- Sterile gloves of the correct size
- Surgical pack containing a sterile towel

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine agency policy** for duration of the surgical scrub and the type of cleansing product to be used. This is typically 2 to 5 minutes.
Policies vary from institution to institution, although all should be based on sound principles for infection control designed in accordance with CDC and the Association of periOperative Registered Nurses (AORN) guidelines and follow manufacturer's directions for product use. The type of cleansing agent determines how long to scrub. Typically, alcohol-based handrub is rubbed onto hands and arms until dry.

2. **Before starting the scrub,** gather supplies and set up sterile gloves, gown, and towel for use after the scrub.
To maintain sterility of the hands after the scrub, the sterile gloves, gown, and towel must be ready before washing.

3. **Observe recommended hygiene.**
   a. Do not wear artificial nails and extenders and chipped polish: Nails should be free of polish and not extend beyond the end of the fingers (¼ inch or less).
   The AORN and CDC recommend avoiding these when in direct contact with patients or in high-risk situations, such as the perioperative setting or among those receiving immunosuppressant therapy. Individuals wearing artificial nails have been shown to harbor more pathogenic organisms in the subungual area than those with natural nails, particularly gram-negative bacilli, especially pseudomonas, and various strains of yeast. Long nails can tear gloves.
   b. Remove rings, watches, and bracelets before starting the scrub.
   Hand jewelry can prevent the handrub from reaching all skin areas and increase the spread of potential pathogens. Risk of infection from microorganisms increases exponentially in relation to the number of rings worn.

4. **Don shoe covers, a cap, and** a mask. Tuck hair completely under the cap.
Masks filter out possible airborne pathogens carried in the nose or mouth, preventing contamination of sterile areas. Covering the hair reduces the transmission of pathogenic organisms that adhere to the hair shaft or scalp, which is a warm, moist environment for organisms.

5. **Perform a prewash** before the surgical scrub. Use a pick to remove dirt and debris from under the nails; discard.
Prewash removes any visible soil, reduces the number of microorganisms on your skin, and allows you to begin the surgical scrub with clean hands. The nailbed harbors dirt and debris in which microorganisms live.

6. **To begin the surgical scrub,** turn on the water, using the knee or foot controls or motion controls. The temperature usually adjusts automatically in a surgical scrub sink.
Water temperature that is too hot can cause injury to the skin, making it prone to disruption in the skin integrity. In addition, it can remove the skin's normal flora and natural oil, which has a protective effect.

7. **Wet hands and forearms** from the fingertips to elbows, keeping hands above the elbows and away from the body at all times.
Prevents water running down from your elbows and forearm over washed and rinsed hands. a. First scrub the hands and arms to 2 inches above the elbows, as follows:

8. **Dispense a palm full of** antibacterial cleansing solution into your dominant hand. Insert the fingertips of your nondominant hand into the cleansing solution using a twisting motion to apply the product to the fingertips and nails. Then dispense soap into your nondominant hand and repeat.

9. **Vigorously rub all surfaces** of your nondominant hand and fingers, adding water as needed. Be sure to rub each digit on all sides. Do not touch the inside of the sink during the cleansing procedure.
Complete contact and friction are necessary for removal of microorganisms adherent to the skin's surface. The inside of the sink is considered contaminated with microbes and should be avoided. Incidental contact necessitates repeating the cleansing procedure.

10. **Rub the hands together** palm to palm.
    a. Bend the fingers of both hands and "hook" the curved fingers together at the ends. Using your right palm, clean the back of your left hand. Then rub your left palm over your right hand.
    b. Then rub your palms together with your fingers interlaced.
    c. Rub the back of your fingers on your closed right hand and rub them back and forth across your left palm, again with your curved fingers "hooked" together. Do the same with your other hand.
    d. Using a rotational movement, clasp your right thumb with your left hand. Repeat on the other hand.
    e. Hold your fingers together on the right hand and move them back and forth and in a circular pattern against your other palm, and vice versa.
    Although the palmar surface carries more organisms than the back side of the hands and arms, this area nonetheless should be cleansed thoroughly to reduce microbial colonization.

11. **Rinse using deep basin sink** with knee-, foot-, or motion-operated controls.
Improved adherence to sterile technique commonly results from use of motion- or foot/knee-operated or motion controls for faucets.

12. **Next cleanse the remaining 2/3** of the arms, beginning at the wrist, to 2 inches above the elbow. Cover every aspect of the middle and upper third of the forearm.

13. **Dispense cleansing solution** into the hands each time you cleanse a new area. Be sure the dispenser is not blocked.
A blocked dispenser can interfere with obtaining the amount of product needed for reducing bacterial colonization.

14. **First, scrub the nondominant arm** wrist-to-elbow. Then repeat the wrist-to-elbow scrub on the dominant arm. Rinse each arm thoroughly and independently on the dominant arm.

15. **This completes 1 washing cycle.** Using the same motions, beginning with Step 8, perform a 2nd cycle. Then finish with a 3rd cycle in which you scrub only the hands (Steps 8–11). The scrub is complete after cleansing every aspect of the hands and forearms for 3 full minutes.
The AORN promotes a 2- to 3-minute scrub time using an antiseptic detergent in order to achieve maximal microbicidal activity while avoiding irritant contact dermatitis associated with use of an abrasive sponge. Reduced time required to perform the surgical scrub often results in increased compliance with the prescribed technique.

16. **With arms flexed and hands** held higher than the elbows away from the body, move to the area with the sterile towel and gown.
This position prevents water running down from your elbows and forearm over rinsed hands.

17. **Grasp the sterile towel,** and back away from the sterile field. Lean forward slightly, and allow the towel to fall open, being careful not to let it touch clothing or gown.
This motion is performed to maintain a dry sterile field and prevent inadvertent brushing against the table and contaminating the field.

18. **Use one end of the towel** to dry one hand and arm using a dabbing motion. Dry the other hand and arm with the opposite end of the towel.
Use of a separate section of the towel guards against inadvertently rewetting the skin or contaminating an already clean area.

19. **Allow time for the skin to dry** thoroughly before donning sterile gloves.
Dry skin prevents maceration and allows the gloves to go on more easily. Moisture left on the skin can be a source of further microbial contamination.

20. **Once the brushless scrub is** complete, prevent contamination of the hands and forearms when moving from the scrub sink to the sterile table by keeping the hands in front of the body and above the waist. It may be necessary to enter backwards through the door of the surgical suite to prevent contamination of the scrubbed hands.

(continued on next page)

Procedure 23-5 ■ Surgical Handwashing: Brushless System (continued)

Documentation

A brushless surgical hand scrub does not require documentation in the patient's medical record. However, you must adhere to the institution's policy for performing the technique.

Patient Teaching

If the patient is able to observe the procedure, explain the purpose of a diligent approach to surgical scrub for promoting a low-risk environment for infection.

Home Care Adaptations

Sinks in the home environment typically do not have knee- or foot-operated controls or motion-sensor on/off devices. Therefore, when scrubbing for a sterile procedure in the home, contact with the faucet handles is performed with barrier objects (e.g., a paper towel) between the clean hands and the environmental surface.

Practice Resources

AORN (2013a, b); Association for Surgical Technologists (2008); CDC (2002); George, D., & Bhabra, M. A. (2010).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Asepsis: Surgical Handwashing: Brushless System.**

For suggested questions and responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 23-6 ■ Sterile Gown and Gloves (Closed Method)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. For this procedure, also refer to Clinical Insights 23-2, 23-3, and 23-7 if you need more information.

Equipment

- Sterile gloves of the right size
- Sterile gown

(These should be lying on a sterile field. If they are not, you will need to create a sterile field to place them on.)

➤ When performing the procedure always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Grasp the gown at the neckline.** Hold the gown up and allow it to fall open as you step back from the table. Be careful not to allow the gown to come into contact with nonsterile areas while you are lifting it off the table and opening it.
The gown will be contaminated if it touches unsterile objects.

2. **Slide both arms into** the sleeves, but do not extend your hands through the cuffs.

3. **Keep the sleeves of the gown** above waist level.
Hands will contaminate the sleeve edge if allowed to pass through the cuff.

4. **Have a coworker (or the circulating** nurse, if you are in the operating room) stand behind you and pull the shoulders of the gown up and tie the neck tie. The coworker touches only the inside of the gown while pulling it up.
Touching only the inside prevents contamination of the gown with the nurse's hands.

5. **Don sterile gloves** using the closed method.
   a. Open the sterile glove wrapper, keeping your fingers inside the sleeve of the gown. The outer wrapper has already been discarded.
   b. Glove the dominant hand first:
      (1) With your nondominant hand, keeping your hands inside the gown sleeves, grasp the cuff of the glove for your dominant hand. Turn your dominant hand palm up.

Keeping the hand inside the cuff ensures that you are making contact with the sterile gown; sterile is touching sterile.

(2) Lay the glove on the dominant gown cuff, thumb side down with the glove opening pointed toward the fingers, and thumb of glove positioned over the thumb-side of the hand.

(3) Keeping your dominant hand inside the sleeve, grasp the inside of the glove cuff.

(4) With your other hand (inside its sleeve), grasp the upper side of the glove cuff and stretch it over the gown cuff.

(5) Pull the sleeve of your gown up to pull the glove cuff over your wrist as you move your fingers into the glove fingers.

c. **Glove the nondominant hand.**

(1) Place the fingers of your gloved hand under the cuff of the second glove. Lay the glove on the forearm of your nondominant hand. Grasp and anchor the inside glove cuff with your nondominant (ungloved) hand through the gown, being careful to keep fingers inside the gown.

(2) With your dominant (gloved) hand, pull the glove cuff over the cuff of the gown as you move your fingers into the glove.

d. **Adjust the fingers in both gloves so the excess glove is pulled over the fingertips.**

Maintains sterility of the gown and gloves by maintaining a closed system. The final adjustment of the gloves is done when both gloves are in place to prevent contaminating the gloves. Taut gloves, especially over the fingertips, allow better feel and dexterity.

6. Grasp the waist tie on the gown, and hand the tie to the circulating nurse or a coworker who is wearing a hair cover and mask. Your coworker will grab the tie with sterile forceps.

The tie is considered sterile. You will need help pulling it around you. A coworker can help you. Using sterile forceps keeps the tie sterile.

7. Make a three-quarter turn, and receive the tie from your coworker.

Because only areas within your field of vision are considered sterile, a coworker must pull the waist tie around you.

8. Secure the waist tie.

Ensures that the gown is secured and will not expose clothing to a sterile field.

(continued on next page)

Procedure 23-6 ■ Sterile Gown and Gloves (Closed Method) (continued)

Patient Teaching

If the patient is alert during the procedure, explain:

- The need for the sterile procedure
- Why he must not touch the drapes
- Why he must not move or talk once the drapes are in place
- Explain any special precautions during the procedure

Documentation

- Donning sterile gown and gloves does not require documentation.
- You will need to chart the procedure performed and how the patient tolerated it.
- In the operating room, the circulating nurse charts about the surgery and the patient's response.

? What if . . .

- **Your hand inadvertently comes through the cuff opening when putting on the gown?**

  Change gowns. The cuff would have been contaminated and would then contaminate your glove.

Practice Resources

AORN (2010a, 2013a, 2013b); CDC (2002).

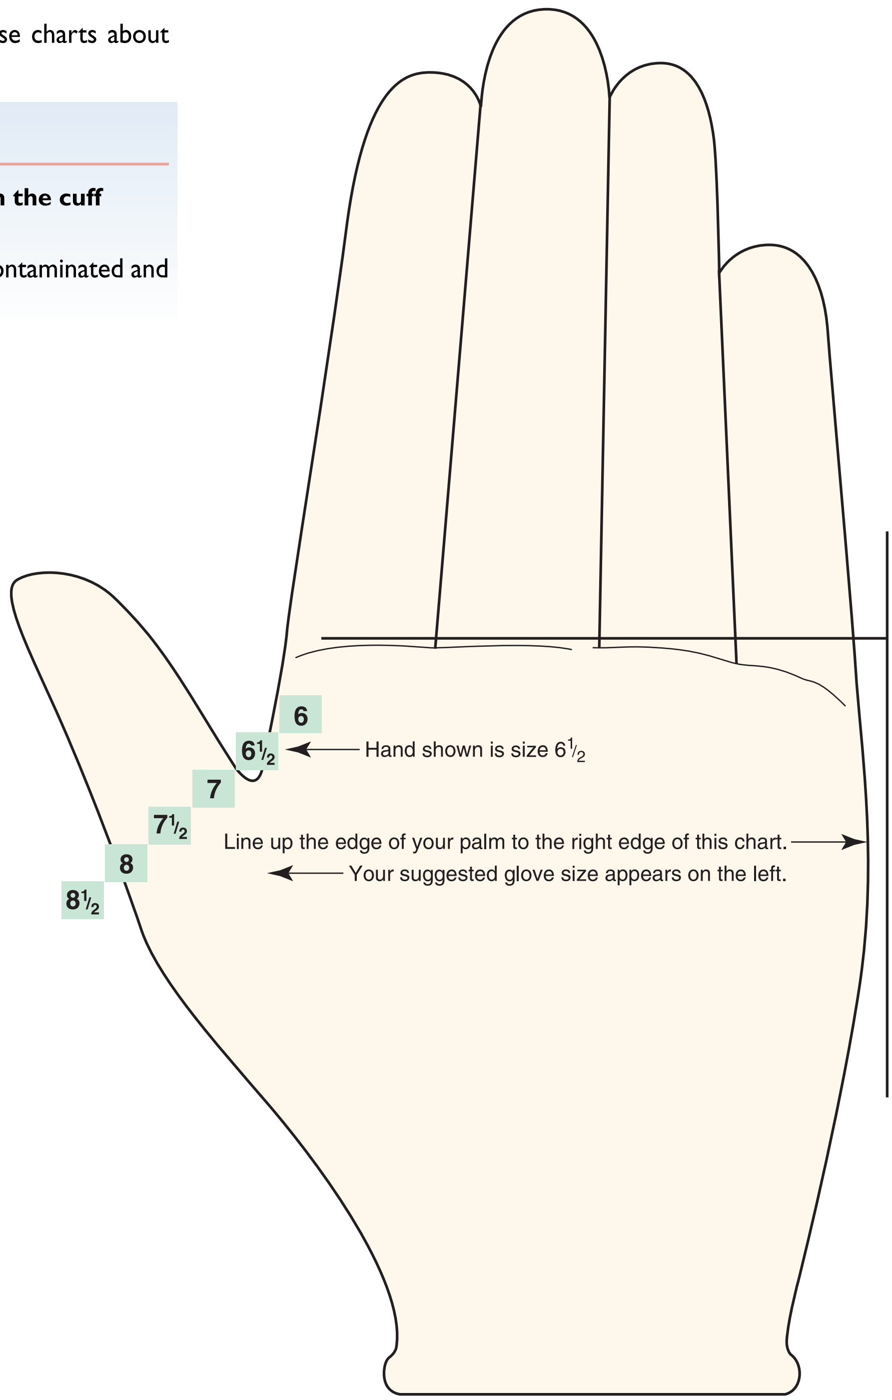
Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Asepsis: Sterile Gown and Gloves (Closed Method).**

For questions and suggested responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*



Sterile glove sizes. This can help you determine the proper size glove you need for your hand.

Procedure 23-7 ■ Sterile Gloves (Open Method)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover 2. For this procedure, also refer to Clinical Insights 23-2, 23-3, and 23-7 if you need more information.

Equipment

- Sterile gloves of the correct size

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine the correct size** of sterile gloves (see the drawing of glove sizes accompanying Procedure 23-6). The gloves should be snug, but not tight.
   Gloves that are too loose are more easily contaminated and make handling equipment or supplies difficult. Gloves that are too tight are uncomfortable and may tear during use.

2. **Assess the glove package** for intactness and expiration date. Do not use the gloves if the package is torn, has become moist, or is past the expiration date.
   Torn packaging may allow the gloves to become contaminated. Moisture allows wicking and may cause contamination. Expired gloves are not considered sterile.

3. **Assess the patient's environment** for a space that is clean and has adequate space to allow you to open the glove package. Don the gloves without touching a nonsterile item.
   Inadvertently touching a nonsterile item will contaminate the gloves.

4. **Open the outer wrapper** and place the inner glove package on a clean, dry surface.

5. **Open the inner glove package** so that the glove cuffs are closest to you. Be careful to fully open the flaps of the package so that they do not fold back over and contaminate the gloves.
   The outer 1-inch border of the glove package is considered contaminated.

6. **With your nondominant hand** grasp the inner surface of the glove for the dominant hand. Lift the glove up and away from the table, keeping it away from your body. Take care to not touch anything else on the sterile field
   The inside of the glove is not considered sterile because it is in contact with your skin. Lifting the glove up and away from the table prevents you from accidentally touching the table or your clothing while donning the glove and thereby contaminating the glove.

7. **Slide your dominant hand into** the glove, keeping your hand and fingers above your waist and away from your body.
   The area below the waistline is considered contaminated. Keeping gloves away from your body prevents accidental contamination.

8. **Slide your gloved fingers under** the cuff of the glove for the nondominant hand, keeping your gloved thumb well away from your ungloved hand. Lift the glove up and away from the table and away from your body.
   The outside of the glove is sterile and may be touched with your sterile gloved hand.

9. **With gloved fingers still under** the cuff, slide your nondominant hand into the glove and pull it on, being careful to avoid contact with your gloved hand, especially the thumb.

(continued on next page)

Procedure 23-7 ■ Sterile Gloves (Open Method) (continued)

10. Adjust both gloves to fit your fingers. If necessary, pull the fingers of the gloves down so that no excess is at the fingertips.
Adjusting your gloves after both have been donned decreases the risk of contamination and allows for greater dexterity during the procedure.

11. Keep your hands between shoulder and waist level in front of you.
Keeps the gloves within your field of vision to avoid contamination.

NOTE: To remove soiled gloves after the procedure, refer to Procedure 23-3.

Patient Teaching

Explain the reason sterile gloves are needed for the procedure.

Home Care

- Many home care procedures are clean rather than sterile. The client is in his own environment and not surrounded by other patients, who may serve as hosts for infection.
- You may need to teach caregivers how to apply sterile gloves for some procedures. No modifications are required. Demonstrate the procedure, and have the caregiver do a return demonstration.

Documentation

- No special documentation is needed for sterile gloving.
- Chart the procedure you performed and the patient's response to the procedure.

Practice Resources

AORN (2010a, 2013a, 2013b).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Asepsis: Sterile Gloves (Open Method).**

For questions and suggested responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 23-8 ■ Sterile Fields

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. For this procedure, also refer to Clinical Insights 23-2, 23-3, and 23-7 if you need more information.

Equipment

- Package of sterile supplies required for the procedure
- Sterile gloves of the correct size

Procedure 23-8A ■ Setting Up a Sterile Field

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Assess the sterility of all packages and equipment. Check to make sure the packaging is intact and the expiration dates have not passed.
Only sterile items should enter a sterile field. Any compromise in packaging means that the item is assumed not to be sterile.

2. Arrange the environment for performing the sterile procedure.

a. Remove all items from the surface you will use to set up the sterile field.
Inadequate space causes inadvertent contamination during sterile procedures.

b. Position the patient as needed for the procedure.
Allows you to immediately proceed with the planned procedure. Once the sterile field is established, air movement can create contamination of the sterile items.

Procedure Variation. Using Sterile Packaged Equipment

3. Place the sterile package on a clean, dry surface.
Prevents contamination of the sterile item. If a surface is damp, strike-through may occur, making the item unsterile.

4. **Open the flap away from you** first to prevent passing an unsterile arm over the sterile items.
   If you move an unsterile item over a sterile field, the field is no longer considered to be sterile.

5. **Open the side flaps.**

6. **Pull the final flap toward you.** The wrapper is now the sterile field. The area 1 inch from the edge of the wrapper and 1 inch from the table edge is considered unsterile. Do not readjust the sterile area after the package has been opened.
   Only the horizontal surface of the draped area is considered sterile. Any part of the sterile wrapper that falls below the level of the sterile area (e.g., top of the table) is considered unsterile. If you move the field after opening, the field shifts and places unsterile areas of the wrapper on the surface.

Procedure Variation. Opening a Fabric- or Paper-Wrapped Sterile Package

7. **Check and remove** the chemical indicator strip.
   The indicator tape per manufacturer or institution confirms that the package was sterilized. The pack usually is also dated.
8. **Remove the outer wrapper** and place the inner wrapped package on a clean, dry surface.
   The outer wrapper is not considered sterile and is discarded.
9. **Open the inner wrapper** following the same technique described in Steps 3 through 6.

Procedure Variation. Using a Sterile Drape

Omit Steps 3 through 9.

10. **Place the package on a clean,** dry surface. Hold the edge of the package flap down toward the table, grasp the top edge of the package, and peel back.
    The sterile drape is inside the outer wrapper. This maneuver opens the package without contaminating the sterile drape.

11. **Pick up the sterile drape by the corner.** Allow the drape to fall open, away from your body and away from unsterile surfaces. Place it on a clean, dry surface by touching only the edge of the drape. Avoid fanning the drape.
    A 1-inch border around the sterile drape is considered unsterile.

Procedure 23-8B ■ Adding Supplies to a Sterile Field

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Hold the sterile package in your** dominant hand. Grasping the corner of the wrapper, peel each corner back with your nondominant hand.
   The inside of the wrapper is sterile and will be used as a barrier when placing the sterile item onto a sterile field.
2. **Holding the contents several** inches above the field, allow the supplies to drop onto the field inside the 1-inch border of the sterile field. Do not let your arms pass over the sterile field.
   By holding the package upside down, you ensure that the sterile part of the package is facing the sterile field and that you deposit the item onto the sterile field.

3. **Dispose of the wrapper**, and continue opening any needed supplies for the procedure.

Key Point: ***Once sterile gloves are on, you will not be able to add items without contaminating the gloves.***

(continued on next page)

Procedure 23-8 ■ Sterile Fields (continued)

Procedure 23-8C ■ Adding Sterile Solutions to a Sterile Field

Procedure Steps

1. **Use a sterile bowl or receptacle** if the sterile field is fabric or at risk for soaking through. You may add a sterile bowl to the field by unwrapping (as discussed above) and holding the bowl through the sterile wrapper as you place it near the edge of the sterile field. The sterile bowl may also be placed next to the sterile field.
If you place the sterile bowl on the field, place it near the edge so that you can pour the sterile solution from the back of the sterile field. This prevents you from reaching over and thereby contaminating the field.

2. **Check that the sterile solution** and concentration are correct, and confirm that the expiration date has not passed.

3. **Remove the cap off the solution** bottle by lifting it directly up and throw it away.
The edge of the container is considered contaminated after the contents have been poured and the sterility of the contents cannot be ensured if the cap is replaced.

4. **Hold the bottle 4 to 6 inches** above the bowl and pour the needed amount of the solution into the bowl.
Prevents you from inadvertently touching the sterile bowl with the bottle and thereby contaminating the bowl. Limited height reduces the risk of splashing, which strikes through and contaminates a cloth or permeable sterile field. A disposable sterile drape generally has a plastic membrane in the middle to prevent strike-through.

5. **Discard the remaining solution.**
Reusing open containers may cause contamination due to drops contacting the unsterile areas and running back over the container opening.

6. **Before donning sterile gloves** to perform the procedure, double-check that all supplies have been added to the field using sterile technique. Do not leave the sterile field unattended. Do not turn your back to the sterile field.
If a sterile item is out of your field of vision, it is no longer considered sterile because airborne particles, insects, or liquids could contaminate the field.

Home Care

- Most sterile procedures in the home are done by visiting nurses.
- Procedures performed by clients or family members are usually clean rather than sterile.

Documentation

- You will not document the actual setting up of the sterile field.
- Document the procedure, your assessment of the patient's tolerance for the procedure, and your assessment of the area being treated by the procedure.

What if . . .

- **The nurse observes a breach in sterility by the surgeon?**
The nurse's duty is to protect the patient above all else, even when fearing an uncomfortable confrontation with the healthcare provider. The nurse is obligated to follow the institution's policy and advocate for patient safety.

Practice Resources

AORN (2010a; 2013b); Simko (2012).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Asepsis: Sterile Fields.**

For questions and suggested responses,

Go to Chapter 23, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

CLINICAL INSIGHTS

Clinical Insight 23-1 ➤ Guidelines for Hand Hygiene

Handwashing

When to Wash

- When hands are visibly dirty or soiled with blood or body fluids
- When arriving on and leaving the patient care unit
- Before direct contact with a patient, even if you intend to wear procedure gloves
- Before donning gloves (either procedure or sterile)
- When gloves are changed during a procedure
- After removing gloves
- After contact with a patient's intact skin (e.g., when lifting a patient or taking a blood pressure)
- After contact with body fluids, mucous membranes, non-intact skin, and wound dressings even if hands are not visibly soiled
- When moving from a contaminated body site to a clean body site during patient care
- Before and after contact with objects and equipment in the patient's immediate vicinity
- Before eating and after using a restroom. Use soap and water.
- Before and after touching any area on your face and hair

What to Use

- Use alcohol-based handrub (at least 60% alcohol) for routine hand hygiene and if hands are not visibly soiled.
- Use soap and water when hands are dirty or visibly soiled.
- Use soap and water after using a restroom.
- Use soap and water if there is potential for exposure to *Bacillus anthracis* (or other spore-producing bacteria such a *C. difficile*). *Alcohol-based solutions are not effective against spores.*
- Use warm, not hot, water.
- Use disposable paper towels.

If you are interested in a comparison of the effectiveness of various hand-hygiene antiseptic agents,

Go to Chapter 23, **ESG Table 22-2, Antimicrobial Spectrum and Characteristics of Hand-Hygiene Antiseptic Agents,** on Davis*Plus*.

How to Wash

Refer to Procedure 23-1 and also the *Nursing Fundamentals Skills,* **Asepsis: Hand Hygiene.**

Fingernails

- Do not wear artificial nails or extenders when caring for patients at high risk (e.g., in intensive care and oncology units).
- The 2007 epic2 guidelines in the United Kingdom recommend artificial nails and extenders not be worn at all (Pratt, Pellowe, Wilson, et al., 2007). The CDC's position is that although studies provide evidence that wearing artificial nails poses an infection hazard, additional studies are warranted.
- It is best to not wear nail polish because it chips easily and can harbor microorganisms.
  The area under the nails, artificial nails/extensions, and chipped polish act as reservoirs for microorganisms.
- Keep nail tips less than ¼ inch long from the fingertips (CDC).
  Longer nails are associated with increased microbial carriage on the hands.

Jewelry

- We recommend that you not wear a watch or rings in the clinical setting, especially rings with stones.
  The CDC has stated jewelry is still an unresolved issue. They noted that hand contamination with pathogens increased when nurses wear rings, but that no studies have related that practice to the transmission of pathogens to patients. However, the epic2 guidelines advise against wearing wrist and hand jewelry.
- If your agency permits you to wear jewelry, clean it thoroughly and often.

Practice Resources

AORN (2013b, 2013c); Boyce, J., & Pittet, D. (2002); Pratt, R., Pellowe, C., Wilson, J., et al. (2007); Rupp, M., Fitzgerald, T., Puumala, S., et al. (2008); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Clinical Insight 23-2 ➤ Providing a Clean Patient Environment

The following guidelines are used along with standard precautions for all patients. A clean environment includes the surfaces in a patient's room, as well as supplies, equipment, and other objects brought into the room.

Supplies and Equipment

- Do not stock rooms with unnecessary supplies.
- Consider supplies that are brought into a patient's room contaminated. Do not return them to the linen or supply cart; instead, handle them according to agency policy.
- Consider contaminated any items brought from the patient's home, gifts from visitors, and so forth.
- Mobile computing devices should be cleaned (e.g., pagers, smart phones, point-of-care keyboards, and medication administration devices). However, most hospitals lack infection prevention policies for mobile devices. Be sure to wash your hands after using such a device.
  Often, electronic devices cannot be decontaminated without damage; in that case, only hand hygiene can protect you and the patient from these vectors.
- Clean stethoscopes with alcohol before use on a patient. Disposable stethoscopes are commercially available, but not commonly seen in healthcare agencies (some hospitals do have disposable stethoscopes for patients in isolation or on transmission-based precautions).
  Stethoscopes are often contaminated with Staphylococcus aureus because care providers do not clean them adequately between patients.
- Clean reusable equipment that is soiled with blood or body fluids according to agency policy—typically, autoclaving, ethylene oxide gas, or dry heat.
- Do not reuse equipment for the care of another patient until it has been cleaned and reprocessed appropriately.
- Dispose of single-use equipment that is soiled with blood or body fluids in appropriate biohazard containers.
- Wear gloves when handling equipment that is visibly contaminated. Perform hand hygiene.

Linens

- Carefully handle contaminated linens to prevent skin and mucous membrane exposures, contamination of clothing, and transfer of microorganisms to other patients or the environment.
  Linens may harbor microorganisms that may transfer to your clothing, open skin, or mucous membranes, to then be carried to other clients or environment.
- Bag and remove soiled linens from the room immediately.

Uniforms and Lab Coats

- Do not wear a uniform (e.g., scrubs) or a lab coat for more than one day without laundering.
  Care provider clothing is often contaminated as care providers move from patient to patient. The traditional white lab coats are being banned in some hospitals because they are vehicles for dangerous pathogens. Although contaminated clothing has not been implicated directly, the potential exists for it to transfer pathogens to patients (CDC, 2008).
- If you wash your uniforms at home, they require only washing with warm or hot water and detergent (except in the case of possible exposure to multidrug-resistant organisms, for which you should add bleach).

Spills and Waste

- Empty and clean bedpans, urinals, and emesis basins immediately after use.
- Place soiled dressings, drains, and so forth, in appropriate waterproof bags for disposal. Do not leave such used supplies in an open trashcan.
- Wipe up small spills from tabletops and floors. Notify the housekeeping or environmental services department for large spills.

Needles and Sharps

Do not recap, bend, break, or hand-manipulate used needles. If recapping is necessary, use a one-handed "scoop" technique. Place used sharps in puncture-resistant containers.

For Home Care

- Teach patients and caregivers to keep the home environment clean.
- To disinfect the home environment, use and teach caregivers to create, a dilute bleach solution. Mix 1 part regular-strength bleach to 50 parts water. The mixture may be stored for a month in an opaque container. NEVER mix the solution with other household cleaners. *Note*: Be careful not to splash the bleach because it removes color from fabric and other objects, and keep it out of reach of children.
- Washing dishware and eating utensils in a dishwasher with hot water and detergents is sufficient decontamination.
- Healthcare workers in the home are a potential source of pathogens and should use caution to avoid infecting the patient.

Practice Resources

Carling, P., Parry, M., & Von Beheren, S. (2008); CDC(2008); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Clinical Insight 23-3 ➤ Following CDC Standard Precautions

Standard precautions (Tier 1) apply to all clients and should be used whenever there is a possibility of coming in contact with blood, body fluids (except sweat), excretions and secretions, mucous membranes, and breaks in the skin.
These precautions are designed to protect you from exposure to potential pathogens, to decrease the likelihood that you will transmit pathogens among patients, and to protect the patient from microorganisms that you may carry.

Assume that every person may be infected or colonized with an organism that could be transmitted to others.

TIER 1 COMPONENT	RECOMMENDATIONS
Hand Hygiene	■ Perform hand hygiene after touching blood, body fluids, secretions, excretions, contaminated items; immediately after removing gloves; between patient contacts. Refer to Clinical Insight 23-1 for details.
Respiratory Hygiene/Cough Etiquette for Patients	■ Instruct symptomatic persons to cover mouth/nose when sneezing/coughing. ■ Provide and use tissues and dispose in a no-touch receptacle. ■ Perform hand hygiene after soiling hands with respiratory secretions or after using a tissue or covering the mouth/nose. ■ Wear a surgical mask if tolerated (some patients may not be able to tolerate the decreased oxygen that is available when breathing room air through a mask), or do not come within 3 feet of another person if possible.
Masks and Eye Protection (for the Nurse)	■ Wear a mask and eye protection or a face shield to protect mucous membranes of the eyes, nose, and mouth during patient care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, and excretions. *Barrier protection helps keep microorganisms from accidentally entering your mucous membranes, eyes, nose, or mouth.*
Patient Placement	■ Place in a single-patient room if the patient is at increased risk of transmitting or acquiring infection, does not maintain appropriate hygiene, is likely to contaminate the environment, or is at increased risk of developing adverse outcome following infection.
Gowns	■ Wear a clean, nonsterile, nonpermeable gown during procedures and activities when you anticipate contact of clothing or exposed skin with blood or body fluids, secretions, and excretions (e.g., when there is a risk of spray or splash onto clothing). ■ Promptly remove the gown once it is soiled. Avoid contaminating clothing when removing the gown. ■ Wash hands after removing the gown. ■ See Procedures 23-2 and 23-3, Donning PPE and Removing PPE.
Needles and Sharps	■ Never recap, bend, or break used needles, or otherwise manipulate them using both hands, or use any other technique that involves directing the point of a needle toward any part of the body. Instead, use either a one-handed "scoop" technique or a mechanical device designed for holding the needle sheath (see Procedure 25-10, Recapping needles. . .). ■ Use safety features when available. ■ Place "sharps" (e.g., scalpels, needles, and so on) in puncture-resistant containers for disposal.
Patient Resuscitation	■ Use one-way valve mouthpieces, resuscitation bags, or other ventilation devices as an alternative to mouth-to-mouth resuscitation methods in situations when the need for resuscitation is predictable. *To prevent contact between rescuer's and client's mucous membranes and airflow, preventing transmission of microorganisms.*
Soiled Patient Care Equipment, Environment, Textiles & Laundry	■ See Clinical Insight 23-2 for details. ■ Wear gloves if the equipment or laundry is visibly contaminated. ■ Handle equipment, textiles, and laundry in a manner to prevent transfer of microorganisms to others and the environment.

(Continued)

Clinical Insight 23-3 ➤ Following CDC Standard Precautions—cont'd

TIER I COMPONENT	RECOMMENDATIONS
	■ Perform hand hygiene. ■ Develop procedures for routine care, cleaning, and disinfection of environmental surfaces, especially frequently touched surfaces in patient care areas.
Gloves	***When to Wear*** ■ If you have an area of irritation or a break in the skin, wear gloves or apply an occlusive dressing during patient contact. ■ Wear gloves when contact with blood or other potentially infectious materials, mucous membranes, and nonintact skin could occur.
	When to Remove or Change ■ Remove gloves immediately after caring for a patient. Avoid touching clean items, environmental surfaces, or another patient. ■ Do not wear the same gloves for care of more than one patient; do not wash gloves and reuse gloves between patient contact. *Research shows that washing and reusing gloves between patient contacts results in increased bacterial counts on the hands.* ■ Change gloves during patient care if moving from a contaminated body site to a clean site. ■ Change gloves between tasks or procedures on the same patient if you have made contact with material that may contain a high concentration of microorganisms.
	Use and Storage ■ When preparing for a procedure, first collect equipment and place at the bedside ready for use; then wash your hands and don gloves just before performing the procedure. Donning gloves ahead of time allows them to become contaminated before the procedure. ■ Do not carry gloves in your pocket. Keep them in their original box and remove them when and where required. ■ Do not store gloves on top of trash containers or on windowsills. ■ Handwashing or disinfection is required regardless of whether gloves are used or changed. Gloves are not completely impermeable to microorganisms; furthermore, they may leak or tear. Hands can be easily contaminated when removing gloves, as well.

For a comparison of glove materials (latex, nitrile, vinyl, and polyethylene),

Go to Chapter 23, **DP Table 23-4, Comparison of Glove Materials,** on Davis*Plus*.

Practice Resources

Boyce, J., & Pittet, D. (2002); Occupational Safety & Health Administration, U.S. Department of Labor (n.d.); Pratt, R., Pellowe, C., Wilson, J., et al. (2007); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007); U.S. Department of Labor (n.d.a).

Clinical Insight 23-4 ➤ Following Transmission-Based Precautions

Note: Refer to Clinical Insight 23-3 if you need to review standard precautions.

When to Use: Use transmission-based (Tier 2) precautions when the routes of transmission are not completely interrupted using Standard Precautions alone. Pathogens may be transmitted by contact, droplet, or air. Each mode of transmission requires a different approach to prevent infection, and has a different set of precautions. For some diseases, you may need to use more than one of the categories.

Contact Precautions

Follow all standard precautions.

When to Use: Use contact precautions when direct contact with the patient or the patient's environment can lead to spread of the pathogen. This is the most common form of transmission. Draining wounds, dressings, patient supplies, and secretions are sources of infection. Indirect contact, or contact with fomites, can also transmit pathogens that spread by this method.

Patient Placement and Transport

- Always choose a private room if one is available. When there is no private room, and when you have no choice but to place the patient with one who has a different infection, ensure that the patients are physically separated by more than 3 feet. Keep the privacy curtain closed. This minimizes contact between patients. Ideally, consult with an infection preventionist for patient placement. A private room provides the most effective protection.
- Limit transport outside the room to medically necessary purposes; if transport is necessary, the patient should wear a mask. The transporter is not required to mask.
- Ideally, consult with an infection preventionist for patient placement.
- Place in a private room, if available. Private room provides the most effective protection.
- If no private room is available, place patient in a room with a patient with an active infection caused by the same organism and no other infections.
- When transporting the patient, ensure that infected or colonized areas of the body are contained and covered.
- *Ambulatory care:* Place the patient in an exam room or cubicle as soon as possible.

Personal Protective Equipment

- Wear clean nonsterile gloves when touching the patient's intact skin. Don gloves on entry to the room.
- Wear a clean gown if you anticipate your clothing may contact the patient or any contaminated items in the room.
- Remove PPE and observe hand hygiene before leaving the room. Take care that your skin and clothing do not contact environmental surfaces on the way out of the room.

Equipment, Supplies, and Environment

- Keep contact precaution supplies just outside the patient's room on a cart.
- Double bag all linen and trash (or use a single waterproof bag), and clearly mark them contaminated.
- Use disposable equipment (e.g., blood pressure cuffs) if possible; otherwise, clean and disinfect the equipment per institutional policy before removing them from the room and before use on another patient.
- Ensure that the patient room is cleaned and disinfected at least daily.
- *Home care:* Limit the amount of nondisposable equipment brought into the home. If possible, leave the equipment in the home until discharge from home care.
- *Home care:* If equipment cannot remain in the home, clean and disinfect items before taking them from the home, or place them in a plastic bag for transport to a reprocessing area.

Other

- Follow any additional precautions specific to the microorganism.
- Discontinue contact precautions after signs and symptoms have resolved or according to pathogen-specific recommendations.

(Continued)

Clinical Insight 23-4 ➤ Following Transmission-Based Precautions—cont'd

Droplet Precautions

Follow all standard precautions.
Follow all contact precautions.

When to Use: Use droplet precautions when the pathogen can be spread via moist, large droplets (e.g., sneezing, coughing, talking). Droplets can spread infection by direct contact with mucous membranes or through indirect contact, for example, suctioning or touching a bedside table that was contaminated with moist droplets and then rubbing your eyes.

Patient Placement and Transport

- Always choose a private room if one is available. If there is no private room, and when you have no choice but to place the patient with one who has a different infection, ensure that the patients are physically separated by more than 3 feet. Keep the privacy curtain closed. This minimizes contact between patients. Ideally, consult with an infection preventionist for patient placement. A private room provides the most effective protection.
- Limit transport outside the room to medically necessary purposes; if transport is necessary, the patient should wear a mask. The transporter is not required to mask.

Personal Protective Equipment

- Keep droplet precaution supplies just outside the patient's room on a cart.
- Wear a mask when working within 3 feet of the patient. Don the mask on entry into the room. Whether to wear goggles is an unresolved issue. Follow agency policy.
- Change PPE and perform hand hygiene between contact with patients in the same room, regardless of whether one or both patients are on droplet precautions.

Other

- Instruct patients to observe respiratory hygiene/cough etiquette.
- Discontinue droplet precautions after signs and symptoms have resolved or according to pathogen-specific recommendations.

Airborne Precautions

Follow all standard precautions.
Follow all contact precautions.

When to Use: Use airborne precautions to control the spread of infections that are transmitted person-to-person on air currents. These include tuberculosis, varicella (chickenpox), severe acute respiratory syndrome (SARS), and rubeola (measles). Pathogens spread by this method are very small and can be easily transmitted through ventilating systems as well as by any activities that stir the air, such as fanning sheets, shaking out towels, or sweeping the floor.

Patient Placement and Transport

- Place the patient in an airborne infection isolation room (AIIR)—one with negative pressure that discharges and exchanges the air outside or through a high-efficiency particulate air (HEPA) filtration system. Monitor air pressure daily (usually this is via an electronic device with an alarm).
- If such a room is not available, transfer the patient to a facility where one is available.
- Keep the room door closed when not required for entry and exit. To maintain the negative pressure and contain the airborne organisms.
- In the event of an outbreak involving large numbers of patients who require airborne precautions, consult with infection preventionists for patient placement.
- Limit transport of the patient outside the room to medically necessary purposes. If transport is necessary, cover any infectious skin lesions and have the patient wear a mask. The transporter is not required to mask if the patient is wearing a mask and infectious skin lesions are covered. Notify the receiving department. So the receiving department can take airborne precautions.
- *Ambulatory care*: Triage and identify patients with suspected airborne precautions upon entry to the agency. Place the patient in an AIIR as soon as possible. If one is not available, place a mask on the patient and place him in an exam room. Do not reuse the room for at least an hour after the patient leaves it.

Clinical Insight 23-4 ➤ Following Transmission-Based Precautions—cont'd

Personal Protective Equipment

- Keep airborne isolation supplies just outside the patient's room on a cart.
- Don a mask on entering the room. Wear a special, fit-tested, approved mask (e.g., N-95 respirator) if the patient is suspected of having pulmonary tuberculosis or smallpox.
- Remove your respirator/mask outside the room after closing the door. If the respirator is not disposable, clean and store according to the manufacturer's instructions.
- When using a respirator mask, check the seal. Hold your hands over the respirator and exhale. If you feel air around your nose, adjust the nosepiece; if you feel air at the edges, adjust the straps.
- When the patient has rubeola, chickenpox, or disseminated zoster, CDC makes no recommendation about use of PPE if, based on your history of vaccination or disease, you think you are presumed immune to the disease.
- If the patient has or is suspected of having measles (rubeola) or varicella (chickenpox), only immune caregivers should provide care. Immune caregivers do not need to wear masks.

Other

- Discontinue airborne precautions according to pathogen-specific recommendations of the CDC.
- Tape a waterproof bag to the bedside. To facilitate proper disposal of tissues.

Practice Resources

Pratt, R. J., Pellowe, C. M., Wilson, J. A., et al. (2007); Siegel, J. D., Rhinehart, E., Jackson, M., et al. (2007); U.S. Department of Labor (n.d.a).

Clinical Insight 23-5 ➤ Preventing the Transmission of Multidrug-Resistant Organisms (MDROs)

Note: Refer to Clinical Insights 23-1, 23-2, 23-3, and 23-4, which are also followed in preventing the transmission of MDROs.

Preventing the transmission of MDROs requires some measures over and above the other precautions, but does not replace them.

Note: The CDC recommends that hospitals try to reduce infection rates by improving hygiene and standard precautions; and resorting to special measures, such as screening all high-risk patients, only if other methods fail.

General Recommendations

- **Perform meticulous hand hygiene, for *all* patient care.**
- **Observe standard precautions for *all* patients.** See Clinical Insight 23-2.
  Standard precautions, including hand hygiene, are absolutely essential in preventing spread of infection. There is some evidence that standard precautions alone may be as effective as isolating methicillin-resistant Staphylococcus aureus (MRSA) patients in private rooms and wearing PPE (Halcomb, Griffiths, & Fernandez, 2008a). However, most studies reporting successful MDRO control used a combination of several control measures.
- **Observe (or modify) contact precautions** routinely for patients infected or colonized with target MDROs. Usually this continues until the patient has a negative culture for the organism.
  The type of organism and extent of disease it causes vary by population and institution. Approaches to prevention and control must be tailored to the needs of individual institutions and populations.
  - ***MRSA:*** Prevention is a national priority. The organism can survive on hands, clothing, environmental surfaces, and equipment, so healthcare institutions are targeting it with staff education, aggressive handwashing, increased use of protective gloves and gowns, and targeted screening (Klevens, Morrison, Nadle, et al., 2007).
  - ***C. difficile:*** Prevention focuses on the following:
    Contact precautions for patients with diarrhea
    Accurate patient identification
    Consistent hand hygiene, using soap and water rather than alcohol-based handrubs (for mechanical removal of spores)

(Continued)

Clinical Insight 23-5 ➤ Preventing the Transmission of Multidrug-Resistant Organisms (MDROs)—cont'd

Patient Placement and Transport

- Assign the patient to a single room, if available. Give highest priority to those having conditions that may lead to transmission of infection (e.g., uncontained secretions or excretions, inability to follow cough hygiene).
- If no single room is available, place with a patient with the same MDRO.

Personal Protective Equipment

- Use masks according to standard precautions when performing splash-generating procedures (e.g., wound irrigation). Masks are not recommended for routine care (e.g., upon room entry).
- Use gloves and gowns according to standard precautions.
- *Home care and ambulatory care:* Follow standard precautions for PPE.

Equipment, Supplies, and Environment

- Ensure that patient rooms are cleaned well and often. Disinfect high-touch surfaces (e.g., bedrails, door knobs, bedside commodes) in the room.
- Dedicate noncritical equipment (e.g., stethoscope, blood pressure cuff) to use on individual patients colonized or infected with MDROs.
- Follow standard precautions for handling linens and eating utensils.
- For *C. difficile:* Use a bleach-containing disinfectant for environmental disinfection.
- *Home care:* Limit the amount of patient care equipment brought into the homes of patients infected or colonized with MDROs. See Contact Precautions in Clinical Insight 20-4 to review this.

Other

- Actively observe for symptoms of infections, such as MRSA. Some institutions require screening cultures at admission, or on admission to certain units (e.g., intensive care).
- Be aware of and practice preventive measures, such as:
  Use intravenous and urinary catheters only when essential, and with scrupulous sterile technique.
  Special measures to prevent lower respiratory tract infection in intubated patients
  Judiciously select and use antimicrobials.
- *For C. difficile:* Use a bleach-containing disinfectant for environmental disinfection.

If Further Measures Are Needed

Note: If MDROs continue to be a problem in spite of diligent infection control measures, your agency might consider intensifying infection control practices. For example:

- Donning gowns and gloves before or upon entry to the patient's room
- Assigning the same personnel to the care of MDRO patients only
- Stopping new admissions to the unit or facility
- Obtaining environmental cultures
- Screening high-risk patients on admission

Practice Resources

AORN (2013a); Association for Professionals in Infection Control and Epidemiology (APIC) (2010); CDC (n.d.f, last modified February 5, 2013); Halcomb, E., Griffiths, R., & Fernandez, R. (2008); Institute for Healthcare Improvement (n.d.a, n.d.b); Siegel, J., Rhinehart, E., Jackson, M., et al. (2006).

Clinical Insight 23-6 ➤ Maintaining a Protective Environment in Special Situations

The CDC recommends a protective environment (isolation) for a special class of stem cell transplant patients, who are neutropenic (and therefore immunocompromised) secondary to chemotherapy. You may, in some facilities, encounter protective isolation for other types of patients, as well. However, in most instances, standard and transmission-based precautions are adequate protection for those patients.

In special situations:

- **Follow standard precautions** meticulously, including hand hygiene before and after patient contact.
- **Follow transmission-based precautions** as indicated by a suspected or proven infection.

Patient Room

- Maintain a protective environment (PE) room.
- Avoid a standing collection of water in the room (e.g., with fresh flowers or humidifiers) to prevent fungi and bacteria typically found in this water.

Personal Protective Equipment

- PPE is not required for care providers or visitors for routine entry into the room, unless approaching the patient.
- If the patient must have diagnostic or other procedures that cannot be performed in the PE room, provide respiratory protection (e.g., an N-95 respirator, minimal contact with others).
- Gown, gloves, and mask are used for visitors and care providers according to standard precautions and as indicated for suspected or proven infections for which they are recommended.

Clinical Insight 23-6 ➤ Maintaining a Protective Environment in Special Situations—cont'd

- Refer to Clinical Insight 23-2 and Procedure 23-5 to review donning and removing PPE.

Care Providers, Visitors

- Only healthy caregivers should provide care. Do not care for such a patient if you have an upper respiratory infection, for example.
- Healthcare workers caring for patients in protective isolation should not also be providing care for other patients with active infections.
- Restrict visitors who have a cold or contagious illness.

Housekeeping/Environmental Services

- Carpeting in patient rooms or halls traps soil and can wick moisture, creating an environment for growth of microbes.
- Upholstered furniture and furnishings tend to harbor microbes.
- Avoid dusting methods that scatter particles in the air.
- If vacuum cleaning is necessary, use a vacuum cleaner equipped with a HEPA filter.
- Wet-dust horizontal surfaces daily with EPA-registered disinfectant or detergent.

Engineering

- Use of 99.7% efficiency particulate air (HEPA) filters to remove particles for incoming air at a specified flow rate of air
- Well-sealed rooms—no air leaks
- Ventilation as for airborne precautions
- Directed air flow within the room
- Positive room air pressure in relation to the corridor
- Back-up ventilation equipment (e.g., portable fans or filters)
- For patients who require both protected environment and airborne isolation, use an anteroom to control air in and out of the room.

Practice Resources

AORN (2013a); American Society of Healthcare Engineering (n.d.); Bartley, J. M., Olmsted, R. M., & Haas, J. (2010); Siegel, J. M., Rhinehart, E., Jackson, M., et al. (2007).

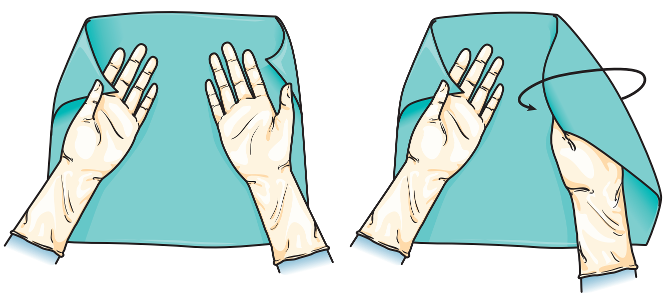
Clinical Insight 23-7 ➤ Guidelines for Preparing and Maintaining Sterile Fields

For steps in setting up a sterile field and adding supplies and solutions, see Procedure 23-7.

Key Point: ***Sterile touches sterile. Unsterile touches unsterile.***

Setting Up the Field

- Close doors and limit foot traffic when setting up a sterile field.
  Air currents can carry dust and microorganisms.
- Prepare a sterile field as close as possible to the time of use.
  To minimize the opportunity for contamination via air currents.
- You may establish a sterile field by using a sterile drape or by using the inner side of a sterile package wrapping. Touch the inside of the wrapper only after you don sterile gloves.
- When you are placing a sterile drape, protect your gloved hands by cuffing the drape over your hands.



Protecting gloved hands.

What Areas Are Considered Sterile?

- A sterile field is sterile only on the horizontal plane. Consider nonsterile any material that drapes over the horizontal plane.
- Consider a 1-inch margin around the drape unsterile, even if it remains on a horizontal surface.
  Because it is in contact with contaminated surfaces.
- If you are wearing sterile attire, only in the front of your body from the chest to the level of the sterile field is considered sterile.
- Sleeve cuffs are considered unsterile when your hands pass beyond the cuff (they are sterile if you don gloves using the closed method).

Keeping the Field Sterile

- No one in unsterile garb should come near a sterile field.

Remain at least 1 foot away from nonsterile areas if you are wearing sterile garb. Never turn your back to a sterile field. A sterile field or open sterile items must be kept in constant view. *You are responsible for monitoring and maintaining the sterility. If you cannot see the field, you do not know if it has become contaminated.*

- Keep conversation to a minimum around the sterile field.
  To reduce the spread of droplets.

(Continued)

Clinical Insight 23-7 ➤ Guidelines for Preparing and Maintaining Sterile Fields

- Avoid reaching over a sterile field even if you are in sterile garb.
- Handle sterile equipment only if you are wearing sterile gloves.
- Limit the amount of time a sterile field remains set up in advance of a procedure.
- Liquid can act as a wick and contaminate a field. Sterile liquids must be contained in sterile bowls on the field or the sterile drape must be nonpermeable in order to avoid wicking.

Adding Sterile Items

- Only sterile items can be placed on a sterile field.
- Before adding items to a sterile field, inspect them immediately for proper packaging, integrity, and inclusion of a sterilization indicator.
- Never assume an item is sterile. If there is any doubt about its sterility, consider it contaminated.
- All items applied to a sterile field must be sterilized in an approved manner.

Practice Resources

AORN (2010a, 2013a, 2013b); Association for Surgical Technologists (2008); Siegel, J., Rhinehart, E., Jackson, M., et al. (2006).

DIAGNOSTIC TESTING

Common Tests for Evaluating the Presence of or Risk for Infection

TEST	DESCRIPTION
White blood cell (WBC) count with differential	A breakdown of the number and types of WBCs; normal WBC count is 5,000–10,000/mm^3.
Blood cultures	A sample of blood placed on culture media and evaluated for growth of pathogens. Normally, should show no growth of infectious microorganisms.
Urine cultures	Urine is normally sterile with no microorganism growth.
Throat cultures, wound cultures	Presence of microorganisms is normal, but there should be no growth of infectious microorganisms. To yield the most reliable results, blood cultures should be obtained from peripheral sites, using venipuncture by trained phlebotomists, unless a culture is specifically ordered from a central catheter or peripherally inserted central catheter.
Disease titers	Blood tests for specific disease immunity (e.g., to rubella)
Panels to evaluate specific disease exposure	Blood tests to evaluate exposure to specific diseases (e.g., HIV, hepatitis)
Immunoglobulin (IgG, IgM) levels	Blood tests to evaluate humoral immunity status
C-reactive protein (CRP)	A blood test to measure inflammatory change or bacterial infection
Agglutinins, warm or cold	Used to diagnose atypical infections by detecting antigens in the blood
Erythrocyte (red blood cell) sedimentation rate (ESR or sed rate)	A measure of inflammatory changes. Sed rate increases with inflammation. Normally it is @15 mm/hr for men and <20 mm/hr for women.
Iron level	Normally 60–90 grams/100 mg. Lower in chronic infection.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mr. Long, a frail elderly man, is in the hospital because he has become dehydrated and needs intravenous fluids and other supportive care. The nurse administered intravenous fluids. Mr. Long also has a fairly large decubitus ulcer (bedsore), which was cultured recently and found to be infected with *Staphylococcus aureus*. The nurse wore gloves to treat the ulcer. While doing so, she noticed that the IV was infusing too fast and, without thinking, regulated the IV without removing her soiled gloves. The next nurse to regulate the IV did so with her bare hands, and then, without realizing it, rubbed her neck. Later, the nurse developed a boil on her neck, which was infected with *S. aureus*.

THINKING

1. *Theoretical Knowledge:*
   a. What are the six links in the chain of infection?
   b. Why do you think the *S. aureus* was able to thrive in Mr. Long's decubitus ulcer?
   c. What are the three modes of transmission of microorganisms? Which one is the most frequent mode of transmission?
2. *Critical Thinking (Reflecting):*
   a. What was the reservoir for the *S. aureus*?
   b. What was the exit from Mr. Long?
   c. What was (were) the fomite(s) for transmission to the nurse?
   d. What was the portal of entry into the nurse?

DOING

3. *Nursing Process (Implementation):* In addition to wearing gloves, what other PPE (if any) does the nurse need if she is performing decubitus care and changing Mr. Long's bed linens?

CARING

4. *Self-Knowledge and Ethical Knowledge:* Think of one instance in the clinical setting in which you did *not* follow standard precautions? Why do you think that happened?

Critical Thinking and Clinical Reasoning

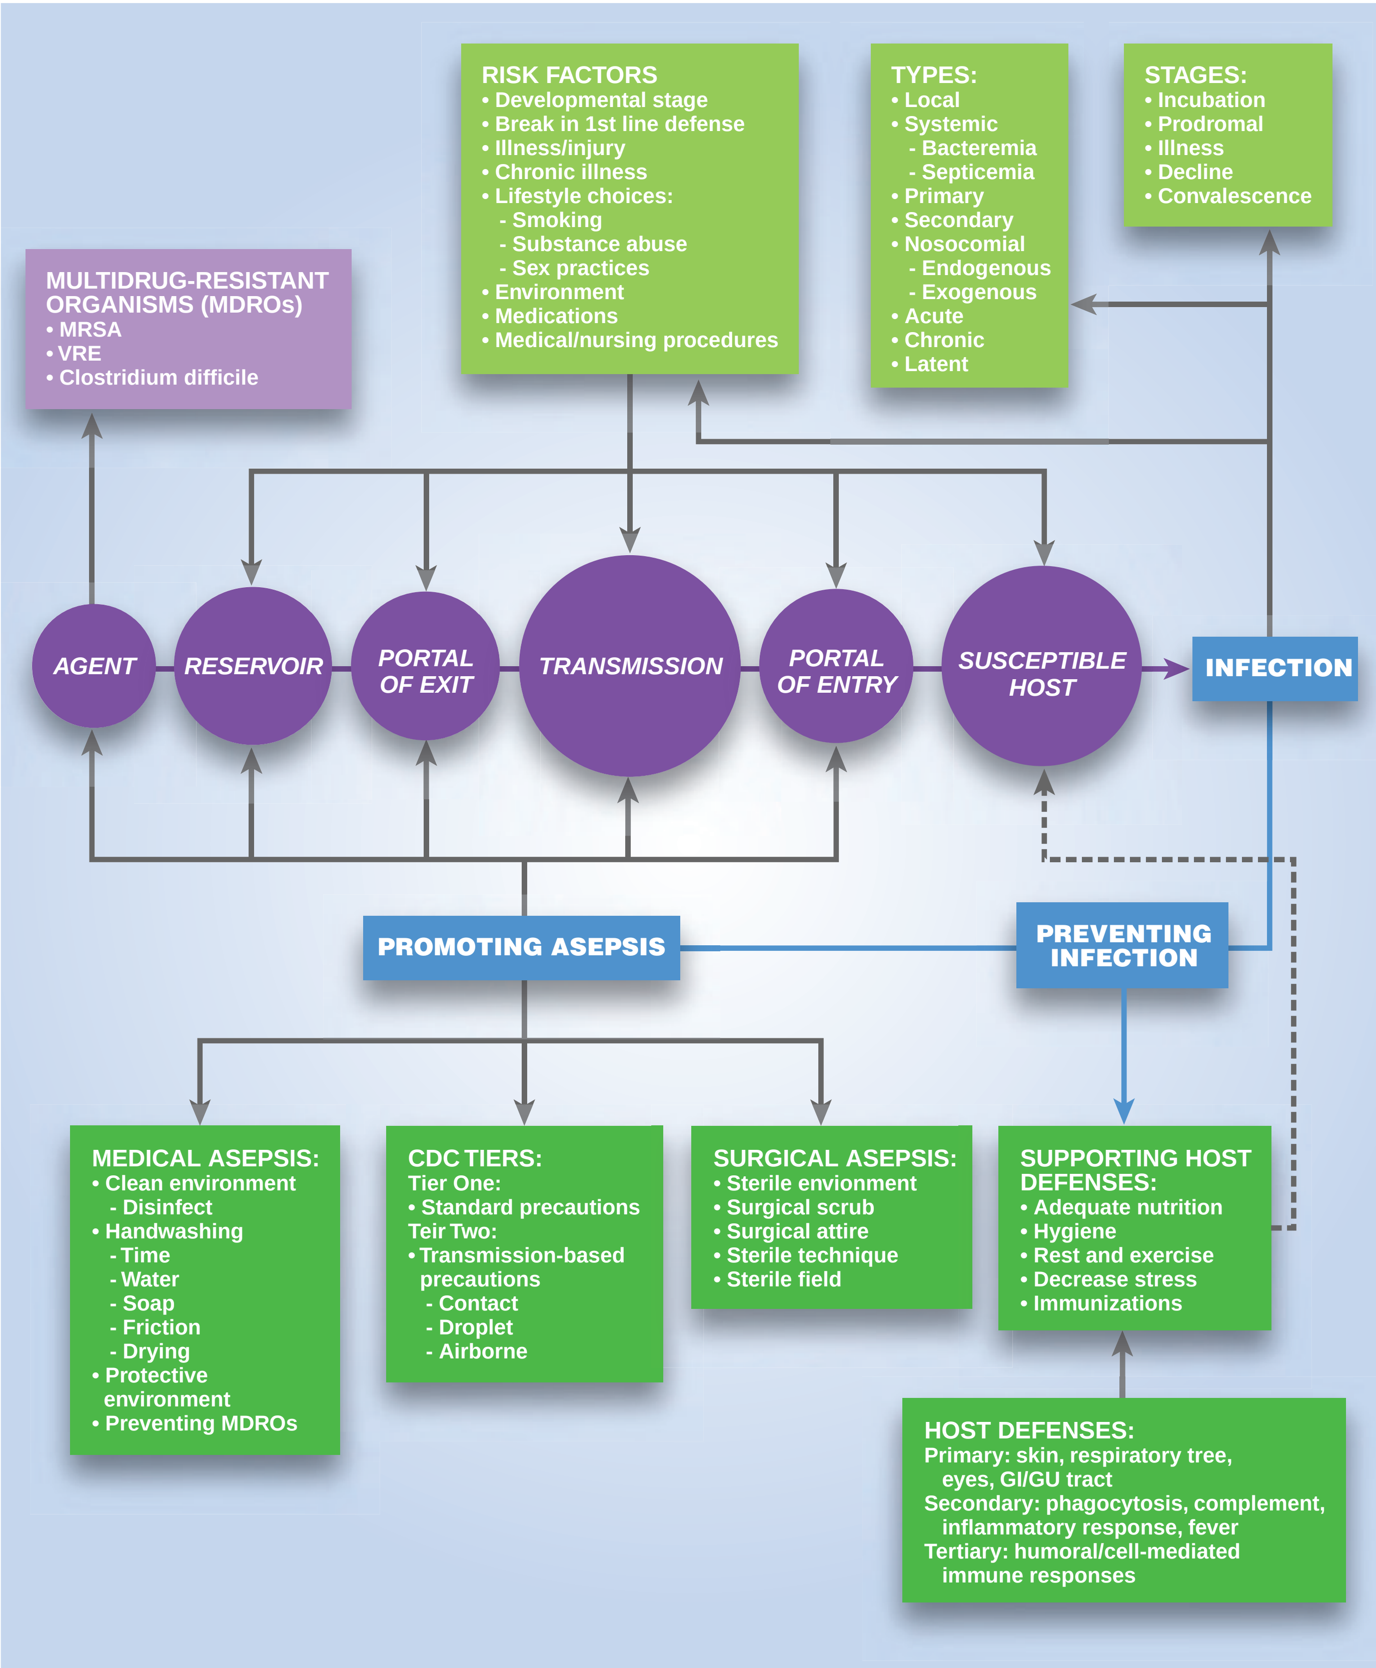
1. You notice that your clinical instructor is not washing his hands between patients. What should you do?
2. As you are gowning and gloving for your first experience in the operating room, you become nervous and forget the proper procedure for applying sterile surgical garb. How should you handle this situation?
3. What action should you take if you contaminate yourself while gowning and gloving?
4. Refer to Procedure 23-7, the open method for donning sterile gloves. In the photograph at Step 7, you can see that the nurse has a sterile glove on her right hand and is touching the glove with her bare left hand. Is the nurse breaking the "sterile-touches-sterile" principle? Explain your thinking.
5. Refer to Procedure 23-6, the closed method of donning a sterile gown and gloves. Examine the very last photograph, in which one nurse is preparing to turn and receive her gown tie from a coworker. The gowned nurse has already donned sterile gloves, using the closed method. When the gowned nurse turns to receive the tie, what must she take care to not touch? What can she touch?
6. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or promoting asepsis and preventing infection. Note that these are *not* to be merely definitions.

   Chain of infection
   Pathogens
   Asepsis
   Healthcare-related infections
   Multidrug-resistant organisms (MDROs)
   Contamination
   Standard precautions
   Transmission-based precautions
   Protective isolation
   Sterile
   Medical asepsis
   Surgical asepsis

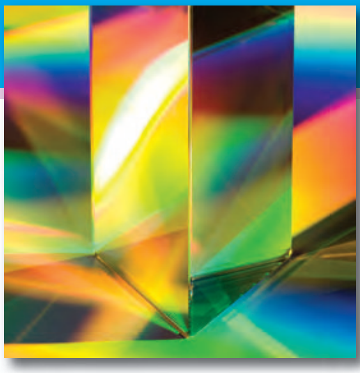
What Are the Main Points in This Chapter?

- Healthcare-related infections (infections that are acquired in healthcare facilities) are a major health problem worldwide.
- The chain of infection consists of six links that must all be present for infection to be transmitted from one individual to another: infectious agent, reservoir, portal of exit, mode of transmission, portal of entry, and susceptible host.
- Pathogens are strains of bacteria, viruses, fungi, protozoa, helminths, and prions that cause disease.
- Drug-resistant and multidrug-resistant organisms (MDROs) have mutated to develop resistance to one or more classes of antimicrobial drugs. They are a serious problem because: (1) options for treating MDRO infections are limited; (2) they are associated with increased hospital lengths of stay and hospital charges; and (3) they are associated with serious illness and increased mortality.
- Many emerging pathogens are airborne and widely spread by air travel before the carrier shows any symptoms. They have the potential for causing epidemics and pandemics.
- Infectious illnesses typically follow five predictable stages: incubation, prodromal stage, illness, decline, and convalescence.
- Primary body defenses, such as intact skin and mucous membranes, block entry of pathogens into the body.
- Invading microorganisms trigger the body's secondary defenses, which include phagocytosis, the complement cascade, the inflammatory response, and fever.
- The humoral immune response results in the production of antibodies that neutralize pathogens or trigger their destruction.
- The cell-mediated immune response results in the production of T cells that destroy infected body cells.
- Nutrition, hygiene, rest, exercise, stress reduction, and immunization protect the body against infection.
- Anything that weakens the body's defenses or increases the person's exposure to pathogens makes the person more susceptible to infection. Such factors include illness, injury, medical treatment, infancy or old age, frequent public contact, and various lifestyle habits.
- Medical asepsis requires that objects and surfaces in the healthcare environment be disinfected.
- Scrupulous handwashing markedly decreases the transmission of infection and is the most important aspect of medical asepsis.
- Standard precautions are used with all clients whenever there is a possibility of coming in contact with blood, body fluids (except sweat), excretions and secretions, mucous membranes, and any break in the skin.
- Transmission-based precautions are added to standard precautions when there is concern about transmission of infection via contact, droplets, or air currents.
- Isolation precautions are designed to prevent the spread of disease, not to isolate the person who has the disease.
- Surgical asepsis is an attempt to prevent the patient from coming in contact with *any* microorganisms.
- Sterile technique is required in many patient activities, such as administering an injection, starting an intravenous line, or performing a sterile dressing change.
- Exposure to blood, body secretions, or body tissues containing blood or secretions requires immediate action. Minimize the exposure by washing hands or flushing the area thoroughly. Contact the infection preventionist or employee health nurse as soon after the exposure as possible, complete an injury report, and seek medical care.
- The task of the infection preventionist is to minimize the number of infections in the healthcare facility.
- A key factor in minimizing infectious outbreaks is recognizing unusual disease patterns.

Knowledge Map



CHAPTER 24



Promoting Safety

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing responses to the questions) on Davis*Plus.

Caring for the Nguyens

Refer to the database for Nam Nguyen in the front of this book. Use full-spectrum thinking to identify safety hazards for Mr. Nguyen, his 3-year-old grandchild (Kim Phan, who lives with him), and his widowed mother, Mai Nguyen, who lives alone.

A. Without even using any patient data from the database (except ages), what theoretical knowledge do you have that will help you to identify risks that commonly occur in the developmental stages represented by these three clients?
Mr. Nguyen
Mr. Nguyen's 3-year-old grandchild, Kim
Mr. Nguyen's widowed mother, Mai

B. From Mr. Nguyen's database, what data can you put with your theoretical knowledge to identify the most likely safety risks for him? What are those risks?

C. From the risks and possible risks you have identified, for which one do you definitely need more data before deciding whether it increases his risk for accidents? That is, which piece of data is especially vague? What do you need to find out?

D. You know the theoretical (or possible) risks for Mr. Nguyen's mother. What data do you need in order to determine her *actual* safety risks?

E. What, if any, data do you have that would help you to identify any *actual* safety risks for Mr. Nguyen's grandchild? What, if any, are those risks?

F. What would you want to assess at the child's preschool to be sure that safety measures exist for preventing falls?

PracticalKnowledge knowing **how**

Nursing interventions to promote safety in the home focus mainly on patient teaching. In hospitals and long-term care facilities, however, you will take a more proactive role in preventing injury to patients. In addition to patient advocacy activities, you will need practical knowledge of measures other than restraints (e.g., bed and chair monitors) you can use to prevent falls. You must also know how to apply and manage restraints safely.

PROCEDURES

Procedure 24-1 ■ Using a Bed Monitoring Device

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

Bed or chair exit monitoring device

There are at least four types of staff notification systems that may be utilized to warn caregivers that a patient is leaving a bed or chair: (1) pressure sensitive, (2) posture indicators, (3) motion sensors, and (4) pull-cord and combination alarms.

Delegation

As the nurse, you must determine whether a monitoring device is needed. You must also select the appropriate device and provide ongoing evaluation of its effectiveness. You may delegate to a nursing assistive personnel (NAP) the installation of the device, after verifying the NAP has the necessary knowledge and skill.

Pre-Procedure Assessments

- Assess for intrinsic factors that increase the risk for falls:
  - Older than age 75
  - History of a recent fall or fear of falling
  - Bowel and bladder incontinence (particularly urge bladder incontinence)
  - Cognitive impairment
  - Mood changes, lability
  - Dizziness
  - Functional impairment
  - Medications (especially new medications or changes in regimen)
  - Comorbidities (diseases such as dementia, hip fracture, type 2 diabetes, Parkinson's disease, arthritis, and depression)
- Assess for environmental factors that increase the risk for falls:
  - Use of an assistive device
  - Equipment in the room
  - Wet or uneven floors
  - The use of physical restraints
  - Inappropriate footwear
  - Poor lighting
  - Lack of grab rails and bars in the bathroom
  - Furniture and adaptive aids that are in disrepair or unstable (e.g., bed rails, IV poles)
  - Clothing that may cause tripping
- Identify factors that increase risk for more severe injury in the case of a fall. These include use of anticoagulants (e.g., Coumadin, Plavix, or aspirin) and osteoporosis.
- Check the alarm on the monitoring device to ensure that it is working properly.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Apply the device.

Bed or Chair Monitor

Place sensor pads under the patient's buttocks.

The sensor will alarm when the patient attempts to get out of the bed or chair; it alarms when there is no weight on it for more than a few seconds. Many electronic beds have bed exit and patient position monitors for which you must select the desired alarm sensitivity. For example, you may set the system to alarm when the patient exits the bed, when the patient attempts to exit the bed, or even when the patient moves in the bed.

Leg Sensors

Place sensors on the patient's thigh.

The alarm will sound when the leg assumes a near-vertical position.

Infrared Beam Detector
Attach next to the bed or on the wall.

Cord-Activated Sensor
Attach one end of the cord (clip) to the patient's garment. Attach the other end to the control unit. The cord should be long enough to allow moderate movements, but short enough to prevent false alarms. Be sure the cord is free to pull straight out from the monitor and is not blocked by pillows, bedding, or bedrails.
The alarm is activated when the patient's movement causes the cord to be detached from the control unit. Some patients will deactivate the alarms, including removing the alarms clipped to their garments.

2. **Connect the control unit to the sensor pad.**

Bed or Chair Monitor
Mount the control unit on the bed or chair.

Leg Sensor
Mount the control unit directly on the leg sensor.

Infrared System
Mount the control unit next to the bed or on the wall.

Cord-Activated System
Mount the control unit next to the bed or on the wall.

3. **Connect the control unit to the nurse call system,** if possible.
   Allows for a quicker response; however, not all call systems will accommodate this.
4. **Disconnect or turn off the alarm** before assisting the patient out of the bed or chair.
   Prevents false alarms. Some systems have a standby setting to allow the alarm to be temporarily suspended.
5. **Reactivate the alarm** after assisting the patient back to the bed or chair.
   Helps improve the timeliness of staff response, which may prevent patient falls.
6. **Be sure the patient can access** to the nurse call light easily.

Evaluation

- Assess the sensitivity of the monitoring device, and adjust as needed to ensure that the alarm is activated if the patient tries to get out of the bed or chair.
- Continue to assess fall risk per agency policy and as indicated by the patient's physical and/or mental status.
- In the event of a fall, perform a post-fall assessment to identify possible causes. Monitor patients closely for 48 hours after a fall.

Patient Teaching

- Explain to the patient and family that a bed or chair exit monitoring device alerts the staff when the patient tries to get out of the chair or bed.
- Explain that the purpose of the device is to help prevent falls using the least restrictive method possible will reassure the patient and family.
- Explain to the patient that she will need to call for assistance when she wants to get up.
  Calling for assistance will prevent the alarm from sounding. Summoning for help can prevent the patient from falling.

Documentation

Document the initial sensor placement, including type of sensor used and the location of placement.

- After documenting initial placement, follow agency policy for documenting the use of bed exit monitor. Usually, the minimum documentation for exit monitors is every 8 hours.
- Place the patient on fall risk precautions according to agency policy.
- Document on the fall risk assessment sheet, restraint flowsheet, and nursing notes according to agency policy.

Sample documentation

9/14/16 1230. Client becomes easily disoriented while sitting in wheelchair and attempts to rise to a standing position. Safe standing and walking with assistance x1. Reminded to ask for assistance when standing or walking and placed next to nurse's station. ——————

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos*, **Using Bed and Chair Monitoring Devices.**

For questions and suggested responses,

Go to Chapter 24, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 24-2 ■ Using Restraints

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ **Caution:** This procedure describes Medicare standards, but state and agency policies may be more restrictive.

Equipment

- Restraint of the appropriate size: belt, vest, wrist or ankle, or mitt
- Soft gauze or cotton padding for bony prominences

Delegation

As the nurse, you must determine whether restraints are needed in each specific situation. You must also select the least restrictive type of restraints, evaluate their effectiveness, and continue to assess for complications that may occur. You may delegate to NAPs the application and periodic removal of ordered restraints, after verifying that the NAP has the knowledge and skill to do so.

Pre-Procedure Assessments

- Assess the patient's risk for falls, including mobility status and level of awareness.
- Assess for need for restraints: The immediate physical safety of the patient, a staff member, or others is threatened.
  If a patient must be temporarily restrained so that a procedure may be performed, this is not considered "restraint."
- Determine that all less restrictive interventions have been tried unsuccessfully.
- Identify the appropriate restraint:
  - The least restrictive possible
  - Does not interfere with care or exacerbate patient's medical condition.
  - Does not pose a safety risk to the patient.
  - Can be changed easily to keep it clean.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine whether dangerous** behaviors continue despite attempts to eliminate causal factors using less restrictive interventions.

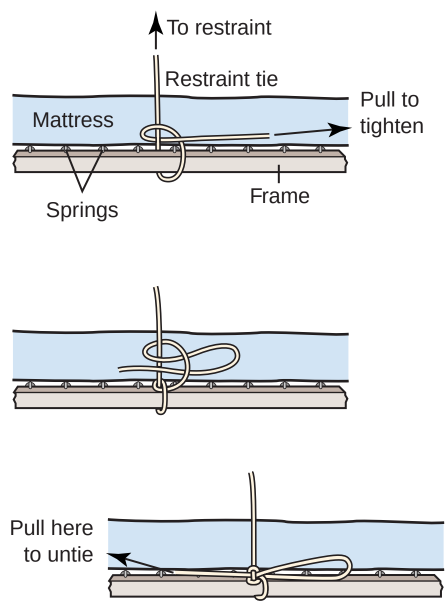
2. **Obtain a physician's prescription** for restraint, including type of restraint, indications for use, site of restraint application, and duration. Determine if the restraint is being used for medical–surgical or behavioral reasons.
   Federal and state regulations and laws permit healthcare facilities to use restraints only when they are medically needed. Restraints can be used only with a physician's or advanced registered nurse practitioner's (ARNP) order for a specified and limited time. When you apply restraint in an emergency, obtain the order as the restraint is being applied, or as quickly as possible afterward. When the restraint prescription expires (maximum 24 hr), physician assessment and a new prescription are needed.

3. **Notify the family of the change in patient status and the need for restraints.** Obtain patient and family consent when clinically feasible.
   Patients have the right to refuse treatment. Consent may not be necessary if there is an immediate threat to patient safety; however, as a rule, the family must be notified of the use of restraints if the patient has cognitive impairment. Many times family members prefer to sit with the patient as an alternative to restraint.

4. **Pad bony prominences** and apply the appropriately sized restraint, using appropriate knotting techniques. ➤

   Use a quick-release knot, such as the half-bow, when tying restraints to the bed frame or wheelchair. Do not tie restraints to the siderails.

   A quick-release knot is used to prevent patient injury and for ease of caring for the patient. Tie the knot on an immovable part of the bed to prevent injuring the patient if the siderails or head of bed is lowered. A quick-release knot will not tighten or slip when the patient moves about, but unties quickly when you pull on the loose end.



Belt Restraint

a. Place the belt restraint at the patient's waist, removing any wrinkles.
b. Make sure that the belt is snug but does not constrict the patient's waist.
c. Some belts have a key-locked buckle to prevent slipping.

A belt restraint is used mainly to prevent a patient from falling when getting up from a chair or wheelchair and may be used to remind a patient not to get out of bed unassisted.

Vest or Jacket Restraint

a. Place the patient in the vest restraint. A zipper-style vest is preferred.
   A vest restraint with a rear zipper is less likely to accidentally strangle the patient.
b. Attach the vest straps to the bed or wheelchair.
   A vest restraint is used mainly to prevent a patient from falling out of a chair or wheelchair and sometimes to prevent a patient from getting out of bed unassisted.

Wrist or Ankle Restraint

a. Apply the padded portion of the wrist or ankle restraint around the patient's wrist or ankle.
b. Make the restraint snug enough to prevent the patient from being able to slip it off, but not tight enough to impair circulation.
c. Attach the restraint strap to the bed frame. Do not attach to bed rails.
   A wrist restraint is used mainly to prevent an agitated patient from pulling at tubes, such as IV sites and nasogastric tubes.

Mitt Restraint

a. Place patient's hand in the mitt restraint, ensuring that fingers are slightly flexed in the mitt.
b. Attach restraint strap to the bed frame if necessary.
   A mitt restraint is used mainly to prevent a patient from pulling at tubes, such as IV sites and nasogastric tubes. Mitt restraints limit the use of the fingers, which may be enough to prevent the patient from grasping the tube. If this is the case, mitts that are not tied to the bed frame are the least restrictive restraint.

Enclosed Bed

a. Place patient in the bed and zip all sides. Be sure zippers are completely closed and zipper tabs are positioned in the upper aspects of the net panels out of the patient's reach.
b. Adhere to the manufacturer's minimum height and weight recommendations.
c. Never leave the bed in the high position with the patient unattended.
   An enclosed bed is a canopy-like padded bed that is used mainly to keep a patient from wandering or from falling out of bed. The bed has nylon netting on all four sides, with zippered panels that can be opened to provide care. The patient has full freedom of movement and access to all parts of his body. Patients in enclosed beds have a higher risk of becoming entrapped between the bed rails and the mattress, risking suffocation. The dangers are greater for smaller patients and when the bed is left in a high position.

5. **Adjust the restraint** to maintain good body alignment, comfort, and safety. You should be able to slide two fingers under a wrist or ankle restraint.
   The restraint should be snug enough to prevent it from slipping off, but not tight enough to impair circulation.

6. **Release restraints at least** every 2 hr to provide skin care, passive and active range of motion (ROM), ambulation, toileting, hydration, and nutrition at least every 2 hr. Assess for the continued need for restraint.
   Prevents impaired circulation and injury. Medicare- and Medicaid-certified healthcare agencies must ensure that a patient's abilities do not decline unless the decline cannot be avoided because of the patient's medical condition. Patients often lose the ability to bathe, dress, walk, toilet, eat, and communicate when they are regularly restrained. If restraints are necessary, they must be used in a way that does not cause these losses.

(continued on next page)

Procedure 24-2 ■ Using Restraints (continued)

7. Place the patient on fall risk precautions according to agency policy.
Patients who are restrained have a higher incidence of falls.

? What if . . .

- **I must apply a restraint in an emergency, for the safety of the patient or others?**

In such an emergency, an RN may initiate a restraint. When you apply restraint in an emergency, obtain the order as the restraint is being applied, or as quickly as possible afterward.

Evaluation

- Assess the initial restraint placement, circulation, and skin integrity. Observe for pallor, cyanosis, and coolness of extremities when extremities are restrained.
- Check the restraint every 30 minutes (more often for a behavioral restraint).
- Reassess the restraint, circulation, the patient's response to the intervention, and the need for continuing the use of the restraint every 2 hours; remove it when it is no longer needed.
  Ensures that the restraint is still functioning as intended. Monitoring and reassessment are critical components of caring for patients in physical restraints. Frequency of monitoring is determined by the type of restraint (behavioral vs. medical-surgical). Patients in behavioral restraints require more frequent monitoring and in some circumstances require continual observation.
  - Check every 24 hours to see that the restraint prescription has been renewed.
  - Remove the restraint as soon as possible.
  - Modify the plan of care to reflect the application of restraints and the plan for monitoring.

Patient Teaching

- Explain to the patient and family the need for the restraints.
- Explain that the restraints will be removed as soon as possible.

Home Care

- The same guidelines apply to clients in the home.
- Evaluate caregivers' knowledge and skill in using restraints, and provide teaching as needed (e.g., regarding padding bony prominences and the need to periodically release restraints).
- If an enclosed bed is used in the home, instruct the caregiver in safe use.

Documentation

Document the following:

- All nursing interventions that were done to eliminate the need for the restraint (e.g., moving patient closer to the nurses' station, asking a family member to remain with the patient, reorienting the patient)
- Reasons for placing the restraint (e.g., patient behaviors)
- The initial restraint placement, location, circulation, and skin integrity
- The teaching session with the patient and family members
- Circulation checks, ROM, and restraint removal per agency protocol
- Entries on fall risk assessment sheet, restraint flowsheet, and nursing notes according to agency policy

Sample documentation

12/24/16 1230. Continues to be confused, pulling at IV lines. Physician notified and evaluated patient. Mitt restraints ordered and placed on bilateral hands. Fall risk precautions initiated. Mitt restraints explained to patient and wife. Wife agreed that mitt restraints would help keep her husband from removing IV line. ——— Mary Clinton, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the *Davis's Nursing Skills Videos,* **Safety, Using Restraints: Belt Restraint, Mitt Restraint, Vest Restraint, and Wrist/Ankle Restraint.**

For questions and suggested responses,

Go to Chapter 24, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

CLINICAL INSIGHTS

Clinical Insight 24-1 ➤ Preventing Needlestick Injury

Use needleless systems (e.g., retractable needles) when possible. More than 80% of needlestick injuries can be prevented with the use of safe needle devices (ANA, 2002).

Before beginning a procedure:

- Provide adequate lighting and space to perform the procedure.
- Place the sharps container near the work area, if it is moveable.
- Obtain assistance if there is a risk the patient may be uncooperative, combative, or confused.
- Inform the patient about the procedure and explain the importance of avoiding any sudden movement.

During the procedure:

- Be sure you can see the sharps container at all times.
- When handling a sharp, be aware of other persons in the immediate area.
- Do not hand-pass exposed sharps from one person to another.
- When using a safety needle, observe for audio or visual cues that the feature has engaged.

Handling needles:

- Do not shear or break contaminated needles
- Avoid recapping, bending, or removing contaminated needles and other sharps unless there is no feasible alternative.
- When you must recap a sterile needle, use a mechanical recapping device or a modified "scoop" technique (see Procedure 26-10).
- Never carry syringes in your uniform pocket.

Sharps containers:

- Keep puncture-proof needle disposal containers in every room.
- Place sharps containers at eye level; do not overfill the container.
- Make sure the container is large enough to hold the entire sharp device.
- Dispose of sharps immediately. Do not wait until you have finished the procedure.
- Inspect sharps and waste containers for protruding sharps. If found, notify safety personnel for removal of the hazard.

If your agency does not use needleless systems or protective devices you should do the following:

- Explain the OSHA Bloodborne Pathogens Standard (BPS) to your employer, including the need to provide needleless systems or protective devices for blood products and parenteral medication administration.

Refer your employer to the OSHA Web site at www.osha.gov/needlesticks/needlefaq.html

- OSHA requires worker involvement in evaluating, selecting, and implementing the use of safer needle products; volunteer to serve on that committee.
- Ask your agency for a copy of their exposure control plan, which is required by the BPS for monitoring compliance with the new law.
- Keep a record of needlestick injuries on your unit and of "near-misses" (e.g., overfilled sharps containers, sharps left on bed or overbed table).
- Submit written concerns to your employer.
- If your employer refuses to purchase safety devices, you may want to file an OSHA complaint. If you do so, refer to Chapter 44's Whistleblowing section. Complaints can be filed anonymously.
- For complaint filing,

http://www.osha.gov/as/opa/worker/complain.html

Practice Resources

Adapted from: ANA (2002); Centers for Disease Control and Prevention (CDC) (2011b.); National Institute for Occupational Safety and Health (NIOSH) (n.d., updated 2010.); U.S. Department of Labor, Occupational Safety and Health Administration (OSHA) (n.d.); Wilburn, S. (2004).

Clinical Insight 24-2 ➤ What You Should Know About Using Restraints

- ***Restraints are a last resort.*** The current standard of care is restraint-free. Restraints should be a last-resort intervention.
- ***Individualize care.*** Before using restraints, try to understand the message in the patient's behavior. The best way to achieve restraint-free care is to individualize care to avoid the risky behavior.
- ***Try less restrictive interventions*** before resorting to restraints. For example, request family involvement as an alternative to restraint. Family members may be able to interpret a patient's gestures or understand what is bothering him. For other suggestions,

Go to Volume 1, **Preventing the Need for Restraints.**

- ***Follow agency policy,*** professional guidelines, and state laws for using restraints.
- ***Use restraints only for safety*** to ensure the immediate physical safety of the patient or others.
- ***No standing orders*** or "as needed" orders for physical restraint are allowed.
- ***You must obtain a medical prescription*** from a physician or other licensed care provider.
- ***Guidelines are more restrictive when restraints are used for behavior management.***
- ***You must renew restraint prescriptions every 24 hours*** (more often for behavioral restraints).
- ***You must modify the plan of care*** to reflect the application of restraints and the plan for monitoring.
- ***Explain the need for the restraints*** if you must use them.
- ***Obtain consent*** from the patient and family when feasible.
- ***Always use the least restrictive restraint that ensures safety.***
- ***Remove the restraint as soon as possible.***
- ***Monitor and reassess.*** These are critical components of caring for patients in physical restraints. Assess restraints every 30 minutes (more frequently for patients with behavioral restraints, who may need continuous monitoring).
- ***Remove restraints for assessment, feeding, toileting, and skin care every 2 hours.*** Patients in medical-surgical restraints should be evaluated by an RN at least every 2 hours. Those in behavioral restraints require more frequent monitoring.
- ***Medications are considered a restraint*** when they are used to restrict the patient's freedom of movement or to manage behavior.
- ***Physical holding of a patient is not always considered restraint.*** Sometimes it is necessary to use devices or methods that involve the physical holding of a patient for routine physical examinations or tests.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Get Up and Go Test

Conduct the Get Up and Go Test as part of a routine assessment when dealing with older persons. Its purpose is to detect "fallers" and to identify those who need evaluation. The staff should be trained to perform the Get Up and Go Test at check-in and query those with gait or balance problems for falls.

Initial Check

All older persons who report a single fall should be observed as they "get up and go":

- Move from a sitting position and stand without using their arms to help them rise and stand.
- Walk several paces, turn, and return to the chair.
- Sit back in the chair without using their arms for support.

Those who have difficulty or demonstrate unsteadiness performing this test require the following follow-up assessment.

Follow-Up Assessment

In the follow-up assessment, ask the person to:

- Sit.
- Stand without using their arms for support.
- Close his eyes for a few seconds, while standing in place.
- Stand with eyes closed, while you push gently on his sternum.
- Walk a short distance and come to a complete stop.
- Turn around and return to the chair.
- Sit in the chair without using his arms for support.

If the client has difficulty performing those tests, refer for a comprehensive evaluation.

Referring for Comprehensive Evaluation

A comprehensive evaluation should be performed by a practitioner with advanced skills and experience (AHI of Indiana, n.d.; American Academy of Neurology, 2008a, 2008b; Hendrich, 2007; Kenny, Rubenstein, & Tinetti, et al., 2011). In any of the following situations, you should refer the patient for a comprehensive fall evaluation.

- The patient is seeking care because of a fall.
- The patient or family reports recurrent falls in the past year.
- The patient's gait or balance is abnormal.

Focused Assessment

The Timed Up & Go Test for Fall Risk Assessment

Physicians are asked to assess annually all patients who are 65 years or older using the **Timed Up & Go Test.**

Timed Up & Go Test

1. Have the patient in a seated position.
2. Place a visible object 8 feet away from the patient.
3. Ask the patient to get up and walk around the object, and then sit back down.
   - Allow the patient to practice once.
   - Then time the patient three times as he performs these steps.
   - Scores greater than 8.5 seconds are associated with high fall risk in community-dwelling older adults.

Practice Resources

American Academy of Neurology (2008a, 2008b); Hendrich, A. (2007); Kenny, R., Rubenstein, L., Tinetti, F., et al. (2011); Podsiadlo, D., & Richardson, S. (1991).

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Recall your patient, Alvin Lin, from Meet Your Patient in Volume 1. Mr. Lin is a 79-year-old man who was just transferred from a long-term care facility to your medical unit. His admitting diagnosis is dehydration and pneumonia. In the handoff report you were told he had rested well during the night and was alert and oriented. When you enter his room, he is confused and does not know where he is. He is becoming combative and is trying to get out of bed.

THINKING

1. *Theoretical Knowledge:*
   a. What is the pathophysiology of pneumonia?
   b. When the oxygen level of the blood falls, what is the effect on the central nervous system? If you don't know the answer to this question, consult a reliable reference.
   c. What are the defining characteristics for the NANDA-I diagnosis, Deficient Fluid Volume?
2. *Critical Thinking (Considering Alternatives):*
   a. Which of the three defining characteristics (in 1c) may increase Mr. Lin's risk for falls? Why?
   b. What else may be increasing his confusion and his risk for falls?

DOING

3. *Practical Knowledge:* Suppose you have tried all the less restrictive restraints, but Mr. Lin still attempts to get out of bed. He has even pulled out his intravenous line. You decide you must apply restraints to keep him safely in bed. You have called the physician, but he has not returned your call. You cannot wait any longer because you have other patients who need you, and yet you must stay with Mr. Lin to keep him from falling. What should you do right now?
4. *Nursing Process (Diagnosis):* Which nursing diagnosis seems more useful to you in planning care for Mr. Lin?
   Confusion related to disease process
   Risk for Falls related to confusion and possibly r/t weakness

CARING

5. *Self-Knowledge:*
   a. Do you think having a restraint-free facility is a valuable goal, or not? Explain your thinking.
   b. How did you come to believe that?
6. *Ethical Knowledge:* Suppose Mr. Lin is too confused to give consent for restraints, and you cannot reach his family by telephone. How can you justify applying restraints, and what must you do later to follow up?

Critical Thinking and Clinical Reasoning

1. Recall from Meet Your Patient in Volume 1 the clients you encountered in the community setting. Teresa was caring for her 2-year-old daughter and her elderly grandmother. The grandmother has a fear of falling. In Volume 1, we addressed some of the issues related to child-proofing the home. You would like to suggest ways for Teresa to make the home safe for her frail grandmother.
   a. Refer to the critical-thinking model and questions in Table 2-1 of Volume 1. What questions in the Inquiry section should you ask before making suggestions to Teresa?

Go to Table 2-1, **Critical Thinking Model,** in Volume 1.

   b. What specific information do you need about the grandmother? About the home?
   c. Once you have the necessary information, what suggestions could you make about home safety measures?
   d. Consider alternatives. What types of assistive devices might be helpful in preventing falls?
   e. Explore the alternatives. For example, are they practical? What do you need to know about this family to determine whether it is practical for them to obtain such devices?
   f. Think now about Teresa. Given the situation, what might create a safety risk for her?

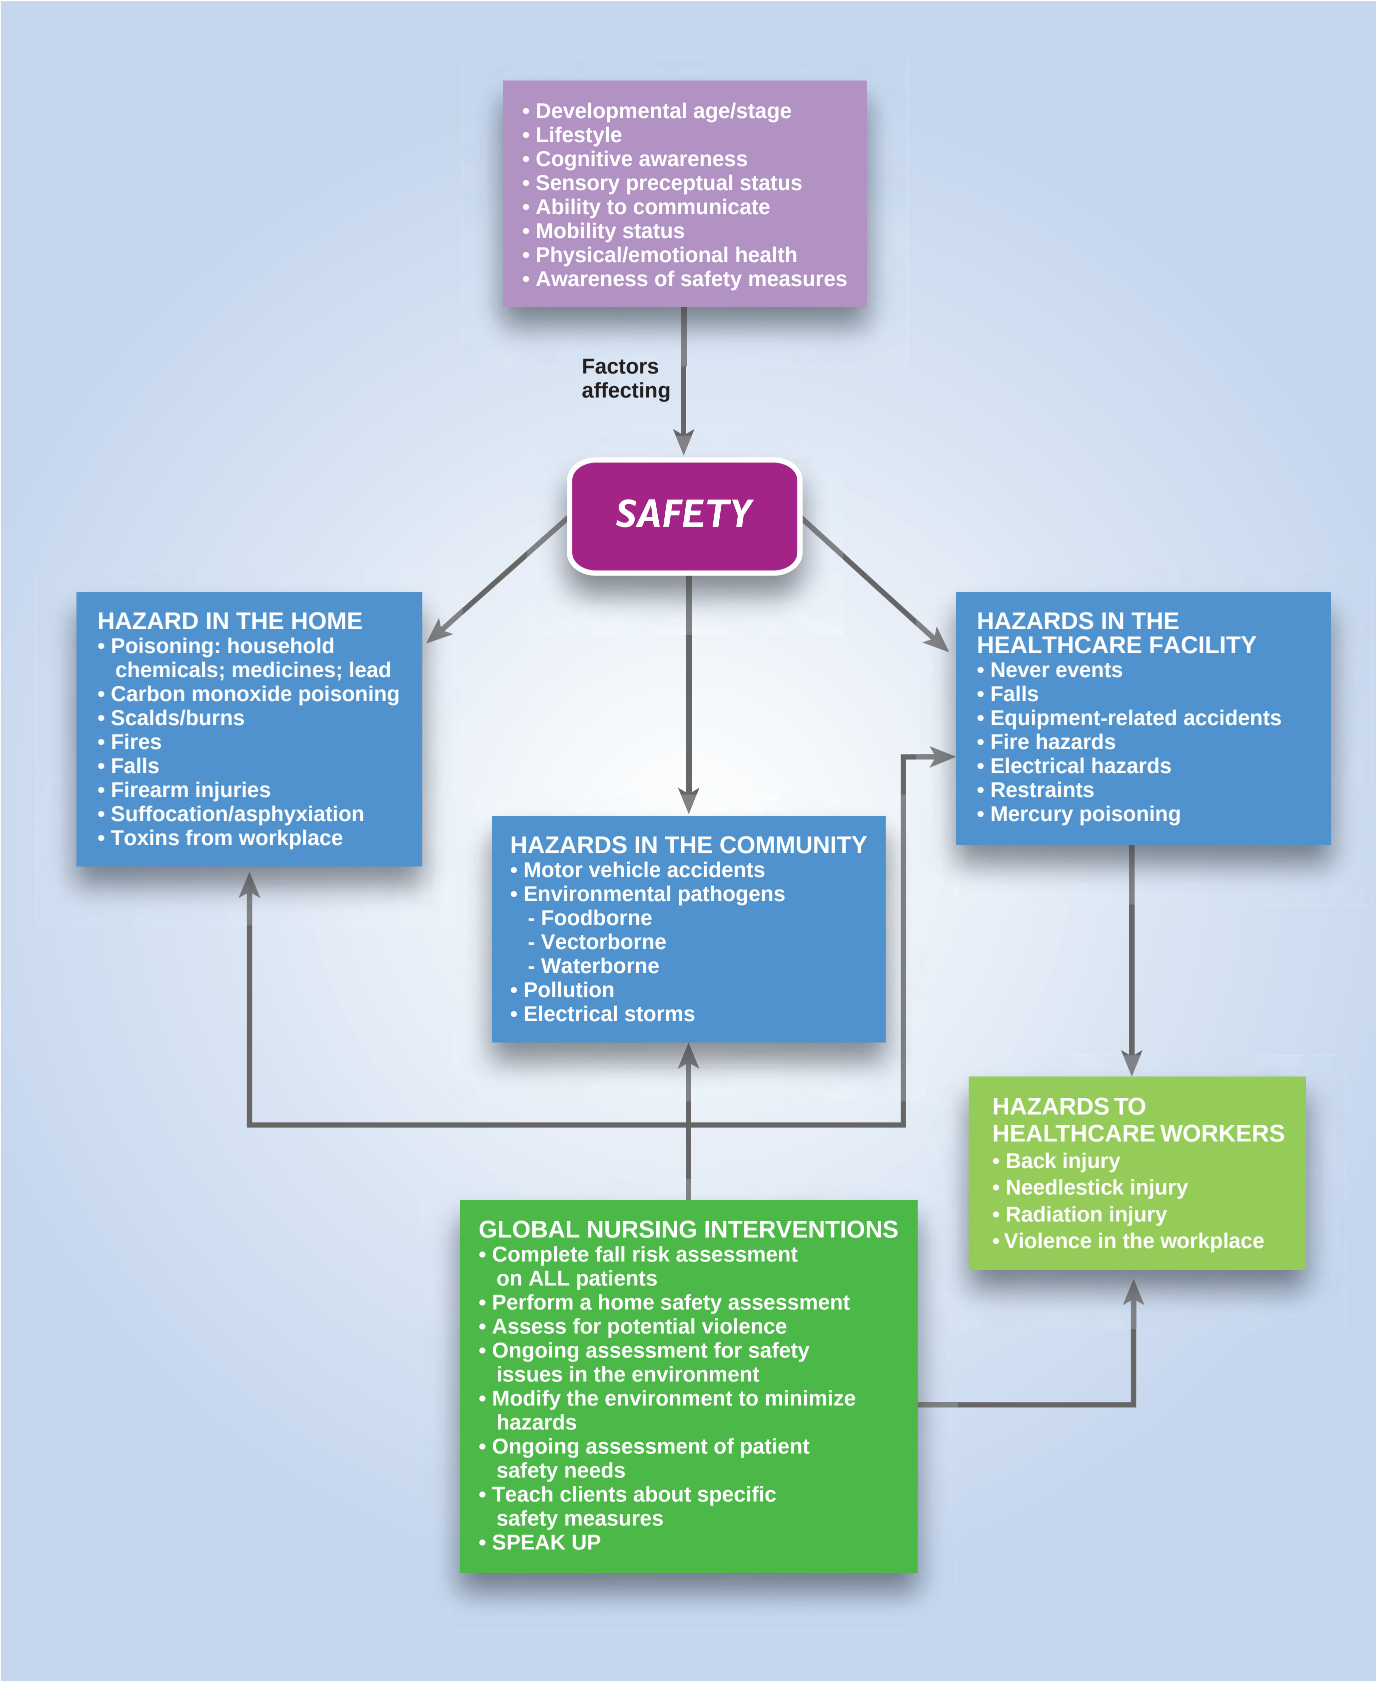
2. Recall Alvin Lin (Meet Your Patients, in Volume 1), the 79-year-old man you were assigned to care for on your first day on the medical unit. The initial report you received was that he was alert and oriented, but you find that he is now confused and is becoming combative.
   a. What should be your first two priorities in this situation?
   b. What specific patient data do you need to determine what might have caused this change in behavior? How could you get that data?
   c. What alternatives to restraints might you consider?
3. A friend calls to tell you she thinks her 18-month-old daughter swallowed some of her sleeping pills. The child is very sleepy, and your friend is having difficulty arousing her. Your friend has ipecac in her medicine cabinet and wonders whether she should try to get her awake enough to take it.
   a. What is the first thing that you would recommend that the mother do?
   b. What is a major concern with inducing vomiting, given that you must assume from the mother that the child is very drowsy? What could go wrong if the child vomits?
   c. If the mother decides to take the daughter to the hospital instead of taking time to call the poison control center (PCC), what should you remind her to take with her?
4. An older couple has health problems and both are taking several medications. The husband has assumed care for himself and his wife, Ethyl, because Ethyl has been exhibiting confusion at times. He says he sometimes becomes overwhelmed with everything he has to do, and he is not sure that he always gives the medicine at the right times.
   a. What information do you need to know to be able to help with this situation? About the medications? About resources? How would you obtain the information?
   b. What suggestions can you make to help the husband organize the medications?
5. You are caring for a patient 12 hours after surgery following an abdominal hysterectomy for cancer. She asks you to help her to walk to a chair. You note that she has IV fluids infusing and is receiving opioids via a patient-controlled analgesia (PCA) pump. She states that she has not been out of bed since surgery and that she has just administered some medication and would like to get up while she has pain relief. You also notice that there is a Foley (indwelling urinary) catheter connected to a bedside drainage.
   a. What environmental factors could be safety hazards when this patient gets out of bed?
   b. What assessments and other interventions would help to ensure safe ambulation despite those obstacles?
6. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or promoting safety. Note that these are *not* to be merely definitions.

Environmental hazard	Choking rescue maneuver
Pathogens	Refrigeration
Poisoning	Mosquito control
Scald injuries	Rodent control
Falls	Reduce, reuse, recycle, respond
Teaching firearm safety to children	Back injuries
Pollution	Needlestick injuries
Radiation	Time, distance, and shielding
Restraint	Gang culture
Ambularm	Morse Fall Scale

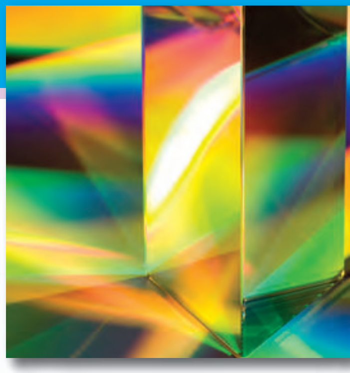
What Are the Main Points in This Chapter?

- Safety is a basic human need.
- Unintentional injuries are the fifth leading cause of death in the United States.
- Major causes of unintentional deaths in the United States are motor vehicle accidents, poisoning, and falls.
- The environment includes the physical and psychosocial factors that contribute to the life and well-being of each person. It may be identified as any setting where the nurse and client interact.
- A person's safety is influenced by developmental factors as well as individual factors, such as lifestyle, cognitive awareness, sensoriperceptual status, ability to communicate, mobility status, and sensory losses, particularly hearing and vision losses.
- The main safety hazards in the home are poisoning, carbon monoxide poisoning, scalds and burns, fires, falls, firearm injuries, suffocation and drowning, and take-home toxins.
- Most fatal home fires occur while people are asleep, and most deaths result from smoke inhalation.
- More than half of all falls occur in the home; about 80% involve people older than age 65.
- Community hazards include motor vehicle accidents, pathogens, improper sanitation, pollution (air, water, noise, and soil), and electrical storms.
- Safety hazards in the healthcare agency include falls, equipment-related accidents, fires and electrical hazards, restraints, mercury exposure, and biological hazards.
- When possible, nurses should use alternative interventions instead of restraints.
- Medical prescriptions for restraints must be renewed at least every 24 hours.
- Workplace hazards to nurses include back injuries, needlestick injuries, radiation injury, and violence.
- All inpatients should be assessed for their risk for falls.
- Identifying anxiety may allow the nurse to intervene before a patient becomes aggressive.
- The Heimlich maneuver differs from the American Red Cross choking rescue maneuver in that the Heimlich does not include back blows.
- Nursing interventions for promoting safety in the home focus on client teaching.
- Nursing interventions for promoting safety in the healthcare facility focus on assessing for risk and creating a safe environment.

Knowledge Map



CHAPTER 25



Facilitating Hygiene

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 25:

- **Response sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Facilitating Hygiene (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, **Chapter 25, Podcast—Chapter Overview,** on Davis *Plus.*

Caring for the Nguyens

Yen Nguyen works as a preschool teacher. She schedules a clinic visit to discuss a variety of concerns. For each of the concerns she mentions, answer the following four questions:

1. What theoretical knowledge do you need?
2. Where could you find it?
3. What, if any, additional patient information do you need?
4. How would you respond to Mrs. Nguyen's concerns?

(Continued)

Caring for the Nguyens (continued)

A. Yen tells you that her skin is very dry and irritated.

B. Yen tells you that several of the children at the preschool have recently been diagnosed with head lice. She would like to know how to assess for pediculosis.

C. Yen tells you that her 3-year-old grandson, Kim, frequently refuses to bathe. She asks for advice on how to handle this.

PracticalKnowledge knowing how

The following procedures and techniques provide the practical knowledge you will need to assist patients with personal cleanliness and grooming. As a nurse you are responsible for providing the necessary assistance and, at the same time, promoting as much self-care as possible. Self-care in activities of daily living (ADLs) promotes increased activity, independence, and self-esteem.

This Practical Knowledge section also contains clinical insights for providing hygiene care and a guideline for assessing hygiene needs. For standardized language tables for Self-Care Deficits and other nursing diagnoses related to hygiene,

Go to Chapter 25, **Standardized Language,** on Davis *Plus.*

PROCEDURES

Procedure 25-1 ■ Bathing: Providing a Complete Bed Bath Using a Prepackaged Bathing Product

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Prepackaged bathing product with disposable wipes (e.g., Comfort Bath)
- Bath blanket
- Clean patient gown (with shoulder snaps or Velcro closures if the patient has an IV line)
- Clean bed linen
- Orangewood stick
- Deodorant, lotion, and/or powder as needed
- Emollient (if not included in prepackaged bathing product)
- Procedure gloves (for anal and perineal care)
- Bedpan or urinal
- Laundry bag
- Plastic trash bag for used wipes and other disposable soiled items

Delegation

You can delegate this procedure to the NAP if you conclude that the patient's condition and the NAP's skills allow. Perform the following assessments, and inform the NAP of the specific type of bath (e.g., packaged bath, bag bath) and the amount of help the patient needs. Inform the NAP of any special considerations, such as IV lines, drains, and so on. Ask the NAP to report the condition of the patient's skin, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- Assess mobility, activity tolerance, type of bath needed, and level of ability to perform bathing self-care.

A patient who has decreased activity tolerance or mobility (e.g., chest pain or shortness of breath with exertion) may have limited ability to assist with the bath. Having the patient assist as much as possible increases mobility and sense of control and comfort.

- Check for positioning or activity restrictions (e.g., maintaining hip abduction following a total hip replacement).
  Prevents injuring the patient during the procedure.
- Determine the number of people you need to safely bathe and reposition the patient.
  Helps prevent injury to the patient or the nurse.
- Assess for personal and cultural issues that may be of concern to the patient regarding the bath.
  Bathing may conflict with the patient's sense of privacy or modesty. Cultural norms and individual preferences must be considered.
- Assess for specific patient needs and preferences during a bath, such as lotions and extra wipes or towels.
  Advanced age, certain skin conditions, or skin breakdown may require special soaps and/or lotions. Incontinence or drainage may require additional wipes, towels, and precautions. Meeting patient preferences helps prevent depersonalization and promotes patient cooperation with the procedure.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* You may find that you need to adapt the bathing order and other steps to meet individual needs.

Procedure Steps

1. **Provide for patient privacy** and comfort.
   a. Close the door or privacy curtains, adjust room temperature, and assist the patient with elimination as needed.
   b. Ask the patient and family if they wish family members to assist with the bath.
   Assisting the patient with elimination before beginning the bath helps prevent interruptions during the procedure. Bathing practices differ among cultures and individuals, but are often private. The patient or family may wish to have a family member assist with the bath, or the patient may prefer that they leave the room.

2. **Peel open the label on the commercial bath** without completely removing it.
   Allows for steam to escape as contents heat without spilling the contents.

3. **Heat the package** in the microwave for no longer than 1 minute. The temperature of the contents should be approximately 105°F (41°C). This is controversial. Some references suggest, for safety, using the commercial bag bath at room temperature.
   Heating to 105°F (41°C) brings contents to a safe and comfortable temperature. This must be done with caution to prevent burning, especially in patients who have fragile skin.

If Using a Warmer Unit

You do not need Step 3 because the bags are always warm.

4. **Adjust the bed** to working height, lower the siderail nearest you, and position the patient supine close to the side of bed you will be working on.

   Raise the siderail before you leave that side of the bed.

   Prevents patient falls and keeps you from having to lean over the patient or reach across the siderail, which can cause back strain or injury.

5. **Remove the bedspread,** and spread the bath blanket over the top sheet; then ask the patient to hold the bath blanket in place while you remove the top sheet.
   Protects modesty and prevents chilling. If no bath blanket is available, you can use the top sheet in its place. However, if the sheet becomes damp, it may chill the patient.

Note: Before proceeding, assist the patient with oral hygiene as needed. See Procedures 25-6 and 25-7.

6. **Remove the patient's gown,** keeping the patient covered with the bath blanket. During the bath, expose just the part of the body you are bathing.
   Maintains the patient's modesty and prevents chilling.

Patient With an IV Line

The patient may be wearing a gown that has snap-open sleeves.

a. Some tubing systems include a needlefree 2-way connector that maintains a closed line even when you disconnect the tubing. In that case, you simply open the connection, remove the gown, and then reconnect the tubing. After the bath, follow the same procedure to place the clean gown on the patient.

b. If there is no 2-way, needlefree connector on the tubing, remove the gown first from the arm without the IV. Lower the IV container, and pass the gown over the tubing and the container, taking care to keep the container above the level of the patient's arm.
Keeps blood from backing up into the IV line.

c. Never disconnect this type of IV tubing connection; this breaks the sterile system and provides a portal of entry for pathogens.

(continued on next page)

Procedure 25-1 ■ Bathing: Providing a Complete Bed Bath Using a Prepackaged Bathing Product (continued)

d. Rehang the container; check the flow rate.
Manipulating the IV equipment may change the flow rate; flow rate must be maintained as prescribed.

e. After the bath, replace the gown by threading the IV equipment from inside the arm of the gown and onto the affected arm. Then place the unaffected arm through the other gown sleeve.

7. Don clean procedure gloves if exposure to body fluids is likely or if either you or the patient has any breaks in the skin.
Follows universal precautions; helps prevent transfer of microorganisms.

8. Wash the patient's face, neck, and ears.

a. Fold the wipe around the hand to make a mitt, tucking in loose corners.
Keeps loose ends from dragging across the skin. This is uncomfortable because loose ends cool quickly.

b. Wash the face using one wipe.

c. Use a different corner of the wipe to gently wipe each eyelid outward from the inner canthus.
Some wipes contain chlorhexidine gluconate (CHG) an antimicrobial, which can be irritating to the eyes and mucous membranes. Use pH-balanced prepackaged wipes for the face, or use gauze squares moistened with agency-approved water or normal saline. A major principle is cleaning from "clean to dirty" to prevent contamination of a cleaner area. The inner canthus is considered the cleanest area. Prevents moving debris toward the nasolacrimal duct, which is located near the inner canthus.

d. Wash the rest of the patient's face, neck, and ears.
Move sequentially through the bath to make it less tiring for the patient and more efficient for the nurse.

e. Allow areas to air dry. Do not rinse.
Prevents the emollient and surfactant skin protectants from being removed.

9. Discard each wipe after use.
Ensures following the "clean to dirty" principle.

10. Wash the patient's arms, using a new, clean wipe.

a. Fold the bath blanket off one arm at a time, and place a folded bath towel under the arm. Beginning with the patient's far arm, support the arm, and wash the arm from the hands upward using long strokes.
Long strokes increase circulation in the extremity. Washing from distal to proximal increases venous return from the periphery. Lifting the arm provides range of motion (ROM) to preserve joint mobility.

b. Continue to support the arm while washing the axilla.
Prevents potential injury to the joints. A sprain, subluxation, or dislocation of the joint can occur when an extremity is not properly supported, especially in older adults.

c. Allow the areas to air dry; do not rinse.
Prevents the emollient and surfactant skin protectants from being removed.

d. Apply deodorant and/or powder if desired.
Follow patient preferences whenever possible to increase feelings of comfort.

e. Clean under the nails with an orangewood stick as needed.

f. Repeat the preceding Steps 8a–d for the arm nearest you.

11. Wash the patient's chest, using a new clean wipe.

a. Cover the patient's chest with a bath towel, and lower the bath blanket to the patient's waist.
Maintains patient comfort and modesty.

b. For women, gently lift each breast to wash the skinfold if needed. Keep the chest covered between the wash and rinse.
Skinfolds are a source of odor and can become reddened and irritated because of skin-to-skin irritation and dampness from perspiration.

c. Cover to maintain privacy and warmth.

d. Allow the areas to air dry; do not rinse.
Prevents the emollient and surfactant skin protectants from being removed

12. Wash the abdomen, using a new, clean wipe.

a. Fold the bath blanket down to the perineal area, and cover the chest with a bath towel.

b. Wash the abdomen, including the umbilical area; allow to air dry. Pay special attention to skinfolds.
Perspiration and moisture do not evaporate well from skinfolds, predisposing them to maceration.

c. Cover the abdomen and chest with the bath blanket.
Prevents chilling.

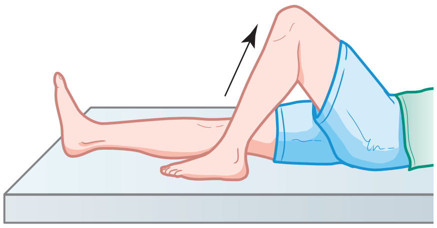
13. Wash the legs and feet, using a new, clean wipe for each leg.

a. Uncover one leg at a time, beginning with the leg farthest from you. Place the bath towel under the leg.
Keeps the sheet dry; prevents chilling.

b. Wash the leg from distal to proximal with long, gentle strokes. Allow the leg to air dry.

Do not massage the calves of the legs.

Washing from distal to proximal may help to promote venous return. If a venous thrombus is present, massaging might dislodge the clot and cause an embolus.



c. Thoroughly wash the foot and toes. Allow the foot to air dry. Apply lotion if the prepackaged bath product does not include emollient and as needed, but not between the toes.
Disease processes frequently decrease circulation to the feet and lower legs, increasing the likelihood that minor skin irritations may become more severe. Applying emollient between the toes can lead to skin breakdown.

d. Repeat the procedure on the other leg and foot.

14. Wash the back and buttocks, using a new, clean wipe.

a. Position the patient on his side with his back facing you, or in the prone position. Make sure the siderail on the far side of the bed, facing the patient, is still up.
Provides for clear visualization of back and access to the area.

b. Exposing only the back and buttocks, place the bath towel under the back and buttocks. Wash the back first and then the buttocks. Observe for redness and skin breakdown in the sacral area.
Maintains the principle of "clean to dirty." The sacral area is a common site of pressure sores.

c. Unless contraindicated, give the patient a back rub, applying lotion to the back and buttocks (see Chapter 34, Procedure 34-1: Giving a Back Rub).
Stimulates circulation and maintains the health of the skin. Because the patient is in bed, he is at risk for skin irritation and breakdown from immobility and friction. A back rub may be contraindicated for patients with musculoskeletal injuries or cardiovascular disease.

d. Don procedure gloves if you have not already done so, and wash the rectal area, removing any fecal matter with tissues before washing with the wipe. Wash from front to back.
Washing the rectal area at this time removes the need for the patient to turn to his side again and helps prevent soiling clean linen when changing the linen in an occupied bed. Fecal matter usually contains microorganisms. Washing from front to back helps prevent transferring bacteria from the rectum to the vagina and urethra.

e. Discard the soiled wipe. If linens are soiled, cover them with a clean sheet before repositioning the patient.

f. Remove soiled gloves and wash hands or use an alcohol-based handrub. Don new procedure gloves before providing perineal care.
Prevents transferring microorganisms from anal to genital area—cleansing the gluteal and anal areas contaminates the wipe. Maintains standard precautions during the bath and prevents soiling of clean linens during bed change and cross-contamination to other body sites.

15. Cleanse the perineal area. See Procedure 25-4: Providing Perineal Care.

16. After providing perineal care, reposition and cover the patient with the bath blanket. Remove soiled gloves and wash hands or use alcohol-based handrub. Help the patient put on a clean gown, and attend to other hygiene needs (e.g., hair grooming).
Prevents contaminating clean linen with soiled gloves. Ensures proper body position and warmth.

17. Change the bed linen as needed, including soiled linen or linen that became damp during the bath. See Procedure 25-14: Making an Occupied Bed.
Ensures patient safety, comfort, and privacy.

? What if . . .

- **You are bathing the patient without assistance, or you are not tall enough to comfortably reach across the patient?**

  These situations put you at risk for back strain. Thus, you may want to bathe one side of the body—that is, the right arm, trunk, right leg—and then move to the other side of the bed to bathe the opposite side of the body (instead of the order given in Steps 8 and 9). Move the patient close to you before beginning the bath.

- **You are bathing a patient in leg traction?**

  You may decide to bathe the arms and trunk first. Then have the patient sit forward so that you can cleanse his back. Then have the patient lift up slightly so that you can wash his buttocks. Finally, wash the lower extremities.

- **You are bathing a patient with dementia?**

  Use your knowledge of the person's bathing practices and preferences to determine a time of day and a routine the person will accept. Keep stimulation to a minimum. Turn on some calming music, speak softly and reassuringly, and don't rush. Keep the patient warm. If the patient becomes agitated and you cannot calm him, do not force him to bathe. You may wish to consider a towel bath (Procedure 25-2) for patients with dementia. Also refer to Clinical Insight 25-2.
  Many steps in the bathing process may be misinterpreted or stressful for the person with dementia and may present with disruptive or agitated behaviors. If forced to bathe, the patient may be upset for hours. Towel baths are effective hygiene measures.

(continued on next page)

Procedure 25-1 ■ Bathing: Providing a Complete Bed Bath Using a Prepackaged Bathing Product (continued)

- **Your patient becomes agitated and uncooperative during the bath?**

  Speak calmly and softly. Give the patient a few minutes to calm down. Discontinue the bath if the patient remains upset.

- **Your patient is an older adult?**

  a. Some clinicians recommend bathing older adults every other day instead of daily, and it is generally agreed that they should not bathe more than once a day unless soiling occurs.
  These help prevent skin dryness.

  b. Assure that the wipes are warm prior to use, but not hot.
  Prevents burns (older adults may have decreased sensation in their extremities).

  c. If you are not using a commercial packaged bath, use antibacterial soap or a mild soap substitute. If you must use soap, it should be non-perfumed and rich in moisture. If you use soap, rinse the skin well.
  To avoid skin irritation.

  d. Pat the skin dry or air dry; do not rub.

  e. Apply a moisturizer immediately after drying, while there is still moisture in the skin. Wash your hands before applying the moisturizer.

  f. Cleanse the skin immediately after every incident of soiling (e.g., when the patient has a bowel movement).
  Prevents maceration and irritation from enzyme activity.

Evaluation

- Assess how well the patient tolerated the procedure. Was there any discomfort, shortness of breath, and so on?
- Observe the patient's mobility, both ROM and ease of movement.
- Note the condition of the patient's skin, including redness and other abnormal findings, especially in skinfolds.
- Ask the patient whether he is comfortable and satisfied.
- If someone other than the nurse performs the procedure, the nurse must still evaluate the care to be certain that it was done and performed satisfactorily.

Patient Teaching

- Discuss the need for activity (e.g., moving about in bed) and the hazards of immobility.
- Discuss usual skin care and how to increase the health of the skin.
- Demonstrate bathing procedure to family or other caregivers.

Home Care

Note: Many of the following apply to older adults and others with self-care deficits.

- Evaluate the home for bathing safety considerations (not limited to bed bath), such as the following:

  Safety bars in the bathroom?
  To facilitate transfers and provide support while washing.

  A safe water supply for bathing?

  Bathing supplies that are available and accessible?

  Nonskid mat or abrasive strips for shower or tub?

  Stool for shower; transfer bench or stool for getting into the tub?

  Handheld shower spray?

  Long-handled brush or sponge?

- Assess the client's ability to help with the bath or to bathe independently.
- Ask how the client usually bathes (e.g., shower, at the sink). Follow the client's preference as much as possible.
- Ask what supplies the client usually uses for the bath, and ask where they are stored. You will need to adapt the procedure depending on the available equipment and supplies.
- Suggest the use of large plastic trash bags or a shower curtain to protect the mattress during a bed bath.
- Instruct caregivers to wear gloves when handling linens that are soiled with blood or other body fluids. Linens should be washed in cold water, separately from other household laundry, and then washed again, using hot water, detergent, and bleach.
  Hot water coagulates proteins in the blood and makes it more difficult to remove. Detergent and bleach are used to destroy pathogens.

Documentation

Chart the type of bath given, how much patient was able to help with the bath, how well the patient tolerated the procedure, the patient's mobility, and any abnormal findings. Hygiene care is charted on checklists and flowsheets in most agencies.

Sample electronic documentation

0630 complete bed bath given, pt. unable to assist in care. Patient tolerated procedure well, VSS, denied pain. Patient turned side to side with assist of one. Skin warm, dry and intact. Emollient applied to dry areas. Encouraged patient to shift weight while in bed to prevent injury to skin.
———————— K. Barnett, RN

(2008); Johnson, Lineweaver, & Maze (2009); O'Flynn, J. (2007); Powers, J., Peed, J., Burns, L., et al. (2012); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007); Sievert, D., Armola, R., & Halm, M. (2011).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Bathing: Providing a Complete Bed Bath Using a Prepackaged Bathing Product. Also go to Providing Perineal Care, Brushing and Flossing the Teeth, and Providing Foot Care.**

For questions and suggested responses,

Go to Chapter 25, **Thinking About the Procedure Questions and Suggested Responses,** on Davis *Plus*

Procedure 25-2 ■ Bathing: Providing a Towel Bath

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* Because the towel bath is a variation of the bed bath, only the steps differing from a bed bath are listed.

Equipment

- Large plastic bag containing a bath blanket (or a very large towel, about 3 ft × 6 ft), one standard bath towel, and two or three washcloths
- Dry bath blankets (two or more) and dry bath towels.
- Pitcher and approximately 2 qt (2,000 mL) of warm distilled, sterile or filtered water (105°F [41°C]), according to agency policy
- 30 mL of no-rinse liquid soap or commercial solution of soap, moisturizer, and disinfectant (preferably a CHG and water solution)
- Other supplies for a bed bath; see Procedure 25-1.

Delegation

You can delegate this procedure to the NAP if you conclude that the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments and inform the NAP of the amount of help the patient needs and any special considerations, such as IV lines and drains. Ask the NAP to report the condition of the patient's skin, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- Assess the patient's mobility and activity tolerance to determine whether she will be able to assist with the bath, whether a towel bath is appropriate, and the amount of help you will need.
  A patient with decreased activity tolerance or mobility (e.g., because of chest pain or shortness of breath with exertion) may have a limited ability to assist with the bath, making a towel bath the most appropriate choice. For severely compromised patients, having two nurses give the bath will make the procedure much quicker and less demanding on the patient.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Prepare the towel bag.**
   a. Prefold the bath blanket.
   Allows for organized application and ease of handling the blanket.
   b. Fill a large pitcher with 2,000 mL warm water (approximately 105°F [41°C]). Distilled, sterile, or filtered water is recommended (follow agency policy).
   Using tap water for bathing exposes patients to waterborne pathogens if biofilm is present in the water lines or faucets. This differs among agencies. The amount of water varies depending on the size of the bath blanket and bath towel. Use enough water to saturate them. Hot water can injure the patient and removes more of the skin's protective oils, but if the water is too cool, the patient may become chilled.
   c. Add 30 mL of no-rinse soap or commercial solution to the water according to the manufacturer's instructions.
   Adding a prescribed amount of soap to the water before pouring into the bag prevents excessive sudsing.
   d. Pour the about 2,000 mL of the solution into the bag, over the bath blanket, bath towel, and wash cloths. Ensure even distribution.
2. **If you do not plan to change** the linen, work one dry bath blanket under the patient.
   Protects the linen and provides warmth.
3. **Spread a dry bath blanket** over the patient; remove the patient's clothing, working underneath the blanket.
   Protects privacy and prevents chilling.
4. **Replace the dry blanket with** the wet blanket:
   a. Take the wet bath blanket or towel out of the bag, squeezing out excess water so that it does not drip.
   b. Push the dry bath blanket down to the patient's waist, and place the wet bath blanket on the patient's chest.
   c. Continue to unfold the wet bath blanket until it covers the patient, pushing the dry bath blanket out of the way as you do so.
   The wet bath blanket will feel warm and relaxing. You will use the dry bath blanket to dry the patient.
   d. If necessary, place yet another dry blanket on top of the wet one.
   This helps hold in the warmth if the patient is chilling or the room is cool.
5. **Bathe the patient**, beginning at the feet and working toward the head.

(continued on next page)

Procedure 25-2 ■ Bathing: Providing a Towel Bath (continued)

a. Keeping the patient covered, use the wet bath blanket to wash the legs, abdomen, and chest.
b. As you work, replace the wet bath blanket with the dry one.
Keeps the patient from chilling.

c. Fold the wet bath blanket as each area is bathed, allowing only clean surfaces to contact clean surfaces.
Prevents contamination of the clean side of the wet bath blanket.
d. Use one of the wet washcloths to wash the patient's face, neck, and ears.
Notice that this varies from the order of most baths, which proceed from head to toe. However, this is the most efficient way to accomplish a towel bath. It does not really compromise the "clean to dirty" principle because the legs, abdomen, and chest are usually equally "clean," and you are washing those before the back, buttocks, and perineum.

6. **Don procedure gloves.** Roll the client to one side, unfold the wet bath towel so the clean surface covers the patient, and use the wet bath towel to wash the back and then the buttocks.
7. **Remove procedure gloves,** wash your hands. Wash the perineal area with a washcloth. See Procedure 25-4: Providing Perineal Care.
8. **Finish the bath** as in Procedure 25-1. Follow patient preferences whenever possible to increase feelings of comfort.
9. **Change linen as needed,** including soiled linen or linen that became damp during the bath. You will almost certainly need to change the linen if you have not padded the bottom sheet well before the bath.
Ensures patient safety and comfort. Because the bath is finished rapidly, there is no real need to pad the bottom sheet if you know that you will have time to change the linens after the bath.

? What if . . .

- **Your patient becomes agitated and uncooperative during the bath?**
Speak calmly and softly. Give the patient a few minutes to calm down. Discontinue the bath if the patient remains upset.

Practice Resources

AACN (2013); Downey, L., & Lloyd, H. (2008); Flori, L. (2007); Joanna Briggs Institute (2007); Larkin, C. (2011); Warchol, K. (2013).

Procedure 25-3 ■ Bathing: Using a Basin and Water

Key Point: ***The potential exists (1) that bath basins can become a reservoir for microorganisms and for cross-contamination of the immediate environment and healthcare personnel and (2) biofilm is commonly present in hospital water lines and faucets. Use this method only when a patient is grossly contaminated or a patient refuses other types of bath.***

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2.

Equipment

- Disposable water basin for single-patient use
- Tap, distilled, filtered, or sterile water (depending on facility policy)
- CHG and water solution (for bathing the patient and cleaning the basin)
- Lotion, deodorant, and/or powder as needed
- Bath blanket
- Clean patient gown (gown with shoulder snaps or Velcro closures if the patient has an IV line)
- Clean linen
- Procedure gloves

Delegation

You can delegate this procedure to the NAP if you conclude that the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the amount of help the patient needs and of any special considerations, such as IV lines and drains. Ask the NAP to report the condition of the patient's skin, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

Assessments are the same as in Procedure 25-1: Bathing: Providing a Complete Bed Bath Using a Prepackaged Bathing Product.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Fill the disposable basin** with warm water (approximately 105°F [41°C]). Check the temperature with a thermometer or your hand. If possible, ask the patient to test the water temperature.

   Using tap water for bathing exposes patients to waterborne pathogens; use distilled, filtered, or sterile water if available. This differs among institutions, so follow agency requirements. Use water that is comfortable for the patient. Hot water removes protective skin oils and can injure the patient. If the water is too cool, the patient may become chilled.

2. **Prepare a solution** of 60 mL CHG solution diluted in 3 qt (2.85 L) of water for bathing the patient (Powers, Peed, Burns, et al., 2012).

   Evidence indicates that use of CHG is effective in preventing the bath basin from becoming a reservoir for microorganisms and in helping to prevent HAIs.

3. **Prepare the patient for the bath** as described in Procedure 25-1.
4. **Using one washcloth for each body area,** wash the patient following the sequence in Procedure 25-1. Rinse and wring water from the washcloth as you move from each body area.
5. **Rinse body areas as needed**, if you use soap, and pat dry.

   Preserves skin integrity by preventing the drying effect of the soap on the skin.

6. **Apply emollients** after the bath.

   Aids in preventing dry skin.

7. **Put used washcloths in the laundry** for future use.
8. **Help patient don a clean gown.**
9. **Provide a back rub**, if not contraindicated.
10. **Reposition patient**, as needed.
11. **Change linens**, as needed.
12. Clean and dry the basin.
    a. Wipe the basin with a paper towel and place upside down on a table to air dry.
    b. Label the basin for bathing only. Discard it if it becomes contaminated with vomit or other body fluids.
    c. Designate an additional basin for storage of bath supplies.

For Evaluation, Documentation, and Patient Teaching, see Procedure 25-1: Bathing: Providing a Complete Bed Bath Using a Prepackaged Bathing Product.

Practice Resources

Doughty, D., Junkin, J., Kurz, P., et al. (2012); Joanna Briggs Institute (2007); Larson, E., Ciliberti T., Chantler, C., et al. (2004); Ritz, J., Pashnik, B., Padula, C., et al. (2012); Rönner, A. C., Berland, C. R., Runeman, B., et al. (2010).

Procedure 25-4 ■ Providing Perineal Care

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Procedure gloves
- Prepackaged bathing product (i.e., Comfort Care)
- Bedpan or portable sitz tub (optional)
- Bath towel
- Toilet paper
- Plastic trash bag for used wipes and other disposable soiled items
- Perineal ointment or lotion if needed

If prepackaged bathing product is not available:

- Sterile, filtered, distilled, or tap water according to agency policy
- Disposable basin or perineal wash bottle, if needed
- Perineal cleansing solution or no-rinse soap
- Wash cloths

Delegation

You can delegate perineal care to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the amount of help the patient needs and any special considerations (e.g., presence of a urinary catheter, vaginal drainage). Ask the NAP to report the condition of the patient's perineum (skin, drainage), level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- Assess the patient's mobility and activity tolerance.

  Determine whether the patient will be able to assist with the perineal care. Doing as much self-care as possible increases the patient's sense of independence and maintains modesty .
- Check for positioning or activity restrictions, such as maintaining hip abduction following a total hip replacement.

  Prevents injuring the patient during the procedure.
- Assess for psychosocial issues that may concern the patient regarding perineal care.

  You must consider cultural norms to ensure that the perineal care is appropriate for the patient. For example, in some cultures a woman would find it completely unacceptable for a male nurse to perform her perineal care (pericare).
- Assess for any specific patient needs for perineal care.

  For example, if there are lesions or skin breakdown, you may need to use special soaps and/or lotions. Incontinence or drainage requires assessment and follow-up to prevent Impaired Skin Integrity.
- Assess for the presence of a urinary drainage catheter, perineal surgery, or lesions.

  You may need to adapt the procedure to clean around an indwelling urinary catheter or surgical incisions.

(continued on next page)

Procedure 25-4 ■ Providing Perineal Care (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Adjust the room temperature,** and assist with elimination as needed.
Assisting the patient with elimination before perineal care helps prevent interruptions during the procedure and allows for thorough cleansing. Adjusting room temperature prevents chilling.

2. **Warm the perineal bathing product.**

If Using a Microwave

Heat the package in the microwave for no longer than 1 minute. The temperature of the contents should be approximately 105°F (41°C). This step is controversial. Some references suggest, for safety, using the commercial bag bath at room temperature.

If Using a Warmer Unit

You do not need Step 2 because the bags are always warm.

3. **Prepare the patient.**
   a. Position the patient on her back (supine). Place waterproof pads under the patient if they are not already in place. You may wish to place the patient on a bedpan or portable sitz tub, especially if the perineum is grossly soiled. Place a waterproof bag within reach to discard wipes.
   Placing the patient on a bedpan raises the hips to increase visualization and allows for more thorough cleansing. A bedpan also allows for using water when needed.
   b. Wear procedure gloves (and other protective wear as needed) when providing perineal care. If you are using a basin and water you may wear a procedure gown and goggles if you are concerned about splashing (e.g., if the patient is confused and may be unable to follow instructions).
   When providing perineal care there is a possibility of coming in contact with urine, vaginal secretions, or fecal material.
   c. Drape the patient to protect privacy.

For Female Patients

- Drape the bath blanket so that one point faces the patient's head (drape it in the shape of a diamond).
- Take one of the side points of the diamond, and wrap it around the patient's leg. Anchor the end of the blanket under the patient's foot.
- Repeat on the other leg with other point of the diamond.

- Fold the center lower point of the diamond up to expose the patient's perineum.

This draping technique covers the patient as much as possible, which helps maintain privacy and prevents chilling during the procedure. The patient can also relax her legs against the bath blanket.

For Male Patients

- Place the bath blanket over the patient's chest.
- Fold the bed linens down to expose only the patient's groin.

   d. Remove any fecal material with toilet paper.
   Prevents contamination of the perineum with feces, which can lead to bladder or incisional infections. If you are providing perineal care as part of giving a bed bath, you will have cleaned the anal area when the patient was in the lateral position.

4. **Wash the perineum,** using a warm wipe. In both males and females, cleanse the skinfolds of the groin area thoroughly. Examine the skin creases for redness or excoriation.

For Female Patients

Wash the perineum from front to back, using a clean portion of the wipe for each stroke. Cleanse the labial folds and around the urinary catheter, if one is in place.
Prevents contaminating the urethra with fecal material. Any fecal particles that are left can cause skin breakdown due to enzyme activity, and may increase the risk of a urinary tract infection because of the presence of Escherichia coli in the feces.

Male Patient

Retract the foreskin, if present, and gently cleanse the head of the penis using a circular motion. Replace the foreskin, and finish washing the shaft of the penis, using

firm strokes. Then wash the scrotum, using a clean portion of the wipe with each stroke. Handle the scrotum with care, because the area is sensitive.
To adequately clean the head of the penis in an uncircumcised male, you must retract the foreskin. After cleaning, replace the foreskin to prevent constriction and edema of the penis. Firm strokes may help to prevent an erection. Using a clean portion of the wipe for each stroke prevents fecal contamination of the urethra and perineum.

Detects and prevents excoriation in skinfold areas, where moisture accumulates.

5. **Allow body areas to air dry**; do not rinse.
Prevents the emollient and surfactant skin protectants from being removed.

6. **Discard each wipe after use**, or place on the waterproof pad to discard when finished.
Ensures following the "clean to dirty" principle.

7. **If perineal care is not being** done as part of the bath, also clean the anal area. Ask the patient to turn to the side, wipe the buttocks and anal area as needed.
Fecal contamination of the perineum can lead to urinary tract infections and skin irritation. Therefore, the anal area is cleansed last.

8. **Apply skin protectants** as needed. Powder only if the patient requests it.
If urinary or fecal incontinence is present, skin barriers may be used to prevent urine, feces, or other drainage from contacting the skin. This helps prevent skin breakdown. For female patients, powder is a medium for bacterial growth. In the presence of moisture, it also creates a paste, which irritates the skin.

9. **If the patient has an indwelling** catheter and if agency policy requires special catheter care, you will usually provide the care at this point. Don clean gloves before providing catheter care, and follow the agency's procedure. For more information about catheter care, see Clinical Insight 28-1: Caring for a Patient With an Indwelling Catheter.

10. **Reposition and cover the patient** with the bath blanket. Remove soiled gloves, discarding in a waterproof bag.
Prevents contaminating clean linen with soiled gloves.

11. **Change linen as needed**, including soiled linen or linen that became damp during perineal care.
Ensures patient safety, comfort, and privacy.

? What if . . .

- **The patient is unable to control bowel and/or bladder?**

  Gently cleanse the perineal/perigenital area after each incontinence/soiling and apply a moisture barrier according to agency protocols.
  Minimizing contact with irritants such as moisture, urine, and stool can decrease the development of incontinence-associated dermatitis.

  Use a spray, no-rinse cleanser and soft wipes.
  These aid in preventing irritation from friction, and reducing drying effects on the skin.

  Follow agency policy and use skin assessment tools (some geared particularly to perineal skin).

  Assess for signs of secondary infection in addition to irritation and report as needed.

  Consider bowel and bladder retraining and scheduling to reduce frequency of incontinence.

- **Your patient is postpartum?**

  Educate the patient about perineal care. Include the importance of handwashing before and after cleansing the perineum, measures to keep the perineum clean, frequent changing of sanitary pads, and checking for signs and symptoms of abnormal lochia. If the patient had an episiotomy, laceration, or tear, teaching should also include management of discomfort and signs of wound infection.

Evaluation

- Assess the patient's responses to the procedure. Was there any discomfort?
- Observe for difficulty with movement or ROM during the procedure.
- Note the condition of the skin, including redness and other abnormal findings.
- Ask the patient whether she feels comfortable now.

Patient Teaching

- Discuss adaptations to perineal care. For example, if the area is tender, (1) wash the area with warm moistened wipe after going to the bathroom, instead of using toilet paper; or (2) use a skin protectant on the area.
- Review the importance of handwashing after elimination.
- If appropriate, teach the caregiver how to provide perineal care, including the major concept of cleaning front to back ("clean to dirty"). Stress the importance of wearing gloves and washing hands.
- Advise women not to douche because it disturbs the balance of normal vaginal flora and can irritate or injure mucosal cells.
- Explain that scented and deodorant feminine hygiene products are not necessary for cleanliness and may even be harmful. Daily cleansing is the most effective means of odor control.

Home Care

- Evaluate the ability of the client or caregiver to provide perineal care.

(continued on next page)

Procedure 25-4 ■ Providing Perineal Care (continued)

- Determine the availability of supplies needed for perineal care.
- You will need to adapt the procedure depending on the available equipment and supplies. Major issues involved in perineal care in the home are the lack of clean water and/or linens. In some instances, you may need to use bottled water or boil water for the procedure. One option is to use prepackaged moistened towelettes to provide the care (e.g., Comfort Bath towelettes).

Documentation

Usually perineal care is part of routine hygiene care and is charted on a flowsheet. If you need to write a narrative note, chart that perineal care was given, any patient responses to the procedure, and the condition of the perineal area.

Sample documentation

8/16/16 1430 Perineal care given. Patient had no complaint of discomfort. No redness or discharge noted. ——————————— Nora Noyes, RN

Practice Resources

AACN (2013); Bliss, D., Zehrer, C., Savik, K., et al. (2006); Gray, M., Bliss, D., Doughty, D., et al. (2007); National Guideline Clearinghouse (NGC) (2006, revised 2011); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Providing Perineal Care.**

For questions and suggested responses,

Go to Chapter 25, **Thinking About the Procedure Questions and Suggested Responses,** on Davis *Plus.*

Procedure 25-5 ■ Providing Foot Care

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* This procedure describes foot care using a basin and water. It may also be done with prepackaged wipes, along with the bath.

Equipment

- Procedure gloves (if there are open lesions)
- Pillow (if procedure is done with the patient in bed)
- Disposable basin for water (distilled, sterile or filtered tap water, per agency requirement)
- Liquid no-rinse soap
- Bath towel and washcloth
- Waterproof pad
- Orangewood stick
- Toenail clippers and nail file
- Lotion or prescribed ointment or cream

Delegation

You can delegate foot care to the NAP if the patient's condition and the NAP's skills allow. For example, as a rule you should not delegate care if the patient has impaired peripheral circulation or foot ulcers. Perform the following pre-procedure assessments, and inform the NAP of the amount of help the patient needs and any special considerations (e.g., ability to sit in a chair). Ask the NAP to report the condition of the patient's skin and nails, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- As you assess the feet and toenails, compare findings for both feet.
- Assess bilateral dorsalis pedis pulses, capillary refill, skin color, and warmth. Compare right and left feet. Palpate pulses at the same time bilaterally to determine whether one side is weaker than the other.
  Decreased circulation to the feet increases the risk for tissue injury and infection. A variety of diseases can cause poor circulation. For example, cardiac or renal disease may cause pedal edema, which impairs circulation to the skin, and diabetes causes vascular changes leading to poor circulation to the lower extremities.
- Assess for diseases (e.g., diabetes mellitus and peripheral vascular disease) that create risks for foot problems.
- Thoroughly assess all areas of the feet for skin integrity, edema, condition of toenails, and any abnormalities. Check carefully between the toes.
  Decreased circulation in the feet commonly causes such problems as thickened toenails, dry skin, and increased risk of infection. Changes in vision and mobility can increase the risk for injuries to the feet. Patients with diabetes also may have neuropathy, which prevents them from knowing when they have injured their feet. Identifying abnormalities enables you to provide interventions to help prevent potential problems.

- Check institutional policy to verify whether a nurse is allowed to trim nails. Obtain a primary provider's prescription for trimming the patient's nails, if necessary.
  Patients who have diabetes or impaired circulation to the lower extremities require a prescription for trimming their nails. Refer the patient to a podiatrist if the circulation is severely compromised or if edema would make the procedure difficult.
- Assess the patient's usual footwear.
  Improperly fitting shoes, especially if they are too tight, are a common cause of foot problems (e.g., bunions, ingrown toenails).
- Assess the patient's self-care ability to provide foot care. Evaluate the need for a referral. Determine whether the patient has the necessary vision and mobility to be able provide his own foot care.
- Assess the patient's knowledge about foot care, including usual foot care practices.

Identify potential deficits in understanding that may require additional teaching or referral to a podiatrist, general practice physician, or advanced practice nurse.
Many home remedies for foot problems can damage the tissue. For example, corn pads can increase pressure on the tissue, compromising circulation and causing local tissue ischemia. Cutting the sides of the toenails can lead to ingrown toenails.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

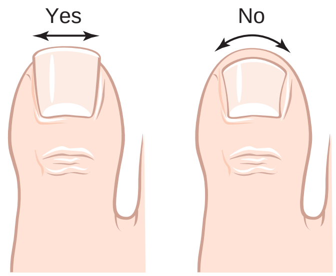
1. **Wear procedure gloves** and other protective wear as needed when providing foot care.
   Follows standard precautions. The heel is a common place for skin breakdown, so use gloves if you are unable to see the area without lifting the foot. If the patient has significant drainage to the area, such as a draining wound, you may need to wear a protective gown.
2. **Ask the patient to sit in a chair** with a waterproof pad or bath towel under the feet, if possible. If the patient is unable to sit in a chair, place him in semi-Fowler's position in bed; place a pillow under his knees.
   It is easier to perform the procedure with the patient in a chair. The pillow supports the knee joints and prevents muscle fatigue.
3. **Fill the basin halfway** with warm water (approximately 105°F to 110°F [40°C to 43°C]).
   Recent research recommends the use of filtered, distilled or sterile water. Using tap water for bathing exposes patients to waterborne pathogens that may be contained in biofilm in water lines and faucets. Hot water can injure the skin. Warm water promotes circulation. Filling the basin halfway prevents spilling when the patient places his foot in the water.
4. **Help the patient place one foot** in the water, first checking with the patient that the temperature is comfortable.
   a. If the patient is in a chair, place the basin on the floor (on the waterproof pad).
   b. If the patient is in bed, place the basin near the foot of the bed on the waterproof pad; pad the basin with a towel.
   The waterproof pad keeps the bed dry. Padding the basin prevents pressure on the back of the leg, which could cause discomfort and interfere with circulation.
5. **Allow the foot to soak** for 5 to 20 minutes, depending on the patient's tolerance and the condition of his feet.
   Soaking is not recommended for patients with diabetes or peripheral vascular disease (PVD).
   Soaking softens the skin and helps relax the patient. For patients who have diabetes or PVD, soaking is not recommended because it may remove natural oils, cause cracking of the skin, and may cause burns even if the water is at the recommended temperature.
6. **Cleanse the foot** with mild or no-rinse soap.
   Removes loose debris. No-rinse soaps do not dry the skin.

7. **Clean under the nails** with the orangewood stick while the foot is still in the water.
   Water softens the nails and makes cleaning easier.
8. **Remove the foot from** the water, and dry it gently and thoroughly.
   Remaining moisture, especially between the toes, can cause maceration and promotes development of fungal infections.
9. **Change the water.**
   Ensures proper temperature and prevents cross-contamination.
10. **Soak the opposite foot** while performing Steps 11 through 14 for the first (clean) foot.
    Saves time.
11. **Gently push the cuticles back** with the orangewood stick or towel.
    Increases cuticle health. Do not damage the cuticle; doing so can increase the risk of infection.
12. **Trim the nails straight across** with toenail clippers, if not contraindicated by the patient's condition and if permitted by agency policy. Note whether the nail has cut into the skin of the toe being trimmed or the adjacent toes. If the nails are brittle or thick, allow the foot to soak for 10 to 20 minutes before trimming.
    Trimming straight across prevents ingrown toenails. Early recognition

(continued on next page)

Procedure 25-5 ■ Providing Foot Care (continued)

and treatment of problems will prevent further complications, such as infection.



13. File the nails with an emery board.
Smooths the edges to prevent scratching the skin with the toenails.

14. Apply cream, lotion, or foot powder lightly to the feet and toes.
Cream hydrates the skin; however, excess cream can cause maceration. Foot powder absorbs moisture and functions as a nonirritating deodorant for patients whose feet perspire heavily.

15. Repeat Steps 11 through 14 with the second foot.

16. Check the patient's footwear for rough edges that may injure feet.

? What if . . .

- **My patient has Impaired Bed Mobility?**

  Apply protective devices (e.g., lamb's wool) as needed.

- **My patient has an injury, lesions, or pain?**

  You may need to use a bed cradle to keep the pressure of the bedding off the patient's feet. Refer to Chapter 35 for other measures to preserve skin integrity.

- **My patient has diabetes mellitus?**

  In addition to controlling blood glucose levels, adhering to a specific foot care plan is essential for people with diabetes. Include the following in your teaching:
  - The importance of inspecting the feet daily
  - Ways to protect the feet (e.g., by wearing shoes when out of bed)
  - Potential complications involving the feet
  - Management of symptoms
  - When to seek advice from a healthcare professional
  - What to include in the foot care regimen (apply moisturizing lotion on tops and bottoms of feet but not between toes)—and what not to do (cut corns and calluses, use topical corn removers, or soak the feet)

Elderly patients with diabetes are especially at risk for development of foot-related complications. Visual changes and loss of flexibility could make it challenging to bend and visualize the feet. Plastic mirrors may be helpful in this regard.

Early detection and treatment of problems can minimize foot-related complications.

Evaluation

- Observe that feet are clean, smooth, and intact; nails are trimmed and smooth; skin is pink and warm.
- Be sure that foot problems are identified and interventions provided.
- Ask the patient to demonstrate or describe correct foot care.

Patient Teaching

For patient teaching,

Go to the **Self-Care box, Teaching Your Client About Foot Care,** in Volume 1.

Home Care

The procedure does not vary in the home. The nurse must:

- Work with the client and care provider to determine the availability of supplies needed for foot care (clean water and so on).
- Identify home care practices, and teach the client and/or caregiver proper foot care techniques. Influencing older adults can be especially difficult if they have usual routines, such as walking barefoot, that put them at risk for injury. For clients with diabetes, the biggest risk to foot health is inadequate regulation of their blood glucose levels.

Documentation

In most agencies you will not document routine foot care (except, perhaps, on a checklist) unless there are problems. If you do document, chart that foot care was given, and chart assessment findings.

Sample documentation

09/25/16 0900. Foot care given. 2 cm circular reddened area on right heel. Skin abrasion outer lateral aspect of 5th toe, left foot —bioocclusive dressing applied.
————————————————Ann Hopkins, RN

Practice Resources

AACN (2013); NGC (2008); Plummer, E., & Albert, S. (2008); Powers, J., Peed, L., et al. (2012); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Providing Foot Care.**

For questions and suggested responses,

Go to Chapter 25, **Thinking About the Procedure Questions and Suggested Responses, on DavisPlus.**

Procedure 25-6 ■ Brushing and Flossing the Teeth

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Toothbrush or sponge toothettes
- Toothpaste
- Dental floss (two pieces, each about 10 in. long) and floss holder (optional)
- Tonsil-tip suction connected to suction source (if aspiration is a concern)
- Emesis basin
- Towel
- Glass of water (distilled, sterile or filtered water, according to agency requirements)
- Mouthwash and/or lip moisturizer, if desired
- Procedure gloves; mask and goggles if splashing may occur

Delegation

You can delegate oral hygiene to the NAP if the patient's condition and the NAP's skills allow. Perform the following assessments, and inform the NAP of the specific type of oral care and the amount of help the patient needs. Ask the NAP to report the condition of the patient's mouth, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- Assess the patient's ability to assist with oral care.
  Having the patient assist whenever possible promotes independence and supports a positive self-image.
- Determine whether the patient has dentures, bridgework, or partial plates.
  Determines how you will provide oral care.
- Assess general oral health, including gag reflex and the condition of the teeth, gums, and mucous membranes. If a patient has dentures, examine the mouth with and without the dentures.
  If the patient has a hypoactive or absent gag reflex, you will need a suction setup to prevent aspiration. Inflammation or lesions in the mouth increase the patient's risk of infection and may make eating difficult or painful, leading to malnutrition. Poorly fitting dentures can cause irritation of the gums.
- Assess the patient's usual oral care, including cultural practices.
  Helps determine the type of oral care you will provide and identifies areas of patient teaching needed.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Position the patient** in a high-Fowler's position or in a chair, if possible. Position the patient on her side if the head of bed cannot be elevated.
   Prevents aspiration and makes the procedure easier.
2. **Set up suction**, if needed. Attach suction tubing and tonsil-tip suction; check suction.
   Suctioning equipment may be needed to prevent aspiration of secretions during the procedure, especially if the gag reflex is decreased.
3. **If the patient is able to perform self-care:**
   a. Arrange supplies within the patient's reach.
   Promotes the patient's ability to do self-care and therefore independence.
   b. Assist the patient with brushing and flossing as needed.
   Ensures that the teeth are thoroughly cleaned.

For Nurse-administered Brushing and Flossing,
Follow the remaining steps.

4. **Place the towel across** the patient's chest.
   Prevents getting the patient's gown or linen wet during the procedure.
5. **Don procedure gloves** as needed. Wear gown and goggles if splashing might occur, such as with a confused patient.
   Follows standard precautions.
6. **Adjust the bed to working** height; lower the siderail nearest you.
   Prevents you from having to lean over the patient or reach across the siderail, possibly causing back strain or injury.
7. **Moisten a small, soft toothbrush**, and apply a small amount of toothpaste. See Equipment for type of water to use.
   A small toothbrush fits more easily into the mouth and reaches more areas. The soft bristles can be used to brush the tongue and also the gums if the patient is edentulous. Excessive toothpaste does not increase the cleaning, and toothpaste residue has a drying effect on the mucosa. Moistening the toothbrush increases patient comfort because patients frequently have a dry mouth.
8. **Place, hold, or ask the patient** to hold the emesis basin under the chin.
   Collects oral secretions and protects clothing and linens.
9. **Brush the teeth**, holding the bristles at a 45° angle to the gumline.
   a. Using short circular motions, gently brush the inner and outer surfaces of the teeth, from the gumline to the crown of each tooth.
   b. Brush the biting surface of the back teeth by holding the brush bristles straight up and down to the teeth and brushing back and forth.
   This is the most effective technique for removing all food particles and plaque from the teeth and gums. Removing debris and subsequent plaque helps to decrease microbial colonization.

(continued on next page)

Procedure 25-6 ■ Brushing and Flossing the Teeth (continued)

c. If the patient is frail, perform oral suctioning when fluid accumulates in the mouth.
Prevents choking and aspiration.

Brush teeth, holding bristles at a 45° angle to the gumline. Using short circular motions, gently brush the inner and outer surfaces of the teeth, including the gumline.

Clean front teeth.

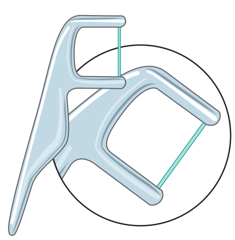
Clean both inner and outer surfaces of the teeth.

Brush the biting surfaces of the back teeth with the brush bristles straight up and down.

Brush the surface of the tongue.

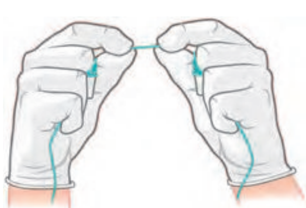
10. Gently brush the patient's tongue.
Removes coating and accumulated debris that can be a reservoir for bacteria. Brush gently to prevent gagging or vomiting.

11. Floss the teeth. Grasp dental floss in both hands, or use a floss holder.



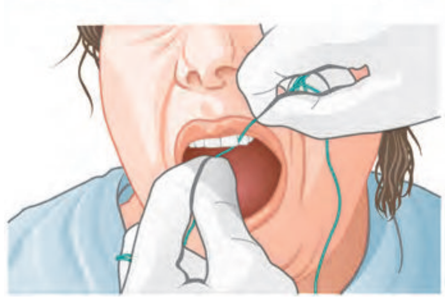
If you are not using a floss holder

a. Wrap one end of the floss around the middle finger of each hand.



b. Stretch the floss between your thumbs and index fingers, and move the floss up and down against each tooth.

c. Floss between and around all teeth.
Moving the floss up and down instead of back and forth prevents damaging the gums.



12. Assist the patient in rinsing his mouth, suctioning as needed. Or, ask the patient to rinse vigorously and spit the water into the emesis basin.
Removes food particles from mouth. Suction if the patient has a decreased or absent gag reflex.

Key Point: ***Recent studies recommend that hospitalized patients at high risk for infection avoid exposure to hospital water and use distilled, sterile, or filtered water instead (follow agency policy).***

13. Offer a mild or dilute mouthwash, and apply lip moisturizer, if desired.
Prevents irritation of the mucous membranes. Apply lip moisturizer for dry lips, for unconscious patients, or those on a ventilator, or per patient preference.

14. Reposition the patient as needed and return the bed to the low position.
Ensures patient comfort and safety.

? What if . . .

- **My patient has an excessively dry oral cavity?**

  You may need to use a saliva substitute.
  Aging, adverse medication effects, and illness often lead to decreased salivary production.

- **My patient has viscous (thick) mucus?**

  Use appropriately diluted sodium bicarbonate to dissolve viscous mucus.

- **My patient has a high risk of gum bleeding (e.g., such as associated with thrombocytopenia), has painful mouth lesions, or toothbrushing is otherwise contraindicated?**

  You may use foam or cotton mouth swabs instead of a toothbrush. Do not use glycerin swabs, lemon glycerin swabs, or gauze squares. Use normal saline mouthwash.
  Foam swabs are less effective in removing debris and plaque, so it is best to brush when not contraindicated. Lemon glycerin swabs are drying to the mucosa and may cause decalcification of tooth enamel. Mouthwashes may be painful.

- **My patient has dementia or is uncooperative and agitated for other reasons?**

  Use dementia-focused behavior management strategies:
  Older adults with dementia frequently accumulate greater amounts of plaque and calculus, exhibit a higher incidence of periodontal gingival bleeding, and demonstrate a greater prevalence of denture-related oral mucosal lesions, yet they often resist oral care.

  - Provide oral hygiene at the same time every day, not necessarily at bathing time.
  - Use as many staff members as necessary.

- Give care in a quiet, distraction-free environment. Keep stimulation to a minimum, turn on some calming music.
- Speak softly; give one-step directions in short, simple sentences.
- Use a relaxed, slow approach; be sure your facial expression does not reflect tension.
- Give reassuring body contact and use gentle touch.
  Promotes trust. Quick or forceful touch may frighten the patient.
- Provide diversion.
  Occupies the patient's hands and prevents "grabbing."
- Never place your fingers between the teeth.
- Try placing a spare toothbrush or a rolled facecloth in the patient's hands while you provide oral care.
Minimizes "grabbing."
- Use the "hand over hand" technique to gently guide the patient's own hand.
- Try starting the task (e.g., brushing), then having the resident help finish it.
- If the procedure is not going well, find another caregiver to come in and attempt the task.
- Use modified equipment and aids, if available (e.g., mouth props, backward-bent and suction toothbrushes).

- **My patient is on a ventilator, is a frail older adult, or has undergone cardiac surgery?**

  Be certain the teeth are brushed twice a day.
  In addition to brushing, use moisturizer on lips and oral mucosa every 2 to 4 hours.
  Apply a 0.12% chlorhexidine gluconate solution twice daily to complement oral care.

- **My patient is receiving chemotherapy?**

  Stress the importance of good oral hygiene, including brushing the teeth after meals and before going to bed.
  Chemotherapy can cause neutropenia (reduced white blood cell count), predisposing the patient to infections. The oral cavity is a common site for infections in patients with neutropenia.

  Routine rinses of mouthwashes with chlorhexidine are not recommended. Instead, use a bland rinse of diluted salt and/or sodium bicarbonate. Patients should swish for a minimum of 30 seconds and then expectorate the residue.
  Chlorhexidine products have not proved superior to bland rinses in preventing or reducing either chemotherapy/radiation-induced mucositis or yeast colonization. In addition, chlorhexidine products may contain alcohol, may cause discomfort, may alter taste sensations, and may stain teeth. Bland rinses containing 1 teaspoon of salt or sodium bicarbonate per pint of water reduce the acidity of oral secretions, lessen mucus accumulation, and discourage yeast colonization.

  An antifungal agent or a multiagent rinse (sometimes labeled "magic" or "miracle" rinse) may be used, followed by a short NPO period of 30 to 60 minutes. If other mouthwashes or rinses are also being used, allow 30 minutes to pass between their use and the use of an antifungal agent.

  Multiagent rinses typically contain lidocaine. The resulting numbing effect may pose risks for a biting injury or aspiration. These rinses can neutralize antifungal agents.

Evaluation

- Inspect the teeth, gums, and mucous membranes to verify that they are free of food particles.
- Inspect for abnormalities, such as bleeding, that may have been stimulated by the brushing or flossing.
- Observe for patient discomfort or gagging during the procedure.
- If the procedure was performed by the NAP, the nurse should still perform an evaluation of the care. This includes a physical assessment of the oral cavity as well as objective and subjective findings related to the patient's tolerance of and satisfaction with the care.

Patient Teaching

- Discuss the importance of daily oral care.
- Review any areas of brushing or flossing that the patient has not been performing adequately.
- Discuss any problems that need further follow-up, such as inflammation, bleeding, dryness, caries, missing teeth, or broken or missing dentures.

Home Care

The procedure does not vary in the home. The nurse must:

- Work with the client and care provider to determine supplies needed for the home.
- Determine whether suction is needed (e.g., if the client is unconscious or has a decreased gag reflex). Explain to the client and/or caregiver how to obtain a portable suction unit.
- Demonstrate how to position the client and perform the procedure if the height of the bed is not adjustable or if both sides of the bed are not accessible.

Documentation

Document that oral care was given, the patient's response, any abnormal findings, and nursing interventions. Oral care is usually charted on a flowsheet.

Sample documentation

mm/dd/yyyy 0815 *Oral care given. Mucous membranes intact, pink, and dry. No choking or complaints of discomfort. Patient encouraged to increase fluid intake.* —— Nancy Botha, RN

(2008); Joanna Briggs Institute (2004); Philip, P., Rogers, C., Kruger, E., et al. (2012); Weening-Verbree, L., Huisman-de Waal, G., van Dusseldorp, L., et al. (2013).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Brushing and Flossing the Teeth.**

For questions and suggested responses,

Go to Chapter 25, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 25-7 ■ Providing Denture Care

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- See Procedure 25-6: Brushing and Flossing the Teeth.
- Denture cup

Delegation

You can delegate denture care to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the specific care and the amount of help the patient needs. Ask the NAP to report the condition of the patient's mouth and dentures, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

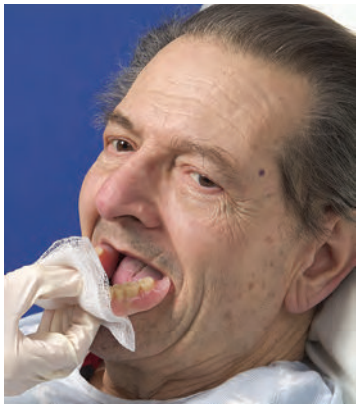
See Procedure 25-6: Brushing and Flossing the Teeth.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don gloves, and remove** dentures (if the patient cannot do so).
   a. ***Upper denture:*** With a gauze pad, grasp the denture with your thumb and forefinger, and move it gently up and down. Tilt the denture slightly to one side to remove it, without stretching the lips. Place the denture in the denture cup.
   The gauze gives you a better grip. Breaking the seal on the top dentures can be difficult; movement breaks the suction. Always place dentures in a denture cup as soon as you remove them to prevent accidental breakage.

   b. ***Lower denture:*** Use your thumbs to push up gently on the denture at the gumline to release from the lower jaw. Grasp the denture with your thumb and forefinger, and tilt it to remove it from the patient's mouth. Place the denture in the denture cup.
   A gauze pad is not usually needed to grasp the lower dentures; however, you can use one if the dentures are difficult to grasp. Pushing up on the dentures breaks the seal. Rotating the dentures is necessary to remove the dentures from the patient's mouth.



2. **Place the towel in the sink**, and pour cool water over the dentures to cleanse them. Follow agency policy for type of water to use.
   Heat can damage some dentures. The towel helps prevent the dentures from breaking if they are accidentally dropped. Dentures are expensive and usually not reimbursed by insurance. Institutions vary with regard to the existence of biofilm in the water lines.
   c. Apply a small amount of special denture paste to a soft-bristled toothbrush.
   Denture paste assists in cleaning. Toothpaste and stiff-bristled brushes may be too abrasive for dentures. However, follow the patient's preference in use of denture cleaner. Some patients prefer to soak their dentures in a cleanser overnight. If dentures have been soaking, rinse them well before placing them in the patient's mouth.
   d. Brush all surfaces of each denture.
   Loosens all food particles and any old denture adhesive.

e. Rinse thoroughly with cool water.
Removes loosened particles and the cleaning agent. Do not use hot water with dentures, because hot water can react to make the denture material sticky. Hospitalized patients at high risk for infection should avoid exposure to hospital water and use distilled sterile or filtered water instead.

Note: You can soak stained dentures in a commercial cleaner, following the manufacturer's instructions. Do not soak the denture overnight if the appliance has metal parts.
Soaking can cause corrosion of the metal parts.

3. **Inspect dentures** for rough, worn, or sharp edges.
These can irritate the tongue, gums, or mucous membranes of the mouth.

4. **Inspect the mouth** under the dentures for redness, irritation, lesions, or infection.
If present, refer to a dentist to check the fit of the dentures or to make needed repairs.

5. **Apply denture adhesive** as needed (ask the patient whether he uses denture adhesive).
Adhesives are needed to "seal" some dentures and prevent slipping and irritation of the gums.

6. **Moisten the top denture**, if it is dry. Then insert the top denture, at a slight tilt, and press it up against the roof of the mouth.
Moistening the dentures eases insertion. You can tell when you have securely seated the dentures by checking to feel for any slippage or to confirm that the dentures stay in place. Because the top denture is larger, it is removed first and inserted first for ease of insertion.

7. **Moisten the bottom denture**, if it is dry. Then insert bottom denture, rotating it as you put it in the patient's mouth.
Because it is smaller, the bottom denture is inserted after the top one.

8. **Ask the patient whether** the dentures are comfortable.
Ensures that the dentures are properly placed.

9. **If the patient does not wish to** wear the dentures, cover them with water in a clean denture container with a lid. Label the container with the patient's name and the agency identifying number. Place denture container in bedside drawer rather than on top of bedside table for safekeeping.
Drying can cause dentures to warp. Hospitalized patients at high risk for infection avoid exposure to hospital water and use sterile water instead. Having the denture out of the mouth for several hours a day relieves pressure on the oral tissues, allows saliva to clean the tissues, and helps to minimize gingival irritation.

10. **Offer mouthwash.**

? What if . . .

- **My patient develops Candida-related denture stomatitis?**

  Follow agency protocols. Microwave disinfection of complete dentures has been documented as an effective treatment of *Candida*-related denture stomatitis and can reduce the recurrence of infections.
  Denture stomatitis ranges in severity. Treatment includes good oral and denture hygiene and administration of antifungal agents. Recurrence of infection after treatment can be due to colonization of Candida on the dentures.

Evaluation

- See Procedure 25-6: Brushing and Flossing the Teeth.
- Check to see that dentures are comfortable and fit properly.

Other

For Documentation, Patient Teaching, and Home Care, see Procedure 25-6: Brushing and Flossing the Teeth.

Procedure 25-8 ■ Providing Oral Care for an Unconscious Patient

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Toothbrush with soft bristles or sponge oral swabs
- Toothpaste
- Denture cup, if the patient has dentures
- 4 in. × 4 in. gauze pad to remove dentures if present
- Tonsil-tip suction connected to suction source (you may use a product that combines the toothbrush or oral swab with the suction device)
- Tongue blade (padded) or bite-block
- Towel
- Waterproof linen protector
- Disposable emesis basin
- Water-soluble lip moisturizer
- Procedure gloves and goggles

Source: Courtesy of Sage Products, Inc., Cary, IL.

Delegation

As a rule, you probably should not delegate oral hygiene for an unconscious patient to a NAP. However, in some situations it may be acceptable—for example, when the NAP has a great deal of experience caring for unconscious patients and when the NAP's ability to perform oral hygiene safely for them is documented. Perform the pre-procedure assessments, and inform the NAP of any special considerations for care (e.g., if the patient must have the head of the bed elevated to facilitate breathing). Ask the NAP to report the condition of the patient's mouth and the patient's ability to tolerate the procedure (e.g., ask the NAP to take vital signs before and after the procedure, or to note the oxygen saturation if it is being monitored).

