responsibility
- Trust and respect
- Spending time together, sharing rituals and traditions
- Flexibility
- Commitment: working together to maintain the family
- Spiritual well-being
- Respect for privacy of individual members
- Positive, effective communication
- Ability to compromise and disagree
- Appreciation and affection for each other
- Responding to the needs and interests of all members
- Egalitarian distribution of power
- Health-promoting lifestyle of individual members

HOLISTIC FAMILY NURSING

CHAPTER 15



Culture & Ethnicity

STUDENT RESOURCES

The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on DavisPlus.

To explore learning resources for this chapter,

Go to DavisPlus at DavisPl.us/Wilkinson3.

Caring for the Nguyens

Review the initial assessment of Nam Nguyen, found just before Chapter 1.

A. How might the Nguyens' cultural heritage affect their health beliefs?

B. What factors would you want to consider when performing a cultural assessment of the Nguyen family?

PracticalKnowledge knowing how

Information in this section may be useful for assessing and communicating with clients of cultures different from your own.

CLINICAL INSIGHTS

Clinical Insight 15-1 ➤ Assessing for Biological Variations

People differ genetically and physiologically. Some biological variations create susceptibility to certain diseases and injuries. The following are examples:

Body Build and Structure

- 12% of Native Americans have 25 vertebrae instead of 24, which relates to an increased number of back problems.
- The lower a person's socioeconomic status, the more likely he is to be obese.
- Black and white men are on average about 3.5 inches taller than Asian American men and 2 inches taller than Mexican American men.

Skin Color

- Darker skin challenges the nurse to be more observant when assessing skin color changes (e.g., when assessing oxygenation or skin rashes). Obtain a baseline skin color by asking a family member or someone who knows the patient well.
- To assess for oxygenation and cyanosis in dark-skinned people, examine the sclera, buccal mucosa, tongue, lips, nailbeds, palms of the hands, and soles of the feet.
- To assess for jaundice in Asians, examine the sclera.

Vital Signs

- The average systolic blood pressure of black men between the ages of 35 and 65 is 5 mm Hg higher than that of European American men of the same age.

Laboratory Tests

- Native Americans, Hispanic Americans, and Japanese Americans, on average, have higher blood glucose levels than do whites.
- Bone density is greater in whites than in Chinese, Japanese, and Eskimos.

Susceptibility to Disease

- Blacks have a higher incidence of hypertension and sickle cell anemia than do other groups.
- Asian Americans have a higher incidence of tuberculosis compared with the white population.
- Blacks, Native Americans, and Mexican Americans are more likely to have diabetes mellitus than their white counterparts.

Nutritional Variations

- All groups demonstrate food preferences.
- Soy sauce, used in many Asian foods, is high in sodium.
- There is a high incidence of diabetes mellitus in areas where sugar cane is a major crop.

Enzymatic and Genetic Variations and Body Secretions

- Lactose intolerance, caused by a deficiency of the enzyme lactase, is more commonly seen in blacks, Native Americans, and Asians.

Drug Metabolism

- Native Americans and Asians are more likely to experience facial flushing and palpitations after ingesting alcohol.
- Blacks metabolize alcohol, nicotine, antihypertensives, and beta blockers differently from European Americans; they are more susceptible to side effects of haloperidol and tricyclic antidepressants; and they respond better to diuretic therapy than do whites.
- Asian Americans tend to experience more gastrointestinal side effects from opiates, even though the analgesic effect is less.
- Chinese Americans are more sensitive to the cardiovascular effects of propranolol; they have increased absorption of antipsychotics, antihypertensives, and some narcotics.
- Recall that most drug studies in the past were normed on European Americans, so "variations" refer to differences from those norms.

Practice Resources

Andrews, M. M., & Boyle, J. S. (2011); Purnell, L. D., & Paulanka, B. J. (2008); Spector, R. E. (2013); Suzuki, L. A., & Ponterotto, J. G. (2007).

Clinical Insight 15-2 ➤ Pain Perception in Selected Cultural Groups

The following are some general cultural beliefs about and responses to pain. Remember that these are only a starting point (archetypes) and that you must never stereotype a person on the basis of culture. Assess each person individually.

Cultural Group	Pain Perception and Responses
Black heritage	Depending on the religion, may believe that pain is inevitable and must be endured; therefore, may tolerate a great deal of pain. Depending on the religion, may seek prayers and the laying on of hands for pain relief. May see pain as a test of faith. May see pain as the only sign of illness or disease, so may not follow medical therapies (e.g., for hypertension) if pain is absent.
European American heritage, New England subculture	(These are chronic pain responses.) Copes by working and keeping busy. Stoicism; lack of expressiveness and behavioral pain response, including little wincing and groaning. Pain is viewed as a biological abnormality that can be treated and lived with; may be angry with care providers if treatment is ineffective. *Polish American subgroup*: Strong tendency for nonexpressiveness.
Arab heritage	View pain as unpleasant and something to be controlled. Expect medical science to be able to relieve their suffering. Express pain openly with family members, less so with health professionals. This may cause the nurse to evaluate pain relief as adequate even though the family may be demanding more medication for the patient.
Chinese heritage	Pain expression is similar to traditional U.S. culture, but description of pain may be different (i.e., described more often as "dull" and "diffuse"). Use external pain relief methods, such as massage, oils, warmth, and relaxation.
Filipino heritage	View pain as a part of living an honorable life or as an opportunity to atone for sins. Commonly tolerate severe pain, with stoic acceptance. May not complain of pain or ask for interventions.
Irish heritage	Value stoic response to pain. Ignore, deny, or minimize pain. Delay seeking treatment.
Italian heritage	Verbalization of pain is common and acceptable, even with chronic pain. Women are especially likely to report and express pain. Expect immediate treatment for pain.
Japanese heritage	It is a virtue, and a matter of family honor, to bear pain without expressing it. There may be taboos against use of narcotics for pain relief. May be more accepting of analgesics if reassured that pain control enhances healing.
Jewish heritage	Verbalization of pain is common and acceptable. Knowing the reason for pain is as important as obtaining relief.
Mexican heritage	View pain as the will of God or a part of life. May view pain as punishment for immoral behavior. May view enduring pain as a sign of strength. May endure pain longer and report it less frequently than other groups, or may express vocally with groaning and crying out. May delay seeking help for pain, hoping it will go away. May interpret pain as a loss of manhood or provider role.

(Continued)

Clinical Insight 15-2 ➤ Pain Perception in Selected Cultural Groups—cont'd

Navajo Indian heritage	View pain as a part of life. Do not express pain openly. May hide the intensity of their pain. May not request pain medication. May prefer herbal medications for pain.
Puerto Rican heritage	Loud and outspoken expression of pain is not an exaggeration, but a socially learned coping mechanism. May experience low self-esteem because of pain. Older or rural people may not be able to interpret pain-rating scales. Most prefer oral or intravenous analgesics to intramuscular or rectal routes. Many use herbal teas, heat, and prayer to manage pain.

Practice Resources

Andrews, M. M., & Boyle, J. S. (2011); Bates (1996); Giger, J. N., & Davidhizar, R. (2008); Purnell, L. (2012); Spector, R. E. (2013); Todd, K. (1996); Zborowski, M. (1952).

Clinical Insight 15-3 ➤ Communicating With Clients Who Speak a Different Language

When possible, use a qualified interpreter or a translator.

An **interpreter** is specially trained to provide the meaning behind spoken words from one language to another, whereas a **translator** merely restates into the targeted language. An interpreter can serve as a cultural broker by conveying the client's responses to questions, and by providing general information about the client's culture (Munoz & Luckmann, 2005).

When using any type of interpreter, it is important to do the following:

- Because of confidentiality issues, avoid asking a family member, especially a child or spouse, to act as an interpreter.
- Avoid using an interpreter who is socially or politically incompatible with the client (e.g., you would not ask an Israeli to interpret for a Palestinian).
- Be aware of gender and age differences. (It usually is preferable to have an interpreter of the same gender as the client.)
- Have the interpreter spend some time alone with the patient.
- Ask the interpreter to interpret the words used by the healthcare provider as closely as possible, except where literal translation might be offensive or misunderstood. In such cases, an interpreter (as compared with a translator) would provide the meaning of your words in terms acceptable to the client.
- Do not use metaphors ("happy as a clam") or medical jargon.
- Observe nonverbal communication (e.g., body language) when the client is listening and talking to the interpreter.
- Address your questions to the client, not the interpreter.
- Maintain eye contact with both the client and interpreter.
- Speak slowly and distinctly, facing the client; do not speak loudly.
- Ask one question at a time; allow time for interpretation and response from the client before asking another question.
- Use active rather than passive voice (e.g., say, "The doctor will see you tomorrow." rather than "You will be seen by the doctor tomorrow.")
- Be aware that many clients can understand more English words than they can express.
- Have health education materials translated into the client's language, or have an interpreter audiotape or videotape instructions.

If there is no one available to interpret for you:

In addition to the strategies listed above, Munoz and Luckmann (2005) suggest the following:

- Greet the client with respect. Greet the person formally, using Mr., Ms., and so forth, until given permission to do otherwise. People in some groups consider it disrespectful to use a person's first name.
- Identify the client's primary language, and use any words that you are familiar with in her language to show that you are trying to communicate.
- Use the Internet or computer software to translate words into the client's native language.
- If appropriate, use a third language that both of you speak. For example, some Vietnamese and some Cambodians speak French.
- Speak slowly and clearly, using simple sentences to talk about one question or need at a time.
- Use gestures to help convey meaning.
- Restate in different words, if needed.
- Use pictures or diagrams.
- Be aware that some clients may answer yes even if they don't understand what you have said.

Practice Resources

Munoz, C., & Luckmann, J. (2005); Purnell, L. D. (2012).

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Obtaining Minimum Cultural Information

You should obtain at least this much cultural information from every client. For some, you may need a more in-depth assessment.

- Begin the interview with open-ended questions, such as the following:

  I would like to know more about your family.

  Who will be able to help you when you go home?

  What do you do to help keep yourself well?

- When you and the client are comfortable, be sure to ask a question such as, "What concerns you the most about your illness and treatment?" This allows you to focus on the individual rather than just on his culture.
- You will not need to perform an in-depth cultural assessment on every patient, but you will need to recognize situations in which this is needed. Lipson and Meleis (1985) suggest that the following minimum information is important:

Language(s) spoken; proficiency in the language of the host country	➤ What language(s) do you speak? ➤ Are you comfortable speaking [English], or would you like to have an interpreter?
Length of time client has been here; where client was raised	➤ Where were you raised? ➤ How long have you lived here?
Ethnic affiliation and identity	➤ With what racial and ethnic group(s) do you identify? ➤ How closely do you identify with the values of those groups?
Usual religious practices	➤ What religion do you practice, if any? ➤ Are there any special beliefs, rituals or practices you want us to be aware of?
Nonverbal communication style	➤ You will need to observe the patient and draw on your theoretical knowledge of the patient's cultural group for this information.
Family roles, primary decision maker	➤ Who is in your family? ➤ What is your role in your family? ➤ Who makes most of the decisions? ➤ How are decisions made in your family? ➤ Who should I talk to for decisions about your healthcare?
Social support in the new country	➤ Do you have family and friends here? ➤ Who can you go to when you need help? ➤ Where do you work? ➤ Will you need any help with your healthcare expenses?

Practice Resources

Giger, J. N., & Davidhizar, R. (2008); Giger, J. (2012); Lipson, J., & Meleis, A. (1985); Spector, R. E. (2013); Suzuki, L. A., & Ponterotto, J. G. (2007).

Focused Assessment

Cultural Assessment Using the Transcultural Assessment Model

Assess information listed in the following categories.

Cultural Uniqueness

- Cultural and ethnic identification
- Place of birth
- Time in country

Communication

- Voice quality
- Pronunciation and enunciation
- Use of silence
- Use of nonverbal communication
- Touch
- Spoken language

Space

- Degree of comfort
- Distance in conversations
- Definition of space
- Body movement

Social Organization

- Normal state of health
- Marital status
- Number of children
- Parents living or deceased
- Friends
- Work
- Leisure

Time

- Orientation to time
- View of time
- Physiochemical reaction to time

Environmental Control

- Locus of control
- Value orientation
- Health and illness beliefs

Biological Variations

- Physical assessment (including body structure, skin color, skin discoloration, hair color and distribution, other visible physical characteristics, weight, height, lab variances)
- Susceptibility to illness
- Nutritional preferences
- Psychological characteristics

Other

In addition to the Giger and Davidhizar categories, obtain information about the following:

- Educational experiences (formal and informal)
- Family patterns of healthcare
- Family role and function
- Healthcare beliefs and practices (folk and professional)
- Religious practices and beliefs
- Social networks
- Values orientation

Source: Adapted from Giger, J. N., & Davidhizar, R. E. (2008). *Transcultural nursing: Assessment and intervention* (5th ed.). St. Louis, MO: C.V. Mosby.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mrs. Vasquez, a 70-year-old Mexican American woman, has diabetes mellitus and has come to the hospital because of a sore on her lower leg that will not heal. Mrs. Vasquez, a widow, cares for herself at home. She speaks only broken English and has some difficulty understanding your questions. After great effort on your part, you determine that she has missed her last appointment with her diabetes specialist because she has no transportation, so she has just been putting a dressing on the sore. Mrs. Vasquez tells you that she loves to see her grandchildren, who visit often, and that she enjoys cooking and eating Mexican food. She also says that she believes she is sick because she has not pleased God. However, God is a source of comfort and assurance to her. She prays a lot and has rosary beads in her hand.

THINKING

1. *Theoretical Knowledge (Recall of Facts and Principles):* List six important culture specifics.
2. *Critical Thinking (Application of Knowledge):* Based on your theoretical knowledge, what are your expectations about communicating with Mrs. Vasquez?
3. *Critical Thinking (Compare and Contrast):* Compare your expectations to the actual data you have about her ability to communicate.

DOING

4. *Nursing Process (Assessment):* What are some pertinent cultural data that you should assess for Mrs. Vasquez?
5. *Nursing Process (Analysis/Diagnosis):* Which nursing diagnosis do you think would be best for planning Mrs. Vasquez's care? (Recall that the etiology should suggest your nursing interventions, and the diagnostic label should suggest the expected patient outcomes.) Explain your reasoning.
   - Noncompliance (with clinic appointments) r/t lack of transportation
   - Impaired Skin Integrity r/t self-treatment of ulcer
   - Noncompliance (with clinic appointments) r/t beliefs about God and illness

CARING

6. *Self-Knowledge:* What areas of commonality do you have with Mrs. Vasquez, around which you might form a caring relationship?
7. *Self-Knowledge:* Do you agree with Mrs. Vasquez that illness may be caused by displeasing God?
8. *Ethical Knowledge:* Suppose you do not agree with Mrs. Vasquez that she is ill because she has displeased God. Discuss whether you would explain to her that this is most likely not true and then teach her about the cause of diabetic ulcers.

Critical Thinking and Clinical Reasoning

1. Mrs. Vasquez, a 70-year-old Mexican American woman, has diabetes mellitus and has come to the hospital because of a sore on her lower leg that will not heal. Review the details of Mrs. Vasquez's case in the Full Spectrum Nursing Model Situation, preceding.
   a. Identify Mrs. Vasquez's cultural data and group it under the following culture specifics:

      Communication

      Space

      Time orientation

      Social organization

      Environmental control

      Biological variations

b. What does your theoretical knowledge lead you to expect about Mrs. Vasquez's personal space? What, if any, actual patient data do you have about that?
c. What does your theoretical knowledge lead you to expect about her time orientation, social organization, and environmental control? Compare your expectations with the actual patient data that you have.
d. What theoretical knowledge do you have regarding biological variations among Hispanic people? How does this compare to the actual data, if any, that you have for Mrs. Vasquez?
e. You have learned that cultural data can have implications for nursing care. Answer each of the following:
   - What additional information should you assess for in this situation?
   - What biases do you have that affect your thinking in this situation?

2. An Asian woman comes to your clinic for assessment of her blood pressure. In casual conversation, she tells you that her oldest daughter is about to be married. She reveals that her daughter has some type of anemia for which she needs medication. She tells you that she has recently heard terrible stories about sickle-cell anemia and is afraid that this is what her daughter has.
   a. What additional data do you need to collect in order to answer this client's questions?
   b. What are the biological variations that normally affect this cultural group?
   c. What assurances, if any, can you give this client about her daughter?
3. At times we must care for clients who do not speak our language. This poses a challenge to the nurse who strives to provide culturally competent care to all clients. Even with the assistance of interpreters, this can be difficult because of such barriers as differing dialects, street talk, and jargon. Keeping these facts in mind, answer the following questions:
   a. What options do you have when you encounter a person who cannot speak English?
   b. How do you communicate with such a client if no interpreter is available?
   c. What biases do you have about such a situation? Why?
4. Alma is of European descent; she is Caucasian. She is a Roman Catholic and believes abortion is wrong. She believes that it should be illegal to own a gun. She is a nursing student.

   Violetta's parents came to the United States from Europe. They were born in France. Before that, her great-grandparents lived in Africa. Violetta is an African American. She is Roman Catholic, and she believes that abortion is wrong. She believes that it should be illegal to own a gun. She is a nursing student.

   Darcy is of European descent. She is Caucasian. She laughs at the idea of religion, saying, "Nobody's 'up there' looking out for me; and when you're dead, you're dead." Darcy is a gang member and carries a gun in her purse or her pocket at all times. She did not finish high school, and by the age of 19 she had had two abortions.

   All of the women live in the United States. Which two women do you think share the most cultural commonalities? Explain your thinking.
5. Helen is a 52-year-old divorced African American. Her only child, Tamika, is incarcerated for prostitution and possession of narcotics. Helen is now raising her two grandchildren, Calvin, age 13 years, and Jevetta, age 2. Helen is a nursing assistant at the local hospital. It's hard for her to make ends meet because she has hypertension and diabetes, for which she takes a number of medications, including insulin—that is, when she can afford them. Helen has not applied for medical assistance because she believes she should be able to take care of herself, but she does receive assistance for Jevetta's day-care costs. In addition to her grandchildren, Helen has a large group of friends, many of whom attend her church. She has little time to spend with her friends since she took custody of the children. Jevetta has been admitted to the hospital for asthma. You are Jevetta's student nurse.
   a. Using your data collection skills, identify NANDA-I diagnostic labels that you could apply to Jevetta and to Helen as Jevetta's caregiver.
   b. What resources may be helpful to Helen?
6. Examine the following nursing diagnosis labels. For this set of labels, write an etiology that might be caused by cultural differences. The first one is completed for you as an example.

   - Imbalanced Nutrition: Less than (or More Than) Body Requirements *r/t patient's lack of knowledge about how to adapt his preferred ethnic foods to her prescribed low-fat diet.*
   - Ineffective Health Maintenance
   - Ineffective Role Performance
   - Anxiety
   - Powerlessness
   - Deficient Knowledge

7. For the following set of labels, explain or give an example of how the nurse might misdiagnose or misperceive the data because of cultural differences. The first one is done for you.

- Decisional Conflict

The nurse might ask a woman to make some decision about her care. The woman may seem very indecisive and unable to reach a conclusion. The reason may be that the husband is the decision maker in the family. When the husband arrives, the Decisional Conflict ("problem") may disappear.

- Confusion
- Readiness for Enhanced Breastfeeding or Ineffective Breastfeeding
- Impaired Social Interaction
- Social Isolation
- Noncompliance
- Pain (Acute or Chronic)

8. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or cultural competence. Note that these are *not* to be merely definitions.

Culture
Subculture
Ethnicity
Race
Religion
Acculturation
Health and illness belief
Health and illness practice
Phenomena of culture
Ethnocentric
Folk medicine
Cultural competence
Transcultural nursing
Giger and Davidhizar assessment model
Biological variations among cultures
Prejudice and racism
Professional (e.g., nursing) subculture
Cultural sensitivity
Cultural awareness
Culture universals
Culture specifics

What Are the Main Points in This Chapter?

- The cultural and ethnic composition of North America has changed dramatically over the past several decades, making it essential that nurses understand the healthcare beliefs and practices of diverse populations.
- Culture includes shared values, beliefs, norms, and practices that guide a particular group's thinking, decision making, and actions in a patterned way.
- Through acculturation, most ethnic and cultural groups modify some of their traditional cultural characteristics, values, beliefs, and practices.
- You should be familiar with the common characteristics of different cultural groups in your community.
- The U.S. Census Bureau has identified the following racial categories on the 2010 Census questionnaire:

  White
  Black, African American, or Negro
  American Indian or Alaska Native
  Asian Indian
  Chinese
  Filipino
  Japanese
  Korean
  Vietnamese
  Other Asian
  Native Hawaiian
  Guamanian or Chamorro
  Samoan
  Other Pacific Islander (specify, e.g., Tongan)

- The Census Bureau (2010) categories for ethnicity (or "origin") are (1) Hispanic, Latino, or Spanish and (2) Not Hispanic, Latino, or Spanish. Subcategories under Hispanic origin are Mexican, Mexican American, Chicano; Puerto Rican; Cuban; and Another Hispanic, Latino, or Spanish origin.
- **Culture universals** (commonalities) are the values, beliefs, and practices that people from *all* cultures share. **Culture specifics** (diversities) are those values, beliefs, and practices that are unique to a culture.
- A **cultural archetype**, similar to a model, is an example of something that is recurrent and has its basis in facts. A **cultural stereotype** is a widely held but oversimplified and unsubstantiated belief that all people of a certain racial or ethnic group are alike in certain respects.
- Six organizing phenomena of culture that influence health include communication patterns, space, social organization, time, environmental control, and biological variations.

- Healthcare providers cannot understand the health beliefs and practices of diverse populations if they view them through the lens of the conventional (Western, U.S.) culture of healthcare.
- A variety of "alternative" healing systems exists. Remedies have been passed down from generation to generation and include the use of herbs, customs, and rituals.
- An understanding of cultural concepts, theories, and models can help you develop cultural competence.
- Ethnocentrism, stereotyping, prejudice, and racism are barriers to culturally competent care.
- When assessing a client and making nursing diagnoses, you must consider the client's cultural values, beliefs, and practices related to health and healthcare.
- Culturally competent care requires a nonjudgmental attitude, self-awareness, sensitivity, respect for differences, theoretical knowledge, and the desire to be culturally competent.

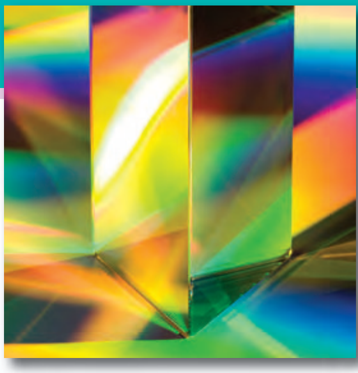
CHAPTER 16



Spirituality

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 16:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Spirituality (suggested readings)**
- **Concept Map of chapter content**

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 16, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Kim Phan is the 3-year-old grandson of Nam and Yen Nguyen. The Nguyens are both practicing Catholics. Kim's mother, Trinh, is the Nguyens' daughter. Trinh feels that Catholicism is "a waste of time" and does not attend church. Kim has had no formal religious experiences or training.

A. At a clinic visit, Nam asks you what you think about keeping religion away from a child. How would you respond?

B. Mr. Nguyen explains his views on the situation: "If anything were to happen to him, he would go to hell. I think we should take him to church and get him baptized right away. I don't know how anyone can live like that. He has no connection to God." Do you agree with this statement? Explain your views.

C. Nam asks you to pray for Kim and his mother. How would you feel about this situation? What would you say to Nam?

PracticalKnowledge knowing **how**

In this section, you will find guidelines for performing spiritual interventions and for performing focused spiritual assessments.

CLINICAL INSIGHTS

Clinical Insight 16-1 ➤ Praying With Patients

Because there is a rich diversity in religious expression, keep the following guidelines in mind when you pray for or with patients:

Ask how the patient prefers to address the divine. Some people prefer the use of parental language in their prayers, for example, *Father God* or *Divine Mother.* Some use the word *Jehovah, Yahweh,* or *Allah.* Hindus may address one or more of multiple Gods, each of whom has several names. So don't be afraid to seek direction from the patient in these matters: Most people are honored to be able to explain their beliefs and practices to someone who is open to the experience.

Before the prayer begins, ask the patient whether any rituals or religious items are necessary. Muslims may want water to wash the mouth, nostrils, and hands before beginning prayer. Roman Catholics may want to hold their rosary beads while praying, and some Buddhists and Hindus meditate with a set of beads called a mala. Others may have a prayer cloth or other item that needs to be accessible.

(Continued)

Clinical Insight 16-1 ➤ Praying With Patients *(continued)*

Always feel free to pray or not to pray. Never feel that you are being forced to do or say something that makes you uncomfortable.

Do not be a compulsive "prayer" or a compulsive avoider of prayer. Always make sure that the patient (and/or family) is comfortable with prayer if he has not yet requested it.

Know that there are appropriate times and places for the offering of prayer. Prayer at the bedside may be most appropriate, although it may make people uncomfortable in a crowded waiting room. Perhaps the statement "I will be praying for you and your family" might be more appropriate for some patients than actually praying aloud at that moment.

When a patient asks for prayer, consider using this reply: "I would be honored to offer prayer. What would you like me to *especially* address in the prayer?" Knowing what the patient hopes for in prayer gives you an idea of the type of prayer the person is requesting.

When the patient tells you what he wants you to pray for, be sure to focus your prayer around the request.

- It is always good to summarize the results of previous conversations with the patient and his needs in the course of your prayer. For example, imagine that a patient with cancer who has been treated with chemotherapy now finds his blood counts are coming back to normal levels. The chemotherapy treatment seems successful at this point, but the patient is afraid of a relapse and asks you to pray for the cancer to be cured.
- Analyze the situation in terms of what has happened in the past, what is happening now, and what the patient is requesting. This will help you organize your thoughts and then put them into the form of a prayer.

Perhaps you would want to take the patient's hand in yours (if appropriate, based on your intuition and the nature of your nurse–patient relationship) and compose a prayer in the following manner:

Dear [Lord], I give you thanks that [John] has done so well with his treatments. Please continue to help him be strong and open to your healing presence. We pray for his family, doctors, and nurses that all may be a part of [John's] continued healing and sense of comfort. I pray that the treatments that he is receiving, together with the prayers that we are offering, may all be effective in his care and in the treatment of his cancer. Watch over [John], and visit us all at this time with your healing presence. [Amen.]

When a terminally ill patient requests a prayer for a cure, total healing, or a miracle, you may be challenged. Knowing how to offer prayers that are "realistic" allows for the occurrence of miracles and healings of all types while also keeping in perspective the physical realities of the nature of disease and the reality of death.

If composing a prayer is difficult for you, you may want to explore the use of the Psalms in the Hebrew Bible (Old Testament) or some New Testament scriptures, if appropriate for the patient. (See especially Psalms 43, 51, 67, 121). In terms of larger themes, the following sources for patients who profess Christianity may be helpful:

Forgiveness and guilt: Psalm 51, Isaiah 55:7, and Matthew 6:9–15
Comfort: Psalm 23, John 14
Hope: Psalm 42, Romans 15:4
Love and acceptance: Matthew 5:11
Caring: 1 Corinthians 12

For exact quotations of these passages,

Go to Chapter 16, **Psalms for Prayers,** on Davis*Plus.*

For patients of religions other than your own, ask whether they have examples of their sacred writings from which you might be allowed to read. Perhaps the patient has a favorite prayer or a text from an authoritative source that brings comfort and hope.

It is always good to include in the course of your prayer a request for God's help and direction with the patient's healthcare team. This expresses the reality that we are all working together for a common good and purpose and that we depend on God and others for our welfare and place in life.

Once the prayer is over, thank the patient for asking you to participate. In that way you can ask whether you can be of any further assistance.

Focused Assessment

S-P-I-R-I-T Assessment

- Obtain information from the patient when possible.
- For an emergency admission or if the patient cannot give information, consult the next of kin or a designated power of attorney (DPOA) as soon as possible for information.

S—Spiritual/religious belief system

Religion, tradition, sect, or denominational affiliation

Text/writing(s) that provide source of authority and codes for behavior

Name and phone number of supporting or affiliated church, synagogue, temple, or other place of worship

Past experience with a belief system (positive or negative)

Beliefs related to health, illness, healthcare, healthcare providers, Western medicine, adjuvant therapies, herbal or natural healing methods or techniques

Beliefs about suffering, terminal or chronic illness, advance directives, autopsy, organ donation

Stigmas related to illness, if applicable

P—Personal spirituality

Individual beliefs and practices of affiliation that the patient or family accepts and attempts to follow (may be directly or indirectly related to above assessment areas)

Individual beliefs that may differ or even be contrary to affiliation beliefs

Whether spirituality is a part of personal experience of religion or a separate entity

Level of comfort discussing spirituality

Whether personal spirituality is viewed positively or negatively at the present time

I—Integration within a spiritual community

Name and title of religious or spiritual leader or authority figure(s)

Names and titles of religious groups that may need to be contacted: Stephen Ministry, prayer group leader, prayer chain support person, shaman, medicine man or woman, men's or women's group within denomination

Role of patient or individual in any of above named groups

R—Ritualized practices and restrictions

Activities that patient's or family's faith encourages or forbids

Needs for modesty and covering of body parts or appendages

Any special beliefs or needs in relation to drawing blood or to laboratory tests or procedures

Dietary needs and restrictions: food preferences, preparation of foods, and location of food preparation areas

Gender-specific roles and responsibilities of care providers

Prayer needs and restrictions: Who delivers and offers such practices?

Articles or other materials needed for worship, devotion, or prayer (rosaries, prayer beads, prayer books, religious tracts, Bibles, crosses, prayer shawls or cloths)

I—Implications for medical care

Beliefs and practices that healthcare providers should remember while providing care

Specific medications that may not be administered and withheld; implications for pain control

Specific medical procedures or products that may not be administered (abortion, blood products)

Communication patterns and needs for effective care delivery: Who makes decisions? What is the role of parents or guardians when children or other vulnerable populations are the recipients of care? Does the guardian reflect the beliefs of patient, if these are known?

T—Terminal events planning

Wishes for advance directives (cardiopulmonary resuscitation, intubation, ventilator assist, feeding tubes)

Wishes for transplantation or organ donation

Need for religious services (last rites, ministries of healing, baptism, initiation, confession, communion)

Clergy or ministry groups to be contacted and when

Ideas of an afterlife

Treatment of the body at the time of death

Funeral planning

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

The HOPE Approach to Spiritual Assessment: Examples of Questions

Mnemonic	Examples of Questions
H—Sources of **hope**, meaning, comfort, strength, peace, love and connection	What are your sources of internal support? What do you hold onto to get you through difficult times? For some people, religious or spiritual beliefs are a source of comfort in dealing with life's ups and downs. Is this true for you?
O—Organized religion	Do you belong to a religious or spiritual community? Does it help you? How important is this to you? What aspects of your religion are helpful to you?
P—Personal spirituality/ Practices	Do you believe in God? What is your relationship with God? Do you have personal spiritual beliefs that are not a part of organized religion? If so, what are they? What aspects of your spirituality are most helpful to you (e.g., meditation, prayer, reading scripture, listening to music, nature)?
E—Effects on medical care and end-of-life issues	Has your illness affected your relationship with God? Or to do the things that usually help you spiritually? Are you concerned about conflicts between your beliefs and your healthcare treatment plan? Do you have any dietary restrictions or other practices I should know about in planning your care? Would you like to speak to a clinical chaplain (or community spiritual leader)?

Source: Based on Gowri, A., & Hight, E. (2001). Spirituality and medical practice: Using the HOPE questions as a practical tool for spiritual assessment. *American Family Physician, 63*, 36–41.

STANDARDIZED NURSING LANGUAGE

Using Selected NIC Interventions and Activities to Support Spirituality

Nursing Diagnoses

Moral Distress	Impaired Religiosity
Spiritual Distress	Risk for Impaired Religiosity
Risk for Spiritual Distress	Readiness for Enhanced Religiosity
Readiness for Enhanced Spiritual Well-Being	

NURSING INTERVENTIONS	NURSING ACTIVITIES
Dying Care	Facilitate obtaining spiritual support for patient and family. Support the patient and family through stages of grief (see Chapter 17). Facilitate discussion of funeral arrangements.
Emotional Support	Explore with the patient what has triggered emotions. Embrace or touch the patient supportively. Make supportive or empathetic statements. Encourage the patient to express feelings of anger, anxiety or sadness.
Forgiveness Facilitation	Listen empathetically without moralizing or offering platitudes. Explore forgiveness as a process.

Using Selected NIC Interventions and Activities to Support Spirituality—cont'd

NURSING INTERVENTIONS	NURSING ACTIVITIES
	Assist client to seek out an arbitrator (objective party) to facilitate the process of individual or group concern. Explore possibilities of making amends and reconciliation with self, others, and/or higher power.
Hope Inspiration	Assist the patient/family to identify areas of hope in life. Help the patient expand his spiritual self. Facilitate the patient/family's reliving and savoring past achievements and experiences. Create an environment that facilitates patient's practicing religion, as appropriate.
Presence	Be physically available as a helper. Remain physically present without expecting interactional responses. Offer to remain with the patient during the initial interaction with others in the unit. Listen to the patient's concerns. Stay with the patient to promote safety and reduce fear.
Religious Ritual Enhancement	Coordinate or provide healing services, communion, meditation, or prayer in the place of residence or other setting. Encourage the use of and participation in usual religious rituals or practices that are not detrimental to health. Assist with modifications of the ritual to meet the needs of the disabled or ill. Treat the individual with dignity and respect.
Self-Awareness Enhancement	Assist the patient to realize that everyone is unique. Assist the patient to identify life priorities. Assist the patient to identify guilty feelings. Assist the patient to identify his source of motivation.
Self-Esteem Enhancement	Encourage the patient to identify strengths. Provide experiences that increase the patient's autonomy, as appropriate. Explore previous achievements of success. Assist the patient to identify the significance of culture, religion, race, gender, and age on self-esteem. Monitor the frequency of self-negating verbalizations. Reinforce the personal strengths that the patient identifies.
Spiritual Growth Facilitation	Encourage conversation that assists the patient in sorting out spiritual concerns. Assist the patient with identifying barriers and attitudes that hinder growth or self-discovery. Offer individual and group prayer support, as appropriate. Encourage participation in devotional services, retreats, and special prayer/study programs. Assist the patient to explore beliefs as related to healing of body, mind, and spirit. Refer for pastoral care or primary spiritual caregiver as issues warrant.
Spiritual Support	Be open to the patient's expressions of loneliness and powerlessness. Encourage chapel service attendance, if desired. Provide desired spiritual articles, according to individual preferences. Be available to listen to the individual's feelings. Listen carefully to the individual's communication, and develop a sense of timing for prayer or spiritual rituals. Be open to the individual's feelings about illness and death.

continued

Using Selected NIC Interventions and Activities to Support Spirituality—cont'd

NURSING INTERVENTIONS	NURSING ACTIVITIES
Values Clarification	Consider the ethical and legal aspects of free choice, given the particular situation, before beginning the intervention. Pose reflective, clarifying questions that give the patient something to think about. Encourage the patient to make a list of what is important and not important in life and the time spent on each. Encourage the patient to list values that guide behavior in various settings and types of situations. Avoid use of the [preceding] intervention with persons with serious emotional problems.

Other NIC Spiritual Care Interventions

Active Listening	Crisis Intervention	Meditation Facilitation	Resiliency Promotion
Anticipatory Guidance	Decision-Making Support	Mood Management	Self-Esteem Enhancement
Anxiety Reduction	Emotional Support	Music Therapy	Self-Modification Assistance
Bibliotherapy	Grief Work Facilitation	Referral	Self-Responsibility Facilitation
Coping Enhancement	Guilt Work Facilitation	Role Enhancement	Support Group
Counseling	Humor	Religious Ritual Enhancement	Touch

Sources: Bulechek, G. M., Butcher, H. K., & Dochterman, J. M., et al. (Eds.). (2012). *Nursing interventions classification (NIC)* (6th ed.). St. Louis, MO: C.V. Mosby; and Gaskamp, C., Sutter, R., Meraviglia, M., et al. (2006). Evidence-based guideline: Promoting spirituality in the older adult. *Journal of Gerontological Nursing, 32*(11), 8–13.

CLINICALREASONING: Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Review the Meet Your Patient scenario to answer the questions below about Charles Johnson, a 75-year-old black man with newly diagnosed cancer of the lung. His physicians want to start chemotherapy to try to increase his life span. He is unsure whether he wants to have chemotherapy.

Go to Chapter 16, **Meet Your Patient,** in Volume 1.

THINKING

1. *Theoretical Knowledge (Recall of Facts and Principles):* Define *forgiveness,* and explain the benefits of forgiving self and others.
2. *Critical Thinking (Application of Knowledge*): Based on your theoretical knowledge about forgiveness, with whom might Mr. Johnson need to reconcile? Why do you think so?

DOING

3. *Practical Knowledge (HOPE Assessment):* Use the Focused Assessment box, The HOPE Approach to Spiritual Assessment: Examples of Questions, and enter Mr. Johnson's data. Identify sections for which you need additional data.

CARING

4. *Self-Knowledge:* How is your religious background similar to or different from Mr. Johnson's?
5. *Self-Knowledge:* (a) How would you feel if Mr. Johnson said to you, "Church folk are all a bunch of hypocrites, if you ask me. I choose not to be a part of any of that"? (b) How would you respond?
6. *Ethical Knowledge:* Imagine that Mr. Johnson's sister comes to visit and leaves some religious pamphlets on a chair, where he will not see them before she leaves. What would you do?

Critical Thinking and Clinical Reasoning

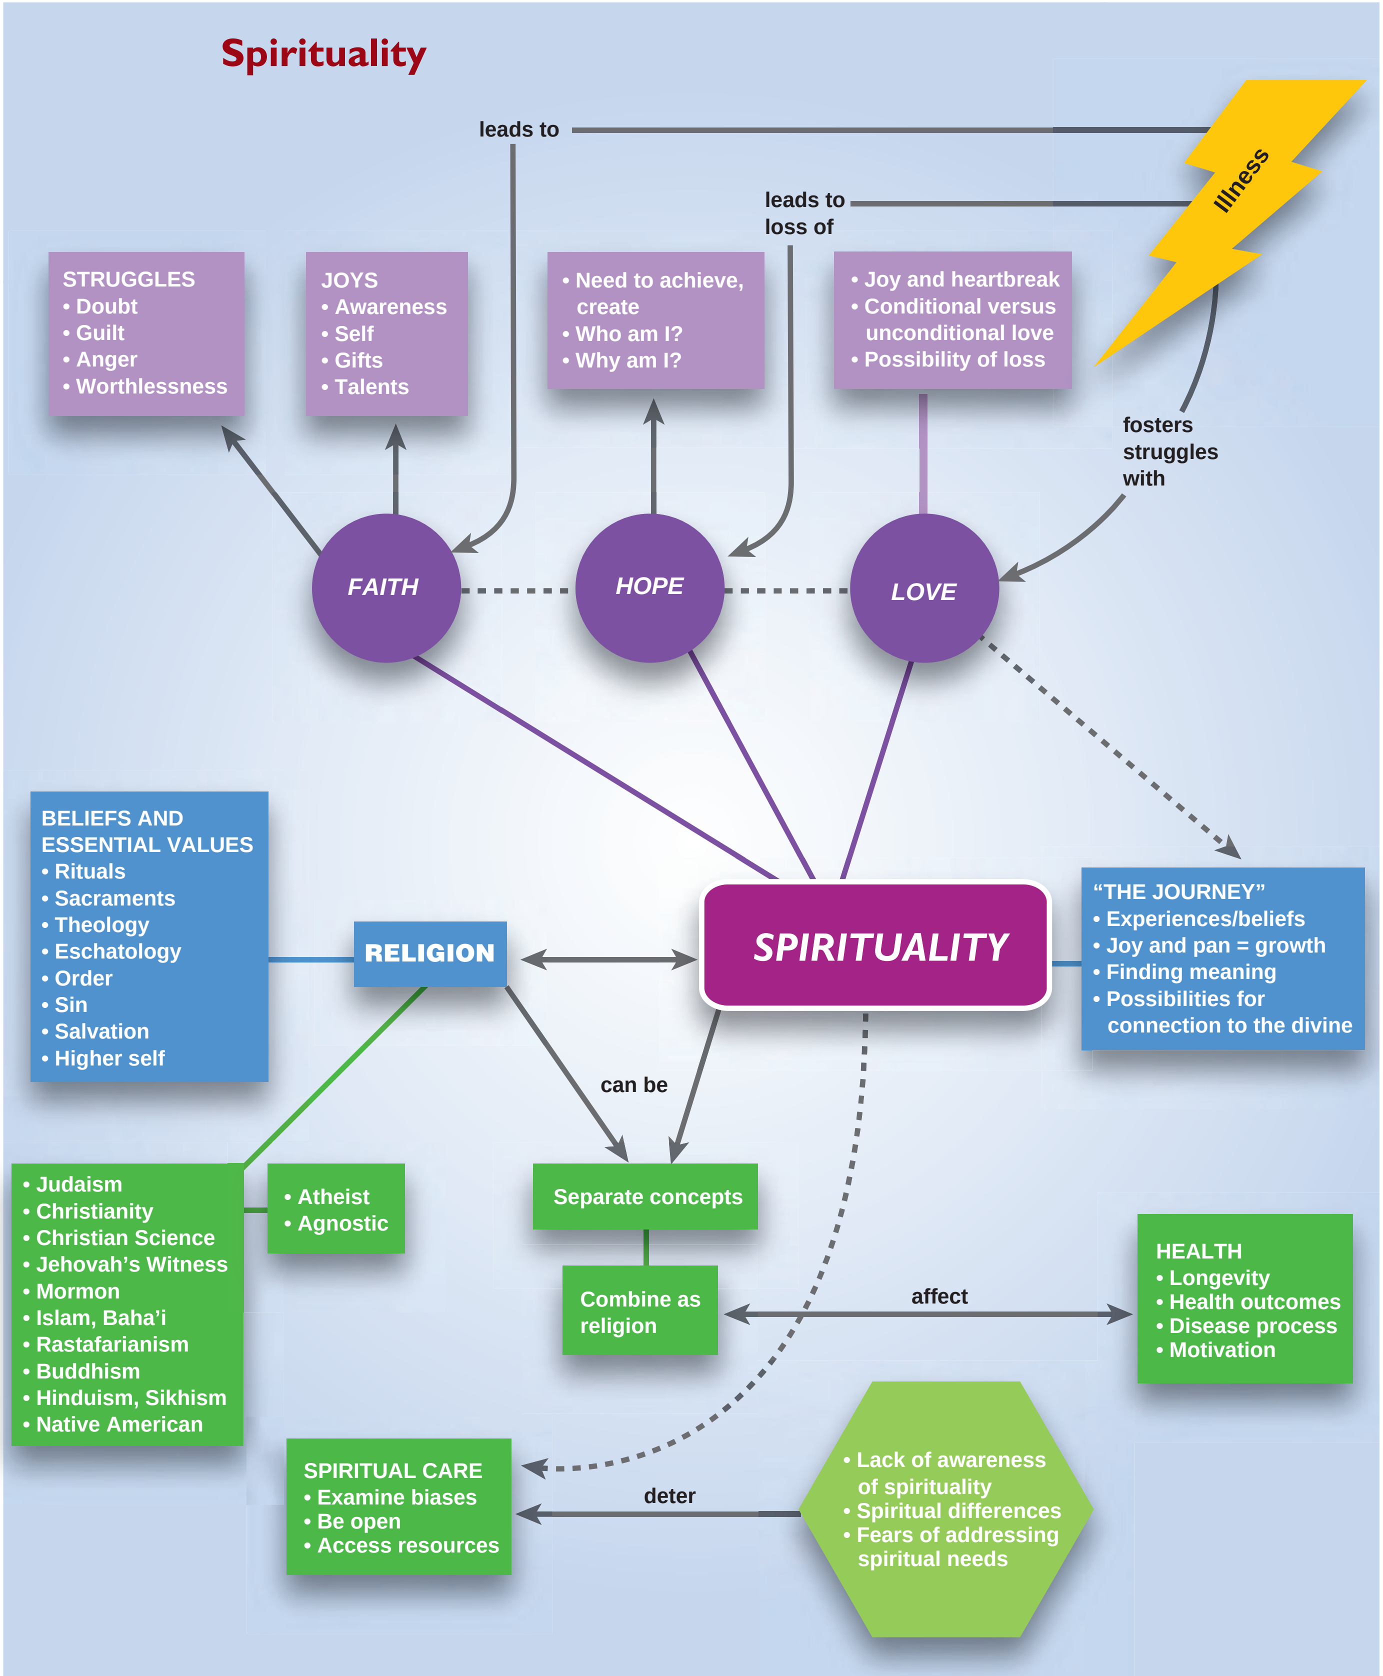
1. A 5-year-old boy was admitted to the hospital last night with a fever of 103°F (39.4°C). He was diagnosed with a serious infection that is easily treated with intravenous (IV) antibiotics. However, his parents are Christian Scientists, and they do not want the boy to be given antibiotics. They have called their Christian Science practitioner to visit as soon as possible.
   a. What practical knowledge do you have that will give you some insight into this situation?
   b. What essential piece of knowledge do you need that is *not* given in this scenario?
   c. If the parents do not agree to accept IV antibiotics for their child, what can you do to (1) ensure that the child receives treatment and (2) support their spiritual needs?
2. A woman is admitted to the emergency department and gives birth to a premature baby boy who is in severe respiratory distress. The woman is a devout Roman Catholic. What interventions could you use to ensure holistic spiritual care in such an emergency situation?
3. Interview nurses in the area where you have your clinical experiences. Discuss the interviews with classmates.
   a. Ask them to describe spiritual problems their patients have had.
   b. Ask them to tell you of any spiritual interventions they have used with patients, and to evaluate their effectiveness.
   c. Ask them how comfortable they are in using spiritual interventions, especially prayer.
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or spirituality. Note that these are *not* to be merely definitions.

   Spirituality and religion
   Nursing research in religion and healthcare
   Major religions and healthcare
   The nurse and spirituality
   Assessment of the spiritual domain of care
   Spiritual care nursing interventions
   Spiritual well-being

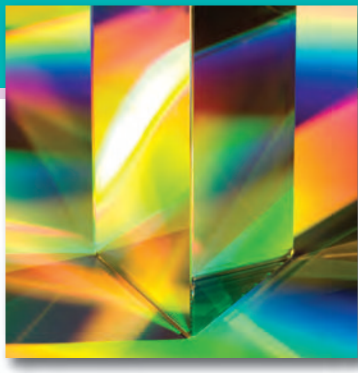
What Are the Main Points in This Chapter?

- Spirituality is a powerful force in the lives of many patients.
- Nursing has historical roots in religion and spirituality.
- Religion is a sort of "map" that outlines and integrates essential beliefs, values, and codes of conduct into a manner of living.
- Spirituality, like a journey, takes place over time and involves the accumulation of life experiences and understandings.
- Religion and spirituality affect health and well-being; in turn, health and well-being affect a person's religion and spirituality.
- Research suggests that patients' beliefs in religion and spirituality are important to healthcare outcomes; however, it does not explain *how* or *why* this is so.
- The more you know about the world's major religions, the more you will be able to offer comprehensive, compassionate care to patients.
- People vary greatly in the degree to which they follow the rituals and practices of their own religion.
- Barriers to spiritual care include (1) lack of awareness of spirituality and your own spiritual belief system, (2) differences in spirituality between you (the nurse) and the patient, (3) fear that your spiritual knowledge is insufficient, and (4) fear of where spiritual discussions might lead.
- Nursing interventions related to spiritual care require you to be self-aware, fully present, supportive, empathetic, and nonjudgmental and to have a desire to benefit the patient.
- When a patient asks you to pray, determine whether he wishes you to pray *for* or *with* him, and ask what he would like you to *especially* address in the prayer.
- A miracle does not necessarily involve the notion of a cure; miracles are more often events that proceed according to natural law but still have a powerful impact on the person's expectations.

Knowledge Map



CHAPTER 17



Loss, Grief, & Dying

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 17, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

At a clinic visit, Nam Nguyen tells you that his father's health is declining rapidly. Mr. Nguyen tells you, "I thought he was doing okay. I knew he had surgery for his prostate, so I thought it was all over. Lately he's been having lots of low back and hip pain. So my mom begged him to go to the doctor, and he told him he has cancer all over." Mr. Nguyen shakes his head and looks away from you. You notice tears in his eyes.

Mr. Nguyen tells you that his family has avoided discussions about serious illness and death. "It just never got discussed. The whole idea made my parents uncomfortable. When my father got sick the first time, he refused to discuss it. 'I'm going to get better. Don't even think about it,' he would say." Now Mr. Nguyen feels the need to discuss this situation with his parents but doesn't know how to bring up the topic. He asks for your advice.

A. What would you think and feel when you see Nam's tears and when Mr. Nguyen asks for this advice?

B. What would you advise Mr. Nguyen?

C. What type of grief is Mr. Nguyen experiencing?

D. Examine the factors that affect grief. Apply these factors to Mr. Nguyen's situation. You will need to review the family history included in the introduction to the Nguyens (in the front of this book) to fully answer this question. Indicate whether the information for any of the factors to be evaluated is insufficient.

PracticalKnowledge knowing **how**

This section provides guidelines for communicating with people who are grieving, caring for dying patients and their families, and providing postmortem care.

CLINICAL INSIGHTS

Clinical Insight 17-1 ➤ Communicating With People Who Are Grieving

Perfect your listening skills. Listen for what is *not* said as well as what is said.

Be alert for and respond to nonverbal cues with appropriate touch and eye contact. A smile, a gentle touch, sitting with a patient, and eye contact all relay a message of genuine care and concern. You may not need to say very much at all.

Encourage and accept expressions of feelings.

- Receiving expressions of intense feelings (e.g., anger and guilt) may be painful for you. It may help to remember that it is therapeutic for people to express their feelings.
- You don't need to change the person's feelings or "make them better." As much as we would like to do this, it is not possible.
- You do need to validate the person's feelings (e.g., "It is normal to feel that way; it is okay").

Reassure the person that it is not "wrong" to feel anger, guilt, relief, or other feelings she may believe to be unacceptable. A dying patient might say, "I know it's awful, but I feel so angry with God for giving me this disease." Or a bereaved spouse might admit, "I shouldn't feel this way, but I'm relieved that it's finally over." Patients need

Clinical Insight 17-1 ➤ Communicating With People Who Are Grieving *(continued)*

to hear you say their feelings are not "wrong" or "bad" and that they are going through a normal process.

Increase your self-awareness. Become more conscious of your own attitudes and feelings regarding death and dying. *If you are comfortable with your perspective, you will be able to hear patients' expressions of anger, guilt, frustration, fear, and loneliness more comfortably.*

Continue to communicate with dying patients even if they are in a coma. Encourage family members to do so as well.

- Talk to the patient. Tell him what is going on around him, what care you are providing, and when you or others enter or are about to leave the room.
- Avoid discussing the dying person as though he were not present. *Research indicates that patients continue to hear even though they cannot respond, sometimes up to the moment of death.*

Practice Resources

Eisenhandler, S. (2004); Emanuel, L., Ferris, F., von Gunten, C., et al. (2008); The Joint Commission (2010, 2013); Kruse, B. (2004); Traylor, E., Hayslip, B., Kaminski, P. L., et al. (2003); Wittenberg-Lyles, Goldsmith, Oliver, et al. (2012).

Clinical Insight 17-2 ➤ Helping Families of Dying Patients

- **View the family as your unit of care.** *Family members often rate communication with clinicians as one of their most important needs.*
- **Provide information, support, and a listening ear.** Include specific facts about the patient's condition and prognosis and whom to call about changes in condition.
- **Communicate medical updates daily.** *Information can relieve anxiety and is useful to the family when making decisions.*
- **Encourage family members to help with care if they are able.** Instruct and supervise as appropriate. If family members are not physically or emotionally able to provide care, accept that. *This helps meet their need to be useful, promotes family ties, and makes the patient more comfortable.*
- **Encourage family members to ask questions.** *They may hesitate to do so for various reasons (e.g., they may not want to interrupt busy care providers).*
- **Listen actively to the patient's and family's concerns.** Make eye content; clarify when you don't understand. *This helps you avoid misinterpreting the family's concerns and needs.*
- **Help the family to understand the goals of care and solve problems when needed.**
- **Follow up with other healthcare team members promptly** if the family has questions that are outside your scope of practice.
- **Arrange for a formal multidisciplinary meeting with the family** soon after the patient's admission, if possible. Discussions should cover personal, cultural, and religious traditions (e.g., how prayers are to be conducted, how the body is to be handled after death, and so on).
- **Encourage the family to visit the hospital chapel and to speak with a chaplain** or with their own spiritual adviser.
- **Provide anticipatory guidance regarding the stages of loss and grief**, so that they will know what to expect after their loved one dies.
- **Acknowledge the family's feelings** and the loss they are experiencing. *Many times family members begin the grieving process before the loved one dies.*
- **Help the family members explore past coping mechanisms;** reinforce successful past coping mechanisms.
- **Refer for ethics consultation** if decision making may become a problem.
- **Remind family members and significant others to take care of themselves.** *Watching a loved one die is a very difficult experience. A sensitive, caring nurse can make it a little easier.*
  - Many times they need "permission" to go to eat or to go home and rest.
  - If the patient is near death and family and friends do not want to leave the patient's side, make them as comfortable as possible.
  - Provide comfortable chairs, coffee, and snacks (according to organizational policy), and be alert for other needs they may have.
- **Teach the family what to expect with regard to medications, treatments, and signs of approaching death.** *If family members know what is normal, they will be less likely to panic or fear the inevitable.*
- **As physical signs of death become apparent, keep the family informed.** You may say something like, "Her blood pressure is becoming difficult to hear. That is one of the signs that she is closer to death." Help the family to understand what the patient is experiencing, as this may be very different from what they are seeing.
- **Reassure families of patients who become withdrawn near the time of death** that this does not mean the patient is rejecting them, but only that his body

(Continued)

Clinical Insight 17-2 ➤ Helping Families of Dying Patients *(continued)*

is conserving energy and that he has come to terms with dying and letting go of his connections with life.

- **When approaching death is apparent, ask family members directly, "Do you want to be present while he is dying?"** Tell them what to expect, if they do not know.
- **When an expected death occurs, shift the focus of your care** to the family and those who were caregivers.

Death does not end the relationship; family and caregivers need support during bereavement.

Practice Resources

Ahrens, T., Yancey, V., & Kollef, M. (2003); Boyle, D. K., Miller, P. A., & Forbes-Thompson, S. A. (2005); Emanuel, L., Ferris, F., von Gunten, C., et al. (2008); Hospice Foundation of America (2005); Hudson, P. (2006); The Joint Commission (2010, 2013); von Gunten C., Ferris, F., & Emanuel, L. (2000).

Clinical Insight 17-3 ➤ Caring for the Dying Person: Meeting Physiological Needs

Active dying usually occurs over a period of 10 to 14 days (although it can take as little as 24 hours). The "final hours" refer to the last 4 to 48 hours of life, in which failure of body systems results in death (Brennan, 2011; Pitorak, 2003).

Encourage the patient to be as independent as possible. *This helps the patient to maintain a sense of control.*

Provide adequate pain control. *This can be a major issue for patients and caregivers. In fact, dying patients are often more concerned about pain and loss of control than about dying itself. Pain is difficult to assess in semiconscious or unconscious patients. See Chapter 31 if you need more information about pain management.*

- Dispel the myths about pain medication (e.g., addiction, overdose). Effective pain control medications exist and can be administered by various routes. Assure the patient and family that analgesics will not be addictive in this situation.
- Respect the patient's informed decision to refuse pain medications. For example, a patient may prefer to endure pain in order to be awake and alert when his family is at the bedside.
- Follow the prescribed pain protocols to ensure that pain is controlled.
- Administer pain medication on a regular schedule instead of waiting until the patient asks (prn), to ensure pain control.
- Teach and perform nonpharmacological pain-relief measures when you judge these may be helpful (e.g., meditation, heat/cold therapies, massage, distraction, imagery, deep breathing, and herbal-scented lotions). It may be soothing to play soft music, add "white noise," or turn off the television.
- Patients who are near death may moan or grunt as they breathe; this does not necessarily indicate pain. Be sure that families understand this. When accompanied by agitation and restlessness, these symptoms may indicate terminal delirium, which may require medications for control.

Monitor the patient's energy level. *Fatigue is a normal part of the dying process. Most dying patients sleep much of the time.*

- Perform hygiene and other care, if the patient tires easily or lacks the energy for self-care (i.e., activities of daily living).
- Remove environmental stressors that interfere with sleep (e.g., noise, too much light, a room that is too hot or too cold).
- Identify psychosocial stressors (e.g., depression, anxiety, fear) that may keep the patient awake (see Clinical Insight 17-4).

Maintain skin integrity. *During the final hours of life, the goal changes from preserving skin integrity to providing comfort. Realize that during this time even excellent care may not prevent skin breakdown.*

- Turn the patient frequently unless contraindicated. Refer to the pain control interventions in the preceding list.
- Assess for increased diaphoresis and/or incontinence.
- Maintain adequate nutrition.

If the patient is comatose or unconscious, provide special care for the eyes so they do not become too dry. Many agencies use a form of artificial tears for this purpose.