Pre-Procedure Assessments

- Determine whether the patient has dentures or partial plates.
  The presence of these appliances determines how you will provide oral care. You may leave dentures out for an unconscious patient to decrease the risk that the dentures will be damaged or block the airway. However, when possible, keep the dentures in place to help ensure they will fit adequately later. Remove partial plates in an unconscious patient to prevent the plate from causing aspiration or damage to the mouth if it becomes loosened.
- Assess the patient's gag reflex.
  If the patient has an intact gag reflex, the risk of aspiration is lower.
- Assess the patient's general oral health, including the condition of the teeth and gums, and hydration of the mucous membranes. If the patient has dentures, examine the mouth with and without the dentures.
  Unconscious patients tend to breathe through the mouth, so oral mucosa are often dry. Because the oral mucosa acts as a barrier against microorganisms, inflammation or lesions in the mouth increase the risk for infection. The lips, gums, and mucous membranes should be pink, moist, and intact. The teeth should be intact and clean. The condition of the mouth determines what you will use to provide oral care. Assess the fit of dentures and the condition of the skin under the dentures to determine whether the fit is proper and whether any irritation is present.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Position the patient side-lying** with head turned to the side and, if possible, with the head of the bed down.
   Secretions will pool in the dependent side of the mouth. This position helps prevent aspiration and facilitates the removal of secretions by gravity.
2. **Don procedure gloves and eye goggles.**
   Follows standard precautions. Eye protection is needed when suctioning because of the risk of splashing.
3. **Place a waterproof pad** and then a towel under the patient's cheek and chin.
   The towel and pad will absorb water and keep the bed linens dry.
4. **Set up suction.** Attach suction tubing and tonsil-tip suction; check suction.
   Suctioning helps ensure that the patient does not aspirate oral secretions during mouth care.

5. Brush the patient's teeth.

a. Use a padded tongue blade or bite-block, as needed, to hold the patient's mouth open.
A padded tongue blade or bite block is used to hold the mouth open so you can visualize and reach the different areas of the mouth without injuring the oral mucosa. It also keeps the patient from biting the nurse's fingers.

b. Place an emesis basin under the patient's cheek.
Catches the secretions draining from the patient's mouth.

c. Moisten the toothbrush, and apply a small amount of toothpaste. Use hospital-approved water (e.g., sterile, distilled, or filtered tap water).
Excessive toothpaste does not increase the cleaning. Brushing the teeth with a soft-bristled brush stimulates the mucosa, which increases the health of the gums.

d. Brush the teeth, holding the bristles at a 45° angle to the gumline.

(1) Using short, circular motions, gently brush the inner and outer surfaces of the teeth, including the gumline.

(2) Brush the biting surface of the back teeth by holding the brush bristles vertical to the teeth and brushing back and forth.

(3) Brush the patient's tongue.
This is the most effective technique for removing plaque and debris from the teeth and gums. The tongue can be a reservoir for bacteria.

e. Perform oral suctioning when fluid accumulates in the mouth.
Removing fluid prevents choking and aspiration.

f. Draw about 10 mL of distilled, sterile or filtered water or mouthwash (e.g., dilute hydrogen peroxide) into a syringe; eject it gently into the side of the mouth. Allow the fluid to drain out into the basin, or suction as needed.
Removes any toothpaste residue, which may have a drying effect. Remove all fluid from the mouth to prevent aspiration into the lungs. Use a minimal amount of solution to prevent aspiration.

6. Provide denture care, if necessary. See Procedure 25-7: Providing Denture Care.

7. Clean the tissues in the oral cavity according to agency policy. Use foam swabs or a moistened gauze square wrapped around a tongue blade. Use a clean swab for each area of the mouth: cheeks, tongue, roof of the mouth, and so on.
Oral tissues may be dry and sticky from mouth breathing. Using separate swabs prevents transfer of microorganisms from one area to another.

8. Remove and dispose of the basin, dry the patient's face and mouth, and apply water-soluble lip moisturizer.
Petroleum-based lip moisturizers (e.g., mineral oil, petroleum jelly) are not recommended because of the possibility of aspiration, which might cause pneumonia. Never use petroleum-based jelly for patients receiving oxygen therapy; it can cause burns.

9. Remove the waterproof pad and towel; turn off suction equipment; discard gloves and used supplies.

10. Reposition the patient as needed.
Maintains good body alignment.

11. Cleanse and store reusable oral hygiene tools in clean containers, separate from other articles of personal hygiene.
Prevents possible contamination from the environment and other personal hygiene tools.

? What if . . .

- **You are providing oral care to a patient receiving mechanical ventilation?**

Provide oral cleansing, including subglottic suctioning, at least every 2 hours and prn. Brush the teeth at least twice a day.
Keeping the oral cavity clean and clear of secretions has been proved to decrease the incidence of ventilator-associated pneumonia (VAP). Pooled oral secretions become rapidly colonized with pathogens that contribute to VAP.

Avoid tap water. Use normal saline or a half-strength solution of saline for oral rinses.
Studies show hospital plumbing and tap water are often colonized with microbial organisms.

Apply a 0.12% chlorhexidine gluconate solution twice daily to complement oral care.

- **It is difficult to floss the patient's teeth, or the patient doesn't tolerate flossing?**

Handheld interdental tools may be used instead of floss. These devices are special small brushes, picks, or sticks.
Toothbrush bristles can't reach between teeth to dislodge food particles and bacteria. Interdental cleaners can be as effective as floss in keeping these areas clean.

- **Oral tissues are dry and sticky?**

Use appropriately diluted sodium bicarbonate to dissolve viscous mucus.

(continued on next page)

Procedure 25-8 ■ Providing Oral Care for an Unconscious Patient (continued)

Evaluation

- Inspect the teeth, gums, and mucous membranes for cleanliness.
- Observe the oral mucosa and gums for hydration, inflammation, bleeding, or infection.
- Observe the patient's overall responses to the procedure (e.g., gagging, coughing, vital signs, skin color).

Patient Teaching

- Discuss with family members any problems that need further follow-up.
- Teach oral hygiene measures, as needed.

Home Care

- The procedure steps do not vary in the home.
- Work with the client and caregiver to determine supplies needed for the home.
- Determine whether suction is needed, and explain to caregivers how to obtain a portable suction unit.
- Demonstrate how to position the client and perform the procedure if the height of the bed is not adjustable or if both sides of the bed are not accessible.

Documentation

Document that oral care was given, any abnormal findings, and nursing interventions. Typically, though, oral care is documented on a checklist or flowsheet.

Sample documentation

mm/dd/yyyy 0730 *Oral care given. Mucous membranes pink and moist. White coating on tongue—physician notified. Patient had no coughing during the procedure. Gag reflex is intact. Patient did not aspirate. Respiratory rate 18.* ——— Susan Hiam, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Providing Oral Care for an Unconscious Patient.**

For questions and suggested responses,

Go to Chapter 25, **Thinking About the Procedure Questions and Suggested Responses,** on Davis *Plus*.

Practice Resources

AACN (2007); American Dental Association (n.d.); Ames, N., Sulima, P., Yates, J., et al. (2011); Berry, A., Davidson, P., Nicholson, L., et al. (2012); Cason, C., Tyner, T., Saunders, S., et al. (2007); Karki, S., & Cheng, A. C. (2012); NGC (2008); Slot, D., Dörfer, C., & Van der Weijden, G. (2008).

Procedure 25-9 ■ Shampooing the Hair

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Delegation

You can delegate this procedure to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the specific type of procedure needed (e.g., in bed, at sink, disposable shampoo equipment) and the amount of help the patient needs. Inform the NAP of any special considerations, such as positions the patient cannot assume or presence of scalp lesions. Ask the NAP to report the condition of the patient's scalp and hair, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- Assess for contraindications to a shampoo (e.g., scalp sutures or limited head or neck movement). A rinse-free shampoo would be more appropriate in these cases.
- Determine the patient's ability to assist with the procedure.
  Promotes independence and provides active ROM.
- Assess the condition of the patient's hair and scalp. Note any dryness or irritation.
  Dry and brittle hair may indicate hypothyroidism or malnutrition and may require special shampoos or conditioners.
- Determine the need for special hair care products.
  Dandruff, lice, and dry hair are examples of conditions that require medicated shampoos or conditioners.
- Ask the patient how she normally cares for her hair.

Procedure 25-9A ■ Shampooing the Hair for a Patient on Bedrest—Using Rinse-Free Shampoo

Equipment

- Rinse-free shampoo (no water is needed); conditioner is optional
- Bath towel
- Brush or hair pick, and comb
- Procedure gloves (if scalp lesion or infestation present)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Elevate the head** of the bed, if possible.
Makes it easier to maintain good body mechanics during the procedure.
2. **Place a protective pad** or bath towel under the patient's shoulders.
Prevents the linen from getting wet.
3. **Don procedure gloves** if lesions or infestations are present.
Helps prevent transmission of disease.
4. **Work your fingers through the hair**, or comb the hair to remove tangles before washing. If the patient has her hair in small braids, do not take out the braids to wash the hair.
5. **Apply rinse-free shampoo.** Apply enough shampoo to thoroughly wet the hair. One application is usually sufficient to clean the hair.
6. **Work the shampoo through the hair**, from scalp down to ends.
Helps prevent pulling on and damaging the hair.
7. **Dry the hair** with a bath towel.
Removes the shampoo. Leaves the hair feeling clean and soft.
8. **Comb or brush hair** to remove tangles, starting at the ends and working toward the scalp.
Prevents excessive pulling on the patient's hair, which may cause breakage.
9. **Dry the hair** with a hair dryer at a medium temperature, if desired.
Use a medium temperature to prevent burning the patient.
10. **When you are finished**, be sure that the patient's clothing and bed linens are dry. Wash and store brushes and combs.

Procedure 25-9B ■ Shampooing the Hair Using Rinse-Free Shampoo Cap

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Warm the shampoo cap** using a water bath or microwave according to package instructions. Be careful to not overheat. Check the temperature before placing on the patient's head to prevent burns.
A commercial no-rinse shampoo cap is a microwavable cap that contains a no-rinse shampoo and conditioner. Different products are available. Be sure to follow the directions on the package.
2. **Place the cap on the patient's hair**, and gently massage.
3. **Remove the cap**, and towel-dry the patient's hair.
Removes the shampoo and excess water.
4. **Complete hair care** according to the patient's needs (see Procedure 25-9A, Steps 7–10, preceding).

Procedure 25-9C ■ Shampooing the Hair Using a Basin and Water

Key Point: ***The use of prepackaged shampoo products is recommended. However, some patients prefer the traditional shampooing technique or may have excessive soiling of the hair and scalp requiring the use of water and basin. This traditional method of hair hygiene can result in significant variation from caregiver to caregiver and increase the risk of hospital-associated infection from contaminated basins and/or tap water. Such techniques also take longer so they require more nursing time. They may also be more tiring for the patient.***

Equipment

- Shampoo; conditioner is optional
- Disposable shampoo tray or commercial system, if available
- Disposable washbasin, plastic pail, small easy-to-handle plastic container
- Towels (2), washcloth, bath blanket
- Waterproof pads or plastic trash bag
- Brush and comb
- Procedure gloves, if indicated by the presence of lesions or infestation
- Hair dryer
- For inpatients, filtered tap water, distilled, or sterile water are recommended (see Key Point above). Follow agency policy, as conditions vary among institutions.

(continued on next page)

Procedure 25-9 ■ Shampooing the Hair (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **If lesions or infestation is** present, don procedure gloves.
Observes standard precautions.

2. **Unless contraindicated** (e.g., by a neck condition), lower the head of the bed, take the pillow from under the patient's neck, and place it under her shoulders.
Hyperextends the neck and helps keep water from the eyes.

3. **Place the waterproof pad** or plastic trash bag under patient's shoulders, and cover with towels. A commercial system will have a drain hose to use.
Protects the bed from getting wet.

4. **Collect warm, not hot, water** (see Equipment) in a container and bring to the bedside.

5. **Place the shampoo tray** under the patient's shoulders (or head, depending on the type of tray). If you are using a hard plastic tray, pad the neck area with a towel. An inflatable shampoo tray needs minimal padding, but you will need to inflate it before beginning the procedure, either by mouth or with an air pump.
Protects the patient from lying on a hard surface and prevents water from leaking out onto the bed.

6. **Ensure that the tray will drain** into the washbasin or plastic pail.
Prevents water draining onto the bed or floor.

7. **Fold the top linens down** to the patient's waist, and cover her upper body with a bath blanket.
Keeps the linen dry; keeps the patient warm.

8. **Work your fingers through** the patient's hair, or comb the hair to remove tangles prior to washing.
It is easier to remove tangles from dry hair. Note that very tangled or matted hair may sometimes indicate a lice infestation.

9. **Wash the hair.**
   a. Wet the hair, pouring warm water from the pitcher. Do not get water in the person's eyes or ears.
   b. Next, apply shampoo and lather well, working from the scalp out and from the front to the back of the head.
   c. Gently lift the patient's head to rub the back of the head.

10. **Rinse thoroughly.**
Shampoo is drying if left in the hair. ▼

11. **Apply conditioner to the hair**, if desired, especially for patients with hair that tangles easily, such as dry, long, curly, or kinky hair. Rinse if needed. Leave-in conditioner can be used and is recommended for curly hair.

12. **Remove the tray**, and blot-dry the hair with the towel. Do not use circular motions to dry the hair.
Circular motions will increase tangles.

13. **Comb or brush hair** to remove tangles, starting at the ends and working toward the scalp.
Prevents excessive pulling on the patient's hair, which may cause breakage.

14. **Dry the hair** with a hair dryer at a medium temperature, if desired.
Use a medium temperature to prevent burning the patient.

15. **When you are finished**, be sure that the patient's clothing and bed linens are dry. Wash the shampoo tray and the brushes and combs.

Procedure Variation: Shampooing the Hair of African American Patients

16. **If the hair is in cornrows or braids**, do not take out the braids to wash the hair. You may need to apply a cloth or net cap to the head prior to shampooing.

17. **Handle the patient's hair very gently**, being careful not to pull on the hair.
Many African Americans have fragile hair that breaks easily. Because it is fragile, apply moisturizer, if needed, to untangle the hair.

18. **When shampooing**, thread your fingers through the hair from the scalp out to the ends. Do not massage the hair in circular motions.

19. **Rinse thoroughly**, then apply a conditioner on the hair if the hair is dry and fragile.
A leave-in conditioner helps minimize tangles and breakage.

20. **Comb through the hair.**
   a. Use a wide-toothed comb or hair pick. Do not use a brush or fine-toothed comb.
   b. Part the hair into four sections and begin combing near the ends of the hair, working through each section.
   c. Use additional moisturizer to help soften and ease combing.
   Never pull on the hair, because it will break easily.

21. **Apply a natural oil to the hair**, if desired. Examples of natural oils are coconut, sweet almond, shea butter, and avocado. Many commercial products use these oils.
Mineral oil and Vaseline tend to clog pores and damage the hair, so use

them only if the patient still prefers them after receiving this information.

22. **Let the hair air-dry** if possible.
Prevents the hair from becoming frizzy. A high temperature, such as from a hair dryer, will also damage the hair.

? What if . . .

- **You do not have a shampoo tray?**
Improvise by using a new bedpan, and reserve it only for washing the hair. Pad it liberally with towels.
- **You discover head lice or nits as you begin the shampoo?**
Stop the procedure. Discuss your findings with the patient and offer reassurance. Leave the patient in a position of comfort and safety. Perform hand hygiene. Report the findings and obtain an order for a prescriptive shampoo.

Evaluation

- Observe that the hair is clean, dry, and free of tangles.
- Observe for patient discomfort or fatigue during the procedure.
- Ask the patient how the hair and scalp feel.

Patient Teaching

- Educate patients and their families about how bathing technology has changed to improve patient care and reduce risk of infection. Products such as rinse-free shampoos or a shampoo cap can make shampooing easier to accomplish for a bedridden patient.
- Advise patients with coarse hair to wash it less frequently (every 3 to 7 days, depending on dryness). Leave-in conditioners are often recommended for dry, curly, or kinky hair.

Home Care

- In the home care setting, determine how the client usually washes her hair.
- If the client is confined to bed, work with the caregiver to develop an effective plan for washing the client's hair. For example, if a shampoo tray is not available, you can make one by using a plastic garbage bag and pillows or rolled towels.
- The newer rinse-free products or the inflatable shampoo tray may be good choices for the client.
- If the client cannot afford the adaptive equipment needed, refer the caregiver to the local resources, such as senior services.
- If the client is ambulatory, recommend a shower stool. The stool needs to fit into the shower or bathtub securely, without wobbling, to prevent the client from falling.
- If the client has only a bathtub, an adaptor for the faucet can be used to attach a handheld showerhead. Using a shower stool will make the procedure easier.

Documentation

Chart that hair was shampooed, the condition of the hair and scalp, and the patient's responses to the procedure.

Sample documentation

mm/dd/yyyy 2045 *Hair shampooed. Scalp without signs of irritation. Hair dry. Conditioner applied. No c/o discomfort. Pt states, "My hair feels wonderful now, and my head doesn't itch anymore."* ——— *Alicia Nelson, RN*

Practice Resources

EZ-Shampoo Instructions for Use (2005); Thompson Healthcare, Inc. (2012). (Caveat: These are not research articles; they are manufacturers' recommendations.)

Procedure 25-10 ■ Providing Beard and Mustache Care

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Scissors or beard trimmer
- Wide-toothed comb
- Mild shampoo; conditioner for coarse and/or dry hair
- Basin (single-patient use, disposable)
- Bath towel
- Procedure gloves (if skin nicks occur, contact with blood may occur)

Delegation

You can delegate beard and mustache care to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the specific type of care needed (e.g., in bed, at sink, safety razor, electric razor). Inform the NAP of any special considerations, such as skin irritation or activity intolerance. Ask the NAP to report the condition of the patient's skin and beard, level of self-care, and ability to tolerate the procedure.

Pre-Procedure Assessments

- Ask the patient or family about preferences for beard and mustache care.
Beards and mustaches may have personal and/or cultural meaning. Men in some cultures never cut or trim their beards. Some patients use a comb and scissors to do a slight trim of their beard and/or mustache, whereas others use a beard trimmer for a closer trim.
- Assess the patient's skin and hair condition.
Determine whether the skin has any reddened or dry areas and whether skin treatments are needed.

(continued on next page)

Procedure 25-10 ■ Providing Beard and Mustache Care (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Drape the towel around** the patient's shoulders.
Protects the patient's clothing from falling pieces of hair and water from shampooing the beard or mustache.

2. **Trim the beard and mustache** when they are dry.
The beard and mustache are often shorter when dry. If they are cut when wet, they may be shorter than desired after they dry.

If Using a Comb and Scissors

a. Comb through the beard, and cut the hair on the outside of the comb. Be conservative; cutting too little is better than cutting too much.
Trimming too much off the beard can be upsetting for the patient, whereas if you cut too little, you can always trim off more.

b. Trim from the front of the ear to the chin on one side, and repeat on the other.
Keeps the beard equal on both sides of the face.

If Using a Beard Trimmer

c. Select the trimming guide to the correct length. Adjust the guide to a longer length rather than a shorter length.
Ensures that you do not cut the beard too short.

d. Trim from the front of the ear to the chin on one side, and repeat on the other.

3. **Trim the mustache.**

a. Comb the mustache straight down.
Cuts the length equally so that the mustache is just above the upper lip. ▼

b. Using either scissors or a beard trimmer, start in the middle, and trim toward one side of the mouth and then toward the other. Do not trim the top of the mustache.
Trimming from the center out toward each side helps you cut both sides equally.

4. **Define the beard line** by one of the following methods:

a. Using either the scissors or a beard trimmer, trim the line of the beard so that it is well defined. Trim very little to ensure that you only define the beard and do not change the length. ▼

b. Shave the neck to define the beard line, particularly for short beards.

5. **Apply procedure gloves**, if needed, and shampoo the beard and mustache using warm sterile, distilled, or tap water and a mild shampoo.
The skin under a beard or mustache can be tender, so treat it gently with a mild shampoo. Follow standard precautions, because it is possible to nick the skin and cause bleeding. Policies about use of tap water vary among institutions.

6. **Rinse well, and pat and wipe** the beard and mustache dry with the towel.
Any shampoo left can irritate the skin, as can rubbing motions with the towel.

7. **Apply conditioner**, if desired.

8. **Comb the beard and mustache** with a wide-toothed comb or a brush.
Do not use a fine-toothed comb, because it will pull the hair.

Evaluation

- Make sure that the beard and mustache are trimmed to the desired length and are clean.
- Verify that skin problems are identified and treatment initiated.

Home Care

No adaptations are required in the home. The patient's usual supplies are sufficient, as a rule.

Documentation

Chart that beard and mustache were trimmed and shampooed; chart the condition of the skin.

Practice Resources

Procter & Gamble (2008). (Caveat: This is not an evidence-based practice article. It is a manufacturer's recommendation.)

Procedure 25-11 ■ Shaving a Patient

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Safety razor or electric razor
- Shaving cream or soap; after-shave lotion, if desired
- Shaving brush, if desired
- Warm water (sterile, distilled, or tap water per agency policy)
- Face towel and bath towel
- Procedure gloves

Delegation

You can delegate shaving to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the amount of help and specific type of care (e.g., safety or electric razor, in bed, or at the sink), the patient needs. Inform the NAP of any special considerations, such as skin irritation or activity intolerance. Ask the NAP to report the condition of the patient's skin, level of self-care, his ability to tolerate the procedure.

Pre-Procedure Assessments

- Determine how much assistance the patient needs.
  Aids you in promoting as much independence as possible.
- Assess the patient's skin and hair condition for redness, skin lesions, or moles.
  Identifies skin problems, and determines whether skin treatments are needed or the procedure must be modified. To prevent abrading the skin, do not shave any areas that have skin lesions or moles.
- Assess the patient's usual shaving method, including use of electric razor or safety razor.
  When possible, follow the patient's routine. The patient may or may not use shaving cream or shaving soap, shaving brush, and after-shave lotion.
- Check for any contraindications to shaving, such as an increased risk of infection or bleeding (e.g., because of neutropenia, thrombocytopenia, or the administration of anticoagulants, such as warfarin or heparin).

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don procedure gloves.**
   To prevent exposure to blood if skin is nicked or scratched.

2. **Place a warm, damp face towel** on the patient's face for 1 to 3 minutes.
   Opens the pores and softens the beard to prevent pulling. Do not use hot water, because it will dehydrate the skin and can burn sensitive skin.

3. **Apply shaving lotion** to the face with your fingers or a shaving brush. Lather well for 1 to 2 minutes.
   Lathering well helps to further soften the beard. Do not use shaving creams that contain numbing agents, because they close the pores and stiffen the beard.

4. **Shave the patient.**
   a. Pull skin taut with your nondominant hand, and gently pull the razor across the skin. If you are using a safety razor, hold the blade at a 45° angle to the skin.
   b. Shave the face and neck in the same direction of hair growth (the direction is not the same for all people). Using short strokes, start shaving at the sideburns, and work down to the chin on each side and then the neck.
   c. Last, shave the chin and upper lip.
   Usually the hair on the face will grow down toward the chin and on the neck up toward the chin. The hair is generally thickest on the chin and upper lip, so shaving them last allows more time for the shaving cream to soften the hair. Shave in the same direction as the hair is growing to prevent skin irritation.

5. **Rinse the razor** frequently while you are shaving.
   Avoids clogging the blade.

6. **When you are finished shaving,** rinse the patient's face with cool water (see Equipment), and gently pat it dry.
   Cool water helps close the pores. Pat dry, do not rub, to prevent irritating the skin.

7. **Apply after-shave lotion,** if desired.
   After-shave lotions that contain alcohol are not recommended, because alcohol stings and dries out the skin. A moisturizer is recommended .

8. **Dispose of the single-use razor** in the sharps container.
   Prevents cutting injury to others.

If Using a Multiuse Razor

Shake the razor to remove excess moisture. Do not bang the razor against objects or dry with a towel. Store the razor in a covered container.
Banging or wiping the razor edge will dull the razor and may damage the holding mechanism. A covered container protects others from a cutting injury.

? What if . . .

- **Your patient has a condition that predisposes him to bleeding (e.g., thrombocytopenia) or infection (e.g., neutropenia)?**
  Such patients must be shaved carefully using an electric razor, if at all.
  A razor scratch or cut causes a break in skin integrity, providing a portal of entry for pathogens. This could be especially serious for a patient whose defenses against infection are compromised. For a patient with a delayed clotting time, a cut could cause excessive blood loss.

(continued on next page)

Procedure 25-11 ■ Shaving a Patient (continued)

Evaluation

- Inspect the patient's face, closeness of the shave, and for nicks or cuts.
- If the procedure was performed by the NAP, ask the patient about his satisfaction with and tolerance of the care.

Patient Teaching

Teach patients about changes that need to be made in their shaving technique as a result of changes in health status. For example, a patient who has begun taking anticoagulants may need to change from a blade to an electric razor because of an increased risk of bleeding.

Home Care

The procedure does not vary in the home. The nurse must:

- Determine the availability of supplies
- Assess the client's or caregiver's ability to perform the procedure.

Documentation

Chart that the patient was shaved and the condition of the skin. There will probably be a flowsheet or checklist for this information.

Practice Resources

Coughlan, M., & Healy, C. (2008); Proctor & Gamble (2008); Men's Health (updated 2011). (Caveat: Except for Coughlan & Healy, the preceding are not evidence-based resources. They are information from manufacturers.)

Procedure 25-12 ■ Removing and Caring for Contact Lenses

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Contact lens wetting solution
- Contact lens soaking solution
- Sterile saline (optional)
- Contact lens case
- Contact lens remover (optional)
- Procedure gloves

Delegation

You can delegate this procedure if the patient's condition and the NAP's skills permit. For example, if the patient is unconscious, you must determine whether contact lenses are present, and you should not delegate their removal.

Pre-Procedure Assessments

- Determine whether the patient is wearing contact lenses. If the patient is unconscious, examine the eyes for the presence of contact lenses by shining a penlight across the eye. You should be able to see the edge of the lens.
- Determine the type of contact lenses in place.
  Hard lenses are smaller than soft lenses. Each type of contact lens has different care requirements. Hard lenses can be worn for only up to 18 hours. Rigid gas-permeable (RGP) lenses may be worn overnight or for about 7 days, depending on the kind. Soft contacts are used for either short or longer periods.
- Ask the patient whether he is able to remove his contact lenses.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* It is difficult to remove a contact lens when wearing procedure gloves. For hard lenses, you can use a suction cup device if one is available.

If you must use ungloved hands (e.g., in an emergency situation), it is extremely important to wash your hands thoroughly before and after the procedure. *Do not* use your fingernails.

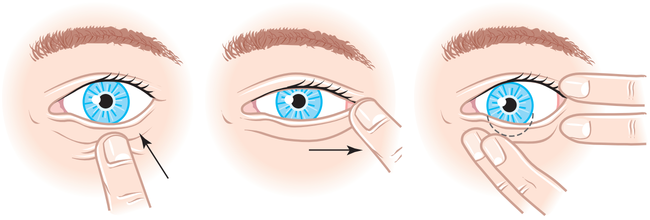
➤ *Note:* Lens cases are marked "L" and "R" to indicate left and right lenses. Clean, rinse, and place the lens you remove first into its designated cup before removing the second lens.

Procedure Steps

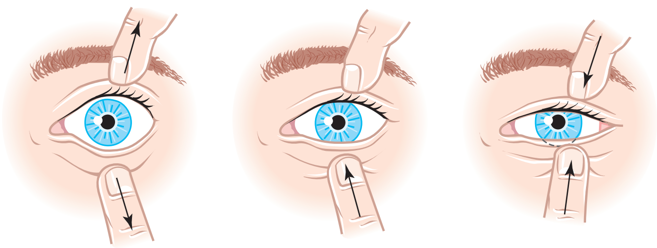
1. **Perform hand hygiene** and don gloves.
2. **Instill one to two drops** of contact lens wetting solution to moisten the lenses.
   Aids in lens removal.
3. **Remove the lenses**.

For Hard or Gas-Permeable Contact Lens

- *Alternative 1:* If the lens is not centered over the cornea, place your finger on the patient's lower eyelid, and apply gentle pressure to move it into position. Place your index finger at the outer corner of the eye, and gently pull sideways toward the ear; position your other hand below the eye to "catch" the lens. Ask the patient to blink. As the skin tightens, the palpebral fissure narrows, the lids catch on the edge of the lens and pop it out.



- *Alternative 2:* Use a small suction cup contact lens remover. Gently press the suction cup end of the remover onto the contact lens, and lift straight up off the eye.
- *Alternative 3:* Gently pull the top eyelid up and the lower lid down beyond the top and bottom edges of the lens. Then gently press the lower eyelid up against the bottom of the lens. When the lens is slightly tipped, move the eyelids together. This should cause the lens to slide out.



For Soft Contact Lens

a. Hold the eye open with your nondominant hand.
Allows you to visualize the contact lens.

b. Gently place the tip of your index finger on the contact lens, and slide it down off the pupil to the white area of the eye.
To prevent potential damage to the eye, do not pinch a lens directly over the pupil.

c. Using your thumb and index finger pads, gently pinch the lens, and lift it straight up off the eye. If the edges stick together, moisten with a few drops of wetting solution. Rub gently until edges separate.
A soft contact lens is very flexible and pinches easily.

4. **Clean the lens** according to the instructions on the cleaning solution bottle. If there is no lens cleaner, use sterile saline. Be careful not to tear soft lenses.
5. **Rinse the lenses** with contact lens solution or sterile saline.
Removes any particles from the lenses.
6. **Place the lenses in a contact** lens case containing soaking solution or sterile saline (see note above regarding lens cases).
Prevents bacterial growth on the contacts and keeps the lenses from drying out.

Evaluation

Examine the eyes for redness or irritation.

Patient Teaching

- Review with the patient and/or family the importance of keeping the contact lenses clean and moist.
- If hard contact lenses are used, they must be removed at bedtime to prevent hypoxia of the cornea.

Documentation

Chart that contacts were removed, what type of lenses they are, what solution they are stored in, and the condition of patient's eyes.

Practice Resources

Bausch & Lomb (2008, 2009); Holman, C., Roberts, S., & Nicol, M. (2005); Massachusetts Eye and Ear Infirmary (n.d., last updated January 5, 2009).

Procedure 25-13 ■ Making an Unoccupied Bed

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Bottom and top sheets, possibly drawsheet
- Pillowcase for each of the pillows
- Linen bag or hamper
- Procedure gloves (if exposure to body fluids is possible)
- Moisture-proof gown (if heavy soiling of linens with body fluids is possible).

Delegation

You can delegate this procedure to the NAP. You are responsible for supervising to ensure that the procedure is performed correctly.

Pre-Procedure Assessments

- Check to see whether the linen (including the mattress pad, blanket, and bedspread) needs to be changed, and what linens are needed.
- Assess whether the patient is able to be out of bed during the linen change.
- Assess for drainage or incontinence to determine whether personal protective equipment, such as procedure gloves and gown, is needed.

Note: This procedure describes bed making by one person. It is more efficient for two people to work together on opposite sides of the bed.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Assist the patient to a chair.** Provide a robe and/or blanket if needed.
Ensures that the patient is comfortable and will be warm enough during the bed change.

2. **Prepare the environment:** Position the bed flat, raise to appropriate working height, put on the brakes, and lower the siderails. Move the overbed table and other furniture, as needed. Place the linen bag or hamper conveniently near the bed.
Maintains good body mechanics and prevents back strain during the procedure. Remove obstacles to allow easy access to the bed. Place all items so you can work efficiently, saving time and energy.

3. **Don protective gloves** and other gear if necessary. Loosen all the bedding.
This observes Standard Precautions and reduces the risk of contaminating your clothing.

4. **If the blanket or bedspread is** clean, fold it and place it on a clean area (e.g., on the back of a chair). *Do not* place on another patient's bed or furniture.
Reuse the blanket and/or bedspread if it is not soiled. Placing the item on a clean area prevents cross-contamination.

5. **Remove the bottom and top sheet**, draw sheet, and pillowcases.
   a. Do not shake the linens.
   Minimizes dispersal of dust, skin cells, and microorganisms into the environment.
   b. Holding the items away from your body, place them in a laundry bag or hamper. Never place linen on the floor. Place the pillows on a clean area (e.g., on a chair).
   Hold dirty linen away from your uniform to prevent contamination. Cross-contamination can occur if you place linens on the floor.

6. **Working from one side of bed**, to save steps:

For a Contour-Bottom Sheet

   a. Fit the contour-bottom sheet on one side of the bed, and smooth it out over half the mattress.

For a Flat-Bottom Sheet

   b. Fold the flat-bottom lengthwise with the center crease in the middle of bed and unfold with the rough side facing down.
   c. Position the bottom sheet so that approximately 10 inches hang over at the top and sides. The hem of the bottom sheet should be just even with the bottom edge of the mattress.
   d. Tuck in the sheet, mitering the sheet at the top corner (see Step 11).
   When using a flat bottom sheet, having extra sheet at the top helps keep it in place when the head of the bed is raised and lowered. Unfold the sheet rather than shake or fan to reduce dispersing microorganisms into the air. The sheet will not be long enough to tuck in at the bottom.

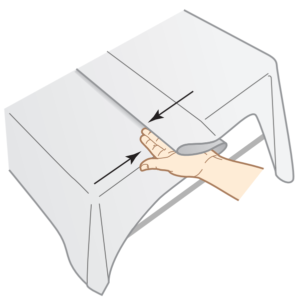
7. **Place the drawsheet** with the center fold in the middle of the mattress and unfold. Tuck the side in under the mattress, and smooth out over half of the mattress.
Ensures that all wrinkles are out of the bottom sheet and drawsheet.

8. **Go to the other side** of the bed, straighten the linen, and finish tucking in the bottom sheet and drawsheet.
   a. Make the drawsheet tight, and smooth any wrinkles in the bottom sheet and drawsheet.

b. If desired, place a waterproof pad on or under the drawsheet.
Pulling the drawsheet tight helps prevent wrinkles from developing under the patient when she moves around in bed.

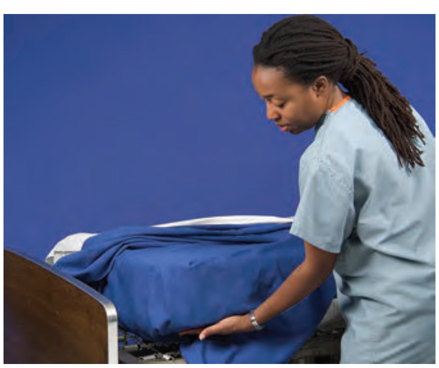
9. Place the top sheet and bedspread along one side of the mattress. Center the top sheet and bedspread, so that when you straighten them from the other side of the bed, they fall equally over each side of the bed.
Putting the linen on one side of the bed saves steps.

10. At the foot of the bed, make a small pleat in the top sheet and bedspread.
Prevents the top covers from placing pressure on the patient's toes.



11. Tuck in the top sheet and bedspread at the same time, mitering the corners.

a. Tuck in the sheet and bedspread at the bottom of the mattress.



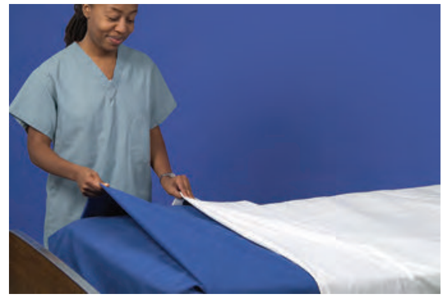
b. Bring the edge of sheet and the bedspread up to make a right angle.

c. Tuck the lower edge of sheet and bedspread under the mattress.

Mitered corners help secure the linen at the foot of the bed.

12. Move to the other side of the bed, smooth top linens, and repeat Step 11. At the head of the bed, fold the edge of sheet down over the bedspread.
Prevents the bedspread from rubbing against the patient's skin.

13. Fanfold the top sheet and bedspread back to the foot of the bed.
Makes it easier for the patient to get into bed.



14. Change pillowcases.

a. Turn the pillowcase wrong side out.

b. Grasp the middle of the closed end of the pillowcase.

c. Reaching through the pillowcase, grasp the end of the pillow.

d. Continuing to grasp the end of the pillow, pull the pillowcase down over the pillow.
Do not hold the pillow under your arm or chin to put on pillowcase because contamination can occur.

15. Assist the patient back to bed, return the bed to the low position, place the call signal within reach, and place the bedside table and overbed table so that they are accessible to the patient.
Provides for patient comfort and safety.

(continued on next page)

Procedure 25-13 ■ Making an Unoccupied Bed (continued)

What if . . .

- **The linens have been contaminated by body fluids?**

  Follow recommended infection control procedures for laundering of linens (e.g., wear procedure gloves, place linen in moisture-proof bags, and so on).

- **The mattress has become contaminated by body fluids?**

  Follow agency policies for cleaning the mattress before putting on clean linens. This often involves notifying another department, such as housekeeping or environmental services, whose members are trained in this procedure.

- **The mattress cover is damaged or worn?**

  Regularly check each mattress cover for any visible signs of damage or wear such as cuts, tears, cracks, pinholes, snags, or stains. Routinely remove the mattress cover and check its inside surface for wet spots, staining, or signs of damage or wear. Check all sides and the bottom of the mattress. Remove any damaged, worn, or visibly stained medical bed mattress according to the healthcare facility's procedures and immediately replace any damaged mattress cover to reduce the risk of infection to patients.

- **The patient has a specialty bed or specialty mattress?**

  Several products are available with specific criteria to match patients' needs in terms of comfort, prevention, or treatment of pressure ulcers, and movement (e.g., specialty beds designed for bariatric patients). Follow the manufacturer's directions (e.g., a recommendation for a specific mattress may be to use only one layer of sheet over the mattress for maximum benefit). If you find the sheets are not large enough to accommodate a specialized mattress, you may need to use two flat sheets to cover it.

Home Care

The only adaptations at home depend on the type of bed the patient has. If the height of the bed is not adjustable or the bed is not accessible from both sides, the procedure may be more difficult.

Documentation

Linen changes are generally recorded on a checklist, if at all. Additional charting would need to be done only if something abnormal occurred, for example, "The drawsheet had a 20-cm circular area of serosanguineous drainage."

Practice Resources

Bloomfield, J., Pegram, A., & Jones, A. (2008); Mitchell, B., Wilson, F., McGregor, A., et al. (2012); Sergent, A. P., Slekovec, C., Pauchot, J., et al. (2012); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007); U.S. Food and Drug Administration (2013).

Procedure 25-14 ■ Making an Occupied Bed

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Bottom and top sheets; drawsheet
- Pillowcase for each of the pillows
- Bath blanket (as needed)
- Linen bag or hamper
- Procedure gloves (if exposure to body fluids is possible)
- Moisture-proof gown (if heavy soiling of linens with body fluids is possible).

Delegation

You can delegate this procedure if the patient's condition and the NAP's skills permit. For example, if the patient is very ill, in pain, or requires two people for turning and repositioning, you should assist with or perform the linen change yourself.

Pre-Procedure Assessments

- Determine the patient's ability to assist with the procedure and whether additional help or assistive devices are needed.
- Make other assessments listed in Procedure 25-13.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* If linen change is done at the same time as the bed bath, some of these steps will vary.

Procedure Steps

1. **Prepare the environment:** Move the overbed table and other furniture, as needed, to allow access to the bed. Place the linen bag or hamper conveniently near the bed.
To allow easy access to the bed and enable you to work efficiently, saving time and energy.

2. **Don protective gloves** and other gear if necessary.
This observes standard precautions and reduces the risk of contaminating your clothing.

3. **Position the bed flat** if possible, and raise it to working height. Lower the siderail nearest you.
Maintains good body mechanics and prevents back strain during the procedure. Having the head of the bed flat makes it easier to smooth the bottom sheet. To prevent the patient from falling out of bed, lower the siderails only on the side where you are standing.

4. **Disconnect the call device**, and remove the patient's personal items from the bed.
Prevents items from getting lost.

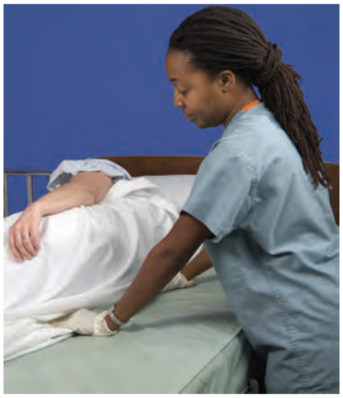
5. **Check that no tubes** (e.g., IV, nasogastric) are entangled in the bed linens.
Prevents dislodging tubes accidentally.

6. **If the blanket or bedspread** is clean, fold it and place it on a clean area (e.g., the back of a chair); do not place it on another patient's bed or furniture.
Reusing the blanket and/or bedspread if it is not soiled conserves resources.

7. **Cover the patient** with a bath blanket, if available, or leave the top sheet over the patient.
Covering the patient prevents chilling and preserves modesty.

8. **Slide the patient to the far side** of bed and place him in a side-lying position, facing the siderail. Place a pillow under his head. If needed for support, place a pillow between the patient and the siderail.
Placing the patient close to the side rail will allow you to place the clean linen over a larger area, making it easier to roll the patient back onto the clean linen. Patients who cannot maintain the side-lying position should have a pillow placed between their chest and the siderail to prevent them from accidentally rolling into the siderail.

9. **Roll or tightly fanfold** the soiled linens toward the patient's back. Tuck the roll slightly under the patient. Cover any moist areas with a waterproof pad.
Cover any moist areas to prevent contact with the clean linen or patient.



10. **Remove soiled gloves**, perform hand hygiene, and don clean gloves.

11. **Place the clean bottom sheet** and drawsheet (or pad) on the near side of the mattress, with the center vertical fold at the center of the bed. Fanfold the half of the clean linen that is to be used on the far side, folding it as close to the patient as possible and tucking it under the dirty linen. Tuck the lower edges of clean linen under the mattress. Smooth out all wrinkles.
Wrinkles under the patient can cause skin irritation.

12. **Roll the patient over the clean and dirty linen**, turning him toward you. Explain to him that he will be rolling over a "lump," and then gently pull the patient toward you so that he rolls onto the clean linen.

13. **Raise the siderail** on the clean side of the bed.
Prevents the patient from falling.

14. **Move the pillows** to the clean side. Position the patient comfortably on his side, near the siderail.
Always ensure patient comfort and safety before going to the other side of the bed.

15. **Go to the opposite side of bed**, and lower the rail. Pull the soiled linen from under the clean linen, and place it in laundry bag or hamper. Never place linen on the floor.
Prevents cross-contamination.

16. **Remove soiled gloves and** don clean gloves. Pull clean linens through, and tuck them in. Pull taut, starting with the middle section.
Ensures that no wrinkles will be under the patient.

(continued on next page)

Procedure 25-14 ■ Making an Occupied Bed (continued)

17. Assist the patient to a supine position close to center of the mattress.

18. Place the top sheet and bedspread along one side of the mattress, and continue making the bed as in Procedure 25-13, Steps 9 through 14, *except* remove the bath blanket from under the top linens before tucking them in.

19. Return the bed to the low position, raise the siderails, and attach the call light within patient's reach. Position the bedside table and overbed table within patient's reach.

Ensures patient safety and comfort.

What if . . .

- **You are making the bed with a patient in leg traction?**

  It may be easier to make the bed from top to bottom, as follows:
  - Loosen all bed linens and bring the dirty linens from the top of the bed to hip area. Put the clean bottom sheet on the top corners of the mattress, bring down to hip level and tuck under the dirty linen. Cover any moist areas with a waterproof pad.
  - Ask the patient to grasp the trapeze and raise his buttocks. If the patient is unable to raise his buttocks, use an assistive device per agency policy.
  - Bring the dirty bottom sheet along with the clean bottom sheet toward the foot of the bed. Remove dirty linen and place in the laundry bag.
  - Tuck the clean sheet under the mattress. Cover with the top sheet. To accommodate traction equipment, do not tuck in the top sheet.

- **You need to move or reposition a patient in bed who is not able to assist or is obese?**

  Before making the occupied bed, assess the patient's ability to move.

  Use assistive equipment such as friction reducing devices, mechanical lifts, air powered mattresses and or lateral transfer devices.

  These are essential tools in preventing work-related injuries. You should limit the need to use your own strength while lifting, turning, or repositioning the patient in bed, because of the stress placed on the weaker muscles in the arms and shoulders.

  Follow agency policies and use of patient moving devices appropriately.
  Many healthcare facilities have adopted safe lifting and patient-handling policies as a means to protect both the patient and the healthcare worker.

Evaluation

- Assess how well the patient tolerated the procedure. Was there any discomfort, shortness of breath, and so on?
- Ask the patient whether he feels comfortable.

Home Care

The only adaptations at home depend on the type of bed the client has. If the height of the bed is not adjustable or the bed is not accessible from both sides, the procedure may be more difficult.

Documentation

Linen changes are usually recorded on a checklist. Additional charting needs to be done only if something abnormal occurred.

Practice Resources

American Nurses Association (ANA) (2013); Bloomfield, J., Pegram, A., & Jones, A. (2008); Collins, J., Nelson, A., Sublet, V. (2006); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Making an Occupied Bed.**

For questions and suggested responses,

Go to Chapter 25, **Thinking About the Procedure Questions and Suggested Responses,** on Davis *Plus.*

Procedure 25-15 ■ Caring for Artificial Eyes

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Procedure gloves
- Normal saline solution
- Labeled container filled with saline or sterile, distilled, or filtered water
- Cotton balls

Delegation

You can delegate this procedure to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of any special considerations. Ask the NAP to report the patient's ability to tolerate the procedure.

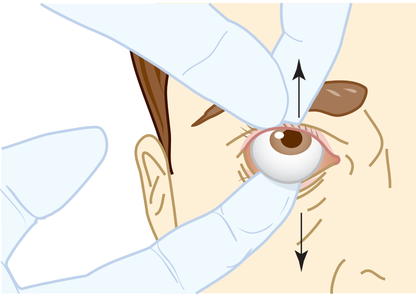
Pre-Procedure Assessments

- Assess the patient's activity tolerance and whether you will need another caregiver to assist.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Wash hands and don gloves.**
2. **Position the patient lying down.**
   If you accidentally drop the eye when removing it, it will fall onto the bed instead of the floor.
3. **To remove the artificial eye:**
   a. Raise the upper eyelid with your nondominant hand, and depress the lower lid with your dominant hand.
   b. Apply slight pressure below the eye to release the suction holding it in place.
   c. Catch the eye in the palm of your dominant hand.
   d. Alternatively, you can use a small bulb syringe, place it directly on the eye, and squeeze to create suction and lift the eye straight up from the socket.



4. **Clean the eye with saline**, and store it in a labeled container filled with saline or sterile, distilled or filtered water. Do not use solvents, disinfectants, or alcohol. These chemicals may irritate the socket or damage the artificial eye.
5. **Wipe the edge of the patient's** eye socket with a moistened cotton ball, wiping from outer canthus toward the nose.
6. **Inspect the socket** for redness, swelling, or drainage.
   Irritation or infection can occur if debris has entered the socket.
7. **To reinsert the eye:**
   a. Remove the prosthetic eye from the container, but do not dry it.
   b. Hold the eye between your thumb and the index finger of your dominant hand.
   c. With your nondominant hand, pull down on the lower lid while lifting the upper lid and guide the eye into the socket.
   The prosthesis will slide into place more easily when it is wet.

Evaluation

- Observe that the eye has been placed correctly in the socket.
- Ask the patient how the eye area feels.
- Observe the eye area for redness or irritation.

Patient Teaching

- Advise the patient to periodically inspect the eye area.
- Review the importance of hand hygiene and proper handling of the eye.
- If the eye wearer experiences dryness or irritation, a lubricant made for ocular prosthetics can be used.
- If the eye needs to be wiped but not removed, wipe from outer canthus toward the nose.
  Wiping outward may dislodge the prosthesis.
- Encourage the patient to sleep in the prosthesis at night and remove it every 1 to 3 weeks for cleaning (follow prosthesis specialist's advice). Some patients do find that it is necessary to remove and clean the prosthesis every day.
  Frequent removal irritates the lining of the socket and increases the amount of discharge produced by the eye socket.
- The eye should be professionally polished every 6 to 12 months. Symptoms that may indicate the need for a polish are irritated or itchy lids, increased drainage or discomfort, or changes in the appearance of the artificial eye.

(continued on next page)

Procedure 25-15 ■ Caring for Artificial Eyes (continued)

Home Care

- In the home care setting, determine how the client usually performs eye care.
- Discuss ways to promote the safety of the artificial eye.
- Work with the client or caregiver to develop a plan of care for cleaning the eye and care of the area associated with the socket.

Documentation

Chart that the artificial eye was cleansed, the condition of the socket, care given to the area around the socket, and the patient's responses to the procedure.

Practice Resources

Erikson Labs Northwest (n.d.); Hospital Info (2008); Peters, R. (2010).

Procedure 25-16 ■ Caring for Hearing Aids

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Face cloth, dry towel
- Damp cloth
- Cotton applicators
- Wax-loop and wax brush, if available
- Pipe cleaner or toothpick, if wax-loop and wax brush unavailable
- Procedure gloves (to prevent contact with earwax or ear drainage)

Delegation

You can delegate hearing aid care to the NAP if the patient's condition and the NAP's skills allow. Perform the pre-procedure assessments, and inform the NAP of the specific type of care needed (e.g., type of hearing aid), and the amount of help the patient needs. Inform the NAP of any special considerations, such as skin irritation or usual volume setting. Ask the NAP to report the condition of the patient's ear, level of self-care, his ability to tolerate the procedure, and his ability to hear in a normal conversation.

Pre-Procedure Assessments

- Determine how much assistance the patient needs.
  Aids you in promoting independence as much as possible.
- Determine the type of hearing aid in use. The three common types of hearing aids are (1) postaural hearing aid, (2) in-the-canal hearing aid, and (3) in-the-ear hearing aid.
  The cleaning procedure varies according to the type of hearing aid.

  To review the types of hearing aids,

  Go to **Figure 25-6,** in Volume 1.
- Assess the patient's ear and outer canal for redness, skin lesions, earwax buildup, or drainage.
  Identify skin problems and determine whether any symptoms of infection exist. Earwax buildup increases with age and doesn't necessarily indicate a health problem.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don procedure gloves.**
   The hearing aid may contain earwax buildup or drainage.

2. **Place a towel on a nearby table** or flat surface.
   The towel helps prevent the hearing aid from breaking if it is accidentally dropped. Hearing aids are expensive.

3. **To remove the hearing aid:**
   a. Turn the hearing aid off by applying slight pressure against the volume control wheel and turning it backward (away from the nose).
   Stops the hearing aid from whistling.
   b. Rotate the earmold slightly forward (toward the nose), and gently pull it out. Do not pull on the battery door or the volume wheel.
   Pulling on the battery door or the volume wheel may damage the faceplate.
   c. Place the hearing aid on the towel.
   The towel will prevent the hearing aid from rolling off the table or banging against the table.

4. **Clean the hearing aid.**
   a. Wipe all external surfaces with a damp cloth.
   b. Clean the canal portion of the hearing aid using the wax-loop and wax brush, cotton-tipped applicator, pipe cleaner, or toothpick. Clean the top portion only. Do not insert anything into the hearing aid itself.
   Poking utensils into any part of the hearing aid except for the canal portion may damage the hearing aid.

For a Detachable Earmold

   c. Disconnect the earmold, and soak it in soapy water. Rinse and dry well, and then reattach it. Do not use alcohol. Never immerse a hearing aid in water, only the earmold.

Detaching an earmold that is glued or fastened by a small metal ring will break the hearing aid. Alcohol will damage the earmold material.

d. Check the hearing aid and any tubings for cracks and loose connections.
A damaged hearing aid will be less effective and may cause injury to the ear. Early detection of hearing aid damage may allow for repair rather than replacement of the device.

5. **Cleanse the outer ear** using the corner of a washcloth or a cotton-tipped applicator. Inspect these areas for redness, abrasions, swelling, drainage, or other irregularities.
Poorly fitting or improperly positioned hearing aids may cause trauma to the ear.

6. **Insert the hearing aid.**
   a. Check that the battery is functioning. Hold the hearing aid in your hand. Close the battery compartment door if open. Turn the power on, turn the volume high, and listen for a whistling sound.
   Whistling indicates proper power level and functioning of the battery.
   b. Set the volume control to "Off."
   Prevents whistling during insertion and a sudden, loud noise.
   c. Handle the hearing aid by the edges using your thumb and forefinger.
   Prevents whistling during insertion.
   d. Holding the hearing aid in your dominant hand, use your nondominant hand to gently pull the ear up and back.
   Opens the ear canal slightly for an easier insertion and better fit.
   e. Insert the canal portion of the hearing aid into the ear. Apply slight pressure and gently rotate the hearing aid back and forth until the canal portion rests flat in the ear.
   Allows a better fit and prevents hearing aid from falling out.

When Inserting a Postaural Hearing Aid

Insert the earmold first and then place the earmold over the ear.

When Inserting an In-the-Canal Hearing Aid

Insert with the volume control at the top. The canal should be facing away from your hand.

When Inserting an In-the-Ear Hearing Aid

Insert with the volume control at the bottom.

7. **Turn the hearing aid on** and adjust the volume by turning the volume control wheel toward the nose. Set the volume control as low as possible.
Normal setting requires a one-third to two-thirds turn of the volume control wheel. A noisier environment requires less volume, or one-fourth turn.

8. **Protect the hearing aid** from curling irons, hair dryers, and hair spray and other hair products.
Heat and moist aerosols will damage the hearing aid.

Procedure Variation: Storing the Hearing Aid

9. **Open the battery compartment** and place the hearing aid in a closed container labeled with the patient's name.
Saves battery power and allows any moisture to evaporate. Protects the hearing aid from accidental damage or loss.

10. **If the hearing aid is to be kept stored** and not worn for a week or more, remove the battery completely.
Prevents battery acid from leaking and damaging the hearing aid.

11. **Store the hearing aid** in a cool, dry place, preferably in the bedside drawer. Keep the hearing aid away from children and pets.
Moisture and heat will damage the hearing aid. Hearing aids and containers are easily lost. A child may choke on the hearing aid. Dogs and cats are attracted to the whistling noise and odor of the hearing aid and sometimes attempt to eat the device.

Procedure Variation: Replacing the Battery

12. **Use your finger** to swing the battery door open. Never force the door.

13. **Peel the tab off the new battery.**

14. **Hold the battery with the** positive (+) side up and slide it into the door, not into the hearing aid itself.

15. **Gently close the battery door.** Never force the door.

16. **Dispose of the old battery** in the regular trash.

Guidelines for Care of the Batteries

- Always dispose of old batteries. Do not throw into a fire.
Minimizes damage from leaking battery acid and prevents mistaking fresh battery from used battery. Heat and fire may cause the battery to explode.
- Store batteries in a cool, dry place. Do not place zinc-air batteries in the refrigerator.
Heat shortens the life of the battery. Cold batteries warming to room temperature are exposed to condensation and subsequent corrosion.
- Do not store batteries near coins or other metals.
Contact with other metals can short-circuit the batteries.
- Do not remove the tab from the battery until the battery is ready for use.
The tab keeps air out of the battery. Once the tab is removed, the battery is activated. Early removal decreases the life of the battery.
- Keep batteries away from children, confused adults, and pets.
Minimizes accidental swallowing.

? What if . . .

- **The hearing aid becomes wet?**
If the hearing aid becomes exposed to moisture, dry it as much as possible. Remove the battery and throw it

(continued on next page)

Procedure 25-16 ■ Caring for Hearing Aids (continued)

away. Keep the battery door open. Place the hearing aid in its container and allow it to dry overnight. Do not place a new battery in the hearing aid until the next morning.
Moisture will cause the battery to corrode.

- **The patient wears bilateral hearing aids?**

Be sure to identify which hearing aid is for the left ear and which hearing aid is for the right ear. Most hearing aids have a color marking for easy identification: red = right ear and blue = left ear.
Attempting to force a hearing aid into the wrong ear may cause trauma to the ear.

- **The patient continues to have hearing difficulties despite hearing aids?**

Hearing aids will not restore full hearing. General tips when communicating with a person with a hearing deficit are listed in Chapter 30, Clinical Insight 30-3: Communicating With Hearing-Impaired Clients.
Hearing aids will not block out background noise. A clear, distinct, low-pitched voice helps the client to understand what is being said.

Evaluation

- Assess how well the patient tolerated the procedure. Was there any discomfort, difficulty with insertion, and so on?
- Note the condition of the patient's skin, including pain, redness, and abnormal discharge.
- Note the condition of the hearing aid itself.
- Assess the patient's ability to hear normal speaking voices.
- Ask the patient whether he feels comfortable and hears satisfactorily.

Patient Teaching

- Discuss the importance of daily hearing aid care.
- Review any areas of care that the patient has not been performing adequately.
- Discuss any problems that need further follow-up, such as earwax build up, faulty or broken hearing aid, or ill-fitting hearing aid.

Home Care

The procedure does not vary in the home. The issues are that the nurse must:

- Work with the patient and care provider to determine supplies needed for the home.
- Determine whether further knowledge is required (e.g., if the patient must expose hearing aids to prevailing weather conditions, uses a telephone extensively, must make several adaptations from quiet to noisy environments throughout the day, and so on).
- Provide a list of available resources (e.g., AARP, National Institutes of Health, Better Hearing Institute).

Documentation

Chart that the patient is wearing a hearing aid, the condition of the ear, and the ability to hear. There will probably be a flowsheet or checklist for this information.

Practice Resources

Department of Veteran Affairs (n.d.); National Institute on Deafness and Other Communication Disorders (2007); U.S. Food and Drug Administration (2009).

CLINICAL INSIGHTS

Clinical Insight 25-1 ➤ Assisting With a Shower or Tub Bath

- Assess the patient's self-care abilities: sensorimotor, musculoskeletal, and cognitive function; activity tolerance; level of knowledge.
- Ensure that the patient has the necessary supplies (e.g., soap, washcloth, towel, clean gown, and so forth).
- Check agency policy regarding the safety of the tap water for general use in bathing patients.
- Hang a sign on the door to ensure privacy.
- Help wash and dry any areas that the patient cannot reach (e.g., feet, back).
- Avoid showering and exposure to faucet water in patients who are immunocompromised or at high risk of infection. Use prepackaged wipes instead.
- Assist the patient to the shower or bathroom as needed.
- Prevention of nosocomial infections related to the use of tubs should include stringent maintenance and cleaning according to facility policy.
- Ensure that there is a nonskid surface or mat in the shower or tub.
- For patients who have impaired mobility or activity intolerance, use a shower chair in the shower or tub.
- Be sure that the shower or tub is safe. Most hospitals and long-term care facilities have grab bars and handrails in the bathrooms.
- To avoid burns, verify water temperature for clients with impaired cognition or decreased sensory perception. Water should be 110°F to 115°F (43°C to 46°C).
- Provide a call device for the patient to obtain help if needed; point out the emergency call device if there is one in the bathroom (usually it is a red button or cord on the wall).

Shower chair

Home Care

- Encourage clients and families to install hand bars on the sides of the bathtub and on the wall next to the tub. Most hospitals and long-term care facilities have grab bars and handrails in the bathrooms, but these may need to be installed in the home.
- Advise parents never to leave a child alone in the tub or shower and to have a way to unlock the bathroom door from outside the room.
- Advise older adults or those who are ill not to lock the bathroom door while bathing so that help can be summoned if needed (e.g., if they become faint or fall).
- Help families to obtain benches for transferring into the bathtub, or use a plastic chair in the shower.
- Ensure that there is a nonskid surface or mat in the shower or tub.

Bathtub with handrail and grab bars

Clinical Insight 25-2 ➤ Bathing a Patient With Dementia

- Focus on the patient, not the task; provide choices.
- Distract with food or by playing relaxing music.
- Use a gentler type of shower head for rinsing. *A strong spray may frighten the patient.*
- Avoid sensory overload: Turn down lights, warm the room, play soft music, speak calmly. *People with dementia have trouble processing information. Overloading the senses may trigger aggression.*
- Ensure continuity of care. *The patient can build a relationship with the caregiver and reduce fear.*
- Encourage the patient to wash her own face if able. *Makes her feel like an active participant; preserves some independence.*
- Bathe at a regular time—preferably the same time that the patient bathed at home.
- Explain the procedure simply, using short sentences.
- Provide privacy. *Patients with dementia do not necessarily lose their modesty and sense of privacy.*
- Let the patient know before you touch her or spray her with any fluids. *Sudden actions are often frightening to patients with dementia.*
- Do not rush. *The patient will feel the tension and may become agitated.*
- Be creative; try bathing one part of the body each day.
- Teach techniques to caregivers at home (e.g., being flexible with time, using a towel bath, etc.)
- Also refer to the What If . . . ? section of Procedure 25-1.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Guidelines for Assessing Hygiene

Assessment of Functional Abilities

The Katz Index of Independence in Activities of Daily Living (ADL) is used extensively to assess functional abilities in activities of daily living (bathing/hygiene, dressing/grooming, feeding, toileting). To use the Katz ADL Index,

Go to Chapter 25, **Tables, Boxes, Figures: ESG Table 25-1,** on Davis *Plus* or **go directly to http://consultgerirn.org/uploads/File/trythis/try_this_2.pdf**

Observe Self-Care Abilities

When bathing, dressing, eating, and toileting, which of the following best describes the patient's ability?

- ➤ Is completely independent; requires no assistance.
- ➤ Requires a device or special equipment (e.g., a walker, a large-handle spoon).
- ➤ Requires help, supervision, or teaching from another person.
- ➤ Requires help, from another person, as well as a device or special equipment.
- ➤ Is totally dependent; does not participate in the activity (e.g., total bed bath).

The Environment

- ➤ Is the room temperature comfortable?
- ➤ Are the siderails up, when indicated? Is the bed in low position?
- ➤ Are bed wheels locked?
- ➤ Are bed linens clean and wrinkle free?
- ➤ Is the patient's call device within reach?
- ➤ Is the overbed table clean and uncluttered?
- ➤ Is the walking space uncluttered?
- ➤ Are there unpleasant odors?

Skin

Subjective Data

Patients may be sensitive about skin problems or poor hygiene practices, so direct your questions to the patient in a nonjudgmental, respectful manner. General questions to ask include the following:

- ➤ How often do you prefer to bathe?
- ➤ How do you usually care for your skin?
- ➤ What soaps, lotions, or other skin care products do you use?
- ➤ Do you have difficulty controlling body odor?
- ➤ Have you ever had an allergic skin reaction to food, medications, plants, skin care products, or other materials?
- ➤ What problems have you had with your skin in the past?
- ➤ What problems are you having with your skin now?
- ➤ For each problem identified, ask:

  What symptoms are you having (e.g., any rash or itching)?

  Where is the problem located?
- ➤ How long have you had this problem?
- ➤ What have you done to provide relief from the symptoms?
- ➤ Do you use any prescription, over-the-counter (OTC), or herbal remedies to treat this problem?
- ➤ Have you seen a healthcare provider about this problem?
- ➤ Was a diagnosis made? If so, what was it?
- ➤ How has this problem affected your life?

Focused Assessment

Guidelines for Assessing Hygiene—cont'd

- How can I best help you with your skin care?
- Also ask about the presence of diseases or other factors that are known to cause skin problems; for example, decreased mobility, decreased circulation, incontinence, inadequate nutrition, or deficient knowledge.

Objective Data

- Note the skin's overall cleanliness, condition, color, texture, turgor, hydration, and temperature.
- Observe for rashes, lumps, lesions, and cracking.
- Look for drainage from wounds or around tubes.
- Observe for four significant color changes: pallor, erythema, jaundice, and cyanosis.

Feet

Subjective Data

Ask the patient the following questions or obtain the data from his records:

- What is your normal foot care routine?
- What type of footwear do you usually wear? Observe what the patient is wearing.
- Have you had any foot problems; what treatments have you had for them?
- Do you examine your feet on a regular basis?
- Do you have diabetes mellitus or peripheral vascular disease?

Objective Data

Compare findings for both feet:

- Observe for cleanliness and skin integrity. Note open areas, drainage, or redness.
- Inspect for swelling, inflammation, or infection.
- Palpate for edema.
- Check the skin between the toes for cracks or signs of a fungal infection.
- Notice the color and temperature of the feet; are they the same bilaterally? The color and temperature provide data about circulation and oxygenation. For example, cold, dusky feet may indicate impaired circulation or tissue perfusion secondary to a peripheral vascular disease.
- Check capillary refill. How many seconds does it take for the color to return after you apply pressure?
- Note the presence of foot odors, if any.

Nails

Subjective Data

Ask about the patient's usual nail care practices, history of nail problems, and their treatments.

Objective Data

Inspect the nails for the following:

- Shape, contour, and cleanliness
- Presence of broken nails, hangnails, or cracked cuticles
- Hands: Do the fingernails appear neatly manicured, or does the patient bite the nails?
- Feet: Are the toenails trimmed appropriately, straight across?
- Presence of redness or swelling at the nail base or sides

Oral Cavity

Subjective Data

- Usual hygiene practices
- History of periodontal disease or other oral problems
- Financial or insurance problems that limit access to dental care
- Nutritional status and dietary habits (e.g., intake of refined sugars)
- Medications, such as anticonvulsants or diuretics
- Medical treatments, such as radiation therapy, oxygen therapy, and nasogastric tubes
- Other factors known to cause oral problems (smoking, alcohol use, NPO status, dehydration, mouth breathing)
- Self-care deficits (e.g., cognitive impairment, activity intolerance, impaired mobility, depression, lack of knowledge, lack of motivation)

Objective Data

- Observe the lips, which should be pink and moist without lesions.
- Inspect the oral mucosa and gums, which should also be pink, moist, smooth, and free of lesions.
- Healthy gums should have a well-defined margin at each tooth. There should be no visible bleeding.
- Instruct the patient to stick out his tongue and to move it around. It should move freely. The tongue should be symmetrical and pink, with a slightly rough surface.
- Assess the teeth for the presence of any loose, missing, or decaying teeth.
- Examine the hard and soft palates for color, lesions, patches, or petechiae.
- Note any unusual mouth odors or halitosis.

Hair

Subjective Data

- Use of special products or medicated shampoos
- History of hair problems or current conditions needing treatment (e.g., pediculosis)
- History or presence of disease or therapy that affects the hair (e.g., chemotherapy)
- Factors influencing the patient's ability to manage hair and scalp care (e.g., Impaired Mobility)
- Personal or cultural preferences for styling of the hair

Continued

Focused Assessment

Guidelines for Assessing Hygiene—cont'd

Objective Data

- Note the condition, cleanliness, texture, and oiliness of the hair.
- Inspect the scalp for dandruff, pediculosis (head lice), alopecia (hair loss), secretions, or lesions.

Eyes

Subjective Data

- If the patient wears glasses, ask when he uses them (e.g., for reading, for driving) and ask how well he sees without them.
- If the patient wears contact lenses, determine:
- The type of lens (hard, soft, long-wearing, disposable).
- How often he wears them (daily, occasionally) and for how long at a time. Are they worn during sleep?
- History of, or present, problems with lens usage (e.g., cleaning, removal).
- Usual practices for cleaning and storage.
- History of, or current, problems with the eyes (e.g., redness, tearing, irritation, dryness or "scratchy feeling").

Objective Data

- Inspect the eyes for redness, lesions, swelling, crusting, excessive tearing, or discharge.
- Check the color of the conjunctivae.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Alice Baker is a frail elderly woman, 93 years old, who lives in a nursing home. She has almost total Self-Care Deficit related to her weakness, painful joints, and dementia. Her mental and physical conditions are not likely to improve. Imagine that your charge nurse has instructed you to provide a complete bed bath and other hygiene care for Ms. Baker. When you enter her room with bath supplies and say, "Good morning, Ms. Baker; it's time for your bath," she screams, "Go away from me. I just had a bath. I don't want a bath." You discuss this with the charge nurse, who says, "She has not had a bath, and she needs one today. You will need to do it whether she likes it or not." You tend to agree that Ms. Baker needs a bath because her clothing and linens have food stains, and she smells of urine and perspiration.

THINKING

1. *Theoretical Knowledge:*
   a. What benefits does a bath have for Ms. Baker?
   b. What are the disadvantages of bathing a patient with dementia who is resisting the bath?
2. *Critical Thinking (Considering Alternatives, Deciding What to Do):*
   a. What do you think Ms. Baker is feeling and experiencing, and how does that help you know what to do?
   b. What are some alternatives to a complete bed bath that would achieve the same purposes?

DOING

3. *Practical Knowledge:* Imagine that you have, indeed, decided that Ms. Baker needs a bath. Which type bath you will give her? What supplies will you need, and where will you find them in the clinical agency you have attended most recently?

CARING

4. *Self-Knowledge:* What is your greatest concern about bathing Ms. Baker; what is the cause of your concern?

Critical Thinking and Clinical Reasoning

1. You are caring for Mrs. Little, a 57-year-old woman who has been experiencing severe arthritic pain for the past 2 years. She rates her pain at an 8 or 9 on a 10-point pain-rating scale. During your assessment, you notice that Mrs. Little has a moderate body odor, long and untrimmed fingernails and toenails, oily hair, and unshaven legs and axillae. Mrs. Little readily admits that she has neglected her hygiene practices.
   a. What is the first hygiene-related nursing diagnosis (problem and etiology) that comes to your mind for Mrs. Little?

b. What data do you have to support a diagnosis of Bathing Self-Care Deficit? What data do you have to support an etiology of "immobility secondary to pain"?
c. With the information in the scenario, how would you rate her Self-Care Deficit: mild, moderate, severe, or total?
d. Anything you could do to help relieve Mrs. Little's pain would facilitate her self-care abilities. However, to plan interventions in which you will assist with her hygiene care, what further patient data do you need?
e. Suppose you assess Mrs. Little further and determine that she has arthritis in multiple joints, including her hands, shoulders, back, knees, and feet. You also determine that she will need a complete bath, either tub or shower, but that she can brush her own teeth if someone provides the necessary supplies. Could you delegate her A.M. hygiene care to an experienced nursing assistive personnel (NAP)? If so, what instructions would you give the NAP?

2. Mr. Thomson is an 87-year-old African American man admitted 2 days ago after being found unconscious in his small apartment. Although Mr. Thomson denies being diabetic, his admission blood sugar was 653 mg/dL. His lower legs are swollen, red, and weeping a clear fluid. His toenails are long, thick, and yellow, and there is a small open sore on the great toe of his left foot. Mr. Thomson's skin is dry and scaly, his hair matted, and he has a strong odor of perspiration and urine. He is uncircumcised. He refuses help with hygiene, saying, "I've taken care of myself for 87 years, and I'll keep doing it. I take my bath once a week on Saturday evening. Now go away!"
   a. What theoretical knowledge will you need in order to know what to assess and how to provide his hygiene care?
   b. Self-knowledge is important in this case as well. What things in this situation would make caring for Mr. Thomson especially difficult for you? What biases, values, or attitudes might interfere with your ability to give your best care?

3. Recall the Meet Your Patients scenario in your textbook. The remaining critical-thinking questions refer to that scenario:

   Your instructor has assigned you to assist the following patients with their hygiene. You must assess the needs of each person, gather information on their bathing habits and preferences, plan nursing measures necessary to meet individual needs, and together with a NAP, provide care.

   The first person on your assignment is Mrs. Williams, a 76-year-old Indian American woman who was admitted yesterday after suffering a stroke that paralyzed her right side. Since the stroke, she has been unable to speak clearly and becomes frustrated as she attempts to communicate her needs. Her daughter says Mrs. Williams is a proud, independent, and tidy woman who has been living alone since her husband's death last year. She has been driving her car, cleaning the house, doing her grocery shopping, and maintaining the yard and garden. She wears eyeglasses for reading and driving and has a hearing aid, although she rarely uses it.

   The second person on your assignment is Mr. Gold, a 68-year-old man of Orthodox Jewish religion, admitted last week after he experienced a massive heart attack. Although his eyes are open, he is unresponsive to external stimuli. Because of Impaired Swallowing, Mr. Gold is unable to take food or fluid orally; his family has chosen to have a feeding tube placed to ensure adequate nutrition and hydration. His oral mucous membranes and lips are dry and crusty. He is incontinent of urine and stool. Mr. Gold's son, Ira, tells you that throughout his life Mr. Gold adhered to Orthodox Jewish law. The son requests that, in honor of his father, certain aspects of these laws be included in the care plan.

   The following questions are about Mrs. Williams:
   a. To assess Mrs. Williams' self-care abilities, what important patient data do you still need?
   b. What problem has resulted from her stroke that will make it difficult for you to find out about Mrs. Williams' hygiene preferences and practices?
   c. From what you know of the patient situation, why do you think Mrs. Williams is becoming frustrated?
   d. How do you think you would react if this were to happen to you?
   e. How could you provide opportunities for Mrs. Williams to maintain her independence?

4. The following questions are about Mr. Gold:
   a. What additional theoretical knowledge do you need to meet Mr. Gold's religious and cultural needs when providing hygiene care?
   b. Where could you obtain such information?
   c. If you decide to delegate Mr. Gold's bed bath to a NAP, how could you incorporate his religious and cultural needs into your delegation decisions?

5. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or facilitating hygiene. Note that these are *not* to be merely definitions.
Personal hygiene

Delegation of tasks	Patient teaching
Cultural differences	Bathing
Skin integrity	Oral care
Life span variables	Environment and comfort
Self-Care Deficits	Hair care
The nursing process	Nail care

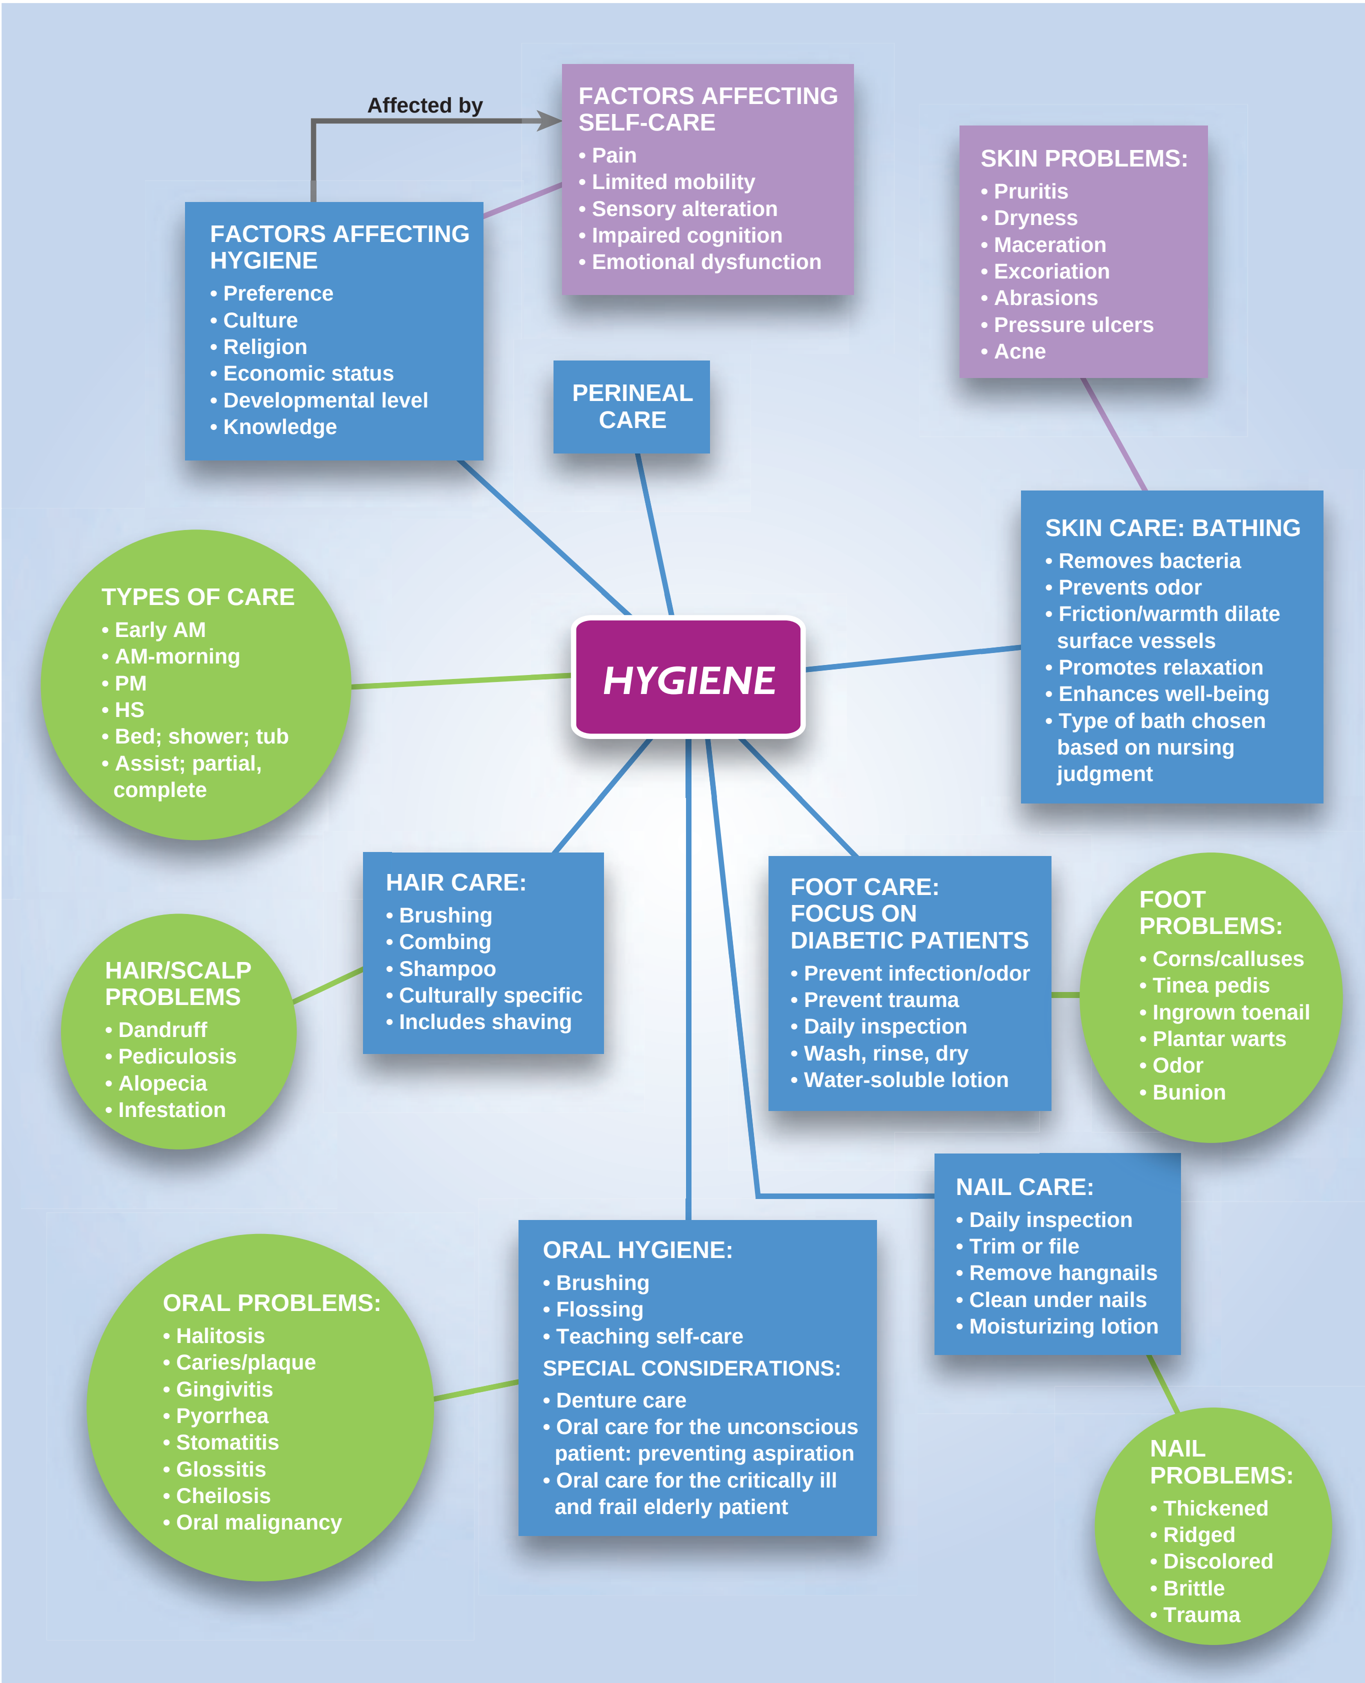
What Are the Main Points in This Chapter?

- Current guidelines are changing the way nurses provide hygiene. The long-held tradition of using a basin, soap, and water to bathe hospitalized patients is no longer the recommended standard of practice.
- Recent recommendations include (1) the use of disposable, single-patient-use basins to reduce risk of bacterial contamination and (2) avoiding the use of unfiltered tap water in hospitals, unless the water lines are known to not contain biofilm. Alternatives include prepackaged bathing products and the use of sterile or distilled water or filtered water from faucets.
- Personal hygiene contributes to physical and psychological well-being by promoting comfort, improving self-image, and decreasing infection and disease.
- Although a patient may need assistance with hygiene measures, the goal is to encourage as much independence with these tasks as possible.
- Numerous factors influence individual hygiene practices, including personal preferences, cultural/religious/spiritual values and beliefs, economic status, living environment, developmental or knowledge level, and physical and emotional health.
- Maintain a respectful, nonjudgmental attitude about cultural and spiritual differences. Avoid the temptation to impose personal values about hygiene practices onto patients.
- Consider patients' personal hygiene preferences, and incorporate them into the care plan whenever possible. This reflects caring and promotes maximum participation and independence with ADLs.
- Although many hygiene measures can be delegated to the NAP, the nurse retains full responsibility for each patient and must instruct the NAP about the patient's limitations and restrictions, amount of assistance necessary, use of any assistive devices, any specific safety precautions to be undertaken, and any other factors influencing the patient's hygiene practices.
- The nurse should assess a patient's functional status regularly.
- Teaching patients about hygiene is a primary function of the professional nurse.
- Intact skin is the body's first line of defense to keep pathogenic microorganisms from entering the body and causing infection.
- Bathing removes perspiration and bacteria from the skin surface. It promotes relaxation and comfort, improves circulation, reduces odor, and enhances well-being by increasing self-image. However, it can be stressful for some patients.
- You should choose the type of bath to meet the patient's needs (e.g., assist bath, total bed bath, bag bath, and so on).
- Bathing is stressful to some patients (e.g., the frail elderly, people with dementia, the morbidly obese). You should focus on the patient's needs for warmth, safety, and comfort, and adapt the bathing procedure to help reduce stress.
- Despite common myths, it does not take a lot of water to get a person clean, and not all patients need a complete bath every day.
- A complete bath includes perineal care.
- Careful assessment of the feet allows for early detection of common foot problems, such as calluses, corns, tinea pedis, ingrown toenail, or foot odor.
- Because dirt and debris can collect under the nails and serve as a source of infection, nail care is an important part of hygiene, especially in patients with diabetes mellitus or peripheral neuropathy.
- To maintain healthy mucous membranes, teeth, and gums, and to prevent tooth loss and gum disease, regular dental checkups and daily mouth care,

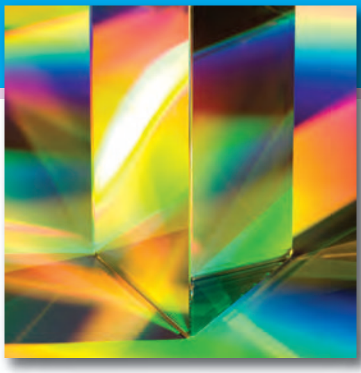
including brushing and flossing the teeth, are necessary.

- For critically ill and frail elderly patients, as well as those using ventilators, special attention to oral hygiene helps to reduce the risk for pneumonia.
- Oral hygiene is challenging for patients with dementia, but it must not be neglected.
- The condition of the hair is a measure of an individual's overall health. Shampooing and daily brushing of the hair massages the scalp, stimulates the circulation, and distributes the natural oils.
- The eyes normally require very little care; however, when necessary, they may be gently cleansed from the inner to the outer canthus.
- Unconscious or critically ill patients who no longer have a blink reflex may need eye care at least every 2 to 4 hours. Keeping the eyes lubricated protects them from corneal abrasions and drying.
- Some contact lenses can be worn for only about 12 hours at a time; others may be worn for up to 30 days. Some are disposable; some are not. All types must be cleaned carefully and regularly.
- Hearing aids are expensive and should be properly handled and stored. They should not be immersed in water.
- When reinserting an artificial (prosthetic) eye, first be certain that it is wet.
- Usually no special care is required for the nose. Excess secretions can be removed by gentle blowing with both nostrils open.
- Clean, wrinkle-free bed linens help to promote comfort and a sense of well-being.
- Room temperature, adequate ventilation, low noise level, and neat and clean surroundings all contribute to a comfortable patient environment.

Knowledge Map



CHAPTER 26



Administering Medications

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your response to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 26:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Administering Medications (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 26, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Kim Phan, the 3-year old grandson of Nam and Yen Nguyen, has been tired and observed to be sitting down a great deal at preschool. Last week, he developed coughing, wheezing, shortness of breath, nasal congestion, and extreme fatigue. The pediatrician at the Family Medicine Center diagnosed asthma. He prescribed a 5-day tapering course of prednisone, a leukotriene inhibitor (Singulair) 4 mg orally daily at bedtime, and periodic treatments with albuterol through a home nebulizer system.

Nam's mother, Mai Nguyen, became very upset when she saw the bottle of prednisone elixir. She was even more upset when she learned that Kim received an injection of the medicine in the office. She advised Yen not to give Kim the medicine because she said it causes weak bones and stunts growth. Yen has called the clinic asking for advice on how to handle this problem.

A. What theoretical knowledge do you need to answer these concerns?

B. What are some reliable sources where you might find this information?

C. What rationale could you offer to Yen to explain the safety of the prednisone prescription? You will need to use a variety of references to answer this question.

D. Yen asks you to explain why Kim received both a shot and pills. How would you respond?

E. Why is Kim receiving a leukotriene inhibitor (Singulair) orally and albuterol by nebulizer? Look up the medications, and use your knowledge of different routes of administration.

PracticalKnowledge knowing how

The practical knowledge you will need to administer medications safely and effectively includes procedures and guidelines for calculating and measuring dosages and administering medications by a variety of routes.

PROCEDURES

Procedures in this section will assist you to prepare, measure, and administer various types of medications, to locate injection sites, and to handle needles safely. Use the following Medication Guidelines for all types and routes.

Medication Guidelines: ■ Steps to Follow for All Medications (Regardless of Type or Route)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ **Key Point:** ***Regardless of the type or route of the medication you are giving, you should always follow the steps below.***

Equipment

- Medication administration record (MAR)
- Medication drawer or portable cart with, as needed, keys to the medication drawer
- Gloves for the procedure, as needed
- Other supplies and equipment needed for the specific procedure (e.g., water, antiseptic wipes)

Delegation

As a registered nurse (RN), you can usually delegate administration of medications (except for intravenous [IV] medications) to a licensed practical nurse/licensed vocational nurse (LPN/LVN). You cannot delegate this task to nursing assistive personnel (NAP). You can instruct a NAP in the therapeutic effects and side effects of medications and to report any effects observed.

Nurse practice acts governing medication administration vary from state to state, and policies vary among healthcare agencies. In some states, with additional education and training, LPN/LVNs can administer IV medications and NAPs can administer some medications. You must know the scope of practice described in your state's nurse practice act. The RN is always responsible for evaluating client responses, which include both therapeutic effects and side effects.

Pre-Procedure Assessments

- Assess your knowledge of the medication (e.g., drug action, purpose, recommended dosage, time of onset and peak action, common side effects, contraindications, drug interactions, and nursing implications).
- Determine whether the prescribed dosage is appropriate for the patient's age and weight.
  Dosages are generally decreased for children because of both age and weight. Usually dosing for elderly patients is not based on weight but on renal function. Both groups have less efficient liver and renal function, increasing the length of time a drug stays in the body before being excreted.
- Check for any history of allergies to medications or food.
  Some medications (e.g., penicillin and cephalosporin) have cross-sensitivity; that is, a patient with a penicillin allergy is at high risk for also being allergic to cephalosporin. Medications can also have cross-sensitivity with certain foods. For more information about how drugs interact with other drugs or with food,

Go to Chapter 26, **Tables, Boxes, Figures: ESG Table 26-5, Drug-Drug and Food-Drug Interactions,** on Davis*Plus*.

- At least the first time you administer medications to a patient, assess his knowledge of the medications being given.
  The patient will be more likely to take the medication correctly if she understands why she is taking the medication.
- Assess for factors that could interfere with drug absorption (e.g., diarrhea, inadequate circulation, foods, impaired liver function, edema, inflammation, age-related changes, and other medication).
- Assess vital signs and check lab studies specific to the medication to determine whether the medication can be safely administered.
  Medications are metabolized more slowly in a person with decreased liver function.
- Assess for situations in which it would not be reasonable to administer the medication (e.g., oral medications prescribed for a patient who is NPO, vomiting, swallowing difficulties, sedated).
  If the medication does not seem reasonable, question the prescriber.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Check the MAR** for the patient's name and identification number, medication, dose, route, time, and drug allergies. The rights of medication administration are: the right patient, right drug, right dose, right route, right time, and right documentation. At the beginning of your shift, check the MAR to determine when medications are due **(1st check)**.
   Medication prescriptions may change even during your shift; checking the MAR helps ensure that you do not miss medication changes.

2. **Verify the prescription.** It should include the patient's name, patient identifier, medication name, dose, route, time, and patient allergies.
   You must note whether it has changed (e.g., since the last time you gave the drug). Clarify any discrepancies before giving the medication.

3. **Follow agency policies** for medication administration, including the time frame. Most agencies allow medications to be given 30 minutes before or 30 minutes after the time indicated on the MAR. Do not prepour medications.
   The time of administration is important for some medications. For example, if an anti-infective agent is given early or late, a therapeutic blood level may not be maintained.

4. **Perform hand hygiene.**
   Hand hygiene minimizes transmission of microorganisms.

5. **Access the patient's medication** drawer, unlock the medication cart, or log onto the medication dispensing computer.

6. **Obtain the narcotic cabinet key** (or code), when administering a narcotic or barbiturate, and sign out the medication, including the patient's name, drug, dose, and other pertinent information per agency policy. Note the drug count when removing a narcotic.
   Federal law governs administration of controlled substances. All narcotics and barbiturates are counted and signed by an outgoing and oncoming nurse every shift.

7. **Select the prescribed medication.** Read the label and compare medication with the MAR for the first five rights (patient, drug, dose, route, time); check for drug allergies:
   - An inpatient should be wearing an identification band with the drug allergies identified.
   - Allergies should be clearly marked in the chart and on the MAR or in the electronic health record (EHR).
   - Ask the patient about allergies the first time you administer a medication and before giving a newly prescribed medication.

(continued on next page)

Medication Guidelines: ■ Steps to Follow for All Medications (Regardless of Type or Route) (continued)

These actions ensure that the correct drug is being given to the correct patient at the correct time in the correct dose by the correct route.

Key Point: ***Correct drug includes the correct form of the drug (e.g., oral, IV).***

8. **Calculate the medication dosage.** Double-check it. If you are unable to measure the dose exactly, contact the pharmacist.
9. **Check the expiration date** (on the label or on the box) of all medications.
   A medication that has expired is no longer guaranteed to be effective.
10. **Do a second check** after preparing the medications, to verify the correct patient medication, dose, route, and time **(2nd check)**.
    Verifies the first five rights of medication administration.
11. **Lock the medication cart.** Never leave an unlocked medication cart unattended.
    This guards against pilferage and protects children, older adults with dementia, or anyone wanting to open the cart.
12. **Administer the medications**.
    a. Take the medication and MAR or a hand-held portable device with the EHR into the patient's room.
    You must be able to do the final check in the patient's room and verify that you are administering the correct medication to the correct patient.
    b. Identify the patient using two forms of identification, according to agency policy: Check the identification bracelet, have the patient state her name, compare the patient to a posted picture of her, and check the patient's date of birth against the MAR.
    Agencies have different means of identifying patients. The Joint Commission requires two forms of identification.

    c. Do a check of the rights of medication: right patient, right medication, right dose, right route, and right time **(3rd check)**.
    Checks for the rights of medication are always required to prevent medication errors. Although it is not actually an "error" until the patient has taken a medication, you may be required to file a report for a "near miss" that was detected during the pre-administration checking process.
    d. Perform any necessary assessments, such as checking the pulse or blood pressure.
    Some medications can be given only if physical findings or vital signs are within certain parameters. For example, antihypertensive medications may need to be held if the blood pressure is lower than the patient's normal baseline.
    e. Explain to the patient that you are there to administer the medication; teach her about the medication.
    Patient teaching increases the patient's understanding of and compliance with treatment. Also, the patient may identify potential errors in medication administration.

    If the patient questions a medication, double-check the medication to be sure you are giving the correct drug and dosage.

    f. Administer the medication using appropriate technique (see the procedures for administering medications by the specified route).
    g. Remain with the patient until you are sure that she has taken the medication.
    If you leave a medication at the bedside, someone else (e.g., another patient or a child) might take it, or the patient might discard it.
    h. Document the medication given in the patient's medication record (date, dose, route, and your name).
    Your initials on the MAR means that you administered the medication to the patient. If the documentation is not in the patient's record, there is a risk that another nurse will assume the medication was not given and administer it again.

? What if . . .

■ **The patient tells you the tablet you are ready to give him is a different color from what he normally takes of a certain prescribed medication?**

Determine why the tablet is different from what the patient is used to taking to be sure you are giving the correct drug and dose. Always verify the identity of the drug, especially when it is called into question by the patient who is familiar with the medication he normally takes.

Double-checking whenever you are uncertain about a medication you are about to administer helps prevent medication errors—it is possible you have the wrong drug or dosage.

- **The label on the medication shows an expiration date that has passed?**

  Do not give the medication. Send it back to the pharmacy for replacement.
  Expired medication can lose its potency.

- **The patient refuses to take the prescribed medication?**

  Discuss with the patient his concerns about the medication. Hold the dose and notify the prescriber of the patient's refusal and explain the patient's concerns.
  The patient has a right to refuse medication.

- **You cannot decipher the prescriber's handwritten medication order?**

  Hold the dose and contact the prescriber for clarification. Never administer medication if you are unable to read the entire order.
  Handwriting that is hard to read is a common cause of preventable error. Electronic prescribing can help to avoid this.

- **Your patient's medication is not available from the pharmacy at the time the dose is due?**

  Do not borrow the medication from another patient's supply. Administer only medication prescribed for that particular patient. Notify the pharmacy of the need to immediately dispense the medication.
  Using another patient's medication increases the risk for error because drug dilution or dosage might vary among patients; or the drug names might sound similar, but might be different medications. Also the safety system for charges and refills is bypassed when doses are borrowed from other patients, resulting in missing doses or erroneous charges.

Evaluation

- Evaluate the therapeutic effects of the medication (e.g., check blood pressure after administering an antihypertensive medication, or check pain level after an analgesic).
- Be alert for any adverse reactions, side effects, or allergic reactions. If present, notify the appropriate care provider.

Patient Teaching

- Describe how the drug is prescribed and when the patient should take the medication.
- Discuss the importance of taking the medication as prescribed.
- Explain the need for any laboratory tests for monitoring the medication, such as tests to measure drug level in the blood, if appropriate.
- Explain the purpose, common side effects, and drug interactions of the medications the patient is taking.
- Teach the patient to observe for side effects that signal the need to contact the prescriber.
- Discuss ways to minimize the side effects of a medication, such as avoiding the sun when taking a medication that causes photosensitivity or rising slowly when taking a medication that causes orthostatic hypotension.
- Discuss potential cultural issues related to taking the medication (e.g., In some Hispanic/Latino cultures, a patient may refuse a medication that is considered "hot" if he believes a "cold" treatment is needed).
- Teach the patient to self-administer medications (e.g., ear drops), as appropriate.

Home Care

- Assess the client's ability to safely self-administer medications.
- Determine the client's financial ability to obtain medications.
- Instruct the client about safe storage of medications.
- Provide instructions for use of each medication.
- Determine whether the client or caregiver has had past problems or present concerns about taking the medications as prescribed.
- If problems have occurred in the past or there are present concerns, discuss possible remedies. For example, you might teach the client or caregiver to use a medication storage container with compartments for the times and days of the week.

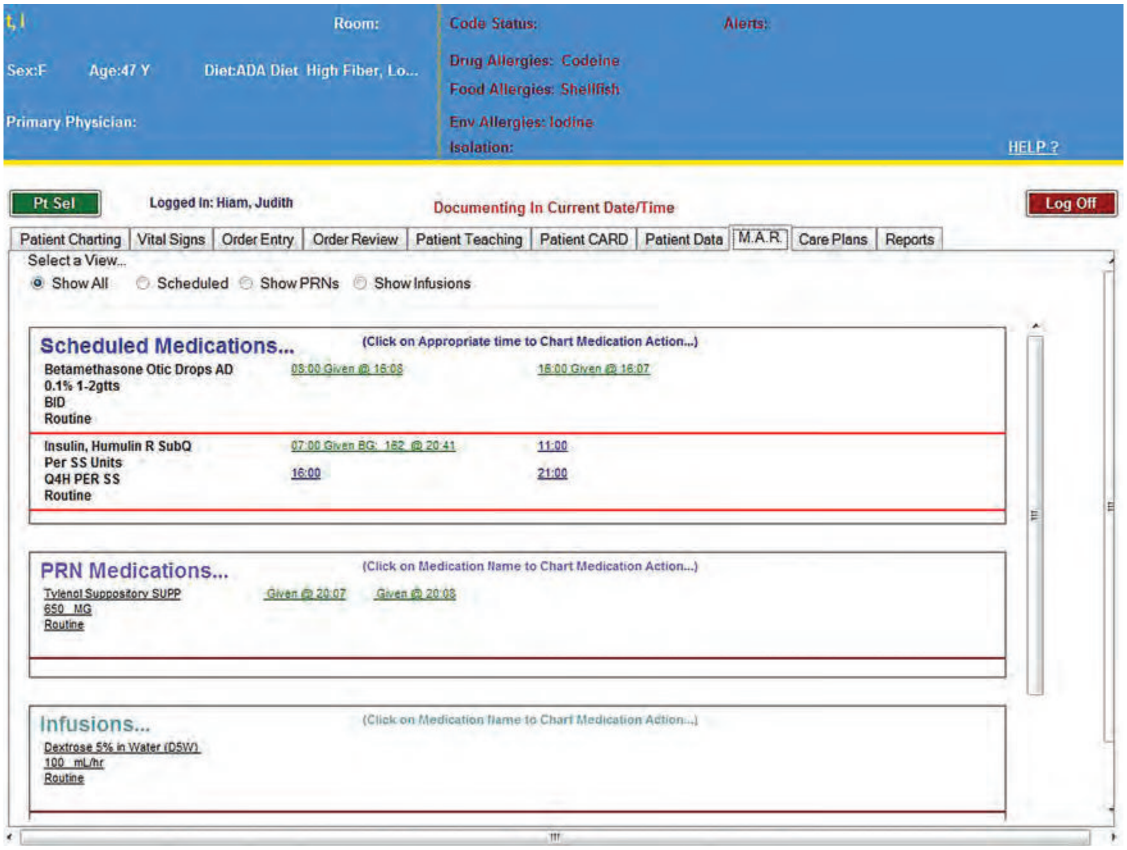
Documentation

- Chart the medication, time, dose, and route given, preadministration assessments, and your signature.
- Do not document before giving the drug; do not document for anyone else; do not ask another nurse to document a drug you have given. Document only *after* administering the medication.
- Chart all therapeutic and adverse effects of the medication. Chart your nursing interventions and teaching of potential adverse effects.
- Record the scheduled medications on the MAR. Record prn medications in the nursing notes and on the MAR, including the reason the medication was given and the patient's response to the medication.
- If the patient is unable or refuses to take the medication, document on the MAR that the medication was not administered and the reason, and inform the physician.
- For parenteral medications, chart the site of injection.

(continued on next page)

Medication Guidelines: ■ Steps to Follow for All Medications (Regardless of Type or Route) (continued)

Sample EHR documentation



Practice Resources

Institute for Safe Medication Practices (n.d.); The Joint Commission (n.d.); U.S. Food and Drug Administration (2012, updated 2013).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Medication Guidelines.**

For suggested questions and responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 26-1 ■ Administering Oral Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Desired liquid for swallowing medications
- Disposable medication cup
- Drinking straw, if needed
- Procedure gloves, if you will need to place a tablet in the patient's mouth
- For enteral medications:
  –Water (for diluting and flushing the feeding tube)
  –60-mL catheter-tip syringe
  –Clean gloves
- Stethoscope (*e.g., to check the apical pulse before administering some cardiac medications*)

Delegation

- As a rule, you can delegate this skill to an LPN/LVN, depending on the medication, but not to a NAP, except under special policies and situations.

Pre-Procedure Assessments

- Assess the patient's condition to determine whether there are contraindications to oral medications or to the specific medication; for example, the ability to swallow.
  Impaired swallowing increases the risk for aspiration.

- Check fluid needs and restrictions. If the patient is NPO (nothing by mouth), check with the prescriber to determine whether the medication should be given by another route or can be given with small sips of water.
  A prescriber may decide it is medically necessary to administer oral medication to a patient who is NPO. If there is a fluid restriction, you need to consider how much fluid you can give with medication. Give additional fluid to a patient with dehydration; offer only sips for the patient with a fluid restriction.
- For enteral medications, check that the NG tube is in the stomach and is patent.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Prepare the medication for administration.

For Tablet or Capsule

a. If you are pouring from a multi-dose container, do not touch the medication. Pour the tablet into the cap of the container, then into the medication cup.

b. If the medication is unit-dose, do not open the package. Place the entire unit-dose package into the cup.

c. Many institutions allow combining all tablets or oral caplets scheduled for the same time for the same patient into the same cup. However, even if the agency protocol permits dispensing from a single container, you will need separate cups for medications that require pre-administration assessment (e.g., checking the apical pulse rate prior to administering digoxin).
If a medication is held because of a pre-administration assessment finding, you can identify it more readily when it has been poured into a separate cup.

d. You may break scored tablets with a knife or a tablet cutter if necessary.
Only scored tablets may be broken. Breaking an unscored tablet would deliver an imprecise dose.

e. If a patient has difficulty swallowing, check to see whether the medication can be crushed. If so, use a mortar and pestle to grind it. If the medication is in a unit-dose package, grind it while it is still inside the package. Mix the ground medication with a small amount of soft food, such as applesauce or pudding.
Crushing some medications (e.g., capsules, enteric-coated tablets, and sustained-release formulas) may alter their effectiveness or result in an overdose due to rapid absorption.

For Liquid Medications

f. Check to see whether you must shake the liquid before opening the container.
Some liquids, such as suspensions, will precipitate and need to be shaken to mix the active ingredient with the suspension liquid.

g. Remove the bottle cap, and place it flat side down on the cart or counter.

h. Hold the bottle with the label in the palm of your hand.
Keeping the label on the upward side of the bottle prevents the liquid from dripping down onto the label and obscuring it.

i. Hold or place the plastic medication cup at eye level, and pour the desired amount of medication. Read the dosage where the lowest part of the concave surface (meniscus) of the fluid is on the line. You can, instead, place the cup on a level surface, pour the medication, then hold the cup at eye level to read the amount.
Measuring liquids above or below eye level will cause you to read the dose incorrectly and pour too much or too little medication.

j. As you finish pouring medication, slightly twist the bottle to prevent the medication from dripping down the lip of the bottle. If medication does drip down over the lip, wipe the outside of the lip with a tissue or paper towel.
Wiping the outside of the bottle helps prevent contamination, particularly for thicker solutions, such as elixirs or syrups containing sugar.

2. Administer the medication.

a. Assist the patient to a high-Fowler's position, if possible.
An upright position facilitates swallowing and prevents choking.

b. ***Powder:*** Mix with liquid at the bedside, and give the mixture to the patient to drink.
Some powders thicken very quickly and must be mixed immediately before administration.

c. ***Lozenge:*** Instruct the patient not to chew or swallow it whole.
Medication is absorbed through the oral mucosa and is generally inactivated by the acidity in the stomach.

d. ***Tablet or capsule:***

1) If the patient is able to hold the medication in her hand, place the tablet or medication cup in her hand.
Promotes independence and is easier for the patient.

2) Give the patient water or other liquid.
Giving the medication with liquid moistens the mouth and helps the patient swallow the tablet or capsule.

3) If the patient is unable to hold the tablet, don procedure gloves and place the medication cup up to her lips, and tip

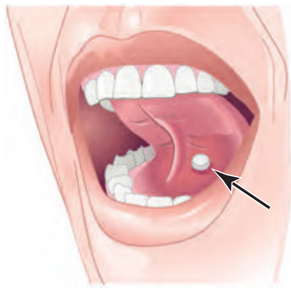
(continued on next page)

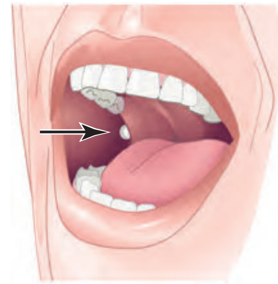
Procedure 26-1 ■ Administering Oral Medication (continued)

the tablet or capsule into her mouth.
Encourage the patient to do as much as possible. Getting the tablet or capsule to the back of the mouth will assist in swallowing.

e. ***Sublingual medications:*** **Have the patient place the tablet under the tongue and hold it there until it is completely dissolved.**
Sublingual medications are made to be rapidly absorbed through the oral mucosa. The area under the tongue is very vascular, so sublingual medications act very rapidly. Sublingual medications are inactivated by gastric acid if swallowed. ➤

f. ***Buccal medications:*** **Have the patient place the tablet between the cheek and gums.**
Buccal medications act by being absorbed through the oral mucosa or by being dissolved and swallowed in the saliva. ➤





3. **Stay with the patient until** all medications have been swallowed or dissolved.
Some patients will "chipmunk" the medication in the side of the mouth without swallowing it, or spit it out. Staying at the bedside until the patient swallows oral medication ensures that the patient receives the dose.

Procedure 26-1A ■ Administering Medication Through an Enteral Tube

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

- **If the patient is receiving a continuous tube feeding,** disconnect it before giving the medications. Leave the tube clamped for a few minutes after administering, according to agency protocol.
- **If the enteral tube is connected to suction,** you will usually discontinue the suction for 20 to 30 minutes after administration, and keep the tube clamped, to allow time for the drug to be absorbed.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* Follow Steps 1a through 1j of Procedure 26-1: Administering Oral Medication, then follow Steps 1 through 10, following. Also, follow precautions for administering enteral medications.

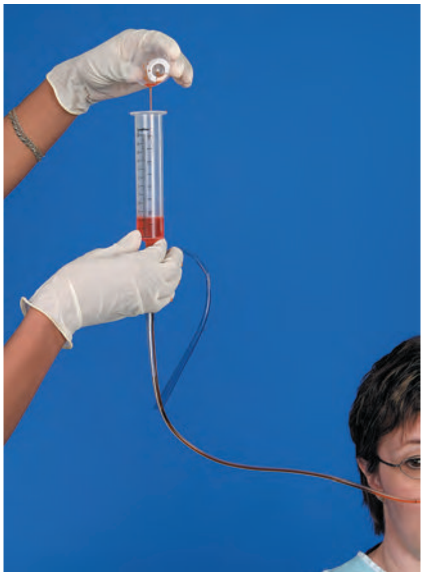
1. **Prepare the medication.**
   a. Give the liquid form of medication, if possible. If the solution is hypertonic, dilute with 10 to 30 mL of sterile water before instilling through a feeding tube.
   Hyperosmolar substances administered too rapidly into the gut can cause bloating, nausea, and osmotic diarrhea.
   b. If tablets or capsules must be given, verify that the medication can be crushed and given through an enteral tube.
   Some tablets (e.g., sustained-release or enteric-coated tablets) should not be crushed or capsules opened because doing so changes their action.
   c. Crush the tablet and mix it with approximately 20 mL of water or obtain a liquid medication. If you are giving several medications, mix and administer each one separately.
   If you are using a small-bore tube, such as a PEG tube, Keofeed NG feeding tube, or jejunostomy tube, always obtain the liquid form of the medication, because small-bore tubes clog easily. Ensure that the medication is diluted enough to pass easily through the tube. Instilling drugs one at a time allows you to identify each medication.
2. **Don nonsterile procedure gloves.**
Gloving maintains standard precautions.
3. **Place patient in a sitting (high-Fowler's) position,** if possible.
An upright position reduces the risk for aspiration and choking.
4. **For NG tubes, check tube** placement (see Chapter 27, Clinical Insight 27-7) by aspirating stomach contents or measuring the pH of the aspirate, if possible. Other, less accurate methods, are injecting air into the feeding tube and auscultating, or asking the patient to speak.

   Never rely on only one bedside method for checking tube placement; use a combination of methods.

   NG tubes can become displaced or positioned in the lungs. If medications are given through a misplaced NG tube, the patient may develop aspiration pneumonia.
5. **Check for residual volume** (see Chapter 27, Procedure 27-3).

6. **Flush the tube.** Based on the type of tube, use a piston tip or luer-lock syringe (usually a 30- to 60-mL syringe). Remove the bulb or plunger; attach the barrel to the tube; and pour in 20 to 30 mL of water.
Flushing ensures patency of the tube and also clears the tube of feeding solution that could clump with medication.

7. **Instill the medication** by using the barrel of the syringe as a funnel and allowing it to flow based on gravity.



For Viscous Medication
Instill the medication by depressing the syringe plunger.

8. **Flush the medication through** the tube by instilling an additional 20 to 30 mL of water.
Flushing ensures that all the medication has been administered and prevents the tube from clogging.

9. **If there is more than one** medication, give each separately, flushing after each.
Some medications are less effective when given in combination, or there may be an additive effect if they have similar actions.

10. **Have the patient maintain a** sitting position for at least 30 minutes after you administer the medication.
An upright position minimizes the risk of aspiration. It takes at least 20 minutes for liquids to pass through the stomach.

What if . . .

- **My patient is an older adult who is to receive medication through an enteral tube?**

Check level of consciousness, mentation, or alertness. Check for potential aspiration risk by checking the patient's swallow and gag reflexes.

- **My patient is a child who is to receive medication through an enteral tube?**

Use only medications that are prepared in liquid form.

Prevents occlusion of the tube.

Position an infant in a prone, side-lying, sitting, or reverse Trendelenburg position for 30 minutes to 1 hour following medication administration.
This position facilitates peristalsis and transport of medication through the intestine.

- **The prescribed medication should be given on an empty stomach?**

If the medication should be taken on an empty stomach, stop the feeding 30 minutes before giving the drug. Resume 30 minutes later.
These times allow for medication absorption to occur before the feedings resume.

Evaluation

For medications administered orally:

- Note whether the patient has difficulty swallowing, gags, or coughs while swallowing oral medication.
- Evaluate for gastric discomfort, nausea, vomiting, or diarrhea.
- Assess for signs of drug allergy or intolerance to the medication.

For medications administered through a feeding tube:

- In addition to the preceding assessments, assess that the NG tube is correctly placed and patent before and after administering the medication.

Patient Teaching

- Refer to Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).
- Discuss drug safety measures with the patient, including use of child-safety caps (or using an easy-open cap for an elderly population or with those likely to have difficulty opening containers of this type); keeping the medication in its original container; discarding expired medications; avoiding transferring medication to another container; and carefully reading the label and directions for each medication.
- Discuss the relationship between food and the medication, if needed. For example, is the medication to be taken with food or not? Does taking medication on an empty stomach contribute to nausea or gastric irritation? Does the medication interact with any foods? For more information about how drugs interact with food,

Go to Chapter 26, **Tables, Boxes, Figures: ESG Table 26-5, Drug-Drug and Food-Drug Interactions,** on Davis*Plus*.

For Enteral Medications

Cover the preceding topics for patient teaching about oral medications, plus the following:

- Discuss the importance of upright positioning for 20 to 30 minutes after taking medication through an enteral tube.
- Instruct the patient to immediately notify his healthcare provider if he chokes or has difficulty breathing during or shortly after medication is given by enteral tube. He should stop the medication immediately, and emergency care might be necessary.

(continued on next page)

Procedure 26-1 ■ Administering Oral Medication (continued)

Home Care

Advise clients who are receiving enteral medication at home to do the following:

- Notify the healthcare provider: (1) if any of the following lasts for more than a day: diarrhea, constipation, nausea, dark urine, bad-smelling urine, or dry mouth; (2) if the tube becomes clogged or seems to be moving farther out or in; or (3) if the feeding tube falls out or you cannot confirm that the end of the tube is in the stomach.
- To prevent a clogged feeding tube, flush the tube with water each time after giving a medication or a feeding.
- Brush your teeth at least twice daily, if an NG tube remains in place continuously.
- Clean daily the area where the NG tube goes into the nostrils. Use a cotton-tip applicator moistened with warm water. If your nose is sore, you might apply water-soluble lubricant.
- Change the nasal tape every other day or when it is loose or soiled.

Documentation

- Scheduled medications are often recorded only on the MAR.
- Document the drug, dosage, time, route, and your name as the healthcare provider administering the medication.
- Document any suspected drug reaction, intolerance, or patient response to the medication.
- For patients whose intake and output are being measured, document the amount of liquid medication and the water used for swallowing medication. Some patients may be on fluid restrictions, so record *all* intake. Follow your clinical facility protocol.

For Enteral Medications

Document the following:

- Patency, residual volume, and verification of placement.
- Any difficulty with administering the medications through the feeding tube.
- On the intake and output record, record the amount of liquid medication and the water used for flushing. Some providers order a specific amount of water to flush with each medication administration or feeding. Some healthcare facilities use a protocol amount of water to flush gastrostomy tubes. Follow the protocol in your clinical facility.

Sample documentation for a PRN oral medication:

mm/dd/yyyy 1800 *Placed client in Fowler's position. Administered Lasix 20 mg. PO tablet with 30 mL water. Patient tolerated medication with no swallowing difficulties.*
S. Smith, RN

Sample documentation for an enteral medication:

mm/dd/yyyy 1400 *Placed client in Fowler's position. GT placement confirmed with pH of 4.5 using gastric aspirate. Administered 10 mL of liquid medication and flushed with 20 mL of water. Tolerated medication with no complaints.*
S. Smith, RN

? What if . . .

- **My patient vomits shortly after taking oral medication?**
  Notify the prescriber for instructions about whether or not to repeat the dose.
- **My patient is unable to sit upright to take oral medication?**
  Assist the patient into a side-lying position and offer a straw to take water with capsules or tablets.
- **My patient has difficulty drinking from a cup?**
  Use a syringe without a needle to place the medication in his mouth. Place the patient in a side-lying or upright position. Place the syringe between the gum and cheek in the back corner of the mouth, and slowly push the plunger to administer the liquid.
- **My patient is NPO (nothing by mouth)?**
  Check with the prescriber to determine whether the medication should be given by another route or can be given with small sips of water.
- **My patient is on fluid restriction?**
  Use the smallest amount of water needed to swallow or dissolve tablets and to flush enteral tubes.
- **My patient is cognitively impaired?**
  Request the patient to open his mouth to see whether he has swallowed the medication; look under the tongue or side pocket near the inside of the cheek.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to the following *Davis's Nursing Skills Videos:*

Administering Oral Medications: Tablet or Capsule
Administering Oral Medications: Sublingual
Administering Oral Medications: Buccal
Administering Oral Medications: Liquid Medications

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Practice Resources

Kelly, J., Eggleton, A., & Wright, D. (2011); Morris, H. (2012); Phillips, N., & Nay, R. (2008).

Procedure 26-2 ■ Administering Ophthalmic Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Eye drops or ointment
- Tissue

For irrigation, add:

- Prescribed eye irrigation solution (e.g., 500 to 1,000 mL of normal saline or lactated Ringer's solution are commonly used)
- IV tubing or eye irrigation insert, such as the Morgan lens (Follow manufacturer's directions for this specialized equipment.)
- Ocular anesthetic, according to protocol or provider's orders
- pH paper
- Basin and towel

Delegation

An RN can usually delegate eye instillations to an LPN/LVN. You usually cannot delegate this task to a NAP, unless the NAP has special training for a specific, defined situation (e.g., "medication aides" in some long-term-care settings). See Delegation, in Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).

Pre-Procedure Assessments

- Assess the patient's eyes for redness, discharge, or other signs of irritation.
- Determine whether the eyes need to be cleansed before administration of the medication.
  Excess tearing, debris, or excess mucus in the eye could interfere with the absorption, and thus effectiveness, of the medication.

Check the prescription for where to instill medication (*Note:* We do not advise using these abbreviations—they have been disallowed by The Joint Commission—but you may still see them written in prescriptions).

OD = right eye OS = left eye OU = both eyes

For irrigations also assess the following:

- Determine the cause of the eye problem—acid, alkaline, or other chemical burn or body fluid splash; or non-embedded foreign body.
  Irrigations are generally used to remove chemical or physical irritants, but they may be done following surgery or to treat a severe infection. Normal saline (NS) or lactated Ringer's is the solution generally recommended for high-volume eye irrigations because the pH of 6 to 7.5 is closest to the normal tear pH of 7.1. Volumes of 500 to 1,000 mL are generally used.
- Assess the patient's eyes for swelling, redness, drainage, or complaints of pain.
  A baseline assessment is useful for determining the need for and effectiveness of irrigation. Sclera should be smooth, white, and glistening.
- Determine the patient's level of discomfort and ability to cooperate with the procedure.
  Combative or otherwise uncooperative patients refusing instillation of medication can interfere with the efficiency of the procedure. If the patient cannot hold still for the procedure, he may need to be sedated.
- Assess the pain level.
  Debris, chemicals, and some liquids in the eye can be extremely painful. The eye may need to be anesthetized before irrigation or a general systemic pain medication given.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

(continued on next page)

Procedure 26-2 ■ Administering Ophthalmic Medication (continued)

Procedure Steps

1. **Assist the patient to a** high-Fowler's position with head slightly tilted back, if possible.

   Do not tilt the head back if the patient has a neck injury or other contraindication. The medication can be given with the patient supine.

   An upright position keeps eye drops in the eye and helps prevent eye drops from draining into lacrimal duct.

2. **Don procedure gloves.**
   Gloving complies with standard precautions.

3. **Cleanse the edges of the eyelid** from the inner to outer canthus, if needed.
   By following the principle of "clean to dirty," you avoid transferring debris into the nasolacrimal duct.

Procedure Variation: Instilling Eye Drops

(Follow Steps 1–3. Note, however, that some sources recommend that the patient lie supine for eye drops.)

4. **Gently rest your dominant** hand (the one with the eyedropper) on the patient's forehead.
   Stabilizes the hand in the event the patient moves—prevents accidental injury to the eye.

5. **With your nondominant hand,** pull the lower lid down to expose the conjunctival sac.
   Allows visualization of the area where you will administer the medication.

6. **Position the eyedropper** about 1.5 to 2.0 cm (½ to ¾ in.) above the patient's eye. Ask the patient to look up, and drop the prescribed number of drops into the conjunctival sac. Do not let the dropper touch the eye.
   Keeping the dropper away from the globe of the eye reduces the risk of accidental injury to the eye and avoids contamination of the dropper. Having the patient look up helps to decrease the blink reflex.

7. **Ask the patient to gently close** his eyes.
   Closing the eyes helps to distribute the medication.

8. **If the medication has systemic** effects, press gently against the same side of the nose for 1 to 2 minutes to close the lacrimal ducts.
   Reduces systemic absorption through the lacrimal duct.

Procedure Variation: Administering Eye Ointment

(Follow Steps 1–3, then move to Step 9.)

9. **Gently rest your dominant** hand, the one with the eye ointment, on the patient's forehead.
   Stabilizing your hand helps to prevent accidental injury to the eye.

10. **With your nondominant hand,** pull the lower lid down to expose the conjunctival sac.
    Allows visualization of area where you will administer the medication.

11. **Ask the patient to look up** as you apply a thin strip of ointment—usually about 2 to 2.5 cm (1 in.)—in the conjunctival sac; twist your wrist to break off the strip of ointment. Do not let the tube touch the eye.
    If the medication ribbon is not broken off, lifting the tube will pull the medication out of the conjunctival sac.

   a. Ask the patient to gently close his eyes for 2 to 3 minutes. Alternatively, release the eyelids and have the client blink several times.
      Helps to distribute the medication.
   b. Explain to the patient that his vision will be blurred for a short amount of time after administration of the ointment.
      The viscosity of the ointment can cause blurring.

? What if . . .

- **My patient is a child who won't open his eye for the application?**

  Try distracting the child by turning on the television or offering an age-appropriate toy in view.
  Distraction and bribery are effective techniques for coaxing a child when cooperation is essential.

  Ask a family member to help you gain cooperation of the child.
  It might be fear or mistrust that is causing him to be unwilling to open his eyes.

- **My patient wears soft contact lenses?**

  Have the patient remove contact lenses before administering the medication and wait at least 15 minutes after instilling eye drops before reinserting the lenses.

Procedure 26-2A ■ Irrigating the Eyes

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Assist the patient to a low-Fowler's position, with the head tilted toward the affected eye, if possible.**
This position helps to drain the irrigating solution from the eye and prevents contamination of the unaffected eye.

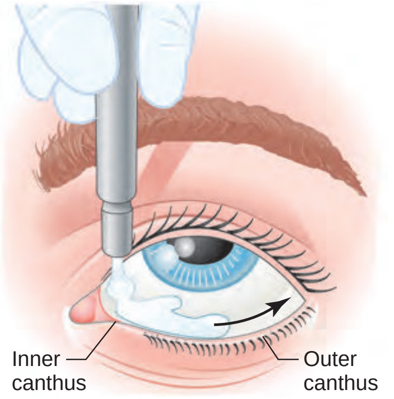
2. **Place the towel and basin** under the patient's cheek to absorb the drainage.
The patient will be more comfortable when he is clean and dry.

3. **Check the pH** by gently touching the pH paper to secretions in the conjunctival sac.
A litmus test determines the correct irrigating solution and whether the irritant is alkaline or acidic. The normal pH of tears is approximately 7.1.

4. **Follow the agency protocol** or prescriber's order regarding use of ocular anesthetic drops.
The ocular anesthetic will be washed out by the irrigation fluid, so it needs to be reinstilled every 2 to 3 minutes, or it can be added to the irrigation solution.

5. **Connect the solution and** tubing, and prime the tubing.
Priming the tubing prevents blowing air across the cornea, which would be uncomfortable.

6. **Irrigate the eye.**
   a. Hold the tubing about 2.5 cm (1 in.) from eye.
   A safe distance helps prevent accidental trauma to the eye.
   b. Separate the eyelids with your thumb and index finger.
   It is easier to irrigate the cornea when the eyelids are separated.
   c. Direct the flow of solution over the eye from the inner canthus to the outer canthus.
   The inner canthus is considered clean, primarily because of the open duct in this area. Flowing irrigation solution in this manner follows the principle of "clean to dirty."



7. **Recheck pH, and continue** to irrigate the eye as needed.
With alkaline or acidic chemical injuries, the pH of the eye needs to be returned to normal as soon as possible to prevent further eye injury.

Evaluation

- Examine the eyes for redness or drainage.
- Observe the patient's ability to follow instructions during the procedure.
- Observe the pain level during the procedure.
- After an irrigation, check for decrease in eye pain.

Patient Teaching

- Discuss how to prevent contaminating eye drops or ointment.
- Teach the best technique for instilling eye drops or ointment.
- Discuss the use of an eye drop guide, if the patient needs assistance with instilling drops.
- Discuss the signs and symptoms to report to the provider, including eye pain and increased redness or drainage.

For irrigations:

- Discuss the cause and prevention of eye injuries, including use of protective goggles.
- Discuss the need for follow-up treatment. If the patient will be instilling eye medications or applying eye patches, ensure that he demonstrates the correct technique.

Home Care

If a splash occurs to the eyes in the home, teach the client to immediately flood his eyes with cool water (as follows):

- Hold your eyelids open and put your head under a faucet or pour water from a clean container.
- Roll your eyes as much as possible while running water across your eyes.
- Flood your eyes for at least 20 minutes.
- Get medical help immediately after rinsing your eyes.

Documentation

- *For instillations:* Chart assessment data before, during, and after instillation. Record on the MAR, as for all medications.
- *For irrigations:* Chart the condition of the patient's eyes before the irrigation, including complaints of pain or burning. Document the eye pH, instillation of anesthetic drops, the type and amount of irrigation fluid used, the eye pH following irrigation, and the patient's response. Also record other treatment (e.g., instillation of lubricating and/or antibiotic ointment; application of eye patches).

(continued on next page)

Procedure 26-2 ■ Administering Ophthalmic Medication (continued)

Sample documentation

08/22/2016 1200. In preparation for discharge and after teaching, patient correctly self-administered Garamycin eye drops 1 gtt in right eye as prescribed. Patient closed her eyes and gently pressed against the right side of the nose for 1 minute after instillation. Stated, "I will not have a problem doing this at home. Thank you for teaching me the right way." No redness, discharge, or complaints of pain.———————— S. Smith, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering Ophthalmic Medication.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Practice Resources

Centers for Disease Control and Prevention (CDC) (2010b); Glaucoma Research Foundation (2012); Heller, J. L. (2011, updated); Mason, I., & Stevens, S. (2010); Terrie, Y. (2012).

Procedure 26-3 ■ Administering Otic Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Ear drops
- Dropper with flexible rubber tip
- Cotton-tipped applicators
- Cotton ball

Delegation

The RN can usually delegate administration of otic medications to an LPN/LVN. You usually cannot delegate this task to a NAP, unless allowed by the state's nurse practice act.

Pre-Procedure Assessments

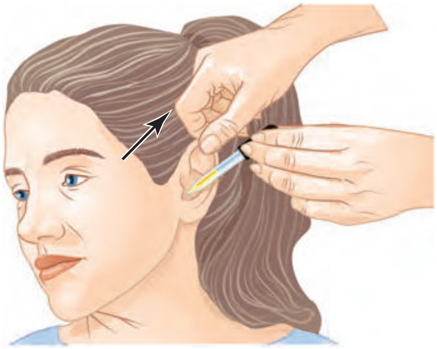
- Assess the external ear and canal for erythema, drainage, and cerumen.
  You may need to clean the external ear to remove obstructions so that the medication can be distributed throughout the ear canal. Use the otoscope to evaluate the tympanic membrane if the drainage is bloody or the patient complains of pain or decreased hearing acuity. Use sterile technique if the tympanic membrane is ruptured.
- Assess for any ear pain or hearing impairment.
  Establishes a baseline that can be used to evaluate the effects of treatment.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Hold the ear drop bottle** in your hand to warm it, or place it in warm water (not hot). Gently shake the bottle before using the drops.
   Warm solution is more comfortable than cool. Also, placing cool solutions in the ear can cause dizziness. Gently shaking the bottle disperses the medication throughout the solution.
2. **Assist patient to a side-lying** position (or turn her head to the side), with the appropriate ear facing up.
   Facilitates administering the drops and prevents drops escaping from the ear.
3. **Clean the external ear** with a cotton-tipped applicator, if necessary.
   Cleaning the ear allows ear drops to reach all areas of the ear canal without trauma. Be careful not to push cerumen further into the ear canal.
4. **Fill the dropper** with the correct amount of medication.
5. **For infants and young children,** ask a parent or another caregiver to immobilize the child while you administer the medication.
   Mobilization and restraint reduce the risk for injury for the child who struggles during the procedure.
6. **Straighten the ear canal.**
   a. For a child younger than 3 years old, pull the pinna down and back.▼

b. For children 3 years and older and adults, pull the pinna up and back.



These positions straighten the ear canal for proper channeling of the medication.

7. Instill the ordered number of drops along the side of the ear canal, being careful not to touch the end of the dropper to any part of the ear.
Avoiding contact between the dropper and the ear reduces the risk of contamination of the dropper.

8. Gently tug on the external ear after drops are instilled.
Facilitates flow of medication into the auditory canal.

9. Instruct the patient to keep her head turned to the side for 5 to 10 minutes.
Assists in distributing the medication and prevents drops from escaping the ear canal.

10. Place a cotton ball, or a piece of it, loosely at the opening of the auditory canal for 15 minutes.
A cotton ball will absorb excess fluid and keep the medication from flowing out.

Keep in mind that cotton left near an infant can be a choking hazard and must be carefully supervised.

What if . . .

- **My patient is a child and rolls over so most of the otic medication flows back out of the ear?**

  Estimate the amount of the dosage that was lost. Replace it by repeating the procedure for instillation of the medication, except next time position the child securely until you are confident the medication has had time to penetrate the ear canal.

- **There is too much cerumen (ear wax) in the canal to instill otic drops?**

You can use special drops for softening the cerumen and allow for easier removal. Gentle irrigation with warm saline is effective, unless the patient has perforation of the tympanic membrane or myringotomy tubes.

You should not use a metal syringe (Pomeroy syringe) for the removal of cerumen because (1) this type of syringe is heavy and difficult to control and (2) may be associated with a higher risk of perforations of the tympanic membrane because of the pressure exerted.

Oral jet irrigators have been associated with some trauma, including tympanic membrane perforation.

You should not attempt to remove impaction by "ear candling," which is the application of hot candle wax.

Evaluation

- Assess for discomfort or pain during the procedure and for relief afterward.
- Evaluate for wax buildup, redness, swelling, or drainage.

Documentation

- Assess the amount, color, character, and odor of drainage, if present.
- Note any swelling or redness in the ear canal.
- Document pain or discomfort and hearing loss.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering Otic Medication.**

For suggested questions and responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 26-4 ■ Administering Nasal Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Medication drops, spray, or aerosol
- Tissues

Delegation

As an RN, you can usually delegate administration of nasal instillations to an LPN/LVN. You usually cannot delegate this task to a NAP.

Pre-Procedure Assessments

- Check for nasal obstruction and congestion.
  Nasal obstruction or congestion can prevent the medication from reaching the nasal mucosa.
- Assess nasal discharge for color, consistency, and odor.
  The appearance of drainage is not always diagnostic of infection, especially for people with chronic sinus problems or polyps. Color can be indicative of the body's response to viral, bacterial, and allergic sources.
- *Assess nasal mucous membranes for redness, color, moisture, excoriation, or trauma.*
- Check the dropper tip to be sure it is not cracked or chipped.
  A cracked or chipped tip might interfere with drawing up the medication and scratch the nasal mucosa.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Explain to the patient** that the medication may cause some burning, tingling, or unusual taste.
   The taste of nasal medications can cause patients to become nauseated or vomit. The medication is more likely to cause burning or tingling if the nasal mucosa is inflamed.

2. **Ask the patient to gently blow** his nose and wash his hands afterward.
   Removing nasal discharge allows the medication to come into contact with the mucous membranes without traumatizing already inflamed mucosa.

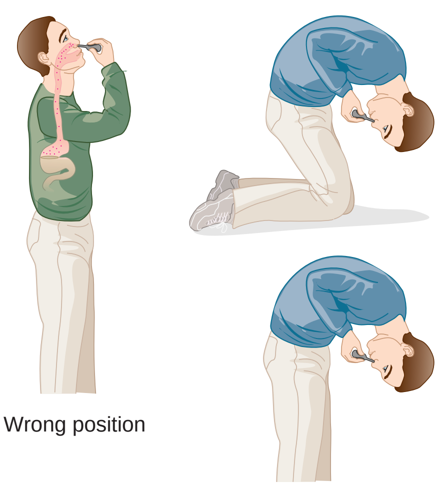
3. **Don procedure gloves.**
   Prevents transmission of microorganisms.

4. **Position the patient.**

When Medicating the Frontal Sinuses With Spray

"Head down and forward." Remember: "To spray your nose, look at your toes!" If the patient can comfortably assume this position, ask him to lean forward or kneel on the bed with his head down. Administer the medication, and then ask the patient to tilt his head back to medicate the nasal passages.

Radionuclide studies have demonstrated that using nasal drops or sprays with the patient sitting and leaning the head back causes poor distribution of the medications into the nasal complex and sinuses. ▼



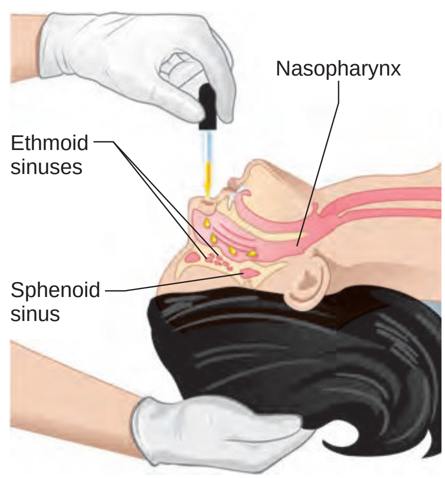
Wrong position

Correct positions

When Medicating the Ethmoid and Sphenoid Sinuses

Assist the patient into a supine position, tilt head back with his head over the edge of the bed. Support the patient's head. Alternatively, place a towel roll behind the patient's shoulders, and allow the head to drop back.

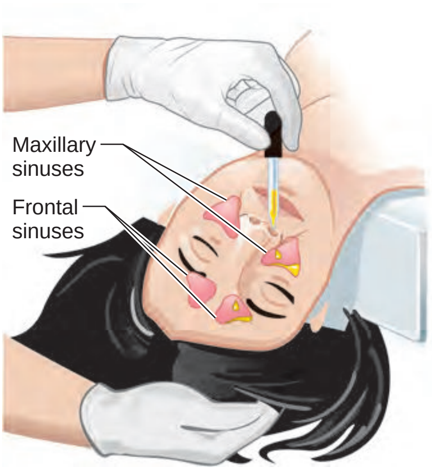
These positions help to prevent straining of the neck muscles and facilitate distribution of the medication to the ethmoid and sphenoid sinuses. ▼



When Medicating the Frontal and Maxillary Sinuses With Drops

With patient supine, tilt the head back over the edge of the bed or place a pillow under the head and turn toward the affected side.

Titling the head promotes gravity to distribute the medication to the frontal sinuses.



5. **Ask the patient to exhale** and then close one nostril.
   Blocking one nostril provides for deeper inhalation.

6. **Then ask the patient to breathe in** deeply through the nose and while he is breathing in, press down firmly and quickly once on the applicator. Ask patient to breathe out through the mouth. After spray, lean head backward for a few seconds. If a dropper is used, do not touch the sides of the nostril.
   Inhaling through the mouth prevents aspiration of the drops into the trachea and bronchi. Touching the dropper to the nostril will contaminate the dropper.

7. **Repeat for the other nostril.**

8. **If nose drops are used,** ask the patient to stay in the same position for 1 to 5 minutes (depending on the manufacturer's guidelines).
   Maintaining this position promotes better absorption by using gravity to disperse the medication throughout the nasal passages and sinuses instead of draining out the nose.

9. **Instruct the patient not to blow** his nose for several minutes.
   To prevent expelling the medication.

What if . . .

- **My patient cannot assume the "head down and forward" position?**

  Help him to hold his head upright to administer the drops or spray.

- **My patient can taste the medicine after it is administered?**

  That means his head was not down enough or he did not inhale long enough. Instruct him to put his head back down and sniff again without the medicine.

- **My patient has an excoriated area on the inside septum?**

  Assess further, examining other areas of the nasal mucosa. Determine if the patient has a history of substance abuse or frequent nasal inhalations. Report the findings to the prescriber before administering nasal medication.

- **My patient begins to have nosebleeds after using nasal medication?**

  First, control the nosebleed. Then hold the medication and notify the prescriber. Assess for other signs of bleeding, bruising, or other petechiae.

Evaluation

Assess for a reduction of symptoms 15 to 20 minutes after administration.

Patient Teaching

- Teach the procedure for administering nasal drops or sprays, including proper positioning.
- Discuss the correct use of the medication and the adverse effects of overusing nasal decongestants.
- Explain the implications of the color of nasal secretions.

Documentation

Chart according to Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route). For example, record the administration of the medication on the MAR.

For nasal instillation, document:

- Pre-medication assessment
- Type and amount of solution administered
- Discomfort the patient experienced during the procedure
- Patient's report of response to nasal administrations, such as nasal discharge, obstruction of nasal passage, bleeding, or other complication following the procedure

Sample documentation

mm/dd/yyyy 1340 *Client complained of nasal stuffiness. Administered mometasone (Nasonex) 2 sprays per nostril as ordered. Client noted nasal tingling following administration of this medication. Client left resting in recliner chair.* —— H. Peralta, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Administering Nasal Medication.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Practice Resources

American Academy of Family Physicians (2004, updated 2011); CDC (2011a).

Procedure 26-5 ■ Administering Vaginal Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Medication: foam, jelly, cream, suppository, douche, or irrigating solution
- Applicator (if indicated)
- Perineal wash solution or wipes for perineal care as needed
- Water-soluble lubricant
- Toilet tissue
- Perineal pad
- Bath blanket
- **For irrigation:** you will also need a waterproof pad, bedpan, vaginal irrigation set (consists of a solution container, nozzle, tubing, and clamp; may be disposable) and IV pole.

Delegation

An RN can usually delegate the administration of vaginal medications to an LPN/LVN. Delegation of this task to a NAP will vary depending on the state's nurse practice acts and the healthcare facility policies. However, the RN is always responsible for evaluating patient responses, both therapeutic effects and side effects. You can instruct a NAP on the expected therapeutic effects and the side effects she should report.

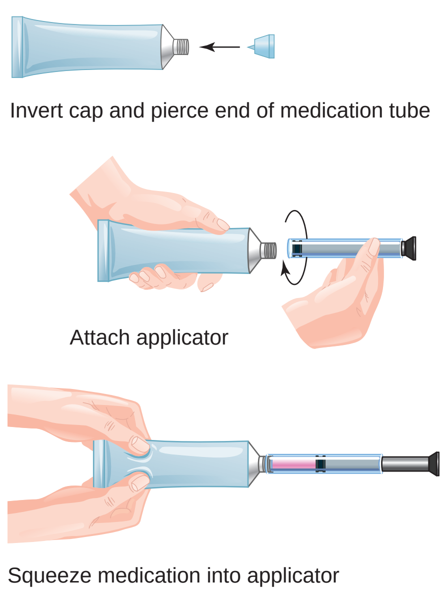
Pre-Procedure Assessments

- Assess for vaginal burning, pruritus, and pain.
  A baseline assessment helps to determine the patient's level of comfort and later the effectiveness of treatment. Infections can cause vaginal burning, itching, and pain.
- Inspect the labia and vaginal orifice for redness and lesions.
  This is a good time to assess the perineal area for signs of sexually transmitted infection or other findings requiring healthcare.
- Check for vaginal discharge, including color, amount, consistency, and odor

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

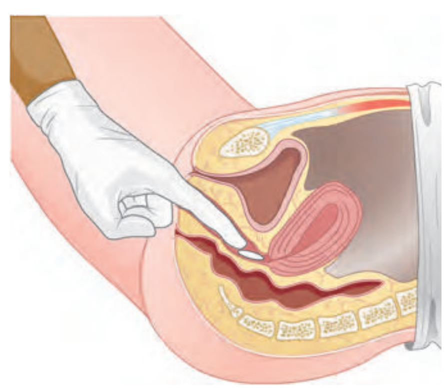
1. **Ask the patient to void** before you insert the vaginal medication.
   The increased pressure associated with a full bladder could cause discomfort during the instillation of vaginal medications.
2. **Position the patient** in a dorsal recumbent or Sims' position; drape the patient with a bath blanket so that only the perineum is exposed.
   a. **Dorsal recumbent position**—supine with knees flexed and legs rotated outward.
   b. **Sims' position**—semiprone on the left side with the right hip and knee flexed.
   These two positions allow for visualization during administration and promote retention of the medication following administration. Draping respects the patient's modesty.
3. **Prepare the medication.** Remove the wrapper from the suppository and place the suppository on the wrapper or in a medication cup; or fill the applicator according to the manufacturer's instructions. For irrigation, use a warm solution of approximately 105°F (40.5°C).
   Some suppositories come with applicators. Using a warm irrigation solution promotes patient comfort and prevents injury to the vaginal tissue.



4. **Don procedure gloves.**
   Prevents contaminating your hands and spreading microorganisms.
5. **Inspect and clean around vaginal orifice.**
   Prevents the introduction of microorganisms into the vagina during medication administration.
6. **Administer the medication.**

For a Suppository

a. Apply water-soluble lubricant to the rounded end of the suppository and to your gloved index finger on your dominant hand.
   Eases insertion and prevents injury to the vaginal tissue.
b. Separate the labia with your nondominant hand.
   Allows visualization of the vaginal orifice.
c. Insert the suppository as far as possible along the posterior vaginal wall (about 8 cm, or 3 in.) or as far as it will go. If the suppository comes with an applicator, place the suppository in the end of the applicator, insert the applicator into the vagina, and press the plunger.
   The posterior vaginal wall is about 2.5 cm (1 in.) longer than the anterior wall.



d. Ask the patient to remain in a supine position for 5 to 15 minutes. You may wish to elevate her hips on a pillow.
Lifting the hips promotes retention and absorption of the medication.

For Applicator Insertion of Cream, Foam, or Jelly

e. Separate the labia with your nondominant hand.
f. Insert the applicator approximately 8 cm (3 in.) into the vagina along the posterior vaginal wall.
g. Depress the plunger on the applicator, inserting the medication into the vagina.
h. Dispose of the applicator, or place it on a paper towel if the applicator is reusable. You will later wash it in the appropriate solution.
i. Instruct the patient to remain in a supine position for 5 to 15 minutes.
A flat position promotes retention and absorption of the medication.

For Irrigations

j. Hang the irrigation solution approximately 30 to 60 cm (1 to 2 ft) above the level of the patient's vagina.
Uses gravity to create enough pressure for continuous irrigation without increasing the pressure so much that it causes the patient discomfort and possibly damages the vaginal tissue.

k. Assist the patient into a dorsal recumbent position, and position a waterproof pad and bedpan under the patient.
Positioning the patient on the bedpan and using a waterproof pad protects the bedding.
l. If using a vaginal irrigation set with tubing, open the clamp to allow the solution to completely fill the tubing.
Flushing the tubing prevents introducing air into the vagina, which can cause discomfort.
m. Lubricate the end of the irrigation nozzle.
Lubrication reduces discomfort and irritation to the vaginal mucosa.
n. Insert the nozzle approximately 8 cm (3 in.) into the vagina, directing it toward the sacrum.
o. Start the flow of the irrigation solution, and rotate the nozzle intermittently as solution flows.
The rotation ensures even distribution of the solution throughout the vagina.
p. After all irrigating solution has been used, remove the nozzle.
q. Assist the patient to a sitting position on the bedpan.
Promotes removal of all the irrigating solution by gravity.

7. **Remove the bedpan and clean** the perineum with perineal wash solution and a washcloth or wipes. Dry the perineum.
Drainage could cause skin irritation.

8. **Apply a perineal pad** if necessary for excessive drainage.

? What if . . .

- **The labia are reddened?**

Pour warm water (bottled or specially filtered tap water) over the labia with an irrigation bottle to soothe irritation and cleanse the area.

Evaluation

- Assess for complaints of vaginal burning, pruritis, or pain.
- Assess for purulent vaginal discharge.

Patient Teaching

- Discuss with the patient personal hygiene and pericare.
- Teach women that douching is not necessary for ordinary female hygiene and that it may even be harmful because it disturbs the normal pH and healthy balance of microorganisms in the vagina.

Documentation

- **For vaginal medications**, chart according to Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).
- **For vaginal irrigations**, chart assessment; the type and amount of solution administered; discomfort the patient experienced during the procedure; and the patient's report of decreased vaginal pain, itching, and/or burning following the procedure.

Sample documentation

mm/dd/yyyy 1500 Explained medication and procedure. Client placed in dorsal recumbent position with knees flexed at 90° angle. Vaginal suppository lubricated with water-soluble lubricant and inserted using two fingers. Instructed client to retain suppository as long as possible. Tolerated procedure well with no voiced complaints of pain or discomfort. ——— S. Snider, RN

Procedure 26-6 ■ Inserting a Rectal Suppository

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Suppository
- Water-soluble lubricant
- Toilet tissue

Delegation

An RN can usually delegate administration of rectal medications to an LPN/LVN. Although in some institutions, you can delegate the administration of a glycerine suppository (nonmedicated) to a NAP, you generally cannot delegate administration of rectal medications to a NAP.

Pre-Procedure Assessments

- Determine the presence of contraindications for rectal administration, such as recent rectal surgery, rectal bleeding, or cardiac disease.
- Assess the rectal area for hemorrhoids or irritation.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Ask whether the patient needs** to defecate before the suppository insertion.
   Stool in the rectum interferes with insertion of medication against the rectal wall and therefore with retention of the medication.

2. **Assist patient to Sims' position**—lying on the left side with the right hip and knee flexed. Drape the patient, keeping her covered as much as possible.
   Sims' position allows visualization of the anus and promotes retention of the medication because the descending colon is on the left side. It also helps relax the external anal sphincter. Keeping the patient covered prevents chilling and maintains privacy.

3. **Don procedure gloves**.
   Gloving prevents exposure to feces and spread of microorganisms; maintains standard precautions.

4. **For an uncooperative patient,** such as a confused patient or a young child, ask someone to help immobilize the patient while you insert the suppository.
   Help holding the patient allows proper instillation of medication and prevents injury to the rectal mucosa.

5. **Prepare the suppository**: Remove the wrapper. Using a water-soluble lubricant, lubricate the smooth end of the suppository and the tip of glove on the index finger. If no lubricant is available, apply cool tap water to the rectal opening.
   Lubrication eases insertion and prevents friction damage to the rectal mucosa during insertion.

6. **Explain that there will be a cool** feeling from the lubricant and a feeling of pressure during insertion.
   The patient should not experience severe pain with the insertion of a suppository, but will feel the coolness of the lubricant and pressure as the suppository is inserted past the rectal sphincter.

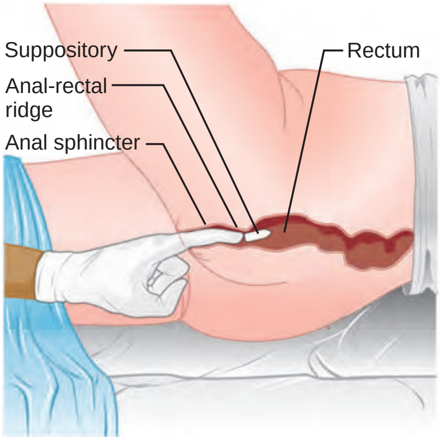
7. **Using your nondominant hand**, separate the buttocks.
   Separation of the buttocks allows you to visualize the anus.

8. **Ask the adult patient to take deep** breaths in and out through the mouth.
   Deep breathing helps relax the rectal sphincter. Pushing a suppository through a constricted sphincter produces discomfort.

9. **Insert the suppository**:
   a. Using the index finger of your dominant hand, gently insert the lubricated smooth end first, or follow the manufacturer's instructions.
   Lubrication eases insertion.

   b. Never force the suppository during insertion.
   Forcing the insertion of the suppository into a fecal mass would affect absorption. Forcing anything into the rectum may cause rectal irritation.
   c. Push the suppository past the internal sphincter and along the rectal wall (½ to 1 in. in infants and 1 to 3 in. in adults).
   The suppository must be in contact with the rectal wall for the medication to be absorbed. Inserting the suppository past the internal sphincter promotes retention. For a child,

inserting the suppository too far could damage the rectal mucosa.



10. **Ask the patient to try to retain** the suppository if he is able. If he has difficulty retaining the suppository, hold his buttocks together for a short time.

11. **Wipe the patient's anus** with toilet tissue.
Wiping maintains hygiene and comfort.

12. **Explain to the patient need** to remain in the side-lying position for 5 to 10 minutes.
Sims' position promotes retention and absorption of the medication. Explanation promotes compliance.

13. **Discard used materials** into a biohazard receptacle and wash hands thoroughly.

14. **Leave the call device within** reach and bedpan handy, if the suppository was a laxative.
In case the patient has a sudden urge to defecate or cannot retain the suppository for the recommended time.

? What if . . .

- **The prescribed dose is only half of the suppository?**

  Cut the suppository lengthwise with a clean, single-edge razor blade.

- **My patient is a child. What is the best way to give a rectal suppository so the child doesn't expel it?**

  For pediatric patients, it may be necessary to gently hold the buttocks together for 5 to 10 minutes.

- **My patient is an older adult? Is there anything special I should know?**

  Older adults may have difficulty retaining a suppository because of poor sphincter control. You may need to put the bedpan under the patient while you are inserting the suppository.

Evaluation

- Assess for pain or burning during and after insertion of the medication.
- Determine that the patient retained the suppository for the desired length of time after insertion (reinsertion may be required).

Patient Teaching

Explain that suppositories may take up to 30 minutes to be absorbed, depending on the medication.

Documentation

- Refer to Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).
- Chart the condition of anal tissue if abnormalities are present, any complaints of discomfort that are outside of the expected feelings and experience, and the length of time that the suppository was retained.
- Chart responses to medication (e.g., symptom relief, side effects).

Sample documentation

06/01/16 2015 Patient temperature 103.2°F and complains of nausea. Tylenol grain X suppository given per rectum with patient in Sims' position. Instructed to remain in this position for 15 minutes. Voiced understanding. No rectal abnormalities observed. Tolerated procedure well with no complaints of pain or discomfort.——————J. Kinsley, RN

Practice Resources

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Inserting a Rectal Suppository.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus*.

Procedure 26-7 ■ Applying Medication to Skin

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

➤ **Note:** Follow agency policy or provider's prescription regarding whether to use prepackaged wipes or soap and water to cleanse the skin.

Delegation

An RN can usually delegate administration of most topical medications to an LPN/LVN. In some institutions you can delegate the administration of an over-the-counter medication to a NAP. Refer to agency policy regarding administration of topical medication.

Pre-Procedure Assessments

- Assess for skin irritation, open lesions, area of hypersensitivity, or other skin abnormality.
- Determine the presence of contraindications for dermal application. Document and report these before administering medication.

Procedure 26-7A ■ Applying Topical Lotion, Cream, and Ointment

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean procedure gloves.**
   Complies with universal precautions and protects your skin from the topical medication.
2. **Cleanse the skin** with cleansing wipes or soap and water (according to agency policy) and pat dry before applying
   Clean skin enhances absorption. Moisture on the skin can interfere with adherence of topical ointment, depending on the product used to suspend the medication.
3. **Warm the medication** in your gloved hands.
   This will be more comfortable for the patient and make the preparation easier to apply.
4. **Use gloved hands or an** applicator to apply and spread the medication evenly, following the direction of hair growth when coating the area.
   Excessive application may irritate the skin. Gloves will protect you so that you will not absorb the medication through your own skin.

Procedure 26-7B ■ Applying Topical Aerosol Spray

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean procedure gloves.**
2. **Cleanse the skin** with cleansing wipe or soap and water (according to agency policy) and pat dry before applying to enhance absorption.
3. **Shake the container to mix** the contents.
   Active ingredients might not be evenly distributed throughout the aerosolized suspension and may settle at the bottom of the container.
4. **Hold the container at** the distance specified on the label (usually 6 to 12 in.), and spray over the prescribed area.
   This distance will prevent excess application to a local area.
5. **You will need to hold most** containers upright when spraying. If you are spraying near the patient's head, cover his face with a towel.
   This will prevent him from inhaling the spray.

Procedure 26-7C ■ Applying Prescribed Powder

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean procedure gloves.**
2. **Cleanse the skin** with a cleansing wipe or soap and water and pat dry before applying to enhance absorption.
   Powder applied to a moist surface creates a pasty solution, which may irritate the skin.
3. **Spread apart skinfolds**, and apply a very thin layer.
4. **Be careful that the patient does** not inhale the powder.
   Particulate matter, such as powder, can irritate lung tissue and lead to pneumonitis or other inflammatory processes.

Procedure 26-7D ■ Applying Transdermal Medication

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean procedure gloves.**
   Complies with universal precautions and protects your skin from the topical medication.

2. **Remove the previous patch**, folding the medicated side to the inside.
   This helps to prevent unintentional contact of the medication on a different area of the patient's skin.

3. **Dispose of the old patch** carefully in an appropriate receptacle, keeping it away from children and pets.
   Even a used patch has some active medication on it. Proper disposal is important to prevent medication exposure to others.

4. **Cleanse the skin of traces** of remaining medication. Allow the skin to dry.
   A clean, dry surface optimizes the effectiveness of adherence and absorption of the medication .

5. **Remove the new patch from** its protective covering, and then remove the clear, protective covering without touching the adhesive or the inside surface that contains the medication.

6. **Apply the patch to** a clean, dry, hairless (or little hair), intact skin area, pressing it down for about 10 seconds with your palm. Be sure the area is free of scars, lesions, and irritation.
   A smooth surface maximizes the contact between medication and the skin. Areas of the skin that are disrupted can become irritated by topical mediation. Other lesions involving thickened layers of skin should be avoided to avoid compromised absorption.

7. **Rotate application sites** with each new application**.** Common sites are the trunk, lower abdomen, lower back, and buttocks.
   Rotating sites prevents irritation to local areas of the skin

8. **Advise the patient *not*** to use a heating pad over the area.
   Heat can cause some ointments to irritate or even burn the skin.

9. **Write the date, the time**, and your initials on the new patch.
   Complete documentation of the dosage administered can reduce medication errors.

10. **Remove your gloves and** perform hand hygiene.

11. **Observe for local side effects,** such as skin irritation, itching, and allergic contact dermatitis.
    If an adverse response occurs at the local site, remove the patch, wipe the skin clean, and notify the prescriber.

? What if . . .

- **The medication is packaged as an ointment form with calibrated paper?**

  Wear gloves; apply the ointment in a continuous motion along those marks to measure the required dose. Fold the paper in half to distribute the ointment evenly on the patch.

- **My patient is a child who does not want the medication to be applied?**

  Hold the child securely while medication is applied. Then cover the site with a dressing to keep the child from disrupting the application of medication.

- **My patient is an older adult and has fragile skin?**

  Avoid areas where penetration of the cream or ointment is likely to be reduced or cause irritation. Be gentle with application of anything to the skin and diligent with your assessment of the skin response to medication. Avoid using tape; use tape alternatives.

Evaluation

- Assess for rash, excoriation, hives, redness, swelling, or signs of allergy or skin sensitivity to topical medication.
- Ask the patient if he feels burning, itching, pain, tenderness, or other sensation to skin where medication was applied.
- Assess for improvement in the patient's condition.

Patient Teaching

- Explain that topical medication may take up to 30 minutes to be absorbed, depending on the medication.
- Tell the patient to never ingest or inhale topical medication.
- Advise the patient to avoid touching his eyes after handling topical medication.
- Inform the patient not to use more medicine than prescribed or directed.

(continued on next page)

Procedure 26-7 ■ Applying Medication to Skin (continued)

Documentation

- Refer to Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).
- Record the skin condition if abnormalities are present and complaints of discomfort during or after administration.
- Document responses to medication (e.g., symptom relief, side effects).

Sample documentation

mm/dd/yyyy 0835 *Transdermal nitroglycerine 74.6 mg patch applied to upper chest. Pt. instructed to leave patch intact for 12 hours. Patient reported mild, transient headache approximately 45 minutes after application of patch. No evidence of flushing, faintness, or dizziness. Patient denies chest pain. ———— M. Finegold, RN*

mm/dd/yyyy 0830 *Fentanyl patch dated mm/dd/yyyy removed from upper left arm. Skin intact, no irritation noted. Fentanyl patch applied to the left anterior chest wall below the clavicle. Patient stated, "this patch really helps my back feel better." ———— M. Finegold, RN*

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Applying Transdermal Medication.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 26-8 ■ Administering Metered-Dose Inhaler (MDI) Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Metered-dose inhaler
- Spacer
- Tissues

Pre-Procedure Assessments

Assess the respiratory status before administration of medication to establish a baseline for evaluating the effects of treatment.

Delegation

An RN can usually delegate administration of MDI medications to an LPN/LVN. You usually cannot delegate this task to a NAP, unless the NAP has special training for a specific defined situation (e.g., "medication aides" in some long-term care settings in some states). If the patient is having respiratory distress, you should not delegate this task. Refer to Medication Guidelines: Steps to Follow for All Medications (regardless of Type or Route).

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine the number of** remaining inhalations of medication in the canister based on the start date and instructions for use. Do not use the old method of floating the canister in water, as it is not an accurate estimate. Replace the canister promptly when it is nearly empty.

Historically, patients have been instructed to float the canister in water to determine how much medication remains. However, propellants affect the weight of the canister and may lead to false reassurance that there is medication in an empty container.

Some MDI medications are used as rescue agents during asthma attacks or periods of dyspnea. It is important to always have medication available for use.

2. **Assist the patient to a seated** or high-Fowler's position if in bed.
   An upright position helps the patient take a deep inhalation when medication is administered.

3. **Ask the patient to rinse** out his mouth and spit the fluid out (not to swallow it).
   This helps to prevent transfer of bacteria from the mouth to the inhaler.

4. **Shake the inhaler**. Then remove the mouthpiece cap of the inhaler and insert the mouthpiece into the spacer while holding the canister upright.
   A spacer is the most efficient method to deliver inhaled medications. It should be used if the patient has difficulty coordinating the use of the inhaler, is using a corticosteroid, or if it is prescribed.

5. **Remove the cap from the spacer.**

6. **Ask the patient to breathe out** slowly and completely. If a patient is unable to use the MDI independently, time the use of the device with the patient's own respirations.
   Deep breathing helps the patient to time the dose with his natural breathing.

7. **Place the spacer mouthpiece** into the patient's mouth and have him seal his lips around the mouthpiece. Sharply press down on the inhaler canister to discharge one puff of medication into the spacer.

If No Spacer Is Used

If a spacer is not used, place the canister 1 to 2 inches (2.5 to 5.0 cm) from or directly into the mouth.

A good seal allows proper delivery of medication.

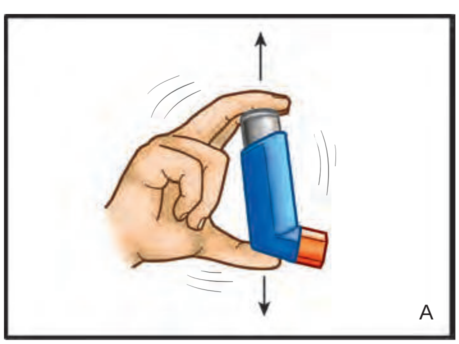
8. **Ask the patient to slowly inhale** and then hold his breath for as long as possible. Encourage the patient to hold his breath for 10 seconds if possible.
   When holding his breath the medication can be delivered deep into the lungs.

9. **If a second puff is needed**, wait at least 1 minute before repeating Steps 6 through 8.
   Pausing allows the medication to be absorbed and the canister to recharge.

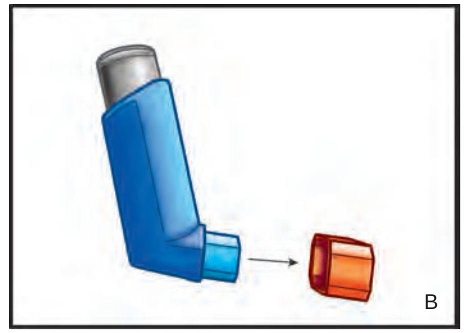
10. **If a corticosteroid inhaler** was used, assist the patient to rinse out his mouth with water and spit out the rinse.
    Prolonged exposure of this medication to the oral mucosa is irritating and can lead to thrush in some patients.

11. **Wipe the mouthpiece** with a tissue or moist cloth and replace the cap. Periodically rinse the spacer, mouthpiece, and cap with water.
    Proper cleaning of the MDI keeps the dispenser from clogging.

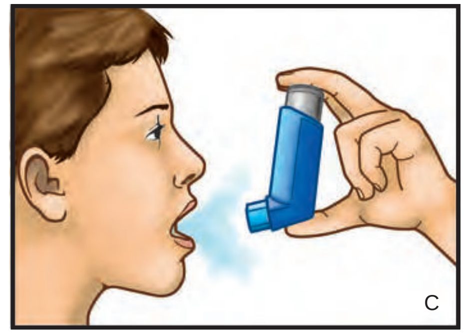
The following illustrations summarize the steps for using an MDI.



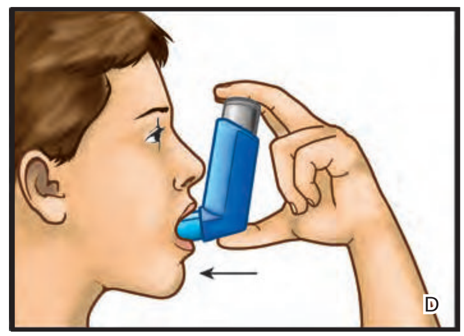
Shake canister.



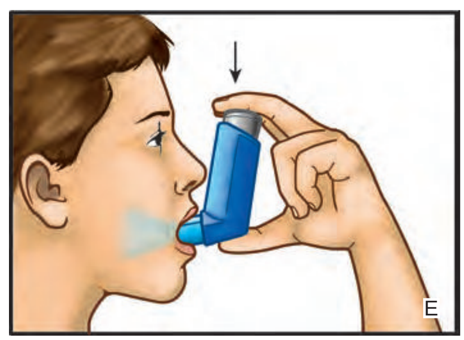
Remove cap. Discharge 2 puffs.



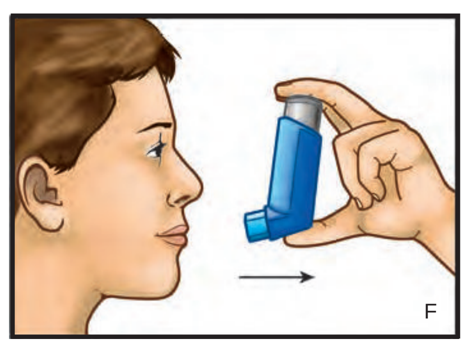
Deep breath out.



Press top. Inhale med slowly.



Hold breath. Exhale slowly.



Remove inhaler from mouth.
Wait 1 minute before next puff.

(continued on next page)

Procedure 26-8 ■ Administering Metered-Dose Inhaler (MDI) Medication (continued)

What if . . .

- **My patient is a small child or frail older adult who is unable to assist with taking medication from the inhaler?**

  You will need to time discharge of the medication with the client's inspiration if the patient is unable to administer the medication with his own deep breaths.

- **My patient uses an albuterol MDI with chlorofluorocarbon (CFC) as a propellant?**

  The FDA made a ruling, effective December 31, 2008, prohibiting use of CFCs in albuterol MDIs. If the patient has an inhaler containing this product, known to be detrimental to the ozone layer, the patient or caregiver can request an alternate prescription.

  Key Point: *In addition to the harmful effects of the propellant on the environment, the medication is also likely to be past its expiration date.*

Evaluation

Assess for change in respiratory status after medication administration.

Patient Teaching

- Explain to the patient when to use the inhaler and what side effects to anticipate.
- Teach and demonstrate to patients how to correctly use a spacer and MDI.
- Teach patients how to determine if the MDI canister is nearly empty.
- Explain that some inhalers are used in combination with others and must be used in correct order to receive the desired effect.
- Be aware that many patients who have not been taught to use dry powder inhalers do not get any medication into their lungs.
- Errors in using dry powder inhalers increase with age and illness severity. Carefully supervise older adults and seriously ill patients.

Home Care

General Information to Tell Patients

- Show your healthcare professional how you're using your MDI. If you're having trouble using your MDI, ask for tips or to recommend another device.
- Never puncture or break the canister.
- Do not immerse the MDI in water.
- Keep the MDI where you can get it quickly when needed, but out of children's reach.
- Store the MDI at room temperature. If it gets cold, warm it by rubbing the canister between your palms. Never use anything else to warm it.

Determining the Number of Remaining Doses

- When you begin using a new MDI, write the start date on the canister.
- The only reliable method for determining the number of doses remaining in a canister is to subtract the number of doses used from the number available. Some devices are equipped with counters. Floating MDIs in water is not accurate for assessing remaining doses and often will clog the valve.

Cleaning the MDI

- Clean your apparatus regularly to avoid drug buildup that might keep the medication from reaching the lungs. Specific maintenance procedures may vary with the manufacturer.
- Remove the metal canister that contains the medication by pulling it out.

Documentation

- Refer to Medication Guidelines: Steps to Follow for All Medications (regardless of Type or Route).
- Document the response to medications.

Sample documentation

mm/dd/yyyy 0800 Pt. c/o shortness of
breath. RR 26 and labored. Combivent MDI 2
puffs administered with spacer. ——————
—————————————— S. Smythe, RN

0815 RR 20 regular, even,
comfortable. ——————————— S. Smythe, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Administering Metered-Dose Inhaler (MDI) Medication.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Practice Resources

American Society of Health System Pharmacists, Inc. (n.d.); Gandhi, K., Dahiya, A., Taruna-Kalra, A., et al. (2012); Lareau, S., & Hodder, R. (2012); U.S. Food and Drug Administration (2013); Werner, R., & Morien, A. (2012).

Procedure 26-9 ■ Preparing, Drawing Up, and Mixing Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Medication vials, ampules, and/or prefilled syringe
- Alcohol prep pad (70% alcohol) or chlorhexidine gluconate (CHG)–alcohol product
- Syringe of the appropriate size for medication volume and viscosity
- Needle of the appropriate size for the site and viscosity to be aspirated through the vial access device (VAD)
- VAD, filter needle, or safety needle.
- Gauze pad or ampule snapper, if you are using ampules

Top: Syringe with a regular needle. *Bottom:* Filter needle.

Vial access device.

Delegation

An RN can delegate administration of some parenteral medications to an LPN/LVN. You usually cannot delegate this task to a NAP. Nurse practice acts governing medication administration vary from state to state, and policies vary further among healthcare agencies. Nevertheless, the RN is always responsible for supervising and evaluating delegated care. You can instruct a NAP in the therapeutic effects expected from the medication.

Pre-Procedure Assessments

- Check the ampule or vial for intactness, cloudiness, particles, and color.
  A change in color, cloudiness, particles, or cracks indicate the medication is altered or contaminated and should not be used.
- Check the compatibility of the medications to be mixed.
  Some medications are either chemically or physically incompatible and cannot be mixed. Other medications may be compatible for only 20 to 30 minutes, so they must be given promptly after they are mixed. Although physically incompatible medications can frequently be identified by a change in appearance, such as precipitation, no such indication exists for chemically incompatible medications.
- Determine the total volume of medications and whether the total volume is appropriate for the administration site.
  Although the reason for mixing medications is to limit the number of injections a patient receives, the total volume of the injections must not be greater than what is appropriate for the site.

Procedure 26-9A ■ Drawing Up Medication From Ampules

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Gently flick or tap the top** of the ampule with your index finger to remove medication trapped in the top of the ampule. Alternate method: Shake the ampule by quickly turning and snapping your wrist, like shaking down a mercury thermometer.
   Medication left in the top of the ampule may lead to administering an inadequate dose. All the medication must be in the bottom of the ampule before you open it.
2. **Wrap a 2 in. × 2 in. gauze pad** (or an unwrapped alcohol wipe) around the neck of the ampule, or use an ampule snapper. Snap the top off, breaking it away from you.
   Prevents you from accidentally cutting your fingers or spraying glass fragments toward you. Do not use an opened alcohol wipe

(continued on next page)

Procedure 26-9 ■ Preparing, Drawing Up, and Mixing Medication (continued)

to break the ampule, because it is not thick enough to prevent injury.

3. **Attach a filter needle** or filter straw to the syringe. If the syringe has a needle in place, remove both the needle and the cap, and place them on a sterile surface (e.g., a newly unwrapped alcohol pad still in the open wrapper), and attach the filter needle or straw.
   The American Society for Health System Pharmacists recommends filtering solutions drawn up from glass ampules to remove glass particles. Opening a glass ampule produces a spray of tiny fractured glass particles, which can enter the ampule and contaminate the contents.

4. **Withdraw the medication** from the ampule with a filter needle by using one of the following techniques. Be careful not to touch the neck of the ampule with the filter straw or needle while withdrawing medication.
   Touching the neck of the ampule with the needle or straw increases the risk of contamination.
   a. *Invert the ampule*, place the filter needle or straw tip in the liquid, and withdraw the prescribed amount of medication. Be careful not to insert needle through the medication into the air at the top of the inverted ampule.
   This method is particularly useful with small ampules. The medication's surface tension prevents the liquid from leaking from the inverted ampule. However, if you insert the needle too far (into the air pocket above the medication), the medication will run out.

   b. *Alternatively, tip the ampule*, place a filter needle or straw in the liquid, and withdraw all medication. Reposition the ampule so that the needle or straw tip remains in the liquid.
   This method allows for easier stabilization of the ampule while you withdraw the medication, and may help keep you from contaminating the needle on the edge of the vial opening.

5. **Hold the syringe vertically**, and draw 0.2 mL of air into the syringe (see Clinical Insight 26-4). Draw up and measure the exact medication dose, plus 0.2 mL of air (the syringe plunger should be at 0.2 mL more than the prescribed dose).

6. **Remove the filter needle** or straw, and reattach the "saved" needle for administering the injection.

7. **Eject the 0.2 mL of air, and read** the dose. After all of the air is removed, if you need to eject some medication to make the dose correct, tip the syringe until it is horizontal to push out the medication.
   - *Pulling air into the syringe allows for an exact dose when the medication is injected; the air will clear the needle (after the medication) so that the patient receives all the medication that is in the syringe.*
   - *The syringe must be vertical to eject air. However, if you eject the medication while holding the syringe vertically, the drug will run down the needle and then track through the patient's tissue during the injection.*

For a filter needle

Use a filter needle only to withdraw, not to measure, medication. Do not eject medication from it.
Pushing the medication out through the filter needle could cause the filter to break and release the glass fragments.

Key Point: ***This is not the old "air lock" technique; you will eject the air before administering the medication to the patient.***

For medications that are irritating to tissues (e.g., parenteral iron)

You can leave the 0.2 mL of air in the syringe for injection. But be sure to account for the air when you read the dose markings on the syringe.

8. **Dispose of the top and bottom** of the ampule and the filter needle in a sharps container.
   Disposal into a puncture-proof container prevents accidental needlestick injury.

Procedure 26-9B ■ Drawing Up Medication From Vials

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ This procedure assumes you are using a vial access device (VAD), since that is preferred. Use a needle only when a filter needle is required.

Procedure Steps

1. **Mix the solution in the vial**, if necessary, by gently rolling the vial between your hands.
Aqueous suspensions will settle to the bottom of the vial, so they need to be mixed. Rolling the vial between your hands will mix the medication without forming air bubbles. Shaking the vial traps air in the medication.

2. **Place the vial on a flat** work surface and thoroughly scrub the rubber top of the vial with an alcohol prep pad or CHG-alcohol product.
The alcohol prep pad removes dust, grease, and microorganisms.

3. **If a needle is attached** to the syringe, remove it and place it on a sterile, opened alcohol pad. Then attach a VAD; do not touch the tip.
VADs can be used only with single-use vials, unless the vial is designed for use with access pins, such as a Life-Shield vial.

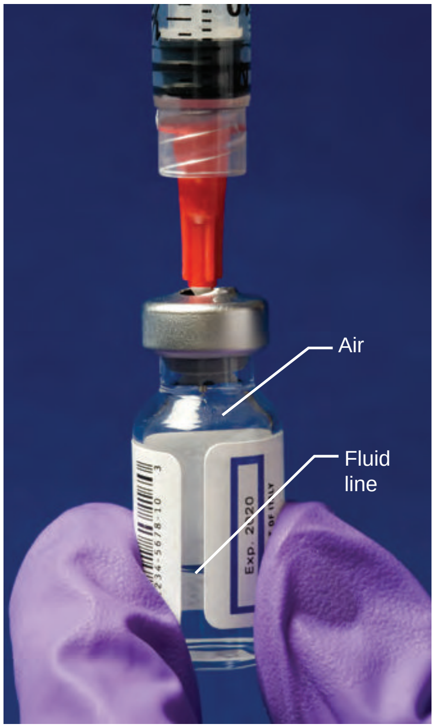
4. **Remove and place the VAD cap** on a clean surface, or hold the cap open-side out between two fingers of your nondominant hand.
This method prevents contamination of the cap and the needle during recapping.

5. **Draw air into the syringe** equal to the amount of medication to be withdrawn from the vial.
Injection of air into the vial makes withdrawing the medication easier. For small unit-dose vials, you may not have to instill air prior to withdrawing the medication, but you will need to maintain backward pressure on the plunger until the needle is completely withdrawn. If you release the plunger, the negative pressure in the vial will pull the medication back into the vial.

6. **Insert the VAD** into the vial without coring and while maintaining sterile technique. Use a needle *only* if for some reason (e.g., the type of medication) requires a filter needle.
   a. Place the tip of the VAD or filter needle in the middle of the rubber top of the vial, with the bevel up at a 45° to 60° angle. ▼

   b. While pushing the VAD into the rubber top, gradually bring the syringe (and VAD) upright to a 90° angle.
   This method helps prevent coring, which occurs when a small piece of the rubber top is trapped inside the VAD during insertion. Coring is more likely to occur with large-gauge needles and VADs. ▼

7. **With the tip of the VAD above** the fluid line, inject the air in the syringe into the air in the vial.
Injecting air into the vial creates positive pressure, making the medication easier to withdraw. Injecting the air into the medication will create air bubbles, which interfere with dosage measurement. ▼

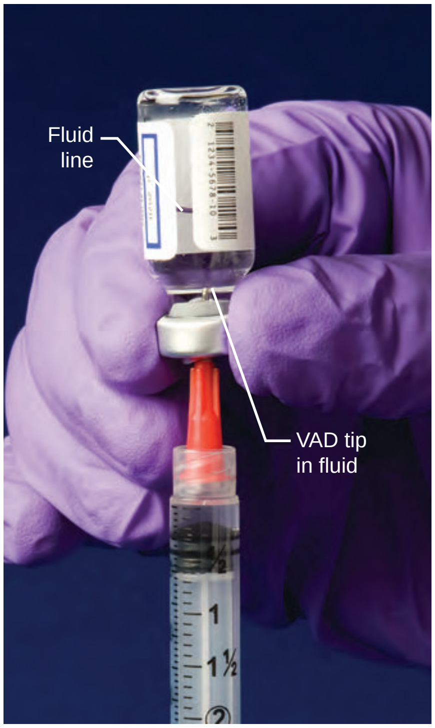


"Air to air."

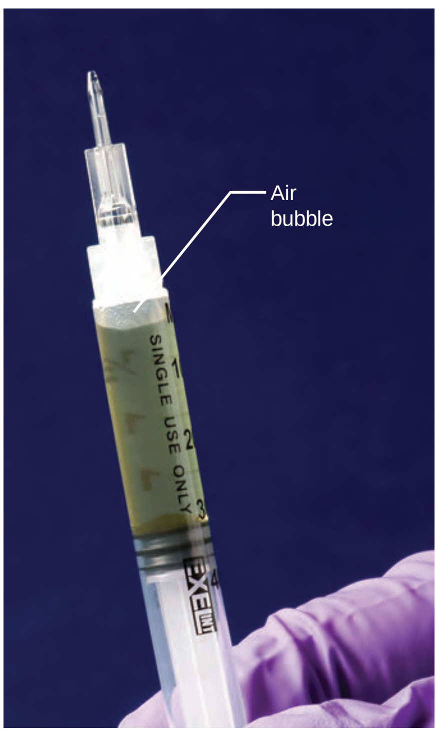
8. **Invert the vial**, keep the VAD vertical in the medication, and slowly withdraw the medication.
The vial needs to be inverted so that all the medication can be withdrawn. Keeping the VAD in the medication and slowly drawing the medication will help prevent you from drawing excess air into the syringe. ▼

(continued on next page)

Procedure 26-9 ■ Preparing, Drawing Up, and Mixing Medication (continued)



9. Keeping the VAD in the vial, remove any air from the syringe:



A, **Incorrect**—If syringe is not vertical, air is trapped near the hub.

B, **Incorrect**—If tip is down, air is trapped at the plunger.

C, **Correct**—Syringe is vertical.

When the VAD is connecting the vial and syringe, a sterile unit is formed. The volume of air in the hub of the syringe and inside the needle/VAD, dead space, will be drawn back into the syringe. Air bubbles alter the dose of medication being administered, so they must be expelled. You can use a pen to tap the syringe if extra force is needed.

a. Carefully stabilize the vial and syringe, and firmly tap the syringe below the air bubbles. When air bubbles are at the hub of the syringe, make sure the syringe is vertical (straight up and down), and push the air back into the vial.
Remember that air rises, so if the syringe is tilted, air will be trapped in it.

b. If additional medication is necessary to obtain the correct dose, withdraw it before removing the VAD from the inverted vial.
When working with only one vial, you can withdraw and eject medication into the vial as many times as needed to expel bubbles from the syringe and obtain the correct dose.

10. When the dose is correct, withdraw the needle or VAD from the vial at a 90° angle.
A vertical angle prevents accidental contamination or bending of the needle.

11. Hold the syringe upright at eye level to recheck the medication dose.
Reading the syringe at an angle can result in inaccurate measurement.

12. Recap the VAD or vial access needle using a recapping device or the one-handed method. See Procedure 26-10.
Although recapping a sterile needle does not present a threat of bloodborne pathogen exposure, using a mechanical recapping device or the one-handed method helps develop safe habits.

13. Change the VAD or filter needle before you inject the medication:

a. Before changing the VAD or filter needle, draw back on the syringe plunger to remove all medication from dead space in the old needle (or VAD).

b. Remove the old needle (or VAD), and reattach a sterile needle for injection (see Clinical Insight 26-4).
You cannot eject medication through a filter needle; you cannot inject a patient with a VAD.

c. Hold the syringe vertically and expel the air. If it is necessary to expel some medication, hold the syringe horizontally to do so.
The difficulty with changing the needles is that you may slightly alter the dose. If you are planning to change the needles, draw slightly more than the ordered dose unless you are combining in one syringe. After changing the needle, re-measure the dose. Holding the syringe

horizontally prevents medication from running down the needle and tracking into the patient's skin.

14. **Dispose of the vial, VAD, or any recapped needles in a sharps container.**
This prevents sharps injury to health-care workers or others in the vicinity.
Proper disposal also reduces the risk of transmitting infectious organisms.

Procedure 26-9C ■ Mixing Medication From Two Vials

➤ First review the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route); Procedure 26-9B (Drawing Up Medication From Vials); and Procedure 26-10A (Recapping Contaminated Needles).

Always use a VAD instead of a needle whenever possible. If you must use a needle, use a safety needle.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Scrub the tops of both vials** with an alcohol pad or CHG-alcohol product. *Note:* Some experts omit this step for single-dose vials.
Not all pharmaceutical companies ensure the sterility of the rubber top on vials, even when they are first opened. However, be aware that once your fingers touch the alcohol pad, it is no longer sterile, either; therefore, you are not sterilizing, but rather are cleaning the vial top.

2. **Draw air into the syringe** in the same amount as the total medication doses for both vials (e.g., if the order is for 0.5 mL for vial A and 1 mL for vial B, then draw up 1.5 mL of air).

3. **Inject air into the vials.**
   a. Maintaining sterility, insert the vial access device [VAD] (or safety needle) into the vial in the middle of the rubber top of the vial with the bevel up at a 45° to 60° angle. While pushing the VAD (or needle) into the rubber top, gradually bring the needle upright to a 90° angle.

Vial A

   This method helps prevent coring of the rubber top.

   b. Keeping the tip of the VAD (or safety needle) above the medication, inject an amount of air equal to the volume of drug to be withdrawn from the first vial (e.g., 0.5 mL for vial A in Step 2); then inject the rest of the air into the second vial (1.0 mL for vial B). Take care to prevent coring.
   Medication is easier to withdraw from a vial with positive pressure. For small unit-dose vials, it may be possible to withdraw the medication without instilling air, but you will need to maintain a slight backward pressure on the plunger until the needle is completely withdrawn. If you release the plunger, the negative pressure in the vial will pull the medication back in. Therefore, it is always safer to instill air.

Vial B

Using One Multidose Vial and One Single-Dose Vial

You must withdraw medication from the multidose vial before withdrawing from the single-dose vial. However, the needle tip should stay above the medication at all times in Steps 3 and 4.
This is an extra precaution to prevent contamination of the multidose vial with medication from the single-dose vial.

When Mixing Two Types of Insulin

If you are mixing two types of insulin at Step 3, put air into the regular insulin last (see Clinical Insight 26-5 for mixing two types of insulin).

(continued on next page)

Procedure 26-9 ■ Preparing, Drawing Up, and Mixing Medication (continued)

4. **Without removing the VAD,** or needle, from the second vial (B), invert it and withdraw the ordered amount of medication. Expel any air bubbles, and measure the dose. Remove the VAD from the vial, then pull back on the plunger enough to pull all medication out of the VAD into the syringe (see Clinical Insight 26-4). Read the dose at eye level. Tip the syringe horizontally if you need to eject any medication.
Allows you to withdraw all the medication. Keeping the needle in the medication and withdrawing the medication slowly helps prevent drawing excess air into the syringe and prevents bubbles.

Vial B (Step 4)

5. **Insert the VAD or needle** into the first vial (A), invert, and withdraw the exact ordered amount of medication, holding the syringe vertical.
   - When finished, the plunger should be at the line for the total/combined dose for vials A and B. (Using the example in Step 2, you would have 1.5 mL of the mixed medications in the syringe.)
   - Be very careful not to withdraw excess medication; keep your index finger or thumb on the flange of the syringe to prevent medication being forced back by pressure. If this occurs, you must discard the medication in the syringe and start over.

Because the medications are mixed, withdrawing extra from the second vial makes the entire mixture incorrect. If you eject excess medication from the syringe, you do not know how much of either medication you have ejected; so even if you have the correct amount of fluid (e.g., 1.5 mL in our example), you would not know how much of that is medication A and how much of it is medication B.

You do not need to change the needle before Step 5 because even if one vial is a multidose vial, you would have withdrawn the medication from it first (in Step 4). It will not matter if you track medication into the single-dose vial.

Vial A (Step 5)

6. **Recap the VAD** or access needle, using a needle capping device or the one-handed scoop method (see Procedure 26-10: Recapping Needles Using a One-Handed Technique).
Although recapping a sterile needle does not present a threat of bloodborne pathogen exposure, using a mechanical recapping device or the one-handed method helps develop safe habits. As a rule, we do not recommend using the one-handed scoop for sterile needles; however, this needle will be discarded anyway, so if it is accidentally contaminated with a one-handed scoop, it will not be a major error.

7. **Remove the VAD** (or access needle), and attach a new sterile needle on the syringe for the injection.
Obviously, you must replace a VAD with a needle for injection. In addition, if you used a needle instead of a VAD, by the time you are finished withdrawing both medications you will have put it through a rubber vial top at least three times. This dulls the needle. A sharp needle causes less trauma to the patient on injection. A new needle also prevents tracking of the medication through the skin and subcutaneous tissues.

8. **Hold the needle vertically** to expel all air and recheck the dosage (the total for both medications).
Allows for more accurate accounting of the dose.

9. **If you have used a VAD or filter** needle, refer to Clinical Insight 26-4.

Procedure 26-9D ■ Mixing Medications From One Ampule and One Vial

➤ First review the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route); Procedure 26-9A (Drawing up Medications from Ampules); Procedure 26-9B (Drawing Up Medication From Vials); and Procedure 26-10A (Recapping Contaminated Needles).

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Begin with the vial**. Scrub the stopper of the vial using an alcohol wipe or CHG-alcohol combination product.
Protects against microbial contamination.

2. **Attach a VAD** and draw **the same volume of air** into the syringe as the dose prescribed for the medication in the vial.

3. **Keeping the tip of the VAD** or safety needle above the medication, inject the amount of air equal to the volume of drug to be withdrawn from the vial. The needle should be injecting air-to-air within the vial.
Draw from the vial first because you do not need to add air to ampules before drawing up the medication. In addition, if it is a multidose vial, you would contaminate it with the medicine if you withdrew from the ampule first.
Injecting air into the vial makes withdrawing the medication easier. For small unit-dose vials, it may be possible to withdraw the medication without instilling air, but you will need to maintain a slight backward pressure on the plunger until the needle is completely withdrawn. If you release the plunger, the negative pressure in the vial will pull the medication back into the vial. Therefore, it is safer always to instill air.

4. **Invert the vial**. Withdraw the prescribed volume (dosage) of medication, keeping the VAD tip in the fluid. See Procedure 26-9B.

5. **Expel any air bubbles** and measure the dose at eye level. Recheck the dosage, and withdraw more or eject the drug as needed.
This prevents air from entering into the needle or VAD.

6. **After safely recapping** the VAD remove it from the syringe. You may place it on an opened, sterile alcohol pad if you need your hands to open the filter needle packaging.
Keeps the needle sterile, if you are using one; you will reuse it. You would not reuse a VAD from this step on.

7. **Attach a filter needle** or filter straw to the syringe.
The use of a 5-micrometer (µm) filter minimizes the possibility of withdrawing small glass fragments.

8. **Flick or tap the top** of the ampule (or snap your wrist) to remove medication from the neck of the ampule.
Flicking the neck of the ampule will help the fluid to drain down into the main part of the ampule, thus reducing waste.

9. **Open the ampule** by wrapping the neck with a folded gauze pad or an unopened alcohol wipe or use an ampule snapper. Snap open away from you.
Snapping outward prevents you from accidentally cutting your fingers or spraying glass fragments toward your face. Do not use an opened alcohol wipe to break the ampule, because it is not thick enough to prevent injury.

10. **Withdraw the exact prescribed** amount of medication from the ampule into the syringe (see Procedure 26-9A). Be very careful in drawing up the second medication; if the total amount of the two medications is incorrect, you must discard the syringe contents and start over.

11. **Draw 0.2 mL of air into the syringe.**
The extra bit of air clears the filter needle (see Clinical Insight 26-4).

12. **Confirm the dose is correct** by holding the syringe vertically and checking the dose at eye level.
Ensures the total volume in the syringe equals the ordered amount of both medications plus 0.2 mL of air from the needle.

13. **Recap the filter needle or straw,** using a needle capping device or the one-handed technique recommended in Procedure 26-10B.
Although recapping a sterile needle does not present a threat of bloodborne pathogen exposure, using a mechanical recapping device or the one-handed method helps develop safe habits. Nevertheless, some scoop techniques pose a significant risk of contaminating the needle, so you must watch carefully that you maintain sterile technique.

14. **Remove the filter needle** or straw and discard it in a sharps container. Replace with a new sterile safety needle for administering the medication to the patient.
This needle-recapping method prevents accidental needlestick injury. You cannot measure the dose accurately with a filter needle. You should not eject medication through the filter needle because of risk of breaking the filter. See Clinical Insight 26-4.

15. **After placing the administration** needle on the syringe, eject the 0.2 mL of air and check for the correct dose. If there is excess medication in the syringe, you must discard it and start over.

16. **Discard used needles** and ampules in a puncture-proof sharps container.

(continued on next page)

Procedure 26-9 ■ Preparing, Drawing Up, and Mixing Medication (continued)

Procedure 26-9E ■ Using a Prefilled Cartridge and Single-Dose Vial—For Intravenous Administration

➤ *Note:* It is best not to use this technique with multidose vials because there is a risk of contaminating the multidose vial with the cartridge medication.

➤ First review the Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route). Review Procedures 26-9 and 26-10, as needed.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Scrub the rubber stopper** of the vial thoroughly with an alcohol prep pad or CHG-alcohol-based product.
2. **Assemble the prefilled cartridge** and holder (see Clinical Insight 26-2).
3. **Remove the needle cap** from the prefilled cartridge, expel the air, and measure the correct dose of medication.
   You must confirm that the dose of the first medication is correct before you mix it with the second medication.
4. **Holding the cartridge with** the needle up, draw in an amount of air equal to the volume of medication you need from the vial.
5. **While continuing to hold** the syringe with needle straight up (vertically), invert the vial and insert the needle into it until the tip of the needle shows in the air above the medication. Then inject the air into the vial. Maintain counter-pressure on the plunger so that air and/or medication do not flow back into the syringe.
   Injecting air into the vial makes the medication easier to withdraw. ▼

6. **While maintaining counter-pressure** on the plunger, pull the needle down into the fluid and allow the pressure in the vial to push the medication into the syringe. Withdraw the prescribed amount of vial medication, being careful not to withdraw any excess.
7. **The pressure will generally push** a little less than you need**,** so carefully withdraw the amount you need for a correct dose—again, do not withdraw any excess.
   Withdrawing excess medication will result in an altered mixed dose, so you would need to discard the syringe and start over.
8. **Recap the needle** (use a one-handed method) and if possible remove the needle from the prefilled syringe and replace it with a sterile injection cannula for IV administration. For an intramuscular (IM) injection, if the prefilled cartridge does not have a safety needle, you would need to transfer the medication to a new syringe with a sterile safety needle for injection.
   VADs and injection cannulas prevent needlestick injury. Unless there is a needle safety device for the prefilled syringe, it is not recommended for IM injections.

? What if . . .

■ **I note particulate matter in the ampule or vial?**
Discard the medication and order a new one.

Documentation

Document on the MAR.

Thinking About the Procedures

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Drawing Up Medication From Ampules, Drawing Up Medication From Vials, Mixing Medication From Two Vials,** and **Mixing Medication From One Ampule and One Vial.**

For questions and suggested responses,

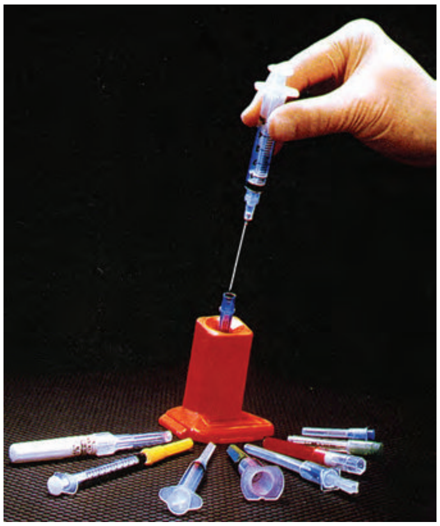
Procedure 26-10 ■ Recapping Needles Using a One-Handed Technique

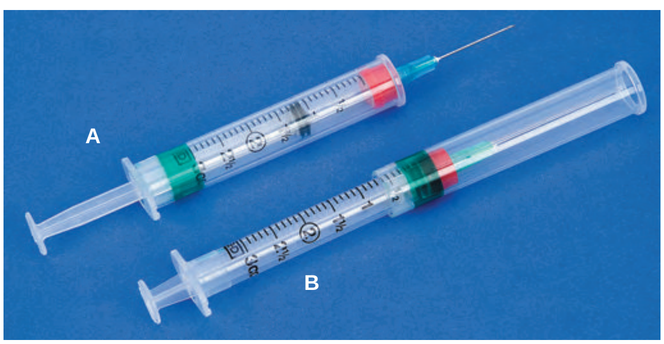
➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

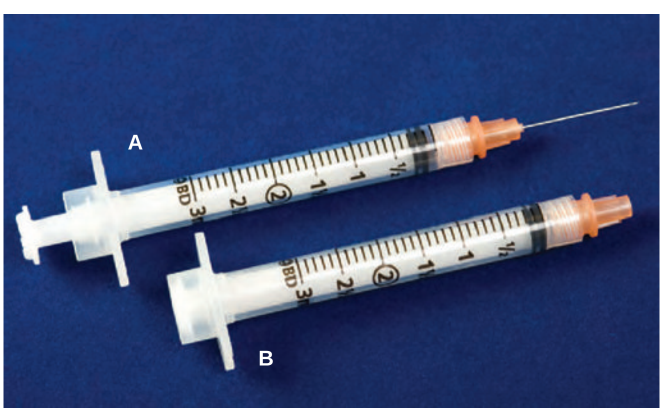
- Mechanical recapping device, if available
- Needle cover
- Safety syringe, if available
- Other supplies depending on the method used.



Needle recapping device.



Safety syringe. *A*, Before injection. *B*, Cover slides up after injection.



Safety syringe. *A*, Before injection. *B*, Needle retracted after injection.

Delegation

Delegation is not usually an issue because recapping needles is done in conjunction with administering parenteral medications, which you will usually not delegate. If you do delegate administration of parenteral medications to an LPN/LVN, you must supervise and evaluate recapping to ensure that the nurse uses proper technique.

Preparation

- **Assess the need to recap the needle.**
  Recap a contaminated needle only if doing so is absolutely unavoidable, according to Occupational Safety and Health Administration (OSHA) standards. As a rule, place a contaminated syringe and needle directly into a puncture-proof sharps container, without capping, bending, or breaking the needle.
- **Identify whether the needle is sterile or dirty.**
  Although a one-handed technique is used to recap both sterile and dirty needles, different considerations exist. When you use the one-handed method for recapping a sterile needle, it is easy to contaminate the needle without realizing it. You should modify the technique to help prevent that—the main consideration is to "protect" the needle. The danger in recapping a dirty needle is that you will stick yourself with it, exposing yourself to pathogens. The main consideration is to protect yourself.
- **Determine the availability of mechanical recapping device or safety syringe.**
  Always use a mechanical recapping device or safety syringe, if one is available.

(continued on next page)

Procedure 26-10 ■ Recapping Needles Using a One-Handed Technique (continued)

Procedure 26-10A ■ Recapping Contaminated Needles

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **If you are using a safety needle,** engage the safety mechanism to cover the needle. (See Equipment.)
   OSHA regulations require the use of safety syringes to prevent needlestick injuries. You must engage the safety mechanism before placing the needle and syringe into the sharps container.
2. **Alternatively, place the needle** cap in mechanical recapping device, if one is available. (See Equipment.)
3. **If a mechanical recapping device** is not available, use the one-handed scoop method to recap the needle.
   a. Place the needle cover on a flat surface.
   Keeps the needle cover from rolling during the needle capping procedure.

   b. Then, holding syringe in your dominant hand, scoop the needle cap onto the needle. Tip the syringe vertically to slip the cover over the needle. Do not hold onto the needle cap with your nondominant hand while scooping.
   A mechanical recapping device protects against accidental needlestick injury. If it is unavailable, the one-handed method of recapping will prevent accidental injuries when your own or the patient's safety is a concern.

   c. Secure the needle cap by grasping it near the hub.
   Prevents an accidental stick if the needle goes through the needle cap. Needles are sharp enough to go through the needle cap if inserted at an angle.

Procedure 26-10B ■ Recapping Sterile Needles

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ Use one of the following techniques to ensure that you do not contaminate a sterile needle. If you contaminate the needle, microorganisms will be introduced with the injection.

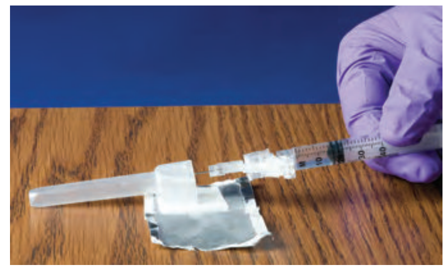
Procedure Steps

1. **Place the needle cap** in a mechanical recapping device, if one is available.
   The device is specially developed to provide safe recapping.
2. **Alternative method: Medication cup.** Place the cap into a small liquid medication cup with the open end facing up. You can then insert the sterile needle into the cap, keeping your free hand well away from the cup.
   This step performs the same function as a mechanical recapping device. The needle and cover need to be taller than the cup you are using, so that the open end of the cap protrudes above the cup. ➤

3. **Alternative method: Scoop technique.** Place the cap on a clean surface so that the end of the needle cap protrudes over the edge of the counter or shelf, and scoop with the needle; keep your free hand well away from the needle and cap as you are recapping.
This method prevents you from inadvertently hitting an unsterile surface with the needle.

4. **Alternative method: Tubular container.** If the syringe is packaged in a hard plastic tubular container, stand the container on its large end; invert the needle cap; and place it in the top of the hard container. Insert the needle downward into the cap.

5. **Alternative method: Alcohol wipe.** Place the needle cap on a sterile surface, such as on an open alcohol prep pad, and use the one-handed scoop technique. Be very careful not to touch anything with the needle other than the inside of the needle cap.
The alcohol prep pad provides a sterile barrier. Because you must bring the needle parallel to the flat surface, and because the alcohol pad is so small, it is easy to contaminate the needle using this method.



Documentation

No documentation needed for recapping needles.

Practice Resources

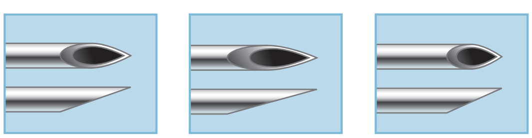
U.S. Department of Health and Human Services (USDHHS) (2012); Wagar, S., Siraj, M., Razzaq, Z., et al. (2011).

Procedure 26-11 ■ Administering Intradermal Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Alcohol prep pad or CHG-alcohol product
- 2 in. × 2 in. gauze pad
- Pen (ink or felt)
- 1-mL syringe (tuberculin) with intradermal needle (25- to 28-gauge, $\frac{1}{4}$- to $\frac{5}{8}$-inch with short bevel)



Regular bevel | Intermediate bevel | Short bevel

Delegation

As an RN, you can usually delegate administration of parenteral medications to an LPN/LVN. You usually cannot delegate this task to a NAP.

Pre-Procedure Assessments

- Assess for allergies, previous reaction to skin testing, and the skin for signs of irritation (e.g., bruising, swelling, tenderness).
Some skin tests, such as the tuberculin test, should not be repeated after positive test results.
Do not give intradermal skin tests if skin abnormalities are present. Also avoid giving them in areas where reading the results may be difficult, such as areas of heavy hair growth.

Preparation

- Have appropriate antidotes (usually epinephrine hydrochloride, a bronchodilator, and an antihistamine) readily available before the start of the procedure.
Because many intradermal injections are used for allergy testing, this is an important consideration.
- Know the location of resuscitation equipment (artificial airway, Ambu bag, and code cart)
Allergic reactions can be fatal.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

(continued on next page)

Procedure 26-11 ■ Administering Intradermal Medication (continued)

Procedure Steps

1. **Draw up the medication** from the vial (see Procedure 26-9B). The usual dose is 0.01 to 0.1 mL.
   Intradermal sites can only accommodate small volumes of medication.

2. **Select the site for injection.** Usual sites are the ventral surface of the forearm and upper back. The upper chest may also be used. If you need to review site locations,

   Go to Chapter 26, **Figure 26-23,** in Volume 1.

   Use areas where subcutaneous fat is less likely to interfere with administration and absorption. The forearm is the standard initial starting point because it has the least amount of subcutaneous tissue. The forearm and upper back usually have little hair, permitting easier visualization to interpret results accurately.

3. **Assist the patient to a** comfortable position. If you are using the forearm, instruct her to extend and supinate her arm on a flat surface. If you are using the upper back, ask the patient to lie prone or lean forward over a table or the back of a chair.
   This method stabilizes the injection site. The procedure will be more comfortable if the patient is able to relax his muscles. Tension, in general, increases pain perception.

4. **Don procedure gloves.**
   Procedure gloves are not required by OSHA for intradermal injections, but they are recommended by the CDC to prevent accidental exposure to bloodborne pathogens.

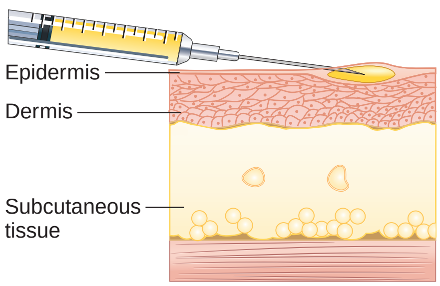
   Remember, gloves cannot prevent needlestick injuries.

5. **Scrub the injection site** with an alcohol prep pad or CHG-alcohol product pad. For an alcohol product, circle from the center of the site outward. For CHG products, use a back and forth motion. Allow the site to dry before administering the injection.
   Cleansing to remove microorganisms follows the principle of "clean to dirty." Alcohol can interfere with the test results if a small amount is introduced during the injection. Also, if the alcohol has not evaporated, it may cause the skin to sting during the injection.

6. **Grasp the syringe between** the thumb and index finger of your dominant hand, and uncap the needle.
   Enables you to administer the solution at the correct angle.

7. **Hold the client's skin taut** with your nondominant hand, by using one of the following methods:
   a. Place your hand under the client's arm and pull the skin tight with your thumb and fingers.
   b. Stretch the client's skin between your thumb and index finger.
   c. Pull the client's skin toward the wrist or down with one finger.
   A downward motion while stretching the skin eases needle insertion. Holding the skin tight can be difficult because of the low angle of administration.

8. **Continuing to hold the client's skin** taut with your nondominant hand, hold the syringe in your dominant hand with the needle bevel up and parallel to the client's skin at a 5° to 15° angle. Slowly insert the needle. There is some controversy about whether it is better to have the bevel down or up; however, the CDC recommends bevel up.
   The low angle of insertion is necessary to place the needle tip in the intradermal layer instead of the subcutaneous tissue. Having the bevel up likely decreases the chance of injecting the medication deeper into the subcutaneous tissue. Patients receiving intradermal injections report bevel up more comfortable.



9. **Advance the needle** approximately 3 mm (1/8 in.) so that the entire bevel is covered. The bevel should be visible just under the skin.
   If the entire bevel is not inserted, the solution will leak out of the tissue. If you can see the bevel under the surface of the skin, you can be sure that the bevel is not in the subcutaneous tissue.

10. **Do not aspirate.** Hold the syringe stable with your nondominant hand.

11. **Release the taut skin and slowly inject the solution.** You should feel firm resistance. A pale wheal, about 6 to 10 mm (1/4 in.) in diameter, will appear over the needle bevel.
   The dermis does not have room to absorb the solution, so a wheal forms, stretching the skin. Slow administration gives you time to terminate the injection should a systemic reaction occur. If a bleb (wheal) forms, you have administered the drug properly. The size of the bleb depends on the amount of medication you injected.

12. **Remove the needle** from the skin, engage the safety device, and dispose of the needle in a biohazard, puncture-proof container. If there is no safety device, place the uncapped syringe and needle directly in a biohazard, puncture-proof container.
   Prevents needlestick injuries.

13. **Gently blot any blood** with a dry gauze pad. Do not rub the skin or cover it with an adhesive bandage.
   Rubbing may cause the drug to leak out and alter absorption. An adhesive bandage can cause irritation and interfere with the skin test.

14. **With a pen, draw a 1-inch circle** around the bleb/wheal.
Marking the site helps you to identify any change in the size of the wheal at a later time.

? What if . . .

- **My patient has a history of a skin reaction to PPD testing?**
Obtain details about the type and severity of the reaction. If the previous reaction involved ulceration at the site, further Mantoux testing is contraindicated. Report this to the prescriber.
- **My patient is pregnant, is receiving chemotherapy, or has severe eczema?**
Defer tuberculosis skin testing and inform the prescriber.
- **My patient received a live vaccine at the time of tuberculosis skin testing?**
Tuberculosis skin testing should be deferred for one month after live viral vaccines or other major viral infection.
- **My patient has topical anesthetic cream on the skin?**
Use a site where the topical anesthetic cream was not applied or reschedule tuberculosis skin testing for another date.

Evaluation

- Reassess the client 5 and 15 minutes after administration for allergic reactions that may subsequently occur.
- Read the site within 48 to 72 hours of injection, depending on the test.
- Observe that a wheal (about 6 to 8 mm in diameter) forms at the site and that it gradually disappears.
- Observe for minimal bruising that may develop at the site of injection.

Patient Teaching

- Explain when the patient needs to have the intradermal injection read to determine whether the result is positive or negative.
- Explain that mild itching, swelling, or irritation may occur at the injection site and is normal.
If the patient has antigens to the injected solution, a histamine response occurs, causing itching, swelling, or irritation. This response generally subsides within a week.
- Discuss the significance of a positive or negative skin test result. Explain that some signs of irritation may occur that do not mean a positive test result.
- Instruct the patient not to scratch, apply lotions or creams, cover the site with a bandage, or scrub the site.
This might cause irritation and interfere with the test, which may produce false-positive results.

Documentation

- See the information in Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).
- Some medications require documentation of lot numbers (check agency policy).
- Chart when the test is to be read.

Sample documentation

mm/dd/yyyy 0800 Explained purpose and procedure for Mantoux skin test. Client stated, "I need a PPD so that I can go to the long term care facility." 0.2 mL of tuberculin purified protein placed in left forearm per physician order. No reaction noted 5 minutes after procedure. Will read test at 0800 on mm/dd/yyyy. ——— M. Saleh, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering Intradermal Medication.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Practice Resources

National Center for HIV, STD, and TB Prevention, Division of Tuberculosis Elimination (2008, updated 2012); CDC (2011a).

Procedure 26-12 ■ Administering Subcutaneous Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Syringe and needle appropriate for volume and site
- Alcohol prep pad or CHG-alcohol product
- Gauze pad (optional)

Delegation

As an RN, you can usually delegate administration of parenteral medications to an LPN/LVN. You usually cannot delegate this task to a NAP.

Pre-Procedure Assessments

- Check the selected site for inflammation, bruising, lumps, or other abnormalities that may contraindicate use of the site.
- Check the area for previous injection sites.
  Alternating among the arms, thighs, abdomen, and back changes the absorption rate of the medication. Absorption is fastest from the abdomen, then the arms, and lastly the thighs and back. Rotate sites within the same extremity or location, approximately 1 inch from the previous injection. Rotating the site helps prevent fat deposits and skin lumps.
- Do focused assessments for the specific medication being administered.

Insulin—Check capillary blood sugar level, and determine when the patient will be having the next meal; check for signs of hypoglycemia or hyperglycemia.
Insulin must be balanced with food intake to prevent the patient from developing hypoglycemia or hyperglycemia. Different insulins have specific rates of absorption, peak action, and duration. Some insulins, such as Humalog and regular insulin, are rapid acting. Before you administer rapid-acting insulin, the capillary blood sugar must be within the normal range or above, and the patient must be ready to eat. With Humalog, the patient's food tray should be in front of him before you administer the insulin.

Heparin—Check activated partial thromboplastin time (aPTT) and for signs of overt bleeding (e.g., bleeding from gums, IV injection sites) and covert bleeding (e.g., blood in urine and stool)
Heparin is an anticoagulant, so the major side effect is bleeding.

Note: The aPTT will not be monitored as frequently with the low-molecular-weight heparins (LMWHs), because bleeding is less likely to occur.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Select an appropriate syringe** and needle.
   a. For insulin administration, you must use an insulin syringe—typically 0.3, 0.5, or 1.0 mL. Most insulin needles are 28- to 31-gauge. Needle length is often 3/16- to 1-inch. For more information about giving insulin, see Clinical Insight 26-5.

   Although both insulin and tuberculin (TB) syringes come in a 1-mL size, they are not interchangeable. Insulin syringes are calibrated in units; they have a permanent (non-removable) needle and a very small amount of dead space.

   b. For other medications, for volumes less than 1 mL, use a tuberculin (TB) syringe with a 25- to 27-gauge, 3/8- to 5/8-inch needle.
   Because of the small increments on the TB syringe, small doses can be measured more accurately.

Top: Insulin syringe. *Bottom:* TB syringe.

   c. For administering a volume of 1 mL, you may use a 3-mL syringe with a 25- to 27-gauge, 3/8- to 5/8-inch needle.
   Although you can measure 1 mL with a TB syringe, it will be difficult to handle the syringe because the plunger will be pulled back as far as it can go. It is easy to pull it inadvertently out of the end of the syringe. Some medications are supplied in prefilled syringes. Examples are enoxaparin sodium (Lovenox) and the other LMWHs.

2. **Draw up the medication.** See Procedure 26-9.
3. **Select an injection site** with adequate subcutaneous tissue. If you need to review site locations,

Go to Chapter 26, **Figure 26-25,** in Volume 1.

   Helps you avoid accidentally injecting into the muscle.
   a. The usual sites are the outer aspect of the upper arms, abdomen (at least 2 inches away from the umbilicus), anterior aspects of the thighs, and high on the buttocks near waist level.

These areas usually have good circulation and are easily accessible. The buttocks are more convenient when someone is giving the injection other than the patient.

b. The anterolateral and posterolateral abdomen ("love handles") sites are the only subcutaneous site used for administering heparin or LMWHs. For more information about giving heparin, see Clinical Insight 26-6.

The tissue 2 inches away from the umbilicus poses less risk of bleeding when an anticoagulant is administered.

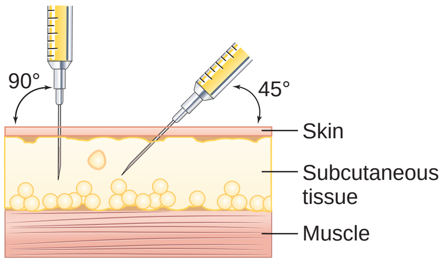
4. **Position the patient** so that the injection site is accessible and the patient is able to relax the appropriate area. Check the site for inflammation, bruising, lumps, or other abnormalities.
Avoid areas with skin abnormalities, which may alter the absorption rates or increase patient discomfort during the injection.

5. **Don procedure gloves.**
To prevent exposure to bloodborne pathogens. You may prefer to don gloves before Step 4.

6. **Scrub the injection site** with an alcohol prep pad or CHG-alcohol product. Allow the site to dry before administering the injection. For alcohol, circle from the site outward; for CHG, use a back-and-forth motion. Do not go back over already scrubbed areas.

7. **Remove the needle cap.**
The needle cap is more difficult to remove when using a one-handed technique.

8. **With your nondominant hand,** pinch the tissue at the injection site, and determine the angle at which to inject the needle. Insert the needle using a 45° to 90° angle, depending on the amount of adipose tissue (the less adipose tissue, the lower the angle). If the adipose tissue pinches 2 inches or more (client is obese), use a longer needle and spread the skin taut instead of pinching.
Grasping and lifting the tissue prevents you from accidentally injecting into the muscle. Also, the subcutaneous injection must be given in the fatty tissue and not into intradermal layer. Traditionally, injections had been given using a 45° angle to ensure medication is deposited into the subcutaneous layer.



9. **Holding the syringe between** thumb and index finger of your dominant hand like a pencil or dart, insert the needle at the appropriate angle into the skinfold.
Quickly inserting the needle through the skin minimizes discomfort.

10. **Using the thumb or index finger** of your dominant hand, press the plunger slowly to inject the medication while stabilizing the syringe with your other hand. Alternatively, after inserting the needle, you can continue to hold the barrel with your dominant hand and use your nondominant hand to depress the plunger.
Slow administration allows the medication to disperse and decreases discomfort. Subcutaneous injections do not need to be aspirated beforehand, because accidental entry into a blood vessel is rare. Stabilize the syringe to avoid discomfort and tissue damage from the needle.

11. **Remove the needle** smoothly along the line of insertion.
Prevents pulling against the skin and tissue and thus minimizes discomfort.

12. **Gently blot the site with gauze** if needed. Do not massage the site unless directed to do so by prescription or policy.
Occasionally there will be blood at the site after the needle is removed. You might have nicked a surface blood vessel when you injected, and blood is following the needle track out to the surface. Massaging or rubbing the site will alter the rate of absorption of the medication.

13. **Engage the needle safety device**, and dispose of the needle in a biohazard container. If there is no safety device, place the uncapped syringe and needle directly into a biohazard, puncture-proof container.
A sharps container prevents needlestick injuries.

Evaluation

- Observe for minimal bruising that may develop at the site of injection.
- Reassess the patient for anticipated response and adverse reaction to medication.

For insulin, observe for signs that patient's blood sugar level has returned to normal and for signs of hypoglycemia.

For heparin, observe that patient has no signs of bleeding.

For other medications, observe for side effects.

Patient Teaching

- Discuss possible lifestyle adaptations that the patient may need to undertake while receiving the medication (e.g., diet and exercise recommendations for managing diabetes mellitus).

Home Care

- Discuss with the client or caregiver the options for insulin administration to determine the most appropriate choice for the person administering the injections.
Many options are available, including specially designed syringes that are easier to handle and read, pen injectors, and prefilled syringes.
- In the home environment, the client might not routinely use an alcohol wipe to cleanse the site. This is acceptable as long as the skin is clean.
In the home environment there is less risk for superinfection with resistant strain organisms, and other hospital-acquired infections.

(continued on next page)

Procedure 26-12 ■ Administering Subcutaneous Medication (continued)

- Do not encourage reusing needles and syringes. However, if the client or caregiver believes they need to reuse syringes and needles in the home, teach them how to safely do so. Teach them the guidelines in Clinical Insight 26-1.

The very small insulin needles (30-gauge) bend very easily and are not recommended for reuse.

Determine whether reusing syringes is appropriate for the patient. Contraindications include inadequate hygiene, immunocompromised status, and difficulty handling equipment to prevent contamination of the needle.

Discuss safety concerns regarding subcutaneous medication administration in the home, such as how to dispose of biohazardous wastes correctly and where to obtain a puncture-proof biohazard container.

The patient or caregiver may use a large plastic bottle or a coffee can. Local regulations regarding disposal must be followed.

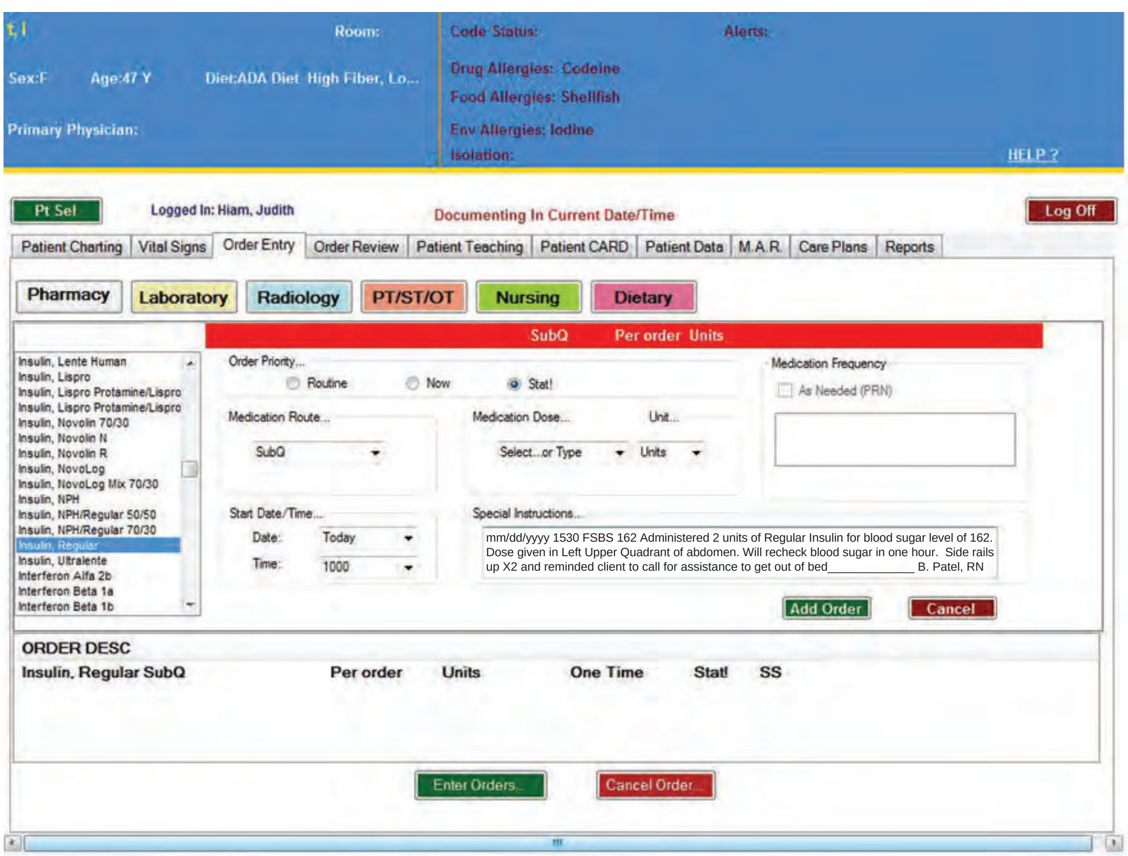
- Discuss with the patient the need to rotate sites and reasons for doing so. Recommend that he give injections at the same time of the day in the same body location about 1 inch from the previous injection site.
  Repeatedly giving the medication in the same site can cause abnormalities in the tissue and alter absorption rates.
- Remind the patient that when changing sites (thigh, arm, abdomen), the absorption rate may be altered.
- If the patient is receiving heparin or LMWHs, discuss the need to avoid nonsteroidal anti-inflammatory (NSAID) medications, such as acetylsalicylic acid (aspirin) and ibuprofen (Motrin, Advil).
  These drugs increase the risk of bleeding.
- For patients receiving heparin or LMWHs, discuss home safety and the need to avoid falls.
  The patient is at risk for bleeding and needs to follow safety guidelines to prevent injury.

Research shows that older females are more susceptible to hematomas after administration of LMWH (Nourbakhsh, Anvari, & Nugent, 2011). Nurses should carefully assess for abdominal bruising and complaints of abdominal pain.

Documentation

- Chart according to Medication Guidelines: Steps to Follow for All Medication (Regardless of Type or Route).
- Some agencies have a specific code for documenting subcutaneous injections, which allows exact site documentation on an outline of the body.
- In the nursing notes, document any related patient assessment findings, such as capillary blood sugar, signs of hypoglycemia or hyperglycemia, bruising, and so on.
- Document in the nursing notes as well as MAR any medication that was given PRN.

Sample EHR documentation



Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering Subcutaneous Medication.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Practice Resources

Bartley, N. (2012); Nourbakhsh, E., Anvari, R, & Nugent, K. (2011); Pledger, J., Hicks, D., Kirkland, F., et al. (2012); Zaybak, A., & Khorshid, L. (2008).

Procedure 26-13 ■ Locating Intramuscular Injection Sites

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Delegation

As an RN, you can usually delegate administration of parenteral medications (including locating injection sites) to an LPN/LVN. You usually cannot delegate this task to a NAP. If you delegate the skill, you are responsible for evaluating the LPN/LVN's ability to locate injection sites correctly.

Pre-Procedure Assessment

Always palpate the landmarks and the muscle mass to ensure correct placement of the needle. Because patients' body shapes differ, the site locations will vary slightly.

Procedure 26-13A ■ Locating the Ventrogluteal Site

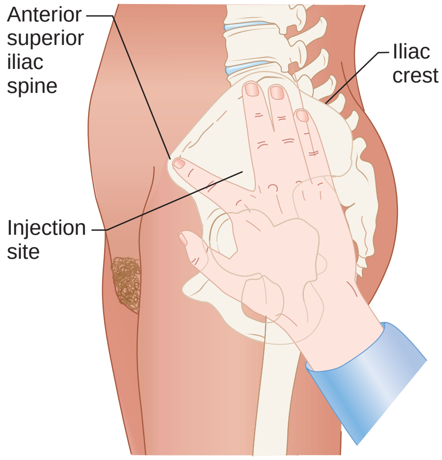
➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

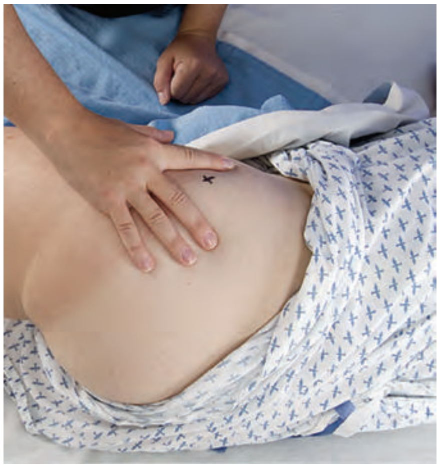
1. **Ask the patient to assume a side-lying** position with the legs straight, if possible.
   This position makes the site easier to locate.

2. **Locate the greater trochanter**, anterior superior iliac spine, and the iliac crest. ➤

3. **Place the palm of your hand** on the greater trochanter, your index finger on the anterior superior iliac spine, and your middle finger pointing toward the iliac crest. (Use your right hand on the patient's left hip; use your left hand on the patient's right hip.) Note that if your hands are very large or very small, the location of the "triangle" will be higher or lower on the hip. Be sure you locate it well in the muscle mass.



4. **The middle of the triangle** between your middle and index fingers **is the injection site.**
   This is a safe site for IM administration because it is not in close proximity to any major blood vessels or nerves. The landmarks are easy to find. This large muscle can take volumes up to 5 mL in the average adult. It is safe for patients of all ages and the preferred site for adults and children older than 7 to 12 months (there is some disagreement over the age; always palpate to assess adequacy of muscle mass, regardless of age). ➤



Procedure 26-13B ■ Locating the Deltoid Site

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

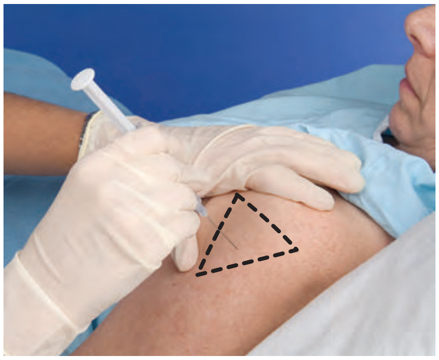
Procedure Steps

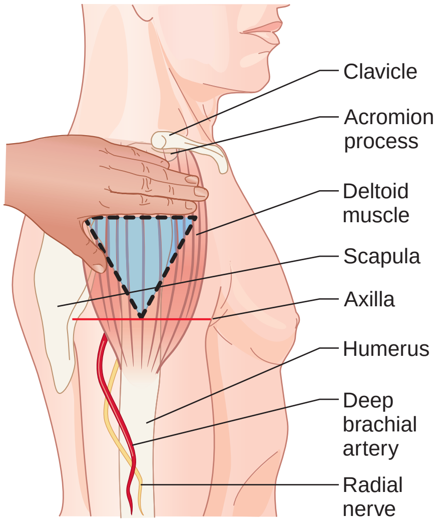
1. **Completely expose the patient's** upper arm. Remove the garment; do not roll up the sleeve.
   Incomplete exposure of site and landmarks creates a risk of injecting into other than muscle tissue. This is a small site, and it is easy to make an error in location.

(continued on next page)

Procedure 26-13 ■ Locating Intramuscular Injection Sites (continued)

2. **Locate the lower edge** of the acromion process (knobby part of shoulder). This imaginary line forms the base of a triangle.





3. **Draw an imaginary line** from each end of the triangle base downward 1 to 2 in (3 to 5 cm) to the midpoint of the lateral arm.
4. **The deltoid site is in the center of the resulting** inverted triangle.
5. **An alternative approach** is to place four fingerbreadths across the deltoid muscle, with your top finger on the acromion process. The injection goes three fingerbreadths below the process in the midline of the upper arm.
   Locates the appropriate site while avoiding the radial nerve and deep brachial artery. Because it is a fairly small muscle, only 0.5 to 1 mL of medication can be administered.

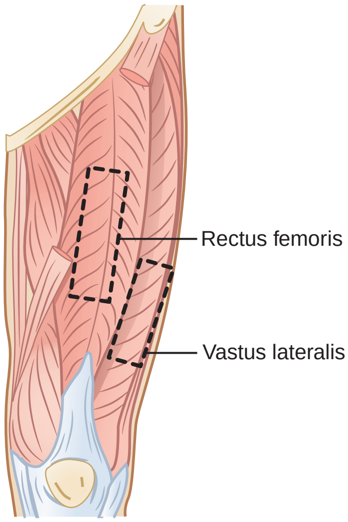
Procedure 26-13C ■ Locating the Vastus Lateralis Site

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Position the patient** lying supine or sitting.
   The patient may perceive the injection as less painful if supine because he cannot see the needle enter his leg. For some people this provokes anxiety and intensifies pain.
2. **Locate the greater trochanter** and the lateral femoral condyle.
3. **Place your hands on the thigh**, with one hand against the greater trochanter, and the other edge of hand against the lateral femoral condyle.
4. **Visualize a rectangle** between your hands across the anterolateral thigh.
   - The index fingers of your hands form the smaller ends of the rectangle.
   - The long sides of the rectangle are formed by (a) drawing an imaginary line down the center of the anterior thigh and (b) drawing another line along the side of the leg, halfway between the bed and the front of the thigh.
   - This box marks the middle third of the anterolateral thigh, which is the injection site.

   The rectus femoris lies on the top (or anterior) portion of the thigh and partially covers the edge of the vastus lateralis. Therefore, do not inject too near the midline of the anterior thigh. Because it is not near any major blood vessels or nerves, the vastus lateralis site is safe for patients of all ages and is the recommended site for children younger than 7 months.



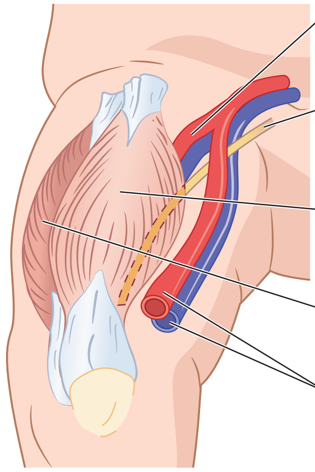
Procedure 26-13D ■ Locating the Rectus Femoris Site

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Use this site only if no other sites are accessible and no other medication routes are feasible.

1. **Position the patient** lying supine or sitting.
2. **Divide the top of the thigh** from the groin to the knee into thirds, and identify the middle third.
3. **Visualize a rectangle** in the middle of the anterior surface of the thigh. This is the location of the injection site. Also refer to the drawing of the adult thigh in Procedure 26-13C. ➤



? What if . . .

- **My patient is a child. What is the best site to give an IM injection?**

  Because an infant's muscles are not fully developed, site selection is limited.

  For children who are walking, use the ventrogluteal site.

  For children who are not yet walking, use the vastus lateralis. Once the gluteal muscles are develop further, which occur with walking the ventrogluteal site can be used.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Locating the Ventrogluteal Site; Locating the Deltoid Site; Locating the Vastus Lateralis Site;** and **Locating the Rectus Femoris Site.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 26-14 ■ Administering an Intramuscular Injection

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

➤ The z-track method is preferred for all IM injections, except in a rare instance in which it is contraindicated.

Equipment

- Syringe and needle appropriate for volume and site
- Alcohol prep pad or CHG-alcohol product
- Gauze pad or adhesive bandage
- Medication
- Procedure gloves
- Biohazard (sharps) container
- Small piece of gauze or cotton ball
- Small adhesive bandage

Delegation

As an RN, you can usually delegate administration of parenteral medications to an LPN/LVN. You cannot delegate this task to a NAP.

Pre-Procedure Assessments

- Identify the site of the previous injection.
- Assess the site for adequate muscle mass, bruises, edema, tenderness, redness, or other abnormalities.
  Muscle mass must be large enough to absorb the amount of medication prescribed. Abnormalities at the site increase patient discomfort and alter the absorption rate of the medication.
- Assess for factors that might affect absorption of the medication, such as decreased intramuscular blood flow, as found in shock or muscle atrophy.
  Decreased peripheral circulation or muscle atrophy decreases the absorption of the medication.

(continued on next page)

Procedure 26-14 ■ Administering an Intramuscular Injection (continued)

Procedure 26-14A ■ Intramuscular Injection: Traditional Method

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Select the appropriate syringe** and needle.
   a. The usual syringe size is 1 to 3 mL, depending on volume of medication to be given. For doses less than 1 mL, you can use a tuberculin syringe with an intramuscular needle.
   b. The needle size is usually 21- to 25-gauge, 1½ inch in length for adults (or 1 in. for deltoid site), but a longer needle (3 in.) might be necessary to penetrate the muscle if the patient is obese.
   For IM administration, the needle gauge must be appropriate for the viscosity of the medication, and the needle must be long enough to deliver the medication into the muscle.
   c. Some medications are supplied in prefilled syringes, which are used for administration.

2. **Draw up the medication** (see Procedure 26-9A) or obtain prescribed unit dose and verify medication. If the volume for injection is more than 3 to 5 milliliters, divide the dose for separate injections.

3. **Don procedure gloves.**
   Procedure gloves are required by OSHA to prevent exposure to bloodborne pathogens. You may prefer to don gloves at Step 6, while waiting for the antiseptic to dry.

4. **Position the patient** so that the injection site is well exposed and the patient is able to relax the appropriate muscles. Be sure the lighting is adequate.
   When the patient's muscles are relaxed (and not tense), it is easier to perform the injection and it reduces patient discomfort during injection. You must be able to fully visualize and safely access the site.
   a. *Deltoid site:* Position the patient with the arm relaxed at the side or resting on a firm surface, and completely expose the upper arm.
   b. *Ventrogluteal site:* Position the patient on the opposite side, with the upper hip and knee slightly flexed.
   This position may cause the trochanter to become more prominent, making it easier to locate the site.
   c. *Vastus lateralis:* Position the patient supine or sitting, if the patient prefers.
   d. *Rectus femoris:* Position patient supine. Because this site often causes more discomfort than others, use it only if all other sites are inaccessible and no other route is feasible.
   e. *Dorsogluteal:* Do not use this site because of the muscle's proximity to the sciatic nerve and major blood vessels.

5. **Using appropriate landmarks**, identify the injection site (see Procedure 26-13). If the client is to receive more than one injection, rotate sites.
   Volumes of 1 to 5 mL may be given, depending on the muscle size (for adults, 0.5 to 1 mL in the deltoid; and typically 1 to 3 mL but up to 5 mL in the vastus lateralis site). If the volume for injection is more than 3 to 5 mL, then divide the dose for a separate injection. Rotating sites reduces discomfort and tissue trauma.

6. **Gently, but vigorously scrub the injection site.** Do not "go back over" already cleansed areas.
   a. If using an alcohol prep pad scrub by circling from the center of the site outward.
   b. If using a CHG-based antiseptic, use a back and forth motion.
   Cleanse to remove microorganisms; follow the principle of "clean to dirty."

7. **Place the wipe on the patient's** skin outside the injection site, with a corner pointing to the site. Allow the site to dry before administering the injection. Do not fan the site.
   Leaving the antiseptic prep pad on the skin with a corner pointing to the injection site helps identify the location for the injection. If the antiseptic has not evaporated, it may cause the skin to sting during injection.

8. **Remove the needle cap.**

9. **With your nondominant hand**, spread the skin taut between your thumb and index finger.
   It is quicker, easier, and less painful to insert a needle through the skin that is taut.

10. **Tell the patient what** you are going to do and that he will feel a prick as you insert the needle. Then hold the syringe between thumb and fingers of your dominant hand like a pencil or dart and insert the needle at a 90° angle to the skin surface. Insert fully.
   Quickly inserting the needle through the skin minimizes discomfort. A 90° angle is needed for the needle to penetrate through the subcutaneous and adipose tissue to the muscle.

11. **Stabilize the syringe** with your nondominant hand.
   This prevents the needle from moving around in the tissue, thereby causing discomfort and possible tissue trauma.

12. **Aspirate by pulling back** on the plunger and waiting for 5 to 10 seconds. If you obtain a blood return, remove the needle, discard the syringe, and prepare the medication again. If there is no blood return, continue with Step 13.
   Aspirating blood indicates that the needle is in a blood vessel. Injecting would result in administering the medication intravenously instead of intramuscularly. If the needle is in a small vessel, it may take a few seconds for the blood to appear in the syringe. **Key Point:** ***There are variations in practice regarding the requirement to aspirate for blood. Be sure to check with your instructor or the institution's protocol for the recommended method.***

13. **Using the thumb or index** finger of your dominant hand, press the plunger slowly to inject the medication (5 to 10 sec/mL).
Slow administration allows the medication to disperse and decreases discomfort.

14. **Remove the needle** smoothly along the line of insertion.
Removing the needle in this way prevents pulling against the skin and tissue and minimizes discomfort.

15. **Engage the safety needle** device, and dispose of the entire syringe in a biohazard container. If there is no safety device, place the uncapped syringe and needle directly into a biohazard puncture-proof container.
The biohazard sharps container prevents needlestick injuries.

16. **Gently blot the site** with a gauze pad, and apply an adhesive bandage as needed.
Apply pressure to stop the bleeding but do not massage or rub the site after IM injection. This can cause medication to disperse into the subcutaneous tissue where the needle was injected, which might be irritating to the tissue.

Procedure 26-14B ■ Intramuscular Injection: Z-Track Method

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

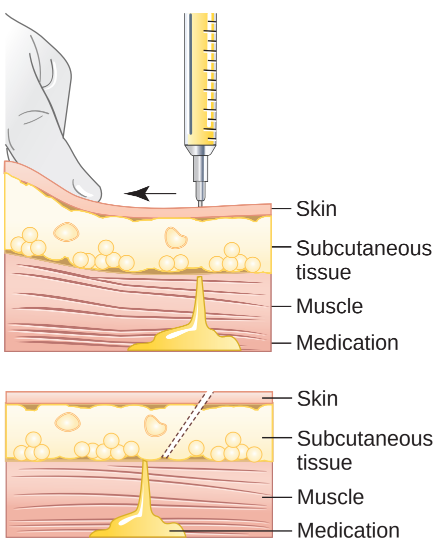
Procedure Steps

1–8. Follow Procedure 26-14A, traditional method, preceding.

Step 5 Variation. For Z-Track Method, use the larger muscles:

a. *Ventrogluteal site:* Position patient on the side with upper hip and knee slightly flexed.
b. *Vastus lateralis:* Position patient supine or sitting.

9. **With the side of your** nondominant hand, displace the skin away from the injection site, about 2.5 to 3.5 cm (1 to 1.5 in.).
This displaces the skin and subcutaneous tissue over the muscle, so that when it is released after the injection, the medication is sealed in the muscle.



10. **Holding the syringe between** the thumb and fingers of your dominant hand like a pencil or dart, insert the needle at a 90° angle to the skin surface. Insert smoothly, quickly, and fully.
Quickly inserting the needle through the skin minimizes discomfort. A 90° angle is needed for the needle to penetrate through the subcutaneous and adipose tissue to the muscle.

11. **Stabilize the syringe** with the thumb and forefinger of your nondominant hand while continuing to displace the skin with your other three fingers. Do not release the skin to stabilize the syringe.
Stabilizing the needle reduces discomfort and possible tissue injury. You must keep the skin retracted to create a seal after the medication is injected and the skin released.

12. **Aspirate by pulling back slightly** on the plunger for 5 to 10 seconds. If you obtain a blood return, remove the needle, discard the syringe, and prepare the medication again.
Aspirating blood indicates that the needle has penetrated a vein. Continuing could result in administering the medication intravenously instead of intramuscularly. Practice varies on whether to aspirate, so follow institutional policy.

13. **Using the thumb or index** finger of your dominant hand, press the plunger slowly to inject the medication (5 to 10 sec/mL).
Slow administration allows the medication to disperse and decreases discomfort.

14. **Wait for 10 seconds**, then withdraw the needle smoothly along the line of insertion, then immediately release the skin.
Waiting before withdrawing the needle leaves a zigzag needle track that traps the medication in the muscle, preventing it from leaking up into the subcutaneous tissue.

15. **Engage the safety needle device**, and dispose of it in a biohazard container. If there is no safety device, place the uncapped syringe and needle directly in a biohazard puncture-proof container.

16. **Hold a cotton ball** or gauze pad with light pressure over the injection site. Do not massage the site. Apply an adhesive bandage if necessary.
Light pressure will stop superficial bleeding at the injection site. Massaging and rubbing can force medication into the subcutaneous tissues.

? What if . . .

- **My patient is unable to cooperate during the procedure?**
Ask another healthcare provider or family member to help keep the patient from moving during the injection or to help position the patient.

(continued on next page)

Procedure 26-14 ■ Administering an Intramuscular Injection (continued)

■ **My patient is a child; is there anything different about giving an IM injection?**

Adapt the procedure to decrease pain: Apply topical anesthetic cream (e.g., EMLA) or a topical cooling spray if time permits. If not, distract the child with conversation, or give him something to do, such as squeeze a hand. Or apply a cold compress over the site.

Adapt the way you spread the skin to inject: In infants and small children, grasp the muscle with your thumb and index finger; in obese children, spread the skin and then grasp the muscle.

Adapt the medication volume: Inject no more than 1 mL in a single injection, 0.5 mL in a small infant.

Be aware of the controversy about needle size: The CDC recommends 1- and 1¼-inch needles for children 1 year old or younger. Follow agency procedures.

■ **My patient is an older adult?**

Many older adults have decreased muscle mass, so use a shorter needle; spread the skin and grasp the muscle to localize and stabilize the site for injection.

Older adults tend to bleed from the site after injection because of reduced tissue elasticity. Apply a small pressure bandage if needed.

Evaluation

- Observe for minimal bruising or oozing that may occur at the site of injection.
- Observe for local reactions at site (e.g., pain, swelling, redness).

Home Care

- Discuss safety concerns with administering medication intramuscularly in the home, such as correct disposal of biohazardous wastes and where to obtain a puncture-proof biohazard container.
  The caregiver or patient can use a large plastic bottle. The local regulations must be followed for disposal.
- Discuss with the client the need to rotate sites.
  Repeatedly giving the medication in the same site can cause abnormalities in the tissue and alter absorption rates.

Documentation

- Refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).
- Document related assessment findings, such as pain level or presence of nausea.
- Unless the medication is prn, you will typically document it only on the MAR.

Sample documentation for PRN medication:

mm/dd/yyyy 1600 Client reports of nausea after ambulating 150 feet with assistive device. Phenergan 25 mg administered IM in right ventrogluteal site. No complaints of pain or discomfort. See MAR ——— M.Santos, RN

mm/dd/yyyy 1700 Client reports "I don't feel like I'm going to vomit anymore." ——— M.Santos, RN

Practice Resources

Advisory Committee on Immunization Practices (ACIP) (n.d.); CDC (n.d.); Bartley, N. (2012); Walsh, L., & Brophy, K. (2011).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Intramuscular Injection: Traditional Method** and **Intramuscular Injection: Z-Track Method.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 26-15 ■ Adding Medications to Intravenous Fluids

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Prescribed IV solution
- Syringe for measuring medication
- Needleless access device or safety needle (if a VAD is not available)
- Antimicrobial swab
- Label with medication, dose, date, time, and your initials

Delegation

As an RN, you would not usually delegate adding medications to IV fluids to LPN/LVNs. Nurse Practice Acts governing IV medication administration vary from state to state, and policies can further vary among healthcare agencies regarding which additives may be added by LPN/LVNs. Even if you delegate the skill, you are always responsible for evaluating the patient's responses, both therapeutic effects and adverse effects.

Pre-Procedure Assessments

- Assess the patency of the IV site.
- Assess the appearance of the IV site.
- Check the medication insert or PDR for appropriate time or rate for infusion and for preparation.

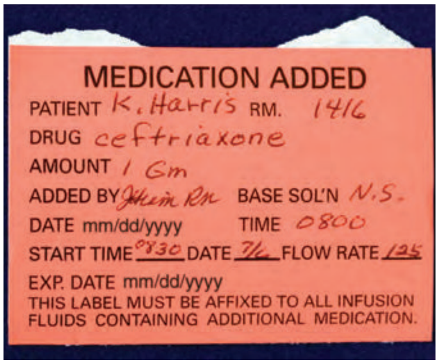
Procedure 26-15A ■ Adding Medication to a New IV Bag or Bottle

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine whether** the medication(s) are compatible with the IV solution and with each other.
   Not all medications or other additives can be mixed with the glucose or saline normally found in the primary IV bag. Multiple additives increase the possibility of incompatibility.
2. **Calculate or verify the amount** of medication to be instilled into the IV solution, and the rate of administration.
   Verifying the dose and the rate of infusion prevents medication errors.
3. **Remove any protective covers,** and inspect the bag or bottle for leaks, tears, or cracks. Inspect the fluid for clarity, color, and presence of any particulate matter. Check the expiration date.
   Double-checking the IV solution reduces the risk of infusing contaminated or expired solutions.
4. **Using the appropriate technique,** draw up the prescribed medication (see Procedures 26-9, as needed). Alternatively, insert a VAD transfer device into the medication vial.
   Medications can come in vials, ampules, or bags.
5. **Scrub all surfaces of the IV** additive port with an alcohol or CHG-alcohol combination product.
   Diligent scrubbing with antimicrobial products reduces the transmission of microorganisms and helps maintain the sterility of the solution.
6. **Remove the cap from** the syringe, insert the needle or the needleless access device into the injection port, and inject the medication into the bag, maintaining aseptic technique.

7. **Mix the IV solution and** medication by gently turning the bag from end to end.
   Ensures even distribution of the medication or additive into the solution.
8. **Place a label on the bag** so that it can be read when the bag is hung; include the medication name, dose, route, and your name. Be sure the label does not cover the solution label or volume marks.
   A label informs you and others of additives to IV solutions.



9. **Dispose of used equipment**, syringe, or VAD appropriately.

(continued on next page)

Procedure 26-15 ■ Adding Medications to Intravenous Fluids (continued)

Procedure 26-15B ■ Adding Medication to an Infusing IV

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

1. **Determine the compatibility** of the medication being added to the existing solution.
   Not all medications and solutions are compatible.
2. **Note the volume** in the existing IV bag and the amount needed for dilution of medication.
   Adequate solution is needed to dilute the medication.
3. **Clamp the running IV line.**
   Clamping prevents medication from directly infusing into the patient.
4. **Scrub all surfaces of the IV** additive port with the antimicrobial swab (alcohol or CHG-alcohol combination product).
   Vigorous scrubbing decreases the transmission of microorganisms and maintains the sterility of the solution.
5. **Remove the cap from** the syringe, insert the safety needle or the needleless VAD into the injection port, and inject the medication into the bag, maintaining aseptic technique. ➤

6. **Mix the IV solution and** medication by gently turning the bag from end to end. Keep the bag above the level of the patient's IV insertion site and do not invert the drip chamber.
   Turning the IV bag ensures even distribution of the medication or additive into the solution. Because of gravity, the height of the bag keeps blood from backing up in the IV tubing.
7. **Place the label on the bag** so that it can be read when the bag is hung. Be sure the label does not cover the solution label or volume marks.
   A label provides information regarding additives to IV solutions.
8. **Unclamp the IV line**, and run the IV at the prescribed rate.
9. **Dispose of used equipment**, syringe, needle, or VAD appropriately.

? What if . . .

■ **The IV fluid infiltrates into a peripheral site.**

Discontinue the infusion. Restart the peripheral IV, making sure you have good blood return and the line flushes easily. Some IVs are positional. This means the flow may be partially obstructed when the cannula in the vein lodges against the vein wall. In this case, the rate of the IV fluid to be delivered is likely to be compromised.

If the tissue at the site of infiltration appears to be swollen and tender, you might apply a cool compress to the site. If the infusion contained irritating substances, such as calcium, dopamine, or various chemotherapy agents, you might need to contact the prescriber for an order to inject antidote medication into the intradermal layer.

Evaluation

- Check the IV line at least once every hour to ensure that the ordered or calculated rate is maintained.
- Assess the patient for complaints of pain at the infusion site.

Patient Teaching

- Discuss reasons the medication is being given intravenously.
- Let the patient know whether it is a continuous or intermittent infusion.
- Explain the need to report immediately any reactions to the medication, such as breathing problems, rashes, or pain at the IV insertion site.

Documentation

- Document information according to Medication Guidelines: Steps to Follow for All Procedures (Regardless of Type or Route).
- If you added medication to an existing IV setup, document related patient assessment findings, such as appearance of IV site and complaints of pain or discomfort during administration.
- Findings are usually documented on an IV flow record rather than in the nursing notes. Chart a nursing note only if there is something outside of the expected findings (e.g., if the IV has infiltrated).

Practice Resources

Infusion Nurses Society (INS) (2011a); Lavery, I. (2011).

Procedure 26-16 ■ Administering IV Push Medication

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

Equipment

- Syringe appropriate for medication volume and the type of line (e.g., peripheral IV, PICC)
- If you are administering through an intermittent device:
  - Two 5- to 10-mL syringes, or one 10-mL syringe with 2 to 10 mL of normal saline or heparin for flushing the line. Heparin 100 units/mL rather than with saline solution is recommended (Bertolino, Pitassi, Tinelli, et al., 2012).
    Although either is acceptable, separate syringes pose less risk of contamination.
  - Depending on site and facility policy, one 5- to 10-mL syringe containing 2 to 5 mL of heparin flush (or saline) solution
    Evidence-based support and agency procedures differ: Some use saline to flush; others use heparin. New evidence recommends using heparin 100 units/mL (Bertolino, Pitassi, Tinelli, et al., 2012).
- Alcohol prep pad, or CHG-alcohol combination product and gauze pad
- Procedure gloves

Delegation

As an RN, you may, in some situations, be able to delegate administration of parenteral medications to an LPN/LVN. However, this is not a common practice.

Pre-Procedure Assessments

- Check the compatibility of the medication with the existing IV solution, if it is infusing.
  Medications can be physically or chemically incompatible with the IV solution. Physical incompatibility is often obvious because precipitation may occur. Chemical incompatibility is not obvious and may result in the medication's having a weaker or a stronger effect than anticipated.
- Assess the patency of the IV line.
  If the line is occluded, you will not be able to instill the medication.
- Check the site for redness, swelling, tenderness, and other signs of infiltration or phlebitis.
  Some medications are irritating and may be toxic to the tissue. If the IV line is infiltrated, the medication may leak into the tissue and cause injury. IV medications can also irritate the veins and cause phlebitis. Do not infuse a medication into a compromised site.

Procedure 26-16A ■ Administering IV Push Medications Through a Primary IV Line

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine how fast the** medication may be administered and whether the medication needs to be diluted for administration. Also, check to be sure the medication is compatible with the solution infusing.
   IV push medications are frequently injected over 1 minute. Some must infuse over a longer time period, and some require diluting before administration. Giving an IV push medication too fast and/or undiluted can result in local or systemic adverse reactions.
2. **Prepare the medication** from a vial or ampule or obtain the prescribed unit dose and verify medication with the order (refer to Procedure 26-9). Dilute as needed. Temporarily pause the infusion pump to administer the medication. If the primary bag is infusing by gravity, simply clamp the tubing.
3. **Don procedure gloves** and thoroughly scrub all surfaces of the injection port closest to the patient with an alcohol prep pad or CHG-alcohol combination product.
   (1) Scrub time: *Follow agency policy. Some facilities require nurses to cleanse the port for 1 minute when accessing venous access devices. (2)* The port: *Using the port closest to the patient minimizes the distance the medication must travel and gets it into the patient's circulation faster. You must use an injection port, which is self-sealing because if you puncture the plastic IV tubing, it will leak. (3)* Scrub agent: *Use povidone-iodine solution (Betadine) only if the patient is sensitive to alcohol or CHG-alcohol combination.*
4. **Insert the medication syringe** into the injection port. If a needleless system is not available, use a syringe with a safety needle.
   Using a needleless system prevents needlestick injuries.
5. **Pinch or clamp the IV tubing** between the IV bag and the port.
   Occluding the tubing upline of the port prevents the medication from being injected back toward the IV bag.

6. **Gently aspirate** by slowly pulling back on the plunger to check for a blood return. **NOTE:** Some newer connectors do not require or allow for aspiration. Follow institutional policy.
   (a) In tubing that allows for or requires aspiration, a blood return is one indication that the IV catheter is in the vein. An IV site may still be patent if no blood is returned, and an infiltrated IV line may have a blood return. Use the blood return as one indication of patency

(continued on next page)

Procedure 26-16 ■ Administering IV Push Medication (continued)

(Phillips, 2010). (b) Injecting an IV medication into an IV site that is not patent administers the medication into the local tissue at the IV site. Some medications will cause tissue irritation and even necrosis if infused into the subcutaneous tissue. In addition, the patient would not receive the immediate therapeutic benefit from the drug.

7. **If you have aspirated and obtained a blood return**, administer a small increment of the medication while observing for reactions to the medication.
Slow injection allows you to observe adverse reactions to the medication before all the medication has been injected. Administering IV push medications carries the highest potential risk to the patient because immediate, life-threatening reactions can occur.

8. **Administer another increment** of the medication (you may pinch the tubing while injecting medication and release it when not injecting; this is optional).

9. **Repeat Steps 7 and 8 until** the full dose of medication has been administered over the prescribed amount of time.
Medications require different administration times. Follow agency guidelines, physician orders, and pharmaceutical information regarding whether the medication needs to be diluted and the rate of administration.

10. **If you clamped the IV tubing** during the infusion, open it now and reset the pump at the correct infusion rate, if necessary.

11. **Dispose of used supplies safely** and according to agency procedures.

Procedure 26-16B ■ Administering IV Push Medications Through an Intermittent Device (IV Lock) When No Extension Tubing Is Attached to the Venous Access Device

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Check the compatibility** of the medication with the intravenous solution, if one is infusing. Determine how fast the medication may be administered and whether the medication needs to be diluted for administration.
IV push medications are frequently injected over 1 minute. Some medications must be administered over a longer time period, and some medications must be diluted before administration. Giving an IV push medication too fast and/or undiluted can result in an adverse local or systemic reaction.

2. **Prepare the medication** from a vial or ampule. Dilute as needed. Refer to Procedure 26-9.

3. **Select the appropriate size** of syringe for flush solution.
Smaller syringes exert more pressure against the wall of the IV catheter than do larger syringes. Check with the IV catheter manufacturer for specific recommendations, and follow agency policy.

4. **Don procedure gloves.**

5. **Thoroughly scrub all surfaces** of the injection port closest to the patient with an alcohol prep pad or CHG-alcohol combination product. Use povidone-iodine solution (Betadine) only when the patient cannot tolerate an alcohol-based disinfectant.
Follow agency policy. Some facilities require nurses to scrub all surfaces of the port with an alcohol-based antimicrobial product for 1 minute when accessing venous access devices. Using the port closest to the patient minimizes the amount of medication in the IV line.

6. **Insert the flush syringe** into the injection port. Depending on the equipment, you may then need to aspirate for a blood return.
In tubing that allows for or requires aspiration, a blood return is an indication that the IV catheter is in the vein. An IV site may still be patent if no blood is returned; conversely, an infiltrated IV may have a blood return. Use the blood return as only one indication of patency.

7. **Administer a flush solution** (usually 1 to 3 mL) to clear the line if blood return is obtained. Use a forward pushing motion on the syringe, with a slow, steady injection technique. If blood is not returned, see the What If . . . ? section at the end of Procedure 26-16.
(a) Flush syringes may be prefilled; and in some cases, the amount to inject may be a part of agency policy. (b) Rapid flushing causes a jet effect that can cause the catheter tip to migrate to other venous locations; this should be avoided. (c) Injecting an IV medication into an IV site that is not patent administers the medication into the local tissue at the IV site. Some medications will cause tissue irritation and even necrosis if infused into the subcutaneous tissue.

8. **Continue to hold the injection** port; remove the flush syringe; and again scrub the port with the alcohol prep pad or CHG-alcohol combination product. Use povidone-iodine only when the patient is sensitive to alcohol-based disinfectants.
Cleansing the port reduces the risk of introducing microorganisms into the bloodstream.

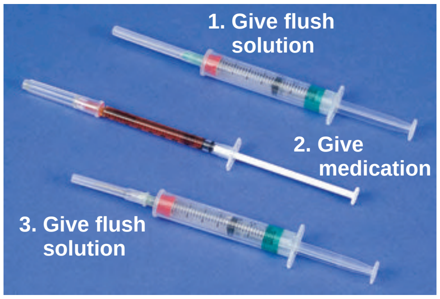
9. **Attach the medication** syringe and inject the medication in small increments over the correct time interval. Use a slow, steady injection technique until the correct dose is instilled over the prescribed amount of time.

For example, if 1 mL of the medication is to be given over 1 minute, inject approximately 0.25 mL every 15 seconds.

10. **Continuing to hold the injection** port, remove the medication syringe, and vigorously scrub all surfaces of the port with alcohol prep pad or CHG-alcohol–based product for at least 15 seconds. Attach the flush syringe.
Vigorous scrubbing reduces the chance of contamination of the port.

11. **Administer the flush solution** usually 1 to 3 mL, or according to prescription or agency policy.
Flushing ensures that all the medication has been administered and prevents occlusion of the IV catheter.

12. **Use a slow, steady injection** pressure technique when removing the syringe by placing your thumb or index finger to avoid movement of the plunger. (Follow equipment guidelines; you may not always need to do this.) Continue to administer the flush solution while withdrawing the syringe cannula from the injection port.
This positive-pressure technique prevents blood backflow into the IV catheter, which might cause an occlusion. Follow equipment guidelines because some injection ports maintain positive pressure by removing the syringe and then closing the clamp.



13. **Discard the flushing syringe** from the needleless connector into a safety disposal container.

Procedure 26-16C ■ Administering IV Push Medications Through an Intermittent Device With IV Extension Tubing

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Check the compatibility** of the medication with the intravenous solution, if one is infusing. Determine how fast the medication may be administered and whether the medication needs to be diluted for administration.
IV push medications are frequently injected over 1 minute. Some must be administered over a longer time period, and some require diluting prior to administration. Giving an IV push medication too fast and/or undiluted can result in a local or systemic adverse reaction.

2. **Prepare the medication** from a vial or ampule. Dilute as needed. Refer to Procedure 26-9.

3. **Determine the volume** of any extension tubing attached to the access port.
The volume of extension sets can be greater than the IV push medication being given. If not accounted for, all the medication may be injected into the patient's bloodstream at once when the second flush solution is given.

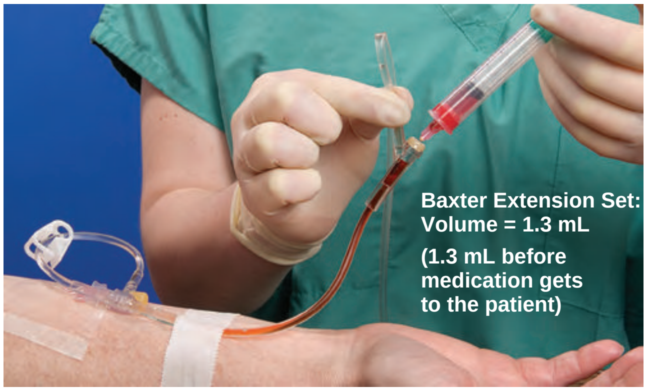
4. **Don procedure gloves.**

5. **Scrub all surfaces of the injection** port with an antiseptic wipe.

6. **Insert the flush syringe** into the injection port. Depending on the equipment, you may then need to aspirate for a blood return as one sign of vein patency. Some equipment does not require or allow aspiration. If a needleless system is not available, use a syringe with a safety needle.
(a) In tubing that allows for or requires aspiration, a blood return is a sign that the IV catheter is in the vein. However an IV site may still be patent if no blood is returned. (b) Using a needleless system prevents needlestick injuries.

7. **Administer the flush** (commonly 1 to 3 mL) after establishing patency of the IV line. If blood appears in the tubing, administer the rest of the flush. If blood is not returned, assess patency by administering a small amount of the flush solution and monitoring for ease of administration, swelling at the IV site, or patient complaint of discomfort at the site.

8. **Again scrub the port.** Attach the medication syringe and inject a volume of medication equal to the volume of the extension set at the same rate as the flush solution.
   - When using a 5-mL syringe for peripheral lines and a 10-mL syringe for central lines, administer the flush solution briskly.
   - When you use a smaller syringe, use a slower rate to prevent excess pressure damaging the vein or shearing of the IV cannula.



(continued on next page)

Procedure 26-16 ■ Administering IV Push Medication (continued)

The medication clears the line of saline solution and fills it with medication; it also flushes the IV catheter with saline as the medication pushes the saline through the catheter.

9. **Using a slow, steady injection** technique, administer the remainder of the medication over the prescribed time interval for the specific medication.
Rapid flushing can create a jet effect that can cause the catheter tip to migrate to an unintended venous location.

10. **Continuing to hold the** injection port connector, remove the medication syringe, vigorously scrub all surfaces of the connector for at least 15 seconds, then attach the flush syringe. **Key Point:** ***The only time you should open the catheter hub is when the needleless connector or primary continuous IV set must be changed, usually at 96-hour intervals or as otherwise prescribed.***

11. **Administer the same amount** of flush solution at the same rate as the medication, using a slow, steady injection technique. For example, if the extension tubing has a volume of 1.3 mL, give the first 1.3 mL of the flush solution at the same rate as the medication. Then administer the remainder of the flush solution.
(a) At this step, the extension tubing contains all the medication. Administering the flush solution all at once pushes the medication too fast (it will enter the vein all at once). (b) Once you have incrementally cleared the medication from the extension tubing and all the medication is already in the vein, then the rate no longer matters as far as the medication is concerned.

12. **Use a slow, steady injection** pressure technique when removing the syringe. Continue to administer the flush solution while withdrawing the syringe cannula from the injection port. Follow equipment instructions regarding the method and order of removing the syringe, closing the clamp, and maintaining positive pressure.

13. **Discard the flushing syringe** from the needleless connector into a safety disposal container.

? What if . . .

■ **When using equipment requiring aspiration, no blood is returned?**

Do not give IV push medication until you can verify the patency of the IV site. If the patency of the IV site is questionable, restart the IV at another site.

Further assess the patency of the IV line by administering a small amount of the saline flush and monitoring for ease of administration, swelling at the IV site, or patient complaint of discomfort at the site.

Another technique to determine patency is to lower the IV bag below the level of the IV site—a blood return should occur.

If the IV catheter is a small gauge, a blood return may not always be aspirated.

■ **There is resistance when flushing the line?**

Never force the flush solution into the VAD; look for a closed clamp on the catheter or tubing. Or you may check to see if an inline filter is clogged. Do not proceed with the medication infusion until you are sure the catheter is still correctly positioned and that the fluid pathway is unobstructed.

■ **The IV infusing a dextrose solution infiltrates into the surrounding tissue of a peripheral catheter?**

Immediately stop the running fluid and remove the catheter. Initially apply a cool, moist compress to the site and later use heat to promote comfort.
Infiltration can cause tissue injury, inflammation, and edema and may even lead to tissue necrosis and sloughing.

Some medications, such as vasopressors (e.g., dopamine), might need intradermal injection of an antidote, such as phentolamine (Regitine), to reverse the effects of extravasation.
If the IV fluid contains dextrose at greater than 10% concentration, calcium salts, potassium salts, sodium bicarbonate, blood, and parenteral nutrition, contact the primary care provider, who will likely prescribe injection of hyaluronidase (Amphadase) into the surrounding tissue.

Evaluation

- Assess the patient for complaints of pain or discomfort at the site.

Patient Teaching

- Discuss why the medication is being administered intravenously.
- Explain the need to report immediately any reaction to the medication.

Home Care

- Discuss with the client and/or caregiver how to care for the IV site, including flushing. Many IV push medications need to be administered by a nurse. However, cost-cutting efforts have led to short hospital stays, and some clients are now being taught to administer their own IV antibiotics at home.
- Explain how to identify problems with the IV site, such as infiltration and phlebitis.
- Determine whether the client has adequate facilities for storing the medication, such as refrigeration if needed.
- Discuss safety issues, such as keeping medications and needles and syringes secure and away from children and pets.

Documentation

Besides charting according to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route), document related patient assessment findings, such as the appearance of the IV site and patient complaints of pain or discomfort during IV administration. You will usually document on an IV flow record and/or MAR rather than in the nursing notes. Chart a nursing note only if there is a problem (e.g., if the patient experiences pain when you administer the medication).

Practice Resources

CDC (2011a); INS (2011a, 2011b); Phillips, D. (2010).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Administering IV Push Medications Through a Primary IV Line, Administering IV Push Medications Through an Intermittent Device (IV Lock) When No Extension Tubing Is Attached to the Venous Access Device,** and **Administering IV Push Medications Through an Intermittent Device With IV Extension Tubing.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 26-17 ■ Administering Medication by Intermittent Infusion

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route). For step-by-step instructions in using volume-control devices (pumps), see Procedure 38-3.

Equipment

- Correct size syringe for measuring medication
- Needleless access cannula or safety needle
- Volume-control IV set (e.g., Buretrol, Volutrol, Soluset) or small bag of diluted medication with piggyback tubing
- Primary IV solution and tubing (unless one is already infusing)
- Antimicrobial swabs
- Labels for the IV tubing and medication administration system

Delegation

Nurse practice acts governing IV medication administration vary from state to state, and policies can further vary among healthcare agencies, regarding which medications or methods of administration the LPN/LVN may perform. You cannot delegate this procedure to a NAP.

Pre-Procedure Assessments

- Check the compatibility of the medication with the IV solution.
  Medications can be physically or chemically incompatible with the IV solution. Physical incompatibility will be obvious if precipitation occurs. Chemical incompatibility is not obvious and may result in the medication having a weaker or a stronger effect than anticipated.
- Assess the patency of the IV line.
  If the line is occluded or if the fluid has infiltrated the medication will not infuse.
- Check the site for redness, swelling, tenderness, and other signs of infiltration or phlebitis.
  Some medications are irritating to the tissue. If the IV fluid has infiltrated, medication would leak into the tissue and cause injury. IV medications can also irritate the veins and cause phlebitis. Do not infuse a medication into a compromised site.
- Determine the amount of IV solution needed to administer the specific medication.
  Most medications specify (on the order or on the label) specific dilution to prevent potential harm to the patient.
- Determine the time period over which the solution needs to be infused.
  Infusing a medication too slowly may result in an inadequate blood level to achieve therapeutic levels, and infusing a medication too rapidly can cause harm.
- Perform assessments that will provide a basis for evaluating the drug's effectiveness, such as checking blood pressure after administering an antihypertensive agent.

Procedure 26-17 ■ Administering Medication by Intermittent Infusion (continued)

Procedure 26-17A ■ Using a Volume-Control Administration Set

- For step-by-step instructions in using volume-control devices (pumps), see Procedure 38-3. If you have not already done so, affix a label to the secondary bag indicating the name and amount of medication, date and time given, and your name or initials.
- When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Prepare the volume-control set.**
   a. Close both the upper and lower clamps on the tubing, if they are not already closed.
   Clamping prevents air bubbles from forming in the tubing.
   b. Open the clamp of the air vent on the volume-control chamber.
   Venting allows air to escape, which lets the IV solution enter the chamber.
   c. Maintaining sterile procedure, attach administration spike of the volume-control set to the primary IV bag.
   d. Fill the volume-control chamber with the desired amount of IV solution by opening the clamp between the bag and the volume-control chamber. When the correct amount of solution is in the chamber, close the clamp.
   The drip chamber provides solution for priming the tubing and diluting the IV medication.
   e. Prime the rest of the tubing by opening the clamp below the chamber and running the IV fluid until all the air has been expelled.
   Priming clears the IV tubing of air.
   f. Recheck the amount of fluid in the volume control chamber, and add more fluid to the desired amount, if needed.
   Priming the tubing alters the volume in the chamber. You must fill to the desired amount.

2. **With an alcohol or CHG**-alcohol swab, vigorously scrub all surfaces of the injection port closest to the patient.
Vigorous cleansing is necessary to removes microorganisms and particles from the IV port, which could potentially enter the patient's bloodstream.

3. **Connect the end of the** volume-control IV line to the patient's IV site (e.g., directly to the IV catheter, to the extension tubing, or to the injection port closest to patient).

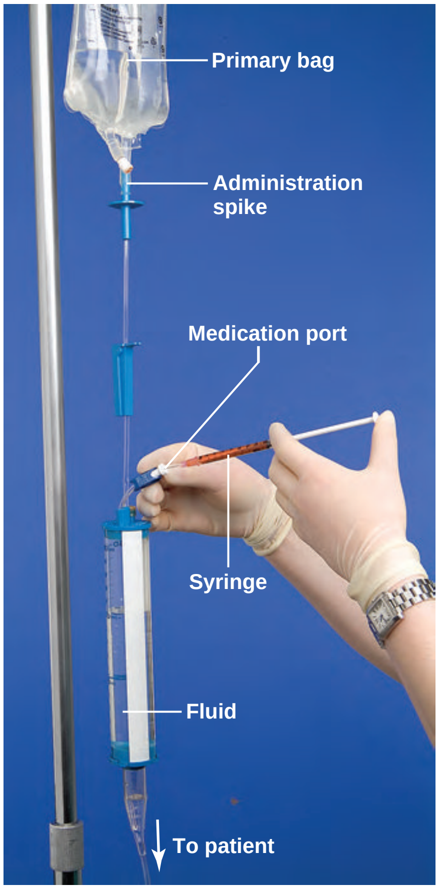
4. **Vigorously scrub the injection port** on the volume-control chamber, attach the medication syringe (preferably with a blunt, needleless device), and inject the medication into the solution in the chamber.

5. **Gently rotate the chamber** to mix the medication in the IV solution.
Distributes the medication within the IV solution.

6. **Open the lower clamp**, and start the infusion at the correct flow rate.
Unclamping allows the infusion of the medication. A correct flow rate infuses the medication over the correct amount of time and prevents a toxic reaction to it.

7. **Label the volume-control** chamber with the date, time, medication and doses added, and your initials, according to agency policy.

8. **When the medication has** finished infusing, add a small amount of the primary IV fluid to the chamber, and flush the tubing. For the flush volume, use twice the volume in the dead space of the tubing; check the tubing package for the amount.
Flushing the line ensures all the medication is given to the patient and does not adhere to the tubing.



Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to Davis's *Nursing Skills Videos*, **Using a Volume-Control Administration Set.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 26-17B ■ Using a Piggyback Administration Set With a Gravity Infusion

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

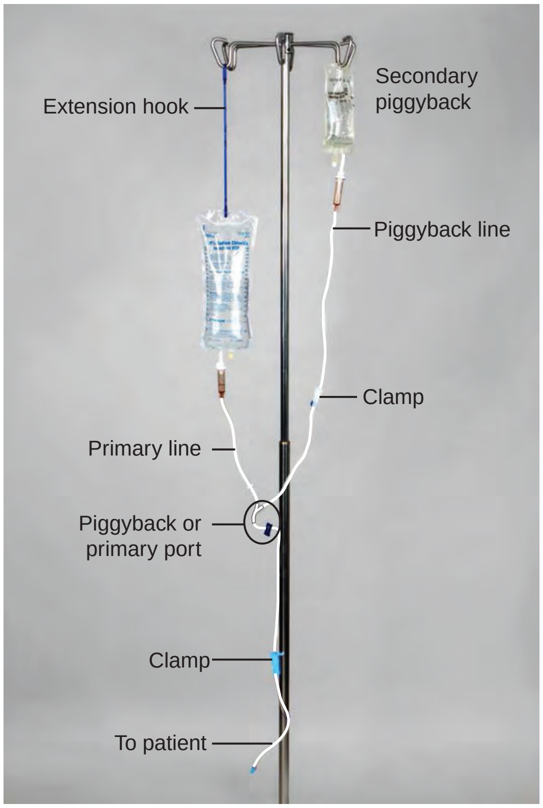
Procedure Steps

1. **Obtain the medication.** IV medications usually are premixed and labeled in small bags by the pharmacy. Rarely, you may need to draw up the medication, and inject it into the piggyback solution (see Procedure 26-15). Date and initial the medication bag label. Verify that it has the patient's name, amount of medication, date, and time given.
2. **Obtain and attach** the piggyback tubing to the medication bag. Do not touch the spike.
   Tubing connects the piggyback to the primary line. Prevents contamination of tubing and solution. Piggyback tubing is short.
3. **Be sure the slide clamp is closed.** Squeeze the drip chamber, filling it one-third to one-half full.
   Clamping prevents excess air coming into the line when you are priming the tubing.
4. **Open the clamp and prime** the tubing, holding the end of the tubing lower than the bag of fluid. Do not let more than one drop of fluid escape from the end of the tubing. Close the clamp.

Alternative. "Backflushing" the Piggyback Line

a. Clamp the piggyback tubing.
b. Scrub all surfaces of the primary "Y" port, and attach the piggyback setup with the needleless connector.
c. Open the clamp on the piggyback tubing, and lower the bag below the primary bag to prime the piggyback line.
d. Once all the air is expelled from the piggyback tubing, clamp the tubing and finish the procedure.
   Priming removes air from the tubing and maintains sterility of the system. Medications are diluted in small amounts of fluid (usually 50 to 100 mL), so you cannot waste any medication. The backflush method ensures you will not do so.

5. **Label the piggyback tubing** with the time, the date, and your initials.
   Tubing used for intermittent infusions can be used for 48 to 72 hours, depending on facility policy; labeling allows the nurse to know when it must be changed.
6. **Hang the piggyback container** on the IV pole. Lower the primary IV container to hang below the level of the medication bag.
   Gravity causes the higher bag (the piggyback IV setup) to flow instead of the primary IV setup. When the piggyback IV solution has infused, the primary IV line will resume infusing.
7. **Open the clamp** of the piggyback line, and regulate the drip rate with the roller clamp on the primary line. Regulate to the prescribed infusion rate for the medication.
   Because the piggyback is the only bag running, the primary roller clamp regulates the speed of the piggyback bag.
8. **When the medication is all infused**, clamp the piggyback tubing, and move the primary bag back to its original height. Use the roller clamp to reset the primary bag to its correct infusion rate.
   This ensures that the primary fluids infuse at their ordered rate rather than flowing at the rate the piggyback medication was flowing—which would probably be either faster or slower than the prescribed primary fluid rate.



Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Using a Piggyback Administration Set With a Gravity Infusion.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

(continued on next page)

Procedure 26-17 ■ Administering Medication by Intermittent Infusion (continued)

Procedure 26-17C ■ Using a Piggyback Administration Set with an Infusion Pump

➤ For step-by-step instructions in using intermittent infusion devices (pumps), also see Procedure 38-3.

➤ *Note:* This procedure describes the use of a one-piston infusion pump. The steps for using a two-piston pump vary slightly.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Obtain the medication.** IV medications usually are premixed in small bags and labeled by the pharmacy. If this is not the case, inject the medication into the prescribed piggyback solution (see Procedure 26-15). Date and initial the medication bag label. Verify that it has the patient's name, amount of medication, date, and time given.

2. **Be sure you have the correct secondary infusion tubing.** Hang the piggyback container on the IV pole. Attach the piggyback tubing to the medication bag. Do not touch the spike.
   Piggyback tubing is short; tandem tubing is much longer. Secondary tubing connects the piggyback to the primary line. Touching the spike would contaminate the tubing and solution.

3. **Be sure the slide clamp** is closed. Squeeze the drip chamber, filling it one-third to one-half full.
   Clamping prevents excess air coming into the line when you are priming the tubing.

4. **Open the clamp and prime** the tubing**,** holding the end of the tubing lower than the bag of fluid. Do not let more than one drop of fluid escape from the end of the tubing. Close the clamp.

Alternative. "Backflushing" the Piggyback Line

   a. With the drip chamber one-third filled, air will be in the secondary tubing.
   b. Pause the infusion pump.
   c. Scrub all surfaces of the "Y" port on the primary line and attach the piggyback set-up with a needleless connector.
   d. Open the clamp on the piggyback tubing, and lower the bag below the primary bag to prime the piggyback line. The fluid from the primary line will flow up through the secondary tubing until all air is removed from the tubing. Restart the pump.
   e. Once the line is primed, clamp the tubing and finish the procedure.
   Priming removes air from the tubing and maintains sterility of the system. Medications are diluted in small amounts of fluid (usually 50 to 100 mL), so you cannot waste any medication. The backflush method ensures you will not do so.

5. **Label the piggyback tubing** with the time, the date, and your initials.
   Tubing used for intermittent infusions can be used for 48 to 72 hours, depending on facility policy; labeling allows the nurse to know when it must be changed.

6. **Lower the primary IV** container to hang below the level of the piggyback medication bag.
   The tubing system works such that the higher bag (the piggyback IV setup) flow instead of the primary IV setup.

7. **Program the pump** by selecting the secondary infusion button
   This converts the fluid infusing from the primary line to the secondary line.

8. **Program the rate and total volume** to be infused. (Some pumps allow you to select the medication and dose.)
   Ensures accurate infusion amount and restart of primary fluids.

9. **Scrub the port** of the primary line.
   Minimizes the introduction of microorganisms.

10. **Remove the cover from** the secondary tubing and connect it to the connection port of the primary line. (This was done at Step 4 if the blackflush priming method was used.)

11. **Open the clamp** on the secondary tubing.

12. **Press "start"** on infusion pump.

13. **Check drip chambers** to ensure that the secondary solution is infusing and the primary solution is not.
    This ensures that medication is infusing and patient does not receive an overload of fluids.

14. **Check the pump information** again to ensure the correct rate and volume.

15. **At the end of the infusion**, the primary IV line will resume infusing. Once the secondary infusion is complete, the pump programming will re-set to the previously programmed primary rate.
    This ensures that the primary fluids infuse at their ordered rate rather than flowing at the rate the piggyback medication was flowing—which would probably be either faster or slower than the prescribed primary fluid rate.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Using a Piggyback Administration Set With an Infusion Pump.**

For questions and suggested responses,

Go to Chapter 26, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Evaluation

- Assess for pain or discomfort at the site.
- Intermittent infusions via a pump are generally infused over 30 to 60 minutes; therefore, you need to assess the patient as soon as the medication begins infusing and every 15 to 20 minutes until it is absorbed.

Patient Teaching

- Discuss why the medication is being administered intravenously.
- Explain the need to report immediately any reaction to the medication.
- Ask the patient to activate the call device if the infusion pump starts to alarm. Explain common reasons for the alarm to minimize anxiety.

Home Care

- Discuss with the client and/or caregiver how to care for the IV site. Only a nurse should add medications to the IV.
- Explain how to identify problems with the IV site, such as infiltration and phlebitis.
- Assess whether the client has adequate facilities for storing the medication, such as refrigeration if needed.
- Discuss safety issues, such as keeping medications, needles, and syringes secure and away from children and pets.

Documentation

- Chart information according to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).
- Document related patient assessment findings, such as the appearance of the IV site and patient complaints of pain or discomfort during the administration.

Practice Resource

INS (2011a; 2011b); Wiegand, D. (2011).

Procedure 26-18 ■ Administering Medication Through a Central Venous Access Device (CVAD)

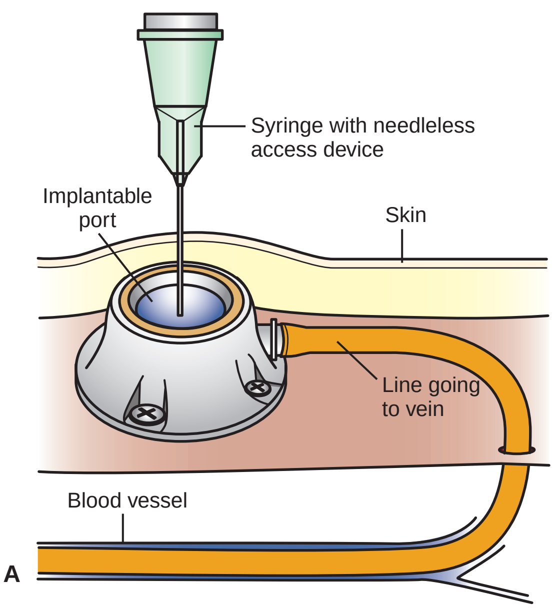
➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. Also refer to Medication Guidelines: Steps to Follow for All Medications (Regardless of Type or Route).

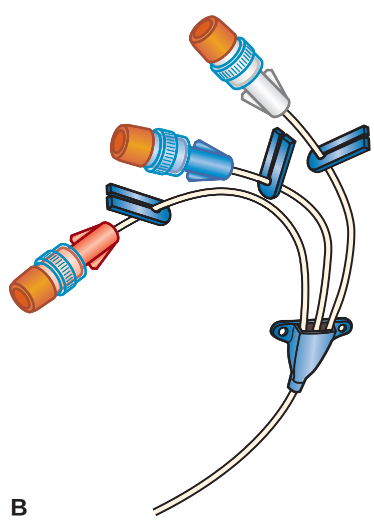
Equipment

- Syringe appropriate for medication volume (10 mL or larger)

  Use of syringes smaller than 10 mL when flushing a CVAD can cause increase pressure and may rupture the CVAD.

- Needleless device or safety syringe with a filter needle for drawing up the medication (you would also need a sterile needle for injection)
- Two syringes for the flush solution
- Saline or heparin flush solution, as prescribed. New evidence supports flushing peripheral venous catheters with heparin 100 units/mL rather than with saline solution (Bertolino, Pitassi, Tinelli, et al., 2012).
- Prep pad: CHG-alcohol combination product or appropriate antiseptic solution and gauze pad
- One pair nonsterile procedure gloves





(continued on next page)

Procedure 26-18 ■ Administering Medication Through a Central Venous Access Device (CVAD) (continued)

Pre-Procedure Assessment

- Carefully palpate the area around the insertion site through the dressing. If the patient has tenderness, assess further for other signs of infection. Check the surrounding catheter insertion site for intact sutures, redness, swelling, warmth, or drainage.
  This can indicate catheter-related infection.
- Assess the patient's external chest wall for engorged veins at the surface of the skin. If the jugular's site is used, also assess for difficulty moving the neck or jaw, headache, or ear pain.
  This can indicate vein thrombosis.
- PICC line sites should be observed daily for swelling, tenderness, drainage, or streaking. Take site measurements at regular intervals during dressing changes and compare to pre-insertion arm circumference.
  May indicate problems with phlebitis and/or catheter sepsis.
- Conduct a comprehensive pain assessment, looking for unusual pain or discomfort.
  Pain can be associated with the catheter's position in the vein, especially if the line is not in an optimal position

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Prepare the medication.

a. Check compatibility of the medication with the existing IV infusion.

b. Verify the medication that can safely be administered through a central site. Double-check the infusion rate as well.
Some medication might be incompatible with infusion solution or additives. Because dosage may be different for medications given centrally versus peripherally, and because the medication enters the heart almost instantly, any error is potentially life threatening.

c. Draw up the medication using a needleless device or needle with a filter. Then change to a sterile safety needle or needleless device for administering the medication.
Filter needles prevent small particles from entering into the line.

d. Recap any needles throughout, using a needle-capping device or approved one-handed technique that has a low risk of contaminating the sterile needle (see Procedure 26-10B: Recapping Sterile Needles).
Recapping prevents needlestick injury and, performed correctly, maintains the sterility of the needle.

e. Dilute the medication, if needed. Fill the medication syringe to the exact volume to be infused; expel excess volume.

f. Label the syringe with the contents, including medication name, dilution, time to be administered, route, and name of person constituting the medication.
Excess volume of medication in the syringe is a risk for inadvertent overdosing.

2. Flush the line.

a. Obtain heparinized or saline solution for flushing the CVAD, following the institution's protocol or the prescription.
The usual concentration for heparin is 10 to 100 units/mL of solution for adults. The recommended volume of flush varies by institution. Most facilities recommend 3 to 5 mL of solution to flush the catheter, although some are flushed with 10 mL to flush the line. Some medication might be incompatible with infusion solution or additives.

Dosage for centrally administered drugs is critical because the medication enters the heart almost instantly, so any error is potentially life threatening

Using heparin flush in venous access devices is becoming more controversial because of the potential for heparin-induced thrombocytopenia. Be sure to follow the manufacturer's guidelines, prescriber's order, and the policy of your institution.

b. Before flushing the CVAD, examine the syringe for bubbles. Remove them by flicking the syringe. Eject the air and bubbles, but be sure you have enough flush solution remaining in the syringe.
Flicking causes the bubbles to rise to the top. Remove bubbles from the syringe before giving medication through the CVAD port to avoid injecting air into the patient's vein and causing an embolus.

c. With clean procedure gloves, using pressure and friction, vigorously scrub all surfaces of the CVAD connectors as well as the luer-locking threads, and the luer-lock, including the extension "tail," with an alcohol wipe, CHG-alcohol combination product, or other antimicrobial product for at least 15 seconds. Then let it dry for 15 seconds. Do not touch this connector after cleansing.
Antimicrobial swabs reduce the risk of line-related infection by decreasing colonization of the port and tubing.

d. Insert the flush syringe at a vertical (90°) angle into the port using a needleless system or safety syringe.
A 90° angle reduces stress on the access port, which may cause shearing or mechanical trauma to the material.

e. Open the clamp between the syringe and the patient.
The clamp between the access port and the tubing that goes to the

patient must be patent for medication to be injected through the CVAD.

f. Check for blood return, if necessary. Equipment differs regarding the need to aspirate, so follow agency protocols.
In some administration systems, aspiration is one indication that catheter placement is in the vein.

g. Inject saline or heparinized flush solution into the line, per agency protocol or provider's orders and type of catheter. Some catheter types (e.g., Groshong) do not require heparin in the flush solution. Close the clamp.
Saline or heparin flush is used, depending on the type of CVAD, institutional protocol, and manufacturer recommendations.
- *Saline is generally indicated when simple clearing of the line is needed.*
- *If blood is likely to backflow into the line, then heparin might be used in the flush solution in order to reduce the risk of clot formation.*
- *Most often heparin is used for implanted CVADs to reduce the risk of occlusion from a clot forming on the device.*
- *Different catheters require different volume of flush solutions. Some are more prone to clot formation, depending on whether they are open or closed system devices. The initial flush maintains patency of the line and removes any heparin that was left if the catheter was used previously.*

h. Never force the flush solution into the venous access device if you feel resistance. Look for a closed clamp on the catheter or tubing. Check to see if an inline filter is clogged.
Forcing fluid creates a risk of rupturing the catheter.

i. Disconnect the flush syringe.
CAUTION: Techniques of flushing and clamping may vary depending on the type of connector you are using. Consult agency protocols and manufacturer's instructions.
If using a needleless connector, in general, do the following:

If Using Negative Fluid Displacement Device

Use a positive-pressure technique:
- For a blunt cannula with split septum, or mechanical valve, withdraw the cannula before the syringe is completely empty, keeping your thumb on the syringe plunger.
- For a mechanical valve device with negative displacement, maintain pressure on the syringe plunger, close the clamp on the IV line between the needleless connector and the patient; and then disconnect the syringe.

If Using a Positive Fluid Displacement Device

Do not use a positive-pressure technique. Flush using a push-pause technique. Wait 10 seconds (or per manufacture guidelines) to allow fluid displacement to occur. Remove syringe, and only then may you clamp the catheter.
The positive-pressure technique would keep the internal mechanism from functioning properly.

For Neutral Fluid Displacement Devices

Any flushing technique can be used. The clamping and disconnecting sequence does not matter.
The clamping sequence is directly dependent upon the needleless connector being used and is critical for the final locking solution.

i. After removing the flush syringe from the port, discard it into a safety disposal container.

3. **Administer medication** through the CVAD.
   a. Scrub all surfaces of the external ports, tubing, and connectors with a CHG-alcohol combination product for at least 15 seconds. Allow the port to dry for 15 more seconds or follow manufacturer's guidelines.
   Antimicrobial swabs reduce the risk of line-related infection by decreasing colonization of the port and tubing.
   b. Close the clamp to the infusion if a primary IV is running.
   The medication could travel back up the line rather than infuse into the patient if the clamp is open.
   c. Inject medication into the port, according to the medication order (infusion time).
   Some medication is infused as a bolus; other medication is given over a period of time.

4. **After scrubbing all surfaces** of the port again with a CHG-alcohol product or other approved antiseptic, administer the second syringe of flush solution.
The flush prevents incompatible medication or fluid from mixing at later administrations and ensures that all of the medication clears the catheter and enters the bloodstream.

5. **Clamp the tubing** between the syringe and the CVAD port. If there is an infusing primary IV, make sure the tubing is open between the IV fluid and the patient.

? What if . . .

- **My patient is a child; how should I secure the line?**
  Dress infants and younger children in a one-piece undershirt that fastens between the legs and tape the line to the shirt, leaving a little bit of slack to allow for movement.
- **The line does not flush easily?**
  Make sure all clamps are unclamped. Check to see if the central line is kinked or twisted.
  After straightening lines, attempt to flush the central line again. If the flush solution cannot be injected easily from the syringe into the CVAD, do not force the flush.
  Too much flush pressure may dislodge a clot that has formed in the central line.
  Check to see if an inline filter is clogged.
  Assess the insertion site to see if the stabilization device or dressing may be causing the occlusion.
  Try to reposition the patient to lying down and turn to one side.
  You might also have the patient lift his arms above his head and then attempt to flush the central line.
  If it is still difficult to flush after repositioning, notify the provider.
- **The central line inadvertently comes out?**
  Hold firm, constant pressure on the site to control bleeding. Have a colleague notify the provider immediately.

(continued on next page)

Procedure 26-18 ■ Administering Medication Through a Central Venous Access Device (CVAD) (continued)

- **The central line is cracked or leaking?**
  Close the clamp between the break or leakage in the line and the patient's line insertion site. Wrap an alcohol wipe and gauze around the broken part of the line. Immediately change the tubing.
- **The clamp on the line is broken?**
  Change the tubing. Assure the clamp works properly on the new tubing. This essential for patient safety.
- **The central line gets caught on or pulled by the patient's clothing?**
  Loop the tubing over the dressing and secure with tape.
- **My patient is short of breath or complains of chest pain?**
  Notify the provider immediately.
  These symptoms could be a sign of fluid overload or other complications, such as a dislodged clot or embolism.
- **My patient feels pain in the neck or ear on the side where an implantable CVAD is located? Or the patient hears swishing noises or has palpitations?**
  Notify the provider immediately.
  In this case, the implanted device might be dislodged. Placement must be confirmed by x-ray.

Patient Evaluation

- Monitor for signs of catheter complications (e.g., shortness of breath, chest pain, and palpitations).
- Monitor for signs of catheter dislodgement (e.g., neck swelling or pain, bleeding at the site or within the line, palpitations, or gurgling noise).
- Assess for signs of catheter-related infection (e.g., fever, increased WBC count, redness, warmth at the site).
- Observe for leaking or blood backup at the injection ports, tubing connections, and the site.
- Observe for bleeding at the CVAD site.
- Assess for signs of allergic response or adverse effects to medication.

Patient Teaching

- Teach patients, families, and caregivers that the overall goal is to maintain a patent CVAD or PICC line that is free of infection, occlusion, or dislodgement.
- Avoid obtaining blood pressure readings in the arm where a PICC line is inserted.
- If a PICC line is in place, do not immerse the arm in water. The patient may shower if the site is covered by an occlusive dressing.
- Follow prescribed activity restrictions.
- Teach signs of catheter complications including line-related infection, thrombosis, and accidental dislodgement.
- Teach signs of catheter dislodgement to include pain or swelling in the neck or area near the ear of the affected side of the CVAD. Gurgling sounds might also indicate a problem with the placement of the CVAD.

Home Care

- The goals of home care for clients receiving medication through a CVAD or PICC line are medication safety and maintaining an infection-free line.
- Candidates for home IV therapy through a CVAD or PICC line are those who:
  - Have a family member or other caregiver who can competently provide or assist with care of the line.
  - Have telephone access—either via landline or cell phone.
  - Have access to reliable transportation in case of a line-related emergency.
  - Ideally, caregivers should be able to read instructions for home care.
- Procedures in the home environment are similar to the hospital setting, except clean technique is used instead of sterile.
- Home health supplies may be different than the ones used in the hospital.
- After discharge, follow-up care in the home environment is important to ensure safety.

Documentation

- Document any signs of allergic response to or adverse effects of medication.
- Note any signs of catheter complications or dislodgement
- Document signs of catheter-related infection.
- Record the date and time tubing and port cap are changed.
- Document all medications infused through the CVAD.

Sample Documentation

June 18, 2015 1200. PICC line insertion site clean and dry. No redness, swelling, or drainage. Arm circumference 16 inches; same as pre-insertion measurement. Pt reports no pain at site. Flushed with 10 mL of NS, no resistance noted. —————————— Sue Creas, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

CLINICAL INSIGHTS

Clinical Insight 26-1 ➤ Reusing Needles and Syringes: Home Care

Assess for the Following:

- Is the patient capable of safely recapping a syringe: adequate vision, manual dexterity, and no obvious tremor?
- Are there contraindications to needle reuse (e.g., poor personal hygiene, an acute illness, open wounds on the hands, or decreased resistance to infection)?

Teach How to Use Needles Safely:

- Consult your healthcare provider before beginning this practice.
- Examine the needle carefully before reusing it. The new 30- and 31-gauge needles can easily be bent at the tip to form a hook, which can lacerate tissue or break off within the skin. Never reuse a needle that is deformed in any way.
- Recap the needle immediately after use if you plan to use it again.
- To recap a needle, hold the syringe in one hand, rest that arm or hand on a solid surface, and with the other, replace the cap with a straight motion of the thumb. Do *not* guide both the needle and cap to meet in midair, because this frequently results in needlestick injury.
- Do not mix insulin types if you reuse needles and syringes. Use one syringe for each insulin type. That means more injections, but certain insulins cannot be mixed without reducing their effectiveness.
- Dispose of needles safely. Do not bend or break a needle; doing so increases the chance of injury. Use a coffee can or other puncture-proof container with a lid to dispose of needles.

Teach Your Patient When to Discard A Needle:

- Discard needles when they become dull. Usually they cannot be used more than 10 times.
- When a needle hurts too much, it's time to discard it. Increased pain means that the silicone coating is wearing off.
- Do not reuse a needle if it has come in contact with anything other than the injection site.

Teach How to Clean and Store Needles:

- Do not use alcohol to cleanse the needle. Alcohol may remove the silicone coating that makes for less painful skin puncture. It is best not to clean the needle after use; just carefully recap it.
- You may store the syringe and needle at room temperature. The potential benefits or risks of refrigerating the syringe are unknown.

Teach How to Recognize and Avoid Infection:

- Be aware that reusing needles and syringes increases the risk of infection, although most insulin preparations have bacteriostatic additives that inhibit growth of bacteria commonly found on the skin.
- Inspect injection sites for redness or swelling. If these signs are present, do not reuse a needle; consult your healthcare provider.
- Never share syringes or needles with another person. This poses a risk of acquiring a bloodborne viral infection (e.g., hepatitis).

Clinical Insight 26-2 ➤ Using Prefilled Unit-Dose Systems

Prefilled systems are commonly used in a variety of health-care settings, and in self-administration. Depending on the system used, the need to remove the cartridge from the holder may create a needlestick risk for nurses.

Technique

1. Check each medication cartridge and dose carefully, because all of the cartridges look alike.
2. No medication preparation is necessary.
3. Insert the cartridge into the holder.
4. Swing or twist the plunger into place, depending on the type of syringe you use. Lock it securely at the needle end.
5. Attach the plunger, if necessary. (The system may come with plunger attached.)

6. Expel air and excess medication.
7. Don gloves.
8. Administer the medication.
9. Dispose of the empty cartridge. Some types are available for reuse.

Technique Variations

The needle gauge or length is not correct for the patient.
You can transfer the medication into a regular, disposable syringe, maintaining sterile technique. There are two ways you can do it.

Cartridge without removable needle:

1. Pull back on the plunger of the regular disposable syringe and keep a capped, sterile needle ready.
2. Insert the cartridge needle through the open tip of the disposable syringe.
3. Eject the medication into the regular syringe.
4. Replace the capped needle onto the regular syringe.
5. Eject the air and check for the correct dosage.

Cartridge with removable needle:
The capped needle can be removed from some prefilled cartridges, allowing the cartridge to be used as a vial. This allows you to safely draw the medications into a different (disposable) syringe, using a vial access device or safety needle. Do not inject air into a cartridge, because the excess pressure may eject the movable bottom.

Clinical Insight 26-3 ➤ Reconstituting Medication

1. **Remove the caps of both the medication and diluent vials.**
2. **If a multidose vial is used, scrub the tops of both vials** with alcohol or other antiseptic wipe.

To clean the cap of dust and reduce the number of microorganisms.

3. **Use a VAD or, if agency policy allows, attach a filter needle to the syringe.**

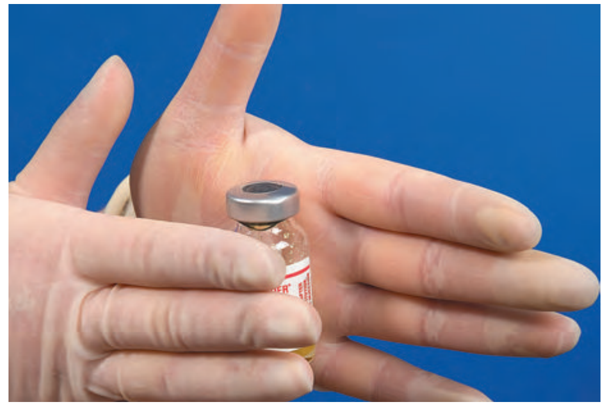
To prevent withdrawing glass and rubber particles, which have been found in medications withdrawn from vials and ampules.

4. **Draw up the diluent into the syringe.**
   a. Draw air into the syringe in a volume equal to the amount of diluent you will be withdrawing.
   b. Insert the filter needle (or VAD) carefully through the center of the rubber cap and, keeping the bevel of the needle (or cannula) above the diluent, inject the air.

The air prevents negative pressure inside the vial when you withdraw the diluent, allowing you to withdraw the diluent easily. Keeping bevel above diluent helps prevent bubbles.

   c. Withdraw the diluent in the specified amount.

5. **Inject diluent into the medication vial** by inserting the VAD carefully through the center of the rubber cap and then injecting the diluent.
6. **Mix the medication, taking care not to create bubbles** (e.g., roll, do not shake, the vial). If medication does not mix easily, remove the needle or cannula from the vial, and place the syringe and needle on a sterile field (e.g., the wrapper the syringe came in) while you mix more. Alternatively, recap the sterile needle (see Procedure 26-10A).



7. **Reinsert filter needle or VAD if it was removed** in Step 7, and withdraw the reconstituted medication into the syringe.
8. **Remove the filter needle or the cannula from the syringe**, and replace it with a sterile needle before measuring the medication.

This ensures that the dose is correct and minimizes discomfort. It also prevents tracking of medication through the tissues; filter needles are usually larger than you need for an injection. In addition, you should not eject fluid through a filter needle.

9. **Hold the syringe vertically, and carefully eject all air** from the syringe, but do not eject the medication. Read the dosage.
10. **If necessary, hold the syringe horizontally to eject unneeded medication** from the syringe to reach the prescribed dose.

Clinical Insight 26-4 ➤ Measuring Dosage When Changing Needles

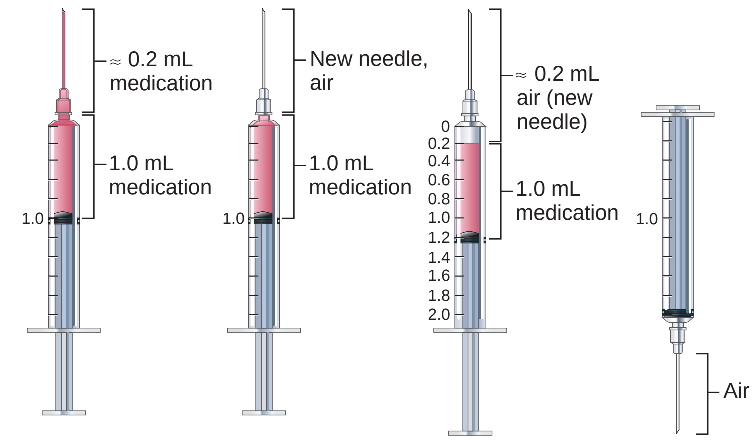
Note: These are not the old "air lock" techniques.

Using a Nonfilter Needle

When drawing medication from a multidose vial, you may sometimes need to use two regular needles. Alternately, you may use a needleless reconstitution device that is designed with a dispensing spike instead of a needle on one end, and a luer-lock port on the other end that attaches to the syringe.

Equipment. One needle (or needless reconstitution device) for drawing up the medication; and one needle for injecting the medication into the patient.

1. **Using Needle #1, draw up the prescribed amount of medication.** When using a vial, inject air into the air pocket within the vial. Then withdraw the correct amount of medication from the vial. Be sure to keep the tip of the needle in the fluid in order to avoid aspirating air bubbles into the syringe.
2. **Remove bubbles; eject the air.** After drawing up the medication, tap on the barrel of the syringe to remove air bubbles, if necessary. Then eject the air from the syringe (keeping the syringe vertical) while retaining the correct amount of medication in the syringe. Check the volume closely at eye level.
3. **Remove the Needle #1 and discard it** into a needle-safe container. Put on a fresh needle (Needle #2) for injection.
4. **Using Needle #2**, pull back on the plunger, and draw an extra 0.2 mL of air to account for the air within the needle.
5. **Check the medication dosage.** Your plunger should be 0.2 mL more than the ordered dose.
6. **Still using Needle #2, when you inject the patient**, she will receive the correct dose**.** The air will drive the medication from the needle into the patient's tissues. This is important when giving irritating medications, such as iron. (This is called an air lock.)



Nonfilter needles.

Using a Filter Needle

Always use a filter needle to withdraw medications, if one is available. You must change needles to give the injection, because:

- Filter needles are too large. To give the injection, you must use a needle of the correct gauge and length.
- You must eject air to measure the medication, but you should not push medication out of the syringe through the filter needle because it can break the filter and release glass (and other) fragments.

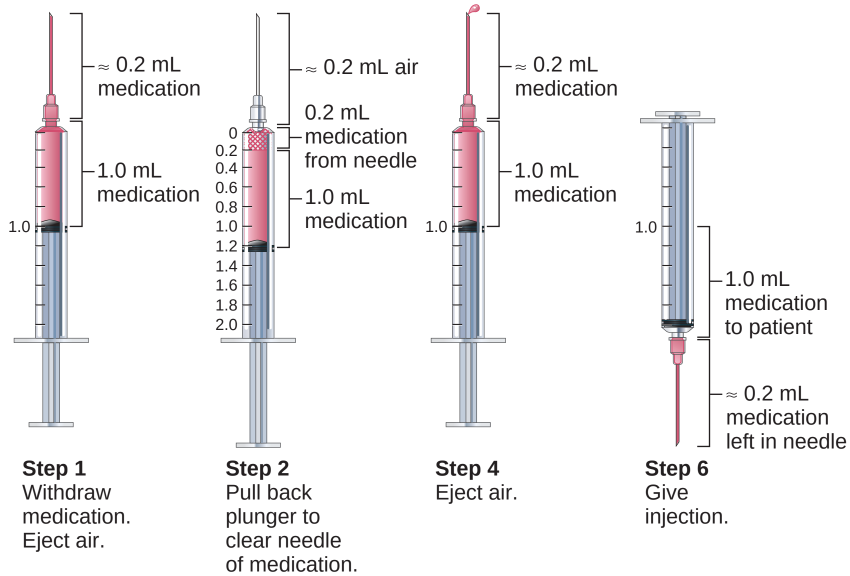
In the following method, pulling air into the syringe allows for exact dosage when the medication is injected. When ejected, the air will clear the needle so that the patient receives all the medication that is in the syringe.

Equipment. One filter needle (or filter cannula) and one regular needle.

1. **With the filter needle (or cannula)**, withdraw the exact amount of medication. Eject air bubbles (keeping the syringe vertical) as needed to obtain correct dose. Remember, you must not eject fluid through the filter needle.

Clinical Insight 26-4 ➤ Measuring Dosage When Changing Needles—cont'd

2. **Pull back on the plunger to withdraw all the medication from the filter needle (or filter cannula) into the syringe.** Depending on the size of the access cannula, this may be as much as 0.2 mL. It will now appear that you have more than the ordered dose in the syringe (but you do not; the air is taking up some of the space).
3. **Change to the needle you are going to use for injection.**
4. **Hold the syringe vertically, and eject air** until you see a drop of medication at the tip of the needle ("drop to the top").
5. **Measure the medication.** It should be at the correct syringe marking. If it is not, then tip the syringe horizontally, and eject the medication until the dose is correct.
6. **When you inject the patient, she will receive the correct dose** even though some medication will remain in the needle.
7. **If you are giving an irritating medication** (e.g., iron) draw 0.2 mL of air into the syringe before giving the injection. (This is called an air lock.)



Filter needles.

Clinical Insight 26-5 ➤ Mixing Two Kinds of Insulin in One Syringe

What You Should Know

Various combinations of rapid-acting, intermediate-acting, and long-acting insulin may be prescribed. Some can be mixed; some cannot.

- Lente insulins (Lente and Lantus) can be mixed with each other, but not with neutral protamine Hagedorn (NPH).
- Even though they are compatible, do not mix Lente with regular insulin, except for patients who are already controlled on this mixture. Lente will bind with regular insulin, delaying the onset of action.
- A general rule is "clear before cloudy." Regular insulin is clear; all other types are cloudy. Therefore, you would draw up regular insulin into the syringe before Lente or NPH insulin, which are modified. If you draw up a modified type first, the needle may transfer it into the unmodified (regular) vial.

What You Should Do

Follow these steps when drawing up insulin from two vials into one syringe. The procedure assumes you are mixing regular (unmodified) insulin with a modified (e.g., NPH) insulin.

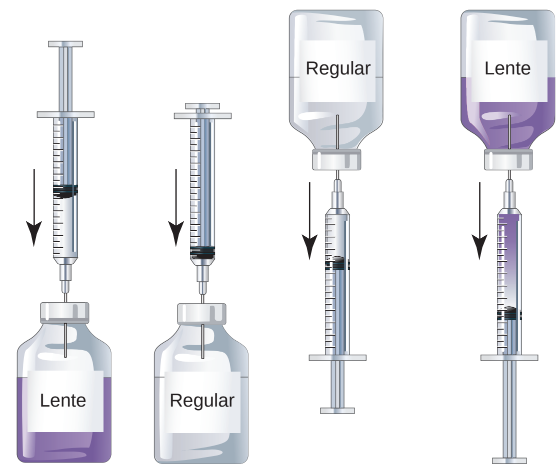
1. **Maintain sterile technique throughout.**
2. **Before preparing the insulin**—Rotate the vials between the palms of your hands for at least 1 minute, and invert them to ensure an adequate concentration. Do not shake the vials because this can create bubbles, which take up space and make it difficult to measure the dose precisely.
3. **Scrub vial stoppers** with alcohol or other antiseptic (they are usually multidose vials).
4. **Inject air into "cloudy" vial—**Using an insulin syringe and needle, inject an amount of air equal to the amount

(Continued)

Clinical Insight 26-5 ➤ Mixing Two Kinds of Insulin in One Syringe—cont'd

of insulin to be withdrawn from the vial of modified insulin (cloudy vial). Do not allow the needle tip to touch the insulin.

5. **Inject air into "clear" vial—**Using the same syringe, inject the appropriate amount of air into the vial of regular insulin (clear vial).
6. **Withdraw insulin from "clear" vial—**Do not withdraw the needle; withdraw the correct dose of regular insulin.
7. **Measure the dose of "clear"—**Remove the syringe from the regular insulin. Eject air, and remove all air bubbles to measure the correct dose.
8. **Calculate combined dose—**Calculate the total amount on the syringe that the combined types of insulin should measure.
9. **Withdraw insulin from "cloudy" vial.**
   a. Return to the (first) vial of modified insulin (cloudy), and draw the correct dose into the syringe. (For example, if you have 5 units of regular insulin in the syringe and you need 10 units of NPH, the plunger should be at the 15-unit mark when you have drawn up the NPH.)
   b. Recall that you have already added air to this vial in a previous step. Draw up the medication slowly and exactly to the total dose, being very careful not to create bubbles and to withdraw only the amount needed. You cannot return any excess to the vial because it is now a mixture of two medications.
10. **Administer the insulin mixture** within 5 minutes after preparation. Even NPH insulin will bind with regular insulin and delay the onset of its action.



Total dose is mixture of clear and cloudy insulins.

Clinical Insight 26-6 ➤ Administering Anticoagulant Medication Subcutaneously

Because of the anticoagulant properties of heparin and enoxaparin (Lovenox), you will need to adapt your technique for subcutaneous injections in the following ways:

- Enoxaparin-prefilled syringes and graduated prefilled syringes are available with a system that shields the needle after injection.
- Use a ⅜-inch, 25- or 26-gauge needle.
- After drawing up the correct dose, add 0.2 mL of air to the syringe.
  To ensure that all of the medication is injected into the subcutaneous tissue and is not tracked into the superficial tissue.
- Do not expel the air bubble from the syringe before the injection.
  To avoid the loss of drug when using prefilled syringes.
- With your nondominant hand, pinch or spread the skin; insert the needle at a 90° angle, using your dominant hand.
  - If the patient has very little subcutaneous tissue, use a ⅝-inch needle and insert it at a 45° angle.
  - Introduce the whole length of the needle into a skinfold held between the thumb and forefinger; hold the skinfold throughout the injection.
- Alternate administration among sites on the abdomen. Give the injection subcutaneously deep on the abdomen, at least 2 inches away from the umbilicus.
- Do not aspirate before injecting.
  Doing so can traumatize tissue and cause bruising.
- Do not massage the site after injecting.
  Doing so can cause bleeding and bruising. It may also cause the heparin to be absorbed more rapidly than desired.
- Keep a record of the sites used. Most agencies have a chart of the body on which to record the sites injected.

Several mix-ups between heparin and insulin have been reported. To help avoid this, in addition to observing the "3 checks and 6 rights":

1. Do not store heparin and insulin vials beside each other.
2. Have another RN check your preparation before administering IV heparin or insulin.
3. Think critically (e.g., ask yourself if giving heparin—or insulin—makes sense given the patient's diagnosis) (Cohen, 2007; Mattox, 2012).

Clinical Insight 26-7 ➤ Taking Action After a Medication Error

First check the patient. Take his vital signs, and perform assessments related to the medication that was given.

- If you are unfamiliar with the side effects of the medication, consult a drug reference source.
- Verify that you have made a medication error, and identify the type of error.
- Notify the nurse in charge for guidance if this is your first error.
- Notify the prescriber and follow her orders for intervention.
- Document on the chart that the medication was given, but do not indicate that it was given in error. This alerts anyone reviewing the chart that an error was made.
- Complete an incident report according to the facility's policies. Ask for assistance if you are unfamiliar with the format or requirement of this form. It is important that the information you provide is factual and accurate.
- Do not document in the patient's chart that an incident report was filed. This alerts anyone reviewing the chart that an error was made and makes the incident report available for legal review in the event of a lawsuit.
- When you are calmer and can think clearly, critically review the error. Identify the influences that led to your making the error. Were you rushed? Did you check the prescription? Did you follow the rights of medication? Whatever the reason, use this situation as a learning experience to improve your practice.

TABLES: ABBREVIATIONS

Because abbreviations can be easily misread, it is better to write words in full, especially when you are working with medications. However, you might still see the following abbreviations, so you should be familiar with them. Be sure you are familiar with the list of abbreviations approved for use in your particular agency. Abbreviations should be used cautiously and avoided when possible.

Common Medication-Related Abbreviations

ABBREVIATION	EXPLANATION	ABBREVIATION	EXPLANATION
ac	before meals: Example: 0700, 1100, 1700 hours	mL	Milliliter
ad lib	as desired	OTC	over-the-counter
a.m.	Morning	oz	Ounce
bid	twice a day: 0900, 2100 hours	pc	after meals: Example: 0900, 1300, 1900 hours
c̄	With	p.m.	Evening
fl oz	fluid ounce	po or PO	by mouth
g, gm, or GM	Gram	prn	as needed
gtt	Drop	qh, qr (q1h, q1hr)	Every hour
h, hr	Hour	q2h, q2hr	every 2 hours: Example: 0800, 1000, 1200 hours, etc.
IM	Intramuscular	q3h, q3hr	every 3 hours: Example: 0900, 1200, 1500 hours, etc.
IV	Intravenous	q4h, q4hr	every 4 hours: Example: 0200, 0600, 1000, 1400, 1800, 2200 hours
IVPB	intravenous piggyback	q6h, q6hr	every 6 hours: Example 0600, 1200, 1800 hours, 2400.
Kg or kg	Kilogram	qid or QID	four times a day: Example 1000, 1400, 1800, 2200
KVO	keep vein open		
L or l	Liter		
mEq	Milliequivalent		

(Continued)

Common Medication-Related Abbreviations—cont'd

ABBREVIATION	EXPLANATION	ABBREVIATION	EXPLANATION
qs or QS	sufficient quantity	Tab or tab	Tablet
s̄	Without	T or Tbsp	Tablespoon
stat or STAT	at once	tid or TID	three times a day: 1000, 1400, 1800 hours
sup or supp	Suppository	t or tsp	Teaspoon
susp	Suspension		

Institute for Safe Medication Practices (ISMP) List of Error-Prone Abbreviations, Symbols, and Dose Designations

ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
µg	Microgram	Mistaken as "mg"	Use "mcg."
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use "right ear," "left ear," or "each ear."
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use "right eye," "left eye," or "each eye."
BT	Bedtime	Mistaken as "BID" (twice daily)	Use "bedtime."
cc	Cubic centimeters	Mistaken as "u" (units)	Use "mL."
D/C	Discharge or discontinue	Premature discontinuation of medications if D/C (intended to mean: "discharge") has been misinterpreted as "discontinued" when followed by a list of discharge medications	Use "discharge" and "discontinue."
ij	Injection	Mistaken as "IV" or "intrajugular"	Use "injection."
IN	Intranasal	Mistaken as "IM" or "IV"	Use "intranasal" or "NAS."
HS	Half-strength	Mistaken as bedtime	Use "half-strength."
hs	At bedtime, hours of sleep	Mistaken as half-strength	Use "bedtime."
*IU	International units	Mistaken as IV (intravenous) or 10 (ten)	Use "International units."
o.d. or OD	Once daily	Mistaken as "right eye" (OD-oculus dexter), leading to oral liquid medications administered in the eye	Use "daily."
OJ	Orange juice	Mistaken as OD or OS (right or left eye); drugs meant to be diluted in orange juice may be given in the eye	Use "orange juice."
per os	By mouth, orally	The "os" can be mistaken as "left eye" (OS-oculus sinister)	Use "PO," "by mouth," or "orally."
*q.d. or QD	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "i"	Use "daily."
qhs	Nightly at bedtime	Mistaken as "qhr" or every hour	Use "nightly."
qn	Nightly or at bedtime	Mistaken as "qh" (every hour)	Use "nightly" or "at bedtime."

Institute for Safe Medication Practices (ISMP) List of Error-Prone Abbreviations, Symbols, and Dose Designations—cont'd

ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
*q.o.d. or QOD	Every other day	Mistaken as "q.d." (daily) or "q.i.d." (four times daily) if the "o" is poorly written	Use "every other day."
q1d	Daily	Mistaken as q.i.d. (four times daily)	Use "daily."
q6PM, etc.	Every evening at 6 PM	Mistaken as every 6 hours	Use "6 PM nightly" or "6 PM daily."
SC, SQ, subQ, or subq	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as "5 every"; the "q" in "sub q" has been mistaken as "every (e.g., a heparin dose ordered sub q 2 hours before hours before surgery) surgery" misunderstood as every 2	Spell out "subcutaneous."
ss	Sliding scale (insulin)	Mistaken as "55"	Spell out "sliding scale"; use "one-half."
SSRI, SSI	Sliding scale regular insulin	Mistaken as selective-serotonin reuptake inhibitor; mistaken as Strong Solution of Iodine (Lugol's)	Spell out "sliding scale (insulin)."
i/d	One daily	Mistaken as "tid"	Use "1 daily."
TIW or tiw	3 times a week	Mistaken as "3 times a day" or "twice in a week"	Use "3 times weekly."
*U or u	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4U seen as "40" or 4u seen as "44"); mistaken as "cc" so dose given in volume instead of units (e.g., 4u seen as 4cc)	Use "unit."

DOSE DESIGNATIONS OR OTHER INFORMATION	INTENDED MEANING	MISINTERPRETATION	CORRECTION
*Trailing zero after decimal point (e.g., 1.0 mg)	1 mg	Mistaken as 10 mg if the decimal point is not seen expressed in whole numbers	Do not use trailing zeros for doses.
*No leading zero before a decimal dose (e.g., .5 mg)	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit.
Drug name and drug dose run together (e.g., Inderal 40 mg)	Inderal 40 mg	Mistaken as Inderal 140 mg	Place adequate space between the drug name, dose, and unit of measurement.
Numeric dose and unit of measurement run together (e.g., 10 mg)	10 mg	The "m" can be mistaken for a zero, leading to a 10-fold dosing error	Place adequate space between the drug name, dose, and unit of measurement.
Abbreviations such as mg. or mL. with a period following the abbreviation	mg or mL	The period is unnecessary and could be mistaken as the number 1 if written poorly.	Use mg, mL, etc. without a period.
Large doses without properly placed commas (e.g., 100000 units or 1000000 units)	100,000 or 1,000,000 units	100000 has been mistaken for 10,000 or 1,000,000; 1,000,000 has been mistaken for 100,000.	Use commas for dosing units at or above 1,000 or use such words as 100 "thousand" or 1 "million" to improve readability.

Institute for Safe Medication Practices (ISMP) List of Error-Prone Abbreviations, Symbols, and Dose Designations—cont'd

DRUG NAME ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
NOTE: PHARMACIES DO NOT ACCEPT ORDERS FOR ABBREVIATED MEDICATIONS			
ARA A	vidarabine	Mistaken as cytarabine (ARA C)	Use the complete drug name.
AZR	zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use the complete drug name.
CPZ	prochlorperazine (Compazine)	Mistaken as chlorpromazine	Use complete drug name.
DPT	Demerol-Phenergan-Thorazine	Mistaken as diphtheria-pertussis-tetanus	Use complete drug name.
DTO	Diluted tincture of opium, or deodorized tincture of opium (Paregoric)	Mistaken as tincture of opium	Use complete drug name.
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (The "H" is misinterpreted as "K.")	Use complete drug name unless expressed as a salt of a drug.
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name.
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone (seen as HCT 250 mg)	Use complete drug name.
*$MgSO_4$	magnesium sulfate	Mistaken as morphine sulfate	Use complete drug name.
*MS, MSO_4	morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name.
MTX	methotrexate	Mistaken as mitoxantrone	Use complete drug name.
PCA	procainamide	Mistaken as patient-controlled analgesia	Use complete drug name.
PTU	propylthiouracil	Mistaken as mercaptopurine	Use complete drug name.
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name.
TAC	triamcinolone	Mistaken as tetracaine, adrenaline, cocaine	Use complete drug name.
TNK	TNKase	Mistaken as "TPA"	Use complete drug name.
$ZnSO_4$	zinc sulfate	Mistaken as morphine sulfate	Use complete drug name.
STEMMED DRUG NAMES	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
"nitro drip"	nitroglycerine infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name.
"Norflox"	norfloxacin	Mistaken as Norflex	Use complete drug name.
"IV Vanc"	intravenous vancomycin	Mistaken as Invanz	Use complete drug name.

Institute for Safe Medication Practices (ISMP) List of Error-Prone Abbreviations, Symbols, and Dose Designations—cont'd

SYMBOLS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
ʒ	dram	Symbol for dram mistaken as "3"	Use the metric system.
♏	Minim	Mistaken as "mL"	Use the metric system.
x3d	for 3 days	Mistaken as "3 doses"	Use "for 3 days."
< and >	greater than and less than	Mistaken as opposite of intended; mistakenly using incorrect symbols	Use "greater than" or "less than."
/ (slash mark)	separates two doses or indicates "per"	Mistaken as the number 1 (e.g., "25 units/10 units" misread as "25 units and 110" units)	Use "per" rather than a slash mark to separate doses.
@	at	Mistaken as "2"	Use "at."
&	and	Mistaken as "2"	Use "and."
+	plus or and	Mistaken as "4"	Use "and" or "plus."
°	hour	mistaken as zero (e.g., q2° seen as q 20)	Use "hr", "h", or "hour."

MEASURING AND CALCULATING DOSAGE

Medications are not always available in the exact dosage the patient needs. Therefore, you must be proficient in calculating drug dosages to be sure your patients receive the correct amount of medication.

Drugs in solid form (e.g., tablets, powders) are measured by weight (e.g., milligrams, grains). Drugs used for irrigation, infusion, and injection are liquids (usually solutions), measured by volume, generally milliliters. A **solution** can be either a solid dissolved in a fluid, or a given volume of one liquid dissolved in a given volume of another liquid. Solution concentrations may be expressed as a proportion. A 1/100 solution is a solution of 1 gram of solid dissolved in 100 mL of fluid, or 1 mL of fluid mixed with 100 mL of another fluid.

When measuring and calculating, you can think of solutions as a quantity of "solid" drug dissolved in a quantity of "liquid" diluent. The diluent merely carries the medication. When you see a vial marked "50 mg/mL," for example, you will know this means that in each milliliter of diluent there are 50 mg (in weight) of the solid, active medication. Your task is to determine how many milliliters of liquid you need to give the patient the number of milligrams of active drug ordered.

Medication Measurement Systems

Medications are usually ordered and measured using the metric system; however, there are still a few medications that use the apothecary and household systems, so you need to learn how to work with all three systems.

Metric System

The metric system is the preferred system. The basic metric units of measurement are the **meter** (the unit for linear measurement), the **liter** (for capacity or volume), and the **gram** (for weight). A meter is a little longer than a yard, a liter a little larger than a quart, and a gram a little more than the weight of a steel paper clip. The metric system promotes accuracy by allowing for calculation of small drug dosages. A disadvantage of this system in the United States is its limited use among people outside of healthcare. The following are the metric units you will use in preparing medications.

Weights

1 mg (milligram)	=	1000 mcg or (micrograms)
1 gm (gram)	=	1000 mg (milligrams)
1 kg (kilogram)	=	1000 g or gm (grams)

Volume

1000 mL (milliliters)	=	1 L (Liter)
1000 (cubic centimeters)	=	1 L (Liter)

The following are examples of medication orders using the metric system:

Milk of Magnesia 30 mL orally daily at bedtime
Ancef 1 gm IV q8hr

Apothecary System

The British apothecary system of measurement has been in use in the United States since colonial times. Only a few medications (e.g., aspirin) are measured using this system because it is less precise. Prescribers usually write apothecary measurements using Roman numerals, but you may also see them in Arabic numerals. The system uses fractions (e.g., gr ¼) instead of decimals (e.g., 0.25 gr). **Key Point:** ***Keep in mind the apothecary abbreviations are prone to misinterpretation and error because they are not often used.*** The following are the units used in preparing medications:

Volume

1 minim (m)	=	1 drop (gtt)
1 fluid dram (dr)	=	60 minims
1 fluid ounce (oz)	=	8 fluid drams

Weight

1 dram (dr)	=	27.34 grains (gr)
1 grain	=	60 milligrams (mg)

The following are Roman numerals you will use most often:

M	=	1000	X	=	10
D	=	500	V	=	5
C	=	100	II	=	1
L	=	50	II	=	2

The following are examples of medication orders using the apothecary system:

Aspirin grains V orally q4hr prn for fever greater than 101°F
Chloramphenicol otic 2 gtts in each ear tid daily

> Many institutions are no longer using the apothecary system of measurement. If a prescription contains this unit of measurement, verify the intended dose with the prescriber and pharmacist.

Household Measurements

Because most people are familiar with the household system, it is easier to teach a patient about home medications using this system. However, nurses use it only occasionally because dosages measured in this system are usually only approximate. The following are household units of measurement with metric conversion:

Volume

1 tsp (t)	=	5 mL		
1 tablespoon (tbsp or T)	=	3 teaspoons (tsp)	=	15 mL
6 tsp or 2 T	=	1 ounce (oz)	=	30 mL
16 T or 8 oz	=	1 cup (c)	=	240 mL
16 T or 8 oz	=	1 glass	=	240 mL
2 C	=	1 pint (pt)	=	480 mL
2 pt	=	1 quart (qt)	=	946.4 mL
4 qt	=	1 gallon (gal)		

Weight

1 oz	=		=	28.35 gm
16 oz	=	1 pound (lb)	=	0.45 kg

Length

12 inches (in.)	=	1 foot (ft)	=	30.5 cm
3 feet (ft)	=	1 yard (yd)	=	91.4 cm

The following is an example of a medication order using the household system:

Amoxicillin 250 mg per 5 mL Give 1 tsp PO tid

Special Measurements: Units and mEq

Insulin, a drug used by diabetics to assist in the control of blood sugar, is measured in **units**, with 100 international units (U100) being the standard strength preparation. In this strength, 1 mL of the fluid medication contains 100 units of insulin. Heparin (an anticoagulant) and penicillin are also ordered in units.

> Be aware that not all units are the same. You must always read the container label to know the number of units per milliliter.

The following are medication orders using units:

NPH insulin 14 units subcutaneous q morning
Heparin 4000 units subcutaneous bid (twice daily)

Milliequivalents (mEq) indicate the strength of the ion concentration in a drug. A milliequivalent is the number of grams of a solid contained in one milliliter of a solution. Electrolytes, such as potassium chloride (KCl), are measured in mEq. The following are medication orders using mEq:

KCl 20 mEq orally bid (twice daily)
D_5W 1000 mL with KCl 40 mEq q8hr

Note that units and mEq *cannot* be directly converted to the apothecary, metric, or household system.

Calculating Dosages

You should be able to calculate accurately using several different methods and formulas. Inaccurate calculations result in incorrect dosages and could harm the patient. One easy formula to remember is the following:

$$\frac{\textbf{Dose on hand}}{\textbf{Quantity (or volume) on hand}} = \frac{\textbf{Desired Dose}}{\textbf{Quantity (or volume) desired}} \quad \textbf{or} \quad \frac{\textbf{DH}}{\textbf{QH}} = \frac{\textbf{DD}}{\textbf{X}}$$

Or

$$\frac{\textbf{DH}}{\textbf{QH}} = \frac{\textbf{DD}}{\textbf{X}}$$

Remember: You must pay attention to *both* the milligrams (weight of the drug) marked on the medication container *and* the milliliters (amount of liquid in which the medication is dissolved). For example, suppose you have a prefilled syringe containing 50 mg of meperidine (Demerol) in 1 mL volume, but you wish to administer only 25 mg to the patient. How much of the liquid (how many mL) would you give?

$$\frac{\textbf{DH}}{\textbf{QH}} = \frac{\textbf{DD}}{\textbf{X}} \quad \textbf{or} \quad \frac{\textbf{50 mg}}{\textbf{1 mL}} = \frac{\textbf{25 mg}}{\textbf{X}}$$

Therefore (recalling your algebra),

50X = 25 mL,
so X = 25 divided by 50,
so X = 0.5 mL

Here is an alternative formula you can use for calculating dosages:

$$\frac{\textbf{Dose desired (DD)}}{\textbf{Dose on hand (DH)}} \times \textbf{quantity on hand (QH)} = \textbf{desired quantity}$$

ThinkLike a Nurse 26-1A

Mr. Pearson (Meet Your Patients, in Volume 1) has been ordered nifedipine (Procardia XL) 60 mg orally daily. You have available Procardia XL (extended-release nifedipine) 30-mg tablets. Calculate the number of tablets you will need for one dose. How many tablets per day?

Conversions Within One System

When a drug prescription is written in the same system as the preparation you have on hand, you can easily make conversions. For example, in the metric system, if you want to convert grams to milligrams, you simply multiply by 1000 (because 1 g = 1000 mg). So, if you have 2.5 grams,

2.5 gm × 1000 = 2500 mg

To change milligrams to grams, *divide* by 1000—move the decimal three places to the left. For example, if you wanted to know, in grams, the equivalent of 250 mg:

You know that 1000 mg = 1 g
By dividing: 250 mg ÷ 1000 mg = 0.25 g
Or by moving the decimal point three places to the left: 250.0 mg = 0.250 g

Use exactly the same procedures to convert liters (L) and milliliters (mL). For example, if you wanted to know how many milliliters are the equivalent of 0.25 L:

You know that 1 L = 1000 mL
By multiplying: 0.25 L × 1000 = 250 mL
By moving the decimal point three places to the right, 0.250 L = 250 mL (Notice that you must add a zero to *have* three places to the right.)

Within the apothecary system or the household system, use the equivalents and follow a similar process of multiplying and dividing (of course, you cannot just move the decimal in these systems). For example, suppose you have a dr ii (2 dram) tablet and you need to know how many grains you have (apothecary system). You know that 1 dram = 27.3 grains, so multiply:

2 drams (dr) × 27.3 grains (gr) = 54.6 gr,
rounded to 55 gr.

In the household system, suppose you have 4 tbsp of a liquid and you need to know what part of a cup that represents. You know that 1 cup = 16 tablespoons, so substitute the equivalent and divide:

16 tbsp = 1 cup

So,

4 tbsp = 16 ÷ 4 = 1/4 cup

KnowledgeCheck 26-1A

Lanoxin 0.25 mg orally daily is prescribed for a patient with congestive heart failure. The label on the package you have reads "Lanoxin 0.125 mg" How many tablets will you give? Use the "dose on hand (DOH)" formula.

Conversions Between Systems

You will sometimes need to make conversions from one measurement system to another. For example, you may need to convert pounds to kilograms because many medications are ordered as milligrams per kilograms (e.g., "Give 2 mg per kg of body weight"). The following are the basic methods for converting between systems. For an excellent summary of converting measurements within and between different systems,

Go to Chapter 26, the **Supplemental Materials, Measuring and Calculating Dosage,** on DavisPlus.

- **Metric and Apothecary—Weights**
  Grams and grains
  (Memorize: 1 g = 15 gr)
  To convert grams to grains—*multiply* the grams by 15
  To convert grains to grams—*divide* the grains by 15
  Grains and milligrams
  (Memorize: 1 gr = 60 mg)
  To convert grains to milligrams—*multiply* the grains by 60
  To convert milligrams to grains—*divide* the milligrams by 60
- **Metric and Apothecary and Household—Liquid Volume**
  Liters and ounces
  (Memorize: 1 L = 34.4 oz)
  To convert liters to ounces—*multiply* the liters by 33.4
  To convert ounces to liters—*divide* the ounces by 34.4
  Ounces and milliliters
  (Memorize: 1 oz = 30 mL)
  To convert ounces to milliliters—*multiply* the ounces by 30
  To convert milliliters to ounces—*divide* the milliliters by 30
  Milliliters and drops
  (Memorize: 1 mL = 15 drops or 15 minims)
  To convert milliliters to minims or drops—*multiply* milliliters by 15
  To convert minims and drops to milliliters—*divide* the minims or drops by 15

KnowledgeCheck 26-2A

Work the following conversions:

- How many drops in 4 mL?
- How many mL in 2 oz?
- Convert 16 oz to liters.
- You have 3 g. How many grains is this?
- You have 10 mg. How many grains is this?

How Should I Calculate Dosage for a Child?

You must be very careful when calculating medication dosages for children and infants. Most drug references list normal pediatric ranges, which can serve as additional verification.

You should rarely need to calculate a child's dosage on the basis of an adult dose, because medication prescriptions should specify the exact dosage for the individual child. However, when you must, you can use either the Body Surface Area Formula by using the nomogram for Children or Clark's Rule for Children to verify the safety of pediatric orders. To find a child's BSA using the nomogram, you must know the child's height and weight.

To use the nomogram, go to Chapter 26, **Tables, Boxes, Figures: ESG Figure 26-2: Nomogram,** on Davis*Plus*.

Orders for pediatric dosages are usually either calculated by the prescriber or stated in terms of "milligrams per kilogram of body weight." For example, you might have a prescription for "Erythromycin 30 mg/kg of body weight." You know that 1 kg equals 2.2 lb. If the child weighs 44 lb, then to convert to kilograms you divide 44 by 2.2; the child thus weighs 20 kg. So, 30 mg/kg would be 30 mg × 20, or 600 mg (the dosage for a 20-kg child).

For Clark's Rule, you would apply a formula using the child's weight in pounds. If you want to use Clark's Rule,

Go to Chapter 26, **Tables, Boxes, Figures: ESG Box 26-2,** on Davis*Plus*.

For a variety of Web-based dose calculators you can use,

Go to Manuel's Web site at http://www.manuelsweb.com/nrs_calculators.htm

Your electronic study guide (ESG) contains several practice problems for calculating adult and child dosages.

Go to Chapter 26, **Dosage Calculation Problems,** on Davis*Plus*.

If you cannot work the practice problems easily, you should obtain a dosage calculation book and practice the various formulas until you are proficient with conversion.

CLINICALREASONING
Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Leonard LeMonte is a 57-year-old African American man who has come to his primary care provider because of persistent headaches that increase in intensity over the course of a day. His overall health has been good, although he is approximately 50 to 60 pounds overweight. Past medical history is significant for borderline primary hypertension and non-insulin-dependent diabetes, type 2 (diet controlled). Mr. LeMonte tells you he works in a high-stress environment. He shares great concern with you that he fears losing his job and not being able to pay his bills and meet other financial commitments for his family. Mr. LeMonte tells you he has little time for hobbies or recreational outlets because he works so many hours.

THINKING

1. *Theoretical Knowledge (Facts and Principles):* You see in the chart that the provider prescribed repaglinide (Prandin), 2 mg tid (3 times/day), to treat Mr. LeMonte's diabetes. By what route is this medication given?
2. *Critical Thinking (Inquiry):* If you did not know the answer to the first question, specifically how did you get the information? State your source.

DOING

3. *Nursing Process (Assessment):* To evaluate Mr. LeMonte's responses to his diabetes medication, what questions do you need to ask him?
4. *Practical Knowledge (Skills):* Mr. LeMonte tells you that he forgot to take his Prandin this morning and also at lunchtime. What should you do?

CARING

5. *Self-Knowledge:* In what areas do you feel compassion for Mr. LeMonte, on which you might build a caring relationship?
6. *Self-Knowledge:* What do you identify as your strength in dealing with Mr. LeMonte's healthcare needs?
7. *Ethical Knowledge:* Mr. LeMonte tells you that he frequently skips doses of his Prandin because he can't afford the expense. He asks you not to tell his wife about this because he doesn't want her to worry. What will you do?

Critical Thinking and Clinical Reasoning

1. Your patient is prescribed Humulin R insulin 30 units subcutaneously. You have available in a multidose vial Humulin R insulin; the label reads "100 units per mL."
   a. What equipment and supplies do you need to administer this medication? Be specific.
   b. What practical knowledge (psychomotor skills) will you need?
   c. With regard to the psychomotor skills, what are the two aspects that require the most careful attention? Explain your thinking.
   d. What will you do to ensure that you have the correct dosage?
   e. What specific technique steps will you take to decrease the risk for infection?
   f. Suppose that after drawing the insulin into the syringe, you see that instead of the 30 units prescribed, you have only 20 units in the syringe. What will you do?
2. A physician orders heparin 4,000 units subcutaneous q12hr for Mr. Dale. You have on hand heparin 10,000 units/mL. How many milliliters should you draw up?

Patient Information for Exercises 3 Through 6 and 8

Recall the patients from Chapter 26, **Meet Your Patients,** in Volume 1. Exercises 3 through 6 and 8, following, refer to those patients. They are listed here for your convenience.

- Margaret Marks, an 82-year-old woman who has a fractured hip and experiences periods of confusion
- Cary Pearson, a 70-year-old man with feeding and swallowing difficulties who receives his medications through a gastrostomy tube
- Cyndi Early, a 32-year-old woman with diabetes who is scheduled for surgery at 1000 today
- James Bigler, a 44-year-old man who has had a repair of a compound fracture of the right arm and is receiving IV fluids and medications
- Rebecca Jones, an 84-year-old woman with compression fractures of two lumbar vertebrae resulting from a fall.

3. It is 0800, and you have begun organizing your medication pass for this shift by verifying the MAR entries against the provider's orders. You notice that Mr. Bigler has been prescribed Toradol 30 mg IM q6hr. His last dose was supposed to have been given at 0600, and there is no documentation that the medication was administered.
   a. What should you do?
   b. Should you assume the night shift nurse gave the medication but forgot to document that she had given it, and give the 0600 dose late? Why or why not?
   c. When should the next dose be given?
   d. If the night nurse did *not* give the medication as ordered, what type of medication error did she make? What factors that could have caused this error?
   e. Assuming that the nurse *did* give the medication as ordered at 0600, what error did the night nurse make? Which of the "rights of medication" was violated?
4. You receive the laboratory results for Cary Pearson's potassium level and find it to be 3.1 mEq/L. You notify the provider and receive a verbal order to add 20 milliequivalents of KCl to his IV of D_5 ½NS (5% dextrose in half-strength normal saline [0.45% saline]) to infuse at 125 mL/hr. The IV infusing is a new 1000-mL bag that is almost full.
   a. Write the prescription as you would write it on the order sheet.
   b. What information must you put on the additive label for this bag?
   c. Suppose the situation were slightly different. There is only 100 mL of IV fluid left in Mr. Pearson's IV bag when you call the provider, who prescribes, "Add 10 mEq to the IV, and infuse it at 125 mL/hr." Would you ask for clarification of this order? Why or why not?

   d. Change the situation again. You have taken the order in this way: "Add 20 mEq of KCl to 1000 mL of D_5 ½NS and infuse at 125 mL/hr." You are preparing this medication and find that Mr. Pearson currently has 500 mL remaining in his IV. Should you add the KCl to this infusing IV or wait until you hang a new 1000-mL bag? If you do add it, how much KCl will you add? What is your rationale for your decision?
   e. You begin preparing the infusion with the 20 mEq of KCl to be added and find you have available a vial containing KCl 40 mEq in a 10-mL vial. How many milliliters of KCl will you add to the bag of fluids?
5. Dr. Xi has ordered heparin 8000 units subcutaneous q12hr for Mrs. Marks.
   a. You have vials of heparin containing 10,000 units/mL. How many mL of heparin will you administer?
   b. To prevent tissue trauma and hematoma, and to help ensure adequate absorption, what precautions should you take while administering heparin?
   c. What syringe and needle will you select for administration, and why?
6. You are checking Mrs. Early's chart and find that the provider has prescribed a medication the patient lists as an allergy. What steps should you take?
7. A patient has been taking warfarin sodium (Coumadin) 3 mg daily for the past 3 years. She has tolerated the medication well, but recently she has noticed more bleeding tendencies, such as nosebleeds and hematuria (blood in the urine). You assess the patient and find that she has gross hematuria today and numerous bruises over her body. To answer the following questions, what theoretical knowledge do you need, and where can you find it? (*Note:* After you get the information you need, answer the following questions.)
   a. What could be causing these bleeding episodes?
   b. What laboratory test is indicated in this situation, and what do you expect the result to be?
   c. What actions should you take in this situation?
8. James Bigler has had a postoperative repair of a compound fracture of the right arm and is receiving IV fluids and medications, including opioid analgesics and antibiotics. He also has a herniated intervertebral disk and severe muscle spasms. He was given his first dose of an oral muscle relaxant, cyclobenzaprine (Flexeril) 10 mg, at midnight. At 0800 he received another dose. At 0900 he received an IV antibiotic, and, while awake, he has been self-administering his opioid analgesic using his patient-controlled analgesia (PCA) IV pump about every 4 hours in a low dose. Consider these facts:
   - The most common side effect of Flexeril is drowsiness. It has a half-life of 24 to 72 hours.
   - Common side effects of opioids are drowsiness, decreased respiratory rate and depth, decreased blood pressure, and constipation (if taken long term).
   - Aside from allergies, the most common adverse effect of Mr. Bigler's antibiotic is diarrhea.