If the patient is not able to take fluids, wet the lips and mouth frequently with cool water or with a prepared product to prevent dryness and cracking of lips and mucous membranes of the nose, mouth, and eyes.

There is some evidence that glycerin swabs dry the mucous membranes and should not be used.

Provide artificial hydration (unless the patient has an advance directive requesting no artificial hydration) per nasogastric (NG) or IV route. *IV fluids can cause edema, nausea, and even pain in a patient who is actively dying. Dehydration is thought not to cause distress during the last hours, and may even be protective (Campbell, 2010; Emanuel, Ferris, von Gunten, et al., 2008).*

Take the vital signs often, unless contraindicated; observe for decreased level of consciousness and pallor.

Assess and provide interventions for constipation, urinary retention, and incontinence. *Constipation may be associated with decreased fluid intake, inactivity, weakness, hypercalcemia, hyperkalemia, and lack of privacy. It can contribute to pain, nausea, vomiting, and anorexia, so intervention is an important comfort measure. Incontinence may occur because of fatigue and loss of sphincter control. It can be distressing to patients and family members.*

Clinical Insight 17-3 ➤ Caring for the Dying Person: Meeting Physiological Needs *(continued)*

- Administer laxatives, stool softeners, and lubricants for constipation.
- Catheterize the patient if he is unable to void and the bladder becomes distended.
- Use pads for incontinence, but change them frequently to prevent skin breakdown and, near the end, to promote comfort.
- Use a rectal tube if diarrhea is severe.

Intervene for "death rattle" if it occurs and if it is distressing to the family.

- Turn the patient on his side, and elevate the head of the bed.
- Administer antispasmodic and anticholinergic medications if necessary.

Provide medication for other symptoms, such as nausea and breathlessness.

Continue to speak to the patient as if he can hear.

Do not talk about the patient to others in his presence. *The patient is usually able to hear even after he can no longer respond to sounds and other stimuli. Assume the unconscious patient hears everything.*

Document changes in vital signs and level of consciousness. Record intake and output, noting changes. Document the times of cardiac arrest and cessation of respirations.

Practice Resources

American Nurses Association (2010); Covington (2013); Emanuel, L., Ferris, F., von Gunten C., et al. (2005); Harvey, J. (2001); The Joint Commission (2010, 2013); Qaseem, A., Snow, V., Shekelle, P., et al. (2008).

Clinical Insight 17-4 ➤ Caring for the Dying Person: Meeting Psychological Needs

Patients experience many emotions at end of life, including anger, sadness, depression, fear, relief, loneliness, and grief. At this time, communication and support are most helpful. Discussing concerns and issues is a viable means of coping.

If there is an advance directive or living will, locate the documents. Review the documents to be certain you understand the patent's wishes. If you have not already done so, notify all relevant health professionals of the existence of these documents.

Answer all questions honestly.

Explain all care and treatments even if the patient is unconscious. *He may still be able to hear.*

Realize that the patient may feel he is losing control.

- Help the person recognize what he does have control over.
- Include the patient in care decisions as much as he is able.

Attend to social needs. *Relationships are a priority at this time. Some patients may simply need to keep the bonds with family members and friends intact. For other patients, this may be a time to reestablish or mend relationships.*

- Notify family members when the patient wishes to see them.
- Allow the patient and family to discuss death at their own pace.
- Offer to contact a chaplain or other spiritual leader if the patient chooses.
- Pray with the patient if he requests it and you are comfortable doing so.

Encourage the patient to express feelings. Be prepared to accept a wide range of feelings, including anger, hopelessness, loneliness, and depression.

Early in the dying process, assess the sources of financial support for the patient and family. *Finances may be a concern and may place an additional burden on the family; or the patient may feel he is a burden to care for.*

Be aware of sexual needs. Provide realistic information about these issues. For example, suggest ways a couple can be close and affectionate at this time. Be aware that expressions of sexuality may change as a person becomes closer to death. *Some people may feel it is not right to have sexual feelings when the person they love is dying. Others may be afraid of harming the patient if they are sexually intimate.*

When the patient is very near death, focus on relieving symptoms (e.g., pain, nausea) and emotional distress.

(Continued)

Clinical Insight 17-3 ➤ Caring for the Dying Person: Meeting Physiological Needs *(continued)*

If the person can communicate, ask about immediate concerns:

- "Are you in pain?" "Are you comfortable?"
- "What are you afraid of now?"
- "What can we do to help you go peacefully?"
- "Who do you want in the room with you right now?"

If the patient asks whether he is dying, be honest.

If the patient cannot communicate, ask a significant other what the patient would want. Ask the family member or person who is most likely to know.

When the patient is very near death, it may be helpful to say something like, "Your family will be fine" rather than, "It is okay for you to go now." *Be aware that some people seem to wait to die until after a significant date (birthday, anniversary, and so on) has passed. Others wait for family to gather; whereas, others wait until loved ones leave so they will not upset the family by dying in their presence.*

Practice Resources

Brennan, C., Prince-Paul, M., & Wiencek, C. (2011); Duffy, S., Jackson, F., Schim, S., et al. (2006); Emanuel, L., Ferris, F., von Gunten, C., et al. (2008); Hancock, K., Clayton, J., Parker, S., et al. (2007); Law, R. (2009); The Joint Commission (2010, 2013); Pitorak, E. (2003).

Clinical Insight 17-5 ➤ Providing Postmortem Care

Supporting the Family

- **At the moment of death, do not interrupt or intrude on the family.** Wait quietly and observe, or if they would feel more comfortable being alone with the patient, leave the room. Give them as much time as they need. When they move away from the body, or have expressed their last good-byes, then it is time to assess the patient and report the lack of vital signs.
- **Immediately after death, express sympathy to the family.** This is very important. Make a simple statement, such as, "I am sorry for your loss." Avoid statements that interpret the situation for the family, such as, "It's God's will." Also avoid attempts to mitigate the family member's grief, for example, "It will get better in time," or "You still have your son."
- **If the family wishes to be alone with the body,** straighten the bedcovers and make the patient look as natural as possible. Remove any tubes, IV lines, and so on, according to the institution's policy, and have the patient positioned in a way that appears comforting (e.g., bedcovers pulled up, hands at the side).
- **Be accepting of family members' behavior at this time,** no matter how strange it may seem to you. A family might want to take a picture, or the spouse may lie down beside the deceased person.
- **If no family members are present, identify the next of kin** and be sure the family is informed of the patient's death.
- **If family members arrive after the death, offer to take them to the bedside.**
- **If family members wish to be involved in postmortem care,** encourage them to do so. This can facilitate their grieving process.
- **Ask whether each family member wishes to spend time alone with the deceased person,** and arrange for them to do so. Never remove the body until the family is ready. Viewing the body is useful to many individuals.
- **Ask, "How can I help?" "What do you need?" "What would you like for me to do?"**
- **Locate personal effects and give them to the family/next of kin.** If you can't remove a ring, wrap it with gauze, tape it in place, and tie the gauze to the wrist to prevent subsequent loss.

Legal Responsibilities

- **Notify the primary provider of the death.** Usually the physician must pronounce death; however, in some areas a coroner or a nurse may also perform this task.
- **The person who pronounces death must sign the death certificate.** In some agencies, the nurse is responsible for checking to see that it has been signed.
- **If the patient is donating organs,** review and make any necessary arrangements.
- **If an autopsy is to be performed,** as a rule, the physician (or other person designated by the institution) is responsible for obtaining signed permission from the next of kin.

Care of the Body

- **Follow agency policies, and respect cultural and spiritual preferences.**
- **Wash the body if there has been any incontinence or drainage.** Place absorbent (ABD) pads between the buttocks to absorb rectal drainage. Ask the family before washing the body. *In some cultures, the body is not washed, or family members arrange to have someone special do it.*
- **Dress the body in a clean gown, comb the hair, and straighten the bed linens.**
- **Place the body supine in a natural position.**
  - Place the dentures in the mouth before rigor mortis occurs.
  - Close the eyes and mouth before rigor mortis occurs. Close the eyes by gently pressing on the lids with your fingertips. If they do not stay closed, place a moist

Clinical Insight 17-5 ➤ Providing Postmortem Care *(continued)*

compress on the eyelids for a few minutes and then try to close them again.
  - Tie a strip of soft gauze (e.g., Kling) under the chin and around the head if your institution requires it (not all do). Alternatively, you can place a folded towel under the chin to keep the jaw closed. *This keeps the mouth set in a natural position in case there is a viewing later.*
  - Place a pillow under the head and shoulders. *This prevents blood from settling there and causing discoloration.*
- **Be sure that dressings are clean, and unless an autopsy is to be done, remove all tubes and drains.** Be careful when removing tape or dressings. Apply small adhesive bandages to puncture sites. *After death, the skin loses its elasticity and can be torn easily.*
- **If the family asks about the coldness and color of the body, explain to them about algor mortis and livor mortis.**
- **After the family has spent time with the body, arrange to have it sent to the morgue,** where either an autopsy will be performed, or, if not, the funeral home in charge of arrangements will arrive to transport the body.
  - Pad the wrists and ankles to prevent bruising; tie them together with gauze.
  - Wrap the body in a shroud or body wrap for transfer to the morgue.
  - If no relatives were present to receive patient belongings, bag them, label the bag, and send with the patient to the morgue.
  - If possible, close doors to adjoining rooms before transport.
- **Make sure there are identification tags on the body, on the shroud or body bag, and on the patient's possessions; and if necessary, hazard labels**. Follow agency policy for number and location of tags. They will usually include the patient's name, room and bed numbers, date and time of death, and the physician's name. Misidentification can create legal problems, for example, if the body is prepared incorrectly for a funeral.
- **Follow institutional policy if the patient has died of a communicable disease.** By law, there are special preparations to perform in such cases.
- **Handle the body with dignity.**

Documentation

Documentation varies among healthcare facilities. However, you will almost always document the time that you noted absence of heartbeat and respirations, any auxiliary equipment still present (e.g., mechanical ventilator), the disposition of the patient's possessions (especially money and jewelry), and the date and time the body is transported to the morgue or funeral home.

FORMS

DO NOT RESUSCITATE ORDERS

Physician: Complete Part I & II to initiate order. Part III is to be completed every seven days.

☐ **DNR forms completed on previous admission. Verified by:** ______________________________.
Date of original order: ____________________. Signature Date

NOTE: Words that appear in the directions in all capital letters are listed in the DNR definitions.

PART I: ☐ If this patient suffers a cardiac or respiratory arrest, a Cart is not to be called and no resuscitation measures are to be carried out.

PART II: ☐ This order is to be transcribed and instituted immediately. All required documentation is complete.

or

☐ This order is to be transcribed and instituted only after the CONCURRING PHYSICIAN'S statements have been completed. I have requested Dr. ____________________ to be the CONCURRING PHYSICIAN.

______________________________, M.D. ______________________________, R.N.
Signature of ATTENDING PHYSICIAN Signature of Transcribing Nurse

Date Time Date Time

PART III: Review of DNR ORDER

This is to verify that review and determination of continued appropriateness of the DNR ORDER and the conditions under which it was obtained was done: (to be documented at least every 7 days)

Date	By	Date	By
			Continued on reverse side

PART IV: Wavier to DNR ORDER

I, the undersigned, have previously consented to a DO NOT RESUSCITATE ORDER. During the procedure and until I am returned to my room, I hereby waive my consent to the DO NOT RESUSCITATE ORDER and authorize my ATTENDING PHYSICIAN to write such an order.

Signature of patient or SURROGATE or PROXY (or parent or legal guardian for minor) Date Signature of WITNESS Date

☐ DNR ORDER suspended during the peri-operative period, as noted above.

______________________________, M.D. ______________________________, R.N.
Signature of ATTENDING PHYSICIAN Signature of Transcribing Nurse

Date Time Date Time

PART V: Revocation of DNR ORDER

I, the undersigned, hereby revoke the DO NOT RESUSCITATE ORDER previously consented to by me.

Signature of patient or SURROGATE or PROXY (or parent or legal guardian for minor) Date Signature of WITNESS Date

☐ DNR ORDER revoked.

ASSESSMENT GUIDELINES

You can use these guidelines for assessing dying patients as well as for other types of loss.

Focused Assessment

Assessing Grief and Loss

1. Assess the patient and significant others for common grief reactions.

Physical	Emotional	Behaviors	Cognition
Loss of appetite	Sadness	Forgetfulness	Decreased concentration
Weight loss/gain	Guilt	Withdrawal	Forgetfulness
Fatigue	Relief	Insomnia or too much sleep	Impaired judgment
Decreased libido	Shock	Dreaming of deceased	Obsessive thoughts of the deceased or lost object
Decrease in immune system	Numbness	Verbalizing the loss	Preoccupation
Decreased energy	Loneliness	Crying	Confusion
Possibly physical symptoms, such as headache or stomach pain	Fear	Loss of productivity at work or school	Questioning spiritual beliefs
	Anxiety		Searching to understand
	Powerlessness		Searching for purpose and meaning
	Helplessness		
	Depression		

2. Assess knowledge base of patient and significant others.

a. Can they make informed decisions about healthcare choices? You might ask the following questions:
   - "Tell me what you understand about your illness."
   - "Are there any questions about your illness that you'd like me to answer?"
   - "What are your options for treatment?"
   - "Do you know how to reach your provider if you have questions about your care?"

b. What and how much do the patient and family want to know? *Some people wish to have all the details of their condition and care. For others, the details cause anxiety.*

3. Assess the history of loss.

Determine whether the patient or family has sustained recent losses or major changes (e.g., death, moving, divorce, retirement). Ask such questions as:
- "Have you had any recent changes in your life?"
- "Tell me about your family."
- "Are your parents still living?" (as appropriate)
- "What previous experiences have you had with the loss of someone you loved (or with this condition)?"

4. Assess coping abilities and support systems.

Questions to assess coping include the following:
- "What do you do to reduce stress?"
- "Which family/friends can you talk with?"
- "What would you say is your greatest support when going through difficult times?"
- "Tell me about a previous loss and what you did to cope with it."
- "Are you using any community resources to help you get through this? Do you know what they are?"

The way individuals have coped in the past will affect how they cope with dying or with their current loss. It may also be therapeutic for them to identify their resources and supports.

5. Assess the meaning of the loss or illness.

Be alert for statements that may indicate the patient or family is struggling to find meaning, such as:
- "I'm being punished."
- "She doesn't deserve this."
- "Why is this happening to me?"

In trying to "make sense" of their loss or their dying, people try to attach a meaning to their suffering.

6. Differentiate between grief and depressive disorder.

a. Symptoms common to both grief and depressive disorder: sadness, insomnia, poor appetite and weight loss. Feelings of sadness and depression are a normal part of grief, provided the depression does not linger too long.

b. Symptoms that indicate grief. For example, the person may feel relatively better in certain situations, such as when she is with friends and family. However, triggers, such as the deceased person's birthday, an anniversary, or holidays, cause the feelings to resurface more strongly.

c. Symptoms that indicate depressive disorder:
   - The depression is more pervasive. That is, the person rarely gets any relief from the symptoms.
   - Feelings of guilt not related to the loved one's death
   - Thoughts about own death or of suicide (other than feelings the person would be better off dead now that the loved one is gone)

(Continued)

Focused Assessment

Assessing Grief and Loss—cont'd

- Preoccupation with own "worthlessness"
- Sluggishness
- Hesitant and confused speech
- Prolonged and marked difficulty in carrying out activities of daily living
- Hallucinations, other than thinking he hears the voice of or sees the deceased person

7. Perform a physical assessment. Look for signs of increased stress, such as tension, forgetfulness, distraction, increased or decreased appetite and sleep, weight gain or loss, fatigue, and decreased self-care (e.g., deficient hygiene). *A thorough physical examination adds data to help you determine how well the patient is coping with the loss or illness.*

8. Perform a cultural and spiritual assessment.

a. Assess the patient's and family's religious beliefs, any spiritual needs they may have (e.g., forgiveness, hope, meaning, love), and cultural influences that may affect the way they cope.

b. Do not assume that a person adheres closely to the dominant values of his religious or cultural group. Always assess. For example, ask: "To what religious and ethnic groups do you belong?" and "How closely do you identify with those groups?"

See Chapters 15 and 16 for details of cultural and spiritual assessment, if you need them.

9. Perform these specific assessments for dying patients. For dying patients, in addition to the other assessments in this guideline, you should also assess the following:

a. When the patient and family are ready, encourage them to talk about what the patient might want for burial or cremation or whether there are tasks that the person would like taken care of (e.g., giving away valuables, calling family members).

b. Determine whether the dying person has a living will or advance directives.

c. Discuss with the patient and family the possibility of organ donation if appropriate for the patient's circumstances.

d. Observe for physical changes indicating the approach of death:

1 to 3 months before death: Beginning withdrawal from others, increased sleep, decreased appetite, difficulty digesting food (especially meats), prefers liquids. *Anorexia may be protective, as the resulting ketosis can diminish pain and increase the person's sense of well-being.*

1 to 2 weeks before death: Cardiovascular deterioration brings decreased blood pressure, pulse and respiration changes (decreased or increased), a yellowish pallor to the skin, extreme pallor of extremities. Observe for temperature fluctuations, increased perspiration, brief periods of apnea during sleep, rattling breathing sounds caused by congestion, nonproductive cough

Days to hours before death: A brief surge of energy and mental clarity, with a desire to eat and talk with family members

- Dehydration, difficulty swallowing, decreasing blood pressure, weak pulse
- Mucous membranes dry and tacky; cracked lips. *Dehydration during the last hours of dying is thought to not cause distress, and perhaps to stimulate endorphin release.*
- Sagging of tongue and soft palate, diminished gag reflex, secretions accumulating in the oropharynx and/or bronchi
- Shallow, rapid, or irregular breathing; respiratory congestion; Cheyne-Stokes respirations; apnea of 10 to 30 seconds; "death rattle." ***Cheyne-Stokes breathing*** *is a cyclic pattern consisting of a 10- to 60-second period of apnea and then a gradual increase in depth and rate of respirations. Respirations gradually become slow and shallow, and then the cycle begins again with apnea.*
- Decreased peripheral circulation, increased perspiration, "clammy" skin; extremities cool and mottled; dependent body parts darker than the rest of the body
- Decreased urinary output, concentrated and foul-smelling urine, secondary to decreased kidney function
- Slack facial muscles ("drooping")
- Retained feces; bowel and bladder incontinence *due to decreased peristalsis and relaxation of sphincters*
- Blurred vision; eyes open but unseeing
- Restlessness or agitation (check for impacted stool, distended bladder, pain, medications, cerebral hypoxia, unresolved emotional or spiritual issues)
- Decreased communication, quiet, withdrawal. Some become more coherent and energized for a time.
- Fatigue

Moments before death: Does not respond to touch or sound; cannot be awakened. There may be a short series of long-spaced breaths before breathing stops entirely and the heart stops beating. Auscultate to determine whether apical pulse and respirations are absent.

Sources: Emanuel, L., Ferris, F., von Gunten, C., et al. (2008); Ferszt, G. G., & Leveillee, M. (2006); Pitorak, E. (2003); Widera, E., & Block, S. (2012).

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Marie is 84 years old and has had a right-sided cerebrovascular accident (CVA, stroke, or brain attack). Doctors say she is unlikely to regain much physical function, if she even awakens from the coma. She was alert and active before her stroke and was able to maintain her independence with the help of a home health aide, who assisted her with ADLs and meal preparation three times a week. Kelly and Dan, her children, have met with the physician, who tells them that Marie's chance of survival is slim. He wants to put a feeding tube into Marie and has asked whether they want Marie to be resuscitated in case of cardiac or respiratory arrest. Kelly wants to do what is best for her mother, but she feels that Marie would not want to be kept alive in this condition. She is also concerned about putting her through uncomfortable procedures if there is no chance of recovery. Her brother, Dan, thinks Marie should have the feeding tube. Kelly asks to speak with you and wants to know the best thing to do for her mother.

THINKING

1. *Theoretical Knowledge (Recall of Facts and Principles):* If Marie and Dan agree that they do not want Marie to be resuscitated, the physician will complete a DNAR (AND) order. What do the letters *DNAR* and *AND* represent?
2. *Critical Thinking (Problem-Solving):* At this stage of your education, you probably need more information about CVAs and tube feedings. Write a PICO question you could use to search the literature for information about these two topics and how they are related. See Chapter 8 if you need to review PICO questions.

DOING

3. *Practical Knowledge (Nursing Diagnosis):* Write a possible nursing diagnosis to describe Kelly's situation.
4. *Practical Knowledge (Basic Skills):* If Marie and Dan agree to tube feedings for Marie, as her nurse, what basic nursing skills will you need to perform? How will you learn to perform these skills, if you do not already know how to do them?

CARING

5. *Ethical Knowledge:* How do you think the situation came to this? What might Kelly, Dan, and Marie have done before the stroke to prevent this confusion and indecision?
6. *Self-Knowledge:* What are your responsibilities in this situation? What could you do to help Kelly and Dan?

Critical Thinking and Clinical Reasoning

1. Jessie McCarthy is a 69-year-old woman who is terminally ill with multiple myeloma. She is currently hospitalized for a week of chemotherapy. Her husband of 49 years is recuperating from recent hip surgery and has difficulty getting around. Her daughter and son-in-law are very close to them, and her granddaughter, 14 years old, has a very special relationship with her "Gammie." The side effects of Mrs. McCarthy's chemotherapy include nausea and headaches. She doesn't like to have people around when she feels this way. Jessie's pastor comes to visit every other day and seems to bring her comfort. Her 50th wedding anniversary will occur when she is in the hospital. She verbalizes fear of "not making it home this time." You are her nurse in a hospital where palliative care is provided. Initiate a holistic plan of care for Mrs. McCarthy, addressing the main issues noted.
   a. What immediate physical problems does Mrs. McCarthy have? Do not use her medical diagnosis as an answer.
   b. What might you do to meet her physical needs?
   c. What psychological needs does Mrs. McCarthy have: (1) What are her fears? (2) What social and emotional issues is she facing? (3) How might you help meet her needs?
2. You are caring for Jack Wirtz, a 37-year-old man who was admitted to the hospital for a lumbar laminectomy (surgery of his lower spine). As you are doing Jack's preoperative assessment, he tells you that his 12-year-old son died 6 months ago in an automobile accident in which Jack was the driver. He is a builder and has been out of work since the accident. His wife now works to help support them. Jack's affect is flat, and he talks in a monotone.
   a. What losses has Jack experienced?
   b. What further assessments need to be made for Jack, and why?

3. A patient requests your participation in a plan for assisted suicide or passive euthanasia. What are your options as a nurse? Use the Internet to get information about this.
   a. List the URLs for the pages you found to be helpful in answering the question. Beside each URL, state the name of the organization, person, or agency to which the Web site belongs.
   b. For each URL, state what you believe to be the *purpose* of the Web site.
4. Find a partner. Take 5 minutes to describe to her a personal loss you have had (e.g., a person, a pet, an object, an aspect of health). The partner must listen silently and not speak at all during these 5 minutes. When you have finished, answer the following questions:
   a. What did you feel when describing your loss?
   b. Did you feel that the listener was really listening to you?
   c. How did the listener respond to you?
5. Now reverse the process; you become the listener. When you have finished, answer the following questions:
   a. What did you feel while you were listening?
   b. Did the time go quickly or seem long?
   c. What did you learn from this listening experience?
6. John is 17 years old and volunteers at the hospital. He has just moved from another state because of his father's work, so he is a new senior in high school. As you chat with him, he reveals that his mother is getting radiation and chemotherapy treatments for breast cancer and has been very ill. What are some loss issues this young man is facing?
7. Sharon is your 48-year-old patient who is in the hospital for a hysterectomy (removal of her uterus) because of fibroids and heavy bleeding. With teary eyes, she shares with you that she is feeling "down" and doesn't want any visitors this evening. She says, "I really thought I would feel better after having this surgery done."
   a. Why do you think Sharon is teary and feeling "down"?
   b. What should you do to begin helping Sharon cope with her loss?
8. You are having lunch with a nursing colleague, who reveals to you that her mother has Alzheimer's disease. Her mother has been placed in a nursing home because she is losing her memory and is not safe at home. Your friend describes feeling distracted, angry for no reason, and unable to shake her feelings of sadness.
   a. What might be causing your colleague to feel distracted and angry?
   b. How would you respond to her?
9. You are caring for Mr. Bishop, a 57-year-old man who is terminally ill with metastatic bone cancer. He wants to donate his organs for research after his death, but his wife is totally against this.
   a. What could you do or say to him to help resolve this issue? Go to the following URL, and download the Organ Donation and Transplantation page for information to use in this situation: http://organdonor.gov/about/index.html
   b. Now go to the top of the Web page and look at the logo and other information. Who do you think provides and maintains the content for this Web site? What else would give you a clue about the source of the site?
   c. Look at the bottom of the Web page. What department of the U.S. government "owns" this page?
10. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or loss, grief, and dying. Note that these are *not* to be merely definitions.

    Physical loss
    Actual loss
    Complicated grief
    Disenfranchised grief
    Significance of the loss
    Stages of grief
    Advance directives
    Assisted suicide
    Palliative care

What Are the Main Points in This Chapter?

- How people cope with loss directly affects their healing and well-being.
- Loss may be actual or perceived, physical or psychological, external or internal.
- Grief is the physical, psychological, and spiritual response to loss.
- People do not move neatly from one stage of grief or dying to the next; there is constant movement and overlap between and among them.
- Factors that affect the grieving process include the significance and circumstance of the loss, the timeliness of the death, the bereaved support system, spiritual beliefs, cultural values, the person's developmental stage, and conflicts existing at the time of death.
- Patients experience loss of independence, body image, self-esteem, and so on, when they are ill and/or hospitalized. Recognizing these as losses, you can assist the patient with the grieving process, thus promoting physical, emotional, and spiritual healing.
- The Uniform Determination of Death Act states that death has occurred when "an individual . . . has sustained either (1) irreversible cessation of circulatory and respiratory functions, or (2) irreversible cessation of all functions of the entire brain, including the brainstem. . . ."
- Palliative care focuses on providing comfort care and symptom relief, without further efforts to stop the disease process or prevent death.
- Hospice care is a movement and an approach to allow terminally ill persons to face death with dignity and surrounded by the comfort of their home and family.
- Healthcare providers are responsible for educating staff and patients about advance directives.
- A do not attempt resuscitation (DNAR) or allow natural death (AND) order is a specific order to *not* perform cardiopulmonary resuscitation.
- Nurses should be aware of what is involved with assisted suicide and euthanasia. You should think ahead about what your response might be if a patient wants to discuss these topics. You may find the American Nurses Association (ANA) position statement on the nurses' roles and responsibilities in end-of-life care helpful.
- An autopsy is a medical examination of the body to determine the cause of death.
- When a patient is dying or has experienced a loss, you should perform a thorough, holistic assessment.
- Most grief is normal, not dysfunctional; you should not diagnose Complicated Grieving for every person who is grieving a loss.
- You can facilitate grief work by validating feelings ("It's normal to feel that way") and providing an opportunity and encouragement to talk about the lost person or object.
- Active dying usually occurs over a 10- to 14-day period, although it can take as little as 24 hours. During the final 4 to 48 hours, failure of body systems results in death.
- When the patient is very near death, focus on relieving physical symptoms and emotional distress. If he can communicate, ask about immediate concerns, such as, "Who do you want in the room right now?"
- At the moment of death, do not interrupt or intrude upon the family; give them as much time as they need to say good-bye to their loved one. Express your sympathy.
- Care of the body includes making it presentable for the family, carefully placing identification tags, and arranging to have the body sent to the morgue.
- The death certificate must be signed by the person who legally pronounced the death (usually a physician).
- It is normal for the nurse to feel grief when a patient dies.

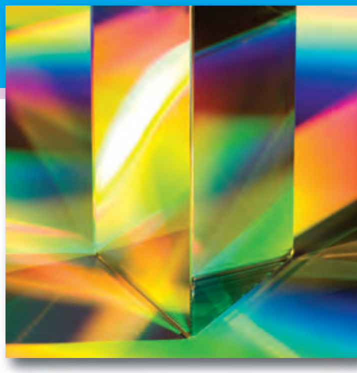
Essential Nursing Interventions

CHAPTER 18



Documenting & Reporting

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

- **Resources for Caregivers and Health Professionals**
- **Reading More About Documenting & Reporting (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 18, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Yen Nguyen arrives at the Family Medicine Clinic complaining of pain and drainage from her right eye. She requests an appointment. As part of your clinical experience working as a triage nurse at the clinic, you must evaluate the patient's status and determine whether she needs to be seen today. Below is your conversation with Mrs. Nguyen.

Mrs. Nguyen: I don't have an appointment, but I need to see someone today. My husband is a patient here. I have an appointment in 2 weeks for a physical, but I've never been here before. I just can't wait 2 weeks.

You: What seems to be the problem?

Mrs. Nguyen: My eye is killing me. My right one. It burns and stings, and there's all this nasty gunk coming out. I think I need some medicine for it.

You: Tell me a little more about this problem. When did this start?

Mrs. Nguyen: I woke up yesterday with a painful, itchy eye. I used some saline drops, but the eye seems to be worse. I work at a preschool, and they won't let me work unless I take care of this. I also think I need to be checked for other things. I haven't had an appointment in a long time. I suppose I just need some tests. My husband just found out he has high blood pressure, but I don't think I do. I guess I'm not old enough. I'm 55, but my mother got high blood pressure when she was 70.

As she is talking, you notice a large amount of thick, yellow-green drainage in the corner of her right eye and the eye is reddened. She is rubbing this eye vigorously and dabbing at it with a tissue. The skin is puffy around the eye as well. Her left eye is slightly red, but there is no drainage.

Her vital signs are as follows: blood pressure, 132/76 mm Hg; heart rate, 88 beats/min; respirations, 18 breaths/min; and temperature 98.9°F (37.2°C). Based on your brief assessment, you ask the receptionist to give Mrs. Nguyen an urgent appointment.

A. Make two charting entries to describe the above events. First make a brief narrative note.

B. Next, construct a SOAPIER note. Be sure to follow charting guidelines when you prepare your note.

Practical Knowledge knowing how

CLINICAL INSIGHTS

Clinical Insight 18-1 ➤ Giving Oral Reports

For all types of report formats

Remember the acronym CUBAN (Currie, 2002):
Confidential, **U**ninterrupted, **B**rief, **A**ccurate, **N**amed nurse

Use a Standardized Format Such as the Following:

PACE

Patient/Problem—Include patient's name, room number, diagnosis, reason for admission, and recent procedures. State the present problem. Briefly summarize medical history relevant to the current problem.

Assessment/Actions—Nursing assessments and interventions directed to the problem.

Continuing/Changes—Continuing needs and potential changes include:

- Patient care and treatments that must be monitored on other shifts (e.g., dressing changes)
- Changes in the patient's condition or the care plan, recent or anticipated (e.g., new orders, changes in discharge date)

Evaluation—Evaluation of responses to nursing and medical interventions, progress toward goals, and effectiveness of the plan

SBAR/SBAR-R

Identify yourself, the patient, and the agency.

S*ituation*—"Here's the situation . . ."

B*ackground*—"The supporting background information is . . ."

A*ssessment*—"My assessment of the situation is that . . ."

R*ecommendation*—"I recommend that you . . ."

R*ead back*—"To repeat the information and . . ."

For additional information about SBAR, see Clinical Insight 21-3.

Include the Following Content:

In a handoff report:

- Patient's name, age, and room number
- Patient's admitting diagnosis—one or several may exist.
- Patient's relevant past medical history
- Treatments the patient has received during this admission, such as surgery, line placements, breathing treatments
- Upcoming diagnostic tests, surgeries, or treatments
- Patient restrictions, such as diet, bed rest, isolation, activity limits
- Plan of care, such as IV therapy, pain management, current medications, wound care, and patient or family concerns
- Significant assessment findings from the previous shifts

In a transfer report:

- Your name, facility, and phone number
- Patient's name, age, gender, and admitting and current diagnoses
- Patient's physician(s), if still following patient
- Procedures or surgeries performed
- Current medications and last date/time each was taken/time next dose is due
- Patient status at present as well as progression since admission
- Last set of vital signs, plus any pertinent trends since admission
- Tubes in the patient, such as IVs, catheters, drainage tubes, along with the intake and output of each tube or drain
- Presence of wounds or open areas of the skin plus current interventions for each
- Names and contact numbers for family and significant others
- Special directives, such as code status, presence of advanced directives, preferred intensity of care, or isolation required
- Reason the patient is being transferred
- Location of above information (on transfer form, in medical records, etc.)

When Your Report Is Finished:

- Ask the receiving nurse whether he has any questions.
- Get the nurse's full name, and then record it plus the transfer date and time in your transfer documentation.

Practice Resources

Children's Hospital of Wisconsin (n.d.); Grbach, W., Vincent, L., & Struth, D. (2008); Haig, K., Sutton, S., & Whittington, J. (2006); Kaiser Permanente of Colorado (updated 2011); Schroeder, M. (2011); Schroeder, S. (2006).

Clinical Insight 18-2 ➤ Receiving Telephone and Verbal Orders

You should accept verbal and telephone orders only in specific situations when the primary care provider is not able to write or enter the orders personally.

- **Have a second nurse listen to the order**, if possible, to verify its accuracy.
- **Write or enter the order electronically only if you heard it yourself**; no third-party involvement is acceptable.
- **Repeat the written order** even if you believe you have clearly understood it.
- **Spell unfamiliar names** when repeating to be sure the spelling is correct.
- **Pronounce digits of numbers separately.** For example, instead of "seventeen," say "one, seven." Mishearing a number can lead to a serious error in medication dosage.
- **Make sure the order makes sense** given the patient's current status.
- **Transcribe the order directly into the chart as quickly as possible.** Writing it on a piece of paper, then copying it again onto a paper order sheet introduces an additional chance of error. If entering the order electronically, it's best to have the EHR's order entry area open and begin entering the order as the prescriber is dictating it to you.
- **Write the order while the prescriber remains on the telephone or in the building** so that you can ask any necessary questions immediately without the need for a return call.
- **When writing the order on a paper order sheet, first document the date and time.** Next write the text of the order. Following the text of the order, depending on how you received the order, write "TO" (telephone order) or "VO" (verbal order) followed by the ordering provider's name and then your name. The following is an example of a telephone order:

  12/17/16 0815 Morphine 2 mg IV push 1 for pain now. ——————
  TO Dr. Clayton Kent/Sarah Hogan, RN; order read back for verification and validated. ——————

- **Sign electronically to activate the order.** If entering the order electronically, indicate during order entry that the order was given verbally or over the telephone, the date and time the order was given, and then search for and select the ordering provider's name. Click "sign" or whatever option in your EHR indicates the order is signed and is now active.
- **Be sure you have the provider's phone number** so that you can reach her if future questions arise.
- **All verbal and telephone orders must be countersigned** by the physician, physician assistant, or nurse practitioner within 24 hours.

Practice Resources

The Joint Commission (2008).

Clinical Insight 18-3 ➤ Guidelines for Documentation

When to Document

Guideline	How to Apply	Rationale or Example
Documentation begins at the start of your shift.	■ *Hospital or long-term care facility*—start of shift ■ *Home visit or outpatient facility*—when you first encounter the client ■ Document the condition of your patient when you first observed him. Was he awake? Was he in bed? Did he have any complaints? What did you do?	
Document immediately.	Discipline yourself to document as soon as possible after making an observation or providing care.	The longer you wait, the more likely you will forget important details.
Never chart ahead.	Never chart before performing an intervention.	It is impossible to see into the future and be sure that what you expect to happen will actually happen. To do this threatens the record's credibility.

Clinical Insight 18-3 ➤ Guidelines for Documentation *(continued)*

Guideline	How to Apply	Rationale or Example
Avoid "block" charting.	Each entry needs to be made individually; record the time each was done	Do not chart an entry time as "From 1300 to 1500."
Chart chronologically.	■ *On paper:* Document times in chronological order. ■ *EHRs:* Most automatically insert the current date and time when forms are opened. Follow the documentation system's guidelines for changing those dates and times before signing.	Chronological charting communicates the changing status of the patient.
Designate late entries (paper).	■ If you forget to make an important entry while charting, you will later need to add "late entry" to the first available line. ■ Record the time and date you are making the addition; clearly designate it is a late entry. ■ If you know legal action is pending, do not place a late note in the health record without notifying the nurse manager or risk management officer first.	■ Late entry example: 5/11/16, 1400; late entry for 5/11/16, 1200 ■ It is a criminal offense to alter a patient record after the organization's approved time limit for doing so has passed.
Designate late entries (EHR).	■ Open the appropriate form and change the automatically generated current date/time to the date/time your care was actually done; then sign. ■ Follow the agency policy regarding the time period for making a late entry.	
	What to Document	
Questions to aid your recall.	As your shift or visit progresses, you will perform assessments and nursing interventions. To remind yourself what to record, ask yourself these example questions.	■ What were your assessment findings? ■ Did any abnormalities exist? ■ What was the patient's response to your intervention? Did any changes occur from the initial assessment?
Interventions, patient responses, and evaluation of progress toward goals.	■ These are often recorded on an IPOC. ■ Clearly describe what your patient is experiencing. ■ **Key Point:** *Do not chart a symptom without also documenting what you did about it and how the patient responded.*	(Symptom) Pt complained of pain, rated 6 on a 0–10 scale. (Intervention) Administered Tylenol 1,000 mg, by mouth, at 0900. At 1030, pt rated pain as 3.
Significant events or changes in condition.	When possible, quote the patient's interpretation of the event or change.	Quoting the patient directly gives all healthcare providers objective data.
Informed consent.	■ If you are asked to obtain informed consent for a procedure, document your actions. ■ In most states, your signature (paper or electronic) confirms only that the patient signed the consent. ■ For further discussion of informed consent, see Chapters 44 and 45.	The primary provider conducting the procedure is legally responsible for discussing the procedure and its risks and benefits.

(Continued)

Clinical Insight 18-3 ➤ Guidelines for Documentation *(continued)*

Guideline	*How to Apply*	*Rationale or Example*
Patient teaching.	■ Include instruction about medications and patient diagnoses. ■ Include discharge teaching. ■ If the patient's physical or cognitive condition prevents teaching, explain that in your documentation.	Documenting patient teaching can positively affect insurance and other payments to the institution.
Spiritual or other concerns expressed by the patient and/or family.	Document your interventions.	Addressing spiritual concerns ensures that the patient receives holistic healthcare.
Attempts made to contact the primary care provider.	■ Contacts may, for example, be to notify the provider of the patient's condition, or to clarify orders. ■ If you are unable to contact the primary provider, document your contacts with your charge nurse, nurse manager, supervisor, medical director, and hospital administrator.	You must indicate that you made every effort to communicate your concerns.
Patient leaving the facility against medical advice. (AMA)	■ Chart the patient's condition, any explanations of risks and consequences given to the patient, the patient's destination (if known), and your notification of the patient's care providers. ■ If your facility has specific forms for AMA departures, use the designated form. ■ If the form is hard-copy paper, have the patient sign the form before leaving. ■ If the patient refuses to sign, note this in your chart.	Your actions and responsibilities in the situation must be made clear in the record.
Patient's refusal of treatment.	■ Try to determine the reason for refusal. ■ Quote the exact language the patient used in this situation whenever possible.	Helps ensure charting facts instead of inferences.
Use of restraints.	■ Most facilities have a separate form that allows you to document the reason for restraint use, the type of restraint, and frequent checks of the patient. ■ You must have contacted the primary care provider.	■ The primary care provider must place a signed order for restraints in the chart or in the EHR. ■ Restraint orders must be reordered inside a specific time frame set by the organization or the restraints are discontinued (see Chapter 24).
"Occurrences."	■ Chart your findings accurately and objectively. ■ Fill out a separate occurrence form and send to the risk manager (paper forms). ■ Do not make reference to the occurrence form anywhere in your charting.	■ Examples of occurrences: falls and medication errors. ■ Occurrence forms are not part of the client's health record. See **Occurrence Reports** in Volume 1.

Clinical Insight 18-3 ➤ Guidelines for Documentation *(continued)*

Guideline / *How to Apply* / *Rationale or Example*

Complete data about medications.

- *Paper MAR*—Include the date, time, and medication given, and your initials.
- *Electronic MAR*—Ensure your entry is accurate, then sign electronically that administration was accomplished successfully.

Accurate documentation is an essential component of the nurse's role.

prn, unscheduled, IV infusions,and STAT medications.

- Record on the MAR.
- Include comments regarding the medication in your narrative charting or insert a comment in your electronic charting.
- Chart a timely evaluation of patient's response to the medication.

Certain prn medications require a follow-up response be documented within a specific period of time set by the organization, usually 15 to 30 minutes after the medication is given.

Medications not administered.

- Document omission on the MAR.
- If the patient states a reason for refusing the medication:
  Paper notes—Quote the patient in your narrative notes.
  Electronic MAR—Use pull-down or other menu.

- *Examples:* Patient refuses medication; dose accidentally omitted.
- Most electronic MARs include an explain with a selection from a drop-down list such as "Patient refused" or "Patient not available."
- Some MARs also contain a narrative section to type a comment about why a medication was not given.

How to Document

Know your organization's requirements for reimbursement.

- Requirements typically specify frequency of charting and the type of data that must be recorded.
- Fulfilling documentation requirements helps to ensure appropriate reimbursement.
- Home care, hospitals, clinics, office settings and long-term care facilities have specific guidelines for documentation necessary for payment.

Date and time all your documentation.

- Most organizations use a 24-hour clock or military time to avoid confusion between a.m. and p.m.
- For detailed guidelines for converting a 12-hour clock to military time (24-hour clock),

Go to **Tables, Boxes, Figures: ESG Box 18-1,** on Davis*Plus*.

- The day begins at 0001 (1 minute past midnight) and ends at 2400 (12 midnight).
- *Morning hours*—Most people have little difficulty with early morning hours. Example: 9:00 a.m. is 0900.
- *Hours after 12 noon*—To convert to military time after 12 noon, simply add 12 to the clock time.
  Example: 7:30 p.m. + 12 = 1930 in military time.

Many healthcare facilities use the 24-hour clock.

(Continued)

Clinical Insight 18-3 ➤ Guidelines for Documentation *(continued)*

Guideline	*How to Apply*	*Rationale or Example*
Document accurately and objectively, using nonjudgmental language.	■ Avoid labeling patients or team members. ■ Do not chart judgments about decisions made by members of the care team. ■ Document objective facts, so the reader can draw an informed conclusion. ■ Quote the patient in his own words, when possible.	■ *Chart:* "Pt says, 'I'm not taking that medicine. Take it away." ■ *Do not chart:* "Patient obnoxious and refuses prescribed medication."
Avoid vague, subjective words.	■ When possible, give specific examples.	■ Terms such as *good*, *average*, or *normal* do not clearly define the status of the client. ■ Descriptive details allow caregivers to better understand your patient's individual needs.
Use only the abbreviations authorized by your organization.	See Tables, Abbreviations Commonly Used in Health Care, following.	
Use correct spelling and grammar.	Incorrect spelling may raise questions about what you are attempting to communicate. Incorrect grammar implies carelessness on your part and creates a question of your competence if your chart is reviewed.	
Chart your own nursing actions.	Do not allow anyone to chart for you; do not document the actions of others as though you had performed them.	Each nurse is responsible for documenting his assessments, interventions, and evaluations. A deviation from this principle can imply coverup, carelessness, or a blatant disregard of policy and standards of practice.
You may need to document the actions of someone else.	■ Try to avoid this, but if you must do it, be sure to designate clearly whose actions they are. ■ *EHRs*—You can indicate another person performed the action in an added comment, or by searching for and selecting the other care provider in the appropriate field, then signing.	For example, if the NAP (nursing assistive personnel) helps the patient ambulate: *Do not chart:* "Patient assisted to bathroom." *Do chart:* "J. Scott, NAP, assisted patient to bathroom."
Avoid charting what someone else said, heard, felt, or smelled.	■ If the information is critical and you *must* chart it, use quotations and attribute the remarks to the person who made them.	*Example:* "Wife stated, 'My husband told me that he is in a lot of pain, but does not want to bother the nurses.'"

TABLES

Abbreviations Commonly Used in Healthcare

ABBREVIATION	MEANING	ABBREVIATION	MEANING
ADL	Activities of daily living	GI	Gastrointestinal

CLINICAL REASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Ellen is 85 years old and has sustained a right-sided cerebrovascular accident (CVA, stroke, or brain attack). Doctors say she is unlikely to regain much physical function, if she even awakens from the coma. Her children, Mary and Dale, have met with the physician, who tells them that Ellen is not likely to survive. The physician wants to insert a feeding tube and has asked whether they want Ellen to be resuscitated in case of cardiac or respiratory arrest. Mary tells you she wants to do what is best for her mother, but she feels that Ellen would not want to be kept alive in the condition she is in. She is also concerned about putting her through uncomfortable procedures if there is no chance of recovery. Her brother, Dale, says, "Mom needs the feeding tube. I can't sit and watch her starve to death. As long as she's alive, there's hope."

THINKING

1. *Theoretical Knowledge (Recall of Facts and Principles):* You plan to use the Focus Charting® format to document this interaction.
   a. Write the focus for this note.
   b. What does the acronym DAR stand for?
2. *Critical Thinking (Contextual Awareness):*
   a. What aspects of this situation have you experienced or observed before in your role as a caregiver?
   b. How might those past experiences affect your perception in this situation?

DOING

3. *Practical Knowledge (Handoff Report):* Ellen's last name is Smith; assume her children are also named Smith. Ellen is in room 820. Using the PACE format, what would you say to the oncoming nurse during handoff report? You will be able to address only a small amount of physiological information because the scenario does not provide it.

CARING

4. *Self-Knowledge:* In what way(s) can you identify with any of the people involved?

Critical Thinking and Clinical Reasoning

1. You are caring for a 96-year-old patient, James Wilson. Mr. Wilson has been admitted to the hospital for pneumonia. He is normally alert and oriented to place, time, and person. However, during this admission he has become confused and agitated. He frequently yells at staff and resists care by kicking and hitting. While you are providing morning care, Mr. Wilson becomes very agitated and yells and curses at you. When you attempt to provide oral hygiene, he throws his dentures at you. The dentures break when they hit the floor.
   a. Construct a nurse's note about this situation using the paper charting format you prefer.
   b. You will need to complete an occurrence report regarding the broken dentures. The report asks you to identify actions that you might have taken to prevent this incident. Brainstorm this question with your peers. Identify one or two actions that might have prevented this incident.
2. The primary care provider has written an order on your patient's paper chart that you find illegible. A veteran nurse states that she can read it, and she translates it for you. What factors should you consider before determining how to proceed?
3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or documenting and reporting. Consider both paper and electronic documentation in each. Note that these are *not* to be merely definitions.

   Narrative charting
   SOAP(IER) charting
   Nursing admission form
   Medication administration record
   Occurrence report
   Flowsheets
   Charting by exception
   Signing documentation forms
   Handoff report
   Late entry

What Are the Main Points in This Chapter?

- The client record is a collection of documents that form a legal record of the client's healthcare experience.
- The client record is used by health professionals to communicate about the client's care, to legally document the care delivered to the client and the client's responses to that delivered care, to document care for reimbursement, to educate students, to determine whether care is adequate, as a data source for health research, and as the basis for determining the cost of care.
- In source-oriented records, members of each discipline record findings in a separately labeled section.
- In problem-oriented records, members of each discipline chart on shared notes, and the record is organized around a problem list.
- In electronic health records (EHRs), members of each discipline all chart inside the same EHR. The EHR can be organized as source-oriented, problem-oriented, or a combination of the two.
- The EHR can be accessed by many members of the healthcare team at the same time.
- In narrative charting, the writer tells the story of what has occurred in a chronological format.
- SOAP(IER) is an acronym for Subjective data, Objective data, Assessment, Plan (and Intervention, Evaluation, and Revision). This format may be used to address a single problem or to document summative notes on a patient.
- In Focus Charting®, data is entered in a Data–Action–Response (DAR) format.
- Charting by Exception (CBE) utilizes pre-printed or electronic flowsheets to document most aspects of care. CBE assumes that unless a separate entry is made—an exception—all standards have been met and the patient has responded as expected.
- Paper and electronic flowsheets and graphic records are used to record recurring assessments, such as vital signs, intake and output, weight, hygiene, and ADLs.
- Paper progress notes are used to document the patient's responses to care. They may be in the form of narrative, SOAP(IER), PIE, or Focus-style notes.
- A discharge summary should be completed when the patient is discharged from the organization. A transfer form should be completed when the patient is transferred within the organization.
- An occurrence report, or incident report, is a formal record of an unusual occurrence or accident that is not part of the patient's chart.
- The most commonly used paper and electronic home health documentation form is OASIS, a federally required form that includes history, assessment, demographics, and information about the client's and caregiver's abilities.
- Federal law requires that a resident in long-term care be evaluated using the Minimum Data Set for Resident Assessment and Care Screening (MDS) within 4 days of admission. The MDS must be updated every 3 months and with any significant change in client condition.
- The handoff report is designed to alert the next nurse about the client's status, changes in the client condition, planned activities, tests or procedures, or concerns that require follow-up.
- A consistent, structured (standardized) format should be used in handoff reports that contain critical key items to minimize miscommunication and other errors.
- Nurses should not take verbal and telephone orders unless the ordering provider is in a situation in which the order can't be written or entered or the patient is in a life-threatening situation.
- Telephone orders offer more room for error because of unfamiliar terminology and differences in background noise.
- Charting should be accurate and nonjudgmental.
- You should document as soon as possible after you make an observation or provide care.
- You should never share your electronic username or password with someone else.
- Document any significant events or changes in condition, teaching performed, use of restraints, and patient refusal of treatment or medications.
- You are responsible for documenting the care you provided. Never chart the actions of others as though you had performed them.
- If you believe a provider's order is inappropriate or unsafe, you are legally and ethically required to question the order.

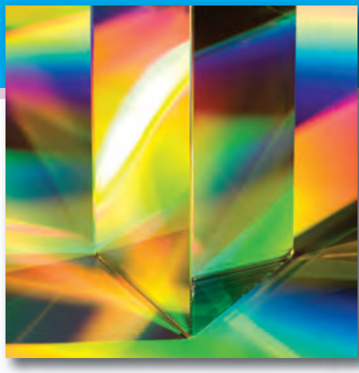
CHAPTER 19



Teaching & Learning

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

Caring for the Nguyens

Nam Nguyen has medical diagnoses including hypertension, type 2 diabetes mellitus, obesity, and osteoarthritis. There is a positive history of tobacco abuse. Based on the information you know about Nam and his family, consider the following questions.

A. What kinds of information does Nam probably need?

B. What would be the best approach to teach Nam about his healthcare conditions?

C. You have been asked to teach Nam about weight loss. What theoretical knowledge must you have, and where can you obtain it?

D. What patient information do you need to know before planning your teaching?

E. Nam tells you that he feels overwhelmed with his recent diagnoses. He does not believe he can begin a weight-loss program or attend any teaching sessions. How might you handle this concern?

F. Nam has been prescribed the following medicines. Devise one or more teaching sessions focused on these medications. You will need to use your pharmacology reference books to devise this plan. As you plan your teaching, recall that Nam is overwhelmed by his recent diagnoses.

Lisinopril 20 mg PO daily
Hydrochlorothiazide 25 mg PO daily
Metformin 500 mg PO bid

Practical Knowledge knowing how

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Learning Assessment Guidelines

Pre-assessment

Before assessing the learner, think about the following:

- ***Time constraints.*** How much information do you need to present? How much time do you have to do it?
- ***Available resources.*** What equipment and supplies do you have to work with? Do you have access to the Internet? Audiovisual and projection equipment? A whiteboard? A scanner? Books? Do learners have mobile devices with downloaded applications for interactive classroom learning?

Assessing the Learner

You can assess the learner in several ways: through informal conversations, structured interviews, interviews, questionnaires, tests, observations, and information obtained from the client's chart. You will pick up many cues in your initial comprehensive assessment of the client. A teaching/learning assessment should include the following:

- ***Intended audience.*** Who are you teaching? What is the person's age, occupation, developmental level, and cultural affiliation? Will you be teaching a person or a group?
- ***Learning needs.*** The client's need for information is based on actual or anticipated healthcare or developmental needs. What is the client's health (or other) problem? What behavioral changes are needed? What self-care knowledge and skills does the client need?
- ***Client's knowledge level.*** Determine what the client already knows so that you can reinforce accurate information, correct misinformation, and adapt the teaching plan to the client's learning needs. Ask questions such as: "What do you think caused or worsened your health problem? What are your concerns about it? How has the problem affected your usual activities? What are your concerns about treatment (tests, surgery, and so on)?"
- ***Health beliefs and practices.*** Teaching will not be effective unless it falls into the range of beliefs and practices that are acceptable to the client. People are unlikely to incorporate changes that do not fit into their value system. Ask the client to give a general description of her health. Ask: "What do you usually do to stay healthy? What problems do you think you are at risk for? What lifestyle changes would you be willing to make in order to improve your health?"
- ***Physical readiness.*** The client must have adequate concentration, manual dexterity skills, and minimal pain to be able to listen and learn.
- ***Emotional readiness.*** Find out whether the client is experiencing anxiety or emotional distress that will interfere with the learning process. Also ask the client whether she would like a family member or friend to be present during the learning.
- ***Ability to learn.*** What are the learner's cognitive and psychomotor developmental level and ability? How does the client learn best (e.g., by memorization or recall, or by problem-solving or applying information)? How well does the client recall previously presented material?
- ***Health literacy level.*** Does the patient have the ability to understand basic health information and services needed to make appropriate healthcare decisions? Is the information the healthcare provider offers in the patient's primary language? Is the health teaching provided in a format the patient can understand? Is medical jargon or unnecessary technical information used? Can the person read and write?

  Adults who have low health literacy may react to learning situations by withdrawal, avoidance, or repeated noncompliance. They may claim that they were too tired, were too busy, or just didn't feel like reading. They may also ask you to read to them with the excuse that their eyes are tired, they are not interested, or they have no energy. They may fail to ask questions or ask for clarification.
- ***Neurosensory factors.*** What is the client's ability to feel, see, hear, and grasp? Does the client have a medical condition that causes neurosensory compromise?
- ***Learning styles.*** Ask the person: "How do you prefer to learn new things? For example, do you prefer to read about them, talk about them, watch a video, be shown how to do it, listen to the teacher, or use a computer? Do you like to read? Where do you get information about your health—online, from books, magazines, your family, your healthcare provider? Do you learn best alone or with other people?"

CLINICAL REASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Katrina Peplowsi is a 22-year-old college student from Ukraine who is transported to the emergency department of a local hospital after passing out in her dorm room. Katrina had been sick with a viral illness and she had a fever for 5 days with nausea, vomiting, and diarrhea. She had been drinking large amounts of Gatorade because of her insatiable thirst, thought to be related to the fever and vomiting. Before the illness, Katrina's friends and family had been commenting about her remarkable weight loss since she started school 2 months earlier in spite of her increased appetite. On arrival to the emergency department, Katrina's blood sugar is 585 mg/dL. She is diagnosed with diabetes mellitus, type 1. After her blood sugar is stabilized with fluid therapy and insulin infusion, Katrina regains consciousness. Although Katrina speaks some English, her proficiency is somewhat limited.

THINKING

1. *Theoretical Knowledge (Recall of Facts and Principles):* As your patient is newly diagnosed with diabetes mellitus, type 1, there are many areas in which Katrina will need healthcare education. List at least six important topics that are relevant to her care.
2. *Critical Thinking (Application of Knowledge):* What considerations do you make as you are devising a teaching plan for Katrina?
3. *Critical Thinking (Synthesis of Knowledge):* What factors would you consider important for customizing her teaching plan, considering the extent of her ability to communicate?

DOING

4. *Nursing Process (Assessment):* What are some pertinent personal factors that you should assess for Katrina when devising a teaching plan that is best suited to her learning needs?
5. *Nursing Process (Planning):* When setting up a teaching plan involving other members of the healthcare team, how would you plan to optimize Katrina's motivation to learn how to best manage her diabetes after discharge?

CARING

6. *Self-Knowledge:* What areas of commonality do you have with Katrina, around which you might form a caring relationship?
7. *Ethical Knowledge:* Suppose Katrina refuses to receive information from you about diabetes mellitus. She states she is not interested in knowing how to give herself insulin because she doesn't want to give herself injections at home. How should you best respond to Katrina's requests?

Critical Thinking and Clinical Reasoning

1. For the following Nursing Outcomes Classification (NOC) standardized outcomes (Moorhead, Johnson, & Maas, 2013), try to figure out which NANDA-I diagnoses might be linked to each outcome. Consult the NANDA-I handbook as necessary.
   Knowledge: Breastfeeding
   Knowledge: Child Physical Safety
   Knowledge: Diabetes Management
   Knowledge: Infant Care
   Knowledge: Disease Process
   Knowledge: Energy Conservation
   Knowledge: Health Behavior
   Knowledge: Healthy Diet
   Knowledge: Prescribed Activity
   Knowledge: Infection Management
2. Recall that Heather (Meet Your Patient in Volume 1) is a 20-year-old mother of a 4-year-old preschooler. They have come to a family practice clinic for a well-child checkup. You notice that the child speaks only in one- or two-word phrases. Heather is impatient with her and repeatedly tells her to "stop using that baby talk." Your nursing instructor tells you that you need to assess for teaching needs and provide anticipatory guidance to the mother regarding safety, nutrition, and normal preschooler growth and development.
   a. Heather says, "I don't know what I'm doing wrong. All her little friends are taller and talking more. She was even small when she was born, so I suppose it's my fault." How do you assess Heather's learning needs without reinforcing her feelings of self-blame?

   b. Your assessment shows that although the child is below the 5th percentile for height and weight, she has grown appropriately since her last clinic visit. What teaching could you provide that might help address her mother's learning needs related to childhood growth and development?
   c. In addition to information on growth and development, your anticipatory guidance should include safety measures and nutrition for a 4-year-old. How can you evaluate whether your teaching has been effective and further promote Heather's retention of all of this new information?
3. As a student, you have learned about discharge planning. Your instructor tells you that you need to begin teaching for discharge as soon as the client is admitted. You hear the nurses complaining that they just don't have time for any teaching. So where do you begin? You will need to use the teaching process for your assigned client.

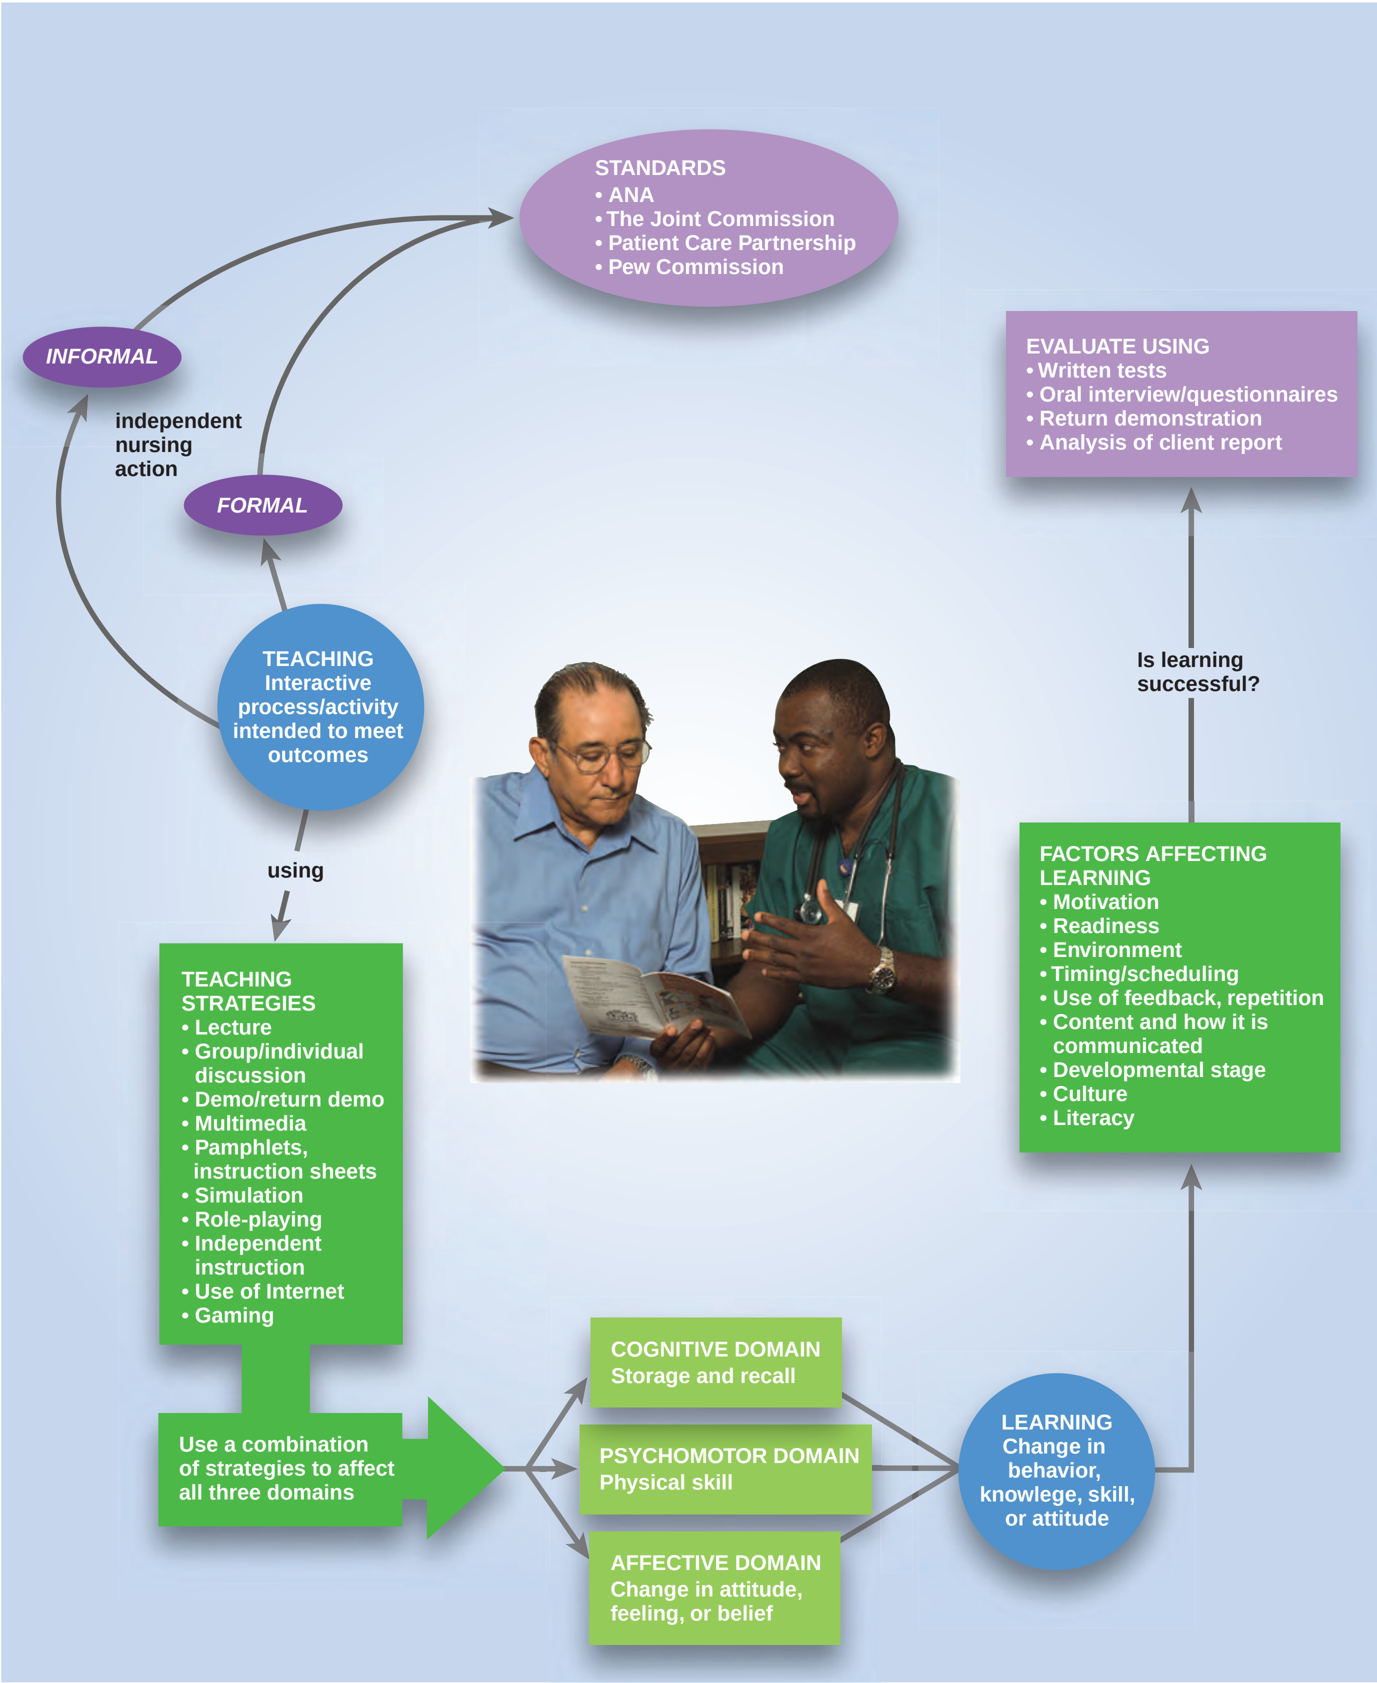
   Your client is a 9-year-old girl who is being admitted to the outpatient procedures unit for testing because of chronic recurrent urinary tract infections. Daily, she receives an antibiotic, methylphenidate (Ritalin) for attention deficit-hyperactivity disorder (ADHD), and an asthma inhaler for sports activities. She is accompanied by her mother and father, a younger sister, and her big, pink teddy bear. She is scheduled for x-ray studies and blood work. Depending on the results of her tests, she may require surgery or dilation of her ureters. The parents appear very anxious and tell you that their daughter "has a hard time understanding things and needs a lot of repetition." You have an hour to prepare her for the procedures and testing.
   a. Assessment
      (1) What information do you already have that will be significant for your teaching plan?
      (2) What other information will you need to gather?
   b. Diagnosis
      (1) What possible diagnoses are involved in this situation? Consider a diagnosis for your client and another one for at least one of her family members.
   c. Planning
      (1) What information will you present first?
      (2) What teaching techniques would you use for this situation?
      (3) Who would you include in the teaching?
      (4) Where would you complete the teaching?
   d. Goals and interventions
      (1) Write an appropriate goal for your client (the child). Remember to make the goal client-centered, timed, and realistic. You have only an hour to complete this teaching.
      (2) What content and methods would you include in your teaching plan?
      (3) How can you incorporate a stuffed teddy bear in your teaching?
   e. Evaluation
      (1) How would you determine whether your teaching was effective?
      (2) What further teaching do you need to continue to prepare your client for discharge?
4. For each of the following situations, determine which teaching techniques would be most effective.
   a. A group of adolescents with diabetes needs to plan for their prom. The after-prom party lasts until 6:00 a.m. and will interfere with their usual schedule for insulin administration. You need to help them decide how to manage this problem. They are all busy with after-school activities and attend three different schools.
   b. An 80-year-old man has experienced a cerebrovascular accident (CVA) (stroke) with right-sided weakness. He will need mobility training and assessment of his home situation for safety hazards. Currently he lives alone.
   c. A new mother must learn how to feed her infant, who has a cleft palate. She is in considerable pain after an emergency cesarean section and unexpected blood loss.
5. You are assigned to a client with a diagnosis that you are unfamiliar with. You are expected to prepare a teaching session for this client and family as well as for your classmates. How should you prepare for this assignment?
6. Give an example of teaching content you might need to present to a 58-year-old patient who has been diagnosed with hypertension. What chapters in this text (Volume 1) might be useful if you need theoretical knowledge about hypertension to answer this question? Where would you look to verify where this information is located?
7. Do you think it is appropriate for a nurse to offer personal experiences in the teaching process? Explain your thinking.
8. A client refuses to make eye contact during a teaching session. This makes it difficult for you to determine whether she is actually paying attention to what you are saying. How can you assess whether she is focused on the teaching session?

9. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or teaching clients. Note that these are *not* to be merely definitions.
Role of teaching in nursing practice
Principles of teaching and learning
Factors that affect the learning process
Factors that affect the teaching process
Timing
Choice of techniques
Relevance
Learning styles
Amount of information to be presented

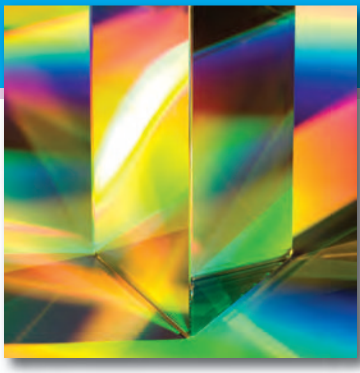
What Are the Main Points in This Chapter?

- Teaching is an essential component of professional nursing.
- Nurses do formal and informal teaching for individuals and groups.
- To be effective, teaching requires cooperation between the learner and the teacher.
- Learning is a change in behavior, knowledge, skills, or attitudes that occurs as a result of exposure to environmental stimuli.
- Bloom and Krathwohl (1956) identified three domains of learning: cognitive, psychomotor, and affective.
- Teaching includes motivating the learner.
- Teaching is interactive and requires communication.
- Readiness means that the learner is both motivated and able to learn at a specific time.
- Other factors that affect learning include emotions, timing, active involvement, feedback, repetition, environment, amount and complexity of the content, communication, developmental stage, culture, and literacy.
- Common barriers to teaching in the hospital setting include failure to see teaching as a priority and lack of time, preparation, space, privacy, poor coordination, and third-party reimbursement for teaching.
- Barriers to learning include illness, physical discomfort and fatigue, anxiety, low health literacy, environmental distraction, overwhelming amount of behavioral change needed, not enough time, lack of positive reinforcement, and feelings of discouragement.
- The teaching process is similar to the nursing process.
- The nursing diagnosis Deficient Knowledge may be the primary problem or the etiology of other problems; this diagnosis is often overused or used incorrectly.
- A teaching plan is similar to a nursing care plan, except that (1) interventions are actually teaching strategies and (2) the plan includes the content of the teaching, the sequencing of the content, and the materials to be used.
- Demonstration and return demonstration are the most effective strategies for teaching psychomotor skills.
- A certain amount of forgetting is normal. You can aid learner retention by using strategies that require learner participation and by providing printed materials to use at a later time.
- It is important to document specifically what teaching you did as well as your evaluation of the learning that occurred.

Knowledge Map



CHAPTER 20



Measuring Vital Signs

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 20, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Recall that on Nam Nguyen's preliminary visit to the Family Medicine Center, his blood pressure (BP) was 162/94 mm Hg. On subsequent visits, his BP was 168/100 and 174/96 and he was continuing to gain weight. Mr. Nguyen was diagnosed with hypertension and prescribed an antihypertension medication to be taken each morning. This morning Mr. Nguyen has come to the clinic for follow-up. The following information is gathered as he checks in for his visit.

VS: BP, 168/92; pulse, 80 beats/min; respirations, 20 breaths/min; temperature, 98.4°F (36.9°C)
Weight: 180 lb (82 kg)

Caring for the Nguyens (continued)

Review the preliminary data and the preceding information to answer the following questions:

A. What patterns do you see in the data?

B. Do you have enough information to draw any conclusions? If not, what other information should you gather?

C. Identify three alternatives that may explain what is happening with Mr. Nguyen's vital signs.

D. How could you determine which of these alternatives provides the best explanation of what is happening?

E. Why is it important to intervene in this situation?

PracticalKnowledge knowing how

Use the Procedures, Clinical Insights, and tables in this section when assessing your patients' vital signs.

PROCEDURES

Procedure 20-1 ■ Assessing Body Temperature

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Thermometer (An oral thermometer generally has a blue tip. A rectal thermometer generally has a red tip.)
- Glass-and-mercury thermometers should not be used in any healthcare setting, but because some people still use them at home, we include them in this procedure. They should be used with disposable covers, and cleaned and sterilized regularly according to the manufacturer's instructions.
- Thermometer cover, if needed
- Procedure gloves, if taking a rectal temperature or if there is risk of contact with body fluids (e.g., saliva)
- Water-soluble lubricant, if taking a rectal temperature
- Towel, if needed, for taking an axillary temperature (*to dry the axillae*)
- Tissues

Delegation

You can delegate temperature measurement to nursing assistive personnel (NAP) if you conclude that the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments that follow, and inform the NAP of the route and type of thermometer used. Explain any special considerations (e.g., tell the NAP if the patient had food or oral fluids in the last 20 to 30 minutes; inform the NAP if the patient is confused). Ask the NAP to record and report the temperature to you, and to report immediately if the temperature is elevated (e.g., greater than 100°F [37.8°C]).

(continued on next page)

Procedure 20-1 ■ Assessing Body Temperature (continued)

Pre-Procedure Assessments

- Determine the site that is most appropriate for the patient. Consider patient comfort, safety, and accuracy. For example, do not use the oral route for patients who are unable to hold the thermometer properly, for children or others who cannot follow instructions (e.g., unconscious patients), or for patients who use "mouth breathing."
- For an oral temperature: Determine how long it has been since the patient smoked, had anything to eat or drink, or chewed gum.
  Smoking, eating, drinking, and chewing gum can all affect an oral reading. If any of these have occurred, wait 20 to 30 minutes before taking an oral temperature.
- Assess for any contraindications to using the site you have chosen. For example:
  Tympanic: Assess for impacted earwax or hearing aid.
  Rectal: Check the client record for diarrhea or impacted stool.
  Axillary: Check the client record for presence of fever or hypothermia.
  Skin: Assess for the presence of conditions that require a very precise, reliable reading (e.g., fever, hypothermia).
  Some conditions increase the risk for patient injury; others contribute to inaccurate, unreliable temperature measurement.
- What were the previous recordings, if any?
  Noting changes over time is important in all patient assessments.
- Assess for clinical signs and symptoms of temperature alterations.

Procedure 20-1A ■ Taking an Axillary Temperature

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Slide the thermometer into a** protective sheath (depending on type of thermometer).
   A protective sheath provides a barrier to prevent transmission of organisms.
2. **Dry the patient's axilla,** as needed.
   Moisture from perspiration alters the temperature reading.
3. **Position the patient** and the thermometer.
   a. Assist the patient to a supine or sitting position.
   b. Place the thermometer tip in the middle of the axilla.
   c. Position the patient's upper arm down, with the lower arm across the chest.
   Puts the thermometer in close proximity to the axillary blood vessels, allowing it to better reflect the core temperature. ▼

4. **Hold the thermometer in place** for the recommended time.
   a. Leave an electronic probe in place until it beeps.
   b. Leave a glass or plastic thermometer in place for 8 minutes, or according to agency policy (usually 5 minutes for children).
   Study findings differ for accuracy of temperature measurements at the axillary site. Follow agency policy.
5. **Remove the thermometer** and discard the thermometer cover. If there is no cover, wipe the thermometer with a tissue.
   Removes any moisture that may have accumulated in 8 minutes' time.
6. **Read the temperature.**
   a. Electronic thermometer: Read the digital display.
   b. Glass or plastic thermometer: Hold at eye level, and rotate it until the markings are clear.
7. **Clean and replace the thermometer** in the storage base, following agency policy.
   Prevents microbial growth on thermometers and recharges the battery.

Procedure 20-1B ■ Taking an Oral Temperature

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **For a glass or plastic thermometer,** shake down the liquid if necessary. Use a glass thermometer only if you must.
   a. Stand in an open area away from tables and other objects.
   Prevents thermometer breakage.
   b. Hold the end opposite the bulb between your thumb and forefinger, and snap your wrist downward.
   c. Shake the thermometer until the reading is less than 96°F (36°C).
   The reading must be lower than the anticipated temperature measurement.
2. **Slide the thermometer into** a protective sheath.
   Provides a barrier to prevent transmission of microorganisms.

3. **Place the thermometer tip** under the tongue in the posterior sublingual pocket (right or left of frenulum).
Puts the tip in close proximity to the major blood vessels under the tongue, allowing the thermometer to reflect the core temperature.

4. **Have the patient close her lips** around the thermometer, cautioning her not to bite down on it.
Protects the thermometer from exposure to the air, which could alter the reading. Biting may break a glass thermometer, injuring the mouth.

5. **Leave the thermometer in place** for the recommended time.
   a. Glass or plastic thermometer: 5 to 8 minutes
   b. Electronic (digital) thermometer: Until it beeps
   c. According to agency policy
   Research findings differ on the optimal time for measuring an oral temperature, so follow agency policy.

6. **Remove the thermometer;** discard the cover. If there is no cover, wipe the thermometer with a tissue.
Wiping removes mucus that can make the markings on a glass or plastic thermometer difficult to read.

7. **Read the temperature.**
   a. Glass or plastic thermometer: Position the thermometer at eye level, and rotate it until the markings are clear.

   b. Electronic thermometer: Read the digital display.

8. **Clean and replace the thermometer.** Follow agency policy.
Prevents microbial growth on thermometers and recharges battery of electronic thermometers.

Procedure 20-1C ■ Taking a Rectal Temperature

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure primarily describes use of an electronic (digital) thermometer.

Procedure Steps

1. **Slide the thermometer into** a protective sheath.
A protective sheath provides a barrier to prevent transmission of microorganisms.

2. **Position an adult patient** in Sims' position (on the side with the knees flexed); place a child in the prone position. Drape the patient so that only the anal area is exposed.

Procedure Variation for a Small Child
You can lay the child face down across your lap or a parent's lap.
Flexing the knees helps relax the muscles to ease insertion and aid in visualization. Draping provides privacy and decreases embarrassment.

3. **Lubricate the tip** of the thermometer by squeezing water-soluble lubricant onto a tissue and then applying it to the thermometer.
Prevents injury to the rectal mucosa and eases insertion. Inserting the thermometer into the lubricant container would contaminate contents of the container.

4. **Don a procedure glove** on your dominant hand, or on both hands if necessary.

5. **With your nondominant hand,** separate the patient's buttocks to visualize the anus.

6. **Gently insert** the thermometer approximately:
Adult: 1 to 1.5 in. (2.5 to 3.7 cm)
Child: 0.9 in. (2.5 cm)
Infant: 0.5 in. (1.5 cm)
The thermometer must be placed past the rectal sphincter.
   a. Have the patient take a deep breath. Insert the thermometer as he exhales.
   Taking a deep breath helps relax the anal sphincter.
   b. If you feel resistance, do not use force.
   Inserting the thermometer too far or forcing against resistance may injure the rectal mucosa.

7. **Hold the thermometer in place** until it beeps. (For a glass thermometer, hold the thermometer 3 to 5 minutes. Avoid using a glass thermometer when at all possible.)
The thermometer must be held in place to prevent inadvertent injury to the patient. An electronic thermometer will beep when a constant temperature is reached. Research differs on the optimal time for measuring a rectal temperature, so follow agency policy.

(continued on next page)

Procedure 20-1 ■ Assessing Body Temperature (continued)

8. **Remove the thermometer**, discard the cover, and read the digital display.

9. **Remove the procedure glove(s)** and discard in a biohazards container.

10. **Follow agency policy** for cleaning and storing thermometers.

Prevents microbial growth on thermometers and recharges electronic thermometer battery.

Procedure 20-1D ■ Taking a Temporal Artery Temperature

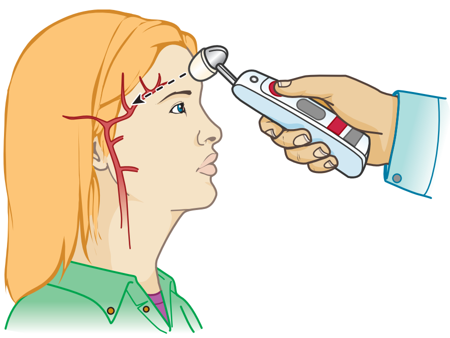
➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

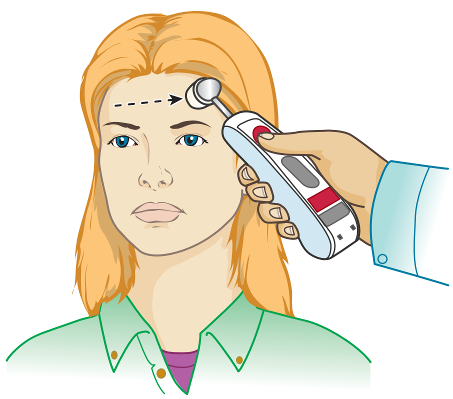
NOTE: If the patient has been lying down, do not measure the temperature on the side that was lying on the pillow. Do not measure if a cap or hair has been covering the area over the temporal artery.
These can prevent heat dissipation and produce a falsely high reading.

1. **Remove the protective cap** from the instrument; clean the lens/probe according to the manufacturer's instructions.

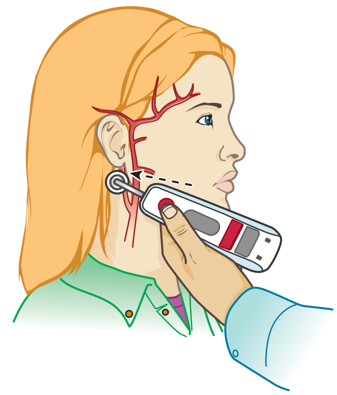
2. **Place the probe flat** on the center of the forehead, midway between the eyebrow and the hairline. ▼



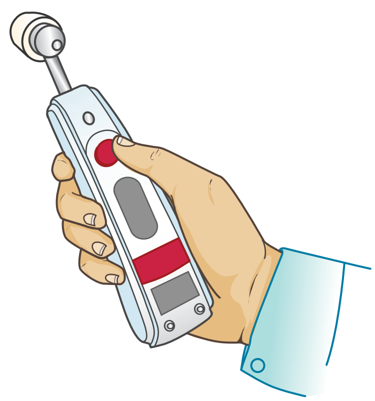
3. **Press and hold the button** while you stroke the thermometer medially to laterally across the forehead; keep the lens/probe flat and in contact with the skin, and slide in a reasonably straight line until you reach the hairline. ▼



4. **Still holding the button,** touch the thermometer lens/probe behind the ear lobe, in the soft depression below the mastoid.
This step is necessary for an accurate reading if there is any moisture at all on the patient's forehead. ➤



5. **Release the button for** the temperature reading. ▼



Procedure 20-1E ■ Taking a Tympanic Membrane Temperature

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

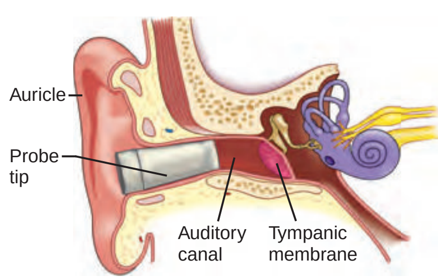
Procedure Steps

1. **Make sure the thermometer** lens is intact and clean.
Ensures an accurate reading.

2. **Place a disposable cover tightly** over the lens, making sure the clear film is smooth across the lens.
Ensures an accurate reading and prevents cross-contamination.

3. **Position the patient's head** to one side. If you are right-handed try to use the right ear; if you are left-handed, use the left ear.
This allows you to better visualize the ear canal.

4. **Straighten the ear canal,** or follow the manufacturer's instructions. As a rule: ➤



a. For an adult, pull the pinna up and back.

b. For a child, pull the pinna down and back.

Some tympanic thermometers require you to straighten the ear canal; others do not. Some instruct, for adults, to pull the ear up, backward, and slightly away from the head. Some models instruct, for a child, to pull the pinna straight back instead of down and back. The external auditory canal is curved upward in children younger than 3 years of age. In an adult, it is a slightly S-shaped structure.

5. **Insert the probe into the ear** canal gently and firmly, directing it toward the tympanic membrane and inserting far enough to seal the opening.
   Creates a seal to obtain an accurate reading without causing trauma to the ear canal.

6. **Rotate the probe handle** towards the jaw (for some thermometer models). Follow the manufacturer's instructions; not all models require this.
   Aims the lens toward the tympanic membrane.

7. **Take the measurement.**
   a. Press and release the button to obtain the reading.
   b. Follow the instructions for the specific tympanic thermometer being used.
   Some tympanic thermometers record the reading immediately; for some you must wait for about 3 seconds.

8. **Remove the thermometer** when you hear a beep and the display flashes. Note the reading in the display window.

9. **Repeat the measurement** in the other ear.
   A study of 132 adults found significant differences in temperature in the left compared with the right ear. In addition, the left ear tended to register a lower temperature than the right ear at temperatures below 36.7°C (98.1°F) and a higher temperature above 36.7°C (Heusch & McCarthy, 2005) or when taken by a female (Helton & Carter, 2011).

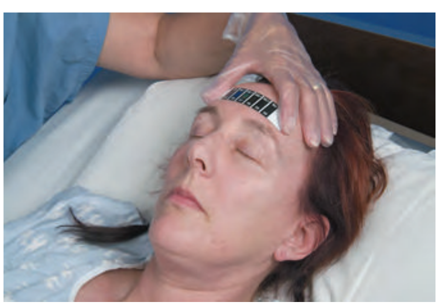
10. **Discard the probe cover** (usually you will press an "eject" button to do this), and replace the thermometer in its charging base.
    Recharges the battery and protects the instrument.

Procedure 20-1F ■ Taking a Skin Temperature Using a Chemical Strip Thermometer

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Place the thermometer strip** (paper or tape) on the patient's skin, generally on the forehead or abdomen.
   The thermometer strip must be in contact with the skin to work properly.



2. **Leave the thermometer strip** in place 15 to 60 seconds (or as the manufacturer directs).

3. **Observe for color changes.**
   Chemical strips have indicators that change colors to indicate temperature changes.

4. **Read the temperature before** removing the strip from the patient's skin.
   Ensures the most accurate reading.

5. **Remove and discard** the thermometer strip.

? What if . . .

- **The patient's temperature is not within normal range?**

  Identify whether the temperature reading indicates hypothermia, fever, or hyperthermia (e.g., heat stroke).
  Perform other assessments to determine the cause or severity of the findings.
  Assess for clinical signs to confirm an abnormal temperature reading.
  Institute interventions to raise or lower temperature, as appropriate.
  Provide comfort measures (e.g., change linens if they are wet from diaphoresis).

- **You are must use a glass thermometer?**

  Be sure the thermometer does not contain mercury.

- **Before and after using, shake down the thermometer as needed.**

- **Clean the thermometer** before and after using with soap and water or approved solution; rinse.

- **Use disposable covers, if available.**

- **When reading the thermometer,** hold it at eye level and rotate it until the markings are clear and easy to read.

  Handle carefully and store in an appropriate container to avoid breakage.

(continued on next page)

Procedure 20-1 ■ Assessing Body Temperature (continued)

Evaluation

- Compare to normal range for developmental stage, site used, and client's baseline data.
- Look for trends to identify potential concerns.
- Notify the appropriate healthcare provider of abnormal findings.

Patient Teaching

- Inform the patient of the temperature reading.
- Explain the significance of the temperature reading and any interventions that may be needed.

Home Care

- Clients commonly use chemical strip (disposable), glass, or tympanic membrane thermometers at home. Teach the following points:
- Do not use an oral thermometer to take a rectal temperature. Use a specially shaped, more rounded, rectal thermometer *to avoid injury to the rectum.*
- Do not use glass-and-mercury thermometers. If you discover a glass-and-mercury thermometer, or any kind of glass thermometer, urge the client to replace it with a safer instrument (e.g., a plastic thermometer). Arrange for an exchange if there is a procedure for this in your agency or community.

  Glass-and-mercury thermometers carry the risk of breakage, cuts, and exposure to toxic mercury.
- If you obtain a high or low reading using a chemical strip or a tympanic thermometer, retake the temperature using a plastic or digital thermometer.
- Teach the same procedures you have learned for measuring temperature. Observe as the client takes a temperature to ensure correct technique.
- Clients often use the oral site. Remind them to not drink, eat, or smoke for 30 minutes before taking the temperature.
- Reinforce the following points about care of reusable thermometers:
  - If you use the same thermometer for more than one person, use disposable covers, if possible; clean the thermometer well between uses.
  - If the person has an infection or communicable illness, soak the thermometer in 70% isopropyl alcohol between uses.
  - Clean the thermometer after each use, even if it is used for only one person. Wash with soap and water, rinse with cold water, dry well, and store in a clean, dry container.
  - If you store a thermometer in alcohol, rinse it with cold water before taking the temperature.
  - Do not use the same thermometer for both oral and rectal temperatures.

Documentation

You will usually record temperature on a graphic flowsheet (see Forms section). In some situations (e.g., a fever), you may need to write a nurse's note. If so, follow these suggestions:

- Document the temperature, indicating the route of measurement, according to agency policy.
- Notify the appropriate provider of abnormal findings.
- Document supporting findings, such as "Skin is hot and dry" and state whether the temperature reading is consistent with the client's condition.

Sample documentation

mm/dd/yyyy 1230 *Oral temperature 105°F; it has risen steadily since the first elevation at 0630, when it was 100°F. Skin hot and dry. Patient is voiding only small amounts, but states no burning. Urine dark but clear. No chills. I & O begun. Gave Tylenol 650 mg by mouth and notified Dr. Anderson of patient's condition and medication.* — Mary Clinton, RN

Practice Resources

Amoore, D. (2010); Heusch, A., & McCarthy, P. (2005); Lockwood, C., Conroy-Hiller, T., & Page, T. (2004); Quatrara, B., Coffman, J., Jenkins, T., et al. (2007); Rabinowitz, R., Cookson, S., Wasserman, S., et al. (1996); Robinson, J., Jou, H., & Spady, D. (2005); Therapeutic Research Center (2007); Vital Signs (1999).

Thinking About the Procedure

To practice applying clinical reasoning to these procedures,

Go to the *Davis's Nursing Skills Videos,* **Taking an Axillary Temperature, Taking an Oral Temperature, Taking a Rectal Temperature, Taking a Temporal Artery Temperature,** and **Taking a Tympanic Membrane Temperature.**

For questions and suggested responses,

Go to Chapter 20, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus.*

Procedure 20-2 ■ Assessing Peripheral Pulses

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Watch with a second hand or digital readout
- Pen, pencil, and flowsheet or personal digital assistant (PDA)

Delegation

You can delegate measurement of pulses to the nursing assistive personnel (NAP) if you conclude that the patient's condition and the NAP's skills allow. For example, if pedal circulation is critical and you suspect it may be difficult to palpate, you should not delegate assessment of the pedal pulse. If you do delegate, perform the pre-procedure assessments and tell the NAP which site (e.g., radial, brachial) to use. Inform the NAP of any special considerations (e.g., to note what the patient's activity has been just before taking the pulse). Ask the NAP to record and report the pulse to you and to report immediately if it is outside normal limits (you must specify what is "normal" for each patient).

Pre-Procedure Assessments

- Determine why assessment of pulses is indicated.
  Conditions requiring an assessment of pulses include blood loss, cardiac or respiratory disease, diabetes mellitus, and other conditions that affect oxygenation.
- Assess factors that may alter the pulse, such as activity and medications. If the client has been active recently, wait 5 to 10 minutes before measuring.
  Activity increases the pulse rate; increased intracranial pressure decreases the rate; medications such as digoxin decrease the rate; other medications, such as albuterol, increase the pulse rate.

Procedure 20-2A ■ Assessing the Radial Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **With the patient sitting or supine,** flex the patient's arm, and place the patient's forearm across his chest.
2. **Palpate the radial artery.**
   The radial site is the most frequently used to calculate the patient's heart rate because it is generally the easiest site to use.
   a. Place the pads of your index or middle fingers (or both) in the groove on the thumb side of the patient's wrist, over the radial artery.
   b. Press lightly but firmly until you are able to feel the radial pulse. Start with light pressure to prevent occluding the pulse, and gradually increase the pressure until you feel the pulse.
   The fingertips are the most sensitive parts of the hand to palpate arterial pulsations. Avoid using the thumb, because it has its own pulsation and may interfere with the accuracy of your count. ➤

3. **Note the rhythm and quality** of the pulse. Note whether the thrust of the pulse against your fingertips is bounding, strong, weak, or thready.
   The rhythm and quality of the pulse are a reflection of the patient's cardiac output. The strength of the pulse reflects the volume of the blood that is ejected against the arterial wall with each contraction of the heart. An irregular or weak pulse indicates decreased cardiac output. A bounding pulse indicates increased cardiac output.
4. **Count the pulse:**
   a. Count for 60 seconds the first time you take a patient's pulse. After that, you can count a pulse with a regular rhythm for 15 seconds and multiply by 4, or count for 30 seconds and multiply by 2 to get the beats per minute. If you do not know the patient well, count for a full minute to be certain to detect irregularities. See Step 4c rationale.
   b. Begin timing with the count of 1—starting with the first beat that you feel.
   c. Count an irregular pulse for 1 full minute (60 seconds).
   Research is conflicting. Some studies indicate that a 60-second count is most accurate; others say that accuracy is not affected by a 30-second, or even a 15-second, count if the pulse is regular. You must count an irregular pulse for 1 full minute to be accurate.
5. **For an admission assessment** or peripheral vascular check, palpate the radial pulses on both wrists simultaneously. Note any difference in the quality of the pulse between arms. Is the pulse on one side weaker than that on the other?
   Palpating simultaneously enables the recognition of small differences in the peripheral circulation.

(continued on next page)

Procedure 20-2 ■ Assessing Peripheral Pulses (continued)

Procedure 20-2B ■ Assessing the Brachial Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Palpate the brachial artery.**
   a. Using firm pressure, press in the inner aspect of the antecubital fossa until you palpate the brachial artery.
   b. If you have difficulty palpating the pulse, ask the patient to pronate the forearm (i.e., turn the palm of the hand downward).
   This brings the brachial artery over a bony prominence and makes the pulse easier to feel. ▼

2. **Assess pulse rate, rhythm, and** quality, and assess bilaterally (see Procedure 20-2A).
   The brachial pulse is used most frequently to assess blood pressure and to identify the presence of a pulse during cardiopulmonary resuscitation (CPR) in an infant.

Procedure 20-2C ■ Assessing the Carotid Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Caution! Do not palpate the carotid pulse except during cardiopulmonary resuscitation in an adult, and in certain situations to assess for circulation to the head.
Pressure on the carotid (especially in older adults) can stimulate the vagus nerve, causing the pulse and blood pressure to drop suddenly, and perhaps fainting or circulatory arrest. It can also decrease circulation to the brain.

Procedure Steps

1. **Palpate the carotid artery lightly.** Place your fingers on the patient's trachea, and slide them to the side into the groove between the trachea and the sternocleidomastoid muscle.
   Compressing the carotid arteries can stimulate the carotid bodies and significantly decrease the patient's heart rate and blood pressure.

NEVER compress the carotid artery on both sides of the neck at the same time. ➤

2. **Assess the rate, rhythm, and** quality, and compare bilaterally.

Procedure 20-2D ■ Assessing the Dorsalis Pedis Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Palpate the dorsalis pedis pulse.**
   a. Run your fingers up the groove between the great and first toes to the top of the foot.
   b. Palpate very lightly.
   The dorsalis pedis pulse is easily obliterated, so use very light pressure.
   The dorsalis pedis pulse is used to access circulation of the foot.

Owing to atherosclerosis or hardening of the arteries, the dorsalis pedis may be difficult to palpate in older adults.

2. **Assess pulse rate, rhythm, and** quality, and assess bilaterally. ➤

3. **If you are unable to palpate the dorsalis pedis pulse,** use a Doppler ultrasound device to assess the pulse and circulation to the lower extremity.

Procedure 20-2E ■ Assessing the Femoral Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Palpate the femoral pulse** by pressing deeply in the groin midway between the anterosuperior iliac spine and the symphysis pubis.
The femoral artery lies very deep and requires significant pressure to palpate. You may need to use both hands to feel the pulse on an adult. ➤

2. **Assess pulse rate, rhythm, and** quality, and assess bilaterally.
The femoral pulse is used to determine the presence of a pulse during CPR and to assess circulation to the leg.

Procedure 20-2F ■ Assessing the Posterior Tibial Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Palpate the posterior tibial pulse** by pressing on the inner (medial) side of the ankle below the medial malleolus.
The posterior tibial pulse is usually palpated easily, but it may be deeper in some people. So, press down moderately and then increase pressure until you feel the pulse. It is relatively easy to obliterate. ➤

2. **Assess pulse rate, rhythm, and quality, and assess bilaterally.**
The posterior tibial pulse is used to assess circulation to the lower extremity; it is assessed along with the dorsalis pedis pulse.

Procedure 20-2G ■ Assessing the Popliteal Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Palpate the popliteal pulse** by pressing behind the knee in the middle of the popliteal fossa.
The popliteal pulse can be difficult to feel. It is used only when specifically indicated because of absence of pedal pulses or for taking a thigh blood pressure. ➤

2. **Assess pulse rate, rhythm, and** quality, and assess bilaterally.
The popliteal pulse is used to assess circulation of the lower leg and auscultate a thigh blood pressure.

(continued on next page)

Procedure 20-2 ■ Assessing Peripheral Pulses (continued)

Procedure 20-2H ■ Assessing the Temporal Pulse

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Palpate the temporal pulse** by pressing lightly lateral (outside area) and superior to (above) the eye.

2. **Assess pulse rate, rhythm, and** quality, and assess bilaterally as for the radial pulse (see Procedure 20-2A).
The temporal pulse is easily accessible and is used frequently in infants.

What if . . .

- **The patient is an infant or a child younger than age 3 years?**
Auscultate an apical pulse rate. Rates are faster and small arteries more difficult to feel in a child or infant.
If a parent is present, encourage the parent to hold the child to reduce anxiety.
Fear increases the pulse rate.

- **The patient is an older adult?**
Have the patient at rest for 15 to 20 minutes after activity and before assessing the pulse.
The pulse tends to return to baseline more slowly in older adults.
If the pulse is fast, take repeated measures; if a pattern of fast rate emerges, note this for the primary care provider for further evaluation.
An elevated heart rate is related to increased mortality in older adult women, so it is a simple index of general health status.

- **The pulse is faint or weak?**
Use a Doppler ultrasound device to detect blood flow.
Lack of pulses indicates inadequate circulation to the lower extremities. If you cannot feel the pulse, you must determine whether the pulse is absent or whether you are having difficulty feeling. To draw the conclusion that the pulse is "absent," you must use a Doppler.
Apply transmission gel to the end of the probe. Do not use water-soluble lubricant as a substitute for transmission gel.
Place the probe lightly on the skin over the artery you are using.
Turn on the instrument and set the volume control to the lowest setting.
Tilting the probe to a 45° angle to the artery, move the probe slowly in a circular motion to locate the signal (a rhythmic hissing noise). Count for 60 seconds.
Move the probe slowly to avoid distorting the signal.
When you are finished, wipe the gel off the patient's skin. Clean the probe with soapy water or an antiseptic solution. Do not immerse the probe or bump it against anything hard.
Clean the probe to prevent cross-contamination to other patients. Probes are fragile and may malfunction if bumped against a hard surface.

Evaluation

Especially if pedal pulses are decreased, observe for other indications of inadequate circulation, such as cool skin, decreased capillary refill, and bluish or ashen skin tone. You must provide supporting evidence if you chart that pedal pulses are decreased or absent. The complete absence of a pulse requires immediate intervention.

Patient Teaching

- Teach the patient about the significance of any abnormalities in pulse rate or rhythm.
- Explain any interventions that may be needed.

Home Care

Assess the skill level of the person who will be assessing the client's peripheral pulses in the home, and provide instruction if necessary.

Documentation

Usually you will document routine vital signs (VS), including pulse, on a flowsheet or graphic. If you record it in a nurse's note, document the pulse rate, rhythm, quality, and site (e.g., "radial pulse 64 beats/min, regular, and strong bilaterally").

Practice Resources

Alexis, O. (2010); *Best Practices* (2007); Lockwood, C., Conroy-Hiller, T., & Page, T. (2004); Perk, G., Stessman, J., Ginsberg, G., et al. (2003); Trim, J. (2005); Vital Signs (1999).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos*, **Assessing Peripheral Pulses.**

For questions and suggested responses,

Go to Chapter 20, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus*.

Procedure 20-3 ■ Assessing the Apical Pulse

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Watch with a second hand or second readout
- Stethoscope
- Alcohol wipes (to clean stethoscope)

Delegation

You can delegate measurement of the apical pulse to the nursing assistive personnel (NAP) if you conclude that the patient's condition and the NAP's skills allow. First perform the pre-procedure assessments. Then inform the NAP of any special considerations (e.g., to note what the patient's activity has been just before taking the pulse, or to mark the time exactly so you can compare it to the patient's ECG). Ask the NAP to record and report the pulse to you, and to report immediately if it is outside normal limits (you must specify what is "normal" for each patient).

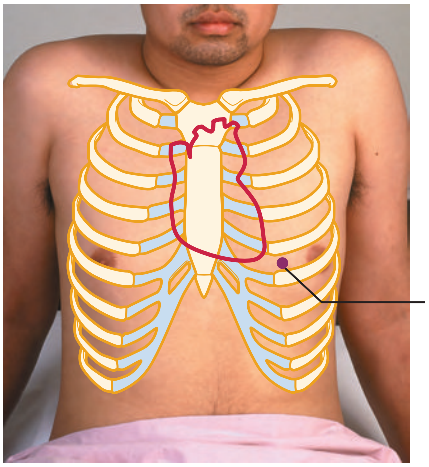
Pre-Procedure Assessments

- Determine why assessment of the apical pulse is indicated.
  Conditions that require assessment of the apical pulse include digitalis therapy, blood loss, cardiac or respiratory disease, or other conditions that affect oxygenation status.
- Assess factors that may alter the pulse, such as activity and medications. If the client has been recently active, wait 10 to 15 minutes before obtaining a measurement.
  The apical pulse is generally best heard at the point of maximum impulse (PMI) in the 5th intercostal space at the midclavicular line. The PMI is located over the apex of the heart.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **With the client supine or sitting,** expose the left side of the chest, but only as much as necessary.
   Prevents distortion of sound from the patient's gown rubbing on the stethoscope, while also protecting the patient's privacy. ▼



2. **Wipe the stethoscope with** a 70% alcohol or benzalkonium chloride wipe before and after examining the patient.
   Cleaning can reduce the bacterial count by up to 100%.

3. **Palpate the 5th intercostal space** at the midclavicular line for the apical pulse.
   The left ventricle of the heart and the point of maximum impulse lie in this area. The apical pulse is generally best heard at the PMI, over the apex of the heart.
   a. To locate the 5th intercostal space, slide your finger down from the sternal notch to the angle of Louis (the bump where the manubrium and sternum meet).
   b. Slide your finger over to the left sternal border to the 2nd intercostal space.
   c. Now place your index or ring finger (depending on which hand you use) in the 2nd intercostal space, and count down to the 5th intercostal space by placing a finger in each of the spaces.
   d. Slide over to the midclavicular line, keeping your finger in the 5th intercostal space.

4. **Palpate the apical pulse.**
   a. The palpated apical pulse is also called the point of maximal impulse (PMI).
   b. The pulse area should be about the size of a quarter, without lifts or heaves.
   A larger than normal pulsation may indicate ventricular hypertrophy.

5. **Warm the stethoscope** in your hand for 10 seconds. Then place the diaphragm over the PMI, and listen to the normal S_1 and S_2 heart sounds (lub dub).
   A cold stethoscope placed on the skin may startle the patient and increase the heart rate. Heart sounds result when blood moves through the valves of the heart. The first heart sound is louder at the apical area and should be audible when the pulse is auscultated.

Go to Student Resources, **Sound files, Heart Sounds,** on Davis*Plus*.

6. **Count the apical heart rate** for 1 full minute.
   Ensures accuracy. Because the apical heart rate is needed as an assessment measure for the administration of some medications (e.g., digoxin), accuracy is essential. Some cardiac conditions cause either slow or irregular rates, both of which must be counted for a full minute to ensure accuracy.

(continued on next page)

Procedure 20-3 ■ Assessing the Apical Pulse (continued)

? What if . . .

- **The apical rate is less than 60 beats/min?**

  (**Note:** You may also see "bpm" as an abbreviation for "beats per minute" or for "beats/min.")
  If the patient is taking cardiac medications, withhold them and consult with a physician about whether to adjust dosage.
  Certain cardiac medications (e.g., digoxin) are given to slow the heart rate; bradycardia may indicate that blood levels are too high.
  Assess for chest pain, dizziness, dyspnea.
  May indicate decreased cardiac output

- **The apical rate is greater than 100 beats/min?**

  Obtain a complete set of vital signs. Assess for pain, anxiety, fever, dehydration, decreased oxygenation, hypotension, and decreased exercise.
  These factors may increase pulse rate.

Evaluation

- Are the findings within normal limits?
- Are there other factors supporting the findings?
- What are the trends over time?
- Is the skin pink, warm, and dry?
- Is there any cyanosis?

Patient Teaching

- Teach the patient about the significance of any abnormalities in the pulse rate or rhythm.
- Explain any interventions that may be necessary.

Home Care

- Assess the skill level of the person who will be assessing the client's apical pulse in the home, and provide instruction if necessary.
- Teach the home caregiver when to hold medications and/or to call primary care provider (e.g., to hold the digitalis if the rate is <60).
- Before leaving the home, clean the stethoscope with detergent or disinfectant, when possible; or place it in a plastic bag for transporting to the reprocessing location.
- If the patient has a multidrug-resistant organism infection, reusable equipment such as stethoscopes should remain in the home. If the stethoscope cannot remain in the home, clean and disinfect it before leaving the home, using a low to intermediate level disinfectant. If this is not practical, place the stethoscope in a plastic bag and transport it to another site for cleaning and disinfection.

Documentation

Document the pulse rate, rhythm, and site.

Sample documentation

mm/dd/yyyy 0800 *Apical pulse regular rhythm, and strong, rate of 64.* ——————
—————————— *Janice Jonas, RN*

Practice Resources

Alexis, O. (2010); *Best Practices* (2007); Centers for Disease Control and Prevention (CDC) (2008); Lockwood, C., Conroy-Hiller, T., & Page, T. (2004); Vital Signs (1999); Wall, R. (2009).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos,* **Assessing the Apical Pulse.**

For questions and suggested responses,

Go to Chapter 20, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus*.

Procedure 20-4 ■ Assessing for an Apical-Radial Pulse Deficit

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Watch or clock with a second hand or second readout
- Procedure gloves, if indicated
- Stethoscope
- Alcohol wipes to clean the stethoscope

Delegation

Instead of delegating measurement of an apical-radial pulse to a NAP, you would most likely ask the NAP to assist you in this procedure because it is best performed by two persons working together.

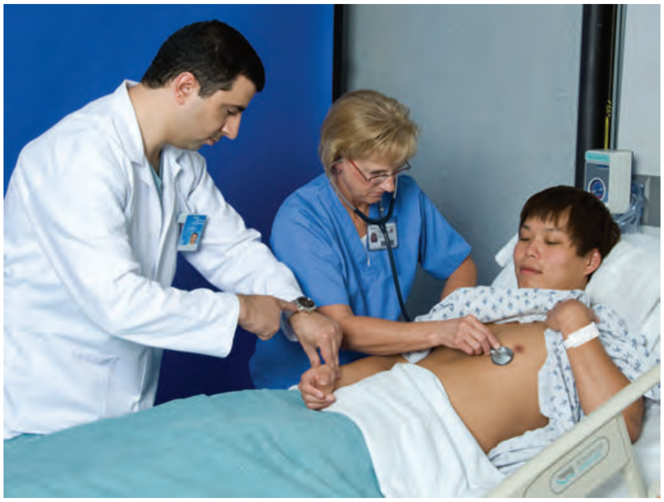
Pre-Procedure Assessments

- Determine why assessment of pulse deficit is indicated.
  Conditions that require assessment of pulse deficit include digitalis therapy, blood loss, cardiac or respiratory disease, and other conditions that affect oxygenation status.
- Assess factors that may alter the pulse, such as activity and medications.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Wipe the stethoscope with** a 70% alcohol or benzalkonium chloride wipe before and after examining the patient.
   Cleaning can reduce the bacterial count by up to 100% and prevent the transmission of microbes.
2. **Expose the left side** of the patient's chest, minimizing patient exposure.
   Prevents distortion of sound from the patient's gown rubbing on the stethoscope and protects privacy.
3. **Place the watch so that the** second hand is visible to both nurses (if two nurses are performing the procedure).
   Using one watch increases accuracy of counts.
4. **Nurse 1 palpates the** 5th intercostal space at the midclavicular line for the apical pulse, and holds the diaphragm of the stethoscope in place, using firm pressure.
   Aids in hearing high-pitched sounds and ensures good contact between the diaphragm of the stethoscope and the skin. ➤



5. **Nurse 2 palpates the radial pulse** and assesses rate, rhythm, and quality.
6. **Nurse 2 says "Start"** when ready to begin and "Stop" when finished. Both nurses count the pulse simultaneously for 1 full minute.
   Count simultaneously to ensure accuracy. Counting for 1 full minute is necessary for an accurate assessment of any discrepancies that may exist between the two sites.
7. **To obtain pulse deficit, subtract** the radial rate from the apical rate.

   Apical Rate – Radial Rate = Pulse Deficit

   Atrial and ventricular dysrhythmias may cause beats that do not perfuse, so although you hear an apical heart beat, you do not feel a peripheral pulse. The pulse deficit is the number of heartbeats that do not perfuse.

? What if . . .

- **There is not another nurse available to assist?**
  Hold the stethoscope in place with the one hand while palpating the radial pulse with the hand wearing the watch.
  Even if you cannot manage to count both rates, you should be able to feel any differences between the apical and radial pulses.
- **There has been an increase in pulse deficit since the last measurement?**
  An increase in pulse deficit means that the patient's cardiac output has decreased.

(continued on next page)

Procedure 20-4 ■ Assessing the Apical Pulse (continued)

Evaluation

- Identify the presence of an apical-pulse deficit, and compare to previous findings.
- Assess other measures of cardiopulmonary status to identify a decline in the patient's condition.
- Look for trends.
  The presence of any apical-radial pulse deficit is abnormal.

Patient Teaching

- Teach the patient about the significance of an apical-radial pulse deficit.
- Explain any necessary interventions.

Home Care

- Assess the skill level of the person(s) who will be measuring the client's apical-radial pulse deficit in the home, and provide instruction if necessary.
- Before leaving the home, clean the stethoscope as described in the Home Care section of Procedure 20-3.

Documentation

Document the apical-radial pulse deficit.

Sample documentation

01/15/15 0900 Apical-radial pulse deficit is 4 beats/min. —————— Jon Albertson, RN

Practice Resources

Alexis, O. (2010); *Best Practices* (2007); CDC (2008); Lockwood, C., Conroy-Hiller, T., & Page, T. (2004); Siegel, J., Rhinehart, E., Jackson, M., et al. (2006); U.S. Department of Health and Human Services, Agency of Healthcare Research and Quality (AHRQ) (2008); Vital Signs (1999).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos,* Assessing for an Apical-Radial Pulse Deficit.

For questions and suggested responses,

Go to Chapter 20, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus.*

Procedure 20-5 ■ Assessing Respirations

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ NOTE: To listen to breath sounds,

Go to **Student Resources, Sound Files: Breath Sounds,** on Davis*Plus.*

Equipment

- A watch with a second hand (or a wall clock)

Delegation

You can delegate the counting of respirations to the nursing assistive personnel (NAP) if you conclude that the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of any special considerations (e.g., the need to keep the patient in a certain position). Ask the NAP to record and report the respirations to you, and to report immediately if they are not within the normal range for this patient (specify the range).

Pre-Procedure Assessments

- Observe for signs of respiratory distress—breathing faster or slower than normal, gasping breaths, confusion, circumoral (around the month) cyanosis.
  Signs of hypoxemia may indicate that the patient is not adequately oxygenated.
- Determine the baseline respiratory rate and character of respirations.
- Assess for factors that may affect the respiratory rate (e.g., pain, activity, fever, respiratory disorders).

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Position the patient.** With the patient in a sitting position (preferably), flex the patient's arm, and place her forearm across her chest.
Aids in counting the patient's pulse rate by making the rise and fall of the chest more discernible and by making the patient less aware that you are measuring the respiratory rate. The patient's awareness might alter the respiratory rate and/or pattern because respirations are partially under voluntary control.

2. **Palpate and count the radial** pulse; remember that number.
3. **Then, keeping your hand** on the patient's wrist, count the respirations.
Allows you to count the respirations unobtrusively.
4. **Observe the respiratory rate**, rhythm, and depth.
   - *Rate*: Normal for patient's age, fast (tachypnea), or slow (bradypnea)
   - *Rhythm*: Regular or irregular
   - *Depth*: Normal, shallow, or deep (e.g., Kussmaul's)

   All of these characteristics are necessary to evaluate respiratory status. Different pathologies affect each of these characteristics differently.
5. **Count the number of breaths** per minute. Begin timing the respirations with a count of 1, not 0 (the same as with pulse measurement).
   a. If the respiratory rhythm is regular, count the rate (one inhalation and one exhalation is one respiration) for 30 seconds, and multiply by 2.
   b. If the rhythm is irregular, count the rate for 1 full minute (60 seconds).
   Variations in rhythm may cause an inaccurate rate when counted for less than 1 minute.

? What if . . .

- **The patient is an infant?**

Place your hand on the abdomen to assess the respiratory rate. Auscultate breath sounds with a stethoscope.
Infants and young children breathe rapidly and are abdominal breathers, so it is difficult to see each and every rise and fall of the abdomen. Using a stethoscope increases the accuracy of the count, as well as providing information about the breath sounds.

For infants and very young children, count for 1 full minute.
Infants and young children have irregular respirations. Counting for a full minute provides a more accurate rate for irregular respirations.

- **The patient is receiving oxygen therapy, or requires careful assessment of respiratory status?**

Apply a pulse oximeter (see Procedure 36-2, Monitoring Pulse Oximetry).
Evidence suggests that pulse oximetry is useful for detecting deterioration of physiological function that might otherwise be missed (e.g., during the perioperative period or in seriously ill patients).

Evaluation

- Compare the respiratory rate and rhythm with previous readings.
- Note other vital signs, especially temperature.
- Look for trends, and note whether the respiratory rate and rhythm are changing in conjunction with changes in the other vital signs.
If the patient has an elevated temperature, the respiratory rate will increase. Corresponding elevation in pulse with respiratory rate may indicate hypoxemia. If respirations are not within normal parameters, assess oxygenation with a pulse oximeter.