   Mr. Bigler's muscle relaxant (Flexeril) is to be given every 8 hours. When you enter his room to give it again at 1600, you find that he is extremely sleepy. He will awaken when you shake him or speak to him, but he falls right back to sleep, and is slurring his words. These are new symptoms for him.
   a. Is there anything obvious about his medical diagnosis that might be producing these symptoms. If so, what?
   b. Which of his medications could cause these symptoms, and why?
   c. What would you do? Would you give the 1600 dose of cyclobenzaprine (Flexeril)?
9. Mrs. Thomas lives alone and until a few months ago was able to take care of herself. When her eyesight began to deteriorate, she experienced difficulty self-administering her medications.
   a. Discuss the assessment required to determine whether she is at risk for ineffective management of her medication regimen.
   b. Mrs. Thomas was prescribed lorazepam (Ativan) 1 mg orally. Is this prescription complete? If not, what is missing? What actions should you take?
   c. Mrs. Thomas has an order for digoxin (Lanoxin) 1.25 mg orally each a.m. You have available Lanoxin 0.25 mg, and you calculate that 5 tablets should be administered. You check a drug guide and find that the usual dose is 0.125 mg to 0.25 mg orally daily. What actions should you take?
10. Calculate dosages for the following medications that you will be administering during your medication pass today. Are there any orders you would question? If so, why?
   a. Cephalexin (Keflex) 500 mg IV q6hr. You have on hand Keflex 1 gram in 1 mL of solution.
   b. Furosemide (Lasix) 280 mg orally daily. You have 40-mg tablets of Lasix available.
   c. Meperidine (Demerol) 10 mg intramuscularly, to a child. You have Demerol 25 mg/mL available in a prefilled syringe. In addition to calculating the dosage, describe the equipment you would use to administer the Demerol to a child.

11. Describe the procedure for giving atropine sulfate 0.4 mg IM along with morphine 10 mg intramuscularly using the same syringe. The atropine is in a single-dose vial containing 0.4 mg of atropine in 0.5 mL of fluid. The morphine is in a prefilled 10 mg injectable cartridge containing 10 mg in 1 mL of fluid.
12. You have an order to give injectable phenytoin (Dilantin) and furosemide (Lasix). You would like to give them in the same syringe. What theoretical and practical knowledge do you need to decide whether you can do this?
13. For each of the following patient problems (1) state what you think might be the cause and (2) state one thing you might have done to prevent the problem.
    a. When you give Mrs. King an intramuscular injection in her ventrogluteal muscle, she complains of pain.
    b. Several weeks after receiving an intramuscular injection in the dorsogluteal site, Mr. Aguilar begins having pain in his left lower back and hip; the pain proceeds down his leg. He is beginning to limp when he walks.
    c. Several days after receiving a subcutaneous injection, Patti Deal's upper arm is red, hot, painful, and swollen. There is pus oozing from the injection site.
    d. Immediately after an intramuscular injection, a patient starts showing severe, unexpected symptoms.
14. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or administering medications. Note that these are *not* to be merely definitions.

Pharmacology
Drug classification systems (e.g., according to use or chemical traits)
The *United States Pharmacopoeia (USP)* and the *National Formulary* (U.S.)
Drug excretion
Therapeutic levels
Side effects and adverse reactions
The apothecary system
Household measurements
Units and milliequivalents
Standing orders
"Rights of medication" administration
Ventrogluteal site for intramuscular injection
Medication errors

What Are the Main Points in This Chapter?

- Drugs are classified according to their use, body systems, and chemical or pharmacological traits. Learning the classifications helps you to remember the characteristics of individual drugs.
- The form (preparation) of a drug affects its speed of onset, intensity of action, and route of administration.
- In the United States, the Food and Drug Administration (FDA) regulates the manufacturing, sale, and effectiveness of all medications. Various state and federal agencies and legislation also regulate the administration of medications.
- Controlled substances must be stored, handled, disposed of, and administered according to regulations established by the U.S. Drug Enforcement Agency (DEA).
- In general, IV medications are absorbed most rapidly, followed by intramuscular, subcutaneous, buccal, and oral medications.
- Metabolism is the chemical inactivation of a drug into a form that the body can excrete; drug metabolism takes place mainly in the liver.
- The primary route of drug excretion is from the kidneys; other routes are the liver, gastrointestinal tract, lungs, and exocrine glands.
- The therapeutic level of a drug is the concentration in the blood serum that produces the desired effect without toxicity.
- Medication effects can be primary (therapeutic and intended) or secondary (nontherapeutic and unintended). Secondary effects include side effects, adverse reactions, toxic reactions, allergic reactions, and idiosyncratic reactions.
- The metric system is preferred for medications; however, for a few medications, the apothecary and household systems are still used.
- You are legally responsible for the medications you administer. You must question orders you believe to be incorrect.
- To help prevent medication errors, observe the "three checks" (before and after pouring or drawing up a medication, and at the bedside) and "rights of medication" (right drug, right dose, right time, right route, and right patient, as well as right documentation immediately after giving the medication).
- If you make a medication error, it is absolutely necessary that you immediately assess the patient's vital signs and physical status; report findings to the primary care provider; and notify the nurse manager of your unit.
- The oral route is the one most commonly used; it is convenient and safe.
- Buccal and sublingual medications are held in the mouth so that they will be absorbed through the mucous membrane.

- For patients who cannot swallow or who have feeding tubes, you can give oral medications through enteric (e.g., NG and gastrostomy) tubes. The medications are given one at a time and the tube must be flushed before and after each medication.
- Topical medications may have local and systemic effects; transdermal patches are applied for their systemic effect.
- Nebulization is the production of a fine spray, fog, powder, or mist from a liquid drug.
- Parenteral medications require the use of sterile technique to prevent infection.
- Needle length and gauge are chosen based on the type of medication, the route of administration, and the amount of adipose and muscle tissue the patient has.
- Needleless systems and safety syringes reduce the likelihood of needlestick injury.
- Always dispose of needles in special "sharps" containers. If you must recap a needle, use a one-handed technique.
- The ventrogluteal site is the preferred intramuscular injection site for adults. Other sites are the vastus lateralis and the deltoid. Use the rectus femoris site only if no other sites are available, and never in infants and children. Do not use the dorsogluteal site.
- Experts agree the anterolateral thigh (vastus lateralis) is preferred for infants who are not walking and some recommend using it throughout childhood. Others recommend using the ventrogluteal site when the child starts walking and the gluteal muscle increase in mass. The deltoid can be used for older children if you are certain that the muscle mass is adequate.
- Medications may be given intravenously by adding the medication to a large-volume (primary infusion), by the IV push technique, or by intermittent (piggyback setup) infusion.
- You should report medication errors immediately after they occur; a risk management process for monitoring causative factors should be in place.
- The most common reasons for a patient to have a central venous access device (CVAD) are to:
  - Give long-term IV therapy
  - Provide total parenteral nutrition when the patient cannot eat normally
  - Have blood drawn without the trauma and complications of repeated venipuncture
  - Be used when peripheral IV placement is difficult

Knowledge Map

DRUG NAMES:
- Chemical name
- Generic (official) name
- Brand name (trade)

DRUG CLASSIFICATIONS:
- By their use
- By body systems
- By pharmacological traits

EFFICACY INFLUENCED BY:
- Pharmacokinetics
  - absorption
  - distribution
  - metabolism
  - excretion
- Pharmacodynamics
  - interaction with target cells
  - how biological response occurs

DRUGS
- Prescription
- Non-prescription (OTC)

FACTORS CONTRIBUTING TO DRUG SAFETY:
- Reliable drug info
  - USP; national formulary; PDR; drug reference books
- State/Federal Regulation
  - Nurse Practice Act
  - U.S. drug laws
  - Regulation of controlled substances
- Improved storage/ distribution systems

MEDICATION ADMINISTRATION

MEDICATION ORDERS

TYPES:
- Standard written
- Verbal
- Telephone
- Standing
- One-time

CORRECT COMPONENTS:
- Patient name
- Date/time
- Drug name
- Dose and frequency
- Route
- Signature of prescriber

ADMINISTRATION SAFEGUARDS

PREPARING: THREE CHECKS →
- Label against MAR prior to pouring
- Label against MAR AFTER preparing med at the bedside

ADMINISTRATION: SIX RIGHTS →
- Drug
- Dose = accurate calculations
- Time → know "window"
- Route
- The Joint Commission two patient identifiers
- Documentation

ROUTES OF ADMINISTRATION

NON-PARENTERAL:
- Oral
  - buccal
  - sublingual
- Topical
  - cream/ointment
  - transdermal
- Ophthalmic
- Otic
- Nasal
- Vaginal/rectal
- Inhaled

PARENTERAL:
- Intradermal
- Subcutaneous
- Intramuscular
- Intravenous

NURSING SKILLS:
- Appropriate needle/syringe
- Withdrawal from amp/vial
- Correct site
- Correct administration technique

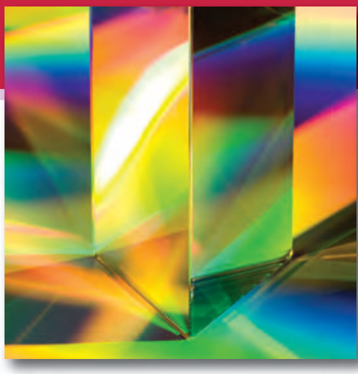
ERROR PREVENTION

- 3 checks/6 rights
- Check calculations w/second person
- Watch look-alike, sound-alike drugs
- Check decimals; use correctly
- Question multiple vials/tabs if single dose
- Question abrupt increase in doses

unit 4

Supporting Physiological Functioning

CHAPTER 27



Nutrition

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 27:
- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Nutrition (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources: Chapter 27, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Nam Nguyen has been diagnosed with hypertension, type 2 diabetes mellitus, obesity, osteoarthritis, and tobacco abuse. Zach Jackson has advised an 1,800-kcal diabetic diet with no added salt and a daily brisk 30-minute walk. Mr. Nguyen discusses these challenges with his daughter, Trinh.

A. Why might Zach have selected this diet plan? Discuss the rationale for each component (i.e., 1,800 kcal, diabetic diet, no added salt).

B. Mr. Nguyen's diet is complex. He tells you he is overwhelmed by the many changes asked of him. How might Zach streamline his instructions about his diet?

C. Nam asks what is the best way for him to monitor his weight loss progress at home and how Zach Jackson will monitor his progress. How would you respond?

D. Identify teaching tools that might help Nam understand his diet.

PracticalKnowledge knowing how

To apply concepts that support patient nutrition, you will need to master techniques for assessing nutritional status, feeding patients, administering supplemental feedings, and working with nasogastric (NG) and nasoenteric (NE) tubes.

PROCEDURES

Procedure 27-1 ■ Checking Fingerstick (Capillary) Blood Glucose Levels

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Blood glucose meter
- Test strip
- Sterile lancet (and injector, if available)
- Alcohol (or other antiseptic) pad, if required by policy
- 2 in. × 2 in. gauze pad or cotton ball
- Procedure gloves

Glucometers, fingerstick devices, and injectors should be assigned to individual patients. If this is not possible, you must clean and disinfect the devices between patients. If they are available, use single-use lancets that permanently retract upon puncture.

Store these supplies on a tray or cart outside patient's room. Do not carry supplies in your pocket. If there are unused supplies, leave them in the room; do not use them for another patient.

These measures help prevent needlestick injury and transmission of bloodborne pathogens (Centers for Disease Control and Prevention [CDC], 2005).

Delegation

Assess the patient first. If the patient's condition allows, you can delegate this procedure to a licensed practical nurse (LPN) or nursing assistive personnel (NAP) who has been adequately trained in performing the skill. Most patients perform this procedure independently at home.

Pre-Procedure Assessments

- Assess the patient's comprehension of the procedure.
  Allows you to tailor instructions to the individual patient.

- Assess potential puncture sites for bruising, inflammation, open lesions, poor circulation, or edema.
  Avoid such sites because of risk for infection and inaccurate results.
- Check for factors such as anticoagulant therapy, bleeding disorders, or low platelet count that place the patient at risk for bleeding after skin puncture.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* The steps of this procedure will vary, depending on the type of glucose meter used.

Procedure Steps

1. **Verify the medical prescription** for frequency and timing of testing.
   A prescription is necessary for testing. Timing and frequency of testing are crucial for accurate insulin dosing.

2. **Ask the patient to wash her hands** with soap and warm water, if able, and to dry completely using a clean towel.
   Reduces the risk for infection and dilates capillaries at the puncture site. Also ensures that the testing site is free of any sugar residue.

3. **Turn on the blood glucose meter.** Calibrate it according to the manufacturer's instructions.
   Calibration readies the meter for testing and checks it for accuracy of the machine.

4. **Check that the strip is the correct type** for the monitor. Check the expiration date on the container of reagent strips. If the strips are expired, replace them.
   Expired strips may alter test results. Different brands of monitors use different kinds of reagent strips.

5. **Don procedure gloves.**
   Gloving protects against exposure to blood.

6. **Remove the reagent strip** from the container and place it into the blood glucose meter. Then tightly seal the container.
   A tight seal protects reagent strips from exposure to air and light.

7. **Select and clean** a fingerstick site. If the patient is unable to do so, wash her hands with soap and water and dry them.
   Helps prevent infection by removing some surface microorganisms.

8. **Use a different site each time** you check the glucose.
   Adult and child: the lateral aspect of a finger (palmar surface, distal phalanx)
   Infant: heel or great toe
   The lateral aspect of the finger contains fewer nerve endings than the central fingertip, so it hurts less. Capillaries in infants are too small to obtain an adequate blood sample.

9. **Position the finger** (or heel or great toe for an infant) in a dependent position, and massage from the base toward the tip of the finger.
   A dependent position promotes blood flow to the site via gravity and pressure, ensuring an adequate specimen. The massaging action increases blood flow to the tip of the finger, which may prevent the need for repuncture.

10. **Prick the finger** (or other site) with the lancet:

Exposed-Blade Disposable Lancet

a. Remove the cover from the lancet, if there is a cover.
b. Place the back of the patient's hand on the table, or otherwise secure the finger (e.g., hold the finger and hand firmly).
c. Use a darting motion to puncture the site at a 90° angle to the skin.

Semi-Automatic Injector

d. Engage the sterile injector and remove the cover.
e. Place the disposable lancet firmly in the end of the injector.
f. Place the back of the patient's hand on the table, or otherwise secure the finger (e.g., hold the finger and hand firmly).
g. Position the end of the injector firmly against the skin, perpendicular (at a 90° angle) to the chosen puncture site.
h. Push the release switch, allowing the needle to pierce the skin.
Proper positioning and stabilization of the site ensure that the lancet pierces to the correct depth. This prevents patient injury and allows for adequate blood sampling. Patients tend to pull away as you perform the puncture.

11. **Lightly squeeze the patient's** finger above the puncture site until a drop of blood has collected.
    Squeezing promotes a better blood sample for testing without causing injury to the puncture site.

12. **Place the reagent strip** test patch close to the drop of blood. Allow contact between the drop of blood and the test strip. Do not "smear" the blood over the reagent strip.

(continued on next page)

Procedure 27-1 ■ Checking Fingerstick (Capillary) Blood Glucose Levels (continued)

13. Insert the strip into the meter, if you have not already done so (follow the manufacturer's instructions); allow the blood sample to remain in contact with the test strip for the amount of time specified.
For some meters you insert the test strip before pricking the finger; with others you put the blood on the reagent strip and then insert the strip into the meter. The blood sample must be on the reagent strip for the specified amount of time to ensure accurate test results.

14. Using a gauze pad, gently apply pressure to the puncture site.
Pressure stops the bleeding by promoting coagulation.

15. After the meter signals, read the blood glucose level indicated on the digital display.▼

16. Turn off the meter. Dispose of the reagent strip, gauze pad, alcohol pad, and lancet in the proper containers (e.g., a sharps container for the lancet).
Proper disposal prevents sharps injury and the spread of infection via bloodborne pathogens.

17. Remove your gloves, and dispose of them in the covered trash receptacle or biohazards container. Perform hand hygiene.
Safe disposal reduces the transmission of pathogens.

What if . . .

- **The patient has poor circulation or is a child or older adult?**

  Place a heel warmer or warm cloth on the site for about 10 minutes before obtaining the blood sample. Alternatively, position the patient's hand below the waist for 1 minute.
  Capillaries in infants are very small; older adults may have poor peripheral circulation. Warmth dilates the capillaries, and may help you obtain an adequate amount of blood; when dangling the extremities, gravity allows blood to pool in the extremity, making an ample specimen easier to obtain.

- **The patient is taking an anticoagulant such as warfarin sodium (Coumadin)?**

  After the procedure, hold pressure for 2 min and then apply a pressure bandage if needed. Recheck the site after 5 min to make sure bleeding has stopped.

- **The monitor shows an extremely unusual result or an error message?**

  Repeat the process using a different finger or site.

- **The patient uses a noninvasive method to measure blood glucose?**

  A new device called a continuous blood glucose monitor is available. It is worn like a wristwatch. Using an electrical current, it pulls fluid from the skin to give a blood glucose reading. It can take readings automatically every 20 min for up to 12 hr. Advise the patient to shave his arm if it is very hairy, or the reading may not be accurate. The patient should wear the device for a 3-hour warm-up before taking a reading, and should not bathe or swim during that time. The purpose of continuous monitoring is to track trends in blood glucose. It does not replace the patient's fingerstick method.

Evaluation

- Assess the puncture site for bleeding or bruising.
- Evaluate the patient's understanding of the procedure and the test results.
- Promptly notify the primary care provider of abnormal test results, or administer insulin based on test results, if prescribed.

Patient Teaching

- Explain the procedure, test results, and treatment to the patient.
  Information allows the patient to participate in his plan of care, and typically increases adherence to the therapeutic regimen.
- Discuss the importance of maintaining glycemic control.
- If the patient will be performing fingerstick blood glucose testing at home, teach the patient how to perform the procedure. Ask the patient to perform a return demonstration. Teach the patient to do the following:
  - Read the manufacturer's instructions carefully and call their toll-free number if he has any questions.
  - Always use the test strips that are recommended for the meter.
  - Take your meter to your health provider's office so she can make sure you are measuring your blood sugar correctly.
  - Perform quality control checks (read the instructions) to make sure the meter is measuring accurately.
  - Clean the meter according to the manufacturer's directions. Some meters will give you an electronic alert telling you when to clean them.

Home Care

- Assess the client's ability to perform fingerstick blood glucose monitoring independently.
  A change in the patient's condition may not allow the patient to perform testing. Certain conditions, such as arthritis and limited vision, may limit dexterity.
- Provide information about purchasing home glucose-monitoring equipment.
- Explain how to dispose of lancets in a labeled, puncture-proof container, such as an empty bleach container.

- Instruct caregivers to wear gloves when obtaining a blood sample for glucose monitoring.
- At home, patients should not cleanse their fingers with an alcohol wipe before puncturing it. However, they should wash their hands with soap and water and dry well.

Documentation

- Record the fingerstick blood glucose result in the progress notes or special flowsheet, including the date and time the test was performed.
- Note whether the physician was notified and record any treatment given.
- Document patient teaching.
- If the fingerstick is performed in response to patient symptoms, you may need to write a narrative note.

Sample documentation

8/12/16 1435 Patient reported feeling "cold and shaky." FBBS 62. Alert and able to swallow. Pt ate 5 saltine crackers with peanut butter and drank 3 ounces of orange juice. FSBS 92 at 1430. Will notify physician for further orders. ——————————— N. Jones, RN

Practice Resources

American Diabetes Association (n.d., 2011); CDC (2005); Glucose Monitoring (2008); Hortensius, J., Slingerland, C., Kleefstra, N., et al. (2011); U.S. Food and Drug Administration (2007b).

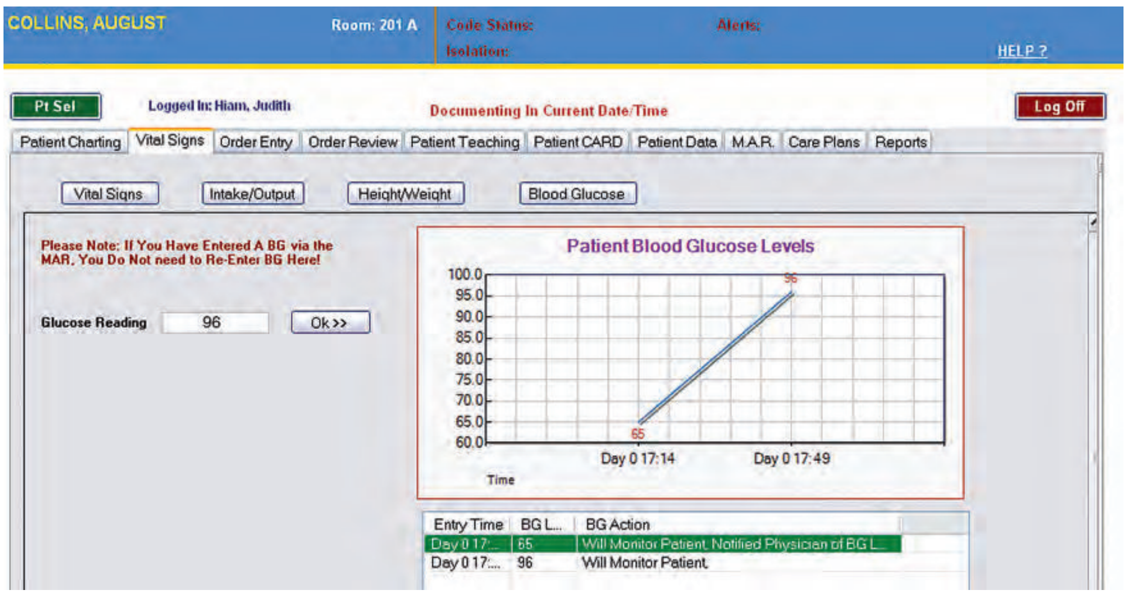
Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Checking Fingerstick (Capillary) Blood Glucose Levels.**

For questions and suggested responses,

Go to Chapter 27, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.



Procedure 27-2 ■ Inserting Nasogastric and Nasoenteric Tubes

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

To watch an animated demonstration of inserting a nasogastric tube,

Go to **Animations: Inserting a Nasogastric Tube,** on Davis*Plus*.

Equipment

- Nasogastric tube (commonly 16 or 18 Fr for adults, but sometimes smaller) or nasoenteric (small bowel) tube (8 Fr, 10 Fr, or 12 Fr)
- Stylet or guidewire (for small-bore tubes), according to agency policy
- Procedure gloves
- Linen-saver pad or towel
- Water-soluble lubricant
- 50- to 60-mL catheter-tip syringe or bulb syringe for Salem sump tubes; 30-mL luer-lock syringe for small-bore feeding tubes
- Hypoallergenic tape (about 2.5 cm [1 in.] wide) or tube fixation device
- Indelible marker
- Skin adhesive
- Stethoscope
- Emesis basin
- Basin with warm water (for plastic tube) or ice (for rubber tube). Most tubes are plastic.
- Glass of water with a straw
- Penlight
- Tongue blade
- pH test strip
- Tissues
- Safety pin
- Gauze square or small plastic bag
- Rubber band
- Suction equipment (if tube is being connected to suction)

Delegation

This procedure should not be delegated because it requires knowledge of anatomy and physiology and the ability to adapt the procedure based on patient responses. You can, however, delegate associated oral hygiene needs.

Pre-Procedure Assessment

- Verify the medical prescription for type of tube to be placed and whether it is to be attached to suction or drainage.
- Confirm the patient's need for NG or NE intubation (e.g., surgery involving the gastrointestinal (GI) tract, impaired swallowing, or decreased level of consciousness).
  NG or NE intubation decreases the risk for aspiration in these patients. In many institutions, only specially trained nurses are allowed to place small-bowel feeding tubes.
- Assess each naris for patency, deviated septum, and skin breakdown. Ask the patient to close each nostril alternately and breathe. Select the nostril with the greatest air flow. Ask the patient to blow her nose, if not contraindicated.
  A septal defect or facial fracture may cause obstruction, placing the patient at risk for nasal membrane trauma if insertion is attempted through the affected naris.
- Check medical history for anticoagulant therapy, coagulopathy, nasal trauma, nasal surgery, epistaxis, or deviated septum.
  Patient history may place the patient at risk for injury during NG or NE insertion. Contraindications to NG insertion by a nurse include maxillofacial disorders, surgery, or trauma; esophageal tumors or surgery; laryngectomy; skull fracture; unstable high cervical spinal injuries; and esophageal varices (although these patients may have tubes placed by a medical professional via endoscope or fluoroscope).
- Assess the level of consciousness and ability to follow instructions.
- Assess for a gag reflex, using a tongue blade.
  Absence of gag reflex places the patient at risk for aspiration.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Prepare the tube.**

Plastic Tube

Wrap the tube around your index finger and then unwrap it and proceed or place in a basin of warm water for 10 minutes and proceed.

Rubber Tube

Place in a basin of ice for 10 minutes.

Small-Bore Tube

Insert a stylet or guidewire and secure into position, according to agency policy. (Small-bore tubes may come with the guidewire in them. If so, flush the tube with tap water to lubricate the wire for easy removal.) Leave the wire in place until the tube is positioned and its placement has been checked on x-ray film. Once the guidewire is removed, do not reinsert it. Agency policy determines which nurses are authorized to place small-bore tubes.

Warm water softens a plastic tube, and ice stiffens the rubber tube to make it easier to insert. (Most tubes are polyurethane or silicone-based.) Wrapping a plastic tube around your index finger helps the tube flex into a curve and aids in insertion. A guidewire facilitates passage of small-bore tube but can cause trauma if not secured in a proper position.

2. **Assist the patient into a** high-Fowler's position with pillow behind the head and shoulders. Raise the bed to a comfortable working level.
   This position facilitates tube insertion and prevents aspiration should the patient vomit during tube insertion. Gravity

facilitates passage of the tube. Raising the bed reduces strain on the nurse's back.

3. **Measure the tube for placement.**

Nasogastric Tube

Measure the length of the tube to be inserted by measuring from the tip of the nose to the earlobe, and from the earlobe to the xiphoid process. Mark the length with tape or indelible ink.

This measurement indicates how far the tube must be inserted to reach the stomach.

Nasoenteric Tube

Add 8 to 10 cm (3 to 4 in.) to the NG tube measurement, as directed, and mark the tube.

4. **If you are right-handed**, stand on the patient's right side; if you are left-handed, stand on the left side if. Drape a linen saver pad over the patient's chest, and hand her an emesis basin and facial tissues.
   Draping protects the patient's gown from becoming soiled during tube insertion.

5. **Prepare the fixation device.** Cut a 10-cm (4-in.) piece of hypoallergenic tape if securing tube with tape; split the bottom end lengthwise 2.5 cm (2 in.). If using a commercial feeding tube attachment device, have it ready at this time.
   To more readily secure the tube after insertion.

6. **Arrange a signal** by which the patient can communicate if she wants to stop (e.g., raising her hand).
   Relieves anxiety by giving the patient some control over the procedure.

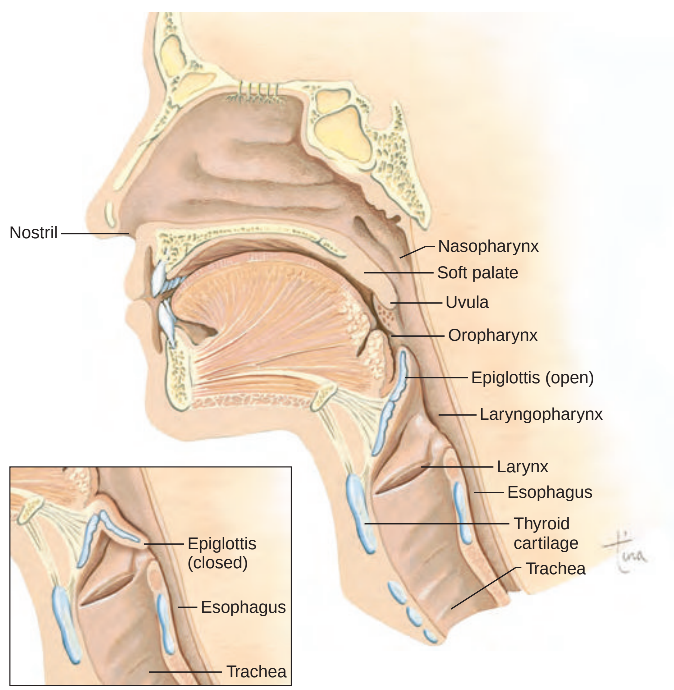
7. **Don procedure gloves** if you have not already done so.
   Reduces the spread of pathogens.

8. **Wrap 10 to 15 cm (5 to 6 in.)** of the end of the tube tightly around your index finger, then release.
   Forms the tube into a curve that helps it conform more easily to the shape of the nasopharynx.

9. **Lubricate the distal 10 cm** (4 in.) of the tube with a water-soluble jelly.
   Lubrication eases the passage of the tube and prevents injury to the nasal mucosa. Water-soluble lubricant will dissolve if it is aspirated, whereas oil-based lubricants do not dissolve in the respiratory tract and cause inflammation and blockage of airways if they enter the lungs. Some nurses prefer water as a lubricant because aqueous jelly dries and can block and irritate nasal passages. Some tubes have a surface lubricant and require only that you dip them in room-temperature water.

10. **Hand the patient a glass** of water with a straw, if she is awake, alert, and able to swallow.
    Swallowing water during insertion eases passage.

11. **Instruct the patient** to hold her head straight up and extend her neck back against the pillow (slightly hyperextended). Begin inserting the tube.
    a. Grasp the end of the tube above the lubricant with the curved end pointing downward.
    b. Carefully insert the tube along the floor of the nasal passage, on the lateral side, aiming toward the ear.
    c. You will feel slight resistance when the tube reaches the nasopharynx; use gentle pressure, but do not force the tube to advance. The patient's eyes may tear; if so, provide tissues.
    d. Continue inserting the tube until just past the nasopharynx by gently rotating the tube toward the client's opposite naris.
    Hyperextending the neck straightens the curve where the nasal passage meets the pharynx (nasopharyngeal junction). Gentle insertion prevents trauma to the nasal mucosa. Tears are normal.

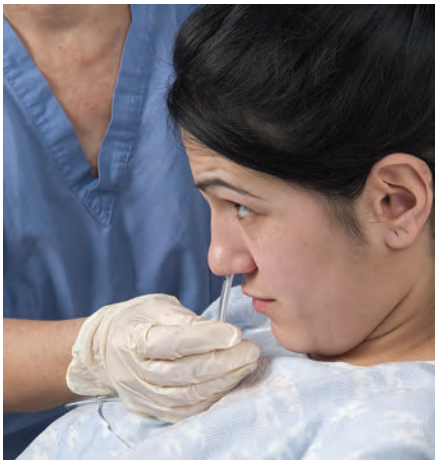


(continued on next page)

Procedure 27-2 ■ Inserting Nasogastric and Nasoenteric Tubes (continued)

12. **Pause for a moment** to allow the patient to relax, and perhaps use tissues. Explain that the next step requires her to swallow.
Stopping to relax can give the patient a feeling of control. Also, the rest can reduce gagging.

13. **Instruct the patient to flex** her head toward her chest, take a small sip of water, and swallow.
This maneuver closes the trachea and opens the esophagus.



14. **Rotate the tube 180°.**
Rotation helps to redirect the tube so that it will not enter the patient's mouth.

15. **Direct the patient to sip** and swallow the water as you slowly advance the tube. (If the patient is not allowed water, instruct her to dry swallow or suck air through the straw.) Advance the tube 5 to 10 cm (2 to 4 in.) with each swallow.
Moving the tube with each swallow uses normal peristaltic movement to help advance the tube into the stomach. Swallowing closes the epiglottis so that the tube cannot advance into the trachea.

16. **Continue advancing the tube** to the desired distance.

17. **Temporarily secure the tube** with one piece of tape. Then verify tube placement (see Clinical Insight 27-7). Never rely on a single bedside method. You can use a combination of the following methods to verify placement at the bedside; however, radiographic verification is the only reliable method and should be done before medications or fluids are given through the tube for the first time (Joanna Briggs Institute, 2012).
If you do not secure the tube temporarily, it may move out of position—especially if you are waiting for placement to be confirmed by x-ray film.
   a. Inspect the posterior pharynx for presence of coiled tube.
   Visualization confirms that the tube has gone beyond the oropharynx.
   b. Aspirate gently to withdraw stomach contents; measure aspirate pH. The pH of stomach contents is normally 1 to 5.5.
   This may be difficult with small bore tubes. Refer to Clinical Insight 27-7, for rationale and further information about this method.
   c. Take note of the amount, color, and consistency of the aspirate. Gastric aspirates are cloudy tan, off-white, or greenish and may be curdled. Intestinal aspirates will be smaller in quantity, clear, and yellowish owing to the presence of bile, and not curdled.
   d. Inject air into the NG tube and listen with a stethoscope over the stomach. Use this only to confirm other methods because it is the least reliable method.
   If the tube is in the stomach, injecting 5 to 30 mL of air with the syringe should produce a gurgling sound.
   e. Ask the patient to speak.
   If she can do so, the tube is probably in the stomach. Use this only to confirm other methods; it is not reliable enough to use as the primary method of verification.

18. **After checking for placement,** if the tube is not in the stomach, advance it another 2.5 to 5 cm (2 to 4 inches) or as much as directed in the radiologic review. Repeat Steps 17a–e.

19. **After you confirm proper** placement, clamp the end of the tube or connect it to the drainage bag, feeding, or suction machine.

20. **Secure the tube using** one of the following methods.

Securing the Tube With 1-Inch (2.5 cm) Tape

   a. Apply skin adhesive to the patient's nose, and allow it to dry.
   A skin adhesive helps the tape to adhere and protects skin from breakdown.
   b. Use the 5 cm (2 in.) piece of hypoallergenic tape, split lengthwise for 2.5 cm (1 in.) at one end.
   A split tape can be wrapped around the tube in opposite directions to hold the tube in place more securely.
   c. Apply the intact end of tape to the patient's nose.
   d. Wrap the split strips around the tube where it exits the nose. Fold over the ends if adjustment is needed.

Securing the Tube With 1/2-Inch Tape

   e. Use half-inch (1.3 cm) tape, 4 inches (10 cm) long. Apply one end of tape to the patient's nose and wrap the other end downward around the tube and then back up to secure on the opposite side of the nose (see photo).

Securing the Tube With a Tube Fixation Device

   f. Peel the backing off the pad and place the wide end of the pad over the bridge of the nose.
   g. Position the connector around the NG or NE tube where it exits the nose.

21. **Curve and tape the tube** to the patient's cheek (not necessary with some commercial tube fixation devices).
Securing the tube to the cheek reduces the tension on the naris.

22. **Fasten the tube to the patient's** gown: Tie a slipknot around the tube with a rubber band. Loop a rubber band in a slipknot near the connection. (Alternatively, wrap a short piece of tape around the tube to form a tab.) Then fasten the rubber band or the tab to the gown with a safety pin (or tape).
Reduces discomfort produced by the weight of the tube and prevents movement that may cause dislocation of the tube and irritation of the nose.

23. **Elevate the head of the bed** 30° unless contraindicated.

24. **Mark the tube with tape** where it enters the naris, or measure the length from the naris to the connector.
A marked tube allows you to easily notice whether tube placement has changed.

What if . . .

- **The patient is confused, combative, or comatose?**
  - If the patient is comatose, place him into a semi-Fowler's position. Have a co-worker use a pillow to help position the patient's head forward for insertion.
  - If the patient is confused and combative, ask a coworker to assist you with insertion.
- **The patient gags, coughs, chokes, or vomits [at Steps 11 and 15]?**
  1. Stop advancing the tube. Ask the patient to take deep breaths and drink a few sips of water.
  Helps suppress the gag reflex.
  2. Instruct the patient to breathe easily and take some sips of water.
  3. If coughing continues, pull the tube back slightly.
  4. If gagging continues, use a tongue blade and penlight to check the tube position in the back of the throat.
  The tube may be coiled in the back of the throat.
  5. Continue to advance the tube to the desired distance.
- If the tube is coiled in the back of the throat, the patient coughs excessively during insertion, the tube does not advance with each swallow, or the patient develops respiratory distress (e.g., gasping, coughing, or cyanosis), withdraw the tube completely and allow the patient to rest before reinserting.
The tube may be in the patient's trachea.
- **You are unable to obtain an aspirate (at Step 17b) when confirming tube placement?**
  1. Use a 50-mL syringe and aspirate very slowly over at least 5 minutes.
  2. Flush the tube with air, then aspirate.
  3. Turn the patient to the left side, wait 20 minutes, then aspirate again.
  An aspirate might be difficult to obtain with small bore tubes.
- **The prescription states the tube needs to be in the jejunum?**
  1. To advance the tube into the jejunum after the tube has been placed in the stomach, position the patient on the right side.
  Positioning on the right side allows gravity to assist tube passage through the pyloric sphincter.
  2. Advance the tube 5 to 7.5 cm (2 to 3 in.) hourly, over several hours (up to 24 hours) until radiographic study confirms placement.
  Weighted tubes will advance by gravity and peristalsis if a loop of the designated length is made at the entrance to the naris. After reading the initial x-ray, the radiologist or primary physician can provide the measurement needed to advance the tube to the desired position. Note that specially trained nurses usually place these tubes at the bedside.
- **The procedure is anticipated to cause pain or discomfort?**
Commercial hurricane spray or viscous lidocaine is sometimes used to aid in patient comfort. Some practitioners use them for all NG insertions.
  - You may insert 2% viscous lidocaine into the nasal passage using a syringe before tube placement, if prescribed by the primary provider.
  - Alternatively, you can apply an anesthetic spray to the nasal and oropharyngeal mucosa.
- **The patient is a child?**
  - Children usually require a smaller diameter tube.
  - Encourage parents to comfort infants and children and participate in their care.
  - You may need to apply restraints during insertion to prevent dislodging of the tube.
  - Monitor more frequently for complications.
  Small children are not able to communicate problems with the tube.

Evaluation

- Assess how well the patient tolerated the procedure (e.g., discomfort, gagging, coughing?)
- Note the color, consistency, and pH of NG or NE aspirate.
- Ask the patient whether she feels comfortable.
- Assess respiratory status.

Patient Teaching

- Explain that the sensation of the tube should decrease with time.
- Explain the importance of immediately reporting tension on the tube or displacement of the tape or fixation device.
- Discuss the need for frequent mouth care while the tube is in place.

Home Care

- Assess the client or caregiver's ability to maintain an PEG, or gastric button at home if long-term nutritional support is needed.

(continued on next page)

Procedure 27-2 ■ Inserting Nasogastric and Nasoenteric Tubes (continued)

- Assess the home environment to determine the client's risk for infection.
- Instruct the client or caregiver about aspirating stomach contents and measuring pH for NG tubes only.
- Teach the client or caregiver how to verify tube placement.
- Teach client or caregiver to assess the nare for skin breakdown.
- Reinforce the need for frequent mouth care.

Documentation

- Chart the date and time of insertion, size and type of the NG or NE tube and insertion site (which naris), length of tube from tip of the nose to the end of the tube, tolerance of the procedure, any abnormal findings, and methods for confirming NG or NE tube placement.
- Document description of gastric contents and respiratory status.
- NG or NE tube insertion is documented in the progress notes and flow sheets in most agencies.

Practice Resources

American Association of Critical-Care Nurses (AACCN) (2005a, revised 2009; 2005b, revised 2009); Rauen, C., Chulay, M., Bridges, E., et al. (2008); Shlamovitz, G. Z., & Shah, N. R. (2008); Wiegand, D. (2010); Wolfe, T., Fosnocht, D., & Linscott, M. (2000).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Inserting Nasogastric and Nasoenteric Tubes.**

For questions and suggested responses,

Go to Chapter 27, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 27-3 ■ Administering Feedings Through Gastric and Enteric Tubes

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Prescribed feeding formula at room temperature
- Filtered water or prescribed diluent
- Tube feeding administration set with safety adapter that is not compatible with IV tubing, including bag for formula
- 60-mL luer-lock or catheter-tip syringe (two needed for syringe feeding)
- Connector to connect administration set to the feeding tube
- Stethoscope
- Enteral feeding infusion pump (if used). Recommended for all continuous feedings.
- IV pole
- Linen-saver pad
- Graduated container
- pH strip
- For gastrostomy and jejunostomy tubes: a small precut gauze dressing

Delegation

You can delegate the procedure to the NAP or LPN if the patient's condition is stable and the NAP's skills allow. You must verify peristalsis, tube placement, and feeding tube patency before the feeding is started. Remind the NAP to position the patient upright and to report patient discomfort and any difficulty with the infusion.

Pre-Procedure Assessment

- Check the length of the exposed tube: (1) Compare the length from the naris to the connector recorded after x-ray confirmation of placement; or (2) observe the mark that was made on it where it entered the nostril after insertion. Refer to Clinical Insight 27-7 for other bedside methods of verifying tube placement.
  These methods help confirm that the tube has not become displaced since radiography. If there is significant change in length, tube position must again be confirmed by radiography.
- Assess date and time of previous feeding bag set change. Bags should be changed every 24 hr or according to unit protocol.
- Assess for fluid volume excess or insufficiency by checking breath sounds, mucous membranes, skin turgor, edema, and intake and output.
- Obtain baseline weight and laboratory studies before starting the first feedings.
  Weight change is a sensitive measure reflecting fluid and nutritional status.
- Monitor vital signs before and after feedings.
  Vital signs may vary from baseline due to pain, impaction, or dehydration.
- Auscultate for bowel sounds before each feeding or every 4 to 8 hours for continuous feedings. Also check for distention, nausea, vomiting, and diarrhea.
  These symptoms may indicate intolerance of tube feedings. If GI motility is impaired, feedings accumulate in the stomach along with gastric secretions, predisposing the patient to reflux and aspiration. Some medications (e.g., opioids) also slow gastric emptying.
- Check patient history for food allergies.
  Helps prevent allergic reaction to ingredients in the feeding formula.
- For gastrostomy and jejunostomy tubes: Assess the exit site at every shift. Report redness or drainage to the primary care provider.
  Leaking of gastric or intestinal contents may cause skin breakdown.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Verify the feeding tube is in proper placement** prior to starting the procedure.
Tube placement after insertion must be verified by radiography. For subsequent feedings, aspirate and measure gastric residual volume (GVR). For patients with a jejunostomy tube, do not measure the residual volume. See Clinical Insight 27-7 for methods for checking feeding tube placement.

2. **Elevate the head of the bed** (HOB) at least 30° to 45° unless contraindicated. If the patient cannot tolerate a backrest elevated position, use the reverse Trendelenburg position to elevate the HOB, unless contraindicated. And, place a linen saver pad under where the connection end of the feeding tube will be.
A position in which the stomach is higher than the gut reduces the risk for aspiration of gastric contents, a serious risk factor for pneumonia or hypoxia. It also aids digestion.

3. **Check the prescription** for the type of feeding, rate of infusion, and frequency of feeding.
A medical prescription is required for enteral feedings.

4. **Check the expiration date** of the tube feeding formula.
Expired formula should be discarded.

5. **Prepare the formula.**
   a. Inspect the container of feeding solution. If the bag, bottle, or can has been opened or damaged in any way, don't use it.
   b. Shake the feeding formula thoroughly. Examine the solution. It should be uniform in color and consistency. Most often the formula is room temperature. Follow the manufacturer's instructions for safe storage.
   Because the formula goes directly into the stomach and is not warmed by the mouth and esophagus, cold formula may cause abdominal cramping and increase the risk for diarrhea.

6. **Prepare the equipment for** administration.
   a. Fill a disposable tube feeding container with a 4- to 6-hour supply of feeding formula. Or use a prefilled bottle with feeding formula. Follow similar procedure for flush bag if using a two-bag system.
   Limit hang-time to help prevent bacterial growth and prevent air from entering the GI tract.
   b. Label the container with the patient's name, room number, date, start time, formula type, feeding rate, and your initials. Write a warning using large, bold letters, for instance, "WARNING! For Enteral Use Only—NOT for IV Use."
   Labeling identifies the formula and prevents misconnection of the feeding tube into an IV line. Labeling also helps avoid administering formula past the expiration date.
   c. Be sure adapters and connectors used in the enteral system are incompatible with female luer-lock rigid connectors used for IV infusion.
   Prevents tube feeding misconnection with an IV line.
   d. Hang the tube-feeding container on an IV pole with the label facing forward. A prefilled container can safely hang for 24 to 36 hours (some agencies allow for 48 hours).
   Closed systems decrease the risk of contamination and prevent air from entering the GI tract.
   e. Open the administration set package. Make sure the tubing does not touch the floor.
   f. Close the clamp on the tubing before attaching the set to the container.
   g. Remove the cap from the end of safety connector. This adapter must not be fit with IV tubing. Do not touch the end of the connector or let it touch another surface.
   h. Insert the proximal end of the tubing (with the safety adaptor) into the cross-shaped opening of the port on the feeding tube bag. Twist the collar in a clockwise direction until it is securely fastened.

7. **Prime the tubing with the feeding solution.**

8. **Thread the administration set** tubing through the infusion pump according to the manufacturer's instructions. Be sure to close the roller clamp.
Clamping the tube prevents air from entering the stomach or gastric contents from leaking out.

(continued on next page)

Procedure 27-3 ■ Administering Feedings Through Gastric and Enteric Tubes (continued)

9. **Connect the distal end of the tubing** primed with feeding solution to the connector or directly to the NG or NE tube.

10. **Turn on the infusion pump.** Set the correct infusion rate and volume to be infused. Follow the pump manufacturer's instructions.

    Trace the tubing from the bag back to the patient before starting the feeding to ensure that you have not inadvertently hooked the feeding bag or bottle to the IV line

11. **Unclamp the tube** and begin the infusion.

12. **When the feeding volume is complete**, stop the flow, flush the tube, and disconnect the feeding by turning off pump and closing the roller clamp.

13. **Disconnect the feeding tube** from the administration tubing.

14. **Flush feeding tube** with the prescribed amount of water—typically 50 to 100 mL.

15. **Cap the proximal end** of the feeding tube.
    Prevents spillage of gastric contents and stops air from entering the stomach.

16. **Keep the head of the bed elevated** at least 30° to 45° for 1 hour after administering the tube feeding.
    Elevation reduces the risk for aspiration of gastric contents.

17. **Provide or assist with regular oral hygiene** and encourage frequent gargling.
    Oral care reduces oropharyngeal discomfort from the tube.

18. **When you finish the procedure**, remember the Universal Steps that apply after all procedures. For example, leave the patient in a safe, comfortable position with the call device in easy reach.

Procedure 27-3A ■ Administering Feedings Through Gastric and Enteric Tubes Using an Open System: Syringe

Procedure Steps

First follow Steps 1 through 4, above. Then proceed as follows:

1. **Prepare the equipment** for administration.
   a. Don procedure gloves.
   b. Label the syringe with the patient's name, room number, date, time, formula type, feeding rate, start time, and your initials.

      Write a warning using large, bold letters, for instance, "WARNING! For Enteral Use Only—NOT for IV Use."

      Labeling identifies the formula and prevents misconnection of the feeding tube into an IV line. Labeling also helps avoid administering formula past the expiration date.
   c. Remove the plunger from the syringe.

2. **Clamp or pinch off** the end of the feeding tube to begin the feeding.
   Prevents air from entering the feeding tube.

3. **Attach the syringe to** the proximal end of the feeding tube.

4. **Fill the syringe** with the prescribed amount of formula.

5. **Unclamp the feeding tube**, and elevate the syringe. Do not elevate the syringe more than 18 inches (45 cm) above the insertion site. Allow the feeding to flow slowly.
   Gravity allows the formula to flow through the feeding tube. Rate of flow is determined by the height of the syringe. Feeding slowly prevents sudden stomach distention, which can lead to diarrhea, cramping, nausea, and vomiting.

6. **When the syringe is nearly** empty, refill the syringe until the prescribed amount of feeding has been administered.
   If the tubing runs dry, air may enter the stomach and cause discomfort associated with gas.

7. **When the feeding volume** is infused, clamp or pinch the end of the feeding tube.

8. **Disconnect the syringe** from the feeding tube.

9. **Flush feeding tube** with the prescribed amount of water—typically 50 to 100 mL.

10. **Cap the proximal end** of the feeding tube.
    Prevents spillage of gastric contents and stops air from entering the stomach.

11. **Keep the head of the bed elevated** at least 30° to 45° for 1 hour after administering the tube feeding.
    Elevation reduces the risk for aspiration of gastric contents.

12. **Provide or assist with** regular oral hygiene and encourage frequent gargling.
    Oral care reduces oropharyngeal discomfort from the tube.

What if . . .

- **When checking for residual, the volume is more than the formula flow rate for 1 hour or more than 150 mL?**

  Reinstill the gastric residual volume. Residual gastric contents should be reinfused in the absence of pain or abdominal distension.

  If the residual is >250 mL and if there is no abdominal pain or distension, continue the infusion. Recheck in 1 hour. If the residual is still >250 mL, stop the infusion for 4 hours and recheck. If still >250 mL, call healthcare provider (Bankhead, Boullata, Brantley, et al., 2009).

  If residual is <250 mL, restart the infusion at 50% original rate and monitor (Kenny & Goodman, 2010).

  If the gastric residual volume is ≥250 mL after a second gastric residual check, a promotility agent may be considered in adult clients (American Medical Directors Association (AMDA), 2010; American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.), 2009a; Bankhead, Boullata, Brantley, et al., 2009).

  High residual volumes indicate delayed gastric emptying.

- **When checking for residual, none is obtained?**

  Use a large syringe (e.g., 60 mL) and inflate 20 mL of air into the tube, if agency policy permits; this may move the tube away from the gastric wall or clear the tube of any residual formula, medication, or water.

- **When irrigating the feeding tube, resistance is met? Or when instilling the feeding, the fluid does not flow?**

  Do not force the solution. Do not use any fluid other than water for flushing. Check for kinks in tubing and that the pump is working correctly. Turn the client onto his left side. Remove any enteral feeding solution remaining in the tube. Try instilling 5 mL of warm water into the tube and clamping the tube for 5 minutes. Then apply gentle negative pressure to the tube with a syringe. Try flushing with a smaller (e.g., 10 or 20 mL) syringe. If these measures fail, the tube may need to be removed and a new one inserted; contact the primary care provider.

  Note: *There are other methods, such as the alkalinized enzyme method; they require a medical prescription.*

  Forcing the solution may damage the tube. However, you can use a smaller syringe to exert slightly more pressure.

- **The patient has a cuffed tracheostomy tube?**

  Inflate the cuff before administering the feeding, and keep the cuff inflated for at least 15 minutes afterward, if the agency permits.

  Cuffing helps to prevent aspiration.

- **During the feeding, the patient vomits or complains of nausea or feeling too full?**

  Stop the feeding and assess the patient's condition. Flush the tube, wait an hour, then measure gastric contents and restart the feeding at a slower rate. You may need to obtain a medical order to decrease the volume of the feedings.

- **The patient has a jejunostomy tube?**

  Do not instill air into the tube or check for residual before feeding.

  The tube is in the jejunum rather than the stomach, and the jejunum isn't normally a reservoir; therefore, no residual volume is present in the jejunum. Gastrostomy and jejunostomy tubes are often placed through the upper abdominal wall; these tubes, of course, cannot inadvertently migrate into the airway. Injecting air into the tube is not necessary and introduces air into the GI tract, causing the patient discomfort from gas.

  Clean the insertion site daily with soap and water. You may apply a small, precut gauze dressing to the site.

  Helps prevent bacterial growth; prevents infection.

  Be aware that the delivery rate will likely be slower for jejunostomy tubes because of the loss of the stomach as a reservoir.

Evaluation

- Evaluate the patient's tolerance to the tube feeding; did the patient have any abdominal discomfort, nausea, vomiting, or diarrhea?
- Auscultate bowel sounds and vital signs every 4 hours.
- Check gastric residual volume every 4 hours.
- Monitor intake and output every 8 hours.
- Weigh patient at least 3 times per week.
- Assess the exit site for signs of skin breakdown.
- Assess characteristics and frequency of bowel movements.
- Check laboratory values to evaluate nutritional status.

Patient Teaching

- Demonstrate the procedure to the patient and caregiver if the patient will be continuing tube feedings at home.
- Explain the importance of flushing the feeding tube with tap water every 4 hours while the patient is awake to maintain tube patency and fluid and electrolyte balance.
- Discuss the importance of remaining upright for at least 1 hour after the feeding.

Home Care

- Provide written instructions.
- Be sure the client has a 7-day supply of enteral feedings.
- Identify with the client the person who will be responsible for care of the enteral tube and administration of feedings at home.
- Explain to the client and caregiver how to measure the prescribed amount of tube feeding formula and water for flushes by using household measuring equipment.
- Explain the importance of washing reusable equipment thoroughly with soap and water to prevent the spread of infection.
- Discuss how and where to purchase and store the formula.
- If home feedings are to be delivered by pump:
  - Facilitate a home care visit to provide training about the feeding pump.

(continued on next page)

Procedure 27-3 ■ Administering Feedings Through Gastric and Enteric Tubes (continued)

- Arrange for delivery of the feeding pump before discharge (or refer to the appropriate professional for this).
- Ensure that the client has a 7-day supply of disposable feeding sets and 50- or 60-mL syringes upon discharge.

Documentation

- Chart the type of tube feeding, rate and volume of infusion, amount of gastric residual volume (if any), and tolerance of procedure.
- Tube feeding intake is documented on the intake and output portion of the flowsheet in most agencies.
- Record all flushes as intake. Subtract any liquids that you aspirate and do not reinstill (e.g., when gastric residual is too high).

Practice Resources

(2006); Rauen, C., Chulay, M., Bridges, E., et al. (2008); U.S. Preventative Services Task Force (USPSTF) (2009); Yantis, M. A., & Velander, R. (2011).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills,* **Administering Feedings Through Gastric and Enteric Tubes With Infusion Pump and Administering Feedings Through Gastric and Enteric Tubes Using an Open-System Syringe.**

For questions and suggested responses,

Go to Chapter 27, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 27-4 ■ Removing a Nasogastric or Nasoenteric Tube

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Linen-saver pad
- 60-mL luer-lock or catheter-tip syringe
- Nonsterile gloves
- Stethoscope
- Disposable plastic bag
- Emesis basin
- Gauze square

Delegation

This procedure should not be delegated to the LPN or NAP.

Pre-Procedure Assessments

- Auscultate the abdomen for the presence of bowel sounds.
  Bowel sounds and flatus confirm peristalsis, which indicates bowel function is present.
- Assess the patient's ability to consume an oral diet.
  Confirms readiness for discontinuing the NG or NE tube.
- Determine how long it has been since the patient's last enteral feeding.
  Wait at least 30 minutes after a feeding to remove the NG tube.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Check the patient's health** record to confirm removal of the tube. For feeding tubes, make sure tube feeding has been stopped at least 30 minutes before removal.
2. **Assist the patient to a sitting** or high-Fowler's position.
   Proper body alignment facilitates tube removal.
3. **Place the plastic bag and emesis** basin on the bed or within reach. Hand the patient facial tissue. Explain that the procedure may cause some gagging or nasal discomfort, but it will be brief.
   Patients often need to blow their nose after this procedure.
4. **Drape a linen-saver pad or towel** across the patient's chest, and don procedure gloves.
   Draping protects the gown and linens from soiling. Maintains universal precautions.
5. **Wash your hands and don nonsterile** gloves, if you have not already done so.
6. **If the NG tube is connected to** suction, turn off the suction and disconnect the tube.

7. **If you are right-handed,** stand on the patient's right side; and stand on the left side if left-handed.

8. **Attach the syringe** to the proximal end of the NG or NE tube and flush the tube with 10 mL of water, normal saline, or air.
Flushing clears the tube of feeding formula or gastric secretions that could cause irritation or be aspirated during tube removal.

9. **Unpin the tube** from the patient's gown, and then untape the tube from the patient's nose and cheek. Use an adhesive-remover pad to help loosen the tape as necessary.

10. **Clamp or pinch the end** of the tube in your hand. Hold gauze up to the patient's nose and be ready to grab the tube with the towel in the opposite hand upon removal.
This prevents gastric fluids from leaking out the end of the tube onto the nurse or patient.

11. **Ask the patient to take a deep** breath and hold it.
Breath holding closes the epiglottis to prevent aspiration.

12. **Withdraw the tube quickly,** steadily, and smoothly and place it in the plastic bag.
Rapid removal in one steady motion prevents tissue trauma. The plastic bag acts as a barrier to gastric fluids until the tube can be placed in the trash. Seeing and smelling the tube may cause the patient to become nauseated.

13. **Clean the patient's nares** and provide mouth care, if the patient cannot do so. Remove the tape residue from her nose with adhesive remover.
Promotes patient comfort and prevents infection.

14. **If the NG tube was connected** to suction, measure the drainage and note the character of the content. Dispose of the tube and drainage equipment in a biohazardous waste receptacle according to facility policy.
For patients receiving enteral feedings or gastric suction, record their intake and output. Proper equipment disposal prevents the spread of infection.

15. **Remove and dispose of gloves** in the nearest receptacle.

Evaluation

- Assess the nares for signs of skin breakdown or bleeding.
- Monitor the patient for signs of GI dysfunction, such as food intolerance, nausea, vomiting, and abdominal distention. Auscultate for bowel sounds.
  GI dysfunction could necessitate reinsertion of the tube.
- Monitor intake and output every 8 hours.
- Weigh the patient regularly.
- Check laboratory values to evaluate nutritional status.

Patient Teaching

- Explain the importance of reporting nausea, vomiting, food intolerance, or abdominal distention to the physician.
- Explain the importance of and procedure for drinking fluids, if not contraindicated.

Home Care

- The procedure does not require special adaptation for home care, except that you might want to place the tube in a plastic zippered storage bag before discarding it in the trash receptacle.

Documentation

- Chart the date and time of removal as well as the patient's tolerance of the procedure.
- Document the amount of drainage if the tube was connected to suction.
- Note any complications following NG or NE tube removal, such as food intolerance, nausea, vomiting, and abdominal distention.

Sample documentation

4/13/16 1010 Explained to pt and wife NG tube was to be removed and procedure for removing NG tube. Pt stated, "I am ready to get this thing out." Untaped NG tube from gown and nose. Removed tube while asking pt to hold his breath. Pt tolerated procedure well without vomiting or bradycardia. Provided mouth care and facial cleansing. ———— A. Hiam, RN

4/13/16 1230 Taking clear liquids since NG tube was removed with no nausea, vomiting, or abdominal distention. Bowel sounds faint but audible in all 4 quadrants. ———— A. Hiam, RN

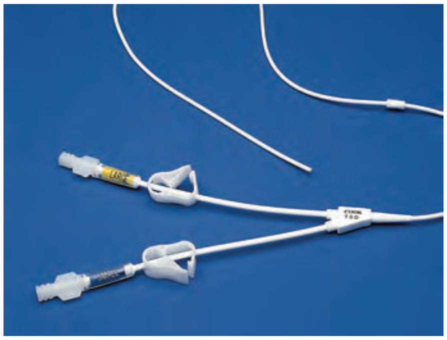
For questions and suggested responses,

Go to Chapter 27, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 27-5 ■ Administering Parenteral Nutrition

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment



- Parenteral nutrition (PN) solution
  - Keep the PN refrigerated until 60 min before use; do not give cold. Do not hasten warming by placing in a microwave oven or hot water bath.
    Cold solution can cause pain, hypothermia, and venous spasm. Nutrients in PN solution are stable only for this short period of time. Nutrients could precipitate, causing catheter blockage or emboli.
  - Some pharmacies deliver the solution before infusion. Be sure the PN has not been mixed more than 24 hours beforehand. However, in home care you may find that solutions are mixed and delivered weekly.
- Procedure gloves
- Sterile gloves. (*Note*: If the central line has an injection cap and if IV tubing is connected onto the cap via luer-lock, some agencies do not require gloves.)
- Intravenous administration set, extension set if indicated (free of plasticizers, such as DEHP, when fat emulsion is to be infused)
- 0.22-micron filter (1.2-micron filter if solution contains albumin or lipids)
  A 0.22-micron filter will remove most particulates and microorganisms that might have been introduced during mixing, but it is too fine for larger-molecule lipids to infuse properly.
- Time tape
  Even though the PN is delivered by infusion pump, there have been numerous recalls of infusion pumps because of malfunction. This simple tape provides valuable information quickly and is an additional safety measure.
- 70% alcohol pads or chlorhexidine gluconate (CHG)-alcohol (e.g., 2% CHG in 70% isopropyl alcohol)
- Infusion pump
- 10-mL syringe and saline
- Blood glucose testing monitor
- Intake and output record
- Transparent dressing or sterile gauze and tape (if dressing is to be changed)
- Catheter stabilization device (e.g., StatLock)
  These are recommended for all catheters and must be changed with each dressing change.
- If the dressing is to be changed, you also need a transparent dressing or sterile gauze, tape, and a mask.

Delegation

Do not delegate this skill to the LPN or NAP because administration of parenteral nutrition requires advanced assessment and critical-thinking skills. The LPN or NAP can assist by monitoring vital signs, checking blood glucose, and verifying patient identity with you. Instruct them about complications associated with PN and ask them to inform you of any signs or symptoms or change in the patient's condition.

Pre-Procedure Assessments

- Assess nutrition status and nutritional needs (e.g., daily weights, intake and output [O], lab results). Patients requiring PN have complex nutritional needs, and actual nutritional status is assessed by a nurse or dietician specializing in nutritional support.
- Check the prescriber's orders for type and concentration of additives in each container and for rate of infusion. (Standardized order forms are recommended by the (A.S.P.E.N.).
- Check the patient's record to confirm that proper central venous catheter (CVC) tip placement has been established before the initial PN administration.
- Check agency policy.
  A few may require tubing and filter change with every bottle or bag. The CDC recommends changing the PN set every 72 hours and a fat emulsion set at least every 24 hours.
- Check the blood glucose level.
- Assess for apparent patency of the IV site.
  If PN is being administered continuously by pump and the infusion is running and there is no leakage from the insertion, you can begin the first few steps of the procedure. Actual patency is checked at Step 14.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Gather equipment** and place at the bedside.
   Promotes efficient use of time.
2. **Identify the patient**, using two identifiers, according to agency policy. Some institutions require, as an extra precaution, that two people identify the patient.
   Multiple patient identifiers help to avoid "wrong-patient" errors. PN solutions are mixed to meet individual needs.

3. **Explain to the patient** the procedure and the rationale for it.
Respects the patient's right to be informed.

4. **Perform hand hygiene.**
Reduces transmission of infectious microorganisms.

5. **Position the patient supine** in bed.

6. **Obtain and examine the PN** container. Check for leaks, cloudiness, or floating particles. Do not use if any of these are present. Some agencies require that two people examine the solution.

For Solutions Containing Lipids (3-in-1 Admixture)

Do not administer the admixture if it has a brown layer, oil droplets, or oil on the surface. This indicates that the emulsion has "broken," and the large lipid droplets can cause fat emboli if administered. Also note that this solution requires a 1.2-micron filter.
To reduce the risk of adverse events such as fat emboli.

7. **Compare the bag** to the patient's identification band; check for correct bag number, expiration date, and additives and their concentration. Compare with the original prescription. Have a coworker verify with you.
Ensures that the correct solution is administered. Check the expiration date to ensure that the solution will be discarded after that date and time. PN solutions are carefully calculated and prepared using the latest recommendations for sterile compounding of solutions. Therefore, you should not add any medications to the bag either before it is hung or while it is infusing.

8. **Connect the IV tubing to the PN** solution; prime the tubing. Note that priming may be done manually now or later (on the pump after the tubing is loaded into the pump), depending on the design of the pump.
Priming tubing removes air bubbles and prevents air from entering the patient's bloodstream, possibly causing air embolism. If there is PN already infusing, the old tubing must be removed from the pump and the rate regulated manually for the short period it takes to prime the new administration set.

When Using IV Tubing Without an Inline Filter

If the IV tubing does not have an inline filter, attach the filter and the extension tubing before priming. Attach the filter as close to the catheter site as possible.

9. Be sure to identify the correct port and IV line. Trace the PN tubing from the bag to the patient before starting the feeding.
Ensures that you have not inadvertently hooked the feeding bag or bottle to the IV line

10. **Place the IV tubing in** the infusion pump. (Prime the tubing if not done in Step 8.) Set the pump to the prescribed rate.

Administration via pump (preferably volumetric) helps prevent complications associated with too-rapid infusion. PN solutions must be administered by infusion pump with reliable, audible alarms. Catheter tip placement must be confirmed before initial PN administration.

11. **Identify the correct IV catheter** and lumen for the PN. This is usually a peripherally inserted central catheter (PICC) line or a centrally inserted venous line designated solely for PN. Never infuse PN into an IV line that is not central.
PN must be administered via a central venous catheter (e.g., subclavian catheter, internal jugular, or PICC) whose tip is positioned in the superior vena cava/right atrial juncture. Most guidelines state that a specific intravenous line be reserved for parenteral nutrition and not used for any other purpose. If a single-lumen catheter is used, it is used only for PN. If a multilumen catheter is used, one lumen will be dedicated for the PN, and blood and other fluids should not be given through that lumen.

12. **Clamp the catheter** and the old PN administration set, if still connected, before disconnecting the tubing.
    a. A clamp should be present on the central line catheters with valves built into the catheter itself.
    The central line for the PN should already be clamped if no PN is running. If a previous bag is running, always clamp the PN line near the patient before disconnecting. Clamping prevents air from entering the catheter when you open the connection.
    b. As an additional, optional safety measure, instruct the patient to perform the Valsalva maneuver just as you change the tubing.
    c. If Valsalva is contraindicated for a patient, instruct the patient to exhale at a specific time when the lumen is open.
    The Valsalva maneuver increases intrathoracic pressure and creates positive pressure in the central vessels, also helping prevent air embolism.

13. **Remove and discard gloves.** Perform hand hygiene.
In Steps 1 through 11, you were observing Universal Precautions. From this step forward, the emphasis is on preventing the introduction of microorganisms into the catheter lumen or the catheter insertion site.

14. **Don clean gloves (or sterile** gloves, if your agency policy requires them). Disconnect the old administration set. Using a chlorhexidine gluconate (CHG)–alcohol pad or a 70% alcohol pad, thoroughly cleanse all surfaces of the central line injection cap and extension leg (in a needleless system) or the luer-lock, including threads.
Because PN solutions are a good medium for growth of pathogens, and because the IV line enters the central circulation, the risk for sepsis is relatively high.

15. **Determine patency of the line.** Use a 10-mL syringe to aspirate for blood, looking for a brisk return with pulsating pressure; then flush with saline. If the PN is running continuously on a pump, there are no occlusion alarms, and the dressing is dry and intact, these are also signs—but not proof—of patency.

(continued on next page)

Procedure 27-5 ■ Administering Parenteral Nutrition (continued)

When PN is running continuously on a pump, the pump creates a constant fluid flow through the lumen to help keep it patent. There is some controversy about this step. Some experts prefer to aspirate for blood only for the first bag of a continuous infusion, and thereafter to flush without aspirating. As always, follow agency policy.

16. Attach the infusion tubing to the designated PN port and then turn the luer-lock to secure the connection. "Luer-slip" connections should not be used. Do not use tape. Trace the tubing from the patient back to the PN container to be certain you are using the correct lumen.
Securing the connection with a luer-lock connection prevents separation of the connection and decreases the risk for sepsis or embolism. Tape, even sterile tape, has been found to be a medium for bacterial colonization.

If the Previous Infusion Is Still Connected

Be sure the access line and the line to the "old" infusion bag are clamped (Step 11). Quickly disconnect from the central line, thoroughly cleanse the port, and connect the new infusion.

17. Trace the tubing from the bag back to the patient. Then start the infusion. Check again to make sure the catheter-tubing connection is secure. Infuse at the rate prescribed (depending on the patient's tolerance, PN is usually started at a rate of 40 to 50 mL/hr and then advanced 25 mL/hr every 6 hours).
PN solutions may contain as much as 70% dextrose. A gradual rate increase allows the patient's pancreatic beta cells time to increase their insulin output to handle the increased glucose load. For lower concentrations of dextrose, you can usually run the same rate for the complete 24-hour volume.

18. Label the tubing with the date and time of change (if it is new tubing or if you have changed the tubing).
Labeling allows other nurses to know when tubing is due to be changed and a new solution must be hung.

19. Remove and discard gloves. Perform hand hygiene.

What if . . .

- **When you flush the catheter (at Step 15), you meet resistance?**
  Examine the insertion site for leaking fluid or inflammation. Aspirate and try again to flush *gently*. Never forcibly flush against resistance. Remove syringe from luer-lock connection, then reconnect. Reposition the patient and ask him to cough. Roll the patient's shoulder or raise the arm on the same side the catheter is on. If these measures fail, notify the primary care provider.
  Occlusion may be caused by a clot; drug precipitation; or catheter migration, kinking, or compression; or may be related to incomplete connection with the luer-lock. Forceful flushing may discharge a clot into circulation. Other measures to clear a catheter require a medical order.
- **The rate falls behind or the pump gives occlusion alarms?**
  First check to be sure the pump is turned on, the bag is not empty, and all clamps are fully open. Change the filter if it is clogged. Perform the steps in the preceding item. If those measures do not work, change the pump and send it to biomedical engineering to be checked. Do not attempt to catch up by increasing the rate.
  A slow rate may indicate a clogged filter or injection cap, a kinked catheter, or a malfunctioning pump. A clogged filter must be changed; you cannot run the PN without a filter.
- **The 24-hour total deviates from the prescribed infusion rate by 10% or more?**
  Notify the primary provider or nutrition support team.
- **A PN solution must be discontinued abruptly for any reason?**
  Notify the primary provider or nutrition support team. Another solution of 5% or 10% dextrose may be started.
  The dextrose solution is started to prevent rebound hypoglycemia. Note that if it is a catheter complication that requires this discontinuation, 10% dextrose is the highest concentration that can be infused through a peripheral vein because infiltrated hyperosmolar fluid causes tissue injury.
- **The patient no longer needs parenteral nutrition?**
  You may need to decrease the rate gradually, perhaps over 48 hours, before discontinuing the infusion completely. Be sure the patient either receives enteral nutrition or consumes food during the next few hours after stopping PN.
  To prevent rebound hypoglycemia.

Evaluation

These are post-procedure evaluations. For ongoing monitoring, see Clinical Insight 27-8.

- Assess vital signs, I&O, and weight.
- Observe that the solution is infusing at the prescribed rate.
- Assess patient's tolerance to the infusion (e.g., observe for pulmonary edema; check lab results).
- Observe for skin rashes, flushing, color changes, or other signs of allergic reactions; notify the primary provider.

  Note: These are not common.
- Monitor blood glucose and do not increase the infusion rate until glycemic control is established.

Patient Teaching

- Inform the patient and family of the purpose and duration of the nutritional support.
- Teach them to recognize and report to the nurse symptoms of complications associated with PN.
- Teach the patient that the dressing must remain occlusive, and to notify nurse if it comes loose or gets wet.
- Teach the patient the importance of measures to prevent blood infections.

Home Care

- The home environment must provide dry storage space for supplies, a refrigerator for storing admixtures, a clean low-traffic area for procedure preparation, and electronic outlets for any electronic equipment.
- Teach safe disposal of supplies.
- Provide verbal and written instructions of the procedures; demonstrate and ask for a return demonstration. Role-play "what would you do if . . ." situations with the patient.
- Clients at home often administer their daily 24-hour total over 12 to 16 hours during the night. This allows them to disconnect from the infusion in the morning, flush the central line, and be free to pursue their usual activities during the day.
- Instruct about solution hang time and management of the access device.
  Depending on the anticipated length of therapy, patients may be sent home with a permanent venous access device.
- Provide 24-hour phone numbers for the primary care provider and home care agency.
- Home PN is less expensive than treatment in the hospital, and in many cases is associated with a lower risk of infection.
- Home nutritional support is usually under the direction of specialized nutrition support teams.

Documentation

- A special form may be used for documenting PN administration.
- Bag number, date and time hung, volume, type of fluid, rate of delivery, additives
- Date and time of dressing or tubing change (if performed)
- Patient's tolerance of procedure
- Pre- and post-administration assessment data, including complications and response to therapy
- Results of fingerstick blood glucose checks
- If insulin is required, type, amount, and route/site administered
- Weight
- I&O

Practice Resources

Board of Directors & Task Force for the Revision of Safe Practices for Parenteral Nutrition (2004); Bankhead, R. Boullata, J., Brantley, S., et al. (2009); Infusion Nurses Society (INS) (2011); National Guideline Clearinghouse (NGC) (2006a, 2008b).

Procedure 27-6 ■ Administering Lipids

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* If administering through a central line, refer to Procedure 27-5 for precautions associated with central lines.

➤ *Note:* This procedure is for administering fat emulsions. If you are administering an admixture with the parenteral nutrition solution, use Procedure 27-5.

Equipment

- Intravenous lipid solution (not refrigerated)
- Special tubing (infusion set) for lipids (must be without plasticizers [DEHP]). Set should be labeled to that effect)
- Needleless cannula (if using a split septum needleless connector that requires it)
- 70% isopropyl alcohol or chlorhexidine gluconate (CHG)-alcohol pads
- Procedure gloves
- Time tape
- Infusion pump
- I&O record
- If a filter is a used, it must be a 1.2-micron filter
  Lipid particles are large and will clog a smaller size.

Delegation

Do not delegate this skill to the LPN or NAP because administration of lipids requires advanced assessment and critical-thinking skills. The LPN or NAP can assist by monitoring vital signs and verifying patient identity with you. Instruct them about complications associated with lipids and ask them to inform you of any signs or symptoms or change in the patient's condition.

Pre-Procedure Assessments

- Assess for rash; eczema; dry, scaly skin; poor wound healing; and sparse hair.
  These are signs of essential fatty acid deficits.
- Check the history for anemia; coagulation disorders; and abnormal liver, pancreatic, or respiratory function.
  These factors predispose to fat emboli. Your role as a staff nurse is to be certain the PN prescriber is aware of these factors; they do not necessarily contraindicate giving the PN.
- Check peripheral IV site for erythema, infiltration, and patency. Check the central venous access site for erythema or other signs of infection.
- Take baseline vital signs just before infusing the lipids.
  An immediate reaction can occur upon starting the infusion. Note that not all guidelines require this action.

(continued on next page)

Procedure 27-6 ■ Administering Lipids (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Review the prescriber's orders**, identify the patient, and explain the purpose of the procedure.
   Verifying helps to prevent dosage and wrong-patient errors. Explaining respects the patient's right to be informed and encourages cooperation.

2. **Gather equipment** and place at bedside. Adjust lighting as needed.
   Organization promotes efficient use of time.

3. **Perform hand hygiene** and don procedure gloves.
   Hand hygiene and gloving reduces transmission of infectious microorganisms.

4. **Position the patient supine** in bed.

5. **Be certain lipids are not cold.**
   Cold infusion can cause discomfort.

6. **Examine the container** for a layer of froth or for separation into fat globules or layers.
   Do not use the lipids if these occur.

7. **Label the container** with the patient's name, room number, date, time, rate, and start and stop times. Label the tubing with date and time. ***Note:*** *When lipids are infused with parenteral nutrition, the lipid infusion must be completed within 12 hours.*
   Labeling helps ensure that the patient receives the correct infusion.

8. **Compare the lipid container** to the patient's wrist band (bag number, expiration date); compare to the original prescription. Have a colleague verify.

9. **Determine patency of the IV** line.

10. **Cleanse the stopper** on the IV bottle with an antiseptic swab; allow to dry.

11. **Connect the special DEHP-free** lipids-infusion tubing to the container, twisting the spike as you insert it. **Key Point:** ***You must use new tubing for each bottle.***
    Twisting the spike helps ensure that particles from the stopper do not fall into the bottle. New tubing reduces the growth of microorganisms (the feeding provides a medium for fungal growth). DEHP is considered a toxin in the bloodstream.

12. **Place the primed tubing** in the pump and attach the tubing to the IV catheter lumen.

    Identify the correct IV line and port for the infusion. Trace the tubing from the bag back to the patient. *Infusing enteral medication or feeding solution into an intravenous line could be life threatening.*

    a. Thoroughly scrub the catheter injection port or hub and the luer-lock threads with an antiseptic wipe.
    b. If you are infusing lipids simultaneously with PN, attach the primed lipid tubing to the injection port/hub closest to the patient, below the tubing filter, or through a Y-connection at the catheter hub.
    c. Turn the luer-lock to secure the connection.
    d. *Note:* If a previous infusion has been running, clamp the catheter lumen and the old administration set tubing before disconnecting and changing the tubing.
    Prevents blood backup in the line.

13. **Begin the infusion.** Ideally, infuse slowly at first: 1.0 mL/min for adults and 0.1 mL/min for children (or as prescribed by the physician). Check again to be sure the catheter-tubing connection is secure.
    Slow infusion allows time to identify adverse reaction to the lipids and to stop the infusion before the patient has received a large volume. Nausea, vomiting, and elevated temperature have been reported when lipids are infused quickly.

14. **Take the vital signs** now, then every 10 minutes for 30 minutes. Observe for side effects (e.g., chills, fever, flushing, dyspnea, nausea, vomiting, headache, back pain).

15. **If no reactions occur**, adjust to the prescribed infusion rate and continue monitoring according to your agency's protocol.

16. **Remove gloves** and perform hand hygiene.

17. **When the infusion is finished**, discard the bottle and IV administration set.
    Formula contains sugars that are a medium for growth of pathogens.

? What if . . .

- **The entire bottle of lipids is not used?**
  Discard partially used bottles to prevent contamination.

Evaluation

- If ordered, monitor serum lipids 4 hours after discontinuing the infusion.
- Monitor the IV site for infection, inflammation, and infiltration.
- Monitor for symptoms of fat emboli.
- Monitor the IV line for patency.
- Monitor for allergic reactions (nausea, vomiting, headache, chest pain, back pain, fever).
- Monitor for lipid intolerance (triglyceride levels, liver function tests, hepatosplenomegaly, decreased coagulation, cyanosis, dyspnea).

Patient Teaching

- Inform the patient and family of the purpose and duration of the nutritional support.
- Teach the patient to recognize and report symptoms of complications associated with lipids infusion.

Home Care

- The home environment must provide dry storage space for supplies, a refrigerator for storing solutions, a clean low-traffic area for procedure preparation, and electronic outlets for any electronic equipment.
- Teach safe disposal of supplies.
- Provide verbal and written instructions for the procedures; demonstrate and ask for a return demonstration.
- Instruct about solution hang time and management of the access device.
- Provide 24-hour phone numbers for the primary care provider and home care agency.

Documentation

- A special form may be used for documenting lipids and PN administration.
- Lipid container number, date and time hung, volume, type of fluid, and rate of delivery
- Status of dressing, and date and time of dressing or tubing change (if performed)
- Patient's tolerance of the procedure and any problems encountered
- Pre- and post-administration assessment data and blood tests, if any
- Condition of the IV site
- Weight
- I&O

CLINICAL INSIGHTS

Clinical Insight 27-1 ➤ 10 Tips for Building Healthy Meals

	HEALTHY EATING TIP	HOW TO DO IT
1	Make half of your plate fruit and vegetables.	Choose vegetables rich in color; they are usually rich in nutrients. Good ones are sweet potatoes, beets, broccoli, spinach, and many others. Fresh fruits and vegetables are less expensive and more flavorful when bought in season.
2	Add lean protein to your meals.	High protein selections will help you to build muscle and reduce your carbohydrates. Be sure to eat lean beef, pork, or chicken; tofu; and beans. Seafood is a must at least twice a week.
3	Whole grains rule.	Like fiber, whole grains are more nutritious than refined or multigrain products. Try to cut out refined flour altogether. "If it's white, don't bite."
4	Dairy is a big deal.	To be sure you have essential nutrients, calcium, and vitamin D in your diet, plan your meal with fat-free or low-fat milk, soymilk, or low-fat yogurt.
5	Stay away from extra fat.	Stay clear of gravy, heavy sauces, salad dressings, and too much cheese on top of your food. It adds unneeded fat calories!
6	Take your time eating.	Eating slowly allows you to enjoy the taste and texture of your food. Savor your food by taking small bites and chewing thoroughly. Your body also has a chance to realize it is full before you eat too much.
7	Serve food on a smaller plate.	Serving food on a smaller plate is one good way to control portion size and keep from overeating.
8	Control your food. Don't let it control you.	Just say "no" to extra large portions. Choose healthier food options because you're worth it. Remember that nothing tastes as good as healthy feels!
9	Be open to trying new foods.	Eating a variety of foods is a good way to feed your body the essential vitamins and minerals it needs. Keep it interesting by trying different fresh foods without fillers, additives, or *trans*-fats.
10	Satisfying your sweet tooth doesn't have to be unhealthy.	Indulge in naturally sweet fruit. Serve it in an attractive way or use interesting spices to make it even more appealing.

Clinical Insight 27-2 ➤ Skinfold Measurement

- Take measurements directly on the skin, not through clothing.
- Take each reading as soon as the jaws of the caliper come into contact with the skin and the reading has stabilized.
- In each site, take three readings in quick succession, and average the results to the nearest 0.1 mm. Note that the accuracy of this method varies with the technique.
- Add the averages of all skinfold sites to arrive at a total skinfold measurement.
- To determine the percentage body fat, compare the final calculated measurement with the values in the appropriate body fat and skinfolds table for the age and gender of the patient.

Measuring Triceps Skinfold

- Locate the midpoint on the posterior side of the dominant upper arm.
- With the client's arm hanging loosely at the side, palpate the measurement site at the midpoint to become familiar with distinguishing muscle from adipose soft tissue.
- From 1 cm above the midpoint, grasp a vertical pinch of skin and only the subcutaneous fat layer between the thumb and index finger. Gently pull the skinfold away from the underlying muscle.
- Place the skinfold caliper at the midpoint, and slowly release the jaw of the caliper while maintaining a grasp of the skinfold (see the figure).

Triceps skinfold.

Measuring Subscapular Skinfold

- Follow the same procedure, except measure on the back, just under the shoulder blade. Grasp below the tip of the inferior angle of the scapula 45° to vertical.

Subscapular skinfold.

Measuring Biceps Skinfold

- Follow the same procedure, except measure the muscle belly of the biceps. With the patient's arm hanging loosely at the side, grasp the skin and subcutaneous fat layer on the front of the upper arm, over the biceps, about level with the nipple.

Measuring Suprailiac Skinfold

- Follow the same procedure, except measure approximately 1 inch above the hipbone, above the iliac crest in the mid-axillary line.

Calculating Body Mass Index

Calculate the BMI using this formula:

$$\text{BMI} = \text{weight in kilograms} \div (\text{height in meters})^2$$

Clinical Insight 27-3 ➤ Measuring Circumferences to Evaluate Body Composition

Measuring Mid-Upper Arm Circumference

- Keeping the client's dominant arm parallel to the body, bend the elbow 90°.
- Using a tape measure, measure the distance between the **acromion** (the bony protrusion of the back of the upper shoulder) and the **olecranon process** (tip of the elbow).
- Mark the midpoint between these two landmarks.
- Ask the client to relax the arm, so that it hangs loose and parallel to the body.
- Position the tape around the upper arm at the marked midpoint. Make sure the tape is snug but not so tight as to indent or pinch the skin.
- Record the circumference to the nearest 0.1 cm.

Calculating Waist-to-Hip Ratio (WHR)

WHR ratio greater than 1.0 in men and greater than 0.8 in women is considered obese.

- Use a tape measure to measure the circumference of the waist (at the umbilicus with stomach muscles relaxed).
- Use a tape measure to measure the circumference of the hips at their widest point.
- Calculate the waist-to-hip ratio using the following formula:

waist circumference (in.) ÷ hip circumference (in.)

Note: *Abdominal obesity is defined by World Health Organization (1999) as waist-to-hip ratio greater 0.85 in women, and greater than 0.9 in men.*

Example: Robert's waist measurement is 32 inches, and his hip measurement is 34 inches. His WHR is 32 ÷ 34 = 0.94.

Clinical Insight 27-4 ➤ Interventions for Patients With Impaired Swallowing

Provide Nutritional Support

Nutritional support includes the following activities from the NIC intervention Swallowing Therapy (Bulechek, Butcher, & Dochterman, 2012, pp. 707–708):

- Position the patient in a full upright, 90°, if possible.
- Provide/use assistive devices, as appropriate.
- Avoid use of drinking straws.
- Assist the patient to position head in forward flexion in preparation for swallowing (chin tuck).
- Assist patient to place food at the back of the mouth and on the unaffected side.
- Monitor the patient's tongue movements while she is eating. Frequently cue patient to chew and swallow. Patient may need to double swallow.
- Check mouth for pocketing of food after eating.
- Monitor body weight.
- Monitor body hydration (e.g., intake, output, skin turgor, mucous membranes).

Take Aspiration Precautions

(Bulechek, Butcher, & Dochterman, 2012, p. 145):

- Monitor level of consciousness, cough reflex, gag reflex, and swallowing ability.
- Position the patient upright 90° or as far as possible.
- Keep suction setup available.
- Feed in small amounts.
- Avoid liquids.
- Cut food into small pieces.
- Keep HOB elevated for 30 to 45 minutes after feeding [your text recommends 1 hour].

Clinical Insight 27-5 ➤ Interventions for Patients Who Have Nausea

- Identify the cause of the nausea (e.g., anxiety; pain; constipation; cough; dehydration; electrolyte disorders; treatments, such as surgery, radiotherapy, or chemotherapy; disease processes, such as peptic ulcer or pancreatitis).
- Keep tissues and water to rinse the mouth at the bedside.
- Maintain a calm environment.
- Provide cool, fresh air.
- Instruct the patient to wear loose clothing.
- Avoid wearing perfume. Discourage scented candles and other aromatic items while the patient is nauseated.
- Try serving cool or cold foods. Avoid greasy, warm, spicy, or aromatic foods. In some cases cold food is better tolerated. Allow the patient to eat what she finds appetizing and tolerates well. The sight and smell of hot food can induce nausea.
- Provide or assist with frequent oral hygiene.
- Ask the patient to sit in an upright position for 30 to 45 minutes after eating, unless contraindicated.
- Offer six small meals instead of three large ones.
- Instruct the patient to keep crackers by the side of the bed to eat before getting up if nausea occurs upon wakening. It can also help to eat lean meat or cheese before going to bed.
- Provide cool (not cold or iced) cola to drink. Drinks with sugar to calm the stomach.
- Have the patient suck on an ice cube, Popsicle, or sorbet, or even a piece of frozen fruit (pineapple, kiwi, or apple).
- Recommend a dietary consultation if nausea and vomiting persist.
- For malnourished patients, consult a dietitian. Consider dietary supplements; however, these are often poorly tolerated and may sometimes cause even more nausea.
- Assess for dehydration, if nausea and vomiting is severe or persistent; you may need to administer parenteral fluid and electrolytes.
- Certain psychological techniques may be effective when the nausea is related to anxiety, stress, or anticipation of nausea. The following may be helpful: distraction, relaxation techniques, guided imagery, systematic desensitization, self-hypnosis, biofeedback, and music therapy.
- Administer antiemetics as prescribed or per hospital protocol.

Clinical Insight 27-6 ➤ Assisting Patients With Meals

General Guidelines

- Recommend having one staff person for every two or three patients who need assistance, allowing about 20 to 30 minutes to feed a patient. Prolonged meal times do not promote appetite; nor does hurrying.
- Feeding assistants should be supervised by an RN or LPN.
- Do not interrupt meals with medications.
- Encourage family members to share mealtimes.
- If the patient's condition allows, encourage him to get out of bed for meals.
- Encourage residents in long-term care settings to eat meals in the dining room instead of in the bedroom (Leydon & Dahl, 2008).

Preparation

- Assess for rituals used before meals (blessings of food, and so on).
- Provide an opportunity for toileting, oral hygiene, and handwashing before meals.
- Assist the patient to eat and drink only as necessary; encourage independence.
- Provide privacy during meals if the patient is embarrassed; to further maintain dignity, use a napkin, not a bib, over the patient's clothes.
- Check for proper fit of dentures.
- Provide music during the meal if the patient wishes.
- Demonstrate the use of assistive devices and alternative methods for eating and drinking.

Assisting the Patient

- If the patient must eat in bed, place the head of the bed at the highest tolerable level, and adjust the overbed table to be in easy reach.
- If the patient can feed himself, prepare the food on the tray for him (e.g., open food containers, cut the meat, peel an orange, open the milk and butter containers, mash food if needed).
- If the client is visually impaired, identify the locations of the meal on the tray based on a clock face (e.g., "The coffee is at 1 o'clock above the plate on the right").

Feeding the Patient

- Feed the patient if she is unable to feed herself.
- Sit down while feeding the patient; do not rush.
- Position yourself so you can make eye contact.
- Be sure to provide adequate time for her to chew and swallow.
- If possible, ask her what food she would like next.
- Serve one food at a time; serve small amounts.
- Serve finger foods (e.g., fruit, bread) to promote independence.
- Cue older adults whenever possible with words or gestures.
- Have casual conversation with the patient while feeding her to make mealtime more pleasant and relaxed.

After the Meal

- Help the patient to wash hands or use the rest room.

Clinical Insight 27-6 ➤ Assisting Patients With Meals—cont'd

- Record the amount of food and fluid the patient consumed.
- Document feeding behaviors.
- Document changes in nutritional status.
- Document staffing and staff education, and availability of a supportive interdisciplinary team.

Assisting Older Adults With Dementia

As do all people, older adults with dementia differ in their abilities to eat and communicate. The following are general tips, but you should tailor interventions to each person's specific abilities to achieve the best results. In addition to many of the preceding interventions, try some of the following measures.

- Assess the patient's self-feeding abilities.
- Assess the patient's cognitive limitations and communication abilities.
- Assess for and treat pain.
- Minimize distractions: Turn off the TV; discourage people from entering the room.
- Help the patient to a comfortable chair if possible.
- Assist with oral hygiene and hand hygiene.
- Remove any unnecessary eating utensils; serve only one food at a time.
- Remove items that should not be eaten (e.g., packets of salt or pepper), and hot items that could be spilled.
- Cue the patient verbally to help with self-feeding (e.g., "take a bite," "chew," "swallow").
- Pantomime eating motions so the patient can imitate them.
- Place your hand over the patient's to begin and guide self-feeding (hand-over-hand).
- When assisting, sit at eye level and interact socially with the patient.
- Involve family members if they have assisted with feeding at home.
- Train and supervise NAPs in interacting with and feeding patients with dementia.
- Do not assist too soon—give the patient time to eat independently.
- Do not feed too fast. Feed at a rate that is safe and comfortable for the patient.

Clinical Insight 27-7 ➤ Checking Feeding Tube Placement

Tube placement must be verified by x-ray before the initial feeding is given. Because none of the bedside methods is foolproof, always use pH measurement in combination with one of the other methods.

To Aspirate Stomach Contents:

- Don procedure gloves. This is a clean, not sterile, technique.
- Just before feeding, draw up 10 to 30 mL of air in a 30- to 60-mL syringe, insert the syringe in the distal end of the feeding tube, and inject air.
  To flush out formula, medications, and other substances. This also helps keep a small-bore tube from collapsing when you aspirate.
- With the same syringe, aspirate the air and 20 to 30 mL of stomach or intestinal contents. Use slow, gentle suction—over 3 to 5 minutes if necessary.
  It can take a long time to obtain enough fluid, especially from a small-bore tube.
- If you could not aspirate any fluid, inject another 20 mL of air and use a smaller syringe to aspirate again.
  Using a small (<10 mL) syringe for very small tubes creates less negative pressure and makes it less likely the tube will collapse.
- If you still do not aspirate fluid, repeat the procedure with this variation: Insert air with the large syringe; insert the small syringe into the end of the tubing, and leave it for 15 minutes to allow fluid to accumulate before aspirating.
- If you are still unsuccessful, reposition the patient and try again after 20 minutes.
  Repositioning may move the tube into a place where fluid has pooled.

Inspecting the Aspirate

- Aspirate stomach contents, as described above. Gastric contents are normally greenish brown and liquid. If the patient is receiving enteral feedings, gastric contents should be curdled and white or a greenish color; intestinal contents will be a more yellow (bile) color with no curdling.

Intestinal contents are usually yellow-green because of the influence of bile. The colors of gastric and pulmonary secretions are altered by a variety of conditions, so observation of the visual characteristics of feeding tube aspirates is of little value in differentiating between respiratory and GI placement (Joanna Briggs Institute, 2010a, 2010c).

(Continued)

Clinical Insight 27-7 ➤ Checking Feeding Tube Placement—cont'd

Measuring the Volume and pH of the Aspirate

- Aspirate stomach contents, as described above. Then measure the residual volume of the aspirate.
  Unexpected changes in volume of the aspirate can indicate poor GI motility. Gastric volumes will generally be larger than intestinal or esophageal volumes.
- Measure the pH of the aspirated fluid using nitrazine paper. See the accompanying figure.

- The lower the pH, the more likely that the tube is in the stomach. The pH of gastric contents is typically 1 to 5.5. Measuring the pH is useful only if the fluid you aspirate is acidic, indicating gastric placement.
- Intestinal contents usually have a pH of 6 or greater.
- The pH of respiratory secretions is 7 or higher; however, respiratory secretions may occasionally have a pH as low as 6.
- Remember that many variables can make the gastric pH results unreliable (e.g., blood in the stomach, antacid medications).
- Measuring bilirubin, trypsin, and pepsin in the aspirate can also be used to diagnose placement of a feeding tube in the respiratory tract (Elpern, Killeen, Talla, et al., 2007; Peter & Gill, 2009).

Measuring and Observing the Length of the Tube that Extends From the Body

When the tube was inserted, it should have been marked with indelible marker where it exits the body (e.g., the naris), and the external length recorded. Compare the external length with previous measurements and with the mark made on the tube when it was inserted. If tube placement does not change, the external length should remain the same.

Injecting Air into the Feeding Tube

Although some professionals still inject air into the feeding tube, this method is the least accurate of the bedside methods.

- Draw 5 to 30 mL of air into a syringe; place the tip of the syringe in the end of the feeding tube.
- Place a stethoscope over the stomach.
- Listen with the stethoscope as you inject the air through the tube. If you hear a gurgling or whooshing sound in the left upper quadrant, the tube may be in the stomach. If the tube is in the lungs, you should hear no gurgling.

Ongoing Patient Assessments

The following require repeated assessments over time to be useful for confirming other methods of tube placement.

- ***Observe for respiratory distress.*** Note cyanosis or difficulty breathing, coughing, choking. These symptoms are a good indicator that the tube is in the respiratory tract; but keep in mind that the tube could instead be in the stomach and the symptoms caused by something else. Absence of symptoms does not necessarily indicate correct placement in the stomach. The tube might be in the airway and not be causing any respiratory symptoms.
- ***Assess whether the patient can speak.*** Keep in mind that some clients can speak even when the tube is in a lung.

Other Bedside Verification Methods

Capnometry and additional tests of gastric juices may also serve as measures to help verify that the tube is correctly placed. To find discussion of these methods,

Go to Chapter 27, **Checking Feeding Tube Placement,** in Volume 1.

Clinical Insight 27-8 ➤ Monitoring Patients Receiving Enteral Nutrition

Monitor the following:

- ***Position of the feeding tube.*** Periodically check the placement of the tube. As a rule, check on each shift or at each intermittent feeding. For double-lumen tubes, keep the air vent above the level of the patient's stomach so it will not act as a siphon and leak stomach contents.
- ***NG or NE tube insertion site.*** An NG or NE tube is secured by adhesive to the nose. Regularly check the skin, gently cleanse the area (with soap and water, as for normal washing; avoid harsh skin cleansers), and retape the tube as needed. Report tissue breakdown, epistaxis (nosebleed), or sinusitis, as they may signal a need for insertion of a percutaneous endoscopy gastrostomy (PEG) tube.
- ***Gastrostomy tube, PEG/PEJ insertion site.*** Inspect the insertion site for erythema or drainage, which are signs of infection. Clean it daily with soap and water.
- ***Fluid balance.*** Measure all intake and output.
- ***Weight.*** To assess the adequacy of the feeding, regularly weigh the patient. There is usually a medical prescription for frequency of weighing. Frequent weight checks allow adjustment of the feeding orders to achieve the desired goal.
- ***Tube feeding residual volume.*** To assess residual volume, aspirate the feeding tube to determine the amount of feeding remaining in the stomach. If the aspirate quantity is equal to or greater than the formula flow rate for 1 hour (or alternatively, a total of 150 mL), the patient may be receiving too much fluid or may have delayed gastric emptying. However, you should not automatically stop the feeding; if you obtain a single sample of an increased residual volume, recheck it in 1 hour. See Clinical Insight 28-7.
- ***Frequency of bowel movements.*** Bowel movements should occur regularly.
  - Constipation is usually due to inadequate water or fiber. Some commercial feedings contain fiber. You may add free water and perhaps fiber to other formulas.
  - Diarrhea may indicate intolerance of the formula, excessive feeding, or gastrointestinal disease.
- ***Bowel sounds.*** Check before each feeding, or every 4 to 8 hours for continuous feedings. Peristalsis must be present. Flatus is a better indication of complete bowel function than bowel sounds.
- ***Abdominal distention.*** Measure abdominal girth daily, at the umbilicus.
- ***Serum electrolyte levels.*** Monitor regularly (per protocol or prescription).
- ***Urine for sugar and acetone.*** This is sometimes done as a bedside screen for hyperglycemia. However, treatment is based on blood sugar levels.
- ***Skin turgor, hematocrit, and urine specific gravity.*** These are indicators of dehydration and overhydration, although skin turgor alone is not a reliable sign.
- ***Serum blood urea nitrogen (BUN) and sodium levels.*** This is especially important for high-protein formulas. Insufficient fluid intake combined with high protein intake may overload the kidneys so that nitrogenous wastes are not excreted adequately.

Clinical Insight 27-9 ➤ Preventing Infection in Patients Receiving Enteral Feedings

Contamination of the feeding can have serious consequences for a patient.

- Check dates on feeding solutions and supplies. Do not use any that are outdated.
- Use sterile equipment and supplies; once you have opened them, handle them as little as possible.
- Disposable feeding equipment is meant for one-time use. Do not wash and reuse.
- Use meticulous hand hygiene; wear nonsterile gloves.
- Replace feeding equipment after 24 hours.
- Store opened feeding solutions in the refrigerator in covered and labeled containers. Allow the solution to return to room temperature before giving it to the patient. Discard after 24 hours.
- Keep unopened solutions at room temperature.
- Follow agency policy regarding how long a solution may be left hanging. Usually:
  - Sterile feedings may be hung for up to 24 hours (or per unit policy).
  - Nonsterile feedings (i.e., reconstituted powder feedings) may hang for up to 4 hours (or per unit policy).
  - Label the feeding containers with the patient's name and the date and time hung; document the time in the patient record.
- Use sterile water for (1) patients who are immunocompromised, (2) patients receiving jejunal feeds, or (3) initially following a gastrostomy insertion.
- Never allow a feeding to hang below the height of the patient's stomach.
- Do not transfer sterile feedings into a second container.
- Replace the feeding tubes according to the manufacturer's recommendations (or agency policy if that is sooner).

Bankhead, R., Boullata, J., Brantley, S., et al. (2009).

Clinical Insight 27-10 ➤ Monitoring and Other Interventions for Patients Receiving Parenteral Nutrition

Monitoring

For patients receiving PN, you will need to monitor the following:

Catheter Insertion Site

- Assess catheter insertion site for swelling, redness, drainage, or tenderness (signs of infection (and/or phlebitis in PICC lines).
  The hypertonic PN creates a risk for phlebitis.
- Observe for swelling in the extremity on the same side of catheter insertion (sign of infiltration or phlebitis).
- Observe for catheter retraction from the vein; observe the length of the catheter from the insertion site to the hub at insertion and periodically.

Supplies and Equipment

- Monitor tubing connections to see that they are secure.
- Monitor to see that the dressing is secure and dry.
- Check the rate and amount infused at least hourly, to ensure the line is patent, the PN is flowing freely, and the pump is functioning properly.

Weight

- Regularly weigh the patient (according to medical order or agency policy, but commonly daily or 3 times per week).
  (1) Frequent weight checks allow for assessing the adequacy of the formula and making adjustments as needed to achieve the desired goal. (2) Because of the hypertonicity of the solutions, fluid overload can occur. Rapid weight increase is an indicator.

Glucose

Check blood glucose every 4 to 6 hours until stable, and then at least daily.

The high proportion of glucose in the formulas can cause hyperglycemia, the most common complication of PN. You may need to administer regular insulin according to a sliding scale (or the pharmacist may add it directly to the PN solution). The risk for hyperglycemia is less with 3:1 PN solutions.

Fluids

Monitor intake and output. Diuresis and dehydration can occur if hypertonic dextrose is infused too rapidly.

Lab Values

Patients receiving PN require regular lab studies (the following are examples and not a comprehensive list). The frequency of the studies depends on the patient's condition.

- Electrolytes, blood sugar, albumin, BUN, and creatinine (used for formula adjustment and to evaluate electrolyte balance and glucose metabolism).
- Albumin, transferrin, transthyretin (prealbumin), or retinol-binding protein (used to assess visceral protein status).
- 24-hour urine for urine urea nitrogen (weekly), to evaluate nitrogen balance.
- Complete blood count (CBC) and differential (to monitor changes in immune function).
- Liver function studies
- Serum zinc
- Plasma urea
- Plasma and urine osmolality
- Blood gases

Symptoms of Complications:

- *Electrolyte imbalances*. Symptoms depend on the electrolytes affected. Monitor lab values.
- *Sepsis*. Temperature greater than 100°F (37.8°C) orally, rapid pulse from baseline, chills, hypothermia, edema or erythema of skin, exudate from catheter insertion site, malaise, leukocytosis (increased white blood cell count), altered level of consciousness.
- *Air embolus*. Cyanosis, tachypnea, hypotension, heart murmur
- *Catheter dislodgement or thrombosis*. Swelling of arm or neck, pain, difficulty flushing catheter, difficulty infusing PN

Nutritional Status

- Calculate the daily calorie intake.
- Perform nutritional assessment at 2-week intervals.
- Possibly measure arm circumference and triceps skinfold thickness.
- Monitor serum albumin levels.
- Most agencies have specialized nutrition teams who will monitor these parameters.

Maintenance

- Change the dressing over the catheter every 24 hrs or according to agency policy; or when it becomes wet, soiled, or nonocclusive. Use sterile technique.
- Secure connections with luer-lock connectors; do not use tape.
- Change the filter every 24 hrs.
- Do not hang PN bottles for more than 12 hr (some guidelines and agency policies specify 24 hrs).
  Its high nutrient concentration makes PN solution ideal for bacterial growth.
- Use sterile aseptic technique when changing the dressing for a central line, as well as when changing the solution and tubing.
- Do not use the PN infusion line for administering any other medicines or solutions.
  To decrease the risk of contamination and infection.
- Infuse PN by pump with a reliable, audible alarm, to protect against "free flow."
- If an infusion falls behind schedule, do not increase the rate in an attempt to catch up. This can cause osmotic diuresis and dehydration.
- When PN is discontinued, it may be done gradually (perhaps over as many as 48 hours). To prevent a sudden drop in blood sugar.

SCREENING FOR NUTRITIONAL PROBLEMS

Clients who have risk factors for nutritional problems should be evaluated using one of the methods in this section: Subjective Global Assessment, Nutrition Screening Initiative (NSI), Nutrition Screening for Older Adults with Dementia, and Mini-Nutritional Assessment.

Focused Assessment

Subjective Global Assessment

Using the subjective global assessment (SGA) method, an experienced clinician examines the general medical history and physical examination to evaluate a client's nutritional status. There are six components pertinent to nutritional status:

1. *Weight history*—over previous 6 months
2. *Dietary history*—including a comparison of usual, recommended, and current intake, as well as changes in eating patterns over the past weeks or months
3. *Gastrointestinal symptoms history*—anorexia, nausea, vomiting, and diarrhea
4. *Energy level*—including activity level and functional abilities
5. *Existing disease*—evaluation of the metabolic demands of any disease states along with acute stressors that may alter those demands
6. *Physical examination data*—regarding loss of fat stores, muscle wasting, and the presence of edema and ascites

As a clinician, you would analyze these components to rate the client's nutritional status as normal, mild, moderate, or severe. The effectiveness of this method depends largely on the experience of the clinician (Bankhead, Boullata, Brantley, et al., 2009; Barone, Milosavljevic, & Gazibarich, 2003; Detsky, McLaughlin, Baker, et al., 1987). For a link to view this tool online and use with patients,

Go to Chapter 27, **Resources for Caregivers and Health Professionals, Subjective Global Assessment,** on Davis*Plus*.

Focused Assessment

Nutrition Screening Initiative (NSI), for Older Adults: Indications of Impaired Nutritional Status

Recognizing the importance of nutrition in our aging population, the American Academy of Family Physicians, the American Dietetic Association, and the National Council on Aging developed the Nutrition Screening Initiative (NSI) (1991). The NSI includes (1) a self-administered checklist to evaluate risk, (2) the Level I Screening Tool designed for health professionals, and (3) a Level II Screening Tool for use in healthcare facilities.

The NSI addresses nutritional concerns associated with chronic diseases that older adults frequently experience. The NSI requires collection and evaluation of data in four areas: clinical, dietary, body composition, and biochemical. In addition, it identifies indicators of impaired nutritional status (following).

MAJOR INDICATORS	MINOR INDICATORS	SYMPTOMS	PHYSICAL SIGNS	LAB VALUES
➤ Significant weight loss over time ➤ Significant high or low weight for height ➤ Significant change in functional status ➤ Significant and inappropriate food intake ➤ Significant reduction in mid-arm circumference ➤ Significant decrease in skinfold ➤ Osteoporosis or osteomalacia ➤ Folate or vitamin B deficiency	➤ Concurrent syndromes ➤ Alcoholism ➤ Cognitive impairment ➤ Chronic renal insufficiency ➤ Multiple concurrent medications ➤ Malabsorption syndromes	➤ Anorexia, nausea, or dysphagia ➤ Early satiety ➤ Changed bowel habits ➤ Fatigue or apathy ➤ Memory loss	➤ Poor oral or dental status ➤ Dehydration ➤ Poorly healing wounds ➤ Loss of subcutaneous fat or muscle mass ➤ Fluid retention	➤ Reduced levels of serum albumin, transferrin, or prealbumin ➤ Folate deficiency ➤ Iron deficiency ➤ Zinc deficiency ■ Reduced levels of ascorbic acid

(Continued)

Focused Assessment

Nutrition Screening Initiative (NSI), for Older Adults: Indications of Impaired Nutritional Status—cont'd

To learn more about the NSI and for tools to use for nutritional screening of older adults,

Go to Chapter 27, **Tables, Boxes, Figures: ESG Figure 27-4, Nutrition Screening Initiative (for older adults): Determine Your Nutritional Health,** on Davis*Plus*.

Nutrition Screening for Older Adults with Dementia

For a tool to use in assessing nutritional status for patients with dementia,

Go to **Try This, Issue D11.1: Eating and Feeding Issues in Older Adults with Dementia: Part I: Assessment,** at http://www.hartfordign.org/Resources/Try_This_Series/

Focused Assessment

Mini Nutritional Assessment

The Mini Nutritional Assessment (MNA) is a quick and easy method of identifying individuals with nutritional risk or with malnutrition. (See the accompanying figure.) This tool was developed primarily for use with older clients. It consists of two parts. The first part screens for nutritional risk. The second part is completed only if the individual is identified to be at risk. The final score, which tallies the scores of both parts, is the Malnutrition Indicator Score. Indications of malnutrition require multidisciplinary follow-up.

To see and use the MNA,

Go to Chapter 27, **Tables, Boxes, Figures: ESG Figure 27-6, Mini Nutritional Assessment (MNA),** on Davis*Plus*.

Literature related to the MNA is regularly updated. For more information,

Go to the Nestlé Nutrition Institute Web site, which is regularly updated, at www.mna-elderly.com

FOCUSED NUTRITIONAL ASSESSMENT

If you identify nutritional problems or risks using the screening tools, you should perform a more in-depth nutritional assessment, such as the following.

Focused Assessment

Focused Nutritional Assessment

Nutritional History

Item	*Components*
Demographic data	Name, date, age, sex, date of birth, address, occupation, workplace
Chief complaint	Client's subjective statement of health problem, including onset and duration
Present illness and current health	Detailed data about chief complaint as it relates to nutrition status
	Recent diet changes and reasons
	Recent weight loss or gain and over what period of time
	Usual body weight: 20% above or below desirable weight?
	Change in appetite
	Unusual stress/trauma (surgery, job, family)
	Medications, prescriptions
	Alcohol, nicotine, caffeine consumption
Health history	Previous illnesses, trauma, major dental problems, or issues that could interfere with ability to shop, prepare food, chew, or swallow
	Allergies (i.e., environmental, foods, drugs)

Focused Nutritional Assessment—cont'd

	Eating disorders
	Chronic disease or surgery that affects gastrointestinal tract
	Substance abuse
	Nutritional programs
	Depression
Family health history	Genetic/familial disorders that could affect nutritional status: cardiovascular or gastrointestinal disorders, Crohn's disease, diabetes, cancer, sickle cell anemia, allergies, celiac disease, other food intolerances, obesity
Dietary history	Current food intake pattern using one of the following methods: 24-hour–7-day recall, as appropriate; food frequency questionnaire; food record; and comparison to dietary guidelines and Dietary Reference Intakes (DRIs)
	Special dietary considerations, restrictions
	Fad diets
	Vitamin and mineral supplements
	Commercial dietary supplements
	Nonconventional dietary supplements
	Food preferences, dislikes
	Dietary influences from ethnic, cultural, or religious practices
	Counseling needs (based on food knowledge)
Medication history	Recent use of steroids, immunosuppressants, chemotherapy, anticonvulsants, or oral contraceptives
Socioeconomic factors	Adequate food storage, refrigeration, food preparation, payments:
	Supplemental Security Income (SSI), food stamps, Women, Infants, and Children (WIC) program
	Who shops for, prepares, and cooks food?
	Location/availability of retail food/grocery store or availability of transportation
Personal factors	Stress/coping mechanisms, self-concept, social supports
	Daily activity level and exercise regimen

Nutrition-Focused Physical Examination

Correlate the following physical examination findings with the dietary history, screening methods, anthropometric measurements, and laboratory results.

I. The General Survey

Assess vital signs, height, weight, and overall impressions.

- ***Overall appearance.*** Does the client look ill? Does he appear adequately nourished? You will want to investigate any hunches as you move through the physical exam.
- ***Temperature.*** An increase in temperature raises the client's metabolic rate and need for fluid, is a sign of infection, and may decrease the client's appetite.
- ***Blood pressure (BP) and heart rate*** are affected by fluid status. An elevated BP may be related to fluid volume excess; a low BP may be a sign of dehydration. Heart rate usually increases when fluid volume is low.
- ***Height and weight.*** Calculate the body mass index (BMI) on the basis of these measures:

BMI = weight in kilograms ÷ (height in meters)^2

Classification of Body Mass Index Values

Classification	*BMI (kg/m^2)*	*Risk of Comorbidities*
Underweight*	<18.5	Low
Normal weight	18.5–24.9	Average
Pre-obese	25.0–29.9	Mildly increased
Class I obesity	30.0–34.9	Moderate
Class II obesity	35.0–39.9	Severe
Class III obesity	≥40.0	Very severe

**Note:* In adults in long-term care settings or with serious illness, nutritional support should be implemented for those with a BMI less than 21. In this population a BMI of less than 21 is associated with increased mortality (American Medical Directors Association, 2010).

(Continued)

Focused Assessment

Focused Nutritional Assessment—cont'd

II. Integumentary System

- ***Skin turgor*** is an indicator of fluid status. Poor skin turgor may result from dehydration. Swelling may result from overhydration.
- ***Skin integrity*** reflects overall nutritional status. Poor wound healing may suggest inadequate intake of protein, vitamin C, or zinc. Patients with uncontrolled diabetes or severely restricted diets often experience slow-healing wounds, especially in the feet and legs.
- ***Areas of warmth or erythema.*** These are signs of inflammation or infection.
- ***Other nutrition-related skin changes*** include red, swollen skin lesions (due to niacin deficiency); excessive bleeding seen as petechiae or ecchymosis (due to vitamin K or C deficiency); and xerosis (dry skin).
- ***Abnormal nail findings*** include spoon-shaped, brittle nails (due to iron deficiency); dull nails with transverse ridge (due to protein deficiency); pale, poor blanching, or mottled nails (due to vitamin A or C deficiency); bruising or bleeding beneath nails (due to protein or caloric deficiency); and splinter hemorrhages (due to vitamin C deficiency).
- ***Hair*** will grow slowly, thin, or break easily if protein is deficient.

III. The Head and Neck

The condition of the mouth, teeth, and gums has a major effect on a client's choice of food, ability to chew, and ability to swallow.

- ***Facial paralysis or drooping*** of one side of the face may be a result of stroke, injury, or nerve irritation, which also affects the ability to chew and swallow (dysphagia).
- ***Enlarged thyroid gland.*** Look for swelling of the thyroid, which may be related to hypothyroid or hyperthyroid states. Both disorders affect metabolic rate and energy requirements.
- ***Eyes.*** Nutritional deficits may cause the eyes to be red and dry and the conjunctiva pale.
- ***Lips and tongue.*** The lips may be chapped, red, or swollen. The tongue may be bright red, purple, or swollen or may have longitudinal furrows.
- ***Teeth and gums.*** Look for cavities, mottled or missing teeth, and spongy, bleeding, or receding gums.
- ***Lymph nodes.*** Palpate for enlarged or tender lymph nodes under the chin and along the neck. Nodes that are swollen can signal infection, such as a sore throat.

IV. Cardiovascular System

You will have gained initial information about the cardiovascular system by taking the vital signs. As you follow up and listen to the heart and check pulses, you should explore any abnormal vital signs.

- ***Bounding pulses*** are associated with fluid overload, fever, and hypertension.
- ***Weak, thready pulse*** may indicate dehydration, shock, or hypotension.
- ***Edema in the extremities*** may be a sign of fluid overload, inadequate protein stores, or electrolyte imbalance.

V. Abdominal Exam

- ***A scaphoid or concave abdomen*** indicates loss of subcutaneous fat, possibly caused by malnutrition.
- ***A round or protuberant abdomen*** points to obesity due to excess caloric and/or high fat intake.
- ***A generalized enlarged abdomen*** may signify **ascites** (fluid in the abdominal cavity) due to liver malfunction. Ascites results from three mechanisms: abnormal movement of protein and water into the abdomen; sodium and fluid retention; and decreased albumin production in the liver.
- ***Hyperactive bowel sounds*** are heard with gastrointestinal infection, laxative use, and malabsorption disorders.
- ***Hypoactive bowel sounds*** suggest sluggish motility in the GI tract.

VI. Musculoskeletal System

- ***Thin extremities with excess skinfolds*** may indicate muscle atrophy and fat loss related to malnutrition, especially protein and calories. This may also occur as a result of prolonged bed rest and inadequate food intake. Skinfold measurement is also useful in assessing muscle and fat stores.
- Look for any obvious ***swelling, deformities, or limitation in range of motion*** of the joints.
- ***Kyphosis*** of the spine may indicate osteoporosis and possible insufficient calcium intake.
- ***Joint pain*** on palpation or with movement is a sign of arthritis or gout. Arthritis may affect ability to shop for groceries, prepare food to eat, and use utensils for eating and drinking. Gout is often induced by diets high in **purines** (food substances that break down into uric acid), obesity, and excess alcohol intake.

Focused Assessment

Focused Nutritional Assessment—cont'd

VII. Neurological System

The neurological examination will give you insight into the client's ability to perform independent tasks.

- Look for ***altered level of consciousness or signs of behavioral disturbances and dementia*** through general conversation and appropriateness of answers to specific questions.
- Assess ***coordination and reflexes***.
- Assess for ***cognitive deficits or severe psychiatric disorders***. A client with cognitive deficits or severe psychiatric disorders may have difficulty preparing food or judging appropriate nutrient choices.
- Assess for ***motor or sensory deficits***. Clients with motor or sensory deficits may be unable to purchase, prepare, or eat a variety of foods.
- ***Confusion, weakness, diminished reflexes, paresthesia, and sensory loss*** may be cues to vitamin B deficiencies.
- ***Tetany or severe and generalized muscle spasm*** may indicate calcium or magnesium deficits.

VIII. What Are the Signs of Severe Malnutrition?

Malnutrition is a condition of impaired development or function caused by a long-term deficiency, excess, or imbalance in energy and/or nutrient intake.

- Symptoms of undernutrition due to insufficient food include reduced physical activity, weight loss, and reduced height.
- Children, older adults, and people with chronic illnesses such as cancer, HIV infection, and chronic obstructive pulmonary disease (COPD) are most likely to experience malnutrition. Malnutrition can occur with obesity.
- To assess for malnutrition in children, compare weight, height, and head circumference to the standards (norms) for the child's age.
- Other indicators in children include the presence of iron-deficiency anemia.
- In adolescents, look for a delay of stages of sexual maturation.

DIAGNOSTIC TESTING

Diagnostic Testing

Tests Reflecting Nutritional Status: Norms

Note: Norms are for adults (ages 19 to 65) unless otherwise noted.

Blood glucose	70 mg/dL to 100 mg/dL. Capillary blood sugar is frequently assessed at the bedside with a simple fingerstick. Serum blood glucose levels are assessed by drawing a venous blood sample. The level is measured in the laboratory.
	The American Diabetes Association (2011) recommends for diabetic patients a preprandial plasma glucose level of 70 to 130 mg/dL.
Serum albumin	3.4–4.8 g/dL
Prealbumin	12–42 mg/dL (age 6 years–adult)
Globulin	2.3–3.4 g/dL
Blood urea nitrogen (BUN)	5–18 mg/dL (children)
	8–21 mg/dL (age 14–adult); 10–31 mg/dL (adult older than 90)
Creatinine	0.5–1 mg/dL (female)
	0.6–1.2 mg/dL (male)
Hemoglobin	13.2–17.3 g/dL (male)
	11.7–15.5 g/dL (female)
	12.6–17.4 g/dL (male, older adult)
	11.7–16.1 g/dL (female, older adult)

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mrs. O is a 75-year-old retired schoolteacher who suffered a stroke 8 months ago. Since leaving the hospital, she has been living in a nursing home. Mrs. O has residual weakness on the right side—her dominant side—and has not mastered the use of tableware with her left hand. On admission to the nursing home 7 months ago, she weighed 150 pounds. Today she weighs only 125 pounds. Mrs. O refuses to go to the dining room for meals. The NAPs report that she eats a few bites of most foods, but never eats more than half of anything.

THINKING

1. *Theoretical Knowledge:*
   a. Based on Mrs. O's gender, age, and activity level, make a rough estimate of the number of kcal/day she needs.
   b. What are two other, more precise, ways you could determine Mrs. O's ideal body weight?
2. *Critical Thinking (Considering Alternatives):* What are some possible explanations for why Mrs. O is not eating all her food?

DOING

3. *Practical Knowledge:*
   a. Suppose you have decided to use the general ideal weight guide to determine Mrs. O's ideal weight. What, specifically, would you need to do? You do not need to actually calculate; just list the action steps.
   b. Suppose you have decided to determine Mrs. O's body mass index (BMI). What equipment would you need?
   c. What is the formula for calculating BMI from the height and weight?
4. *Nursing Process (Diagnosis):* Write a nursing diagnosis for Mrs. O. Use just the data provided in the situation. Assume her BMI is 20.

CARING

5. *Self-Knowledge:* What would you be feeling if you were in Mrs. O's situation?
6. *Ethical Knowledge:* What are one or two things you would do to help Mrs. O feel cared for and cared about?

Critical Thinking and Clinical Reasoning

1. Recall the employees (Isaac Schwartz and Sujing Lee) interviewed in the Meet Your Patient scenario in Volume 1. In addition, you now have two more patients, Wakenda Pierre and Luceno Jarin. Their information is provided below.
   - Isaac Schwartz, a 65-year-old accountant, works long hours. He describes a sedentary lifestyle, no tobacco use, infrequent alcohol use, no medical problems, and a nutritional history of skipping meals and daily consumption of restaurant food. You measure his height as 69 in. and weight as 245 lb.
   - Sujing Lee, a 29-year-old project manager, regularly works 65 hours per week. Sujing is 30 weeks pregnant. She does not smoke or drink and has never been hospitalized or had surgery. She has gained a total of 25 lb since becoming pregnant. Her diet consists mainly of traditional Chinese food. She eats three meals a day and always brings lunch from home. Lately she has felt "tired all the time." At the screening, she weighs 126 lb and measures 63 in. tall.
   - Wakenda Pierre is a 38-year-old administrative assistant. She exercises at the gym 4 to 5 days per week, smokes an occasional cigarette, has two to three drinks every night before dinner, struggles with keeping her blood pressure under control, and eats fast food for breakfast and lunch every day. She is 72 in. tall and weighs 165 lb.
   - Luceno Jarin is a 65-year-old business executive. He tells you he was diagnosed with type 2 diabetes mellitus 5 years ago. He is struggling to follow his prescribed diet. He drinks alcohol sporadically and walks briskly 30 minutes every day of the week. He is 67 in. tall and weighs 205 lb.

   a. Determine each client's BMI. Based on these results, what conclusions can you make about their weight status?

b. What are the likely causes of each person's weight status?
c. What additional work-up would be recommended for each individual?
d. What indications would lead you to believe that each client has adopted a healthier lifestyle?

2. The following are three clients admitted to the medical-surgical unit of your local hospital. On their admission, the primary nurse collected the following information.

	CLIENT 1	CLIENT 2	CLIENT 3
Weight	175 lb	100 lb	250 lb
Height	70 in.	59 in.	65 in.
Gender/Age	Male/40 years old	Female/18 years old	Male/65 years old
Usual Daily Caloric Intake	2,500 kcal	1,000 kcal	2,500 kcal
Usual Activity Level	Moderate	High	Light
Serum Albumin	Normal	Low	Normal
Serum Glucose	Normal	Low	High

a. Identify which client(s) is/are at risk for nutritional imbalance.
b. Which client is at risk for developing malnutrition?
c. What additional information would support this conclusion?
d. What nursing interventions would you initiate at this time?

3. After 3 days, you examine how well each of these clients is doing using the same parameters as admission day.

	CLIENT 1	CLIENT 2	CLIENT 3
Weight	170 lb	103 lb	250 lb
Current Daily Caloric Intake	2,500 kcal	1,500 kcal	1,500 kcal
Intake (mL)	2,000	2,000	1,000
Output (mL)	1,800	1,900	500
Current Activity Level	Up as tolerated	Up as tolerated	Bedrest
Serum Albumin	Normal	Low	Normal
Serum Glucose	Normal	Low	High

a. In comparison with the admission data, there are some changes. Which client's health status is a priority now, and why?
b. What is/are the most likely cause(s) of this concern?
c. Which nursing interventions should be initiated for this client while hospitalized? Focus on nutritional needs.
d. Identify appropriate education that should begin during hospitalization for this client.

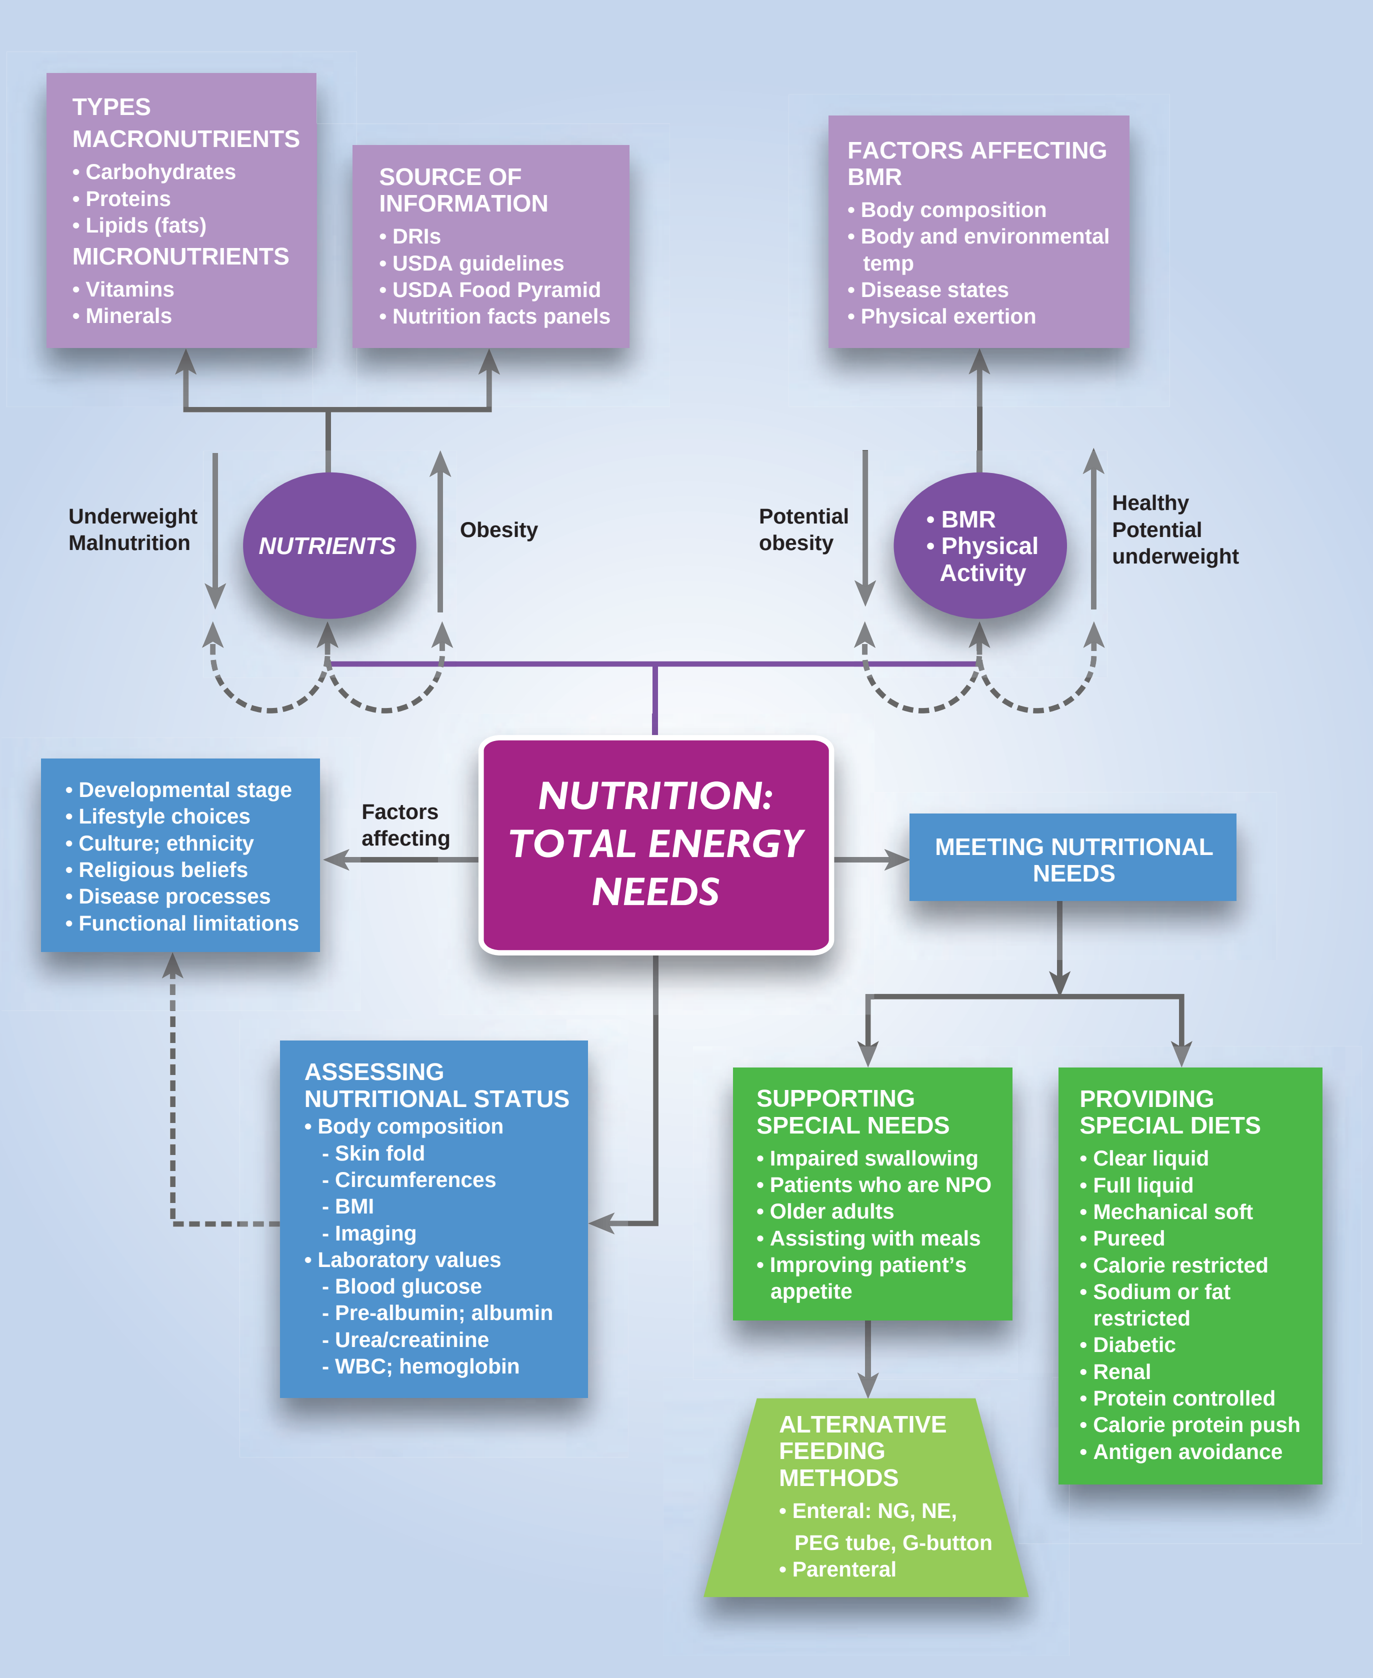
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or nutrition. Note that these are *not* to be merely definitions.

Energy balance
Body mass index
Weight management
Body weight standards
Parenteral nutrition
Nutritional screening
Basal metabolic rate
Nutrients
Nutritional history
Enteral feedings
Special diets

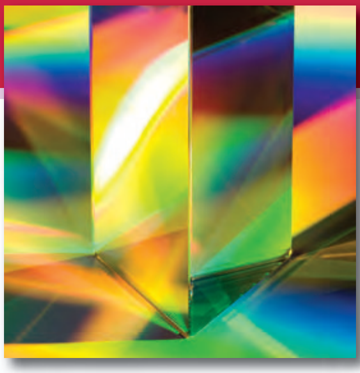
What Are the Main Points in This Chapter?

- Reliable guidelines for designing a nutritious diet include the Dietary Reference Intakes (DRIs), the USDA Dietary Guidelines, and the nutrition facts panel found on packaged foods in the United States.
- ChooseMyPlate is a food guide that illustrates healthful dietary choices. It stresses six concepts for healthy eating: activity, moderation, personalization, proportionality, variety, and gradual improvement.
- Energy nutrients are carbohydrates, proteins, and fats (lipids). Other important nutrients are water and the micronutrients: fat-soluble vitamins, water-soluble vitamins, and minerals.
- Carbohydrates include simple sugars called monosaccharides and disaccharides and complex carbohydrates called polysaccharides.
- Glucose, a monosaccharide, is the primary source of energy for the brain, as well as for the body during moderate-to-intense physical activity.
- Proteins are made up of amino acids and are required for cell and tissue growth, maintenance, and repair. They also act as buffers in acid–base balance. Proteins are an energy source.
- Lipids, including fats and oils, are classified as glycerides, sterols, and phospholipids. They are essential components of cells, fuel the body at rest and during light activity, aid in absorption of fat-soluble vitamins, and promote a sense of satiety when eaten. Low-density lipoproteins (LDLs) are the "bad" cholesterol. High-density lipoproteins (HDLs) are the "good" cholesterol.
- Saturated fats and *trans*-fats are less healthful lipid choices than mono- and polyunsaturated fats. Saturated fats and *trans*-fats raise LDL cholesterol levels in the blood.
- The essential fatty acids omega-6 and omega-3 help protect against heart disease when they replace *trans*-fats in the diet. They are found mainly in vegetable oils, nuts, seeds, and fatty fish.
- Nutrients must be consumed at least at a minimal level in order to meet the body's physiological needs. This level is called Dietary Reference Intake (DRI).
- The fat-soluble vitamins are A, D, E, and K. Water-soluble vitamins are C and the B-complex vitamins.
- Minerals (e.g., calcium, iron, magnesium) are important for transmitting nerve impulses, regulating fluid balance, strengthening bones, and producing energy.
- The basal metabolic rate (BMR) is a measure of the energy required by resting tissue to maintain basic function.
- Factors influencing a client's nutritional status include developmental stage, pregnancy and lactation, education, lifestyle choices, vegetarianism, dieting for weight loss, culture, religion, disease processes, functional limitations, economic factors, and modified or special diets.
- Many people must follow a modified diet to assist in managing their illness. In addition, all inpatients must have a diet prescribed by their primary care provider.
- When examining an individual's nutritional balance, it is important to screen for nutritional problems. When risk factors are present, thoroughly assess nutritional history, physical findings, anthropometric measurements, imaging techniques, and biochemical values.
- A food record is the most accurate method of obtaining data about a client's actual food intake.
- The body mass index (BMI), skinfold measurements, and body part circumferences are estimates of body composition.
- Laboratory or biochemical indicators of nutritional status include blood glucose and serum protein levels or indices such as albumin, urea, and hemoglobin.
- Vitamin and mineral supplementation may be appropriate for some people, but they do not replace the need for a balanced diet.
- Government programs provide some assistance for clients who cannot afford to buy food.
- Nutritional requirements of older adults are similar to those for all adults, with a slight reduction in the need for calories, and the more likely need for nutrient supplementation. nutritional problems are also similar, but the incidence is higher among older adults.
- Nurses can help support nutrition for patients who have Self-Care Deficits or Impaired Swallowing by assisting patients with meals and providing swallowing therapy.
- Nutritional imbalance can range from either inadequate or excessive amounts of a single nutrient relative to overall caloric intake.
- Obesity is a major problem in the United States, both in children and adults.
- Interventions for underweight/undernutrition include measures to improve the patient's appetite, assisting with meals, and providing enteral and parenteral nutrition.
- Nasogastric tubes are inserted to lavage the stomach; collect a specimen of the stomach contents, or prevent nausea, vomiting, and gastric distention. They are also placed to facilitate enteral feeding.
- The most accurate way to check enteral tube placement is by radiographic (x-ray) verification. To check enteral tube placement at the bedside, you could also use a combination of techniques: aspirate stomach contents to observe color and measure the pH (normally 1 to 5.5 for stomach contents); the "whoosh test"; serial observations for respiratory distress, residual volume, length of tube extending outside the body; and capnometry. Do not rely on a single technique.
- Potential complications associated with enteral feedings include aspiration, infection, diarrhea, and electrolyte imbalance.
- Meticulous sterile technique when administering parenteral nutrition is critical because the solution is delivered into a large central vein; if infection occurs, sepsis is almost immediate.

Knowledge Map



CHAPTER 28



Urinary Elimination

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 28:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Urinary Elimination (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 28, **Podcast—Chapter Overview**, on Davis*Plus*.

Caring for the Nguyens

At a recent visit to the Family Health Center, Nam and Yen Nguyen confide that Nam's mother, Mai Nguyen, has had several "accidents." She has denied the problem but Yen tells you that she helped her mother-in-law with laundry recently and many of the clothes smell of urine. They ask you how to approach Mai about this problem.

A. How would you respond?

B. What suggestions, if any, could you make to the Nguyens about treatment for Mai?

C. Yen says that she has been told that surgery is the best form of treatment. She asks you whether this is true. How would you answer her question?

PracticalKnowledge knowing how

This section provides procedures and clinical insights you will need to support your patients' urinary function. You will also find assessment guidelines, information about diagnostic tests of urinary function, and standardized nursing language tables.

PROCEDURES

Procedure 28-1 ■ Measuring Urine

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover. .

Equipment

- Bedpan or urinal
- Clean procedure gloves
- Graduated container
- Toilet paper, as indicated
- Washcloth or towel
- Hand sanitizer for patient's hands

Measuring Post-Void Residual Urine Volume With a Portable Bladder Scanner

- Portable bladder scanning device
- Ultrasound gel
- Clean gloves
- Tissues
- Antiseptic swabs or wipes

Delegation

Measuring urine, including post-void residual volume (PVR) using a portable bladder scanner, may be delegated to specially trained nursing assistive personnel (NAP) in some facilities. However, you must be sure that the NAP knows how to perform the procedure correctly, including proper cleansing of the bedpan/urinal and the graduated container according to the facility's policies. Also complete the following assessments and instruct the NAP when to stop the procedure and seek assistance from the nurse, and to report the results immediately. In some instances, you may choose to perform the bladder scan to ensure accuracy and expedite any necessary treatment.

Pre-Procedure Assessments

- Cognitive status

(continued on next page)

Procedure 28-1 ■ Measuring Urine (continued)

To determine whether the patient can be instructed to complete this procedure on her own and/or whether she can follow directions.

- Mobility status
  To determine whether the patient can be permitted to get out of the bed to use the toilet.
- Urinary status
  To determine the patient's ability to control bladder function.
- Post-void residual urine volume, ikkf needed.
  To determine the timing and amount of the last voiding.
  Note: A bladder scan should be done as soon as possible after voiding and within no more than 10 to 15 minutes.
- Palpate the bladder to assess for distention.

Procedure 28-1A ■ Measuring Urine Output From a Bedpan or Urinal

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Perform hand hygiene** and don clean procedure gloves.
   Prevents transmission of bacteria.
2. **Place a bedpan or urinal** in the appropriate position.
   See Procedure 29-2 for placing a patient on the bedpan.
3. **Remove the bedpan or urinal**, being careful not to spill the urine. Reposition the patient and transport the urine to the bathroom.
4. **Pour the urine into a graduated** cylinder or calibrated measuring container while still wearing procedure gloves.
   a. Be sure that the measuring device is labeled with the correct patient information (in many institutions, labels are preprinted or barcoded).
   b. Do not use a measuring device for more than one patient.
5. **Place the measuring device** on a flat surface (e.g., shelf, table that is not used for food or personal care products), if available, and read the amount at eye level.
   When looking at fluid level from an angle, the meniscus may appear falsely low or high. Urine collection containers are considered "dirty" and should not be near to "clean" personal items.
6. **Observe the urine for color,** clarity, and odor.
7. **Discard the urine in the toilet**. If a specimen is required, transfer 30 to 60 mL of urine to the designated container.
8. **Clean the measuring container** and store in the patient's bathroom.
9. **Remove gloves.** Perform hand hygiene.
10. **Record the time and volume** on the intake and output (I&O) record.

Procedure 28-1B ■ Measuring Urine From an Indwelling Catheter

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Wearing clean gloves**, place the drainage spout for the collection bag inside a calibrated measuring container. Avoid touching the spout to the inside of the container.
   Prevents transmission of bacteria.
2. **Unclamp the drainage spout**, and direct the flow of urine into the measuring device, still keeping the spout away from the sides of the container.
   Prevents contaminating the drainage spout. ➤

3. **Reclamp the spout** when the collection bag is empty.
4. **Wipe the drainage spout** with an alcohol pad or disinfecting wipe, and replace the spout into the slot on the collection bag.
   A clean spout reduces transmission of bacteria when the nurse touches it.
5. **Measure urine output** from the indwelling catheter at the end of each shift, or if the urine bag is getting full.

6. **Discard the urine in the toilet.**
7. **Remove gloves and wash your hands**.

Procedure 28-1C ■ Measuring Post-Void Residual Urine Volume With a Portable Bladder Scanner

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Perform hand hygiene** and apply clean gloves.
   Prevents transmission of bacteria.

2. **Assist the patient to a supine** position. Uncover only the patient's lower abdomen and suprapubic area.

3. **Clean the scanner head** with antiseptic wipes.
   Prevents transmission of microorganisms between patients.

4. **Turn the device on.**

5. **Select the patient's gender.** If a woman has had a hysterectomy, follow manufacturer's directions for gender selection. In some cases, you will select the MALE icon for a woman who has undergone hysterectomy.
   The device is calibrated to adjust for uterus and bladder anatomy.

6. **Palpate the symphysis pubis** and then apply an ample quantity of warmed, ultrasound gel midline on the abdomen, approximately 2.5 to 4 cm (1 to 1.5 in.) above the symphysis pubis.
   The gel ensures proper transmission of the ultrasound. Warm gel is more comfortable for the patient.

7. **Position the scanner head** in the **gel** and aim it towards the bladder, pointing slightly downward toward the patient's coccyx.
   Proper placement allows for an accurate reading.

8. **Press and release the SCAN** button. Hold the scanner head steady until the scan is finished.
   An audible tone indicates the scan is complete.

9. **Read the bladder volume** measurement. Repeat the scan several times to ensure accuracy. *Note: Some scanners will also display an image of the bladder. The bladder image should be centered on the crossbars. If it is not, reposition the scanner head and repeat the scan.*
   Taking several readings ensures maximum accuracy.

10. **Press DONE when finished.** Print the results by pressing PRINT.
    A printout provides for accurate documentation and may, in some facilities, be added to the patient record.

11. **Wipe the gel from** the patient's skin with tissue, cover the patient, and return the patient to a comfortable position.

12. **Clean the scanner head** with antiseptic. Remove gloves and perform hand hygiene.

? What if . . .

- **The provider orders hourly monitoring of the patient's urine output?**
  You will need to obtain a special collection bag with a small measuring chamber; document urine output on the I&O record every hour. Be sure that the cylinder does not overflow in the hour. Check the collection bag more frequently if the input is increased or if the patient has diuretic.

Evaluation

- Note any unusual characteristics of the urine (e.g., color, odor, presence of sediment or mucus).
- Note any difficulties with urination (e.g., pain, dribbling, difficulty beginning urination).
- Continue to assess that drainage from the indwelling catheter is not obstructed and that the drainage bag is below the level of the bladder.
- Assess for bladder distention.
  Bladder distention indicates poor bladder emptying. Utilize the bladder scanner to quantify the volume of urine in the bladder. A normal post-void residual volume is less than 50 to 100 mL.

Patient Teaching

Instruct the patient and/or primary caregiver to document fluid intake and urine output on the I&O record.

Home Care

Teach the client and/or the primary caregiver how to collect and measure urine, and how to document fluid intake and urine output on the I&O record.

(continued on next page)

Procedure 28-1 ■ Measuring Urine (continued)

Documentation

- Document urine volume and record the time and date the specimen was collected, per agency policy (e.g., in the nurse's notes or a patient graphic flow sheet, depending on the agency).
- Document the characteristics of the urine, including color, odor, particulate matter, blood, and clarity.
- Document any difficulty with voiding, including pain or burning with urination, frequency, or difficulty starting the urine flow.
- For PVR, document the time and amount of the last void prior to the scan and the amount of residual urine. Follow agency policy related to attaching a printout of the bladder scan to the patient record.

Sample documentation

12/15/16 1500 Voided 75 mL of clear, yellow urine with no odor, blood, or mucus. Pt states that he still feels full. Bladder palpated just above level of symphysis pubis. Bladder scan performed—350 mL of residual urine in bladder. Dr. Roy contacted and straight catheterization prescribed.
—S. Tran, RN

Thinking About the Procedures

To practice applying clinical reasoning to these procedures,

Go to *Davis's Nursing Skills Videos,* **Measuring Urine Output from a Bedpan or Urinal, Measuring Urine from an Indwelling Catheter,** and **Measuring Post-Void Residual Urine Volume With a Portable Bladder Scanner.**

For questions and suggested responses,

Go to Chapter 28, Thinking About the Procedure Questions and Suggested Responses, on DavisPlus.

Procedure 28-2 ■ Obtaining a Urine Specimen for Testing

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

Collecting a Clean-Catch Urine Specimen

- Prepackaged collection kit
- If no kit is available:
  - Sterile specimen container
  - Antiseptic solution
  - Sterile cotton balls or 2 in. × 2 in. gauze pads
- Washcloth and towel, or perineal wipes
- Perineal wash solution
- Two pairs of clean procedure gloves
- Patient identification labels
- Bedpan or bedside commode for an immobile patient

Obtaining a Sterile Urine Specimen From a Catheter

- Clean gloves
- Antiseptic swab or wipe
- Sterile specimen container with a lid
- Patient identification label
- Sterile 5–10-mL syringe with a 21- to 25-gauge needleless access device

Collecting a 24-Hour Urine Specimen

Note: Some tests require using a double-storage container. Be sure to find out if you need a double-storage container and preservative, and if there are special instructions for collection of the sample.

- Basin and ice, possibly. Check with the laboratory to determine whether the specimen needs to be kept in a basin of ice during the 24-hour collection.
- Large collection container

Delegation

This procedure may be delegated to the NAP but you must be sure she knows how to perform the procedure correctly, including proper cleansing and maintaining sterility of the container. You must complete the following assessments and instruct the NAP to report any abnormalities seen in the urine (e.g., blood, foul odor, mucus) or any patient complaints of dysuria. Instruct the NAP to bring the specimen to you for inspection.

Pre-Procedure Assessment

- Cognitive status
  Knowing whether the patient can follow directions or not helps you to determine whether the patient learn to complete this procedure on her own.
- Mobility status
  Helps you to determine where the specimen will be collected (e.g., bed, commode, bedpan).
- Urinary status
  Patients with impaired ability to control urinary flow may not be able to collect a specimen in this manner.

Procedure 28-2A ■ Collecting a Clean-Catch Urine Specimen

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don procedure gloves.** Cleanse, or instruct the patient to cleanse, around the urinary meatus. Allow the area to dry.
   Cleansing prevents contamination of the specimen with surface bacteria.

2. **Remove soiled gloves**, perform hand hygiene, and don clean procedure gloves.

3. **Open the prepackaged kit** (if available), and remove the contents. Open the sterile specimen cup, being careful not to touch the inside of the lid or container and place within easy reach. Make sure to place the lid with the inside surface facing upward.

Variation for Women

a. Open the antiseptic towelette provided in the prepackaged kit. If there is no kit, pour the antiseptic solution over the cotton balls.

b. To cleanse the perineum, spread the labia, wipe down one side of the meatus using one pad, and discard it. Then wipe the other side with a second pad. Wipe down the center over the urinary meatus with the third pad; then discard it. Use each towelette or cotton ball only once. Maintain separation of the labia until the specimen is obtained.
   Following the "clean to dirty" principle decreases the likelihood of contamination of the specimen and the urethra with feces. Antiseptic helps reduce the number of bacteria.

Variation for Men

c. If the penis is uncircumcised, retract the foreskin back from the end of the penis.
   Allows for better access when cleansing the area around the meatus.

d. Use the towelette provided in the prepackaged kit or pour antiseptic solution over cotton balls. You might also use 2 in. × 2 in. gauze pad soaked with povidone-iodine to cleanse the periurethral area.

   Before using an iodine-based solution, be sure to check the patient's health history for allergy to iodine.

e. With one hand, grasp the penis gently. With the other hand, cleanse the meatus in a circular motion from the meatus outward, and cleanse for a few inches down the shaft of the penis. Repeat this cleansing two more times, using each towelette or cotton ball only once.
   Cleansing the site helps in this manner prevent contaminating the specimen with bacteria.

f. Keep one hand in place to retract the foreskin (if uncircumcised); or to hold the penis (for a patient who is unable to assist).

4. **Pick up the sterile specimen container** and hold it near the meatus. Instruct the patient to begin voiding.

5. **Allow a small stream of urine to pass**, and then without stopping the urine stream, place the specimen container into the stream, collecting approximately 30 to 60 mL. Check with the agency lab for specific advice as to how much urine to collect.
   Midstream urine collection prevents specimen contamination.

6. **Remove the container from the stream**, and allow the patient to finish emptying the bladder.
   Note: For men, if the penis is uncircumcised, replace the foreskin over the glans when the procedure is finished.

7. **Carefully replace the container lid**, touching only the outside of the cap and container. Avoid touching the rim of the cup to the genital area. Do not get toilet paper, feces, pubic hair, menstrual blood, or anything else in the urine sample.
   These measures maintain sterility of specimen and prevent cross-contamination.

8. **Label the container** with the correct patient information (in many institutions, labels are preprinted or barcoded). Place the container in a facility-specific carrier (usually a plastic bag) for transport to the lab.

9. **Remove your gloves and** perform hand hygiene.

10. **Assist the patient back to bed**, if applicable.

11. **Transport the specimen** to the lab in a timely manner.
   Delayed testing can cause inaccurate results (e.g., casts in the urine will break up if urine is allowed to sit for an extended period of time).

(continued on next page)

Procedure 28-2 ■ Obtaining a Urine Specimen for Testing (continued)

Procedure 28-2B ■ Obtaining a Sterile Urine Specimen From a Catheter

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don procedure gloves** and empty the drainage tube of urine into the collection bag.
2. **Clamp the drainage tube** below the level of the specimen port for 15 to 30 minutes to allow a fresh sample to collect. If the client's urine is flowing briskly, you may not need to clamp the catheter.
3. **Replace contaminated gloves** with a sterile pair, before scrubbing the specimen port with an antiseptic swab or wipe.
   Aseptic technique is used to obtain a catheter sample of urine (Loveday, Pratt, Wilson, et al., 2014)
4. **Insert the needleless access device** with a 10-mL syringe into the specimen port, and aspirate to withdraw the amount of urine you need. ➤

5. **Once you have the sample,** transfer the specimen into a sterile specimen container.
6. **Discard the needleless access device** and syringe in a safe container.
7. **Tightly cap** the specimen container.
8. **Remove the clamp** from the catheter. Remove gloves and disinfect the hands.

   Be sure to unclamp the tubing of the urinary collection bag after you obtain the sample.

   Urine backflow can cause bladder distention and lead to stasis-induced urinary tract infection.

9. **Label and package the specimen** with the correct patient identification according to agency policy.
   To avoid a wrong-patient error.
10. **Transport the specimen to the lab.** If immediate transport is not possible, refrigerate the sample per agency policy.

    Never disconnect the catheter from the drainage tube to obtain a sample. Interrupting the system creates a portal of entry for pathogens, thereby increasing the risk of contamination.

Procedure 28-2C ■ Collecting a 24-Hour Urine Specimen

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Use a large collection container** (usually supplied by the lab), and collect all urine voided in the 24-hour period. If you need to use more than one container during the 24-hour period, use one container at a time. When it is full, collect the urine in the next container. Occasionally you will be asked to collect each voiding in a separate container.
2. **To begin collection,** have the patient void, and record the time. *Note: Discard this first voiding.*
   This marks the beginning of urine collection period.
3. **Collect all urine voided** during the next 24 hours. Just before the collection period ends, ask the patient to void again and add this last specimen to the collection container.
4. **Inform the patient and all staff** about the collection.
   Communication can help to prevent accidental discarding of urine.
5. **Post signs in prominent** locations, such as the patient's bathroom or entry door, to remind staff of the ongoing collection.
   Key Point: ***It is essential that none of the urine voided during the 24-hour period is accidentally discarded.***
6. **Apply a label on the specimen,** with the patient's name, date, and time the test ended on the storage container. Transport it to the lab in a timely lab, following agency protocol.

? What if . . .

- **A urine culture is ordered on the specimen?**

  Be sure to list current antibiotic therapy on the laboratory request form.
  This information is important to determine sensitivity of the microorganisms.

- **A clean-catch urine sample is needed for an immobile patient?**

  For the patient using a bedpan, raise the head of the bed to a semi-Fowler's position.
  Facilitates correct direction of urine flow down into the specimen container you are holding. In addition, this is the anatomical position for voiding.

- **You need to collect a urine sample from an infant?**

  1. Remove the paper covering adhesive patches on the back side of the specimen bag before applying it to the clean and dry perineal area. Start at the narrow area between the anus and vaginal or scrotal area. Press the adhesive sides firmly

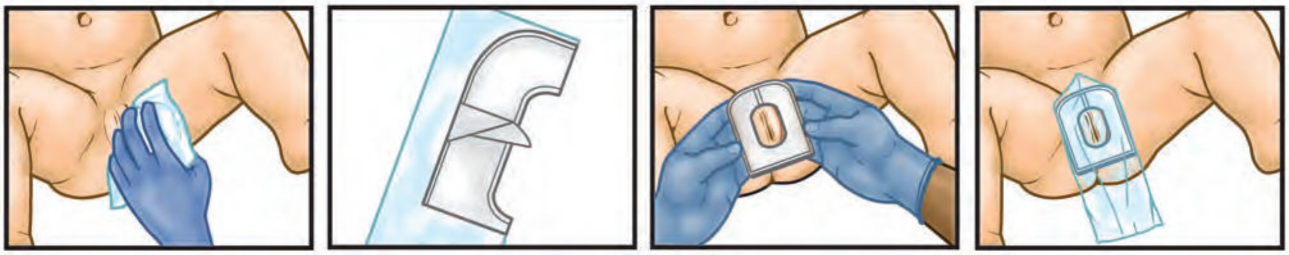
against the skin while avoiding wrinkles in the skin against the patch.

2. It is easier to apply the lower portion of the bag first. The area must also be dry in order for the adhesive to stick to the skin. Since infants urinate frequently, it is best to work quickly to catch the specimen. Work upward to secure the bag around the entire genital area.

3. After the specimen bag is has been applied, put a diaper on the infant/child. Remember to check the collection bag every 15 to 30 minutes to see if there is a specimen. If the infant has not urinated in 2 to 3 hours, discard the bag, re-cleanse the area, and apply a new bag.

It is possible there was a leak in the seal between the skin and the adhesive sides of the specimen collection bag.

4. Once a specimen is obtained in the bag, remove it gently and pour the urine into a sterile specimen cup. Label it with the patient identifying information.



Evaluation

- Note any unusual characteristics of the urine (e.g., color, odor, clarity, crystals, blood, mucus).
- Note any difficulties with urination (e.g., pain, burning, dribbling, difficulty beginning).

Patient Teaching

- For clean-catch specimens, teach the patient the steps of the procedure, focusing on how to maintain sterility of the specimen. Explain that prepackaged antiseptic wipes cannot be flushed down the toilet.
- For the 24-hour urine specimen, explain the procedure to the patient, emphasizing the need to collect all urine during the 24-hour period. If the procedure is to be completed at home, tell the patient to refrigerate the urine specimen for up to 24 hours until it can be transported to the lab. Instruct the patient to place the specimen in a plastic bag, separate it from food items, and label it appropriately.
- For clean-catch and 24-hour urine specimens, instruct a menstruating woman that perineal cleansing is especially important. The woman may use a tampon to prevent leakage during specimen collection. Instruct her to notify the lab that she is menstruating.

Documentation

- Document urine volume in the patient record, per agency protocol, and the time and date that the specimen was collected.
  Some facilities use the Kardex to indicate the urine collection is either needed, in progress, or completed. Other facilities have nurses chart specimen collection in the nursing notes or electronic health records.
- Document the characteristics of the urine: color, odor, particulate matter, blood, clarity, or other qualities.
- Document any difficulty with voiding, including pain or burning with urination, frequency, or difficulty starting the urine flow.

Sample documentation

mm/dd/yyyy 0800 *Order noted for clean-catch urine specimen. Explained to client the procedure for cleaning and obtaining urine specimen. Client stated "I must clean my bottom from front to back using the toilet in here. Then begin to void and stop voiding. Then void directly into this container." Assisted client to bedside commode. 100 mL of clear yellow urine without foul odor, blood, or particles collected. Pt. denies difficulty voiding, pain, and burning. Urine container labeled per protocol and sent to laboratory.* — L. Schaaf, RN

mm/dd/yyyy 1000 *Order noted for sterile urine specimen. Foley catheter clamped for 15 minutes. Port on Foley cleansed with antiseptic agent. 30 mL of pink tinged-urine without foul odor or sediment removed. Specimen labeled per protocol and sent to laboratory.* — L. Schaaf, RN

mm/dd/yyyy 1200 *Order noted for 24-hour urine collection. Explained procedure to client. Client stated, "I will call you when I void. This first void will be flushed and the test will begin. During the test, I will void in the white hat that is in the commode. Then every time that I void, I will call you to empty the urine into the big container. The big container for the urine must be kept cold with ice."* — L. Schaaf, RN

(continued on next page)

Procedure 28-2 ■ Obtaining a Urine Specimen for Testing (continued)

Practice Resources

Loveday, Pratt, Wilson, R.A., et al. (2014); St. Jude Children's Research Hospital (2004a, 2004b); Van Leeuwen, A. M., Poelhuis-Leth, D., & Bladh, M. L. (2011).

Thinking About the Procedure

To practice applying clinical reasoning to Procedure 28-2B,

Go to *Davis's Nursing Skills Videos*, **Obtaining a Sterile Urine Specimen from a Catheter.**

For questions and suggested responses,

Go to Chapter 28, Thinking About the Procedure Questions and Suggested Responses, on Davis*Plus*.

Procedure 28-3 ■ Testing Urine at the Bedside

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

Dipstick Testing

- Procedure gloves
- Dipstick testing kit

Refractometer Testing

- Refractometer
- Procedure gloves
- Distilled water
- Dropper
- Small urine sample

Delegation

You may delegate bedside urine testing to the NAP if you know that he has the knowledge and skill to perform the procedure. Ask the NAP to report the test results to you and to save the urine sample in case you should need to repeat the test.

Pre-Procedure Assessment

- Mobility status
  Knowing whether the patient can get out of bed or not helps you to determine where the specimen will be collected (e.g., toilet, bedside commode, bedpan).
- Urinary status
  Knowing whether the patient has an indwelling urinary catheter or not helps you to determine how the specimen will be collected.

Procedure 28-3A ■ Dipstick Testing of Urine

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Read the instructions** and check the expiration date on the diagnostic kit.
2. **Wash your hands and** don procedure gloves.
   Hand hygiene and gloving prevents the transmission of bacteria.
3. **Have the patient void** into the collection container or obtain urine from the indwelling urinary catheter. See Procedures 28-1A and 28-1B for measuring urine.
4. **Obtain a test strip from the kit**, dip it into the urine, and begin timing. Follow the manufacturer's directions regarding the time needed for the reagent to develop.
5. **Compare the results to the color** chart at the specified time; record the findings. You will need good lighting to evaluate the results.

Procedure 28-3B ■ Measuring Specific Gravity of Urine

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Clean the equipment lens** with distilled water and dry with a soft, nonabrasive cloth.
   To ensure accurate results.
2. **Calibrate the refractometer** before use, following the manufacturer's instructions. When calibrated, the refractometer should read 1.000.
3. **Perform hand hygiene** and don clean procedure gloves.
   Hand hygiene and gloving prevent the transmission of bacteria.
4. **Use fresh urine**; if you cannot perform the test within 1 hour, refrigerate the specimen.
5. **Wearing procedure gloves,** use the dropper to place one or two drops of urine on the prism surface (at the notched bottom of the cover).

6. **Hold the refractometer** horizontally, and turn toward the light. Rotate the eyepiece until the scale is in focus.
7. **Read the scale** at the point where the dividing line between bright and dark fields crosses the scale. The scale reads from 1.000 to 1.035 in increments of 0.001.
8. **Record the results.**
9. **When you are finished**, add a drop of distilled water to cleanse the prism. Dry the equipment with a soft, nonabrasive cloth.

What if . . .

- **The diagnostic kit for dipstick testing is outdated?**
  Contact the pharmacy and/or work with the patient's caregiver to obtain a kit that is not expired.

Evaluation

- Characteristics of urine output (e.g., volume of output, color, clots, mucus).
- Abnormally concentrated or dilute urine

Patient Teaching

- Explain test procedures to the patient and the patient's caregiver and family members as indicated.

Home Care

- Teach the client or caregiver the steps of the procedure.
- Tell the client or caregiver that the urine must be tested within an hour or refrigerate the specimen to test later.
- Instruct the client or caregiver that the specimen should be tested as ordered by the healthcare provider.
- Teach the client or caregiver to record results on the flow sheet per agency protocol.

Documentation

- Document urine volume in the patient record, per agency protocol, and the time and date that the specimen was collected.

  Some agencies use the Kardex or a procedure checklist to indicate the urine collection is either needed, in progress, or completed. Other facilities have nurses chart specimen collection in the nursing notes.
- Document the urine specific gravity and pH and note the presence of hemoglobin, glucose, ketones, protein, white blood cells, bilirubin, casts, crystal, and nitrites.
- Chart other characteristics of the urine: color, odor, clarity, particulate matter, gross blood, mucus shreds, or other qualities.
- Record any difficulty with voiding, including pain or burning with urination, frequency, or difficulty starting the urine flow.

Sample documentation

3/4/16 1515 Pt voided in bedside commode. Urine is straw-colored with sediment. No unusual odor, blood, or mucus evident. No hemoglobin, glucose, ketones, protein, WBC, bilirubin, casts, or crystal nitrates noted on urine dipstick. Specific gravity 1.015, pH 6.6, and 3+ protein noted.
——— L. Schaaf, RN

Practice Resources

Chernecky, C. C., & Berger, B. J. (2013); Stuempfle, K. J., & Drury, D. G. (2003).

Procedure 28-4 ■ Inserting a Urinary Catheter

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

Intermittent Urinary Catheter (Straight Catheter)

- Washcloth and towel
- Periwash solution
- Procedure gloves, at least two pairs
- Catheter insertion kit containing:
  Sterile gloves
  Urinary catheter
  Antiseptic cleansing agent, forceps, and cotton balls or a packet of sterile antiseptic swabs or wipes
  Sterile waterproof drapes
  Sterile lubricant
  Urine receptacle
  Specimen container
- Extra pair of sterile gloves and extra sterile catheter
  Obtaining extra supplies prevents the need to leave the bedside to obtain additional supplies should the gloves or catheter become contaminated.
- Bath blanket
- Procedure lamp or flashlight
- Topical anesthetic gel [e.g., 2% lidocaine, (Xylocaine)] (according to agency policy and patient need)

Straight catheter kit

(continued on next page)

Procedure 28-4 ■ Inserting a Urinary Catheter (continued)

Indwelling Urinary Catheter

An indwelling catheter is designed to remain in the urinary bladder. In addition to the supplies contained in a straight-catheter kit, an indwelling catheter kit will include the following:

- A double-lumen or triple-lumen catheter with a balloon tip for inflation instead of a single-lumen catheter
- A syringe prefilled with sterile water (to inflate the catheter balloon)
- Urine collection bag with drainage tubing attached; often the tubing is also attached to the catheter
- Commercial catheter securement device, such as a catheter tube holder or Velcro leg strap, if available. If not, hypoallergenic tape may be used.
- Safety pin and elastic band (if needed to secure the tubing to the bed; you can usually use the clamp on the drainage tubing)

Indwelling catheter kit.

Delegation

In some institutions, NAPs receive special training to learn this skill. In such instances, you may delegate this task to the NAP. However, you must complete the following assessments and instruct the NAP when to stop the procedure and what abnormal findings to report. You must, from time to time, supervise to ensure that the procedure is being performed correctly.

Pre-Procedure Assessments

- Assess the patient's cognitive level.
  To determine whether the patient will be able to follow instructions.
- Assess for the presence of conditions that may impair the patient's ability to assume the necessary position.
  To determine whether you will need assistance to help the patient maintain the correct position.
- Assess the presence and degree of bladder distention.
  To establish a baseline against which to evaluate future data.
- Determine time of last voiding or last catheterization.
- Assess the general body size of the patient and size of the urinary meatus.
  To determine whether you need to choose a different size catheter.
- Determine whether the patient has an allergy to iodine (if that is the antiseptic solution in the kit). If so, use a different solution.
- Determine whether the patient is allergic to latex.
  Many catheters are made of latex.
- Note signs and symptoms of bladder infection (e.g., elevated temperature, urinary frequency, dysuria).
- Note conditions (e.g., enlarged prostate in men) that may make it difficult to pass the catheter.
- Assess the need for additional lighting.
  It is sometimes difficult to visualize a woman's urinary meatus. Supplemental, direct lighting helps.

Procedure 28-4A ■ Intermittent Urinary Catheterization

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* The following steps are described for a *female* patient. If your patient is a male, refer to the procedure variation for Intermittent Urinary Catheterization (Straight Catheter) for a Male Patient, immediately following the Procedure Steps for females.