Patient Teaching

Teach the patient about factors that affect respiratory status, such as smoking and activity.

Home Care

Assess the skill level of the person(s) who will be measuring the client's respiratory rate in the home, and provide instruction as needed.

Documentation

You will document routine VS (including respirations) on a graphic or flowsheet. When a nurse's note is needed, follow these guidelines.

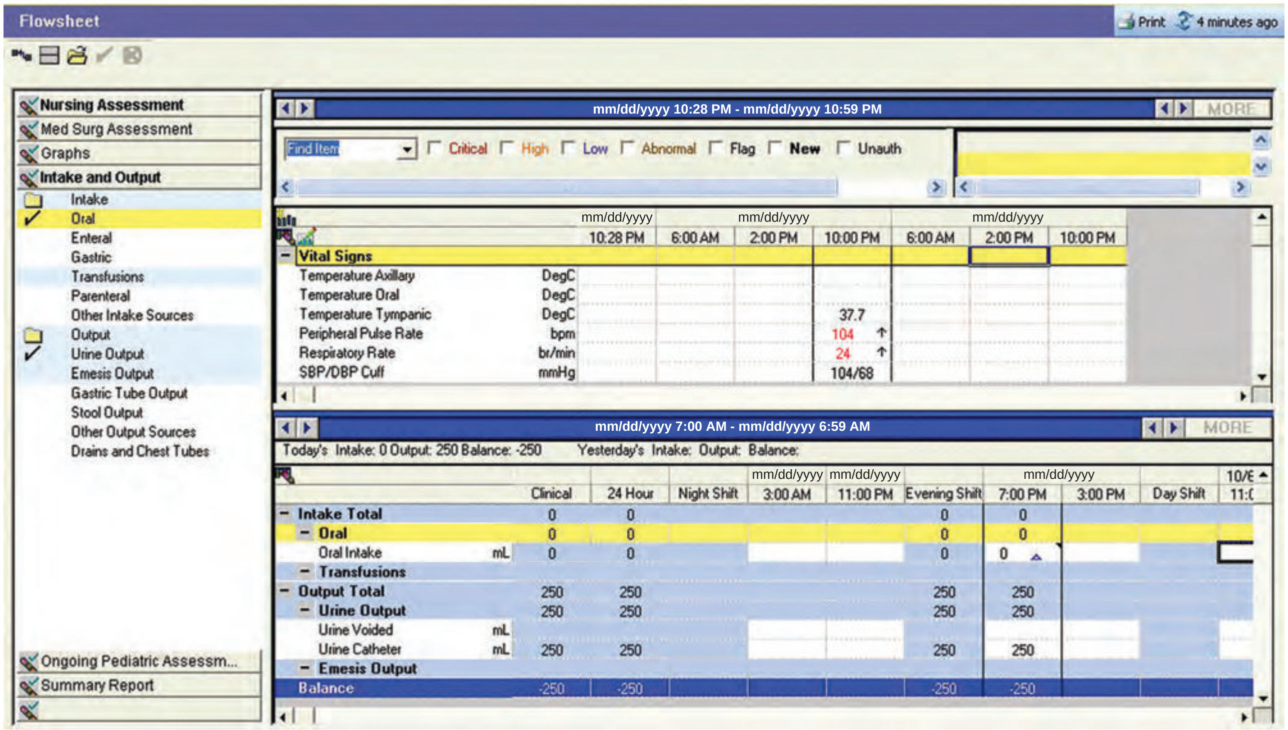
- Document the respiratory rate and rhythm.

Document that respirations are either labored or unlabored; if labored, describe in what way (e.g., intercostal retractions, use of accessory muscles, nasal flaring).

(continued on next page)

Procedure 20-5 ■ Assessing the Apical Pulse (continued)

Example of Electronic Health Record



Practice Resources

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos,* Assessing Respirations.

For questions and suggested responses,

Go to Chapter 20, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus.*

Procedure 20-6 ■ Measuring Blood Pressure

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Stethoscope

NOTE: Do not wear a stethoscope around your neck. There is a slight risk that you can entangle it in intravenous and other lines. There is also a risk that a psychotic or delirious patient could use it to harm you. Also, wearing a stethoscope can be a source of cross-contamination.

- 70% alcohol or benzalkonium chloride wipes.
  For cleaning stethoscope before and after use. Clean all parts.
- Sphygmomanometer with a cuff of the appropriate size. Refer to Clinical Insight 20-1.
  Using a cuff that is too small will result in a false-high reading; using a cuff that is too large will result in a false-low reading.
- *Note:* This procedure describes the use of an aneroid manometer or an electronic measuring device.

Delegation

You can delegate measurement of BP to the NAP if you conclude that the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the site (e.g., radial, brachial) to use. Inform the NAP of any special considerations (e.g., not to place a BP cuff on the same side as the site of a mastectomy). Ask the NAP to record and report the BP to you, and to report immediately if it is outside normal limits (you must specify what is "normal" for each patient). Tell the NAP that if BP is elevated, to note which arm, the patient's position during measurement, and activity immediately preceding the measurement.

Pre-Procedure Assessments

- Check for factors or activities that may alter the readings.
  Caffeine, smoking, exercise, and stress can all elevate the BP. Be certain the patient has been lying or sitting for at least 5 minutes (30 minutes after strenuous exercise) and is relaxed.
- Check the previous recording, if any.
  Noting changes over time is important with all patient assessments. Because BP changes constantly and because so many factors affect it, you cannot draw conclusions from a single measurement.

➤ When performing the procedure, always identify your patient using two identifiers according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* To improve the accuracy of your readings, also refer to Clinical Insights 20-1 and 20-2.

Procedure Steps

1. **Clean the stethoscope before** and after the procedure.
   Although only a small percentage of microorganisms are pathogenic, cleaning can reduce the bacterial count by 94% to 100%.

2. **Position the patient** comfortably, ensuring that:
   a. The legs are uncrossed, the back is supported, and the feet are resting on the floor (if the patient is sitting in a chair); or that the patient is supine.
   This position allows for the most accurate reading. Crossing the legs may elevate the BP reading.
   b. The measurement arm is supported at heart level, slightly flexed, with the palm facing upward.
   The blood pressure will decrease if the arm is above the heart and increase if the arm is below the heart or not supported.

3. **Fully expose the arm**, being careful that clothing is not tight. Remove clothing rather than rolling up a sleeve. *Note:* There is some evidence to suggest that readings taken over sleeves do not affect blood pressure results, and that it may actually be preferable because of concerns about hygiene, privacy and religious beliefs (Pinar, Ataalkin, & Watson, 2010). While you are learning, and until there is evidence, we advise that you will find it easier to hear the BP sounds on a bare arm.
   Clothing that is tight enough to restrict blood flow will alter the reading.

4. **Place the cuff** on the upper arm. ➤

   a. Wrap the cuff snugly.
   b. Ensure that the cuff is totally deflated, and palpate the brachial artery.
   c. Place the bottom edge of the cuff approximately 1 in. (2.5 cm) above the antecubital space.
   d. Place the center of the cuff bladder directly over the brachial artery (the center is often indicated with an arrow on the BP cuff).
   The center of the cuff bladder needs to be directly over the brachial artery to obtain an accurate reading. Loose application of the cuff results in overestimation of the pressure.

5. **Place the stethoscope ear pieces** in your ears, pointing slightly forward.
   When the earpieces point slightly forward, they direct sound into the ear canal, making the sounds more audible.

6. **Palpate the brachial artery** on the arm with the cuff. (Use the radial artery for this step if you prefer.)
   For correct stethoscope placement

7. **Inflate the cuff, as follows:**
   a. Close the sphygmomanometer valve and inflate the cuff rapidly to about 80 mm Hg.
   b. Then palpate the pulse while you continue inflating in 10 mm Hg increments until you no longer feel the pulse.
   c. Note the pressure at which the pulse disappears.
   d. Go to step 8 or the variation, as you prefer.
   Palpating the artery while inflating the cuff ensures that the cuff is inflated higher than the systolic BP. If the patient has an auscultatory gap, the systolic pressure can be mistakenly identified as lower than it actually is. Palpation is particularly important if the baseline systolic BP is unknown or if the patient is hypertensive.

8. Continue inflating the cuff to a pressure that is 20 to 30 mm Hg above the level at which the pulse disappeared. Move to Step 9.
   Helps ensure you will not miss an auscultatory gap or a faint first sound.

Variation in Cuff Inflation Technique

- Do not continue palpating after the pulse disappears; instead, deflate the cuff rapidly.
- Wait 2 minutes, then place the stethoscope over the brachial artery and inflate the cuff to a pressure that is 20 to 30 mm Hg above the palpated level.
- Continue with steps 9 and 10.

9. **Place the stethoscope over** the brachial artery as follows: ➤

(continued on next page)

Procedure 20-6 ■ Measuring Blood Pressure (continued)

a. Be certain that the stethoscope tubing is not touching anything and that the diaphragm is not tucked under the edge of the cuff.
When the tubing rubs against clothing, for example, it produces artifact sounds that make it difficult to hear the BP sounds. Placing the bell or diaphragm under the cuff can partially occlude the brachial artery, delaying the appearance of the Korotkoff sounds.

b. Using the bell will enable you to hear BP sounds more accurately, especially at diastolic pressures. However, most people use the diaphragm because it is easily placed and because some stethoscopes do not have a bell.

10. Deflate the cuff slowly (2 to 3 mm Hg per second or per beat), listening for the Korotkoff sounds as you deflate.
Deflating the cuff slowly increases patient discomfort and may alter the reading. Deflating the cuff faster may cause errors in hearing the Korotkoff sounds.

a. Note the point on the manometer at which you hear the first sound. This is the systolic BP. (If you are using an electronic BP device, read the digital screen when the numbers appear. Follow the manufacturer's instructions.)
The 1st Korotkoff sound is the systolic pressure.

b. Continue deflating the cuff, and note the level at which the sounds become muffled and disappear. The diastolic pressure is the point at which the sound disappears.
The 5th Korotkoff sound (the disappearance of sound) is the diastolic BP in adults. The 4th Korotkoff sound (the muffling of sounds) is the diastolic BP in children. The AHA recommends recording the first sound, muffling, and last sound in children younger than 13 years, pregnant women, and people with high cardiac output or peripheral vasoconstriction.

11. If you need to repeat the measurement, deflate the cuff completely, and wait 2 minutes before reinflating it.
Prevents venous congestion and false high readings.

? What if . . .

■ **You cannot feel the brachial pulse?**

While supporting the arm at the elbow, have the patient pronate her forearm.
This moves the brachial artery more over a bony prominence, making the pulsation easier to feel.

■ **You have difficulty hearing BP sounds for many patients?**

You may need a stethoscope with a built-in amplifier.

■ **You are not certain of the systolic reading when you begin to deflate the cuff?**

Do not stop cuff deflation to recheck the systolic reading. Deflate the cuff completely and wait 2 to 3 minutes before taking another measurement.
Stopping deflation and retaking the BP too soon can lead to a muffling of the Korotkoff sounds and inaccurate results.

■ **You must use a mercury manometer?**

Because mercury is a health hazard, mercury manometers should not be found in healthcare agencies. Use an aneroid manometer or an electronic BP device if one is available. If you must use a mercury manometer, be certain the meniscus of the mercury is at eye level when taking the reading. Take care not to bump equipment against the glass cover over the column of mercury.

■ **You are using an automatic blood pressure device?**

Follow the same guidelines as for a manual BP (e.g., cuff size and placement, patient position).
Turn on the machine; be sure the cuff is deflated.
Apply the cuff.
Press the button to start the measurement.
At the tone, read the digital measurement.

■ **You do not have a cuff size to fit the upper arm?**

Use the forearm, thigh, or calf. See procedure Variations A, B, and C, respectively.

■ **The patient requires contact or isolation precautions?**

Follow agency guidelines for equipment (e.g., stethoscope, BP cuff). Generally the equipment remains in the room with the patient; otherwise it must be disinfected before leaving the room. For information about contact precautions and protective isolation, see Chapter 23, Clinical Insights 2, 3, and 4.

Procedure Variation A. Measuring Blood Pressure in the Forearm

- Place a properly sized cuff on the forearm, midway between the elbow and the wrist. Auscultate over the radial artery.
- Note that a forearm reading is not interchangeable with an upper arm reading.

Procedure Variation B. Measuring Blood Pressure in the Thigh

- Use the thigh or the calf if the cuff will not fit either the upper or lower arm.

  Note: The thigh systolic measure may be 20 to 30 mm Hg higher than an arm BP reading. The diastolic reading is generally comparable.
- Place the patient in a prone position. If patient cannot be prone, place supine with knee slightly bent.
- Choose the correct cuff size. Wrap the cuff snugly around the thigh so that the lower edge of the cuff is approximately 1 in. (2.5 cm) above the popliteal fossa and the center of the cuff bladder is

positioned directly over the popliteal artery (often indicated with an arrow on the blood pressure cuff).
- Palpate and auscultate over the popliteal artery.

Procedure Variation C. Measuring Blood Pressure in the Calf

- Use the thigh or the calf if the cuff will not fit either the upper or lower arm.
- Place the patient supine.
- Choose the correct size cuff. Wrap the cuff snugly around the calf so that the lower edge of the cuff is approximately 2.5 cm above the malleoli or ankle.
- Place the stethoscope over either the dorsalis pedis or the posterior tibial artery.

Note: Calf BP measurements are not equivalent to upper arm measurements in adults; they tend to produce a higher systolic BP.

Procedure Variation D. Palpating the Blood Pressure

- Apply the cuff, and palpate for the radial or brachial pulse.
- Begin to inflate the cuff. When you can no longer feel the pulse, inflate the cuff about 30 mm Hg more.
- As you release the valve and slowly deflate the cuff, note the reading on the manometer at which you once again feel the pulse.
- Record the palpated blood pressure according to the way it was assessed (e.g., "Palpated, low Fowler's, left arm 86/——" [or "86 systolic"]).

Evaluation

- Compare the BP reading with previous readings.
- Look for trends. Is the BP slowly decreasing (e.g., impending shock) or slowly increasing (e.g., hypervolemia)?
- Look for a corresponding change in pulse rate, indicating potential hypoxemia.
- If this is the first BP measurement for the client, check readings in both arms.

  A difference of 10 mm Hg or less is normal.
- Report any significant changes in the BP reading.

Patient Teaching

Teach the patient about:

- Normal BP values (keep in mind that prehypertension is diagnosed at a lower level when using self-monitored readings).
- Significance of the BP reading.
- Further follow-up that may be necessary.

Home Care

- The American Heart Association (AHA) and other guidelines recommend self-monitoring of BP at home. It is thought that self-measurement of BP provides more reliable data than office BP because of the availability of multiple readings. It is also thought to improve adherence to treatment regimens.
- If possible, use the same equipment each time to prevent false changes in measurement.
- Explain the need for frequent recalibration of the home-monitoring device.
- Assess the skill level of the person(s) who will be measuring the patient's BP in the home, and provide instruction if necessary.
- Assess whether self-monitoring is causing the client to be anxious.

  Some clients do become overly anxious when they know they must monitor their BP, or when they obtain a high reading. Self-monitoring should not be used if it produces too much anxiety; this raises the BP even more.
- Teach clients not to change their medication dosage without consulting their primary provider when their BP goes up or down.
- Before leaving the home, clean the stethoscope and sphygmomanometer with detergent or disinfectant, when possible; or place them in a plastic bag for transporting to the reprocessing location.
- If the client has an infection with a multidrug-resistant organism, reusable equipment such as stethoscopes should remain in the home. If the stethoscope and sphygmomanometer cannot remain in the home, clean and disinfect them before leaving the home, using a low to intermediate level disinfectant. If this is not practical, place them in a plastic bag and transport them to another site for cleaning and disinfection.

Documentation

- You will usually document BP on a flowsheet (such as in Procedure 20-5, Documentation).
- Document the blood pressure systolic/diastolic readings (e.g., 130/80).
- If you hear the 4th Korotkoff sound or muffling, document systolic/muffling/diastolic (e.g., 130/80/70). If you hear an auscultatory gap, document "systolic/diastolic with an auscultatory gap from . . ." For example, "170/90 with an auscultatory gap from 170 to 140."
- Follow agency policy regarding the recording of muffled sounds.
- If you chose an alternate site, document the site used and the reason for not using the upper arm.

(continued on next page)

Procedure 20-6 ■ Measuring Blood Pressure (continued)

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos,* **Measuring Blood Pressure.**

For questions and suggested responses,

Go to Chapter 20, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus.*

CLINICAL INSIGHTS

Clinical Insight 20-1 ➤ Choosing a Blood Pressure Cuff Size

- The *width* of the bladder should cover approximately two-thirds of the *length* of the upper arm (or other extremity) for an adult, and the entire upper arm for a child.
- Another method for sizing: (1) The cuff width should be 40% of the arm circumference, and (2) the *length* of the bladder should encircle 80% of the arm.
- Perhaps the easiest sizing method is to measure *arm circumference* and follow the chart in columns 2 and 3. →

For arm circumference	Cuff should be
22–26 cm (8½ × 10¼ in.)	"small adult" size: 12 × 22 cm (4¾ × 8¾ in.)
27–34 cm (10½ × 13½ in.)	"adult" size: 16 × 30 cm (6¼ × 11¾ in.)
35–44 cm (13¾ × 171/4 in.)	"large adult" size: 16 × 36 cm (6¼ × 14¼ in.)
45–52 cm (17¾ × 101/2 in.)	"adult thigh" size: 16 × 42 cm (6¼ × 16⅝ in.)

Source: Pickering, Hall, & Appel (2005).

Clinical Insight 20-2 ➤ Taking an Accurate Blood Pressure

To improve your technique and accuracy of measurement, use the following tips in addition to Procedure 20-6.

- Explain the procedure, particularly on admission or when changing the routine.

Reduces patient anxiety

- Wait 30 minutes before assessing BP after client has ingested caffeine or smoked.
- Do not assess BP while the client is in pain.
- Apply the cuff over bare skin, if possible. Controversy surrounds this issue, so follow the manufacturer's instructions and agency policy. Advise clients who are home monitoring to apply the cuff over bare skin.
- Instruct the client not to talk during BP measurement. You should not talk either.
- Keep environmental noise and client movement to a minimum.
- Hold the stethoscope lightly but completely against the skin; do not put your thumb on top of the bell or diaphragm. Try not to allow the tubing to brush against your clothing or the bed.
- Do not be influenced by the client's previous BP measurements.
- Use the same limb for each measurement, unless you are comparing arms or averaging readings from both arms.
- For the initial reading, measure the BP in both arms and use the arm with the higher reading for subsequent measurements.
- If you obtain an elevated reading, confirm in the other arm.
- Do not draw conclusions based on one reading. Take two or more readings, at least 2 to 5 minutes apart, and average them. If the readings differ by more than 5 mm Hg, obtain and average additional readings.

CLINICALREASONING:
Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

A patient in the critical care unit had a stable pulse and BP for the first few days. He has become more ill and now his pulse and BP are weak and difficult to palpate. His last BP reading was abnormally low, so it must be monitored frequently. He is receiving intravenous fluids in both arms.

THINKING

1. *Critical Thinking (Reflecting and Deciding What to Do):* Which of the patient's vital signs (TPR and BP) might you delegate to a NAP?

DOING

2. *Practical Knowledge:* How would you take the patient's blood pressure? Be specific: (a) What site would you use? (b) What equipment would you use?
3. *Nursing Process (Assessment):*
   a. Will you need to validate any of the vital signs you obtain? If so, why?
   b. How could you validate those vital signs?

CARING

4. Assume that you are very busy. How would you demonstrate caring to this patient while you are assessing his vital signs (the ones you did not delegate to a NAP)?

Critical Thinking and Clinical Reasoning

1. Recall the clients in the Meet Your Patients scenario (in Volume 1 of your textbook). Two-year-old Jason's oral temperature was 102°F (38.9°C) and his skin was warm, dry, and flushed. His mother told you that he had been eating poorly and was very irritable. What cues alert you that something is wrong?
2. You have already established (in Think Like a Nurse 20-3, Vol. 1) what, if any, additional information you need to determine the meaning of Jason's temperature elevation.
   a. What theoretical knowledge may account for Jason's temperature?
   b. Are there any actions you should take while meeting with Jason and his mother? If so, what?
   c. What biases do you have that affect your thinking about this situation? (This requires self-knowledge.)
3. Suppose you have the following data: In a long-term care center, where most patients are older, the average normal oral temperature of the patients is 97.1°F (36.2°C). In a local well-baby nursery, the average skin temperature of the newborns ranges from 97.7°F to 98.6°F (36.5°C to 37.0°C), but it fluctuates during the first 24 hours after birth. At a walk-in surgery center, the average oral temperature of the healthy clients is 98°F (36.7°C).
   a. What conclusion might you draw about what is causing the differences in average body temperature among these three groups? (*Clue:* First list the average temperatures in order, from highest to lowest.)
   b. What theoretical knowledge did you use to answer that question?
4. Suppose you have the following data about patients' temperatures:
   Patient A, 58 years old: 0600, 97.7°F (36.5°C); 1200, 98.8°F (37.1°C); 2100, 99°F (37.2°C)
   Patient B, 14 years old: 0600, 97.5°F (36.4°C); 1200, 97.9°F (36°C); 2100, 98.4°F (36.9°C)
   Patient C, 80 years old: 0600, 96.4°F (35.8°C); 1200, 96.8°F (37.1°C); 2100, 97.2°F (36.2°C)
   What conclusion can you draw about what is probably affecting the patients' temperatures? (*Clue:* Look at the pattern for each patient. How are the patterns similar?)
5. Organize a small group of classmates. Obtain several different sizes of blood pressure cuffs for each member of the group. Practice checking blood pressures on each other. Vary the size of the cuffs used, and note the variation generated by the change in cuff size. List your findings here (for at least three different people and at least two cuff sizes).

	Cuff Size		
BP READING	**LARGE**	**MEDIUM**	**SMALL**
Person A			
Person B			
Person C			

6. Analyze the following scenario. A 46-year-old man is hospitalized for multiple trauma after a mountain bike accident.
Vital signs on admission: BP, 138/90; pulse, 108 beats/min; respirations, 24 breaths/min; temperature, 37.2°C (98.9°F)
8 hours later: BP, 162/100; pulse, 122 beats/min; respirations, 26 breaths/min; temperature, 37.9°C (100.2°F)
He is restless, agitated, and in pain.
   a. What is going on in this situation that may be influencing the VS?
   b. Do you have enough patient information to determine what is happening?
   c. What nursing actions should you consider?
   d. Should you involve others in your discussion of possible actions? If so, who?
   e. What can you delegate in this situation?
   f. Should you report this change in vital signs to the primary care provider? Why or why not?
7. Ms. Alvin is an 80-year-old patient in a long-term care facility. Her blood pressures have been in the range of 120/70 to 130/80 mm Hg for the past month. When she is newly assigned to your care, you see that according to her medical records, she has a history of hypertension. She is taking an antihypertensive medication. You observe that she is very thin, especially her extremities. She weighs only 90 lb (40.8 kg), although she is of average height.
   a. Do you think the charted BPs are probably accurate? Why or why not?
   b. How could you make sure that the recorded BP readings are accurate?
   c. After looking for a small BP cuff, you discover that there is only one size available in the agency: a standard adult size. What should you do?
8. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, and measuring vital signs. Note that these are not to be merely definitions.

Vital signs	Radial artery
Circadian rhythm	Brachial artery
Metabolism	Apical pulse
Shivering	Diaphragm
Fever	Oxygen saturation and pulse oximetry
Pulse	Blood pressure
Stethoscope	Peripheral resistance

What Are the Main Points in This Chapter?

- Vital signs (temperature, pulse, respirations, and blood pressure) are indicators of a person's state of health and functioning of the body systems.
- Many factors, such as age, activity, smoking, and gender, cause normal variations in vital signs.
- Body temperature is the balance between heat production and heat loss.
- Fever is a symptom, but it is also beneficial to the immune response.
- A normal pulse rate varies widely according to age, from an average of 120 beats/min for newborns to 80 beats/min for adults.
- Assess the pulse for quality, bilateral equality, volume, and rate.
- Respiration is the process of supplying the body with oxygen and disposing of carbon dioxide.
- Assess respirations for rate, depth, rhythm, and associated clinical signs (e.g., breath sounds, chest movement, cough, pallor, and cyanosis).
- Blood pressure is the pressure of the blood as it is forced against arterial walls during cardiac contraction.
- Prehypertension is blood pressure ranging between 120 and 139 systolic or between 80 and 89 mm Hg diastolic obtained with two readings taken 6 minutes apart.
- Hypertension is persistent elevated BP (> 140 systolic or > 90 mm Hg diastolic) on more than two separate occasions.
- Clients can prevent or modify hypertension through certain lifestyle changes (e.g., exercise, weight control, and stress management).
- Nurses can delegate the activity of taking vital signs, but the nurse is responsible for evaluating the meaning of the data.

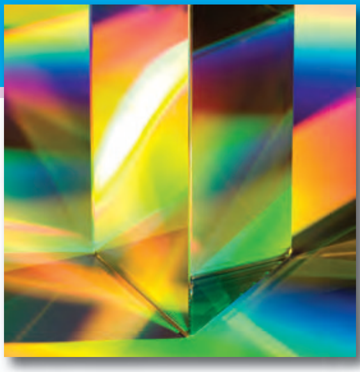
CHAPTER 21



Communication & Therapeutic Relationships

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 21:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Communication & Therapeutic Relationships**
- **Concept Map of chapter content**

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 21, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Below is a transcript of an interaction that occurred during Nam Nguyen's first visit to the family healthcare clinic. As you may recall, Zach Jackson is a family nurse practitioner who is examining Nam Nguyen. Analyze the interaction. Identify open-ended and closed questions and therapeutic communication techniques. Comment on responses that Zach might have improved on.

Zach: "Are your parents still living?"
Nam: "Yes, they're both alive. My father is 80 years old and my mother is 76."

Caring for the Nguyens (continued)

Zach: "I'd like to hear a little more about your family history. Tell me about your father's cancer. How old was he when he was first diagnosed? Has he had treatment?"

Nam: "He was probably about 60 when he first found out about it. I know he had some kind of surgery and takes medicines, but I don't know the details. He seems all right though."

Zach: "Your father also has high blood pressure and heart disease. Please tell me a little more about that."

Nam: "My father and mother both have high blood pressure and heart disease. They both take medication for their blood pressure. My father had a small heart attack about 10 years ago. My mother has never had a heart attack that I know of, but she sometimes has chest pain."

Zach: "Your mother also has diabetes?"

Nam: "She's had that for a long time. A lot of people in my family, especially on my father's side, have diabetes but nobody in my mother's family. Yet my mother is the one with the diabetes!"

Yen: "A lot of people in my family have diabetes too. But so far I'm okay, I think.

Zach: "Have you had a health exam lately, Mrs. Nguyen?"

Yen: "Not in about a year, but I'm going to schedule an appointment here."

PracticalKnowledge knowing how

This section provides clinical insights and assessments for communicating with patients.

CLINICAL INSIGHTS

Clinical Insight 21-1 ➤ Enhancing Communication Through Nonverbal Behaviors

Nonverbal Behaviors	*Interpretation*
Direct eye contact	Demonstrates interest and attention. Consider the client's cultural heritage when determining how much eye contact is appropriate.
Concerned facial expression	Lends credibility, if congruent with conversation.
Leaning forward	Shows interest in the conversation.
Personal space	Maintaining a distance of 18 inches to 4 feet allows most clients to feel comfortable during the interaction. Adjust the distance within that range based on the client's preference.
Professional appearance	Gives people an impression of how you may act in your role as a healthcare provider.
Sitting down to talk	Communicates willingness to listen and a sense of not wanting to rush the interaction with the client.
Touch	Conveys caring and concern when used appropriately.

Clinical Insight 21-2 ➤ Techniques for Assertive Communication

- Maintain eye contact, as culturally appropriate.
- Speak clearly and firmly.
- Project a clear tone of voice.
- Communicate self-confidently.
- Maintain professional composure.
- Communicate in a positive manner.
- Refrain from sarcasm.
- Ensure congruence between verbal and nonverbal messages.
- Guide the direction of the discussion.
- Use "I" statements.
- Focus on the issues.
- Do not invite negative responses.
- Avoid overly modest or timid statements.

Clinical Insight 21-3 ➤ Communicating With SBAR*

Situation	In 10 seconds, identify yourself and the patient and describe the present situation that prompted you to call. State: your name your unit the patient's name and room number the problem
Background	Give other information pertinent to the situation—not the patient's entire history since admission, but circumstances leading up to the situation (e.g., medications, lab results, current symptoms).
Assessment	State the problem and what you think is causing it. This is an inference rather than traditional data collection.
Recommendation	State what you think will correct the problem, or what you need from the physician.

*If you need other information about SBAR, see Clinical Insight 18-1, Giving Oral Report. Also,

Go to to **Chapter 18,** in Volume 1.

Practice Resources

De Meester, K., Verspuy, M., Monsiers, K. G., et al. (2013); Institute for Healthcare Improvement (2011, updated 2013); Military Health System, U.S. Department of Defense. (n.d.).

Clinical Insight 21-4 ➤ Communicating With Clients From Another Culture

General Guidelines

- Most important: Be aware of your own cultural beliefs and attitudes.
- Learn about other cultures, especially those in your area.
- Convey empathy and show respect.
- Be certain the communication strategies you usually use are culturally appropriate for the individual.
  - Is direct eye contact viewed as aggressive or impolite? Or is it perceived as engaged and caring?
  - How much space should you keep between yourself and the patient?
- Use touch cautiously. In some cultures, it is inappropriate to touch certain parts of the body.
- Proceed slowly. Rushing may cause the patient to be more anxious, and is offensive to some.
- Smile and be polite, but not overfriendly or casual. Use the patient's title and last name when introducing yourself.
- Use short words and sentences. Don't give too much information in one sentence.
- Present one idea at a time.
- Provide written teaching materials.

If There Is a Language Barrier

- Written information provided must be appropriate to the population served and the language of the patient (The Joint Commission, 2011).
- Use a trained medical interpreter, if possible.
- To review guidelines for communicating with clients who speak a different language, see Clinical Insight 15-3 in Chapter 15 of this book.
- Some medical dictionaries or Web-based resources have a comprehensive list of English–Spanish phrases.

Clinical Insight 21-4 ➤ Communicating With Clients From Another Culture *(continued)*

- The following are some useful Spanish words and phrases.

English	***Spanish***
How do you feel?	¿Como se siente?
Good	Bien
Bad	Mal
Have you any difficulty breathing?	¿Tiene dificultad al respirar?
Are you thirsty?	¿Tiene sed?
Have you any pain?	¿Tiene dolor?
Show me where	Enséñeme dónde
Is it worse now?	¿Está peor ahora?

English	***Spanish***
Cough	Tosa
Open your mouth	Abra la boca
Take a deep breath	Respire profundamente
You may eat	Puede comer
Tea	Té
Coffee	Café
I will give you something for	Le dare algo para eso
A pill	Una píldora

Spanish Patient-Education Materials

Several U.S. government Web sites offer free, reliable patient education materials in Spanish. For links to these and other online resources:

Go to Chapter 21, **Resources for Caregivers & Health Professionals,** on Davis*Plus.*

Clinical Insight 21-5 ➤ Communicating With Clients Who Have Impaired Speech

Healthcare agencies should address the communication needs of those with vision, speech, hearing, language, and cognitive impairments. .

- Nonverbal communication is the key to communication with clients with impaired speech.
- Ask the client to use hand gestures and a picture board, as appropriate.
- Solicit family assistance in understanding the client's speech.
- Provide a comfortable environment for the client to practice speaking.
- Be positive and patient.
- Although the client may have difficulty speaking, you should continue to speak and explain all procedures.
- A referral to a speech pathologist may be necessary.

Practice Resources

The Joint Commission (2010a, 2010b).

Clinical Insight 21-6 ➤ Communicating With Clients Who Have Impaired Cognition or Consciousness

Clients Who Are Cognitively Impaired

Always try to communicate. Make every effort to communicate, even if you think that the client cannot understand you.

Do not use the in-room intercom to speak with the patient. A voice sounding from the intercom on the bedside call system might frighten the patient and cause confusion, delirium, or other cognitive impairments. It is better to talk face-to-face.

Don't rush the client. Provide adequate time to allow the client to communicate. He needs time to respond to your questions or commands.

Reduce environmental distractions. Extraneous noises, lights, and even smells can compete for attention when talking with or providing instructions to the patient. For example, you might turn off the TV or close the door if you want to reduce distractions.

Approach the patient directly. To avoid frightening the patient, approach the patient from the front, make eye contact, address the person by name, smile, and speak in a calm, friendly voice.

(Continued)

Clinical Insight 21-6 ➤ Communicating With Clients Who Have Impaired Cognition or Consciousness *(continued)*

Talk first and touch second.	Touching a patient before establishing a basic trust might frighten the confused or cognitively impaired patient.
Do not argue or insist the patient agree with you.	The patient with altered perception or cognition might not have the capacity to understand or accept reality. Pushing him to agree with you simply can create anxiety or hostility.
Use multiple communication modalities.	Provide verbal and written discharge instructions. Review the instructions several times with the client before discharge, and include family members in the teaching.
Provide reminders.	Use memory aids, schedules, and reminder notices to reinforce information.
Orient the client.	Verbally orient to time, person, and place, and provide visual orientation materials, such as a calendar or schedule.
Stimulate memory.	If the client loses his place in the conversation, stimulate memory by repeating his last expressed thought (e.g., "We were talking about your back pain. Tell me more about your back pain").
Use short sentences.	Use short sentences containing a single thought (e.g., "Are you hungry?"). Avoid complex statements (e.g., "You look hungry. Would you like a sandwich or a milk shake, or can you hold off until dinner?")
Ask yes or no questions.	Ask direct questions that require only a yes or no answer (e.g., "Are you hungry?").
Limit choices.	Limit choices to avoid confusing or frustrating the patient.
Be concrete and specific.	Do not use vague comments to indicate that you are listening. The client may be unable to interpret comments such as, "I see." Instead, repeat the client's words and directly state your response (e.g., "You are cold. I will bring you a blanket").
Avoid slang and jargon.	The client may not understand, and may become anxious.
Use gestures.	Model desired behaviors. You might say "Brush your teeth now" and then pantomime brushing your teeth.
Don't assume.	Bear in mind that the client cannot behave differently and that he may be confused about reality. When the person is talking about superficial, routine matters, he may seem more competent than he is.
For clients with expressive difficulties:	■ If you are sure of the word the person is trying to say, repeat it. Don't guess, though. ■ Pay close attention to nonverbal communication. ■ Assess for and anticipate unmet needs, such as hunger, thirst, and pain. ■ Respond to the emotion, not the words. ■ Do not reprimand the patient if she curses or is aggressive.

Patients Who Are Unconscious

- Touch and speak to unconscious or sedated patients, and advise them of the care you are providing. Although the patient may not be able to respond, she may be able to hear your comments. The patient may also benefit physiologically when hearing your voice or that of his loved ones.
- Consult with previous caregivers or the family to determine what the patient responds to.
- Begin each interaction by identifying yourself and calling the patient by name.
- Speak calmly and slowly, even if the patient doesn't seem to be alert and oriented.
- Explain all healthcare procedures as you are doing them.
- Provide soothing music and periods of rest.

Patients Who Have Suffered a Stroke

- Remember that many stroke survivors may have trouble communicating their thoughts. They also commonly experience emotional ups and downs. Do not take these moods personally.
- With aphasia, speak slowly, not louder. Be careful not to use patronizing tone.
- **Augmentive and alternative communication** (AAC) might be helpful to patients experiencing expressive aphasia. AAC includes all forms of communication other than speech to express thoughts, needs, wants, and ideas, such as communication boards and electronic devices.
- Be a good listener and allow time for the patient to express his thoughts.

Practice Resources

Alzheimer's Society (2012); American Heart Association (2012); American Speech-Language-Hearing Association (n.d.); Miller, C. A. (2008); Simoes, J., Jesus, L. M. T., & Voegeli, D. (2009); Zembrzuski, C. (2013, revised).

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Communication

A focused assessment should identify factors that alter a patient's ability to receive, understand, and transmit verbal and nonverbal messages.

Medications

Is the patient taking medications that might interfere with speech, cognition, or level of consciousness?

Language Barriers

- What is the patient's primary language?
- Does the patient have sufficient command of the dominant language?
- Is an interpreter (foreign language or sign language) required?
- Can the patient read and write? At what level and in what language?

Cognitive Function

- What is the patient's level of consciousness?
- Is there short-term or long-term memory loss, or both?
- Is intellectual function at, below, or above expectations for age?
- Can the patient read simple instructions?
- Can the patient follow simple spoken instructions?
- Can the patient understand a yes or no choice?
- Are there symptoms or a diagnosis of mental illness or dementia?
- If the patient is unconscious, are there nonverbal responses that indicate he can hear you (e.g., blinking, moving the head, squeezing your hand)?

Hearing

- Ask the patient, and observe, whether there are hearing problems.
- Is the patient wearing a hearing aid? If so, is it working properly? Does the patient appear to be reading your lips?
- Is the patient trying to use sign language to communicate?
- Refer to Chapter 19 for tests of hearing (e.g., ticking watch).

Vision

- Is the patient wearing glasses or contact lenses?
- Is the patient able to see adequately?
- Refer to Chapter 22 for vision tests.

Also see Procedure 22-20, **Brief Bedside Assessment,** in this volume.

Aphasia

- Is there a history of stroke, or a diagnosis of aphasia?
- Is there receptive aphasia (inability to receive or interpret verbal or nonverbal messages)?
- Is there expressive aphasia (inability to express verbal or nonverbal messages)?

Physiological Barriers

Does the patient have conditions that cause difficulty speaking, such as:

- Dyspnea?
- Artificial airway?
- Oral problems, such as poorly fitted dentures?
- Cleft palate or other structural problems?

Communication Style

- Is it difficult to understand what the patient says (e.g., slurring words, stuttering, inability to pronounce certain sounds)?
- Does the patient speak readily, or refuse to speak?
- Does the patient speak slowly or rapidly; spontaneously or hesitantly?
- Is the vocabulary adequate for the purpose needed?
- Has the vocabulary changed from the person's normal vocabulary?

Other

- Are verbal communication and nonverbal communication congruent?

CLINICALREASONING:
Applying the Full-Spectrum Nursing Model

Choose *two* of the following communication techniques and plan to consciously use them with your next patient. Use the following thinking, doing, and caring questions to reflect on your interaction.

Active listening
Communicating assertively by making "I" statements
Restating a message
Clarifying messages
Validating messages
Sharing observations about body language
Asking open-ended questions
Using silence
Summarizing the conversation

THINKING

1. *Critical Thinking (Contextual Awareness):* Before you have the conversation, make a note of what is going on in the situation (e.g., values, environment, culture) that might influence the effectiveness of the two techniques you will be using.

DOING

2. *Nursing Process (Assessment):* Before using the two techniques, assess for factors that might affect the patient's ability to communicate. Make a note of them.
3. *Nursing Process (Implementation):* As soon as possible after using the techniques, record the conversations. Try to remember the exact words.
4. *Nursing Process (Evaluation):* Evaluate your ability to use the two techniques you chose.
   a. Did you use them at appropriate times in the conversations: as an appropriate response to something the patient said?
   b. What effect did what you said have on the interaction? How did the patient respond to what you said?
   c. Do you think your communication was therapeutic for the patient?

CARING

5. *Self-Knowledge:*
   a. What were your thoughts and feelings before, during, and after the interaction?
   b. In what way has your comfort level with these two techniques changed?
   c. Describe the type of patient or situation in which you would be the least confident in your ability to communicate therapeutically.

Critical Thinking and Clinical Reasoning

1. Mrs. Washington arrives at the clinic complaining of a painful lump in her left breast. She is 40 years old and appears very nervous. She tells you, "I was afraid to come in, but I guess I have to find out what this is."
   a. How might you acknowledge Mrs. Washington's feelings? Give examples.
   b. What might you say to clarify and validate her messages?
   c. Write a hypothetical conversation with Mrs. Washington that:
      - What will I learn this semester?
      - Acknowledges her feelings
      - Establishes trust
      - Explores the issue
      - Clarifies and validates the client's messages
      - Uses silence
      - Summarizes the conversation
2. Paramedics bring a 35-year-old man and his 14-year-old son to the emergency department (ED). Both have been involved in a recreational vehicle gas explosion and have suffered burns. The son is placed in one of the trauma rooms adjacent to his father. He has partial and full-thickness burns over his face, neck, chest, arms, and hands, and he is unresponsive. The father has partial-thickness burns on his right hand and

forearm. He appears to be in a lot of pain and is screaming for his son in Spanish. He speaks limited English. Thirty minutes later, his wife (who is also the boy's mother) arrives at the ED. She is crying and asking whether her husband and son will be okay. Her English is fluent.

a. Identify at least two interventions to help you communicate with the father.
b. What kind of body language would you expect from the father?
c. How could you show acceptance of and establish trust with the father?
d. Identify at least two factors that will influence communication with the son.
e. Identify at least two communication strategies to use with the son.
f. Explain or give an example of how to use the following techniques as you communicate with the anxious wife and mother:
   - Establishing trust
   - Using silence
   - Offering nonverbal support

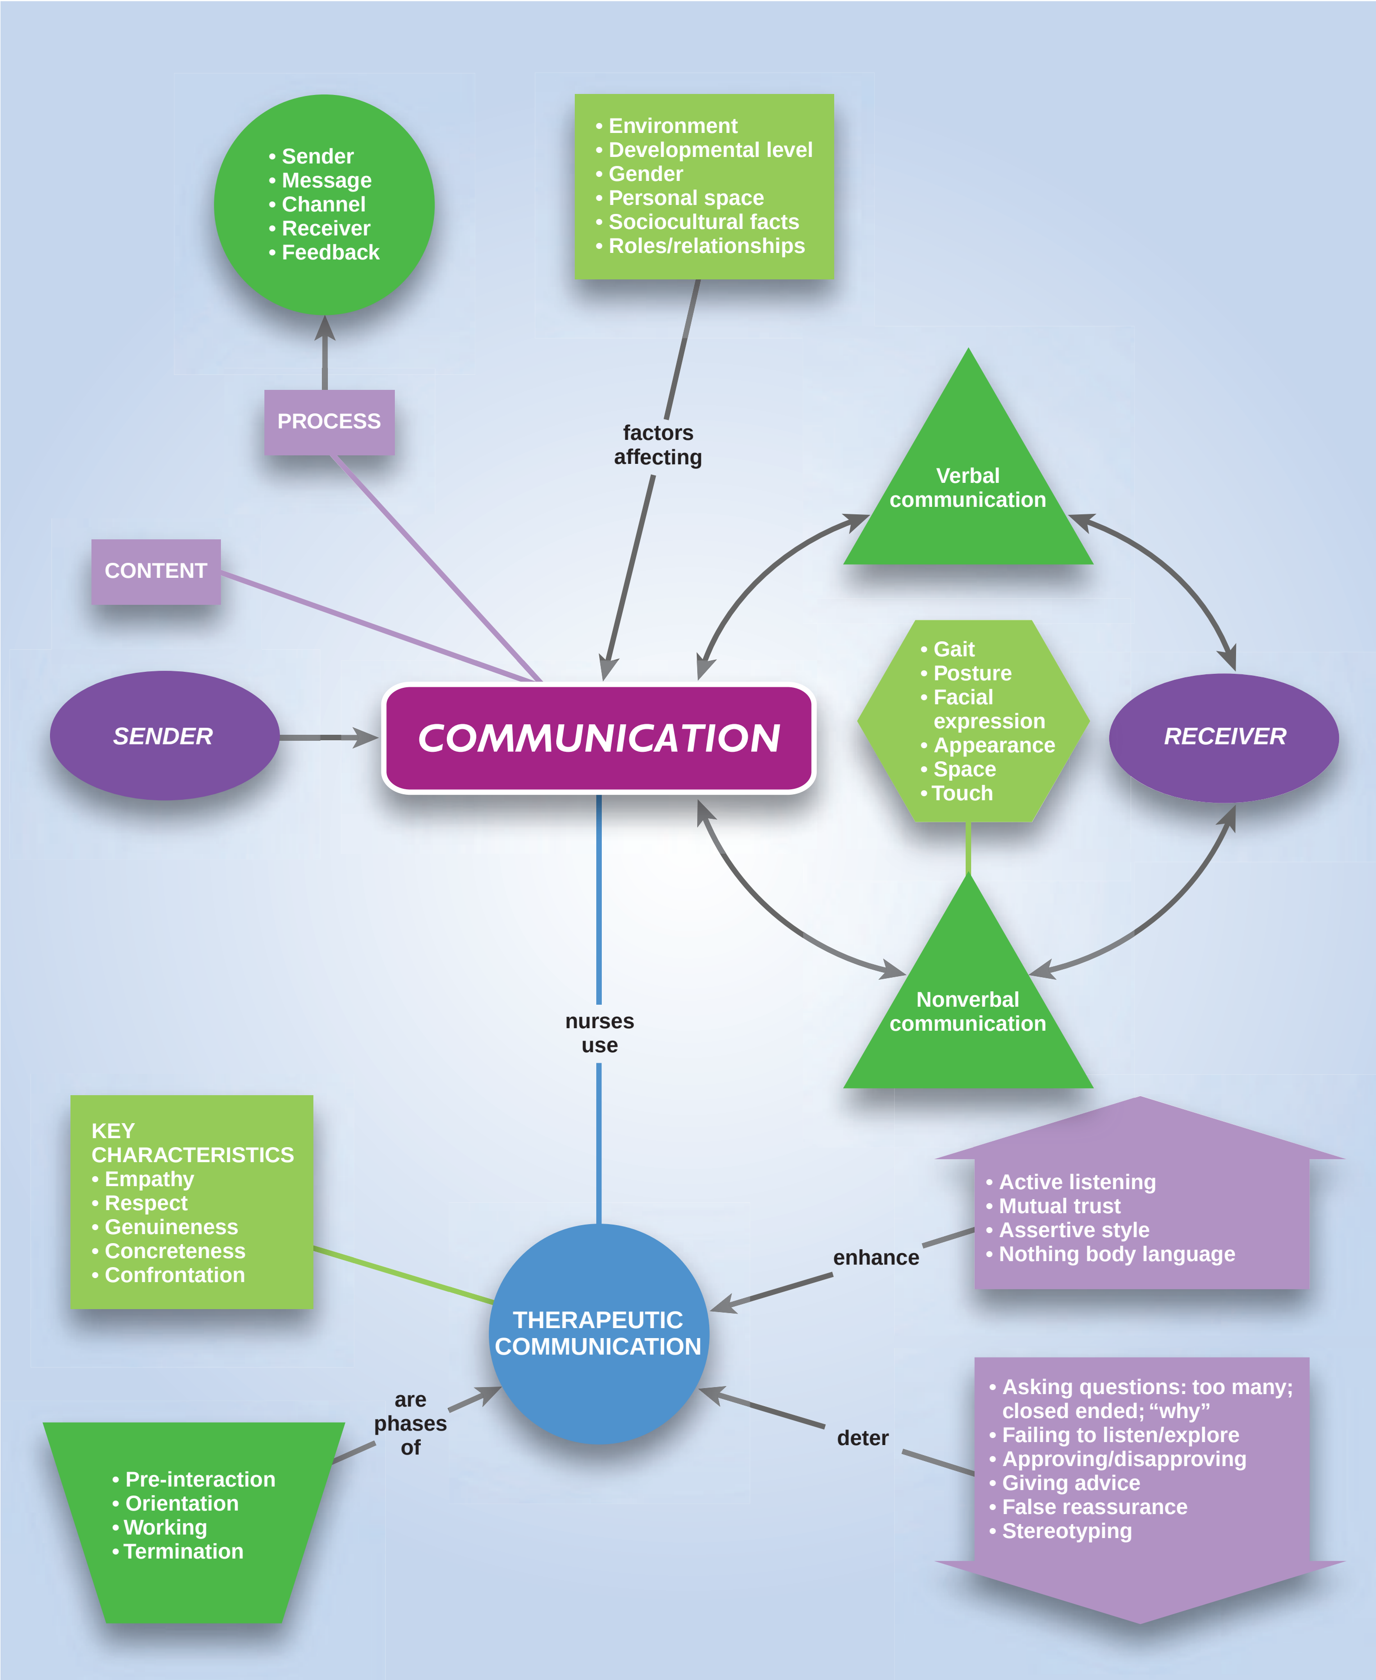
3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or communication. Note that these are *not* to be merely definitions.

Verbal communication	Therapeutic communication
Nonverbal communication	Therapeutic relationship
Intrapersonal communication	Barriers to therapeutic communication
Interpersonal communication	Distance between sender and receiver
Group communication	Communication strategies

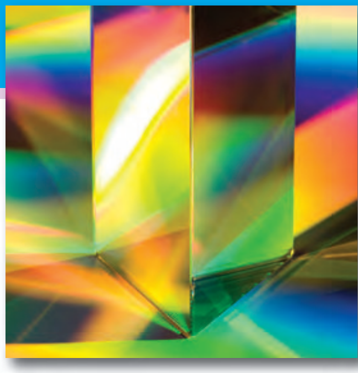
What Are the Main Points in This Chapter?

- Communication is a dynamic, reciprocal process of sending and receiving messages.
- Communication occurs on three levels: intrapersonal, or self-talk; interpersonal (between two or more people); and group communication.
- The sender delivers a message to the receiver via verbal and/or nonverbal communication. The receiver provides feedback to the sender.
- Verbal communication is the use of spoken and written words.
- Nonverbal communication, sometimes called body language, communicates how someone is feeling and gives a more accurate account of an individual's true sentiment.
- Physical development, maturity, language skills, intellectual abilities, culture, gender, roles, and relationships influence the communication process
- Collaborative professional communication is assertive without being aggressive.
- Communication is most successful in a comfortable environment. A favorable environment is quiet, private, free of noxious smells, and at a comfortable temperature.
- The distance between individuals engaged in communication is affected by the relationship of the individuals, the nature of the conversation, the setting, and cultural influences.
- Relationships affect the choice of vocabulary, tone of voice, use of gestures, and distance associated with the communication.
- Therapeutic communication is the use of communication skills that results in a positive effect on client care; it is the foundation of professional nursing practice.
- Therapeutic communication occurs in the context of a helping relationship. The helping relationship has four phases: pre-interaction, orientation, working phase, and termination.
- Group communication occurs when you are interacting with a family, a community, or a committee. Groups may be focused on a task, self-improvement, coping skills, or work-related issues.
- To enhance communication, listen actively, establish trust, be assertive, restate messages, clarify and validate messages, interpret body language, share observations, explore issues, use silence, summarize the conversation, and make use of process recordings while you are learning.
- Barriers to communication include asking too many questions; asking why; fire-hosing information; changing the subject inappropriately; failing to listen; failing to probe; expressing approval or disapproval; offering advice; providing false reassurance; stereotyping; and using patronizing language.
- Language barriers, sensory perceptual alterations, impaired cognitive skills, and physiological barriers make therapeutic communication challenging, but nursing activities can enhance communication with these clients.

Knowledge Map



CHAPTER 22



Health Assessment

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: **Chapter 22, Podcast—Chapter Overview** on Davis*Plus*.

Caring for the Nguyens

Nam Nguyen has had a comprehensive physical examination with Zach Jackson, the nurse practitioner at the clinic. To review the note written by Zach,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

(Continued)

Caring for the Nguyens (continued)

A. Discuss how each of the following would differ from the examination Zach Jackson conducted and what would be expected if:
- A registered nurse conducted the exam.
- A nursing student performed the exam.

B. Review Zach's documentation of the exam. Identify the abnormal findings.

C. Review the laboratory work. Identify the abnormal findings.

D. What conclusions, if any, can you draw from these findings? What actions should you consider based on these conclusions?

E. Identify at least two nursing diagnoses based on these findings.

F. Zach Jackson has identified a problem of Imbalanced Nutrition: More Than Body Requirements for Mr. Nguyen.
- What information do you need to determine the etiology of this problem?
- Because you do not have that information, write a two-part diagnostic statement describing Mr. Nguyen's nutritional status.

G. Now rewrite the nutrition statement as a three-part statement, using "as evidenced by."

H. Zach Jackson has identified the diagnosis Acute Pain (knees) for Mr. Nguyen. If the pain is caused by a medical condition, osteoarthritis, how would you write a two-part diagnostic statement to describe this health status?

I. How would the examination of Yen Nguyen differ from the exam Nam experienced?

J. How would the examination of Kim Phan, Nam's 3-year-old grandson, differ?

K. If you were responsible for examining Nam Nguyen, what aspects of the exam would you find most challenging? Explain why.

PracticalKnowledge knowing **how**

The registered nurse is responsible for patient assessment. As the RN, you should (1) perform the initial assessment to establish a baseline and (2) perform follow-up assessments for any changes. You can instruct nursing assistive personnel (NAPs) to report any changes to you. You can delegate measurement of height, weight, and vital signs to the NAP. However, you may want to obtain the first set of vital signs yourself, because they will serve as a baseline.

In the remainder of this chapter, you will find all the procedures and assessment guidelines necessary for a complete physical examination (Procedures 22-1 through 22-19). Procedure 22-20 describes a brief bedside assessment. In addition, you will find Clinical Insights and an Abnormal Atlas at the end of the chapter.

PROCEDURES

When examining each body system be sure to compare findings on both sides of the body. The following procedures are described mainly for adult patients, but modifications for children and older adults are also included. If you want to further review ways in which to adapt your examination to people of different ages,

Go to **How Do I Modify Assessment for Different Age Groups?,** in Volume 1.

Procedure 22-1 ■ Performing the General Survey

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

See Equipment Needed for Physical Examination, below.

Equipment Needed for Physical Examination

Usual Equipment for Ongoing Assessment

Thermometer (for measuring temperature)

Stethoscope (for measuring blood pressure and listening to heart, lung, and bowel sounds)

Sphygmomanometer (for measuring blood pressure)

Tape measure (to measure circumference and length)

Pocket ruler (to measure size or distance)

Scale (to measure weight and height)

Gloves (to wear if there is any possible exposure to blood or body fluids)

(continued on next page)

Procedure 22-1 ■ Performing the General Survey (continued)

Equipment Needed for Physical Examination—cont'd

Additional Equipment for a Comprehensive Assessment

Snellen acuity chart (for screening vision)

Ophthalmoscope (for inspection of the internal structures of the eye)

Otoscope (for examining the external auditory canal and tympanic membrane)

Nasal speculum (for examining the nasal turbinates)

Tuning fork (for auditory screening and assessment of vibratory sensation during the neurological exam)

Percussion hammer (for eliciting deep tendon reflexes)

Penlight (for visualizing the eyes and inside of mouth, or highlighting a skin lesion)

Vaginal speculum and lubricant (for examining the female pelvis; lubricant is also used for rectal exams)

Cotton-tipped applicators (for obtaining specimens)

Cotton balls, tongue depressor, strong-smelling substance, a glass of water (for testing various cranial nerves)

Positioning

- Have the client seated as you begin the examination (on an exam table or on the side of the bed).
- If the client is unable to sit, use Fowler's or semi-Fowler's position.

Focused History Questions

- How are you feeling today?
- (If the client is an outpatient) What brings you to the clinic today?
- Are you in any discomfort or pain?
- Have you had any hospitalizations or surgeries?
- What medicines do you take? That means prescribed as well as over-the-counter drugs.
- How much alcohol do you drink per day? Do you smoke cigarettes? If so, how many per day? Do you use drugs for non-medical purposes?
- Do you use any herbal products or natural remedies?
- Do you have any difficulty falling asleep or staying asleep?

Developmental Modifications for Infants and Children

- Encourage the parents to be present for the examination. Position an infant on a padded examination table or held against the parent's chest.
  Infants and toddlers usually feel most secure if a parent is present.
- Offer toddlers choices. Involve the parent in the exam. Praise the toddler for cooperation.
- Allow the preschool child to sit in the parent's lap if she wishes. Let the child help with the exam. Give reassurance as you proceed. Compliment the child on her cooperation.
  Preschoolers often are fearful of body injury and invasive procedures.
- Support the school-age child's independence. Develop rapport by asking the child about his teacher or favorite school and play activities. Allow the child to undress himself and get up and down from the exam table. Demonstrate and let the child touch your equipment before you use it.
  Equipment will seem less threatening to the child if she touches it. It is unlikely that the child would break the equipment.
- Adolescents should be examined without parents or siblings present unless they request otherwise. Provide privacy.
  Adolescents are self-conscious and introspective.

Developmental Modifications for Older Adults

- Observe the older adult's energy level during the physical examination, and provide rest periods if needed. If the client tires easily, arrange the exam sequence to limit position changes.
- Allow extra time to interview and examine older adults.
- Be aware that stiff muscles and arthritic joints may make it impossible for older adults to assume certain positions.
- Be alert for hearing and vision deficits in older adults, and adapt your interview techniques accordingly (e.g., elicit feedback to be sure the client has heard you correctly).
- Assess the older adult's functional status. You can use the Lawton Instrumental Activities of Daily Living (IADL), found in the section Assessment Guidelines and Tools in Chapter 3 of this volume.
- Work the SPICES assessment into the examination of various body systems: **S**leep disorders, **P**roblems eating or feeding, **I**ncontinence, **C**onfusion, **E**vidence of falls, **S**kin breakdown.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation

Procedure Steps	Expected and Abnormal Findings
1. **Identify signs of distress** (e.g., pain, fear, or anxiety). If signs of distress are present, perform a focused assessment, and address the immediate problem.	**Expected findings:** The client is in no apparent distress. Appears relaxed, with no evidence of pain, fear, or anxiety. **Abnormal findings:** Pain, grimacing, breathing problems, skin color changes
2. **Observe apparent age, sex, and race**. Ask the patient, "What racial or ethnic group do you identify with?" Ask yourself, ■ Is apparent age consistent with biological age? ■ Are there cultural or gender-related factors that influence the exam or findings?	**Expected findings:** Client appears his stated age. Makes eye contact consistent with his cultural norms. Is reasonably comfortable with being examined.
3. **Note facial characteristics**, including facial expression, symmetry of facial features, and the condition and color of the skin. Ask yourself, ■ What is the client's face telling me? ■ Is the facial expression appropriate to the situation?	**Expected findings:** Face is symmetrical; visible skin is intact without excessive wrinkling, discoloration, or deformity.

(continued on next page)

Procedure 22-1 ■ Performing the General Survey (continued)

- Are facial features symmetrical (palpebral fissure and nasolabial folds)?
- Are there any changes in condition or color of skin?
- Does the client maintain eye contact?

---

4. **Note body type and posture**. Greet the client with a handshake. Be aware that shaking hands is not acceptable in all cultures.
   Allows you to assess muscle strength and surface skin characteristics while at the same time conveying that you care.
   Ask yourself,
   - Is the body build stocky, slender, average, obese, or **cachectic** (very thin, wasted appearance)?
   - Are the body parts proportional to the client's overall size?
   - Does the client have abnormal fat distribution?
   - Does the client assume a specific position for comfort (e.g., sitting versus supine)?

Expected findings: Posture is upright, and body appears proportionate. Grip is strong.

---

5. **Observe gait**, and note any abnormal movements. If the client has Impaired Bed Mobility, determine ability to move and amount of assistance needed. Ask yourself,
   - Does the client move in a coordinated manner?
   - Are there any obvious gait problems?
   - Does the client walk with a wide base of support or short stride length?
   - Does the client use assistive devices?
   - Are there any abnormal or spastic movements?

Expected findings: Movements are coordinated; gait is steady; does not use assistive devices.

Abnormal findings: Unstable or shuffling gait; spastic movements, stiff movements

---

6. **Listen to your client's speech pattern**, pace, quality, tone, vocabulary, and sentence structure. Ask yourself,
   - Are the responses appropriate?
   - Is there any difficulty with speech?
   - Does the client's tone of voice match her statements?

Expected findings: Client responds appropriately to questions. Tone of voice matches responses. Speech is clear, evenly paced, and rises and falls based on content.

Abnormal findings: Rapid speech, slow speech, slurred speech

---

7. **Assess mental state and affect.**
   a. Determine level of consciousness.
   b. Determine orientation to time, place, and person.

Ask yourself,
   - If the client is disoriented, does he reorient easily?
   - What is the client's mood? Is it appropriate for the situation?

   Many medical conditions and medications can affect mental status. If you note any abnormal findings: During the general survey, be sure to focus on them when you assess mental status during the sensorineurological examination.

Expected findings: Awake, alert, and oriented to time, place, person, and self. Mood is appropriate for the situation.

Abnormal findings: Confusion and irritability, inability to recall information or provide history, lethargy and somnolence, bizarre responses

---

8. **Observe dress, grooming, and hygiene.** Ask yourself,
   - Is the client appropriately and neatly dressed?
   - Is the client well groomed?
   - Are there any unusual odors?

Expected findings: Client is dressed appropriately for the climate. Skin is clean, and clothing is in good repair. No noticeable odor.

Abnormal findings: Poor hygiene, dirty skin or nails, uncombed hair, visible soiling of clothing, mismatched or wrinkled clothing, objectionable odor

---

9. Measure vital signs: blood pressure, temperature, radial pulse, respiratory rate. If your initial observations and interview indicate that the client is in pain, perform a pain assessment, as well. See Chapter 31.

Expected findings: BP: < 120/80 mm Hg

Temperature: 97.3°F–98.6°F (36.3°C–37°C) oral

Pulse: 60–100 beats/min, regular, and easily palpated

Respiratory rate: 12–20, regular and even

Abnormal findings: See Chapter 20.

10. Measure height and weight.

a. For adults: Calculate BMI, or use the accompanying table.

$$\frac{\text{Wt (lb)} \times 703}{\text{Ht (in.)}^2} = \text{BMI}$$

b. For children: Plot height and weight on growth chart.

Developmental Modifications

Infants and children

- Weigh infants without clothing; weigh older children in their underwear.
- For infants and children younger than 2 years, position supine to measure height; be sure knees are extended.
- For infants and children younger than age 2, also measure head circumference.

Expected findings: For adults: BMI is 18.5–24.9.

For children: Height and weight are consistent with previous trend on growth chart.

Abnormal findings: BMI < 18.5 = underweight

BMI 25–29.9 = overweight

BMI > 30 = obese

BMI 30–34.9 = Level I Moderate obesity

BMI 35–39.9 = Level II Severe obesity

BMI > 40 = Level III Morbid obesity

What if . . .

- **There is an apparent language barrier?**
  Obtain an interpreter; and refer to Clinical Insight 21-4, in Chapter 21 of this volume.

Use this table to find body mass index, based on height and weight, or use a BMI calculator such as the ones found at, http://www.nhlbi.nih.gov/health/educational/lose_wt/BMI/bmi_tbl.htm

Weight (lb)

Height (ft/in)	120	130	140	150	160	170	180	190	200	210	220	230	240	250	260	270	280	290	300	310	320	330

Less risk — More risk

(continued on next page)

Procedure 22-1 ■ Performing the General Survey (continued)

Documentation

- Document BP as right or left arm, and note the patient's position: sitting, standing, or lying.
- Document temperature measurement route: oral, rectal, or tympanic membrane.
- For children, document height and weight on a growth chart.

Go to Chapter 22, **Supplemental Materials: Growth Charts,** on Davis*Plus*.

- If you need more information about documenting, see the form, Graphic Flowsheet, in the Forms section of Chapter 20. Also,

Go to Chapter 18, **Documenting and Reporting,** in Volume 1.

Practice Resources

Centers for Disease Control and Prevention (CDC) (last updated September 13, 2011); CDC (last updated April 27, 2012); National Guideline Clearinghouse (NGC) (2005, revised January 2013); National Heart, Lung, and Blood Institute (n.d.).

Procedure 22-2 ■ Assessing the Skin

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex gloves (if exposure to body fluids is a possibility)
- Flexible transparent ruler
- Penlight
- Magnifier
- Pen and record form

Focused History Questions

Ask the patient about the history or presence of any:

- Rashes
- History of allergies
- Areas of skin that have changed color
- Skin lesions
- Skin with rough or unusual texture
- Skin that is always warm or cool, regardless of room temperature

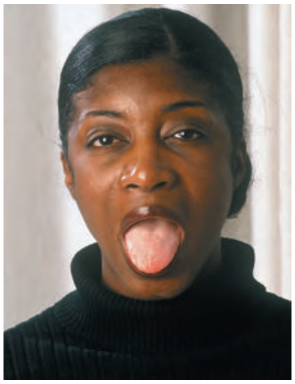
Developmental Modifications for Older Adults

- Assess the level of risk for pressure ulcers. For assessment tools (Braden scale, Norton scale), go to Chapter 35 in this volume.
  As adults age, the subcutaneous tissue layer thins. The dermal layer loses elasticity as a result of changes in collagen fibers; and the strong bond between the epidermal and dermal layers decreases. These changes make the skin prone to breakdown.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Inspect skin color**, including mucous membranes, tongue, and conjunctiva.
   To assess color changes of exposed and unexposed areas. Color changes and odors may indicate underlying disease and should be fully investigated.
   a. Provide good lighting.
   b. In dark-skinned clients, look for color changes in the conjunctiva or oral mucosa, tongue, lips, nailbeds, palms of the hands, and soles of the feet.
   Skin color varies widely among individuals by age and ethnicity, but in each individual skin color is fairly uniform over his body.



Step 1

Expected and Abnormal Findings

Expected findings: Skin color is uniform, with darker exposed areas. Mucous membranes and conjunctiva are pink and moist. No unusual odors.

Developmental Variations

Newborns—May be jaundiced for a few weeks. Blue-black Mongolian spots and pink-red capillary hemangiomas are common and fade with time.

Older adults—May have thin, translucent skin and wrinkles due to loss of elasticity. Fragile skin is not uncommon among lighter skinned, older adults.

Abnormal findings: Pallor, jaundice, cyanosis, erythema, hyperpigmentation, hypopigmentation. If there are abnormal findings, ask the patient (or someone who knows him well) about the baseline skin color. See the Abnormal Atlas: Skin Color Changes at the end of this chapter for examples of color changes.

c. Note any unusual odors.

d. To assess for cyanosis, be sure to examine the tongue.

Exposure to cold causes the lips to turn blue, but not the tongue. Cyanosis affects the color of the skin, mucous membranes, and tongue.

---

2. Palpate skin for temperature.

a. Wear procedure gloves and discard after examining any open areas of the skin.

b. Use dorsal aspect of hand or fingers.

c. Compare bilaterally.

The dorsa of the hands and the fingers are most sensitive to temperature variations.

Expected findings: Skin is warm; temperature is the same bilaterally.

Abnormal findings: Local area(s) that are warmer or cooler than the rest of the skin; generalized temperature increase or decrease. If the skin is excessively warm, assess for fever. Localized warmth with erythema can indicate an infection. Cool skin might be a sign of compromised circulation or dehydration, particularly in the older adult.

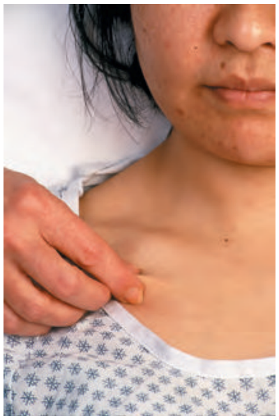
---

3. Palpate skin for turgor. Test an unexposed area, such as the area below the clavicle, inner thigh, sternum, or forehead, by gently pinching up the skin, noting its return when you release it.

Developmental Modifications

Infants—Check skin turgor on the abdomen.

Older adults—Check skin turgor over the sternum or clavicle.



Skin turgor

Expected findings: Skin returns immediately to its original position.

Developmental Variations

Older adults have decreased skin turgor due to decreased elasticity.

Abnormal findings: Decreased or increased turgor. Tenting (decreased turgor): Skin takes several seconds to return to original position.

Decreased turgor or tenting is seen with dehydration or normal aging. It predisposes the patient to skin breakdown.

Increased turgor: Skin tension does not allow the skin to be pinched up.

---

4. Palpate the skin for texture.

Texture varies, depending on the area being assessed and the age of the client.

Expected findings: Skin is smooth and soft. Exposed areas and extensor surfaces (e.g., elbows and knees) are drier and coarser than other areas.

Developmental Variations

Infants and young children—Have smooth skin.

Abnormal findings: Coarse, thick, rough, or dry skin; very smooth, thin, fine-textured, shiny skin

(continued on next page)

Procedure 22-2 ■ Assessing the Skin (continued)

5. Palpate skin for moisture/hydration. Use the dorsum of your hand.

Expected findings: Skin is warm and dry.

Developmental Variations

Older adults—Skin may be dry and flaky because of decreased activity of sebaceous and sweat glands.

Adolescents—May have skin that is oilier than normal.

Abnormal findings: Increased moisture (skin feels damp, visible diaphoresis); decreased moisture (skin feels dry)

---

6. Inspect for edema.

a. Press firmly with your fingertip for 5 seconds over a bony area, such as the tibia.
b. Release your finger, and observe the skin for the reaction.
c. If edema is present, note the location, degree, and type of swelling. For example, if you observe edema in the lower leg, how far up the leg does it extend?

Expected findings: No edema. Normally there will be no evidence of the pressure once you release your finger. If pitting edema is present, you will see a depression in the skin.

Grading System

Trace: Minimal depression with pressure.

+1: 2 mm depression; rapid return of skin to position.

+2: 4 mm depression that disappears in 10–15 seconds.

+3: 6 mm depression that lasts 1–2 minutes. Area appears swollen.

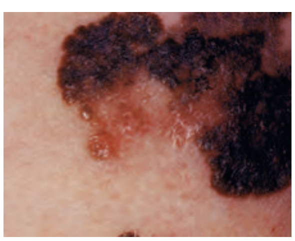
+4: 8 mm depression that persists for 2–3 minutes. Area is grossly edematous.

Abnormal findings: Edema is an abnormal finding.

---

7. Identify any skin lesions.

a. Inspect and palpate lesions.
b. When you notice bruises, be alert for signs of abuse (see Chapter 9).
c. Ask the client: "Do you have any new moles or other lesions? Has there been any change in existing moles/lesions?"
d. Assess for malignant lesions using ABCDE:
   A (asymmetry)
   B (irregular borders)
   C (color variations)
   D (diameter: 0.5 cm)
   E (elevation).



Malignant melanoma

Expected Finding: No lesions are present.

Normal variations include moles, freckles, birthmarks, striae (in pregnant women or clients who have lost much weight), and wrinkles.

Developmental Variations

Newborns—**Milia** (tiny collections of sebum, usually on the face) are common.

Adults—**Acrochordons** (skin tags) may be seen around the neck, axillae, skinfolds, or areas where clothing rubs.

Older adults—Flat beige or brown macules are common on exposed skin areas.

Abnormal findings: See the Abnormal Atlas: Skin Lesions at the end of this chapter. Also see the table Describing Skin Lesions following this procedure.

Adolescents—Acne is a common abnormal finding among adolescents.

Describing Lesions

When you observe a lesion, evaluate and describe the following:

- **Size.** Measure the length, width, and depth of the lesion.
- **Shape and pattern.** Describe the *shape* of individual lesions. If there are clusters or groups, describe the *pattern*. Is it linear or circular? Are the *borders* distinct, or do they run together? Is the border smooth or irregular?
- **Color.** Describe the color of the lesion, and determine whether there is any variation of color within the lesion.
- **Distribution.** Are the lesions distributed over the entire body? Are they confined to a specific region? What parts of the body are affected?
- **Texture.** The texture (e.g., smooth, rough, scaly) of a lesion helps with classification.
- **Surface relationship.** To assess surface relationship, you will need to palpate the lesion. Is it flat, raised, or depressed? Is it firmly attached to the surrounding skin or mobile?
- **Exudate.** Examine the lesion(s) for signs of drainage. Describe the color, appearance, amount, and odor of drainage, if present.
- **Tenderness, pain, or itching.** Press on the lesion, and determine the patient's reaction. Does touching the lesion cause pain or discomfort?

Patient Teaching

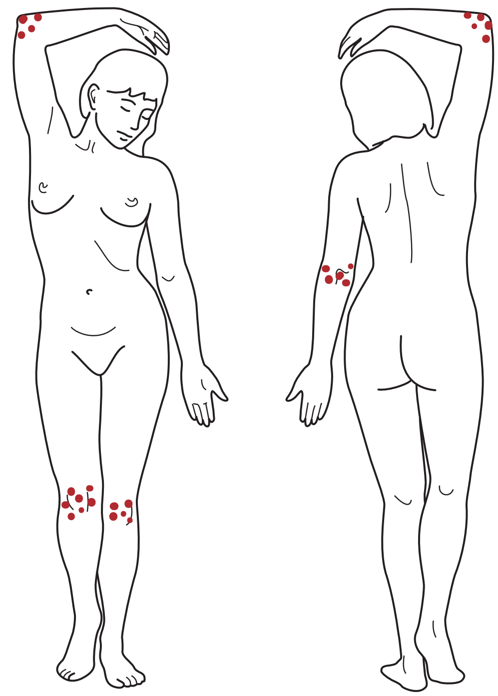
Teach the patient the signs and symptoms of skin cancer, the importance of the skin exam, and preventive measures.

Home Care

- Assess the skill level of the caregiver. Instruct the caregiver in the importance of skin assessment and measures to prevent skin breakdown.
- Be alert for lesions (e.g., burns, bruises) that may signal physical abuse. For more signs of abuse, refer to Procedure 9-1.

Documentation

- If lesions are present, describe the history: onset, duration, associated or aggravating factors (e.g., itching), factors that relieve symptoms, treatments that have been used, and responses to treatment.
- Sketch the location of skin lesions on body diagrams, if available (see example below); or sketch a body if necessary.



If you need more information about documenting, review Caring for the Nguyens, and

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

(continued on next page)

Procedure 22-2 ■ Assessing the Skin (continued)

Describing Skin Lesions

TYPES		DESCRIPTION
Primary Lesions Macule (nonpalpable, < 1 cm) 	Macule (nonpalpable, < 1 cm) 	Flat and colored. Examples: freckle, petechiae, birthmark, Mongolian spot
Papule (palpable) < 1 cm; Plaque > 1 cm 	Papules (seborrheic keratosis) 	Elevated and raised, but superficial Examples: mole, psoriasis
Vesicle (palpable), < 1 cm; Bulla, > 1 cm 	Vesicles (blisters)  	Elevated and filled with serous fluid. Examples: blister, herpes simplex

Describing Skin Lesions—cont'd

TYPES		DESCRIPTION
Cyst (palpable), < 2 cm 	Keratogenous cyst 	Palpable, fluid-filled, and encapsulated. If not fluid-filled, called a nodule
Pustule (palpable) 	Pustules (acne) 	Elevated and filled with pus. Examples: acne, folliculitis, impetigo
	Nodule (palpable) 	Elevated, solid, and firm, with depth into dermis. Examples: wart, lipoma (fatty cyst)
Wheal 	Hive 	Elevated, superficial, with localized edema. Examples: insect bites, hives

(continued on next page)

Procedure 22-2 ■ Assessing the Skin (continued)

Describing Skin Lesions—cont'd

TYPES		DESCRIPTION
Secondary Lesions Excoriation 	Excoriation from pruritus 	Abrasion or loss of skin that does not extend beyond the superficial epidermis. Examples: scratches, stasis dermatitis, atopic dermatitis
Erosion 	Erosions 	Loss of superficial epidermis, usually secondary to rupture of a blister. Examples: abrasions and impetigo
Fissure 	Cheilitis 	Linear break in the skin ("crack"); may extend to the dermis. Examples: athlete's foot, cheilitis
Ulcer 	Stasis ulcer 	Irregularly shaped with loss of tissue. Graded based on depth and tissue involvement. Examples: pressure ulcers, stasis ulcers

Describing Skin Lesions—cont'd

TYPES		DESCRIPTION
Crust 	Crust 	Elevated, rough texture with dried exudate. Examples: impetigo, herpes simplex
Scales 	Psoriasis 	White to tan flaking, dead skin cells; may be adherent or loose. Examples: psoriasis and dandruff
Scar 		Fibrous tissue at site of injury, trauma, or surgery. Examples: surgical site, trauma site
Keloid 	Keloids 	Raised and irregular scar due to excess collagen formation. Examples: surgical scars, ear piercing

Practice Resources

Linton, C. P. (2011); Reddy, M. (2008).

Procedure 22-3 ■ Assessing the Hair

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex procedure gloves (if exposure to body fluids is a possibility)
- Pen and record form

Focused History Questions

- Have you had any changes in hair texture?
- Have you had any hair loss?
- Do you use dyes or chemical treatments for curling or straightening?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Inspect the hair and scalp. Check the color, quantity, and distribution of the hair and the condition of the scalp. Note the presence of lesions or pediculosis.
Sex, genetics, and age affect hair distribution on the head, legs extremities, pubis, and axillae. With aging, melanocyte function declines and sebaceous gland function decreases.

Expected and Abnormal Findings

Expected findings: The hair is evenly distributed on the scalp, and fine body hair is present over the body. The hair is clean and free of debris or pediculosis.

Developmental Variations

Infants—May have very little scalp hair.

Adolescents—May have oily hair. Puberty marks the onset of pubic hair growth and increased hair growth.

Older adults—Scalp, axillary, leg, and pubic hair may be dry and thin; hair of the ears, nostrils, and eyebrows may become coarse.

Abnormal findings: Generalized hair loss not attributed to genetics or aging; patchy hair loss; **hirsutism** (excess facial or trunk hair). See the Abnormal Atlas at the end of this chapter.

---

2. Palpate the texture of the hair.

Expected findings: Hair texture varies (fine, medium, coarse) depending on genetics and treatments.

Abnormal findings: Very dry, coarse hair; very fine, silky hair

---

3. Palpate the scalp for mobility and tenderness.

Expected findings: Scalp is smooth, firm, symmetrical, nontender, and without lesions.

Abnormal findings: Tenderness, lesions.

Patient Teaching

If indicated, teach the patient to check for head lice, and provide preventive measures.

Documentation

If you need more information about documenting, review Documentation of Physical Assessment Findings for Nam Nguyen, in Volume 1.

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-4 ■ Assessing the Nails

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex gloves (if exposure to body fluids is a possibility)
- Pen and record form

Focused History Questions

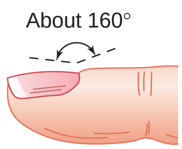
- Have you had any recent changes in the way your nails grow or look?
- Have you had any recent trauma to your nails?
- Do you use acrylic nails?
- Do you have any medical problems, such as peripheral vascular disease or diabetes?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Inspect nails.

- Check nails for color, condition, texture, and shape.
- Examine nails on both hands and feet. However, for efficiency you may defer examination of the toenails until the assessment of peripheral circulation.



Expected and Abnormal Findings

Expected findings: Healthy nailbeds are level, firm, and similar to the color of the skin. The shape is convex, with a nail plate angle of about 160°.

Developmental Variations

Newborns—Have very thin nails.

Children—May bite their nails. Most children outgrow this habit.

Older adults—Nails grow more slowly, become thicker, and tend to split.

Abnormal findings: Yellow, blue, or black discoloration. White spots may indicate zinc deficiency. Spoon-shaped (concave) nails are associated with iron deficiency. See the Abnormal Atlas: Nail Appearance at the end of this chapter.

---

2. Inspect and palpate for texture.

Grooves or lines in the nails provide information about nutrition and health problems.

Expected findings: Nails are smooth and uniform in texture.

Abnormal findings: Thickened, brittle, or soft nails; nails with deep vertical grooves

(continued on next page)

Procedure 22-4 ■ Assessing the Nails (continued)

3. **Assess capillary refill.** Briefly press the tip of the nail with firm, steady pressure; then release and observe for changes in color.
This test assesses circulatory adequacy rather than the nails themselves. However, circulatory insufficiency affects the nails and nailbeds. It is convenient to perform the assessment at this point in the exam.

Step 3

Expected findings: Normal capillary refill is < 2 to 3 seconds.

Developmental Variations

Older adults—Capillary refill time (CRT) is slower.

Males—CRT faster than in women

Environment—CRT is slower in a cool environment.

Abnormal findings: Delayed capillary refill.

Documentation

If you need more information about documenting

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Practice Resources

Anderson, B., Kelly, A. M., Kerr, D., et al. (2008); Linton, C. P. (2012).

Procedure 22-5 ■ Assessing the Head and Face

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex gloves (if exposure to body fluids is a possibility)
- Penlight (to transilluminate the sinuses)
- Pen and record form

Positioning

The client should be sitting, if possible.

Focused History Questions

- Have you had any recent headaches?
- Have you ever had a head injury or loss of consciousness?
- Have you ever had a seizure?
- Do you have jaw or facial pain?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Inspect the head.** Check for size, shape, symmetry, and position.

Developmental Modifications

- *Newborns and infants*—Assess and transilluminate fontanels, and measure head circumference.

Expected and Abnormal Findings

Expected findings: There is wide variation in head size and shape, although the shape should be symmetrical and rounded. The head should be erect, midline, and proportional to the body size based on age.

Developmental Variations

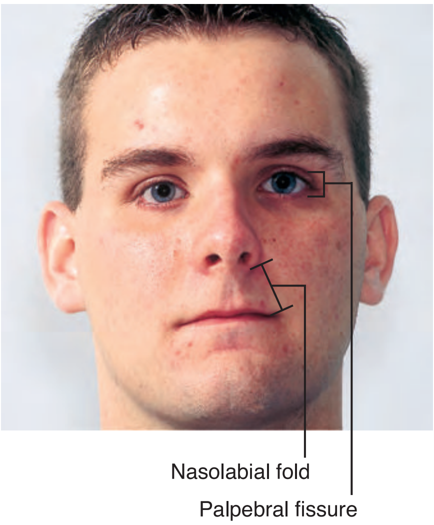
Newborns and infants—Cranial bones are not fused at birth, and head shape may reflect normal pressure or trauma during vaginal birth for several weeks. The anterior fontanel ("soft spot") fuses at about 18 months; the posterior, at about 8 weeks. Infants normally cannot hold their head up until about 6 months of age.

Abnormal findings: Larger or smaller than expected size for age, asymmetry of skull

---

2. **Inspect the face.** Note the client's facial expression. Ask yourself,
   - Are the facial features symmetrical?
   - Are there any abnormal facial movements?
   - Are there any visible lesions of abnormal hair distribution?

Helpful hint: Look for symmetry in the palpebral fissures and the nasolabial folds.



Step 2

Expected findings: Facial expression is appropriate for the situation. No visible lesions. Facial features and movement are symmetrical.

Abnormal findings: Facial appearance inconsistent with sex, age, or racial/ethnic group; asymmetry of facial features or facial movement.

Bell's Palsy

Cushing's Syndrome

---

3. **Palpate the head.** Check for masses, tenderness, and scalp mobility.

Developmental Modifications

Newborns and infants—Palpate anterior and posterior fontanels.

Expected findings: The head should be relatively smooth, with no tenderness or lesions.

Abnormal findings: Contour abnormalities (e.g., indentations, "bumps")

(continued on next page)

Procedure 22-5 ■ Assessing the Head and Face (continued)

4. **Palpate the face for symmetry, tenderness,** muscle tone, and temporomandibular joint function.

Palpating the TMJ

Expected findings: Smooth, symmetrical movement with no pain, crepitus, or clicking of the jaw

Abnormal findings: Irregular or uneven movement of the jaw; pain or popping with movement

Documentation

- If you need more information about documenting, review Documentation of Physical Assessment Findings for Nam Nguyen,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-6 ■ Assessing the Eyes

For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex gloves—if exposure to body fluids is a possibility
- Visual acuity chart with color bars (Snellen)
- A card—to cover one eye during the acuity exam
- Penlight
- Cotton ball and cotton-tipped applicator
- Ophthalmoscope
- Pen and form

Positioning

The client should be sitting, if possible.

Focused History Questions

- Have you noticed any changes in your vision?
- Do you wear glasses or contact lenses?
- Have you ever had an eye injury?
- Have you ever had an eye infection or stye?
- Do you have problems with excessive tearing or dry eyes?
- Have you ever had eye surgery?
- Have you ever experienced blurred vision?
- Do you have difficulty with nighttime vision?
- Do you ever see halos of light, spots or floaters, or flashes of light?
- Do you have a history of eye problems, such as glaucoma, or medical problems, such as diabetes or hypertension?
- When was your last eye exam?
- Do you use any prescription or over-the-counter eye medications?

When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Test distance vision.**
   - Depending on patient's age and literacy level, use the Snellen standard eye chart or Snellen E chart (for those who cannot read). Picture charts are available for preschoolers.
   - If the client wears corrective lenses, they should be worn during a test.
     a. Have the patient sit or stand 6 m (20 ft.) from the chart. With a card, cover the eye not being tested;

Expected and Abnormal Findings

Expected findings: Expect 20/20 vision in the right eye, left eye, and both eyes. The top number of the fraction indicates the distance the person was standing from the chart; the bottom number is the distance from which a person with normal vision would be able to read the chart.

Developmental Variations

Children—Distance vision does not reach 20/20 until around 6 or 7 years of age.

ask the patient to read the smallest line of print that he can distinguish. Consider a line to be read correctly if the client makes no more than two mistakes in that line.

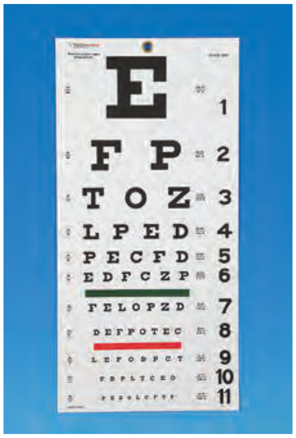
b. Test the opposite eye.
c. Test both eyes together.
d. At the end of each line of the Snellen chart is a fraction—the top line is 20/200. After each test, record the resulting fraction: the number at the end of the smallest line the patient could read with no more than two errors.

Middle adults—At about middle age, the lens of the eye begins to lose some ability to accommodate to near objects.

Abnormal findings: A smaller fraction (e.g., 20/100) indicates diminished distant vision or myopia. A larger fraction (e.g., 20/15) indicates diminished near vision, called hyperopia.

Preliterate chart

Snellen E chart



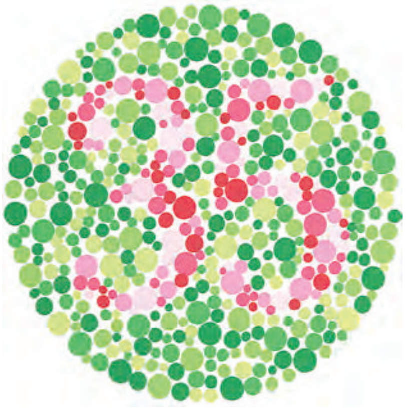
Snellen standard chart

2. **Test near vision**. Test the client's ability to read newsprint at a distance of 35.5 cm (14 in.) from the eyes. Use print-sized pictures if the patient is unable to read.

Expected findings: The client reads newsprint at a distance of 35.5 cm (14 in.).

Abnormal findings: The need to hold the print at a greater distance indicates hyperopia or presbyopia.

3. **Test color vision.**
   a. Have the patient differentiate patterns of colors on color cards or identify the color bars on the Snellen eye chart.
   b. Inability to distinguish colors requires a thorough evaluation using the Ishihara cards to determine the scope of the color deficit.



Ishihara card

Expected findings: Color vision is intact.

Developmental Variations

Older adults—Experience some decline in color vision, especially in the ability to see purples and pastels.

Abnormal findings: Inability to distinguish colors

(continued on next page)

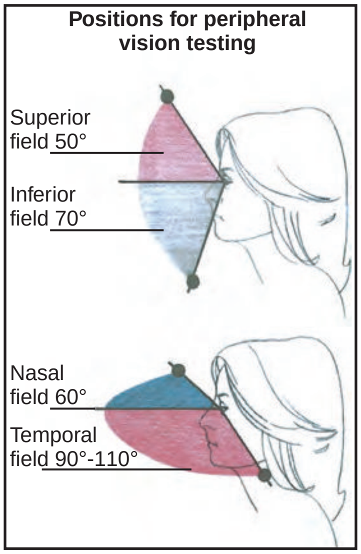
Procedure 22-6 ■ Assessing the Eyes (continued)

4. Test peripheral vision.
   a. Seat the client 60–90 cm (2–3 ft) from you.
   b. Have client cover one eye and fix the gaze straight ahead while you bring an object in from the periphery to the center of the visual fields. Be sure to begin by holding the object well outside the range of normal peripheral vision. Instruct the client to identify when the object becomes visible.
   c. Repeat this in each of the four visual fields, moving clockwise.

Expected findings: Expect no deficits in the visual fields.

Abnormal findings: Loss of peripheral vision. Report gross deficits to an ophthalmologist for further assessment.

Step 4



Testing peripheral vision.

5. Assess extraocular movements.
   a. Inspect the eyes for parallel alignment.
   b. Test the corneal light reflex by shining a penlight at the bridge of the nose. Note where the light reflects on the cornea of each eye.

a. **Expected findings:** The eyes should be in parallel alignment.
b. **Expected findings:** Corneal light reflex appears at the same position in each eye.

Abnormal findings: An asymmetrical corneal light reflex may indicate weak extraocular muscles or strabismus.

c. Test the six cardinal fields of gaze. Stand in front of the patient, and have the patient follow an object through the six cardinal fields without moving his head.

c. **Expected findings:** The eyes move through all six gaze positions.

Abnormal findings: Inability to move through all gaze positions

Up left

Side left

Down left

Down right

Side right

Up right

d. Perform the cover/uncover test. Cover one eye and have the patient gaze at a distant object. Uncover the eye. Repeat on the opposite side.

d. **Expected findings:** The gaze should be steady when the eye is covered and uncovered.

Abnormal findings: A shift in gaze indicates weak eye muscles.

6. **Inspect the external structures.**

a. **General appearance.** Check the color and alignment of the eyes.

a. **Expected findings:** Eyes clear, bright, and in parallel alignment.

Developmental Variations

Older adults—A decrease in periorbital fat may give the eyeballs a sunken appearance.

Abnormal findings: Glazed eyes may indicate a febrile state.

b. **Inspect the eyelids.** Note the presence of any lesions, edema, or lid lag. Refer to Eyes: Abnormal Lesions, at the end of this chapter.

b. **Expected findings:** No lesions present; lids move freely. Upper eyelid covers half of the upper iris.

Developmental Variations

Older adults—The lower lids may sag; skinfolds are prominent in the upper lids.

Abnormal findings: Asymmetry of lids may result from CN III damage or from a stroke. Lesions may be benign (e.g., a stye) or pathological (e.g., basal cell carcinoma).

c. **Inspect the eyelashes.** Note symmetry and distribution.

c. **Expected findings:** Eyelashes are evenly distributed and curve outward. No crustations or infestations are present.

Abnormal findings: Inflammation of the eyelids, which may be caused by infection; inverted eyelashes (entropion); everted eyelashes (ectropion); visible sclera between the iris and upper lid

(continued on next page)

Procedure 22-6 ■ Assessing the Eyes (continued)

d. **Inspect the lacrimal ducts and glands.** Note any edema, excessive tearing, or drainage.

d. **Expected findings:** No periorbital edema or lesions are present. No drainage.

Abnormal findings: Swelling, redness, drainage, or tenderness.

e. **Inspect the conjunctivae**. Note the color, moisture, and contour of the conjunctivae.
   (1) The palpebral conjunctivae cover the lids. To assess, have the patient look up as you place a cotton-tipped applicator on the upper lid, gently grasp the upper lid and lashes, and evert the lid over the cotton-tipped applicator.
   (2) The bulbar conjunctiva covers the eyeball. To assess, pull the lower lid down.

e. **Expected findings:** The palpebral conjunctivae are smooth, glistening, and peach in color. Minimal blood vessels are present. The bulbar conjunctivae are clear with few underlying blood vessels and white sclera visible.

Developmental Variations

Older adults—The conjunctivae may be pale or have a slightly yellow tint due to fat deposits.

Abnormal findings: Pallor, dryness, edema; pterygium; subconjunctival hemorrhage

Examining the palpebral conjunctiva

Examining the bulbar conjunctiva

f. **Inspect the sclera**. Note the color of the sclera and whether lesions are present.

f. **Expected findings:** The sclera should be smooth, white, and glistening. Dark-skinned patients may have a yellowish cast to the peripheral sclera or small brown spots more centrally.

Abnormal findings: Yellow (icteric) sclera

g. **Inspect the cornea and lens**. As the client looks straight ahead, shine a penlight at an angle to the eye, and move it across the corneal surface. Note the color and whether any lesions are present.

g. **Expected findings:** The cornea and lens are clear, smooth, and glistening.

Developmental Variations

Older adults—**Arcus senilis** (white, gray, or blue opaque ring in the corneal margin) is a normal variant.

Abnormal findings: Lens opacities (cataracts); roughness or irregularity of the cornea

h. **Test the corneal reflex**. Touch the cornea with a wisp of sterile cotton, or use a needleless syringe to shoot a small amount of air over the cornea.

> *Note:* This is not routinely performed on conscious patients. A conscious person can blink intentionally, so there is no need. In addition, there is a slight risk of corneal abrasion from cotton.

h. **Expected findings:** Blink reflex is prompt.

Abnormal findings: Failure to blink may result from neurosensory deficits.

i. **Inspect the iris and pupils.** Note the color, size, shape, and symmetry.

i. **Expected findings:** The iris is blue, green, brown, or a combination of these colors; its shape is circular. The pupils are round and of equal size. Unequal pupils (anisocoria) can be a normal variation if the difference is less than 0.5 mm.

Developmental Variations

Older adults—Pigment degeneration may cause the iris to be pale with brownish discolorations.

Abnormal findings: Damage to one eye may cause the iris to be a different color. Absence of part or all of the iris is a congenital problem. Unequal pupils may result from CN III damage, brain herniation, or increased intracranial pressure.

j. **Test pupillary reaction.** In a dimly lighted room, have the patient look straight ahead. Bring a penlight in from the side, and shine the light onto one eye. Note the reaction, equality, and speed of response of both eyes. For example, when you shine a light onto the right eye, the right pupil reaction is direct; the left eye is consensual. Repeat the test on the opposite eye.

Testing pupillary reaction to light

j. **Expected findings:** Normal direct and consensual response to light is brisk, with equal constriction of both pupils.

Developmental Variations

Older adults—Pupil reaction may be slower but should be symmetrical.

Abnormal findings: Sluggish or fixed pupils may result from CN II damage or brain injury. Absence of consensual response may result from nerve compression or anoxia.

k. **Test pupil accommodation.** Have the patient look straight ahead and focus on an object about 30 cm (12 in.) from his face. Slowly bring the object in toward the patient's eyes. Note pupil size and location.

k. **Expected findings:** The pupils constrict and the eyes cross as a person attempts to focus on a near object.

Developmental Variations

Older adults—Accommodation may be slow.

Abnormal findings: One or both pupils fail to accommodate, or they accommodate slowly.

l. **Inspect the anterior chamber.** Shine a penlight across the eye from the side as the patient looks straight ahead. Observe color, size, shape, and symmetry.

l. **Expected findings:** The chamber should be clear and symmetrically curved.

Abnormal findings: Blood or pus in the chamber. Also see the Abnormal Atlas: Eyes at the end of this chapter.

(continued on next page)

Procedure 22-6 ■ Assessing the Eyes (continued)

7. **Palpate the external structures**.
   a. Gently palpate the globe (eyeball) with your fingertips on the upper lids over the sclera. Note the consistency and any tenderness.
   b. Palpate the lacrimal glands and ducts by palpating below the eyebrow and below the inner canthus of the eye. Note tenderness and excessive tearing or discharge.

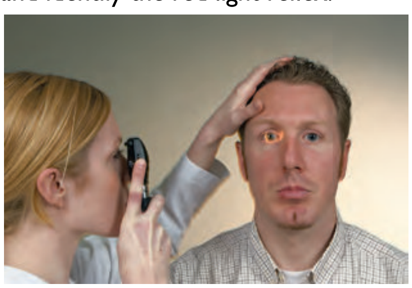
7. **Expected findings:** The globe is firm and nontender. Lacrimal glands are nonpalpable; no tenderness is present.

Abnormal findings: Firm or tender globe; swelling and tenderness over the lacrimal glands. Also,

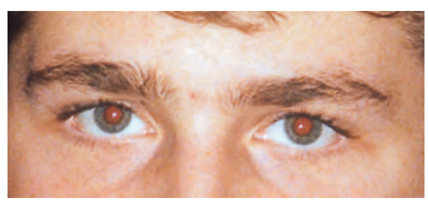
Go to the Abnormal Atlas at the end of this chapter.

---

8. **Assess the internal structures via ophthalmoscopy.** This is an advanced physical assessment technique.
   a. Darken the room.
   b. Stand about 1 foot from the patient at a 15° lateral angle.
   c. Dial the lens wheel to zero with your index finger. Hold the ophthalmoscope to your brow.
   d. Have the patient look straight ahead while you shine the light on one pupil and identify the red light reflex.

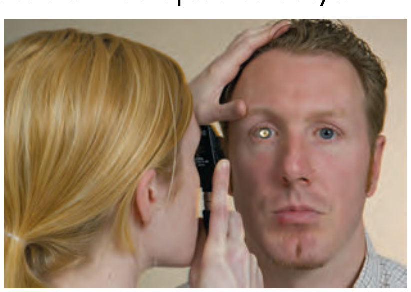


Checking red reflex



Red reflex over pupil area

   e. Once you identify the red light reflex, move in closer to within a few inches of the eye and observe the internal structures of the eye. Adjust the lens wheel to focus as needed. Use your right eye to examine the patient's right eye, and your left eye to examine the patient's left eye.



Examining internal structures of the eye

Normal fundus

   f. Repeat for the opposite eye.

Expected findings: A positive red light reflex. On internal examination, the optic disk is round with sharp margins. There are no opacities and the cup to disk ratio is 1:2. The disk is yellow with a white cup.

Abnormal findings: Any findings not consistent with the above should be reported promptly.

Patient Teaching

Teach the patient the importance of routine eye examinations.

Documentation

If you need more information about documenting, review **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-7 ■ Assessing the Ears and Hearing

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex gloves (if exposure to body fluids is a possibility)
- Tuning fork
- Watch
- Otoscope with pneumatic tube
- Pen and record form

Positioning

Have the patient seated, if possible.

Focused History Questions

- Do you have any hearing problems?
- Have you ever had ringing in your ears?
- Have you had any changes in your hearing?
- Do you have any ear drainage? If yes, how much and what color?
- Do you have any ear pain?
- Do you have any balance problems, dizziness, or vertigo?
- Do you have a history of head trauma?
- Are you exposed to noise pollution at work or in your home environment?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

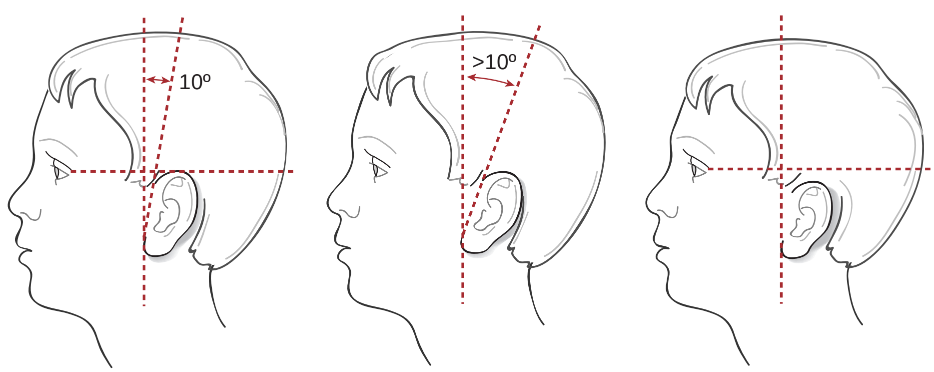
1. Inspect the external ear.

a. Check the placement and angle of attachment of the ear. ▼

Expected and Abnormal Findings

a. **Expected Findings:** The normal angle of attachment is 10°.

Abnormal findings: High or low placement of the ear may be a sign of hearing deficit or genetic problems.

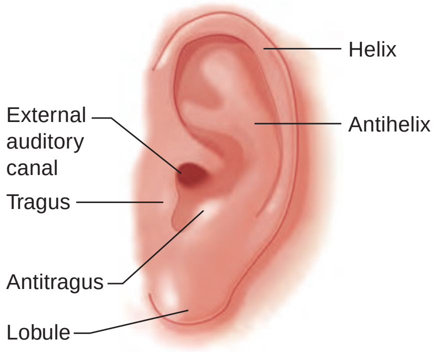


Normal ear attachment   Deviated alignment   Low-set ear attachment

(continued on next page)

Procedure 22-7 ■ Assessing the Ears and Hearing (continued)

b. Note the shape, size, and symmetry of the ears.



b. **Expected findings:** The helix, antihelix, antitragus, tragus, and lobule are present. The ears are 4–10 cm in length and symmetrical in size and shape.

Developmental Variations

Older adults—The ear changes shape as the lobe elongates.

Abnormal findings: Absence of any of the landmarks may indicate a hearing deficit. Ears that are <4 cm long or >10 cm long may indicate a genetic disorder.

c. Observe the color of the ear.

c. **Expected findings:** Color is consistent with skin color.

Abnormal findings: Redness may indicate inflammation or infection.

d. Observe the condition of the skin; observe for drainage and visible lesions.

d. **Expected findings:** Skin is intact with no drainage or lesions. Piercings may be present.

Developmental Variations

Older adults—May have coarse hair on the helix, antihelix, and tragus; skin may be dry.

Abnormal findings: Bloody or purulent drainage; lesions. The ears are a common location for skin cancer.

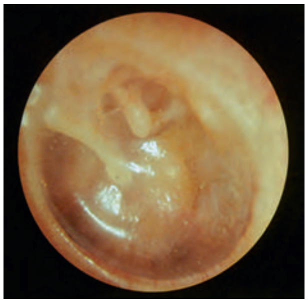
2. **Palpate the external structures of the ear.** Note the consistency of the skin, the presence of lesions, and any signs of tenderness.

Expected findings: Skin is soft, pliable, and nontender. No nodules or lesions are present.

Abnormal findings: Tenderness is often associated with infection.

3. **Perform an otoscopic exam.**
   a. This is an advanced physical assessment technique.
   b. Use a speculum with the largest diameter and shortest length that the ear canal can accommodate. 4 mm is a common size for adults.
   c. Have the patient tilt his head to the side not being examined.
   d. For adults, grasp the pinna and gently pull upward and back. For a child, position the pinna down and back. *Positions the ear canal with more direct alignment, allowing for improved visualization.*

Expected findings: The ear canal is light in color and patent, with a small amount of yellow cerumen (color may vary). TM is shiny and pearly gray with a cone of reflective light on the nasal aspect that would be 7 o'clock in the left ear and 5 o'clock in the right ear. Bony landmarks are visible. The TM is mobile. No bulging or retraction of the TM.



Normal fundus

e. Insert the speculum no further than halfway into the ear canal. As you advance the speculum, examine the canal for redness, open areas, drainage, foreign objects, and so on.

Otoscope insertion with handle up

Otoscope insertion with handle down

f. Look through the magnifying lens.
   (1) Observe the ear canal.
   (2) Observe the tympanic membrane.

g. Test the mobility of the tympanic membrane by using the otoscope's pneumatic tube to gently "puff" air into the external ear canal while observing movement of the cone of light.

NOTE: The ears are mirror images, with the cone of light at 7 o'clock in the left ear and 5 o'clock in the right ear.

Developmental Modifications

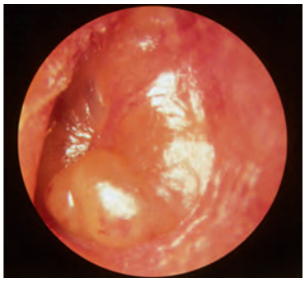
Children—Many young children fear the otoscopic examination. Demonstrating the procedure on a parent or a doll may relieve their anxiety.

h. Carefully remove the otoscope from the ear canal, being careful not to traumatize the delicate tissue.

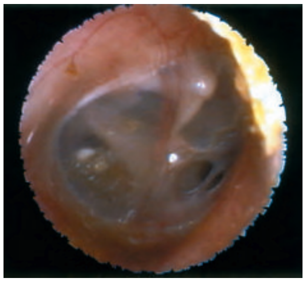
Developmental Variations

Older adults—May have dry ear wax. The TM is translucent, and the light reflex may be diminished.

Abnormal findings: Excessive wax may occlude the canal. TM that is red, with a distorted light reflex, suggests otitis media. A change in the position or shape of the cone of light reflex indicates an imbalance in middle ear pressure.



Otitis media



Perforated TM

---

4. Test gross hearing.

a. Stand 1–2 ft behind the patient. Have the patient cover one ear as you whisper some words. Repeat on the other side. Have the patient repeat the words she heard. *A test of hearing also indicates cranial nerve XIII is intact.*

b. Have the patient occlude one ear. Hold a ticking watch next to the patient's unobstructed ear. Slowly move it away until the patient says she can no longer hear the sound. Repeat for the opposite ear.

Expected Findings: The patient is able to hear you whisper on both sides. The patient hears the watch at a distance of about 12 to 13 cm (5 in.).

Developmental Variations

Older adults—Often have a generalized loss of hearing. It first occurs in the high-frequency sounds (*f, s, sh,* and *ph*) and then progresses to include all frequencies.

(continued on next page)

Procedure 22-7 ■ Assessing the Ears and Hearing (continued)

Developmental Modifications

Infants—For infants younger than 3 months of age, loudly clap your hands behind the infant and observe whether he startles. After 3 months of age, the infant should turn his head or eyes toward a sound, for example, when the parent stands behind the infant and calls his name.

Abnormal findings: Problems with the whisper test indicate low-tone hearing loss. Problems with the watch-tick test indicate a high-pitch deficit.

5. **Perform the Weber test.** Place a vibrating tuning fork on top of the patient's head. Ask the patient whether the sound is the same in both ears or louder in one ear.

Weber test

Expected findings: The patient hears the sound equally in both ears.

Abnormal findings: Sound is louder in one ear.

- If there is a conductive hearing loss, the vibration will be louder in the impaired ear. Conductive hearing loss may be caused by external or middle ear problems, such as infection, blockage of the canal by cerumen, or trauma to the TM.
- If there is a sensorineural hearing loss, the sound will be louder in the unaffected ear. Sensorineural loss may result from inner ear problems or from some medications.

6. **If the Weber test is positive: Perform the Rinne test.**
   a. Strike a tuning fork on the table. While it is still vibrating, place it on the patient's mastoid process.
   Tests bone conduction of sound.
   b. Measure the elapsed time in seconds that the patient hears the vibration.
   c. Move the tuning fork to 2.5 cm (1 in.) in front of the ear, and measure the elapsed time until the patient can no longer hear the vibration.
   Tests air conduction of sound.

Expected findings: Normally, sound transmission through air (step 6c) is twice as long as transmission through bone (step 6b); that is, AC = 2 × BC.

The ratio of AC to BC is similar in both ears.

Abnormal findings:

- Conductive loss: AC is less than 2 × BC.
- Sensorineural loss: AC is greater than BC but not 2 × longer; or the patient is unable to hear the tuning fork through BC.
- A difference between ears indicates unilateral hearing loss.
- Inability to hear the tuning fork through BC indicates sensorineural hearing loss.

d. Repeat for the opposite ear.

Rinne test

Step 6c

7. **Perform the Romberg test**. Have the patient stand with feet together, hands at side, with eyes opened and then with eyes closed. Note the patient's ability to maintain balance.

- Stand nearby in case the client loses his balance.

Tests for balance. Strictly speaking, it does not assess the ears, but the vestibular nerve and other parts of the central nervous system. Therefore, you may prefer to perform the test during the neurological exam.

Expected findings: The patient maintains balance with minimal sway.

Abnormal findings: Positive Romberg (swaying) is seen with vestibular and cerebellar disorders.

Patient Teaching

Teach the patient the importance of routine hearing examinations.

Documentation

- If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-8 ■ Assessing the Nose and Sinuses

For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex procedure gloves (if exposure to body fluids is a possibility)
- Penlight
- Nasal speculum or otoscope with a wide-tipped speculum
- Pen and record form

Positioning

Have the patient seated, if possible.

Focused History Questions

- Do you have any nasal congestion?
- Do you have a history of nose or sinus problems?
- Do you have problems with seasonal or environmental allergies?
- Do you have a history of sinus headaches?
- Do you experience nose bleeds (*epistaxis*)?
- Have you ever broken your nose?
- Have you had any changes in your sense of smell?
- Do you use any nasal sprays or allergy medications?

(continued on next page)

Procedure 22-8 ■ Assessing the Nose and Sinuses (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Position the client for the exam.**

2. **Inspect the external nose.** Note the position, shape, and size. Observe for discharge and flaring.

Expected findings: The nose is midline and symmetrical. No discharge or flaring

Abnormal findings: Asymmetry suggests congenital deformity or trauma. Flaring suggests respiratory distress (especially in infants, who cannot breathe through the mouth). Clear drainage suggests allergy; yellow or green drainage suggests upper respiratory infection; bloody drainage may result from trauma, hypertension, or a bleeding disorder.

3. **Check for patency of the nasal passages.** Ask the patient to close his mouth, hold one naris closed, and breathe through the other naris. Repeat with the opposite naris.

Expected findings: The client breathes freely through both nares.

4. **Inspect the internal structures.**
   a. Use a nasal speculum or an otoscope with a large speculum (or a penlight with a speculum) to assess the internal structures.
   b. Tilt the patient's head back to facilitate speculum insertion and visualization.
   c. Brace your index finger against the patient's nose as you insert the speculum.
   d. Insert the speculum about 1 cm into the nares. Use the other hand to position the client's head and to hold the penlight if you do not have a lighted scope. ➤
   e. Observe the nasal mucosa for color, edema, lesions, erosion or ulceration, blood, and discharge. Inspect the septum for position and intactness.
   f. Check for sense of smell using commonly recognized objects, such as a lemon or vanilla. Do not use a noxious odor. You can defer this test until the sensorineurological part of the exam if you choose, but keep the same order for every exam.

   Cranial nerve I is intact when the patient shows an ability to detect odor.

Expected findings: Nasal mucosa is pink and moist. Septum is intact and midline. No lesions

Abnormal findings: Deviated septum; polyps. Pale boggy mucosa is seen with allergies; bright red mucosa is associated with rhinitis, sinusitis, and cocaine use. Clustered vesicles suggest herpes infection. Erosion of nasal mucosa should signal you to investigate further for other signs or history of crack/cocaine use. Blood in the nasal passage indicates trauma, nose bleeds, or polyps.

Step 4d

Developmental Modifications

Infants and children—You will not need a speculum to examine internal structures. Push the tip of the nose upward with your thumb, and direct a penlight into the nares.

5. Transilluminate the frontal and maxillary sinuses. First, darken the room.

a. *Frontal sinuses:* Shine a penlight or the otoscope with speculum below the eyebrow on each side.

Step 5a

a. **Expected findings:** A red glow is seen above the eyebrow, indicating that the frontal sinus is patent.

b. *Maxillary sinuses:* Place the light source below the eyes and above the cheeks. Look for a glow of red light at the roof of the mouth through the client's open mouth.

Step 5b

b. A red glow may be (but is not always) seen in the roof of the mouth, indicating that the maxillary sinus is patent.

Abnormal findings: Absence of transillumination may result from mucosal thickening or sinusitis.

---

6. Palpate the external structures.

Expected Findings: No tenderness, lesions, or deformity

---

7. Palpate the frontal and maxillary sinuses.

Expected findings: No tenderness

Abnormal findings: Tenderness may indicate infectious or allergic sinusitis.

Documentation

- If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-9 ■ Assessing the Mouth and Oropharynx

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex procedure gloves
- Penlight
- Tongue blade
- Small gauze pad
- Pen and record form

Positioning

Have the patient seated, if possible.

Focused History Questions

- Do you have any problems with your mouth or teeth?
- When was your last dental exam?
- Do you have any discomfort in your mouth or throat?
- Have you had any recent changes in your mouth or teeth?
- How often do you brush your teeth? Floss?
- Do you smoke or chew tobacco?
- Do you have any sores or irritation in your mouth? If so, when did you first notice this?

(continued on next page)

Procedure 22-9 ■ Assessing the Mouth and Oropharynx (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Inspect the mouth externally.** Locate the placement of the lips and their color and condition. Ask the client to purse his lips.

Expected and Abnormal Outcomes

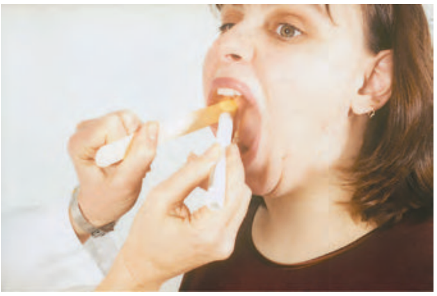
Expected findings: The lips are midline, symmetrical, moist, and intact with no lesions. Coloring is consistent with ethnic group/race. The client can purse his lips.

Abnormal findings: Asymmetry (may be due to congenital deformity, trauma, paralysis, or surgical alteration); pallor; cyanosis; redness; inability to purse lips (may indicate facial nerve damage); lesions (may be caused by bacteria, viruses, or trauma)

2. **Note the color and condition of the oral mucosa and gums.**
   a. Don procedure gloves.
   b. Inspect and palpate the lower lip. Pull the lower lip away from the teeth, and inspect the inner side of the lip. Palpate any lesions for size, mobility, and tenderness.

Expected findings: Oral mucosa is pink, moist, and intact; no lesions. Gingiva is consistent in color with the other mucosae and is intact, with no bleeding. Buccal mucosa is pink and moist, with no lesions. Mucosa is darker in dark-skinned clients.