Procedure Steps

1. **If you are right-handed,** stand and work at the patient's right side; if you are left-handed, stand and work on the patient's left side.
2. **Place the patient supine** (dorsal recumbent), in a position to allow you to see the urinary meatus:
   a. Flex the patient's knees, and place her feet flat on the bed (dorsal recumbent position).
   b. Instruct the patient to relax her thighs and allow them to rotate externally. Obtain help if the patient is confused, unable to cooperate or follow directions, or unable to hold her legs in a correct position.
   The urinary meatus is sometimes difficult to visualize on women because it may resemble skinfolds or other anatomical landmarks in the area.
3. **Don clean procedure gloves.**
4. **Drape the patient.** Fold the blanket in a diamond shape, wrapping the corners around the patient's legs and folding the upper corner down over the perineum. (To review draping, see Procedure 25-4.)

Providing privacy promotes comfort.

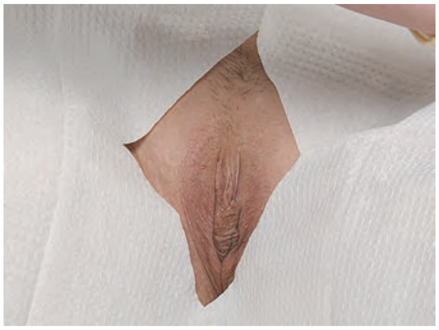
5. Lift the corner of the privacy drape to expose the perineum; position the procedure light to allow optimal visualization of the perineum, and then locate the urinary meatus.
Locating the meatus during this step helps prevent delays at subsequent steps when it is important to maintain sterile technique.

6. Cleanse the perineal area with periwash solution; dry.
Cleansing the perineum before inserting the catheter reduces the number of skin bacteria, thereby helping to prevent transmission of microorganisms into the bladder.

7. Remove and discard gloves. Perform hand hygiene.
To prevent the transmission of microbes.

8. Organize your work area.
a. Arrange the bedside table or overbed table within your reach.
b. Open the sterile catheter kit according to manufacturer's instructions, and place it on the bedside or overbed table.
c. Position a plastic bag or other trash receptacle so that you will not have to reach across the sterile field (between the patient's legs) to dispose of soiled cotton balls and so forth (e.g., a trashcan on the floor beside the bed; a trash bag on the bed near, but not between, the patient's feet; or the outer wrapping of the catheter kit).
Carrying contaminated objects above a sterile field can contaminate the field.

9. Place the sterile underpad and drape. *Note: This step assumes the waterproof drape is packed as the top item in the kit. If your kit is different, see the What if. . . section.*
These drapes provide sterile work surfaces and help prevent contaminating your gloves and sterile supplies.
a. Place the sterile underpad: Remove the underpad from the kit carefully, allowing it to fall open as you remove it. Do not touch other kit items. Place it flat on the bed, shiny side down, and tuck the top edge under the buttocks, taking care to touch only the corners of the drape.
b. Remove the sterile glove package, and don sterile gloves (see Procedure 23-7). *Note: Once you are wearing the sterile gloves, you may touch items inside the catheter kit, arranging the supplies as needed.*
c. Place the fenestrated drape: This has a hole in the center. Pick up the drape, allowing it to unfold as you remove it, without touching any other objects from the kit. Place the drape over the perineum with the hole over the labia.▼



10. Organize kit supplies on the sterile field, and prepare the supplies in the kit.
a. Open the antiseptic package and pour solution over the cotton balls.
Note: Some kits contain a packet of sterile antiseptic swabs or wipes. Open the end of the packet where you feel the "sticks," leaving the swabs covered by the packet.
b. Lay the forceps near the cotton balls.
c. Open the specimen container if you need to collect a specimen.
d. Remove any unneeded supplies, such as the urine specimen container, from the urine collection basin.
e. Remove the plastic wrapper from the catheter, if it is covered.
f. Open the packet or uncap the syringe filled with sterile lubricant.
g. Squeeze sterile lubricant into the kit tray; roll the catheter slowly in the lubricant to generously lubricate the first 2.5 to 5 cm (1 to 2 in.). Leave the catheter tip in the lubricant or on the sterile field until ready to use.
Lubrication allows for ease of insertion of the catheter. Prevents trauma to the mucosa.
h. Touching only the box or sterile side of the wrapping, place the sterile catheter kit down onto the sterile field between the woman's legs.
This approach allows you to reach supplies during catheter insertion. It also extends the sterile field created by the sterile underpad.

11. Cleanse the urinary meatus.
a. Place your nondominant hand above the labia, and with your thumb and forefinger spread the patient's labia, pulling up (or anteriorly) at the same time, to expose the urinary meatus. Hold this position throughout the procedure—firm pressure is necessary. If the labia slip back over the urinary meatus, it is considered contaminated, and you will need to change gloves and repeat the cleansing procedure.
When a woman is supine, gravity may cause tissues above the meatus to fall downward and obscure the meatus from sight. Once placed on the patient's perineal area, your hand is considered contaminated.
b. With your dominant hand, pick up a moistened cotton ball with the forceps (or swab) and cleanse the perineal area, taking care not to contaminate your sterile glove.
- Use one stroke and a new cotton ball or swab for each area.
- Wipe from front to back (clitoris to anus).
- *If there are five cotton balls or swabs:* Wipe in this order: far labium majora, near labium

(continued on next page)

Procedure 28-4 ■ Inserting a Urinary Catheter (continued)

majora, inside far labium, inside near labium, and directly down the center over the urinary meatus.

- *If there are only three cotton balls or swabs:* Cleanse only the inside far labium minora, inside near labium minora, and down the center of the urethral meatus.
- Discard the used cotton balls or swabs as you use them. Be careful not to move them across the open and sterile kit.

Because the urethra is close to the anus in female patients, thorough cleansing of the perineum is very important to reduce contamination of the catheter and prevent bacteria from being introduced into the urethra. Following the "clean to dirty" principle prevents recontamination of the cleansed area.

12. Prepare the urine receptacle. Place it 10 cm (4 in.) from the meatus (for women).
The end of the catheter will need to reach into the container to catch the draining urine.

13. Insert the catheter.

a. Grasp the catheter with your dominant hand, no more than 5 to 7.5 cm (2 to 3 in.) from the tip. Keep the rest of the catheter coiled in the palm of your hand. Slowly insert the end of the catheter into the meatus. Ask the patient to take slow, deep breaths until the initial discomfort has passed.
Bearing down helps relax the external sphincter and makes insertion easier and more comfortable. Holding the catheter close to the distal end will help to keep the tip stable and prevent it from being inserted into the vaginal opening. Deep breathing helps to relax the sphincters. Coiling the catheter in your hand keeps you from contaminating the catheter.

b. Ask the woman to bear down as though she is trying to void.

c. Continue inserting the catheter gently until urine flows, for a distance of 5 to 7.5 cm (2 to 3 in.). After you see urine, insert the catheter another 2.5 to 5 cm (1 to 2 in.).

> If you feel slight resistance as the catheter goes through the sphincters, twist the catheter slightly or apply gentle pressure, but do not force the catheter while inserting it. You might need to remove it and cautiously attempt the insertion action again using a new catheter.

Forcing may damage mucosa. Insert the catheter more deeply after urine flow to be sure the catheter is well into the bladder so that the bladder can empty completely. The catheter might not advance while inserted when it is misplaced in the vagina or if there is a stricture within the urethra or sphincter spasm.

d. If the catheter touches the labia or unsterile linens, or if you inadvertently place it in the vagina, it is contaminated and you must insert a new, sterile catheter. Leave the contaminated catheter in the vagina while you are inserting the new one into the meatus.
Leaving the catheter in the incorrect location serves as a visual landmark and helps you to avoid making the same mistake again.

14. Manage the catheter and/or urine collection device.

a. Continue to hold the catheter securely with your nondominant hand while the urine drains from the bladder.
Holding the catheter like this prevents the catheter from being expelled by bladder or urethral contractions.

b. If you are to collect a urine specimen, use your dominant hand to take the specimen container and put it into the flow of urine until you obtain the correct amount of urine. Cap the container, maintaining sterile technique. See Procedure 28-2B.

c. When the flow of urine has ceased and the bladder has been emptied, pinch the catheter and slowly withdraw it from the meatus. Discard the catheter in an appropriate receptacle.
Withdrawing slowly promotes adequate urinary drainage, preventing urinary stasis. Pinching prevents urine from dribbling out of the end of the catheter.

d. Remove the urine-filled receptacle, and set it aside outside the patient care area to be emptied when the procedure is finished.
Keeps the urine from spilling onto the bed.

15. Cleanse the patient's perineal area as needed; dry.
This removes residual antiseptic solution from the area, an especially important step if you used povidone-iodine (Betadine). Betadine left on intact healthy skin can cause irritation.

16. Remove and discard disposable supplies (e.g., drapes).

17. Remove your gloves and wash your hands.
Prevents transmission of bacteria.

18. Return the patient to a comfortable position.

Procedure Variation: Intermittent Urinary Catheterization (Straight Catheter) for a Male Patient

Procedure Steps	Nursing Action
1. Position the patient.	Position the patient supine, legs straight and slightly apart.
2. Drape the patient.	Cover the patient's upper body with a blanket; fold bed sheets down to expose the penis.
3. Don procedure gloves and cleanse the perineum.	After donning procedure gloves, wash the penis and perineal area with perineal wash solution; dry. If you are using a topical anesthetic gel (e.g., Xylocaine), use a syringe (no needle) to insert it into the urethra now. Remove and discard gloves.
4. Organize the work area.	Perform hand hygiene before starting. Open the sterile catheter kit and place on overhead table without contaminating the inside of the wrap. Position a trash receptacle nearby.
5. Place the sterile underpad and sterile drape.	Remove underpad from the kit before donning sterile gloves. Place the drape shiny side down between or across the patient's thighs.
6. Don sterile gloves.	Remove the sterile glove package, and don sterile gloves (see Procedure 23-7). *Note: Once you are wearing the sterile gloves, you may touch items inside the catheter kit, arranging the supplies as needed.*
7. Place the fenestrated drape.	Allow the fenestrated drape to fall open while removing it from the kit and without touching other kit items. Place the drape with the center hole over the penis.
8. Organize kit supplies on the sterile drape.	■ Open the antiseptic package and pour over cotton balls or use antiseptic swabs or wipes. ■ Open the sterile specimen container. ■ Remove any unneeded supplies. ■ Remove the wrapper from the catheter. ■ Touching only the kit or inside of the wrapping, place the sterile catheter kit down onto the sterile field between the patient's legs.
9. Lubricate the catheter.	■ Do not lubricate the catheter if you have already inserted a lubricant (lidocaine-based product) directly into the urethra. ■ If the lubricant comes in a packet, squeeze it into the kit tray and roll the catheter slowly in it to generously lubricate 12.5 to 17.5 cm (5 to 7 in.) of the catheter. Leave the catheter tip in sterile lubricant or on the sterile field until ready to use. ■ If your kit contains a prefilled syringe of lubricant, gently insert the tip of the syringe into the urethra and instill the lubricant.
10. Expose the urinary meatus.	■ With your nondominant hand, grasp the penis, taking care not to contaminate the surrounding drape. This glove is no longer sterile. ■ Hold the penis gently, but firmly, at a 90° angle to the body, exerting gentle traction. ■ If the penis is uncircumcised, retract the foreskin to fully expose the meatus. If the foreskin accidentally falls over meatus and does not remain retracted or if you drop the penis during cleansing, you must change gloves and repeat the cleansing procedure.
11. Cleanse the urinary meatus.	■ Continuing to hold the penis with your nondominant hand, hold the forceps in your dominant hand and pick up a cotton ball. Cleanse the glans in a series of circular motions, starting at the meatus and working partially down the shaft of the penis. ■ Repeat with at least two more cotton balls or swabs. Discard the cotton balls or swabs as they are used. Do not move them across the open sterile kit and field.
12. Prepare the urine receptacle.	■ Maintaining sterile technique, with your dominant hand place the plastic urine receptacle between the patient's thighs, close enough to the urinary meatus for the end of the catheter to rest inside the container as the urine drains. ■ Hold the catheter 5 to 7.5 cm (2 to 3 in.) from the tip with remainder coiled in the palm of the hand and the distal end of the catheter is in the plastic container.
13. Insert the catheter into the urinary meatus.	■ Ask the patient to bear down as though trying to void; slowly insert the end of the catheter into the meatus. Instruct the patient to take slow, deep breaths until the initial discomfort has passed. If you feel resistance, withdraw the catheter. Do not force against resistance. ■ Continue inserting the catheter to about 17.5 to 22.5 cm (7 to 9 in.) or until urine flows. After you see urine, insert the catheter another 2.5 to 5 cm (1 to 2 in.).
14. Collect a specimen if needed.	If a urine specimen is to be collected, continue to grasp the penis, and use your dominant hand to place the specimen container into the flow of urine; cap container using sterile technique.
15. Manage the catheter.	When urine flow stops and the bladder has been emptied, pinch the catheter and slowly withdraw it from the meatus. Replace the foreskin. Discard the catheter in an appropriate receptacle.
16. Finish the procedure.	Remove gloves and perform hand hygiene. Return patient to a comfortable position.

(continued on next page)

Procedure 28-4 ■ Inserting a Urinary Catheter (continued)

Procedure 28-4B ■ Indwelling Urinary Catheterization

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* The following steps are described for a ***male*** patient. If your patient is a female, refer to procedure variation for Indwelling Urinary Catheterization for a Female Patient, immediately following the Procedure Steps for males.

Procedure Steps

1. **Place the patient supine** with legs straight and slightly apart. If the patient is confused, unable to follow directions, or unable to hold his legs in correct position, obtain help with the procedure.

2. **If you are right-handed**, stand and work at the patient's right side; if you are left-handed, stand and work on the patient's left side.

3. **Drape the patient.** Cover the patient's upper body with a blanket; fold the bedsheets down to expose the penis.
   Covering the patient preserves modesty and enhances a feeling of security, while ensuring that you can visualize the urinary meatus.

4. **Don clean procedure gloves.** Cleanse the penis and perineal area with antiseptic solution; dry.
   Cleansing the area of skin bacteria reduces the risk of transmitting microbes into the bladder.

5. **If you are using topical anesthetic** gel, use a syringe (no needle) to insert it into the urethra.
   This is frequently used for men to provide local anesthesia. You insert it now because it takes 5 minutes for the gel to take effect at the time you are ready to insert the catheter.

6. **Remove and discard gloves.** Perform hand hygiene
   To prevent the transmission of microbes.

7. **Organize your work area:**
   a. Arrange the bedside table or overbed table within your reach.
   b. Open the sterile catheter kit according to the manufacturer's instructions, and place it on the bedside or overbed table.
   c. Position a plastic bag or other trash receptacle so that you will not have to reach across the sterile field to dispose of soiled cotton balls and so forth (e.g., a trash can on the floor beside the bed; a trash bag or the kit outer wrapper on the bed near, but not between, the patient's feet).
   Carrying contaminated objects above a sterile field can contaminate the field.

8. **Place the sterile underpad** and drape. *Note: This step assumes the waterproof drape is packed as the top item in the kit. If your kit is different, see the What If . . . section.*
   These drapes provide sterile work surfaces and help prevent contaminating your gloves and sterile supplies.
   a. Remove the underpad from the kit carefully. Drop the underpad shiny side down between or across the patient's thighs, touching only the corners.
   b. Remove the sterile glove package and don sterile gloves (see Procedure 23-7).
   Note: Once you are wearing the sterile gloves, you may touch any items inside the catheter kit, arranging the supplies as needed.
   c. Place the fenestrated drape: This has a hole in the center. Pick up the drape, allowing it to unfold as you remove it, without touching any other objects. Place it with the center hole over the penis.

9. **Organize the kit supplies** on the sterile field, and prepare the supplies in the kit.
   a. Pour antiseptic solution, such as Betadine, over the cotton balls. *Note:* Some kits contain a packet of sterile antiseptic swabs or wipes. Open the end of the packet where you can feel the "sticks," leaving the swabs covered by the remainder of the packet.
   b. Lay the forceps near the cotton balls.
   c. Open the specimen container, if you are to collect a specimen.
   d. Remove any unneeded supplies, such as the specimen container, from the kit.
   e. Remove the plastic wrapper from the catheter, if it is covered.
   f. Do not lubricate the catheter if you have already inserted a lubricant (xylocaine gel) directly into the urethra.

Variation: Lubricant in a Syringe
If the sterile lubricant in the kit is packaged in a syringe, you will insert the lubricant into the urethra at Step 11.

Variation: Lubricant in a Packet
If the lubricant comes in a packet, squeeze the lubricant into the kit tray and roll the catheter slowly in the lubricant. Generously lubricate 12.5 to 17.5 cm (5 to 7 in.) of the catheter. Leave the catheter tip in sterile lubricant or on the sterile field until ready to use.

   g. Attach the sterile water-filled syringe to the balloon port of the catheter.
   h. Touching only the box or sterile side of the wrapping, place the sterile catheter kit down onto the sterile field on top of the man's thighs. You may, as an alternative, set up the sterile field between his legs.
   Placement of supplies in this manner allows you to reach supplies during catheter insertion.
   i. If the bedside bag is preconnected to the catheter itself, leave the bag on or near the sterile field until after the catheter is inserted.

10. Cleanse the urinary meatus.

a. With your nondominant hand, reach through the opening in the fenestrated drape and grasp the penis, taking care not to contaminate the surrounding drape. This glove is no longer sterile. Hold the penis gently, but firmly, at a 90° angle to the body exerting gentle traction.
Supporting the shaft with the fingers straightens the urethra, easing insertion of the catheter.

b. If the penis is uncircumcised, retract the foreskin to fully expose the meatus. If the foreskin accidentally falls over the meatus or if you drop the penis during cleansing, you must change gloves and repeat the cleansing procedure.
Retracting the foreskin allows for full cleansing of the area.

c. Continuing to hold the penis with your nondominant hand, hold the forceps in your dominant hand and pick up a cotton ball. Cleanse the glans in a series of circular motions, starting at the meatus and working partially down the shaft of the penis.

d. Repeat with at least two more cotton balls or swabs. Discard the cotton balls or swabs as they are used. Do not move them across the open sterile kit and field.
Following the "clean to dirty" principle prevents recontamination of the cleansed area.

11. Lubricate the catheter if xylocaine gel was not instilled previously.

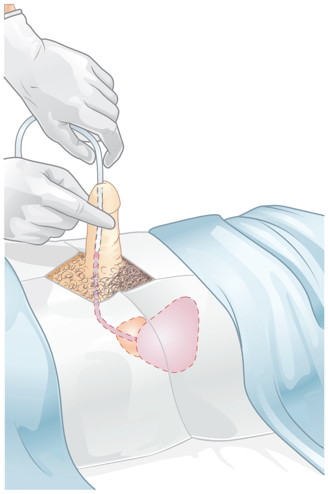
Lubricant Packaged in a Syringe

If the kit contains a prefilled syringe of lubricant, gently insert the tip of the syringe into the urethra and instill the lubricant.

Lubricant in a Packet

If the kit contains a single packet of lubricant, make sure you have already generously lubricated 12.5 to 17.5 cm (5 to 7 in.) of the catheter.

12. Insert the catheter.



a. With your dominant hand, stabilize the catheter before inserting it by holding the catheter approximately 5 to 7.5 cm (2 to 3 in.) from the tip. Keep the rest of the catheter coiled in the palm of your hand if the catheter is not already preconnected.
Grasping the catheter close to the distal end aids in control and helps to avoid inadvertent contamination. Frequently the catheter and drainage bag are connected by the manufacturer.

b. With your nondominant hand, continue to hold the penis gently but firmly at a 90° angle to the body, exerting gentle traction.

c. Ask the patient to bear down as though trying to void; slowly insert the end of the catheter into the meatus. Ask the patient to take slow deep breaths until the initial discomfort has passed.
These strategies help the patient to relax the external sphincter and make insertion easier and more comfortable.

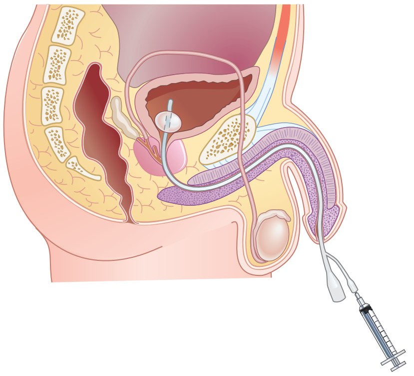
d. Continue inserting the catheter to about 17.5 to 22.5 cm (7 to 9 in.) or until urine flows. You will feel slight resistance at the level of the internal sphincter. Continue to advance almost to the bifurcation (Y connector).

You will commonly feel resistance at the prostatic sphincter. Hold the catheter firmly against the sphincter until the resistance eases. Then advance the catheter, but do not force it.

e. Lower the penis and replace the foreskin.
This prevents compromised circulation and painful swelling.

13. Manage the catheter.

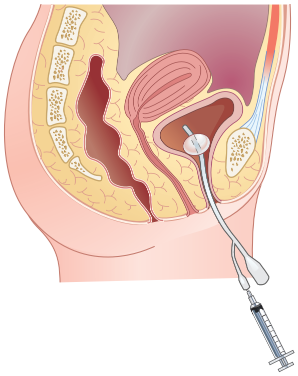
a. Continue to hold the catheter securely with your nondominant hand to stabilize the catheter's position in the urethra. Use your other hand to pick up the water-filled syringe and inflate the catheter balloon.
Holding the catheter until the balloon is inflated decreases the chance that the catheter will be expelled by bladder or urethral contractions. The inflated balloon prevents the catheter from slipping out of the bladder.



A Catheter placement, male.

(continued on next page)

Procedure 28-4 ■ Inserting a Urinary Catheter (continued)



B Catheter placement, female.

b. If the patient complains of pain on inflation of the balloon, withdraw the water from the balloon, and reposition the catheter by advancing it 2.5 cm (1 in.).

Pain usually indicates that the balloon was in the urethra instead of in the bladder.

c. After the balloon is inflated, pull back gently on the catheter until you feel resistance. Lower the penis and replace the foreskin.
This indicates that the balloon is correctly positioned at the neck of the bladder.

14. **Connect the drainage bag** to the end of the catheter if it is not already preconnected. Hang the drainage bag on the side of the bed, below the level of the bladder.
Hanging the drainage bag below the bladder promotes adequate urinary drainage by gravity, preventing urinary stasis.

15. **Using a commercial catheter** securement device (such as a catheter tube holder or Velcro leg strap), if available, secure the catheter to the thigh or the abdomen. Otherwise, hypoallergenic tape may be used.
Securing the catheter prevents urethral irritation related to tugging or pulling of the catheter. Commercial catheter securement devices are preferable to tape for catheter securement.

16. **Cleanse the patient's perineal area** as needed; dry. Cover the patient.
Removes residual antiseptic solution from the area, an especially important step if you used povidone-iodine (Betadine). Betadine left on intact healthy skin can cause irritation.

17. **Remove and discard disposable** supplies (e.g., drapes).

18. **Remove gloves** and perform hand hygiene.

19. **Return the patient** to a comfortable position.

Procedure Variation: Indwelling Catheter Insertion for a Female Patient

Procedure Steps	Nursing Action
1. Position the patient.	Flex the patient's knees, and place her feet flat on the bed (dorsal recumbent position). Instruct the patient to relax her thighs and allow them to rotate externally. *Note:* Obtain help if the patient is confused, unable to follow directions, or unable to hold her legs in the correct position.
2. Drape the patient.	Fold the blanket in a diamond shape, wrapping the corners around the patient's legs and folding the upper corner down over the perineum (see Procedure 28-4A).
3. Cleanse the perineal area.	■ Don clean procedure gloves. ■ Lift the corner of the privacy drape to expose the perineum; ■ Position the procedure light to allow optimal visualization of the perineum and then locate the urinary meatus. ■ Cleanse the perineal area with antiseptic solution; dry. ■ Remove and discard gloves. Wash hands.
4. Organize the work area.	Arrange the bedside table or overbed table within your reach. Open the sterile catheter kit according to the directions, and place it on the table. Position a plastic bag or other trash receptacle so that you will not have to reach across the sterile field to dispose of soiled cotton balls and so forth.
5. Apply the sterile underpad and fenestrated drape.	■ Remove the sterile underpad from the kit before donning sterile gloves. Be sure not touch other kit items with bare hands. Touching only the corners, place the drape shiny side down under the patient's buttocks. ■ Carefully remove the sterile glove package from the kit and don sterile gloves. ■ Pick up the fenestrated drape; allow it to unfold without touching other objects; place over the perineum with the hole over the labia. ■ Remove the sterile glove package and don sterile gloves.
6. Organize the kit supplies on the sterile field.	■ Open the antiseptic packet and pour solution over the cotton balls, and position forceps nearby. Or if the kit comes with antiseptic swabs, open the packet so the sticks are convenient to grasp.

- Open the specimen container if a specimen is to be collected. Remove any unneeded supplies.
- Remove the plastic wrapper from the catheter, if it is covered. Squeeze the sterile lubricant into the kit tray. Roll the catheter slowly in the lubricant, being sure to generously lubricate the first 2.5 to 5 cm (1 to 2 in.) of the catheter. Leave the catheter tip in the sterile lubricant or on the sterile field until ready to use.
- Attach the sterile water-filled syringe to the balloon port of the catheter. Leave the syringe attached to the catheter.
- Touching only the box or sterile side of the wrapping, place the sterile catheter kit down onto the sterile field. You may, as an alternative, set up the sterile field between her legs.

7. Spread the labia and cleanse the urinary meatus.

- Place your nondominant hand above the labia, and, with thumb and forefinger, spread the patient's labia, pulling up at the same time to expose the urinary meatus. Use firm pressure to hold this position throughout the procedure. If the labia accidentally slip back over the meatus during cleansing, repeat the procedure.
- Wipe from the clitoris to the anus, wiping in the order of: far labium majora, near labium majora, inside far labium, inside near labium, and directly down the center over the urinary meatus.
- Discard cotton balls or swabs as they are used; do not move them across the open, sterile kit and field. Use only one stroke and a new cotton ball or swab for each area.

8. Insert the catheter.

Ask the woman to bear down as though she is trying to void. Grasp the catheter with your dominant hand, no more than 5 to 7.5 cm (2 to 3 in.) from the tip. Slowly insert the end of the catheter into the meatus. Ask the patient to take slow, deep breaths until the initial discomfort has passed.

9. Manage the catheter.

- Continue inserting the catheter gently until urine flows, for a distance of 5 to 7.5 cm (2 to 3 in.). After you see urine, insert the catheter another 2.5 to 5 cm (1 to 2 in.).
- If the catheter touches the labia or unsterile linens, or if you inadvertently place it in the vagina, it is contaminated and you must insert a new, sterile catheter. Leave the contaminated catheter in the vagina while you are inserting the new one into the meatus.
- After urine flows, stabilize the catheter in the urethra with your nondominant hand; use the dominant hand to pick up the sterile water-filled syringe and inflate the catheter balloon.

> If the patient complains of pain when inflating the balloon, withdraw the water out of the balloon. Then reposition the catheter by advancing it 2.5 cm (1 in.).

10. Secure the catheter.

Using a commercial catheter securement device, if available, secure the catheter to the thigh. Remove and discard disposable supplies. Remove and discard gloves. Return the patient to a comfortable position.

11. Finish up.

? What if . . .

- **The sterile gloves are packed as the top item in the catheter kit?**
  - Remove the sterile glove package and don sterile gloves (see Procedure 23-7). *Note:* Once you have donned the sterile gloves, you may touch any item inside the catheter kit, arranging the supplies as needed.
  - Place the sterile underpad: Grasp the edges of the sterile drape. Fold the entire edge down 5 to 7.5 cm (2 to 3 in.) and toward you, making a "cuff" to protect your gloves. Take care not to touch unsterile objects with your gloves or the drape.

For women: Carefully slide the drape under the patient's buttocks without contaminating your gloves. Ask the patient to raise her hips slightly if she can.

For men: Drop the sterile underpad across thighs.

- Continue with the fenestrated drape as described in the standard procedures.

- **A woman is unable to maintain a dorsal recumbent position?**

  Use Sims' position (side-lying with the upper leg flexed at the hip). Cover the rectal area.

  Prevents contamination from the rectal area to the urethra.

- **A man has an erection during the procedure?**

  Treat the situation professionally. Take a break until the erection subsides. Never force the catheter.

  Forcing the catheter can cause urethral trauma.

(continued on next page)

Procedure 28-4 ■ Inserting a Urinary Catheter (continued)

Evaluation

- Note any difficulty with catheter insertion.
  This can indicate structural problems, especially in an older male patient with an enlarged prostate gland.
- Note the characteristics of the urine obtained (e.g., amount, color, odor, presence of sediment or mucus).
- Assess for absence of bladder distention.
  Palpating the bladder helps you to determine if it has been emptied. A portable bladder scanner may also be used to help you determine whether residual urine remains.
- For indwelling catheters, continue to monitor that drainage is not obstructed and that the drainage bag is below the level of the bladder.

Home Care

Indwelling Catheter

For inserting indwelling catheters in the home, teach clients:

- When to change the catheter
  Changing indwelling catheters at routine, fixed intervals is generally not recommended (Gould, Umscheid, Agarwal, et al., 2009). Clients should be taught to change catheters based on clinical indications, such as impaired urine drainage or encrustration.
- How to prevent catheter blockage (e.g., increase fluid intake)
  Fluids increase the urine volume, helping to reduce the deposit of sediment or other particles in the tubing.
- To empty the drainage bag frequently and to keep the bag below the level of the bladder
- How to prevent urinary tract infections (e.g., maintain a closed system, handwashing prior to handling catheter equipment, prevent blockage of urine outflow, adequate fluid intake, taking a shower rather than a bath.)
- How to prevent discomfort at the urethra
- Use of a leg bag
- To eat foods that help acidify the urine: meat, eggs, cheese, prunes, cranberries, and whole grains
- How to obtain additional supplies suitable for individual needs (Loveday, Pratt, Wilson, et al., 2014).

Documentation

- Document the time and date of the procedure.
- Document the size of catheter used.
- Record the amount of urine obtained on the I&O portion of the graphics sheet. Record the color of urine, odor, presence of mucus, blood, and so on, in the nursing notes.
- Record the patient's subjective statements.
- Document if you collected a specimen, and note the time it was sent to the lab.
- *For an indwelling catheter:* In addition, some facilities require that you record the amount of sterile water used to inflate the balloon.

Sample documentation

3/4/16 1010 Order noted for insertion of indwelling catheter. Explained the procedure to pt and reason for insertion. Pt verbalized understanding of the procedure and need for catheter. Placed pt in a dorsal recumbent position with blankets to keep pt warm and provide privacy. Perineal care completed. 14 Fr. Foley catheter inserted using sterile technique per protocol. Foley draining dark yellow urine with sediment and foul odor. No mucus or blood noted in urine. Bladder is not distended. Client returned to semi-Fowler's position. No needs noted at this time. Reminded pt to call nurse if there is any discomfort associated with urinary catheterization. Call light placed in pt's dominant hand.
———————— C. Chin, RN

Thinking About the Procedure

To practice applying clinical reasoning to these procedures,

Go to *Davis's Nursing Skills Videos*, **Intermittent Urinary Catheterization, and Indwelling Urinary Catheterization.**

For questions and suggested responses,

Go to Chapter 28, Thinking About the Procedure Questions and Suggested Responses, on Davis*Plus*.

Procedure 28-5 ■ Applying an External (Condom) Catheter

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Condom catheter
- Two pairs of clean procedure gloves
- Washcloth and towel
- Disposable basin of soap and purified water or antiseptic wash
- Bath blanket, if available
- Urine collection bag (e.g., bedside drainage bag or leg bag)
- Disposable tape measure
- Skin prep (per agency policy)
- Scissors
- Commercial leg strap

Delegation

You may delegate the application of a condom catheter to the NAP once you have assessed the NAP's skill level and completed the pre-procedure assessments. Instruct the NAP to report any alterations in the skin integrity along the shaft of the penis.

Pre-Procedure Assessments

- Assess the patient's cognitive status.
  Knowing whether the patient can follow directions helps you to determine how to approach the procedure and also to know if the patient may be prone to pulling on the catheter.
- Assess pattern of voiding (e.g., degree and time of incontinence).
  Knowing how often and how much the patient voids helps you to determine when the condom catheter should be applied.
- Assess the skin along the shaft of the penis, the glans, and the meatus (for swelling or excoriation).
  The condom catheter cannot be used on excoriated, irritated skin or over areas of impaired skin integrity.
- Note whether and how much the penis is retracted towards the body.
  There is an increased risk of nonadherence and leakage of urine in a patient with a retracted penis.
- Assess for the presence of neuropathy.
  Patients with neuropathies that affect sensation in the penis may not feel skin irritation from the condom catheter and will need to be assessed more frequently.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine appropriate size** of the external catheter by measuring the circumference of the penis using a disposable paper tape. Obtain a correctly sized catheter.
   A catheter that is too small impairs circulation. A catheter that is too large allows leakage of urine.
2. **Perform hand hygiene** and don clean procedure gloves.
   Hand hygiene and gloving prevent the transmission of bacteria.
3. **Organize supplies** and prepare the leg bag or bedside drainage bag for attachment to the condom catheter by removing it from the packaging and placing the end of the connecting tubing near the perineal area.
4. **Position the patient supine.** If the patient has difficulty breathing, raise the head of the bed to 30°.
5. **Fold down the bedcovers** to expose the penis, and drape the patient using the bath blanket.
   Covering the patient reduces patient embarrassment.
6. **Gently cleanse the penis** with soap and filtered water or antiseptic perineal wipes. Rinse and dry it thoroughly. If the patient is uncircumcised, retract the foreskin, cleanse the glans, and replace the foreskin. Excess hair along the shaft of the penis may be carefully clipped off with the scissors.
   Cleansing the penis not only helps to prevent infection but it also helps the condom catheter to adhere better to the shaft.
7. **Perform hand hygiene** and change procedure gloves.
8. **Apply skin prep** (if used by your agency), and allow it to dry. *Note: Some external condom catheters require the placement of the special adhesive strip onto the penis before the application of the condom. Follow the manufacturer's directions.*
9. **Hold the penis** in your nondominant hand. With your dominant hand, place the condom catheter at the end of the penis, and slowly unroll it along the shaft toward the patient's body. Leave 2.5 to 5 cm (1 to 2 in.) between the end of the penis and the drainage tube on the catheter.
   Careful unrolling in this manner helps to prevent irritation of the glans due to rubbing and allows for expansion of the penis if an erection were to occur.

10. **Secure the condom catheter** in place on the penis.
    a. Ensure that the condom is not twisted.
       Twisting can obstruct urine flow.
    b. Do not use regular bandage or surgical dressing tape to hold an external condom catheter in place.
       Regular tape does not expand and could lead to decreased blood flow to the penis.

Catheter With Internal Adhesive

   c. Gently grasp the penis and compress so that the entire shaft comes in contact with the condom.

Catheter With External Adhesive Strip

   d. Wrap the strip around the outside of the condom in a spiral direction, taking care not to overlap the ends.
      Prevents constriction of blood flow to the penis.

(continued on next page)

Procedure 28-5 ■ Applying an External (Condom) Catheter (continued)

11. Assess the proximal end of the condom catheter. If a large portion of the condom is still rolled above the adhesive strip, you may need to clip the roll (Geng, Bonns, Eelen, et al., 2008; WOCN Continence Committee, 2008).
Clipping the roll prevents constriction of blood flow.

12. Attach the tube end of the condom catheter to a drainage system (e.g., a leg bag). Make sure there are no kinks in the tubing.
Kinks impede the flow of urine. Urine that does not drain away from the meatus can cause irritation and skin breakdown and possibly cause the condom catheter to fall off.

13. Secure the catheter tubing to the patient's thigh using a commercial leg strap. (Hypoallergenic tape may be used if a commercial leg strap is unavailable. Follow agency protocol.)
A leg strap controls movement of the tubing and accidental pulling on the condom catheter.

14. Cover the patient and return him to a comfortable position. Raise the siderails and lower the bed.

15. Remove your gloves and perform hand hygiene.

16. Change the condom daily or more often if needed.
This helps to prevent urinary tract infection and allows for inspection of the skin.

? What if . . .

- **The urine flow becomes obstructed?**
  Check the catheter and collecting tube for kinking; readjust if needed and make certain that the tubing is secured properly to the patient's thigh. Replace the catheter and tubing, if necessary.

Evaluation

Within 30 minutes of condom application, assess for:

- Urine flow (should not be obstructed)
- Swelling or discoloration of the penis
  Swelling or discoloration might indicate that the condom is too tight.

Monitor:

- Penis for circulatory changes
- Position and patency of the drainage tubing
- Characteristics of the urine (e.g., amount, color, odor, bleeding)
- Patient comfort
- Leakage of urine

Home Care

- Clients and caregivers should wash their hands before and after any manipulation of the penis or apparatus.
- Daily bag decontamination with a diluted (1:10) bleach solution has been found effective in reducing bacteria.
- Teach the client and caregiver to recognize the signs and symptoms of skin irritation and excoriation, as well as the symptoms of urinary tract infection.
- Teach the client/caregiver to notify the care provider and discontinue use of the condom catheter if skin irritation or swelling occurs; if the urine becomes thick and cloudy, pink or red; if the urine has mucus in it; or if no urine has drained from the catheter in 6 to 8 hours.
- Change the external condom catheter every 24 hours.
- Keep the collecting bag below the level of the bladder.
- Regularly empty the collection bag before it becomes completely full.

Documentation

- Document the date and time of application of the external catheter in the nursing notes.
- Note any unusual findings related to the condition of the skin on the penis.
- Document characteristics of urine (e.g., color, odor, consistency, blood).

Practice Resources

Geng, V., Bonns, E., Eelen, P., et al. (2008); WOCN (2008).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Applying an External Condom Catheter.**

For questions and suggested responses,

Go to Chapter 28, Thinking About the Procedure Questions and Suggested Responses, on Davis*Plus*.

Procedure 28-6 ■ Removing an Indwelling Catheter

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Syringe (5 to 30 mL, depending on balloon size)
- Clean procedure gloves
- Towel or drape
- Receptacle for the catheter, such as an emesis basin)
- Hygiene supplies (washcloth, warm filtered water or perineal wash solution, towel)

Delegation

In some institutions, unlicensed NAPs undergo special training to learn this skill. In such instances, you may delegate this task to the NAP. However, you must complete the following assessments and instruct the NAP about what abnormal findings to report.

Pre-Procedure Assessment

- Assess the patient's cognitive level.
  Knowing whether the patient can follow directions or not helps you to determine how to approach the procedure and also to know if the patient may be prone to pulling on the catheter or your hands when you are removing the catheter.
- Assess the condition of bladder (e.g., distention), perineum, and meatus (e.g., color, swelling, crusting, drainage, lesions).
  This information helps you to establish a baseline for later assessment.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Perform hand hygiene** before and after removing the catheter.
   For mechanical removal of microorganisms.
2. **Wear clean procedure gloves** during the removal.
   Gloving prevents transmission of bacteria.
3. **Explain** that this procedure is nearly always pain-free.
4. **Instruct** the patient to assume a supine position.
5. **Place the catheter receptacle** near the patient (e.g., on the bed).
6. **Place a waterproof drape** or towel.

Variation, Female

Place the drape between the patient's legs and up by the urethral meatus.

Variation, Male

Place the drape on his thighs.

These methods preserve modesty and a feeling of security, and prevent soiling of the bed.

7. **Obtain a sterile specimen** (see Procedure 28-2B), if needed. Some agencies require a culture and sensitivity test of the urine when an indwelling catheter is removed.
8. **Wash the perineum** with soapy water or periwash prior to removal of the catheter.
   The perineum and surface of the colonized with bacteria. Cleansing this area reduces the risk for urinary catheter-associated infection.
9. **Remove the device securing** the catheter to the patient
10. **Deflate the balloon completely** by inserting a syringe into the balloon valve and allowing the balloon to self-deflate. Allow at least 30 seconds for the balloon to deflate. *Note: Follow the manufacturer's directions for balloon deflation. If the direction is to attempt aspiration, it should be done slowly and gently.*
    Aspiration of the balloon may collapse the lumen and cause the formation of creases and ridges that may make removal of the catheter difficult (WOCN, 2009).
11. **Verify that the total fluid** volume has been removed by checking the balloon size written on the balloon port.
    If water remains in the balloon, removal of the catheter make cause urethral trauma.
12. **Ask the patient to relax** and take a few deep breaths as you slowly withdraw the catheter from the urethra. Pinch the catheter while removing it.
    Deep breathing helps the patient to relax the sphincters.
13. **Wrap the catheter in the towel** or drape or place in the catheter receptacle.
14. **Again cleanse the perineal area** with warm filtered water or perineal wash solution on gauze pads or perineal disposable wipes. A mild soap may also be used.
    Cleansing the perineum prevents transmission of bacteria.
15. **Measure the urine** and then empty it in the toilet; discard the catheter, drainage tube, and collection bag in the biohazard waste.
16. **Explain to the patient** the need to monitor the first few voidings after catheter removal. If the patient toilets independently, place a receptacle in the toilet or use a bedside commode. Ask the patient to notify the nurse when she voids and to save the urine.
17. **Remove and discard gloves**; perform hand hygiene.

(continued on next page)

Procedure 28-6 ■ Removing an Indwelling Catheter (continued)

18. Record the date and time of the procedure; the volume, color, and clarity of the urine; and your patient teaching.

19. Return the patient to a position of comfort.

? What if . . .

- **The balloon does not empty completely?**
  Do not pull on the catheter. Report to the charge nurse or the primary care provider before continuing the procedure.
  Pulling on the catheter could cause injury to the urethra.

Evaluation

- Observe for signs and symptoms of infection.
  Signs of a catheter-associated urinary tract infection include the presence of significant bacteriuria in a patient with signs or symptoms of a UTI such as fever, malaise, flank pain, dysuria, altered mental status, or hematuria.
- Observe the condition of the meatus.
- After removing the catheter, monitor the next few voidings. Place a collection container in the commode if the patient is ambulatory.
- Assess the characteristics of the urine at the time the catheter is removed. Then note the time of the first voiding and the amount voided, and observe the urine for color, amount, odor, and presence of blood.
- Compare voidings over the next 8 to 10 hours to the patient's intake.
- Monitor for bladder distention. A portable bladder-scanning device may be used to quantify any residual urine.

Patient Teaching

- Explain to the patient that you need to monitor the first few voidings after catheter removal to ensure that he does not have difficulty re-establishing bladder control.
- Teach the patient to notify you when he voids and to save the urine (if the patient toilets independently).

Home Care

For clients who will have catheters at home, teach the client and family the following:

- The steps for removing the catheter that you learned in this procedure
- To notify a healthcare provider if the client is unable to urinate within 8 hours after catheter removal, or if his abdomen becomes distended and painful
- The signs and symptoms of urinary tract infection
  Signs and symptoms of a urinary tract infection develop rapidly and can include a strong, persistent urge to urinate; a burning sensation when urinating; passing frequent, small amounts of urine; blood in the urine (hematuria); fever; flank pain; or an alteration in mental status.
- Increase fluid intake if not contraindicated by other health conditions.

The client should never remove a catheter unless trained by a healthcare provider. Remove the catheter only when prescribed by the provider.

Documentation

Document the following:

- Date and time the catheter was removed
- Amount of urine (on the I&O portion of the graphics sheet)
- Characteristics of urine (e.g., color, odor, cloudiness, turbidity, or blood)
- The time the specimen was sent to the lab
- The amount of fluid returned from balloon by self-deflation, amount of urine in drainage bag, and notification of first void
- Any unusual findings in your assessment of the perineum
- How the patient tolerated the procedure
- Patient teaching

Sample documentation

3/4/16 1010 Order noted for removal of indwelling catheter. Explained the procedure to patient. Pt stated, "I'm finally getting this thing out." Placed pt in a dorsal recumbent position with blanket to provide privacy. Perineal care completed. Allowed retention balloon to self-deflate, obtaining 10 mL of liquid. Removed catheter, using gentle pulling motion. Pt expressed no discomfort during removal. Perineal care again given. 250 mL of clear, yellow, strong-smelling urine noted in drainage bag. Instructed client to increase fluid intake, especially water, and to notify a nurse when she voids for the first time.——————— C. Chin, RN

Practice Resources

Geng, V., Cobussen-Boekhorst, H., Farrell, J., et al. (2012); Hooton, T. M., Bradley, S. F., Cardenas, D. D., et al. (2010); Parker, D., Callan., L., Harwood, J., et al. (2009a, b); Smith, J. M. (2006); WOCN (2009); Yates, A. (2008).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Removing an Indwelling Urinary Catheter**

For questions and suggested responses,

Go to Chapter 28, Thinking About the Procedure Questions and Suggested Responses, on Davis*Plus*.

Procedure 28-7 ■ Irrigating the Bladder or Catheter

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

Intermittent Irrigation Through a Three-Way Catheter

- Bag of sterile irrigation solution
- Connecting tubing (to connect the bag to the irrigation port)
- IV pole
- Antiseptic swabs or wipes
- Bath blanket

Intermittent Irrigation via the Specimen Port Using a Syringe

- Sterile container
- Sterile 60-mL syringe with large-gauge needleless access device
- Sterile irrigation solution
- Two pairs of clean procedure gloves
- Antiseptic swabs or wipes

Continuous Bladder Irrigation

- Three-way (or triple-lumen) indwelling catheter in place
- Sterile irrigation solution at room temperature
- Connecting tubing
- Antiseptic swabs or wipes
- IV pole
- Bath blanket
- Measuring container
- Pair of clean procedure gloves

Delegation

Irrigation of an indwelling catheter requires nursing assessment and clinical decision-making. Because of the high potential for urinary tract infection, you should not delegate this procedure to the NAP. Bladder/catheter irrigation may be delegated with supervision to qualified LPNs who are trained in the procedure.

Pre-Procedure Assessment

- Note the characteristics of the urine (e.g., amount, color, odor, presence of clots or mucus).
- Assess for the presence and degree of bladder distension.
  This information helps you to establish a baseline for assessment.
- Note patient complaints of discomfort.
- Assess the patient's cognitive status.
  Helps you to determine whether the patient can follow directions and remain still during the procedure.
- Check the chart for the amount and type of sterile solution to use.
- Determine whether the irrigant is to remain in the bladder for any length of time.

Procedure 28-7A ■ Intermittent Bladder or Catheter Irrigation

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This is the procedure for the closed methods of irrigation. The "open" method is no longer recommended. Because of the risk for infection, you should never disconnect the drainage tubing from the catheter.

Procedure Steps

Procedure Variation Three-Way (Triple-Lumen) Indwelling Catheter

1. **Before starting irrigation**, prepare the connection tubing and irrigation solution warmed to room temperature.
   a. Close the clamp on the connection tubing.
   b. Spike the tubing into the appropriate portal on the irrigation solution bag, using aseptic technique.
   c. Invert the solution and hang it on an IV pole.
   d. Remove the protective cap from the distal end of the connection tubing. Hold the end of the tubing over the sink or trash receptacle. Open the roller clamp, and allow the solution to fill the tubing. Be sure to keep the end sterile.
   e. Reclamp the roller on the tubing to stop the flow of irrigation solution.
   f. Recap the tubing.
2. **Perform hand hygiene** and don procedure gloves.
   To reduce the transmission of microbes.
3. **Position the patient in the supine**.
4. **Drape the patient** so only the connection port on the indwelling catheter is visible.
   Protects patient privacy.
5. **Before beginning the flow** of irrigation solution, empty any urine that is in the drainage bag, and perform hand hygiene. Then document the volume on the I&O record.
   Starting the procedure with an empty drainage bag gives you a baseline for correct calculation of true urine output during irrigation.
6. **Scrub the catheter port** with antiseptic swabs or wipes.
7. **Connect the irrigation tubing** to the catheter port.
8. **Slowly open the roller clamp** on the irrigation tubing to the desired flow rate.
   Slow instillation prevents patient discomfort.
9. **Instill or irrigate** with the prescribed amount of irrigant. If the

(continued on next page)

Procedure 28-7 ■ Irrigating the Bladder or Catheter (continued)

irrigant is to remain in the bladder for a certain time period, clamp the drainage tubing for that time.

10. When the correct amount of irrigant has been used and/or the goals of the irrigation have been met, close the roller clamp on the irrigation tubing, leaving the tubing connected to the catheter for use during the next irrigation.
You can assess whether the goals of irrigation have been met by inspecting the color of the urine and assessing for presence of clots, mucus, or blood. Clamping the drainage tubing prevents immediate outflow.

11. Remove gloves, perform hand hygiene, and return the patient to a position of comfort.

Procedure Variation Two-Way Indwelling Catheter

12. Don clean procedure gloves. Empty any urine currently found in the bedside drainage bag.
Emptying the bag will ensure accurate output results.

13. Perform hand hygiene and then apply clean gloves.
Gloving prevents the transmission of microorganisms.

14. Drape the patient so that only the specimen removal port on the drainage tubing is exposed. Place a waterproof drape beneath the exposed port.
Draping ensures patient privacy and prevents soiling of the bed linens.

15. Open the sterile irrigation supplies. Pour approximately 100 mL of the irrigating solution, warmed to room temperature, into the sterile container, using aseptic technique.
Warm solution is more comfortable to the patient.

16. Scrub all surfaces of the specimen removal port with an antiseptic swab or wipe.
Cleaning the port reduces the risk of transmission of pathogens into the bladder.

17. Draw up irrigation solution into the syringe. Connect the syringe to the specimen port. For catheter irrigation, use a total of 15 to 20 mL; for bladder irrigation the amount is usually 30 to 60 mL, unless irrigation is prescribed postoperatively (in which case more irrigation might be needed).

18. Clamp or pinch the drainage tubing distal to the specimen port.
Clamping prevents irrigant from going down into the drainage bag instead of into the catheter and/or bladder.

19. Inject the solution into the port. Hold the specimen port slightly above the level of the bladder. If you meet resistance, have the patient turn slightly, and attempt a second time. If resistance continues, stop the procedure and notify the primary care provider.
Holding the port above the level of the bladder enhances gravitational flow of irrigant into the bladder. ➤

20. When the irrigant has been injected, remove the syringe. Refill the syringe if necessary.

21. Unclamp or release the drainage tubing, and allow the irrigant and urine to flow into the bedside drainage bag by gravity. (If the solution is to remain in the bladder for a prescribed time, leave the tubing clamped for that time period.)

22. Repeat the procedure as necessary until the prescribed amount has been instilled or until the goal of the irrigation is met (e.g., removal of clots and mucus, free flowing of urine).

23. Remove gloves, perform hand hygiene, and return the patient to a position of comfort.

Procedure 28-7B ■ Continuous Bladder Irrigation

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. If one is not already present, insert a three-way (triple-lumen) indwelling catheter.
A triple-lumen catheter provides an access for the irrigation solution without disrupting the sterile drainage unit.

2. Prepare the irrigation fluid and tubing by warming it to room temperature:

a. Close the clamp on the connecting tubing.

b. Spike the tubing into the portal on the irrigation solution container, using aseptic technique.
This prevents the introduction of microorganisms into the solution.

c. Invert the container, and hang it on the IV pole.
The elevated bag allows the solution to flow by gravity.

d. Remove the protective cap from the distal end of the connecting tubing. Hold the end of the tubing over a sink or other receptacle. Open the roll clamp slowly, and allow the solution to fill the tubing

completely. Reclamp the tubing. Recap the tubing.
Priming the tubing flushes air from tubing, preventing bladder distension.

3. **Perform hand hygiene** and don clean procedure gloves.
These two actions prevent the spread of microorganisms.

4. **Place the patient supine** and drape him so that only the connection port on the indwelling catheter is visible.
Draping prevents exposure of the genital area and protects patient privacy.

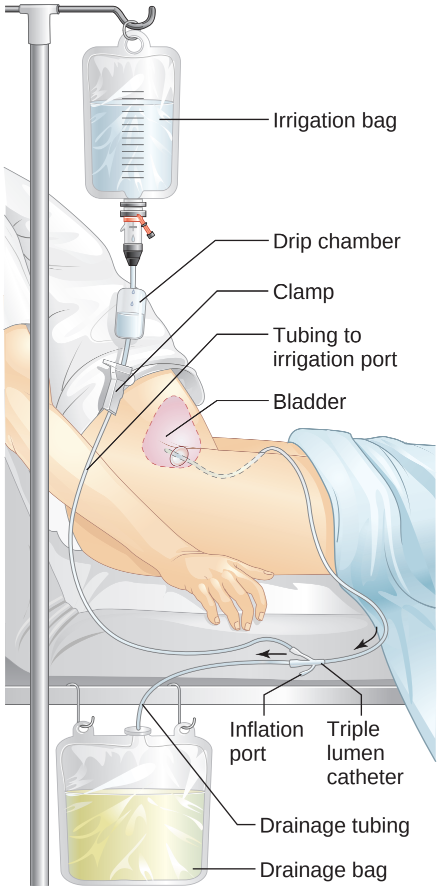
5. **Place a waterproof barrier** drape under the irrigation port. Scrub the irrigation port with antiseptic swabs or wipes. Pinching the tubing and using aseptic technique, connect the end of the irrigation infusion tubing to the irrigation port of the catheter.

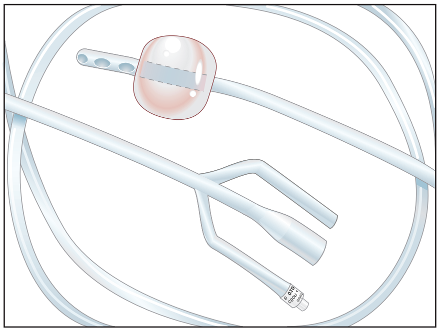
6. **Before beginning the flow** of irrigation solution, empty any urine that may be in the bedside drainage bag, and document the volume on the I&O record.
Starting the procedure with an empty bag gives you a baseline for correct calculation of true urine output during irrigation.

7. **Remove your gloves** and perform hand hygiene.
Gloving and hand hygiene prevent the transmission of microorganisms.

8. **Cover the patient**, and return him to a position of comfort.

9. **Open the roller clamp** on the tubing, and regulate the flow of the irrigation solution to meet the desired outcome for the irrigation.
The goal of continuous bladder irrigation for patients who have had a transurethral resection of the prostate is to keep the urine light pink to clear.





10. **Monitor the flow rate** for 1 to 2 minutes to ensure accuracy.
Monitoring the irrigation fluid for a minute or two prevents rapid introduction of solution into the bladder, which would cause patient discomfort.

? What if . . .

- **The draining irrigant solution and/or urine looks like it has red blood cells in it?**

  Stop the irrigation and report to the primary care provider.
  Increased red blood cells in the urine may indicate bladder irritation and possible trauma to the inner mucosal lining of the bladder.

- **You meet resistance when irrigating?**

  Ask the patient to turn slightly, and attempt a second time. If resistance continues, stop the procedure and notify the primary care provider.

Evaluation

- Note the flow rate of irrigant and/or inability to instill irrigant into the catheter.
- Note the characteristics of urine output (e.g., presence of output, color, amount, clots, mucus).
- Note patient report of discomfort (e.g., pain, spasms).
- Assess for development of bladder distention accompanied by lack of urine outflow. A portable bladder scanner may be used to quantify the amount of fluid retained in the bladder.

Home Care

For clients who will have continuous bladder irrigation at home, you will need to teach the family the necessary steps of the procedure. Also teach them to:

- Empty the urine collection device before beginning the procedure.
- Utilize strict aseptic technique when irrigating the bladder or catheter.
- Irrigate the catheter using the closed method, which carries the least risk for introducing bacteria into the bladder. The catheter and drainage tubing should never be disconnected.
- Identify signs and symptoms of urinary retention and urinary tract infection.
- Wash their hands before and after any manipulation of the catheter site or apparatus.
- Be certain to maintain unobstructed flow.
- For the syringe method, the client will need access to syringes and needleless access devices and a process to dispose of them properly.

Documentation

- Document the date and time of procedure, the type of irrigant, and the total volume infused.
- Document the characteristics of the urine (e.g., color, odor, clarity, sediment, presence of clots or mucus).
- Record evidence of catheter patency (e.g., flow of urine, absence of distention).

CLINICAL INSIGHTS

Clinical Insight 28-1 ➤ Caring for a Patient With an Indwelling Catheter

An indwelling catheter is connected to a drainage tube and collection bag, which constitute a closed system.

Goal 1: Prevent urinary tract infection.

- **Observe standard precautions** when providing catheter care.
- **Wear gloves when handling the catheter** or drainage system.
  Gloving prevents possible exposure to body fluids.
- **Clean around the meatus and perineum** before inserting or removing an indwelling urinary catheter; use aseptic technique and sterile equipment; perform strict and frequent catheter care (Gould, Umscheid, Agarwal, et al., 2009; Loveday, Pratt, Wilson, R.A., et al., 2014).
  Reduce the risk of urinary catheter-associated infection.
- **Maintain a closed system.** Do not disconnect the tubing or open the drainage system (e.g., to obtain specimens or measure the urine).
  A closed system minimizes the chance for pathogens to enter the system and infect the urinary tract.
- **Regularly check connections** between the catheter and drainage tubing and the drainage tube and collection bag.
  Loose connections cause leaks and serve as entry points for pathogens.
- **If the system becomes disconnected**, wipe the ends of both tubes with antiseptic (e.g., alcohol or chlorhexidine gluconate (CHG)–alcohol combination product) before reconnecting them.
- **If the catheter becomes soiled** from drainage or feces and after each bowel movement, cleanse it with mild soap and water by cleaning from the meatus outward. Rinse the catheter well, and pat it dry.
  This removes the medium for growth of microorganisms.
- **Empty the collection bag** at least every 8 hours and more frequently if urine output is high.
  This prevents stagnation of urine.

Clinical Insight 28-1 ➤ Caring for a Patient With an Indwelling Catheter—cont'd

- **Avoid touching the spout** to any surfaces when emptying the collection bag. If the spout is accidentally contaminated, cleanse it with an antiseptic (e.g., alcohol or CHG-alcohol combination product).
- **Keep collection bag below the level of the bladder**, but do not allow it to lie on the floor. Never place the bag on the bed.
  This prevents backflow of stagnant urine into the bladder. Assist the patient to take a shower regularly if his condition permits.
- **Teach the patient to report signs of UTI** (e.g., burning at the meatus); observe for cloudy, strong-smelling urine, chills, or fever.
- **Change the indwelling catheter** only when necessary (e.g., sediment collects in the tubing or catheter or when the urine does not drain well). Some agencies have a policy specifying that catheters be changed at specific intervals (e.g., monthly). However, this is not advisable because the more often a catheter is changed, the more likely an infection will develop

Goal 2: Maintain free flow of urine.

- **Keep the tubing and bag** below bladder level to prevent backflow.
  Urine drains by gravity in this system.
- **If the collecting bag must be higher** than the bladder at any time, you must clamp the catheter.
  Clamping prevents backflow of stagnant urine into the bladder.
- **Frequently inspect the tubing** to ensure that the urine flows freely.
  Kinks, coils, or compression of the catheter or tubing may impede flow and cause backup into the bladder.
- **If urine is not flowing**, check to be sure the patient is not lying on the tubing.

Goal 3: Prevent transmission of infection.

- Observe standard precautions when providing catheter care.
- **Wear gloves** when handling the catheter or drainage system.
  Gloving prevents possible exposure to body fluids.

Always perform hand hygiene before and after providing care to any patient, including one with an indwelling catheter.

Goal 4: Promote normal urine production.

Adequate urine production flushes pathogens out of the bladder, provides natural irrigation of the tubing, and prevents stasis of urine.

- **Encourage oral intake** of at least 8 to 10 glasses (approximately 2,000 to 2,500 mL) of fluid per day, unless contraindicated by other health problems (Turner & Dickens, 2011; WOCN, 2009). For patients who are unable to take oral liquid, provide an equivalent amount of parenteral or enteral fluids.
- **Monitor intake and** output at least every 8 hours. More frequent monitoring may be required if the patient is experiencing fluid and electrolyte problems.
- **For accurate determination of output**, empty the urine into a calibrated container.
  Although the urine collection bag has volume markings, they are only approximate.
- **Observe the urine output** for color and other characteristics. Report evidence of blood, sediment, or infection to the primary care provider.
- **Encourage the patient to be active** and out of bed as much as possible.

Goal 5: Maintain skin and mucosal integrity.

Perineal skin and mucosa can be irritated by feces and by movement or encrustation of the catheter.

- **Secure the tubing** by applying a commercial catheter securement device, such as a catheter tube holder or a Velcro strap, to the patient's thigh. Hypoallergenic tape may be used if a catheter securement device is unavailable. For men, if the catheter will remain in place for an extended period, secure the tubing to the abdomen to prevent damage to the penile–scrotal juncture.
  Failure to secure the tubing may cause significant injury to the bladder neck and urethra. Although the inflated balloon helps maintain the catheter in the bladder, you will need to secure the tubing to the leg to prevent traction on the bladder and urethral meatus.
- **Assist with routine hygiene care** as needed. Cleanse the area around the meatus with mild soap and filtered tap water or perineal wash solution daily, after each bowel movement, and more often if there is drainage or excessive sweating. Be sure to rinse well and pat dry.
  Routine hygiene care normally provides adequate cleanliness. Rinsing helps to avoid irritating the skin with soap residue.
- **Avoid using powders or lotions** in the perineal area.
  Topical products can be irritating to the skin.
- **Monitor the urethral meatus** and upper drainage tube.
  Encrustation, as evidenced by sandy particles at the meatus, is irritating to the mucosa and signals a need to change the catheter.

Clinical Insight 28-2 ➤ Caring for Patients With Urinary Incontinence

Most urinary incontinence (UI) is managed with skin care and behavioral interventions, but medications and other collaborative treatments are sometimes used.

Open Discussion about Incontinence

- Patients and families often do not raise the issue. Be direct and ask about continence using simple questions in a way that will not embarrass the patient, such as "Do you wear a pad to keep your clothes dry?" "Do you ever wet your clothing?"
- If you determine that the patient is incontinent, ask follow-up questions to identify the type of incontinence. For example: "Do you sometimes not make it to the toilet in time?" "Do you ever dribble urine when you sneeze or cough?"
- Encourage use of a bladder diary for at least 3 to 7 days, covering routine day-to-day activities as well as atypical situations.
- Advise patients to contact a healthcare provider if:
  - They have not been previously evaluated for this problem.
  - The urinary stream is weak.
  - There is burning, fever, chills, pain, or passing little urine for 1 to 2 days.
  - Urine is cloudy or unusually foul smelling.
  - Discharge occurs from the penis or vagina.
- Advise women who have a body mass index (BMI) >30 to lose weight (Rainsbury, Fabricius, & McLarty, 2011).
- Advise patients to take prescribed diuretics early in the morning. Diuretics taken at night can cause nocturia and lead to interrupted sleep.

Lifestyle Modification

Make the following recommendations to patients over for changes in lifestyle:

- **Increase daily oral fluids** to 8 to 10 glasses (or 2,000 to 2,500 mL), as tolerated. High fluid intake is good for flushing of the bladder. Limiting fluid intake has not been shown to be useful in preventing the development of incontinence (Townsend, Jura, Curhan, et al., 2011) and increases the risk for UTIs, constipation, and dehydration (Lucas, Bedretdinova, Bosch, et al., 2013).
- **Limit caffeine intake** to less than 100 mg. daily. This is about one cup of coffee or two 12-ounce cans of cola. Caffeine is a diuretic and a bladder stimulant.
- **Try limiting the intake** of alcohol, artificial sweeteners, spicy foods, and citrus fruits. These are thought to irritate the bladder.
- **Lose weight** (for persons with a BMI >30). Studies have shown this to be more effective for women than for men. Weight reduction by as little as 5% to 10% alleviates incontinence symptoms and improves the quality of life.
- **Stop smoking.** Smoking has been linked to stress UI and urge UI among women, and to urge UI in men.
- **Take prescribed diuretics early in the morning.** Diuretics taken at night can cause nocturia and lead to interrupted sleep.
- **Avoid constipation.** (See Chapter 29 for interventions to promote normal bowel elimination.) Fecal impaction and chronic constipation, especially in older adults, are associated with increased risk of UI.
- **Consider low-impact exercise.** High-impact exercise (e.g., running, jumping rope) is associated with increased stress UI.

Bladder Training

The goal of bladder training is to enable the patient to hold increasingly greater volumes of urine in the bladder and to increase the between voidings.

- Teach the mechanisms of urination.
- Teach distraction and relaxation strategies to help inhibit the urge to void. For example:
  - Instruct the patient to perform serial subtractions or become involved in an activity that requires concentration (e.g., a crossword puzzle) when she feels the urge to void.
  - Alternatively the patient might perform several rapid pelvic floor muscle contractions to quiet the sensations from the bladder.
  - Other techniques include deep breathing and guided imagery.
- **Scheduled voiding** is a form of bladder training involving timed voiding and habit retraining. The patient must be mentally and physically capable of self-toileting.
  - Assist the patient to the toilet, commode, or bedpan on a timed schedule. Initially this may be every 2 hours or even more often.
  - As a pattern develops and the person gains greater control, the length of time between voiding may be increased.
  - Scheduled voiding is usually combined with other techniques, including lifestyle adjustments and pelvic muscle exercises.
  - Ask the patient to keep a daily record of her adherence to the schedule and of the number of incontinence episodes.
  - When the patient can adhere to the schedule comfortably, the voiding interval can be increased by 15 to 30 minutes.

Pelvic Floor Muscle Exercises (PFMEs)

Teach patients the following routine to strengthen pelvic floor muscles:

- Imagine that you are urinating and wish to stop the flow; also tighten your rectum as though you are trying to keep from passing gas. The muscles you contract to interrupt flow are the pelvic floor muscles. *Note: Caution the patient against doing PFMEs while actually urinating because this may cause backflow of urine.*
- You should feel your rectum tighten. Women may also feel the vagina tighten. Your abdomen should not tighten—check by placing your hand lightly on your abdomen. Do not contract the thigh and gluteal muscles.
- Hold each contraction for 5 to 10 seconds and then rest for 5 to 10 seconds. Some people may be able to hold for only

Clinical Insight 28-2 ➤ Caring for Patients With Urinary Incontinence—cont'd

3 seconds at first. Count, "one-and-two-and-three. . . ." Keep contraction and relaxation times equal. That is, if you hold a contraction for 5 seconds, rest 5 seconds before the next contraction.

- A recommended daily exercise routine is to perform 10 to 15 PFMEs three times a day. Do not do all 30 to 45 exercises at one time; spread them out through the day.
- One way to remember to perform your exercises it to associate them with an activity. For example, do PFMEs at every stoplight or stop sign when you are in the car. Or, do some of these exercises every time you go to the bathroom—but not while you are urinating.

Supportive Interventions

Supportive interventions focus on helping the patient reach the toilet and perform toileting self-care.

- Ask where the toilet is and whether the patient can get there easily. If he cannot, it may be useful to place a commode near where the patient spends most of his time.
- Provide a bedside commode, raised toilet seat, bedpan, urinal, or other aids to make it easier to urinate independently. For some patients, a commode should be placed by the bedside on a large, absorbent, washable mat (to absorb any urine that leaks).
- Advise and assist the patient with gait and strength training to improve the person's ability to reach the toilet in time.
- When continence cannot be achieved, provide absorbent products with waterproof coverings. Meticulous skin care must be given when these are used. Under no circumstances should you refer to these as "diapers," as this is disrespectful of the patient's dignity.
- Men with urinary incontinence can use a drip collector, which is a small pocket of padding worn over the penis and held in place with underwear.

Practice Resources

Dowling-Castronovo, A., & Bradway, C. (2012); Goode, P. S., Burgio, K. L., Richter, H. E., et al. (2010); Lucas, M. G., Bedretdinova, D., Bosch, J., et al. (2013)

Clinical Insight 28-3 ➤ Caring for Patients With Urinary Diversions

The overall goals are for the patient to become comfortable with his changed body and to assume self-care.

- **Perform a thorough assessment.** A healthy stoma ranges in color from deep pink to brick red, regardless of skin color, and is shiny and moist at all times. A pale, dusky, or black stoma often indicates inadequate blood supply. Immediately document and report such findings to the surgeon.
- **Assess the skin surrounding the stoma for signs of irritation**, such as redness, tenderness, and skin breakdown.
  Key Point: *Skin care is critical. When the normally acid urine remains in contact with the skin, it becomes alkaline. Encrustations collect on the skin and the skin becomes macerated and excoriated. Skin breakdown may lead to infection, pain, and leakage.*
- **Be certain that the collection device fits** snugly against the skin. A moisture-proof skin barrier is usually placed around the stoma.
  Moisture on the skin can lead to irritation and maceration.
- **Barrier creams** may be prescribed for irritated skin; if fungal infection develops, nystatin may be prescribed.
- **Monitor the amount and type of drainage** from the stoma.
- **Empty the device frequently** during the day; connect it to a larger collection bag during the night when the patient is sleeping.
- **Be available to discuss the patient's reaction** to the stoma.
  Key Point: *Be careful your facial expressions do not convey disgust or disapproval when working with the patient and his stoma.*
- **Provide ample time** to explain stoma care and use of ostomy appliances.
  For most patients this is a life-long task; therefore, patient teaching is essential.

Patients with a continent urinary reservoir

These patients will also need instruction about catheterizing their reservoir to drain the urine. Once healed, the reservoir will need to be catheterized four or five times a day.

Patients with a neobladder

- These patients will not have a stoma, but will require bladder training once the postoperative retention catheter has been removed.
- The patient should be instructed to perform pelvic floor muscle exercises three times a day and empty the bladder on a schedule, as often as every two hours initially. Once bladder capacity builds, the interval between voidings may be increased.
- The patient will need to relax the pelvic muscles and bear down to release urine from the bladder. He may also need to use **Credé's maneuver**, applying manual pressure over the bladder to promote emptying.
- If the patient is unable to fully empty the bladder with these techniques, he may need to perform intermittent self-catheterization.

Clinical Insight 28-4 ➤ Teaching Clients About Clean, Intermittent Self-Catheterization

You will need to teach self-catheterization to clients who have compromised ability to spontaneously empty their bladders. In the home setting, this is a clean procedure rather than a sterile one. It is referred to as clean, intermittent self-catheterization (CISC).

Goals of intermittent self-catheterization

1. Completely empty the bladder.
2. Prevent urinary tract infections.

Teaching Considerations

- In teaching the steps of the procedure, consider the client's physical ability to manipulate the catheter equipment and reach the urethra (e.g., range of motion, fine motor skills, degree of sensation).
- Encourage the client to drink 8 to 10 eight-ounce glasses of fluid without caffeine each day to ensure a quantity of urine adequate to flush the bladder.
- Teach the client to report the signs and symptoms of urinary tract infection: burning, frequency, urgency, dull abdominal ache, fever, or malaise; or urine that contains sediment or becomes cloudy.

Older adults may experience confusion before the other signs and symptoms occur.

- Advise the client to contact a healthcare provider if there is bleeding, pain, or difficulty inserting the catheter.
- Some CISC catheters can be reused; some are disposable.
- Instruct the patient to wash her hands thoroughly before handling the equipment or performing the catheterization.
- Catheterize as often as needed. Most patients will need to catheterize 4 to 6 times daily.
- Discard a reusable catheter when it becomes difficult to clean or difficult to insert. A CISC catheter may be reused up to seven days (Newman & Willson, 2011).
- Recommendations for cleaning a reusable catheter include washing with soap and water, boiling or microwave sterilization, or soaking in an antiseptic solution. Running tap water forcefully through the catheter may remove encrustation or mucus deposits. Check for specific cleaning recommendations from the catheter manufacturer.

Procedure for Men

1. **Try to void before catheterization.** If you are unable to void or if the amount is less than 3 ounces (or the amount specified by your healthcare provider), then insert the catheter.
2. Assemble the catheter, lubricant, and drainage receptacle.
3. **Thoroughly wash** your hands with soap and water; cleanse the penis and the urethral opening.
4. **Lubricate** the catheter to 6 inches (15 cm).
5. **Stand over the toilet** or assume a comfortable position (e.g., sitting on the toilet).
6. **Hold the penis** perpendicular (at a right angle) to your body.
7. **Gently insert** and advance the catheter.
8. **When you meet resistance**, at the level of the prostate, take deep breaths to try to relax, and advance the catheter.
9. **When urine flow starts,** advance the catheter 1 inch (2.5 cm) more; return the penis to its natural position; hold the catheter in place until the urine flow stops and bladder is empty.
10. **Withdraw the catheter** slowly in small increments to be sure the entire bladder empties.
11. **Wash the catheter** with soap and water, if it is reusable (or follow the manufacturer's instructions for cleaning). Rinse and dry it well. If it is disposable, discard it immediately.
12. **Store catheters** in a clean, dry, secure place.
13. **Record the amount** of urine obtained.

Procedure for Women

1. **Try to void before catheterization.** If you are unable to void or if amount is less than 3 ounces (or the amount specified by your healthcare provider), then insert the catheter.
2. **Assemble the catheter,** lubricant, and drainage receptacle; a good light is important for women.
3. **Thoroughly wash hands** with soap and water.
4. **Cleanse your labia and urethra** with soap and water or with a moist towelette; rinse well. Cleanse and rinse from front to back.
5. **Lubricate the catheter** to about 1 inch (2.5 cm).
6. **Assume a comfortable position** for urinating. Some women perform CISC standing up with one foot on the toilet.
7. **Use a hand mirror** to locate the urethral opening, which is between the clitoris and the vagina.
8. **Spread your labia** with the second and fourth fingers; use the middle finger to feel for the urethral opening.
9. **Gently insert the catheter** into the opening, guiding it upward toward your umbilicus (belly button) until urine flows. This is usually 2 or 3 inches (5 to 8 cm) past the urethral opening.
10. **When urine flows,** advance the catheter another 1 inch (2.5 cm). Hold it in place until the urine stops and your bladder is empty.
11. **Withdraw the catheter slowly** in small increments, to be sure the entire bladder empties.
12. **If the catheter is reusable,** wash it with soap and water; rinse and dry it well (or follow the manufacturer's instructions for cleaning). If it is disposable, discard it immediately.
13. **Store catheters** in a clean, dry, secure place.
14. **Record the amount** of urine obtained.

Practice Resources

Joanna Briggs Institute (2011); Newman, D. K., & Willson, M. M. (2011).

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Urinary Elimination History Questions

Usual Urination Pattern

- How often do you urinate?
- Do you get up in the middle of the night to urinate?
- Do you have difficulty getting to the bathroom in time to urinate?
- Do you ever leak urine when you cough, laugh, or exercise?
- Do you ever leak urine on the way to the bathroom?
- Do you need to use pads or tissue in your underwear to catch urine?
- Do you have any difficulty starting to void?

Appearance of Urine

- How would you describe your urine?
- Have you noticed unusual odor with urination?

Changes in Urination Habits or Urine Appearance

- Have you experienced any changes in your voiding pattern recently?
- Have you experienced any changes in the appearance or odor of your urine?

History of Urination Problems

- Have you experienced any problems with urinary tract infections or kidney and bladder problems?
- Have you ever lost control of your urination?
- Have you ever had urinary tract surgery or diagnostic procedures?

Use of Urination Aids

- What aids, if any, do you use to help you urinate?
- What is your usual fluid intake over the course of a day?
- What medications are you taking? Have they had any effect on your urination pattern?

Lifestyle Questions

- Where is your bathroom located? Can you get to it easily?
- Can you manage your clothing when you go to the bathroom?
- How much fluid do you drink each day?
- How many caffeinated beverages do you drink?
- Do you smoke?
- Are you bothered with constipation?
- Do you do high-impact exercise (e.g., jogging)?

Presence of Urinary Diversions

- Have you ever had urinary tract surgery?
- If so, what and when?
- Gather data on the client's usual care of the stoma, use of appliances, and adjustment to the ostomy.

For Infants and Young Children

- Has the child been toilet-trained?
- What elimination routines have been established?

Focused Assessment

Guidelines for Physical Assessment for Urinary Elimination

Physical assessment for urinary elimination includes examination of the kidneys, bladder, urethra, and skin surrounding the genitals, as appropriate. For a complete discussion of physical examination of the genitourinary system, see Chapter 22, Procedures 22-17 and 22-18, in this volume.

The Kidneys

Technique	*Rationale*
The **costovertebral (CV) angle** is formed by the junction of the 12th rib and the spine on both sides of the back. Place one palm flat on the CV angle and lightly strike it with the closed fist of the other hand (see the accompanying figure).	You cannot usually palpate the kidneys. Instead, examine them by assessing for costovertebral angle tenderness (CVAT). If kidney inflammation is present, percussion of this angle produces pain.

(Continued)

Focused Assessment

Guidelines for Physical Assessment for Urinary Elimination—cont'd

The Bladder

Inspect, palpate, and percuss the lower abdomen. Correlate your findings with data about the client's fluid intake and voiding.

➤ Inspect the lower abdomen.	An empty bladder, or one with limited urine, is small and sits below the symphysis pubis. In contrast, a distended bladder rises above the symphysis pubis. If it is very distended, you may be able to see a rounded swelling above the symphysis pubis.
➤ Lightly palpate the lower abdomen to define the bladder margin. Observe the patient's response to palpation, noting signs of tenderness or discomfort.	An empty bladder, or one with limited urine, will not be palpable.
➤ Percuss the area.	A distended bladder produces a dull sound as opposed to the normal tympanic sound of intestinal air.

The Urethra

➤ Inspect the urethral orifice. Look for erythema, discharge, swelling, or odor.	These are all signs of infection, trauma, or inflammation.

The Perineal Area

➤ Frequently inspect skin color, condition, texture, turgor, and presence of urine or stool.	Clients who have urine leakage or a urinary catheter are at risk for perineal skin problems. Ammonia in the urine may result in skin excoriation, skin breakdown, and subsequent infection. If both urine and stool are present on the skin, the likelihood of skin breakdown increases.

Diagnostic Testing

Urinalysis

Characteristic Findings	Expected	Variations
Color	A freshly voided sample is pale yellow to deep amber.	Urine becomes lighter in color and may even be clear if fluid intake is high or urine output is excessive. Urine becomes dark in color as it becomes more concentrated with decreased fluid intake or excessive fluid loss. Color is also affected by diet and medications.
pH	5.0–9.0	Indicates kidneys' ability to help maintain balanced hydrogen ion concentration in the blood. The pH increases (more alkaline) if the client eats dairy products or citrus fruits or has a vegetarian diet. The pH decreases (more acidic) if the client eats a high-protein diet or consumes cranberry juice.
Specific gravity	1.002–1.030	This is a reflection of the kidney's ability to concentrate urine. Specific gravity rises with limited fluid intake or dehydration. It may also rise with kidney disease. Specific gravity decreases as fluid intake increases.
Clarity	A freshly voided sample should be translucent. If the urine sits for a period of time, it will become cloudy.	Cloudiness in a freshly voided sample indicates the presence of other constituents in the urine. These may include bacteria, RBCs, WBCs, sperm, prostatic fluid, or vaginal discharge.
Odor	Fresh urine is mildly odorous.	Certain foods, such as garlic, onions, and asparagus, may give urine a distinctive odor. Bacteria will give urine an ammonia-like odor. A sweet syrup odor may indicate an inborn metabolic disorder (maple syrup urine disease).
Protein	<20 mg/dL	Proteinuria is the most common indicator of renal disease. Protein is increased in diabetic nephropathy, glomerulonephritis, nephrosis, and toxemia of pregnancy. May be increased in benign proteinuria secondary to stress or physical exercise.

Diagnostic Testing

Glucose	Negative	Glucose is found in the urine with elevated blood sugars and diabetes.
Ketones	Negative	Presence of ketones indicates impaired carbohydrate metabolism. Ketones may be detected with diabetes, fever, fasting, high-protein diets, starvation, vomiting, and during the postanesthesia period.
Hemoglobin	Negative on dipstick If RBCs are assessed via microscopic exam: <5 per high-power field	Hemoglobin may be detected with infection of the urinary tract, disease of the bladder, glomerulonephritis, pyelonephritis, trauma, nephrolithiasis, hemolytic reactions, or trauma. It also may be present in samples from women who are currently menstruating.
Bilirubin	Negative	Increased bilirubin occurs with liver disease.
Urobilinogen	Up to 1 mg/dL	Increase is found in cirrhosis, heart failure, liver disease, infectious mononucleosis, malaria, and pernicious anemia.
Nitrite	Negative	Nitrite is used to test for bacteriuria. Increased in the presence of nitrite-forming bacteria, such as *Escherichia coli*.
Leukocyte esterase	Negative If WBCs are assessed via microscopic exam: <5 per high-power field	Leukocytes are increased in bacterial infection, calculus formation, fungal or parasitic infection, glomerulonephritis, interstitial nephritis, or tumor.
Renal cells	None seen	Renal cells come from the lining of the collecting ducts. Their presence indicates damage to the tubular network.
Transitional cells	None seen	Transitional cells line the renal pelvis, ureter, bladder, and proximal urethra. Their presence is seen with infection, trauma, and malignancy.
Squamous cells	Rare	Typically insignificant: Squamous cells line the vagina and distal portion of the urethra.
Casts	Rare hyaline; otherwise negative	Large numbers of hyaline casts are seen in renal disease, hypertension, with diuretic use, and fever. Granular casts are seen in renal disease, viral infection, or lead intoxication.
Crystals	Absent in freshly voided sample	Crystals in the urine may indicate an old sample, stone formation in the urinary tract, gout, high dietary intake of oxalates, liver disease, or side effect of chemotherapy.
Bacteria, yeast, parasites	None seen	Microbes in the urine indicate an infection of the urinary tract.

Diagnostic Testing

Blood Studies: BUN and Creatinine

Normal Ranges

Blood urea nitrogen (BUN)	8–21 mg/dL
Creatinine	0.5–1.2 mg/dL

Levels may be increased in:

- Renal failure
- Impaired renal perfusion
- Kidney inflammation
- Kidney obstruction
- Dehydration
- Excessive protein intake
- Use of total parenteral nutrition (TPN)

Levels may be decreased in:

- Inadequate protein intake
- Malabsorption syndromes
- Liver disease

Source: Adapted from Van Leeuwen, A. M., Poelhuis-Leth, D., & Bladh, M. L. (2011). *Davis's comprehensive handbook of laboratory & diagnostic tests—with nursing implications* (4th ed.). Philadelphia, PA: F.A. Davis.

Studies of the Urinary System

Direct Visualization Studies

Cystoscopy

Direct visualization of the urethra, bladder, and ureteral orifices by insertion of a scope. May be used to obtain biopsies and treat pathology of visualized areas.

Preparation

- Instruct the patient that the procedure is performed under anesthesia. This anesthesia may be general, spinal, or local.
- Ensure that a signed consent form is on the chart.
- Restrict food and fluids for 8 hours if the patient is receiving general anesthesia. For local anesthesia, allow only clear liquids for 8 hours before the procedure.

Post-Procedure Care

- Monitor vital signs and intake and output (I&O).
- Observe the characteristics of urine after the procedure.
- Encourage increased fluid intake.
- Report suprapubic or flank pain, chills, or difficulty urinating.

Cystometry

This test is done to determine whether a muscle or nerve problem is causing problems with how well the bladder holds or releases urine. A catheter is inserted into the bladder and a pressure probe into the rectum. Warm fluid is injected and connected to cystometer, which measures how much the bladder can hold and the pressure in the bladder. Sometimes a gas or contrast material is used.

Preparation

- Ensure a signed consent form is on the chart.
- Explain that patient cooperation with positioning and activity is crucial during the test.
- There are no food or fluid restrictions before the test.

Post-Procedure Care

- Monitor vital signs and I&O.
- Encourage increased fluid intake.
- Report suprapubic or flank pain, chills, or difficulty urinating.

Indirect Visualization Studies

Intravenous Pyelogram (IVP) & Retrograde Pyelogram

An IVP uses intravenous radiopaque contrast medium to visualize the kidneys, ureters, bladder, and renal pelvis. It evaluates renal function by analyzing flow of contrast over time.

A retrograde pyelogram uses radiopaque contrast medium to visualize the renal collecting system. Contrast media is injected via a ureteral catheter inserted through a cystoscope.

Preparation

- Assess for history of allergies. Radiopaque dyes can be highly allergenic for some patient; therefore, this test is contraindicated for patients with allergies to shellfish or iodinated dye.
- Ensure baseline BUN and creatinine results are available. This test is contraindicated for patients who are in renal failure.
- Ensure that a signed consent form is on the chart.
- Restrict food and fluids for 8 hours prior to the procedure. Check agency protocols for specific guidelines, especially related to fluid intake.
- Some patients may require a laxative the evening before the surgery to clear the GI tract and improve visualization.
- Check to be sure diabetic patients who take insulin make an adjustment to the insulin dose when fasting for this examination.
- Determine the patient is not pregnant, breastfeeding, or with an intrauterine device (IUD) in place.
- Ask if the patient has had an X-ray test using barium contrast material (such as a barium enema) or have taken a medication containing bismuth (e. g., Pepto-Bismol) in the four days prior to the test. These can affect the test results.
- Check for a history of bleeding disorders or if the patient is taking any anticoagulant, aspirin, or other medications that affect blood clotting. It may be necessary to hold these medications prior to the procedure.

Post-Procedure Care

- Encourage increased fluid intake.
- Monitor vital signs and I&O.
- Observe for reactions to the contrast media: rash, nausea, hives.

Ultrasound

Using contrast media, computerized tomography (CT) scanning examines body sections from different angles using a narrow x-ray beam to produce a three-dimensional picture of the area of the body being scanned.

Preparation

- Ensure a signed consent form is on the chart.
- There are no food or fluid restrictions with renal ultrasound. A patient undergoing bladder ultrasound may be required to drink five to six glasses of fluid 90 minutes before the procedure to ensure a full bladder.

Post-Procedure Care

- No special care is required.

Computerized tomography

Using contrast media, a CT scan examines body sections from different angles using a narrow x-ray beam to produce a three-dimensional picture of the area of the body being scanned.

Diagnostic Testing

Preparation

- Obtain history of allergies. This test is contraindicated for patients with allergies to shellfish or iodinated dye.
- Ensure a signed consent form is on the chart.
- For a renal CT scan, food and fluids are usually restricted for 2 to 4 hours prior to the procedure.
- Remove all metal objects from the patient's body (e.g., eyeglasses, rings, safety pins).

Post-Procedure Care

- Monitor vital signs and I&O.
- Observe for reactions to the contrast media: rash, nausea, hives.

Renal biopsy

Removal of a piece of kidney tissue for microscopic evaluation, usually done with ultrasound guidance.

Preparation

- Ensure baseline coagulation studies and hemoglobin results are available.
- Ensure a signed consent form is on the chart.
- NPO 6 to 8 hours prior to an open biopsy procedure and at least 4 hours prior to a needle biopsy procedure. Protocols may vary among facilities.
- Instruct the patient that sedation and/or pain medication may be given.

Post-Procedure Care

- Monitor vital signs and I&O.
- The patient will be on bedrest for 6 to 24 hours as ordered.
- Monitor biopsy site for bleeding.
- Monitor urine for presence of blood.

Source: Adapted from Van Leeuwen, A. M., Poelhuis-Leth, D., & Bladh, M. L. (2011). *Davis's comprehensive handbook of laboratory & diagnostic tests—with nursing implications* (4th ed.). Philadelphia, PA: F.A. Davis.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

You are providing care to an older-adult patient, Mrs. Patel, who has a number of health concerns, including diabetes and obesity. Mrs. Patel seeks healthcare because she is experiencing burning with urination, frequency, and urgency. You explain to her these are signs of a urinary tract infection. You discover while taking your nursing history that she also has difficulty with urinary continence. When asked about her toileting habits, she tells you she often doesn't "make it to the bathroom" even while at home. This has been going on for about 3 years. She has trouble getting up and walking upstairs to the bathroom because of a foot ulcer that doesn't seem to be healing well. Mrs. Patel's affect is flat with little expression. During your time with her, she seems to have little interest in talking about her health concerns. When you ask her about what she does to get out or socialize, she admits to being hesitant to go far because she is afraid of wetting without knowing it and carrying an odor that would be embarrassing to her.

THINKING

1. *Theoretical Knowledge (Recall of Facts and Principles):*
   a. What kind(s) of incontinence is this patient likely to have?
   b. What are this patient's risk factors for incontinence?
2. *Critical Thinking (Contextual Awareness):*
   a. What aspects of this situation have you experienced or observed before in your role as a caregiver?
   b. How might those past experiences affect your perception in this situation?

DOING

3. *Practical Knowledge (Patient Teaching):*
   a. How could you encourage this woman to seek healthcare for managing her urinary incontinence?
   b. What might you ask your patient to do in order to get a better idea of her bladder history and toileting habits?
   c. By looking at Mrs. Patel's bladder diary, you see a pattern suggestive of urinary incontinence. What other behavioral strategies might you suggest to improve her ability to have control of her bladder?

CARING

4. *Self-Knowledge:*
   a. Have you ever personally experienced urinary urgency when you had trouble getting to the bathroom in time? Reflect on this experience and examine how you might feel if you were incontinent much of the time.
   b. In what way(s) can you show compassion for the patient who has urinary incontinence?

Critical Thinking and Clinical Reasoning

1. You receive a report from the NAP that a patient with no history of urinary elimination problems has had 150 mL of oral liquids in 6 hours and has voided 100 mL of clear, dark amber urine. His vital signs at the start of the shift were as follows: blood pressure, 108/76 mm Hg; pulse, 72 beats/min; respirations, 18 breaths/min; temperature, 98.6°F (37.0°C). The most recent check revealed blood pressure, 112/80 mm Hg; pulse, 88 beats/min; respirations, 22 breaths/min; and temperature, 100.4°F (38.0°C).
   a. What conclusion might you draw about what has caused these symptoms?
   b. What actions should you take?
2. As you make patient rounds, you discover a collection bag for an indwelling catheter placed on the bed above the level of the patient's bladder.
   a. What should you do first? What assessments should you make?
   b. What teaching would be important in this situation?
3. Nursing assistive personnel (NAP) complain that Mr. Jones, a patient with dementia, keeps urinating in his trashcan and in the hallway.
   a. What special measures could be taken to assist Mr. Jones in finding the bathroom?
   b. What data could be helpful in developing a plan for Mr. Jones?
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or urinary elimination. Note that these are *not* to be merely definitions.

Blood pressure
Kidney tubules
Developmental stage
Privacy
Hydration
Specific gravity
Urinary incontinence

What Are the Main Points in This Chapter?

- The urinary system consists of two kidneys, two ureters, the urinary bladder, and the urethra.
- The kidneys filter nitrogen and other metabolic wastes, toxins, excess ions, and water from the bloodstream and excrete them as urine.
- The bladder has a normal average storage capacity of 500 mL (1 pint), but it may distend, when needed, to a capacity twice that amount.
- Voiding occurs when contraction of the detrusor muscle pushes stored urine through the relaxed internal urethral sphincter into the urethra.
- The kidneys produce urine at a rate of approximately 60 mL per hour, or 1,500 mL per day. Most people urinate about five to six times per day.
- Voiding and control of urination require normal functioning of the bladder and the urethra, as well as an intact brain, spinal cord, and nerves supplying the bladder and urethra.
- As an adult ages, the number of functional nephrons gradually decreases, along with the ability to dilute and concentrate urine. The potential volume of the bladder also decreases as the bladder wall loses elasticity; thus, older adults need to urinate more frequently.
- Substances that contain caffeine act as diuretics and increase urine production.
- A diet high in salt causes water retention and decreases urine production.
- Medications with anticholinergic effects inhibit the free flow of urine and may contribute to urinary retention.
- An adequately hydrated adult produces clear yellow urine. Concentrated urine is darker in color, but dilute urine can appear colorless.

- A clean-catch urine specimen is preferred for many diagnostic tests. To collect this specimen, the client must cleanse the genitalia before voiding and collect the sample in midstream.
- Sterile urine specimens may be obtained by inserting a catheter into the bladder or withdrawing a sample from an indwelling catheter.
- Twenty-four-hour urine collection requires collection of all urine voided in the time period. The start time of the 24-hour collection begins when the first-voided urine is discarded.
- A routine urinalysis is one of the most commonly ordered laboratory tests. It is used as an overall screening test as well as an aid to diagnose renal, hepatic, and other diseases.
- Normal urine is free of bacteria, viruses, and fungi. Urinary tract infections are often caused by the introduction of *E. coli*, which normally live in the colon, into the urethra and bladder.
- Urinary retention is an inability to empty the bladder. It may occur because of obstruction, neurological problems, infection, surgery, medications, or anxiety.
- Urinary catheterization is the introduction of a pliable tube (catheter) into the bladder to allow drainage of urine.
- Urinary incontinence (UI) is a lack of voluntary control over urination. Nurses can independently perform the primary interventions to manage UI.
- A urinary diversion is required when the bladder must be removed or bypassed. There are three options: a conventional urostomy or ileal conduit, a continent urinary reservoir, or a neobladder.
- A patient with a urinary diversion requires physical and psychological care. The goal is to have the patient become comfortable with his changed body and assume self-care.

Knowledge Map

STRUCTURES:
Kidneys – filter; regulate
Nephrons – urine formation
Ureters – urine transport
Bladder – urine storage
Urethra – urine transport
Sphincters – flow control

FACTORS AFFECTING:
- Developmental stage: infants, elders
- Personal; sociocultural; environmental
  - time; privacy; loss of dignity
- Nutrition; hydration
- Activity
- Medications
- Surgery/anesthesia

PATHOLOGICAL CONDITIONS AFFECTING URINATION:
- UTI
- Calculi
- BPH
- Cardiovascular & metabolic diseases
- Neurogenic bladder
- Impairments: mobility, communication, cognition

URINATION

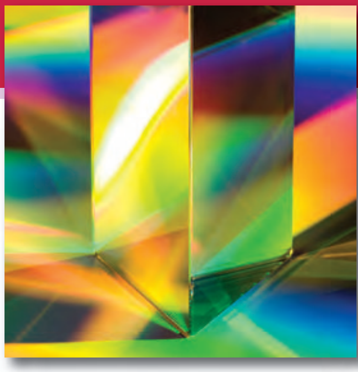
ASSESSING URINE:
- Intake and output
- Urine studies
  - analysis
  - specific gravity
  - dipstick
- Specimens from:
  - fresh-voided
  - clean-catch
  - sterile specimen
  - 24-hour collection

PROMOTING NORMAL URINATION:
- Provide privacy
- Position properly
- Establish toileting routines
- Provide adequate fluids/ nutrition
- Assist with voiding

COMMON URINARY PROBLEMS:
- Urinary tract infections
  - urethritis; cystitis; pyelonephritis
- Urinary retention
- Urinary incontinence:
  - urge
  - stress
  - overflow
  - functional
  - transient
  - reflex
  - enuresis
- Urinary diversions
  - cutaneous ureterostomy
  - ileal conduit
  - Kock pouch (continent urostomy)

URINARY CATHETERIZATION
- Straight catheter
- Indwelling catheter
- Suprapubic catheter

- Skin care
- Lifestyle changes
- Bladder training
- Scheduled voiding
- Kegels
- Biofeedback
- Anti-incontinent devices



CHAPTER 29

Bowel Elimination

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 29:
- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Bowel Elimination (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 29, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Yen Nguyen arrives at the family health center for a scheduled appointment, accompanied by her grandson, Kim Phan. Recently, Yen has been constipated and has had several episodes of bleeding with bowel movements (BMs). She has read that a change in bowel habits is a sign of colon cancer and is worried about that. She brought her grandson along because he is also having bowel problems. Kim's bowel habits are erratic. At times he has a soft BM daily. However, he has also had bouts of constipation and diarrhea. Yen would like advice on her grandson's elimination status. As a critical thinker, you will begin by obtaining accurate, credible information.

(Continued)

Caring for the Nguyens (continued)

A. What history questions would be appropriate to ask Yen regarding her bowel concerns? What data do you need? How can you get the data? Are the data accurate? What information is important; what is not? Write some specific questions, just as you would ask them in an interview.

B. What physical assessments would you conduct for Yen to add to, and possibly to validate, your subjective data?

C. Now you must consider the context. What factors must you consider when gathering a history on Kim?

D. The family nurse practitioner (FNP) examines Yen and determines that she has external hemorrhoids that have been bleeding because of recent straining at stool. The FNP prescribes rectal suppositories to decrease the swelling of the hemorrhoids and asks you to teach Yen about necessary lifestyle changes. What additional information will you need to gather to provide this teaching? Recall that you have already obtained a significant amount of information from the history questions. Again, think about context: Whatever the content of your teaching, Yen will be using that information to care for herself and her grandson in her home.

E. The FNP examines Kim and tells you that the examination is normal. Use your theoretical knowledge of bowel elimination and Kim's developmental stage to think of possible reasons for his erratic bowel pattern.

PracticalKnowledge knowing how

To help you promote normal bowel elimination and support patients who have bowel elimination problems, this section applies concepts from Volume 1 to provide practical knowledge of procedures and clinical insights. You will also find assessment guidelines for assisting patients who are having diagnostic studies of the gastrointestinal system.

PROCEDURES

The procedures in this chapter will help you provide care to patients who have problems with bowel elimination.

Procedure 29-1 ■ Testing Stool for Occult Blood

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* According to colorectal screening guidelines, all persons age 50 or older should be screened every 1 to 2 years for occult (hidden) blood in the stool. High-risk groups require initial screening at a younger age, and should perhaps undergo genetic testing. Some guidelines recommend that decisions should be made to screen those over age 75 only on an individual basis.

Equipment

- Clean gloves
- Tongue blade or other wooden applicator
- Clean, dry collection container to place in the commode, or a clean, dry bedpan
- Facility-specific fecal occult blood test (FOBT) slide or test paper
- Developing solution

Delegation

You can delegate the collection and testing of a stool sample for occult blood to the nursing assistive personnel (NAP) if the NAP has the necessary skills and the patient's condition is stable. Inform the NAP of any special considerations (e.g., the need to assist the patient with ambulation or the need for a bedpan). Instruct the NAP to inform you if there is visible blood in the stool and to show you the FOBT slide for evaluation of results when the test is complete.

Pre-Procedure Assessment

- Assess the patient's mobility status.
  Determines the patient's ability to participate in stool collection, the need for a bedpan or commode, and so forth.
- Assess the patient's dietary history for the past 24 to 48 hours.
  Some foods, such as red meat, chicken, fish, horseradish, turnips, or raw vegetables, may lead to a false-positive reading. Vitamin C in excess of 250 mg per day can produce a false-negative result (MEDLINE Plus, 2013).

- Assess medication history.
  If the patient is taking medications, such as salicylates, NSAIDs, iron, oxidizing drugs, reserpine, corticosteroids, anticoagulants, colchicines, and high doses of vitamin C, consult with a physician. These medications may cause a false-positive reading. If possible, they will be discontinued for 7 days before the test. If the patient must have them, then the results must be interpreted taking them into consideration.
- Assess for the presence of hemorrhoids.
  Any source of blood may cause a false-positive result for intestinal bleeding.
- If the patient is female, ask whether she is menstruating.
- Check the expiration date on the developing solution for the FOBT test slide.
- Assess the patient's or family's understanding of the need for the stool test.
  Provides a baseline for health teaching.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine whether the test** will be done by the nurse at the point of care (e.g., in the home or at the bedside) or by lab personnel.
   Because of the regulatory and billing practices in some settings, this test may be completed by lab personnel.
2. **Gather the necessary testing** supplies. Be sure you understand the directions for the testing kit you are using.
   This procedure gives instructions for using the FOBT slide method.
3. **Ask the patient to void** before collecting the stool specimen.
   Helps prevent contaminating the stool with urine.
4. **Perform hand hygiene and** don procedure gloves.
5. **Place a clean, dry container** for the stool specimen into the toilet or bedside commode in such a manner that any urine falls into the toilet and the fecal specimen falls into the container. Obtain a clean, dry bedpan for a patient who is immobile.
   Using a sample of stool that comes in contact with either urine or water may produce an inaccurate test result.
6. **Instruct the patient to defecate** into the container, or place the patient on the bedpan. Do not contaminate the specimen with toilet tissue.
7. **Once the specimen has been obtained** and the bedpan removed or the patient assisted to bed as necessary, perform hand hygiene, and don clean procedure gloves.
   Prevents the spread of intestinal bacteria.
8. **Explain the purpose of the test.** Explain to the patient that serial specimens may be needed.
   Testing serial specimens decreases the chances of a false-negative finding.
9. **Open the specimen side** of the FOBT slide. With a tongue depressor or other applicator, collect a small sample of stool and spread it thinly onto one "window" of the FOBT slide.
10. **With a different applicator** or the opposite end of the tongue blade, collect a second small sample of stool from a different location in the large sample. Spread the second sample thinly onto the second "window" of the slide.
    Reduces the possibility of a false-negative result.

11. **Wrap the tongue depressor** in tissue and a paper towel; place it in a waste receptacle. Do not flush it.
    Prevents transfer of microorganisms. Flushing would likely clog the plumbing.
12. **Close the FOBT slide.**
    Prevents the transfer of microorganisms from the specimen smears on the slide.
13. **If the test is to be done by** laboratory personnel, transfer the specimen to a clean dry container, being careful not to contaminate the outside of the container with feces. Label the specimen in the presence of the patient according to agency policy, and place it into the proper receptacle for transportation to the lab.
14. **If you are to perform the test,** turn the slide over, and open the opposite side of the FOBT slide. Follow the directions on the package regarding the number of drops of the developing solution.
    Ensures an accurate reading.

15. **Remove gloves and** perform hand hygiene.

(continued on next page)

Procedure 29-1 ■ Testing Stool for Occult Blood (continued)

Evaluation

- Observe the color of the paper inside the FOBT slide windows for 30 to 60 seconds.
- If the paper turns blue, consider the test for occult blood to be positive.

Patient Teaching

- Inform the patient of the reasons for performing the test.
- Explain the possible implications of a positive occult blood test, if one is obtained.

Home Care

- Determine the client's level of cognition and manual dexterity to assess his ability to follow instructions and physically perform the test.
- Explain necessary dietary and medication restrictions (see the Pre-Procedure Assessment section of this procedure).
- Instruct the client to collect the specimen in a clean, dry container. If an appropriate container is not available, the client may use the toilet.
- If defecating in the toilet, the client should flush it immediately prior to obtaining the sample. If commercial toilet bowl cleaners are in use, remove them from the tank, and flush twice. Then lay rice paper (from the kit) directly on the water; it is okay to get it wet. When using the probe to take the stool sample, take the sample from any area of stool that is above the water line.
- Protect the slide from heat, light, and household chemicals.
- Home collection slides come in a kit, connected together as a set of three. Instruct the client not to tear them apart.
- Emphasize to the client that each sample should be from separate bowel movements on separate days.
- After all three specimens have been collected over the course of at least 3 days, store the slide in a paper envelope to air-dry.
- The client must place the slides in the special mailing pouch that comes with the slides, if they are to be sent back to the lab. The slides should be returned to the care provider or lab no later than 14 days after the first sample was collected.

For additional instructions,

Go to the **Hemoccult** Web site at www.hemoccultfobt.com

Documentation

- Document the date and time of the specimen collection, both in the patient record and on the specimen container or FOBT kit.
- Note the appearance of the stool (e.g., color, odor) and the presence of blood, mucus, or other abnormal constituents.
- Note any rectal bleeding or discomfort during and after defecation.
- Document the test results on the appropriate agency form.
- Notify the appropriate care provider of the results.

Sample documentation

06/14/15 0915 Specimen taken from 2 separate sections of yellowish-brown soft stool containing mucus. No rectal bleeding or discomfort with defecation. Specimen sent to lab; test results pending. ——————— S. Hoeszle, RN

Practice Resources

American Cancer Society (2013); Flitcroft, K. L., Irwig, L. M., Carter, S. M., et al. (2012); Gomella L., & Haist, S. (n.d.); Institute for Clinical Systems Improvement (ICSI) (2012); The Joint Commission Accreditation Program (2013); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Procedure 29-2 ■ Placing and Removing a Bedpan

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Bedpan
- Two pairs of clean gloves
- Toilet tissue
- Prepackaged disposable wipes
- Waterproof pad
- Bedpan cover

Delegation

You may delegate the placement and removal of a bedpan to the NAP after ensuring that the NAP has the necessary skills and that the patient's condition is stable. Complete the pre-procedure assessments, and inform the NAP of any special considerations (e.g., medical or surgical conditions that will necessitate the use of a fracture pan, extra care with turning or required positioning based on medical condition).

Pre-Procedure Assessments

- Assess the patient's level of consciousness, ability to follow directions, mobility status and physical status.
  Helps determine whether one or two persons are needed to complete the procedure
- Determine the patient's comfort level—note the presence of rectal or abdominal pain, hemorrhoids, or perianal irritation.
  Pain can cause difficulty with positioning and bearing down during defecation. Any unexplained pain should be evaluated by the primary care provider.
- Identify factors that will necessitate the use of a fracture pan. (Examples include a fractured pelvis; total hip replacement; lower back surgery; presence of casts, splints, or braces on lower limbs; or obesity.)

- Auscultate bowel sounds, and palpate for distention if indicated.
  The colon when full with fecal matter is a rounded, firm mass. A smooth, round mass above the symphysis pubis is a distended bladder.
- Review the patient's chart to determine the need to obtain a stool specimen.
  Promotes efficiency by allowing you to obtain a specimen container before placing the patient on the bedpan.

Procedure 29-2A ■ Placing a Bedpan

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Obtain the necessary supplies,** and take them to the patient's room. Leave prepackaged disposable wipes at the bedside for use during bedpan removal.
   The patient will need to wash her hands after using the bedpan.
2. **If the bedpan is metal**, place it under warm, running water for a few seconds. Then dry it, making sure bedpan is not too hot.
   A warm bedpan allows the patient to be more comfortable and helps relax the anal sphincter. Most bedpans now are made of disposable plastic.
3. **Raise the siderail** on the opposite side from where you are working.
   Prevents patient from falling out of bed and gives the patient something to hold onto while moving around in bed.
4. **Raise the bed** to a comfortable working height.
   Allows you to use good body mechanics and prevents muscle strain.
5. **Prepare the patient** by folding down the covers to a point that will allow for placement of the bedpan, yet exposing only as much of her body as necessary.
   Privacy facilitates elimination by promoting relaxation.
6. **Perform hand hygiene** and don clean procedure gloves.
   Prevents the spread of microorganisms via contact with urine or feces.
7. **Observe for the presence of** dressings, drains, intravenous fluids, and traction; and be sure there is a linen saver pad in place.
   These appliances may hinder the patient from assisting with the procedure and may create the need for assistance from another caregiver.

Procedure Variation For the Patient Able to Move/Turn Independently in Bed

8. **Position the patient.**

Supine Position

a. Lower the head of the bed, placing the patient in a supine position.
b. Ask the patient to lift her hips. The patient may need to raise her knees to a flexed position, place her feet flat on the bed, and push up. You can also assist the patient to raise her hips by sliding a hand under the small of her back.

Semi-Fowler's Position

c. Place the bed in a semi-Fowler's position.
d. Ask the patient to raise her hips by pushing up on raised siderails or by using an overhead trapeze.

9. **Place the bedpan**.

Regular Bedpan

a. Place the bedpan under the patient's buttocks so that the wide, rounded end is toward the back.
   Sliding the pan against the patient's skin may cause damage to skin.

Fracture Pan

b. Place the wide, rounded end of the pan toward the front.

10. **Instruct or assist the patient** to lower her hips onto the bedpan. Move to Step 16.

Procedure Variation For the Patient Unable to Move/Turn Independently

11. **Ask for help** from another health-care worker if the patient's condition warrants.
12. **With the patient in the supine** position, lower the head of the bed.
13. **Assist the patient to** the side-lying position. Use a turn sheet, if necessary.
14. **Place the bedpan.**

Regular Bedpan

a. Place the bedpan under the patient's buttocks so that the wide, rounded end is toward the back. Do not push the pan under the patient's buttocks. ➤

Fracture Pan

b. When using a fracture pan, place the wide, rounded end toward the front. ➤

15. **Holding the bedpan in place,** slowly roll the patient back and onto the bedpan.

(continued on next page)

Procedure 29-2 ■ Placing and Removing a Bedpan (continued)

16. **Replace the covers**; raise the head of the bed to a position of comfort for the patient. Place a rolled towel, blanket, or small pillow under the sacrum (lumbar curve of the back).

17. **Place the call light** and toilet tissue within the patient's reach. Return the bed to its lowest position and raise the upper siderails.
Provides privacy, comfort, and safety.

18. **Remove your gloves** and perform hand hygiene.
Prevents the transmission of intestinal bacteria.

Procedure 29-2B ■ Removing a Bedpan

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean procedure gloves.** Open the prepackaged disposable wipes and place them near the work area.

2. **If the patient is immobile**, lower the head of the patient's bed. Pull down the covers only as far as needed to remove the bedpan.
Lowering the head of the bed is necessary only if the patient is immobile.

3. **Offer the patient toilet paper.** Assist patients who are unable to complete this task independently.

4. **Ask the mobile patient to raise her hips.** Stabilize and remove the bedpan. If the patient is unable to raise her hips, stabilize the bedpan and assist her to the side-lying position, and remove the bedpan.
Stabilizing the bedpan prevents spillage of contents.

5. **Cleanse the buttocks** with a warm, prepackaged disposable wipe. Allow to air dry.
Provides comfort and hygiene and decreases the risk of skin irritation and breakdown.

6. **Replace covers, and position** the patient for comfort. Offer the patient the second wipe to cleanse her hands.
Encourages independence with personal hygiene and decreases transmission of bacteria.

7. **Empty the bedpan** into the patient's toilet. Measure the output if that is part of the treatment plan. Clean the bedpan, following facility-specific guidelines.
If there is no toilet in the patient's room, cover the bedpan and carry it to the nearest toilet or soiled utility room for emptying.

8. **Remove the soiled gloves** and perform hand hygiene.
Prevents transmission of infectious microorganisms.

? What if . . .

Your patient is an older adult?

Offer a bedpan at set intervals, perhaps in conjunction with a turning schedule. For elderly clients with limited mobility you may wish to keep the bedpan readily available.
To minimize episodes of incontinence and/or falls. Trying to get out of bed to use the toilet is a common cause of falls

Evaluation

- Assess the amount and characteristics of any urine and/or stool.
- Observe the skin on the perineum and buttocks for redness and breakdown.

Home Care

Teach the patient's family the steps of this procedure.

Documentation

- Document the amount of urine voided if intake and output are being recorded.
- Note the presence of any unusual characteristics of either stool or urine, and include in the nursing notes. If there are no unusual characteristics, document the passage of stool or urine in the graphic records.

Practice Resources

Ayello, E., & Sibbald, R. (2008); Balas, M., Casey, C., & Happ, M. (2008); Gray-Micelli, D. (2008); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Placing a Bedpan** and **Removing a Bedpan.**

For questions and suggested responses,

Go to Chapter 29, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 29-3 ■ Administering an Enema

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Enema administration container, correct enema solution, or prepackaged enema—depends on the type of enema ordered.
  - *Enema kit:* This may be a grouping of supplies that includes a small plastic bucket or a 1-liter plastic bag with attached tubing, disposable toweling, lubricant, and castile soap.
  - *Prepackaged enema solution:* If a prepackaged enema (e.g., Fleets) is ordered, you may need to obtain the preparation from the pharmacy or central supply department.
- Prepackaged disposable wipes and/or toilet tissue
- Bath blanket
- Waterproof pad
- Bedpan with cover or bedside commode, if needed
- Water-soluble lubricant
- Clean procedure gloves
- IV pole

Delegation

You may delegate this procedure to the NAP if the NAP is trained and the patient is stable. Complete the pre-procedure assessments, and instruct the NAP about conditions under which the procedure should be stopped (e.g., severe abdominal pain occurs, bleeding is seen, or the patient is unable to retain the solution). Instruct the NAP to report the results of the enema and show you any stool that appears to be abnormal (e.g., containing blood or pus).

Pre-Procedure Assessments

- Assess for history of bowel disorders (e.g., diverticulitis, ulcerative colitis, recent bowel surgery, abdominal pain, abdominal distention, hemorrhoids).
  Some disorders put the patient at risk for complications, such as mucosal irritation or perforation. Abdominal pain along with hypoactive bowel sounds and distention could indicate a bowel obstruction.
- Inspect the abdomen for the presence of distention.
  Establishes baseline for effectiveness of the enema.
- Review the patient's chart for the presence of increased intracranial pressure, glaucoma, or recent rectal or prostate surgery.
  These conditions contraindicate an enema.
- Review lab results, paying particular attention to blood urea nitrogen (BUN), creatinine, and electrolytes.
  Hypertonic and hypotonic enemas have been linked to fluid and electrolyte changes. Phosphate enemas (Fleets) have been associated with hyperphosphatemia and hypocalcemia.
- Note the date and time of the patient's last bowel movement, recent bowel movement pattern, and bowel sounds.
  Establishes baseline for evaluating bowel function.
- Assess the patient's cognitive level and mobility.
  Determines the patient's ability to follow instructions and the need for placing him on a bedpan for the enema.
- Assess the patient's rectal sphincter control.
  Determines whether you need to administer the enema with the patient on the bedpan. Also influences the amount of solution to instill.
- Assess for fecal impaction.
  May necessitate the need to obtain a prescription for a different type of enema.

Procedure 29-3A ■ Administering a Cleansing Enema

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Place the bedpan nearby** or the commode near the bed.
   So you can reach the bedpan during the procedure; or so the patient can easily get to the commode.
2. **Open the enema supplies or kit.** Attach the tubing to the enema pail, if you are using a pail.
   The 1-liter enema bag comes with preconnected tubing.
3. **Close the clamp on the tubing**, and fill the container with 500 to 1,000 mL of warm solution. The water temperature should be lukewarm—105°F to 110°F (40°C to 43°C).

   Check the temperature with a bath thermometer. Never warm the enema solution in a microwave oven.

   a. For infants: Use 50 to 150 mL of solution.
   b. For toddlers: Use 250 to 350 mL of solution.
   c. For school-age children, use 300 to 500 mL of solution.
   Cold solution causes intestinal cramping. Very hot solution can damage the intestinal mucosa. Use the correct amount of solution to decrease the necessity of repeating the procedure.
4. **Add castile soap** (or the soap solution used by your facility) to the fluid at this time if a soapsuds enema has been prescribed.
   Soap causes mucosal irritation, which stimulates peristalsis and defecation.

(continued on next page)

Procedure 29-3 ■ Administering an Enema (continued)

5. **Hang the container** on the IV pole. Holding the end of the tubing over a sink or waste can, open the clamp and slowly allow the tubing to prime (fill) with solution. Reclamp the tubing when the tubing is filled.
   Expresses air from the tubing. Air introduced into the bowel may cause intestinal distention and discomfort.

6. **Don clean procedure gloves.**
   Prevents the transmission of intestinal bacteria.

7. **Position the patient:** Ask or assist the patient to turn, to a left side-lying position with the right knee flexed.
   Allows the enema solution to fill the rectum and lower intestine following the natural flow of gravity.
   a. If the patient has shortness of breath associated with a respiratory condition, elevate the head of the bed very slightly. Avoid the semi-Fowler's position.
      The semi-Fowler's position increases the likelihood that gravity will cause the solution to leak out.
   b. Do not administer the enema with the patient on the toilet. The curved rectal tubing can scrape the rectal wall.
   c. If the patient has poor sphincter control, position him on the bedpan in a comfortable dorsal recumbent position.
      He will not be able to retain all of the enema solution.

8. **Place the waterproof pad** under the patient's buttocks or hips.
   Prevents soiling of bed linens.

9. **Drape the patient** with the bath blanket, exposing only the buttocks and rectum. See Procedure 25-4 to review the procedure for draping.
   Promotes patient privacy.

10. **Depending on the patient's** mobility status, place the bedpan flat on the bed, directly beneath the rectum, up against the patient's buttocks.

11. **Lubricate the tip of the enema** tubing generously.
    Allows for ease of insertion, decreases patient discomfort, and helps prevent mucosal irritation.

12. **If necessary, lift the superior buttock** to expose the anus. Slowly and gently insert the tip of the tubing approximately 7 to 10 cm (3 to 4 in.) into the rectum. Have the patient take slow, deep breaths as you complete this step. If the tube does not pass with ease, do not force it. Allow a small amount of fluid to infuse and then try again, inserting the tube slowly.
    Helps the patient to relax, provides additional lubrication, and decreases reflex tightening of the anal sphincter.

13. **Remove the container from the IV pole**, and hold it at the level of the patient's hips. Unclamp to begin instilling the solution.
    Lowering the container slows the force of the instillation, decreasing pressure, cramping, discomfort, and reflex expulsion of the solution.

14. **Slowly raise the level** of the container, so that it is 30 to 45 cm (12 to 18 in.) above the level of the hips. Adjust the pole and re-hang the container. Continue a slow, steady instillation of the enema solution.
    The height of the container determines the speed of the flow. A slow, steady rate of infusion decreases cramping and increases the patient's ability to retain the solution.

15. **Continuously monitor the patient** for pain or discomfort and ability to retain the solution. If the patient has difficulty with retaining the solution, lower the container, stop the flow for 15 to 30 seconds, and then resume the procedure.

If the patient feels pain or you meet with resistance at any time during the procedure, stop and consult with the primary care provider.

16. **When the correct amount** of solution has been instilled, clamp the tubing, and slowly remove it from the rectum. If there is stool on the tubing, wrap the end of the tubing in a disposable wipe or toilet tissue until it can be rinsed or disposed of. Remove the bedpan.
    Prevents transmission of pathogens.

17. **Clean the rectal area**, cover the patient, and instruct him to hold the enema solution for approximately 5 to 15 minutes. Place the call light within reach.
    Retention of the enema solution will distend the bowel and increase the stimulus to defecate. Leaving the solution in the bowel too long may result in fluid and electrolyte complications. Retaining hypertonic solutions may result in dehydration related to large amounts of fluids moving from the capillary bed into the bowel. Excessive retention of hypotonic solutions may cause fluid overload.

18. **Dispose of the enema supplies** or, if they are reusable, clean and store them in an appropriate location in the patient's room.
    Maintains a pleasant environment and helps prevent transfer of pathogens.

19. **Remove your gloves and perform hand hygiene.**
Prevents transmission of intestinal pathogens.

20. **Depending on the patient's mobility**, assist him onto the bedpan, to the bedside commode, or to the toilet when he feels the need to defecate. Perform hand hygiene and use clean procedure gloves as necessary.

21. **After the patient has defecated**, remove the bedpan or assist the patient to bed; inspect the stool for color, consistency, and quantity.

Procedure 29-3B ■ Administering a Prepackaged Enema

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Open the prepackaged enema.** Remove the plastic cap from the container. Clip the tip of the container if it does not have a hole in it. The tip of the enema container comes prelubricated. However, you may need to add extra lubricant.
Extra lubricant decreases discomfort and eases insertion of the tube into the rectum.

2. **Follow Steps 6 through 12 of Procedure 29-3A** (regarding gloving, positioning, draping, and inserting the enema tip).

3. **Tilt the container slightly** and slowly roll and squeeze the container until all of the solution is instilled.
Ensures that the container empties completely and that an adequate amount of solution is instilled.

4. **Withdraw the container tip** from the rectum. Wipe the area with a disposable wipe or toilet tissue.
Prevents transmission of pathogens.

5. **Cover the patient, and instruct** him to hold the enema solution for approximately 5 to 10 minutes. Place the call light within reach.
Retention of the enema solution will distend the bowel and increase the stimulus to defecate. Retaining the solution for longer than the prescribed time has been associated with dehydration and electrolyte imbalances.

6. **Dispose of the empty container.**
Maintains a pleasant environment.

7. **Follow Steps 18 through 21 of Procedure 29-3A** (regarding equipment disposal, assisting the patient, and observations of stool).

Procedure 29-3C ■ Administering an Oil-Retention Enema

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* An oil-retention enema may be administered to help a client pass hard stool; it also may be administered before digital removal of stool; or it may be given at least 1 hour before a cleansing enema. See Procedure 29-4 for digital removal of stool.

Procedure Steps

1. **Obtain a commercial** oil-retention enema kit; these kits include a small rectal tube. If a commercial kit is not available, use a small tube and about 90 to 120 mL of the prescribed solution.
A small tube allows for slower infusion, which minimizes cramping and thereby promotes retention.

2. **Warm the oil** to body temperature by running warm tap water over the container. Test a drop on your arm.
If the oil is too cold, it will cause cramping and expulsion of the oil. If it is too warm, it may injure the patient.

3. **Follow Steps 6 through 12 of Procedure 29-3A** (regarding gloving, positioning, draping, and inserting the enema tip).

4. **Instill the oil into the rectum**.
Softens stool and lubricates the rectum for easier passage of stool.

5. **Withdraw the container tip** from the rectum. Wipe the area with a disposable wipe or toilet tissue.

6. **Cover the patient and instruct** the patient to retain the oil for at least 30 minutes.

7. **Follow Steps 18 through 21 of Procedure 29-3A** (regarding equipment disposal, assisting the patient, and observations of stool).

(continued on next page)

Procedure 29-3 ■ Administering an Enema (continued)

Procedure 29-3D ■ Administering a Return-Flow Enema

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* A return-flow enema (Harris flush) may be ordered to help a patient expel flatus and relieve abdominal distention.

Procedure Steps

1. **Obtain a rectal tube and solution** container (e.g., bag or pail).
2. **Prepare 100 to 200 mL** (for adults) of tap water or saline.
3. **Follow Steps 6 through 12 of Procedure 29-3A** (regarding gloving, positioning, draping, and inserting the enema tip).
4. **Instill all the solution** into the patient's rectum.
5. **Lower the tube and container** below the level of the rectum, and allow the solution to flow back into the container.
6. **Repeat this process several times**, or until the distention is relieved.
7. **Follow Steps 18 through 21 of Procedure 29-3A** (regarding equipment disposal, assisting the patient, and observations of stool).

What if . . .

- **The solution for a return-flow enema becomes thick with fecal matter?**

  Discard it and begin again with new solution.

Evaluation

- Observe the amount, color, and consistency of the stool.
- Evaluate the patient's tolerance of the procedure (e.g., amount of cramping, discomfort).
- Determine whether the prescriber's orders require subsequent enema administration.
- Some bowel exams require repeated enemas or enemas administered until the returns are "clear." For the latter, you will need to examine the return and determine whether stool particles are still present. "Clear" does not mean absence of color, but rather absence of stool particles and transparency of the liquid.

Patient Teaching

- Teach the patient that dependence on enemas can disrupt the normal process that stimulates defecation.
- Teach dietary and lifestyle changes that promote regular elimination (e.g., increased fluid intake, diet high in fiber, increased exercise).

Home Care

- Show the patient the box for a prepackaged enema, and instruct him that he may purchase this type of enema at a local grocery or pharmacy.
- Assess the patient's ability to administer his own enema. If you determine that he will be unable to do so, encourage him to seek assistance and instruct the caregiver in the task.
- Teach the patient or caregiver proper handwashing. Encourage them to purchase nonsterile procedure gloves.
  Patients and caregivers may not be aware of the serious infections that can be caused by gram-negative intestinal bacteria.
- If the patient will be attempting to self-administer a cleansing enema, help him determine how and where to hang the container so that it is at the proper height.
- If a soapsuds enema is to be administered in the home setting, teach the patient which household soaps may be substituted for castile soap.
  Some soaps used in the home for cleaning purposes may be too harsh and irritating to the intestinal mucosa.

Documentation

- Document on the nursing notes type of enema given and, if applicable, the amount of the solution instilled; patient's tolerance of the procedure; characteristics and amount of stool.
- If the prescription is to administer enemas until the returns are clear, document the color of the return solution and the amount of stool seen.
- For prepackaged enemas, some facilities require documentation on the medication administration record (MAR) of the time given and the nurse's initials.

Sample documentation

06/04/2015 0825 Fleets enema administered (see MAR). Patient had no cramping; retained enema for 5 minutes. Passed moderate amount of solid, formed, brown stool with no mucus, but with streaks of bright red blood on the surface.——— R. Cline, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering a Cleansing Enema.**

For questions and suggested responses,

Go to Chapter 29, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 29-4 ■ Removing Stool Digitally

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Two pairs of clean procedure gloves
- Water-soluble lubricant (containing lidocaine, if agency policy permits)
- Bedpan and cover
- Prepackaged disposable wipes (or moistened towelettes)
- Bath blanket
- Waterproof pad

Delegation

This procedure should not be delegated to a NAP. Ongoing assessment of the patient by the professional nurse is required when stool is manually removed from the rectum. The nurse must monitor the patient for complications, such as bleeding and vagal nerve stimulation. Nursing judgment is necessary in determining the need to halt the procedure.

Pre-Procedure Assessments

Assess the patient's baseline vital signs and history of heart disease. Be sure to monitor the patient's pulse before and during the procedure.
Digital removal of stool can stimulate the vagus nerve, causing bradycardia. Patients who have a history of heart disease or dysrhythmia are at greater risk.

- Assess the patient's white blood cell (WBC) count.
If the patient has a compromised immune status, evidenced by a low WBC count, you should discuss this procedure with the primary care provider to evaluate the risks and benefits of the procedure.
- Assess the patient's cognitive level and mobility.
Determines the patient's ability to follow directions and turn in bed.
- Determine the time of the patient's last bowel movement.
The longer stool remains in the lower bowel, the more water can be absorbed and the more likely it is that hard stool may form in the rectum.
- Assess the patient for history of fecal impaction.
Can be a recurrent problem for immobile, disabled, or institutionalized patients.
- Assess stool consistency.
Patients who are immobilized may become incontinent of watery stool. They may be able to pass small sections of hard stool or small quantities of watery stool. The latter, which may be intermittent or continuous, is a symptom of high colon impaction.
- Ask whether the patient has pain on defecation.
Pain can cause the patient tends to suppress defecation, exacerbating the problem.
- Assess the patient's pattern of bowel movements, diet, exercise, mobility, and medications (e.g., iron supplements or opioid analgesics).
Determine whether any of these factors contribute to the problem and add this information to the nursing care plan to help prevent recurrence.
- Assess bowel sounds and any abdominal distention.
Peristalsis may be present without gastrointestinal patency. This creates abdominal distention, which can aggravate constipation.

Guidelines

- Prevention of fecal impaction is the best treatment, but if impaction has occurred, the stool must be removed. The procedure is both painful and embarrassing to your patient.
- Some practitioners may prescribe an oil-retention enema before the procedure to soften and moisten the stool, making removal easier.
- Many also advise that you follow digital removal of stool with either an oil-retention and/or tap water enema, to ensure evacuation of stool that may not have been reached by digital removal.
- Trim and file your fingernails if they extend past the end of your fingertips.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Determine whether lubricant** containing lidocaine is to be used, and obtain the correct lubricant.
May decrease rectal discomfort for the patient.

2. **Drape the patient** with the bath blanket. Go to Procedure 24-4 to review the procedure for draping. Assist him to turn on his left side, with his right knee flexed toward his head. Place the waterproof pad halfway beneath his left hip.
Provides privacy and exposes the anus for visualization. The pad protects the bed from being soiled.

3. **Don clean procedure gloves.** Some sources recommend double-gloving.
Prevents the transmission of intestinal bacteria.

4. **Expose the buttocks.** Place a clean, dry bedpan on the waterproof pad next to the buttocks in line with the rectum.

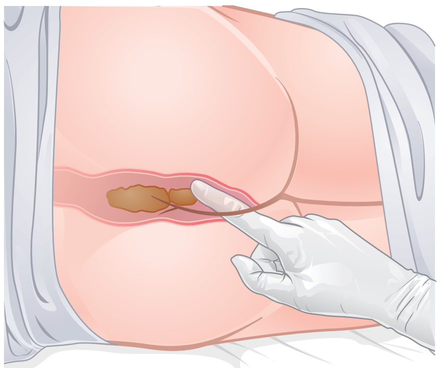
5. **Open the packet of prepackaged disposable** wipes, or have toilet tissue ready to cleanse the rectal area when you complete the procedure.

(continued on next page)

Procedure 29-4 ■ Removing Stool Digitally (continued)

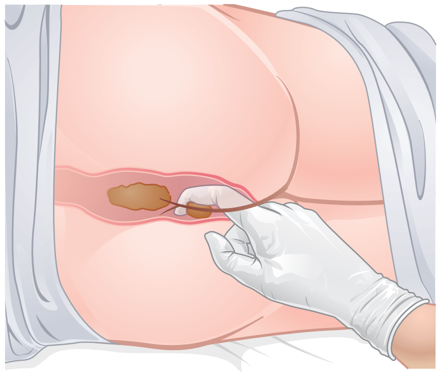
6. **Generously lubricate either** the gloved forefinger and/or middle finger on your dominant hand.
Helps prevent discomfort, pain, and mucosal injury.

7. **Slowly slide one lubricated** finger into the rectum. Observe for perianal irritation.
The patient may need skin care to reduce pain during additional bowel evacuation.



8. **Gently rotate your finger** around the mass and/or into the mass.
Assists in determining the amount and texture of the fecal bulk.

9. **Begin to break the stool** into smaller pieces. At this point, you may insert a second finger and gently "slice" apart the stool, using a scissoring motion. Remove pieces of stool via the rectum as they become separated, and place them in the bedpan.



10. **As you proceed, instruct** the patient to take slow, deep breaths.
Helps the patient to relax his anal sphincter.

11. **Continue to manipulate** and remove pieces of stool, allowing the patient to rest at intervals. Reapply lubricant (containing lidocaine, if permitted) each time you reinsert your fingers.
Rest periods allow for assessment of and attention to the patient's comfort level and tolerance for the procedure.

12. **Assess the patient's heart rate** at regular intervals.
Bradycardia is a sign of vagal stimulation. Stop the procedure if the patient's heart rate falls or the rhythm changes from your initial assessment.

CAUTION: Some resources suggest that this procedure should be done in small steps (no more than four finger insertions in one session), giving a series of suppositories between stool removal episodes.

Prevents patient fatigue and pain. Reduces the risk of injury to the rectal tissue and vagal stimulation.

13. **When removal of stool** is complete, cover the bedpan and set it aside. Use a prepackaged disposable wipe and/or toilet tissue to cleanse the rectal area.
Provides personal hygiene and decreases transmission of pathogens.

14. **Assist the patient to return** to a position of comfort. Note the color, amount, and consistency of the stool, and dispose of it properly.

15. **Remove your gloves and** perform hand hygiene.
Prevents transmission of intestinal pathogens.

? What if . . .

■ **The patient is an infant?**

When treating infants with fecal impactions, avoid enemas and mineral oils. Glycerin suppositories may be used to soften the stool before removal.

Evaluation

- Determine whether evacuation of the retained stool was complete. Perform a rectal exam to assess for presence of stool.
- Reassess vital signs, and compare the results to the initial assessment. Continue to monitor for 1 hour for bradycardia.
- Assess bowel sounds.
- Palpate the abdomen for tenderness and firmness.
- Ask the patient whether he feels relief from rectal pressure or abdominal discomfort.

Patient Teaching

Retained stool is most often the result of poor dietary habits, lack of fluid intake, lack of exercise, inattentiveness to the urge to defecate, and laxative abuse. Focus patient teaching on lifestyle changes that will facilitate a regular bowel elimination pattern.

Home Care

Home care should focus on preventing constipation that would require the digital removal of stool. Teach clients about high-fiber foods, adequate water intake, and the importance of exercise. Digital removal of stool may be necessary for some clients as part of a bowel program, for example patients who are paraplegic or tetraplegic (quadriplegic). You can teach this procedure to the caregiver in the home.

Documentation

- Document the bowel movement on the graphic record.
- Document the procedure and the patient's tolerance for the procedure in the nursing notes.
- Record the patient's pulse rate on the vital signs record.
- Document any unusual characteristics of the stool (e.g., black or green color, blood, or mucus).

Sample documentation

07/11/15 1815 Impacted stool removed digitally. No perianal irritation noted. Removed moderate amount (approximately 6 oz [170g]) dry, hard, gray-colored stool. Pulse 78 before removal; 84 after. Encouraged 8 oz of fluid every hour. ——————————— C. Bryan, RNC

Practice Resources

National Guideline Clearinghouse (NGC) (1996, revised 2009, 2010); Obokhare, I. (2012); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Procedure 29-5 ■ Inserting a Rectal Tube

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- 22- to 34-French rectal tube for adults. Choose the size according to the size of the client. For children or petite adults, a smaller size tube (12- to 18-Fr) may be required.
- Water-soluble lubricant
- Procedure gloves
- Toilet paper
- Skin care items (e.g., soap, skin cleanser, disposable wipes)
- Collecting device (waterproof pad, graduated cylinder partially filled with water, a urine collection bag nicked at the top to vent)
- Paper tape
- Stool specimen container if needed

Pre-Procedure Assessments

- Obtain baseline vital signs.
- Auscultate bowel sounds; percuss for tympany.
- Observe and palpate the degree of abdominal distention.
- Ask whether the patient is passing any flatus.
- Assess discomfort caused by flatulence.
- Assess the condition of perianal tissues.
- Assess the history of cardiac disease.
  Insertion of a rectal tube can stimulate the vagus nerve, causing bradycardia.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Wear procedure gloves.**
   Follows standard precautions.

2. **Ask the patient to lift his hips** or roll from side to side to place a waterproof pad.
   Protects against soiling of linens.

3. **Attach a collecting device** to the end of the rectal tube: Tape a plastic bag or urine collection bag around the distal end of the rectal tube and vent the upper side of the bag. Alternatively:

   Use one of these alternatives:
   - Insert the tube into the specimen container.
   - Place the end of the tube in a graduated container partially filled with water.
     Collects small pieces of stool expelled with flatus. Venting the plastic bag prevents overinflation and bursting the bag. An advantage of using water in the container is that gas generates bubbles, and you will be able to assess the effectiveness of the rectal tube based on the amount of bubbling in the container.

4. **Place patient in left side-lying** position. Drape for privacy.
   Allows the tube to follow the normal curve of the rectum and sigmoid colon when inserted.

5. **Lubricate the tip** of the rectal tube.
   Prevents trauma to the rectal mucosa.

6. **Separate the buttocks** and ask the patient to take a deep breath. Gently insert the tube into the rectum.
   Adults: 10 to 12.5 cm (4 to 5 in.)
   Children: 5 to 10 cm (2 to 4 in.).
   Deep breaths relax the anal sphincter and ease tube insertion.

7. **For adults, tape the tube** in place; for children, hold it manually.

8. **Leave the rectal tube in** place for 15 to 20 minutes. If distention persists, you may reinsert the tube every 2 to 3 hours.
   Leaving the tube in place for more than 20 minutes may cause pressure necrosis of the mucosa; prolonged stimulation of the anal sphincter may result in loss of the neuromuscular response.

9. **Assist the patient to move** about in bed to promote gas expulsion. A knee–chest position is ideal.
   Because gas is lighter than fluid or solid, the position promotes passage of flatus. Unfortunately, many patients cannot tolerate this position.

10. **Remove the tube**, wipe the patient's buttocks with tissue, and assist to clean the rectal area as needed.
    Prevents transmission of microorganisms from feces; promotes patient comfort and skin integrity.

11. **Dispose of used equipment**; or clean it if it is to be reused. Follow agency procedures for cleaning.

(continued on next page)

Procedure 29-5 ■ Inserting a Rectal Tube (continued)

Evaluation

- Evaluate the patient's response to the procedure (e.g., vital signs, fatigue).
- Assess abdominal distention and abdominal comfort.

Patient Teaching

- Teach the patient that chewing gum, sucking on hard candy, using a straw, smoking, and drinking carbonated beverages increase air swallowing and abdominal distention.
- Teach factors that promote normal elimination (e.g., exercise, increased fluid intake, adequate dietary fiber).

Documentation

Record the following:

- Date and time tube was inserted
- Size of tube and characteristics of feces collected
- Abdominal distention before and after the procedure
- Pulse and respiratory rates before and after the procedure
- Tolerance of procedure and any complications
- Patient and family teaching

Procedure 29-6 ■ Changing an Ostomy Appliance

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.
➤ *Note:* Some pouches come with the wafer attached, some without. These instructions assume that the wafer is attached.
➤ *Note:* Also see Clinical Insight 29-2: Guidelines for Ostomy Care.

Also go to **Animations: Colostomy,** on Davis*Plus*.

Equipment

- Ostomy pouch
  - One-piece pouch with the wafer attached, or a two-piece system with a separate wafer and pouch
  - Clamp for pouches with an opening at the bottom (a new clamp is not used each time; usually one clamp is packaged with each box of pouches)
- Skin care items per agency protocol or recommended by the enterostomal therapist (e.g., pH balanced skin cleanser, skin prep, skin barrier wipe, adhesive remover, adhesive paste, and stoma paste if needed to fill and smooth skin surface)
- Stoma measuring guide (or precut template)
- Scissors
- Pen or pencil
- Two pairs of clean procedure gloves
- Prepackaged disposable wipes
- Toilet tissue
- 4 in. × 4 in. gauze pad
- Bedpan or container for **effluent** (fecal material)
- Plastic bag (for disposal of used pouch)
- Plastic bag for disposal of other contaminated articles
- Waterproof pad
- Ostomy deodorant
- Hypoallergenic paper tape (optional) or ostomy belt
- Bath blanket

Delegation

During the immediate postoperative period, the professional nurse must assess the newly created stoma and peristomal skin area and use clinical judgment when changing a pouch. You may delegate to a NAP if it is a preexisting, stable stoma and if you are sure the NAP is qualified to perform the task. If you do delegate this task, instruct the NAP to report any changes or unusual findings (e.g., changes in stoma color, swelling, peristomal redness, excoriation, deviations from expected amount) and color and consistency of drainage from the stoma.

Pre-Procedure Assessments

- Assess the type of stoma (e.g., ileostomy, colostomy, urostomy), number of stomas, and location on the abdomen (e.g., is the stoma near structures that will impact care?).
  Determines the type of pouch or system to use.

- **Assess stoma color, shape, size, and/or length of protrusion or retraction; stoma construction (end, loop, double barrel); direction of stoma lumen; and discharge. Does the stoma lie flat or does it protrude?**
  The stoma should be moist and red or pink. Alterations in stoma color (purple, black, or blue) may indicate poor circulation and possible necrosis and should be reported to the primary provider. Protruding or retracted stomas will need special adjustments in wafer measurement and placement. It is normal for a new stoma to have yellow or blood-tinged mucus or dried blood on it.
- **Assess peristomal skin for redness, rash, irritation, or excoriation. Observe the existing skin barrier and pouch for leakage and length of time in place. You may have to remove the pouch to observe the stoma fully, depending on the type of pouch (i.e., if the pouch is opaque). Notify the provider or an ostomy specialist immediately if you note peristomal skin abnormalities.**
  Preserving peristomal skin is critical because skin excoriation may cause an ineffective seal between the wafer and the skin and leakage of effluent. This in turn causes more skin and tissue damage. Leakage may indicate the need for a different type of pouch system or sealant.
- **Determine the changing schedule for the pouch.**
  Pouches are usually changed every 3 to 5 days, preferably before leakage occurs. Frequency also depends on the type of stoma, the equipment used (e.g., one- or two-piece pouch), the effluent, the patient's preference, and the climate (i.e., pouches are changed more frequently during the summer). To decrease skin irritation, avoid changing the entire system. In a one-piece or two-piece pouching system, change the skin barrier only every 3 to 7 days, never daily.
- **Observe abdominal shape and incision, if present.**
  Abdominal shape determines the proper placement of the pouch. Because of stomal and abdominal characteristics, some patients may need convexity in their ostomy pouching system to avoid leakage.
- **Assess the patient's willingness to look at the stoma, touch the appliance, and discuss or participate in the task.**
  May indicate a readiness or desire to learn.
- **Assess the patient's condition and self-care ability. Consider vision, dexterity or mobility, and cognitive ability.**
  Helps determine best type of appliance to use.
- **Auscultate for bowel sounds.**
  Determines the presence of peristalsis.
- **Observe for effluent from the stoma, and document your findings.**
  Change the skin barrier pouch at times of lower effluent output. Avoid changing after meals, when the gastrocolic reflux increases chance of fecal effluent output. Mucous secretion is normal.
- **Assess whether a new clamp will be needed or the one on the pouch can be used again.**
- **Consult a peristomal nurse or the primary care provider to determine whether an ostomy should be irrigated.**
  Many patients with left-end colostomies may be safely irrigated as a method of continence management. An ileostomy, however, drains liquid containing high concentrations of sodium, chloride, potassium, magnesium, and bicarbonate.

Ileostomies should never be irrigated, except in cases of food blockage near the stomal outlet. Only a qualified person, such as an enterostomal therapy nurse, may perform a gentle lavage. For lavage procedure, see Procedure 29-7.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Perform hand hygiene** and don clean procedure gloves.
   Prevents transmission of pathogens.
2. **Fold down the bed covers** to expose the ostomy site. Place a clean towel across the patient's abdomen under the existing pouch.
   Helps prevent spilling effluent onto the patient.
3. **Position the patient** so that no skinfolds occur along the line of the stoma.
   Ensures an adequate seal between the wafer and the skin, preventing leakage.
4. **If the present ostomy pouch** is drainable, empty it into the bedpan.
   Pouches should be drained when they are one-third to one-half full because the weight of the contents may dislodge the skin seal; ostomy drainage is irritating to the skin. The pouch also collects flatus, which needs to be expelled because it can disrupt the skin seal.
   a. To calculate the amount of output in milliliters for an ostomy with a liquid effluent (e.g., ileostomy or urostomy), use a graduated measuring container.
   b. For pouches that you open by unrolling them at the bottom, you must remove a clamp to empty the pouch. Save this clamp for reuse.

   Note: Some pouches cannot be drained.
5. **Remove the appliance** by applying a silicone-based (hexamethyldisiloxane) adhesive remover, with one hand as you press the skin away from the wafer barrier with your other hand. Avoid pulling the appliance straight off. Begin at the top and work downward.

(continued on next page)

Procedure 29-6 ■ Changing an Ostomy Appliance (continued)

Silicone-based adhesive removers are preferred over alcohol- or oil-based products. Pulling the appliance from the skin tends to strip the loosely bound epidermal skin layers, making the skin more susceptible to moisture loss and irritation from effluent. Silicone-based products reduce the bind strength, whereas alcohol dissolves the adhesives; thus alcohol may cause dryness and irritation. It also causes pain if the skin is not intact. If you use an oil-based solvent, the new pouch will not adhere to the oily skin.

6. **Place the old pouch and wafer** in the plastic bag for disposal. If the pouch is not a drainable one, dispose of it according to agency protocol.
   Prevents transmission of infections caused by fecal bacteria.

7. **Inspect the stoma** and peristomal skin area for redness, rash, irritation, or excoriation (see Pre-Procedure Assessments).

8. **Cleanse the stoma** and surrounding skin using a skin cleansing agent with a pH of 5.5 that is designed to both cleanse and moisturize the skin.
   Removes old adhesive and any effluent that has leaked. Helps prevent skin irritation and/or breakdown and maintain skin moisture. Select cleansing agents that protect the stratum corneum lipids and proteins.

9. **Measure the size of the stoma.** You can accomplish this in several ways.
   a. Place a standard stoma measuring guide over the stoma.
   b. Reuse a previously cut template.
   c. Measure the stoma from side to side (approximating the circumference).
   The stoma may need to be remeasured frequently during the initial postoperative period because the size of the stoma may change as edema subsides. ➤

10. **Place a clean 4 in. × 4 in. gauze pad** over the stoma.
    Gauze will absorb any leaking effluent, keeping the skin clean and dry during application of the new pouch.

11. **Remove your gloves** and perform hand hygiene.
    Decreases the spread of intestinal bacteria.

12. **Trace the size of the opening** (obtained in Step 9) onto the paper on the back of the new wafer. Cut the opening. The opening in the wafer should be approximately 1/16 to 1/8 in. (1.5 to 3 mm) larger than the circumference of the stoma.
    Allows for skin movement with activity and prevents impaired circulation to the stoma.

13. **Peel the paper off the wafer.** Some resources suggest first holding the wafer between the palms of your hand to warm the adhesive ring.
    Enhances the integrity of the seal by making the ring more "sticky" so that it will bond better with the skin.
    Note: Some ostomy wafers come with an outer ring of tape attached. Do not remove the backing on this tape until the wafer is securely positioned.

14. **Don clean procedure gloves.**

15. **Apply ostomy skin care products** at this time using your clinical judgment, hospital protocol, or the recommendations of the enterostomal therapist (e.g., wipe around stoma with skin prep, apply skin barrier powder or paste, or apply extra adhesive paste).
    These products prevent or treat excoriated skin and/or ensure a tight seal between the wafer and the skin.

16. **Remove the gauze** from the stoma. Center the wafer opening around the stoma, and gently press it down. Make sure the bag is pointed toward the patient's feet. Press your hand firmly against the newly applied wafer and hold for 30 to 60 seconds.
    Heat from the hand activates the adhesive ring, making it adhere better thus promoting optimal wear time. Some sources also suggest taping down the edges of the wafer.

17. **Remove your gloves** and perform hand hygiene.

18. **Return the patient** to a comfortable position.

19. **Dispose of the used ostomy** pouch following your facility's policy for biohazardous waste.

? What if . . .

- **Your patient has a two-piece pouch?**
  After applying the wafer around the stoma with a good seal (Step 16), attach the bag following manufacturer's instructions.
- **Your patient's ostomy uses an open-ended pouch?**
  After applying the wafer securely around the stoma, fold the end of the pouch over the clamp, and close the clamp, listening for a "click" to ensure that it is secure.
- **When cleansing the stoma (Step 8), you notice that the stoma is bleeding?**
  Slight bleeding of the stoma is normal; report excessive bleeding to the primary care provider.

Evaluation

Make the following observations:

- Characteristics of stoma: color, size, presence of edema, and shape
- Presence of blisters, redness, or excoriation on peristomal skin
- Amount and characteristics of effluent: color, odor, consistency
- Whether the patient expressed a desire to participate in the task
- Whether the patient demonstrated nonverbal cues that she is ready to learn about the task (e.g., looking at the stoma)

Patient Teaching

Patient teaching is aimed at preparing the patient to complete this skill at home. She (or a caregiver) will need to be instructed in how to complete all the steps of the procedure.

Home Care

- Assess the patient's self-care ability and assist the client to establish a routine for changing the stoma wafer/pouch (see Clinical Insight 29-2).
- The client may need to stand in front of a mirror or sit to change her ostomy appliance if she is unable to view the stoma easily.
- Teach the client that slight bleeding is normal when the stoma is washed.
- The client should not use soaps and lotions containing oils. They decrease the adhesiveness of the wafer.
- The appliance and wafer cannot be flushed down the toilet.
- Teach the client to report changes in the color or size of the stoma and/or the presence of peristomal irritation or skin breakdown to the primary care provider.
- Provide information about ostomy supply vendors and community support groups, such as Ostomates.

Documentation

Document the following:

- Your assessment of the stoma and peristomal skin area
- Patient's tolerance of the procedure
- Type of appliance used, including the manufacturer and part number
- Use of any special ostomy skin care products
- Amount of liquid effluent (on the intake and output [I&O] portion of the graphics record)
- Patient teaching and the degree to which the patient participated in the procedure

Sample EHR documentation

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Changing an Ostomy Appliance.**

For questions and suggested responses,

Go o to Chapter 29, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 29-7 ■ Irrigating a Colostomy

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* Also see Clinical Insight 29-2: Guidelines for Ostomy Care.

Equipment

- Irrigation equipment
  - One-piece system with a fluid container connected to tubing with cone or two-piece system with a container separate from tubing with cone
  - Irrigation sleeve; a sleeve without adhesive backing requires a belt to hold it in place
  - Clamp for a sleeve with an opening at the top
  - Prescribed irrigating solution (usually 500 to 1,000 mL warm tap water, 100°F to 105°F (37.8°C to 40.6°C)
- IV pole or other equipment to hang the irrigation container
- Chair
- Water-soluble lubricant
- Silicone-based adhesive remover
- Skin cleansers and barriers as recommended by your agency
- Toilet tissue
- Prepackaged disposable wipes
- Waterproof pad
- Two pairs of clean procedure gloves
- Toilet facilities that include a flushable toilet and a hook or some other device to hold the irrigation container; or bedpan or bedside commode (for patients with impaired mobility)
- New ostomy appliance and skin barrier or stoma cap cover
- Ostomy deodorant (optional)
- Plastic bag for disposal of the used pouch

Delegation

The initial irrigation of a newly created colostomy requires nursing judgment and clinical decision making. Initially, this procedure should not be delegated to the NAP, although in some situations it may be delegated to an LPN, depending on agency policy.

Pre-Procedure Assessments

- Evaluate the defecation pattern (or absence) nature of stool, placement of stoma, abdominal distention, and nutritional pattern.
  Findings may indicate the need to irrigate to stimulate elimination function; consistency of stool varies along the length of the gastrointestinal (GI) tract.
- Assess the type of ostomy.
  Many patients with left-end colostomies may be safely irrigated as a method of continence management. However, do not irrigate an ileostomy.
- Assess the patient's usual bowel pattern.
  The purpose for irrigating a colostomy is to promote a regular pattern for bowel elimination.
- Assess for abdominal distention.
  Report distention to the primary care provider, as it may indicate excess gas or inflammation.
- Assess hydration.
  The colon may absorb some of the irrigation fluid if the patient is very dehydrated.
- Assess cognitive level and mobility.
  Determines the necessity for a bedpan or bedside commode. Also determines whether patient teaching will be effective.
- Assess the patient's ability to maintain a sitting position.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Place an IV pole near** the location of the procedure (e.g., in the bathroom, next to the bedside commode, or next to the bed).
   Allows you to work efficiently.

2. **Assist the patient to the bathroom** or commode, if possible. Ask the patient whether she prefers to sit directly on the toilet or on a chair in front of it. If the patient must remain in bed, elevate the head of the bed.
   Patients with impaired mobility can sit directly on or in front of the bedside commode, or they may remain in bed in the side-lying position.

3. **Prepare the irrigation container.**
   a. For two-piece systems, connect the tubing to the container. Clamp the tubing. Fill the container with 500 to 1,000 mL of warm tap water.

   Water that is too cold will cause cramping, nausea, and discomfort. Water that is too hot will damage the intestinal mucosa.

   Note: Some ostomy resources suggest that using 1,000 mL of water will promote a more effective irrigation of the entire colon and decrease the necessity to irrigate more than once a day.

   b. Unclamp the tubing to prime it and allow it to fill.
   Removes air from the tubing, preventing gas pains.

4. **Hang the solution container** on the IV pole. Adjust the pole so that it reaches the height of the patient's shoulder (approximately 45 cm [18 in.] above the stoma).
   The height of the container regulates the force of the flow.

5. **Perform hand hygiene** and don clean procedure gloves.
   Prevents the transmission of pathogens.

6. **Remove the existing colostomy** appliance (if the patient is wearing

one) following the steps in Procedure 29-6.
Use of ostomy skin care preparations may be needed when you replace the pouch.

7. **Dispose of the used colostomy** appliance properly. Empty the contents into the bedpan or toilet, and discard the pouch in a moisture-proof (e.g., plastic) bag.
Prevents transmission of intestinal bacteria.

8. **Assess the characteristics** of the stoma and the surrounding skin (see Clinical Insight 29-2).

9. **Apply the colostomy irrigation sleeve**, following the manufacturer's directions.
   - *If your patient is sitting on a toilet* or bedside commode, then the end of the sleeve should hang down past the patient's pubic area, but not down into the water. Place a waterproof pad under the sleeve over the patient's thighs.
   - *If your patient is in bed*, place the end of the sleeve into the bedpan.

   Prevents leakage and spilling of irrigation fluid and effluent.

10. **Generously lubricate the cone** at the end of the irrigation tubing with water-soluble lubricant.
Prevents irritation and damage to the stoma and intestinal lumen.

11. **Open the top of the irrigation** sleeve; insert the cone gently into the colostomy stoma, and hold it solidly in place.
Gentle insertion prevents damage to the mucosa.

12. **Open the clamp on the tubing**, and slowly begin the flow of water. The fluid should flow for about 10 to 15 minutes or as the patient can tolerate.
Proceeding slowly allows the patient to adjust to the distention of the bowel.

13. **If the patient complains** of discomfort, stop the flow for 15 to 30 seconds, and ask the patient take deep breaths.
Allows the patient to rest and adjust to the pressure of solution. Cramping may indicate that the bowel is ready to empty, the water is too cold, the flow is too fast, or the tube contains air.

14. **When the correct amount** of solution has instilled, clamp the tubing, and remove the cone from the stoma.

15. **Wrap the end of the cone** in tissue or paper towel until you can clean or dispose of it properly.
Prevents transmission of intestinal bacteria.

16. **Close the top of the irrigation** sleeve with a clamp.
Prevents spillage of irrigation fluid and feces.

17. **Wait for evacuation to occur:**
   - *If the patient is sitting*, ask her to remain sitting until most of the irrigation fluid and bowel contents have evacuated. Alternatively, you can clamp the end of the sleeve and ask the patient to ambulate to stimulate complete evacuation of stool.
   - *If the patient is in bed*, massaging the abdomen may also help stimulate return.

   This should take about 30 minutes on average. You might wait for about an hour to be certain all the fecal material has been returned.

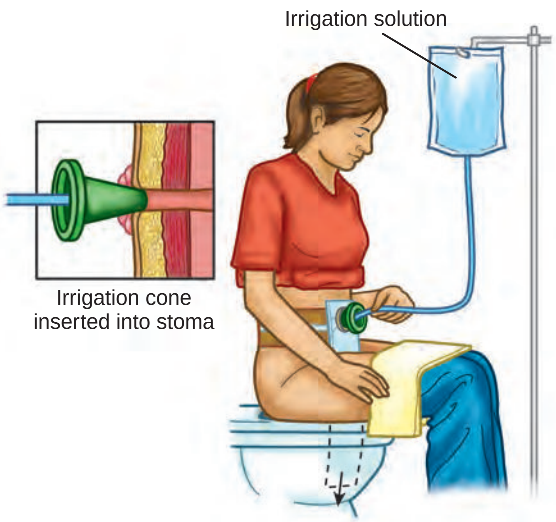
18. **When evacuation is complete**, open the top clamp, and rinse and remove the irrigation sleeve. Set it aside.
The irrigation sleeve is reusable, but it should be rinsed promptly to make thorough cleansing easier in the following steps.

19. **Cleanse the stoma** and peristomal skin area with a warm prepackaged disposable wipe. Prep the skin and apply a new colostomy appliance, if the patient is wearing one, following the steps in Procedure 29-6. Otherwise, cover the stoma with a small gauze bandage.

20. **Clean the irrigation sleeve** with mild soap and water. Allow it to dry. Place the irrigation supplies in the proper place (e.g., in a plastic container or plastic bag).
The irrigation sleeve must be cleaned well to avoid odors and transmission of pathogens.

21. **Remove your gloves** and perform hand hygiene.
Prevents healthcare-associated infections.

22. **Assist the patient back to** a position of comfort.



? What if . . .

- **Your patient has a colostomy sleeve without an adhesive backing?**

  Place the belt around the patient's waist, and attach the ends to the pouch flange on either side.

(continued on next page)

Procedure 29-7 ■ Irrigating a Colostomy (continued)

Evaluation

Observe the following:

- Characteristics of the stool: color, amount, consistency
- Signs of bleeding from stoma or bowel
- Presence or absence of abdominal distention
- Patient's tolerance of procedure (e.g., cramps, fatigue)
- Patient's ability to participate in the irrigation

Patient Teaching

- Teach the patient the purpose for the procedure.
- Explain that using sufficient fluid will decrease the need for multiple irrigations during the day.
- Teach the steps of the irrigation procedure to prepare the patient to complete the task at home.
- Explain that it takes approximately 6 to 8 weeks to achieve bowel regulation with irrigations.

Home Care

- Help the client determine where this procedure will be completed in the home setting.
- Make sure the client has resources for purchasing the supplies for the irrigation. Provide contact information.
- Help the client locate a place to hang the irrigation container. There may be a hook on the bathroom wall, for instance.
- If the irrigating solution does not flow well, the client should:
  Check the tubing for kinks.
  Change the position of the cone.
  Put the container at a slightly higher level.
- Explain and demonstrate how to care for the irrigation supplies (e.g., how to rinse and clean the sleeve and/or belt, if used).

Documentation

Document:

- Your assessment of the stoma and peristomal area
- The amount of irrigation solution used
- The date and time that you performed the irrigation
- Characteristics of the stool returned in the irrigation fluid
- Patient teaching

Sample documentation

06/14/15 0830 AM Ostomy irrigated with 750 ml warm tap water. Small amount of loose, formed, flakey stool returned in the fluid, with some undigested food apparent. No blood; very small amount of mucus. Stoma pink, peristomal area without redness. Explained procedure steps to patient as it was performed. Patient stated he will do some of the steps tomorrow. ——————————— C. Hiam, RNC

Go to Chapter 29, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 29-8 ■ Placing Fecal Drainage Devices

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

External Fecal Collection Device

- pH-balanced soap and water or recommended skin cleanser
- Skin protection wipes (e.g., peristomal wipes to protect skin and improve adherence)
- Self-adhesive fecal containment device
- Procedure gloves
- Linen-saver pad
- Scissors

Internal Fecal Collection System

- Fecal device kit: Contains soft silicone catheter tube assembly, a syringe, and a collection bag.
- Water-soluble lubricant
- Approximately 100-mL container of tap water or saline. (Follow the manufacturer's directions for amount and type of solution.)
- 500 mL of lukewarm irrigant (water or saline)
- 60-mL luer-tip syringe and a catheter tip syringe (if not contained in the kit)
- Protective skin-care dressing (e.g., Stomahesive, DuoDerm)
- Tape

- Procedure gloves, mask, and goggles
- pH-balanced soap and water or recommended skin cleanser
- Scissors
- Linen-saver pad

Delegation

Application of an external fecal collection system may be delegated to the NAP. Insertion of a internal fecal collection device is usually performed by a professional nurse, but may be delegated to an LPN depending on agency policy.

Pre-Procedure Assessments

- Assess the patient's bowel patterns.
  Fecal diversion is indicated when the patient is incontinent of liquid or semi-liquid stools (flowing).
- Assess for allergies to silicone. If the patient is sensitive or allergic to any of the materials in the device, it cannot be used.
- Inspect perirectal skin.
  External devices should not be used in patients with impaired skin integrity.

For Indwelling Devices, in Addition:

- Assess whether the patient has had a recent bowel movement.
  Patients who have not had a bowel movement for two or more days should be considered as having firm stool and will likely be given a bowel prep or enema before insertion of the indwelling device.
- Check for the presence of any indwelling anal or rectal device (e.g., thermometer for continuous temperature monitoring).
  The treatment plan may need to be changed. If suppositories or enemas are a part of the current treatment plan, collaborate with the prescriber, as these medication delivery mechanisms will need to be changed.
- Identify factors that increase your patient's risk for bleeding, including medications (anticoagulant and/or antiplatelet therapy) and lab results (PT, PTT, platelets).
  Patients with an increased risk of bleeding should be monitored carefully.
- Check the chart for contraindications to an indwelling fecal management system (e.g., proctitis, lacerations, rectal surgery in the past year, large or painful hemorrhoids).
  If your patient has a history of any of these problems, contact the primary care provider immediately. You may elect to use an external device, but an internal fecal catheter is contraindicated.
- Internal fecal catheters should not be used for children.

Procedure 29-8A ■ Applying an External Fecal Collection System

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Recruit another nurse** or nursing assistant to help you. Assist the patient to a side-lying position and drape to expose the buttocks.
   For successful application (without leakage) it is best to have one caregiver position the patient and a second person apply the device.
2. **Don procedure gloves.**
   Observes standard precautions.
3. **Cleanse the perineal area** and dry well. If perianal hair is present, trim it away.
4. **Wipe the area with** skin protectant wipes
   To obtain a leak-proof seal, the device should be attached to clean, dry skin. The wipes protect the skin and improve adherence.
5. **Spread the buttocks apart** to expose the rectum.
6. **Remove the backing from the adhesive** on the fecal bag, then apply it, being careful to place the opening in the bag over the anus and to avoid gaps and creases.
   Careful application helps to obtain a leak-proof seal.
7. **Release the buttocks.** Connect the fecal incontinence pouch to a drainage bag.
8. **Hang drainage bag below the patient.**
   To collect and promote gravity drainage of fecal material.

(continued on next page)

Procedure 29-8 ■ Placing Fecal Drainage Devices (continued)

Procedure 29-8B ■ Inserting an Indwelling Fecal Drainage Device

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* Because devices differ markedly, it is best to follow the manufacturer's instructions for placing the device. The following are generic instructions.

➤ *Note:* Also see Clinical Insight 29-1: Caring for a Patient With an Indwelling Fecal Drainage Device.

Procedure Steps

1. **Ensure that a primary care** provider has performed a digital rectal exam.
To assess for contraindications and to check sphincter tone. When sphincter tone is compromised, the patient may not be able to retain the device.

2. **Don procedure gloves,** mask, and goggles.
To protect from splatters when irrigating or disconnecting the device. Usually the devices are used for incontinence of loose, if not liquid, stool.

3. **Position the patient** in the left side-lying position.
Allows access to the rectum.

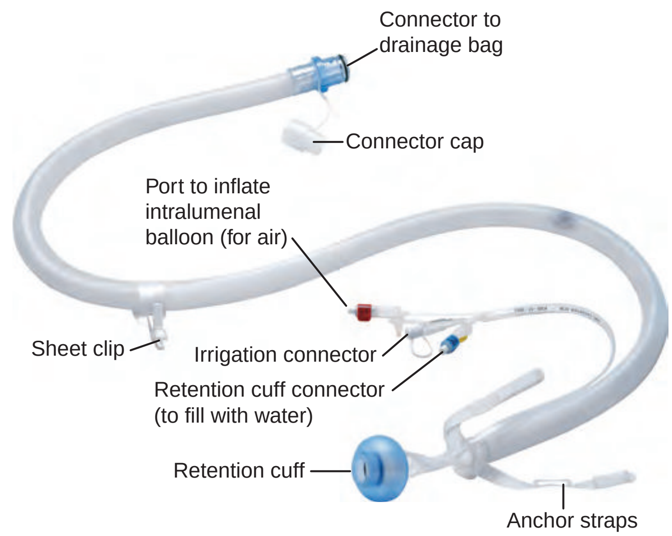
4. **Remove any indwelling device.**
The presence of a foreign body between the inflated balloon and rectum may damage rectal mucosa and a seal cannot be maintained.

5. **Depending on the type** of device, verify proper inflation and deflation of the intraluminal balloon. Attach the syringe, inflate with the recommended amount of air, deflate, and remove the syringe.

6. **Again depending on the device,** fill the retention cuff with 35 to 40 mL of water; disconnect syringe and check for leaks. After verifying function, slowly and completely aspirate all fluid from cuff and balloon and disconnect the syringe.

7. **Connect the indwelling tube** to the collection bag. Clamp and hang the bag lower than the level of the patient.

8. **Some systems have an** "introducer," which you must inflate with about 25 mL of air through a connector on the tube. Disconnect the syringe.

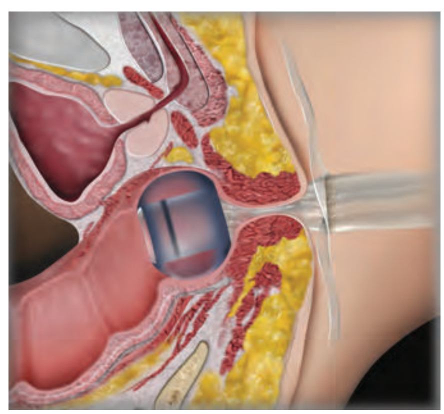


An indwelling fecal drainage device. (Courtesy of Hollister Incorporated, Libertyville, IL.)

9. **Insert your lubricated, gloved** index finger into the balloon cuff finger pocket (located above the position indicator line) and coat the balloon generously with lubricant.
This allows for digital guidance during insertion.

10. **Gently insert the balloon end** of the catheter through the anal sphincter until the balloon is beyond the anus and well inside the rectal vault.
This helps prevent accidental expulsion of the device.

11. **Inflate the retention cuff** with water or saline per the manufacturer's guidelines. Do not overfill. If the catheter will not accept the recommended amount of fluid, see the What If . . . ? section at the end of this procedure.



Indwelling fecal drainage device inserted in rectum, with retention cuff inflated. (Courtesy of Hollister Incorporated, Libertyville, IL.)

12. **Remove the syringe** from the inflation port and put gentle traction on the catheter.
To determine whether the balloon is securely in the rectum and appropriately positioned against the rectal floor.

13. **If you inflated an intraluminal** balloon or introducer in Step 8, you must now completely aspirate the air from it.

Do not leave an air-inflated intraluminal balloon inflated in an unattended patient.

An inflated balloon can cause tissue necrosis after a period of time.

14. **If the device has anchoring** straps, apply protective skin care dressing and tape one strap to each of the patient's buttocks.
Prevents internal migration of the tube and occlusion by twisting of the tube.

15. **Position the tubing along** the patient's leg, avoiding kinks and obstruction and position the collection bag lower than the patient.
Promotes flow of stool from the rectum to the collection bag.

16. **Dispose of used supplies** and perform hand hygiene.

What if . . .

- **When irrigating, the catheter will not accept the recommended amount of fluid?**

Deflate the balloon and reposition the catheter.
The catheter is probably not positioned correctly. Do not use more than the recommended amount of fluid, as this would result in excessive pressure on the rectal vault and may cause mucosal or sphincter damage.

- **Rectal bleeding occurs with an internal fecal management device?**

Discontinue the device and notify the physician.
Bleeding may indicate pressure necrosis from the device.

Evaluation

- Confirm catheter/bowel lumen patency by irrigating the bowel according to manufacturer's instructions and physician order. Regular irrigation is required to facilitate evacuation through most devices.
Stool needs to be of loose consistency to pass through the indwelling tube.
- Assess how well the patient tolerated the procedure.
- Note the color, consistency, and odor of stool.
- Monitor the amount of stool in the collection bag. When the collection bag is approximately two-thirds full, change it.
- Monitor for abdominal distention and pain.
- Regularly assess that connections are secure and that the device is not leaking.

In addition, for indwelling devices monitor:
- Length of time the device is in place
Not intended for use longer than 29 days.
- Rectal bleeding
May indicate tissue necrosis, bowel perforation, or fistula formation; device must be removed.

Documentation

- Date, time, and type of collection device used
- Your assessment of the perineal skin
- Patient's tolerance of the procedure
- Characteristics and amount of stool in the collection bag (output)
- Patient/family teaching

Sample documentation

09/15/15 1435 After prepping skin, an external fecal collection device was applied. Patient tolerated procedure well. Rationale for device was explained. Pt and family verbalized they will report leaking, pain, or discomfort. Device is draining large amounts of brown liquid stool, with no visible mucus or blood.—————— J. Smiley, RN

For questions and suggested responses,

Go to Chapter 29, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

CLINICAL INSIGHTS

Clinical Insight 29-1 ➤ Caring for a Patient With an Indwelling Fecal Drainage Device

With an indwelling fecal drainage device, a catheter is present in the rectum and connected to a drainage tube and collection bag.