Step 2b



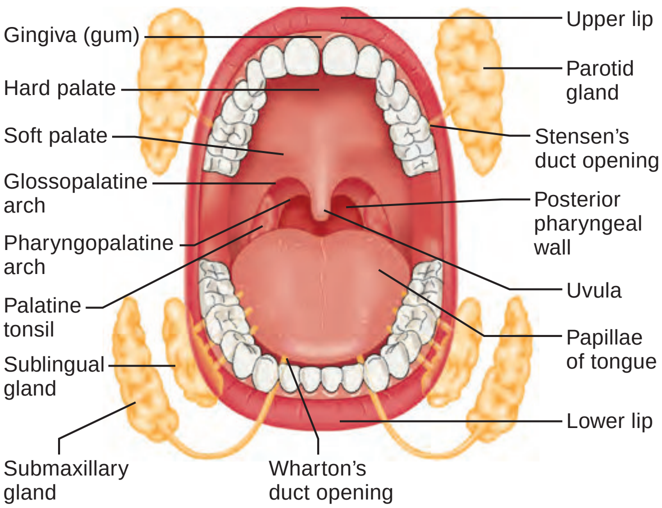
Step 2b

   c. Inspect the buccal mucosa, top to bottom and back to front.
      - Ask the client to open his mouth. Use a tongue depressor to retract the cheek, then shine a penlight onto the mucosa.
      - Using a tongue blade and penlight, inspect the Stensen's duct openings to the parotid glands.
   d. Finally, palpate inside each cheek by placing a finger inside and thumb outside. Grasping the cheek between them, move the finger about. Repeat on both sides.
   e. As you are inspecting the buccal mucosa, also examine the gums. Check for color, bleeding, edema, retraction, and lesions. Press gum tissue gently with gloved finger or tongue blade to assess firmness.

Developmental Variations

Older adults—Mucosa is drier than in young adults because of decreased salivary gland activity; brownish pigmentation of gums may be seen, especially in dark-skinned people.

Abnormal findings: Receding gums, sponginess, bleeding, inflammatory changes, gingival hyperplasia, ulcerations, or other lesions



Structures of the mouth and oropharynx

3. Inspect the teeth. You can do this while you are inspecting the oral mucosa and gums, in step 2.

a. Observe the number, color, and condition of the teeth. Note the occlusion ("bite") and any loose teeth.

b. If the client wears dentures, ask her to remove them. Inspect for cracked or worn areas; assess the fit.

Gingival recession

Expected findings: Most adults have 28 teeth, or 32 if the wisdom teeth have erupted. Children have 20 teeth. The teeth should be white, in good repair, with no caries and good occlusion. The top front teeth should slightly override the lower ones.

Developmental Variations

Older adults—May have receding gums, so teeth appear longer. Teeth may be chipped, eroded, or stained.

Abnormal findings: Missing or poorly anchored teeth, misalignment, and brown or black enamel (indicative of dental caries or staining, e.g., from taking tetracycline). White spots may indicate excessive fluoride intake.

4. Inspect the tongue and the floor of the mouth.

a. Ask the client to "stick out" his tongue. Examine the upper surface for its color, texture, position, and mobility.

b. Ask the client to roll his tongue upward and move it side to side.

c. Have the client place the tip of his tongue on the roof of his mouth, as far back as possible. Using the penlight, inspect the underside of the tongue, the frenulum (which fastens the tongue to the floor of the mouth, in the center), and the floor of the mouth.

d. Inspect the two Wharton's duct openings to the submaxillary glands, on either side of the frenulum.

e. Use a tongue blade or gloved finger to move the tongue aside and examine the lateral aspects of the tongue and the floor of the mouth bilaterally. Use caution when placing your finger into the mouth of a noncompliant client.

Expected findings: Tongue is moist, and the coloring is consistent with the client's race. Mucosa has no lesions or discoloration. Papillae are intact. Tongue is midline with full mobility. The base of the tongue is smooth with prominent veins. No tenderness; no palpable nodules. A geographic tongue is a common normal variant.

Developmental Variations

Older adults—May have varicosities under the tongue.

Abnormal findings: Red, smooth, or painful tongue; inflamed mucosa or ducts; tongue that is not midline or has restricted mobility; ulcerations of the tongue or the floor of the mouth (e.g., from trauma, viral infection, or cancerous changes); white plaque or black, hairy tongue (fungal infection).

Geographic tongue

Red, beefy tongue

Black, hairy tongue

Leukoplakia

Cancer of the tongue

(continued on next page)

Procedure 22-9 ■ Assessing the Mouth and Oropharynx (continued)

5. **Palpate the tongue and floor of the mouth.** Stabilize the tongue by grasping it with a gauze pad. Palpate top, bottom, and sides with your other index finger.

6. **Inspect the oropharynx (hard/soft palate, tonsils, and uvula).** Note the color, shape, texture, and condition.
   a. Have the client tilt his head back and open his mouth as widely as possible. Depress the tongue with a tongue blade, and shine a penlight on the areas to be inspected.
   b. To inspect the uvula, ask the client to say "ah," and watch the uvula as the soft palate rises.
   c. Inspect the oropharynx by depressing one side of the tongue at a time, about halfway back on the tongue.
   d. Note the size and color of the tonsils; note any discharge, redness, swelling, or lesions.
   e. Look and palpate for cleft palate, especially in infants.

Expected findings: Hard and soft palates are pink and smooth. Uvula is midline and rises symmetrically. Tonsils are pink, symmetrical, and without lesions or exudate.

Developmental Variations

Children—Until about age 12, the tonsils may extend beyond the palatine arch.

Abnormal findings: Redness, edema, lesions, plaques, drainage; yellow or greenish streaks on the posterior wall of pharynx (indicate postnasal drainage); tonsils that are red, edematous, or enlarged or have white or pale patches of exudates. Asymmetrical rise of the uvula may indicate a problem with CN IX or X.

7. **Test the gag reflex** by touching the back of the soft palate with a tongue blade.

Expected findings: Positive gag reflex is present.

Developmental Variations

Older adults—May have a slightly slower gag response.

Abnormal findings: Absence of a gag reflex is seen with extreme sedation, head injury, or damage to CN IX and X. Also see the Abnormal Atlas: Mouth and Oropharynx, at the end of this chapter. Inability to articulate the specified words indicates CN XII is not intact.

8. **Ask the client to repeat the following words:** Light, tight, dynamite. Again, you may defer this test to the sensorineurological portion of the exam if you choose.

Patient Teaching

Instruct the patient in the importance of dental care and the need for regular checkups.

Documentation

- If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-10 ■ Assessing the Neck

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Stethoscope and antiseptic wipe
- Pen and record form

Positioning

- Have the client seated, if possible.
- For infants and children, position supine.

Focused History Questions

- Do you have any difficulty swallowing?
- Do you have any neck pain or stiffness?
- Do you have any neck masses or lumps?
- Do you have any history of thyroid disease?
- Do you have any difficulty swallowing?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Inspect the neck**. Note symmetry, range of motion (ROM), and the condition of the skin.
   - Inspect the neck in a neutral position.
   - Inspect the neck when it is hyperextended.
   - Inspect the neck when the patient swallows water.

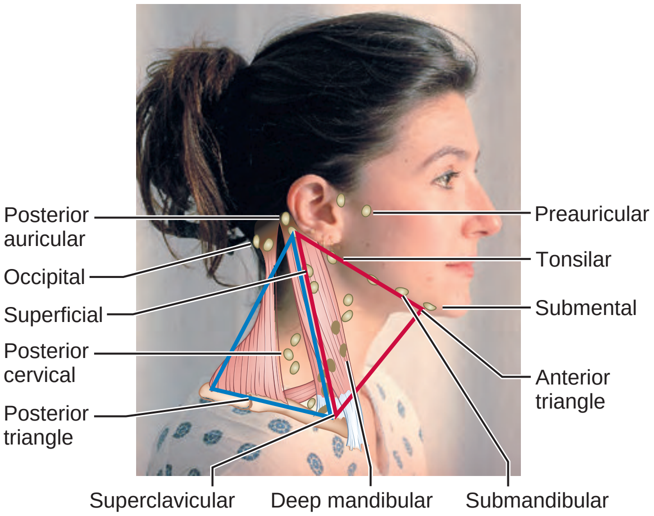
Expected and Abnormal Findings

Expected findings: Neck is erect, midline, and symmetrical with full ROM. No masses are present; skin is intact. Larynx and trachea rise with swallowing. Thyroid is not visible.

Abnormal findings: Swollen lymph nodes may be visible. An enlarged thyroid may be visible in the lower half of the neck.

2. **Palpate the cervical lymph nodes**. Note the size, shape, symmetry, consistency, mobility, tenderness, and temperature of any palpable nodes.
   a. Use light palpation with one or two fingerpads in a circular movement.
   b. Palpate the cervical nodes in the following order:
      (1) *Preauricular*—in front of the ear
      (2) *Posterior auricular*—behind the ear
      (3) *Tonsilar*—at the angle of the jaw
      (4) *Submandibular*—halfway up the lower jaw
      (5) *Submental*—under the tip of the chin
      (6) *Occipital*—at the base of the skull in the occipital area
      (7) *Superficial cervical*—below the tonsilar node over the sternocleidomastoid muscle
      (8) *Deep cervical*—under the sternocleidomastoid muscle
      (9) *Posterior cervical*—in posterior triangle along trapezius muscle
      (10) *Supraclavicular*—above the clavicle
   c. Use the same sequence every time so that the steps will become automatic and you will not omit any area.

Expected findings: Lymph nodes are supple and nontender; no masses are palpable.



Abnormal findings: Lymphadenopathy (palpable nodes 1 cm or greater). Immobile nodes may indicate malignancy, inflammation, or infection in the area they drain.

(continued on next page)

Procedure 22-10 ■ Assessing the Neck (continued)

3. Palpate the thyroid.

To use the posterior approach:

a. Stand behind the client, and ask her to flex her neck slightly forward and to the left.
b. Position your thumbs on the nape of the client's neck.
c. Using the fingers of your left hand, locate the cricoid cartilage, which is located below the thyroid cartilage. Push the trachea slightly to the left with your right hand as you palpate just below the cricoid cartilage and between the trachea and sternocleidomastoid muscle.
d. Ask your client to swallow (give her small sips of water if necessary), and feel for the thyroid gland as it rises up.
e. Reverse and repeat the same steps to palpate the right thyroid lobe (use the fingers of your left hand to displace the trachea to the right, while using the fingers of your right hand to palpate the thyroid to the right of the trachea).

To use the anterior approach:

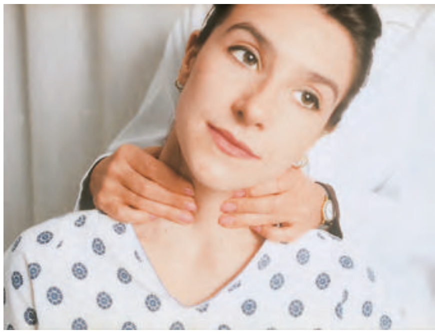
f. Stand in front of the client, and ask her to flex her neck slightly forward and in the direction you intend to palpate.
g. Place your hands on the neck, and apply gentle pressure to one side of the trachea while palpating the opposite side of the neck for the thyroid as the client swallows.
h. Reverse and repeat the same steps on the opposite side.

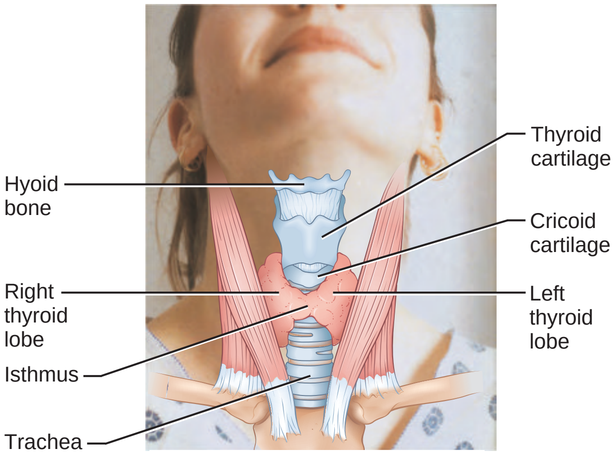
? What if . . .

- **The thyroid gland is enlarged or there is a mass?**
  Auscultate the thyroid for bruits using the bell portion of the stethoscope. Ask the client to hold her breath as you auscultate. There should be no bruits.

Expected findings: The thyroid is generally nonpalpable. If some tissue is palpable, the consistency is firm and smooth. There is no nodularity, enlargement, or tenderness.

Abnormal findings: An enlarged thyroid may signify a tumor or goiter. A tender thyroid is associated with inflammation.





Steps 3a–d

Patient Teaching

Teach the patient how to perform a "neck check"—self-check the thyroid with a glass of water and a handheld mirror. Tell the patient: "Hold the mirror in your hand and focus on your neck just below the Adam's apple and above your collarbone. Tip your head back, take a drink of water, and swallow. As you swallow look at your neck. Check for any bulges in this area as you swallow." To download Neck Check instructions, and for more information about thyroid health,

Go to **http://www.thyroidawareness.com.**

Documentation

- If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-11 ■ Assessing the Breasts and Axillae

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the the inside back cover.

Equipment

- Nonlatex procedure gloves, if exposure to body fluids is possible
- Glass slide
- Culturette
- Pen and record form

Positioning

The patient must assume several positions during breast examination (see step 1).

Focused History Questions

- Do you have a lump or thickening in your underarm or breasts that persists throughout your menstrual cycle?
- Do you have any breast pain or discharge?
- Have you noticed any changes in the skin on your breasts, nipples, or underarms?
- Have you had any changes in your nipples?
- Have your breasts changed in size, shape, or contour?
- Do you perform breast self-examination (BSE)?
- Are you taking any medications or hormones?
- If you are premenopausal, when was your last period?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Inspect the breasts.** Note size, shape, symmetry, and color. Inspect with the client in each of the following positions:
   a. Sitting or standing with arms at her side
   b. Sitting or standing with arms raised slightly but not over her head

   Aids in detecting dimpling or retraction of breast tissue

   c. Seated or standing with her hands pressed on her hips

   Aids in detecting dimpling or retraction of breast tissue

   d. With the client leaning forward

   Helpful when examining large, pendulous breasts

   e. With the client supine with a pillow under the shoulder of the breast being examined

   Helps spread the breast tissue over the chest wall

Expected and Abnormal Findings

Expected findings: The breasts are symmetrical; however, the dominant side may be more developed, resulting in a slightly asymmetrical appearance. Skin color is lighter than exposed areas, and there are no lesions, redness, or edema. Texture is smooth, with no dimpling or retraction. Striae are a normal variation.

Developmental Variations

Newborns—You may see breast enlargement and watery, white discharge from the nipples during the first 2 weeks of life.

Children—Breasts typically begin to develop at about 13 years of age; the breasts may not develop at equal rates.

Pregnancy—Breast size increases; areolae and nipples darken; superficial veins become prominent; stretch marks may be present; colostrum (a thick, yellow precursor to breast milk) can sometimes be expressed as early as the second trimester.

Older adults—Breasts lose firmness and become flaccid and pendulous.

Abnormal findings:

- Asymmetry warrants further investigation.
- Swelling or erythema may be seen in infection (mastitis).
- **Peau d'orange** (dimpled skin texture) skin changes may be seen with lymphatic obstruction that is present in some forms of breast cancer.
- Puckering, lesions, and retraction may also be seen with breast cancer.
- **Gynecomastia** (enlargement of breasts in males) may indicate hormone imbalance.

(continued on next page)

Procedure 22-11 ■ Assessing the Breasts and Axillae (continued)

2. **Inspect the nipples and areolae.** Note color, shape, and symmetry. Observe for any discharge.

Expected findings: The areolae and nipples are darker in color than breast tissue. Nipples are everted and point in the same direction. No discharge is present, except in newborns and during pregnancy and lactation. No lesions or erosion is present.

Abnormal findings:

- Nipple discoloration that is not associated with pregnancy
- Nipples pointing in different directions. Such findings warrant follow-up as a potential sign of an underlying mass.
- Flat or inverted nipples, which are caused by shortening of the mammary ducts. May make breastfeeding difficult.
- Any nipple discharge not associated with newborns, pregnancy, or breastfeeding requires a thorough evaluation
- Cracks and nipple redness, which may occur with breastfeeding

3. **Inspect the axillae.** Note the color, condition of the skin, and hair distribution.

Expected findings: Skin is intact with no lesions or rashes. Presence of hair depends on the age of the client and personal preference. Axillary hair develops with puberty. Some women may choose to shave the hair, whereas others will allow it to grow.

Abnormal findings: Rashes, redness, or unusual pigmentation may indicate infection or allergy to deodorants. Dark-pigmented, velvety skin may be seen with ***acanthous nigricans,*** a condition associated with obesity and type 2 diabetes mellitus.

4. **Palpate the breasts,** wearing procedure gloves if necessary. Using the fingerpads of your three middle fingers, make small circles with light, medium, and deep pressure. Begin at an imaginary line drawn straight down the side from the underarm; move across the breast to the middle of the sternum. Check the entire breast area, moving down until you feel only ribs and up to the clavicle.

   Follow one of the following three patterns (evidence suggests the vertical strip method is best).

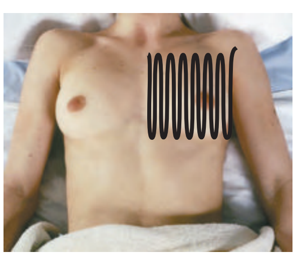
   a. ***Vertical strip method:*** Start at the sternal edge, and palpate the breast in parallel lines until you reach the midaxillary line. Go up one area and down the adjacent strip (like "mowing the grass").
   b. ***Pie wedge method:*** This method examines the breast in wedges. Move from one wedge to the next.
   c. ***Concentric circles method:*** Start at the outermost area of the breast at the 12 o'clock position. Move clockwise in concentric, ever smaller, circles.

Expected findings: Breasts are soft and nontender with no lesions or masses. Consistency depends on age; premenopausal women have firm and elastic tissue, whereas postmenopausal women have softer tissue that may be stringy or cord-like.

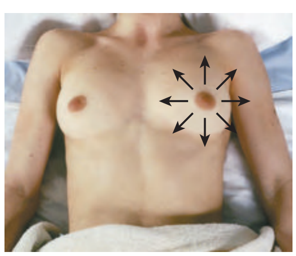
Abnormal findings: Breast lumps or masses may be benign or malignant and require follow-up.

Technique Hints

- Do not remove your fingers from the skin surface once you have begun palpating. Move from area to area by sliding the fingers along the skin.
- Most breast lesions in women are found in the upper outer quadrant.
- Most breast cancer in men occurs in the areola.



Vertical strip method



Pie wedge method

Concentric circle method

5. Palpate the nipples and areolae.
a. If the woman is supine, place a small pillow or folded towel under the shoulder of the breast you are examining.
b. Squeeze the nipple gently between your thumb and finger to check for discharge.
c. Note tissue elasticity and tenderness.

Expected findings: Nipples are elastic and nontender. No discharge is present.

Abnormal findings: Loss of elasticity may indicate underlying malignancy. Bloody, purulent discharge may indicate infection. Other forms of drainage may indicate malignancy. Nipple tenderness is normal when establishing breastfeeding.

6. Palpate the axillae and clavicular lymph nodes.
a. Have the woman sitting with her arms at her sides or supine.
b. Using your fingerpads, move your fingers in circular fashion.
- *Central nodes:* located high in the midaxillary region
- *Anterior pectoral nodes:* located on the lower border of the pectoralis major in the anterior axillary fold
- *Lateral brachial nodes:* located high in the axilla on the inner aspect of the humerus
- *Posterior subscapular nodes:* located high in the axilla on the lateral scapular border
- *Epitrochlear nodes:* located above the elbow
- *Infraclavicular nodes*: located below the clavicle
- *Supraclavicular nodes*: located above the clavicle

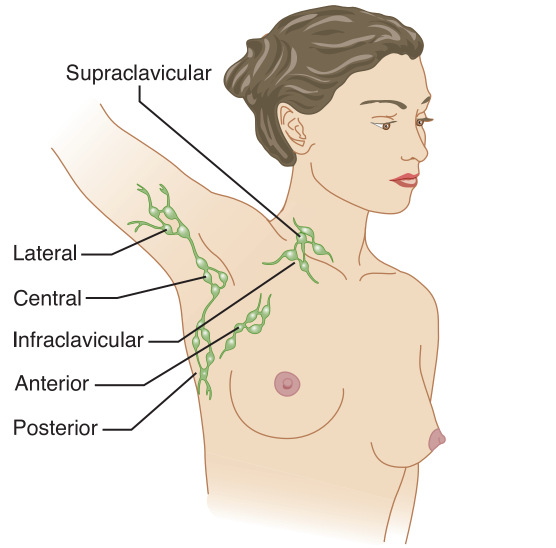
Expected Findings: Nodes are nonpalpable.

Abnormal findings: Palpable nodes may be seen with infection or malignancy. Enlarged lymph nodes caused by infection are tender.

? What if . . .

- **There is a nipple discharge?**

If there is nipple discharge in a woman who is not pregnant or breastfeeding, obtain a specimen by placing a glass slide up to the breast to capture a drop of discharge. Transport the slide to the laboratory as soon as possible. If there is ample discharge, obtain a swab of the discharge with a culturette.



Location of normal lymph nodes

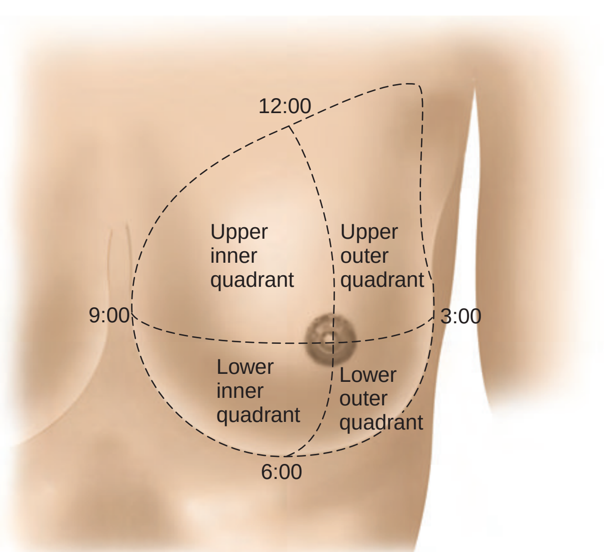
Patient Teaching

You should demonstrate BSE procedure as part of client teaching for self-care, if the patient chooses to perform BSE. Instruct clients that clinical breast exams should be done annually for women aged 40 and older, and every 1 to 3 years for women aged 20 to 39 (ACOG, 2011). Guidelines vary as to the age at which women should start having clinical breast exams (CBE) and mammograms to screen for breast cancer. Annual or biennial mammograms or breast thermography most commonly begin after age 40, or at a younger age and more often for those at high risk (American Cancer Society, n.d., revised 2013a, n.d., revised 2013b). Evidence at present does not support the need for a CBE if a mammogram is done (AHRQ, 2005 October, revised March 2013).

Documentation

- If you palpate a mass or lump, document its size, shape, symmetry, mobility, tenderness, and skin color changes. To document the location, divide the breast into four quadrants by intersecting vertical and horizontal lines. With the nipple as the center, locate the mass or lump as though the breast were a clock; state the distance in cm from the nipple (e.g., 4 o'clock, 2.5 cm from nipple).
- If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.



Practice Resources

Agency for Healthcare Research and Quality (AHRQ) (2005 October, revised March 2013); American Congress of Obstetricians and Gynecologists (ACOG) (2009, 2011); American Cancer Society (n.d., last revised 2013b); Maurice, A. Evans, D.G. Affen, J. et al. (2012); Smith, R. A., Duffy, S. W., & Tabár, L. (2012).

Procedure 22-12 ■ Assessing the Chest and Lungs

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Stethoscope and antiseptic wipe
- Felt-tipped marker and ruler
- Pen and record form

Positioning

- Have the client sitting, if possible, and leaning forward for the posterior approach.
  If the client is unable to sit up, findings will be distorted.
- If the client is lying down, findings are more evident on the dependent side; help her change positions so that you can assess with each side dependent.

Focused History Questions

- Do you have fatigue or activity intolerance?
- Do you have any current respiratory problems?
- Have you had any recent respiratory problems?
- Do you have a cough?
- Do you have any difficulty breathing?
- What, if anything, causes you to be short of breath?
- Have you had any chest pain?
- Do you have a history of allergies or asthma?
- Do you smoke? If so, how much and for how long?
- If you smoke, have you tried to quit? Would you like to quit?
- Are you exposed to air pollutants at home or at work?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Count the respiratory rate, and observe the rhythm and depth; observe the symmetry of chest and respiratory movements.**
   (See Chapter 20 if you need more information about counting respirations.)

Expected and Abnormal Findings

Expected findings:

- Respirations are quiet with a regular rhythm and depth; rate 12–20 breaths/min for adults. Chest movement is symmetrical.

Developmental Variations

Infants and children—The normal respiratory rate varies by age. A newborn may have a respiratory rate of 40–90. The rate gradually declines as the child matures. Newborns breathe abdominally, so you will see little chest movement.

Older adults—Rate changes very little; however, respirations decrease in depth as muscles become weakened.

Abnormal findings:

- Chest asymmetry may be seen with musculoskeletal disorders of the spine, such as kyphosis or scoliosis.
- Asymmetrical movement during breathing is seen in rib fractures, pneumothorax, and atelectasis; affected chest area may not move at all with respiration.
- Sternal and intercostal retractions are seen with hypoxia, respiratory distress, and airway obstruction.
- Respiratory rate may be increased with activity, smoking, fever, pain, or anemia.

---

2. **Inspect the chest.**
   a. Inspect the anteroposterior (AP):lateral ratio.
   Anteroposterior diameter—as viewed from the side
   Lateral diameter—as viewed from the front (or back)

a. **Expected findings:** The normal adult AP:lateral ratio is 1:2.

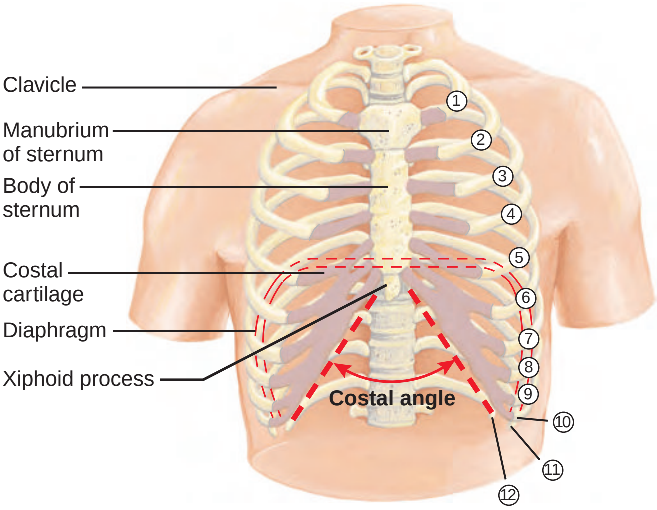
Developmental Variations

Infants—AP is equal to the lateral diameter

Older adults—Kyphosis and osteoporosis change the size and shape of the chest; weakening thoracic and diaphragm muscles allow the chest to widen and become more barrel-shaped, as does COPD.

Abnormal findings: AP:lateral ratio is increased in COPD (barrel chest).

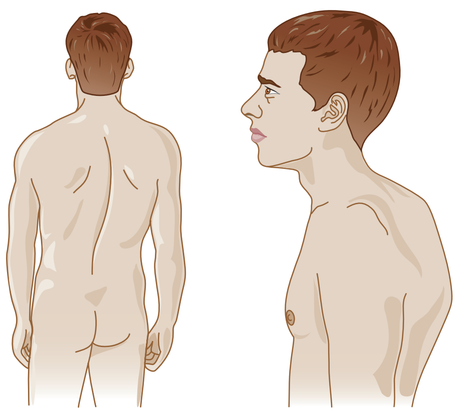
b. Inspect the costal angle.



b. **Expected findings:** The costal angle is < 90°.

Abnormal findings: Costal angle is > 90° in COPD.

c. Identify any spinal deformities.



Scoliosis Kyphosis

c. **Expected findings:** The spine is straight without lateral curvatures or deformity.

Abnormal findings: Scoliosis is a lateral curvature of the spine. Kyphosis is excessive thoracic curvature.

d. Observe the effort required to breathe.

d. **Expected findings:** Respirations appear effortless. No retraction or use of accessory muscles.

Abnormal findings: Sternal and intercostal retractions are seen in severe hypoxia or respiratory distress.

e. Note the color and condition of skin.

e. **Expected findings:** Skin color and hair distribution are consistent with the client's gender, ethnicity, and exposure to the sun. The skin is intact with no scars.

Abnormal findings: Cyanosis of the chest wall (due to extreme hypoxia or cold temperature).

3. **Palpate the trachea.** Place your fingers and thumb on either side of the trachea and note its position. (In a comprehensive exam, you may have already done this with the neck examination.)

Developmental Modifications

Infants—Neck is short, so it may not be possible to palpate the trachea.

Expected findings: Trachea is in the midline.

Abnormal findings: Tracheal deviation may occur from a mass in the neck (e.g., thyroid enlargement) or from excess pressure in the lungs (e.g., tension pneumothorax).

(continued on next page)

Procedure 22-12 ■ Assessing the Chest and Lungs (continued)

4. Palpate the chest.
- Observe for tenderness, masses, or **crepitus** (crackling skin due to air in the subcutaneous tissue).
- Palpate the anterior, posterior, and lateral chest by placing your hands on the chest wall.

Expected findings: The chest is nontender. No masses or crepitus present.

Abnormal findings: Pain in the chest wall may be due to fracture, inflammation, or trauma. Crepitus results from air leaking into the subcutaneous tissue. It is most likely to occur around wounds, central IV line sites, chest tubes, or a tracheostomy.

5. Palpate chest excursion (expandability).

a. Place your hands at the base of the client's chest with fingers spread and thumbs about 5 cm (2 in.) apart (at the costal margin anteriorly and at the 8th to 10th rib posteriorly).

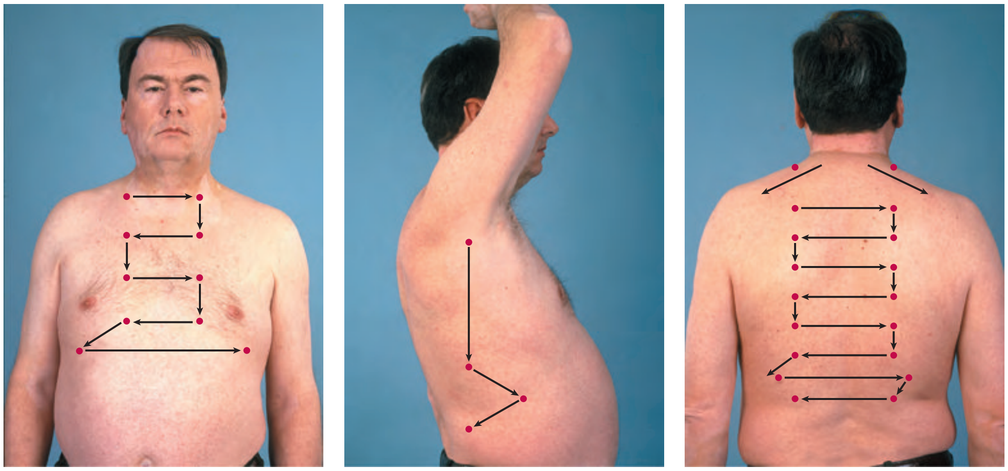
b. Press your thumbs toward the client's spine to create a small skinfold between them.

c. Have the client take a deep breath, and feel for chest expansion. This may be performed on the anterior or posterior portion of the chest, or both.

Expected findings: Chest excursion is symmetrical on the anterior and posterior aspect of the chest (you should feel equal pressure on your hands; thumbs should move apart equal distances).

Abnormal findings: Limited chest excursion may occur with shallow breathing, restrictive clothing, or restrictive airway disease. Asymmetrical excursion may result from airway obstruction, pleural effusion, or pneumothorax.

6. Follow the same pattern and sequence for palpating fremitus, percussing, and auscultating the chest. See the accompanying diagram.



7. Palpate the chest for tactile fremitus.

a. Use the palmar surface of your hands, but raise the fingers off the client's chest so that you palpate with the bony metacarpophalangeal joints of your hands.

Bony prominences are best for detecting vibrations.

Expected Findings: Tactile fremitus is equal bilaterally on the anterior and posterior chest; it is diminished at midthorax. Fremitus is normally diminished if the chest wall is very thick or the voice very soft.

b. Palpate for vibrations as the client says "99."

Developmental Modifications

Infants—Place your hand over the chest while the infant is crying.

Developmental Variations

Children and thin adults—May have increased fremitus.

Abnormal findings: Increased fremitus occurs with conditions that cause fluid in the lungs (e.g., pulmonary edema). Decreased or absent fremitus occurs when there is decreased air movement or tissue consolidation (e.g., emphysema, asthma).

---

8. Percuss the chest.

- Percuss over the intercostal spaces rather than over the ribs.

Percussion over bone produces less resonance.

- Use the indirect percussion method on the anterior, posterior, and lateral chest, following the diagram in step 6. Compare the right side to the left side.

Expected findings:

- The anterior chest is resonant to the 2nd ICS on the left and to the 4th ICS on the right.
- The lateral chest is resonant to the 8th ICS.
- The posterior chest is resonant to T12.

Abnormal findings: Dullness is heard with fluid or masses in the lungs. Hyperresonance is heard with air trapping that occurs with emphysema.

---

9. Percuss the posterior chest for diaphragmatic excursion.

a. Percuss the level of the diaphragm on full expiration. Have the client exhale completely and hold his breath while you percuss (beginning just below the scapula) from resonance over the lung downward toward the diaphragm. The sound will become dull at the diaphragm. Mark the area with a pen.
b. Percuss the diaphragm level on full inspiration. Have the client take a deep breath and hold it as you percuss again. Mark the location.
c. Measure the distance between the two marks.

Expected findings: Diaphragmatic excursion (the distance between the two marks) is normally 3–6 cm.

Abnormal findings: Decreased excursion may indicate paralysis, atelectasis, or COPD with overinflated lungs.

---

10. Auscultate the chest.

a. Follow the pattern in Step 6.
b. Use the diaphragm of the stethoscope.
c. Have the client take slow, deep breaths through his mouth as you listen at each site through one full respiratory cycle.

For lung sounds, refer to the tables at the end of this procedure. To listen to some lung sounds,

Go to the sound file, **Breath Sounds,** on Davis*Plus*.

Expected findings: No abnormal or adventitious sounds are heard. Lung fields are clear to auscultation. *Bronchial* breath sounds are heard over the trachea. *Bronchovesicular* breath sounds are heard over the sternum anteriorly and between the scapulae posteriorly. *Vesicular* breath sounds are heard over most of the lung fields.

Developmental Variations

Infants—Breath sounds are louder than in adults.

Abnormal findings: Crackles or rales, rhonchi, wheezing, stridor, friction rub, grunting

(continued on next page)

Procedure 22-12 ■ Assessing the Chest and Lungs (continued)

11. Auscultate for abnormal voice sounds if there is evidence of lung congestion. Follow the pattern in Step 6.

a. Assess for *bronchophony* by having the client say "1, 2, 3" as you listen over the lung fields.
b. Assess for *egophony* by having your client say "eee" as you listen over the lung fields.
c. Assess for *whispered pectoriloquy* by having your client whisper "1, 2, 3" as you listen over the lung fields.

Expected findings: No abnormal voice sounds are heard.

Abnormal findings:

a. **Bronchophony** is present if the words are clearly heard over the lungs.
b. **Egophony** is present if the sound you hear is "ay."
c. **Whispered pectoriloquy** is present if you hear, "One, two, three" clearly.

Patient Teaching

Instruct the patient about the dangers of tobacco use, especially smoking; exposure to air pollutants and environmental pollutants, such as radon or asbestos; and the signs and symptoms of lung cancer.

Home Care

- Instruct clients or caregivers to identify any pollutant within the home that may cause respiratory problems, such as radon, dirty heating/air-conditioning systems, or mold.
- Instruct caregivers or patients with allergies and/or asthma to eliminate potential allergens, such as cigarette smoke, dust, feathers, and pet dander.

Documentation

If you need information about documenting your findings,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Normal Lung Sounds

NORMAL LUNG SOUNDS	LOCATION	DESCRIPTION	ILLUSTRATION
Bronchial or tubular	Heard over the trachea	Blowing, hollow sounds; inspiration is shorter than expiration and lower-pitched.	Bronchovesicular	Heard over the 1st and 2nd ICS anteriorly and over the scapula posteriorly	Medium-pitched, medium intensity, blowing sounds; inspiration and expiration are equal length and similar pitch	Vesicular	Heard over the lung periphery	Soft, low-pitched sounds; inspiration is longer, louder, and higher-pitched than expiration	

Abnormal Lung Sounds

ABNORMAL LUNG SOUNDS	CAUSE	CHARACTERISTICS	EXAMPLES
Crackles (sometimes called rales)	Air bubbling through moisture in the alveoli	Bubbling, crackling, popping. Soft, high-pitched, and very brief sounds, usually heard during inspiration	Pneumonia Congestive heart failure (CHF) Bronchitis Emphysema
Rhonchi	Mucous secretions in the large airways	Coarse, snoring, continuous low-pitched sounds heard during inspiration and expiration. May clear with coughing.	Bronchitis Emphysema Narrowed airways Fibrotic lungs
Wheezes	Narrowing of small airways by spasm, inflammation, mucus, or tumor	High-pitched musical or squeaking sounds heard during inspiration or expiration	Acute asthma Emphysema
Stridor*	Partial upper airway obstruction or tracheal or laryngeal spasm	High-pitched, continuous honking sounds heard throughout the respiratory cycle but most prominent on inspiration	Acute respiratory distress Foreign body in airway Epiglottitis
Friction Rub	Rubbing together of inflamed pleural layers	A high-pitched grating or rubbing sound that may be heard throughout the respiratory cycle. Loudest over lower lateral anterior surface.	Pleuritis
Grunting	Retention of air in the lungs	A high-pitched tubular sound heard on expiration	Emphysema

*Patients with stridor need immediate medical evaluation.

Procedure 22-13 ■ Assessing the Heart and Vascular System

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Combination stethoscope with bell and diaphragm
- Alcohol or other antiseptic wipes
- Two rulers
- Pen and record form

Clean stethoscope and rulers before and after use unless they are only used for one patient.

Positioning

Place the client in three positions: sitting, supine, and left lateral (to facilitate hearing specific sounds).

Focused History Questions

- Have you experienced any fatigue or activity intolerance?
- Do you have a history of high blood pressure or stroke?
- Have you ever passed out or felt light-headed?
- Do you have any problems with your heart or circulation?
- Do you ever experience chest pain? If so, describe the circumstances that triggered the pain.
- What was the pain like? What did you do to relieve it?
- Do you ever experience palpitations or a rapid heart beat?
- Do you ever feel short of breath?
- Do you ever get swelling in your feet?
- What medications are you taking?

(continued on next page)

Procedure 22-13 ■ Assessing the Heart and Vascular System (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Inspect the neck.

a. With the patient supine, inspect the carotid and jugular venous system in the neck for pulsations.

Expected and Abnormal Findings

Expected Findings: Carotid pulsation is easily visible. A slight pulsation in the supraclavicular area or suprasternal notch indicates jugular venous pressure. The pulsation should be easily obliterated when you apply pressure to the area.

b. Assess jugular flow: Compress the jugular vein below the jaw. The vein collapses, and the jugular wave is more prominent at the supraclavicular area.

The jugular venous pulse is easily obliterated with gentle pressure.

Assessing jugular flow

Abnormal findings: Significant jugular vein distention suggests right-sided heart failure.

c. Assess jugular filling: Compress the jugular above the clavicle. The vein distends and the jugular wave disappears.

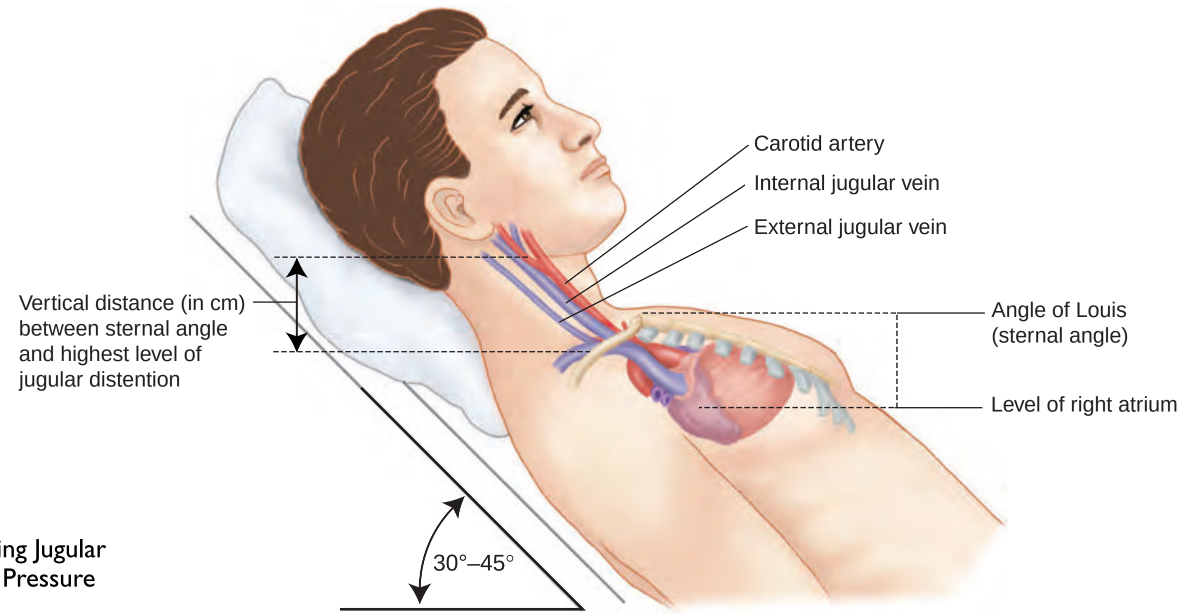
Assessing jugular filling

2. Measure jugular venous pressure (JVP).

a. Elevate the head of the bed to a 45° angle.
b. Identify the highest point of visible internal jugular filling.
c. Place a ruler vertically at the sternal angle (where the clavicles meet).
d. Place another ruler horizontally at the highest point of the venous wave.
e. Measure the distance in centimeters vertically from the chest wall.

Expected findings: Normal jugular venous pressure is <3 cm.

Abnormal findings: Elevated JVP (in CHF or constricted flow into the right side of the heart); low JVP (in hypovolemia)



Measuring Jugular Venous Pressure

3. Inspect the precordium for pulsations. (Have the patient supine with tangential lighting.)

Developmental Modifications

Children—Look for the PMI more medially and at about the 4th ICS in children younger than age 8.

Expected findings: Visible pulsation at the point of maximal impulse (PMI, the 5th ICS in the midclavicular line)

Developmental Variations

In thin adults and children, a pulsation may also be visible over the base of the heart.

Abnormal findings: A pulsation (a heave or lift) displaced toward the axillary line indicates left ventricular hypertrophy. Pulsations to the right of the sternum may indicate an aortic aneurysm.

4. Very gently palpate the carotid arteries.

NOTE: that this step is not done for all patients. It is a part of a thorough cardiovascular assessment and is done only when indicated.

a. Palpate each side separately.

Bilateral pressure may impair cerebral blood flow.

b. Avoid massaging the carotid artery as you palpate.

Increased pressure on the carotid will lead to a drop in the heart rate and blood pressure.

c. Note the rate, rhythm, amplitude, and symmetry of the pulse.

d. Note the contour, symmetry, and elasticity of the arteries.

e. Note any thrills.

Expected findings:

- Rhythm is regular with +2 amplitude.
- Contour: There should be a smooth upstroke with less acute descent.
- Symmetry: Pulses are equal bilaterally.
- Elasticity: Carotids are soft and pliable.

Developmental Variations

Pulse rate is age dependent.

Older adults—The carotids may be stiff and cord-like.

Abnormal findings: A thrill indicates turbulent flow.

5. Palpate the precordium.

a. For this part of the examination, have the patient sit up and lean forward. If lying down, have him turn to the left side.

b. Palpate in all five areas: apex, left lateral sternal border, epigastric area, base left, and base right.

Expected Findings: PMI is palpable at the apex over a 1–2 cm area. Slight pulsation from the abdominal aorta may be felt at the epigastric area. No pulsations, lifts, heaves, or thrills are palpable.

(continued on next page)

Procedure 22-13 ■ Assessing the Heart and Vascular System (continued)

c. Feel for pulsations, lifts, heaves, and thrills.
Brings the apex of the heart closer to the chest wall.

Helpful Hint: ***Perform cardiac palpation and auscultation from the patient's right side, whenever possible.***
This allows you to stretch the stethoscope during auscultation so that you minimize interference and "static."

Abnormal findings: A pulsation, lift, or heave may be seen with left ventricular hypertrophy. A ***lift*** is a pulsation that is forceful enough to seem to lift the examiner's fingers with palpation. A **heave** is a pulsation that feels rolling under your fingers. A **thrill** indicates turbulent flow and feels like a vibration over the PMI.

6. **Auscultate the carotids.**
   b. Place the bell portion of the stethoscope over the carotid artery to listen for bruits.
   Bruits are low-pitched sounds, best heard by the bell portion.
   c. Have the patient hold his breath as you listen.
   Breath sounds over the trachea are loud and could interfere with the ability to hear a bruit.

Expected findings: No audible bruit is present.

Developmental Variations

Children—Bruit may be heard because of a high-output state.

Abnormal findings: In adults, a bruit suggests carotid stenosis.

7. **Auscultate the jugular veins.**
   a. Place the bell portion of the stethoscope lightly over the jugular veins to listen for a low-pitched venous hum.
   b. Have the patient hold his breath as you listen.

Expected findings: No venous hum is audible.

Developmental Variations

Children—A venous hum may be heard. This is a benign condition whereby, blood travels to the brain and back down again to the heart, causing the vein walls to vibrate.

8. **Auscultate the precordium.** To review heart sounds,

Go to the Sound File, **Heart Sounds,** on Davis*Plus*.

- Ask the patient to sit upright and lean forward a bit.
  This will position the heart closer to the chest wall for clearer auscultation.
- Listen for the S_1, S_2, S_3, and S_4 sounds.
- Listen for murmurs.
- Listen with both the bell and the diaphragm at the sites in the following figure:
  These sites are located along the pathway the blood takes as it flows through the atria, ventricles, and valves of the heart.

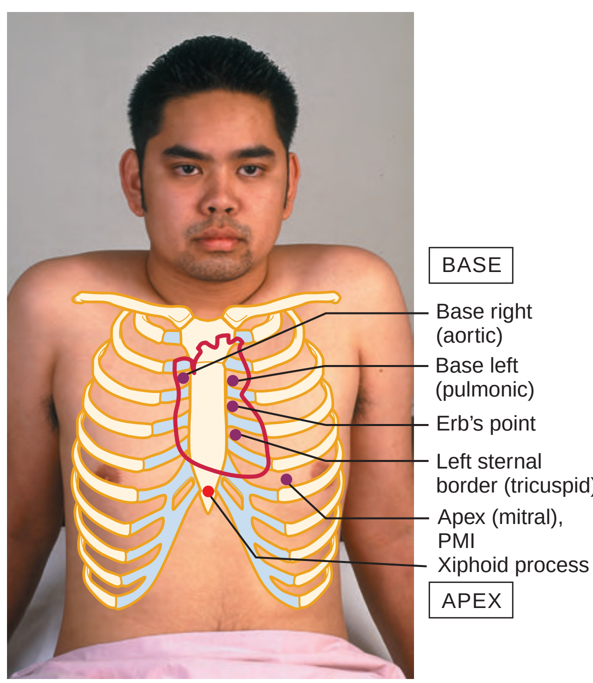
Expected findings: No extra sounds are heard. No murmurs, clicks, or rubs are present.

Developmental Variations

Infants—You may hear a split S_2 when the child takes a deep breath.

Children—The chest wall is thinner, so heart sounds are louder than in adults.

Older adults—An S_4 sound is considered normal; extra systoles per minute are considered normal.



Cardiac auscultation sites

a. *Base right (aortic valve)*. Locate the angle of Louis. (It is the prominence on the sternum, two to three fingerbreadths below the suprasternal notch.) Slide your fingers laterally until you feel the 2nd ICS.

The right 2nd ICS is the best place to auscultate the aortic valve.

a. **Expected Findings:** $S_1 < S_{2t}$

b. *Base left (pulmonic valve)*. Locate the angle of Louis (the prominence on the sternum, two to three fingerbreadths below the clavicular notch). Slide your fingers laterally until you feel the 2nd ICS.

The left 2nd ICS is the best place to auscultate the pulmonic valve.

Palpating base left

b. **Expected findings:** $S_1 < S_2$

c. *Apex (mitral valve)*. You may be able to locate the apex by observing the pulsation at the PMI. It is at the 5th ICS in the midclavicular line.

c. **Expected findings:** $S_1 > S_2$

Developmental Variations

Children—You will hear S_3 at the apex in about 30% of children.

d. *Left lateral sternal border (LLSB) (tricuspid valve)*. From the apex, *slide* your finger up to the 4th ICS, then move close to the sternum.

d. **Expected findings:** $S_1 \geq S_2$. You may hear a split S_1.

Abnormal findings: Extra sounds (S_3 or S_4), murmurs, clicks, or rubs. NOTE: A diastolic murmur or a murmur greater than grade 3/6 is never innocent. Also, *in infants,* a split S_2 sound during normal respirations may indicate an atrial-septal defect.

Assessing Murmurs

Auscultating murmurs is an advanced technique that requires practice and experience. However, if you hear a murmur, assess its:

- Location
- Quality
- Frequency (high, medium, or low pitch)
- Intensity (loudness)
- Timing (in relation to S_1 and S_2)
- Duration
- Configuration (constant or crescendo/decrescendo)
- Radiation (can you hear this in other locations?)
- Respiratory variation (does it change with breathing?)

Classifying Murmurs

Grade

1/6 Very faint, comes and goes

2/6 Quiet, but heard immediately

3/6 Moderately loud

4/6 Loud, associated with a thrill

5/6 Heard with stethoscope half off the chest wall; thrill present

6/6 Heard with stethoscope entirely off the chest wall; thrill present

For a description of murmurs,

Go to Chapter 22, **Tables, Boxes, Figures: ESG Table 22-1,** on Davis*Plus*.

(continued on next page)

Procedure 22-13 ■ Assessing the Heart and Vascular System (continued)

9. **Inspect the periphery for color, temperature, and edema.** (You will probably already have done this when examining the integumentary system.)

Expected findings: Skin is warm. No edema is present. Color is appropriate for race.

Abnormal findings: Pallor, cyanosis, coolness, shininess, sparse hair growth, and clubbing of the nails (may indicate pulmonary oxygenation problems or impaired central or peripheral circulation)

10. **Palpate the peripheral pulses:** radial, brachial, femoral, popliteal, dorsalis pedis, and posterior tibial.
    - Using the distal pads of your second and third fingers, firmly palpate pulses.
    - Palpate firmly but not so hard that you occlude the artery.
    - If you have trouble finding a pulse, vary your pressure, feeling carefully at the correct anatomical location.
    - Assess pulses for rate, rhythm, equality, amplitude, and elasticity.
    - Describe pulse amplitude on a scale of 0–4:
      0 = absent, not palpable
      1 = weak, barely palpable, easily obliterated by the finger
      2 = normal, obliterated by strong finger pressure
      3 = full, increased, not easily obliterated
      4 = bounding, forceful, obliterated only by strong finger pressure

Expected findings: All pulses are regular, strong, and equal bilaterally. Pulse amplitude is +2.

Developmental Variations

Older adults—Arterial pulses may be difficult to palpate because of decreased arterial perfusion.

Abnormal findings: Weak, absent, or asymmetrical pulses may indicate partial or complete occlusion of the artery. Other signs of arterial occlusion include pain, pallor, cool temperature, paresthesia, or paralysis.

11. **Inspect the venous system.** If a client has varicosities, assess for valve competence with the manual compression test, following:
    a. With the client standing, compress the distal portion of the vein.
    b. Still holding the distal portion, compress the proximal portion.

Expected Findings: Veins are not distended. Superficial spider-like veins, especially on the lower extremities, may occur with normal aging.

If the valves are competent, you will not feel backflow. If the valves are incompetent, you will feel a wave pulsation with your lower hand as a result of backflow when you press on the proximal segment of the veins.

Developmental Variations

Older adults—Often have peripheral edema as a result of chronic venous insufficiency.

Abnormal findings: Rope-like, distended, tortuous, or painful veins **(varicosities)**

? What if . . .

- **The patient is obese and heart sounds are difficult to hear?**

  The larger the body mass over the heart, the more difficult it is to hear heart sounds clearly. However, it may help to have the patient sit upright and lean forward as you auscultate.

- **Findings from inspecting and palpating peripheral pulses are abnormal?**

  If inspection or palpation findings are abnormal, perform the tests in the table, More Extensive Tests for Abnormal Findings, at the end of this procedure.

Patient Teaching

Instruct the patient in the risk factors of heart disease and stroke and in the signs and symptoms of heart disease.

Documentation

If you need information about documenting your findings,

Go to Chapter 19, **Documenting Physical Assessment Findings,** in Volume 1.

If you need more information about assessing apical and peripheral pulses and measuring blood pressure,

Go to *Davis's Nursing Skills Videos*, **Vital Signs.**

More Extensive Tests for Abnormal Findings

TESTS	EXPECTED FINDINGS
1. *Perform the capillary refill test* anywhere you note signs of diminished blood flow. a. Press the skin with sufficient pressure to produce blanching. b. Release the pressure and observe the return of color.	1. Color returns in <3 seconds.
2. *Perform Allen's test* to assess abnormal pulse findings and arterial flow in the hands. a. Have the client form a tight fist with one hand. b. With her fist still clenched, compress her radial and ulnar arteries. c. Ask the client to open her hand; observe for pallor. d. Release the ulnar artery and watch for natural color to return. e. Then repeat the process, but release the radial artery.	2. In a healthy individual skin color returns rapidly with each maneuver. Failure to return to normal color indicates impaired flow through the open artery. Normally pallor resolves in 3–5 seconds.
3. *Check the ankle–brachial index (ABI)* to assess circulatory impairment of the feet. a. Use a Doppler (handheld ultrasonic device) to measure blood pressure at the posterior tibialis or dorsalis pedis pulse sites. b. Compare that pressure with blood pressure obtained over the brachial artery. c. To calculate the ABI, divide the systolic pressure at the ankle by the systolic pressure at the brachial site.	3. Normally ankle pressure is higher than brachial pressure. The following is a summary of ABI findings. Normal: 1 or greater Minimal disease: 0.8–0.95 Moderate disease: 0.79–0.4 Severe disease: 0.39–0 *Example:* If the systolic pressure at the ankle is 75 and at the brachial artery is 100, the ABI is 75/100, or 0.75. This indicates moderate peripheral vascular disease.
4. *Perform the color change test* to assess arterial circulation in the legs. a. While the client is lying supine, elevate the legs to increase venous return. b. Have the client quickly move to a sitting position with the feet dangling.	4. Normal color should return to the feet in less than 10 seconds. Pallor with the legs elevated and dependent rubor (reddish-purple color) are signs of arterial insufficiency.

Procedure 22-14 ■ Assessing the Abdomen

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Stethoscope and antiseptic wipe
- Felt-tipped marker
- Tape measure and ruler
- Penlight or examination light
- Pen and record form

Clean stethoscope and other equipment before and after using unless they are only used for one patient.

Positioning

Begin with the client supine, arms at sides, with small pillows under the head and knees.

Relaxes the abdominal muscles.

Focused History Questions

- What types of foods do you typically eat?
- Are there any foods that you cannot eat? If so, why?

(continued on next page)

Procedure 22-14 ■ Assessing the Abdomen (continued)

- How many cups of coffee, tea, cola, or caffeinated beverages do you drink per day?
- Do you smoke? If so, how much and at what age did you start?
- Do you drink alcohol? If so, how many drinks per day? Per week?
- Do you use any drug for non-medical purposes?
- Do you have any abdominal pain?
- How often do you have a bowel movement (BM)?
- Have you noticed any changes in your BMs?
- Are you having any problems with constipation, diarrhea, or getting to the bathroom in time to use the toilet?
- Have you ever seen blood in your stool or noticed blood when you wipe after a BM?
- Have you ever had black, tarry stools?
- How often do you use antacids, laxatives, enemas, aspirin, or anti-inflammatory medicines such as Anaprox or Motrin?
- What home remedy, herbal, or over-the-counter medicines do you use?
- What prescription medicines do you use?
- Have you ever been immunized for hepatitis?
- Have you ever had a blood transfusion?
- What is your occupation?
- Have you ever been diagnosed with an ulcer, hemorrhoids, hernia, bowel problem, cancer, hepatitis, liver problems, cirrhosis, or appendicitis?
- Have you ever had abdominal surgery? If so, when, what type, and what if any follow-up was done for the problem?
- Do you have any family history of abdominal problems, such as ulcers, gallbladder disease, bowel disease, or cancer?
- Do you ever have trouble with: swallowing, heartburn, nausea, vomiting, diarrhea, bloating, excess gas, yellowing of the skin?

Developmental Modifications

For older adults, recall that "Problems with eating" is a part of the SPICES assessment. Ask clients, for example:

- Do you have difficulty chewing or swallowing your food?
- How is your appetite?
- Are you able to shop for and prepare your food?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Expected and Abnormal Findings

1. Have the client void before the exam.
Empties the bladder so that you do not mistake a full bladder for a mass.

2. Position the client supine with the knees slightly flexed.
Relaxes the abdominal muscles.

3. Inspect the abdomen.

a. Observe the size, symmetry, and contour of the abdomen.
   (1) Stand at the client's side and view across the abdomen.
   (2) If distention is present, use a tape measure to measure girth at the level of the umbilicus.
   (3) Have the client raise his head and check for bulges.
Accentuates hernia, if present.

a. **Expected Findings:** Abdomen is flat, slightly rounded, scaphoid (concave), or slightly protuberant; sides are symmetrical. No visible masses or distention are present.

Developmental Variations

Infants and toddlers—Protuberant abdomen is normal.

Abnormal findings: Tumors, cysts, bowel obstruction, or scoliosis may cause asymmetry.

b. Observe the condition of skin and skin color. Look for lesions, scars, striae, superficial veins, and hair distribution (if you have not already done this in your examination of the integumentary system).

b. **Expected findings:** Skin color is consistent with ethnicity but is usually lighter in color than exposed areas. No lesions are present. Hair distribution is appropriate for age and gender. Striae, superficial veins, and scars are common variations.

Abnormal findings:
- Skin color changes may be associated with bruising, internal bleeding, or jaundice.
- Striae occur after periods of rapid growth or weight gain. Pink striae are new. Older striae are silver-white in color.
- Dilated veins are associated with liver disease and obstruction of the vena cava.

c. Note abdominal movements.

c. **Expected findings:** On a thin client, peristalsis and aortic pulsations may be visible. Men tend to use their abdominal muscles for breathing.

Developmental Variations

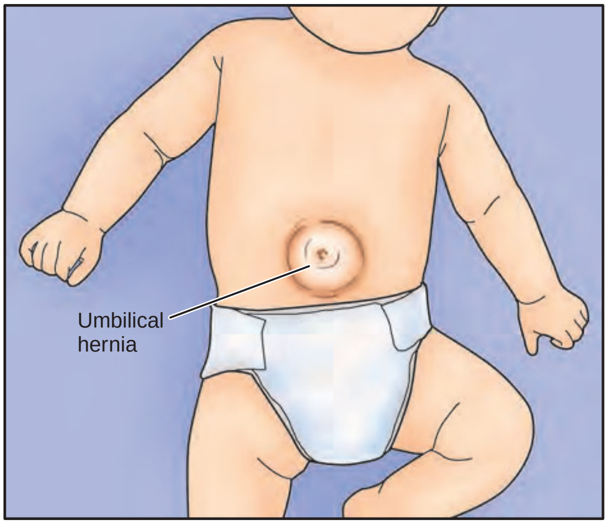
Infants and children—Peristaltic waves are often visible. Abdominal breathing is common in infants and young children.

Older adults—Abdomen may be more rounded because of decreased muscle tone.

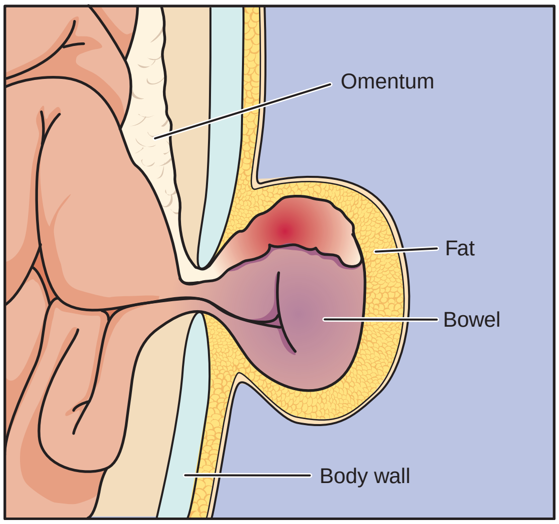
Abnormal findings:

- Peristaltic waves may be seen if there is intestinal obstruction.
- Abnormal respiratory movements may be seen with respiratory distress.
- Pulsations (in other than a thin client) may indicate an aortic aneurysm.

d. Note the position, contour, and color of the umbilicus.



d. **Expected findings:** Umbilicus is inverted and in the midline. No discoloration or discharge is present.



Abnormal findings: Protrusion of the umbilicus may result from a hernia or underlying mass.

4. **Auscultate the abdomen.** To hear a sample of bowel sounds,

Go to **Sound Files: Bowel Sounds,** on Davis*Plus*.

a. Ask the client when he last ate.

Bowel sounds are loudest 5 or 6 hours after the person eats, when the small intestine contents empty through the ileocecal valve into the large intestine. They also increase immediately after eating.

(continued on next page)

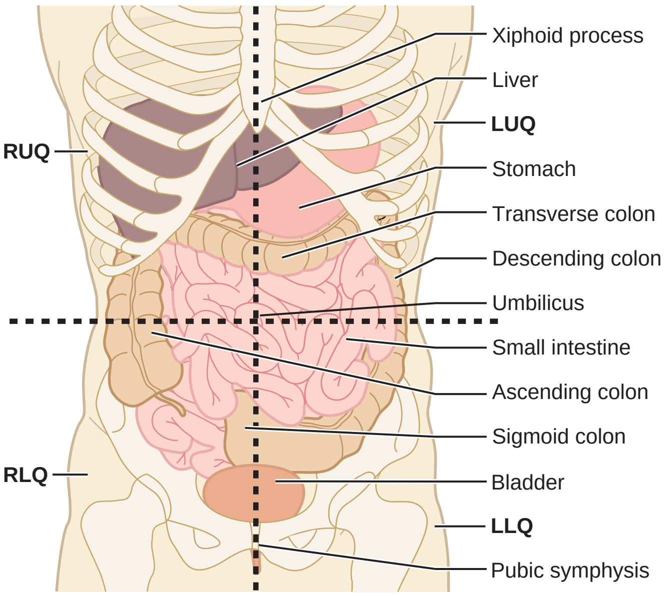
Procedure 22-14 ■ Assessing the Abdomen (continued)

b. Listen for bowel sounds.
   (1) Using the stethoscope diaphragm, listen in several areas in all four quadrants (see the figure).

The diaphragm of the stethoscope is used because bowel sounds are high-pitched.

   (2) If bowel sounds are infrequent or difficult to hear, listen to the right of the umbilicus over the ileocecal valve.
   (3) Listen for up to 5 minutes before concluding that bowel sounds are absent.

c. Use the stethoscope bell to listen for bruits over the aorta and the renal, femoral, and iliac arteries.



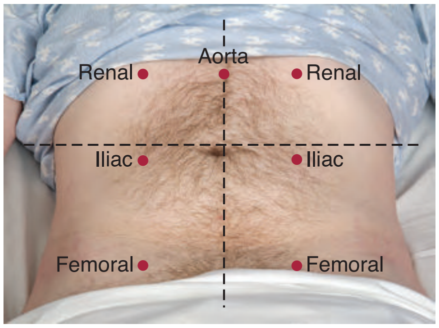
The four abdominal quadrants

b. **Expected findings:** Audible bowel sounds, occurring every 5–15 sec or 5–30 times per min.

Abnormal findings:
- ***Hyperperistalsis*** (hyperactive): >2 or 3 sounds per sec or >30 sounds per min
- ***Hypoperistalsis*** (hypoactive): <5 sounds per min
- ***Absent*** bowel sounds: none after listening for 5 min

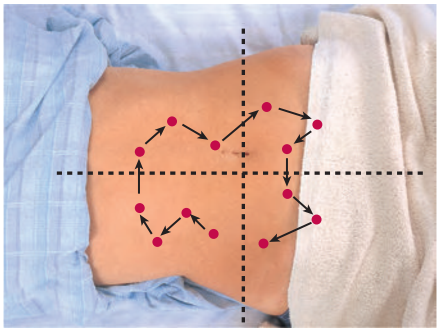
c. **Expected Findings:** No audible bruits are present.

Abnormal findings: A bruit is abnormal and may indicate an aneurysm or altered blood flow.



Locating abdominal arteries

5. **Percuss the abdomen.** (See Clinical Insight 22-1.)
   a. Use indirect percussion to assess at multiple sites in all four quadrants.
   b. Estimate organ size by noting the change in sounds as you percuss over the liver, spleen, and bladder.



Expected findings: Tympany, with dullness over organs or fluid, is present. No tenderness

Abnormal findings: Extremely high-pitched tympanic sounds are heard with distention. Extensive dullness indicates organ enlargement or underlying mass.

6. Using fist or blunt percussion, percuss the costovertebral angle (where the end of the rib cage meets the spine) bilaterally to assess for kidney tenderness.

Expected findings: No costovertebral angle tenderness is present.

Abnormal findings: Pain or tenderness is associated with kidney infection or musculoskeletal problems.

---

7. Palpate the abdomen.

a. **Begin with light palpation** throughout the abdomen. Identify surface characteristics, tenderness, muscular resistance, and turgor.
   (1) If the client is having pain in one area of the abdomen, palpate that area last.

A guarding response to pain from palpation can interfere with your assessment of the other areas.

   (2) Using your fingertips, press down 1–2 cm in a rotating motion.
   (3) Lift your fingers and move to the next site.
   (4) Palpate the entire abdomen if possible.
   (5) Proceed in an organized fashion through all quadrants, using the same sequence in every examination.
   (6) Observe for grimacing, guarding, or verbal statements of tenderness or pain.

a. **Expected findings:** The abdomen is soft and nontender, with no masses. Muscles are easily palpated; no guarding is present.

Abnormal findings: Guarding and rigidity may indicate peritonitis. Tenderness on light palpation indicates the need for further evaluation.

Developmental Modifications

Encourage a child to place her hand lightly over yours as you palpate.

Caution: Do not palpate the abdomen if the client has a Wilms' tumor, a large diffuse pulsation, or a history of organ transplant.

b. **Use deep palpation** to palpate organs and masses. See the table Deep Palpation Techniques at the end of this procedure.

b. **Expected Findings:** Tenderness may be noted in a normal adult near the xiphoid process and over the cecum and sigmoid colon.

Developmental Variations

Older adults—May have a higher pain threshold, so they may not react to palpation even if there is an abnormality in the abdomen.

Abnormal findings: A mass indicates the need for further evaluation.

(continued on next page)

Procedure 22-14 ■ Assessing the Abdomen (continued)

c. **Palpate the liver.**
(1) Stand at the client's right side.
(2) Place your right hand at the client's right midclavicular line under the costal margin, parallel to the right costal.
(3) Place your left hand under the client's back at the lower (11th to 12th) ribs, and press upward. This elevates the liver toward the abdominal wall.
(4) Ask the client to inhale and deeply exhale while you press in and up, gently but deeply, with your right fingers.

Alternative approach: Hooking technique. Place your hands over the right costal margin, and hook your fingers over the edge. Have the client take a deep breath, and feel for the liver's edge as the liver drops down on inspiration and then rises up over your fingers during expiration. ➤

c. **Expected findings:** The liver is not normally palpable unless the client is very thin. If it is palpable, the edge should be smooth and nontender.

Developmental Variations

Children—Liver is relatively large and can be palpated 1–2 cm (0.5–1 in.) below the right costal margin.

Abnormal findings: Palpation below the costal margin indicates enlargement.

d. **Palpate the Spleen**
(1) Stand at the client's right side.
(2) Reach across the client to place your left hand under the costovertebral angle, and pull upward to move the spleen anteriorly.
(3) Place your right hand under the left anterior costal margin, and have the client take a deep breath.
(4) During exhalation, press your hands together (inward) to try to palpate the spleen. ➤

d. **Expected Findings:** The spleen is not normally palpable.

Abnormal findings: Splenic enlargement or tenderness may result from infection, trauma, or cancer.

? What if . . .

- **The patient is ticklish or guarding when you palpate the abdomen?**

  Distract the person by giving her a task, such as "Count aloud to 10" or "Count backward from 100." Alternatively, have the client place her hand on her abdomen; place your hand on hers and begin light palpation. When she begins to feel more relaxed, slip your hand underneath hers and continue.

- **The patient complains of abdominal pain?**

  Check for rebound tenderness: Place your hand perpendicular to the abdomen. Press firmly and slowly then release quickly.
  If pain increases when you remove your hand, this indicates peritoneal irritation. Rebound tenderness in the right lower quadrant may be a sign of appendicitis.

Patient Teaching

Instruct the patient in the importance of proper diet, the signs and symptoms of colorectal cancer, and the importance of screening colonoscopy.

Documentation

If you need more information about documenting your findings,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Deep Palpation Techniques

DEEP PALPATION: ONE-HANDED TECHNIQUE

- Using your fingertips, press down 4 to 6 cm in a dipping motion.
- Proceed in an organized fashion through all four quadrants.

DEEP PALPATION: BIMANUAL TECHNIQUE

- This technique is useful when palpating a large abdomen.
- Place your nondominant hand on your dominant hand.
- Depress your hands 4 to 6 cm (1.5 to 2 in.) in a dipping motion.
- Proceed in an organized fashion through all four quadrants.

? What if . . .

- **You palpate a mass?**

  Have the client tighten her abdominal muscles.
  If the mass is in the abdominal wall, it will become easier to palpate. If it is deep in the abdomen, it will be difficult to palpate.

Procedure 22-15 ■ Assessing the Musculoskeletal System

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Tape measure
- Goniometer
- Pen and record form

Developmental Modifications

For older adults, recall that "Problems with falls" is a part of the SPICES assessment. If your facility has a falls assessment tool, perform that focused assessment.

Focused History Questions

- Do you have any difficulty with coordination (e.g., folding clothes, brushing your teeth)?
- Do you now have, or have you ever had, musculoskeletal problems, pain, or disease? If so, what medications or treatments are you using?
- Have you ever injured your bones or joints?
- Do your joints, muscles, or bones limit your activities?
- Do you lose your balance or fall?
- Do you have any occupational hazards that could affect your muscles and joints?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps	Expected and Abnormal Findings
1. Assess posture.	
a. Note the body and head position.	a. **Expected findings:** Posture is erect, with the head in the midline.
b. Check the alignment and symmetry of the shoulders, scapula, and iliac crests. Inspect from the front, back, and side.	b. **Expected findings:** The shoulders, scapula, and iliac crests are symmetrical.

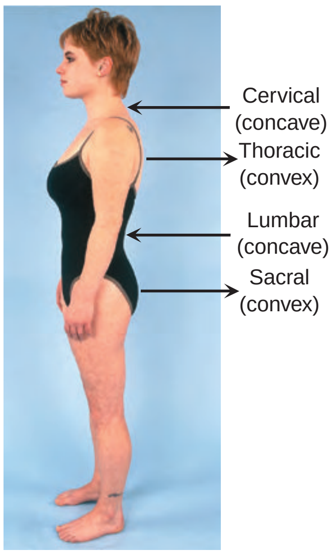
(continued on next page)

Procedure 22-15 ■ Assessing the Musculoskeletal System (continued)

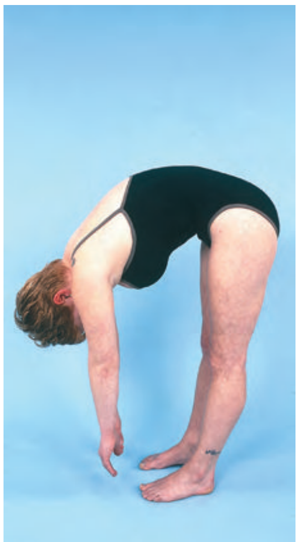
Developmental Modifications

Newborns—Palpate clavicles for fractures that may have occurred at birth. Check for congenital hip dysplasia (dislocation) by examining for asymmetry of the gluteal folds or shortening of the femur.

c. Assess the spinal curvature by:
   (1) Observing the client's profile while he is standing erect.
   (2) Having the client bend forward at the waist with arms hanging free at the sides.



Assessing for normal curves



Assessing for kyphosis and scoliosis

c. **Expected findings:** Cervical and lumbar curves are concave; thoracic and sacral curves are convex.

Developmental Variations

Children—**Lordosis** (exaggerated lumbar curve) is normal before age 5.

Abnormal findings: Kyphosis, scoliosis, lordosis

See the Abnormal Atlas: Musculoskeletal System at the end of this chapter.

d. Have the client stand upright with the feet together. Note the position of the knees.

d. **Expected findings:** Patella is in the midline on an imaginary line drawn from the anterior superior iliac crest to the feet.

Developmental Variations

Children—**Genu varum** (bowlegs) is normal for 1 year after a child begins to walk.

2. Assess gait by observing the client walking.

Developmental Modifications

Children—Observe them at play.

a. Pay attention to the base of support (distance between the feet) and stride length (distance between each step).

a. **Expected findings:** Average base of support for an adult is 5–10 cm (2–4 in.). Average stride length is 30–35 cm (12–14 in.); the longer the legs, the longer the stride length.

Abnormal findings: Abnormal gait can be caused by muscle weakness, joint stiffness, pain, deformities, and central nervous system dysfunction. A wide base of support and shortened stride length reflect a balance problem, placing the client at risk for falls.

b. Observe the phases of the gait.

b. **Expected findings:** Movements are smooth and coordinated, weight is evenly distributed, arms swing in opposition, and toes point forward.

Abnormal findings: Toeing in or out, jerky or shuffling movements, touching the floor first with the toe rather than the heel, arms held out to the side or front.

Also refer to the Abnormal Atlas: Abnormal Gaits at the end of this chapter.

Stance Phase

Heel strike

Foot flat

Midstance

Push-off

Swing Phase

Accelerate

Swing-thru

Decelerate

(continued on next page)

Procedure 22-15 ■ Assessing the Musculoskeletal System (continued)

3. Assess balance.

If the client was unsteady when walking, do not complete this portion of the exam. Proceed only if the gait is steady; stand nearby in case the client loses his balance.

a. Have the client tandem walk heel-to-toe.
b. Have the client walk alternately on heels and toes.
c. Ask the client to do a deep knee bend.
d. Ask the client to hop in place on each foot several times.
e. Perform the Romberg test (if you did not already do so when examining the ears): Have the client stand with feet together and eyes open. Then have him close his eyes and stand still.

Expected Findings: The client is able to perform each of these maneuvers smoothly. The Romberg test (see Procedure 22-7) is negative—the client is able to maintain balance with minimal sway with eyes open and closed.

Developmental Variations

Infants—Should be able to sit alone by age 8 months.

Abnormal findings: Balance problems may indicate a cerebellar disorder, an inner ear problem, or muscle weakness.

Step 3a. Walking heel-to-toe

Step 3b. Walking on heels

Step 3b. Walking on toes

Developmental Modifications

Infants—Observe sucking, swallowing, and kicking movements.
Children—To assess a child's movement, coordination, ROM, and so on, watch the child at normal play. Cerebellar function cannot be tested on infants and toddlers because of their immature neuromuscular system.

4. Assess coordination while the client is seated.

a. Test upper extremity coordination by having the client perform finger–thumb opposition. Test one side and then the other.

b. Test rapid alternating movements by having the client alternate between supinating and pronating her hands.
c. Assess lower extremity coordination by having the client perform rhythmic toe-tapping, one side at a time.
d. Have the client run the heel of one foot down the shin of the other leg. Repeat on the opposite side.

Expected findings: The client is able to perform these movements smoothly and in a coordinated fashion. The dominant side (usually the right) may be slightly more coordinated.

Developmental Variations

Older adults—Decreased coordination and reaction time may result from slower nerve conduction and loss of muscle tone.

Abnormal findings: Slowness or awkwardness with movement may indicate a cerebellar disorder or muscle weakness.

5. Test accuracy of movements. Have the client touch his finger to his nose with his eyes open. Repeat with his eyes closed.

Expected findings: The movement is accurate with eyes open and closed.

Abnormal findings: Inaccurate movements indicate cerebellar dysfunction.

---

6. Measure the limbs.

a. Measure arm length from the acromion process to the tip of the middle finger.
b. *Apparent leg length*—Measure from the umbilicus (a nonfixed point) to the medial malleolus.
c. *True leg length*—Measure from the anterior superior iliac crest, crossing over the knee to the medial malleolus

a., b., c. **Expected findings:** The differences in length between the right and left arm and leg are 1 cm or less.

Abnormal findings: Leg length discrepancies may cause back and hip pain and gait problems. A *true leg length* discrepancy results from unequal bone length; an *apparent leg length* discrepancy may result from a pelvic tilt or flexion deformity of the hip.

Apparent leg length

True leg length

d. Measure the circumference of the forearms, upper arms, thighs, and calves.

d. **Expected findings:** The differences in circumference between the right and left arm and leg are 1 cm or less.

Abnormal findings: Circumference differences >1 cm may reflect atrophy or hypertrophy.

---

7. Inspect muscles and joints bilaterally for symmetry and shape.

Developmental Modifications

Older adults—Observe for surgical scars indicating joint replacement or joint surgeries.

Expected findings: Size and shape are symmetrical. Muscles and joints are smooth, nontender, and similar in color and temperature to surrounding tissue.

Developmental Variations

Older adults—Muscle mass and tone decrease.

Abnormal findings:

- Hot, red, swollen, stiff, or painful joints may indicate injuries, arthritis, gout, bursitis, or other inflammatory diseases.
- ***Heberden's nodes*** are hard, painless nodules over the distal interphalangeal joints—usually seen with degenerative joint disease (DJD), but they may be seen with rheumatoid arthritis (RA).
- Severe misalignment and deformity are more often a result of DJD than of RA.
- Crepitus may be heard in DJD.

(continued on next page)

Procedure 22-15 ■ Assessing the Musculoskeletal System (continued)

8. Test active ROM by asking the client to move the following joints through ROM:

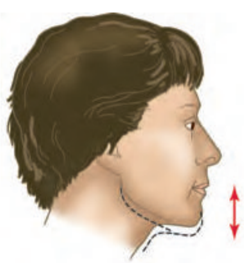
a. Temporomandibular joint (TMJ)
b. Neck
c. Thoracic and lumbar spine
d. Shoulder
e. Upper arm and elbow
f. Wrist
g. Hands and fingers
h. Hip
i. Knee
j. Ankles and feet

Expected findings:

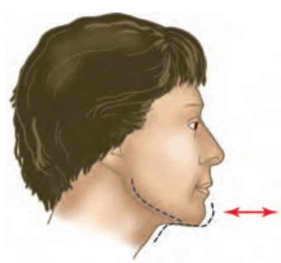
a. *TMJ*—Able to flex, extend, move side to side, protrude, and retract the jaw.
b. *Neck*—Flexes, extends, hyperextends, bends laterally, and rotates side to side.
c. *Spine*—Able to bend at the waist, stand upright, hyperextend (bend backward), bend laterally, and rotate side to side.
d. *Shoulder*—Able to move the arm forward and backward, abduct, adduct, and rotate internally and externally.
e. *Upper arm and elbow*—Able to bend, extend, supinate, and pronate the elbow.
f. *Wrist*—Flexes, extends, hyperextends, and moves side to side.
g. *Hands and fingers*—Able to spread the fingers (abduct), bring them together (adduct), make a fist (flex), extend the hand (extend), bend fingers back (hyperextend), and bring thumb to index finger (palmar adduction).
h. *Hip*—Able to extend the leg straight, flex the knee to the chest, abduct and adduct the leg, rotate the hip internally and externally, and hyperextend the leg.
i. *Knee*—Able to flex and extend the knee.
j. *Ankles and feet*—Able to dorsiflex, plantar flex, evert, invert, abduct, and adduct the feet and ankles.

If a patient cannot move the limb, put the joint through passive ROM. Never force a joint against resistance or if it causes discomfort.

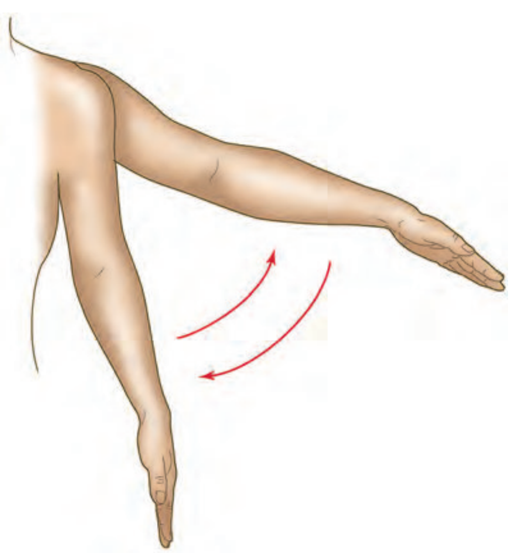
Joint movements



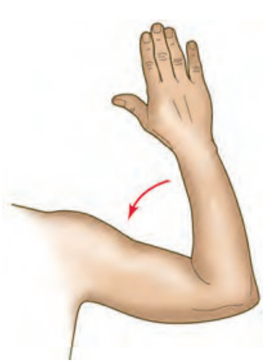
Depression: lowering a body part
Elevation: raising a body part



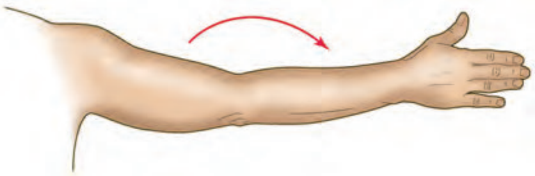
Retraction: moving backward
Protraction: moving forward



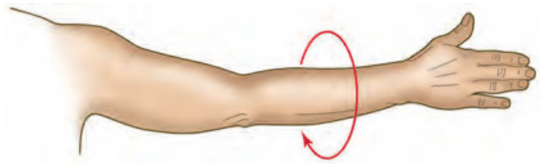
Abduction: moving away from midline
Adduction: moving toward midline



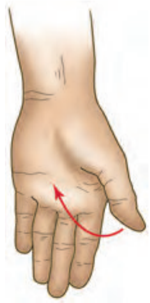
Flexion: bending, decreasing joint angle



Extension: straightening, increasing joint angle



Circumduction: moving in a circular fashion

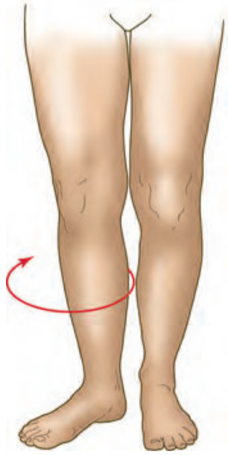


Reposition

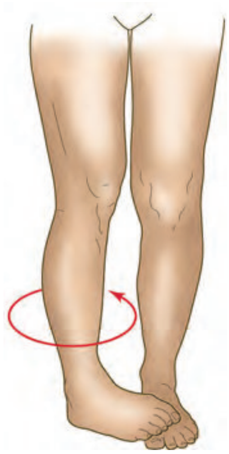
Opposition

Supination: turning upward

Pronation: turning downward



External rotation: turning away from midline



Internal rotation: turning toward midline

Eversion: turning outward

Inversion: turning inward

9. **Test muscle strength by repeating ROM against resistance.** Use the rating scale at the end of this step.
   a. **Test hand grip** by crossing your middle and index fingers and asking the patient to squeeze. (*Tip: If you are wearing rings, a strong hand grip on those fingers can be painful.*)
   b. **Test biceps strength**. Place one hand on the client's biceps and have the patient raise the forearm (flex the elbow) as you apply resistance at the wrist.
   c. **Test triceps strength** by having the client straighten the arm at the elbow (extend the elbow) as you apply resistance at the wrist.
   d. **Test leg strength** by having patient raise leg (straighten the knee) against your hand as you apply resistance.
   e. **Test ankle strength** by asking the patient to point the toes downward (plantar flexion) at the ankle while you apply resistance to the plantar surface of the foot.
   f. **Test ankle strength** by having the client point the toes toward the knee (dorsiflexion) as you apply resistance to the top of the foot.

Expected findings: Expect active motion against full resistance. There should be no crepitus (clicking) or pain with joint movement.

Step 9a

(continued on next page)

Procedure 22-15 ■ Assessing the Musculoskeletal System (continued)

Muscle Strength Rating Scale

RATING	CRITERIA	CLASSIFICATION
5	Active motion against full resistance	Normal
4	Active motion against some resistance	Slight weakness
3	Active motion against gravity	Weakness
2	Passive range of motion	Poor range of motion
1	Slight flicker of contraction	Severe weakness
0	No muscular contraction	Paralysis

What if . . .

- **There is limited range of motion in a joint?**
  Use a goniometer to measure the limited motion in degrees. Place the goniometer over the joint, matching the angle of the joint.

Using a goniometer

Documentation

If you need information about documenting your findings,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Procedure 22-16 ■ Assessing the Sensory-Neurological System

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* This procedure provides guidelines for performing a comprehensive neurological exam. Steps 1–10 assess cognitive status, and the box at the end of the procedure contains questions that are useful for screening cognitive status.

Equipment

- Pen and record form
- Wisp of cotton
- Sharp object, such as a toothpick or sterile needle
- Objects to touch, such as a coin, button, or key
- Something fragrant, such as coffee or rubbing alcohol
- Something to taste, such as sugar, salt, or lemon
- Tongue blade
- Two test tubes
- Reflex hammer
- Ophthalmoscope

Developmental Modifications for Children

- For children younger than age 5 years, use the Denver Developmental Screening Test II to assess neurological and motor function.
- Check the child's ability to understand and follow instructions.

Developmental Modifications for Older Adults

You may need to perform the sensorineurological exam over several sessions. The full exam is lengthy, and older adults fatigue easily. If the client seems to be getting tired, stop the test and finish at a later time.

Focused History Questions

- Do you have any neurological ("nerve") problems?
- Have you ever had head trauma, loss of consciousness, dizziness, headaches, or seizures?
- Do you have memory problems, forgetfulness, or inability to concentrate?
- Have you noticed any changes in your ability to see, smell, taste, hear, feel, or maintain balance?
- Do you have any weakness, numbness, or paralysis?
- Do you have any problems performing activities of daily living (ADLs)?

- Do you have any problems walking?
- Do you have mood problems or depression?
- Do you use alcohol or drugs for non-medical purposes? If so, how much and how often?
- Have you ever been treated for neurological or psychiatric problems?
- Do you have a history of hypertension, diabetes, stroke, or circulation problems?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Assess behavior**. Note the client's facial expression, posture, affect, and grooming.

Expected and Abnormal Findings

Expected findings: The client is well groomed, with an erect posture, pleasant facial expression, and appropriate affect.

Abnormal findings: Inappropriate behavior may result from neurological or psychological problems, as well as from a variety of medications, alcohol, and street drugs.

---

2. **Determine level of arousal (LOA):**
   a. Note the client's response to verbal stimuli.
   b. If the client does not respond to verbal stimuli, try **tactile stimulation**: Gently shake the client's shoulder.
   c. If the client does not respond to tactile stimuli, try **painful stimuli**: Squeeze the trapezius muscle, rub the sternum, apply pressure on the mandible at the angle of the jaw, or apply pressure over the "moon" of the nail.

The Glasgow Coma Scale and the FOUR Scale at the end of this procedure provide standard references for assessing LOA for a patient with head injury.

Expected findings: The patient is awake and alert and readily responds to verbal stimuli.

Abnormal findings: Lethargy, stupor, or coma may result from trauma, neurological disorder, hypoxia, or chemical substances

A changing level of arousal (along with forgetfulness, restlessness, or sudden quietness) is one of the earliest indicators of increased intracranial pressure, which can be life threatening.

---

3. **Determine the level of orientation.**
   a. *Orientation to time:* Ask the client to state the year, date, and time of day.
   b. *Orientation to place:* Ask the client to state where he is (i.e., city, state, where he lives).
   c. *Orientation to person:* Ask the names of family members. Ask, "Do you know who I am?" If the client cannot answer these questions, ask him to state his name.

Self-identity remains intact the longest.

Expected findings: The client is awake, alert (see Step 2), and oriented to time, place, and person (AAO $\times$ 3).

a. Hospitalized patients commonly lose track of date and time of day, but they easily reorient. As a rule, they should at least know the year.
b. Interpret data carefully. In some situations (e.g., after an automobile accident away from home), the patient may know he is in the hospital but not know which hospital or which city.
c. Patient should know you are a healthcare worker, but not necessarily your name.

Developmental Variations

Older adults—The stress of an unfamiliar situation can create confusion in an older adult.

Abnormal findings: Disorientation may result from physical or psychological problems. Bizarre responses are usually associated with psychiatric problems.

---

4. **Assess memory.**
   a. *Assess immediate memory* by asking the client to repeat a series of three numbers that you speak slowly (e.g., 1, 5, 8). Gradually increase the length of the series until the client cannot repeat the series correctly. Record the length of the last correct series (e.g., "Successfully repeats a series of 7 numbers correctly.")

Expected findings: Immediate, recent, and remote memory are intact. Average series recall is 5–8 numbers in sequence and 4–6 numbers in reverse order.

Developmental Variations

Children—Number of objects recalled is usually fewer than the child's age in years.

(continued on next page)

Procedure 22-16 ■ Assessing the Sensory-Neurological System (continued)

b. *Repeat the test,* beginning with a series of three numbers, but ask the client to repeat them back to you in reverse order.
c. *Assess recent memory* by naming three items (e.g., "mirror, truck," and "the letter *X*") and asking the client to recall them later during the exam. Alternatively, you can ask questions such as, "How did you get to the hospital? What did you have for breakfast?" However, you will need to verify the patient's answers.
d. *Assess remote memory* by asking the client his birth date or the date of a major historical event.

Developmental Modifications

Children—Assess memory by using names of toys (e.g., truck, ball, puzzle), names of people in his family, or names of familiar cartoon characters.

Older adults—Loss of immediate and recent memory is common; long-term memory is usually not impaired.

Abnormal findings: Memory problems may be benign or may signal underlying neurological problems. Temporary memory loss may occur after trauma.

---

5. Assess mathematical and calculation skills.
a. Have the client solve a simple mathematical problem, such as 3 + 3.
b. If he is able to solve that problem, present a more complex example, yet simple enough that regardless of math skills the client could still determine the appropriate response, such as, "If you have $3 and you buy an item for $2, how much money will you have left?"
c. To assess both calculation skills and attention span, ask the client to count backwards from 100.
d. A more difficult test is to have the client perform serial threes or serial sevens. Ask him to begin at 100 and keep subtracting 3 (or 7).

Consider the person's language, education, and culture in deciding whether this test is appropriate for him.

Expected findings: Mathematical and calculation ability is appropriate for the patient's age, education level, and language ability. The average adult can solve simple mathematical problems and can complete serial sevens in about 90 seconds with 3 or fewer errors.

Abnormal findings: Inability to calculate at a level appropriate for age and educational level may indicate neurological impairment or developmental delay.

---

6. Assess general knowledge.

You can ask questions directly or work this into the overall interaction with the client.

Ask the client how many days in the week or months in the year.

Expected findings: Vocabulary and general knowledge are intact.

---

7. Evaluate thought processes. Assess throughout the exam. Notice attention span, logic of speech, ability to stay focused, and appropriateness of responses.

Expected findings: Thought processes are clear, client responds appropriately, and speech is coherent and logical.

Abnormal findings: Alteration in thought processes may be due to physical disorders, such as dementia; psychiatric disorders, such as psychosis; or alcohol and drugs.

---

8. Assess abstract thinking. Ask the client to interpret a maxim (or saying), such as "A penny saved is a penny earned" or "A rolling stone gathers no moss."

Developmental Modifications

Children—The ability to think abstractly does not develop until the late school-age years or adolescence. To assess a

Expected findings: Abstract thinking is intact.

Abnormal findings: Inability to think abstractly is associated with dementia, delirium, mental retardation, and psychoses.

child under the age of 12, ask her to describe things that are like and unlike a named object (e.g., "Tell me something that is like a cup").

9. Assess judgment.
Ask the client to respond to a hypothetical situation, such as, "If you were walking down the street and saw smoke and flame coming from a house, what would you do?"

Expected findings: Judgment is intact.

Abnormal findings: Impaired judgment may be associated with dementia, psychosis, or substance abuse.

10. Assess communication ability.

a. **Listen to the client's speech.** Note the rate, flow, choice of vocabulary, and enunciation.

a. **Expected findings:** Speech flows easily, and patient enunciates clearly. Vocabulary is consistent with the client's age, education, and language fluency.

Abnormal findings: Problems with flow (e.g., halting speech, stuttering, very rapid speech, slurred words) may be due to language problems, nervousness, anxiety, or neurological problems.

b. **Test spontaneous speech:** Show the client a picture, and have him describe it.

b. **Expected findings:** Spontaneous speech is intact.

Abnormal findings: Impaired spontaneous speech is associated with cognitive impairment.

c. **Test motor speech** by having the client say "Do, re, mi, fa, so, la, ti, do." Assess ability to swallow. Observe for clarity of speech, facial mobility, drooling, and oral hypotonia. Ask the client to repeat a short phrase 2 or 3 times and observe for lack of coordination.

c. **Expected findings:** Motor speech is intact.

Abnormal findings: Impaired motor speech is associated with problems with CN XII or with coordination of speech muscles.

d. **Test automatic speech** by having the client recite the days of the week.

d. **Expected findings:** Automatic speech is intact.

Abnormal findings: Cognitive impairment or memory problems cause difficulty with automatic speech.

e. **Test sound recognition** by having the client identify a familiar sound, such as clapping hands.

e. **Expected findings:** Sound recognition is intact.

Abnormal findings: Temporal lobe problems may be the cause of impaired sound recognition.

f. **Test auditory–verbal comprehension** by asking the client to follow simple directions (e.g., "Point to your nose; rub your left elbow").

f. **Expected findings:** Auditory–verbal comprehension is intact.

Abnormal findings: Temporal lobe problems affect reception. Frontal lobe problems affect expression.

g. **Test visual recognition** by pointing to objects and asking the client to identify them.

g. **Expected findings:** Visual recognition is intact.

Abnormal findings: Impaired visual recognition indicates parieto–occipital lobe problems.

h. **Test visual-verbal comprehension** by having the client read a sentence and explain its meaning.

h. **Expected findings:** Visual–verbal comprehension is intact.

Abnormal findings: Impaired visual–verbal comprehension indicates cognitive impairment.

i. **Test writing** by having the client write her name and address.

i. **Expected findings:** Writing ability is intact.

j. **Test ability to copy figures** by having the client copy a circle, letter X, square, triangle, and star.

j. **Expected findings:** The client is able to copy figures.

(continued on next page)

Procedure 22-16 ■ Assessing the Sensory-Neurological System (continued)

11. Test cranial nerve I—olfactory nerve.

NOTE: You can assess CN I with your examination of the nose and sinuses (see Procedure 22-8).

a. Before testing, check the patency of the nostrils by gently occluding each nostril and having the client sniff.
b. Have the client occlude one nostril and hold an aromatic substance (e.g., lemon, coffee, vanilla, alcohol) under the nostril.
c. Repeat with a different substance under the other nostril.

Developmental Modifications

Children—Select a substance that you are certain the child is familiar with (e.g., bananas or apples).

Expected findings: The client can identify the substances.

Developmental Variations

Older adults—May have a decreased sense of smell.

Abnormal findings: Anosmia is the loss of the sense of smell. It may be genetic, related to chronic nose or sinus problems, heavy tobacco use, snorting cocaine, or zinc deficiency.

12. Test cranial nerve II—optic nerve.

NOTE: You can assess CN II with your examination of the eyes (see Procedure 22-6).

a. Test visual acuity by asking the client to identify the smallest print readable on the Snellen chart.

Developmental Modifications

Use picture chart for small children, Snellen E for school-age children.

b. Identify visual field by having the client describe the boundaries of the visual field while her eye is in a fixed position.
c. Perform a fundoscopic exam. (See Procedure 22-6.)

a. **Expected findings:** Visual acuity is 20/20 in the right eye, left eye, and both eyes.

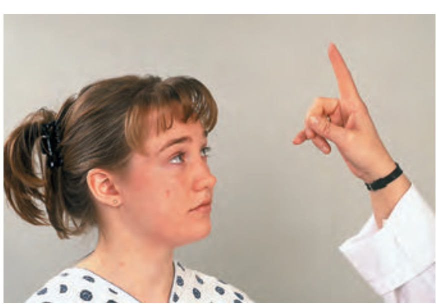
Abnormal findings: Many visual deficits are correctable with eyeglasses or contact lenses. They are not necessarily caused by optic nerve damage.

b. **Expected findings:** Peripheral vision range is approximately 50° in the superior field, 70° in the inferior field, 60° in the nasal field, and 90°–110° in the temporal field.
c. **Expected findings:** Disc margins are sharply demarcated. The cup is half the size of the disc or less.

Abnormal findings: CN II deficits may be due to tumor or CVA.

13. Test cranial nerves III, IV, and VI—oculomotor, trochlear, and abducens nerves.

a. Test EOMs by having the client move the eyes through the six cardinal fields of gaze while holding her head steady.



b. Test pupillary reaction to light and accommodation.

NOTE: See Procedure 22-6 for further details on each of these tests.

Expected findings: Client can move her eyes through the six cardinal fields of gaze. Pupils are equal in size and react to light and accommodation.

Abnormal findings: Changes in intracranial pressure (ICP) may affect EOMs and pupillary reaction.

14. Test cranial nerve V—trigeminal nerve.

a. Test motor function by having the client move his jaw from side to side, clenching his jaw, and biting down on a tongue blade.

NOTE: You can assess this function in your examination of the mouth and oropharynx (see Procedure 22-9).

b. Test sensory function by having the client close her eyes and identify when you are touching her face at the forehead, cheeks, and chin bilaterally—first with your finger and then repeat with a toothpick.

c. Test the corneal reflex by touching the cornea with a wisp of cotton or puffing air from a syringe over the cornea.

The corneal reflex is not usually tested on a conscious person because the procedure is unpleasant and a corneal abrasion can occur. A conscious person can blink intentionally, so there is no need to stimulate the blink.

NOTE: You can assess the corneal reflex in your examination of the eyes (see Procedure 22-6).

Expected findings: The client is able to perform all motor functions and can perceive light touch and superficial pain bilaterally; corneal reflex is intact.

Abnormal findings: Inability to perceive light touch and superficial pain may indicate peripheral nerve damage. An absent corneal reflex is an ominous neurological sign.

---

15. Test cranial nerve VII—facial nerve.

a. Test motor function by having the client make faces, such as smile, frown, or whistle.

Note:You can assess this function in your examination of the head and face (see Procedure 22-5).

b. Test taste on the anterior portion of the tongue by placing sweet (sugar), salty (salt), or sour (lemon) substance on the tip of the tongue. Do not test taste by using pungent, bitter, or markedly unpleasant flavors.

Note: You can assess this function in your examination of the mouth and oropharynx (see Procedure 22-9).

Expected findings: The client is able to perform all movements and can distinguish sweet, salty, and sour tastes.

Developmental Variations

Older adults—Have decreased taste sensation, especially sweet and salty, due to taste bud atrophy and diminished sense of smell.

Abnormal findings: Asymmetrical movement may be seen with nerve damage from a CVA or Bell's palsy. Impaired taste may be associated with nerve damage, chemotherapy, or radiation to the face or neck.

---

16. Test cranial nerve VIII—acoustic nerve.

Note:You can assess this function in your examination of the ears (see Procedure 22-7).

a. Perform watch-tick test for hearing by holding a watch close to the client's ear.

b. Perform Weber and Rinne tests to assess air and bone conduction.

c. Test balance with the Romberg test, if it has not already been performed.

See Procedures 22-7 and 22-15 for further details on these tests.

Developmental Modifications

Children—Romberg test is appropriate only after age 3.

Expected findings: Hearing is intact. Romberg test is negative.

Abnormal findings: Hearing loss, loss of balance, or vertigo may result from acoustic nerve damage.

(continued on next page)

Procedure 22-16 ■ Assessing the Sensory-Neurological System (continued)

17. Test cranial nerves IX and X—glossopharyngeal and vagus nerves.

a. Observe ability to talk, swallow, and cough.
b. Test motor function by asking the client to say "ah" while you depress a tongue blade and observe the soft palate and uvula.
c. Test sensory function by taking a tongue blade and gently touching the back of the pharynx to induce a gag reflex.
d. Test taste (sweet, salty, and sour) on the posterior portion of the tongue. Avoid bitter or repulsive tasting substances.

Expected findings: Swallow and cough reflex are intact. Speech is clear. The uvula and soft palate rise symmetrically, and the gag reflex is intact. Taste on the posterior tongue is intact.

Developmental Variations

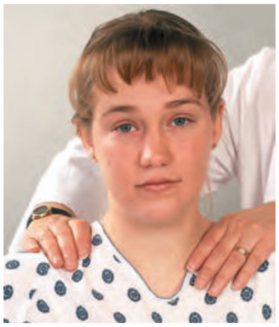
Older adults—Have decreased taste sensation, especially sweet and salty, due to atrophy of the taste buds and a diminished sense of smell.

Abnormal findings: Damage to CN IX and X impairs swallowing. Damage to CN X changes voice quality.

18. Test cranial nerve XI—accessory nerve.

NOTE: You can assess this motor nerve function with your examination of the musculoskeletal system (see Procedure 22-5).

a. Place your hands on the client's shoulder, and have the client shrug his shoulders against resistance.
b. Have the client turn his head from side to side against resistance.



Expected findings: Movement is symmetrical and pain-free. Full ROM of the neck with +5 strength.

Abnormal findings: Asymmetrical movement, pain, or absent movement indicates CN XI disorders.

19. Test cranial nerve XII—hypoglossal nerve.

a. Ask the client to say "d, l, n, t."
b. Have the client protrude the tongue and move it from side to side.

Expected findings: The client can articulate the sounds and move the tongue easily.

Abnormal findings: Tongue paralysis

20. Test superficial sensations.

- Begin with the most peripheral part when testing the limbs (e.g., test the foot before the leg).

If the client can feel sensation in the most peripheral part, you can assume the sensory nerve is intact to that point.

- If the client does not perceive the touch in an area, determine the boundaries of the dysfunction by testing at about every inch (2.5 cm). Sketch the area of sensory loss.
- Wait about 2 seconds before moving to each site.

Wait so that you can be sure that the patient is perceiving each stimulus separately.

Testing light touch

a. *Light touch:* With the patient's eyes closed, brush a cotton wisp on various areas of the body, comparing sides. Ask the client to say, "Now," when he feels your touch and to point to the spot you are touching.

b. *Pain:* With the patient's eyes closed, use a toothpick (or sterile needle) with dull and sharp ends. Touch various areas of the body (except the face), and have the patient identify whether the sensation is dull or sharp. Alternate the dull and sharp ends as you move from spot to spot. Compare sides of the body.

c. *Temperature sensation:* Test only if the patient's perception of pain is abnormal. Use test tubes filled with hot and cold water. Touch the tube to various areas of the body, comparing sides; have the client say "Hot," "Cold," or "Don't know."

If pain sensation is intact, temperature will be, too, because sensations for pain and temperature are transmitted along the same tracts.

a. **Expected findings:** Able to identify areas of light touch.

Abnormal findings: Diminished sensation or areas of absent perception

b. **Expected findings:** The client is able to identify the areas stimulated and the type of sensation.

Abnormal findings:

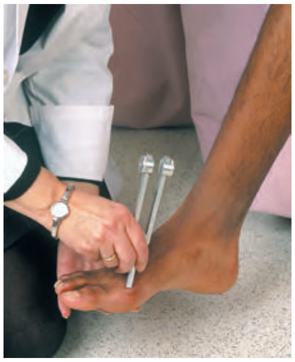
- **Hyperalgia:** increased pain sensation
- **Analgesia:** no pain sensation
- **Paresthesia:** numbness and tingling

Developmental Variations

Older adults—May have a decreased perception of temperature and deep pain.

21. Test deep sensations.

a. *Assess vibratory sensation* by placing a vibrating tuning fork on a metatarsal joint and distal interphalangeal joint. Have the patient identify when she feels the vibration and when it stops.



a. **Expected findings:** Vibratory sense is intact bilaterally in the upper and lower extremities.

Abnormal findings: Diminished or absent vibration sense is seen with peripheral nerve damage from vascular disease, diabetes, alcoholism, or damage to the posterior column of the spinal cord.

22. Test kinesthetic sensation (position sense).

By holding the client's finger or toe on the sides and moving it up or down. Keeping her eyes closed, have the client identify the direction of the movement.

Expected Findings: Position sense is intact bilaterally in the upper and lower extremities.

Developmental Variations

Older adults—May lose position sense in the great toes.

Abnormal findings: Diminished or absent position sense indicates nerve or spinal cord damage.

(continued on next page)

Procedure 22-16 ■ Assessing the Sensory-Neurological System (continued)

23. Test discriminatory sensations.

a. Assess *stereognosis* by placing a familiar object (e.g., a coin or a button) in the palm of the client's hand and having her identify it.

a. **Expected findings: Stereognosis** (the ability to recognize the form of solid objects by touch) is intact bilaterally.

b. Assess *graphesthesia* by drawing a number or letter in the palm of your patient's hand and having the patient identify what was drawn.

b. **Expected findings: Graphesthesia** (the ability to recognize outlines, numbers, or symbols written on the skin) is intact bilaterally.

c. Test *two-point discrimination* with toothpicks. Have the patient close her eyes. Touch her on the finger with two toothpicks simultaneously. Gradually move the points together, and have the patient say, "One," or "Two," each time you move the toothpicks. Document distance and location at which she can no longer feel two separate points. ➤

c. **Expected findings: Point discrimination** (recognizing whether 1 or 2 areas of the skin are being touched). Discriminates between two points on fingertips no more than 0.5 cm apart.

d. Test *point localization* by having the patient close her eyes while you touch her. Have her point to the area you touched. Repeat on both sides and the upper and lower extremities.

d. **Expected findings: Point localization** (the ability to identify where one is being touched) is intact bilaterally in the upper and lower extremities.

e. Test *sensory extinction* by simultaneously touching the patient on both sides (e.g., on both hands, both knees, both arms). Have the patient identify where he was touched.

e. **Expected findings:** Extinction is intact: Client should feel the sensation on both sides of his body.

Abnormal findings: Abnormalities in any of the discriminatory sensation tests may indicate a lesion or disorder of the sensory cortex or disorder of the posterior column of the spinal cord.

Developmental Modifications

Older adults—May need more time to respond to a stimulus, as reaction time may be slower.

24. Test deep tendon reflexes.

(See the accompanying scale to grade responses.)

Deep Tendon Reflex Grading Scale

0 No response detected
+1 Diminished response
+2 Response normal
+3 Response somewhat stronger than normal
+4 Response hyperactive with **clonus** (involuntary contractions that continue after the first contraction is elicited by the hammer)

Developmental Variations

Older adults—Reflex responses may not be as strong as in young adults. Reaction time is slower as well.

a. *Biceps reflex* (spinal cord level C5 and C6). Rest the patient's elbow in your nondominant hand, with your thumb over the biceps tendon. Strike the percussion hammer to your thumb.

a. **Expected findings:** +2 response: You can feel the biceps contract with your thumb; slight flexion of the elbow.

b. *Triceps reflex* (spinal cord level C7 and C8). Abduct the patient's arm at the shoulder, and flex it at the elbow. Support the upper arm with your nondominant hand, letting the forearm hang loosely. Strike the triceps tendon about 2.5–5 cm (1–2 in.) above the olecranon process.

b. **Expected findings:** +2 response: Contraction of triceps with slight extension at elbow.

c. *Brachioradialis reflex* (spinal cord level C3 and C6). Rest the client's arm on her leg. Strike with the percussion hammer 2.5–5 cm (1–2 in.) above the bony prominence of the wrist on the thumb side.

c. **Expected findings:** +2 response: Flexion at elbow and supination of forearm

d. *Patellar reflex* (spinal cord level L2, L3, and L4). Have the client sit with her legs dangling. Strike the tendon directly below the patella.

d. **Expected findings:** +2 response: Contraction of quadriceps with extension of leg

(continued on next page)

Procedure 22-16 ■ Assessing the Sensory-Neurological System (continued)

e. *Achilles reflex* (spinal cord level S1, S2). Have the patient lie supine or sit with her legs dangling. Hold the patient's foot slightly dorsiflexed, and strike the Achilles tendon about 5 cm (2 in.) above the heel with the percussion hammer.

Developmental Modifications

Newborns—test the following reflexes:

- **Rooting reflex**—Stroke the cheek; the head should turn to the side you touched.
- **Palmar grasp**—Place one finger in the baby's hand; his fingers should curl around your finger.
- **Tonic neck reflex**—Position the baby supine; turn his head to one side. The arm and leg on that side should extend, and those on the other side will flex.

e. **Expected findings:** +2 response: Plantar flexion of foot.

Developmental Variations

Older adults—May lose this reflex.

Abnormal findings:

- Absent or diminished responses are seen with degenerative disease, nerve damage, or lower motor neuron disease.
- Hyperactive reflexes are seen with spinal cord injuries and upper motor neuron disease.
- Rooting, palmar grasp, and tonic neck reflexes present after 6 months of age.

---

25. Test superficial reflexes.

- Plantar reflex (Babinski response): With your thumbnail or pointed object, stroke the sole of the client's foot in an arc from the lateral heel to medially across the ball of the foot. Record response as negative (normal) or positive (abnormal).

Developmental Modifications

Older adults—This reflex may be difficult to elicit.

Expected findings: Babinski response is negative. All the toes curl downward or there is no response.

Infants and children—Positive Babinski is normal until age 2 or until the child begins walking.

Abnormal findings: A positive Babinski response: dorsiflexion of the great toe and fanning of the other toes. Seen with drug or alcohol intoxication or upper motor neuron disease.

26. Mental status screening.
The following questions may be used for a rapid evaluation of cognitive status. You may have already assessed for some aspects of mental status (e.g., orientation to time).

Questions for Evaluating Cognitive Status

This complete set of questions is included so you can use them for a mental status exam that is not part of a comprehensive assessment. In a comprehensive assessment, do not repeat questions you have already covered in other portions of the assessment.

QUESTION	FUNCTION ASSESSED
What is today's date?	Orientation to time
What time is it?	Orientation to time
Where are you?	Orientation to place
What is the reason for your visit? (If the patient is hospitalized, modify the question as: Why are you in the hospital?)	Communication, vocabulary, thought processes, recent memory
Ask the patient to count backward from 100.	Word comprehension, abstract reasoning
Ask the patient to name several objects that you point to. Be sure to use common objects such as a pen, shoe, or window.	Vocabulary, general knowledge, and word comprehension
Write a brief command, such as "Clap your hands," on a slip of paper. Hand the paper to the patient and ask him to follow the instructions.	Reading comprehension
Ask the patient to write the names of his family members, along with their relationship to him.	Writing, thought processes, memory, sound recognition
Ask the patient to name three things that begin with the letter *D*.	Auditory comprehension, thought processes
Ask the patient to draw a circle, square, and triangle next to each other on a sheet of paper.	Word comprehension, mathematical and calculation skills, communication (naming
Difficulty with any of these questions requires further evaluation.	

? What if . . .

- **The patient is an older adult?**

For a mental-status exam for older adults,

Go to the link to the Mini-Cog exam in **Chapter 22, Resources for Caregivers & Health Professionals,** on Davis*Plus*.

You should also assess older adults for dementia, which is characterized by these four features:

- Mental status change of sudden onset, or fluctuating course
- Difficulty focusing attention, distractible
- Disorganized, illogical thinking
- Increased or decreased level of consciousness (e.g., hyperalert, lethargic)

Delirium occurs in 15% to 60% of older hospitalized patients. You should assess them frequently to facilitate prompt identification and management of delirium.

For a reliable tool for assessing confusion and dementia in older adults,

Go to the link for the Confusion Assessment Method Instrument in **Chapter 22, Resources for Caregivers & Health Professionals,** on Davis*Plus*.

Home Care

Instruct caregivers in home safety if the client has cerebral function deficits or sensory or motor deficits.

Documentation

If you need more information about documenting,

Go to Chapter 22, Documenting Physical Assessment Findings, in Volume 1.

(continued on next page)

Procedure 22-16 ■ Assessing the Sensory-Neurological System (continued)

Glasgow Coma Scale

EYE RESPONSE	SCORE	MOTOR RESPONSE	SCORE	VERBAL RESPONSE	SCORE
Opens spontaneously	4	Obeys verbal commands for movement	6	Oriented and converses	5
Opens to verbal commands	3	Reacts purposefully to localized pain	5	Disoriented but converses	4
Opens to pain	2	Withdraws in response to pain (generalized body response)	4	Uses inappropriate words	3
No response	1	Assumes flexor posture (decorticate posturing—arms flexed to chest, hands clenched and internally rotated) in response to pain. *Indicates problem is at or above the brainstem*	3	Makes incomprehensible sounds No response	2 1
		Assumes extensor posture (decerebrate posturing—arms extended, hands clenched and hyperpronated); *Indicates problem at the brainstem level* No response	2 1		
Totals					

Full Outline of UnResponsiveness (FOUR)

Eye Response

4—Eyelids open or opened, tracing, or blinking on command
3—Eyelids open but not tracking
2—Eyelids closed but open to loud voice
1—Eyelids closed but open to pain
0—Eyelids remain closed with pain

Motor Response

4—Thumbs-up, fist, or peace sign
3—Localizing to pain
2—Flexion response to pain
1—Extension response to pain
0—No response to pain or generalized myoclonus status

Brainstem Reflexes

4—Pupil and corneal reflexes present
3—One pupil wide and fixed
2—Pupil or corneal reflexes absent
1—Pupil and corneal reflexes absent
0—Absent pupil, corneal, and cough reflexes

Respirations

4—Not intubated, regular breathing pattern
3—Not intubated, Cheyne-Stokes breathing pattern
2—Not intubated, irregular breathing
1—Respirations greater than ventilator rate
0—respirations at ventilator rate or apnea

***Note:* Education is necessary to use this scale properly.**

To see how to use it,

Go to Iyer, V., Mandrekar, J., Danielson, R., et al. (2009). Validity of the FOUR score coma scale in the medical intensive care unit. *Mayo Clinic Proceedings, 84*(8), 694–701, at http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2719522/

Sources: NGC (2008); Rauen, A., Chylay, M., Bridges, E., et al. (2008); Wijdicks, E. F. M., Bamlet, W. R., Maramattom, B.V., et al. (2005).