Nursing Goal 1: Prevent injury to rectal sphincter and/or rectal mucosa.

- Do not add air or fluid to the balloon port of the catheter.
- Check the catheter frequently for kinks or obstructions.
- Monitor for signs of complications and notify the health-care provider immediately if patient experiences rectal pain, rectal bleeding or abdominal distention and/or pain.
- Monitor stool for change in consistency (solid or soft-formed stool cannot pass through the catheter and will cause an obstruction).
- How to discontinue the catheter:
  1. Attach a 60-mL syringe to the balloon inflation port and deflate the retention balloon by pulling back on the plunger.
  2. Grasp the catheter as close to the patient as possible and slowly slide it out of the anus.
  3. Dispose of the device accordance to the agency policy for disposal of medical waste.

Nursing Goal 2: Maintain free flow of liquid stool.

- Monitor the patient for changes in stool consistency. If the stool is no longer liquid and flowing, the device must be discontinued.
- Make sure the tubing and bag remain below the level of the patient.
- Irrigate the tube as often as necessary to maintain patency:
  1. Fill a 60-mL syringe with room-temperature tap water.
  2. Attach it to the irrigation port of the catheter and flush by depressing the plunger.

> Be sure you are using the irrigation port, NOT the balloon inflation port.

  3. Be sure to subtract the irrigation fluid from the stool volume to maintain an accurate record of I&O.
- Change the collection bag when it is three-fourths full.
  1. Remove the collection bag from the tubing. Snap the cap onto the used bag and dispose of according to agency policy for medical waste.
  2. Snap new collection bag securely onto the device.

Nursing Goal 3: Prevent transmission of pathogens to others.

- Follow the agency protocol for hand hygiene. Always wear clean procedure gloves when handling the fecal management device.
- Monitor stool cultures and implement isolation protocols as indicated. If a stool sample is ordered, you may obtain it from the collection bag:
  1. If the collection bag is more than 24 hours old, place a new collection bag before obtaining a sample.
  2. Cut the collection bag at the bottom and transfer stool to an appropriate container for transport to the lab.
  3. Apply a new collection bag to the connector at the end of the catheter.

Nursing Goal 4: Maintain perineal skin integrity or prevent wounds from being contaminated by stool.

- Monitor insertion site for leakage and signs of infection.
- If perineal wounds are present, keep clean and dry; notify the primary provider if signs of infection are present.
- Perform perineal care according to agency policy.

Clinical Insight 29-2 ➤ Guidelines for Ostomy Care

Assess stoma appearance.

- The stoma should be moist and red or pink. Immediately report to the surgeon a stoma that is pale, dusky, or black in color; dry; or with sloughing tissues.
  These are signs of inadequate blood supply to, and possible necrosis of, the portion of intestine that has been externalized.
- Protruding or retracted stomas will need special adjustments in wafer measurement and placement. It is normal for a new stoma to have yellow or blood-tinged mucus or dried blood on it.

Preserve peristomal skin.

- Preserving peristomal skin is critical because skin excoriation may cause an ineffective seal between the wafer and the skin. Leaking effluent will then cause skin and tissue damage. A different type of pouch system or sealant may be needed.
- Use recommended moisture-proof barrier creams and skin care products.

Plan for and change the pouch as scheduled.

- Change the skin barrier pouch at times of lower effluent.
- Avoid changing after meals, when the gastrocolic reflux increases chance of fecal effluent.
- Pouches are usually changed every 3 to 5 days, preferably before leakage occurs. Frequency also depends on the type of stoma, the type of equipment used, the effluent, the patient's preference, and the climate (e.g., pouches are changed more frequently during the summer).
- To decrease skin irritation, avoid changing the entire system. Try to change the skin barrier only every 3 to 7 days, never daily.

Assess the patient's self-care ability.

- Patients with poor vision may need to use magnification mirrors and yellow-tinted sunglasses to help reduce glare and improve contrast when they perform stoma care.
- Patients with immobility or spinal cord injury may need equipment that has a longer pouch that a seated patient can empty independently.
- Impaired dexterity or vision may warrant the use of a one-piece system or precut pouch and skin barrier. A two-piece system may be better for patients who need to keep the skin barrier in place for several days.
- Patients who are blind can be taught to change their own equipment.

Determine whether the ostomy should be irrigated.

- Consult a peristomal nurse or the primary care provider to determine whether an ostomy should be irrigated.
- Many patients with left-end colostomies may be safely irrigated as a method of continence management. An ileostomy, however, drains liquid containing high concentrations of sodium, chloride, potassium, magnesium, and bicarbonate.

Ileostomies should never be irrigated, except in cases of food blockage near the stomal outlet. Only a qualified person, such as an enterostomal therapy nurse, may perform a gentle lavage. For lavage, normal saline is preferred because excessive lavage could lead to a serious fluid and electrolyte imbalance.

Promote psychological adaptation.

- Be available to discuss the patient's reaction to the stoma. Your attitude and willingness to discuss the patient's body changes will help your patient begin adapting.
- Show acceptance when working with the patient and the stoma.
- Provide adequate ventilation and odor control when assessing the stoma or ostomy appliance.
- Provide ample time to explain stoma care and use of ostomy appliances. For most patients, this is a lifelong task.
- Teach the client about diet modifications.
- Encourage patients to return to their usual activities as much as possible.
- Encourage patients to discuss intimacy issues associated with the ostomy. Use the PLISSIT model (in Chapter 33) if necessary, and convey to them that sexual functioning is an appropriate topic to discuss. You may wish to use The United Ostomy Associations of America's *Intimacy After Ostomy Surgery Guide*, or give it to the patient (Turnbull, revised 2009).
- Refer the patient to the local ostomy association. Most of the counselors have ostomies and are able to share practical and personal information based on their own experience. To find the local chapter consult your phone book, or

Go to the **United Ostomy Associations of America** Web site at http://www.uoaa.org

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Bowel Elimination

Nursing History

Ask questions such as the following:

1. **Normal bowel pattern**
   - How often do you have a bowel movement (BM)?
   - What time of day do you usually have a BM?
   - Do you follow any routines to help you have a BM?
2. **Appearance of stool**
   - How would you describe your stool?
   - What color is your stool?
   - How would you describe the texture of your stool—hard, soft, or watery?
   - What shape is the stool?
   - Have you noticed unusual odor with your stool?
3. **Changes in bowel habits or stool appearance**
   - Have you had any changes in your bowel pattern recently?
   - Have you noticed any changes in the appearance, texture, or odor of your stool?
4. **For clients with a bowel diversion**, also gather data on the client's usual care of the stoma, use of appliances, and adjustment to the ostomy.
5. **History of elimination problems**
   - What has been your experience with bowel elimination problems?
   - Have you had any problems with constipation, diarrhea, or severe bloating or gas?
   - Have you ever lost control of your bowels?
   - Have you ever had bowel surgery or diagnostic procedures of the digestive tract?
6. **Use of bowel elimination aids**, including diet, exercise, medications, and remedies
   - What aids, if any, do you use to help you have a BM?
   - What foods help you maintain your bowel pattern?
   - What foods do you avoid? What effect do these foods have on you?
   - What is your usual fluid intake over the course of a day?
   - What is your usual exercise pattern?
   - What medications are you taking? Have they had any effect on your bowel elimination pattern?
   - What is your current stress level? What effect does stress have on your bowel elimination pattern?

Physical Assessment

Examine the abdomen, rectum, and anus.

- Recall that in abdominal assessment, the order of the exam is inspection, auscultation, percussion, and palpation.
- Observe the size, shape, and contour of the abdomen.
- Listen to bowel sounds. Describe them as follows:

  Normal—high-pitched, approximately 5 to 15 gurgles per minute.

  Hyperactive—very high-pitched, more frequent than normal.

  Hypoactive—low-pitched, infrequent, and quiet. Indicates decreased peristalsis.

  Absent—If after listening for 3 to 5 minutes, you hear no bowel sounds.
- When listening to bowel sounds, note the presence and timing of the sounds and the presence of any bruits.
- Percuss and palpate the abdomen for tenderness, presence of air or solid, and presence of masses.
- Inspect the anus for signs of hemorrhoids.
- Depending on the policies of your institution as well as your skill with assessment, you might also palpate the anus and rectum for the presence of stool or masses. For a complete discussion of physical examination of the abdomen, rectum, and anus, see Procedures 22-14 and 22-19.

DIAGNOSTIC TESTING

Diagnostic Testing

Direct Visualization Studies of the Gastrointestinal Tract

- Because all of the following studies are invasive procedures, you should ensure that the patient has signed an informed consent.
- All of the procedures require some degree of advance preparation, such as fasting. Check agency policy, because preparation may vary.
- Preparing the patient includes telling him what he will experience and feel during the procedure.
- When the patient is sedated (e.g., with midazolam or diazepam), an emergency medical cart ("crash cart") must be in the room during the procedure, and the patient monitored with pulse oximetry.
- All of the procedures require teaching for aftercare.
- For all tests, explain that rectal bleeding is normal for a few days if polyps were removed or a biopsy was taken.

Diagnostic Testing

Direct Visualization Studies of the Gastrointestinal Tract—cont'd

For more specific nursing responsibilities before, during, and after each test,

Go to Chapter 29, **Tables, Boxes, Figures: ESG Box 29-1, Direct Visualization Studies of the Gastrointestinal Tract: Nursing Care,** on Davis*Plus*.

Esophagogastroduodenoscopy (EGD)

Provides direct visualization of the upper GI system. A *fiberoptic endoscope*, a long, flexible tube with a light and lens, is introduced through the mouth and advanced for visualization of the esophagus, stomach, and duodenum. The physician may also perform tissue biopsies or coagulate bleeding sites through the endoscope.

Sigmoidoscopy

Allows visualization of the anal canal, rectum, and sigmoid colon. A rigid metal scope or a flexible fiberoptic scope may be used. The patient is usually not sedated. During the exam, the physician may perform a biopsy, remove polyps (small growths), or coagulate sources of bleeding in the area. A sigmoidoscopy is recommended as a screen for colon cancer for middle and older adults. Subsequent screening depends on the findings of the sigmoidoscopy as well as patient and family history; however, it is commonly done every 5 years.

Fiberoptic Colonoscopy

Provides direct visualization of the rectum, colon, entire large intestine, and distal small bowel. A flexible scope is inserted through the rectum and advanced to the cecum. Colonoscopy is useful in detecting lower GI disease. Many patients and healthcare providers choose a colonoscopy for cancer screening instead of a sigmoidoscopy, because colonoscopy provides greater visualization of the colon. This is the preferred test for clients with suspected problems above the level of the sigmoid colon. It may be done in a clinic or physician's office.

Source: American Cancer Society (2011). *Detailed guide: Colon and rectum cancer; Revised 06/25/13.* Retrieved from http://www.cancer.org/acs/groups/cid/documents/webcontent/003096-pdf.pdf; Van Leeuwen, A., Poelhuis-Leth, D., & Bladh, M. (2011). *Davis's comprehensive handbook of laboratory and diagnostic tests with nursing implications* (4th ed.). Philadelphia: F.A. Davis.

Diagnostic Testing

Indirect Visualization Studies of the Gastrointestinal Tract:

For nursing responsibilities before, during, and after each test,

Go to Chapter 29, **Tables, boxes, Figures: ESG Box 29-2, Indirect Visualization Studies of the Gastrointestinal Tract: Nursing Care,** on Davis*Plus*.

Abdominal Flat Plate

An anterior to posterior (AP) x-ray view of the abdomen is used to detect gallstones, fecal impaction, and distended bowel. This test requires no preparation and no special post-test care.

Barium Enema (BE)

A barium enema is a radiological examination of the rectum, colon, and distal small bowel. A rectal tube is inserted into the rectum or an existing ostomy. Barium (a contrast medium) is instilled. The patient must retain the barium through several position changes while air is instilled and radiographs are obtained. The test is especially useful for visualizing polyps, diverticula, and tumors. In addition, it may be used to reduce certain obstructions. As a rule, patients are not sedated. The test is invasive, so a signed informed consent is necessary.

Ultrasonography (Ultrasound)

Ultrasonography detects tissue abnormalities such as masses, cysts, edema, or stones. An ultrasound probe, called a transducer, is moved over the skin surface of the abdomen. The probe emits a sound wave that abdominal tissue and organs reflect back based on their density. The sound waves may be transformed into images visible on a computer screen.

Computed Tomography (CT) Scan

Computed tomography (CT) examines body sections from different angles using a narrow x-ray beam. It produces a three-dimensional picture of the area of the body being scanned. This test is useful in diagnosis of many abdominal disorders. A CT scan may be enhanced by injecting contrast dye that allows for improved visualization of circulatory function. The patient needs to lie very still during the procedure.

Magnetic Resonance Imaging (MRI)

Magnetic resonance imaging (MRI) produces cross-sectional images of the body. MRI utilizes a strong magnetic field and radio waves. This type of diagnostic test does not use ionizing radiation, so it is free of the hazards of x-rays. MRIs are very sensitive and may be used to detect edema, hemorrhage, blood flow, infarcts, tumors, and infections in organ structures. When used, the contrast medium is noniodinated, and it is administered intravenously to enhance contrast between normal and abnormal tissues. The patient must lie still in a narrow tube, sometimes for up to an hour.

Source: Van Leeuwen, A., Poelhuis-Leth, D., & Bladh, M. (2011). *Davis's comprehensive handbook of laboratory and diagnostic tests with nursing implications* (4th ed.). Philadelphia: F.A. Davis.

CLINICAL REASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Lucy Franklin is a frail, elderly woman, a long-time resident in a long-term care facility. She can no longer communicate and lies however the NAPs place her in bed, seldom moving. She is very thin, does not eat or drink, and is being fed entirely through a gastrostomy tube. She is incontinent of both stool and urine, and has recently started having copious diarrhea, probably from the tube feedings, but that has not been established definitely. The skin on Lucy's back, buttocks, and perineum is still intact, but it is quite red now. The healthcare team is considering various measures for controlling the diarrhea, but until that can be achieved, nurses want to protect her skin integrity.

THINKING

1. *Theoretical Knowledge:*
   a. Other than tube feedings, what else could be causing Lucy's diarrhea?
   b. In addition to Impaired Skin Integrity, what are some other risks associated with diarrhea?
   c. Why is fecal incontinence, especially with diarrhea, a risk factor for Impaired Skin Integrity?
2. *Critical Thinking:*
   a. *(Contextual Awareness):* What other factors in Lucy's situation do you think might make her even more vulnerable to Impaired Skin Integrity? If you do not yet have the theoretical knowledge you need, draw on your own experiences—and think carefully about everything you know about Lucy.
   b. *(Considering Alternatives):* A fecal incontinence pouch is being discussed as an intervention to preserve Lucy's skin integrity. Do you think it should be an external system or an internal system? Why?

DOING

3. *Practical Knowledge:*
   It has been decided that an external fecal collection system will be used. Describe the steps you will take to apply this system after you have made the necessary assessments.
4. *Nursing Process (Assessments):*
   What ongoing assessments will you need to make after the fecal collection system is applied?

CARING

5. *Self-Knowledge:*
   How comfortable would you be applying Lucy's fecal collection system? What aspects of the situation make you most uncomfortable?

Critical Thinking and Clinical Reasoning

1. Your neighbor is aware that you are a nursing student and calls you for advice. She has a 12-year-old daughter with diarrhea. "Everything runs through her," states the mother. There are also two other children in the house, ages 6 years and 18 months. Both have had watery stools this morning. Your neighbor explains that her husband has an ileostomy and has been hospitalized since yesterday. Your neighbor has no symptoms but is very worried. She asks, "Do we all need to go to the hospital?"
   a. Consider alternatives. What are the most likely explanations for the diarrhea?
   b. Based on your theoretical knowledge, how would you explain why her husband was hospitalized, while the rest of the family members, who have the same symptoms, remain at home?
   c. After reassuring her, what advice should you offer your neighbor about self-care for her and the children's elimination problem?
2. Consider the following patients:
   - A 54-year-old man diagnosed with colon cancer who now has a new sigmoid colostomy
   - A 21-year-old woman with Crohn's disease (an inflammatory bowel disorder) who has just had an ileostomy
   - A 36-year-old trauma victim who has a new double-barreled transverse colostomy

   a. How are these patients similar?
   b. In regard to their surgery, what nursing care priorities do these patients share?

c. How do the major concerns for these patients differ? (Consider the context. How are their surgical and self-care situations different?)

3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or bowel elimination. Note that these are *not* to be merely definitions.
   Digestion (in the mouth, esophagus, stomach, and small intestine)
   Large intestine (colon)
   Rectum and anus
   Fluid intake
   Location of a bowel diversion
   Bowel sounds
   Providing privacy
   Diarrhea

What Are the Main Points in This Chapter?

- Bowel elimination is a normal process by which waste products are eliminated from the body.
- Feces are a mixture of insoluble fiber and other indigestible material, bacteria, and water.
- During defecation, the internal and external anal sphincters relax; the rectum contracts; and peristalsis increases in the sigmoid colon, propelling feces through the anus.
- The frequency of bowel movements (BMs) varies. As long as stools are passed without excessive urgency, with minimal effort and no straining, and without the use of laxatives, bowel function is regarded as normal.
- Adequate fiber, fluid, and exercise are required to maintain a person's normal bowel pattern.
- Factors affecting bowel function include developmental stage, personal and sociocultural factors, nutrition, hydration, activity level, stress, anesthesia, medications, pregnancy, surgery and other procedures, and pathological conditions.
- To promote regular defecation, provide privacy for the patient and allow time to use the toilet.
- Constipation is a decrease in frequency of BMs and the passage of dry, hard stool that requires more effort to pass.
- Bulking agents are the preferred medication for treating constipation.
- Habitual use of laxatives, with the exception of bulking agents, may cause reliance on medication for bowel elimination.
- Fecal impaction is detected by digital examination of the rectum. To treat a fecal impaction, enemas and/or digital removal of stool is required.
- An enema is the introduction of solution into the rectum to soften feces, distend the colon, and stimulate peristalsis and evacuation of feces.
- Monitor patients with diarrhea for intake and output, body weight, and vital signs to assess for fluid losses; provide hygiene measures to protect the skin.
- Bowel incontinence may be managed by providing assistance to the bathroom at regular intervals and at the times BMs are most likely to occur, and by beginning a bowel training program.
- External or internal fecal collection devices can be used to protect perianal skin or to collect large stool samples. They minimize odor, allow for accurate measurement of output, and improve patient comfort.
- A bowel diversion is a surgically created opening for elimination of digestive waste products.
- The **effluent** (fecal matter) of an ostomy ranges from liquid to solid, depending on the part of the bowel that is being diverted.
- A healthy stoma ranges in color from deep pink to brick red and is shiny and moist at all times.
- A client with a bowel diversion must adapt to the stoma for elimination and learn to care for the stoma.

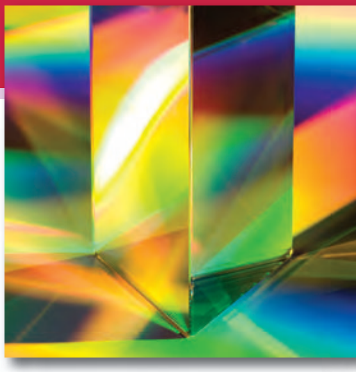
CHAPTER 30



Sensation, Perception, & Cognition

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 30:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Sensation, Perception, & Cognition (suggested readings)**
- **Concept Map of chapter content**

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 30, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Mai Nguyen, Nam Nguyen's mother, has been experiencing blurred vision. At a recent ophthalmology appointment, she was told she has bilateral cataracts that will require surgical removal. She reports to the primary care clinic today, accompanied by Nam. Mai tells you, "I don't know what happened. I was pulling into a parking space at the grocery store, and the next thing you know, I hear this loud boom. I don't know how I did it, but I hit the car next to me. I just didn't see it."

Nam is very concerned and questions whether his mother should be allowed to drive. Mai is visibly upset. "I don't want to hurt anyone, but I don't want to lose all my freedom." Nam insisted on this appointment to discuss his concerns.

(Continued)

Caring for the Nguyens (continued)

A. What data will you need to gather from Mai and Nam?

B. What assessments will you need to perform?

C. How will cataract surgery most likely affect Mai? You will need to learn about the surgery and recovery to answer this question. Use a textbook, or, for a list of helpful Web sites you can access,

Go to Student Resources: Chapter 30, **Resources for Caregivers and Healthcare Professionals,** on Davis*Plus*.

D. What information would you offer to Mai and Nam?

Go to Student Resources: Chapter 30, **Caring for the Nguyens Response Sheet,** on Davis*Plus*.

PracticalKnowledge knowing how

To provide support for patients with sensorineural alterations, you will need practical knowledge about assessing and diagnosing sensorineural functions. Nursing interventions involve caring for patients who have vision and hearing deficits. This section includes a procedure for otic irrigations, which may be used to correct hearing loss resulting from a cerumen-blocked ear canal. Some procedures to support sensory function, such as instilling medications and irrigating the eye, are presented in the procedures in Chapter 26 of this volume. For other interventions,

Go to **Chapter 26: Administering Medications,** and **Chapter 30: Sensation, Perception, & Cognition,** in Volume 1.

In this section you will also find techniques for communicating with patients who have visual or hearing deficits, as well as assessment guidelines.

PROCEDURES

Procedure 30-1 ■ Performing Otic Irrigation

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- An ear irrigation system, such as the Welch Allyn ear wash system or an electronic jet ear irrigator

  Using a metal syringe is no longer recommended and is considered dangerous. *An ear irrigation system is also preferred over an Asepto or bulb syringe because of the better ability to control pressure and remove cerumen (Harkin, n.d.).*

- Asepto syringe, or rubber bulb syringe (if an ear irrigation system is not available)
- Irrigating solution (usually water, but may be an antiseptic solution), warmed to 98.6°F (37°C)
- Bath towel and moisture-resistant towel
- A headlight if one is available
- Emesis basin
- Otoscope
- Cotton balls
- Procedure gloves

Delegation

You must assess the client before performing this procedure and evaluate client responses during and after the procedure. The procedure requires knowledge of anatomy and physiology, use of an otoscope, and, sometimes, use of sterile technique. Therefore, you should not delegate otic irrigation to nursing assistive personnel (NAP).

Pre-Procedure Assessments

- Determine whether there are contraindications for ear irrigation.

  Contraindications include ruptured tympanic membrane, present or recent middle ear infection, prior surgery on the ear, cleft palate, or acute inflammation of the ear canal.

- Assess the external ear for drainage.

  Do not irrigate the ears if drainage is present. Drainage from the ear may be a sign of rupture of the tympanic membrane.

- Assess the external ear for cerumen.
  Impacted cerumen is the most common reason for performing an ear irrigation.
- Assess the external ear canal for redness, swelling, or foreign objects; visualize the tympanic membrane. If a foreign object is present, attempt to remove it before irrigation.
  Establishes the baseline. If you irrigate with a foreign object in the ear, it may cause the object to swell and become more difficult to remove. Also, if you cannot visualize the tympanic membrane, it may be perforated; if so, otic irrigation is contraindicated.
- Assess for pain or hearing loss.
  Establishes the baseline. Cerumen blockage in the ear canal may result in a conductive hearing loss.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Warm the irrigating solution** to body temperature (98.6°F [37°C]), and fill the reservoir of the irrigator.
   Placing cool solutions in the ear can cause dizziness.

2. **Assemble the irrigator** if necessary, and place a clean disposable tip on it.

3. **Assist the client into a** sitting or lying position, with the head tilted slightly toward the affected ear. Explain what you are going to do.
   Positioning facilitates administering the solution and allows fluid to run along the roof of the ear canal. Knowing what to expect may decrease patient anxiety and improve his ability to cooperate during the procedure.

4. **Don gloves;** put on the headlight.
   The gloves are needed because of the risk of exposure to body fluids. The headlight facilitates direct vision.

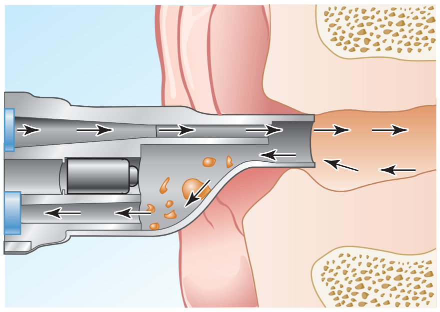
5. **Drape the client** with a plastic drape, and place a towel on the client's shoulder on the side being irrigated. Ask the client to hold an emesis basin under his ear to collect the irrigating fluid that drains out of the ear.
   Note: An emesis basin is not necessary if a comprehensive ear wash system is used.
   Drape and towel protect the client's clothing.

6. **Set the irrigator pressure** to the minimum level. Let it run for 20 to 30 seconds to prime the tubing or nozzle before irrigation. (If you must use an Asepto or rubber bulb syringe, fill the syringe with about 50 mL of the irrigating solution, and expel any remaining air.)

7. **Straighten the ear canal.**
   a. For a child younger than 3 years old, pull the pinna down and back.
   b. For older children and adults, pull the pinna upward and outward.
   Straightens the ear canal so that the solution can flow through the length of the canal.

8. **Instruct the client to notify** you if he experiences any pain or dizziness during the irrigation. Explain to the client that he may feel warmth, fullness, or pressure when the fluid reaches the tympanic membrane.
   Pain or dizziness may indicate a contraindication to the procedure.

9. **Place the tip of the nozzle** (or syringe) about 1 cm (½ in.) above the entrance of the ear canal, and direct the stream of irrigating solution gently along the top of the ear canal toward the back of the client's head.
   a. Do not occlude the ear canal with the nozzle.
   b. Instill the solution slowly.
   c. Allow the solution to flow out as it is instilled.
   d. Repeat these steps for 5 minutes or until you can see cerumen in the return solution.
   Directing the flow directly onto the tympanic membrane could injure the membrane. Strong pressure can cause discomfort and may even damage the tympanic membrane.



10. **Inspect the ear with** an otoscope to evaluate cerumen removal. See Procedure 19-7 if you need to review otoscopic examination.
    Allows visualization of the canal.

11. **Continue irrigating until** the examination indicates the canal is cleaned of cerumen and debris.
    The irrigating solution will soften the cerumen, easing removal. Blocking the canal prevents the outward flow of the solution.

12. **Place a cotton ball loosely** in the ear canal, and ask the client to lie on the side of the affected ear.
    The cotton ball will absorb excess fluid that drains by gravity.

13. **Clean and disinfect the irrigator**, according to the manufacturer's instructions or agency protocols. Dispose of the disposable tips.

? What if . . .

- **The cerumen is very hard or you have difficulty removing it?**
  The irrigating solution will help soften it, so you may attempt again after 15 minutes.
- **The patient is an infant or young child?**
  Ask another caregiver to immobilize the child during the irrigation.

(continued on next page)

Procedure 30-1 ■ Performing Otic Irrigation (continued)

Evaluation

- Observe the quantity and quality of ear cerumen you removed.
- Observe the appearance of the ear canal.
- Assess for complaints of pain or dizziness.
- Assess for improvement in hearing acuity.
- Reassess for drainage on the cotton ball.

Patient Teaching

- Avoid use of cotton-tipped swabs.
  They simply push cerumen deeper into the ear.
- Keep the ear dry for a few days. Use cotton balls coated with petroleum jelly when bathing.
  Exposure to a wet environment, such as a swimming pool, may increase the risk of bacterial or fungal infection. Petroleum jelly serves as a barrier to keep water from entering the ear.
- Clean ears daily with washcloth, soap, and water. If wax buildup is a problem, over-the-counter preparations (oils) can be used.
- Notify the primary care provider if you experience ear pain, vertigo, or "ringing in the ears."
  Ear irrigation is an invasive procedure and may result in otitis media, trauma to the external meatus, vertigo, tinnitus, and perforation of the tympanic membrane, although this is not common.

Home Care

- Provide the caregiver with instructions on ear care as stated above.
- Teach parents that it is best to avoid irrigation in young children unless absolutely necessary. Oil- or water-based ear drops may be used to treat a wax problem in a child, applying the oil when the child is asleep.

Documentation

- Document the ear solution used, the quantity, character, and odor of cerumen or drainage.
- Chart the condition of the ear canal and tympanic membrane after the irrigation.

Sample documentation

mm/dd/yyyy 1400 *Pt c/o bilateral decreased hearing acuity. External ear canals occluded with dried cerumen. Irrigated with warm water using electronic jet ear irrigation system. Large amount of dry, brown cerumen removed with irrigation. External canals and tympanic membrane intact to otoscopic inspection after irrigation.* — N. Ephrain, RN

Practice Resources

Burtin, M., & Doree, C. (2009); Chau, J., Lee, D., & Lo, S. (2012); Harkin, H. (n.d.); Roland, P. S., Smith, T. L, Schwartz, S. R., et al. (2008).

CLINICAL INSIGHTS

Clinical Insight 30-1 ➤ Seizure Precautions

Institute seizure precautions for patients with a new diagnosis of a seizure disorder or any seizure activity within the past 12 months; frequent seizure activity; history of head trauma (including surgery) within the past 3 years; withdrawal of antiseizure medication or adjustment of the medication regimen.

The goal of seizure precautions is to protect the patient from injury and prevent serious complications.

Before a Seizure Event

- Explain to the patient the reasons for the precautions.
- If the patient has frequent or prolonged seizures, establish IV access.
  To provide a route to administer medications (e.g., diazepam [Valium]) in the event of a seizure. For intermittent episodes, you can use rectal diazepam (Diastat), lorazepam (Ativan), or midazolam (Versed).
- Obtain a bed with full-length siderails.
- Cover the headboard, footboard, and siderails with commercial pads or bath blankets. Tape the blankets in place.
  Padding protects the patient's limbs and head from injury if he has a seizure.
- Keep the rails raised and the bed in low position.
  To prevent falls and minimize injuries.
- Place oral or nasal suction equipment at the bedside. Test to be certain it is working.
- Place an airway at the bedside or tape to the wall, depending on your agency protocol.
- Make sure the family knows how to use a call bell.
  To summon help in the event of a seizure.
- Assign the patient to a room in close proximity to the nurses' station.
  To allow closer monitoring.
- You may delegate to the NAP the tasks of setting up seizure precautions.

Clinical Insight 30-1 ➤ Seizure Precautions—cont'd

When a Seizure Occurs

- If you are present when the patient reports having an aura, help him into bed, lower the head, and raise the siderails. If in another location, help him to the floor and put something soft under his head.
  To keep the head from being injured by hitting the floor, counter, or other hard object.
- Provide privacy.
- Stay with the patient.
- You may insert an oral airway.
  To keep the tongue from blocking the airway.
- Don't put anything into the patient's mouth and don't force the airway in place.
  This might break the teeth or cause other injury.
- Don't try to hold the jaw open or put your hands in the mouth.
  You may be bitten.
- Turn the patient on his side.
  This allows secretions to drain and the tongue to fall forward, keeping the airway patent.
- Loosen restrictive clothing.
- Move hard or sharp objects out of the way.
- Do not try to restrain the patient or control his movements.
  This might cause muscle and joint injury.
- If the seizure is prolonged or hypoxemia is present, administer oxygen as prescribed.
  To avoid hypoxia during the event.
- Usually little nursing action is required beyond preventing physical injury and maintaining a patent airway. The exception is with status epilepticus, in which the patient has repeated seizures without regaining consciousness. In that event, notify a physician immediately.
- Observe the characteristics of the seizure: how it started, location and duration of motor activity, type of movements (e.g., stiffening, jerking, twitching, loss of muscle tone), crying out, visual and auditory symptoms, tachycardia, pupil dilation, change in level of consciousness). Note the first symptom and how the seizure progressed.
  To help identify the area of the brain involved.
- You cannot delegate care of a patient who is having a seizure because nursing assessments and interventions are required. You can ask the NAP to obtain help.
- Administer prescribed antiseizure medication if the seizure is prolonged, typically >6 minutes.

After the Seizure

- Turn the patient on his side and apply suction, if needed.
  To allow secretions to drain and maintain a patent airway.
- Reorient and reassure the patient, and make him comfortable. If the patient was incontinent, change bedding and clothing.
- Examine for injuries.
- Keep the room quiet and the lighting dim.
- Stay with the patient, as he may be sleepy or confused.
- Do not give any food or drink until the patient is fully conscious and alert.
- Monitor vital signs and mental status every 15 to 30 minutes for 2 hours. You can delegate this activity to a NAP.
- Observe post-seizure behavior: Evaluate muscle strength, ability to speak, memory, and orientation.
- Pad the siderails, if not already done.
- Ask the patient whether he experienced an aura and what activities preceded the seizure.
  The type of aura helps locate the area in the brain where the seizure originated.
- Document what happened and your post-procedure assessment.

Lifestyle Management

Sleep deprivation lowers the threshold for seizure activity. The patient should have sufficient rest and a healthy diet. Advise the patient to visit his primary care provider regularly, take prescribed antiseizure medication on time, and avoid excess alcohol and any drugs that may interact with seizure medications.

Living with epilepsy. Seizure dogs are trained to respond to seizures by alerting families for help and by lying next to the person to prevent injury.

References

American Association of Neuroscience Nurses (2007, revised 2009); Wiegand, L. (2011).

Clinical Insight 30-2 ➤ Communicating With Visually Impaired Clients

The Joint Commission (2010) requires that institutions address the communication needs of patients with impaired vision.

- Introduce yourself when you enter the room.
- Call the client by her name so that she can be certain you are addressing her.
- When you enter a room with a client who is visually impaired, describe the room, room layout, and activities that are occurring.
- Explain unfamiliar sounds, such as the paging system and monitor and pump alarms.
- If the client has limited vision, be sure to position yourself in the client's field of vision.
- Speak to the visually impaired person before you touch her so that she is prepared for your touch.
- Do not speak loudly unless the client has a hearing impairment.
- Let the client know when you are leaving the room.
- Use the words "see" and "look" as you would with a sighted person.
- Avoid expressions, such as "over there" or "right here." Guide the client to the location or place her hand on the object.

Clinical Insight 30-3 ➤ Communicating With Hearing-Impaired Clients

Healthcare agencies should address the communication needs of those with vision, speech, hearing, language, and cognitive impairments (The Joint Commission, 2010).

Assess the patient's method of receiving speech.

- If the patient wears a hearing aid, check to see that it is turned on.
- If not, does the patient read lips or use sign language? Remember that only about $\frac{1}{3}$ of spoken words can be understood by speech reading.
- If possible, arrange a hearing evaluation for the client and construction of any required hearing aids.

Position yourself and minimize noise.

- Don't chew gum or eat while talking. Many clients use lip reading to help them interpret your speech.
- Make sure you are clearly visible to the client before you start speaking. Use touch to get the client's attention.
- Face the client directly; keep your hands away from your mouth.
- If the hearing deficit is predominantly in one ear, move closer to the less affected ear.
- Minimize environmental noise (e.g., turn off the TV).

Send the message.

- Speak slowly and articulate clearly, in a natural way. Don't shout. Shouting distorts your words.
- Don't drop your voice at the end of a sentence.
- Use simple, plain language, but longer phrases (e.g., "Would you like me to get you a drink of water?" instead of "Do you want a drink?")
- Use gestures to provide visual cues (e.g., act out what you want the patient to do).
- Use paper, pencil, or computer communication when necessary. Consider literacy skills.

Interpret the client's responses.

- Observe the client's verbal responses, facial expressions, and body language for clues to understanding. An inappropriate response indicates misunderstanding.
- Be aware the person may nod agreement or say "yes" even when she does not understand what is being said.
- Confirm that the client understood you by asking her to repeat what you said, especially if you are giving specific information, such as a time or place. Many numbers and words sound alike (e.g., "fifteen" and "fifty"; or "Prozac" and "Prograf").
- If the person does not understand what you've said, rephrase your statement. Don't repeat the same words.

For older adults: Use a low-pitched voice. The ability to hear high-pitched tones is lost first with aging.

ASSESSMENT GUIDELINES AND TOOLS

As a nurse, you should always consider your client's sensory–perceptual status. Sensory deficits and excess or inadequate stimulation have a significant influence on quality of life and may be especially troublesome for institutionalized clients.

Hearing Screening in Older Adults

To find a useful tool to screen hearing in older adults,

Go to the Hartford Institute for Geriatric Nursing, *Try this: Best practices in nursing care to older adults* at http://consultgerirn.org/uploads/File/trythis/try_this_12.pdf

Using this tool, a patient scores as follows. A total of 3 points indicates the need for further evaluation.

1 point for each of the following:

- Older than 70 years
- Male
- Did not attend 12th grade
- Cannot hear and understand (without seeing the face) what a person whispers from across the room.

2 points for each of the following:

- Has ever seen a doctor because of trouble hearing
- Unable to hear and understand (without seeing the face) a person talking in a normal voice from across the room.

Other Sensory Assessment Tools

Focused Assessment

Nursing History: Sensory Perceptual Status

Usual Sensory Function

Ask questions such as the following:

- How would you rate your vision?
- How would you evaluate your ability to see objects up close or at a distance?
- Do you have any difficulty hearing conversations or listening to the radio or television?
- Have you experienced any difficulty locating sounds?
- Do you experience ringing or buzzing in your ears?
- Do you enjoy the taste of food?
- Do you notice any difficulty with your ability to smell?
- Are you experiencing any pain or discomfort?
- Do you have any areas of numbness or tingling on your body?
- Do you have any difficulty with sensing hot or cold?
- Describe your level of coordination.
- What medications are you taking? Have they had any effect on your vision, hearing, sense of taste, smell, touch, or balance?
- What is your current stress level?
- What is your usual activity level?
- What is your preferred activity level?

Assess for Risk Factors for Impaired Sensory Function

- Developmental level (e.g., older adults)
- Health status (usual and current state of health, current health concerns (e.g., Ménière's disease), history of hospitalizations and surgeries)
- Medications (i.e., look up side effects to determine what, if any, effect the medications have on sensory function)
- Stress (current and usual stress level, major sources of stressors, usual coping mechanisms)
- Lifestyle (normal activity, noise, interaction levels, hobbies, and usual lifestyle)

History of Sensory Problems

Ask about the following:

- Have you experienced any problems with blurred vision, double vision, sensitivity to light, blind spots, objects moving in front of your eyes, or eye pain?
- Have you ever felt unable to follow a conversation because of difficulty hearing?
- Have you ever had problems with your ability to taste or smell?
- Have you ever had areas of numbness or tingling?
- Has anyone in your family ever been diagnosed with a stroke or circulation problem?
- Have you ever had episodes of confusion or disorientation?

Use of Sensory Aids, Including Diet, Exercise, Medications, and Remedies

- Does the client wear glasses or contact lenses at any time? If so, determine the following:

  When was the client's last eye exam?

  Are the glasses clean and in good repair? Are the glasses within easy reach?

  Are contact lenses in good condition? Is the client able to care for them?
- Does the client wear a hearing aid? If so, determine the following:

  Can the client hear adequately with the hearing aid in place?

  Are the batteries working?

  Is the hearing aid clean?

  How much help does the client need to place the aid in his ear?

(Continued)

Focused Assessment

- Does the client use a cane or walker? If so:

  Has the cane or walker been properly fitted to the client?

  How often does the client use the device when walking?
- What factors determine when the device will be used?

Assess Mental Status

- Assess behavior, appearance, response to stimuli, speech, memory, and judgment. If you need more specific instructions, see Procedure 21-16, Steps 1–10 and Questions for Evaluating Cognitive Status, at the end of the procedure.
- **For older adults**, a tool called the Mini-Cog is especially useful (Borson, Scanlan, Brush, et al., 2000). It consists of 3 memory questions and instructions to draw a clock face. To use this tool,

  Go to http://consultgerirn.org/uploads/File/trythis/try_this_3.pdf
- Assess level of orientation: Have the client tell you his name, the date, and his current location. If he can answer these questions correctly, describe him as "awake, alert, and oriented to person, place, and time" (AA&O×3).
- Assess level of consciousness:

Alert	Is the patient awake and aware of the environment and himself, speaking clearly, making eye contact?
Confused	Are actions and speech inappropriate?
Lethargic	Is speech slow or sluggish? Are mental processes and movements sluggish?
Obtunded	This is a low level of awareness and response to environment. Document it if it occurs.
Stuporous	This occurs when the patient can be aroused by vigorous stimulation but seems confused during periods of arousal.
Comatose	In this state, there is no spontaneous movement, no verbalization, and only nonpurposeful movement with stimulation. (Huntley, 2008)

- Also see Chapter 22, Procedure 22-16, Assessing the Sensory-Neurological System, Glasgow Coma Scale, and Full Outline of UnResponsiveness Scale.

Assess Support Network for Clients With Sensory Deficit

- Are there support persons to help the client by assuming chores he can no longer perform?
- Are there people who provide comfort to ease the client's distress about sensory losses?
- Who can provide sensory stimulation?
- Who can help reorient and calm the client?
- Does the client need help with transportation in order to maintain social contact?

Focused Assessment

Bedside Assessment of Sensory Function

SENSE	ASSESSMENT PROCESS
Vision	Use the Snellen chart, or have the client read a newspaper.
	Observe for squinting.
Hearing	Perform the whisper test.
	Inspect the ear canals for hardened cerumen.
	Observe client conversations. Are there frequent requests for repeating information or misunderstandings?
	How loud is the client's radio or television?
	To screen hearing in older adults, you will find a useful tool if you Go to http://consultgerirn.org/uploads/File/trythis/try_this_12.pdf
Smell	Ask the client to close his eyes and identify common smells (e.g., coffee, vanilla, cloves, tobacco).
Taste	Ask the client to close his eyes and identify common tastes (e.g., salt, lemon, and sugar). Give water between tastes.
Tactile	With his eyes closed, touch the client with a wisp of cotton. Have him identify when you have touched him. Repeat this process with a sharp object, such as a needle.
	With his eyes closed, ask the client to identify where you are touching his body.
Kinesthesia	Have the client perform the Romberg test. See Procedure 22–7.
	Have the client perform alternating rapid motions, such as tapping heels or clapping.
	Observe the client's gait and movement.

CLINICAL REASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Clint Gossage is an 85-year-old man who lives at home alone. His wife moved to a nursing home a year ago. Although Mr. Gossage has many self-care deficits, he is still able to live at home, with regular visits from a home health nurse and community services to help with some meals and bathing. When you visit him, you notice that he shouts when talking to you, looks at you intently when you speak, and constantly asks you to repeat what you say. You examine his external ear canal and note that there is some hardened cerumen in the canal. He is not wearing a hearing aid. The patient record reveals tympanic membrane scarring and a diagnosis of conductive hearing loss.

THINKING

1. *Theoretical Knowledge:* Describe the pathophysiology of conductive hearing loss.
2. *Critical Thinking (Considering Alternatives):* Based on your knowledge of conductive hearing loss and your assessment of Mr. Gossage, what is the first follow-up question you would ask him about his hearing?

DOING

3. *Practical Knowledge:* At a subsequent visit, you discover that Mr. Gossage has impacted cerumen in his left ear. After obtaining a medical order, you prepare to perform an otic irrigation.
   a. To what temperature will you warm the solution?
   b. What position would you use for Mr. Gossage?
   c. Describe how you would place the tip of the syringe (or ear wash system) for irrigating.
   d. After the ear is cleared of cerumen and you have finished irrigating, what should you do next? And what position will you have Mr. Gossage assume when you do it?
4. *Nursing Process (Diagnosis):*
   a. Write a nursing diagnosis that focuses on Mr. Gossage's safety and that relates to hearing.
   b. Based on your nursing diagnosis, what safety measures would you recommend for Mr. Gossage's home? (Do not address the hearing aid issue here.)

CARING

5. *Ethical Knowledge:* Now think back to the first visit with Mr. Gossage. What are some reasons that he might not have been wearing a hearing aid? Consider physical changes associated with aging.

Critical Thinking and Clinical Reasoning

1. Review the following client scenarios.
   - **Margaret** is 84 years old. She is a retired schoolteacher who loves to read, work in her garden, and volunteer at the local children's hospital. She has developed macular degeneration and is progressively losing her sight.
   - **Rocky** is 55 years old. He is a former guitar player in a heavy-metal band. He now works in music production. He has significant hearing loss related to chronic exposure to loud music. Most recently he has developed tinnitus, which has exacerbated his hearing loss.
   - **Jesse** is 31 years old. He is a chef at a local four-star restaurant. He suffered a head injury in a motor vehicle accident and has lost his sense of smell.
   - **Natasha** is 26 years old. She is a licensed architect working for a firm in the downtown area. She has been taking birth control pills for 5 years. Recently she has been under a lot of stress. She began drinking lots of coffee, smoking cigarettes, and working long hours. She was admitted to the hospital with right-sided weakness and slurred speech. She is being evaluated for a cerebrovascular accident.
   - **Aahan** is 15 years old. He has cerebral palsy. As a result, he has a "scissor walk" and dysarthric speech. He has recently had a series of falls due to increasing problems with balance.

   a. For each client, write a nursing diagnosis to reflect his or her sensory perception problem. Write one other nursing diagnosis that might result from the sensory perception problem. Explain your thinking.
   b. Each of the clients is experiencing a sensory deficit. What interventions would be most appropriate to address each client's concerns?

c. Which client(s) is/are most likely to have difficulty adapting to the sensory deficit? How would you determine how each client is adapting?
d. Which client, if any, is most likely to be experiencing sensory overload?

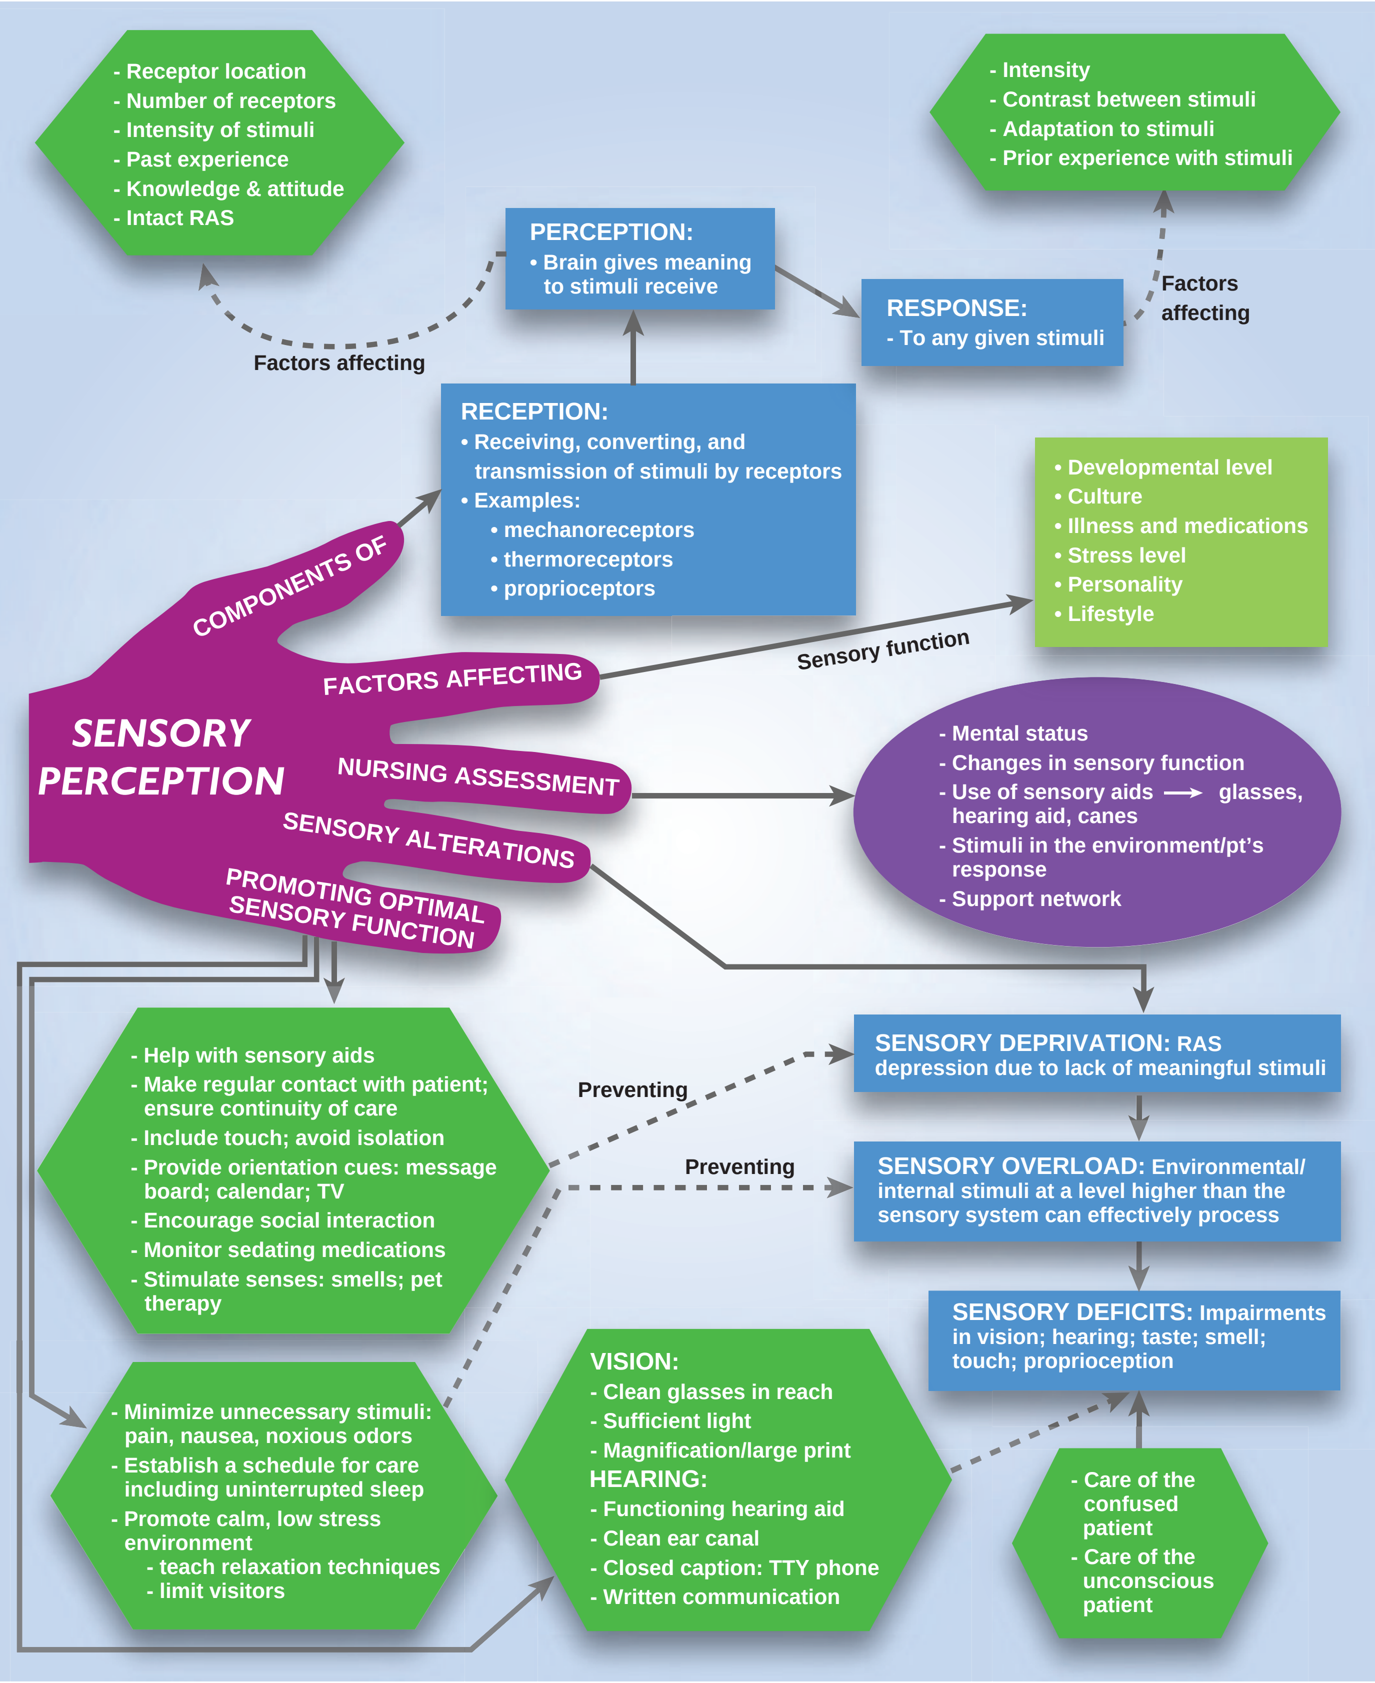
2. Examine the clinical unit that you are visiting for your current clinical rotation. What unit factors contribute to the development of sensory overload?
3. What factors in the clinical unit contribute to the development of sensory deprivation?
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or sensory perception. Note that these are *not* to be merely definitions.

Sensory stimulation
Sensory overload
Sensory deprivation
Sensory deficits
Sensory aids

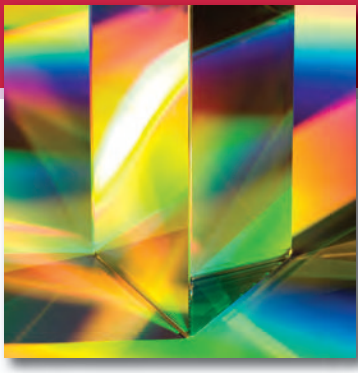
What Are the Main Points in This Chapter?

- The purpose of sensation is to allow the body to respond to changing situations and maintain homeostasis.
- A sensory experience involves four components: stimulus, reception, perception, and an arousal mechanism.
- Reception is the process of receiving stimuli from nerve endings in the skin and body.
- Perception is the ability to interpret the impulses transmitted from the receptors and give meaning to the stimuli.
- Humans respond to sensations when they are alert and receptive to stimulation. The response to a stimulus is based on intensity, contrast, adaptation, previous experience, illness, or injury.
- Sensory deprivation is caused by a deficiency of meaningful stimuli.
- Sensory deprivation can be due to environmental conditions or to interference with the reception or perception of stimuli.
- Sensory overload develops when either environmental or internal stimuli—or a combination of both—exceed a level that the client's sensory system can effectively process. It can also occur in clients with neurological or psychiatric disorders who are unable to adapt to continuing, nonmeaningful stimuli.
- Impaired vision and hearing are the sensory deficits most commonly encountered in nursing practice.
- The client with impaired vision, hearing, tactile sensation, olfactory sensation, or kinesthesia is at risk for injury.
- Visual and hearing changes may diminish the ability to communicate and may hamper social interaction.
- Developmental issues, culture, health status, medications, stress level, and individual preferences affect sensory perception.
- To assess sensory perceptual function, assess factors affecting sensory perception, mental status, recent changes in sensory stimulation, use of sensory aids, the client's environment, and the support network.
- Nursing strategies to address impaired sensory perception include activities to promote sensory function, prevent and treat sensory overload and deprivation, assist clients with sensory deficits, and communicate with clients with altered mental status.

Knowledge Map



CHAPTER 31



Pain

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 31:

- **Response Sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Pain (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 31, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Review the introduction to the Nguyens at the front of this volume. Nam Nguyen has bilateral knee pain secondary to osteoarthritis. To develop a pain management plan, what patient data do you need to know?

A. How will you get the data you need? What sources should you use?

B. What types of nursing knowledge (theoretical, practical, ethical, or self-knowledge) are needed to develop a pain management plan?

PracticalKnowledge knowing how

When caring for patients with pain, you will need to be skilled in medication administration, including use of patient-controlled analgesia (PCA) pumps and caring for patients who have an epidural catheter.

PROCEDURES

Procedure 31-1 ■ Setting Up and Managing Patient-Controlled Analgesia by Pump

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- PCA pump (infuser and central unit)
- Manufacturer's instructions for the pump
- Cartridge, syringe, or other type of sealed unit containing the medication
- Connecting tubing (to connect the PCA device to the patient's IV line)
- Maintenance IV supplies, as needed
- IV pole
- Antiseptic swab
- Flowsheet (electronic or paper)
- 1 pair of clean procedure gloves (if venipuncture is necessary)

Delegation

Because an opioid medication is delivered intravenously to the patient, this procedure is outside the scope of the practice of nursing assistive personnel (NAP) and should never be delegated. Furthermore, the NAP should not administer a dose for the patient, even if he asks her to do so. You can inform the NAP of expected side effects and ask her to report her observations to you.

Pre-Procedure Assessment

- Assess physical conditions that can affect respirations.
  Respiratory diseases (e.g., chronic obstructive pulmonary disease [COPD] and asthma) and conditions such as head injury and sleep apnea increase the risk for respiratory depression with opioid use.
- Assess level of consciousness and cognitive level.
  Determines whether the patient will be able to follow directions for self-dosing.
- Review lab values reflecting liver and kidney function, such as blood urea nitrogen (BUN), creatinine, and liver enzymes.
  Opioid analgesics are typically metabolized through the liver or kidneys.

(continued on next page)

Procedure 31-1 ■ Setting Up and Managing Patient-Controlled Analgesia by Pump (continued)

- **Assess the baseline respiratory rate, pulse, blood pressure, and oxygen saturation.**
  A change in vital signs (e.g., hypotension, respiratory rate below 8) may indicate adverse responses to opioid administration.
- Be aware of the patient's age and weight.
  Age is a factor when you are verifying the dose. Older patients and very young children are at increased risk for respiratory suppression, so may require lower doses.
- Assess the patient's baseline pain level using a standardized pain assessment tool or numeric scale ranging from 0 to 10.
  A quantified self-report is one of the most accurate measures of pain.
- Assess the patient's manual dexterity.
  Patients with impaired fine motor control or upper extremity injury may not be able to operate the self-dosing mechanism.
- Review medications currently in use.
  The risk of respiratory depression increases when a PCA pump is used in conjunction with other CNS depressants, such as diazepam (Valium).
- Assess the extent of family involvement. Identify any family anxiety over the patient's pain. Reinforce that only the patient should use the PCA button.
  Only the patient should administer the medication. "PCA by proxy" (someone other than the patient pushing the dosing button) is a major factor contributing to adverse patient outcomes (Wuhrman, Cooney, Dunwoody, et al., 2007).

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean procedure gloves,** and initiate IV therapy if the patient does not currently have an IV solution infusing. Refer to Procedure 38-1 as needed.
2. **Obtain the medication** and double-check it with the original prescription. You may need to remove air from the vial by pushing the injector into the vial. Connect the PCA tubing to the vial (or cartridge).
   Some vials may not be completely filled with medication. Ejecting the air makes it faster to prime the connecting tubing.
3. **Double-check your dose** calculation with another nurse before starting the infusion or wasting medication.
   To prevent medication errors in dosing.
   a. "On-demand" dose (the amount of drug to be delivered with each push of the button)
   b. The "lockout" interval (the number of minutes allowed between each administration of an on-demand dose [e.g., q10 min]). Even if the patient pushes the button more frequently, the PCA pump will not administer a dose until the preset time between doses has been met.
   c. Basal rate or continuous infusion (the amount of medication to be delivered automatically by the pump over 1 hour) should be used with caution. Giving the medication continuously without the patient having to push a button takes away some of the inherent safety of a PCA.
   d. One-time "bolus" (or *loading*) dose, which you administer after setting up the pump
   e. The 1-hour or 4-hour lockout interval (the maximum dose allowed in that time frame). For example, if the patient has a 4-mg on-demand dose with a 10-minute lockout interval, the patient can receive a maximum of six 4-mg doses per hour for a total of 24 mg/hr and a maximum dose of 96 mg in 4 hours.

   NOTE: PCA prescriptions are usually written in milligrams; however, pump settings may be in milliliters. In such cases, you must verify the concentration (milligrams per milliliter) to set the pump correctly.
4. **Prime the tubing; then clamp** the tubing above the connector.
   Priming prevents air from entering the pump and causing malfunction. Clamping prevents an accidental bolus of medication getting to the patient.
5. **Insert the cartridge or vial** into the pump, and lock the pump. Follow the manufacturer's instruction manual (e.g., some pumps can be set only if the door is closed and locked).
   Depending on the pump, it may be a syringe, a cartridge, or other sealed container that can be "locked" into the pump. Locking the pump prevents unauthorized access to the opioid and dosing features.
6. **Turn the pump on, and set** the parameters according to the prescriptions and your calculations. The settings may include:
   a. On demand
   b. Lockout interval
   c. Basal rate or continuous infusion—if applicable
   d. The 1-hour or 4-hour lockout dosage limit
   e. The one-time loading dose—if applicable
7. **Scrub the port on the IV** tubing closest to the patient, using alcohol or a chlorhexidine gluconate (CHG)–alcohol product; then connect the PCA pump tubing.
   Removes gross contamination and discourages growth of pathogens.
8. **Open the clamp and** administer the bolus (loading) dose if prescribed. Remain with the patient as the dose is delivered.
   A loading dose is usually larger than the basal and on-demand doses because

pain is likely to be more severe before the pump is initiated. Remaining with the patient allows you to observe for adverse effects.

9. **Close the pump door, and lock** the machine with the key.
10. **Check for flashing lights** or alarms that may indicate the need to correct settings.
11. **Be sure to release tubing clamps** if you previously clamped the tubing; press the start button to begin pump operation.
12. **Ensure that the battery life** is sufficient or, preferably, that the pump in plugged into an appropriate electrical outlet.
    To avoid battery failure.
13. **Place the control button** for on-demand doses within the patient's reach. Be sure the PCA cord is placed away from the call bell.
    To avoid error in self dosing with PCA. ➤

? What if . . .

- **The patient cannot verbally communicate pain status?**

  Use an alternate standardized pain tool, such as the FACES pain scale or a behavioral measure to determine pain level.

  Pain assessment in patients who are uncommunicative may include behavioral or physiological indicators to assess and monitor the effectiveness of pain medication.

- **The infusion infiltrates?**

  Discontinue the IV and establish another IV site. Follow facility policy for application of cold or warm compresses to the infiltrated area. Assess pain level. You may need to contact the prescriber for a bolus dose if the IV has been interrupted for an extended period or the patient has insufficient pain relief.

Evaluation

- Monitor the patient's pain level, sedation level, and respiratory rate at least every hour for the first 24 hours or according to facility policy after initiating PCA.
  Promotes the early detection of respiratory depression, oversedation, or inadequate pain control.
- Perform routine assessment of number and frequency of doses and pump settings per facility protocol.
- Check the IV site for redness, infiltration, or phlebitis.
- Check the IV tubing for patency (e.g., for kinks) to be sure the medication is infusing.

Patient Teaching

Patients who are candidates for use of PCA should be trained before surgery rather than in the immediate postoperative period, when the effects of anesthesia impair learning. Reinforce or teach the patient and family the following:

- Safe and correct use of the PCA pump
- The benefits of PCA for controlling pain
- The pump will deliver only the amount of medication prescribed. Pushing the button too many times will not result in overdosing.
- The patient cannot accidentally roll over on the button and unintentionally give additional medication.
- If pain is not being relieved, the patient should tell the nurse so adjustments can be made to the PCA.
- The pump will alarm when nearly empty, alerting nurses to change the syringe.
- The PCA button is to relieve pain—not to help the patient sleep.
- Signs and symptoms of allergic reaction and which ones to report
- How to rate pain using a standard pain scale
- The patient is the only one who may push the pain-dosing button. Explain why family members should not give "doses by proxy."

Documentation

You will usually document PCA initiation on a specialized checklist or flowsheet. Items charted include:

- Time the infusion was begun, including the drug, the patient demand dose, the loading dose, the basal dose if applicable, lockout interval, and hourly limit

(continued on next page)

Procedure 31-1 ■ Setting Up and Managing Patient-Controlled Analgesia by Pump (continued)

- Patient's baseline pain level and evaluation of subsequent pain level performed at intervals determined by facility policy
- Baseline respiratory rate, pulse, blood pressure, and oxygen saturation; routine evaluation of subsequent vital signs performed at intervals determined by facility policy
- Sedation level
- Continuous monitoring of vital signs, level of consciousness, and pain status, as well as the number and frequency of doses
- Unusual occurrences (e.g., oversedation, IV infiltration) in the nursing notes

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Practice Resources

Best practices: Evidence-based nursing procedures (2008); Cohen, M. R., Weber, R. J., & Moss, J. (2006); d'Arcy, (2008a); Post-operative pain management. (2010).

CLINICAL INSIGHTS

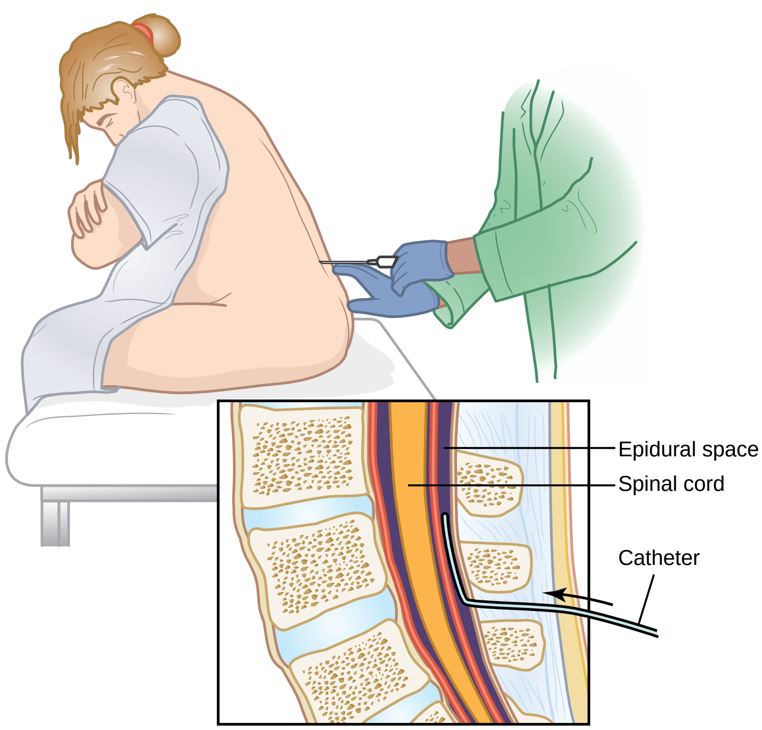
Clinical Insight 31-1 ➤ Caring for the Patient With an Epidural Catheter

Nursing care of the patient with epidural analgesia focuses on safely administering analgesia, assessing pain while achieving maximum pain control, and preventing or identifying adverse reactions (Sawheney, 2012).

Epidural analgesia is contraindicated in patients who received anticoagulant therapy or other bleeding problems, infection at the insertion site or in the bloodstream, or increased intracranial pressure. Additionally, the patient with an allergy to local anesthetic or opioid must not receive this type of pain control. An epidural approach is typically not suited for those who have spinal defects, previous spinal surgery, or certain neurological conditions (e.g., multiple sclerosis) because any new or changed clinical symptoms may be difficult to distinguish.

Monitoring

- Closely monitor the patient's vital signs, especially for respiratory depression and hypotension (every hour for the first 24 hours, then every 4 hours if the patient is stable).



Clinical Insight 31-1 ➤ Caring for the Patient With an Epidural Catheter—cont'd

- Assess the degree of pain intensity using a pain rating scale (per institution's protocol) and degree of motor and sensory block.
- Monitor the site for leaking or drainage.
- Check connections for leaks. This can be fixed by carefully retightening connections. If the filter is cracked, replace with a new one using sterile technique.
- Assess for urine retention. Keep careful intake and output (I&O) records.
  Urinary retention is one side effect of epidural opioids.
- Observe for signs of headache in the patient as a result of dural puncture. Treatment consists of bedrest, analgesics, and liberal hydration. Caffeine is also helpful and may be administered IV. If unresolved after 72 hours, patient might receive an epidural blood patch.
- Observe for signs of catheter migration: nausea, a decrease in blood pressure, and a loss of motor function without a recognizable cause.
- Be alert to signs of local anesthesia toxicity occurring when anesthesia is injected directly into the bloodstream instead of the epidural space. The patient might report numbness or tingling around the mouth or ringing in the ears (tinnitus); or the nurse may assess irritability, tremors, seizures, or cardiac arrhythmias (Portenoy & McCaffery, 2011; Sawheney, 2012).

Prevention

- Clearly label solutions with "For epidural use only" using large font. Store IV and epidural medication in separate locations.
  Prevents errors in medication administration.
- Mark all lines *clearly*: Most epidural tubing is marked with a yellow stripe.
  Epidural lines must not be confused with IV solution for an arterial or venous catheter.
- Ensure the tape on the tubing connected to the patient is secure.
  To prevent catheter migration.
- Use strict aseptic technique when changing tubing, including mask and sterile gloves for access and maintenance procedures.

Discontinuing the Catheter

- If you are specially trained to remove an epidural catheter, first loosen the tape securing the catheter. While wearing clean gloves, apply slow, steady pressure to withdraw the catheter. Inspect the catheter on removal. You must be able to see the tip of the catheter. If not, a portion of the catheter may still be lodged in the patient's epidural space. Notify the anesthesia team immediately of this finding.
- If the catheter cannot be withdrawn with minimal force, try repositioning the patient to the same position for removal as the patient was in during insertion of the catheter.
- Cleanse the insertion site, and cover with a dry sterile dressing.

Clinical Insight 31-2 ➤ Guidelines for Assessing Pain

Assessing for Nonverbal Signs of Pain

When assessing for nonverbal signs of pain, keep the following guidelines in mind:

- **Facial expression, posture, and body position are reliable indicators of the intensity of pain.** Basic and common facial expressions that signal pain are lowering the brow, wincing, clenching jaws, and closing eyelids (Institute for Clinical Systems Improvement, 2005, updated 2011). Guarding a painful site or maintaining a tense position is also a sign of pain.
- **Changes in vital signs generally last only a short time.** The body seeks equilibrium; thus, after an hour or so, the vital signs typically return to baseline even though the patient may still be in pain. Continuous, severe pain may elevate the vital signs again from time to time, but they rarely remain elevated.
- **Key Point:** ***Normal vital signs do not mean that the patient is free of pain.***
- **Patients may be in pain even if they don't "act like" they are.** Unfortunately it has been well documented that healthcare professionals fail to assess pain and tend to underrate the pain the patient is experiencing (McCaffery & Pasero, 1999; McCaffery, Pasero, & Ferrell, 2007). They expect to see frowning, crying, or scowling. Patients who use laughter, distraction, or even sleep to cope with their pain are often undertreated.
  Key Point: ***To assess pain accurately, you must ask your patients and then believe them.***

Assessing Verbal Expressions of Pain

- **Assess for stoicism.** Some patients feel that they are being "bad" or "weak" if they express pain. Such patients

(Continued)

Clinical Insight 31-2 ➤ Guidelines for Assessing Pain—cont'd

may withdraw or become stoic. It is important that you establish a trusting relationship with them. Convey your concern, and acknowledge the person's pain. If the patient trusts you, she will feel free to verbalize thoughts and feelings.

- **Remember to assess for depression** (see Chapter 13 if you need to review). Approximately one-third to one-half of patients receiving treatment for pain also have depression (Hooten, Timming, Belgrade, et al., updated 2013). If depression is not treated aggressively, efforts to manage the pain may not be successful. Avoid the misconception, however, that pain is the cause of the depression and that controlling the pain will eliminate the depression. This is rarely the case.

Using Pain Scales

- **Use an interpreter if the patient speaks a different language.** Ask the interpreter to explain to the patient that it is important to manage pain and that you will be using a pain scale regularly to assess his pain. Have the interpreter translate and write out the explanation and directions for the pain scale so you can refer to these when you assess your patient. With written directions, patients can point to a face or numeric line to tell you about their pain when no one is present to translate.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Pain Assessment

Taking a Pain History

Taking a pain history is the most effective way to perform an assessment. Each agency has a different assessment form for this history, but the questions typically will include the following:

Do you have pain now?

When did the pain begin?

Where is the pain located?

How do you rate your pain? (Use a pain scale.)

How would you describe your pain? Sharp? Dull? Achy? Burning?

How often do you have pain? Is it constant or intermittent?

Is there a rhythm or pattern to your pain? Is there anything you do that triggers the pain?

What makes the pain better? What makes it worse?

How many days this past week has pain interfered in your ability to do what you would like to do?

Does pain interfere with your ability to take care of yourself?

Does pain wake you up at night?

Does pain interrupt your concentration and reduce your ability to think clearly?

Does pain prevent you from participating in pleasurable activities, hobbies, and socializing with friends?

Have you experienced this type of pain in the past?

Do you have any other symptoms (such as nausea and vomiting) when you are experiencing pain?

Have you used any medications to treat the pain? If so, were they effective? How often do you need to take pain relievers?

What, if any, alternative treatments have you used for pain?

What past experiences or cultural factors, if any, influence the pain?

Observing for Nonverbal Indicators of Pain

Physiological (Involuntary) Responses

Sympathetic Responses (Acute Pain)

Increased systolic blood pressure

Increased heart rate and force of contraction

Increased respiratory rate

Increased alertness (resulting from dilated blood vessels to the brain)

Dilated pupils

Rapid speech

Parasympathetic Responses (Deep or Prolonged Pain)

Decreased systolic blood pressure, possible syncope

Decreased pulse rate

Changeable breathing patterns

Withdrawal

Constricted pupils

Slow, monotonous speech

Behavioral Responses (Voluntary)

Withdrawing from painful stimuli

Moaning

Facial grimacing

Crying

Agitation

Guarding the painful area

Focused Assessment

Psychological (Affective) Responses

Anxiety

Depression

Anger

Fear

Exhaustion

Hopelessness

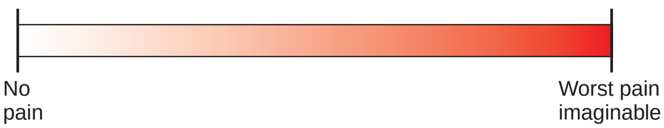
Irritability

Using Pain Scales

The most commonly used pain scales are the Visual Analog Scale (VAS), the Numerical Rating Scale (NRS), the Simple Descriptor Scale (SDS), and the Wong-Baker FACES rating scale.

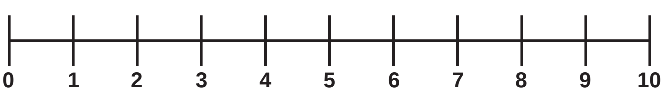
The Visual Analog Scale

The Visual Analog Scale (VAS) is a 10-cm horizontal line in which "No pain" is written on the left side and "Worst pain imaginable" is written on the right. Patients point to a location on the line that reflects their current pain. Although this rating system is simple and quick, some patients have problems with the abstract nature of the scale.



The Numerical Rating Scale

The Numerical Rating Scale (NRS) is a line numbered from 0 to 10. Zero indicates no pain at all, whereas a 10 indicates the worst possible pain. Patients choose a number from 0 to 10 to denote their level of pain. To use this scale, the patient must be able to count to 10. A scale of 0 to 5 may be more helpful for cognitively impaired patients.



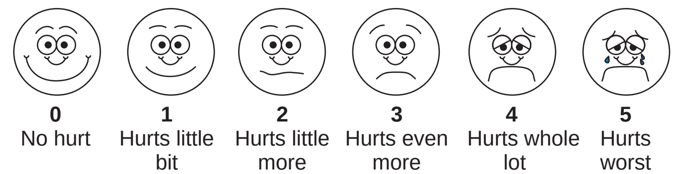
The Simple Descriptor Scale

The Simple Descriptor Scale (SDS) is a list of adjectives that describe different levels of pain intensity. The simplest version of this scale uses the words *mild, moderate,* and *severe*. An SDS with many words is not recommended; it is time consuming to describe and may not be understood by many patients.

The Wong-Baker FACES Pain Rating Scale

The FACES Scale uses simple illustrations of faces to depict various levels of pain. It requires no numerical or reading skill. Initially developed for use with children older than the age of 3, the scale has proved to be extremely useful for adults with communication and cognitive impairments as well.

Wong-Baker FACES Pain Rating Scale



Explain to the person that each face is for a person who feels happy because he has no pain (hurt) or sad because he has some or a lot of pain. Face 0 is very happy because he doesn't hurt at all. Face 2 hurts a little more. Face 3 hurts even more. Face 4 hurts a whole lot. Face 5 hurts as much as you can imagine, although you do not have to be crying to feel this bad. Ask the person to chose the face that best describes how he is feeling. Rating scale is recommended for persons age 3 and older.

From Hockenberry M. J., & Wilson D. (2009). *Wong's essentials of pediatric nursing* (8th ed.). St. Louis, MO: Mosby. Used with permission. Copyright Mosby.

Revised Faces Pain Scales

We commonly ask patients to rate their pain on a scale of 0 to 10. However, the Wong-Baker FACES Scale uses a 0 to 5 scale. To see a revised FACES scale adapted to a 10-point scoring system, see Spragud, L. J., Piira, T., & Baeyer, C. L. (2003). Children's self-report of pain intensity, *American Journal of Nursing, 103*(12), 62–64; or

Go to the **Pediatric Pain Sourcebook** on the International Association for the Study of Pain Web site at http://www.iasp-pain.org/Content/NavigationMenu/GeneralResourceLinks/FacesPainScaleRevised/default.htm

Focused Assessment

Richmond Agitation-Sedation Rating Scale

Sedation Rating Scale

Richmond agitation–sedation scale

Score	Term	Description
+4	Combative	Overtly combative or violent; immediate danger to staff
+3	Very agitated	Pulls on or removes tube(s) or catheter(s) or has aggressive behavior toward staff
+2	Agitated	Frequent nonpurposeful movement or patient–ventilator dyssynchrony
+1	Restless	Anxious or apprehensive but movements not aggressive or vigorous
0	Alert and calm	
-1	Drowsy	Not fully alert, but has sustained (more than 10 seconds) awakening, with eye contact, to voice
-2	Light sedation	Briefly (less than 10 seconds) awakens with eye contact to voice
-3	Moderate sedation	Any movement (but no eye contact) to voice
-4	Deep sedation	No response to voice, but any movement to physical stimulation
-5	Unarousable	No response to voice or physical stimulation

Sessler, C. N., Gosnell, M.S., Grap, M. J., et al. (2002). The Richmond Agitation–Sedation Scale: Validity and reliability in adult intensive care unit patients. *American Journal of Respiratory Critical Care Medicine, 166,* 1338–1344, Retrieved on March 24, 2012, from http://ajrccm.atsjournals.org/content/166/10/1338.full.pdf+html

CLINICAL REASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Dieter Schmidt is a 48-year-old with a 2-year history of cervical spine injury that began after a motor vehicle accident. Three years before the accident, Dieter fell through a roof to the cement basement when inspecting a building under construction. Presenting symptoms were neck pain when turning his head, biceps weakness, and pain down the arm with tingling into the fingertips. He is unable to sit for extended periods or walk distances. Initially he received treatment with medication, TENS to the site, physical therapy, and cervical fusion. Despite trying all treatments available to him, including surgery, Dieter continues to suffer chronic pain and fatigue. After prolonged suffering with no relief, Mr. Schmidt develops a cynical attitude toward healthcare. He begins missing more and more scheduled appointments for physical therapy. He describes stress he feels from the economic downturn impacting his land development business and fears bankruptcy. As a result, he has given up previous hobbies and most social activities. His relationships with his family and friends are increasingly strained as the pain persists over time.

THINKING

1. *Theoretical Knowledge:*
   What is the mechanism that explains how pain is transmitted in the spine?
2. *Critical Thinking (Considering Alternatives, Deciding What to Do):*
   a. When planning care for Dieter, what approach would you take in helping him to set goals for his rehabilitation?
   b. Why do you think Dieter displays a negative attitude and reduced compliance toward rehabilitative therapies?

DOING

3. *Practical Knowledge:*
   a. (*Nursing Process*: *Assessment)*: What questions would you ask Dieter to assess the impact of pain on his daily living and quality of life?
   b. *(Nursing Process*: *Interventions):* In addition to drug therapy, what other measures might you teach your patient to do to control his pain and increase his comfort?

CARING

4. *Self-Knowledge:*
   Have you ever experienced chronic pain, such as back pain, fibromyalgia, arthritis, migraines, sports injuries, or other types? If so, how has it affected your daily life? Has your pain impacted your relationships? Has it interfered with your job or recreational activities? In what other ways would you say chronic pain has reduced the quality of your life?

Critical Thinking and Clinical Reasoning

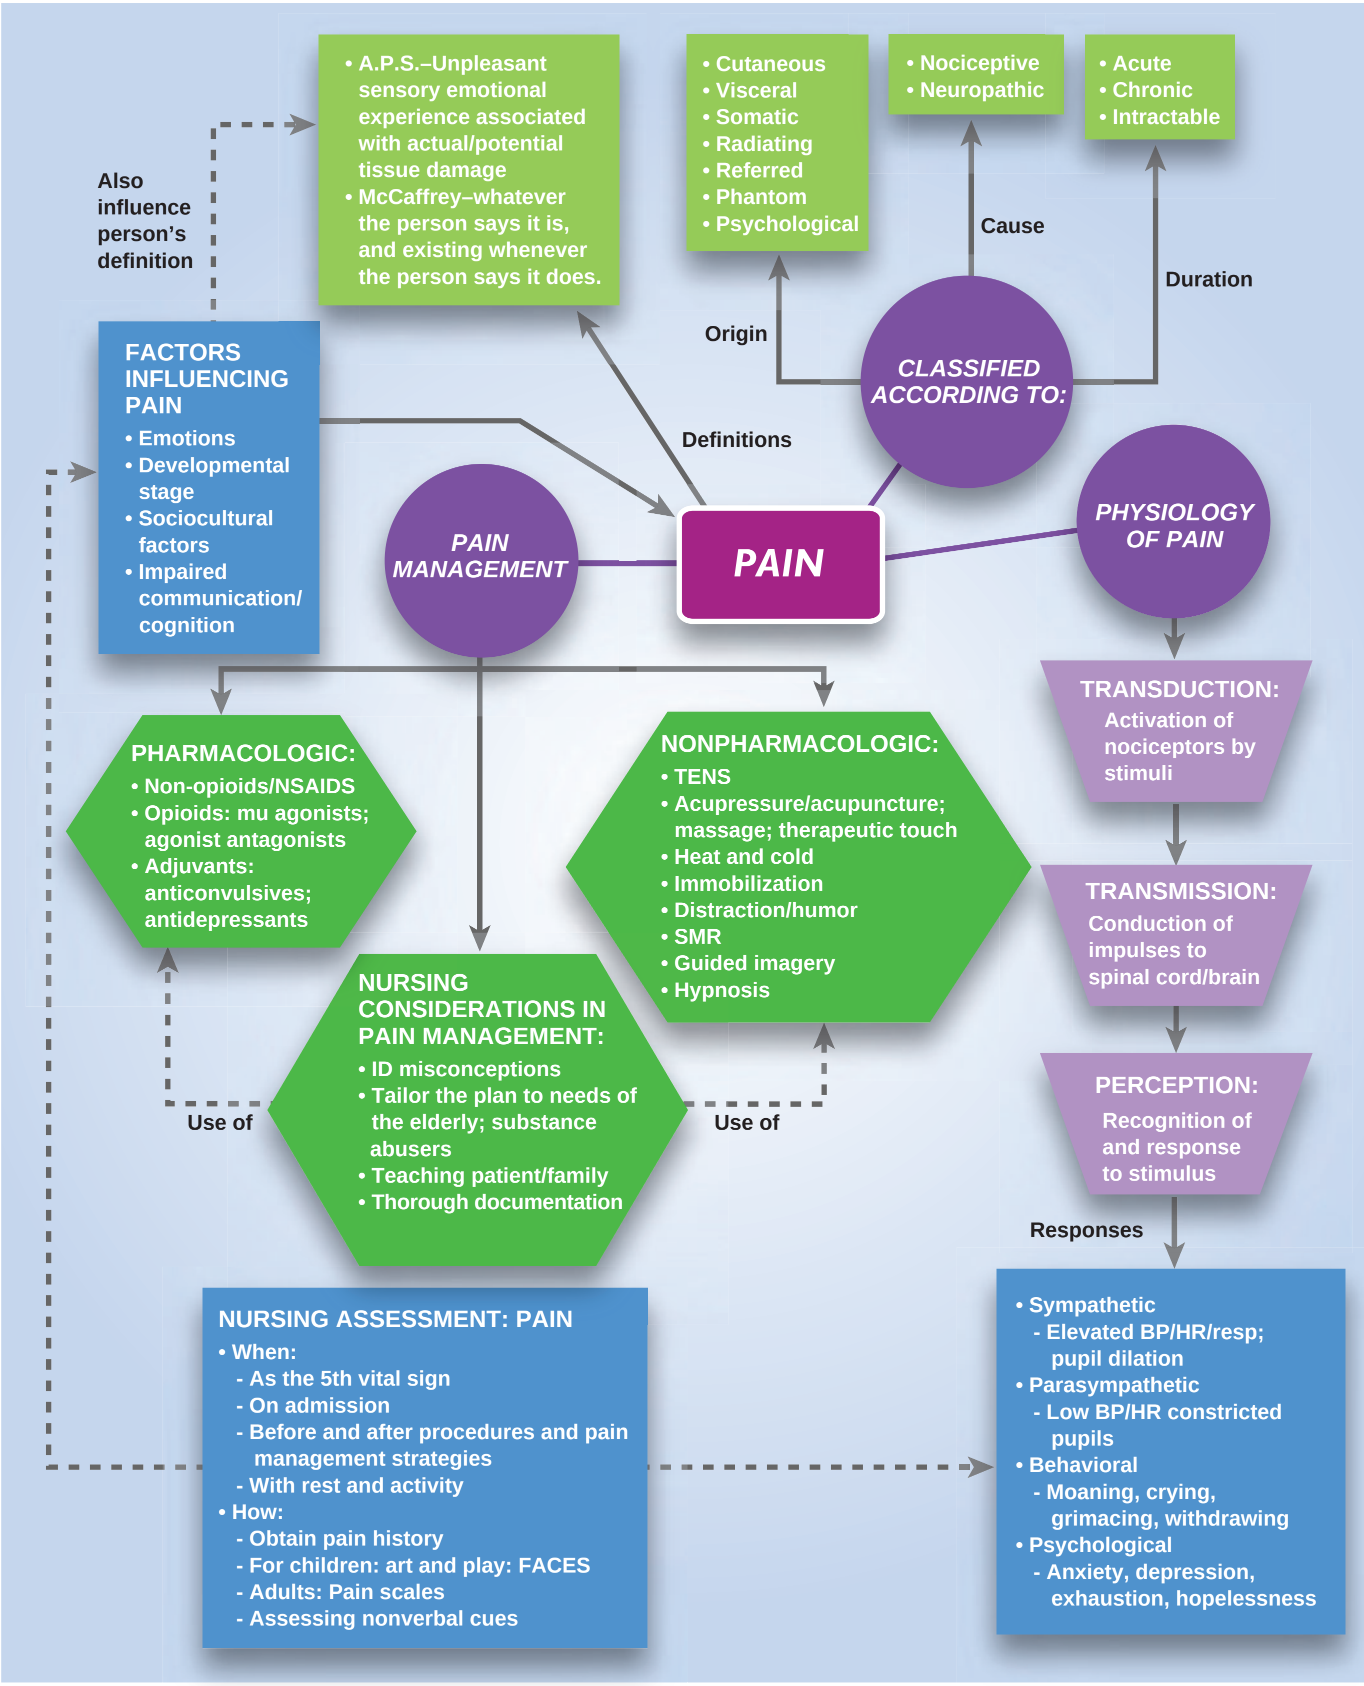
1. Mrs. J is a 29-year-old woman with terminal metastatic breast cancer. She knows she is dying. She has a devoted husband and two children, ages 2 and 4. Her husband has been taking care of her at home, but she is currently hospitalized for intractable pain. She does not want to be heavily sedated because she wants to spend as much time with her family as she can. She has no pain management plan.
   a. What is it about the patient's situation that may intensify her pain?
   b. Would you suggest using alternative therapies? Why or why not?
2. Mr. L is a 39-year-old construction worker who fell from a roof at a construction site 8 months ago and is still having back pain from the accident. To manage pain, he is prescribed an oral opioid every 4 hours on a prn basis. He is still out of work and has great difficulty walking, so he spends most of the day in a recliner watching TV and drinking beer. Mr. L also sleeps most nights in the recliner. He states that the alcohol is the only thing that helps his pain. How would you alter his pain management plan to get better relief? What is your rationale for these changes?
3. How might you encourage a facility to enact a pain assessment strategy of pain as the fifth vital sign if this is not their current policy?

4. If you were delegating vital signs to nursing assistive personnel (NAP), what instructions would you give?
5. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or pain management. Note that these are *not* to be merely definitions.
   - Nociceptive pain
   - Neuropathic pain
   - Unrelieved pain
   - Fear of addiction
   - Nonpharmacological pain management
   - Nonopioid pain medications
   - Opioid pain medications
   - Adjuvant therapies
   - Pain as the fifth vital sign
   - Pain scales
   - Pain flowsheets

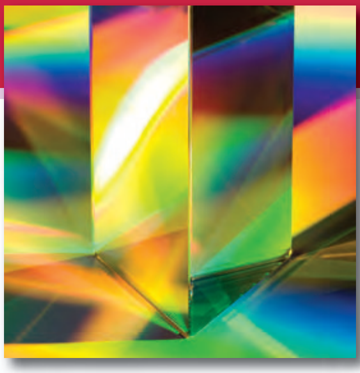
What Are the Main Points in This Chapter?

- Pain is whatever the person says it is and exists whenever the person says it does.
- Pain has a protective function, warning us of potential or actual tissue damage and prompting us to take action.
- Pain can be classified by its origin, cause, duration, and quality.
- Pain begins when mechanical, thermal, or chemical stimuli activate nociceptors, which send pain impulses to the spinal cord.
- Fast pain impulses are carried on large-diameter A-delta fibers, whereas slow pain impulses are carried on thinner C fibers.
- Perception of pain occurs in the frontal cortex of the brain.
- Pain can be modulated by the endogenous analgesic system or by the gate control mechanism.
- Some of the factors that influence pain are emotional factors, life span variations, past pain experiences, sociocultural factors, inability to communicate, and cognitive impairment.
- Serious physiological as well as psychological problems can result from unrelieved pain.
- Nonpharmacological pain relief measures include cutaneous stimulation, immobilization, and cognitive–behavioral intervention.
- Pharmacological measures include nonopioid analgesics, opioid analgesics, and adjuvant analgesics.
- Local and regional anesthesia, nerve blocks, and ablation therapy can relieve short- and long-term pain.
- Surgical interruption of pain conduction pathways is an option for intractable pain. Options depend on the type and location of pain.
- Opioid addiction among individuals being treated for pain is rare.
- Pain should be considered the fifth vital sign and assessed when the patient is admitted to a healthcare facility, with each vital signs check, before and after an intervention, and when the patient reports pain.
- The patient's self-report is the most reliable indicator of pain, especially for those suffering chronic pain.
- Misconceptions about pain can interfere in pain management.
- Older adults are at risk for undertreatment of pain.
- Planning for the patient's pain management program includes discovering the patient's own goals, educating the patient and family, and developing a nursing plan of care.
- It is important to assess continually the effectiveness of pain management strategies.

Knowledge Map



CHAPTER 32



Physical Activity & Mobility

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 32:
- **Response Sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Physical Activity & Mobility**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

To practice documentation for a patient experiencing mobility problems activity and exercise,

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 32, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

As you may recall, Nam Nguyen has been advised to diet and exercise as part of the treatment plan for hypertension, type 2 diabetes mellitus, obesity, and osteoarthritis. Zach Jackson's exam has revealed no other cardiovascular problems.

A. Design a fitness program for Nam. Describe the program in detail. Recall that Nam has been relatively sedentary.

B. Compare the type of program you would recommend for Nam with the type of program appropriate for his grandson, Kim.

C. What type of fitness program would be most appropriate for Mai Nguyen, Nam's mother? What additional information do you need to know to answer this question?

PracticalKnowledge knowing how

In the next sections you will learn about procedures and techniques for positioning, moving, turning, transferring, and ambulating patients safely. Although the American Nurses Association (ANA, 2013) recommends that you use assistive equipment for all patient lifting and transferring, you may encounter situations in which equipment is not available or you do not have time to get it (e.g., in an emergency). In such situations, using good body mechanics may help you decrease the risk of injury to you and the patient.

PROCEDURES

Procedure 32-1 ■ Moving and Turning Patients in Bed

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonlatex gloves, if you may be exposed to body fluids
- Friction-reducing device, such as a transfer roller sheet or scoot sheet
- Pull or lift (draw) sheet
- Pillows, as needed

Delegation

You may ask nursing assistive personnel (NAP) to assist with moving a patient up in bed, turning a patient, or logrolling a patient after ensuring that the NAP has the necessary skills and that the patient's condition is stable. Complete the assessment, and inform the NAP of any special considerations when moving the patient.

(continued on next page)

Procedure 32-1 ■ Moving and Turning Patients in Bed (continued)

Pre-Procedure Assessment

Assess the following:

- Level of comfort
  If the patient is uncomfortable, you may need to administer an analgesic before moving.
- Level of consciousness, ability to follow directions, and ability to assist with the move
- Any restrictions in movement or position (ask the patient and check the provider's orders
- Physical size of the patient and the assistive devices available
- The patient's medical diagnoses. Identify problems that may affect positioning (e.g., respiratory or cardiac problems, pain).
- Presence of equipment such as IV setups, pumps, or casts and know what must be moved with the patient
  The preceding assessments all help determine how many assistants and equipment you need, the patient's ability to assist in the procedure, and how to proceed with the move safely.

Procedure 32-1A ■ Moving a Patient Up in Bed

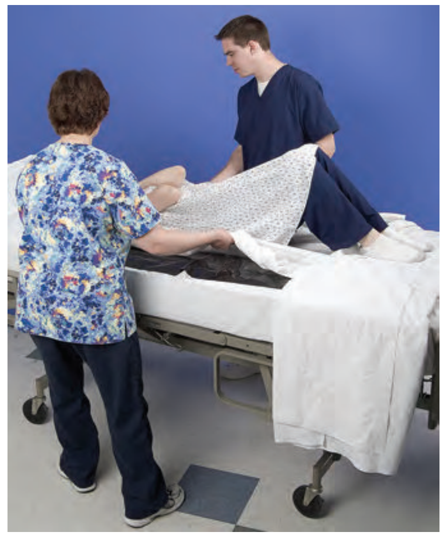
➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Key Point: ***Medicate the patient for pain, if needed, before moving the patient in bed.***

1. **Lock the bed wheels.** Lower the head of the bed, and place the patient in a supine position. Position one nurse on each side of the bed. Lower the siderails on the "working" side of the bed. Raise the height of the bed to waist level.
   Lowering the siderails and raising the bed allows you to move the patient while maintaining good body mechanics and working with gravity.
2. **Ensure that a friction-reducing** device, such as a transfer roller sheet, is in place under the drawsheet. If it is not in place, turn the patient from side to side to place the device under the drawsheet. You can improvise this device by placing a clean, unused plastic bag or plastic film under the drawsheet.
   A transfer roller sheet facilitates movement by reducing friction. This also helps to reduce back injury to the nurse.

   NOTE: This procedure uses a transfer roller sheet. This device is inexpensive and readily available. Scoot sheets further reduce the risk of back and musculoskeletal injury; however, their availability varies. Having a second person to help move a patient up in bed is the safest approach for staff and patients. Also follow the guidelines in Clinical Insight 32-1.
3. **Remove the pillow** from under the patient's head. Place it at the head of the bed.
   A pillow prevents patient from hitting his head on the head board.
4. **Instruct the patient to fold** his arms across his chest. If an overhead trapeze is in place, ask the patient to hold the trapeze with both hands if able. Have the patient bend his knees with feet flat on the bed.
   This position facilitates the patient's assistance with the move.
5. **Instruct the patient to flex** his neck.
   Protects the neck while moving.
6. **With a nurse positioned** on either side of the patient, grasp and roll the drawsheet close to the patient.
7. **Instruct the patient**, on the count of 3, to lift his trunk and push off with his heels toward the head of the bed.
8. **Position your feet with a wide** base of support. Point your feet toward the direction of the move. Flex your knees and hips.
   Allows you to maintain proper body mechanics and prevents injury while moving the patient. ➤



9. **Place your weight on your foot** nearest to the foot of the bed. Count to 3, and shift your weight forward toward the head of the bed.
   Shifting your weight allows you to use your momentum to move the patient, which helps protect your back from injury.
10. **Repeat until the patient** is positioned near the head of the bed. If you used a plastic bag or film to reduce friction, remove it now.
    Plastic is water impermeable, so it allows moisture to pool under the patient. This creates a risk for Impaired Skin Integrity.

11. **Straighten the drawsheet**, and tuck it in tightly at the sides of the bed.
A wrinkle-free sheet prevents uneven pressure, discomfort, and skin irritation.

12. **Place a pillow under** the patient's head, and assist him to a comfortable position.
Provides comfort and good body alignment.

13. **Place the bed in low position**, and raise the siderail.
Helps prevent falls.

14. **Place the call light** in a position where the patient can easily reach it.
Allows patient to call for help, if needed.

Procedure Variation for Use of an Approved Mechanical Lifting Device

15. **Lock the bed wheels.** Lower the head of the bed, and place the patient in a supine position. Position at least one nurse on each side of the bed. Lower the siderails. Raise the height of the bed.

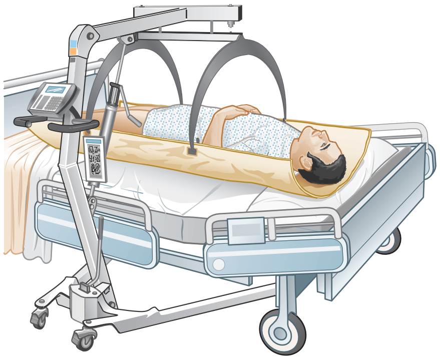
16. **Using the drawsheet, turn** the patient to one side of the bed. Position the midline of the full body sling at the patient's back. Tightly roll the remaining half of the sling, and tuck the fabric under the drawsheet.

17. **With a second nurse positioned** on either side of the patient, use the drawsheet to turn the patient to the opposite side of the bed. Unroll the full body sling, and reposition the patient supine.

18. **Attach the sling** to the overbed lifting device or mechanical lift.

Be sure the fasteners are securely attached to the lifting device.

19. **Engage the lift** to raise the patient completely off the bed. Advance the lift toward the head of the bed until the patient is at the desired level.



20. **Lower the lift**, and turn the patient to the desired position. You may leave the sling in place for future movement, or you may remove it by turning the patient from side to side.

NOTE: If a full body sling is not available, use a friction-reducing device, such as a transfer roller sheet, and at least three staff members.

Procedure 32-1B ■ Turning a Patient in Bed

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

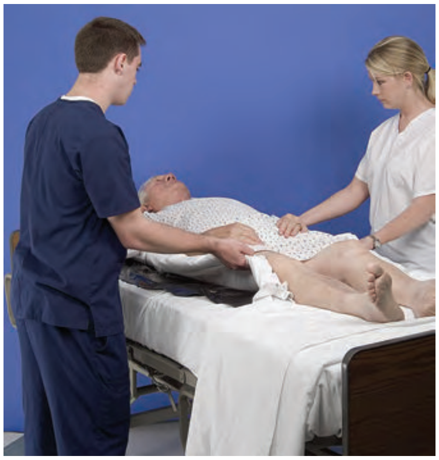
➤ *Note:* This procedure describes the use of a transfer roller sheet. This device is inexpensive and readily available.

Procedure Steps

1. **Lock the bed wheels.** Lower the head of the bed, and place the patient in a supine position. Position one nurse on each side of the bed. Lower the siderail on the side you are standing, but keep the opposite rail in the up position . Raise the height of the bed to waist level.
Lowering the siderails and raising the bed allow you to move the patient while maintaining good body mechanics and working with gravity to prevent injury.

2. **Position the patient for turning.**
   a. Remove the pillow from under the patient's head and place it at the head of the bed.
   b. Roll the patient side to side and place a friction-reducing device under the drawsheet. Smooth any wrinkles as needed. Tuck the friction-reducing device snuggly under the mattress. You can improvise this device by placing a large, clean plastic bag or plastic film under the drawsheet.
   c. Move the patient to the side of the bed you are turning him away from by rolling up the drawsheet close to the patient's body and pulling it.
   d. Align the patient's legs and head with the trunk.

   This allows you to position the patient in the center of the bed after turning.



3. **Place the patient's near leg** and foot across the far leg (e.g., when turning the patient to his right, place his left leg over his right leg).

4. **Place the patient's near arm** (e.g., left when turning right) across his chest. And, position the patient's underneath arm up and away from his body.
Positioning the patient's legs and his near arm facilitates turning. Abducting and rotating the other arm prevents it from being caught under the patient during the turn.

5. **Each nurse positions her feet** with a wide base of support with one foot forward of the other. Bend from the hips, and grasp both ends of the drawsheet at the level of the patient's hip and the other at the level of the shoulder.
A wide base of support allows you to maintain good body mechanics while performing the move.

(continued on next page)

Procedure 32-1 ■ Moving and Turning Patients in Bed (continued)

6. **Instruct the patient** that the turn will occur on the count of 3.
Counting coordinates and facilitates patient cooperation with the move.

7. **On the count of 3, flex** your knees and hips and shift your weight. The nurse positioned on the side toward which the patient will turn shifts his weight to the back foot. The nurse on the opposite side shifts her weight forward.
Provides the best leverage to turn the patient.

8. **If a plastic film is used**, remove it after you turn the patient.

9. **Position the dependent shoulder** forward. Place pillows behind the patient's back and between legs to maintain the patient in the lateral position. Replace the pillow under the patient's head.
Positioning ensures that patient is not putting excess pressure on the inferior shoulder. Pillows help maintain good body alignment.

Go to Chapter 32, **Table 32-2: Positioning a Bed-Bound Patient,** in Volume 1.

10. **Place the bed in low position**, and raise the siderail.
Helps ensure patient safety.

11. **Place the call light** in a position where the patient can easily reach it.
Allows patient to call for help, if needed.

Procedure 32-1C ■ Logrolling a Patient

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Lock the bed wheels.** Lower the head of the bed with the patient supine. Lower the siderail on the side where you are standing, but keep the opposite rail in the up position. Raise the height of the bed to waist level.
Lowering the siderail and raising the bed allows you to move the patient while maintaining good body mechanics and working with gravity to prevent back injury.

2. **You should already have** a drawsheet with an underlying friction-reducing device, such as a transfer roller sheet, to move the patient to the side of the bed on which you are standing. (You can improvise this device by placing a clean, unused plastic bag or plastic film under the drawsheet.)

3. **Position one staff member** at the patient's head and shoulders; she is responsible for moving the head and neck as a unit. Position the other person at the patient's hips. If you need three staff members, position one at the shoulders, one at the waist, and the third at thigh level. One staff member must maintain the patient's head and neck in alignment. The other members assist with moving the rest of the body in alignment.

4. **Each nurse should position her** feet with a wide base of support with one foot slightly more forward than the other.
Facilitates proper body mechanics and minimizes risk of injury to staff members.

5. **Use the drawsheet** or transfer sheet to move the patient to the side of the bed on which the nurses are standing. The move must be smooth so that the patient's head and hips are kept in alignment. Position the patient's head with a pillow.
A transfer sheet maintains straight alignment of the spine.

6. **Instruct the patient to fold** his arms across his chest.

7. **Place a pillow** between the patient's knees.
A pillow prevents internal rotation of the hip and spine with movement. Maintains straight alignment of the spine.

8. **Raise the siderail**, and move to opposite side of the bed.
Siderails keep the patient from falling out of bed.

9. **Lower the siderail** on the "new" side of the bed, and face the patient. All nurses should position their feet with a wide base of support, with one foot forward of the other. Place your weight on the forward foot. Bend from the hips, and position your hands evenly along the length of the drawsheet.
Provides the best leverage to turn the patient while maintaining spine alignment.

10. **All nurses flex their knees** and hips and shift their weight to the back foot on the count of 3. Be sure to support the head as the patient is rolled to his side.
Allows you to maintain straight alignment and body mechanics while performing the move.

11. **Place pillows to maintain** the patient in the lateral position.

Go to Chapter 32, **Table 32-2: Positioning a Bed-Bound Patient,** in Volume 1.

A pillow provides support and maintains proper alignment.

12. **Place the bed in low position**, and raise the siderail.

13. **Place the call light** in a position where the patient can easily reach it.
Allows patient to call for help, if needed.

What if . . .

- **Your facility has instituted a no-lift policy and you have to pull the patient up in bed?**
Use assistive equipment, such as friction-reducing devices, mechanical lifts, air-powered mattresses, and/or lateral transfer devices to help prevent work-related injuries.

- **Your patient is obese or unable to assist (totally dependent) and you need to lift him?**
Minimize manual lifting in all cases and eliminate it where feasible. Therefore, follow facility recommendations/protocols and use approved devices. You should be familiar with the lift devices in your facility.

- **The patient has had a total hip replacement and you have to turn or logroll your patient?**
Maintain the affected leg in abduction, by using a pillow or abduction wedge between the legs.
To ensure the hip will not become dislocated during turning.

- **The patient has a cast or is in traction and you have to turn or logroll your patient?**
Designate a person to assist in the turning by guiding the affected extremity.

- **The patient has an external fixation device and you have to turn or logroll your patient?**
Secure the device in place to keep it from moving when lifting or moving the limb as needed.
By holding onto the device to secure it and keep it from moving, there is less movement of the healing bone, and therefore less trauma and pain.

Evaluation

- Assess the patient's comfort level after the position change.
- Assess body position and alignment after position change.
- Assess skin for pressure areas.

Patient Teaching

- Explain to the patient the importance of maintaining spine alignment.
- Explain to the patient the importance of frequent position changes.
- Instruct the patient to ask the nurse when she needs to be turned sooner than scheduled.
- Teach the patient how she can assist with moving and turning.

Home Care

- Instruct the family member or caregiver in the techniques for moving, turning, or logrolling the client.
- Discuss the shearing effects on the skin from sliding down in bed (see Chapter 35).
- Provide instruction on importance of changing position and maintaining proper body alignment.

Documentation

Repositioning and turning patients are considered routine aspects of care and are not usually charted every time they are done. However, document in the nursing notes any problems with positioning the patient or any areas of skin breakdown. You might also chart turning as an intervention when charting to a specific problem. For example, if the patient has Impaired Skin Integrity, you might describe the skin and chart, "Position changed hourly." Some facilities have flowsheets on which you indicate by a checkmark each time a patient is repositioned.

Practice Resources

Centers for Disease Control and Prevention (CDC) (n.d., updated 2012). Collins, J. W., Nelson, A., & Sublet, V. (2006); Nelson, A., & Baptiste, A. S. (2004); Waters, T. R., Nelson, A. N., Hughes, N., et al (2009).

(continued on next page)

Procedure 32-1 ■ Moving and Turning Patients in Bed (continued)

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Moving a Patient Up in Bed, Moving a Patient Up in Bed Using a Mechanical Lifting Device, Turning a Patient in Bed,** and **Logrolling a Patient.**

For questions and suggested responses,

Go to Chapter 32, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 32-2 ■ Transferring Patients

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonlatex gloves, if you may be exposed to body fluids
- Transfer board (for transferring from bed to stretcher, and sometimes bed to chair)
- Pull or lift (draw) sheet (for transfers)
- Gait transfer belt (for dangling and transferring from bed to chair)

Delegation

You may ask NAP to dangle, transfer a patient from bed to stretcher, or transfer a patient from bed to chair. Ensure that the NAP has the necessary skills and that the patient's condition is stable. Inform the NAP of any special considerations when dangling or transferring the patient and evaluate the patient after transfer.

Pre-Procedure Assessment

- Assess for any restrictions in movement or position by asking the patient and checking the physician's orders.
- Observe for the presence of equipment such as IV lines, drains, or catheters.
- Assess possible side effects of medications (e.g., dizziness and sedation). Assess the patient's level of consciousness, ability to follow directions, and ability to assist with the move.
- Assess the physical size of the patient and your own strength and ability to move the patient.
- Before transferring a patient to a chair, assess the patient's tolerance of dangling.
  The preceding assessments inform you about activity tolerance, readiness to get out of bed, and ability to participate in the transfer. They help you determine how many assistants you need, the appropriate transfer device, and how to proceed with the move while preventing injury and dislodging of equipment.
- Assess vital signs, and monitor for postural hypotension (light-headedness when sitting or standing up quickly from a recumbent position).
  If the patient is at risk for postural hypotension, you may need to allow additional time for the patient to change position.
- Assess the patient's level of comfort using a standardized pain scale.
  If the patient is experiencing pain, you may need to administer an analgesic before moving.

Procedure 32-2A ■ Transferring a Patient From Bed to Stretcher

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Lock the wheels on the bed.** Position the bed so that it is flat (if the patient can tolerate being supine) and at the height of the stretcher.
   Locking the wheels ensures client safety during the transfer. Having the bed flat helps prevent injury to staff, because the patient is easier to move.
2. **Lower the siderails**, and position at least one nurse on each side of the bed. Move the patient to the side of the bed where the stretcher will be placed by rolling up the drawsheet close to the patient's body and pulling it toward the designated side. Align the patient's legs and head with her trunk.
   Positions patient to enable nurses to move her to the stretcher.
3. **Position the stretcher** next to the bed. Lock the stretcher wheels.
   Locking the wheels keeps the stretcher from moving during the transfer; prevents falls.
4. **Place the transfer board** against the patient's back.
   a. Place a friction-reducing device, such as a transfer roller sheet, over the transfer board. (You can improvise this device by placing a clean, unused plastic bag or plastic film under the drawsheet.)
   b. The nurse on the side opposite the stretcher uses the drawsheet to turn the patient away from the stretcher, while the other nurse places the transfer board against the patient's back halfway between bed and stretcher. Turn the

patient to her back and onto the transfer board.
Safely positions the transfer board under the patient, without friction.

5. **Ensure the patient's feet** and shoulder are over the edge of the transfer board.
To prevent injury to the patient from the edge of the board.

6. **Ask the patient raise her head** if able. Use the drawsheet to slide her across the transfer board onto the stretcher.
Facilitates the move to the stretcher; prevents friction on patient's skin.

If Transferring a Patient From Bed to Stretcher With a Slipsheet

A slipsheet may be used instead of a transfer board. A slipsheet is a large, low-friction fabric that facilitates transfer.

7. **Use the drawsheet to turn** the patient away from the bed; remove the board and roller sheet.

8. **Reposition the patient** on the stretcher for comfort and alignment.
Provides support and maintains proper alignment.

9. **Provide a blanket**, if needed for warmth or privacy.

10. **Fasten safety belts**, and raise the siderails on the stretcher.
Prevents falls.

11. **Lock the bed wheels. Position the bed** so that it is flat (if the patient can tolerate being supine) and at the height of the stretcher.
Ensures patient safety during the transfer. Helps prevent injury to staff because the patient is easier to move if the bed is flat.

12. **With the drawsheet, turn** the patient to the side opposite where the stretcher will be placed. Position the midline of the slipsheet under the patient. Roll the remaining half tightly, and tuck it under the patient.

13. **Turn the patient back over to the** side near to the stretcher; and pull the slipsheet through from under the patient.

14. **Place the patient supine**, and lower the siderail on the side where the stretcher will be placed.

15. **Move the stretcher** next to the bed and lock the wheels on the stretcher.

16. **Position at least two nurses** on the far side of the stretcher. Using the slipsheet, pull the patient onto the stretcher.

17. **Be sure to return the stretcher** to the locked position with the siderails raised for patient safety.

18. **Place the call light in reach** of the patient or position the patient where she can be seen by staff members at all times.

Procedure 32-2B ■ Dangling a Patient at the Side of the Bed

When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Lock the bed wheels.** Place the patient in a supine position, and raise the head of the bed to 90°. Keep the siderail elevated on the side opposite where you are standing.
Locking the wheels prevents the bed from moving as you move the patient. Raising the head of the bed prepares the patient to be dangled and requires less effort from you to help the patient sit erect.

2. **Apply a gait transfer belt** to the patient at waist level. Be sure the belt is snug but not uncomfortable. Place the bed in the low position.
Ensures patient safety and proper body mechanics.

3. **Instruct the patient to bend** his knees and turn the patient onto his side, if possible, keeping knees flexed.
Prepares the patient to be able to dangle his legs over side of bed.

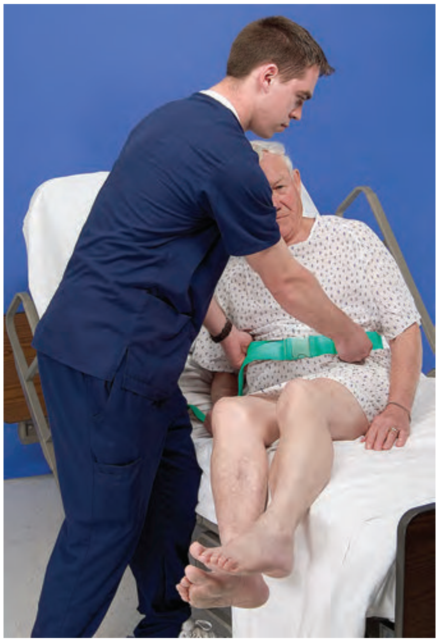
4. **Stand at the side of the bed**, facing the patient and using a wide base of support. Place your foot closest to the head of the bed forward of the other foot. Lean forward, bending

(continued on next page)

Procedure 32-2 ■ Transferring Patients (continued)

at the hips, with your knees flexed. Instruct the patient to use his arm to push off the bed.
Allows you to maintain proper body mechanics and prevents injury.

5. **Position your hands** on each side of the gait transfer belt.
6. **Rock onto your back foot** as you assist the patient toward you with the gait transfer belt, thereby moving the patient into a sitting position at the side of the bed.
Uses your body weight as leverage to reposition the patient, preventing injury to your back.



7. **Stay with the patient** as he dangles. Reassess comfort level and for dizziness.
Helps prevent falls.

Procedure 32-2C ■ Transferring a Patient From Bed to Chair

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Position the chair** next to the bed. If possible, lock the chair.
Prevents the chair from moving during transfer. Ensures patient safety.
2. **Put nonskid footwear** on the patient.
Prevents the patient from slipping during transfer.
3. **Place the bed in a low position**, and lock the bed wheels.
Prevents the bed from moving during the transfer. Low position allows patient to place feet firmly on the floor.
4. **Apply a transfer belt.**
Facilitates transfer of the patient to the chair and helps prevent back injury to the nurse.
5. **Assist the patient to dangle** at the side of the bed (see Procedure 32-2B). Be sure the patient doesn't need support before releasing him.
6. **Stand toward the bed**, facing the patient. Brace your feet and knees against the patient's legs. Pay particular attention to any known weakness. Bend your hips and knees, and, keeping your back straight, hold onto the transfer belt on both sides. If two nurses are available to assist with the transfer, one nurse should be on each side of the patient.
Bracing provides stability. Bending the hips and knees allows you to use the major muscle groups and limit the risk of injury. Lifting the patient at waist level prevents injury to the arm or shoulder. ➤

7. **Instruct the patient** to place his arms around you between the shoulders and waist (the location depends on your height and the height of the patient).
Having the patient hold you on your trunk prevents injury to your neck.

8. **Ask the patient to stand** as you move to an upright position by straightening your legs and hips.
Straightening your thighs and hips uses your large muscle groups and prevents injury to your back.

9. **Allow the patient to steady** himself for a moment. Ask whether he is feeling light-headed.
Provides the patient an opportunity to rest before further movement. Allows you to evaluate his tolerance to activity and ability to maintain an upright posture before continuing.

10. **Instruct the patient to pivot** and turn with you toward the chair.
Pivoting helps prevent twisting and straining the patient's back muscles.

11. **Assist the patient to position** himself in front of the chair. Have the patient flex his hips and knees, and as he lowers himself to the chair, reach for arms of the chair. Guide his motion while maintaining a firm hold on him and keeping your back straight.
Maintains good body mechanics and balance and ensures patient safety.

12. **Assist the patient** to a comfortable position in the chair.

13. **Provide a blanket** if needed for warmth or privacy.

14. **Place the call light in reach** of the patient or position the patient where he can be seen by staff members at all times.

? What if . . .

- **The patient is obese?**

  If the patient is obese or unable to assist, use a full body sling that allows the patient to assume a seated position. You may also use a powered standing assist lift, if one is available.

- **The patient has had hip surgery (replacement or fracture repair).**

  When assisting the patient out of bed, raise the bed to a higher position, allowing the patient to exit the bed without acute hip flexion.
  To avoid hip dislocation.

- **The patient becomes dizzy during the transfer?**

  Return the patient to sitting or recumbent position and assess his vital signs.

- **The patient has a weaker side, for example, from a cerebrovascular accident (CVA) or surgical procedure?**

  Instruct the patient to exit the bed from his unaffected side. Stand on the patient's weaker side.
  The stronger side should lead a transfer.

Evaluation

- Assess the level of patient participation in the transfer.
- Assess the patient's comfort level during the transfer and in the new position.
- Assess proper body position and alignment after his position change.
- Assess the patient's vital signs for postural hypotension after dangling or transferring to a chair.

Patient Teaching

- Explain the importance of frequent position changes and getting out of bed to avoid complications of immobility.

Home Care

- Instruct the family member or caregiver in the proper technique for assisting the client to dangle at the bedside or transfer to a chair.
- Provide instruction in the importance of changing position and maintaining proper body alignment.

Documentation

Patients are usually moved to a stretcher for transport to a test or procedure. The movement is a routine aspect of care and is not documented. When dangling or transferring a patient to a chair, document in the nursing notes how much assistance was required, the use of assistive devices, any problems with positioning the patient, how long the patient was out of bed, and how the patient tolerated the activity.

Practice Resources

Collins, J. W., Nelson, A., & Sublet, V. (2006); Occupational Safety and Health Administration, U.S. Department of Labor. (2009); Waters, T. R., Nelson, A. N., Hughes, N., et al. (2009).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Transferring a Patient From Bed to Stretcher, Dangling a Patient at the Side of the Bed,** and **Transferring a Patient From Bed to Chair.**

For questions and suggested responses,

Go to Chapter 32, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 32-3 ■ Assisting With Ambulation

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonlatex gloves, if you may be exposed to body fluids
- Transfer belt
- Nonskid footwear

Delegation

You may ask nursing assistive personnel (NAP) to assist with ambulation. Ensure that the NAP has the necessary skills and that the patient's condition is stable. Inform the NAP of any special considerations when assisting a patient with ambulation and evaluate the patient after the activity.

Pre-Procedure Assessment

- Assess for any restrictions in movement or position by asking the patient and checking the physician's orders.
- Observe for the presence of equipment such as IV lines, drains, or catheters.
- Assess possible side effects of medications (e.g., dizziness and sedation).
- Assess the patient's level of consciousness, ability to follow directions, and ability to assist with the move.
- Assess the physical size of the patient and your own strength and ability to move the patient.
- Assess the patient's tolerance when dangling before beginning to ambulate.
  The preceding assessments inform you about activity tolerance, readiness to get out of bed, and ability to participate in the transfer. They help you determine how many assistants you need, the appropriate transfer device, and how to proceed with the move while preventing injury and dislodging of equipment.
- Assess vital signs, and monitor for postural hypotension.
  If the patient is at risk for postural hypotension, you may need to allow additional time for the patient to change position and plan for adequate help.
- Assess the patient's level of comfort using a standardized pain scale.
  If the patient is uncomfortable, you may need to administer an analgesic before moving.
- Assess for factors that may increase the risk of falls (elderly, muscle weakness, chronic disease, gait disturbance).
  Identifies patients at risk.

Procedure 32-3A ■ Assisting With Ambulation (One Nurse)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Put nonskid footwear** on the patient.
   Prevents the patient from slipping while transferring and ambulating.
2. **Apply the transfer belt.**
   Allows you to safely support the patient during the transfer and ambulation.
3. **Place the bed in a low position**, and lock the bed.
   Prevents the bed from moving during transfer. Makes it easier for the patient's feet to reach the floor.
4. **Assist the patient to dangle** at the side of the bed (see Procedure 32-2B, if you need to review).
5. **Face the patient.** Brace your feet and knees against the patient's feet and knees. Pay particular attention to any known weakness. Bend your hips and knees, and hold onto the transfer belt.
   Bracing provides stability of the patient's legs. Bending the hips and knees allows you to use the major muscle groups and limit injury. Lifting at the patient's waist level prevents injury to his arm or shoulder.
6. **Instruct the patient** to place his arms around you between the shoulders and waist (the location depends on your height and the height of the patient). Ask the patient to stand as you move to an upright position by straightening your legs and hips.
   Having the patient hold you on your trunk prevents injury to your neck. Straightening your thighs and hips uses your large muscle groups and promotes good body mechanics.
7. **Allow the patient to steady** himself for a moment.
   Allows the patient an opportunity to rest before further movement and to regain equilibrium before walking.
8. **Stand at the patient's side**, placing both hands on the transfer belt. If the patient is weak on one side, position yourself on the weaker side.
   By standing on the weaker side, the patient is freer to reach with the stronger arm and grip wall or bed rails with his strong-side hand, and use the stronger side for strength and balance. This position also keeps you clear of a cane or other assistive device, which would be used on the strong side, and allows you

to support the weaker side to prevent the patient from falling.

9. **Slowly guide the patient** forward. Observe for signs of fatigue or dizziness.
   Helps prevent falls.

10. **If the patient has an IV pole,** ask him to hold on to the pole on the side where you are standing. Assist the patient to advance the pole as you ambulate. Be sure the patient does not rely on the pole for support.
    Provides a grip for the patient and positions the IV pole near you so that you can assist the patient to move the pole.

Procedure 32-3B ■ Assisting With Ambulation (Two Nurses)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Put nonskid footwear** on the patient.
   Prevents the patient from slipping during the transfer and ambulation.

2. **Apply the transfer belt.**
   Allows you to support client during transfer and ambulation.

3. **Place the bed in low position,** and lock the bed.
   Prevents the bed from moving during transfer and prevents the patient from falling.

4. **Assist the patient to dangle** at the side of the bed (see Procedure 32-2B, as needed).

5. **Each nurse should stand facing** the patient on opposite sides of the patient. Brace your feet and knees against the patient, paying particular attention to any known weakness. Bend from the hips and knees and hold onto the transfer belt.
   Bracing provides stability. Bending the hips and knees allows you to use the major muscle groups and limit injury. Lifting at the patient's waist level prevents injury to his arm or shoulder.

6. **Instruct the patient to place** his arms around each of you between the shoulders and waist (the location depends on your height and the height of the patient). Ask the patient to stand as each of you move to an upright position by straightening your legs and hips.

7. **Allow the patient to steady** himself for a moment.
   Allows the patient an opportunity to rest before further movement and to regain equilibrium. Allows you to evaluate the patient's tolerance to activity and ability to maintain an upright posture before ambulating.

8. **Each nurse stands at** the patient's sides, grasping hold of the transfer

(continued on next page)

Procedure 32-3 ■ Assisting With Ambulation (continued)

belt. If no belt is available, the nurses grasp each other's arms at the patient's waist.
Helps patient maintain an erect posture.

9. **Slowly guide the patient forward.** Observe for signs of fatigue or dizziness.
Ensures client safety.

10. **If the patient has an IV pole,** one nurse advances the IV pole along the side of the patient by holding the pole with the outside hand.

Remind the patient not to use the IV pole for support.
Positions the IV pole out of the path of the patient. Because the IV pole is on rollers, it will not support the patient if he starts to fall.

What if . . .

- **The patient has a weaker side (e.g., from a stroke or musculoskeletal injury)?**

If the patient has weakness on one side, provide additional support but allow him to use that side as he is able.
This will force him to use his weaker side.

Evaluation

- Assess the level of patient participation in the transfer.
- Assess patient comfort with ambulation.
- Assess posture and base of support.
- Assess vital signs for postural hypotension.

Patient Teaching

- Instruct the patient to inform you if he feels dizzy or weak.
- Explain the importance of ambulation to prevent complications of immobility.

Home Care

- Teach family members or caregivers how to assist the client with ambulation.
- Provide instruction on importance of ambulation.

Documentation

Document in the nursing notes how much assistance was required, any problems with ambulation, and the distance walked.

Sample Documentation

11/11/15 0630 Pt assisted to ambulate to doorway in room. Required minimal assistance from one nurse. Placed in chair for 30 min and then assisted back to bed. Required maximum assist from two nurses to return to bed. ——— B. Bowen, RN

Go to Chapter 32, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

CLINICAL INSIGHTS

Clinical Insight 32-1 ➤ Applying Principles of Body Mechanics

Principles of body mechanics are the rules that enable you to move your body without causing injury. Use the following guidelines to decrease the risk of back and other injuries. Teach them to your patients as well.

The ANA states you should use mechanical equipment for lifting and transferring whenever possible and not rely on body mechanics alone to prevent injury.

Account for Patient Factors

- **Assess patient dependency levels** and select equipment after determining the patient's ability to assist in the transfer. You will also want to be aware of the patient's strength and ability to bear weight. Height and weight of the patient factor into how you transfer the patient safely.

Transferring Patients According to Dependency Level

PATIENT LEVEL OF DEPENDENCE	ASSISTIVE DEVICE
Complete dependence (immobile; no assistance)	Mechanical lift with full sling
Extensive dependence (holds on to device but with minimal strength)	Mechanical lift with full sling or stand/assist lift
Moderate dependence (no patient assist for lifting from floor)	Mechanical lift with full sling, or if transfer is manual, more than one helper might be needed
Patient assists with limited mobility	Transfer belt or gait belt
Limited dependence	Stand/assist lift or friction-reducing device

Source: Adapted from American Nurses Association (ANA). (2013). *Safe patient handling and mobility: Interprofessional national standards*. Silver Springs, MD: Author.

Make Use of Inanimate Objects and Get Help When Possible

- **Raise the height of the bed and over-the-bed table to waist level** when you are working with a patient.
- **Get help to move a heavy object** or patient. Assess the object or patient you are going to lift. If you have any doubt that you can do it by yourself, get help from a coworker.
- **Use assistive devices at all times** to limit the risk of back and musculoskeletal injury.
- **Maintain competency** in using all assistive and transfer devices.

Use Your Body Correctly

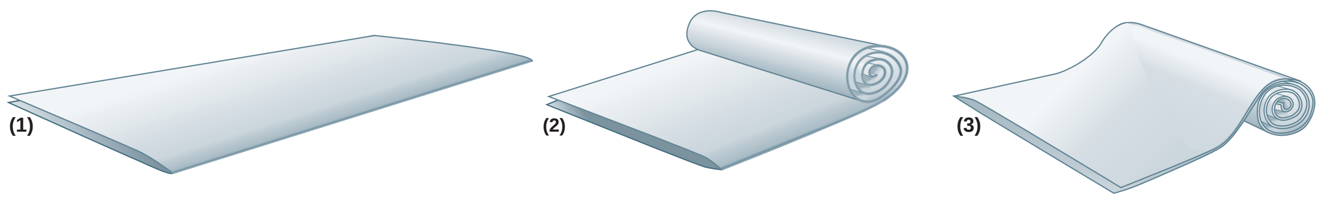
- **Use a wide base of support** (feet spread apart).
- **Minimize bending and twisting.** These movements increase the stress on the back. Instead, face the object or person, and bend at the hips or squat.
- **Squat to lift heavy objects** from the floor. (Squatting lowers your center of gravity.) Push against the strong hip and thigh muscles to raise yourself to a standing position. Avoid bending at the waist.
- **Use the muscles in your legs** as the power for lifting. Bend your knees, keep your back straight, and lift smoothly. Repeat the same movements for setting the object down.
- **Keep objects close to your body** when you lift, move, or carry them. The closer an object is to the center of gravity, the greater the stability and the less strain on the back.
- **Use both hands and arms** when you lift, move, or carry heavy objects.
- **Do not stand on tiptoes to reach** an object. If you must use a ladder or stepstool to reach for an object, make sure it is stable and adequate to position your body close to the object.
- **Push, slide, or pull heavy objects** whenever possible rather than lifting.
- **Maintain a good grip** on the patient or object you are moving before attempting to move it.
- **When possible, keep your elbows bent** when you carry an object.
- **Work with smooth and even movements.** Avoid sudden or jerky motions.

Clinical Insight 32-2 ➤ Using Common Positioning Devices

Applying a Trochanter Roll

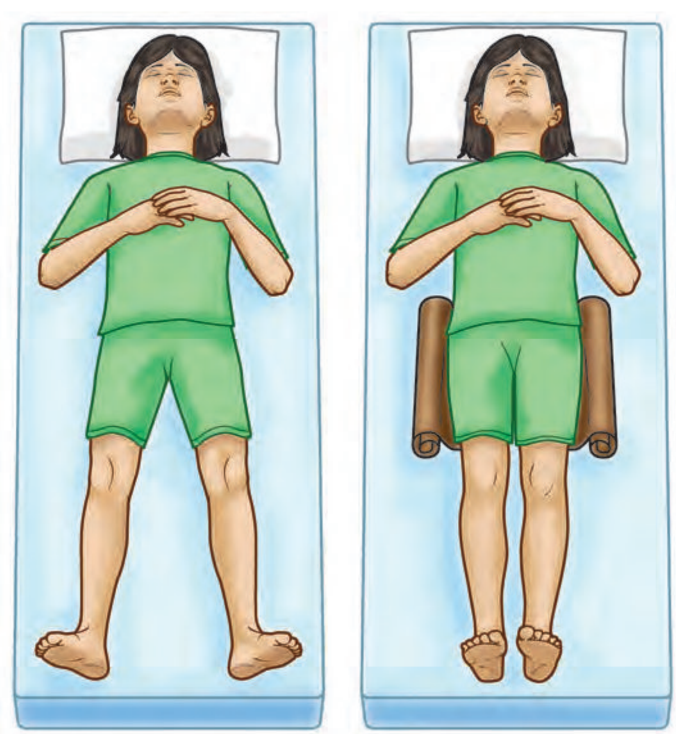
Trochanter rolls prevent external hip rotation when the patient is in a supine position.

- Fold a towel or bath blanket lengthwise.
- Roll the towel or bath blanket tightly.
- Invert the roll. Turning the patient to one side, place the bath blanket or towel under the patient's hip and thigh. Repeat on the other side if needed.
- Roll the sheet or towel under until it is snug against the patient's hip and thigh.
  The patient's weight should keep the roll from moving and help to prevent external (outward) rotation of the hips.
- Make sure the roll does not extend as far as the knee.
  To avoid nerve compression and palsy that can lead to footdrop.



Alternate Method

- Alternately, you can place the patient on a sheet that has been folded so that the top edge is at the top of the hips, and the lower edge is about one-third the way down the thighs. Then place the rolled towels under the sheet and roll the sheet under tightly.



External rotation can occur without a trochanter roll.

Proper alignment using a trochanter roll.

Clinical Insight 32-2 ➤ Using Common Positioning Devices—cont'd

Applying Hand Rolls

Hand rolls help prevent hand contractures.

- Place a rolled up washcloth or commercial hand roll in the patient's palm to maintain a neutral position.
- Secure the strap, if present.
- Roll soft gauze around the hand and secure with nonallergenic, adhesive tape to keep it from falling out of the patient's hand.
- Place another roll in the patient's other hand, if needed.

Applying Cradle Boots

Cradle boots prevent footdrop, hip rotation, and pressure on bony prominences, which lead to skin breakdown.

- Open the slit on the top surface of the boot.
- Place the patient's heel in the round cutout for the heel. If the patient is positioned on her side, you may put the boot on the bottom foot.
- Support the flexed top foot with a pillow.
- Apply the boot to the other foot, as needed.
- Position the patient's legs in neutral alignment with slight flexion.
  Neutral positioning prevents strain on hip ligaments.

Applying Hip Abduction Pillow

Hip abduction pillows prevent internal hip rotation and hip adduction when the patient is in a supine position.

- Place the wedge-shaped, spongy pillow between the patient's legs when she is lying on her back.
- Slide it toward the groin so it touches the legs all along the inside of the thigh.
- Place both upper legs in the pillow's lateral indentations.
- Secure the straps to prevent the pillow from slipping down the mattress.

Clinical Insight 32-3 ➤ Tips for Performing Passive Range-of-Motion Exercises

Passive range of motion (PROM) is the movement of the joints through their full range of motion by another person. Nurses frequently perform PROM to maintain joint mobility.

- **Explain the purpose of PROM.** You may also wish to teach family members and caregivers about the importance of ROM exercises and enlist their help in exercising the patient when they visit.
- **Observe the patient as you perform PROM.** You may need to perform the exercises in several short segments if the patient tires easily or experiences discomfort.
- **Support the patient's limb** above and below the joint that is to be exercised.
- **Move the joint in a slow, smooth, rhythmic manner.** Avoid fast movements; they may cause muscle spasm.
- **Never force a joint.** Some patients may have limited ROM. Move each joint to the point of resistance. This should not be painful.
- **Perform PROM** at least twice daily. Move each joint through ROM three to five times with each session. Consider incorporating PROM into care activities, for example, while bathing or turning the patient.
- **Return the joint to a neutral position** when exercise is complete.
- **Encourage active exercise** whenever possible.

Thinking About the Procedure

To practice applying critical reasoning to this clinical insight,

Go to *Davis's Nursing Skills Videos*, **Performing Passive Range-of-Motion Exercises.**

For questions and suggested responses,

Go to Chapter 32, Thinking About the Procedure Questions and Suggested Responses, on Davis*Plus*.

Clinical Insight 32-4 ➤ Assisting With Physical Conditioning Exercises to Prepare for Ambulation

Patients who have been confined to bed for more than a week or who have sustained major injury require conditioning before they are able to resume walking. Conditioning exercises include the following.

Quadriceps and Gluteal Drills

- Ask the patient to tighten her thigh muscles by pushing downward with her knees and flexing her feet. Each leg may be done separately if moving both is contraindicated.
- Ask the patient to hold the position for a count of 5 and then relax.
- Repeat this process two to three times per hour during the waking hours.
- To exercise the gluteal muscles, ask the patient to pinch her buttocks together.
- Do this exercise when the patient exercises her quadriceps muscles.
- Instruct the patient not to hold her breath as she exercises.

Arm Exercises

- Install a trapeze bar on the patient's bed. Ask the patient to do pull-ups on the bar from a lying position. This exercises the biceps muscles.
- To exercise the triceps muscles, ask the patient to lift his upper body off the mattress by firmly pressing down with the palms.
- The patient can also do push-ups from a seated position at the side of the bed or from a stationary chair or wheelchair.

Dangling

- Dangling is a seated position at the side of the bed, feet resting on the floor.
- Provide a footstool if the patient's feet do not reach the floor.
- Assess for light-headedness or postural hypotension.
- Do not progress to ambulation until the patient is comfortable and stable in the dangling position.

Daily Activities

- Encourage your patient to be active in bed by repositioning and turning herself.
- Encourage the patient to get out of bed and into a chair before attempting to walk.
- Encourage the patient to perform as much of her activities of daily living (ADLs) as possible.
- ADLs exercise many of the muscle groups used in ambulation.

To see a nurse performing passive range-of-motion exercises,

Go to *Davis's Nursing Skills Videos*, **Physical Conditioning Exercises: Quadriceps, Gluteal, Arm, and Dangling.**

Clinical Insight 32-5 ➤ Sizing Walking Aids

Sizing Canes

- Ask the patient to stand erect, and place the cane tip 20 cm (4 in.) to the side of the foot.
- The top of the cane should reach the top of the hip joint so that the patient can hold the cane with her elbow flexed 30°.

Sizing Walkers

- Ask the patient to stand erect, holding onto the walker.
- The walker should extend from the floor to the hip joint so that the patient can comfortably hold the walker with 30° flexion of the elbow.

Sizing Crutches

To measure a patient for an axillary crutch, follow these guidelines:

- Ask the patient to lie down wearing the nonskid shoes that she will use when walking.
- Measure the distance between the heel and the anterior fold of the axilla, then add 2.5 cm (1 in.).
- Select a crutch that can be adjusted to this height.
- Have the patient stand, and position the crutch tip 10 to 15 cm (4 to 6 in.) to the side of the heel. Adjust the axillary crutch pad three fingerbreadths below the axilla.
- Adjust the handgrips so that the patient can comfortably grasp the bar while the elbow is slightly flexed. The patient's axilla should not rest on the crutchpad.

Clinical Insight 32-6 ➤ Teaching Patients to Use Canes, Walkers, and Crutches

Canes

After ensuring the cane is the proper size (refer to Clinical Insight 32-5), instruct the patient to do the following:

- Hold the cane on the stronger side.
- Distribute weight evenly between the feet and cane.
- Advance the cane and weaker leg simultaneously, then bring the stronger leg through.
- Avoid leaning over or on the cane.
- Maintain the integrity of the rubber tip for traction.

Walkers

After ensuring the walker is the proper size (refer to Clinical Insight 32-5), instruct the patient to:

- Stand between the back legs of the walker. Do not stand too far behind the walker.
- Pick up the walker, and advance it as you step ahead. Do not advance it so far as to lose balance.
- If one leg is weaker, move it forward as the walker moves forward.
- Pick up, rather than slide, the walker (unless it has wheels).

Crutches

After ensuring the crutches are the proper size (refer to Clinical Insight 32-5), do the following:

- When first teaching crutch walking, instruct the patient to stand near a wall with a chair behind him. Help the patient to stand and grip the crutches. Ask the patient to sway from side to side on the crutches to become accustomed to weight bearing by the arms.
- *Tripod position* is the basic crutch gait standing position. Place crutches 15 cm (6 in.) in front of the feet, with the crutch point 15 cm from the patient's center. In this position, a triangle is formed by the crutches and the body.
- Five crutch gaits exist (see accompanying chart): 2-point gait, 3-point gait, 4-point gait, swing-to gait, and swing-through gait.

To teach the patient how to go up and down stairs, instruct him to lead with the unaffected leg when going up the stairs and to lead with the affected leg coming down the stairs.

(Continued)

Clinical Insight 32-6 ➤ Teaching Patients to Use Canes, Walkers, and Crutches—cont'd

Navigating stairs with crutches can be dangerous. When possible, have the patient practice this technique before discharge. When having a patient practice, the nurse should always stand below the patient on the stairs to prevent falling.

NOTE: Read this table from bottom to top.

2-Point gait	3-Point gait	4-Point gait	Swing to	Swing through
• Partial weight bearing, both feet; faster, but less support than a 4-point gait	• Non-weight bearing; faster than a 4-point gait; can use with walker	• Partial weight bearing, both feet; patient must shift weight constantly	• Weight bearing, both feet; can use with walker	• Weight bearing; requires the most coordination and balance
4. Advance right foot and left crutch 	**4.** Advance right foot 	**4.** Advance right foot 	**4.** Lift both feet; swing them forward, landing feet next to the crutches 	**4.** Lift both feet; swing them forward, landing feet in front of the crutches 3. Advance left foot and right crutch 	**3.** Advance left foot and both crutches 	**3.** Advance left crutch 	**3.** Advance both crutches 	**3.** Advance both crutches 2. Advance right foot and left crutch 	**2.** Advance right foot 	**2.** Advance left foot 	**2.** Lift both feet; swing them forward, landing feet next to the crutches 	**2.** Lift both feet; swing them forward, landing feet in front of the crutches 1. Advance left foot and right crutch 	**1.** Advance left foot and both crutches 	**1.** Advance right crutch 	**1.** Advance both crutches 	**1.** Advance both crutches Tripod position 	Tripod position 	Tripod position 	Tripod position 	Tripod position

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Assessing Activity and Exercise

Suggested History Questions

Usual Activity

Describe your typical daily activity level.

If the patient has very restricted activity, ask the following questions:

- Are you able to care for yourself in regard to hygiene, dressing, toileting, and getting out of bed?
- If the patient has ADL limitations: Who helps you with these daily activities?

If the patient does not indicate restricted activity, ask the following questions:

- What is your usual form of exercise?
- How often do you exercise?
- How long are your exercise sessions?
- How long have you been engaged in this type of activity?
- What types of exercise or sports have you participated in the past?
- Describe your activity level over the last 10 years.
- Are you exercising more or less than in the past?
- What factors have changed your activity level?

Fitness Goals

What aspects of exercise do you enjoy? What aspects of exercise do you dislike?

What do you think are the benefits of exercise?

How do you schedule your exercise?

What motivates you to exercise?

What are your current fitness goals?

Mobility Concerns

Do you have any pain or discomfort with activity?

Do you avoid any activities because of pain, discomfort, shortness of breath, or chest pain?

If the patient answered *yes* to either question, describe the following:

- Type of problem
- Onset of concern
- Frequency of problem
- Activities that trigger and relieve
- Severity and type of symptoms
- Effect of problem on day-to-day activities
- Treatments used to alleviate and how they worked

Underlying Health Concerns

Do you have any healthcare problem that affects your ability to engage in activity or exercise?

If so, describe the problem and the effect.

What medications do you take?

Have you ever been told you have a bone problem? If so, what was the nature of the problem?

Have you ever experienced a fracture, strain, or sprain? If so, where was the problem? When did it occur? How did it occur?

Have you ever had weakness of the muscles or problems coordinating movement?

Do you have any cardiac or respiratory problems that affect your ability to perform activities?

Have you ever experienced anxiety or depression that affected your ability to participate in activities?

Lifestyle

What kind of work do you do?

Describe your typical work activities.

How many hours per week do you work?

What other commitments do you have (school, family, other obligations)?

External Factors

Are there any restrictions in your home that limit your ability to be active?

Do you feel you need an assistive device?

Are you comfortable exercising outside your home or in your neighborhood?

Focused Physical Assessments for Activity and Body Alignment

With the patient standing, observe from the anterior, posterior, and lateral views. Check for the following:

Shoulders and hips are level.

Toes are pointed forward.

The spine is straight, with no abnormal curvatures noted.

The posture is not slumped.

Ask the patient to sit down; observe as he does so.

Does he have difficulty lowering his torso?

Can he control the movement?

Is he able to get into this position with ease?

When he sits, does he slump?

If the patient cannot stand or sit, assess his alignment in bed. Look for ability to move in bed, as well as the posture the patient maintains.

(Continued)

Focused Assessment

Assessing Activity and Exercise—cont'd

Joint Function

Assessing joint function includes inspection and palpation of the joints and assessment of range of motion.

Begin your assessment at the neck and systematically work your way through each of the joints.

At each joint observe for swelling, erythema, asymmetry, or obvious deformity.

Compare the size of the muscles above and below the joint and on each side of the body.

Palpate the joint for temperature and crepitus. Warmth over a joint indicates inflammation or infection. Be sure to compare body temperature over several joints and right to left. **Crepitus** is a grating sensation when the joint is moved. It can often be heard as well as felt. Crepitus is associated with degenerative joint disease or arthritic changes in the joint.

As you palpate the joint, move it through its range of motion.

Muscle Strength

Assess muscle strength by having the patient push and then pull against your hands.

Start at the neck, and test the strength of all major joints' range of motion.

To see a nurse using a performing passive range-of-motion exercises,

Go to *Davis's Nursing Skills Videos*, **Performing Passive Range-of-Motion Exercises.**

Gait

Gait is divided into two phases: stance and swing.

Stance-In the stance phase, the heel of one foot strikes the ground while the opposite foot pushes off and leaves the ground.

Swing—In the swing phase, the leg from behind moves in front of the body. When the right leg is in stance mode, the left leg is in swing mode.

You must observe the patient walking. Normal gait includes the following features:

- Head is erect, gaze forward.
- Heel strikes the ground before the toe.
- Opposite arm moves forward at the same time.
- Feet are dorsiflexed in the swing phase.
- Gait is coordinated and rhythmic.
- Weight is evenly distributed, with minimal swing from side to side.
- Movement starts and stops with ease.
- Movement is at a moderate pace.

If the patient uses an assistive device, such as a cane, crutch, or walker, pay attention to how he uses it. Ask the patient to ambulate a short distance with and without the device to determine if the device is actually providing stability.

Activity Tolerance

Assess and record vital signs before having the patient engage in 3 minutes of activity.

Select an activity appropriate for the patient. For example, if the patient uses a walker, ask the patient to walk down the hallway. For a patient without obvious health limitations, consider asking her to run in place for 3 minutes.

Observe the patient throughout the exercise. If she shows any signs of distress, stop the exercise, immediately take a set of vital signs, and repeat the vital signs every minute until they have returned to baseline.

If the patient can exercise continuously for 3 minutes, assess the patient at the end of the 3-minute period and at 1-minute intervals. Note the change in heart rate, blood pressure, and respiratory rate.

This type of approach is not appropriate for patients who easily become short of breath, develop chest pain, or are very unsteady on their feet. Instead, for example, limit your assessment to determining the amount of assistance the patient needs to turn in bed or get out of bed.

Muscle Mass and Strength

As you observe the patient, compare muscle mass on the right and left sides. If you notice an obvious discrepancy in size, measure the circumference of the limbs and compare.

To assess strength, ask the patient to push against your hand with the hands and feet. Once again, compare both sides.

For guidelines for assessing mobility in the home,

Go to Chapter 32, **Home Care: Home Assessment for a Patient With Mobility Concerns,** in Volume 1.

TABLES

Range of Motion at the Joints

JOINT	ILLUSTRATION
Neck (Pivot Joint) ***Flexion***—Move the head from upright midline position to the chin, resting the head on the chest. *Normal Range:* 45° from midline ***Extension***—Move the head from flexed to upright midline position. *Normal Range:* 45° from midline ***Hyperextension***—Move the head from upright midline position to as far back as possible. *Normal Range:* 10°	Lateral flexion—Tilt the head laterally from midline position toward the shoulder. *Normal Range:* 40° from midline	Rotation—Rotate the head in a circular motion from upright midline position to as far right or left as possible. *Normal Range:* 180°	Shoulder (Ball-and-Socket Joint) ***Flexion***—Raise the arm from a neutral position at the side to alongside the head. *Normal Range:* 180° ***Extension***—Move the arm from flexed to a neutral position at the side of the body. *Normal Range:* 180° ***Hyperextension***—Move the arm, keeping the elbow straight, from a neutral position at the side of the bed to behind the body. *Normal Range:* 45°–60°	Abduction—Raise the arm laterally from a neutral position at the side of the body to a position at the side of the head, palm facing outward. *Normal Range:* 180° ***Adduction***—Move the arm downward from a position beside the head to across the front of the body as far as possible. *Normal Range:* 230°–320°	
(Continued)

Range of Motion at the Joints—cont'd

JOINT	ILLUSTRATION
Circumduction—Circle the arm from the shoulder. *Normal Range:* 360°	External rotation—Keeping arm held out to the side at shoulder level and bent to a right angle, fingers pointing down, move the arm upward so that the fingers point upward and are above the shoulder. *Normal Range:* 90° ***Internal rotation***—Move the arm forward and down to return to the starting position, fingers pointing down. *Normal Range:* 90°	Elbow (Hinge Joint) ***Flexion***—Bend at the elbow to move the forearm from a straightened position up toward the shoulder. *Normal Range:* 150° ***Extension***—Straighten the arm by bringing the lower arm forward and down. *Normal Range:* 150°	Rotation (for supination)—With the arm at the side, elbow bent, move the hand and forearm so that the palm is facing upward. *Normal Range:* 70°–90° ***Rotation (for pronation)***—With the arm at the side, elbow bent, move the hand and forearm so that the palm is facing downward. *Normal Range:* 70°–90°	Wrist (Condyloid Joint) ***Flexion***—Bend the fingers of the hand toward the inner aspect of the forearm. *Normal Range:* 80°–90° ***Extension***—Straighten the wrist so that it is on the same plane as the forearm. *Normal Range:* 80°–90° ***Hyperextension***—Bend the wrist as far back as possible toward the outer aspect of the forearm. *Normal Range:* 70°–90°	Abduction (radial flexion)—With the hand supinated, bend each wrist laterally toward the thumb side. *Normal Range:* 0–20° ***Adduction (ulnar flexion)***—With the hand supinated, bend each wrist laterally toward the fifth finger side. *Normal Range:* 30°–50°	
Range of Motion at the Joints—cont'd

JOINT	ILLUSTRATION
Hands and Fingers (Condyloid Joints: Interphalangeal Joints Are Hinges) ***Flexion***—Bend the fingers into a fist. *Normal Range:* 90° ***Extension***—Straighten the fingers. *Normal Range:* 90° ***Hyperextension***—Bend the fingers back. *Normal Range:* 30°	Abduction—Spread the fingers apart. *Normal Range:* 20° ***Adduction***—Bring the fingers together. *Normal Range:* 20°	Thumb (Saddle Joint) ***Flexion***—Move the thumb across the palm of the hand toward the fifth finger. *Normal Range:* 90° ***Extension***—Move the thumb laterally away from the fingers. *Normal Range:* 90°	Opposition—Touch the thumb to the top of each finger of the same hand. *Normal Range:* NA	Hip (Ball-and-Socket Joint) ***Flexion***—Move the leg forward and up. *Normal Range:* Knee extended 90° ***Extension***—Move the leg back down beside the other. *Normal Range:* Knee flexed 120° ***Hyperextension***—Move the leg back behind the body. *Normal Range:* 30°–50°	 
(Continued)

Range of Motion at the Joints—cont'd

JOINT	ILLUSTRATION
Abduction—Move the leg laterally. *Normal Range:* 45°–50° ***Adduction***—Sweep the leg inward across the midline. *Normal Range:* 20°–30° beyond the other leg	Circumduction—Circle the leg, keeping the knee straight. *Normal Range:* 360°	Internal rotation—Turn the foot and leg inward toward the other leg. *Normal Range:* 90° ***External rotation***—Turn the foot and leg outward, pointing the toes as far as possible away from the other leg. *Normal Range:* 90°	Knee (Hinge Joint) ***Flexion***—Bend at the knee, bringing the heel back toward the buttocks. *Normal Range:* 120°–130° ***Extension***—Straighten the knee, returning the leg to its original position. *Normal Range:* 120°–130°	Ankle (Hinge Joint) ***Extension (plantar flexion)*—**Point the toes and foot downward. *Normal Range:* 45°–50° ***Flexion (dorsiflexion)*—**Pull the toes and foot upward. *Normal Range:* 20°	Foot (Gliding Joint) ***Eversion***—Turn the sole of the foot laterally. *Normal Range:* 5° ***Inversion***—Turn the sole of the foot medially. *Normal Range:* 5°	
Range of Motion at the Joints—cont'd

JOINT	ILLUSTRATION
Toes (Hinge Joint except intertarsal joints, which are Gliding Joints) ***Flexion***—Curl the toes downward. *Normal Range:* 35°–60° ***Extension***—Straighten the toes. *Normal Range:* 35°–60°	
Abduction—Spread the toes apart. *Normal Range:* 0–15° ***Adduction***—Bring the toes together. *Normal Range:* 0–15°	
Trunk ***Flexion***—At the waist, bend forward toward the toes. *Normal Range:* 70°–90° ***Extension***—Straighten the trunk from the flexed position. *Normal Range:* 70°–90° ***Hyperextension***—Bend the trunk backward. *Normal Range:* 20°–30°	Lateral flexion—Bend the trunk to the side. *Normal Range:* 20°–40°	Rotation—Turn the upper body from side to side (twist at the waist). *Normal Range:* 30°–45°	
CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Mr. Ronald Ornduff is a 72-year-old retired man who lives with his wife in a one-story home. He has excellent general health with no significant health problems. Ronald typically walks with a moderate to fairly vigorous pace in his neighborhood or at the mall in the winter. He belongs to a health club and works out two or three times a week, walking on the treadmill, using the weight machines, or taking a basic conditioning class. Mr. Ornduff considers himself fit and of an acceptable weight for his age. When going outdoors to pick up the morning paper, he slipped on a patch of ice and fell. You are now caring for him 2 days after hip surgery. He is experiencing pain and seems fearful his injury could be the beginning of a decline in his health.

THINKING

1. *Theoretical Knowledge:*
   a. Based on Mr. Ornduff's age, physical condition, and activity level, make a rough estimate of the number of minutes/week of physical activity he should have after he recovers from surgery and resumes full mobility. What are the benefits of this physical activity?
   b. As a nurse planning the care for a patient after hip surgery, what complications of immobility should you assess for?
2. *Critical Thinking (Considering Alternatives):* What are some possible barriers for an older adult's participating in physical activity? What might you teach your patient to do to overcome those barriers?

DOING

3. *Practical Knowledge:*
   a. How might you position your patient after hip surgery?
   b. What equipment would you need to position your patient after surgery? Is there anything you can set up that will help your patient move around in bed when he can tolerate it?
   c. What type of physical activity would you recommend Mr. Ornduff incorporate into his exercise plan after he experiences full recovery from his surgery? What benefit will these exercises provide?
4. *Nursing Process (Diagnosis):* Write at least two nursing diagnoses for Mr. Ornduff. Use just the data provided in the situation. Assume he is 2 days post-op.

CARING

5. *Self-Knowledge:* What would you be feeling if you were in Mr. Ornduff's situation of being physically fit one day and suffering pain and immobility the next?
6. *Ethical Knowledge:* What are one or two things you would do to help Mr. Ornduff feel cared for and cared about?

Critical Thinking and Clinical Reasoning

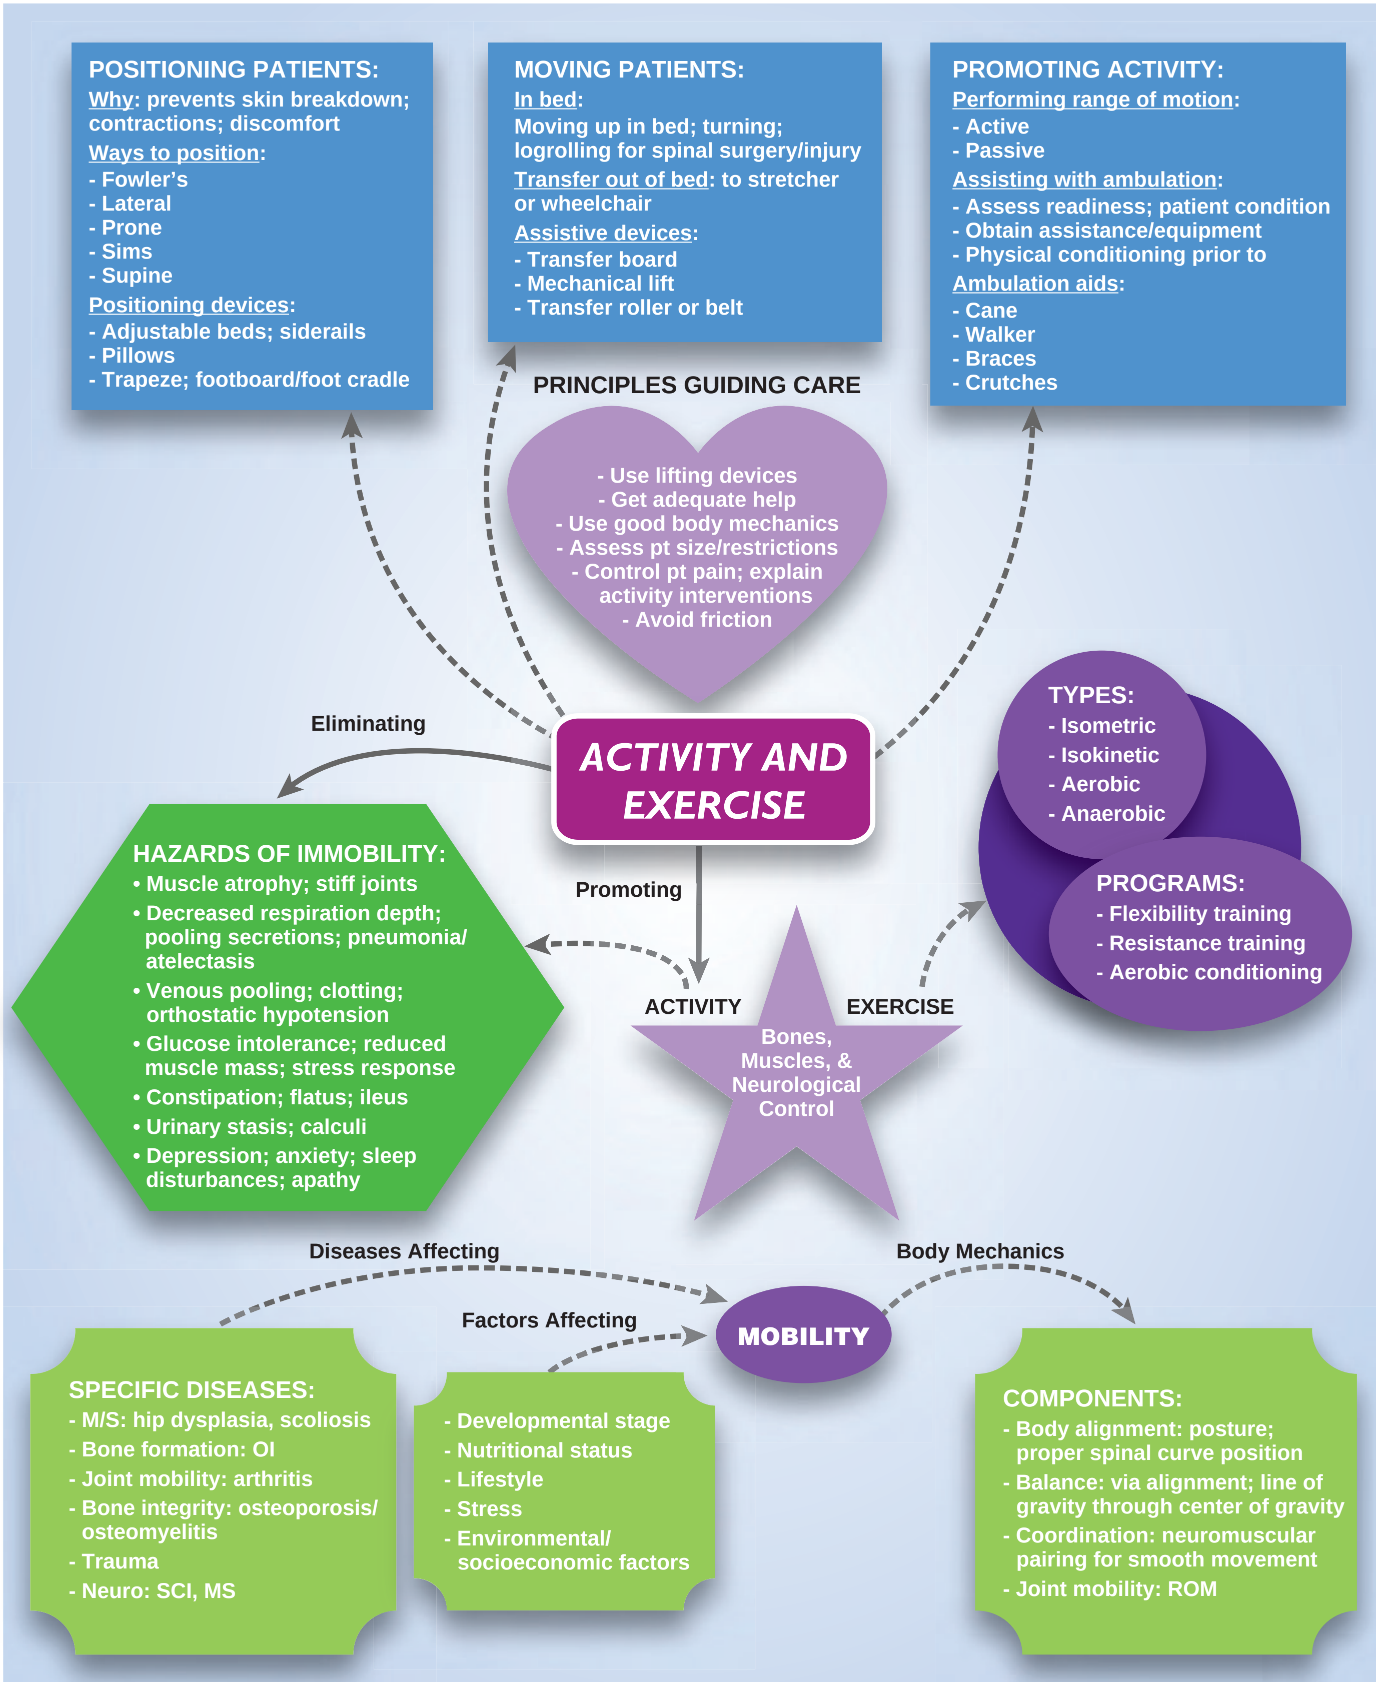
1. In Volume 1, you were introduced (Meet Your Patient) to Helen Jillian, a 72-year-old woman with hypertension, high cholesterol levels, and chest pain. She is 61 inches tall and weighs 290 pounds. Ms. Jillian is admitted to the hospital for another episode of chest pain. You are assigned to care for her. Her physician has ordered her to be out of bed in the chair at least twice daily and to ambulate every day. How will you safely move this patient from bed to chair and assist her with ambulation? Work through that decision by answering the following questions.
   a. What aspects of this situation require the most careful attention (what are the risks; what could go wrong)?
   b. What steps can you take to prevent those difficulties?
2. Ms. Jillian is refusing to get out of bed. "I'm sick," she tells you. "If you make me get out of bed, I'll probably have chest pain." How would you respond to this statement?
3. Vince Fulk is an 85-year-old man who sustained a massive cerebrovascular accident (stroke). He is unresponsive and immobile. What activity or mobility interventions should you incorporate into his plan of care? What is your rationale for these interventions?

4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or activity and exercise. Note that these are *not* to be merely definitions.
   Body mechanics — Activity tolerance
   Exercise — Assistive devices
   Immobility

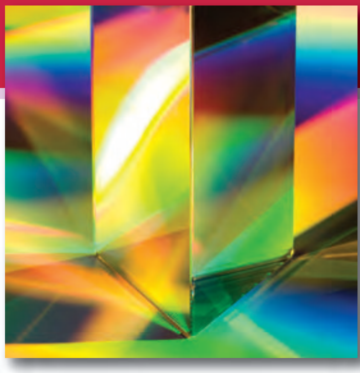
What Are the Main Points in This Chapter?

- The skeletal system includes bones, cartilage, ligaments, and tendons. The skeleton forms the framework of the body and protects the internal organs.
- Movement depends on the interaction between the skeleton and the muscles. The ligaments, tendons, and cartilage serve as the interface between these two systems.
- Contraction of skeletal muscles causes the muscles to shorten, thus causing the bones to move at the joints.
- There are four natural curves to the spine. Proper posture maintains these natural curves in good alignment.
- In the human body, the center of gravity is below the umbilicus at the top of the pelvis. The feet provide the base of support.
- Range of motion (ROM) is the degree of maximum movement at a joint. Active range of motion (AROM) is when the patient independently moves his joints through flexion, extension, abduction, adduction, and circular rotation. Passive range of motion (PROM) is performed by another person when the patient is unable to do so for himself.
- Principles of body mechanics are the rules that allow you to move your body with proper alignment, strength, and balance without causing injury.
- The U.S. Department of Health and Human Services recommends a minimum of 150 minutes per week of moderate-intensity, or 75 minutes per week of vigorous-intensity aerobic physical activity, or an equivalent combination of moderate- and vigorous-intensity aerobic physical activity.
- A well-rounded exercise program focuses on flexibility and balance, resistance training, and aerobic conditioning.
- Regular physical activity each week, sustained for months and years, can produce long-term health benefits. Strong evidence links regular physical activity with a lower risk for early death, heart disease, stroke, type 2 diabetes, hypertension, colon and breast cancers, and depression.
- Together with a healthy diet, regular physical activity aids in weight management, better heart and lung function and muscular fitness, fall prevention, and improved memory and mental clarity in older adults.
- People who are physically active tend to feel better and have more energy. Sleep quality is improved. And, overall, for many people, physical activity promotes a sense of optimism and positive self-esteem.
- Factors that influence activity and exercise level include developmental stage, health concerns, nutrition, lifestyle, attitudes, and external factors.
- Severe illness associated with prolonged immobilization causes physiological changes in almost every body system.
- A nursing history focused on activity and exercise assesses usual activity, commitment to fitness goals, mobility concerns, underlying health concerns and injuries, lifestyle, attitude of hardiness and persistence, and external factors.
- Physical assessment that is focused on activity and exercise examines the musculoskeletal system and activity tolerance. Important data include vital signs, height, weight, body mass index, body alignment, joint function, gait, and activity tolerance.
- Patients require a change of position at least every 2 hours to prevent pressure injury, muscle discomfort, damage to superficial nerves and blood vessels, or contractures.
- Range-of-motion exercises maintain joint mobility and limit the complications of immobility.
- Patients who have been confined to bed for more than a week or who have sustained major injury require ROM and muscle strength conditioning before they are able to resume walking.
- Canes, braces, walkers, and crutches promote stability for patients to walk independently and more safely.

Knowledge Map



CHAPTER 33



Sexual Health

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 33:
- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Sexual Health (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 33, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

As you may recall, Nam and Yen Nguyen are raising their 3-year-old grandson, Kim. Kim has made friends with Dinh, another little boy at preschool. Kim has asked whether they can play together. Yen works at the preschool and knows Dinh and his family. She is unsure whether she should allow her grandson to play with Dinh because she is uncomfortable with his family. Dinh was conceived via artificial insemination and is being raised by a lesbian couple. His parents are open about the relationship and voluntarily shared the conception information with Yen.

A. Yen calls the clinic to speak with you. She explains the situation and asks you whether you think it would be a problem to allow the boys to play together. She is concerned that being around this family may be a bad influence on Kim. How would you respond?

B. Yen remains concerned and presses you for more information. She is concerned that Kim's interest in Dinh may indicate that Kim has homosexual tendencies. How would you address her concerns?

C. Yen admits that Nam does not agree with her. "He told me that sexual orientation is genetic." How would you react to this statement?

PracticalKnowledge knowing how

In this section you will find guidelines to assist you in assessing and planning care related to patients' sexual health.

CLINICAL INSIGHTS

Clinical Insight 33-1 ➤ Providing Care After Sexual Assault

- **Carefully collect information about the incident** and document findings in a fact-based manner, following your institution's protocol.
- **Be sensitive to the victim's fear, anxiety, and guilt** related to the event.
  Open discussion without communicating judgment or disapproval helps with fact finding for better care.
- **Assess the victim's emotional status,** including sexual identity, stress disorder, and risks for suicide and self-harm. Also discuss the potential for sexual and physical violence, including violence within relationships.
- **When collecting a nursing history for people with disabilities, be sure to screen for sexual violence.**
- **Administer prophylactic treatment** to patients who have been assaulted (vaginally, anally, or orally) to prevent sexually transmitted infections (STIs), such as chlamydia and gonorrhea. If there is a significant risk for HIV, prophylaxis may be prescribed within 72 hours of exposure.
- **Administer vaccines to prevent hepatitis B and human papillovirus (HPV),** as prescribed and according to your agency's policy.