Procedure 22-17 ■ Assessing the Male Genitourinary System

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonlatex procedure gloves
- Penlight
- Pen and record form

Developmental Modifications for Children

- Obtain the parent's permission to perform this assessment.
- Explain to the child what you are going to do, and expect some resistance or embarrassment.
  Children are taught to not let strangers touch their genitals, and many children are modest.

Developmental Modifications for Older Adults

- Assess for incontinence.
  Incontinence is one of the elements of the SPICES assessment model for older adults.

Focused History Questions

- Have you noticed any redness, swelling, discharge, or odor in your genital area?
- Have you noticed asymmetry, lumps, or masses in your genitals? If so, describe them, and show me where they are.
- Have you ever been told you have a hernia?
- Have you ever had trauma to your genitals?
- Are you having any problems urinating?
- Are you sexually active? If not, have you ever been?
- Do you have sex with men, women, or both?
- What types of sexual activity do you engage in? Oral, anal, genital?
- Do you have more than one partner? How many partners have you had in the past 6 months?
- Do you use birth control? If so, what type and how often?
- Have you ever been treated for a sexually transmitted infection (STI)? If so, what type?
- Are you concerned about STIs or HIV?
- Do you take any precautions to avoid infections?
- Do you have any concerns about your sexual function?
- Do you have any difficulty achieving or maintaining an erection?
- Have you been taught to examine your testicles?
  In spite of the low prevalence of testicular cancer, men should be aware that a lump in the testicle and/or a feeling of heaviness or swelling in the scrotum could be a sign of testicular cancer and should report these findings to his healthcare provider immediately (American Cancer Society, n.d., last revised 2013a).
- How often do you do testicular self-examination?
- Have you had any surgery of your reproductive tract?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Expected and Abnormal Findings

1. **Instruct the client to empty his bladder and undress** to expose the groin area.

2. **Have the patient stand while you sit at eye level to the genitalia;** alternatively, the patient can lie supine on the exam table with his legs slightly apart.

3. **Inspect the external genitalia.**
   a. *Hair.* Note the hair distribution pattern and condition of pubic hair. See the table discussing Tanner staging, at the end of this procedure.
   The appearance of the external genitalia depends on the client's developmental stage.

a. **Expected findings:** Hair distribution is triangular and appropriate for age. No pediculosis is present.

Abnormal findings: Sparse or absent hair may result from genetic factors, aging, or local or systemic disease.

(continued on next page)

Procedure 22-17 ■ Assessing the Male Genitourinary System (continued)

b. *Skin:* Inspect the condition of the skin of the penis. Observe for the presence or absence of the foreskin. Note the position of the urethral meatus and any lesions or discharge.

b. **Expected findings:** Skin is intact with no lesions or discharge. Color is consistent with ethnicity. The urethral meatus is midline. The foreskin may be absent (circumcised); if present, it covers the glans and easily retracts.

Developmental Variations:

Infants—Foreskin is difficult to retract in the uncircumcised male until about age 3 months.

Older adults—Penis and testes decrease in size.

Abnormal findings: Ulcerations or lesions (may be seen with a number of STIs, such as genital warts and genital herpes); **phimosis** (foreskin cannot be retracted and becomes swollen).

c. *Scrotum:* Observe the condition, size, position, and symmetry of the scrotal sacs.

c. **Expected findings:** The skin should be free of lesions, nodules, swelling, rash, and erythema. The skin is rugated and deeper in color than the rest of the body. Size and shape vary greatly. The left scrotal sac is usually lower than the right.

Abnormal findings: A rash may be caused by **tinea cruris,** a fungal infection often called "jock itch." Swelling may indicate hernia, tumor, or infection.

d. *Inguinal area:* Note the condition of the inguinal areas. Look for swelling or bulges. The best way to do this is to have the client bear down while you palpate the inguinal canal.

d. **Expected findings:** The inguinal area should be free of swelling or bulges.

Abnormal findings: A bulge may indicate a hernia or enlarged lymph node.

4. Palpate the penis.

a. With a gloved hand, use your thumb and fingers to palpate the shaft of the penis. Note consistency, tenderness, masses, or nodules.

b. Retract the foreskin if present.

Expected findings: The penis is nontender with no masses or nodules. Pulsations are present on the dorsal side. The foreskin, if present, easily retracts.

Abnormal findings: Inability to palpate a pulse may indicate vascular insufficiency; difficulty retracting the foreskin or problems with its return to position need further evaluation.

5. Palpate the scrotum, testes, and epididymis.

a. Don a procedure glove and use your thumb and fingers to palpate.

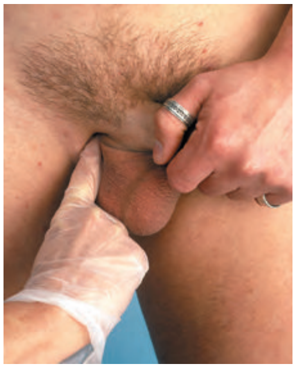
Expected findings: The scrotal skin is rough but without lesions. Each testicular sac contains a testicle and epididymis. The testes are rubbery, round, movable, and smooth. They are sensitive to pressure but nontender. The epididymis is comma shaped. The spermatic cord is smooth and round. There is no swelling or nodules. The left scrotal sac is usually lower than the right.

Abnormal findings:

- A unilateral mass
- Painless intratesticular masses may represent testicular cancer.
- A testicle that is swollen or tender may indicate infection or torsion.

b. Note size, shape, consistency, mobility, masses, nodules, or tenderness.
c. Transilluminate any lumps, nodules, or edematous areas by shining a penlight over the area in a darkened room.

6. **Palpate the inguinal and femoral area for hernias.**



a. Assess for inguinal hernias with a gloved hand. Have the patient hold his penis to one side. Place your index finger in the client's scrotal sac above the testicle, and invaginate the skin. Follow the spermatic cord until you reach a slit-like opening (Hesselbach's triangle). Ask the client to cough or bear down as you feel for bulges.
b. Palpate for femoral hernias by palpating below the femoral artery while having the client cough or bear down.

Expected findings: No bulges or palpable masses are present in the inguinal or femoral area.

Abnormal findings: A bulge or mass often represents a hernia. Refer to the Abnormal Atlas at the end of this chapter.

Direct hernia: protrusion through the abdominal wall.

Indirect hernia: protrusion into the inguinal canal or into the scrotum.

7. **Palpate the lymph nodes** in the groin area and the vertical chain over the inner aspect of the thigh.

Expected findings: Nodes should be <1 cm in size and freely mobile.

Abnormal findings: Enlarged or tender lymph nodes may indicate local or systemic disease. Also see the Abnormal Atlas: Male Genitourinary System.

(continued on next page)

Procedure 22-17 ■ Assessing the Male Genitourinary System (continued)

Documentation

If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Tanner Staging

STAGE	PUBIC HAIR	PENIS	TESTES AND SCROTUM
Stage 1: Preadolescent 	No pubic hair except for fine body hair similar to that on abdomen	Same size and proportions as in childhood	Same size and proportions as in childhood
Stage 2 	Sparse growth of long, slightly pigmented, downy hair, straight or only slightly curled, chiefly at base of penis	Slight or no enlargement	Testes larger, scrotum larger, somewhat reddened and altered in texture
Stage 3 	Darker, coarser, curlier hair spreading sparsely over pubic symphysis	Larger, especially in length	Further enlarged
Stage 4 	Coarse and curly hair, as in adult; area covered greater than in stage 3 but not as great as in adult	Further enlarged in length and breadth, with development of glans	Further enlarged; scrotal skin darkened
Stage 5 Adult 	Hair same as adult in quantity and quality, spreading to medial surfaces of thighs but not up over abdomen	Adult in size and shape	Adult in size and shape

Adapted from: Tanner, J. (1962). *Growth at adolescence* (2nd ed.). Oxford: Blackwell Scientific

Procedure 22-18 ■ Assessing the Female Genitourinary System

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Patient drape
- Additional light source
- Nonlatex procedure gloves (if exposure to body fluids is a possibility)
- Pen and record form

Positioning

Lithotomy position, if possible.

Developmental Modifications for Older Adults

- Assess for incontinence.

Incontinence is one of the elements of the SPICES assessment model for older adults.

- Older women may have arthritis, which, along with muscle weakness, may make it difficult for them to assume the lithotomy position. You may need to use Sims' position and/or provide support for them to maintain a position.

Developmental Modifications for Children

- Obtain parental permission for this examination.
- Explain to the child what you are going to do, and expect some resistance or embarrassment.

Children are taught to not let strangers touch their genitals, and many children are modest.

Key Point: ***Do not perform internal assessment of an adolescent unless the girl is sexually active.***

Focused History Questions

- Are you having any problems urinating?
- Have you noticed any redness, swelling, discharge, or odor in your genital area?
- Have you ever been told you have a hernia?
- Have you ever had trauma to your genitals?
- Are you sexually active? If not, have you ever been?
- Do you have sex with men, women, or both?
- What types of sexual activity do you engage in? Oral, anal, or genital?
- How many partners do you currently have?
- How many partners have you had in the past 6 months?
- Do you use birth control? If so, what kind and how often?
- Have you ever been treated for a sexually transmitted infection (STI)? If so, what type?
- Are you concerned about STIs or HIV?
- Do you take any precautions to avoid infection?
- Do you have any concerns about your sexual function?
- Have you had any surgery of your reproductive tract?
- When was your last menstrual period?
- How often are your periods?
- Do you have any problems with your periods, such as cramping, breast pain, or heavy flow?
- How often do you have a gynecological health exam?
- When was your last Pap smear?
- Have you ever had an abnormal Pap smear? If so, how was it treated?
- How many times have you been pregnant?
- How many children do you have?
- Have you ever had a miscarriage? An abortion?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Inspect the external genitalia.
   a. Note the hair distribution pattern and the condition of pubic hair. See the table Maturation Status in Females at the end of this procedure.

   The appearance of the external genitalia depends on the developmental stage of the client.

   b. Inspect the condition of the skin of the mons pubis and labia. Observe for color, condition, lesions, and discharge.

Expected and Abnormal Findings

a. **Expected findings:** Hair distribution in the pubic region is inverse triangular. Some hair may extend onto her abdomen and upper thighs. Hair distribution is appropriate for age. No **pediculosis pubis** (pubic lice).

Abnormal findings: Sparse or absent hair (may result from genetic factors, aging, or local or systemic disease); lice, **nits** (white lice eggs), or flecks of dried blood on the skin.

b. **Expected findings:** Skin is intact with no lesions or discharge. Labia majora and minora are symmetrical, with smooth to moderate wrinkling. Skin color is consistent with ethnicity. No ecchymosis, excoriation, nodules, edema, rash, or lesions are present.

(continued on next page)

Procedure 22-18 ■ Assessing the Female Genitourinary System (continued)

Developmental Variations

Older adults—Labia and vulva are atrophied.

Abnormal findings: Ulcerations or lesions may occur with a number of STIs.

---

2. **Inspect the clitoris, urethral meatus, and vaginal introitus.**
   a. Wearing gloves, use your thumb and index finger to separate the labia and expose the clitoris. Observe the clitoris for size and position.

a. **Expected findings:** The clitoris is about 2 cm long and 0.5 cm in diameter. No redness or lesions are present.

Abnormal findings: Enlargement of the clitoris may result from androgen excess or swelling related to trauma. Absence of the clitoris, along with parts of the labia, is seen with female circumcision.

   b. With the labia separated, observe the urethral meatus and vaginal introitus. Observe for color, size, and presence of discharge or lesions.

b. **Expected findings:** The urethral meatus is slit-like, midline, and free of discharge, lesions, swelling, or erythema. The mucosa of the introitus is pink and moist. Some clear to white discharge may be present and is odor-free.

   c. Have the client bear down while you observe the introitus.

c. **Expected findings:** The introitus is patent, and there is no bulging or discomfort with bearing down.

Abnormal findings: Discharge, redness, or swelling may result from infection. Pale and dry mucosa may result from aging or use of topical steroids. Bulging may indicate prolapse of the uterus, bladder, or rectum.

---

3. Palpate Bartholin's glands, the urethral glands, and Skene's ducts.
   a. Lubricate the index and middle fingers of your dominant hand with water-soluble lubricant.
   b. To palpate Bartholin's glands, insert your lubricated fingers into the vaginal introitus, and palpate the lower portion of the labia bilaterally between your thumb and fingers.

Expected findings: No swelling, masses, or tenderness of the glands is present. There is no urethral discharge. The labia are uniform in texture, and there is no discharge or pain with palpation. The perineum is smooth and firm in **nulliparous** women (women who have had no children), thinner in **parous** women (women who have had children).

Abnormal findings: Pain or discharge from the glands may indicate infection. Fissures or tears in the perineum are painful and require treatment.

c. To palpate Skene's ducts, rotate your internal fingers upward, and palpate the labium bilaterally. ➤

d. To milk the urethra, apply pressure with your index finger on the anterior vaginal wall, and observe for urethral discharge. Culture any discharge you see.

4. Assess vaginal muscle tone and pelvic musculature.
a. Insert two gloved fingers into the vagina.
b. Ask the woman to constrict her vaginal muscles and then to bear down as though she were having a bowel movement.

Expected findings: Muscle tone should be strong in women who have never given birth. With increasing **parity** (number of births), pelvic muscle tone diminishes. Diminished tone may also result from injury, age, or medication. No bulges should be noted.

5. Palpate the inguinal and femoral area for hernias.

Expected findings: No bulges or palpable masses are present in the inguinal or femoral area.

6. Palpate the lymph nodes **in the groin area and the vertical chain over the inner aspect of the thigh.**

Expected findings: Nodes should be <1 cm in size and freely mobile.

Abnormal findings: Enlarged or tender lymph nodes may indicate local or systemic disease. Also see the Abnormal Atlas: Female Genitourinary System at the end of this chapter.

Documentation

If you need more information about documenting,

Go to Chapter 22, **Documenting Physical Assessment Findings,** in Volume 1.

Maturation Status in Females

STAGE OF DEVELOPMENT	BREASTS	PUBIC HAIR
Stage 1. Prepuberty	Elevation of papilla. 	No pubic hair except for fine body hair similar to hair on abdomen. 
Stage 2	Breast bud. Elevation of breast and nipple and increased diameter of areola. 	Sparse growth of long, slightly pigmented, downy hair, straight or only slightly curled, mostly along labia. 

(continued on next page)

Procedure 22-18 ■ Assessing the Female Genitourinary System (continued)

Maturation Status in Females—cont'd

STAGE OF DEVELOPMENT	BREASTS	PUBIC HAIR
Stage 3	Areola deepens in color and enlarges further. Glandular tissue begins to develop beneath areola. 	Hair becomes darker, coarser, and curlier and spreads sparsely over pubic symphysis. Stage 4	Areola appears as a mound; breast appears as a mound; papilla and areola form a secondary mound. 	Pubic hair is coarse and curly as in adults. It covers more area than in stage 3, but does not extend to the medial thighs. Stage 5. Adult	Mature breast. Areola recesses to general contour of breast; nipple projects forward. 	Quality and quantity are consistent with adult pubic hair distribution and spread over medial surfaces of thighs but not over abdomen. 
Adapted from: Tanner, J. (1962). *Growth at adolescence* (2nd ed.). Oxford: Blackwell Scientific.

Procedure 22-19 ■ Assessing the Anus and Rectum

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Water-soluble lubricant
- Hemoccult test
- Nonlatex procedure gloves
- Pen and record form

Developmental Modification for Infants and Children

You will not usually perform a rectal exam on infants and children.

Focused History Questions

- Do you have any pain or discomfort around your anus?
- Do you ever have difficulty passing stool?
- Have you ever noticed blood on your stool or when you wipe?
- Do you have or have you ever been told you have hemorrhoids?
- For men, have you ever had a prostate exam or a prostate-specific antigen (PSA) blood test? If so, what were the results?

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, and body mechanics.

Procedure Steps

1. **Inspect the anus.** Note the condition of the skin and the presence of any lesions.

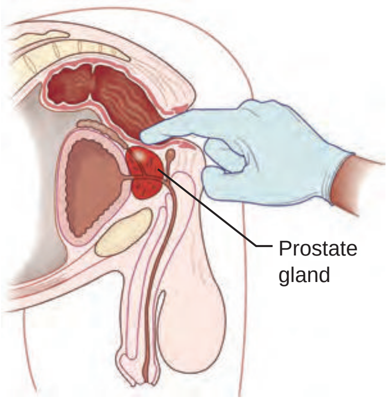
Expected and Abnormal Findings

Expected findings: Anal area is intact, with no inflammation or lesions. Anus is a darker color than surrounding tissue.

Abnormal findings:

- A fissure or tear may be due to trauma, severe constipation, or an abscess.
- External hemorrhoids or skin tags may be visible.

2. **Palpate the anus and rectum.**
   a. *For women,* change gloves to prevent cross-contamination. Insert a lubricated index finger gently into the rectum. Palpate the rectal wall, noting masses or tenderness.
   b. *For men,* have the client bend over the exam table or turn on his left side to recumbent. Insert a lubricated index finger gently into the rectum. Palpate the rectal wall, noting masses or evidence of tenderness.



Step 2b

Test any stool on the gloved finger for occult blood. See Procedure 29-1.

Expected findings: Good sphincter tone. Rectum is nontender. No palpable masses or hard stool. The stool is brown and negative for occult blood.

Abnormal findings:

- Hard stool in the rectum indicates impaction.
- Positive occult blood indicates bleeding in the GI tract.
- A palpable mass or enlarged prostate gland requires further evaluation.
- Internal hemorrhoids may be present.

(continued on next page)

Procedure 22-19 ■ Assessing the Anus and Rectum (continued)

Patient Teaching

Instruct the client in the importance of colonoscopy and prostate exam.

Documentation

If you need more information about documenting,

Go to Chapter 22, Documenting Physical Assessment Findings, in Volume 1.

Procedure 22-20 ■ Brief Bedside Assessment

Note: This assessment is not as detailed as in Procedures 22-1 through 22-19. You might perform such an assessment when admitting a patient to a hospital unit. You can also use it for ongoing assessments. For daily patient assessments, you will modify the procedure to fit the patient's health status. You may be able to omit some portions, and you may need to add in-depth, focused assessments of some body systems. The entire assessment should take no more than 15 minutes after you become skilled.

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Thermometer, stethoscope, sphygmomanometer
- Procedure gloves

Focused History Questions

- Ask about any health problems, allergies, or medications.
- Ask your patient how she feels currently and during the previous month and year.
- Ask other questions as you assess each body system.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Greet the patient and explain what you need to do.** Ask the patient her name and confirm by checking her identity band.
   Assures that you have the correct patient and also allows you to assess mental status and communication.

2. **Observe the environment** (e.g., IV lines, oxygen, urinary catheter) and patient's general appearance (including signs of distress).
   This allows you to identify any immediate actions you may need to take before performing the assessment.

3. **Begin by measuring the vital signs (patient supine or sitting):**
   a. temperature, pulse, respirations, blood pressure
   b. pain status
   c. pulse oximetry

4. **Now assess each body system.**
   a. Use a systematic approach such as head-to-toe.
   b. As you assess each system, observe for mobility, range of motion (ROM), balance, and coordination.
   c. As you talk with the patient, observe her thought processes and level of consciousness.

5. **Assess the integument.**
   a. Ask about any hair, nail, or skin changes, including rashes.
   b. With each body system, inspect skin color, rashes, and lesions; and palpate for temperature, turgor, and texture. Also inspect the hair and nails in that area (e.g., when assessing the legs and feet).
   c. Assess wounds: appearance, size, drainage, dressings, drains.
   d. Inspect and palpate the hair and scalp.

6. **Assess the head and neck.**
   a. Ask the patient about any problems with the head and neck.
   b. **Key Point:** *Remember to continue assessing mental status and orientation to time, place, and person.*
   c. Inspect the external ears; observe for apparent hearing deficit.
   d. Check the eyes for pupil reaction and cardinal fields of gaze. Ask about and observe for any problems with vision.
   e. Inspect the color of the lips, mucous membranes, and conjunctiva.
   f. Inspect the tongue and oropharynx.
   g. Inspect for hydration, color, and lesions of the mucous membranes.
   h. Lightly palpate the carotid pulse (only if indicated by patient's condition) and listen for carotid bruits.

Do not palpate both carotid arteries at the same time. See Procedure 22-16.

7. **Assess the heart.**
   a. Have the patient sit up and lean forward a bit.
   b. Ask about any cardiovascular problems.
   c. Auscultate heart sounds. Note rate, rhythm, S_1, S_2, and extra sounds.

8. **Assess the back while patient is in the sitting position.**
   a. Inspect skin.
   b. Auscultate breath sounds; compare side to side and apex to base.
   c. Assess respiratory rate, rhythm, and effort.
   d. Note cough, secretions, how many pillows used to sleep on, and whether head of bed is elevated for breathing.
   e. Check oxygen order, SaO_2, ability to use incentive spirometer.

9. **Assess the anterior chest.**
   a. Ask about any respiratory problems.
   b. Palpate skin turgor, temperature, and point of maximal impulse (PMI).
   c. Auscultate breath sounds.

10. **Assess the abdomen, with the patient supine.**
   a. Inspect the size, shape, symmetry, and condition of the abdominal skin.
   b. Observe abdominal movements including respirations, pulsations, and peristalsis.
   c. Auscultate bowel sounds in all four quadrants, and the aorta for bruits.
   d. Palpate all four quadrants for tenderness, guarding, and masses; and inspect for rebound tenderness.
   e. Ask the patient about any weight changes, gastrointestinal (GI) complaints, a change in appetite or diet.
   f. Review the pattern for bowel movements, and when examining a woman, ask of her last menstrual period.

11. **Assess urinary status.**
   a. Review voiding pattern with the patient (including frequency and dysuria).
   b. If there is an indwelling catheter, observe for patency, kinks in the tubing, and color of urine; monitor intake and output.
   c. Palpate for bladder distention.

12. **Assess the upper extremities.**
   a. Ask about any problems with the hands and arms, such as weakness, arthritis, change in sensation, temperature or color.
   b. Inspect the condition of the skin and nails.
   c. Palpate skin temperature and bilateral brachial and radial pulses.
   d. Check capillary refill.
   e. Note any stiffness or limited range of motion of the hands and arms.
   f. Test muscle strength by having the patient grip your hands or two fingers.
   g. Note whether the patient has any casts, traction, splints, or slings.
   h. Observe for edema.

13. **Assess the lower extremities.**
   a. Ask about any problems with the legs, such as weakness, numbness, tingling, arthritis, edema, change in sensation, and temperature or color.
   b. Observe ROM and ability to ambulate or move about in bed.
   c. Inspect the condition of the skin and nails.
   d. Palpate skin temperature and pedal pulses; check capillary refill.
   e. Test for leg strength by asking the patient to raise the leg against your counterpressure. (This is more easily done with the patient sitting.)
   f. Check sensation through light touch, proceeding to pain as needed.
   g. Observe for problems such as paralysis.
   h. Observe for edema.

14. **Ask the patient to stand, and inspect for:**
   a. Gross spinal deformities
   b. Balance and coordination of movements
   c. ROM and gait

15. **With the patient seated in bed, legs extended, check for:**
   a. Babinski reflex
   b. Homans' sign

Documentation

- Document your findings and report any significant changes or findings to the primary care provider. As a student, report your findings to the instructor and the patient's assigned RN for validation and action.
- To print out a form to use as a documentation worksheet when performing a brief physical exam,

Go to Chapter 22, ESG Figure 22-2, Documentation Worksheet for Bedside Assessment, on DavisPlus.

- If you need more information about documenting,

Go to Chapter 22, Documenting Physical Assessment Findings, in Volume 1.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*. For questions and suggested responses, go to Chapter 22, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus*.

CLINICAL INSIGHTS

Clinical Insight 22-1 ➤ Performing Percussion

Direct Percussion

Tap lightly with the pads of the fingers directly on the skin.

Direct percussion over the sinuses

Indirect Percussion

- Keep your fingernails short.
- Strive for a quiet environment: Turn off all entertainment media and music, shut the door, and so on. This allows you to better perceive the subtle differences in percussion notes.
- One hand is considered the stationary hand; the other is the striking hand.
- Hyperextend the middle finger of your stationary hand, and place its distal portion firmly against the client's skin over the area you wish to percuss.
- Lift the rest of your fingers off the patient's skin. Prevents dampening the sounds produced.
- Be sure both of your hands are relaxed to best perform the technique. Stiff hands will not effectively produce the percussion sounds for assessment.
- Use the middle finger of your dominant hand as the striking finger (**plexor**), and tap the distal portion of the middle finger of the stationary hand using a quick motion from your wrist.

Indirect percussion.

- Use enough force to elicit a clear sound.
- Percuss two times over each location, then move to a new body location and repeat.

Describing Sounds

Use the terms in the following list to describe the sounds you hear. The terms are based on the components of the sounds produced by percussion:

Amplitude—The loudness or softness of a sound
Pitch—The number of vibrations per second; either high or low in nature
Quality—A distinctiveness about the sound produced
Duration—How long the sound lingers

Percussion Notes

SOUND	AMPLITUDE	PITCH	QUALITY	DURATION	EXAMPLE
Resonant	Medium-loud	Low	Hollow	Medium	Normal lung
Hyperresonant	Louder	Lower	Booming	Longer	Hyperinflated lung (as in emphysema)
Dull	Soft	High	Muffled thud	Short	Liver/spleen
Flat	Very soft	High	Absolute dullness	Very short	Thigh or tumor
Tympany	Loud	High	Musical	Longest	Gastric air bubble, intestinal air

Clinical Insight 22-2 ➤ Performing Auscultation

- Provide a quiet environment to facilitate auscultation.

Clean your stethoscope with a 70% alcohol or benzalkonium chloride wipe before and after using it to examine a patient. Most stethoscopes are colonized by bacteria, although only a small percentage are pathogenic. Cleaning can reduce the bacterial count by 94% to 100%.

- Use the diaphragm to listen to high-pitched sounds that normally occur in the heart, lungs, and abdomen. Press the diaphragm hard enough to produce an obvious ring on the patient's skin.
- Use the bell to hear low-pitched sounds, such as extra heart sounds (murmurs) or turbulent blood flow (bruits). Apply the bell lightly with just enough pressure to produce an air seal with its full rim.
- Place the earpieces facing forward. Seals the ear canal and improves detection of sounds.
- Warm the stethoscope before you place it on the client's skin.
- Place the stethoscope directly on the client's skin. Do not listen through clothing. Clothing can create artifact or reduce the quality of auscultation.
- If body hair prevents good contact with the skin, dampen the hair before you listen.
- Close your eyes as you listen through the stethoscope. This helps improve your focus.
- Concentrate on one sound at a time. Do not try to evaluate breath and heart sounds at the same time. Improves the quality of the data.

Practice Resources

CDC (2009); Muniz, J., Sethi, R. K., Zaghi, J., et al. (2012); Russell, A., Secrest, J., & Schreeder, C. (2012).

Clinical Insight 22-3 ➤ Assisting With a Speculum Exam

Equipment

- Patient drape
- Nonsterile gloves
- Vaginal speculum (see accompanying figure)
  The speculum may be plastic or metal.
  The size of the speculum depends on the patient's history.
    Use a small speculum for a woman who has never been sexually active or an older woman who is not sexually active.
  If a culture or a Pap smear is to be obtained, lubricate the speculum with warm water. Otherwise, use a water-soluble lubricant.
- Lubricant
- Pap smear slide, spatula, brush, or specimen broom and container with solution
- Fixative, if the smear technique is used
- Genital culture supplies
- Additional light source

Equipment. A vaginal speculum

Preparing the Patient

- Explain to the patient that an internal examination of her vagina and pelvic organs will be performed. The examination usually takes only a few minutes, and although it might not be comfortable it should not be painful.
- Have the woman urinate before the examination if needed. Emptying the bladder helps the patient to feel more comfortable during the exam.
- Provide privacy and keep the patient warm during the procedure.
- Assist the woman to the lithotomy position, and cover her with a drape.

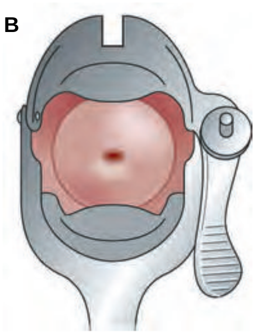
Inserting the Speculum

The speculum is inserted into the vagina to visualize the cervix (see accompanying figure). Once the speculum is inserted, you may need to adjust the light source for the examiner.

A. A vaginal speculum examination. Placement of the speculum in the vagina.

(Continued)

Clinical Insight 22-3 ➤ Assisting With a Speculum Exam—cont'd



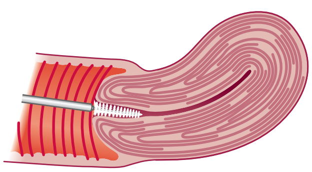
B, View through the speculum

Collecting Specimens

If a routine screening for cervical and uterine cancer is being done, a specimen will be collected. Additional cultures or screens may be required if there is unusual discharge or risk of sexually transmitted infection (STI). Genital cultures are endocervical smears.

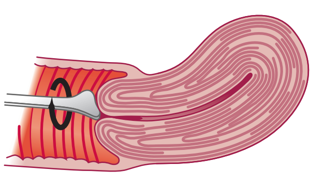
Pap Smear Procedure

Most commonly, the examiner inserts a small brush through the cervical os and rotates it to obtain cells from within the cervical canal (endocervical smear). The brush is then rolled onto the slide.



Using a specimen broom to obtain endocervical cells

A second specimen may be obtained by lightly scraping the cervix with a wooden spatula to obtain cells from the ectocervix (the lowest portion of the cervix that protrudes into the vagina).



Using a spatula to obtain ectocervical cells.

The spatula is then smeared on the slide. Some examiners use both specimen sources and then apply a fixative, usually a spray or liquid, on top of the specimen to preserve it for examination. After the samples are obtained, the speculum is removed.

Pap Smear, Alternative Method

The examiner inserts a specimen broom into the cervical os and rotates it. The broom is then inserted into a fixative solution and rotated to disperse cells into the solution. This technique is gaining popularity because it is considered more sensitive for detection of cervical changes. After the samples are obtained, the speculum is removed.

Bimanual Exam

After removing the speculum, the examiner inserts lubricated gloved fingers into the vagina while pressing down on the lower abdomen and suprapubic area. This is known as a **bimanual exam.** It is used to assess the consistency of the cervix and the size of the uterus, and to detect tenderness over the ovaries, fallopian tubes, or with movement of the cervix.

Post-Procedure

- Assist the woman to a sitting position at the end of the exam.
- You may need to assist the woman with perineal care.
- If there is any bleeding or discharge, provide a perineal pad.
- Document the date and time of the procedure, the name of the examiner, the patient's tolerance of the procedure, and any nursing assessments or interventions performed.

Practice Resources

ACOG (2010a, 2010b); Bates, C. K., Carroll, N., & Potter, J. (2011).

What Are the Main Points in This Chapter?

- A physical examination may be conducted to obtain data about the patient, to further investigate an identified health problem, to monitor a client's health status, or to screen for health problems.
- A comprehensive physical assessment includes a complete head-to-toe examination of every body system. Data from a comprehensive physical assessment provide guidance for care and determine the need for further assessment.
- A focused physical assessment is performed to obtain data about an actual, potential, or possible problem that has been identified. A focused exam adds to the database created from the comprehensive assessment.
- An ongoing assessment is appropriate for periodic reassessment of the client and reflects the dynamic state of the client. This is a less detailed examination than a comprehensive assessment.
- Before a physical assessment, you will need to gather equipment, prepare the environment, review the skills you will use, familiarize yourself with the patient situation, review the nursing plan of care, and assist the patient to relax by taking the time to develop a rapport.
- *Inspection* is the use of sight to gather data. Inspection begins the moment you meet the client.
- *Palpation* is the use of touch to gather data. Use palpation to assess temperature, skin texture, moisture, anatomical landmarks, and abnormalities such as edema, masses, or areas of tenderness.
- *Percussion*, tapping on the skin with short strokes from your fingers, produces vibrations that allow you to determine the location, size, and density of underlying structures.
- *Auscultation* is the use of hearing to gather data. Direct auscultation is unassisted listening. Indirect auscultation is listening to the sounds produced by the body with the help of a stethoscope.

Knowledge Map

PURPOSE:
- Obtain baseline data
- Identify nursing diagnoses, PCs, Wellness dx
- Monitor status of identified problems
- Screening

TYPES:
- Comprehensive:
  - interview
  - head-to-toe
- Focused:
  - data gathered on particular topic, body part/functional ability
- Ongoing:
  - prn with every pt. contact

APPROACHES:
ways to gather data
- Head to toe
- Body systems

Health Assessment

Physical Assessment

PHYSICAL EXAMINATION

PREPARATION

SELF
- Know A&P
- What is purpose of exam
- Know pt. situation & plan of care
- Be familiar with equipment
- Exam technique
- Therapeutic communication
- How to document

ENVIRONMENT
- Provide privacy
- Decrease extraneous noise
- Adequate lighting
- Comfortable temperature

PATIENT
- Promote relaxation
- Develop a rapport
- Position patient properly
- Have patient void prior
- Alert patient to touch
- Attend to cultural preferences

AGE MODIFICATIONS:

Infant: have parent hold

Toddler:
- allow to sit on parent lap
- allow choices; use praise
- invasive assessments last

Preschooler:
- demo assessment on doll
- let child help
- give reassurance

School-age Child:
- develop rapport
- allow independence
- demo equipment

Adolescent:
- no parent/sibling present
- respect privacy during exam
- emphasize healthy lifestyle habits
- assess for suicide potential

Young/Middle-Aged Adult:
- no specific modifications unless acute/chronic disease

Older Adult:
- tailor exam to energy and mobility levels
- adapt techniques for vision & hearing changes

ASSESSMENT SKILLS:

Inspection:
- use of sight/observation

Palpation:
- use of touch: fingertips, dorsum/palm of hand, finger/thumb grasp

Percussion:
- vibrations elicited through tapping
- sound indicates location, size, density of underlying structure

Auscultation:
- use of hearing
- direct via stethoscope

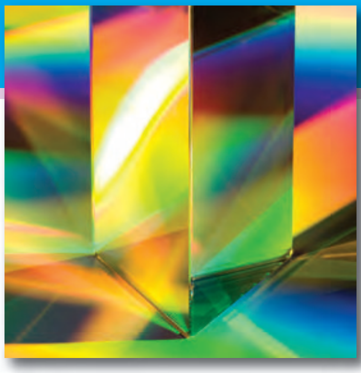
Olfaction: not a formal skill
- use of sense of smell

GENERAL SURVEY:
- Appearance/behavior
- Body type; posture
- Dress; grooming; hygiene
- Mental status
- Vital signs/height/weight assessment

Proceeding to:

Assessment of all body systems

CHAPTER 23



Promoting Asepsis & Preventing Infection

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 23:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Promoting Asepsis & Preventing Infection (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 23, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Mrs. Nguyen works as a preschool teacher in her community. Kim, her grandchild, has been attending the preschool since he came to live with his grandparents. Mrs. Nguyen tells you at a recent visit to the clinic that Kim has had "a lot of problems with colds and a runny nose since he started preschool."

(Continued)

Caring for the Nguyens (continued)

A. Based on your theoretical knowledge of asepsis and immunity, what is the most likely explanation for Kim's symptoms?

B. Do you have enough patient data to make any conclusions? If not, what other information should you gather?

C. Identify three alternatives that may explain what is happening.

D. What strategies could you recommend that Mrs. Nguyen implement at the preschool to help limit the number of infections? Identify at least two strategies.

PracticalKnowledge knowing how

As a nurse, you play a vital role in preventing the transmission of infection. Most infection control measures are independent nursing activities that require theoretical knowledge and scrupulous medical and surgical asepsis technique. The procedures and clinical insights in this volume provide the guidance you will need to implement your theoretical knowledge about infection and infection-control concepts.

PROCEDURES

Procedure 23-1 ■ Hand Hygiene

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing inside back cover. For this procedure, also refer to Clinical Insight 23-1.

Equipment

- Liquid soap
- Paper towels
- Warm, running water
- Hand moisturizer (recommended)

Assessments

- Check your hands for breaks in the skin.
  Breaks in the skin provide a route for microbial entry.
- Inspect the condition of your nails.
  —Nails should be no longer than 1/4 inch from the fingertips.
  —Do not wear artificial nails or extensions.
  —Preferably, do not use nail polish.
  Research indicates the area under the nails, artificial nails/extensions, and chipped polish act as reservoirs for microorganisms.

Procedure 23-1A ■ Using Soap and Water

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Bare your hands and forearms.** Push your sleeves above your wrists, and remove your wristwatch and rings.
   Moist clothing facilitates transfer of microorganisms; jewelry harbors bacteria and creates a moist area on the skin, which facilitates bacterial growth.

2. **Turn on the water.** Adjust the water temperature to warm.
   Warm running water opens pores to aid in removing microorganisms without removing excess skin oils. It also reduces chapping.

3. **Wet your hands and wrists.** Keep your hands below your wrists and forearms.
   The hands are considered more contaminated than the wrists and arms, so prevent water from running from your hands onto your wrists and forearms.
   a. Avoid splashing water onto clothing.
   b. Avoid touching the inside of the sink.
   Microorganisms travel in moisture. The inside of the sink is considered contaminated.

4. **Apply 3 to 5 mL of liquid soap**, which is typically 3 to 4 pumps using a soap dispenser. Rub the soap over all surfaces of your hands.
Three to 5 mL of liquid soap provides adequate amounts to completely cover the hands for maximum effectiveness to remove transient microorganisms.

5. **Vigorously rub your hands together** for at least 15 seconds, lathering all surfaces, interlacing fingers, rubbing around each finger and thumb, rubbing the backs and palms of the hands in a circular motion.
Washing for at least 15 seconds is required for mechanical removal of microorganisms and to give antimicrobial products adequate contact with the skin surfaces to be effective. Attention to all areas of the hands is necessary; research indicates areas of the hands most often missed are the thumb, the wrist, and areas between the fingers.

6. **Clean under your fingernails**, if needed, using a disposable nail cleaner.
Areas under the nails harbor high concentrations of microorganisms. Chipped nail polish and artificial nails/extenders support growth of microorganisms, especially gram-negative bacteria.

7. **Rinse your hands thoroughly.** Keep your hands below your wrists and forearms.
Rinsing hands from wrist to fingertips mechanically washes away debris and microorganisms to flow into the sink and not back up the hand and arm.

8. **Dry your hands thoroughly**, moving from your fingers up to your forearms and blotting with paper towel.
Move from the area you wish to keep cleanest (hands). Blotting decreases skin irritation.

9. **Turn off the faucet with** a dry paper towel if it is not automatic. Do not handle the paper towel with the opposite hand.
Prevents contamination of hands from the faucet. The paper towel has had contact with the contaminated faucet and may transfer microorganisms to your freshly washed hand. Many pathogens can live on environmental surfaces, such as faucets and countertops.

10. **Apply a hand moisturizer** at least twice daily; use hand care products recommended by infection preventionists.
Hand moisturizer is recommended to prevent skin from drying and chaffing, which may lead to transmission of infection. Petroleum-based products compromise latex gloves, resulting in permeability. Anionic-based moisturizers can neutralize the residual effects of chlorhexidine gluconate and chloroxylenol. In most agencies, you will use the moisturizer recommended by the infection preventionist. Many facilities use soaps that contain moisturizer.

Procedure 23-1B ■ Using Alcohol-Based Handrubs

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Use alcohol-based handrubs** when hands are not visibly soiled and when certain pathogens are suspected.
Antiseptic solutions are not effective when organic material or dirt from hands is present. Alcohol handrubs cannot remove spores, and therefore should not be used for hand hygiene when Clostridium difficile *or* Bacillus anthracis *is suspected of being present.*

2. **Bare your hands and forearms.** Push your sleeves above your wrists. Remove your jewelry and wristwatch.

3. **Apply antiseptic solution** in a quantity sufficient (at least 3 mL) to cover the hands and wrists.
All surfaces must be covered with sufficient product to effectively remove microorganisms.

4. **Vigorously rub antiseptic solution** into your hands for 15 to 30 seconds (or as long as it takes to sing "Happy Birthday" if no clock is available), interlacing fingers, rubbing around each finger and thumb, and rubbing the backs and palms of the hands in a circular motion including under the nails until the solution is completely dry.
Fifteen to 30 seconds is recommended by the Centers for Disease Control and Prevention (CDC) for effective disinfection by alcohol handrubs.

(continued on next page)

Procedure 23-1 ■ Hand Hygiene (continued)

Procedure 23-1B ■ Using Alcohol-Based Handrubs

Evaluation

Hands are free of handrub and dry.

Documentation

Hand hygiene is a responsibility of all healthcare providers. It does not require documentation.

Practice Resources

Association of periOperative Registered Nurses (AORN) (2010); Boyce, J., & Pittet, D. (2002); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Asepsis: Hand Hygiene.**

For questions and suggested responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 23-2 ■ Donning Personal Protective Equipment (PPE)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

Following CDC recommendations, you will usually use some combination of gloves, gown, mask, and eye protection, depending on the organism and level of precaution. In certain situations, you may need hair covers and shoe covers (e.g., when full barrier precautions are needed).

- Disposable gloves of the proper size
- Disposable isolation gown
- Face mask (or N-95 respirator mask, as indicated)
- Face shield or goggles
- Hair cover
- Shoe covers

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Assess the need for PPE.** If you need more information about choosing PPE, refer to Clinical Insights 23-3, 23-4, and 23-5.
   a. **Gloves:** When you may be exposed to any body secretions directly or indirectly
   Gloves provide a barrier against body fluids. All patients are considered potentially infected per Standard Precautions (see Clinical Insight 23-3).
   b. **Gowns:** When your uniform (e.g., scrubs) may become exposed to potentially infective secretions
   Examples of such situations include excessive wound drainage, fecal incontinence, or other discharges from the body, or when fluids may be splashed (as in eye irrigation).
   c. **Face mask:** When splashing may occur during close contact (3 ft or less) and potentially contaminate your mouth or nose
   Surgical masks provide a barrier to large-particle droplets (>5 microns in diameter), helping prevent transmission of pathogens to the nurse's mucous membranes.
   d. **Face shield or eye goggles:** When splashing might occur and fluids enter your eyes (e.g., blood splashes, respiratory droplets, or wound debridement). To protect the entire facial area, wear a face shield (for maximum protection, it should protect the crown and chin and wrap around the face to the ear).
   Helps prevent pathogens from entering the conjunctiva directly or indirectly.
   e. **N-95 respirator:** When caring for clients infected with airborne organisms (<5 microns) such as the tuberculosis bacillus.
   This device prevents the airborne transmission of the tuberculosis bacterium. The respirator mask shown is disposable; some are reusable.

   f. **Hair covers:** When there is a potential for spraying or splashing of body fluids
   Although this is not in the CDC report (Siegel, Rhinehart, Jackson, et al.,

2007), agency policy may advise hair covers in certain situations.

g. **Shoe covers:** When there is a potential for contamination of shoes with body fluids

Although this is not in the CDC report (Siegel, Rhinehart, Jackson, et al., 2007), agency policy may require shoe covers in certain situations. The floor (and anything in contact with it) is considered contaminated. However, certain categories of pathogens require full protective gear, and in those circumstances shoe covers are necessary.

2. Determine the availability of appropriate PPE.

A patient gown is not a substitute for a disposable isolation gown. Isolation gowns must be made of moisture-repelling materials to prevent contamination of underlying clothing and skin.

3. Don the isolation gown.

While donning PPE, the goal is to not contaminate the PPE.

a. Pick up the gown by the shoulders, allowing the gown to fall open without touching the floor or other surfaces.

Touching the floor or other surfaces will contaminate the gown with environmental pathogens.

b. Slip your arms into the sleeves.

c. Fasten ties at the neck.

d. Position the gown so that it covers the back, and fasten the ties at the waist. Do not bring ties around to the front of the gown.

The front of the gown is considered contaminated after you enter the patient's room. If the ties are at the front of the gown, they will be contaminated, making it difficult to remove the gown safely.

e. If the gown does not completely cover your clothing in the back, wear two gowns. Don the first gown so that the opening is in the front, and then place the second gown over the first, so that the opening is in the back.

4. Don the face mask or N-95 respirator.

a. Determine how the mask is secured. Identify the top edge of the mask by locating the thin metal strip (nosepiece) that goes over the bridge of the nose.

Surgical masks may be secured by ties at the back of the head and neck, loops around the ears, or elastic bands.

b. Pick up the mask with the top ties or ear loops. Place the mask over your nose, mouth, and chin. Press the flexible metal strip so that it conforms to the bridge of your nose.

The mask must fit snugly to the face for maximum barrier protection. Correct positioning will also keep your glasses or goggles from fogging.

c. Tie the upper ties to the back of your head and the lower ties to the back of your neck or slip the loops around your ears or place the elastic bands as with the ties.

d. Place the lower edge of the mask below your chin, and tie the lower ties.

Covering the nose and mouth creates a barrier to prevent droplet pathogens from entering through the nasal and oral mucous membranes or the respiratory system.

5. Don the face shield or goggles.

a. *Face shield:* Place the shield over your eyes, adjust the metal strip over the bridge of your nose, and tuck the lower edge below your chin. Secure the straps behind your head.

b. *Safety glasses or goggles:* Set them over the top edge of the mask. See Step 1c, d, e for rationale.

6. Don hair cover, if indicated.

Hair covers can be worn to protect from contamination when you anticipate sprays or airborne exposure.

7. Don shoe covers, if indicated.

Shoe covers protect against exposure to airborne organisms or contact with a contaminated environment and as a part of full barrier precautions (e.g., active bleeding).

(continued on next page)

Procedure 23-2 ■ Donning Personal Protective Equipment (PPE) (continued)

8. Don gloves.

a. Select nonsterile disposable gloves of the appropriate size. See Clinical Insight 23-3.
The correct size will prevent gloves from falling off or ripping while you are working with the client.

b. If you are wearing a gown, make sure that the glove cuff extends over the cuff of the gown. If skin is visible between the gown and the glove, tape the glove cuff to the gown cuff, covering all visible skin.
To provide complete protection of hands and wrists, no skin should be visible between the glove and gown.

Patient Teaching

Answer questions the patient may have and educate about the need for PPE, his disease process, and the purpose of isolation.

Home Care

- Identify the type of PPE needed, and ensure that the necessary supplies are available.
- Develop a plan with the client and family for using and disposing of personal protective equipment and contaminated items.
- Teach family members to don PPE as needed.
- Obtain referral for a home health agency to provide support.

Documentation

The use of personal protective equipment is generally assumed and does not require documentation.

Practice Resources

AORN (2013a); Minnesota Dept. of Health (n.d.); Siegel, J. D., Rhinehart, E., Jackson, M., et al. (2007).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Asepsis: Donning Personal Protective Equipment.**

For questions and suggested responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 23-3 ■ Removing Personal Protective Equipment (PPE)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. For this procedure, also refer to Clinical Insights 23-2 and 23-3 if you need more information.

Key Point: ***Considered contaminated: front areas, sleeves, mask, and gloves of the PPE (as well as head and shoe covers if you are wearing them).***

Key Point: ***Considered clean: the inside of the gown, gloves, the ties on the mask, and ties at the back of the gown (as well as the inside of the head and shoe covers if you are wearing them).***

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Remove gloves first (unless the gown ties in front; in that case, see the section What If . . . ?).
Gloves are the most contaminated PPE and must be removed first to avoid contamination of clean areas of the PPE during their removal.

a. Remove the first glove by grasping the outside cuff of the glove with the opposite gloved hand and pulling downward so that the glove turns inside out. Do not touch the skin of your wrist or hand with your gloved hand.
The outside of both gloves are contaminated. To prevent contamination, touch only the outside (contaminated) surface of first glove to outside (contaminated) surface of second glove. "Dirty touches dirty" and "clean touches clean." ➤

b. Hold the removed glove in the palm of your gloved hand. Slip two

ungloved fingers inside the cuff of the remaining glove. Pull the glove off, inside out, over the glove that hand is holding. Do not touch the outside of the soiled glove with your ungloved fingers.
The inside of gloves are considered "clean" because they have not been in contact with client or contaminated surfaces. Therefore, you can touch the insides with your bare hands.

c. Dispose of the gloves in a designated waste receptacle.

2. **Remove the gown**:
   a. Release the waist ties and the neck ties of the gown, bending slightly forward to allow the gown to fall forward.
   The ties and the inside area of the gown are considered clean areas. Gown front and sleeves are contaminated. Allowing the gown to fall forward exposes the clean area for the hands to grasp more readily.
   b. Slip your hands inside the neck and peel the gown away from the shoulders. Reach inside to pull off the cuff and remove your arm from the sleeve. Repeat the maneuver to remove the second sleeve. Do not touch the front of the gown, even if it is not visibly soiled.
   The inside of the gown is clean and will not contaminate your hands. The front of the gown and the sleeves are considered contaminated.

3. **Fold the gown so the inside of the gown is to the outside.** Holding the gown away from your uniform, roll it up with the contaminated front and sleeves in the center, and place in the designated waste receptacle.
The inside of the gown is considered clean. Folding the gown prevents contamination of your hands, clothing, and the environment.

4. **Remove goggles** (if wearing them). Grasp only the earpieces (or head band) of the goggles and pull off the face. Place in the receptacle provided for disinfection if the goggles are not disposable.
Earpieces are considered clean. Some goggles are cleaned and reused.

5. **Remove your mask or face shield** (if wearing one). Untie the lower ties first. Untie the upper ties next, being careful not to let go of the ties. Touch only the ties; do not touch the front of the mask. Dispose of the mask by holding on to the ties and placing it in a designated waste receptacle.
Ties are considered clean. The front of the mask is potentially contaminated; do not touch it with your bare hands.

6. **Remove your hair covering**, if you are wearing one. Slip your bare fingers under the edge of the hair cover, being careful not to touch the outside of it. Lift it up and away from your hair. Touching only the inside of it, place it in a designated waste receptacle.
The inside of the hair covering is considered clean, so you may touch it with your bare hands.

7. **Remove shoe covers**, if wearing them. Be careful to touch only the insides of the covers.

8. **Perform hand hygiene** before leaving the room. Wash your hands after all patient contact even if gloves are worn to prevent contamination.

9. **Close the door.**
Keeping the door closed contains contaminants and makes signage more visible.

? What if . . .

- **The gown is tied in front?**
  This would be an unusual circumstance, but if that occurs, you must untie the front gown ties before removing your gloves; then remove the gloves and untie any back ties (e.g., at the neck).
  Because the front of the gown (including a front tie) is considered contaminated, once you remove your gloves, you could not use your bare hands to untie a front tie.

- **You are wearing two gowns (top one tied in back, inner one tied in front)?**
  Remove gloves; untie waist ties of outer gown, remove the gown and fold it inside out. Remove the inner gown by untying it in front. Fold inner gown inside out. Take off goggles and face mask or shield.

Procedure 23-3 ■ Removing Personal Protective Equipment (PPE) (continued)

Patient Teaching

See Procedure 23-2.

Home Care

See Procedure 23-2.

Documentation

The removal of personal protective equipment is generally assumed and does not require documentation.

Practice Resources

AORN (2013a, 2013c); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007); U.S. Department of Labor (n.d.a); U.S. Department of Labor (n.d.b).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Asepsis: Removing Personal Protective Equipment.**

For questions and suggested responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 23-4 ■ Surgical Handwashing: Traditional Method

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. For this procedure, also refer to Clinical Insights 23-2, 23-3, and 23-7 if you need more information.

Equipment

- Antimicrobial soap (FDA-approved for surgical hand asepsis)
- Soft, nonabrasive scrub sponge
- Disposable single-use nail cleaner
- Deep sink with foot or knee controls
- Surgical shoe covers, cap, and face mask
- Sterile gloves of the correct size
- Surgical pack containing a sterile towel

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine that sterile gloves,** gown, and towel are set up for use after the scrub.
   To maintain sterility, the sterile towel, gown, and gloves must be ready for use immediately after you scrub. If you need to gather supplies after the scrub, you will need to start the scrub procedure over again.

2. **Determine the agency policy for** the duration of the surgical scrub and the type of cleansing agent used. This is typically 2 to 5 minutes.
   The type of cleansing agent determines how long to scrub. Typically, an alcohol-based antimicrobial soap requires 2 to 6 minutes.

3. **Avoid nail polish** and artificial nails**.** Trim so nails do not extend beyond fingertips. Remove rings, watches, and bracelets.
   Rings are a substantial risk factor for harboring moisture and gram-negative bacilli and Staphylococcus aureus; artificial nails and chipped polish are more likely to carry gram-negative pathogens, including pseudomonas, because water collects between the artificial and real nails.

4. **Don surgical shoe covers, cap,** and face mask before the surgical scrub.

5. **Perform a prewash** before the surgical scrub (see Procedure 23-1).
   The prewash removes any visible soil, reduces the number of microorganisms on your skin, and allows you to begin the surgical scrub with clean hands.

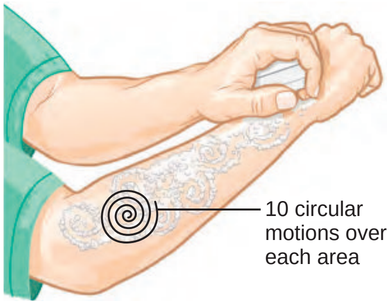
6. **Remove debris from under your nails** using a single-use nail file under running water.
   Decreases the number of microorganisms. ➤

7. **To begin the surgical scrub**, turn on the water, using the knee or foot controls or motion sensors. Adjust the temperature so that the water is warm.
   Hot water removes too many of the skin's protective oils. Knee and foot controls help to prevent contamination of the hands. You cannot touch any unsterile surfaces once you begin the surgical handwash. ➤

8. **Wet your hands and forearms** from elbows to fingertips, keeping hands above elbows and away from your body. If using a scrub sponge, wet the sponge.
Prevents water running down from your elbows and forearm over rinsed hands.

9. **Apply soap** onto your hands and the sponge. Use a liberal amount of antimicrobial; lather well to 2 inches above the elbow. Do not touch the inside of the sink with your fingers, hands, or elbows. Avoid splashing your surgical attire.
Scrub brushes are harsh on the skin. Soft, nonabrasive sponges are recommended instead. Antimicrobial soap reduces the number of microorganisms.

10. **Scrub all the surfaces** of one hand and arm, all surfaces, using a circular motion. Start at the fingers. Scrub at least 10 strokes each on nail, all four sides of each finger, hands, and arms. When scrubbing the arm, use 10 strokes each for the lower, middle, and upper areas of the forearm. Keep your hands higher than your elbows.
All surfaces of the skin must be scrubbed effectively.



11. **Rinse the brush, and reapply soap.** Repeat the scrub on the second hand and arm. Normally the scrub takes at least 2 to 6 minutes.
The purpose of the scrub is to decrease the number of microorganisms on the hands. The length of the scrub depends on the time needed for the particular scrub agent to be effective.

12. **Rinse your hands and arms**, keeping your fingertips higher than your elbows.
Prevents contamination of hands from water running from the upper arm down onto hands.

13. **Repeat Steps 8 through 12** if directed to do so by the soap manufacturer or agency policy.

14. **With arms flexed and your hands** held higher than your elbows, move to the area with the sterile towel and gown.
Avoids contamination of hands from water runoff.

15. **Grasp the sterile towel**, and move away from sterile field.
Moving away keeps the sterile field dry and prevents you from inadvertently brushing against the table, which would contaminate the field.

16. **Lean forward slightly**, and allow the towel to fall open, being careful not to let it touch your clothing.
The towel would be contaminated if it brushed against your uniform.

17. **Use one end of the towel** to dry one hand and arm. Use the opposite end to dry the other hand and arm. Be certain your skin is thoroughly dry before donning sterile gloves.
Dry skin prevents maceration and allows gloves to go on much more easily. Use a separate section of the towel to prevent rewetting the skin.

? What if . . .

- **The agency uses an alcohol-based surgical hand-scrub product?**
  a. Perform Steps 1 through 6. Omit Steps 7 through 17.
  b. Using the indicated amount of handrub, rub all surfaces of the hands, including the nails and up the arm to 2 inches above the elbow, according to the manufacturer's recommendations and agency policy.
  Many different products are on the market. Be careful to follow the manufacturer's guidelines for use for maximum effectiveness.
  c. Allow the handrub to dry completely before you don sterile gloves.

Procedure 23-4 ■ Surgical Handwashing: Traditional Method (continued)

Patient Teaching

If the patient is able to observe the procedure, explain the purpose of the surgical scrub and sterility.

Documentation

A surgical hand scrub does not require documentation. Instead, chart the procedure (or surgery) and how the patient tolerated it.

Practice Resources