Clinical Insight 33-1 ➤ Providing Care After Sexual Assault—cont'd

- **Administer emergency pregnancy prevention** (e.g., the "morning after" pill) to patients who have been vaginally assaulted even if penetration is uncertain, according to your agency's policy.
- **Document pregnancy status** with a urine or blood sample.
- **Teach follow-up care.** The victim should receive follow-up care within 1 week after the event to assess for healing of injuries and presence of STIs. Advise a female victim who has had vaginal penetration to obtain pregnancy testing again 2 weeks after the event.
- **Follow the current reporting requirements** for sexual assault in your state. Some states require reporting assault of children and adolescents, even if they do not consent to the reporting.
- **Know support services** available in your community for victims of abuse. Refer the victim to a sexual assault center for support, counseling, and additional information. Because of the long-term psychological and emotional consequences of sexual assault, most victims benefit from counseling.

Clinical Insight 33-2 ➤ Guidelines for Taking a Sexual History

1. **Provide privacy.**
   - Usually it is not enough merely to pull the curtains around the bed. Ask others who may be able to overhear private conversation behind the curtain to leave the room.
   - Talk to the client alone.
   - In some situations, it is also beneficial to talk to the partners as a unit, with the consent of both of course.
2. **Protect confidentiality.** Assure your client that information will not be shared with others, unless directly related to planning or delivering healthcare.
3. **Be relaxed in your approach**, and allow the client time to fully answer your questions. Your manner and attitude are critical in putting the client at ease.
4. **Make eye contact.** Do not act embarrassed or allow your body language to show your discomfort.
5. **Avoid communication stoppers**, such as:
   - "I'm only asking you these questions because I have to."
   - "I know that you probably won't want to tell me but . . ."
   - "You're not having any sexual problems, are you?"
6. **Consider a more inviting opening**, such as:
   - "Many people are embarrassed when asked questions about their sexuality, but whatever you tell me will remain confidential."
   - "Many people hesitate to talk about sexual problems. However, your sexual health is important to your overall health, and I would like to ask you a few questions about that."
7. **Be aware of verbal and nonverbal cues** that indicate concerns. Many people will cloak their concerns in comments such as, "I suppose that I won't need to worry about sexy lingerie any longer," or "Sex is for the young. I just have to accept that I'm sick and older now." Be careful that your response to such statements does not either negate or validate your patient's identity as a sexual being. Follow up with comments that encourage the client to provide more details (see Chapter 21 if you would like to review communication techniques).
8. **Realize the client may be embarrassed.** If the client is uncomfortable discussing topics about his own sexual health, reassure him by letting him know that some information, because of its private nature, may be difficult to discuss, but important.
9. **Encourage your client to use terminology that he is comfortable with.**
10. **Help the client feel comfortable.** Consider statements such as the following:
    - "Most people wonder how this surgery [or illness] may affect their sexual functioning."
    - "Whenever these medications are suggested, there are questions about sexual side effects."
    - "Have you thought about the kinds of adaptations you may have to make in your sex life after this surgery/treatment/illness?"
11. **Begin with a less sensitive topic** such as "When was your last menstrual period?" or "How is your relationship with your partner [spouse]?" Then you can move into more sensitive areas: "Many older women have some vaginal dryness that creates discomfort during intercourse. Do you have any concerns about this?"

Clinical Insight 33-3 ➤ Teaching Your Patient to Use a Condom

Using Male Condoms

The male condom is a sheath that covers the penis during sexual activity.

- Put the condom on before the penis touches the vagina, mouth, or anus.
- Inspect the package to ensure that the condom has not been damaged.
- Open the package without tearing the condom.
- Squeeze out the air at the tip of the condom, and unroll it over the erect penis, leaving some space at the tip to collect the ejaculate.
- After sex, to avoid breaking the condom, hold the condom at the rim as the penis is withdrawn. Discard the condom. Wash your hands.
- Use a new condom if you want to have sex again.

Using Female Condoms

The female condom is a plastic pouch that fits inside the vagina so that all vaginal tissue is protected from contact with the penis. The condom is inserted with the inner ring placed high in the vagina near the cervix and the outer ring on the labia.

- Insert the condom before the penis touches the vagina.
- Inspect the package to ensure that the condom has not been damaged.
- Open the package without tearing the condom.
- Put the inner ring and pouch inside the vagina.
- Push the inner ring as far into the vagina as it will go.
- Ensure that the outer ring stays outside the vagina.
- If needed, add lubricant to the inside of the condom.
- After sex, gently pull out the condom and discard.

Do

- Use latex condoms unless you or your partner are allergic to latex, or use polyurethane condoms.
- Treat condoms gently, and keep them out of the sun.
- Use only water-based lubricants to reduce friction and prevent tearing.
- Check the expiration date of the condom and packaging. Old condoms may be brittle and more likely to break.

Don't

- Don't store condoms in your wallet or other place where body heat can break down the latex.
- Don't use fingernails or teeth to open the condom wrapper; doing so can tear the condom.
- Don't reuse a condom.
- Don't use lotions or oils with condoms; these may cause breakage.

TABLES

Fertility Control Methods

FERTILITY CONTROL METHOD	ADVANTAGES	DISADVANTAGES
Abstinence—No sexual intercourse	100% effective Cost free	Lack of sexual expression May create stress in relationship.
Fertility awareness (natural family planning, rhythm method)—Intercourse only when a woman is thought to be in the infertile phase of her menstrual cycle	Cost free May be consistent with religious teachings No physical side effect	Requires cooperation of both partners. Menstrual cycle must be regular. Relatively high failure rate: Pregnancy may result. No protection against STIs
Withdrawal (coitus interruptus)—Removal of the penis from the vagina before ejaculation	Cost free	Requires discipline and mutual cooperation. Pre-ejaculatory fluid may contain sperm. Relatively high failure rate; pregnancy may result No protection against STIs

Fertility Control Methods—cont'd

FERTILITY CONTROL METHOD	ADVANTAGES	DISADVANTAGES
Male and female condoms	Obtained without a prescription Relatively inexpensive Protects against STIs	Must be put on before penetration; therefore, may diminish spontaneity of intercourse. May decrease sensation for both partners Cannot use certain types of condoms if either partner has latex allergy
Spermicides—Jelly, creams, or foams placed in the vagina	Obtained without a prescription More effective when used with a barrier (condom)	Significant pregnancy rate when used without a barrier (condom) No protection against STIs
Contraceptive sponge	May offer some protection against STIs Can be inserted into the vagina up to 24 hours before intercourse Inexpensive	Not fully effective against pregnancy
Vaginal ring	Highly effective in preventing pregnancy Does not have to be inserted before each act of intercourse—can be left in place for weeks to months, depending on the type	Requires a prescription because it is a hormonal method. Similar risks as birth control pills Costs similar to or greater than those of birth control pills Correct insertion is key factor in effectiveness of the method.
Oral contraceptives (birth control pills)	Very effective Do not interfere with intercourse Regulate menstrual flow Decrease menstrual cramps	Require a healthcare visit and prescription Significant cost Must be taken as prescribed to be effective Drug interactions No protection against STIs Carry some undesirable side effects Contraindicated for some women (e.g., those who smoke, who have significant varicose veins)
Depo-Provera injections	Last 3 months Highly effective Do not interfere with intercourse	Require a healthcare provider visit Amenorrhea (may be seen as an advantage) No protection against STIs
Intrauterine device (IUD)—A small piece of plastic that also may contain metal or a hormone: placed through the cervix into the uterus by a healthcare provider	Highly effective May remain in place for years Does not interfere with intercourse	Increased risk of pelvic inflammatory disease (PID) Must be inserted by a healthcare provider Increased menstrual flow and cramping No protection against STIs
Diaphragm—Latex dome-shaped cup with a flexible rim that is inserted in the vagina and fits over the cervix	Few side effects Quite effective if used properly with spermicide	Must be inserted prior to intercourse, thereby compromising spontaneity Must be removed about 6 hours after intercourse

(Continued)

Fertility Control Methods—cont'd

FERTILITY CONTROL METHOD	ADVANTAGES	DISADVANTAGES
		Must be used with a spermicide Increased risk of urinary tract infection (UTI) No protection against STIs
Hormonal implant—Small rod(s) containing hormones that are inserted under the skin, usually in the back of upper arm	One of the safest and most effective forms of birth control available (World Health Organization, 2006, updated 2010). Users do not have to think about their birth control every day or for every sexual intercourse. Menstrual periods are fewer and lighter for most women. Effective for 3 years Can be removed at any time Does not contain estrogen	No protection against STIs May be able to see the rod if the woman is very thin A small number of women have longer and heavier periods with breakthrough bleeding. May be limited availability More expensive than some other birth control methods Surgical procedure
Female sterilization (tubal ligation)	Effective Long-term cost-effectiveness May be reversible	May not be reversible No protection against STIs Usually not reversible
Male sterilization (vasectomy)	Effective Long-term cost-effectiveness Does not interfere with sexual performance May be reversible in some cases	Psychological effects No protection against STIs

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Guidelines and Questions for Taking a Sexual History

Topics to Include in a Sexual History

The topics to include in the sexual history depend on the nature of the patient's concern. The following topics are most commonly included:

- Reproductive history
- Sexual self-concept
- History of sexually transmitted infections
- History of sexual dysfunction
- Present sexual functioning
- Other factors that affect sexuality, such as medications and diseases
- Signs or symptoms of sexual abuse (see Procedure 9-1)
- Knowledge level about sex, reproduction, and contraception

Tailor your assessment to meet the client's needs. For example, Frank Thanee (Meet Your Patients, in Volume 1) is concerned about his family's reaction to his lifestyle and sexual orientation. In his situation, you would focus your assessment on his sexual self-concept, family relationships, present sexual functioning, and specific concerns about his heart and the impending family visit.

Questions to Ask Women

Menstrual Cycle

- How old were you when you started your menstrual periods?
- When was your last menstrual period?
- How often are your periods? How would you describe the flow? How long does your period last?
- Do you have any problems with your periods, such as cramping, breast pain, or heavy flow?

Focused Assessment

- Does your menstrual period ever prevent you from going to work or school or doing the activities you enjoy?
- What products do you use during your period, such as tampons and pads? Do you ever use douches, either during your period or at other times?

Cancer Screening

- When was your last Pap smear?
- Have you ever had an abnormal Pap smear? If so, how was it treated?
- Have you received a vaccine for HPV?
- Do you examine your breasts? If so, how often?
- Have you noticed asymmetry, lumps, or masses in your breasts? If so, describe them and show me where they are.
- When was your last mammogram? What were the results?
- Is there any history of breast cancer in your family?

Childbearing History

- How many living children do you have?
- How many times have you been pregnant?
- Have you ever had a miscarriage? An abortion?
- How many of your births were preterm (prior to 38 weeks)? Term?

Sexual Activity

- How often do you typically have sexual intercourse per month?
- Are you satisfied with the frequency or quality of sexual activity?
- Is there anything in your life that prevents you from sexual activity?
- Do you have any difficulty achieving orgasm?
- Is sexual intercourse ever painful for you?
- Are you sexually attracted to women? Have you had oral or genital sexual intercourse with women?

Questions to Ask Men

Sexual Activity

- How many times a month do you typically have sexual intercourse?
- Do you have any difficulty achieving or maintaining an erection or orgasm?
- Are you satisfied with the firmness of your erection?
- Do you experience either premature ejaculation or have difficulty achieving sexual orgasm?
- Are you sexually attracted to men? Have you had oral or anal intercourse with men?

Cancer Screening

- Have you been taught to examine your testicles? Do you practice testicular self-exam?
- Is there a history of testicular cancer in your family?

Questions to Ask Both Men and Women

Illnesses and Medications

- What types of illnesses have you been treated for in the past?
- Have you ever been hospitalized? Have you ever had surgery?
- What medications, herbal remedies, or over-the-counter medicines do you take?
- Has any medical treatment, surgery, or medication affected your sexual functioning?

Family Responsibilities

- Do you have children? If so, how many? How many are still at home? Dependent on you?
- Are you responsible for other children or adults? (This question may reveal whether the person continues to care for an adult, disabled child, or for grandchildren.)

Genitalia

- Have you noticed any redness, swelling, discharge, itching, or odor in your genital area?
- Have you noticed asymmetry, lumps, or masses in the genitals? If so, describe them and show me where they are.
- Have you ever been told you have a hernia?
- Have you ever had trauma to your genitals?
- Are you having any problems urinating?

Sexual Patterns

- Are you sexually active? If not, have you ever been?
- Do you have sex with men, women, or both?
- What types of sexual activity do you engage in? Oral, anal, or genital?
- How many partners do you currently have? How many partners have you had in the last 6 months?
- How would you describe your satisfaction with your current sexual relationship?
- What are your thoughts about how this procedure/illness may affect your sexual relationship?
- Have you experienced any recent changes in your sexual function—in your level of desire, your sexual activity, participation, or satisfaction?
- Do you have any concerns about your sexual function, including your level of desire, activity, participation, or satisfaction?

Contraception (as appropriate)

- Do you use birth control? If so, what type and how often?
- How satisfied are you with your method of contraception?

Sexually Transmitted Infections

- Have you ever been treated for an STI? If so, what type?
- Are you concerned about STIs or HIV?
- What precautions do you take to avoid STIs?

Abuse

- Have you ever been forced to have sex against your will?
- Have you ever been threatened or abused by a partner?
- Do you ever feel threatened by your partner?

For guidelines for your approach to taking a sexual history, see Clinical Insight 33-2.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Debra is perimenopausal at age 52, and her husband Roberto is 59. She has been feeling tired in the afternoon and moody at times. At her annual women's health visit, Debra tells you that she feels a lower level of sexual desire than she used to. Debra says, "I chalk it up to being very busy at work and yet still having so many demands on my time and energy with care of our three kids and housework." Debra is physically active, exercising four times a week, and is in good general health. She takes no medication and is within 15 pounds of her normal weight. Debra still has her period, but the flow is very heavy and cramping is more uncomfortable than it ever had been.

Recently, Debra has noticed that Roberto has been taking longer to achieve an erection, and his erection is not as firm as it used to be. He is in general good health except for high blood pressure and high blood cholesterol levels. He takes medication for both conditions.

THINKING

1. *Theoretical Knowledge (Factual Information):*
   a. What are the common physical and emotional manifestations occurring with perimenopause?
2. *Critical Thinking (Analyzing Alternatives, Deciding What to Do):*
   a. How would you respond to Debra when she asks for information and support regarding her husband's erectile dysfunction?
   b. Debra asks you whether her desire for sexual intimacy will continue to decline after she goes through "the change of life." Describe in detail what you would tell her.

DOING

3. *Practical Knowledge:*
   a. What general topics would you explore with Debra to assess her sexual history?
   b. What questions would you ask Roberto to assess his sexual history?

CARING

4. *Self-Knowledge:* What might you be feeling if you were in Debra's situation?
5. *Ethical Knowledge:* What are one or two things you would do to help Debra and Roberto feel cared for and cared about?

Critical Thinking and Clinical Reasoning

1. A 34-year-old married woman was hospitalized yesterday following an alleged rape. You are assigned to provide her nursing care. She will remain hospitalized for several days because of a head injury she suffered during the rape.
   a. How can you best approach this woman to establish a positive rapport?
   b. What fears is this patient likely to express?
   c. The patient's spouse is coming to visit. What concerns do you think that he may have?
   d. You begin to feel overwhelmed by this couple's emotions and questions. What can you do to help provide this couple with optimal care?
2. You are assigned a 26-year-old male patient who recently had a spinal cord injury. The doctors have talked to him about the possibility of regaining motor function and perhaps being able to walk again after intense therapy. What he now seems to be most concerned about is his relationship with his 25-year-old fiancée.
   a. What aspects of their relationship do you think he is concerned about?
   b. Do you have enough theoretical and patient information regarding his injury to answer all of his concerns?
   c. As you consider some of the changes in sexual functioning that may follow a spinal cord injury, what suggestions might you share with him?
   d. What clues would indicate that talking to the fiancée may be appropriate?

3. You are seeing Jessica, a 14-year-old girl, at the clinic. Her throat culture is positive for gonorrhea. The girl's mother has gone down to the coffee shop. The doctor has left a prescription for antibiotics. You are left to take care of the discharge from the clinic.
   a. How would you explain the culture results to Jessica?
   b. Jessica tells you that she cannot possibly have a sexually transmitted infection (STI) because she has not had sexual intercourse. How would you respond?
   c. Jessica tells you that she has had oral sex with her boyfriend, but no one else. What education regarding STIs and antibiotics would be appropriate?
   d. What information would you give the mother when she returns?
4. A 45-year-old married man with young children has just been informed that he is HIV positive. He is shocked by the news. He admits he had an extramarital relationship with a man 7 years ago.
   a. What concerns is he likely to have? As his nurse, what biases will you have to put aside to help him?
   b. What theoretical knowledge would you need at a later time to help him deal with questions about sexual activity?
   c. What patient information would you need to help him deal with questions about sexual activity?
5. Review the following scenarios from Meet Your Patients in Volume 1.
   - **Jocelyn Carter.** Two days after undergoing a fine-needle aspiration to evaluate a small breast mass, Jocelyn Carter's surgeon informed her that the mass was malignant. He recommended a mastectomy (removal of the breast). Today, she arrives alone at the surgery registration area at 0600. You ask how she is feeling, and she tells you that the past week has been a whirlwind of activity. "I had to arrange child care, cancel a business trip, and organize the house so that I could take a few days off to have the surgery. My husband is working overseas this fall, so he couldn't be here to help me. Honestly, I don't know how I'm feeling. I haven't had time to think about it." A few minutes later, as she waits in the surgery holding area, she begins to cry. You hold her hand and ask whether she would like to talk. She asks you, "Do you think my husband will still want me? I'm afraid he will be turned off when he looks at me now."
   - **Gabriel Thomas.** This patient comes to the outpatient clinic complaining of a throbbing headache for the past 3 days. He explains that he has tried several over-the-counter medicines and has had no relief. You check his blood pressure, and measure the reading at 240/130 mm Hg. When you ask whether he has ever been treated for high blood pressure, he replies, "Are you another one of these people trying to get me to take drugs that will ruin my sex life?"
   - **Frank Thanee.** Frank has heart disease, had a mitral valve replacement 3 days ago. He has been transferred to the cardiology floor for an additional day of hospitalization. His partner, Greg, has spent the last 3 days at the hospital and has just left to check on the apartment and feed their cat. Frank confides that he is worried about his parents' expected visit. "I've never been able to tell them about Greg. They wouldn't be able to understand it, never mind approve. I don't know how to handle this. What do you think I should do?"

   a. Write etiologies for each of the patients. The nursing diagnosis label is provided for you in each case.
      Jocelyn Carter—Ineffective Sexuality Patterns
      Gabriel Thomas—Ineffective Sexuality Patterns
      Frank Thanee—Sexual Dysfunction
   b. For each of the patients, instead of the sexuality diagnosis, identify another nursing diagnosis label that you should explore to see whether it fits the situation better. Consult a nursing diagnosis handbook, as needed.
      Jocelyn Carter:
      Gabriel Thomas:
      Frank Thanee:
6. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or sexual health. Note that these are *not* to be merely definitions.

Sexual health	Sexual expression
Gender	Sexually transmitted infections
Sexual orientation	Fertility control

7. An infant is born with ambiguous sex organs. The provider has informed the parents that they will need to make a decision regarding which gender they want to assign to the child. They also have the option of waiting and letting the child decide at a later date.
   a. What do you think the parents need to consider in making this decision?
   b. What emotional factors may be involved in this decision?

What Are the Main Points in This Chapter?

- Sexuality is a broad and complex aspect of the self, with physical, emotional, social, and spiritual dimensions.
- Sexuality involves how we feel about ourselves as individuals and how we interact with others and our environment.
- Gender, gender roles, gender identity, and sexual orientation contribute to expression of our sexuality throughout the life cycle.
- There are both typical and atypical forms of sexual expression.
- Culture, religion, lifestyle, sexual knowledge, and physical health all influence our attitudes toward sexuality, sexual behaviors, and intimate relationships.
- Sexual victimization is a societal and healthcare concern.
- Physical and psychological health status affects sexuality and sexual functioning.
- Sexual health is challenged by high-risk sexual behaviors, sexually transmitted infections (STI), negative interpersonal relationships, and sexual dysfunctions.
- Four phases of the sexual response cycle are excitement, plateau, orgasm, and resolution.
- A sexual history is a component of the nursing assessment.
- There are strategies you can use to help you gain comfort and competence in collecting sexual data.
- The PLISSIT model was developed as a guideline for counseling for sexual problems: Permission, Limited Information, Specific Suggestions, and Intensive Therapy.
- Sexual well-being may be enhanced through nursing interventions such as counseling for sexual problems; dealing with inappropriate sexual behavior; and teaching about body function and reproduction, self-care, contraception, and prevention of STIs.

CHAPTER 34

Sleep & Rest

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 34, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Yen Nguyen arrives at the clinic accompanied by her husband, Nam. She appears very tired. Nam tells you that she has been sleeping poorly. "She worries so much. She worries about Kim, our grandchild. She worries about our kids. Now she's worried about my mother. When we were going through that mammogram scare, she was even worse!"

Mrs. Nguyen shrugs her shoulders. "I can't help it. I'm like that. I've always been a worrier. But it's gotten worse lately. Now I worry and get so emotional. I lie in bed

Caring for the Nguyens (continued)

thinking about all this stuff and end up in tears. Then, when I finally get to sleep, I wake up covered with sweat. I've tried extra soy for hot flashes, melatonin from the health food store, herbal tea, and even Benadryl—but nothing seems to work. I'm so tired. But when I get up, I have to deal with all these little kids at work. They're bouncing all over the place and noisy. I just get so short-tempered with them. That's not like me. I can't take this anymore."

A. *Patient data:* Clearly Mrs. Nguyen has a sleep problem. Underline the data that are defining characteristics (symptoms) of a sleep problem.

B. *Patient data:* Which data suggest ideas about the etiologies (causes) of Mrs. Nguyen's sleep problem?

C. *Nursing diagnosis:* Two NANDA-I sleep-related nursing diagnoses are Sleep Deprivation and Disturbed Sleep Pattern. You have already identified the patient's defining characteristics. Now, what *knowledge* do you need to decide which of these NANDA-I labels to use?

D. How could you obtain this knowledge?

E. Sleep Deprivation is defined as "prolonged periods of time without sleep" and Disturbed Sleep Pattern is defined as "time-limited disruption of sleep." Can you make the diagnoses on the basis of this knowledge? Why or why not?

F. Following are some of the defining characteristics for these two nursing diagnoses. Certainly there is some overlap between the two sets of symptoms. Nevertheless, which set seems to be a better fit for Mrs. Nguyen? Why?

Disturbed Sleep Pattern	**Sleep Deprivation**
Verbal complaints of not feeling well rested	Daytime drowsiness
Dissatisfaction with sleep	Decreased ability to function
Change in normal sleep pattern	Agitation
Decreased ability to function	Irritability
Reports being awakened	Hallucinations
Reports no difficulty falling asleep	Anxiety
	Inability to concentrate
	Apathy
	Slowed reactions
	Combativeness
	Fatigue
	Fleeting nystagmus
	Hand tremors
	Heightened sensitivity to pain
	Lethargy, listlessness, malaise
	Perceptual disorders (e.g., disturbed body sensation, delusions, feeling afloat)
	Restlessness
	Transient paranoia

G. Write a nursing diagnosis for Mrs. Nguyen.

PracticalKnowledge knowing how

This section will help you learn to give a back massage, assist you in obtaining a sleep history, and provide standardized language to use in planning care for clients with sleep problems.

PROCEDURES

In the not-so-distant past, a relaxing back massage was a part of the evening care routine for every hospitalized patient. In this era of cost containment, this sleep enhancer has become a "nice but not essential" procedure in most agencies. Massage has therapeutic benefits, however. It promotes circulation, physical and emotional comfort, and sleep. Furthermore, it is an independent nursing activity for which you do not need a medical prescription (except in very rare circumstances). Try to offer a back rub whenever you can, and teach and encourage nursing assistive personnel (NAP) to do so as well. Refer to the following procedure.

Procedure 34-1 ■ Giving a Back Massage

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

Skin care lotion

Pre-Procedure Assessment

Check the skin for reddened areas or skin breakdown.

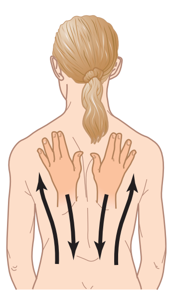
Delegation

You can delegate back massage to the NAP if the patient's condition and the NAP's skills allow. However, giving the back rub yourself provides an excellent opportunity to assess the patient, develop rapport, and provide emotional support.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

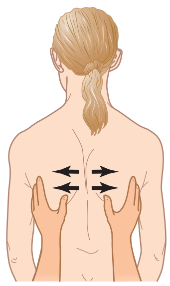
Procedure Steps

1. **Warm the lotion** by placing the bottle in warm water.
   Cold lotion can cause muscle contraction; warming the lotion helps relax the muscles.
2. **Raise the bed to working height.**
   Prevents back strain of the nurse.
3. **Position the patient comfortably** on her side or prone.
   a. Untie the patient's gown, and expose her back.
   b. Raise the siderail on the opposite side of the bed.
   c. Don procedure gloves.
   Siderails prevent the patient from falling off the bed when you turn her toward the side of the bed away from you.
   d. Wash the patient's back with warm water, if needed.
   Warm water will help relax the muscles while removing any sweat and soiling.
4. **Place lotion on your hands.**
   Placing the lotion directly on the back may cause the patient's muscles to tighten.
5. **Place your hands on either side** of the spine at the base of the neck. Using gentle, continuous pressure, rub down the length and then up the sides of the back.
   a. Repeat this motion several times.
   b. Never rub directly over the spine.
   The spine is a vulnerable area.

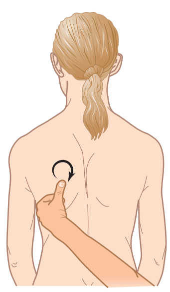


6. **Apply gentle thumb pressure** (using the fleshy part of your thumbs) on either side of the spine at the midback, pushing outward for about 2.5 cm (1 in.).
   a. Repeat from the midback to the base of the neck in a series of small, outward strokes.
   Strokes should be along the muscle length and not across the muscle to help stretch and relax it.
   b. Ask the patient whether the amount of pressure is comfortable. Be careful not to cause the patient discomfort, which might cause further muscle tightness.
   c. Always apply pressure away from the spine, not toward it.
   This gently stretches the muscles and helps prevent placing pressure on the spine.

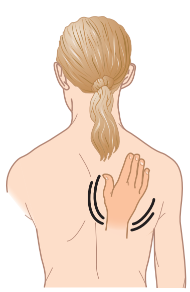
d. If you are unable to massage both sides at the same time, work on one side and then the other.
Work as symmetrically as possible to increase muscle relaxation.



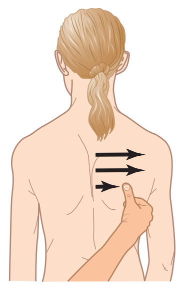
7. **Now go to the spots that felt** the tightest or that the patient states are tight. Work in small circles, using gentle thumb pressure.
Small circular movements can help release muscle "knots" and relax tightened muscles.



8. **Gently shake the scapulae.** Place your palm on one scapula, and gently shake it by quickly moving your palm back and forth. Repeat on the other side.
Movement of the scapula decreases when muscles tighten; gently vibrating the scapula helps loosen the muscles.

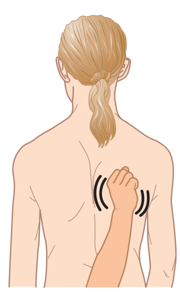


9. **Apply horizontal strokes** across the scapula, using your thumb. Using horizontal strokes from near the spine across the bottom of the scapula, push out all the way across the scapula from the spine. Move up and repeat until you have covered the entire scapula and top of the shoulder. Repeat on the other side.
This movement helps loosen the trapezius muscle.



10. **If you find tender spots**, use the fleshy parts of your fingers in a small circular motion.

11. **Apply pressure in circles** using the heels of your hands down both sides of the spine. Beginning at the upper shoulder and working down to the lower back, apply pressure in medium-sized circles down the sides of the spine with the heels of your hands. Be cautious not to apply too much pressure. Assess patient for comfort.
The circular motion helps relax tightened areas in the paraspinal muscles.



12. **Apply horizontal strokes** using the heels of your hands across the latissimus dorsi muscle. Using horizontal strokes from near the spine below the scapula, push out from the spine across to the ribs, and work down across the lower back with the heels of your hands.
This movement helps relax the latissimus dorsi muscle.

13. **Gently rub your hands up either side** of the spine from the base of the back to the base of the neck and then down the sides of the back. Repeat several times.
Long strokes help increase circulation and promote relaxation of the back muscles.

NOTE: If you are unable to do a complete back massage, ask the patient where she is most uncomfortable, and massage those areas. If the patient has general tightness, use the long strokes down each side of the spine and back up the sides.

Evaluation

Assess the patient's report of comfort, relaxation, and how soon she falls asleep.

Documentation

This is a routine aspect of care and is usually documented on a flowsheet.

Practice Resources

Dosey, B., & Keegan. L. (2009); Sports Injury Clinic (n.d.).

ASSESSMENT GUIDELINES AND TOOLS

This section will assist you in screening for sleep problems.

Questions for a Sleep History

A brief assessment for all patients should include questions about the following:

Usual Sleeping Pattern

- When do you go to sleep and wake up?
- How many hours do you sleep?
- Do you have a regular sleep schedule?
- How would you rate the quality of your sleep on a scale of 1 to 10, with 10 meaning "great"?
- Do you take a nap? If you do, for how long?
- How often do you waken during sleep, for example, to go to the bathroom?
- Do you feel adequately rested when you wake up?

Sleeping Environment

- Would you like a night-light?
- What room temperature do you prefer?
- What noise level do you prefer (for example, radio, television, absolute quiet)?

Bedtime Routines/Rituals

- What do you typically do in the hour before bedtime?
- What do you do to help you fall asleep?

Sleep Aids

- Do you need a special pillow or positioning aid?
- Do you take any sleep medications or other drugs, natural sleep aids, or homeopathic remedies that may affect sleep?

Sleep Changes or Problems

- Have your sleep patterns changed? If so, how?
- How often do you experience difficulty falling asleep? Staying asleep?
- Do you currently, or have you in the past, ever experienced a sleep disorder (e.g., narcolepsy, insomnia)?
- Do you remember your dreams after you wake? Do you ever have night terrors? Do you sleepwalk?
- Do you ever experience an unpleasant creeping feeling, crawling, or tingling, relieved only by moving the legs at night?
- Do you snore? Does your own snoring or grunting ever wake you or anyone in the room?
- Do you wear a cap at night? Do you require oxygen at night? Or any other medical aid or therapy while you sleep?
- Do you grind your teeth while you sleep? Do you wear a dental appliance to prevent grinding?
- Do you experience any kind of pain that makes it difficult for you to fall asleep or stay asleep?
- Is there anything that I have not asked that might help you sleep while you are in the hospital (having surgery, receiving home care)?

If the client reports experiencing satisfactory sleep, that is an adequate assessment, and you merely need to support her usual sleep patterns and rituals. When you suspect a sleep problem, you will perform a more in-depth assessment, such as a detailed sleep history or sleep diary.

Sleep Diary

A sleep diary provides specific information on the patient's sleep–wakefulness patterns over a long period. The diary is usually kept for 14 days and may include the following.

Note: If you work a night shift, adjust the time for sleep and waking in these questions accordingly.

Completed in the morning

1. Time you went to bed:__________
2. Approximate time you fell asleep:__________
3. Times you woke during the night:__________
4. Times you fell back to sleep:__________
5. Time you woke up in the morning:__________
6. Did you feel refreshed upon wakening?__________
7. What did you eat or drink just before bedtime? __________
8. What mental and physical activities did you engage in the 2 to 3 hours before bedtime?__________
9. Were you worried or anxious about anything when you went to bed?__________
10. Sleep medications you have taken:__________ Any repeated doses? __________ Times:__________

Completed in the evening

1. How sleepy did you feel during the day?
   ____ Sleepy; struggled to stay awake during the day
   ____ Somewhat tired
   ____ Fairly alert
   ____ Wide awake
2. Any naps during the day? __________ If so, for how long? __________
3. Frequency of pain medication taken and times __________
4. Exercise during the day? __________ If so, for how long? __________ What time of the day? __________
5. Number of alcoholic drinks __________ What time: __________
6. Number of caffeinated drinks __________ What time: __________
7. Number of tobacco products __________ What time: __________

CLINICAL REASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

A 43-year-old healthy woman, Maria Lupe, is being seen for her annual women's health visit. She tells you she lies awake in bed for hours before falling asleep at night. Sometimes she falls asleep without problems but will wake up and then have trouble going back to sleep. After feeling as though she had been awake nearly all night, Maria wakes in the morning feeling exhausted. She tells you she feels tired all the time and can't seem to get things done during her time off because of her fatigue. Maria admits to feeling irritable with her coworkers and children. Because of her lack of rest, she doesn't have the desire to do things socially anymore.

THINKING

1. *Theoretical Knowledge:* The NANDA-I definition and defining characteristics of Insomnia differ slightly from the medical diagnosis of insomnia.
   a. What is insomnia, as defined medically (e.g., by the National Sleep Foundation)?
   b. What other health conditions might a medical diagnosis of insomnia be confused with?
   c. What factors either lead to or aggravate insomnia, as described medically?
2. *Critical Thinking (Contextual Awareness):*
   a. Obviously Maria has trouble sleeping. Based on the data you have, do you consider her difficulty sleeping significant enough to require consultation with her primary healthcare provider? Explain your thinking.

DOING

3. *Nursing Process (Assessments):*
   a. When conducting a sleep history for Maria, what questions would you ask her in order to (1) describe more fully her sleeping problem and (2) identify the cause of her sleeping problem?
   b. What would you suggest Maria do to help you gain more information about her sleeping problem?

4. *Nursing Process (Nursing Diagnosis):* Based on the data in the Patient Situation, would you use a nursing diagnosis of Sleep Deprivation or Insomnia for Maria? Explain your thinking. Use a nursing diagnosis handbook, as needed, to compare the defining characteristics of the two diagnoses.
5. *Nursing Process (Interventions):* How might you help your patient manage her Insomnia other than using prescription medication? What might you suggest?

CARING

6. *Self-Knowledge:*
   a. Have you ever had trouble falling or staying asleep? How did you feel at the time and in the morning? Describe your experience.
   b. How might you provide better emotional care and support to your patient after recalling your own episodes of sleeping difficulty?

Critical Thinking and Clinical Reasoning

1. You are a nurse working on a psychiatric unit. You are assigned to the care of Sheryl, a 23-year-old woman with the diagnosis of anorexia nervosa (a potentially life-threatening eating disorder characterized by an intense fear of weight gain and extremely restrictive food intake). Sheryl attends therapy each day, seems to be taking her medications, and is eating the required amount of food at each meal. But she continues to lose weight. The nurse working the night shift reports that Sheryl is unable to sleep at night; seems frightened, almost panicky; paces the hall; and cries. Sheryl is unwilling to talk about her inability to sleep, but you read in her chart that she was sexually abused during the night while she was in a foster home. As you are straightening up in her room, you find several of Sheryl's sleeping pills. Sheryl walks into the room and begs you to be her friend and not to tell anyone. She promises to take her pills that night.
   a. What do you think may be contributing to Sheryl's inability to sleep? Explain your reasoning.
   b. How do you *feel* about keeping Sheryl's secret? Why might you want to tell other caregivers about the sleeping pills? What reasons can you think of for *not* telling?
   c. For you to deal effectively with Sheryl's sleep problem, what theoretical knowledge would you need?
   d. Now assess your current theoretical knowledge. Do you need more knowledge about certain topics to help Sheryl? If so, where can you find out what you need to know?
2. Imagine that you are a registered nurse at a local nursing home. Gwen, a 74-year-old woman, has captured your heart. Gwen has severe rheumatoid arthritis with pain and joint deformities, so she cannot ambulate or perform activities of daily living independently. Gwen's family visits every weekend, and they always bring cookies or candy, usually chocolate. Gwen likes to eat these treats just before bedtime, right after her bedtime medications. She receives a stool softener, a sleeping pill, and a pain pill for her arthritis. Lately she has been awakening at least twice each night, seeming quite confused. She tells the day shift nurse that she needs another sleeping pill at bedtime because "I'm not sleeping as well as I used to, because I have to get up so many times to go to the bathroom." She also seems more sluggish than usual during the day. You will need to integrate all available information. Don't worry if you do not know much about arthritis or if there are other things you have not yet studied. Just try to reason out the questions based on the knowledge you *do* have.
   a. If you have not yet studied arthritis and urinary elimination, you may lack some theoretical knowledge you need to answer the following questions. What information do you need? Where would you go to get it?
   b. What are some reasons that Gwen might be awakening?
   c. What might be causing her confusion at night?
   d. Should you address the problem of having chocolate before bed? Why or why not?
   e. List as many different interventions as you can that you might use to address the problem of eating sweets before bed.
   f. Consider the consequences. How might her family react if you suggest that they bring something besides sweets?
   g. What teaching might you do with the family?
3. You are a home health nurse. One of your patients is a 55-year-old man named Grant. He is homebound because of complications of diabetes. He states that he sleeps during the day, taking several naps. His chief complaint today is a pain in his left foot. There are books about alternative medicine and bottles of vitamins

and minerals all over the house. He believes he can cure his diabetes with herbs. He refuses to take any medications that are prescribed for him by his physician.

a. Do you have enough information to conclude that Grant has a sleep problem? Explain your answer.
b. Examine the patient situation (context). What factors lead you to suspect that Grant may not be sleeping enough at night?
c. What would you do to find out whether Grant is getting enough sleep?
d. Imagine how you would feel about Grant's decision to forgo his medication and use herbal treatments.
e. What personal values and biases do you have that will affect the way you respond to Grant?

4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or sleep and rest. Note that these are *not* to be merely definitions.

Sleep	Stages of sleep (e.g., REM sleep)
Rest	Sleep apnea
Theoretical knowledge about the physiology of sleep	Sedatives
Circadian rhythm	Sleep diary

What Are the Main Points in This Chapter?

- Sleep is a basic physiological need.
- Sleep and rest promote physical, mental, and spiritual well-being by restoring energy and reducing body demands while the body repairs itself.
- Illness can interfere with the ability to sleep and rest; conversely, people who suffer from sleep disorders have an increased susceptibility to illnesses.
- The hypothalamus and various neurotransmitters are involved in the physiology of sleep.
- Circadian rhythm is a biorhythm that is influenced by both internal and external stimuli, especially the light–dark patterns of day and night.
- The brain waves produced during REM sleep are similar to those of alert wakefulness. REM is characterized by rapid eye movements and dreaming.
- Duration of sleep varies according to age.
- Factors affecting sleep include developmental needs and stressors, work, exercise, foods, other lifestyle factors, use of medications, illness, pain, and the environment.
- Common sleep disorders include insomnia, sleep apnea, and narcolepsy.
- It is important to obtain information about the patient's usual sleep patterns and rituals; this may require use of a sleep diary.
- Nursing interventions to promote sleep include scheduling nursing care, creating a restful environment, promote comfort, and supporting bedtime rituals and routines.
- Pain is one of the main deterrents to sleep. Hormonal fluctuations and stress also contribute to sleep difficulties.
- Sleep medications, as a rule, should be used only as a temporary measure.
- Teaching patients and their families about the importance of rest and sleep is an important health promotion intervention.

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 35, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Kim Phan, Nam and Yen Nguyen's 3-year-old grandchild, fell at the neighborhood playground. He has abrasions on his knees, a deep puncture wound on his left hand, and a laceration on his scalp. Mr. and Mrs. Nguyen bring him to the clinic for assessment. He is crying loudly and moving all extremities. No treatment has been given.

A. What should be your first course of action?

B. What kind of care will Kim need at the clinic?

C. You determine that the scalp laceration will need to be sutured. What actions should you take to prepare Kim for the suturing?

D. One week later Kim arrives at the clinic with his grandmother to have the sutures removed. The scalp laceration is dried and healed. When you inspect his other wounds, you notice that his left knee is erythematous, warm and painful to touch, and that there is a moderate amount of purulent drainage. What assessment questions should you ask?

E. Yen Nguyen tells you that Kim would not allow her to clean or dress the abraded knees. You cleanse the knee and remove several small pieces of gravel from the wound bed. The wound is yellow and malodorous. What kind of care will Yen need to provide to Kim to heal the left knee?

PracticalKnowledge knowing how

As a nurse, you will care for many patients who have wounds or who are at risk for impaired skin integrity. You will need practical knowledge of wound assessment and wound care.

PROCEDURES

All wounds require a focused assessment. Assessment frequency depends on the condition of the wound, the work setting, the patient's overall condition and underlying disease process, the type of wound, and the type of treatment used for the wound. If you are providing wound care, you will assess the wound with every treatment.

Specific nursing interventions directed at maintaining skin integrity or healing wounds make use of procedures for obtaining wound cultures, cleansing wounds, and dressing wounds, for placing and removing wound closures, caring for wound drains, and applying binders and bandages, as well as Clinical Insights for applying local heat and cold therapy.

Procedure 35-1 ■ Obtaining a Wound Culture by Swab

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

➤ *Note:* his procedure uses modified sterile technique because wound care is now usually performed using a clean approach rather than strict sterile technique.

Equipment

- Three pairs of clean nonsterile gloves
- Aerobic culturette tube with sterile calcium alginate or rayon swab
- Sterile 4 in. × 4 in. gauze in an impermeable tray or separate 4 × 4 packs and an impermeable barrier
- Sterile 0.9% (normal) saline solution for irrigation, warmed to body temperature when possible
  Cold solution lowers the temperature of the wound bed and slows the healing process.
- 20-mL syringe
- 19-gauge angiocatheter
- Gown and face shield
- Emesis basin
- Water-resistant disposable drapes

Delegation

This procedure requires knowledge of wound healing. It needs to be performed by a registered nurse. Do not delegate this skill to nursing assistive personnel (NAP).

Pre-Procedure Assessments

Note: If the wound is covered when you begin, you will make these assessments once you remove the soiled dressing *and* after cleansing the wound.

- Assess for pain.
  Wounds may be very painful, and wound irrigation may increase pain. Provide prescribed pain medication 30 minutes before performing the procedure, if indicated.
- Determine whether the wound requires sterile, modified sterile, or clean technique.
  Sterile technique is used for acute surgical wounds and for wounds that have undergone recent sharp debridement, or when the healthcare provider prescribes it. Chronic wounds are colonized with bacteria and may be cared for using clean technique, as in this procedure. To perform sterile wound irrigation, see Procedure 35-2.
- Assess the amount and type of tissue present in the wound bed.
  Granulating tissue is beefy red with a velvety appearance. It appears with the growth of new blood vessels and connective tissue. Pale pink tissue may indicate compromised blood supply to the wound bed. Necrotic tissue, which is black, brown, or yellow in appearance, is nonviable, and inhibits healing. Only red granulating tissue should be swabbed for a culture.
- Assess the type and amount of exudate.
  Exudate may be a sign of infection.
- Assess the wound for odor.
  A foul odor may indicate infection. Cleanse wounds before you assess for odor because some dressings interact with wound drainage to produce an odor.
- Assess the tissue surrounding the wound edge.
  Surrounding tissue that is red, warm, and/or edematous may indicate infection.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

➤ *Note:* Steps are for aerobic culture.

1. **Place the patient** in a comfortable position that provides easy access to the wound and will allow the irrigation solution to flow freely from the wound, with the assistance of gravity. Position a water-resistant disposable drape between the patient and the bed to protect the bedding from any possible runoff.
2. **After washing and drying hands,** don gown, face shield, and clean nonsterile gloves.
3. **Place an emesis basin** at the bottom of the wound to collect irrigation runoff. Avoid touching the wound with the basin.
   Prevents contamination of wound from the emesis basin; protects linens from runoff.
4. **Remove the soiled dressing.** Dispose of gloves and soiled dressing in a biohazard bag.
5. **Don clean gloves,** after performing hand hygiene.
6. **Using a 19-gauge angiocatheter,** remove the metal stylet needle and dispose into a sharps container. Attach the angiocatheter to a 35-mL syringe and fill with normal saline irrigation solution.
   Prevents contamination and needlestick injury. A 19-gauge angiocatheter with a 35-mL syringe provides 8 psi (pounds per square inch) of pressure and is effective for removing bacteria, necrotic tissue, exudate, and/or metabolic wastes.

   Note: This procedure follows guidelines established by the Agency for Healthcare Research Quality (AHRQ). Commercial irrigation kits containing a piston tip syringe may also be used. Their use is discussed in Procedure 35-2.

(continued on next page)

Procedure 35-1 ■ Obtaining a Wound Culture by Swab (continued)

7. **Holding the angiocatheter** tip 2 cm from the wound bed, gently irrigate the wound with a back-and-forth motion, moving from the superior aspect to the inferior aspect.
   Irrigating from top to bottom prevents flow of contaminated solution over the cleansed area.

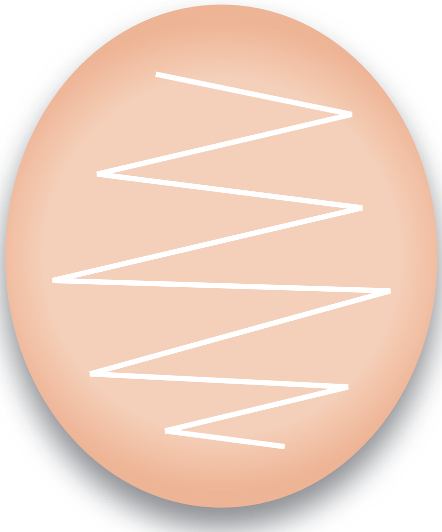
8. **Dispose of the syringe** and angiocatheter in the sharps container, and gloves in the biohazardous waste receptacle.
   Prevents contamination and needlestick injury.
9. **Obtain an aerobic culturette tube** with calcium alginate or rayon swab (not cotton tip), and twist the top of the tube to loosen the swab.
   Swab specimens are not suitable for anaerobic culture. Culture for anaerobic organisms may be obtained in tissue biopsy or needle aspiration specimens only.
10. **Don clean nonsterile gloves**, and locate an area of red, granulating tissue in the wound bed.

Using Levine Technique

a. Withdraw the swab from the culturette tube. Press the swab against the granulating area with sufficient pressure to express fluid from the wound tissue, and rotate the swab using a rolling motion.
   Fluid from deeper within the wound bed is more indicative of the microbial colonization than culturing surface of a wound.

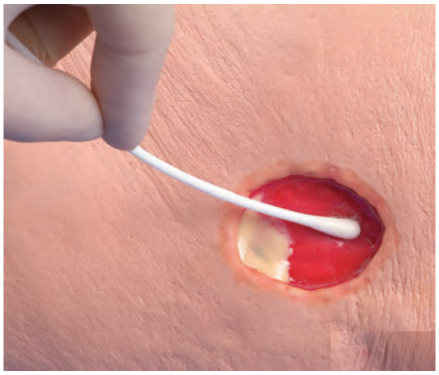
Using Z-Stroke Technique

b. Swab the wound from margin to margin in a 10-point, zigzag pattern, avoiding contact with the wound edge.
   Provides a sampling in different areas of the wound bed.



For Both Technique Variations

c. Do not allow the swab to touch anything other than the granulating area of the wound. Avoid wound edges.
d. Do not swab culture areas where slough or eschar is present.
   These are areas of avascular or necrotic tissue and are contaminated with bacteria. Swab cultures detect only surface bacteria and are not a reliable means for diagnosing wound infection.
e. Do not roll the swab around in a pool of exudative material.
   Pus is a collection of white blood cells that have already done their work, and includes the microorganisms that have already died. Obtaining a culture from this material would not produce reliable culture result. The culture specimen must be of "tissue" or "tissue fluid," not surface fluid or exudate.
f. Do not swab multiple sites with the same culturette. Use more than one culturette if several areas need to be cultured.



11. **Carefully insert the swab** back into the aerobic culturette tube, making sure it does not make contact with the opening of the tube upon reinsertion. Twist the cap to secure the tube.
    Decreases risk of contamination; ensures that any microorganisms that grow in the culture are from the wound and were not introduced from the environment.
12. **Crush the ampule** of culture medium at the bottom of the tube. (*Note:* Inspect the culture tube to determine whether this step is required. In some systems it is not.)
    The ampule contains medium for growth of microorganisms.
13. **Label the culturette tube** with the patient's name, patient identifier, birthdate, source of specimen, and date and time of collection.
    Labeling ensures obtaining the results for the correct patient.
14. **Apply a clean dressing** to the wound, as needed.
15. **Arrange for transport** of the specimen for culture to the lab immediately. Do not refrigerate the specimen.

What if . . .

- **You determined this wound requires sterile technique?**

  After removal of soiled dressing, apply sterile gloves for irrigating, obtaining culture, and applying new sterile dressing.

  Sterile technique is used for acute surgical wounds and for wounds that have undergone recent, sharp debridement, or when the healthcare provider prescribes it.

- **The culture tube is not sent to the lab within 72 hours?**

  If the culture swab is not sent to the lab within 48 to 72 hours, it must be discarded. Be sure to check the policy within your institution.

  The swab culture needs to be exposed to ideal laboratory conditions to allow microbial growth. If the culture sits on the unit too long, the culture medium might not produce reliable results. Most swab transport systems are validated for 48 to 72 hours after collection. However, if bacteria are suspected, the quicker the specimen is sent to the lab, the better.

- **The wound care and culture supplies are kept on a common treatment cart?**

  Common treatment carts should be left in the hall and not taken into individual rooms.

  When a mobile cart is rolled into a room, it is a source for possible cross-contamination.

Evaluation

- Assess the patient's pain level. Medicate according to prescriptions.
- Monitor lab reports for results of the swab culture.

Documentation

Document the following information (some agencies use a wound/skin flowsheet):

- Appearance and location of the wound and surrounding tissue. Note type, consistency and amount of exudate, and odor, if present, after irrigation.
- Patient's pain level before you obtained the culture.
- If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Method by which the wound was cleansed before you obtained the swab culture
- Description of the area where the culture was obtained
- Dressing reapplied to wound, if applicable
- Education provided to the patient

Practice Resources

Association for the Advancement of Wound Care (AAWC) (2005, revised 2010); Baranoski, S., & Ayello, E. (2011); Benbow, M. (2010); Bonham, P.A. (2012); Cooper, R. Thinking About the Procedure

To practice applying clinical reasoning to the procedure,

Go to *Davis's Nursing Skills Videos*, **Obtaining a Wound Culture by Swab.**

For questions and suggested responses,

Go to Chapter 35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 35-2 ■ Performing a Sterile Wound Irrigation

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonsterile gloves
- Sterile gloves
- Gown and face shield
- Water-resistant, disposable drapes
- Tepid (body temperature) irrigation solution
- Cold solution lowers temperature of wound bed and slows the healing process.
- Sterile gauze
- Dressing supplies
- Biohazardous waste container
- Sterile impermeable barrier
- Sterile bowl

For Step 10A Variation:

- Sterile emesis basin
- 35-mL syringe
- 19-gauge angiocatheter (needle removed)

For Step 10B Variation:

- Sterile commercial irrigation kit containing a sterile basin and piston-tip syringe

Delegation

This is an invasive, sterile procedure that requires nursing assessment, judgment, evaluation, and teaching during the procedure. It requires knowledge of wound healing and should be

(continued on next page)

Procedure 35-2 ■ Performing a Sterile Wound Irrigation (continued)

performed by a registered nurse. Do not delegate this skill to nursing assistive personnel (NAP).

Pre-Procedure Assessments

Note: If the wound is covered when you begin, you will make these assessments when you remove the soiled dressing *and* after cleansing the wound.

- **Assess the amount and type of tissue present in the wound bed.**
  Granulating tissue is beefy red with a velvety appearance. It appears with the growth of new blood vessels and connective tissue. Pale pink tissue may indicate a delay in wound healing due to compromised blood supply to the wound bed or lack of proper nutrition. Necrotic tissue, which is black, brown, or yellow in appearance, is nonviable and inhibits healing and is a source of bacterial growth.
- **Determine whether the wound requires sterile, modified sterile, or clean technique for irrigation.**
  Irrigation helps wounds to heal because it removes bacteria, old drainage, and necrotic tissue from the wound bed. Sterile technique is used for acute surgical wounds, for wounds that have undergone recent sharp debridement, or when the health-care provider has ordered it. Chronic wounds are colonized with bacteria and may be irrigated with clean technique. Irrigation using clean technique is presented in Steps 1 through 8 of Procedure 35-1.
- **Assess the wound for signs of infection (erythema, induration, amount and type of drainage).**
  Exudate may be a sign of infection. Infected wounds require higher flow pressures for irrigation.
- **Assess the wound for odor.**
  A foul odor may indicate infection. Cleanse wounds before you assess for odor, because some dressings interact with wound drainage to produce an odor.
- **Assess the tissue surrounding the wound edge.**
  Surrounding tissue that is red, warm, and/or edematous may indicate infection. Tissue that is macerated (white and moist) indicates too much fluid is being held against the skin, usually from saturated dressings.
- **Assess for pain and the need to premedicate.**
  Wound irrigation may be very painful.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Administer pain medication** 30 minutes before the treatment, if necessary.
2. **Place the patient in a** comfortable position that provides easy access to the wound and will allow the irrigation solution to flow freely from the wound, with the assistance of gravity. Position a water-resistant disposable drape to protect the bedding from any possible runoff.
3. **After washing and drying** your hands, apply a gown, face shield, and clean nonsterile gloves.
   Personal protective equipment (PPE) provides a barrier against splattering that commonly occurs during wound irrigation.
4. **Remove the soiled dressing.** Dispose of gloves and soiled dressing in a biohazard bag.
   Soiled dressings contain body fluids and other contaminants and should be treated as biohazardous waste.
5. **Set up a sterile field** on a clean, dry surface. Add the following supplies to the field:
   Sterile gauze
   Sterile bowl
   Dressing supplies
   A sterile commercial irrigation kit, *or* a 19-gauge angiocatheter, 35-mL syringe, and sterile emesis basin.
   Setting up a sterile field at bedside provides easy access to equipment for irrigation and reduces the risk for contamination when retrieving supplies after getting started.

6. **Select irrigation solution** based on the wound assessment and goals of therapy. Sterile saline or sterile water is the solution of choice for irrigation, although commercial cleansers are increasingly used for irrigation for wounds with debris or in dirty, necrotic wounds.

   Do not use povidone-iodine (Betadine) if the patient has an iodine allergy.

   Cleansers contain surfactant (soap-like substance) that removes bacteria and cellular debris with less force and slow growth of bacteria, molds, and fungi. However, some antiseptic solutions can be harmful to healing tissues (e.g., hydrogen peroxide, acetic acid, povidone-iodine, bleach solutions, and sodium hypochlorite solutions [Dakin's solution]).
7. **Pour the tepid (room temperature) irrigation solution into the sterile bowl.**
   Local cooling of wound tissues impairs healing. This can occur if you irrigate with refrigerated solutions and change dressings frequently.

8. Don sterile gloves.
Gloving maintains sterile technique.

9. Place the sterile basin at the bottom of the wound to collect irrigation runoff.

10. Fill the irrigation syringe.

If Using an Angiocatheter

a. Attach the 19-gauge angiocatheter (with needle removed) to the 35-mL syringe, and fill with the irrigation solution.
A 19-gauge angiocatheter (with needle removed) and 35-mL syringe provides 8 psi of pressure and is effective for removing bacteria, necrotic tissue, exudate, and/or metabolic wastes.

If Using a Piston-Tip Syringe

b. Fill a piston-tip syringe with irrigation solution.

11. Gently irrigate the wound. Holding the angiocatheter tip or syringe tip 2 cm from the wound bed and use a back-and-forth motion, moving from the superior aspect to the inferior aspect.
Irrigating from top to bottom prevents flow of contaminated solution over cleansed area. Irrigating a clean, noninfected wound with gentle low-pressure (8 psi) reduces disruption of the healthy, healing tissue. Irrigating an infected wound with higher flow (but <15 psi) selectively debrides necrotic tissue while protecting healthy tissue.

a. Ensure any undermining or tunneling is irrigated as well.
b. Repeat the irrigation until the solution returns clear.
Flushing removes exudate, debris, and some surface bacteria.

12. Remove the basin or sterile container from the base of the wound.

13. Gently pat the skin surrounding the wound dry with sterile gauze, beginning at the top of the wound and working downward.
Moisture on the surrounding tissue may lead to maceration and further breakdown of the wound margins.

14. Dress the wound as prescribed.

15. Consider applying a waterproof skin protectant around the wound if drainage is heavy.
Wound drainage contains irritating chemicals that can damage healthy tissues, especially at the wound edge and surrounding skin. Solutions used to keep the wound bed moist can also macerate or damage healthy skin if allowed to remain on intact skin.

16. Dispose of the contaminated irrigation fluid in a biohazardous receptacle.
Contaminated fluid should is biohazardous waste.

17. Remove soiled drapes from the patient area.

18. Remove your gloves, face shield, and gown. Dispose of these items appropriately.
Contaminants from the irrigation may be present on these items, and they should also be considered biohazardous.

19. Reposition the patient to a comfortable position. Change any linen that may have become wet during the procedure.

20. Wash your hands.
Hand hygiene prevents cross-contamination.

? What if . . .

- **The client has a wound covering a large area of the body?**

  A general rule is that the larger the wound, the more solution needed to clean it.
  The purpose of cleansing a wound is to remove bacteria and debris by flushing the wound.

- **Peroxide or another antiseptic solution is prescribed?**

  First, identify the reason that the solution was ordered for the wound type. Then identify the length of time it is to be used. Weigh the benefit of using the solution with the potential risks to healing tissues. Finally, discuss any concerns with the healthcare provider.
  Peroxide is indicated more for acute, traumatic wounds to remove dirt and other debris. Peroxide and other commercial antiseptics can damage fibroblasts and cause air embolism if used to forcefully irrigate or pack a tunneling wound. Fibroblasts produce collagen, the major structural protein of skin and healing tissues.

(continued on next page)

Procedure 35-2 ■ Performing a Sterile Wound Irrigation (continued)

Evaluation

- Determine whether the patient remains comfortable. If not, medicate according to prescriptions.
- Reassess the wound at regular intervals.

Patient Teaching

- Answer any questions the patient may have.
- Teach the patient about the expected healing process.
- Inform the patient and caregiver about signs and symptoms of infection and the need to report these findings.

Home Care

- Wound irrigation is commonly done in the home. In most cases, clean technique is used in the home setting.
- Irrigation solutions, such as saline, can be made and stored up to 7 days if refrigerated.
- Review with the family proper disposal of contaminated supplies.

Documentation

Document the following information (many agencies use a wound/skin flowsheet):

- Appearance and location of the wound, size, tissue in wound base, periwound tissue, type and amount of exudate, and odor, if present, after irrigation. A photograph is an accurate method for documenting the condition of a wound.
- The patient's pain level. If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Method by which the wound was cleansed
- Dressing reapplied to the wound, if applicable
- Education provided to the patient

Sample documentation

mm/dd/yyyy 0800 *Dressing change to sacral wound using modified sterile technique due to saturation of old dressing with serous drainage. Patient premedicated with Lortab 5 mg PO 30 minutes prior to dressing change. Wound irrigated with normal saline using 19-gauge needle-less angiocatheter and 35-cc syringe. Wound re-packed with saline-moistened fluffed gauze and ABD to cover. Healing Stage IV pressure ulcer with 100% granulation tissue to the wound bed; 4 X 3.5 cm, with 1 cm of undermining at 6:00; copious serous drainage though no odor was noted. Periwound is slightly macerated; therefore zinc- based barrier cream applied for protection. Patient reported no pain with procedure. Will continue to monitor and change dressing as needed.* —— L. Syzmanski, RN

Practice Resources

Fernandez, R., & Griffiths, R. (2012); ICSI (2012); Myers, B. A. (2011); Rolstad, B. S., & Ovington, L. G. (2011); Wilkins, R. G., & Unverdorben, M. (2013); Wound, Ostomy and Continence Nurses Society (WOCNS) (2010).

Procedure 35-3 ■ Taping a Dressing

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonsterile gloves
- Tape (cloth, plastic, foam, silk-like, etc.)

Delegation

As a nurse, you are responsible for assessing the wound and evaluating interventions. However, this procedure may be delegated to nursing assistive personnel (NAP).

Pre-Procedure Assessments

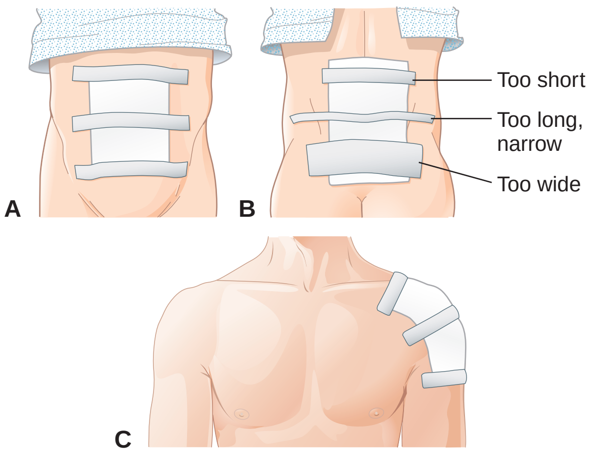
- Assess the degree of importance of the dressing.
  The more critical the dressing, the more adhesion required.
- Assess the characteristics of the dressing material, weight and conformability, and the device or tubing to be held.
  Heavier dressings require higher adhesion. Bulky dressings may need high conformability or greater adhesion.
- Assess the skin surface (i.e., dry, damp, diaphoretic, oily, hairy, edematous, fragile, or impaired skin integrity).
  Fragile skin may require less adhesion while damp or oily skin may require higher adhesion.
- Assess the anticipated wear time.
  Tape adhesion gets stronger over time. Breathable tapes can be used longer. Occlusive plastic tapes build up moisture and are used when adhesion is intended for a shorter period of time.

- Assess the patient's history and current medical conditions.
  Review allergies or sensitivities to tapes. Review medical conditions that may be affected by adhesives.
- Assess for activity level of the patient and the anticipated length of time the dressing will be needed.
  The more active the patient is, the more adhesion will be required.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Wash your hands. Don gloves.**
2. **Choose the type of tape** based on wound size, location, amount of drainage or edema, frequency of dressing changes, patient's activity level, and type of dressings used.
   Tapes come in many different adhesive types and backings. Select the tape based on individual characteristics.
   a. Choose tape of the width that is appropriate for the dressing. The larger the dressing, the wider the tape needed for securing.
   For example, a large abdominal dressing may require 3-inch tape, whereas a small incision on an extremity may need only ½-inch tape.
   b. Choose a tape that stretches if the area is at risk for distention, edema, hematoma formation, or movement.
   Skin distention under tape may cause blistering or skin tears.
3. **Tear strips that extend** 1 to 1½ inches beyond the dressing, depending on the size of the dressing.
   To anchor the dressing to the skin.
4. **Place the tape perpendicular** to the incision.
   Fewer skin tension injuries occur with perpendicular taping.
   a. When taping over joints, apply the tape at a right angle to the direction of joint movement, or at a right angle to a body crease. For example, tape a shoulder or knee horizontally, not lengthwise.
   b. Apply tape with an even amount tension on both sides, being careful not to pull at the edges.
   This reduces the risk of skin damage.
5. **Smooth tape in place** with your fingertips.
   To maximize the tape's adhesion to the skin surface.
6. **Replace tape if site becomes** edematous, or the skin is not intact.



? What if . . .

- **The tape will not adhere to the patient's skin because of excess hair?**
  Remove the hair with clippers or scissors. Do not shave the site with a razor.
  Shaving can cause nicks or abrasions to the skin that could become a portal of entry for bacteria.
- **The patient's skin is diaphoretic or excessively oily?**
  Cleanse the skin with soap and water before the dressing change. Allow the skin to dry before applying the dressing and tape. You may also use polymer skin barriers to place a seal over the skin and allow the tape adhesive to adhere.
- **The patient has fragile skin (e.g., is an older adult)?**
  Use skin sealant preparations under adhesives. Use the least adhesive product possible.
  The junction between the epidermis and dermis on the older adult is not as strong as it is in a younger person.
- **The patient is allergic to tape adhesives?**
  Use hypoallergenic products.
  Circular wraps, ace bandages, or other such products may be used to secure dressings.

(continued on next page)

Procedure 35-3 ■ Taping a Dressing (continued)

Evaluation

- Verify type of tape that is appropriate for the patient and dressing.
- Note whether the tape adheres comfortably to the skin.
- Ensure that the patient verbalized understanding of the treatment.
- Inspect the dressing daily for intactness, edema, or hematoma.

Patient Teaching

- Teach the patient about the expected healing process.
- Educate the patient about the purpose of the procedure.
- Instruct the patient to keep the dressing dry.

Documentation

Document the following information (many agencies use a wound/skin flowsheet):

- Type of dressing and tape applied
- Location and characteristics of wound
- Education given to patient

Sample documentation

2/16/15 0800 Dressing applied to left hip incision using conformable cloth tape. Wound edges are well approximated with no drainage noted. Periwound skin is dry and intact without erythema, induration, or odor. Wound cleaned with normal saline using sterile technique. Educated patient about the purpose of the dressing and expected course for wound healing. Will continue to monitor ——————— B. Hopkins, RN

Procedure 35-4 ■ Removing and Applying Dry Dressings

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

➤ *Note:* This procedure uses clean technique because wound care is now usually performed using clean rather than sterile technique.

Equipment

- Three pairs of clean nonsterile gloves
- Normal saline solution for irrigation, warmed to body temperature when possible
  Cold solution lowers the temperature of wound bed and slows the healing process.
- Tray of sterile 4 in. × 4 in. gauze.
- Sterile gauze for dressings
- Tape
- Adhesive removal pads

Delegation

This procedure requires knowledge of wound healing. It should be performed by a registered nurse. Do not delegate this skill.

Pre-Procedure Assessments

Note: When you begin, the wound will likely be covered with a dressing. You will make these assessments when you remove the soiled dressing *and* after cleansing the wound.

- Assess for pain at least 30 minutes before performing the procedure.
  Wounds may be very painful. Provide pain medication 30 minutes before performing the procedure if needed, to allow the medication time to be distributed in target tissues. Changes in the quality or severity of pain are some symptoms linked with infection.
- Assess the type and amount of exudate.
  Exudate may be a sign of infection.
- Assess the wound for odor.
  A foul odor may indicate infection. Clean wounds before you assess for odor, because some dressings interact with wound drainage to produce an odor.
- Assess the tissue surrounding the wound edge.
  Surrounding tissue that is red, warm, and/or edematous may indicate infection.
- Determine the type of dressing needed.
  The type of dressing depends on the characteristics of the wound and the goal of treatment. Dry dressings are appropriate when there is no need to keep the wound bed moist, such as a wound healing by primary intention or a wound covered by eschar.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps for Removing the Dressing

1. **Place the patient in a** comfortable position that provides easy access to the wound.
Provides for patient comfort and proper nurse body mechanics during dressing change.

2. **Wash your hands**, and don clean nonsterile gloves.
Handwashing is one of the most important measures for preventing infection transmission.

3. **Gently loosen the edges of the tape** of the old dressing at an angle parallel to the skin.
   a. Hold that edge with one hand and gently raise the edge until it is taut, but not pulling on the skin.
   b. Using your other hand, push down on the exposed skin at the point where the tape and skin meet. Push the skin off of the tape. Adhesive remover pads are advised to help prevent tearing of fragile skin
   The pull–push method will help prevent skin stripping from the adhesive and reduce discomfort and skin trauma as you remove the tape.

4. **Beginning at the edges** of the dressing, lift the dressing toward the center of the wound. If the dressing sticks, moisten it with normal saline before removing it completely.
Moistening the dressing decreases the risk of bleeding and/or removal of granulating tissue.

5. **Assess the type and amount** of drainage on the soiled dressing.
Allows for evaluation of wound healing. Purulent drainage is an indication of infection.

6. **Dispose of the soiled** dressing and gloves in a biohazard receptacle.
Soiled dressings contain bodily fluids and other contaminants and should be disposed of as biohazardous waste.

7. **Remove the cover of a tray** of sterile 4 in. × 4 in. gauze. Moisten the gauze with sterile saline.
The sterile container tray is impermeable and allows you to moisten the gauze while maintaining sterility. Gauze will not shed fibers into the wound (as do cotton balls). Fibers and any other foreign bodies in a wound promote inflammation and delay healing.

8. **Don clean nonsterile gloves.**

9. **Gather a gauze pad** by pulling the four corners up toward the middle. Use the center ball of the gauze to cleanse the wound.
Forming a ball with the gauze pads prevents contamination of gloved hands during cleansing.

10. **Gently cleanse the wound** with the saline-moistened gauze by lightly wiping a section of the wound from the center toward the wound edge. Discard the gauze in a biohazard receptacle, and repeat in the next section using a new piece of gauze with each wiping pass.
Removes surface bacteria and exudate.

11. **Discard the gloves** and soiled gauze into a biohazard bag.

12. **Reassess wound** for size, color of tissue present, amount and type of exudate, and odor.

Procedure Steps for Applying Dry Dressing

13. **Wash your hands**, or use an antiseptic hand rub at the bedside.

14. **Open sterile gauze packages** on a clean, dry surface.
Maintains sterility of gauze.

15. **Don clean nonsterile gloves.**

16. **Apply a layer of dry dressings** over the wound. If drainage is expected, use an additional layer of dressings.
The first layer serves as a wick for drainage. A second layer is needed if increased absorption is required.

17. **Place strips of tape at the ends** of the dressing and evenly spaced over the remainder of the dressing. Use strips that are sufficiently long to secure the dressing in place. Tape the dressing around all edges, "window paning," if appropriate.
Edges remain taped down and dressing stays intact.

18. **Remove gloves**, and discard them in a biohazard receptacle.

19. **Assist the patient** to a comfortable position.

? What if . . .

- **Signs of infection are noted with wound assessment?**
  Notify the healthcare provider. Cultures, wound care interventions, and potentially even antibiotics may be required.

- **The wound is not approximated?**
  Place the patient in a supine position, apply adhesive skin closures and cover with sterile saline dressings. Notify primary healthcare provider.
  This could indicate wound dehiscence.

- **The skin surrounding the incision is not intact?**
  Clean the area with sterile saline, dry thoroughly, and apply protective moisture barrier dressing. Consider using Montgomery straps.
  Montgomery straps are useful when dressings must be changed frequently because they do not cause trauma to the skin.

- **A drain or drainage tube is present?**
  Always clean the drain site after cleaning the primary incision site.
  Reduces the risk of cross-contamination.

(continued on next page)

Procedure 35-4 ■ Removing and Applying Dry Dressings (continued)

Evaluation

- Determine whether the dressing is clean, dry, and intact.
- Verify that the patient experienced minimal discomfort during the procedure.

Patient Teaching

- Teach the patient about the expected healing process.
- Inform the patient and caregiver about the signs and symptoms of infection and the need to report these findings.

Home Care

- Help the client to store dressings appropriately to keep them clean, for example, in a plastic container with a lid.
- Teach the client or caregivers to dispose of contaminated dressings and gloves by double-bagging them in moisture-proof bags (e.g., plastic grocery bags).
- Advise the client and family whether they can get the wound wet (e.g., during bathing). If it must be kept dry, demonstrate how to cover it with a waterproof barrier (e.g., a plastic bag).

Documentation

Document the following information (many agencies use a wound/skin flowsheet):

- Appearance and location of the wound, type and amount of exudate, and odor, if present, after cleansing
- The patient's pain level before the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Method of cleansing the wound
- Type of dressing applied to the wound
- Education provided to the patient

Sample documentation

10/22/15 1420 Pt with no report of pain. Gauze dressing removed from lateral aspect of right forearm without difficulty. No drainage noted on gauze. Surrounding skin intact. Abrasion on right, lateral forearm cleansed with normal saline. Sterile gauze dressing reapplied to wound and anchored with cloth tape. Pt instructed to report any change at wound site, such as bleeding, drainage, or increase in pain ———————— D. Enferma, RN

Practice Resources

Armstrong, D. G., & Meyer, A. J. (updated 2014, January 28).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Removing and Applying Dry Dressings.**

For questions and suggested responses,

Go to Chapter 35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 35-5 ■ Removing and Applying Wet-to-Damp Dressings

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

➤ *Note:* This procedure uses clean technique because wound care is now usually done using a clean or modified sterile approach rather than sterile technique. However, sterile technique is recommended for wounds that have recently had sharp debridement, have a drain, or are fresh surgical wounds. Sterile technique might also be used for patients with immunodeficiency.

Equipment

- Three pairs of clean nonsterile gloves
- Sterile or clean solution, typically saline or distilled water (in the hospital setting), warmed to body temperature when possible.
  Cold solution reduces the temperature of the wound bed and slows the healing process.
- Water-resistant disposable drapes
- Sterile fine-mesh gauze in a tray for dressing
- Surgipad
- Tape or Montgomery straps
- Adhesive removal pads

Delegation

This is an invasive procedure that requires knowledge of wound healing. It should be performed by a registered nurse. Do not delegate this skill to nursing assistive personnel (NAP).

Pre-Procedure Assessment

Note: When you begin, the wound will likely be covered with a dressing. You will make these assessments when you remove the soiled dressing *and* after cleansing the wound.

- Assess the amount and type of tissue present in the wound bed.

Granulating tissue is beefy red with a velvety appearance. It appears with the growth of new blood vessels and connective tissue. Pale pink tissue may indicate compromised blood supply to the wound bed. Necrotic tissue, which is black, brown, or yellow in appearance, is nonviable and inhibits healing.

- Assess the type and amount of exudate.
  Exudate may be a sign of infection.
- Assess the wound for odor.
  A foul odor may indicate infection. Clean wounds before you assess for odor, because some dressings interact with wound drainage to produce an odor.
- Assess the tissue surrounding the wound edge.
  Surrounding tissue that is red, warm, and/or edematous may indicate infection.
- Assess for pain.
  Wounds may be very painful. Assess for pain and provide prescribed pain medication 30 minutes before performing procedure, if needed. A change in the quality or intensity of pain may be a sign of infection.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps for Removing the Wet-to-Damp Dressing

1. **Place the patient** in a comfortable position that provides easy access to the wound.
   Provides for patient comfort during dressing change.
2. **Wash your hands**, and don clean nonsterile gloves.
   Handwashing complies with standard precautions, helping to prevent transfer of pathogens.
3. **Gently loosen the edges** of the tape of the old dressing. Hold that edge with one hand and gently raise the edge until it is taut, but not pulling on the skin. Using your other hand, push down on the exposed skin at the point where the tape and skin meet. Push the skin off of the tape. Use adhesive remover pads to avoid tearing fragile skin.
   The pull–push method will help prevent skin stripping from the adhesive and reduce discomfort and skin trauma as you remove the tape.
4. **Beginning with the top layer,** lift the dressing from the corner toward the center of the wound. If the dressing sticks, moisten it with normal saline or bacteriostatic water before completely removing it. Remove first from one side of the wound, first toward the wound, and then from the other side. Continue to remove layers until you have removed the entire dressing.
   Moistening the dressing decreases the risk of bleeding and/or removal of granulating tissue.

5. **Assess the type and amount** of drainage present on the soiled dressing.
   Type of drainage is an indication of the stage of healing. Purulent drainage is an indication of infection.
6. **Dispose of the soiled dressing** and gloves in a biohazard container. Wash your hands.
   Soiled dressings contain body fluid contaminants and should be disposed of as biohazardous waste.
7. **Remove the cover of a tray** of sterile 4 in. × 4 in. gauze. Moisten the gauze with sterile saline or water.
   The sterile container tray is impermeable and allows you to moisten the gauze while maintaining sterility. Gauze will not shed fibers into the wound (as do cotton balls). Fibers and any other foreign bodies in a wound promote inflammation and delay healing.
8. **Don clean procedure gloves.**
   Avoids introducing microorganisms into the wound.
9. **Gather a gauze pad** by pulling the four corners up toward the middle. Use the center of the gauze to cleanse the wound.
   Prevents contamination of your gloves during wound cleansing.
10. **Using gauze moistened** with saline or potable water gently wipe a section of the wound from the center toward the wound edge. Discard the gauze in a biohazard receptacle, and repeat in the next section using a new piece of gauze with each wiping pass.
    Removes surface bacteria and exudate. Prevents transfer of microorganisms from the skin to the wound.
11. **Reassess the wound** for location, amount of tissue present, exudate, and odor.
    Allows for determination of most effective treatment and type of dressing.
12. **Discard the gloves** and soiled gauze into a biohazard bag. Perform hand hygiene.
    Soiled gauze contains contaminants and should be disposed of as biohazardous waste.

Procedure Steps for Applying a Wet-to-Damp Dressing

13. **Open a sterile gauze pack tray** and a surgipad. The amount of gauze you use depends on the size of the wound.
    Maintains sterile field and supplies.

(continued on next page)

Procedure 35-5 ■ Removing and Applying Wet-to-Damp Dressings (continued)

14. Moisten sterile gauze with saline solution or potable water for irrigation.

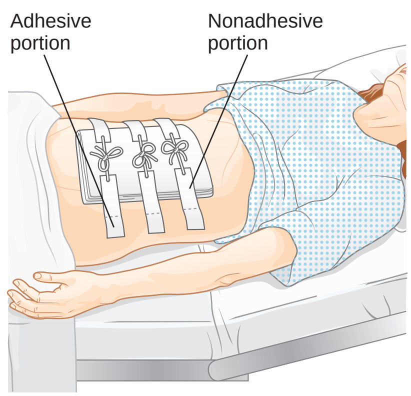
15. Don clean nonsterile gloves.

16. Squeeze out excess moisture from the gauze. Apply a single layer of moist, fine-mesh gauze to the wound. Be sure to place gauze in all depressions or crevices of the wound. You may need to use forceps or a cotton applicator to ensure that you fill deep depressions or sinus tracts with gauze. "Fluff" the mesh gauze before placing in the wound so as it dries it acts as a wick for any drainage.
Maintains a moist environment for the wound bed.

17. Apply a secondary moist layer over the first layer. Repeat this process until the wound is completely filled with moistened sterile gauze—but do not tightly *pack* the gauze into the wound. Do not extend the moist dressing onto the surrounding skin.
Packing the gauze tightly can restrict blood flow to the area. Moist dressings on the surrounding skin can cause maceration.

18. Cover the moistened gauze with a surgipad.
Protects the wound from external contaminants.

19. Secure the dressing with tape or Montgomery straps.
Montgomery straps are useful when dressings must be frequently changed because they do not cause trauma to the skin.



Montgomery straps

20. Dispose of gloves and materials in the biohazard waste receptacle. Perform hand hygiene and date and time the dressing.

21. Assist the patient to a comfortable position.

? What if . . .

- **Gauze becomes dry between dressing changes?**
  Moisten dressings with sterile saline before removing them; change dressing more frequently; consider using a semi-occlusive dressing.
  A moistened dressing prevents debridement of granulating tissue, maintains a moist environment, and prevents tissue injury. Dressings that become too dry will injure healthy tissue and impair healing.

- **The patient has multiple wounds?**
  The most infected wound should be treated last. Remember to always change your gloves in between wound dressing changes.
  The risk of cross-contamination is reduced when moving from clean to dirty and with fresh gloves.

Evaluation

- Evaluate whether the patient experiences pain with the procedure and afterward.
- Note whether the patient verbalizes understanding of the procedure.

Patient Teaching

- Teach the patient about the expected healing process.
- Inform the patient and caregiver about signs and symptoms of infection and the need to report these findings.

Home Care

- Help the client store dressings appropriately to keep them clean, for example, in a plastic container with a lid.
- Teach the client or caregivers to dispose of contaminated dressings and gloves by double-bagging them in moisture-proof bags (e.g., plastic grocery bags).
- Advise the client and family whether they can get the wound wet (e.g., during bathing). If it must be kept dry, demonstrate how to cover it with a waterproof barrier (e.g., a plastic bag).

Documentation

Document the following information (many agencies use a wound/skin flowsheet):

- Appearance and location of the wound, type and amount of exudate, and odor, if present, after cleansing
- The patient's pain level before and after the procedure
- Pain medication given including the dose, time, your name, and the patient's response.
- Method of cleansing the wound
- Type of dressing applied to the wound
- Education provided to the patient

Sample documentation

09/20/15 2120 Red granulating tissue noted throughout the wound bed of a stage IV pressure ulcer on sacrum. No tunneling or undermining observed. Minimal amount of serosanguineous drainage on old dressing. Wound cleansed with normal saline prior to application of new dressing. Wet-to-damp dressing applied. Pt tolerated procedure well with no verbalization of pain throughout procedure. Pt placed on 2-hr turn schedule and educated about pressure relief measures. Pt reports understanding.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Removing and Applying Wet-to-Damp Dressings.**

For questions and suggested responses,

Go to Chapter 35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 35-6 ■ Applying a Negative Pressure Wound Therapy (NPWT) Device

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Suction unit (pump)
- Collection canister with connecting tubing
- Open-pore reticulated polyurethane foam dressing
- Semipermeable transparent adhesive dressing
- Skin preparation product or sealant (skin prep)
- Sterile 4 in. × 4 in. gauze
- Clean nonsterile gloves
- Two pairs of sterile gloves (if using sterile technique)
- Sterile scissors (if using sterile technique)
- Waterproof pad
- Bath blanket
- Goggles or safety glasses, mask, and protective gown
- 10- to 20-mL irrigation syringe
- Normal saline for irrigation
- Emesis basis
- Biohazard bag for contaminated materials

Procedure 35-6A Open-Pore Reticulated Polyurethane Form Therapy . . .

- GranuFoam (black), white or silver foam dressing
- Therapeutic regulated accurate care (TRAC) pad

Procedure 35-6B Gauze Dressing Application (i.e., Chariker–Jeter Dressing Method)

- Fenestrated drain
- Ostomy paste

Delegation

As a nurse, you are responsible for assessing the wound and evaluating interventions. You should not delegate application of a negative pressure wound therapy device to a NAP. However, you may ask the NAP to report to you any changes in the wound dressing, pressure in the unit, or alarms.

Pre-Procedure Assessments

- Assess the type of wound to be treated with negative pressure.
  Negative pressure wound therapy is used to promote wound healing by secondary or tertiary intention in acute, chronic, traumatic, and dehisced wounds; partial-thickness burns; or flaps and grafts. NPWT will prepare the wound bed for closure, reduce edema, promote granulation formation, and remove exudate and infective material.
- Determine if there is any contraindication to use of a NPWT: nonenteric or unexplored fistulas; necrotic tissue with eschar; untreated osteomyelitis; malignancy in the wound or in exposed blood vessels, anastomosis sites, organs, or nerves.
- Assess patients for active or prolonged bleeding; patients who are on anticoagulant therapy or platelet aggregation inhibitors; or patients with infected, damaged, irradiated, or sutured blood vessels.
  Patients who are at increased risk for bleeding should be closely monitored. These conditions could be fatal if negative pressure is

(continued on next page)

Procedure 35-6 ■ Applying a Negative Pressure Wound Therapy (NPWT) Device (continued)

applied and bleeding is uncontrolled (exsanguination could occur). Notify the healthcare provider of these conditions.

- Assess the wound for bone fragments or sharp edges.
  When NPWT is activated, mechanical stress is placed upon the wound. Sharp edges or bone may puncture protective barriers, vessels, or organs, causing injury, and bleeding, if uncontrolled, could be fatal.
- Assess the wound for infection.
  Monitor infected wounds closely, as they may require more frequent dressing changes than noninfected wounds.
- Assess the wound for size (length, width, and depth in centimeters); location and depth of undermining or tunneling; amount, character, and odor of drainage; type and percentage of tissue present in wound bed (granulation, slough, fibrin, necrotic); and periwound condition (i.e., intact, denuded, erythema, induration, or maceration).
  If no response or improvement in the wound condition occurs in 2 weeks, use of NPWT should be reevaluated.
- Assess the patient's nutritional status.
  Adequate protein stores are needed for wounds to heal. Evaluate the patient's albumin or prealbumin level before initiating therapy, as NPWT may deplete these levels and prevent healing.
- Assess for pain.
  Wound care is very painful. Poorly controlled wound pain can lead to wound bed hypoxia. This impairs wound healing and increases infection rates. Wound pain also negatively affects the patient's quality of life.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* The success of NPWT partially depends on the training and expertise of the clinician. Allow adequate time for this procedure. Experienced nurses need at least 15 to 30 minutes. You will need more time if problems arise, and even more if you are a novice.

➤ *Note:* This procedure assumes you are performing the initial application of V.A.C. therapy. If you are changing the dressing, first read the What If . . . section near the end of this procedure.

Procedure Steps

1. **Consider administering pain** medication before initiating negative pressure wound therapy.
   Allow sufficient time for the medication to take effect.

2. **Select the appropriate dressing** (per NPWT system used) to fill the entire wound cavity.
   Dressings should be placed directly against the wound surface to allow for equal suction/pressure throughout the wound bed.

3. **Obtain suction pump** unit as prescribed.
   Negative pressure wound therapy is provided by several different manufacturers. Use the unit and dressing method that is approved by your facility.
   a. Place the suction unit upright on a level surface.
   b. Remove the canister from the sterile package and insert it into the pump.
   c. Connect the tubing to the canister.
   d. Ensure the opposite end of the tubing remains clean before connecting with the tubing from the dressing.
   e. You may place the suction unit at the end of the bed or hang it on an IV pole.
   f. Do not place the unit on the floor. Ensure the unit is not knocked over, as drainage from the canister can back up and contaminate the pump's filter, blocking suction.

4. **Place the waterproof bag** or trash receptacle so you can reach it easily during the procedure.
   Convenient placement facilitates access to safe disposal of the dressing into a trash receptacle for biohazardous waste.

5. **Assist the patient** to a comfortable position that allows for easy access to the wound.
   Facilitates access to the wound site with less contamination and promotes good body mechanics for the nurse.

6. **Drape the patient** (use a bath blanket if needed) to expose only the wound area.
   Draping provides privacy and emotional comfort.

7. **Place a waterproof pad** as needed.
   An underpad protects the linens from moisture and drainage.

8. **Prepare a sterile or clean field,** and add all supplies: gloves, scissors, irrigation supplies, gauze pad, selected wound dressings, tubing, and/or connectors.

9. **Don sterile or clean procedure gloves.** Use a gown and protective eyewear.
   Using sterile/aseptic versus clean technique is based on the wound type, physician preference, or facility protocol. A safe rule to follow is to use sterile gloves for a fresh noninfected wound and clean gloves for other wounds.

10. **Irrigate the wound** with 10 to 30 mL of sterile saline or other prescribed solution before all dressing changes. Use a 35-mL syringe and a 19-gauge angiocatheter (needle removed) to direct the flow of the irrigation fluid from the clean end toward the dirty end of the wound.
    Irrigation facilitates loosening of adherent tissue and removes debris and exudate while adhering to infection control principles of clean-to-dirty.

11. **Remove the excess solution** from the wound. Clean and dry the periwound skin with sterile gauze

sponges, as needed. Consider a skin protectant around the wound edges.
Excess moisture predisposes skin to maceration and possible damage. Applying a skin protectant can assist the drape in sticking to the skin, and protecting the skin when the drape is removed (i.e., from stripping of skin by the adhesive).

12. **Remove soiled gloves** and don new sterile ones for the procedure.
Change gloves during patient care if the hands will move from a contaminated body site (e.g., perineal area or wound) to a clean body site.

13. **To apply appropriate dressing** per preferred negative pressure wound therapy unit, follow Procedure 35-6A or 35-6B.

Procedure 35-6A ■ Open-Pore Reticulated Polyurethane Foam Therapy (i.e., Vacuum-Assisted Closure [V.A.C.])

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Begin with Procedure Steps 1 through 13, at the beginning of Procedure 35-6. Then proceed as follows.

1. **Select the appropriate foam dressing**: black, white, or silver.
Black foam is sufficient for most wounds unless individual patient circumstances require white or silver. White foam is denser and will limit granulation formation. It may be used for painful or superficial wounds, tunneling/sinus tracts/undermining, or where granulation tissue growth needs to be limited. Silver dressings may act as a barrier to bacterial penetration in the wound bed. Silver may eradicate biofilms of colonized bacteria.

2. **Cut the foam dressing** to the appropriate size to fill the wound cavity. Do not cut the foam dressing over the wound. Rub the cut edges to remove any loose pieces.
If you cut the foam over the wound, particles may fall into the wound and create irritation

3. **Gently place the foam** dressing into the cavity without overlapping onto intact skin. Do not overfill the cavity or pack into deep crevices.
   a. Do not place foam into blind/unexplored tunnels.
   Forcing foam dressings into any area may damage tissue, alter the delivery of negative pressure, or hinder exudates or foam removal.
   b. Do not allow foam dressing to overlap onto healthy skin.
   Foam dressing becomes very wet during therapy and will macerate and damage intact skin.
   c. If you use more than one piece, note the total number of pieces that were placed into the wound so you can document them on the transparent dressing and in the patient record.
   An accurate record of the number of foam pieces is necessary to prevent retained material within the wound.

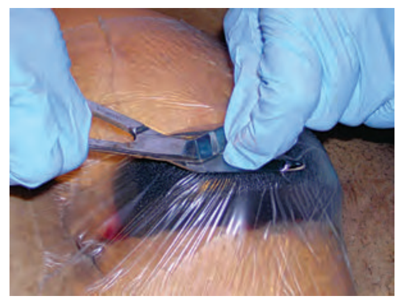
4. **Apply a liquid skin preparation** product to periwound, if needed.
Skin preps can protect the periwound skin from excess fluid, adhesive stripping, or other damage.

5. **Apply transparent film/drape** 3 to 5 cm (1 to 2 in.) from wound margins without pulling, stretching, or wrinkling the drape. Do not push down or compress foam while placing drape.
The occlusive dressing creates a seal to help create negative pressure within the wound. Tension from pulling, stretching, or wrinkling the dressing may lead to tissue injury. More pressure will be placed on the wound bed than necessary if you have flattened the foam before turning on the suction unit.

6. **Avoid placing dressings** that wrap all the way around an extremity. If necessary, place several smaller pieces of drape rather than one continuous piece.
When pressure is applied, a circumferential dressing may interfere with circulation, if wrapped too tightly.

7. **Identify a site over the dressing** for the suction track tubing apparatus.

8. **Pinch up a piece of drape** and cut at least a 2-cm round hole. Do not make a slit or X, as this may close off under pressure.



9. **Place the track adhesive** and suction device directly over the hole in the drape and apply gentle pressure to secure.
Negative pressure removes excess wound exudate from the wound bed.

10. **Connect suction track tubing** to the canister tubing and open clamps. The canister is attached to a vacuum pump that provides either continuous or intermittent negative pressure, adjusted for the type of

(continued on next page)

Procedure 35-6 ■ Applying a Negative Pressure Wound Therapy (NPWT) Device (continued)

wound. Set suction to the prescribed pressure, which is typically in the range of –5 to –125 mm Hg (adjustable pressures, depending on the particular device used).
Suction draws excess exudate away from the wound and into an evacuation container.

11. **Connect tubing from the dressing** to the suction track tubing going to the collection canister.
Allows for collection and measurement of drainage.

12. **Position the tubing** and connector away from bony prominences and skin creases.
Prevents pressure injury to the skin.

13. **Ensure clamps are open** on all tubing.

14. **Turn on power to the pump** and set to the prescribed therapy settings to initiate therapy.
Therapy should be maintained for at least 22 out of 24 hours daily. Alternate wound care should be considered if the vacuum cannot be tolerated for this length of time.

15. **Listen for audible leaks** and observe dressing collapse or wrinkling as pressure is applied to the wound bed.
With an adequate seal, the dressing will collapse almost immediately. Any leak (i.e., between the dressing and drape, around tubing, at skin crevices, or at tubing connection sites) will prevent collapse.

16. **Change the canister** at least once a week or when filled. Write the date on the canister.
This will help to know when it was changed last as well as how often it is being changed for fluid loss.

Procedure 35-6B ■ Gauze Dressing Application (i.e., Chariker–Jeter Method)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Begin with Steps 1 through 13, at the beginning of Procedure 35-6. Then proceed as follows.

1. **Measure the length of drain** from wound margin, starting with the first hole perforation and pull back 1 cm.
2. **Moisten gauze** with normal saline.
3. **Wrap or "sandwich" the drain** in the moistened gauze and place in the wound base. Tuck gauze into any undermining areas to ensure contact with the wound bed.
4. **Apply a strip or small amount of ostomy paste** 1 cm from the wound edge and secure the drain as needed.
Paste is occlusive and will help maintain a seal between the drain and the transparent film dressing. Paste that is too close to the wound edge can get sucked into the drain, and occlude pressure.
5. **Apply liquid skin preparation** product to periwound, if needed. Extra drape, hydrocolloid, or transparent dressing may be used to protect fragile skin.
Skin preps can protect the periwound skin from excess fluid, adhesive stripping, or other damage.
6. **Apply transparent film** approximately 1.0 to 2.5 cm (½ to 1 in.) beyond the wound margin to intact skin. Pinch the film around the drain tubing to ensure a tight seal.
7. **Avoid wrapping dressings** around an extremity. If necessary, place several smaller pieces of drape rather than one continuous piece.
When pressure is applied, a circumferential dressing may interfere with circulation.
8. **Attach filter tubing** to the canister spout.
9. **Connect tubing** from the dressing to the evacuation tubing going to the collection canister.
Allows for collection and measurement of drainage.

10. **Position the tubing** and connector away from bony prominences and skin creases.
Prevents pressure injury to the skin.
11. **Ensure clamps are open** on all tubing.
12. **Turn on power to pump** and set to the prescribed therapy settings to initiate therapy.
Therapy should be maintained for at least 22 out of 24 hours daily. Alternate wound care should be considered if suction cannot be tolerated for this length of time.
13. **Listen for audible leaks** and observe dressing collapse as pressure is applied to the wound bed.
With an adequate seal, the dressing will collapse almost immediately. Any leak (i.e., between the dressing and drape, around tubing, at skin crevices, or at tubing connection sites) will prevent collapse.

14. **Change the canister** at least once a week or when filled. Write the date on the canister.
This will help to know when it was changed last as well as how often it is being changed for fluid loss.

What if . . .

- **You are changing the dressing instead of applying it for the first time.**

Follow the procedure steps below. *Note:* Dressings should be changed every 48 to 72 hours.
Dressings left in the wound longer than the recommended time frame can become difficult to remove if tissue grows into the foam, or can lead to infection or other adverse events.

a. Evaluate the need for analgesia.
b. Turn the suction pump unit off during the procedure.
c. Place a waterproof, biohazard pad under the body part requiring the dressing change.
d. Perform hand hygiene and don sterile or clean gloves as appropriate.
e. Remove the transparent dressing, using a push–pull method to gently pull up drape while pushing it slowly from the skin. Separating the drape from the skin in this manner will decrease the risk of tape stripping.
f. Gently remove gauze or foam dressing. If dressing is difficult to remove, instill normal saline onto the dressing for 15 to 30 minutes.
Dressing removal can damage new granulation tissue if tissue has grown into the dressing.
g. Count all pieces of gauze or foam dressing that were removed to ensure none remain in the wound bed. Ensure no dressing is left in tunneled or undermined areas.
Dressings are not bioabsorbable and can abscess if left in the wound.
h. Discard soiled dressings in a biohazardous waste receptacle.
i. Start at the beginning of Procedure 35-6 and perform Steps 1 through 13. Then, as instructed in Step 13, follow either Procedure 35-6A or 35-6B.

- **After 2 weeks, you see that the wound is not improving?**

Consult with the healthcare provider or a wound care specialist. Average length of therapy is usually 4 to 6 weeks. Therapy should be discontinued if the wound shows no improvement in 1 to 2 consecutive weeks, the patient is unwilling or unable to follow the medical plan, or the goal of therapy has been met.
The longer a wound is open, the longer it takes to heal, and places the patient at risk for complications. A steady decrease in wound size should be seen every week. If NPWT is not effective, alternate wound care should be evaluated.

- **You cannot find or remove a piece of foam?**

Notify the healthcare provider, as this may necessitate surgery.
The material could be retained in the patient and create an inflammatory response.

- **There is a foul odor when the dressing is removed?**

Clean the wound with normal saline to ensure odor is not emanating from the soiled dressing. If other signs of infection are present (i.e., fever, tenderness, redness, swelling, purulent drainage), notify the healthcare provider.

- **Suction cannot be maintained?**

Identify why the seal cannot be maintained. If the wound is very near the coccyx and gluteal fold, use a dollop of paste to help fill in the crack and maintain a seal. If the skin around the wound is moist, adhesive drape will not adhere to skin. Use a skin prep product or drape to protect the skin. If the tube is pulling away from the dressing or tension is being placed on the tube, anchor it with additional drape or tape several centimeters from the dressing or wound.

- **The canister is filling with blood?**

Immediately discontinue negative pressure therapy. The gauze or foam dressing will not stop the bleeding, so take measures to control bleeding (i.e., hold pressure on wound). Do not remove dressing until the treating healthcare provider is consulted.

- **Dressing does not collapse or the alarm sounds?**

a. Press firmly around the transparent dressing to seal.
b. Verify the machine is turned on, and all clamps are open and tubing is not kinked.
c. Check tubing and drape for leaks. Listen for leaks with a stethoscope or by moving your hand around the wound margins while applying slight pressure.
d. Additional small pieces of transparent dressing may be used to seal around hardware, skinfold, or creases.
e. Do not place multiple layers of drape or adhesive dressing.
Several layers may decrease the dressing's moisture vapor transmission rate, increasing the risk of maceration.
f. Never leave foam in place without an adequate seal for more than 2 hours. If an adequate seal cannot be achieved in that time, remove the foam and apply a saline moistened gauze dressing.

(continued on next page)

Procedure 35-6 ■ Applying a Negative Pressure Wound Therapy (NPWT) Device (continued)

Evaluation

- Note the patient's response to the procedure.
- Continue to monitor wound healing and changes in periwound tissues.
- Monitor dressing every 2 hours to ensure it is firm and collapsed in the wound bed while therapy is on.
- Monitor the seal of the dressing and pressure settings.
- Monitor for brisk or bright bleeding, evisceration or dehiscence, and symptoms of infection.
  These must be reported to the healthcare provider.

Home Care

- Refer the client to a home health agency for wound care.
- In limited circumstances, some patients or caregivers may be able to perform dressing changes. Determine their ability to perform dressing changes; teach and demonstrate as needed.
- Instruct the patient or family to visually check the dressing every 2 hours to ensure it is firm and collapsed in the wound bed.
- Review safety labeling, alarms, and pump instructions.
- Review conditions in which to seek medical care: bleeding, infection, unresolved alarms, or loss of suction.
- Review proper disposal of contaminated supplies.

Documentation

Document the following information:

- Date and time of dressing change
- Wound assessment: location of the wound, size (length, width, diameter), undermining or tunneling, amount and character of drainage, odor, wound bed including type and percentage of tissue seen, and periwound appearance
- Evaluation of therapy with evidence of healing
- Treatment selected: type of NPWT, type of gauze or foam, number of pieces placed in the wound
- Treatment settings: pressures, intermittent vs. continuous, or variable pressures
- Patient response to dressing change

Sample documentation for Procedure 35-6B: Chariker-Jeter Dressing Application

9/13/15. 1010 Patient reported pain rating 5 on a scale of 1 to 10. Administered hydrocodone 5.0 mg PO for pain at 0815 before initiation of negative wound pressure therapy. See MAR. Stage IV pressure ulcer to coccyx surgically debrided. Wound is 4 × 6 × 2 with no appreciable undermining. Wound bed is now clean of necrotic tissue with 100% pink tissue noted. Periwound has 2 cm of erythema to wound edges. Scant malodorous serosanguineous drainage. Using sterile technique, moistened saline gauze applied to wound bed with fenestrated drain. Ostomy paste applied at wound edge to assist in seal. Pump activated to 80 mm Hg continuous pressure. Patient rated pain in wound area as a 2 post-procedure. Plan: Begin dressing changes every 48 hours.
———————— L. Opperta, RN

Practice Resources

Chariker, M. (2009); Gabriel, A., & Schraga, E. D. (2013, updated); McCulloch, J. M., & Kloth, L. C. (2010); Moore, C., & Young, J., 2011); NCG (2006, revised 2011); Sullivan, N., Snyder, D. L., Tipton, K., et al. (2009).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Open-Pore Reticulated Polyurethane Foam Therapy (i.e., Vacuum-Assisted Closure [V.A.C.]).**

For questions and suggested responses,

Go to Chapter 35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 35-7 ■ Applying and Removing a Transparent Film Dressing

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Clean nonsterile gloves
- Sterile gauze
- Normal saline solution or specified cleansing agent, warmed to body temperature when possible
  Cold solution lowers the temperature of the wound bed and slows the healing process.
- Scissors (if needed)
- Liquid skin preparation (if needed)
- Transparent film dressing

Delegation

Because assessment of the wound and knowledge of clean technique are important, you should not delegate this procedure to a NAP.

Pre-Procedure Assessment

- Assess the area to determine whether a transparent film dressing is appropriate.
  Transparent film dressings are indicated as primary dressings (dressings that touch the wound or area to be treated) to protect high-risk intact skin; for superficial or partial-thickness wounds that have little to no drainage (i.e., stage I or II pressure ulcers); and to assist in debriding eschar by autolysis. Films may be used as a secondary dressing to protect other types of dressings from bodily fluids (i.e., wounds near the perineum).
- Assess the wound to determine if use of a transparent film is contraindicated.
  Films are contraindicated in third-degree burns, arterial ulcers, and infected wounds. Films should not be used to fill dead space.
- Determine the size of the wound.
  Film dressings are available in many sizes. Select the appropriate size based on wound measurements, allowing for a 2.5 cm (1 in.) perimeter of intact skin around the wound for the adhesive to stick.
- Assess the periwound area.
  Film dressings should be attached to intact skin. The adhesive is not waterproof and will not adhere to wet or moist skin.

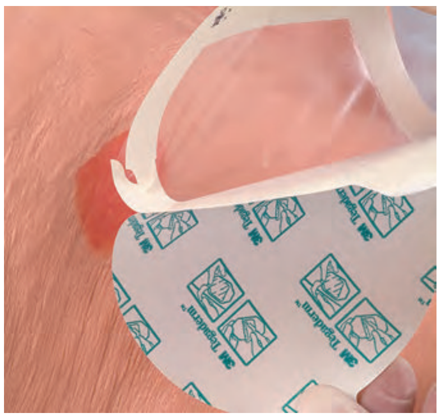
➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Place the patient in a** comfortable position that provides easy access to the wound.

Procedure Steps for Applying the Dressing

2. **If a dressing is present, wash your hands,** don clean nonsterile gloves, and remove the old dressing.
3. **Dispose of the soiled dressing** and gloves in the biohazard waste receptacle.
   Observe universal precautions, preventing transfer of pathogens.
4. **Don clean nonsterile gloves,** and cleanse the skin surrounding the wound with normal saline or a mild cleansing agent. Be sure to rinse the skin well if you use a cleanser. Allow the skin to dry.
   Cleansing prepares the skin for application of the dressing. Skin must be dry for the dressing to adhere.
5. **Cleanse the wound** as prescribed or according to agency procedure.
   Cleansing of wounds removes bacteria and necrotic debris from wound beds.
6. **Consider placing a skin barrier** around the wound before transparent film dressing application.
   Skin sealants may be applied to skin before tape to protect fragile skin from tears or epidermal stripping.
7. **Remove the center backing liner** from the transparent film dressing. ▼



8. **Holding the dressing by the edges,** apply the transparent film to the wound without stretching or pulling the dressing or the skin.
   This reduces the risk of skin damage.
9. **Remove the edging liner** from the dressing.
10. **Gently smooth and secure** the dressing to skin.
    Allows the dressing to adhere fully to the patient's skin.
11. **Dispose of soiled equipment,** and remove your gloves.

Procedure Steps for Removing the Dressing

Transparent film dressings are typically changed every 3 days. Change dressing sooner if drainage extends beyond the edges of the wound onto periwound skin. To remove the dressing, do the following:

12. **Grasp one edge** of the film dressing.
13. **Gently lift the edge.**
14. **Stabilize the skin** underneath the elevated edge with your finger.
    Stabilizing the skin as the adhesive is taken off will prevent epidermal stripping.
15. **With the other hand,** slowly peel the dressing back over itself, "low and slow," in the direction of hair growth. Use of an adhesive removal pad is recommended especially for sensitive skin.
    Removing the dressing at an angle will increase the risk of pulling on the epidermis and causing mechanical trauma.
16. **As dressing is removed,** keep moving your finger as necessary to avoid newly exposed skin.

? What if . . .

- **The adhesive will not adhere to the patient's skin because of excess hair?**
  Hair may be removed with clippers/scissors. Do not shave the site with a razor.
  Shaving can cause nicks or abrasions to the skin that could become a portal of entry for bacteria.

(continued on next page)

Procedure 35-7 ■ Applying and Removing a Transparent Film Dressing (continued)

- **The patient's skin is diaphoretic or excessively oily?**

  Cleanse the skin with soap and water before the dressing change. Allow the skin to dry before continuing with the dressing. Also, polymer skin barriers may be used to place a seal over the skin and allow the tape adhesive to adhere.

- **The patient has fragile skin (e.g., an elderly patient)?**

  Skin sealant preparations may be used under adhesives.

  The junction between the epidermis and dermis on the older adult is not as strong as with a younger person. Less pressure or tension is needed to break those bonds and cause skin damage.

- **The dressing sticks to itself before it can be applied?**

  If a small portion of the dressing is stuck to itself, gently stretch or pull the edges in opposite directions. If a large portion is involved, throw the dressing away and start over.

  Transparent dressings can be difficult to apply because they are polyurethane sheets coated on one side with an acrylic, hypoallergenic adhesive and are flimsy in nature, making them clumsy to work with at times.

- **Purulent-appearing fluid has collected underneath the film dressing?**

  This does not necessarily mean the wound is infected. Remove the dressing and clean the wound per policy. Select an alternate dressing that will be more absorptive.

  Because films do not have absorptive capabilities, any drainage produced by the wound will pool underneath.

Evaluation

- Verify the transparent film dressing is appropriate for the wound.
- Determine whether the dressing adheres comfortably to skin.
- Ensure that patient verbalizes understanding of treatment.

Patient Teaching

- Teach the patient about the expected healing process.
- Teaching the patient about the use of transparent film dressings.
- Inform the patient and caregiver about signs and symptoms of infection and the need to report these findings.

Documentation

Document the following information (many agencies use a wound/skin flowsheet):

- Wound assessment: location of the wound, size (length × width × diameter) undermining or tunneling, amount and character of drainage, odor, wound bed including type and percentage of tissue seen, and periwound appearance
- Appearance and location of the wound, type and amount of exudate, and odor, if present, after cleansing
- The patient's pain level before the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and the patient's response to analgesia.
- Method of cleansing the wound and surrounding skin
- Type of dressing applied to the wound
- Education provided to the patient

Sample documentation

2/22/15 2230 Transparent film dressing applied to stage I pressure ulcer on left lateral heel, 1 × 1 cm. Area is nonblanchable and painful to the touch. Cleaned with normal saline before dressing applied. Heel protectors placed bilaterally to keep heels suspended off the surface of the bed. Discussed pressure ulcer formation with patient, and the need to rotate positions and relieve heel pressure. Will continue to assist patient in turning every 2 hours.

———————— M. K. Leonard, RN

Practice Resources

Association of periOperative Registered Nurses (AORN) (2013); Rolstad, B. S., & Ovington, L. G. (2011).

Procedure 35-8 ■ Applying a Hydrating Dressing (Hydrocolloid or Hydrogel)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Clean nonsterile gloves
- Hydrating dressing 3 to 4 cm (1.5 in.) larger than the wound
- Moisture-proof bag

Obtain the following items, only if needed:

- Normal saline solution warmed to body temperature when possible
  Cold solution lowers the temperature of wound bed and slows the healing process.
- Emesis basin
- Sterile gauze for cleansing
- Disposable clippers or scissors (to trim hair or dressing)
- Skin prep
- Measuring device
- Tape

Delegation

This procedure requires knowledge of wound healing, dressings, and infection control and prevention. You should not delegate this procedure to a NAP.

Pre-Procedure Assessments

- Assess the area to determine whether a hydrating dressing is appropriate.
  Hydrating dressings are appropriate for wounds with minimal drainage. These dressings autolytically debride necrotic tissue from the wound bed. They may also be used to protect skin at risk for breakdown.
- Determine the size of the wound.
  Allows you to select a dressing of the appropriate size. Choosing a dressing size that extends beyond the ulcer ensures complete coverage.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Place the patient** in a comfortable position that provides easy access to the wound.
   Provides for patient comfort and proper nurse body mechanics during dressing change.

2. **If a dressing is present, wash your hands**, don clean nonsterile gloves, and remove the old dressing.
   Prevents transfer of pathogens.

3. **Dispose of the soiled dressing** and gloves in the biohazard waste receptacle.
   Dressings may contain body fluids and other contaminants, so they must be disposed of in moisture-proof containers.

4. **Wash your hands.** Don nonsterile gloves, and cleanse the skin surrounding the wound with normal saline or a mild cleansing agent. Be sure to rinse the skin well if you use a cleanser. Allow the skin to dry. Do not attempt to remove residue that is left on the skin from the old dressing.
   Cleansing and drying prepare the skin for application of the dressing. Removing residue irritates the surrounding skin.

5. **Apply skin prep** to the area covered by tape.
   Skin prep protects intact skin from breakdown from tape removal.

6. **Cleanse the wound as directed.** Wound cleansing may be performed with clean or sterile technique, depending on the type of wound.
   Cleansing the wound removes microbes and necrotic debris from wound bed. Studies show using either saline or tap water is similarly effective for cleansing.

7. **Remove soiled gloves**, and assess the condition of the wound. Note the size, location, type of tissue present, amount of exudate, and odor.
   Granulating tissue is beefy red with a velvety appearance. It appears with the growth of new blood vessels and connective tissue. Pale pink tissue may indicate compromised blood supply to the wound bed. Necrotic tissue, which is black, brown, or yellow in appearance, is nonviable and inhibits healing. A hydrocolloid dressing will interact with wound drainage to produce a thick, yellow gel that may have a foul odor. Clean the wound before assessing for exudate and odor.

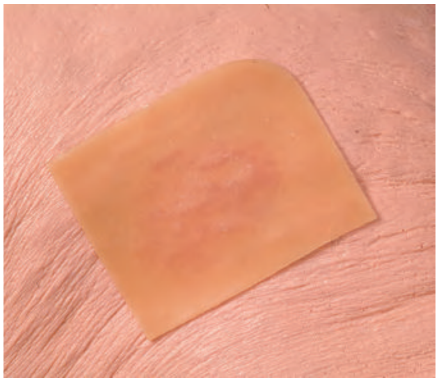
8. **With the backing still intact,** cut the hydrating dressing, if necessary, to the desired shape and size. Size the hydrocolloid dressing so it will extend 3 to 4 cm (1.5 in.) beyond the wound margin on all sides and cover all areas of nonintact skin.
   Provides complete coverage of the wound.

9. **Don clean nonsterile gloves**, and remove the backing of the hydrocolloid dressing, starting at one edge. Place the exposed adhesive portion on the patient's skin. Position the dressing to cover the wound. ▼

(continued on next page)

Procedure 35-8 ■ Applying a Hydrating Dressing (Hydrocolloid or Hydrogel) (continued)

10. Gradually peel away the remaining liner, and smooth the hydrocolloid dressing onto the skin by placing your hand on top of dressing and holding in place for 1 minute. *Warmth helps the dressing adhere to the skin.*



11. Assist the patient to a comfortable position, and remove your gloves. Wash your hands.

What if . . .

- **Signs of infection are noted?**

  Notify healthcare provider. Cultures may be prescribed. A different type of dressing may be prescribed, as well.

- **The surrounding skin is not intact?**

  Choose a larger size hydrocolloid dressing to cover the nonintact area. Document your observations and report new findings to the healthcare provider.

Evaluation

- Verify that a hydrocolloid dressing is still appropriate for the wound.
- Note whether the dressing adheres comfortably to the skin.
- Ensure the patient verbalizes understanding of treatment.
- Inspect the dressing daily. Change it if it becomes dislodged, leaks, or wrinkles or if it develops an odor.

Patient Teaching

- Teach the patient about the expected healing process.
- Inform the patient and caregiver about signs and symptoms of infection and the need to report these findings.

Home Care

- Hydrating dressings may be required in the home setting. Teach caregivers to use the appropriate size and change the dressing if it begins to leak, develops an odor, or begins to separate from the skin.

Documentation

Document the following information (many agencies use wound care flowsheets):

- Appearance and location of the wound, type and amount of exudate, and odor, if present, after cleansing. Include wound measurements, if taken, and condition of surrounding skin.
- The patient's pain level before the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Method of cleansing the wound and surrounding skin
- Type of dressing applied to the wound
- Use of skin prep
- Education provided to the patient

Sample documentation

11/19/15 2230 Pt medicated with ibuprofen 600 mg by mouth for mild wound pain post-op. Pain rated as a 4 out of 10 prior to dressing change. Soiled hydrocolloid dressing removed from shear injury to left mid-scapular area. Wound cleansed with sterile saline and gauze. Shear is 3.5 X 4 cm and 100% covered with yellow slough. Moderate amount of nonodorous, serous drainage. Hydrocolloid reapplied as prescribed. Pain with no complaint of increase in pain. Educated pt. about autolytic action of hydrocolloid, plan of care, and expected outcomes for wound healing. ——————— S. Terril, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Applying a Hydrating Dressing (Hydrocolloid or Hydrogel).**

For questions and suggested responses,

Go to Chapter 35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 35-9 ■ Placing Skin Closures

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Adhesive skin closures
- Tincture of benzoin or skin protectant pads
- Forceps
- Normal saline
- Gauze
- Gloves (sterile if indicated)

Delegation

This procedure may be delegated to a NAP with the required training unless it is a new wound requiring sterile technique or has developed complications (e.g., dehiscence). Assessment of the incision line or wound is a licensed professional's responsibility and cannot be delegated.

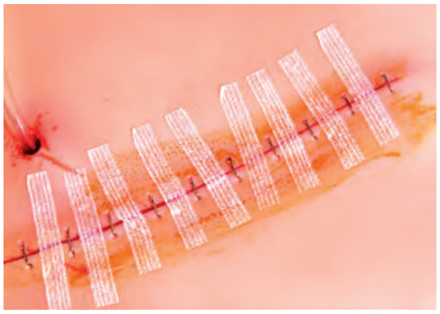
Pre-Procedure Assessments

- Assess the type of wound to be closed.
  Adhesive closures are frequently used to keep surgical incisions well approximated. They may be used in conjunction with staples or sutures or following early staple/suture removal. Closures may be used to approximate the edges of lacerations or skin tears.
- Assess the wound for skin edge approximation.
  Wounds that are gaping or appear to have undermining should not be closed using adhesive closures.
- Assess the wound for drainage, amount, type, and odor.
  Wounds that are draining heavily might not be suitable for adhesive skin closures because the adhesive would not stick to the skin.
- Assess the periwound area or surrounding skin. Assessment should include skin color, texture, temperature, and integrity of the surrounding skin. Look for maceration (caused by heavy drainage), excoriation (from caustic effluent), stripping (from inappropriate adhesive removal), pustules, papules, or lesions.
  Adhesive closures should be placed only on intact skin.
- Assess the length of the wound, the location (over a joint), or if edema may occur, to determine the size of the skin closure used. Consider elastic skin closures if distention or movement is anticipated.
  Closures come in several different lengths, widths, and flexibility capabilities to meet elasticity and conformability needs.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Don clean nonsterile** gloves.
   Gloving prevents cross-contamination.
2. **Cleanse the skin** at least 5 cm (2 in.) around the wound with saline-moistened gauze. Pat the skin dry, allowing it to dry thoroughly.
   The skin surrounding the wound must be clean and dry in order for the strips to adhere.
3. **Apply a skin preparation product**, and allow it to dry (or follow agency procedures). Avoid benzoin on fragile skin.
   Because the strips are prone to peeling off with moisture, benzoin enhances adhesion of the strips.
4. **Do not allow skin preparation** product to come into contact with the wound.
   It may impair healing.
5. **Peel back package tabs** to access the adhesive closures.
6. **Remove the card** from the package using modified sterile technique as necessary.
   Careful technique should be followed when applying to a surgical wound to minimize contamination and promote healing.
7. **Grasp end of the skin closure** with forceps or gloved hand and peel strip from the card at a 90° angle.
   Closures lifted at a lesser angle or directly back on themselves may "curl," complicating handling.
8. **Starting at the middle** of the wound, apply strips perpendicular to the wound, drawing the wound edges together. Apply closures without tension; do not stretch or strap closures.
   a. Apply half of the closure to the wound margin and press firmly in place.
   b. Using fingers or forceps, ensure skin edges are approximated.
   c. Press free half firmly on the other side of the wound in a ladder fashion.
   d. Place the strips so that they extend at least 2 to 3 cm (¾ to 1 in.) on either side of the wound to ensure closure.
   e. Place the wound closure strips 3 mm (⅛ in.) apart along the wound. ▼



(continued on next page)

Procedure 35-9 ■ Placing Skin Closures (continued)

? What if . . .

- **A flap of skin rolls up on the edges?**

  Cleanse the wound with normal saline and reapproximate the edges of the skin flap with the intact epidermis. Apply skin closures across the flap.
- **The skin around the wound is swollen?**

  Apply skin closures without tension, and reapply as swelling increases.

  This prevents pulling on the skin that can delay healing or disrupt the approximated borders of the wound, which is more likely to lead to scarring.
- **Edges are not accurately approximated or tension has been placed on the skin?**

  Remove the closure over the affected area, peeling each side toward the wound, and reapply.

  Use of adhesive products can cause superficial skin damage if the skin is stretched during application or with edema formation. Tension blisters are the most common problem associated with taping.

Evaluation

- Verify that skin closures are appropriate for the wound.
- Note whether the closures adhere comfortably to the skin.
- Ensure the patient verbalized understanding of the treatment.
- Inspect the wound daily. Lifted closure edges may be trimmed or closures replaced if less than half of the strip remains.

Patient Teaching

- Teach the patient about the expected healing process.
- Inform the patient or caregiver about signs and symptoms of infection and the need to report these findings.
- Instruct patients not to pull or tug on the strips.
  Improper removal may damage the underlying skin or the wound itself.
- Instruct patients that they do not need to keep the strips dry. They can bathe and shower as directed by the health-care provider.
- Instruct the patient that adhesive strips are often kept in place until they begin to separate from the skin on their own.

Documentation

Document the following information (many agencies use specialized wound care flowsheets):

- Appearance and location of the wound, type and amount of exudates, and odor, if present, after cleansing
- The patient's level of pain before the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and the patient response to analgesia.
- Method of cleansing the wound and surrounding skin
- Type of skin closures applied
- Education provided to the patient

Sample documentation

02/08/16 2040 Skin closures applied to surgical incision along right forearm. Wound edges are well approximated with slight erythema noted 4 mm from incisional site. Periwound skin is dry and intact with no drainage, induration, or odor noted. Wound cleansed with normal saline using sterile technique. Patient educated on the purpose of the closures and expected time and course of healing. Will continue to monitor. ———— S. Wong, RN

Procedure 35-10 ■ Applying Binders

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Abdominal binder, triangular arm binder, or T-binder
- Clean nonsterile gloves
- Measuring tape

Delegation

This procedure may be delegated to a NAP. Assessment of the incision line or wound is a licensed professional's responsibility and cannot be delegated.

Pre-Procedure Assessments

- Assess the condition of the wound (if one is present). Note the amount and type of drainage. A wound must be dressed before it is bandaged; if there is a significant amount of exudate, you will need to apply a secondary dressing.
- Assess for pain, and check the circulation of the underlying body parts before and after applying the binder. Look for cool, pale, or cyanotic skin, tingling, and numbness.
- Determine whether the patient or family has the skills to reapply the binder when necessary.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ Observe Steps 1 through 7, regardless of the type of binder you use:

Procedure Steps

1. Choose a binder of the proper size.

2. Wash hands. Don nonsterile gloves.

3. Thoroughly clean and dry the part to be covered.
Moisture contributes to skin breakdown.

4. Place the body part in its natural comfortable position (e.g., with the joint slightly flexed) whenever possible.
Prevents strain on ligaments and muscles.

5. Pad between skin surfaces (e.g., under the axilla) and over bony prominences.
Prevents pressure and abrasion of the skin.

6. Fasten from the bottom up, especially for abdominal binders.

Make sure the binder is secured with enough pressure to provide the needed support and control bleeding, but not so tightly as to compromise circulation or impair breathing.

Fastening from the bottom up gives upward support

7. Change binders whenever they become soiled or wet.

Proceed to Step 8, 14, or 20, depending on the type of binder you are using.

Procedure Variation: Applying an Abdominal Binder

8. Measure the patient for the abdominal binder.
   a. Place the patient in supine position.
   b. With a measuring tape, encircle the abdomen at the level of the umbilicus. Note the measurement. This is the length of the binder.

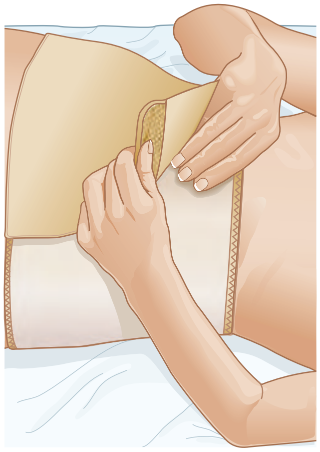
   c. Measure the distance from the costal margin to the top of the iliac crests. This is the width of the binder.
   d. Dispose of gloves and measuring tape, and wash your hands.
   e. Based on the measurements, obtain an abdominal binder.

9. Assist the patient to roll to one side. Roll one end of the binder to the center mark. Place the rolled section of the abdominal binder underneath the patient. Position the binder appropriately between the costal margin and iliac crest.

10. Make sure the binder does not slip upward or downward.
If the binder is positioned too high, it could impair lung expansion and gas exchange. If it is positioned too low, the binder will not provide adequate support.

11. Assist the patient to turn to the other side as you unroll the binder from underneath him. Pad any pressure areas or skin abrasions to avoid pressure injury.

12. With your dominant hand, grasp the end of the binder on the side furthest from you, and steadily pull toward the center of the patient's abdomen. With your nondominant hand, grasp the end of binder closest to you, and pull toward the center. Overlap the ends of the binder so that the hook and loop fasteners (e.g., Velcro) meet.



(continued on next page)

Procedure 35-10 ■ Applying Binders (continued)

13. Assess the abdominal binder every 2 to 3 hours. Observe that the binder has not shifted up or down or compromised the patient's breathing. Remove it to assess the underlying skin and dressings. Change wound dressings if they are soiled, or as prescribed.

Procedure Variation: Applying a Triangular Arm Binder

A triangular arm binder or sling is used to support the upper extremities. Obtain a commercial sling (consisting of a sleeve for the arm and a strap to go around the neck) or a triangular piece of fabric. To form a splint from a triangular cloth, follow these steps:

14. Ask the patient to place the affected arm in a natural position across the chest, elbow flexed slightly.
Slight flexion prevents swelling of the hand and relieves pressure on the shoulder.

15. Place one end of the triangle over the shoulder of the uninjured arm, and allow the triangle to fall open so that the elbow of the injured arm is at the apex of the triangle.

16. Move the sling behind the injured arm.

17. Pull up the lower corner of the triangle over the injured arm to the shoulder of the injured arm.

18. Tie the sling with a square knot at the neck on the side of the arm requiring support.
A square knot will not slip and is easy to untie.

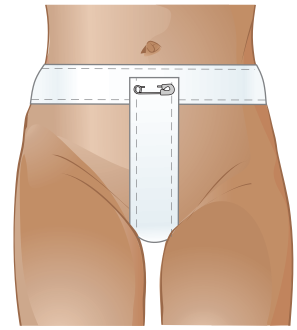
19. Adjust the injured arm within the sling.
To ensure patient comfort.

Procedure Variation: Applying a T-Binder

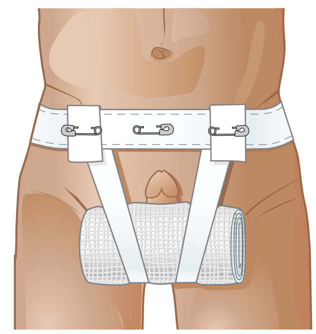
A T-binder is used to secure dressings or pads in the perineal area. A single T-binder is often used for women. A double T-binder is most commonly used for men. To apply a T-binder, follow these steps:

20. Position the waist tails under the patient at the natural waistline. Bring the right and left tails together, and secure them at the waist with pins or clips.

21. For a single T-binder, bring the center tail up between the legs of the patient. Secure the tail at the waist with pins or clips.



22. For a double T-binder, bring the tails up on either side of the penis. Secure the tail at the waist with pins or clips.



23. Fasten the ties at the waist using pins or clips.

? What if . . .

- **The patient is obese?**
  Obtain the appropriate size binder before applying. Do not try to position a binder that is too small for the patient.
  A poorly fitting binder can constrict circulation, cause pressure points that can injure the skin, and can restrict movement of the chest for adequate breathing. A binder that is too tight is uncomfortable and it will not provide the proper support of an incision or wound needed for healing.

Evaluation

- Evaluate whether the patient's physical condition has changed since using the binder.
- Assess circulation to be sure the binder is not secured too tightly. Check color, warmth, tingling, sensation, and capillary refill.
- Assess the depth of breathing to be sure the binder is not restricting ventilation.
- Check the skin under the binder to be sure there are no areas of irritation, pressure, or skin abrasion.
- Assess incisions or wounds under the binder to be sure they are not bleeding and are healing properly.
- Monitor comfort regularly.
- Assess the client's ability to perform ADLs while wearing the binder.

Home Care

- Teach the client and/or caregiver how to apply the binder in the proper position, snugly but not too tightly.
- Teach the family to inspect the site under the binder to be sure the skin is not pinched or with other points of pressure. This is especially crucial for older adults.
- Clean binders in warm, soapy water when soiled. Use a mesh laundry bag to keep the Velcro® straps from catching other clothing in the washer. Air dry thoroughly. Clients should have two binders at home—a clean one to wear while the other is laundered.
- Apply and remove binder to promote comfort and ensure good circulation. This also allows the patient and caregiver to inspect any incision or wound underneath.
- Binders for children at home could be decorated with permanent marking pens.
- Allow children to help with applying and removing the binder.

Documentation

Document the following information (many agencies use specialized wound care flowsheets):

- Appearance and location of the wound or incision under the binder, type and amount of exudates, and odor, if present, after cleansing
- Pain level before and after the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Type of binder applied
- Date and time the binder was applied and removed
- Any change in the appearance of the wound or skin in contact with the binder
- Education provided to the patient

Sample documentation

01/23/16 1230 Abdominal binder applied. Vertical abdominal incision with dressing dry and intact. No sign of active bleeding or wound drainage noted. Oral pain medication given approximately 30 minutes before applying binder (see MAR). Pt reported pain at level 3 on a scale of 1 to 10 while applying binder but improved to a 1 afterward. No report of pressure points. Pt instructed to call if the binder feels too tight or too loose. ——————— C. Marano, RN

Procedure 35-11 ■ Applying Bandages

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Appropriate bandage dressing
- Clean nonsterile gloves (2 pairs)
- Gauze sponges
- Normal saline
- Primary dressing (as prescribed)
- Scissors
- Tape or metal closures

Delegation

This procedure may be delegated to a NAP who has the appropriate training. Assessment of the incision line or wound is a licensed professional's responsibility and cannot be delegated.

Pre-Procedure Assessment

- Determine the body part or area to be bandaged.
  This allows you to choose the correct width of gauze or elastic bandage to use.
- Assess the condition of the wound (if one is present). Assess size (length, width, and depth in centimeters); location and depth of undermining or tunneling; amount, character, and odor of drainage; type and percentage of tissue present in wound bed (granulation, slough, fibrin, necrotic); and periwound condition (intact, denuded, erythema, induration, or maceration)
  Wound dressings should be chosen based on the characteristics of the wound.
- Assess for pain, and check the circulation of the underlying body parts before and after applying the bandage. Look for cool, pale, or cyanotic skin, tingling, and numbness.
  Circulation to an extremity can be compromised if the bandage is too tight or the extremity swells after application.
- Determine whether the client or family has the skills to reapply the bandage when necessary.
  Teaching might be needed for home care.

(continued on next page)

Procedure 35-11 ■ Applying Bandages (continued)

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Observe the following steps, regardless of the type of bandage you use:

1. **Choose a bandage** of the proper width. For example, use a 2.5-cm (1-in.) wide bandage for a finger, a 5-cm (2-in.) wide bandage for an arm, and a wider bandage for a leg.
Prevents pressure and abrasion of the skin.

2. **Thoroughly clean and dry** the part to be covered. Use a nontoxic cleansing solution, such as normal saline.
Cleaning the wound removes debris, exudates, and bacteria. Drainage and moisture on the skin contribute to irritation.

3. **Remove excess moisture** by gently patting the wound and surrounding skin with gauze sponge.
Drainage and moisture contribute to skin breakdown.

4. **Stand facing the patient.**
In this position you can wrap the bandage evenly in the proper direction.

5. **Bandage the body part** in a comfortable position (e.g., with the joint slightly flexed), whenever possible.
This prevents strain on ligaments and muscles. Movement of the extremity (extension) may cause skin damage if the bandage is too tight or the extremity is not properly positioned.

6. **Always work from distal** to proximal (or peripheral to central).
This improves venous return and helps to prevent edema.

7. **If a wound is present,** apply a primary dressing, as prescribed, over the wound.
A primary dressing is any dressing that is placed first in the wound bed. It provides exudates absorption, holds medications in place, provides antimicrobial coverage, or maintains a moist wound bed.

8. **Apply the bandage** with enough pressure to provide the needed support, but do not bandage too tightly. Make sure circulation to the area is not compromised.

9. **If possible, leave the fingers** (if you are bandaging an arm) or toes (if you are bandaging a leg or foot) exposed so that you can assess the circulation to the extremity. Begin the wrap along the pad of the foot or hand, just under the first bend of the toes or fingers (metatarsal or metacarpal joints).

10. **Begin the wrap** with the bandage against the skin. Unwind the bandage as if rolling it over the extremity.
This helps to keep the bandage snug against the skin.

11. **Pad bony prominences** before bandaging if there are pressure concerns.

12. **Change bandages** whenever they become soiled or wet from external sources (stool, urine, etc.) and internal sources (drainage that has wicked on the outer surface of the bandage).
Wound drainage contains chemicals, enzymes, and bacteria that can damage fragile healing tissues.

13. **After bandaging, assess** circulation and comfort regularly.

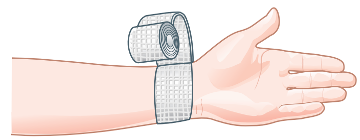
Proceed to Step 14, 16, 19, 25, or 28, depending on the type of bandaging you are using.

Procedure Variation Circular Turns

Use this technique to wrap a finger or toe, or as an anchor at the beginning and end of another wrapping technique.

14. **With one hand, hold one end** of the bandage in place. With the other hand, encircle the body part two times with the bandage—the second wrap should partially cover the first wrap. Continue to wrap the body part by overlapping two-thirds of the width of the bandage.

15. **Secure the bandage** with tape or metal clips when you are finished, if circular turns are not being combined with another technique.



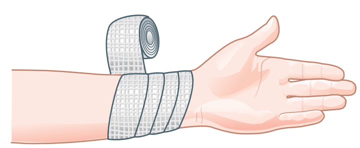
Procedure Variation Spiral Turns

Spiral turns are a variation of the circular turn technique. Spiral turns are most commonly used to wrap an extremity.

16. **Anchor the bandage** by making two circular turns—the second wrap completely covering the first one.

17. **Continue to wrap** the extremity by encircling the body part with each turn angled at approximately 30° so that you are overlapping the preceding wrap by two-thirds the width of the bandage.

18. **Complete the wrap** by making two circular turns and securing the bandage with tape or metal clips.



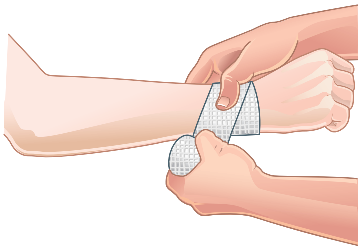
Procedure Variation Spiral Reverse Turns

Spiral reverse turns are used to bandage cylindrical body parts that are not uniform in size.

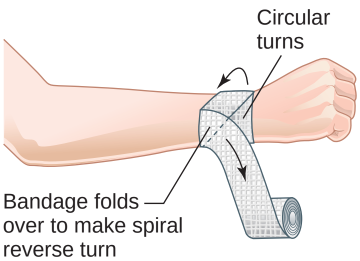
19. **Anchor the bandage** by making two circular turns.

20. **Bring the next wrap up** at a 30° angle.

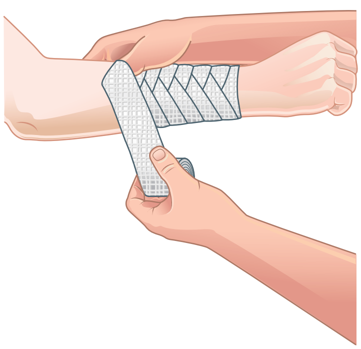
21. **Place the thumb** of your nondominant hand on the wrap to hold the bandage. ➤



22. **Fold the bandage back on itself**, and continue to wrap at a 30° angle in the opposite direction.



23. **Continue to wrap the bandage**, overlapping each turn by two-thirds. Align each bandage turn at the same position on the extremity.



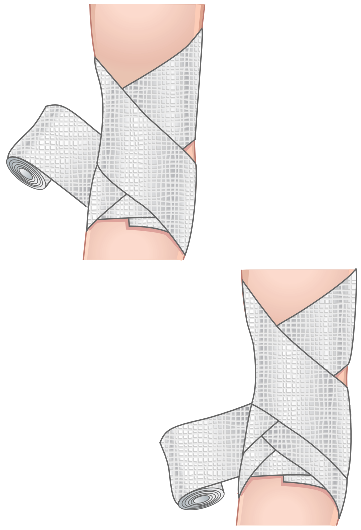
24. **Complete the wrap** by making two circular turns and securing the bandage with tape or metal clips.

Procedure Variation Figure-8 Turns

The figure-8 wrap is used on joints (e.g., ankle, elbow).

25. **Anchor the bandage** by making two circular turns.

26. **Wrap the bandage** by ascending above the joint and descending below the joint to form a figure 8. Continue to wrap the bandage, overlapping each turn by two-thirds. Align each bandage turn at the same position on the extremity.

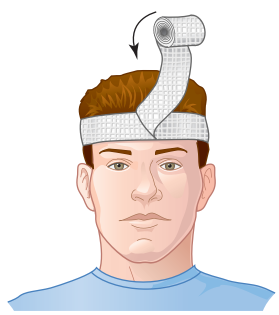


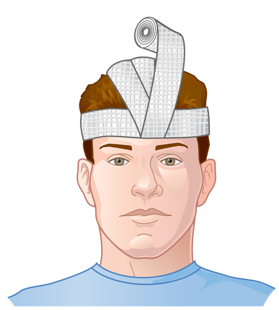
27. **Complete the wrap** by making two circular turns and securing the bandage with tape or metal clips.

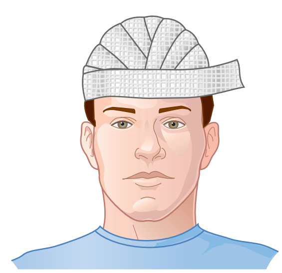
Procedure Variation Recurrent Turns

28. **Anchor the bandage** by making two circular turns.

29. **Fold the bandage back on itself;** hold it against the body part with one hand. With the other hand, make a half turn perpendicular to the circle turns and central to the distal end being bandaged.







30. **Hold the central turn** with one hand, and fold the bandage back on itself; bring it over the distal end of the body part to the right of the center, overlapping the center turn by two-thirds the width of the bandage.

31. **Next, hold the bandage** at the center with one hand as you bring the bandage back over the end to the left of center. Continue holding and folding the bandage back on itself, alternating right and left until the body part is covered. Overlap by two-thirds the bandage width with each turn.

32. **Start and return each turn** to the midline or center of the body part, and angle it slightly more each time to continue covering the body part.

33. **Complete the bandage** by making two circular turns and securing the bandage with tape or metal clips.

? What if . . .

- **Drainage breaks through the outer bandage more frequently than expected?**

  Determine the cause of the drainage if possible (i.e., is it blood or serum?). Increased drainage may be a sign of infection and should be evaluated. You might need to change the dressing more often or an alternate, a more absorbent type of dressing may be needed.

  Wound exudates can harm healing tissues. Dressings that are saturated should be changed as soon as possible to prevent prolonged moisture exposure or maceration.

(continued on next page)

Procedure 35-11 ■ Applying Bandages (continued)

Evaluation

- Be sure the bandage is firmly wrapped without being too tight.
- Check the circulation is not compromised to the area distal of the bandage.
- Evaluate for numbness or pain around or distal to the bandaged area.

Patient Teaching

- Teach the patient about the expected healing process.
- Inform the patient and caregiver about signs and symptoms of infection and the need to report these findings.
- Instruct the patient and family about signs of circulation problems and how to remove the bandage if needed.

Home Care

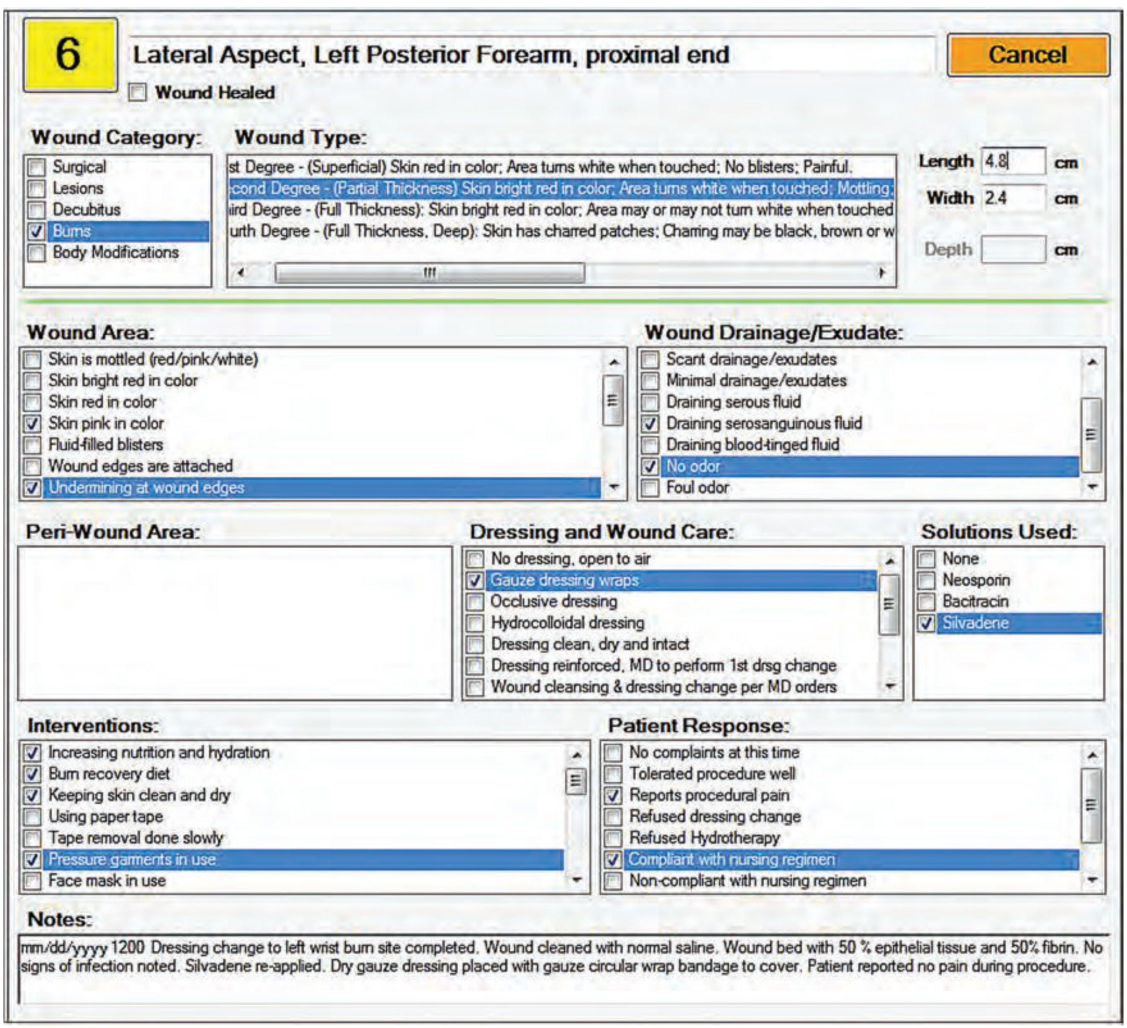
- Refer the client to a home health agency for wound care.
- Some clients or caregivers may be able to perform dressing changes. Determine the client and/or caregiver's ability to perform dressing changes; teach and demonstrate as needed.

Documentation

Many agencies use wound care flowsheets.

- Appearance and location of the wound, type and amount of exudates, and odor, if present, after cleansing.
- Level of pain before the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Method of cleansing the wound and surrounding skin, if performed
- Application of primary and secondary dressings
- Education provided to the patient

Sample EHR documentation



6 Lateral Aspect, Left Posterior Forearm, proximal end
Cancel
[ ] Wound Healed

Wound Category:
[ ] Surgical
[ ] Lesions
[ ] Decubitus
[x] Burns
[ ] Body Modifications

Wound Type:
st Degree - (Superficial) Skin red in color; Area turns white when touched; No blisters; Painful.
cond Degree - (Partial Thickness) Skin bright red in color; Area turns white when touched; Mottling;
ird Degree - (Full Thickness): Skin bright red in color; Area may or may not turn white when touched
urth Degree - (Full Thickness, Deep): Skin has charred patches; Charring may be black, brown or w

Length 4.8 cm
Width 2.4 cm
Depth cm

Wound Area:
[ ] Skin is mottled (red/pink/white)
[ ] Skin bright red in color
[ ] Skin red in color
[x] Skin pink in color
[ ] Fluid-filled blisters
[ ] Wound edges are attached
[x] Undermining at wound edges

Wound Drainage/Exudate:
[ ] Scant drainage/exudates
[ ] Minimal drainage/exudates
[ ] Draining serous fluid
[x] Draining serosanguinous fluid
[ ] Draining blood-tinged fluid
[x] No odor
[ ] Foul odor

Peri-Wound Area:

Dressing and Wound Care:
[ ] No dressing, open to air
[x] Gauze dressing wraps
[ ] Occlusive dressing
[ ] Hydrocolloidal dressing
[ ] Dressing clean, dry and intact
[ ] Dressing reinforced, MD to perform 1st drsg change
[ ] Wound cleansing & dressing change per MD orders

Solutions Used:
[ ] None
[ ] Neosporin
[ ] Bacitracin
[x] Silvadene

Interventions:
[x] Increasing nutrition and hydration
[x] Burn recovery diet
[x] Keeping skin clean and dry
[ ] Using paper tape
[ ] Tape removal done slowly
[x] Pressure garments in use
[ ] Face mask in use

Patient Response:
[ ] No complaints at this time
[ ] Tolerated procedure well
[x] Reports procedural pain
[ ] Refused dressing change
[ ] Refused Hydrotherapy
[x] Compliant with nursing regimen
[ ] Non-compliant with nursing regimen

Notes:
mm/dd/yyyy 1200 Dressing change to left wrist burn site completed. Wound cleaned with normal saline. Wound bed with 50 % epithelial tissue and 50% fibrin. No signs of infection noted. Silvadene re-applied. Dry gauze dressing placed with gauze circular wrap bandage to cover. Patient reported no pain during procedure.

Practice Resources

Bergeron, J. D., Bizjak, G., Le Badour, G., et al. (2009); Rolstad, B. S., & Ovington, L. G. (2011).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Applying Bandages.**

For questions and suggested responses,

Go to Chapter35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 35-12 ■ Removing Sutures and Staples

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonsterile gloves
- Suture removal kit or sterile scissors and forceps (Procedure 35-12A)
- Staple remover (Procedure 35-12B)
- Gauze

Delegation

This procedure cannot be delegated to a NAP. Assessment of the incision line or wound is a registered nurse's responsibility and cannot be delegated. The procedure requires assessment and judgment during removal and may require stopping the procedure if complications occur.

Pre-Procedure Assessment

- Assess staples to ensure none have rotated or turned instead of lying flat along the incision.

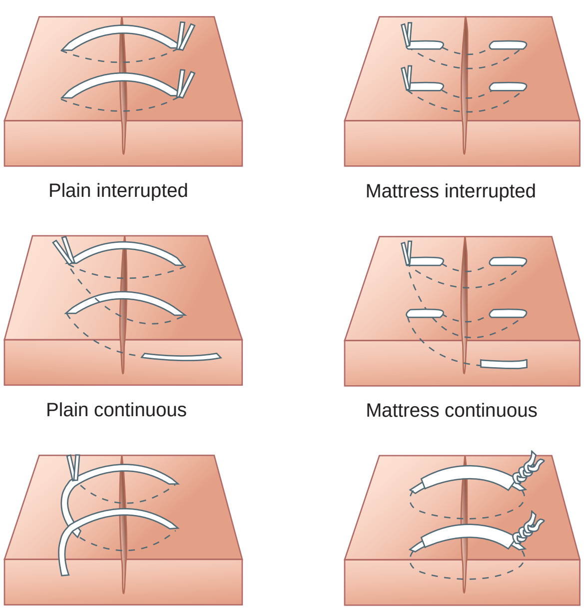
Procedure 25-12A ■ Removing Sutures

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

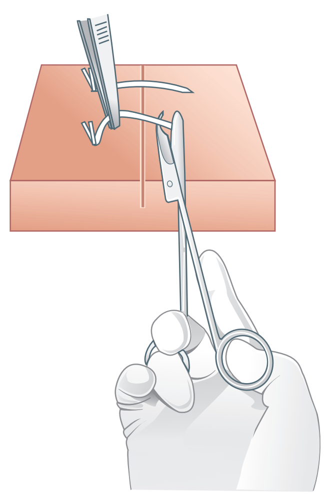
Procedure Steps

1. **Obtain a suture removal kit.**
2. **Wash hands.** Don nonsterile gloves
3. **Cleanse the wound** or suture line.
4. **Use the forceps** to pick up one end of the suture.

Suture types



5. **Slide the small scissors** around the suture, and cut near the skin.
   This helps you avoid pulling the exposed portion of the suture through the underlying tissue.
6. **With the forceps, gently pull** the suture in the direction of the knotted side to remove it.



Removing interrupted sutures

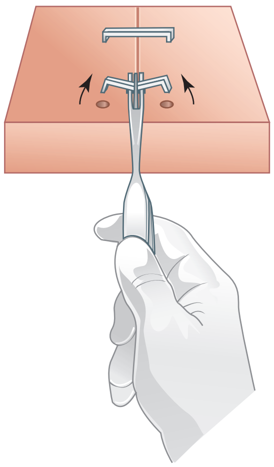
7. **Apply a dressing** or adhesive skin closures if needed.
8. **Remove gloves** and perform hand hygiene.

(continued on next page)

Procedure 35-12 ■ Removing Sutures and Staples (continued)

Procedure 25-12B ■ Removing Staples

1. **Wash hands.** Don nonsterile gloves.
2. **After cleansing the wound** or incision, position the staple remover so that the lower jaw is on the bottom.
3. **Place both tips of the lower jaw** of the remover under the staple. ▼



Removing staples

4. **Ensure the staple is** perpendicular to the plane of the skin. If not, reposition the staple with the tips of the lower jaw and apply gentle pressure, causing it to straighten the ends for easier removal.
5. **Lift slightly on the staple** ensuring that it stays perpendicular to the skin.
6. **Continue to lift slightly** as you gently squeeze the handles together to close.
Spreads the ends of the staples apart, freeing them from the skin.
7. **Lift the reshaped staple** straight up from the skin.
8. **Remove every other staple**, and check the tension on the wound.
9. **If there is no significant pull** on the wound, remove the remaining staples.
Where there are a large number of staples over an area of stress (abdomen, legs), the remaining staples are often removed a day or two later after assuring the incision remains intact.
10. **Place the removed staples** on a piece of gauze.
Staples are small and can be easily lost. Keeping them in one place prevents this.
11. **Apply a dressing** or adhesive closures, if needed.
12. **Dispose of the removed staples** in the sharps container.
Ends of the staples are sharp and should be handled with care.
13. **Remove gloves and wash hands.**

? What if . . .

- **A staple gets stuck?**
Gently manipulate the staple with the remover until it is perpendicular to the skin.
When the skin is stapled, the edges of the staple are crimped to hold the incision together. For the staple to be removed, those edges must be reshaped and straightened. If one edge of the staple is reshaped and the other is not, continuing to remove it can cause pain and tissue trauma.
- **The incision needs a dressing once the staples or sutures have been removed?**
New surgical incisions should be covered with a sterile dressing the first 24 to 48 hours, but not necessarily after that time. Apply a dressing if you are concerned about soiling or per your institution's policy.
In a healing incision, epithelial resurfacing is complete in 24 to 48 hours. Though only a few cells thick, this epithelium is enough to keep the wound closed and provide a bacterial barrier.

Evaluation

- Note whether the incision is well approximated after the procedure.
- Ensure that the patient verbalized understanding of the treatment.
- Inspect the wound daily.

Patient Teaching

- Instruct the patient of signs and symptoms of wound infections (i.e., redness, drainage) and the need to report these findings.
- Instruct the patient that he may be able to shower once sutures or staples are removed, if approved by the healthcare provider.

Documentation

Document the following information (many agencies use wound care flowsheets):

- Appearance and location of the wound, type and amount of exudates, and odor, if present, after cleansing
- The patient's level of pain before and after the procedure. If the patient was medicated for pain, document the drug and dose used, time given, and patient response.
- Method of cleansing the wound and surrounding skin, if performed
- Removal of staples or sutures
- Education provided to the patient

Sample documentation

02/23/16 1815 Staples removed from abdominal midline incision. Incision edges well approximated without erythema, drainage, or swelling. Dry dressing applied. Patient tolerated the procedure without discomfort. Discussed purpose of staple removal with patient. Will continue to monitor wound daily ——— M. Dali, RN

Practice Resources

Hin-Lun, L., & Hon-Ping, C. (2012).

Procedure 35-13 ■ Shortening a Wound Drain

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Nonsterile gloves
- Sterile gloves
- Sterile scissors
- Two safety pins or other clips (sterile)
- Sterile gauze

Delegation

Assessment of the incision line or wound and the drain is a registered nurse's responsibility and cannot be delegated. This procedure should not be delegated to a NAP. The risking for accidentally losing the drain into the body or pulling it out of the wound is too high.

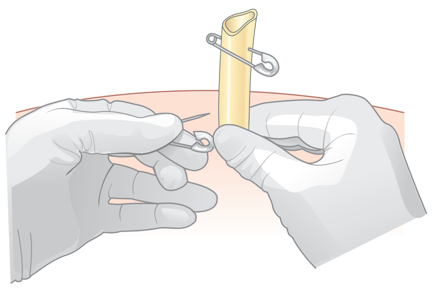
Pre-Procedure Assessment

- Inspect the site around the drain, noting skin excoriation, tenderness, erythema, warmth to the touch, and drainage seeping from the wound.
  Could indicate a wound infection or irritation of the drain at the skin site. Excoriation can be the result of seeping drainage around the tube (e.g., if the tube diameter is not sufficient size to handle drainage output) or, more likely, an obstruction within the tubing.
- Assess the characteristics of the drainage, including color, volume of drainage, presence of blood, odor, pus, and any change in the type or amount of drainage through the tubing.
  A sudden decrease in drainage might indicate a blocked drain. Presence of fresh blood might be a sign of irritation within the wound. Pus and odor in the drainage could indicate wound infection.
- Check the suction apparatus to be sure it is functioning properly.
  A self-suction apparatus might need to be recompressed from time to time to maintain effective vacuum. Electric suction units can fail, delivering too much suction, which can lead to injury. Too little suction can contribute to insufficient drainage, which can lead to pressure on sutures if present, or cause the wound to become infected or heal more slowly.

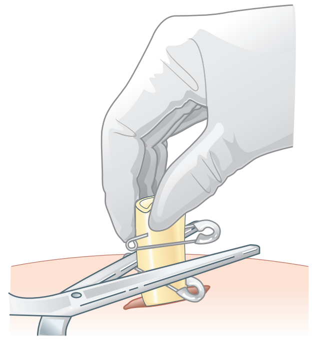
➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

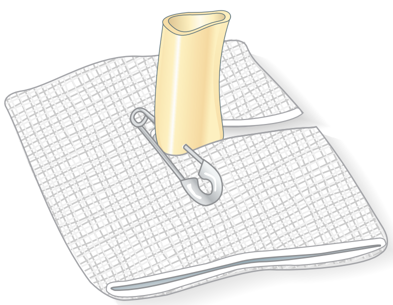
1. **After donning nonsterile gloves**, remove wound dressings.
2. **Remove soiled gloves** and discard in a moisture-proof biohazard collection container.
3. **Open sterile supplies** (scissors, etc.).
4. **Don sterile gloves**; use sterile scissors to cut halfway through a sterile gauze dressing (for later use) or use a sterile precut drain dressing.
5. **If the drain is sutured in place**, use sterile scissors to cut the suture.
6. **Firmly grasp the full width** of the drain at the level of the skin and pull it out by the prescribed amount (e.g., 5 cm [2 in.]).
7. **Insert a sterile safety pin** through the drain at the level of the skin. Hold the drain tightly between your fingers, and insert another pin above your fingers.
   The pin keeps the drain from disappearing into the wound. ➤



8. **Using sterile scissors**, **cut** the drain about 2.5 cm (1 in.) above the skin and pin. ➤



9. **Cleanse the wound**, using sterile gauze swabs and the prescribed cleaning solution. In some situations, you may use sterile forceps to manipulate the swabs.
10. **Apply precut sterile gauze** around the drain; then redress the wound. ➤



11. **Remove gloves** and discard in a biohazard container. Wash your hands.
12. **Leave the patient** in a safe and comfortable position.

? What if . . .

- **You shorten the drain too much?**
  Immediately notify the surgeon who placed the drain.
  The drain will need to be evaluated to be sure it remains intact, which it mostly likely will. Drainage tubing is secured under the skin surface and will probably not be dislodged with shortening.

(continued on next page)

Procedure 35-13 ■ Shortening a Wound Drain (continued)

Evaluation

- Assess the local area of skin around the drain after manipulating it.
- Note the patency of the drain after shortening it.
- Be sure the drain is secure after shortening.
- Evaluate for complications occurring related to shortening procedure.

Patient Teaching

- Patients should not shorten their own drains. Consult a healthcare provider if concerned about the length of tubing or drains.

Documentation

- Record the intervention.
- Note the amount and characteristics of the drainage.
- Document the appearance of the wound.
- Note any complications that occur with shortening a drain (e.g., manipulation of tubing causes bleeding or drainage at the site).

Sample documentation

10/11/15 0930 Penrose shortened by 2.5 cm per post-op orders. Drain intact and not draining. Skin surrounding Penrose slightly erythematous but not warm to touch. Pt. denies tenderness. Pt tolerated procedure without complication ———————— M. Garcia, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure

Go to *Davis's Nursing Skills Videos,* **Shortening a Wound Drain.**

For questions and suggested responses,

Go to Chapter 35, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 35-14 ■ Emptying a Closed-Wound Drainage System

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the page facing the inside back cover.

Equipment

- Drainage container with graduated markings
- Nonsterile gloves
- Biomedical waste disposal sink
- Biohazard disposal receptacle

Delegation

This procedure may be delegated to a NAP who is trained in the skill. Assessment of the wound and drainage characteristics is a licensed professional's responsibility and cannot be delegated.

Pre-Procedure Assessment

- Assess the appearance of the drainage tube site and sutures, if in place.
- Inspect for warmth, edema, redness, or pus where tubing penetrates the skin.
- Check to be sure the closed-wound drainage system is securely fastened at the connections and within the wound.
- Determine whether suction (electric, portable, or manual) is working properly.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

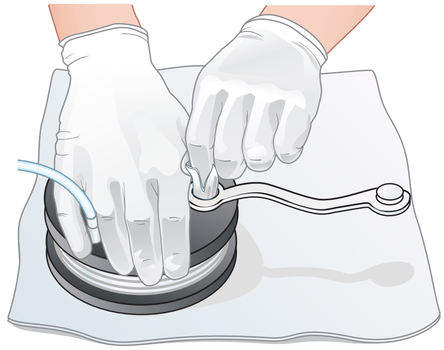
1. **Read the instructions** about the drainage device.
   Procedures vary among manufacturers and different systems.
2. **Don nonsterile gloves** and goggles or mask.
3. **Unpin the drainage device** from the patient's gown.
   The drainage device is often pinned to the patient's gown to prevent it from dislodging.

4. **Open the drainage port**, and empty the drainage into a small graduated container.

5. **With the port still open**, place the collection device on a firm, flat surface (e.g., the over bed table).

6. **Use the palm of one hand** to press down on the device and eject air from it. Do not stand directly over the air vent. Do not touch the drainage port.
It can splash or bubble.

7. **Use your other hand to scrub** the port and plug with an alcohol-based antiseptic or povidone-iodine swab (Betadine), if the patient is not allergic to iodine.



8. **Continuing to press down** on the device, replace the plug in the port. Do not touch the open port or the part of the plug that goes into the port.
Creates a constant, negative pressure vacuum to facilitate suction.

9. **Re-pin the drainage device** to the patient's gown.
Pinning keeps it secure and prevents it from accidentally dislodging.

10. **Measure the drainage** in the graduated container; discard drainage in the disposable container or sink for biohazardous material. Wash the graduated container. Do not stand in front of an air vent while doing so.
Forced air in the room can cause the drainage to splash or bubble, introducing biohazardous material into the environmental air.

11. **Remove your gloves.** Perform hand hygiene.

12. **Document** in the patient's record.

? What if . . .

- **The wound drainage spills?**

  Don nonsterile gloves and protective clothing. Keep people away from the spill area. If sharps are present, remove with forceps. Contain the spill with absorbent pads and place all used materials in a red biohazard bag. Use an approved disinfectant. When finished place all materials including gloves and gowns in the bag and dispose of in the biohazard area.
  Proper handling of contaminated biomedical materials is important to prevent transmission of infectious organisms.

Home Care

- Teach family members who are emptying drainage systems at home to wear gloves and avoid touching the drainage port.

Documentation

- Note the date and time the drainage system is emptied.
- Record the volume lost. Report excess fluid loss to the healthcare provider.
- Describe the appearance of drainage, including presence of blood or purulent material.

Sample documentation

03/12/2016 0750 Hemovac drained 18 mL serosanguineous fluid over 12 hours. No odor or purulent material noted at drainage site. ———— R. Ferretti, RN

Practice Resources

CLINICAL INSIGHTS

Clinical Insight 35-1 ➤ Applying Local Heat Therapy

Preparation

- Determine whether there are any contraindications to the treatment, such as impaired circulation, bleeding, wound complications, or inability to tolerate the treatment.
- Explain the application and rationale to the patient.

Moist Heat (Irrigations, Compresses, Hot Soaks)

If skin is intact:

- Soak a washcloth or towel in warm water (105°F to 115°F [40°C to 46°C]), and wring out the excess before applying to the skin. Reapply and change water frequently to maintain a constant temperature.

For open areas, use a compress, a soak, or a bath:

- To make a compress, soak gauze in the heated solution (105°F to 115°F [40°C to 46°C]), and then apply it to the wound. Usually, you will use sterile gloves, gauze, and solution.
- Reapply compresses or towels, and change the water frequently to maintain a constant temperature.
  Heat disperses quickly.
- **For a soak** you will need to immerse the affected area. Sterilized tubs are often used for this procedure.
- **A sitz bath** soaks the patient's perineal area. A special tub or chair may be used. Because of infection control concerns, disposable sitz baths are preferred. Check that the water temperature is from 105°F to 110°F (40°C to 43°C). Instruct the patient to soak for 15 minutes.

Dry Heat (Electric Heating Pads, Disposable Hot Packs, Hot Water Bags)

Aquathermia pads (also called K-pads) are plastic or vinyl pads that circulate water in the interior.

- Connect the pad via tubing to the electric heating unit, which constantly exchanges water that has been heated to the specified temperature.
- Fill the reservoir about two-thirds full of distilled water.
- Set the temperature control to 98°F to 105°F (37°C to 40.5°C).
- Cover the pad with a towel, and apply it to the body part.
  To prevent tissue injury.

Disposable Hot Packs and Hot Water Bags or Bottles

- Use water that is 115°F to 125°F (46°C to 52°C).
- Fill the bag about two-thirds full of warm tap water, expel the air from the bag, and close the top.
- Tip the bag upside down to test for leaking.
- Wrap the bag in a towel, and place it on the patient.

- Never place a heat source directly on the patient's skin. Burns can occur.

Electric Heating Pads

- Be sure that the body part is dry or that the pad has a waterproof cover.

Safety Precautions for Electric Heating Pads

- Do not use pins (e.g., to hold a cover in place) or other sharp objects on the pad.
  The pin could go through a wire and cause an electric shock.
- Tell the patient to report any discomfort during the treatment
- For home use, warn the patient about the danger of burns from high settings. Use pads with a switch that cannot be turned up.
- Avoid direct contact with the heating device. Cover the heat source with a washcloth, towel, or fitted sleeve.
- Do not place the heating device (pad, bag) under the patient; place it over the body part.
  Helps prevent burns.
- Apply heat intermittently, leaving it on for no more than 15 minutes at a time in an area.
  This helps prevent tissue injury (e.g., burns, impaired circulation). It also makes the therapy more effective by preventing the rebound phenomenon: At the time the heat reaches maximum therapeutic effect, the opposite effect (vasoconstriction) begins.
- Check the skin frequently for extreme redness or blistering.
- Assess for hypotension and faintness. If they occur, discontinue the treatment. Have the patient lie down for several minutes, and check her BP. When the faint feeling passes, assist her to sit up slowly. Recheck the blood pressure (BP) in the sitting position. If the BP remains low, encourage her to remain seated. If the patient is ambulatory, have her dangle her feet for several minutes before getting up.

Clinical Insight 35-2 ➤ Applying Local Cold Therapy

Preparation

- Determine whether there are any contraindications to the treatment, such as impaired circulation, bleeding, wound complications, or inability to tolerate the treatment.
- Explain the application and rationale to the patient.
- Assess for indications for cold application (e.g., fever above 104°F [40°C]). Measure the patient's temperature.

Cooling Baths

A cooling bath is often used to treat a high fever (above 104°F [40°C]). It promotes heat loss through conduction and vaporization.

- Prepare a pan of water with a temperature from 65°F to 90°F (18°C to 32°C).
- You may add a fan to increase heat loss if the temperature is markedly elevated.
- Slowly sponge the face, arms, legs, back, and buttocks with the cool water. Do not dry the areas; cover with a damp towel.
- Take about 30 minutes to complete the bath.
  Cooling the body too rapidly will cause shivering, which will increase heat production.
- You may also place ice bags or cold packs on the forehead in the axillae and the groin.
- Assess the patient constantly during a cooling bath.
  If the patient begins to shiver, the temperature may actually begin to rise.

Cold Compresses

- Apply a cool, damp cloth or towel to the body part.
- Renew the compress or cloth frequently.
  The temperature of the compress or cloth will rapidly rise toward body temperature.

Ice Collars, Ice Bags, Commercially Prepared Cold Packs, Aquapads

- You can make an ice bag out of a nonsterile glove or small plastic bag by filling it with ice chips and tying a knot in the top.
- Fill the ice bag with ice chips or an alcohol-based solution.
- Cover ice bags or packs with a towel or soft cover.
- Apply to the skin for a maximum of 15 minutes, and then remove. You may reapply the cold pack in 1 hour.

Safety Precautions for Cooling Devices

- Measure water temperature with a bath thermometer.
- Tell the patient to report any discomfort during the treatment.
- Avoid direct contact with the cooling device. Cover the cold pack with a washcloth, towel, or fitted sleeve.
- Apply cold intermittently, leaving it on for no more than 15 minutes at a time in an area.
  Helps to prevent tissue injury (e.g., impaired circulation). It also makes the therapy more effective by preventing the rebound phenomenon: At the time the cold reaches maximum therapeutic effect, the opposite effect (vasodilation) begins.
- Observe for tissue damage: bluish purple mottled appearance of the skin, numbness, and sometimes blisters and pain.
- Monitor for elevated blood pressure.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

History Questions for Skin and Wound Assessment

- ➤ What is your typical activity level?
- ➤ Do you ever use a wheelchair or mobile device to get around? Do you require assistance to get out of bed or a chair?
- ➤ Tell me about your usual diet.
- ➤ How much liquid do you drink each day?
- ➤ Do you have any areas of numbness and tingling?
- ➤ Have you had any recent changes in your skin?
- ➤ Do you have any sores or open areas? If so, how long have you had the wound?
- ➤ Have you ever had difficulty with wound healing?
- ➤ What kinds of healthcare problems have you been experiencing?
- ➤ What medications—prescribed, herbal, or over the counter—are you taking?
- ➤ What is your typical hygiene routine?
- ➤ Do you ever lose control of your bladder or bowels?
- ➤ Do you smoke?
- ➤ How much time do you spend outdoors?
- ➤ Do you have diabetes? If so, how often do you check your feet? How often do you see a podiatrist? What is your average blood sugar?

Focused Assessment

Physical Examination: Wound Assessment

All Wounds

Assess all wounds for the following:

Location

Describe the location of the wound in anatomical terms. For example, you would describe an incision from cardiac surgery as a midsternal incision extending from the manubrium to the xiphoid process.

Size

- Measure the length and width of the wound in centimeters.
- To measure wound depth, gently insert a sterile cotton-tip applicator into the deepest part of the wound. Measure the applicator from the skin level to the tip.
- If possible, use photo documentation, indicating the dimensions on the photo. This is especially useful in the case of a wound with an irregular border.

Appearance

Your description of the appearance of the wound should be very detailed. You must describe:

- ***Type of wound*** *(open or closed)*
- ***If the wound is sutured***, examine the closure. Are the wound edges approximated? Is there tension on any aspect of the wound? Are the stitches intact?
- ***The color of the wound.*** Redness and inflammation for the first 2 to 3 days is normal, but erythema or swelling beyond that time may indicate infection.
- ***Condition of the wound bed (in an open wound).*** A beefy red, moist appearance is evidence of healing. A pale color or dry texture indicates a delay in healing.
- ***Examine for necrosis, slough, and eschar.*** Examine for a tunnel or sinus tract in the wound bed; if there is one, inspect and probe it for depth and characteristics.
- ***The skin surrounding the wound.*** Observe for skin discoloration, hematoma, or additional injury to the surrounding tissue. Observe for maceration, tunneling, crepitus, blistering, or erythema. Examine the edges of the wound for epithelial tissue and contraction. Look for undermining beneath the wound margins.

Drainage

- ***Presence of drainage or exudate.*** Describe the color, consistency, amount, and odor.
- ***Assess the quantity of wound drainage*** by weighing dressings before they are applied and again when they have been removed. The change in weight reflects the amount of drainage that they have absorbed.
- ***If a drain is present***, measure the amount of fluid in the collection container.
- ***Odor*** may indicate fistula formation or contamination with bacteria. If a new odor develops, assess carefully for presence of a fistula.

Patient Responses

Ask your patients about pain, discomfort, or itching related to the wound or wound care.

Assessing an Untreated Wound

Your assessment should determine what, if any, additional professional support is necessary. Assess the following same aspects as for treated wounds above: location, size, appearance, description of drainage, condition of wound margins, condition of surrounding skin, and effect of the wound on the patient. In addition, assess the following:

- ***Bleeding.*** If bleeding is profuse, apply direct pressure to the site. If bleeding continues after you apply pressure for 5 minutes or if blood is spurting from the wound, call the physician immediately.
- ***Severity of the wound.*** A gaping wound or a deep wound with fat, fascia, or muscle exposed will need additional care.
- ***Last tetanus immunization.*** Immunization should be given if (1) the last immunization was 10 years ago or longer, (2) the wound is contaminated with dirt or debris and the tetanus injection was given more than 5 years ago, or (3) it is uncertain when the patient last received an immunization.
- ***Whether the wound was caused by a bite.*** Determine whether the wound was caused by any type of bite, animal or human. A deep bite wound usually requires additional observation and/or antibiotics.
- ***Pain.*** Assess for pain. Any wound causing severe pain requires a comprehensive evaluation.
- ***Numbness or loss of movement.*** If any deficit is detected, the patient will need immediate evaluation.
- ***Presence of chronic medical conditions.*** Examples include diabetes, malnutrition, immunocompromise, a bleeding disorder. Patients with conditions that affect wound healing will need ongoing evaluation.

The Braden Scale for Predicting Pressure Sore Risk

BRADEN SCALE FOR PREDICTING PRESSURE SORE RISK

Patient's Name ______ Evaluator's Name ______ Date of Assessment

SENSORY PERCEPTION ability to respond meaningfully to pressure-related discomfort	**1. Completely Limited** Unresponsive (does not moan, flinch, or grasp) to painful stimuli, due to diminished level of consciousness or sedation. OR limited ability to feel pain over most of body.	**2. Very Limited** Responds only to painful stimuli. Cannot communicate discomfort except by moaning or restlessness OR has a sensory impairment which limits the ability to feel pain or discomfort over 1/2 of body.	**3. Slightly Limited** Responds to verbal commands, but cannot always communicate discomfort or the need to be turned. OR has some sensory impairment which limits ability to feel pain or discomfort in 1 or 2 extremities.	**4. No Impairment** Responds to verbal commands. Has no sensory deficit which would limit ability to feel or voice pain or discomfort.				
MOISTURE degree to which skin is exposed to moisture	**1. Constantly Moist** Skin is kept moist almost constantly by perspiration, urine, etc. Dampness is detected every time patient is moved or turned.	**2. Very Moist** Skin is often, but not always moist. Linen must be changed at least once a shift.	**3. Occasionally Moist:** Skin is occasionally moist, requiring an extra linen change approximately once a day.	**4. Rarely Moist** Skin is usually dry, linen only requires changing at routine intervals.				
ACTIVITY degree of physical activity	**1. Bedfast** Confined to bed.	**2. Chairfast** Ability to walk severely limited or non-existent. Cannot bear own weight and/or must be assisted into chair or wheelchair.	**3. Walks Occasionally** Walks occasionally during day, but for very short distances, with or without assistance. Spends majority of each shift in bed or chair.	**4. Walks Frequently** Walks outside room at least twice a day and inside room at least once every two hours during waking hours.				
MOBILITY ability to change and control body position	**1. Completely Immobile** Does not make even slight changes in body or extremity position without assistance.	**2. Very Limited** Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently.	**3. Slightly Limited** Makes frequent though slight changes in body or extremity position independently.	**4. No Limitation** Makes major and frequent changes in position without assistance.				
NUTRITION <u>usual</u> food intake pattern	**1. Very Poor** Never eats a complete meal. Rarely eats more than 1/3 of any food offered. Eats 2 servings or less of protein (meat or dairy products) per day. Takes fluids poorly. Does not take a liquid dietary supplement OR is NPO and/or maintained on clear liquids or IVs for more than 5 days.	**2. Probably Inadequate** Rarely eats a complete meal and generally eats only about 1/2 of any food offered. Protein intake includes only 3 servings of meat or dairy products per day. Occasionally will take a dietary supplement. OR receives less than optimum amount of liquid diet or tube feeding.	**3. Adequate** Eats over half of most meals. Eats a total of 4 servings of protein (meat, dairy products per day. Occasionally will refuse a meal, but will usually take a supplement when offered OR is on a tube feeding or TPN regimen which probably meets most of nutritional needs.	**4. Excellent** Eats most of every meal. Never refuses a meal. Usually eats a total of 4 or more servings of meat and dairy products. Occasionally eats between meals. Does not require supplementation.				
FRICTION & SHEAR	**1. Problem** Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible. Frequently slides down in bed or chair, requiring frequent repositioning with maximum assistance. Spasticity, contractures or agitation leads to almost constant friction.	**2. Potential Problem** Moves feebly or requires minimum assistance. During a move skin probably slides to some extent against sheets, chair, restraints or other devices. Maintains relatively good position in chair or bed most of the time but occasionally slides down.	**3. No Apparent Problem** Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move. Maintains good position in bed or chair.

The Norton Scale for Assessing Risk of Pressure Ulcers

Norton Scale for Assessing Risk of Pressure Ulcers

	Physical Condition	Mental Condition	Activity	Mobility	Incontinent	
	Good 4 Fair 3 Poor 2 Very bad 1	Alert 4 Apathetic 3 Confused 2 Stupor 1	Ambulant 4 Walk/help 3 Chair-bound 2 Bed 1	Full 4 Slightly limited 3 Very limited 2 Immobile 1	Not 4 Occasional 3 Usually/urine 2 Doubly 1	Total Score
Name/Date						

The Norton Scale uses five criteria to assess patients' risk for pressure ulcers. Scores of 14 or less indicate liability to ulcers; scores of <12 indicate very high risk.

The PUSH Tool for Evaluation of Pressure Ulcers

PUSH Tool - Version 3.0

Patient Name:______________________________ Patient ID#:__________

Ulcer Location: ______________________________ Date:______________

DIRECTIONS:

Observe and measure the pressure ulcer. Categorize the ulcer with respect to surface area, exudate, and type of wound tissue. Record a sub-score for each of these ulcer characteristics. Add the sub-scores to obtain the total score. A comparison of total scores measured over time provides an indication of the improvement or deterioration in pressure ulcer healing.

Length x Width	**0** 0 cm^2	**1** <0.3 cm^2	**2** 0.3 - 0.6 cm^2	**3** 0.7 - 1.0 cm^2	**4** 1.1 - 2.0 cm^2	**5** 2.1 - 3.0 cm^2	**Subscore**
		6 3.1 - 4.0 cm^2	**7** 4.1 - 8.0 cm^2	**8** 8.1 - 12.0 cm^2	**9** 12.1 - 24.0 cm^2	**10** > 24 cm^2	
Exudate Amount	**0** None	**1** Light	**2** Moderate	**3** Heavy			**Subscore**
Tissue Type	**0** Closed	**1** Epithelial Tissue	**2** Granulation Tissue	**3** Slough	**4** Necrotic Tissue		**Subscore**
							Total Score

Length x Width: Measure the greatest length (head to toe) and the greatest width (side to side) using a centimeter ruler. Multiply these two measurements (length • width) to obtain an estimate of surface area in square centimeters (cm^2). **Caveat**: Do not guess! Always use a centimeter ruler and always use the same method each time the ulcer is measured.
Exudate Amount: Estimate the amount of exudate (drainage) present after removal of the dressing and before applying any topical agent to the ulcer. Estimate the exudate (drainage) as none, light, moderate, or heavy.
Tissue Type: This refers to the types of tissue that are present in the wound (ulcer) bed. Score as a "4" if there is any necrotic tissue present. Score as a "3" if there is any amount of slough present and necrotic tissue is absent. Score as a "2" if the wound is clean and contains granulation tissue. A superficial wound that is reepithelializing is scored as a "1". When the wound is closed, score as a "0".

4 - Necrotic Tissue (Eschar): black, brown, or tan tissue that adheres firmly to the wound bed or ulcer edges and may be either firmer or softer than surrounding skin.
3 - Slough: yellow or white tissue that adheres to the ulcer bed in strings or thick clumps, or is mucinous.
2 - Granulation Tissue: pink or beefy red tissue with a shiny, moist, granular appearance.
1 - Epithelial Tissue: for superficial ulcers, new pink or shiny tissue (skin) that grows in from the edges or as islands on the ulcer surface.
0 - Closed/Resurfaced: the wound is completely covered with epithelium (new skin).

Note: Refer to the NPUAP Website (www.npuap.org) for further information regarding development and use of the PUSH Tool.

DIAGNOSTIC TESTING

Diagnostic Testing

Tests for Assessing Wounds

Test	Normal Range	Comments
Leukocyte (WBC) count	4,500–11,000/mm^3	Usually done as a part of a complete blood count (CBC) but may be ordered as an independent test. White blood cells (WBCs) may increase when a wound develops; continued elevation may signal infection. A low WBC count may delay wound healing. Leukocytes are responsible for an inflammatory reaction at the wound site, phagocytosis of bacteria and cellular debris, and the creation of antibodies.
Serum protein ***Serum albumin*** ***Serum prealbumin***	6.0–8.0 g/dL 3.4–4.8 g/dL 12–42 mg/dL	Low serum levels indicate limited nutritional stores that delay wound healing or place the patient at high risk for pressure ulcers. Serum protein may be monitored as an indicator of the ability to heal a wound or prevent a pressure ulcer. Serum protein and albumin levels are closely related. However, both fluctuate slowly. A more accurate measure of a patient's immediate protein stores is reflected in the prealbumin level.
Erythrocyte sedimentation rate (ESR)	<50 years old: 0–15 mm/hr; >50 years old: 0–20 mm/hr	In the presence of an inflammatory and necrotic process, blood proteins are altered. This test indicates whether the RBCs stick together, become heavier, and settle at the bottom of a lab tube when held vertically.
Coagulation studies: Partial thromboplastin time, activated (aPTT)	Varies with respect to equipment and reagents used. Critical values: >70 seconds or <53 seconds	Prolonged coagulation times may result in excessive blood loss or ongoing bleeding in the wound bed. Shortened coagulation times increase the risk for blood clot formation problems, such as deep vein thrombosis, pulmonary embolus, or stroke.
Prothrombin time (clotting time)	Critical values: >20 seconds (uncoagulated) or 3 times normal control (anticoagulated)	Altered coagulation may result from anticoagulant medications, a concurrent illness, trauma, or reaction to transfusions.
International normalized ratio (INR)	<2.0 for patients not receiving anticoagulation therapy; 2.0–3.0 for those receiving coagulation therapy	A standardized test to evaluate clotting times, considered the gold standard.
Wound cultures	Negative; no growth of pathogens	Wound cultures may be prescribed to determine the types of bacteria present in the wound. Cultures may be obtained by swab, aspiration, or tissue biopsy. A positive culture may not indicate an infection as chronic wounds are colonized with bacteria.
Tissue biopsy	Negative; no growth of pathogens	Wounds are not considered infected unless the bacteria count exceeds 100,000 organisms per gram of tissue. Exception: The presence of beta-hemolytic streptococci in any number indicates infection.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Tio Santos is a 66-year-old obese man with diabetes and hypertension who is being seen for a wound on his right foot that doesn't seem to be healing. He injured his foot when repairing drywall at home. He is otherwise relatively sedentary at home. The wound is oozing, swollen, tender, and warm to the touch. Mr. Santos is now running a low-grade fever of 100.4°F at home. He tells you his foot is very painful, especially with any weight-bearing, and throbs when he is sitting or lying still. You measure the wound bed to be 6 cm × 4 cm and note purulent exudate at the distal edge. He is referred to an outpatient wound care center for treatment.

THINKING

1. *Theoretical Knowledge:*
   a. What is the Braden scale and why might it be used for Mr. Santos?
   b. What risk factors for delayed wound healing does Mr. Santos have?
2. *Critical Thinking (Considering Alternatives, Deciding What to Do):*
   a. To care for Mr. Santos's wound, should you use sterile gloves, clean nonsterile gloves, or no gloves? Explain your thinking.

DOING

3. *Practical Knowledge (Assessment):*
   a. What symptoms of infection does Mr. Santos have?
   b. To be certain the wound is infected what would you need to know or do?

CARING

4. *Self-Knowledge:* Imagine you have had a wound on your foot for 6 weeks. It has not healed and you have all Mr. Santos's symptoms and, in fact, are in his situation. What would be the most troublesome symptom in your daily life? What would worry you the most?

Critical Thinking and Clinical Reasoning

1. You are caring for a 22-year-old man who is paralyzed from the waist down secondary to an automobile accident. He has been admitted to the hospital with a urinary tract infection manifested by a fever of 102°F (39°C) and lethargy. His family reports he has been withdrawn and sits in his wheelchair watching TV all day long.
   a. What risk factors does this patient have for skin breakdown?
   b. What locations of his body should you be most concerned about in regard to pressure ulcer formation?
   c. What actions should you take to decrease the risk of pressure ulcers in this man? What further information do you need?
2. A 63-year-old man is admitted to your unit after an emergency appendectomy. His appendix was ruptured, and the surgeon has left the wound open to heal by secondary intention. A Jackson–Pratt drain is in place in the wound bed. A moderate amount of purosanguineous drainage is visible in the drain. The surgeon has ordered saline-moistened gauze packing every 4 hours.
   a. What actions should you take as you prepare to do the first dressing change?
   b. How will you secure the dressing?
3. For the following patients, write a NANDA-I diagnosis related to skin integrity. Include problem, etiology, and defining characteristics. If you do not have enough data for one of those components, state what additional data you need.
   a. Mrs. Whitefeather is 95 years old. She has cancer, and she has stopped eating and has become very thin. Recently she has become too weak to move about in bed without help. However, her skin is intact with no redness, even over her bony prominences. She has a very low score on the Braden pressure ulcer assessment scale.
   b. Eddie Allen is 4 years old. He has a severe case of poison ivy, and has blisters on his skin. He has been scratching and has bleeding, excoriated areas over his limbs, face, and trunk.
   c. Allie Newton has a stage II pressure ulcer on her left heel.
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or skin integrity and wound healing. Note that these are *not* to be merely definitions.

Shearing	Preventing pressure ulcers
Friction	Wound assessment
Pressure	Dressing changes
Wound healing process	

What Are the Main Points in This Chapter?

- The layers of the skin are the epidermis (outermost), the dermis, and the subcutaneous layer (innermost).
- The major functions of the skin are protection of the internal organs, unique identification of an individual, thermoregulation, metabolism of nutrients and metabolic waste products, and sensation.
- Age, mobility, nutrition, hydration, moisture underlying conditions, medications, contamination or infection, diminished sensation, cognitive impairment, hygiene, and lifestyle are factors that influence the ability to maintain intact skin and heal wounds.
- If there are no breaks in the skin, a wound is described as *closed*. A wound is considered *open* if there is a break in the skin or mucous membranes.
- Acute wounds may be intentional (e.g., surgical incisions) or unintentional (e.g., from trauma) and are expected to be of short duration.
- Wounds that exceed the anticipated length of recovery are classified as chronic wounds. Chronic wounds include pressure, arterial, venous, and diabetic ulcers. A chronic wound may linger for months or years.
- *Clean wounds* are uninfected wounds with minimal inflammation. *Clean-contaminated wounds* are surgical incisions that enter the gastrointestinal, respiratory, or genitourinary tracts. *Contaminated wounds* include open, traumatic wounds or surgical incisions in which a major break in asepsis occurred. *Infected wounds* are wounds with evidence of infection, such as presence of microorganisms.
- A wound that involves minimal or no tissue loss and has wound edges that are approximated are said to heal by primary intention.
- A wound that involves extensive tissue loss and has margins that cannot be approximated, or is infected, heals by secondary intention.
- Tertiary intention healing, or delayed primary closure, occurs when two surfaces of granulation tissue are brought together. Initially the wound is allowed to heal by secondary intention.
- Healing occurs in three stages. The *inflammatory phase* lasts from 1 to 5 days and consists of two major processes: hemostasis and inflammation. *The proliferative phase* occurs from days 5 to 21. It is characterized by cell development aimed at filling the wound defect and resurfacing the skin. The *maturation phase* begins in the second or third week and continues until the wound is completely healed.
- Wound closure methods include adhesive strips (Steri-Strips), absorbent sutures, surgical staples, and surgical glue.
- Drainage is the flow of fluids from a wound or cavity. It is often referred to as exudate (fluid that oozes as a result of inflammation).
- Complications of wound healing include hemorrhage, infection, dehiscence, evisceration, and fistula formation.
- Pressure ulcers are caused by unrelieved pressure over time that compromises blood flow to tissue, resulting in ischemia in the underlying tissue.
- A stage I pressure ulcer is an area of persistent redness and does not blanch.
- Stage II pressure ulcers involve partial-thickness skin loss of the epidermis, dermis, or both.
- A stage III pressure ulcer is characterized by full-thickness skin loss involving damage or necrosis of subcutaneous tissue, which may extend down to, but not through, the underlying fascia. The ulcer appears as a deep crater.
- Stage IV pressure ulcers involve full-thickness skin loss with extensive destruction; tissue necrosis; or damage to muscle, bone, or support structures. Undermining and sinus tracts (blind tracts underneath the epidermis) are common.
- Extrinsic factors leading to pressure ulcers are those that alter the skin and tissue integrity and blood supply (e.g., aging, low blood pressure, neurological injury, poor nutrition, edema, and fever).
- Extrinsic factors include friction and shearing, and exposure to moisture and pressure.
- Not all lower extremity ulcers are related to pressure. Some are caused by poor perfusion, such as venous stasis ulcers, diabetic foot ulcers, and arterial ulcers.
- An eschar is a black leathery covering of necrotic tissue. An ulcer covered by an eschar cannot be classified because it is impossible to determine the depth.
- The Braden, Norton, and PUSH scales evaluate risk for problems with skin integrity.
- When assessing a wound, note the following: the type of wound, the color of the wound and surrounding skin, the condition of the wound bed, drainage and odor, and the level of pain associated with the wound or wound care.

- Preventing pressure ulcers focuses on skin care, nutrition, turning and positioning, using therapeutic mattresses and cushions, and patient/family teaching.
- Five types of debridement are used: sharp, mechanical, enzymatic, autolytic, and biotherapy (maggot debridement).
- Wound care therapies to promote healing might include negative pressure wound therapy (NPWT), electrical stimulation, tissue growth factors, ultrasound, bioengineered skin substitutes, and surgical options.
- Primary dressings are ones that are placed in the wound bed and touch the wound. A secondary dressing covers or holds a primary dressing in place. Many dressings can act as both.
- Types of wound dressings are absorption, alginate, antimicrobial, collagen, gauze, foam dressings, hydrocolloid, hydrogel, skin sealants, and moisture barriers.
- Ideal wound irrigation pressures range from 4 pounds per square inch (psi) to 15 psi. Current recommendations are to use a 35-mL syringe attached to a 19-gauge angiocatheter. This will deliver the solution at approximately 8 psi.
- Heat application promotes vasodilatation, increases tissue metabolism, increases capillary permeability, reduces blood viscosity, and reduces muscle tension.
- The application of cold causes vasoconstriction, local anesthesia, reduced cell metabolism, increased blood viscosity, and decreased muscle tension.

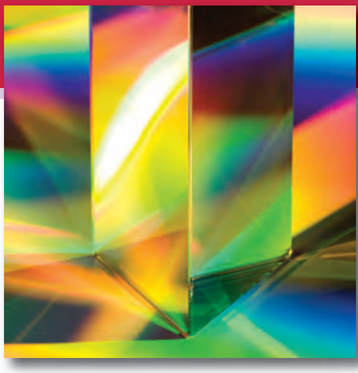
CHAPTER 36



Oxygenation

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 36:
- **Response sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Oxygenation (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 36, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Mai Nguyen, Nam's 76-year-old mother, has been complaining of fatigue and a persistent cough for approximately 2 weeks. Nam scheduled an appointment for her at the family clinic, where you are a nurse. Mrs. Nguyen appears disheveled. Her clothes are mismatched and rumpled, and her hair is tousled. Normally she is dressed neatly and wearing makeup. She has a hard time signing in at the desk and tells the receptionist she has a 1:00 p.m. appointment, but it is now 9:00 a.m. Mrs. Nguyen's vital signs are as follows: BP, 142/90 mm Hg; pulse, 94 beats/min and regular; respirations 24 breaths/min and labored; temperature, 99.6°F (37.5°C) oral.

Caring for the Nguyens (continued)

A. What additional assessment data would be useful to gather at this time?

B. During her visit at the clinic, you notice that Mrs. Nguyen is very confused. Her weight has dropped 7 pounds since her visit last month, her mucous membranes are dry, and she is dyspneic with any activity. She is diagnosed with pneumonia. Because of her rapid decline, Mrs. Nguyen is admitted to the hospital to receive intravenous antibiotics. At the hospital, her initial pulse oximetry reading is 90%, and she is unable to cough up secretions. Write the most appropriate nursing diagnosis to focus interventions for Mrs. Nguyen.

C. What actions should you anticipate taking?

D. The hospitalist (hospital-based physician) writes prescriptions for IV fluids, antibiotics, suction prn, and continuous pulse oximetry. What additional prescriptions will you need to provide care for Mrs. Nguyen? What therapy would you suggest?

E. Mrs. Nguyen requires suctioning to help remove secretions. She has a weak cough and crackles and rhonchi throughout all lung fields. There are few secretions in her oropharynx, and she bites down on the catheter. What technique would you use to suction her? Explain your choice.

F. After 4 days in the hospital, Mrs. Nguyen is discharged to home. She asks the hospital nurse, "What can I do to make sure I never get that sick again?" How would you answer this question?

PracticalKnowledge knowing **how**

As you perform the procedures, apply the concepts and other theoretical knowledge you learned in Volume 1. The registered nurse is responsible for assessing patients' oxygenation and their responses to procedures.

PROCEDURES

In this section you will find procedures necessary for supporting oxygenation. Some, but not all, of the procedures in this section can be delegated to qualified nursing assistive personnel (NAPs). Refer to the delegation notes in each procedure and to agency policies.

Procedure 36-1 ■ Collecting a Sputum Specimen

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

For all sputum specimens, you will need a patient identification label, a completed laboratory requisition form, and a small plastic bag with a biohazard label (or container designated by the agency) for delivering the specimen to the laboratory. Depending on how you obtain the specimen, you also need the following:

Procedure 36-1A: Collecting an Expectorated Sputum Specimen

- Sterile specimen container with lid
- Procedure gloves
- Glass of water
- Emesis basin
- Tissues
- Pillow (if abdominal or chest incision is present)

Procedure 36-1B: Collecting a Suctioned Sputum Specimen

- Sterile suction catheter or sterile suction kit
- Suction device (portable or wall)
- Sterile gloves
- Protective eyewear
- Inline sputum specimen container or trap
- Sterile saline solution
- Oxygen therapy equipment, if indicated
- Linen-saver pad or towel

Delegation

You can delegate collection of an expectorated sputum specimen to a NAP who has been adequately trained in performing the skill. Assess the patient's respiratory status

(continued on next page)

Procedure 36-1 ■ Collecting a Sputum Specimen (continued)

first; if the patient's condition is unstable, do not delegate the procedure. Do not delegate obtaining a specimen by tracheal suctioning.

Pre-Procedure Assessment

- Assess the patient's comprehension of the procedure.
  Understanding allays anxiety and promotes cooperation.
- Assess breath sounds; respiratory rate, depth, and pattern; skin and nailbed color; and tissue perfusion.
  You may need to delay sputum collection if the patient is in respiratory distress.
- Assess ability to deep-breathe, cough, and expectorate.
  If the patient is unable to deep-breathe, cough, and expectorate, suctioning may be necessary to obtain an adequate sputum specimen.
- Determine when the patient last ate or had a tube feeding, especially for a specimen obtained by suction.
  Specimen collection should be delayed for 1 to 2 hours after eating because the procedure may cause vomiting, which creates a risk for aspiration of stomach contents.
- If suctioning is required to obtain the specimen, check for factors such as anticoagulant therapy, bleeding disorders, or low platelet count.
  These factors place the patient at risk for bleeding when the suction catheter is introduced.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Verify the medical prescription** for type of sputum analysis.
   The type of sputum specimen determines the number of specimens required and the time of day the specimen should be collected. For example, specimens to confirm tuberculosis typically require three consecutive morning samples.
2. **Position the patient** according to the required specimen collection technique.
   a. For an *expectorated specimen*, assist the patient to high or semi-Fowler's position or to a sitting position at the edge of the bed.
   b. For a *suctioned specimen*, position the patient in high or semi-Fowler's position.
   These positions facilitate insertion of the suction catheter and the ability to cough. They also promote lung expansion, and prevent aspiration should the patient vomit during the procedure.
3. **Drape a towel or linen-saver pad** over the patient's chest. Ask the patient to rinse his mouth and gargle with water.
   A towel or pad protects the patient's gown from soiling during specimen collection. Rinsing the mouth removes flora that may contaminate the specimen; however, evidence is not conclusive on this point.
4. **If the patient has an abdominal** or chest incision, have the patient splint the incision with a pillow.
   Splinting the incision decreases discomfort when the patient coughs.

Procedure 36-1A ■ Collecting an Expectorated Sputum Specimen

Procedure Steps

Follow Steps 1 through 4, above.

5. **Provide the patient with** the specimen container. Advise the patient to avoid touching the inside of the container. If you must hold the container for her, first don procedure gloves.
   The inside of the container should remain sterile. Wear gloves because you may come in contact with secretions or airborne bacteria when the patient coughs and expectorates.

6. **Ask the patient to breathe** deeply for three or four breaths, and then ask him after a full inhalation to hold his breath and then cough.
   Deep breathing opens airways and stimulates the cough reflex. Coughing after a full inhalation creates enough force to mobilize secretions through the airways and into the pharynx.
7. **Instruct the patient to expectorate** the secretions directly into the specimen container.
   Prevents specimen contamination from outside organisms.

8. **Tell the patient to repeat deep breathing** and coughing until an adequate sample is obtained.
Typically 5 to 10 mL of sputum is required to ensure adequate sputum analysis.

9. **Don procedure gloves** if you are not already wearing them; cover the specimen container with the lid immediately after the specimen is collected.
Gloves protect you in the event the patient's coughing has contaminated the outside of the container. Covering the container immediately prevents spread of microorganisms.

10. **Label the specimen container** with patient identification, the name of the test, and collection date and time.
Correctly identifying the specimen ensures accurate diagnosis and treatment.

11. **Place the specimen in** a plastic bag with a biohazard label. Attach a completed laboratory requisition form.
The plastic bag protects healthcare workers from exposure to microorganisms. The laboratory requisition form ensures proper processing of the specimen.

12. **Send the specimen** to the laboratory immediately, or refrigerate it if transport might be delayed.
If bacterial cultures are delayed, contaminating organisms may grow, producing false culture results and possibly inappropriate treatment.

Procedure 36-1B ■ Collecting a Suctioned Sputum Specimen

Procedure Steps

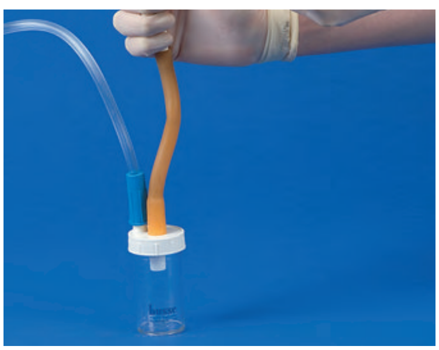
Follow Steps 1 through 4, above

5. **Administer oxygen** to the patient, if indicated.
Suctioning may cause hypoxemia.

6. **Prepare the suction device**, and make sure it is functioning properly.

7. **Don protective eyewear.**
Protects your eyes from splattering of secretions during suctioning.

8. **Attach the suction tubing** to the male adapter of the inline sputum specimen container. ▼



9. **Don sterile gloves.**
Protects the patient's sterile airways from contamination by outside organisms.

10. **Attach the sterile suction** to the flexible tubing on the sputum specimen container. The hand that touches the specimen container is no longer sterile.
Ensures that the sputum specimen goes directly into the specimen container instead of the suction tubing. ▼

11. **Lubricate the suction catheter** with sterile saline solution.
Lubrication eases insertion and prevents trauma to mucosa.

12. **Insert the tip of the suction** catheter gently through the nasopharynx, endotracheal tube, or tracheostomy tube. Advance the tip into the trachea (see Procedure 36-6 or Procedure 36-8).
Gently insertion prevents airway trauma.

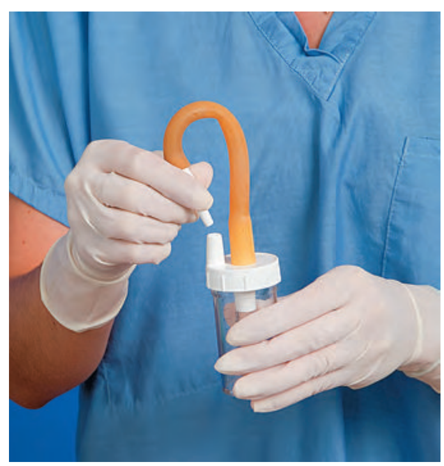
13. **When the patient begins** coughing, apply suction by placing your finger over the suction control port for 5 to 10 seconds to collect the specimen.
Applying suction for longer than 10 seconds can cause hypoxia.

14. **If an adequate specimen** (5 to 10 mL) is not obtained, allow the patient to rest for 1 or 2 minutes, and then repeat the procedure. Administer oxygen to the patient at this time, if indicated.
Allowing the patient to rest and administering oxygen prevent hypoxia. You must assess your patient continually during this procedure to ensure patient safety and respiratory status.

15. **When you have collected** an adequate specimen, discontinue suction, then gently remove the suction catheter.
Applying suction during catheter removal can damage the airway mucosa.

16. **Remove the suction catheter** from the specimen container, and dispose of the catheter in the appropriate container.
Disposal of contaminated supplies prevents the spread of infection.

17. **Remove the suction tubing** from the specimen container, and connect the rubber tubing on the specimen container to the plastic adapter. ▼



(continued on next page)

Procedure 36-1 ■ Collecting a Sputum Specimen (continued)

18. **If sputum comes in contact** with the outside of the specimen container, clean the outside with a disinfectant, according to agency policy.
Prevents spread of infection to staff members who must handle the specimen.

19. **After the patient expectorates**, offer tissues and provide mouth care.
Promotes patient comfort.

20. **Label the specimen container** with the patient's identification, the name of the test, and collection date and time.
Correctly identifying the specimen ensures accurate diagnosis and treatment.

21. **Place the specimen** in a plastic bag with a biohazard label. Attach a completed laboratory requisition form.
The biohazard bag protects healthcare workers from exposure to microorganisms. The laboratory requisition form ensures proper processing of the specimen.

22. **Send the specimen** to the laboratory immediately, or refrigerate it if transport might be delayed.
If bacterial cultures are delayed, contaminating organisms may grow, producing false culture results and possibly inappropriate treatment.

Evaluation

- Evaluate the patient's respiratory status during and after the procedure, especially if suctioning was necessary.
- Examine the color, consistency, and odor of the sputum specimen.
- Promptly report laboratory results to the primary care provider.
- Evaluate the patient's understanding of the procedure and test results.

Patient Teaching

- Explain proper collection techniques to avoid specimen contamination.
- Demonstrate proper coughing techniques to ensure an adequate specimen.
- Explain the importance of avoiding mouthwash before the procedure, as it may alter laboratory results.
- If the patient has an incision, show him how to splint his incision to avoid discomfort during coughing and expectoration.

Home Care

Explain how to collect an expectorated sputum specimen and the importance of sending the specimen to the laboratory immediately after collection.

Documentation

- Record the date and time the specimen was collected, the method of collection, and the type of specimen ordered.
- Note the amount, color, consistency, and odor of the specimen.
- Document the patient's tolerance of the procedure.

Sample documentation:

06/05/15 0700 Patient suctioned via tracheostomy. Sputum specimen obtained and sent for acid-fast bacillus (AFB) analysis. Specimen contained 15 mL of yellow, tenacious, odorless sputum. Patient became short of breath with suctioning. 100% O_2 administered via tracheostomy hood for 10 minutes after suctioning. Shortness of breath abated with treatment. O_2 returned to 40% ———— S. Ryan, RN

Practice Resources

Centers for Disease Control and Prevention (CDC) (2011); Texas Department of State Health Services, Laboratory Services Section Home (2009).

Procedure 36-2 ■ Monitoring Pulse Oximetry (Arterial Oxygen Saturation)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nail polish remover, if necessary
- Oximeter and probe sensor appropriate for patient age, size and weight, and for the desired location.
- Oximeter probe sensor appropriate for patient age, size, weight, and for the desired location

Delegation

Because it is noninvasive and simple to perform, the RN can delegate application of the pulse oximeter probe and measurement of arterial oxygen saturation (SaO_2) to a NAP or LPN who is adequately trained to perform the skill. Inform the NAP or LPN how often to take measurements, and instruct them to notify you immediately if SaO_2 falls below 95%. Although this procedure can be delegated, it is the responsibility of the RN to interpret the results, assess the patient, and notify the primary care provider.

Pre-Procedure Assessment

- Assess the need for SaO_2 monitoring: low hemoglobin level; confusion, decreased level of consciousness, or respiratory distress; or risk factors, such as heart or pulmonary disease, recovering from anesthesia, or ventilator-dependent.
  SaO_2 monitoring helps detect oxygenation problems early. Monitoring is especially important in patients with risk factors. Patients with underlying pulmonary disease may have adapted to low oxygen saturation levels, so you may need to adjust the lower limit alarm and, if you have delegated the procedure, the level for notification for these patients.
- Assess respiratory status, including breath sounds; respiratory rate, depth, and pattern; tissue perfusion; SaO_2; and skin and nailbed color.
  Assessment findings may suggest a decrease in oxygen saturation and validate oximetry readings.
- Determine the optimal location for the oximeter probe sensor, for example, the fingertip, earlobe, forehead, or bridge of the nose. Check the capillary refill and pulse at the pulse closest to the site.
  To ensure accurate monitoring, choose a site that has adequate circulation, is free of artificial nails, and contains no moisture. Clinical Insight 36-1 offers suggestions on site placement based on patient factors.
- Assess for factors that may interfere with pulse oximetry measurement, such as hypotension, hypothermia, and tremors.
  The sensor requires adequate circulation to recognize hemoglobin molecules that absorb the emitted light. Tremors may produce artifact that may be misinterpreted by the oximeter, causing false readings.
- Check patient history for allergy to adhesive.
  An allergic reaction may occur if an adhesive-backed disposable probe sensor is used in a patient with a history of allergy to adhesives.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure explains how to apply a pulse oximeter. Refer to Clinical Insight 36-1 for tips for obtaining accurate pulse oximetry readings.

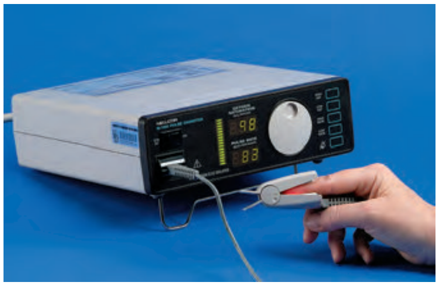
Procedure Steps

1. **Choose a sensor appropriate** for the patient's age, size, and weight and for the desired location.
   - If the patient is allergic to adhesive, use a clip-on probe sensor.
   - If the patient's peripheral circulation is compromised, use a nasal sensor.
   An appropriate type of sensor is more comfortable for the patient and ensures accurate readings.
2. **Prepare the site by cleansing** and drying it. If the finger is the site, remove nail polish or an acrylic nail, if present.
   Dirt and skin oils on the site can interfere with passage of light waves. Nail polish or acrylic nails may interfere with signal transmission, causing inaccurate SaO_2 measurement. However, a recent study found that nail polish did not cause a clinically significant change in readings in healthy people (Chan, Chan, & Chan, 2013).
3. **Remove the protective backing** if you are using a disposable probe sensor that contains adhesive.
4. **Attach the probe sensor** to the chosen site. Make sure the photodetector and light-emitting diodes (LED) on the probe sensor face each other. Most probe sensors contain markings to facilitate correct placement.

When Using a Clip-on Probe Sensor

If you are using a clip-on probe sensor, warn the patient that he may feel a pinching sensation. Choose the site based on the status of circulation to the extremity and patient movement.
Inadequate circulation to the site and artifact caused by motion may alter SaO_2 results. The photodetector diodes and LED must be properly placed to ensure accurate readings.

5. **Connect the sensor probe** to the oximeter and turn it on. Check the pulse rate displayed on the oximeter to see whether it correlates with the patient's radial pulse. (Be sure the pulse oximeter is plugged in to an electrical socket.)
   Correlation between the oximeter pulse display and the patient's radial pulse confirms accurate readings.
6. **Read the SaO_2 measurement** on the digital display when it reaches a constant value, usually in 10 to 30 seconds, but may take up to 2 minutes.
   The oximeter requires time to detect the pulse, calculate oxygen saturation, and register an accurate reading.



7. **Set and turn on the alarm** limits for SaO_2 and pulse rate, according to the manufacturer's instructions, patient condition, and agency policy if continuous monitoring is necessary.
   Alarms must be set at appropriate levels to signify when SaO_2 or pulse rate falls below predetermined levels. Alarms help ensure prompt recognition and treatment of hypoxia.

(continued on next page)

Procedure 36-2 ■ Monitoring Pulse Oximetry (Arterial Oxygen Saturation) (continued)

8. **Obtain readings as prescribed** or indicated by the patient's respiratory status.
Some agencies require a prescription for pulse oximetry to ensure reimbursement.

9. **Rotate the site** if continuous monitoring is indicated.

For an Adhesive Probe Sensor
Rotate the site every 4 hours.

For a Clip-on Probe Sensor
Rotate the site every 2 hours.
Probe sensors and prolonged pressure may irritate the skin; rotating the site prevents skin breakdown.

10. **Remove the probe sensor**, and turn off the oximeter when monitoring is no longer necessary.
Some oximeters are battery powered; leaving them on after use depletes the battery.

Evaluation

- Evaluate the patient's understanding of the procedure and the obtained values.
- Compare pulse oximetry results with the patient's clinical presentation.
- Evaluate the effectiveness of therapy by comparing SaO_2 results before, during, and after treatment.
- Assess the site every 4 hours if you are using an adhesive probe sensor or every 2 hours if you are using a clip-on probe sensor.

Patient Teaching

- Demonstrate the procedure to the patient and caregiver, especially if the patient will be continuing pulse oximetry at home.
- Explain to the patient and caregiver the significance of SaO_2 results.
- Discuss the signs and symptoms of hypoxia (confusion, restlessness, shortness of breath, dyspnea, cyanosis, and somnolence) with the patient and caregiver.

Home Care

- Explain where to obtain a pulse oximeter.
- Tell the client and caregiver when to notify the primary provider of abnormal results or signs and symptoms of hypoxia.
- Help the client identify risk factors that decrease SaO_2 levels.

Documentation

- Record the date and time of each pulse oximetry reading obtained. Most agencies use a flowsheet if frequent monitoring is necessary.
- Document whether readings are intermittent or continuous.
- If readings are continuous, record alarm parameters.
- Chart the patient's vital signs and SaO_2 results, and indicate whether the patient is breathing room air or receiving oxygen therapy. For oxygen therapy, note the oxygen concentration and the mode of delivery.
- Document acute decreases in SaO_2, any precipitating factors, treatment interventions, and the patient's response.

Sample documentation

July 1, 2015 0300 Pt stated "short of breath." Crackles throughout lung fields. BP 140/92, apical pulse 110 beats/min, resp rate 32 breaths/min. Pulse oximetry applied to left index finger, and SaO_2 88% on room air. Places on O_2 at 4 L/min via nasal cannula. Dr. Jones notified. ——— Kate Jackson, RNC

Practice Resources

American Association of Critical-Care Nurses (AACN) (2010); Hill, E., & Stoneham, M. (2000); Rajkumar, A., Karmarkar, A., & Knott, J. (2006); Chan, E. D., Chan, M. M., & Chan , M. M. (2013).

Procedure 36-3 ■ Performing Percussion, Vibration, and Postural Drainage

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Bed capable of being placed in the Trendelenburg position
- Pillows
- Patient gown
- Facial tissues
- Emesis basin
- Sputum specimen container, if needed
- Suction equipment, if needed
- Stethoscope

Delegation

You should assess the patient to determine the need for the procedure and to evaluate whether the patient can tolerate the procedure. You should perform the initial procedure, but you can delegate subsequent treatments to a respiratory therapist or NAP who is adequately trained. Instruct the respiratory therapist or NAP to report any changes in the patient's condition immediately. The RN is responsible for ongoing assessment and monitoring of airway clearance and respiratory status.

Pre-Procedure Assessment

- Check the patient's chest x-ray results.
  Identifies which lung fields require treatment.
- Assess the patient's respiratory status, including respiratory rate, depth, and rhythm; breath sounds; color; and pulse oximetry results.
  Determines the need for and effectiveness of percussion, vibration, and postural drainage.
- Determine when the patient has last eaten.
  Postural drainage should not be performed for at least 2 hours after meals to prevent nausea, vomiting, and aspiration.
- Assess the patient for dysrhythmias, coagulopathy (a defect in blood clotting), hypertension, and pain or tenderness in the chest area being treated.
  If any of these are present, the procedure should be avoided because it might worsen these conditions.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

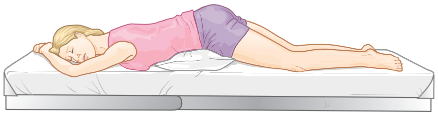
Procedure Steps

1. **Help the patient assume the appropriate** position, based on the lung field that requires drainage.
   Helps mobilize secretions in the affected lung field by gravity.
   a. ***Apical areas of the upper lobes.*** Ask the patient to sit at the edge of the bed, if possible. If needed, place a pillow at the base of the spine for support. If the patient is not able to sit at the edge of the bed, place him in high-Fowler's position.

   b. ***Posterior section of the upper lobes.*** Position supine with a pillow under the hips and knees flexed. Have the patient rotate slightly away from the side that requires drainage.

   c. ***Middle or lower lobes.*** Place the bed in the Trendelenburg position. Position the patient in Sims' position. To drain the left lung, position the patient on his right side. For the right lung, position the patient on his left side.

   d. ***Posterior lower lobes.*** Keeping the bed flat, position the patient prone with a pillow under her stomach.



2. **Have the patient remain** in the desired position for 10 to 15 minutes, if tolerated.
   Allows adequate drainage of secretions by gravity from the desired lung field.
3. **Perform percussion** over the affected lung area while the patient is in the desired drainage position.
   Loosens and mobilizes secretions.
   a. Instruct the patient to breathe deeply and slowly.
   Relaxation helps the patient tolerate the procedure.
   b. Place a towel over the patient's skin or use the patient's gown to cover the area to be percussed.
   Protects the skin and promotes patient privacy and comfort.
   c. Avoid clapping over bony prominences, female breasts, or tender areas of the chest.
   Percussing over these areas may cause discomfort and compromise tissue integrity.
   d. Cup your hands, keeping your fingers flexed and your thumbs pressed against your index fingers.
   Cupping your hands promotes patient comfort during percussion.
   e. Place your cupped hands over the lung area that requires drainage.
   f. Percuss the lung area for 1 to 3 minutes by alternately striking your cupped hands rhythmically against the patient.

4. **Perform vibrations** while the patient remains in the desired drainage position.

   a. Place the flat surface of one hand over the lung area that requires vibration. Place your other hand on top of that hand at a right angle.
   Using the flat surfaces of the hands provides a large surface area to

(continued on next page)

Procedure 36-3 ■ Performing Percussion, Vibration, and Postural Drainage (continued)

transmit vibrations through the chest. Placing one hand on top of the other provides better leverage for vibrating.

b. Instruct the patient to inhale slowly and deeply.
Promotes relaxation and lung expansion.

c. Instruct the patient to make a "fff" or "sss" sound as she exhales.

d. As the patient exhales, press your fingers and palms firmly against her chest wall.
Vibrating during exhalation enhances the downward movement of the rib cage that occurs during exhalation.

e. Push down, and gently vibrate with your hands over the lung area.
Vibration helps mobilize secretions.

f. Continue performing vibrations for three exhalations.

5. **After performing postural** drainage, percussion, and vibration, allow the patient to sit up. Ask her to cough at the end of a deep inspiration. Suction the patient if she is unable to expectorate secretions. If a sputum specimen is needed, collect it in a specimen container.
Coughing helps clear the airway of secretions.

6. **Repeat Steps 1 through 5** for each lung field that requires treatment. The entire treatment should not exceed 60 minutes.
Treating for longer than 60 minutes fatigues the patient.

7. **Provide mouth care.**
Cleanses the mouth of secretions and promotes patient comfort.

Evaluation

- Evaluate the effectiveness of percussion, vibration, and postural drainage.
- Auscultate breath sounds every 2 to 4 hours, as indicated.
- Monitor pulse oximetry and arterial blood gas (ABG) results.
- Evaluate the need for further treatment.

Patient Teaching

- Demonstrate percussion, vibration, and postural drainage if the patient will be continuing it at home.
- Reinforce the importance of immediately reporting shortness of breath or any difficulty breathing.
- Explain the importance of drinking fluids to help thin and mobilize secretions.
- Teach coughing and deep-breathing exercises.

Home Care

- Be sure the client/family/caregiver knows how often the procedure should be done. There should be a prescription from the primary care provider.
- Most clients will not have a bed that can be placed in the Trendelenburg position.
- Demonstrate how to position the client with hips elevated on pillows, higher than the chest, or, if the client is able, to assume a knee–chest position.
- Provide the client and caregiver with contact information of healthcare personnel who can be reached for advice or emergencies.

Documentation

- Document the date and time you performed percussion, vibration, and postural drainage.
- Note the positions used and the length of time the patient maintained each position.
- Note the anatomical locations in which you performed percussion and vibration.
- Document the patient's tolerance of the procedure, as well as any complications and the nursing interventions you used to treat the complication.
- Document the amount, color, odor, and consistency of sputum obtained during the procedure and whether you sent a sputum specimen to the lab.

Sample documentation

June 15, 2015 Percussion and vibration done over Right lower lobe. Expectorated 10 mL thick, yellow, odorless mucus. Specimen to lab. BP 142/78, HR 98 beats/min, respirations 24 breaths/min. Few crackles auscultated over Right lung base, Sao_2 98% on 2 L/min nasal cannula. ——————————— Jeffrey Fine, RN

Practice Resources

Bilton, D. (2012); *Lippincott's Nursing Procedures* (2012).

Procedure 36-4 ■ Administering Oxygen

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Oxygen source
- Flow meter
- Oxygen tubing
- Nasal cannula, oxygen mask, or face tent
- Prefilled humidification device

Delegation

The RN is responsible for assessing respiratory function and initiating oxygen therapy. However, you may delegate reapplication and maintenance of oxygen therapy (e.g., adjusting the face mask) to appropriately trained assistive personnel when necessary.

Pre-Procedure Assessment

- Assess the patient's understanding of oxygen therapy.
- Assessment of the patient's respiratory status; includes respiratory rate, depth, and rhythm; breath sounds; color; capillary refill and pulse oximetry results.
  Determines the need for further treatment and effectiveness of oxygen therapy.
- Assess nares for patency (if a nasal cannula is being used) and behind the ears for signs of skin breakdown.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* Oxygen requires a medical prescription. In an emergency, administer oxygen to the patient to prevent respiratory distress, then notify the primary care provider for a prescription.

Procedure Steps

Also use Clinical Insight 36-3: Oxygen Therapy Safety Precautions.

1. **Attach the flow meter** to the wall oxygen source (the green meter on the wall).

If Using a Portable Oxygen Tank

Attach the flow meter to the tank if it is not already connected. Once tubing is attached to the portable tank, check the amount of oxygen in the tank by looking at the meter.
The flow meter regulates the amount of oxygen delivered per minute.

2. **Assemble the oxygen** equipment. (See the table at the end of this procedure for various oxygen delivery devices.)
3. **Attach the humidifier** to the flow meter. The humidifier is simply a small plastic container containing normal saline. If you are not using a humidifier, attach the adapter directly to the flow meter.
   The humidifier adds moisture in with the oxygen, which can dry the nasal or oral cavity.
4. **Turn on the oxygen** at the flow meter, and adjust the prescribed flow rate.

Procedure Variation for Nasal Cannula

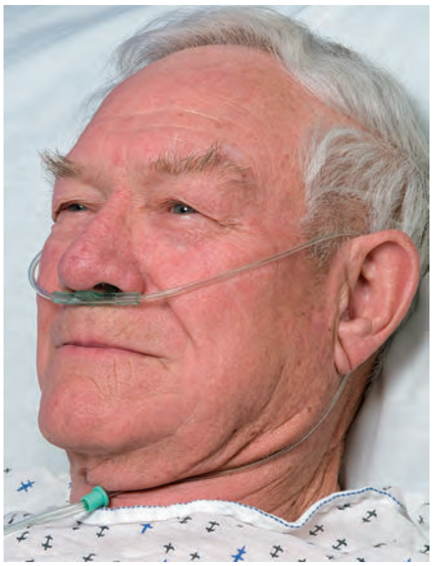
Follow Steps 1 through 4.

5. **Attach the nasal cannula** tubing to the humidifier or the adapter.
6. **Place the nasal prongs** in the patient's nares—prongs curved downward—and then place the tubing around each ear.
   Properly positions the device for optimal oxygen delivery.

(continued on next page)

Procedure 36-4 ■ Administering Oxygen (continued)

7. **Use the slide adjustment device** to tighten the cannula in place under the patient's chin. It must fit securely, but not too tightly. Then proceed to Step 12.
The nasal cannula must fit securely to maximize the amount of oxygen inhaled by the patient. A good fit minimizes the amount of oxygen lost around the prongs.



Procedure Variation for Face Mask

Follow Steps 1 through 4.

8. **Gently place the mask** on the patient's face, applying it from the bridge of the nose to under the chin.

9. **Secure the elastic band** around the back of the patient's head. Make sure the mask fits snugly but comfortably. Then proceed to Step 12.
The mask must fit snugly so that oxygen cannot escape around the edges of the mask. If the mask is too tight, it may cause skin breakdown.

Procedure Variation for Face Tent

Follow Steps 1 through 4.

10. **Gently place the face tent** in front of the patient's face, making sure that it fits under the chin.

11. **Secure the elastic band** around the back of the patient's head.
To keep the face tent in place.

12. **Double-check that the oxygen** equipment is set up correctly and functioning properly.
Ensures that the oxygen is delivered at the prescribed rate. Oxygen delivered at an incorrect rate can cause patient injury.

13. **Assess the patient's respiratory** status before leaving the bedside.
To be certain it is safe to leave the patient.

Evaluation

- Assess respiratory rate, depth, and effort.
- Auscultate breath sounds before leaving the bedside, then monitor every 2 to 4 hours, and as indicated.
- Monitor pulse oximetry until respiratory status improves.
- Monitor ABG results if prescribed.
- Evaluate for skin breakdown, especially behind the ears, cheekbones, and under the chin—areas that are in contact with the oxygen delivery system.
- Notify the primary provider of respiratory status, oxygen, and response and any additional prescriptions needed.

Patient Teaching

- Demonstrate oxygen administration to the patient and caregiver if the patient will be continuing oxygen therapy at home. Allow for time to answer questions, and return demonstration of attaching and placing oxygen on.
- Explain the importance of immediately reporting shortness of breath or any difficulty breathing to the nursing staff before discharge. If the patient is at home, he will need to report the difficulty to the home health and/or primary care provider, and, if needed, to call 911.

Home Care

- Explain to the client and caregivers where to obtain oxygen equipment and what services are available. Make sure they choose a supplier who has 24-hour emergency services.
- Instruct the client and caregiver about oxygen therapy and its use as well as safety measures that they must institute. Safety measures include keeping oxygen away from items that may cause ignition such as lighters, cigarettes, fireplaces, heaters, etc.
- To demonstrate the oxygen is on, client can hold nasal prongs on the side of the cheek to feel air flow or over a glass of water to see air moving water.

- Teach the client and caregiver to clean the nasal cannula or face mask with soap and warm water when it becomes soiled, and allow the mask to air-dry.
- Provide contact information for healthcare personnel who can be reached for advice or emergencies.
- Explain the importance of immediately reporting shortness of breath or any difficulty breathing to the home health and/or primary care provider; and if needed, to call 911.
- In the home, liquid oxygen and oxygen concentrators are more commonly used than portable oxygen tanks. Liquid oxygen may be kept in small, portable containers; an oxygen concentrator removes nitrogen from room air and concentrates O_2. It requires a battery pack or electrical outlet for power. Oxygen concentrators can deliver a flow of 6 to 8 L/min.

Documentation

- Document the date, time, and reason oxygen therapy was initiated.
- Note the type of oxygen delivery system used, the amount of oxygen administered, and the patient's response to oxygen therapy.
- Document vital signs, pulse oximetry values, breath sounds, skin color, and respiratory effort.

Sample documentation

12/14/15 2015. Patient developed acute shortness of breath. RR 36/min & labored, P = 126 beats/min, and BP 212/110 mm Hg. Pulse ox 80% on room air. Crackles and expiratory wheezes auscultated throughout both lungs. Dr. Chow notified of patient's condition. Oxygen with partial rebreather mask @ 10 L/min and Lasix 40 mg IV prescribed and administered. Pulse ox using partial rebreather = 90%. —————— S. Peters, RN

Practice Resources

Lippincott's Nursing Procedures (2012).

Oxygen Delivery Systems

DELIVERY METHOD	FIO_2	DISCUSSION	NURSING RESPONSIBILITIES
 Nasal cannula	1 L/min = 24% 2 L/min = 28% 3 L/min = 32% 4 L/min = 36% 5 L/min = 40% 6 L/min = 44%	▪ Relatively comfortable. ▪ Patients can eat, talk, and cough with a nasal cannula in place. ▪ Works best if the patient breathes through his nose.	▪ Check frequently that the prongs are in the patient's nose. ▪ Assess for dryness of the nasal mucosa. ▪ Humidify flow at rates above 3 L/min (flow rates >3 L/min are drying). ▪ Encourage the patient to take slow, deep breaths so he will inhale more oxygen and less room air.
 **Simple face mask:** A clear, flexible mask that covers the nose and mouth and delivers oxygen flow into the mask.	5–10 L/min = 40%–60% FIO_2	▪ Requires flow rates greater than 5 L/min to prevent accumulation and rebreathing of exhaled CO_2 from within the mask. ▪ Masks are not easily tolerated because they fit tightly and keep heat from radiating from the face, making patients feel hot. ▪ Talking is muffled by the mask, and it must be removed for the patient to eat or drink.	▪ Place face mask securely over the mouth and nose. ▪ Elastic straps fit around the head to hold the mask in place. Place the straps well above the ears to prevent skin irritation and breakdown. ▪ Place gauze or other soft material beneath the straps to prevent irritation. ▪ Check the skin around the mask frequently. ▪ Check the skin over the ears where the mask strap rubs. ▪ Encourage the patient to take slow, deep breaths, so he will inhale more oxygen and less room air.

(continued on next page)

Oxygen Delivery Systems—cont'd

DELIVERY METHOD	FIO_2	DISCUSSION	NURSING RESPONSIBILITIES
 **Partial rebreather mask:** Uses the reservoir bag to capture some exhaled gas for rebreathing	6–15 L/min = 50%–90% FIO_2	▪ Allows higher FIO_2 levels to be delivered because O_2 is collected in the reservoir bag for inhalation. ▪ Exhalation ports allow most exhaled air to escape. ▪ Several types are available. ▪ Can deliver an FIO_2 above 50% at flow rates of 6–15 L/min. ▪ Patient rebreathes some exhaled air along with O_2.	▪ Maintain the flow at a high enough rate to prevent the reservoir bag from collapsing during inhalation. ▪ Encourage the patient to take slow, deep breaths, so he will inhale more oxygen and less room air.
 **Nonrebreather mask:** A type of reservoir bag mask; a valve keeps exhaled air from entering the reservoir bag.	6–15 L/min = 70%–100% FIO_2	▪ Contains only O_2, which allows higher FIO_2 delivery. An FIO_2 of 60%–100% can be delivered at flow rates of 6–15 L/min. ▪ This mask is the only external device capable of delivering an FIO_2 of 100% (in practice, it is rare to achieve a concentration above 75% because the mask does not seal perfectly with the face).	▪ Maintain the flow at a rate high enough to keep the reservoir at least one-third to one-half full during inhalation. ▪ Be sure the mask fits snugly so the patient will breathe in less room air.
 **Venturi mask:** A cone-shaped adapter that serves as a mixing valve to control the amount of O_2 and room air that flows through the mask.	24%–50% FIO_2	▪ The cone-shaped adapter at the base of the mask allows a precise FIO_2 to be delivered. This is very useful for patients with chronic lung disease. ▪ Exhalation ports keep CO_2 buildup to a minimum.	▪ The adapter indicates the required oxygen flow rate needed to deliver the desired FIO_2. Ensure that flow is set at the rate specified to deliver the FIO_2 desired.

Oxygen Delivery Systems—cont'd

DELIVERY METHOD	FIO_2	DISCUSSION	NURSING RESPONSIBILITIES
 **Face tent:** A large, open plastic mask that fits under the chin. It is open at the top and is held in place with an elastic band around the head.	8–12 L/min = 30%–55% FIO_2	▪ Less reliable than a face mask for delivering precise FIO_2 levels. ▪ Allows moderate- to high-density aerosol delivery for humidification. ▪ Patients who feel claustrophobic in a face mask often tolerate a face tent.	▪ Check the skin over the ears where the mask strap rubs.
 **Tracheostomy collar:** A small, cup-shaped device that fits over the tracheostomy opening and is held in place with elastic straps around the neck.	4–10 L/min = 24%–100% FIO_2	▪ It is possible to deliver both high FIO_2 and high humidity with a tracheostomy collar. ▪ Large-bore tubing is used to deliver humidification to the trachea; however, water frequently condenses inside the tubing and can be accidentally drained into the tracheostomy. Usually, a water trap of some sort is placed in the tubing to prevent this problem.	▪ Watch for water accumulation in the tubing.
 **T-piece:** A T-shaped plastic piece; the bottom of the T fits directly and tightly onto the tracheostomy tube.	4–10 L/min = 24%–100% FIO_2	▪ Oxygen and humidity are delivered into one side of the T and exhaled through the other side.	▪ Take care that the oxygen delivery tubing does not pull on the T-piece, which can dislodge the tracheostomy tube and create an airway emergency.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering Oxygen.**

For questions and suggested responses,

Go to Chapter 36, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

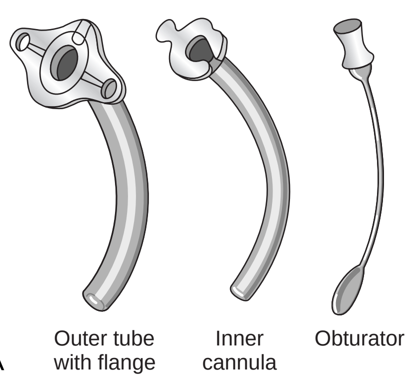
Procedure 36-5 ■ Performing Tracheostomy Care Using Sterile Technique

- For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.
- Also refer to Clinical Insight 36-4.
- Recall that the basic differences in sterile and modified sterile technique are that modified sterile technique uses a sterile catheter and supplies, but nonsterile procedure gloves.

Equipment

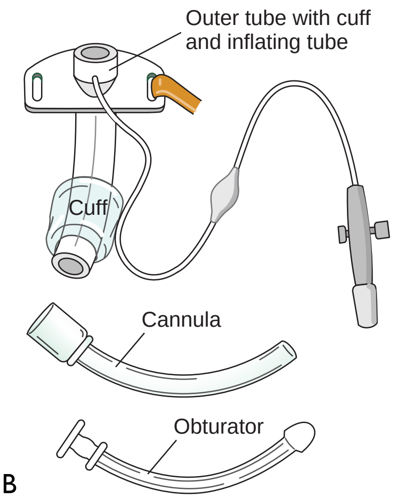
- Tracheostomy suction equipment (see Procedure 36-6)
- Tracheostomy care kit or the following sterile supplies: several cotton-tip applicators, two basins, a brush, sterile 4 in. × 4 in. gauze pads, sterile precut tracheostomy dressing
- Two pairs of sterile gloves (for modified sterile technique, use procedure gloves)
- Disposable inner cannula that is the same size as the tracheostomy, if available. Most tracheostomy tubes have disposable inner cannulas.
- Sterile normal saline solution (for modified sterile technique, you can use distilled or filtered water if agency policy allows)
- Hydrogen peroxide for cleaning of reusable inner cannula only
- Roll of twill tape or hook and loop fastener (Velcro) tracheostomy holder
- Bandage scissors
- Towel or linen-saver pad
- Overbed table
- Face shield and protective gown
- For modified sterile technique: disposable prepackaged wipes, or washcloth and distilled water and soap

Use only the sterile precut dressing, or open and refold a 4 in. × 4 in. gauze pad into a V-shape. Do not cut 4 in. × 4 in. gauze, and do not use cotton-filled gauze squares. The patient may aspirate the cotton or gauze fibers.



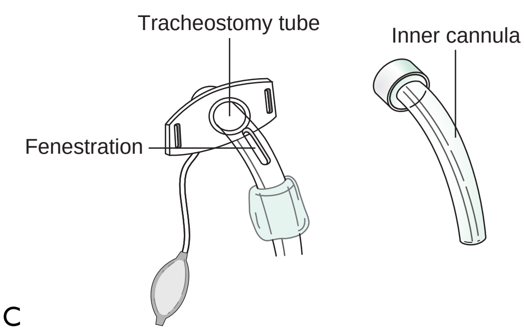
A

***A,* Nondisposable tracheostomy equipment**



B

***B,* Disposable tracheostomy equipment**



C

***C,* Fenestrated tracheostomy equipment**

Delegation

In acute care settings and with new tracheostomies, you should not delegate this procedure to the NAP. For long-standing and well-healed tracheostomies, you can safely delegate care to a NAP or LPN who is adequately trained to perform the skill. This varies by state. In some states only RNs can perform tracheostomy care. If you are not familiar with your state's nurse practice act, contact your state board of nursing.

Pre-Procedure Assessment

- Assess respiratory rate, depth, and rhythm; breath sounds; color; and pulse oximetry results.
  Helps determine whether the patient can tolerate tracheostomy care.
- Assess the tracheostomy site for drainage, redness, or swelling.
  Drainage, redness, or swelling may indicate infection.
- Determine when the patient last ate.
  It is best to schedule this procedure at least 3 hours after a meal to decrease the risk of the patient vomiting and aspirating stomach contents.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* Asterisks indicate steps that differ when using modified sterile technique.

Procedure Steps

1. **Position the patient** in semi-Fowler's position, and place a towel or linen-saver pad over the patient's chest.
   A semi-Fowler's position promotes lung expansion and prevents back strain for the nurse. A towel or linen-saver pad prevents soiling of the patient's gown.

*2. **Don sterile gloves, gown, and** face shield or mask.
   **(For modified sterile technique, don clean procedure gloves.)*

When Using One Sterile Glove

Put a sterile glove on your dominant hand and a clean glove on your other hand.

3. **Hyperoxygenate the patient as needed,** and suction the tracheostomy (see Procedure 36-6 or 36-7).
   Suctioning clears the tracheostomy of secretions that could occlude the outer cannula after the inner cannula is removed for care.

For a Passy–Muir Valve

Remove the Passy–Muir valve (PMV) before suctioning the patient to prepare for tracheostomy care. (A PMV is a device that is used to enable the patient with a tracheostomy to speak. It is attached to the end of the inner cannula at the tracheostomy site.)

4. **Remove and discard** the soiled tracheostomy dressing in the appropriate receptacle, and then remove and discard your gloves. Perform hand hygiene.

5. **Place the tracheostomy care** equipment on the overbed table, and prepare the equipment, using sterile technique.
   Ensures efficiency and helps maintain sterility during tracheostomy care.

   *a. *Disposable inner cannula*—Pour sterile normal saline solution into the two sterile containers.
   **(For modified sterile technique, use filtered tap water or sterile normal saline, per agency policy).*

   b. *Reusable inner cannula*—Pour hydrogen peroxide into one of the sterile solution containers, and pour normal saline solution into the other one. If the inner cannula is not disposable, use hydrogen peroxide to clean only the inner cannula. Use the sterile normal saline (or sterile water) to rinse the inner cannula and clean the faceplate and tracheostomy site.

   *c. *Steps c through g apply to both types of cannula***.** Open two 4 in. × 4 in. gauze packages. Wet the gauze in one package with sterile normal saline, and keep the second package dry. (For modified sterile technique, instead of sterile gauze you may use disposable prepackaged wipes).
   You will use the second package of gauze to dry the skin around the tracheostomy site after cleaning.

   *d. Open one cotton-tip applicator package. Wet the applicators with normal saline solution. (For modified sterile technique, wet the applicators with filtered tap water or normal saline solution.)
   Prepares the applicators for cleaning the exposed surface of the outer cannula and the stoma site located under the faceplate of the tracheostomy tube, respectively.

   e. Open the package containing a new disposable inner cannula.
   Allows for quick replacement of the inner cannula.

   f. Open the package of Velcro tracheostomy ties, or cut a length of twill tape long enough to go around the patient's neck two times. Make sure to cut end of the tape on an angle.
   Allows for quick stabilization of the tracheostomy tube, preventing dislodgement. Cutting the twill tape on an angle allows for easy insertion through the faceplate eyelets.

   g. Position a biohazard receptacle within reach.
   Allows you to dispose of contaminated supplies safely as you use them without leaving the patient or interrupting the procedure.

*6. **Don sterile gloves** (or a sterile glove on your dominant hand and a clean glove on your nondominant hand); keep the glove on your dominant hand sterile. Handle the sterile supplies with the dominant hand only.
   **(For modified sterile technique, don clean procedure gloves. Consider your dominant hand to be clean and handle supplies with that hand only.)*

7. **For patients receiving oxygen:** With your nondominant (nonsterile) hand, remove the oxygen or humidification source. Attach the oxygen source to the outer cannula, if possible. If not possible, have the respiratory therapist set up oxygen blow-by to use while you are cleaning the reusable inner cannula.
   Prevents oxygen desaturation in the patient during the procedure.

(continued on next page)

Procedure 36-5 ■ Performing Tracheostomy Care Using Sterile Technique (continued)

8. Unlock and remove the inner cannula with your nondominant hand, and care for it accordingly.

For a Disposable Inner Cannula

a. **Dispose of the inner cannula** in the biohazard receptacle according to agency policy. You should never clean and reuse a disposable inner cannula.
Prevents contamination by bacteria contained in the inner cannula.

*b. **With your dominant hand**, insert the new inner cannula into the patient's tracheostomy in the direction of the curvature. Following the manufacturer's instructions, lock the inner cannula in place securely to prevent it from dislodging. Remember to keep your dominant hand sterile.
**For modified sterile technique, keep dominant hand clean.*

For a Reusable Inner Cannula

c. If a reusable inner cannula was used, place the inner cannula into the basin filled with hydrogen peroxide.
Hydrogen peroxide helps loosen tenacious (sticky) secretions.

d. Pick up the reusable inner cannula from the container of hydrogen peroxide with your nonsterile hand, and scrub it with the sterile nylon brush, using your sterile dominant hand.

*e. Immerse the inner cannula in the container of sterile normal saline solution (for modified sterile procedure, tap water or normal saline), and agitate it until it is rinsed thoroughly.
Immersing the inner cannula in normal saline solution and agitating it removes the hydrogen peroxide (which can cause tissue irritation) and debris from the inner cannula.

*f. Tap the inner cannula against the side of the container. (For modified sterile technique, shake the cannula to remove water.)
Removes excess fluid so the patient does not aspirate it when you reinsert the cannula.

g. With your dominant hand, reinsert the inner cannula into the patient's tracheostomy in the direction of the curvature. Following the manufacturer's instructions, snap or lock the inner cannula in place securely to prevent it from dislodging. Remember to keep your dominant hand sterile.

For a Passy–Muir Valve

h. Swish the PMV in warm filtered tap water with mild soap.

i. Rinse the PMV thoroughly in warm filtered tap water.

j. DO NOT use hot water, peroxide, bleach, vinegar, alcohol, brushes, or cotton-tip applicators to clean PMV, as this could damage the valve.

k. Shake the PMV to remove excess fluid. If you are going to store the valve, be sure to air-dry the valve before placing it in a storage container.
Removes moisture, which can promote bacterial growth.

l. Set the PMV aside on clean surface to be replaced when the inner cannula is replaced.

For Patients Receiving Oxygen

m. Remove the humidification or oxygen source from the outer cannula, if indicated, using your nondominant hand.

n. Reinsert the inner cannula into the patient's tracheostomy in the direction of the curvature.

o. Following the manufacturer's instructions, lock the inner cannula in place securely. Remember to keep dominant hand sterile.
Lock the inner cannula in place securely to prevent it from dislodging.

p. Reattach the humidification or oxygen source, if indicated.
Provides the patient with needed humidity or oxygen and prevents oxygen desaturation.

***9. Clean the stoma** under the faceplate with cotton-tip applicators saturated with sterile normal saline solution, using a circular motion from the stoma site outward. Use each applicator only once, and then discard it.
*(If using modified sterile technique, applicators may be saturated with filtered tap water or you can use disposable prepackaged wipes.)
Prevents contamination of the cleaned area.

***10. Clean the top surface** of the faceplate and the skin around it with the gauze pads saturated with sterile normal saline solution. Use each gauze pad only once, and then discard it.
*(For modified sterile technique, use the gauze pads if they are contained in the tracheostomy kit, saturated with distilled or filtered tap water.)
Removes secretions that provide a prime medium for microbial growth; prevents contamination of cleaned areas.

11. Dry the skin and outer cannula surfaces by patting them lightly with the remaining dry gauze pad.
Clean, dry skin is needed to avoid skin breakdown and removes moisture, which can promote bacterial growth around the stoma site.

*12. **Seek assistance** from another staff member to help with changing the tracheostomy stabilizers.
Prevents accidental dislodging should the patient begin coughing during the procedure.

13. **Remove soiled tracheostomy stabilizers.**

Removing a Soiled Velcro Tracheostomy Holder

a. With an assistant stabilizing the tracheostomy tube, disengage the Velcro on both sides of the soiled holder, and remove it gently from the eyes of the faceplate. Discard the Velcro holder in the nearest biohazard receptacle.
Removing the soiled holder promotes hygiene and prevents the spread of infection.

Removing Soiled Twill Tape Tracheostomy Ties

b. With an assistant stabilizing the tracheostomy tube, cut the soiled tracheostomy ties using bandage scissors. *Do not* cut the tube of the tracheostomy balloon (if you do, the tracheostomy tube must be replaced). Remove the ties gently from the eyes of the faceplate, and discard them in the nearest biohazard receptacle.
The tracheostomy balloon helps stabilize the tracheostomy in the trachea and prevents an air leak. Cutting the tube to the balloon prevents the balloon from holding air. Removing the soiled holder promotes hygiene and prevents the spread of infection.

14. **Ask the patient to flex** his neck; if he is unable, ask the assistant to hold the patient's head forward, and apply new tracheostomy ties.
Flexing the neck provides the same neck circumference as when the patient coughs and thus ensures you do not place and secure the tracheostomy stabilizers too tightly.

For a Velcro Tracheostomy Holder

a. Thread one end of the Velcro through the eyelet of the faceplate, and fasten it.

b. Bring the holder around the back of the patient's neck.
The holder must be placed around the patient's neck to adequately secure the tracheostomy.

c. Thread the remaining end of the Velcro strap through the empty eyelet of the faceplate and fasten it, making sure that the holder fits securely.

d. Place one finger under the stabilizer to make sure that it is securing the tracheostomy effectively but isn't too tight.
Securing the tracheostomy too tightly might place pressure on the jugular veins; interfere with coughing; or cause necrosis at the tracheostomy insertion site.

Using Twill Tape

e. Thread one end of the twill tape into one of the eyelets on the tracheostomy faceplate.

f. Continue to thread the twill tape through the eyelet, bringing both ends of the tape together.

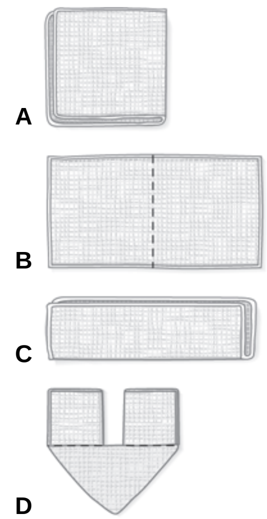
g. Bring both ends of the twill tape around the back of the patient's neck.
To adequately secure the tracheostomy.

h. Thread the end of the twill tape that is closest to the patient's neck through the back of the eyelet on the faceplate.

i. Have your assistant place one finger under the twill tape while you tie the two ends together in a square knot.
Ensures you do not secure the tracheostomy too tightly.

j. Place one finger under the holder to make sure that the holder is securing the tracheostomy effectively but isn't too tight.
See Step 14d.

15. **Don a new pair of sterile gloves,** and insert a precut, sterile tracheostomy dressing under the faceplate and new tracheostomy stabilizers or fold a 4 in. × 4 in. gauze pad into a V shape (below).



The new dressing absorbs secretions and prevents skin breakdown under the faceplate. Never cut the gauze to make a dressing because lint and fibers from the cut edge could enter the trachea and cause respiratory distress.

16. **Dispose of the used equipment** in the appropriate biohazard receptacle according to agency policy.
Helps prevent cross-contamination.

(continued on next page)

Procedure 36-5 ■ Performing Tracheostomy Care Using Sterile Technique (continued)

? What if . . .

- **Your patient begins coughing?**
  a. If the tracheostomy is still secured with ties or Velcro holder, wait to continue tracheostomy care until coughing has ended.
  b. If the tracheostomy is unsecured, stabilize the tube so that it does not become dislodged, being careful not to press too hard on the site. Continue with tracheostomy care when the patient finishes coughing.
  Pressing too hard at the tracheostomy site will stimulate the coughing reflex.
  c. If coughing continues, suspend tracheostomy care and suction the patient to remove any retained secretions.
  Retained secretions may cause increased airway irritation and coughing. Removing these secretions will reduce this irritation.

- **You do not have an assistant to hold the cannula in place while you replace the soiled tracheostomy ties?**

  Never cut the soiled tape before applying the clean tape. Always place the new tape/holders, be certain the tracheostomy is secured, and then cut off the soiled tape or holder.

- **The tracheostomy tube becomes dislodged?**
  a. To prevent this, plan ahead and always have another staff member with you to secure the tracheostomy tube while you change the tracheostomy ties or Velcro holder.
  b. If the tracheostomy tube slips out slightly but is still in the trachea site, gently push it back into the stoma and secure it.
  The pilot balloon will help to keep the tracheostomy tube from completely dislodging.
  c. If the tracheostomy tube becomes completely dislodged, stay with the patient and ask your assistant to call for the respiratory therapist or trained person in your facility to insert a new tracheostomy tube.

- **At Step 9, there are crusts around the stoma when you are cleaning the stoma?**

  Remove the crusts with a cotton-tip swab soaked in hydrogen peroxide; then rinse with a swab soaked in normal saline (or filtered tap water in modified sterile technique). Have the patient hold his breath while you remove crusts so he does not inhale them.

Evaluation

- Assess the area around the stoma site for signs of skin breakdown.
- Evaluate the patient's tolerance of the procedure. Note whether there were any signs of respiratory distress.

Patient Teaching

- Explain to the patient and his family that bloody secretions are normal for 2 to 3 days after tracheostomy tube insertion or for 24 hours after a tracheostomy tube change.
- Tell the patient and/or family to inform the nurse immediately if the tracheostomy tube becomes dislodged.
- Teach tracheostomy care to the patient and caregiver if the tracheostomy is expected to remain long term.

Home Care

- Clean technique can be used for tracheostomy care if the tracheostomy is more than 1 month old.
- Instruct the client and caregiver about home oxygen therapy and suctioning, if necessary.
- Demonstrate tracheostomy care to the caregiver, and ask for a return demonstration.
- Provide the client and caregiver with information about where to obtain tracheostomy care supplies.
- Supply the client and caregiver with contact information of healthcare personnel who can be reached for advice or emergencies.
- Recommend ways of adding moisture to the air, with a goal of maintaining a relative humidity of 50% (e.g., a large humidifier, house plants, wearing damp gauze over the stoma, closing the bathroom door and turning on the hot water to fill the room with steam).
- The stoma should be cleaned, using clean technique, at least twice daily (or more often, depending on the amount of secretions).
- Stress handwashing before and after doing any part of tracheostomy care.
- Remind client and caregiver not to use cotton or gauze.
  These can leave fibers that may get into the airway and increase the incidence of infection.

Documentation

- Document the date and time that you performed tracheostomy care.
- Note the color, amount, consistency, and odor of secretions.
- Note the condition of the stoma and skin around the stoma site, and the presence of drainage, redness, or swelling.
- Document respiratory rate, depth, and pattern; skin color; and breath sounds.

- Document the patient's tolerance of the procedure.
- If problems arose, document any interventions that were necessary.

Sample documentation

Note: Because this is only a partial computer screen, it may not show all the information you would need to record about the patient.

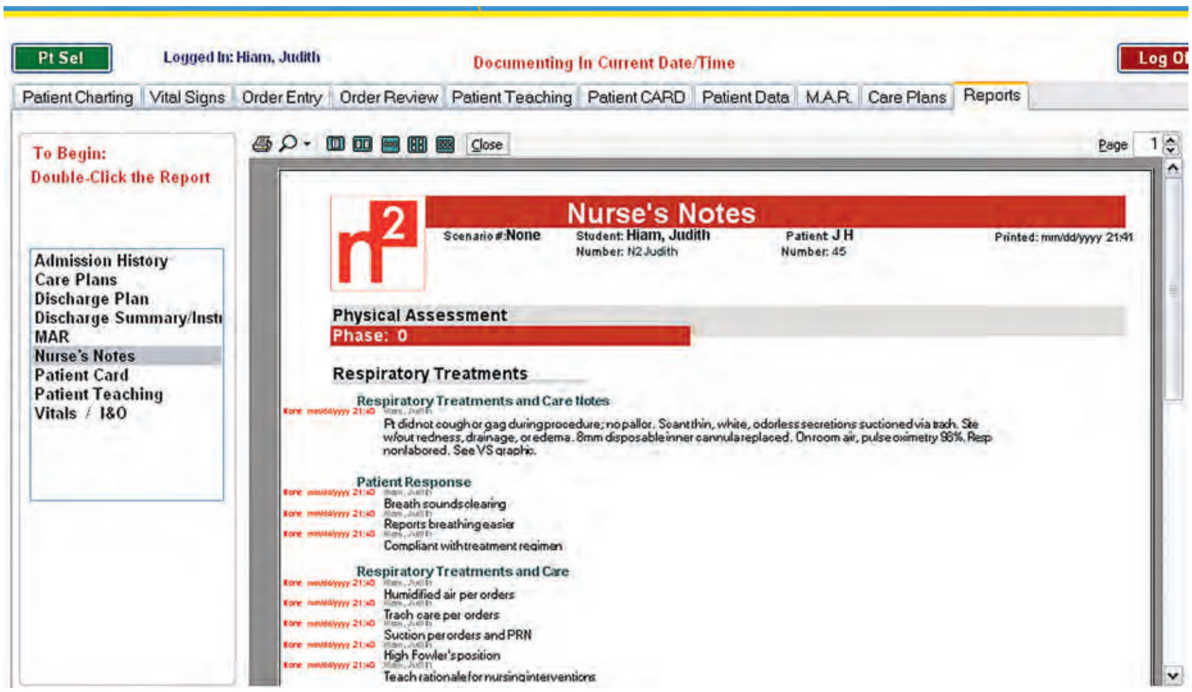
Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Performing Tracheostomy Care Using Sterile Technique.**

For questions and suggested responses,

Go to Chapter 36, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*



Practice Resources

Barnett, M. (2012); Johnston, J., Davis, S., & Sherman, J. (n.d.); Kozin, E., Straton, J., & Kapo, J. (2012); Mitchell, R. B., Hussey, H. M., Setzen, G., et al. (2013); National Guideline Clearinghouse (2011); Siddiqui, J., Sherren, P. B., & Birchall, M. A. (2013); Siegel, J., Rhinehart, E., Jackson, M., et al. (2007).

Procedure 36-6 ■ Performing Tracheostomy Suctioning (Open System)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Portable or wall suction device with tubing and a collection canister
- Linen-saver pad or towel
- Resuscitation bag connected to oxygen source
- Sterile suction catheter kit: adults: 12 to 18 Fr; children: 8 to 10 Fr; infants: 5 to 8 Fr
- If a kit isn't available, collect the following: sterile gloves, sterile suction catheter of the appropriate size, and a sterile container.
- Pour-bottle of sterile, normal saline solution
- Sterile basin or container for fluids
- Prefilled 10-mL containers of normal saline solution
- Face shield or goggles
- Sterile gloves (or procedure gloves; follow agency policy)
- Protective gown

Delegation

As a rule you should not delegate tracheostomy suctioning to an LPN or NAP, because the procedure requires professional-level theoretical knowledge, assessment skills, and problem-solving ability. However, if the patient has a permanent tracheostomy tube in place and the patient will require long-term care, care can be delegated to trained personnel. Refer to individual state board of nursing for rules on delegating this procedure.

(continued on next page)

Procedure 36-6 ■ Performing Tracheostomy Suctioning (Open System) (continued)

Pre-Procedure Assessment

- Assess the respiratory rate, depth, and rhythm; breath sounds; color; and pulse oximetry results.
- Assess for signs that indicate the need for suctioning: restlessness, cyanosis, labored respirations, decreased oxygen saturation, increased heart and respiratory rates, visible secretions in the airway, increased peak airway pressures on the ventilator, decreasing SaO_2 or PaO_2, and adventitious breath sounds during auscultation.

  Suctioning should be performed only when necessary to prevent unnecessary oxygen desaturation and tissue trauma.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure uses modified sterile technique.

Procedure Steps

1. **Position the patient** in semi-Fowler's position unless contraindicated.
   Promotes lung expansion and oxygenation.

2. **Place the linen-saver pad** or towel on the patient's chest.
   Prevents soiling of the patient's gown during suctioning.

3. **Turn on the wall suction** or portable suction machine, and adjust the pressure regulator according to agency policy, using the lowest possible suction pressure. Typically, this is:
   Adults: 100 to 150 mm Hg
   Children: 100 to 120 mm Hg
   Infants: 50 to 95 mm Hg
   Using the appropriate pressure prevents tissue trauma and ensures successful suctioning. Higher pressures are associated with hypoxemia, tissue trauma, and atelectasis, yet do not improve removal of secretions.

4. **Don a nonsterile glove** and face shield or goggles. Test the suction equipment by occluding the connection tubing. Remove and discard the glove. Perform hand hygiene.
   Protective clothing protects you from contamination with secretions that may splash during suctioning. Testing the suction ensures proper functioning before you insert suction catheter.

5. **Open the suction catheter kit** or (if a kit isn't available) the gathered equipment. Maintain sterility of the inside of the suction kit or the gathered equipment.
   This prevents contaminating the airway when you introduce the suction catheter.

6. **Pour sterile saline** into the sterile container.
   Sterile saline is used to clear the suction catheter of secretions after suctioning.

7. **Don gloves.** Follow agency policy, as some guidelines allow for clean nonsterile rather than sterile procedure gloves; follow agency policy. Premeasure the catheter insertion distance for 0.5 to 1 cm (¼ to ½ in.) past the distal end of the endotracheal tube (ETT); the ETT normally sits between 3 and 7 cm (1 to 2¾ in.) above the carina.

   If Using Sterile Technique

   a. Don sterile gloves. Consider your dominant hand sterile and your nondominant hand unsterile.

   If Using Modified Sterile Technique

   b. Don clean nonsterile gloves. Consider your dominant hand clean and your nondominant hand contaminated.
   Keeping your dominant hand sterile (or clean, depending on the technique) prevents contamination of the suction catheter.

8. **Pick up the suction catheter** with your dominant hand, and attach it to the connection tubing. Do not touch the connection tubing with your sterile (or clean) glove.
   Prepares the suction catheter for use.

9. **Put the tip of the suction** catheter into the sterile container of normal saline solution, and suction a small amount through the suction catheter. Apply suction by placing a finger over the suction control port of the suction catheter.
   Lubricates the catheter and helps ensure that the suction equipment is functioning properly. Sterile saline is necessary to clear the suction catheter of secretions after suctioning. The outside of the saline container is not sterile; it would contaminate your dominant hand.

10. **If the patient is receiving supplemental oxygen**, hyperoxygenate the patient according to agency policy. If the patient does not require oxygen, you do not need to hyperoxygenate.
    Helps prevent hypoxia and related complications (cardiac arrhythmias, seizures, arrest) during suctioning. Suctioning clears secretions, but it also removes oxygen from airways.

    If the Patient Requires Mechanical Ventilation

    a. Press the 100% O_2 button on the ventilator. Some agencies require the nurse to manually hyperoxygenate the patient; follow agency policy.
    Ventilators typically have a button that allows you to hyperoxygenate the patient for a total of 2 minutes. Once this time period elapses, the ventilator automatically resumes its previous settings.

    If the Patient Does Not Require Mechanical Ventilation

    b. Obtain the assistance of a second provider.
    c. Have your partner attach the resuscitation bag to the tracheostomy tube, and hyperoxygenate the patient by compressing the resuscitation bag three to five times as the patient inhales. Remove the resuscitation bag, and place it next to the patient when finished.

You must perform hyperoxygenation manually if the patient does not require mechanical ventilation.

11. Perform suctioning.

a. Lubricate the suction catheter tip with the normal saline solution.
Lubrication eases passage of the suction catheter through the tracheostomy tube.

b. Using your dominant hand, gently but quickly insert the suction catheter into the tracheostomy tube.

c. Advance the suction catheter, with suction off, gently aiming downward, and being careful not to force the catheter. Insert to the premeasured length: no farther than the **carina tracheae** (the ridge at the lower end of the trachea that separates the openings of the two mainstem bronchi); do not insert more than 6 inches (15 cm), and do not force against any resistance.
Forcing the catheter during insertion may cause tissue trauma.

d. Apply suction while you withdraw the catheter; rotate the catheter (roll it between your thumb and forefinger) as you remove it. Make sure to apply suction for no longer than 15 seconds.
Applying suction for longer than 15 seconds causes hypoxia and may cause tissue trauma.

12. Repeat suctioning as needed.
Several passes with the suction catheter may be needed to clear the airway of secretions.

a. Allow at least 30-second intervals between suctioning.
b. Hyperoxygenate the patient between each pass.
c. Limit total suctioning time to 5 minutes.

13. Replace the oxygen source if it was removed during suctioning.
To prevent hypoxia.

14. Coil the suction catheter in your dominant hand (alternatively, wrap it around your dominant hand). Pull the sterile (or clean) glove off over the coiled catheter. Discard the glove containing the catheter in a fluid-resistant receptacle designated by your agency.

Prevents contaminating the environment with secretions.

15. Perform hand hygiene, don clean procedure gloves.

16. Using your nondominant hand, clear the connecting tubing of secretions by placing the tip into the container of sterile saline.
Prepares the tubing for later reuse.

17. Turn off the suction units (and the oxygen, if appropriate).

18. Reposition the patient.
Promotes comfort and prevents skin breakdown.

? What if . . .

- **The patient has a cuffed tracheostomy tube?**

  Check to see that it is properly inflated before suctioning. Usually this is 20 to 25 mm Hg or less, but follow the manufacturer's instructions and use a cuff manometer. See Clinical Insight 36-4 to learn how to check cuff inflation.

Evaluation

- Assess the color, amount, and consistency of secretions.
- Evaluate the patient's tolerance of the procedure. (e.g., were there signs of respiratory distress during suctioning?)
- Evaluate the effectiveness of the procedure by comparing breath sounds, vital signs, and pulse oximetry before and after suctioning.

Patient Teaching

- Teach the patient and caregiver how to perform suctioning if the patient will be discharged with an artificial airway. Make sure they can successfully provide a return demonstration.
- Teach the caregiver strategies for managing the patient's airway at home.

Home Care

- Provide the family and caregiver information about where to obtain suction equipment, contact information for healthcare personnel who can be reached for advice or emergencies, and information about home oxygen therapy.
- Guidelines recommend clean technique for home care, and for repeated catheter use as long as the catheter is still clear.
- Teach the family and caregiver how to clean catheters for reuse (soak in hot, soapy water; rinse inside and out with clean water; air-dry; store in a dry container).

(continued on next page)

Procedure 36-6 ■ Performing Tracheostomy Suctioning (Open System) (continued)

Documentation

Document the following:

- Date, time, and reason you performed suctioning.
- The size of the suction catheter you used.
- Amount, color, consistency, and odor of secretions.
- Patient's respiratory status before and after the procedure.
- Patient's tolerance of the procedure.
- Any complications that occurred as a result of the procedure, and interventions you made in response.

Sample documentation

Sept. 18, 2015 0900 Pulse ox 93%, VS elevated, upper airway rhonchi auscultated. Hyperoxygenated with 100% O_2; suctioned moderate amount thick, yellow mucus with #12 Fr suction catheter. After procedure lungs clear, pulse ox 98%, VS WNL.——————Jackie Estes, RN

Practice Resources

Johnston, J., Davis, S., & Sherman, J. (n.d.); Kuriakose, A. (2008); Morrow, B., & Argent, A. (2008); NGC (2010); Rauen, C., Chulay, M., Bridges, E., et al. (2008).

Procedure 36-7 ■ Performing Tracheostomy or Endotracheal Suctioning (Inline Closed System)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

For the once-a-day steps: Procedure gloves and inline suction catheter
When suctioning: Sterile normal saline

Inline suction catheter. (© Unomedical a/s, used with permission.)

Delegation

As a rule, you should not delegate tracheostomy or endotracheal suctioning to an LPN or NAP, because both procedures require professional-level theoretical knowledge, assessment skills, and problem-solving ability. Refer to the individual state board of nursing for rules on delegating this procedure.

Pre-Procedure Assessment

- Assess respiratory status, including respiratory rate, depth, and rhythm; breath sounds; color; and pulse oximetry results.
- Assess for restlessness, cyanosis, labored respirations, decreased oxygen saturation, increased heart and respiratory rates, visible secretions in the airway, and the presence of adventitious breath sounds during auscultation.
  These assessments help determine whether the patient requires suctioning. Suctioning should be performed only when necessary to prevent unnecessary oxygen desaturation and tissue trauma.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure uses modified sterile technique.

Daily Procedure Steps

An inline suction unit is available only for patients on a mechanical ventilator. Most agencies require the respiratory therapy department to set up the inline suction equipment. If this is not the agency's policy, you may need to perform these steps once per day:

1. **Open the inline suction** catheter package, using sterile technique.
2. **Remove the adapter** on the ventilator tubing.
3. **Attach the inline suction** catheter equipment to the ventilator tubing.
4. **Reconnect the adapter** on the ventilator tubing.
5. **Attach the other end** of the inline suction catheter to the connection tubing placed to suction.

Suctioning Procedure Steps

1. **Place the patient in semi-Fowler's** position, unless contraindicated.
   The suction catheter is contained within a sterile unit.
2. **Don clean procedure gloves.**
   You do not need to wear sterile gloves.

3. **Place a linen-saver pad** or towel on the patient's chest.

4. **If a lock is present** on the suction control port, unlock it.

5. **Turn on the wall suction** or portable suction machine, and adjust the pressure regulator according to agency policy or provider's prescription.
Using the appropriate pressure prevents tissue trauma and ensures successful suctioning.

6. **Pick up the catheter** with your dominant hand and use your nondominant hand for the suction port.
Using the dominant hand improves dexterity.

7. **Unlock the inline catheter** and gently insert the suction catheter into the airway by maneuvering the catheter within the sterile sleeve.

8. **Advance the suction catheter** into the airway, being careful not to force the catheter. Ask the patient to take slow, deep breaths if she can cooperate. Advance the catheter to the predetermined and premarked distance. Do not apply suction while advancing.
Forcing the catheter during insertion may cause airway trauma.

9. **Apply suction** by depressing the button over the suction control port as you withdraw the catheter. Make sure to apply suction for no longer than 15 seconds.
Applying suction for longer than 15 seconds causes hypoxia and may cause tissue trauma.

10. **Withdraw the inline suction** catheter completely into the sleeve. The indicator line on the catheter should appear through the sleeve.
The indicator line is a safety mechanism designed to make sure the suction catheter is withdrawn completely to prevent airway obstruction.

11. **Attach the prefilled 10-mL** container of normal saline solution to the saline port located on the inline equipment.
Provides a flush solution to clear the suction catheter of secretions.

12. **Squeeze the 10-mL container** while applying suction.
Clears the catheter of secretions, preparing the catheter for repeat use. If allowed to remain in the catheter or suction line, secretions may dry and harden, reducing line suction efficiency.

13. **Lock the suction regulator port.**
Prevents you from inadvertently applying suction.

? What if . . .

- **The patient experiences a dysrhythmia?**

  Stop suctioning and hyperoxygenate the patient. If a further attempt at suctioning promotes a dysrhythmia, notify the medical care provider.

For Evaluation, Patient Teaching, and Documentation, see Procedure 36-6. Typically, you would not be doing inline suctioning in the home.

Practice Resources

Cleveland Clinic (2009); Kuriakose, A. (2008); Morrow, B., & Argent, A. (2008); National Guideline Clearinghouse (2010); Restrepo, R. D., Brown, J. M., & Hughes, J. M. (2010).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Performing Tracheostomy Suctioning (Inline Closed System).**

For questions and suggested responses,

Go to Chapter 36, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 36-8 ■ Performing Orotracheal and Nasotracheal Suctioning (Open System)

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Portable or wall suction device with connection tubing and a collection canister
- Linen-saver pad or towel
- Sterile, flexible, multiple-eyed suction catheter kit (12 to 18 Fr for adults, 8 to 10 Fr for children, and 5 to 8 Fr for infants). If a kit isn't available, collect the following: sterile gloves, sterile suction catheter of the appropriate size, and a sterile container for fluids
- Pour-bottle of sterile water or sterile normal saline solution
- Face shield or goggles and gown
- Water-soluble lubricant for NT suctioning
- Sputum trap, if a specimen is needed
- Nasopharyngeal airway when frequent NT suctioning is required
- Resuscitation bag with mask

Procedure 36-8 ■ Performing Orotracheal and Nasotracheal Suctioning (Open System) (continued)

Delegation

You should not delegate orotracheal and nasotracheal suctioning to an LPN or NAP, because these procedures require theoretical knowledge, assessment skills, and problem-solving ability.

Pre-Procedure Assessment

- Assess respiratory rate, depth, and rhythm; breath sounds; skin color; and pulse oximetry results.
- Assess for signs that indicate the need for suctioning: gurgling sounds during respiration, restlessness, labored respirations, decreased oxygen saturation, increased heart and respiratory rates, and the presence of adventitious breath sounds during auscultation.
  Suctioning removes oxygen from airways and can cause tissue trauma. It should be done only when essential (i.e., only when less invasive techniques have proved unsuccessful and when the secretions are causing physiological deterioration and/or distress).
- Assess the effectiveness of the cough.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure uses modified sterile technique. Although the oropharynx and nasopharynx are not sterile, you should keep the suction catheter free from other contaminants as much as possible. Some facilities do use sterile gloves for this procedure

Procedure Steps

1. **Position the patient.**

For Orotracheal Suctioning

a. Position the patient in semi-Fowler's position, with the head turned to face you.

For Nasotracheal Suctioning

b. Position the patient in semi-Fowler's position, with his neck hyperextended, unless contraindicated.
Hyperextending the neck makes it easier to insert the suction catheter. Upright position helps to prevent caregiver back strain.

2. **Place the linen-saver pad** or towel on the patient's chest.
Prevents soiling of the patient's gown during suctioning.

3. **Put on a face shield or goggles and gown.**
Protects you from contamination with secretions that may splash during suctioning.

4. **Turn on the wall suction** or portable suction machine, and adjust the pressure regulator according to agency policy. Guidelines from American Association for Respiratory Care (AARC) specify:
   Adults: 100 to 150 mm Hg
   Children: 100 to 120 mm Hg
   Infants: 80 to 100 mm Hg
   Neonates: 60 to 80 mm Hg
The suction regulator must be set appropriately to prevent tissue trauma and hypoxia and yet remove secretions effectively.

5. **Don a procedure glove** and test the suction equipment by occluding the connection tubing. Discard the glove and perform hand hygiene.
Testing the equipment ensures proper functioning before you insert the catheter in the patient's airway.

6. **Open the suction catheter kit** or, if a kit isn't available, the gathered equipment.

Nasal approach: If you are using the nasal approach, open the water-soluble lubricant and a nasopharyngeal airway.

7. **Don gloves.** Follow agency policy, as some guidelines allow for clean nonsterile rather than sterile procedure gloves.

If Using Sterile Technique

a. Don sterile gloves. Consider your dominant hand sterile and your nondominant hand unsterile. Alternatively, put a sterile glove on your dominant hand and a clean procedure glove on your nondominant hand. Consider your dominant hand sterile and your nondominant hand nonsterile. (Note: if you consider both hands sterile, you must remove the cap from the sterile water before donning gloves.)

If Using Modified Sterile Technique

b. Don clean nonsterile gloves. Consider your dominant hand clean and your nondominant hand contaminated.
Keeping the dominant hand sterile prevents contaminating the upper airways with a nonsterile suction catheter. This is a modified sterile suction technique because the catheter enters the trachea via nose or the mouth—which are not sterile. However, take care to keep the catheter free from other contaminants.

8. **Pour sterile saline** into the sterile container, using your nondominant hand.
Sterile saline will be used to clear the suction catheter of secretions after suctioning.

9. **Pick up the suction catheter** with your dominant hand, and attach it to the connection tubing, maintaining sterility of your hand and the catheter.
Prepares the suction catheter for use.

10. **Put the tip of the suction** catheter into the sterile container of normal saline solution, and suction a small amount of normal saline solution through the suction catheter. Apply suction by placing a finger over the suction control port of the suction catheter.
Lubricates the catheter and helps ensure that the suction equipment is functioning properly.

11. **Ask the patient to take several slow, deep breaths.** If patient's oxygen saturation is <94%, or if he is

in any distress, you may need to give supplemental oxygen before, during, and after suctioning. See Procedure 36-4: Administering Oxygen.
Promotes relaxation and helps hyperoxygenate the patient before suctioning.

12. Using your nondominant hand, remove the oxygen delivery device, if present.

For Oral Approach, Patient Receiving Nasal Oxygen

a. If the patient is receiving nasal oxygen and you are doing orotracheal suctioning, you do not need to remove the oxygen source.

For Nasal Approach, Patient Receiving Nasal Oxygen

b. Remove the nasal oxygen and place the nasal cannula in the patient's mouth. See Procedure 36-4.
Placing the cannula in the patient's mouth makes it easier to access the nares for suctioning while still delivering oxygen to the patient (orally).

13. Premeasure to approximate the depth you should insert the suction catheter. For adults, insert the catheter about 15 cm (6 in.) for an oral approach, and 20 cm (8 in.) for a nasal approach. Be careful not to contaminate the catheter while you measure.
Prevents trauma at the carina and ensures suctioning of the full length of the trachea.

For Oral Approach

a. Measure the distance between the edge of the patient's mouth to the tip of the earlobe and down to the bottom of the neck.

For Nasal Approach

b. Measure the distance from the tip of the nose to the tip of the earlobe and down to the bottom of the neck.

14. If using nasal approach, insert nasopharyngeal airway gently into the nostril, with the bevel toward the septum (center of the nose), advance the airway straight in, following the floor of the nose. See Procedure 36-13.
Do not force nasopharyngeal airway into the nostril as this may cause unnecessary edema and trauma.

15. Lubricate and insert the suction catheter.
Lubrication makes it easier to pass a suction catheter through the nares.

For Orotracheal Suctioning

a. Lubricate the suction catheter tip with normal saline solution.

b. Using your dominant hand, gently but quickly insert the suction catheter along the side of the patient's mouth or through the endotracheal tube into the oropharynx.
Quick insertion along the side of the mouth prevents gagging.

c. When the patient inhales, advance the suction catheter to the predetermined distance, being careful not to force the catheter.
Advancing the suction catheter during inhalation ensures that the catheter enters the trachea rather than the esophagus. Forcing the catheter during insertion may cause tissue trauma.

For Nasotracheal Suctioning

d. Lubricate the catheter tip with the water-soluble lubricant.
Water-soluble lubricant is preferred because it will dissolve if it accidentally enters the lungs, whereas an oil-based lubricant (e.g., petroleum jelly) won't dissolve in the respiratory tract and causes complications if it enters the lungs.

e. Using your dominant hand, gently but quickly insert the suction catheter into the nasotracheal tube and down to the pharynx. When the patient inhales, advance the suction catheter, gently aiming downward to the predetermined distance, being careful not to force the catheter.
Ensures that the catheter enters the trachea. Forcing the catheter during insertion may cause tissue trauma.

16. Place a finger or thumb over the suction control port of the catheter. Apply suction while you withdraw the catheter, using a continuous rotating motion. Apply suction for no longer than 15 seconds.
Using a continuous rotating motion and suctioning while withdrawing the catheter prevents trauma to any one area of the airway. Limiting suctioning to less than 15 seconds prevents hypoxia.

17. After you withdraw the catheter, clear it by placing the tip of the catheter into the container of sterile saline and applying suction.

18. Lubricate the catheter, and repeat suctioning as needed, allowing intervals of at least 30 seconds between suctioning. Reapply oxygen between suctioning efforts, if required.
Several passes with the suction catheter may be needed to clear the airway of secretions. Total suctioning time should be limited to 5 minutes, however, to prevent trauma and hypoxia.

(continued on next page)

Procedure 36-8 ■ Performing Orotracheal and Nasotracheal Suctioning (Open System) (continued)

19. Replace the oxygen source.
Prevents hypoxia.

20. Coil the suction catheter in your dominant hand (alternatively, wrap it around your dominant hand). Hold the catheter while you pull the sterile glove off over it. Discard the glove containing the catheter in a biohazard receptacle (e.g., bag) designated by your agency.
These actions prevent contaminating the environment with secretions.

21. Using your nondominant hand, clear the connecting tubing of secretions by placing the tip into the container of sterile saline.

22. Dispose of equipment, and make sure new suction supplies are readily available for future suctioning.
The patient may require suctioning at any time, so equipment must be readily available.

23. Provide mouth care.
Promotes patient comfort and clears the mouth of any secretions the patient may have expectorated.

24. Position the patient in a comfortable position, and allow him to rest.
Comfort and rest help the patient recover from the stress of suctioning.

? What if . . .

- **The patient's oxygen saturation is less than 94%, or if he is in any distress?**

  Administer supplemental oxygen before, during, and after suctioning. Notify the patient's primary provider if the patient does not respond to additional oxygen.

Evaluation

- Assess the color, consistency, and amount of secretions.
- Evaluate the patient's tolerance of the procedure. Note whether there were signs of respiratory distress during suctioning.
- Evaluate the effectiveness of the procedure by comparing breath sounds, vital signs, and pulse oximetry or blood gas data before and after the procedure.

Patient Teaching

- Explain the importance of administering supplemental oxygen or of taking several deep breaths before suctioning.
- Inform the patient that coughing typically increases with suctioning.
- Demonstrate orotracheal or nasotracheal suctioning to the caregiver, and ask for a return demonstration if suctioning will be required at home.

Home Care

- Instruct the family and caregiver about where to obtain suction equipment.
- Provide contact information of healthcare personnel who can be reached for advice or emergencies.
- Explain that the procedure can be performed using clean technique instead of sterile technique in the home.
- Instruct the caregiver that suction catheters can be cleaned for reuse by washing them with soapy water and then boiling them for 10 minutes. After they are cleaned, rinse the catheters with normal saline solution or tap water.
- Instruct to change the secretion collection container every 24 hours, or clean it according to home care agency guidelines every 24 hours.

Documentation

- Document the date, time, and reason you performed suctioning.
- Note the suction technique you used and the catheter size.
- Note the color, consistency, and odor of secretions.
- Document the patient's respiratory status before and after the procedure.
- Document the patient's tolerance of the procedure and any complications that occurred as a result of the procedure.
- Document any interventions you performed to address complications that occurred.

Sample documentation

July 31, 2015 0930 O_2 sat 89% on room air, bilateral rhonchi to bases auscultated, unproductive cough, heart rate 90, RR-18. Assistant nurse recruited for manual ventilation. Client placed in semi-Fowler's position, hyperventilated for 1 minute to 100% O_2 sat, oropharyngeal suctioning performed using sterile technique, resulting in moderate amounts of white, tenacious, yellow-tinged secretions. Improved breath sound with diminished rhonchi auscultated, O_2 sat at 97% on room air, heart rate 78, RR-14. Client smiles when asked how he feels. Bed in low position, call light and fluids in reach. ——————— Kelton Jones, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Performing Endotracheal Suctioning (Open System).**

For questions and suggested responses,

Go to Chapter 36, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*

Procedure 36-9 ■ Performing Upper Airway Suctioning

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

➤ *Note:* Upper airway suctioning may be done via the oropharyngeal or nasopharyngeal route. However, nasal suction is usually required only to improve oxygenation in infants because most adult airway obstruction occurs in the mouth and oropharynx.

Vigorous nasal suction can induce epistaxis (nosebleed) and further complicate an already difficult airway.

Equipment

- Portable or wall suction device with connection tubing and a collection canister
- Linen-saver pad or towel
- Sterile suction catheter kit (12 to 18 Fr for adults, 8 to 10 Fr for children, and 5 to 8 Fr for infants). If a kit isn't available, collect the following: sterile suction catheter of the appropriate size, and a sterile container. If you plan to suction both the oropharynx and the nasopharynx, you need a separate sterile catheter for each.
- Yankauer device can be used for oropharyngeal suction.
- Pour-bottle of sterile normal saline solution
- Sterile basin or other container for fluids
- Face shield or goggles and gown
- Procedure gloves
- Water-soluble lubricant for nasopharyngeal suctioning
- Sputum trap, if a specimen is needed
- Biohazard bag

Delegation

Do not delegate oropharyngeal and nasopharyngeal suctioning to an LPN or NAP, because these procedures require theoretical knowledge, assessment skills, and problem-solving ability. However, the NAP (and the client or family) can use a Yankauer tube to suction the oral cavity because there is less risk for trauma to mucosa than with oro- or nasopharyngeal suctioning.

Pre-Procedure Assessment

- Assess respiratory rate, depth, and rhythm; breath sounds; color; and pulse oximetry results. Note signs that indicate the need for suctioning: restlessness, cyanosis, labored respirations, decreased oxygen saturation, increased heart and respiratory rates, visible secretions in the airway, and the presence of adventitious breath sounds during auscultation.
  You must be certain the patient requires suctioning. Suctioning should be performed only when necessary to prevent unnecessary oxygen desaturation and tissue trauma.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure describes modified sterile technique: sterile supplies with clean procedure gloves. Although the oropharynx and nasopharynx are not sterile, you should keep the suction catheter free from other contaminants as much as possible. Some facilities do use sterile gloves for this procedure.

Procedure Steps

1. **Position the patient**. Explain that suctioning may stimulate coughing or gagging, but that coughing helps mobilize secretions.

Oropharyngeal Suctioning

Position the patient in a semi-Fowler's or high Fowler's position, with his head turned toward you.
Facilitates insertion of the suction catheter and prevents straining your back. It also promotes lung expansion and effective coughing.

For Nasopharyngeal Suctioning

Position the patient in semi-Fowler's or high Fowler's position with his neck hyperextended, unless contraindicated.

2. **Place the linen-saver pad** or towel on the patient's chest.
   Prevents soiling of the patient's gown during suctioning.

3. **Don a face shield or goggles and gown.**
   Protects you from contamination with secretions that may splash during suctioning. Not all guidelines specify wearing a gown for this procedure.

4. **Turn on the wall suction** or portable suction machine, and adjust the pressure regulator according to agency policy, typically:
   Adults: 100 to 150 mm Hg
   Children: 100 to 120 mm Hg
   Infants: 50 to 95 mm Hg
   The suction regulator must be set appropriately to prevent tissue trauma and hypoxia and to function effectively to remove secretions. Higher pressures are associated with hypoxemia, tissue trauma, and atelectasis, yet do not improve removal of secretions.

5. **Test the suction equipment** by occluding the connection tubing.
   Ensures proper functioning before use.

6. **Open the suction catheter kit** or the gathered equipment. If you are using the nasal approach, open the water-soluble lubricant.

7. **Don procedure gloves**; consider (and keep) your dominant hand clean; consider your nondominant hand to be contaminated.
   This is not a sterile suction procedure but care should be taken to keep the suction catheter free from other contaminants. Keeping the dominant hand clean prevents contaminating the upper airways with an unclean suction catheter.

8. **Pour sterile saline** into the sterile container, using your nondominant hand.
   Sterile saline is necessary to clear the suction catheter of secretions after suctioning. The outside of the saline container is not sterile; it would contaminate your dominant hand.

(continued on next page)

Procedure 36-9 ■ Performing Upper Airway Suctioning (continued)

9. **Pick up the suction catheter** with your dominant hand, and use your other hand to hold the connection tubing (to suction) while you attach it.

10. **Put the tip of the suction catheter** into the sterile container of normal saline solution, and suction a small amount of normal saline solution through the suction catheter. Apply suction by placing a finger over the suction control port. When using a Yankauer-type device, the suction is continuous and there is no port to occlude.
Ensures that the suction equipment is functioning properly. If you need to see a Yankauer device,

Go to **Figure 36-14,** in Volume 1.

11. **Approximate the depth** to which you will insert the suction catheter.

For Oropharyngeal Suctioning

Measure the distance between the edge of the patient's mouth and the tip of the patient's earlobe.
Determines the proper distance you should insert the suction catheter for oropharyngeal suctioning.

For Nasopharyngeal Suctioning

Measure the distance between the tip of the patient's nose and the tip of the patient's earlobe.
Helps determine the correct distance you should insert the suction catheter for nasopharyngeal suctioning.

12. ***For nasopharyngeal suctioning only:***
Using your nondominant hand, remove the oxygen delivery device, if present. Have the patient take several slow, deep breaths. If patient's oxygen saturation is <94%, or if he is in any distress, administers supplemental oxygen before, during, and after suctioning. See Procedure 36-4: Administering Oxygen.
Deep breathing helps to hyperoxygenate the patient and helps prevent hypoxia during suctioning.

13. **Lubricate and insert the suction catheter**.

For Oropharyngeal Suctioning

a. Lubricate the catheter tip with the normal saline solution.

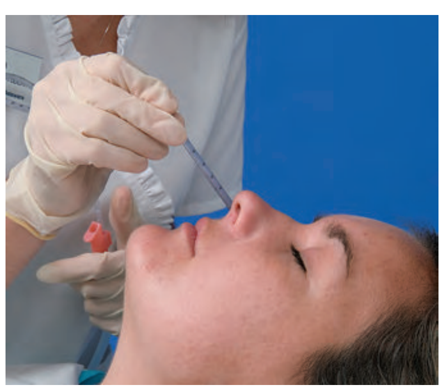
b. Using your dominant hand, gently but quickly insert the suction catheter along the side of the patient's mouth into the oropharynx.
Inserting the suction catheter along the side of the mouth prevents gagging.

c. Advance the suction catheter quickly to the premeasured distance—usually 7.5 to 10 cm (3 to 4 in.) in the adult—being careful not to force the catheter.
Ensures that the suction catheter will reach the pharynx. Forcing the catheter during insertion may cause tissue trauma.

For Nasopharyngeal Suctioning

d. Lubricate the catheter tip with the water-soluble lubricant.
Eases passage of the suction catheter through the naris. Water-soluble lubricant is preferred because it will dissolve if it accidentally enters the lungs, whereas an oil-based lubricant (e.g., petroleum jelly or lotion) will not dissolve in the respiratory tract and causes complications if it enters the lungs.

e. Using your dominant hand, gently but quickly insert the suction catheter into the naris.
Prevents trauma to the naris.



f. Advance the suction catheter, aiming downward to the premeasured distance—usually 13 to 15 cm (5 to 6 in.) in an adult—and being careful not to force the catheter. If you meet resistance, you may need to try the other naris.
Advancing the suction catheter the premeasured distance ensures that the suction catheter will reach the pharynx. Forcing the catheter during insertion may cause tissue trauma.

14. **Place a finger or thumb over** the suction control port of the suction catheter, and start suctioning the patient. Apply suction as you withdraw the catheter, using a continuous rotating motion.

Limit suctioning to 10 to 15 seconds.
Using a continuous rotating motion while withdrawing the catheter prevents trauma to any one area of the airway. Limiting suctioning to less than 10 to 15 seconds prevents hypoxia.

15. **After you withdraw** the catheter, clear it by placing the tip of the catheter into the container of sterile saline and applying suction.
Ensures patency of the catheter for repeat suctioning.

16. **Lubricate the catheter**, and repeat suctioning as needed, allowing at least 20-second intervals between suctioning.
Several passes with the suction catheter may be needed to clear the airway of secretions. The total suctioning time should be limited to 5 minutes, however, to prevent hypoxia and trauma to the mucosal membranes.

For Nasopharyngeal Suctioning

Each time you repeat suction, alternate nares.
Alternating nares prevents trauma that would occur if you used only one naris.

17. **Coil the suction catheter** in your dominant hand. Pull the sterile glove off over the coiled catheter. (Alternatively, wrap the catheter around your dominant, gloved hand, and hold the catheter as you re-

move the glove over it.) Discard the glove containing the catheter in a biohazard receptacle designated by your agency.
Coiling the catheter inside the glove prevents contamination with secretions.

18. **Using your nondominant hand**, clear the connecting tubing of secretions by placing the tip of the tube into the container of sterile saline.
Ensures patency and prepares the equipment for future use.

19. **Dispose of equipment** in biohazard waste container/bag, and make sure new suction supplies are readily available for future suctioning needs.
The patient may require suctioning at any time, so equipment must be readily available.

20. **Provide mouth care.**
Promotes patient comfort and clears the mouth of any secretions the patient may have expectorated.

21. **Discard your other glove** and remaining supplies.

22. **Position the patient** in a comfortable position, and allow him to rest.
Promoting comfort and allowing for a period of rest helps the patient recover from suctioning, which may be very tiring.

? **What if . . .**

- **The patient's oxygen saturation is less than 94%, or if he is in any distress?**
You may need to administer supplemental oxygen before, during, and after suctioning. See Procedure 36-4.

Evaluation

- Assess the color, consistency, and amount of secretions.
- Evaluate the patient's tolerance of the procedure. Note whether there were signs of respiratory distress during the procedure.
- Evaluate the effectiveness of the procedure by comparing breath sounds, vital signs, and pulse oximetry before and after the procedure.

Patient Teaching

- Explain the importance of administering supplemental oxygen to the patient before suctioning.
- Inform the patient that coughing typically increases with suctioning.
- Demonstrate oropharyngeal or nasopharyngeal suctioning to the caregiver, and ask for a return demonstration if suctioning will be required at home.

Home Care

- Instruct the family and caregiver where to obtain suction equipment.
- Provide contact information for healthcare personnel who can be reached for advice or emergencies.
- Explain that the procedure can be performed using clean technique instead of sterile technique in the home setting.
- Instruct the caregiver that suction catheters can be cleaned for reuse by washing them with soapy water and then boiling them for 10 minutes. After they are cleaned, rinse the catheters with normal saline solution or tap water.
- Teach to change the secretion collection container every 24 hours, or clean it according to home care agency guidelines every 24 hours.

Documentation

- Document the date, time, and reason you performed suctioning.
- Note the suction technique you used and the catheter size.
- Note color, consistency, and odor of secretions.
- Document the patient's respiratory status before and after the procedure.
- Document the patient's tolerance of the procedure and any complications that occurred as a result of the procedure, with resulting interventions.

Sample documentation

3/15/15 2200 Resp. labored, rate 28 breaths/min. Pulse oximetry on room air 92%. Breath sounds with rhonchi scattered throughout. Gurgling audible in upper airways. Patient unable to mobilize secretions with coughing. Suctioned by nasopharyngeal route using a 14-Fr. catheter. Approximately 30 mL thin, tan, odorless secretions obtained. After suctioning, resp. nonlabored, rate 20 breaths/min, and lungs clear on auscultation, with no gurgling audible. Pulse oximetry 96%. Patient tolerated procedure with no difficulty. ——————— C.F. Hiam, RN

Procedure 36-10 ■ Caring for Patients Requiring Mechanical Ventilation

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Ventilator Terminology

TERM	EXPLANATION
FIO_2	Fraction of inspired oxygen
Modes of ventilation	Describes the setting on the ventilator that assists the patient to breathe. Can be controlled (CMV), intermittent mandatory (IMV), or synchronized intermittent mandatory (SIMV).
Tidal volume	Amount of air delivered from the ventilator with each breath
Assist-control mode—also known as continuous mechanical ventilation (CMV)	The preset number of breaths per minute delivered by the machine. If the patient is able to initiate breaths, the machine will deliver a breath when the patient begins to inspire. If the patient is unable to breathe on his own, the machine will deliver the preset number of breaths in a rhythmic fashion.
Intermittent mandatory ventilation	A ventilator setting that delivers a minimum number of breaths per minute if the patient does not ventilate independently.
Synchronized intermittent mandatory ventilation (SIMV)	A ventilator setting that delivers a minimum number of ventilations per minute if the patient does not ventilate independently. The ventilator breaths are synchronized with the patient's breaths. This mode is used for weaning patients from the ventilator.
Pressure support	Provides positive pressure on inspiration to decrease the workload of breathing.
Continuous positive airway pressure (CPAP)	Provides positive pressure during inspiration and expiration to keep alveoli open in a spontaneously breathing patient.
Positive end expiratory pressure (PEEP)	Provides positive pressure on expiration to keep airways open for patients on CMV or SIMV mode ventilation.

Equipment

- Two oxygen sources
- Air source that provides 50 pounds per square inch (psi)
- Mechanical ventilator
- Humidification device
- Ventilator tubing, connectors, and adaptors
- Condensation collection device
- Inline thermometer
- Resuscitation bag with oxygen connection tubing
- Pulse oximetry device
- Procedure gloves, protective gown, and eye covering
- Sterile gloves, if you will perform suctioning
- Suction equipment (possibly)
- Sterile water for the humidifier. Some guidelines also recommend sterile water for rinsing the mouth.

Delegation

Care of a mechanically ventilated patient requires advanced knowledge of pulmonary anatomy and physiology and, therefore, should not be delegated to assistive personnel. In critical care settings, specially trained LPNs may provide care, but the RN is responsible for ensuring that procedures are implemented safely and effectively. RNs also provide ongoing assessment of the patient's ventilatory and oxygenation status. Patients requiring long-term ventilation are often cared for at home or in specialized long-term care units, where LPNs and family members may provide care.

Pre-Procedure Assessment

- Review the health record to make sure that mechanical ventilation is included in the options outlined in the patient's advance directive.
  The patient may not wish to pursue mechanical ventilation as a care option. If a patient who does not wish to be ventilated mechanically is currently on a ventilator, consult your hospital ethics committee.
- If the patient's condition allows, assess his understanding of mechanical ventilation therapy.
  Understanding helps allay anxiety and promotes cooperation.
- Assess respiratory rate, depth, and rhythm; breath sounds; color; and pulse oximetry results.
  Confirms the need for mechanical ventilation.
- Assess the oral cavity for bleeding, inflammation, odor, and presence of yeast or plaque.
  May indicate the need for more frequent oral care or for referral.
- Blood will probably be drawn for an ABG analysis
  To establish a baseline and, after that, to monitor response to therapy.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Initial Ventilator Setup

1. **Prepare the resuscitation bag**.
The resuscitation bag should be readily available to provide ventilation in the event of an emergency.

a. Attach a flow meter to one of the oxygen sources.
The flow meter helps regulate oxygen delivery.
b. Attach an adapter to the flow meter, and connect the oxygen tubing to the adapter.
c. Turn on the oxygen, and adjust the flow rate.

2. **Respiratory therapists** are responsible for setting up mechanical ventilation in most agencies. If you must assume the responsibility, refer to the manufacturer's instructions.

3. **Plug the ventilator into** a grounded electrical outlet and turn it on.

4. **Verify ventilator settings** and adjust as medically prescribed.
Ventilator settings must be individualized according to the patient's need for respiratory support. Incorrect settings may cause harm (e.g., hypoxia or barotrauma) to the patient.

5. **Make sure that ventilator alarm** limits are set appropriately.
Inappropriately set alarm limits can result in harm to the patient.

6. **Make sure the humidifier** is filled with sterile distilled water.

7. **Don gloves, gown, and eye protection** if you have not already done so.

8. **Attach the ventilator tubing** to the endotracheal tube or tracheostomy tube.

9. **Place the ventilator tubing** in the securing device.
Prevents dislodging the endotracheal tube or tracheostomy when the patient moves.

10. **Attach a capnographic device**, if available.
To measure levels of carbon dioxide. These data are used to confirm placement of the endotracheal tube and disconnection from or malfunction of the ventilator. Oxygen levels alone are not sufficient for the ventilated patient.

11. **Prepare the inline (closed)** suction equipment (see Procedure 36-7).

Suctioning equipment should be readily available when the patient requires suctioning. Closed catheters are recommended to prevent ventilator-associated pneumonia.

After Initial Ventilator Setup

12. **Check respiratory status** and ABGs again about 30 minutes after setup. Also check whenever there are changes in the ventilator settings and as the patient's condition indicates.
To be certain the patient is being adequately ventilated and not experiencing oxygen toxicity.

13. **Check the ventilator tubing** frequently for condensation. Drain the fluid into a collection device, or briefly disconnect the patient from the ventilator and empty the tubing into a waste receptacle, according to agency policy.

Never drain the fluid into the humidifier.
Condensation in the ventilator tubing can cause resistance to airflow. Moreover, the patient can aspirate it. The fluid should not be drained into the humidifier because the patient's secretions may have contaminated it.

14. **Maintain the patient** in a semirecumbent position (head of bed elevated 30° to 45°). This is extremely important.
To promote lung expansion, reduce gastric reflux, and prevent ventilator-associated pneumonia.

15. **Check ventilator** and humidifier settings regularly.

16. **Check the inline thermometer.**
To ensure that the air being delivered to the patient is close to the body temperature to prevent scalding of the mucosal tissue or instead, cooling the patient (core temperature).

17. **Provide the patient with** an alternative form of communication, such as a letter board or white board.
A patient being mechanically ventilated is unable to speak, which can produce extreme anxiety. The patient must have a way to express her needs and concerns.

18. **Reposition the patient** regularly (every 1 to 2 hours), being careful not to pull on the ventilator tubing.
Repositioning protects skin integrity. However, pulling on the tubing creates pain. Patient comfort promotes relaxation, improving the effectiveness of the ventilator.

(continued on next page)

Procedure 36-10 ■ Caring for Patients Requiring Mechanical Ventilation (continued)

19. Keep the patient's lips moistened with a cool, damp cloth and water-based lubricant; and provide regular antiseptic oral care. A recommended regimen includes the following:
- Brush the teeth twice a day for 3 or 4 minutes.
- Use a soft toothbrush.
- Rinse the mouth with sterile water, according to agency policy.
- Moisturize oral mucosa and lips every 2 to 4 hours.
- Use a chlorhexidine gluconate (0.12%) rinse twice a day during the perioperative period for patients who undergo cardiac surgery (adult patients).
- Use mouthwash twice a day for adult patients. (AACN, 2008)

Mouth care provides comfort and preserves integrity of the mucous membranes. Patients being mechanically ventilated, even for a short period, are at high risk for developing ventilator-associated pneumonia (VAP). VAP is not uncommon, and it is associated with high mortality rates. This regimen is thought to help prevent VAP.

20. Make sure the call light is always within reach, and answer call light and ventilator alarms promptly.
Provides the patient with immediate access to help if a breathing problem occurs; reassures the patient and thus relieves anxiety.

21. Monitor the tracheostomy tube for proper cuff inflation (usually 20 to 25 mm Hg); see Clinical Insight 36-4.

22. Check for gastric distention and take measures to prevent aspiration.
Aspiration creates high risk for pneumonia.

23. Clean, disinfect, or change ventilator tubing and equipment according to agency policy.
There is no good evidence to indicate how often this should be done. Research so far indicates that tubing and equipment should not be routinely changed for infection control purposes (Han & Liu, 2010).

24. Give sedatives or anti-anxiety drugs as prescribed.

Evaluation

- After mechanical ventilation is instituted, assess for chest expansion and auscultate for bilateral breath sounds.
- Evaluate the patient's tolerance of mechanical ventilation. Verify that the patient is being adequately ventilated and that she is breathing in synchrony with the ventilator.
- Auscultate breath sounds every 2 to 4 hours, according to agency policy.
- When monitoring vital signs, count spontaneous breaths as well as those delivered by the ventilator.
- Monitor continuous pulse oximetry, capnography, and ABGs.

Patient Teaching

- Explain mechanical ventilation to the patient and family. Include information about the alarms they will hear.
- When appropriate, explain the weaning process to the patient and family.
- If the patient requires mechanical ventilation after discharge, make arrangements for a home ventilator, and teach the patient and caregiver how to use it.

Home Care

- Consult with your facility discharge planning program and/or case management for discharge plans.
- Explain to the family and caregiver where to obtain a home ventilator, resuscitation bag, and oxygen equipment and what services are available. Make sure they choose a supplier who has 24-hour emergency services available.
- Help the client and caregiver devise a backup plan for ventilating the client in the event of a power failure.
- Tell the caregiver to notify the utility company and area emergency personnel that the client is being maintained on a ventilator at home.
- Instruct the client and caregiver about oxygen therapy and its use as well as safety measures that they must institute.
- Teach the client and caregiver to clean the ventilator tubing with soap and warm water when it becomes soiled.
- Provide contact information of healthcare personnel who can be reached for advice or emergencies.

Documentation

- Document the date and time mechanical ventilation was initiated.
- Note the type of ventilator used and the prescribed settings used.
- Document the client's response to mechanical ventilation, including vital signs, breath sounds, ease of breathing, pulse oximetry, intake and output, skin color, and ABG and chest x-ray results.

Sample documentation

02/26/15 0800 Patient found difficult to arouse. Dr. Henry made aware. ABG obtained; results included: pH 7.28; PCO_2 78 mm Hg; PO_2 48 mm Hg. Dr. Henry in to evaluate patient. Anesthesia called to intubate patient. Medicated with Versed 5 mg IV and intubated orally with a 7.5-Fr. ET tube. Placed on mechanical ventilator: TV 700 mL; FIO_2 80%, respiratory rate 14 breaths/min. Portable chest x-ray confirms ideal placement of ET tube as well as white-out of both lung fields. ABGs to be obtained in 30 min. Pulse oximetry 90% since being placed on ventilator.
——— L. Houck, RN

Practice Resources

AACN (2008, 2010, 2008); Bozyk, P., & Hyzy, R. (2008); Coffin, W., Klompas, M., Classen, D., et al. (2008); Feider, L. L., Mitchell, P., & Bridges, E. (2010); Maselli, D., & Restrepo, M. (2011); Munro, C., Grap, M., Jones, D., et al. (2009).

Procedure 36-11 ■ Setting Up Disposable Chest Drainage Systems

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Two disposable closed drainage systems
- Chest tube insertion kit (common tube size for adults is 36 Fr). Should contain povidone-iodine, local anesthetic, syringe, needles, drapes, scalpel, suture, sterile drapes, chest tube, connecting tubing, and necessary instruments.
- 5-in-1 or Y-connector for two chest tubes, if not contained in insertion kit
- Sterile water (for water-seal system)
- Two rubber-tipped hemostats
- Sterile gloves, masks, and sterile gowns
- Dressings: sterile 4 in. × 4 in. gauze dressings, precut drain dressings, petroleum (or other recommended) gauze dressings, and large drainage dressings
- Tape: 2-in. silk tape, 1-in. silk tape (or nylon banding system)

For disposable dry-seal systems:

- 50-mL syringe and 45 mL of sterile water or saline. Some dry-seal CDUs include these.

Delegation

Some agencies permit only registered nurses in the critical care units to perform dressing changes. The physician must perform dressing changes on other units. You should not delegate this procedure, because it requires advanced knowledge of pulmonary anatomy and physiology. As needed, teach the LPN and NAP how to safely provide care for the patient with chest tubes. Instruct them to notify an RN immediately if the chest drainage system becomes disconnected, the chest tube becomes dislodged, sudden bleeding occurs, or the patient develops respiratory distress.

Pre-Procedure Assessment

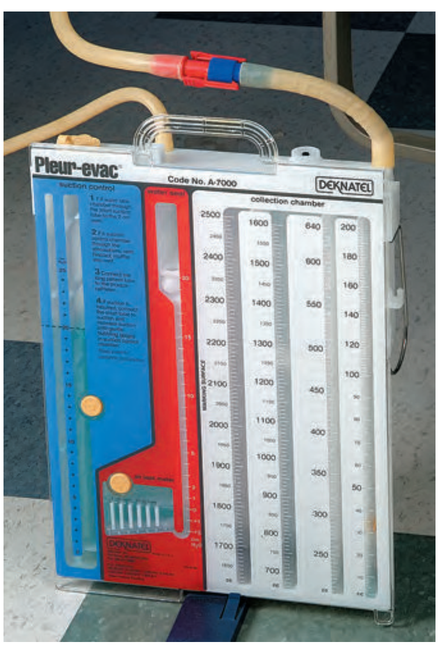
- Ensure that the patient has venous access.
- Assess vital signs.
- Assess the level of consciousness, orientation, responsiveness, anxiety, and restlessness.
  These can indicate hypoxemia.
- Assess the patient's knowledge of chest tube therapy.
  Understanding helps allay fears and anxiety.
- Assess cardiac status; respiratory rate, depth, and rhythm; breath sounds; skin color; pulse oximetry; and ABG results.
  Provides a baseline for comparison after chest tube insertion. Evaluates chest tube functioning afterward.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

Steps for Preparing the CDU

1. **Obtain and prepare** the prescribed chest drainage unit (CDU).▼



Disposable water-seal system.

Disposable dry-seal system.

Procedure Variation for a Disposable Water-Seal CDU Without Suction

2. **Remove the cover** on the water-seal chamber, and, using the funnel provided, fill the second (water-seal) chamber with sterile water or normal saline. Fill the chamber to the 2-cm mark, or as indicated. (Note that some systems come prefilled.)
   The water-seal chamber allows air to exit from the pleural space during exhalation and prevents air from entering the pleural space during inspiration.
3. **Place the chest drainage unit** (CDU) upright, usually on the floor, and at least 30 cm (1 ft) below the patient's chest level.
4. **Replace the cover** on the water-seal chamber.
   Protects the chamber from contamination.

Go to Step 13.

(continued on next page)

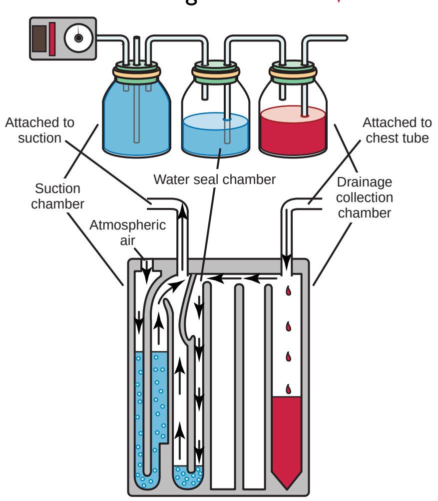
Procedure 36-11 ■ Setting Up Disposable Chest Drainage Systems (continued)

Procedure Variation for a Disposable Water-Seal CDU With Suction

5. **Remove the cover** on the water-seal chamber. If it is not a prefilled system, use a syringe or the funnel provided to fill the water-seal chamber (second chamber) with sterile water or normal saline to the 2-cm mark.
The water-seal chamber allows air to exit from the pleural space during exhalation and prevents air from entering the pleural space during inspiration.

6. **Add sterile water or normal** saline solution to the suction control chamber. Add the amount prescribed by the clinician, typically 20 cm (7 in.). Place the CDU upright, usually on the floor, and at least 30 cm (1 ft) below the patient's chest level.
Suction is regulated by the height of fluid in the suction control chamber.

7. **Attach the tubing** from the suction control chamber to the suction source tubing. Turn on the wall (or other) suction source. A wall suction of –80 mm Hg is common.



Comparison of glass bottles and disposable CDUs.

Go to Step 13.

Procedure Variation for a Disposable Dry-Seal CDU With Suction

8. **Remove the nonsterile** outer protective bag and the sterile inner wrapper following agency policy.

9. **Place the CDU upright**, usually on the floor, and at least 30 cm (1 ft) below the patient's chest level. Some CDUs have hangers for hanging at the bedside.

10. **If suction will be required**, attach the tubing from the suction control chamber to the connecting tubing attached to the suction source.

11. **Fill a syringe** with 45 mL of sterile water or saline (follow agency policy and the manufacturer's recommendation for type of fluid), or use the small bottle of sterile fluid in the CDU package. Fill the air leak monitor on the CDU by injecting the fluid via the needleless injection port on the back until it reaches the fill line.
Once filled, the water may become colored for improved visibility of air leaks. Bubbles in this section of the CDU indicate an air leak.

Go to Step 13.

Procedure Variation for a Heimlich Valve

12. **When a patient has little or no** drainage and does not require suction, the chest tube may be connected to a Heimlich valve instead of a CDU. These valves are attached to the end of the chest tube and allow one-way flow of air out of the chest tube. They contain "flutter" leaflets that allow air to exit but not reenter the pleural space. These valves can also be used for emergency transport until a chest drainage system is available.

Go to Step 13.

Steps for Inserting and Connecting the Chest Tube

NOTE: **The remaining steps apply to all variations.**

13. **Position the patient** according to the indicated insertion site.
    - For removing air: second intercostal space at the midclavicular line
    - For fluid drainage: on the midaxillary line in the fifth or sixth intercostal space

14. **Open the chest tube insertion tray** and set up the sterile field. Using sterile technique, drop any necessary supplies on the field (e.g., 4 in. × 4 in. split gauze dressings, petroleum or other recommended gauze, syringes).

15. **Don a mask, gown, and sterile gloves** and organize the supplies you will need for dressing the chest tube insertion site.
Protective clothing prevents contamination of the surgical site and protects you from splashing.

16. **Provide support to the patient** while the physician or nurse practitioner prepares the sterile field, anesthetizes the patient, and inserts and sutures the chest tube.

17. **As soon as the chest tube** is inserted, attach it to the CDU tubing, using a connector.
Usually the nurse holds the nonsterile tubing that leads to the collection chamber and the physician attaches the sterile chest tube to it. Immediately attaching the chest tube to the drainage system prevents air from entering the pleural cavity.

18. **If suction is prescribed**, adjust the CDU suction to the level the clinician specifies, usually –20 cm H_2O. Also adjust the wall (or other) suction source, usually to –80 mm Hg.

For a Water-Seal Drainage Unit

Adjust the suction source (e.g., wall suction) until gentle bubbling occurs in the suction control chamber. When the tube is functioning properly, the height of the fluid level in the drainage tube fluctuates with the respiratory cycle.

NOTE: Increasing suction at the suction source increases airflow through the system and creates more bubbling, but it does not increase the amount of suction placed on the chest cavity.

For a Dry-Seal Drainage Unit

Adjust the CDU suction (e.g., to –20 cm H_2O) by turning the suction control dial on the CDU. Adjust the wall (or portable) suction pressure to –80 mm Hg or greater until the display on the suction-control chamber confirms adequate suction.

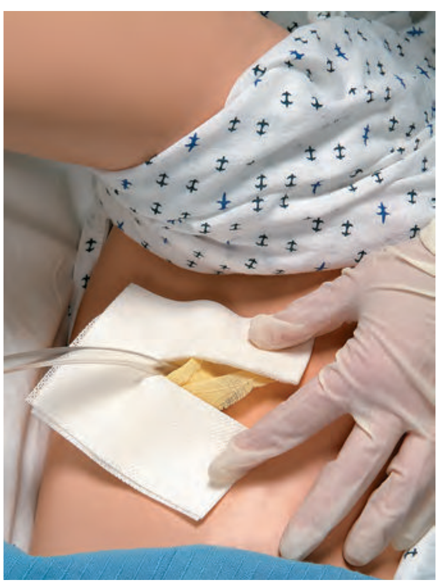
If Suction Is Not Prescribed

Leave the suction tubing on the drainage system open to maintain negative pressure. Follow the manufacturer's directions on the CDU, as models will differ.

Steps for Dressing the Chest Tube

19. **When the chest tube** is functioning properly, the physician or nurse practitioner will suture it in place. Then don a new pair of sterile gloves. Using sterile technique, wrap petroleum, saline-soaked, or other recommended gauze around the chest tube at the insertion site.
    (Note: Sometimes the physician dresses the site.)
    Theoretically, the moistened gauze creates a seal that prevents air from leaking around the site. However, continued use of petroleum gauze or ointments can macerate the skin, so use them with caution. Recent research suggests that saline-soaked, or even dry, gauze may be preferable to petroleum gauze; so follow your agency's policy.

20. **Place a precut, sterile split-drain** dressing over the gauze around the chest tube.
    Absorbs drainage from the insertion site, thereby reducing skin irritation and possible breakdown.



21. **Place a second sterile, precut** drain dressing over the first drain dressing with the opening facing in the opposite direction from the first.
    The second drain dressing helps secure the first drain dressing and provides reinforcement against drainage.

22. **Place a large drainage dressing (e.g., ABD) over the two precut drain dressings.**
    NOTE: Some guidelines recommend that instead of large amounts of tape and padding, a transparent dressing be used. This minimizes moisture collection around the site, allows nurses to inspect for leakage or infection, and does not restrict chest wall movement. Follow your agency's policy.
    The large drainage dressing covers the insertion site, protecting it from outside sources of infection.

23. **Secure the dressing in place,** with wide tape, making sure to cover the dressing completely.
    Creates an occlusive dressing that protects the chest tube from becoming dislodged and provides a seal over the insertion site, protecting it from outside sources of infection.

24. **Date, time, and initial the dressing.**
    Informs other staff members when the dressing change was completed and by whom.

25. **Using the spiral taping** technique, wrap 1-in. cloth tape around the chest tube, starting above the connector and continuing below the connector. Reverse your wrapping by taping back up the tubing (using the spiral technique) until the wrapping is above the connector. The CDU may come with locking connections or bands; if so, use those.
    Ensures a tight connection between the two tubings, thereby preventing an air leak at the connection site.

26. **Cut an 8-in.-long piece of 2-in. tape**. Loop one end around the top portion of the drainage tube, and secure the remaining end of the tape to the chest tube dressing.
    Prevents pulling at the chest tube site when the patient moves.

27. **Make sure the drainage tubing** lies with no kinks from the chest tube to the drainage chamber.
    Facilitates drainage and prevents fluid from accumulating in the pleural cavity.

28. **Prepare the patient** for a portable chest x-ray exam.
    A chest x-ray exam should be performed after the chest tube is inserted to ensure proper placement.

29. **Institute the following safety measures:**
    a. Place two rubber-tipped clamps at the patient's bedside for special situations.
    Rubber-tipped clamps are used to clamp the chest tube to check for an air leak, to change the drainage system, and to assess whether the chest tube can be safely removed.
    b. Place a petroleum gauze dressing at the bedside.
    In case the chest tube leaks or becomes dislodged, placing a petroleum gauze dressing over the insertion site

(continued on next page)

Procedure 36-11 ■ Setting Up Disposable Chest Drainage Systems (continued)

helps keep air from entering the pleural cavity

c. **Keep a spare disposable drainage system at the patient's bedside.** *To use in case the drainage system in use is accidentally upended or the drainage collection chamber becomes filled.* ➤

30. **Position the patient for comfort**, as indicated, but with the head of the bed elevated to at least 30°.
    - If the patient received a chest tube to relieve a pneumothorax, the preferred position is semi-Fowler's position.
    - If the chest tube was inserted to promote fluid drainage, high-Fowler's position is recommended.

Evaluation

- **Evaluate the patient's** tolerance to the chest tube insertion. Determine whether the patient's respiratory status has changed.
- Auscultate breath sounds every 2 hours.
- Check chest drainage every 15 minutes for the first 2 hours, and then check as prescribed. Observe type, color, and amount.
- Monitor the chest tube insertion site for drainage and subcutaneous emphysema at least every 4 hours.
  Crepitus is a sign that air is leaking into the subcutaneous tissues. Drainage is a sign that fluid is leaking around the insertion site. Both may indicate a compromise in tube patency.
- Confirm chest tube patency and determine whether bleeding is present.
- Monitor intake and output (I&O) every 8 hours.
- Check laboratory values to evaluate blood loss and oxygenation.
- Check the disposable chest drainage system for the presence of an air leak
  An air leak indicates that air is leaking from the chest and a tight seal has not yet formed over the site of injury.

Patient Teaching

- Teach the patient and family about chest tube insertion.
- Explain the importance of immediately reporting chest pain, shortness of breath, or tube dislodgement.

Home Care

- Explain to the client and caregiver how to care for the chest tube at home.
- Provide the client and caregiver with contact information should problems with the chest tube arise.

Documentation

- Assessment findings before, during, and after chest tube insertion (e.g., vital signs, breath sounds, cardiac status, pulse oximetry)
- Date and time of the chest tube insertion
- Name of the clinician who performed the procedure
- The location of the insertion site, the size of the chest tube, the type of drainage system, and the amount of suction applied, if any
- Any medications the patient received during the procedure
- Color and amount of drainage
- Chest tube output on the I&O portion of the flowsheet (in most agencies)
- Patient's tolerance to the procedure
- Presence of subcutaneous emphysema or air leak, if any
- Complications and any interventions preformed as a result of the complications
- Chest x-ray findings

Sample documentation

8/25/15 0230 Patient presented with acute shortness of breath, pulse ox 84%, respirations 40 breaths/min and shallow, heart rate 132 beats/min. BP 188/100 mm Hg. Breath sounds absent on right side. Patient received morphine sulfate 4 mg IVP. #36 Fr chest tube placed by Dr. Phan under sterile conditions in right anterior chest, midclavicular line, above the 2nd ICS. Chest tube attached to 20 cm of water pressure. Small air leak present, no crepitus. Portable chest x-ray obtained after procedure, revealed chest tube in good placement and right lung re-expanded. Vital signs post-insertion: pulse ox 94%; BP 153/90 mm Hg, heart rate 100 beats/min, and respiratory rate 24 breaths/min. Breath sounds audible bilaterally.——Pennie Bowen, RNC

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

For questions and suggested responses,

Go to Chapter 36, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*

Procedure 36-12 ■ Inserting an Oropharyngeal Airway

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

The American Heart Association guidelines (2010) direct that you should insert an oropharyngeal airway only if you are trained in its use.

Equipment

- Oral airways in a variety of sizes
- Tongue blade
- Procedure gloves
- Suction equipment
- Resuscitation bag and oxygen source (depending on the patient's status)
- Padded tongue blade

Delegation

You should not delegate this procedure because it requires specialized knowledge, training, and assessment skills.

Pre-Procedure Assessments

- Determine the appropriate airway size by placing the airway on the outside of the patient's cheek. The length of the airway should extend from the front teeth to the end of the jawline.
- Assess breath sounds, respiratory rate and effort, skin color, and pulse oximetry findings.
  Findings confirm the need for the airway and provide a baseline for evaluating the effectiveness of the intervention.
- Assess for contraindications (e.g., patient is conscious or semiconscious; patient has loose teeth or recent oral surgery).
  An oropharyngeal airway may stimulate the gag reflex, causing vomiting or laryngospasm in a conscious patient.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Perform hand hygiene, and don** clean procedure gloves.
   Helps prevent transfer of microorganisms from the patient.
2. **Explain the procedure** to the patient, even if he appears to be unresponsive.
   Recall that hearing is the last sense lost, so the patient may be able to hear you. Information may help relieve the patient's anxiety, if present.
3. **Clear the mouth of any debris** or secretions. You may need to suction the mouth.
4. **Place the patient in supine** or semi-Fowler's position. Hyperextend the neck, unless contraindicated.
   Mild hyperextension allows the airway to slide naturally toward the pharynx.
5. **Gently open the mouth.** Remove dentures, if present.
   Dentures may cause further airway obstruction.

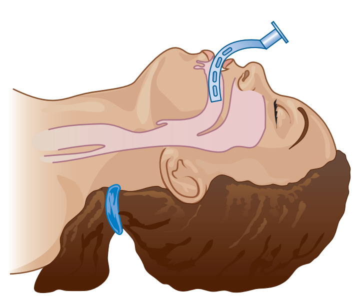
If Using Tongue Blade Technique

Open the patient's mouth and use the blade to depress the tongue.

If Using Crossed Fingers Technique

Place your thumb on the lower teeth. Cross your index finger over your thumb and place the finger on the upper teeth. Push the teeth apart.

6. **You may need to hold** the tongue down with a tongue blade as you insert the airway.
7. **Insert the airway** along the top of the tongue, in the upside-down position (the "C" faces upward toward the nose).
   Prevents pushing the tongue toward the pharynx.

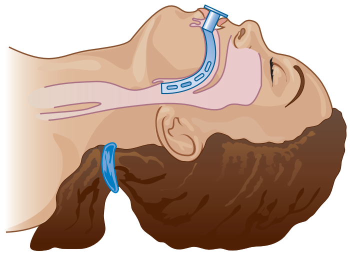


8. **As the airway approaches** the posterior wall of the pharynx, rotate the airway 180° so that the ends of the "C" turn downward over the back of the tongue. Continue to insert the

(continued on next page)

Procedure 36-12 ■ Inserting an Oropharyngeal Airway (continued)

airway until the front flange is flush with the lips. ▼



9. **Keep the patient's head tilted** slightly back and the chin elevated.
This position helps the oropharyngeal airway to function optimally.

10. **Do not tape the airway** in place.
You may need to remove the airway quickly for suctioning. Untaping would delay airway removal, increasing the risk of aspiration.

11. **Position the patient on her side.**
To minimize the risk of aspiration.

12. **Provide oral hygiene** at least every 2 to 4 hours. Remove and cleanse the airway at that time; use hydrogen peroxide and then rinse with water.

? What if . . . .

- **After inserting the airway, respirations are absent or inadequate?**

  Use a mouth-to-mask technique, a handheld resuscitation bag, or an oxygen-powered breathing device to ventilate the patient. Have someone call for help.

Evaluation

- After inserting the airway, verify patency by auscultating for bilateral breath sounds.
- Check for bleeding or tooth damage in the mouth.
  May be caused by airway insertion, especially if it must be done rapidly.
- Check to be certain the patient's lips and tongue are not caught between the teeth and the airway.
  Prevents trauma to the soft tissues.
- Monitor the airway position frequently.
  Ensures correct placement.
- Continually reassess the need for the airway. Remove it when the patient begins to cough or gag.
- Frequently assess oral mucous membranes when you remove the airway for care.
  Prolonged airway use can cause tissue irritation or ulceration.
- Keep suction available at the bedside. Suction the oropharynx as needed by inserting the suction catheter alongside the airway.

Documentation

Document the following:

- Date and time of airway insertion
- Type and size of airway (oropharyngeal or nasopharyngeal)
- Assessments before and after the procedure, including breath sounds and focused respiratory assessment
- Any suctioning performed
- Patient's tolerance of the procedure
- Adverse reactions and interventions taken

Practice Resources

AACN (2010); American Heart Association (2010); Walls, R., & Murphy, M. (2012).

Procedure 36-13 ■ Inserting a Nasopharyngeal Airway

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

The American Heart Association guidelines (2010) direct that you should insert a nasopharyngeal airway only if you are trained in its use.

Equipment

- Nasopharyngeal airway of the correct size
- Tongue blade
- Procedure gloves
- Water-soluble lubricant
- Penlight
- Suction equipment
- Resuscitation bag and oxygen source (depending on the patient's status)

Delegation

You should not delegate this procedure because it requires specialized knowledge, training, and assessment skills. Commonly, this procedure is performed by a respiratory therapist.

Pre-Procedure Assessments

- Determine the appropriate airway size: (1) Measure the diameter of the patient's nostril and use an airway that is slightly smaller than that; and (2) measure the distance from the tip of the patient's nose to the earlobe, and use an airway about 2.5 cm (1 in.) longer than that measurement. Airways are sized by their internal diameter. Generally, the larger the internal diameter, the longer the tube. Airways are available in a variety of pediatric and adult sizes.

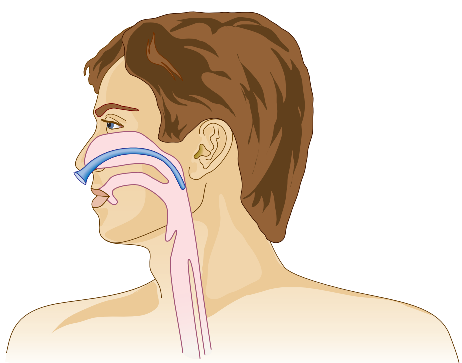
  Small adult: 6 to 7 mm
  Medium adult: 7 to 8 mm
  Large adult: 8 to 9 mm

- Assess breath sounds, respiratory rate and effort, skin color, pulse oximetry findings.
  Findings confirm the need for the airway and provide a baseline for evaluating the effectiveness of the intervention.
- Assess for contraindications (e.g., anticoagulant therapy, hemorrhagic disorder, nasopharyngeal deformity, sepsis).
  Up to 30% of patients experience airway bleeding after insertion of a nasopharyngeal airway.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Perform hand hygiene** and don procedure gloves.
   Helps prevent transfer of microorganisms from the patient.
2. **Position the patient supine** or in semi-Fowler's position. Explain the procedure.
   A semi-Fowler's position facilitates airway insertions. Explaining may alleviate anxiety, enabling the patient to cooperate more with the procedure.
3. **Validate that the airway size** is correct. Hold the airway next to the patient's face. Measure airway from tip of nose to jawline below the ear, and use an airway about 2.5 cm (1 in.) longer than that. Airway should be slightly smaller than the nares.
4. **Lubricate the airway** with water-soluble lubricant.
   Prevents trauma to mucosa during insertion.
5. **Tilt the patient's head backward** to hyperextend the neck. Then push up the tip of the nose and gently insert the tip of the airway into the nose.
6. **Advance the airway** along the floor of the nostril into the posterior pharynx behind the tongue—until the outer flange rests on the nostril. If you meet resistance, rotate the tube slightly to enhance passage. Do not force against resistance.
   Forcing the tube can cause tissue trauma and airway kinking.
7. **Have the patient open her mouth.** Depress the tongue with a tongue blade and inspect the pharynx for proper placement of the tube tip. Use a penlight, if necessary, for better visualization.
   When the tube is fully inserted, the outer flange of the tube should rest on the nostril, and only the tip of the tube should be visible at the top of the posterior pharynx.



8. **Check for correct placement** and function: Close the patient's mouth, and place your finger close to the tube's opening to feel for air exchange.
9. **Auscultate the lungs** for the presence of bilateral breath sounds.
10. **Remove the airway** at least every 8 hours to check nasal mucous membranes for ulceration or irritation. Clean the airway at this time: Place in a basin, rinse with hydrogen peroxide, then rinse with water. Use a pipe cleaner to remove secretions, if necessary. Reinsert the airway in the other nostril.
    To avoid skin and mucous membrane irritation and breakdown and to prevent infection

What if . . .

- **After you insert the airway, the patient coughs, gags, vomits, or has laryngospasm?**
  The tube may be too long. If the tip extends beyond the top of the posterior pharynx, remove it and insert a shorter one.

Evaluation

- Assess respiratory rate and effort.
- Assess breath sounds.
- Observe for bleeding of nasal mucosa; suction as necessary.
- If the patient is receiving artificial ventilation, monitor for gastric distention and hypoventilation.
- Provide frequent oral and nares care; assess the skin around the nostril.

Documentation

Document the following:

- Date and time of airway insertion
- Type and size of airway (nasopharyngeal)
- Assessments before and after the procedure, including breath sounds, focused respiratory assessment, and condition of the mucous membranes
- Suctioning, if performed
- Patient's tolerance of the procedure
- Adverse reactions and interventions taken
- Removal of the airway, cleaning, and replacement in the other nostril

Practice Resources

CLINICAL INSIGHTS

Clinical Insight 36-1 ➤ Tips for Obtaining Accurate Pulse Oximetry Readings

Patient Movement. A nailbed is the most common site to place the probe. However, a tremor, twitch, shivering, or movement in bed can make pulse oximetry readings inaccurate. If the patient is unable to cooperate or control his movement, try using an ear probe or nasal sensor.

Acrylic Fingernails and Nail Polish. If the patient has acrylic nails, place the probe on a toe or earlobe. Many facilities stock individually packaged nail polish remover pads to remove nail polish before placing the probe.

Nail polish or acrylic nails may interfere with signal transmission, causing inaccurate Sao_2 measurement. However, a recent study found that nail polish did not cause a clinically significant change in readings in healthy people (Chan, Chan, & Chan, 2013).

Dirt and Skin Oils. Dirt and oils on the site can interfere with passage of light waves.

Poor Perfusion. A low reading may result from poor perfusion of the area where the probe is placed.

- A bent elbow, for example, may cause a slight decrease in circulation to the nailbed. If Sao_2 results are crucial to the patient's plan of care, use the earlobe to minimize the effect of movement on the reading.
- Keep the extremities warm to obtain a more accurate reading.

  Vasoconstriction due to cool extremities may also limit circulation.
- If poor perfusion is related to a disease process, use the earlobe or nose as the monitoring site.

Lighting. Bright fluorescent lighting may influence the accuracy of the reading. Dim the lights or cover the probe with bed covers or a towel to reduce error.

Anemia, Carbon Monoxide, Intravascular Dyes, and Dark Skin Color. These must be considered when interpreting oximetry readings. Because these factors cannot be controlled, watch for trend changes in the readings.

Equipment Function. Look for a displayed waveform; a reading is meaningless without the waveform. If there is a weak signal or no signal, check the patient's vital signs. If vital signs are satisfactory, check the circulation to the site. If that is satisfactory, check equipment connections.

Accuracy of the Reading. If there is an instantaneous change in saturation (e.g., from 99% to 82%), suspect an error. This is not physiologically possible. For any suspected inaccuracy, check the reading using the equipment on a healthy person. If it seems accurate, check the patient's medications and history of circulatory disorders; also check items listed above. When in doubt, rely on your clinical judgment more than the reading from the machine.

Clinical Insight 36-2 ➤ Guidelines for Preventing Aspiration

To prevent aspiration, use the following guidelines.

For At-Risk Patients

Position the unconscious patient on his side to protect the airway.

Request medications in elixir or liquid form.

Break or crush pills, when appropriate.

Keep a suction setup available for routine and emergency use.

If the patient is intubated, keep the endotracheal or tracheostomy cuff inflated, and suction above the cuff before deflating the cuff.

Do not offer food or fluids if the patient is heavily sedated or in the initial recovery phase of anesthesia.

Enteral Feedings

Check the placement of the nasogastric tube before you administer enteral feedings.

Check gastric residual volume before administering the next enteral feeding. Hold the feeding if the residual volume is high. (*Note:* The amount of acceptable residual volume depends on the amount and frequency of feedings.)

If the patient is receiving continuous tube feedings, the head of the bed must remain elevated.

Also see Procedure 27-3 for step-by-step instructions for administering feedings through gastric and enteric tubes.

Oral Feedings

Position the patient upright or with the head of the bed elevated for feedings or meal.

Be sure the head of bed remains elevated for at least 30 minutes after each feeding or meal.

Offer small, frequent meals.

Avoid thin liquids, or use thickening agents.

Offer foods or liquids that can be formed into a bolus before they are swallowed.

Cut food into small pieces.

Clinical Insight 36-3 ➤ Oxygen Therapy Safety Precautions

- Post signs indicating that oxygen is in use.
- Do not permit smoking near oxygen delivery systems.
- Ensure that three-pronged plugs are used for electrical devices (to prevent sparks).
- Allow no open flames (e.g., candles) near oxygen.
- Do not use electrical equipment with frayed wires or loose connections.
- Do not use petroleum products, aerosol products, and products containing acetone where oxygen is in use. (These are flammable substances that are easily ignited.)
- Secure oxygen tanks to rigid stands.
- Secure portable oxygen cylinders in holders or carriers provided.

Clinical Insight 36-4 ➤ Caring for Patients With Endotracheal Airways

Assisting With Endotracheal Airway Insertion

- **Gather equipment.** You will need an oxygen source and a bag (e.g., Ambu or nonrebreather bag) to inflate the lungs, a laryngoscope, endotracheal tubes of various sizes, water-soluble lubricant, a syringe to inflate the cuff, and tape to secure the tube in place.
- **Keep suction at the bedside** to clear the mouth and airway if secretions are obstructing your view of the cords.
- **You will need a surgical tray** if a tracheostomy is performed to create the direct opening into the trachea.
- **Remain calm, and explain** to the patient that the airway will enable him to breathe effectively.
- **Once the airway is in place, listen to breath sounds** to establish that both lungs are ventilated.
- **Reassess breath sounds periodically.** After the airway is inserted, record the type and size, as well as the patient's response to the procedure.
- **Expect that a portable chest x-ray will be prescribed** to confirm correct placement.

Managing and Monitoring Endotracheal and Airways

The following are activities associated with the care of all types of endotracheal airways.

- **Have emergency equipment**, including a duplicate tracheostomy kit, extra cannula, and suction setup immediately available for reintubation if the tube should become dislodged.
- **Keep an extra cannula at the bedside**, as patients may accidentally decannulate.
- **Secure the endotracheal tube** with ties, Velcro tapes, or a commercial holder to prevent accidental displacement.
- **Provide tracheostomy care every 4 to 8 hours** (Mitchell, Hussey, Setzen, et al., 2013).
- **Change the endotracheal or tracheostomy ties every 24 hours.**
- **Secure the orotracheal tube** to the opposite side of the mouth with each change of tape or ties to prevent skin erosion and breakdown.
- **Inspect skin around the tube** or tracheal stoma for redness, swelling, drainage, or irritation at least every 8 hours.
- **Provide skin care** around the tube and tape or holder at least daily.
- **Perform regular oral care.**
- **Inflate the cuff of the tube with a minimal occlusive volume and monitor cuff pressures** to prevent pressure necrosis inside the trachea. (This is a joint responsibility with the respiratory therapist.) Maximum acceptable tube cuff pressure is 25 mm Hg. The following is a method for checking for minimal occluding volume:
  1. Place stethoscope on patient's neck over the carotid pulse.
  2. Attach a 10-mL syringe to the pilot balloon of the inflated cuff.
  3. Remove air from the cuff—(1 mL at a time) until you hear a slight leak at the peak of inspiration.
  4. When you hear the leak, inject 1 mL of air back into the cuff.
- **Monitor and document cuff pressure** once per shift and when the tube is changed or repositioned.
- **Note the centimeter reference marking** on the endotracheal tube to monitor for possible displacement.
- **Minimize pulling and traction** on the artificial airway by supporting all tubing connected to the airway and using flexible catheter mounts and swivels.
- If he is conscious, **remind the patient not to pull on the airway.**
- **Use a bite block** between the teeth to prevent the patient from occluding an orotracheal tube.
- **Provide 100% humidification** of inspired air. Check the oxygen setup regularly.
- **Routine saline instillation** to thin secretions is no longer recommended.
- **Ensure adequate hydration** with oral or IV fluids to keep the mucosa moist and thin secretions.
- **Suction the airway** when secretions collect. Remember, the patient probably can't cough effectively to clear secretions.

Clinical Insight 36-5 ➤ Managing Chest Tubes

Monitor Breathing, Gas Exchange, and Drainage

- Frequently assess breathing patterns, breathing effort, and breath sounds.
- Assess mental status, heart rate and rhythm, and pulse oximetry readings.
  These reflect adequacy of oxygenation.
- Monitor character, color, and amount of chest drainage. Immediately report sudden or large increases in drainage or new onset of bright red blood, along with an assessment of the patient's condition at that time.
  Drainage is usually greatest when the chest tube is initially inserted and decreases as the lung reexpands. You must replace the chest drainage unit (CDU) when the drainage compartment is almost full.

Prevent Complications or Intervene If They Occur

- Observe the dressing at least every 4 hours. Make sure that the dressing around the tube insertion site is occlusive (e.g., not wet or loose). Usually, petroleum gauze is wrapped around the insertion site to ensure occlusion.
- Inspect for excessive, abnormal, or foul-smelling drainage.
  This may indicate hemorrhage or infection.
- Palpate around the dressing for **subcutaneous emphysema** (air in the subcutaneous tissues).
  This may be caused by an incomplete seal at the chest tube insertion site.
- Assess for pain; medicate as needed.
- Reposition the patient every 2 hours and use pillows to keep the patient's weight off the chest tube.
  To prevent occlusion of the tube, promote drainage, and preserve skin integrity.
- Encourage the patient to use the arm on the affected side. Assist with range-of-motion exercises, if necessary.
  To maintain joint mobility.
- **Recollapse of the lung** can occur because of loss of negative pressure within the system. This is commonly caused by air leaks, disconnections, or breaks or cracks of the bottles or chambers. If any of these occur, immediately place the disconnected end nearest the patient into a bottle of sterile water or saline.
- Do not clamp the chest tube. Clamp chest tubes only for changing the drainage system. Limit the clamp time and monitor respiratory status constantly until the clamp is removed.
  Clamping can rapidly lead to a tension pneumothorax.
- If the tube is accidentally pulled out, immediately cover the wound with a dry, sterile dressing. Listen for air leaking out of the site. If you can hear air, tape the dressing loosely so that you do not occlude the site.
  If air cannot escape from the chest, a tension pneumothorax will occur, eventually compromising cardiovascular function.

Promote Lung Reexpansion

- Encourage the patient to be as active as his condition permits.
  Chest drainage systems are bulky, but with disposable systems, patients can still get out of bed and ambulate, but will need assistance to protect and monitor the system and the patient.
- Instruct the patient to perform deep breathing and coughing every 2 hours, unless contraindicated. Assist the patient to sit upright and splint the chest with a pillow or the hands, and provide analgesia as needed.
  These interventions help to minimize discomfort.

Key Points for Managing a One-Bottle System

- Keep the intake tube below the fluid level in the drainage bottle.
  To prevent drawing air into the pleural space with inhalation.
- Maintain the tubing about 2 cm below the water level. As tubing length below the water increases, more effort is required to exhale.
- Take precautions to see that the bottle is not accidentally tipped over, uncovering the long vent tube and allowing air to enter the pleural space.

Maintain the Drainage System

For All Types of CDUs:

- Make sure the drainage system is located below the insertion site.
  If the drainage system is higher than the insertion site, fluid may flow back into the pleural cavity, compromising the patient's respiratory status.
- Regularly inspect tubing to ensure that connections are airtight and tubing is not kinked or occluded.
  Kinks in the drainage tubing increase pressure in the pleural cavity and prevent fluid drainage.
- Monitor drainage.
  Blood or purulent matter can occlude the tubing.
- Inspect the air vent in the drainage system to make sure it is patent.
  If air builds up in the pleural cavity, pneumothorax may occur.
- Monitor to ensure the system is maintaining consistent negative pressure levels.
- Do not "milk" or strip the tubing.
  Doing so can create excess negative pressure and damage lung tissue
- Most systems will have some type of check system to ensure that the system is operating correctly. Always be sure to verify operation through the users' manual or with the product's vendor.
- To transport or ambulate a patient: (1) Keep the CDU upright below chest level; (2) disconnect the CDU from suction source and make sure the air vent is open.

Clinical Insight 36-5 ➤ Managing Chest Tubes—cont'd

Water-Seal Drainage Systems:

- Take precautions that the CDU is not tipped over (e.g., tape it to the floor).
- Observe for **tidaling** (fluctuations in the water-seal chamber's fluid level that correspond with respiration). The level will increase on inspiration and decrease on exhalation. This will be opposite for a patient on a mechanical ventilator.
- Bubbling in the bottom of the water-seal chamber indicates an air leak. When this occurs, check for poor tubing connections. A small amount of bubbling right after insertion or with exhalation or cough is normal.
- Check the water in the suction control chamber; replace as needed.
  The water can evaporate.
- If the chest tube disconnects from the drainage unit, establish a temporary water seal by immersing the open end of the chest tube in a bottle of sterile water to a depth of 2 cm until a new system can be connected. Cleanse the end of the patient connector on the drain system with alcohol and reconnect it if it has not been contaminated. If the patient connector on the drain system is contaminated, you must initiate a new CDU.

Dry-Seal Drainage Systems:

- Inspect the air vent in the drainage system to make sure it is patent.
  The air vent must remain patent to allow air to escape. If air builds up in the pleural cavity, pneumothorax may occur.
- Check the indicators on the CDU to be certain that suction is operating properly.
  A dry chest drainage system doesn't use water in the suction chamber. A valve inside the regulator continuously balances the forces of suction and the atmosphere. The valve automatically responds and adjusts to changes in patient air leaks and fluctuations in suction source vacuum to deliver accurate suction to the patient. Pressure can be set from –10 cm H_2O to –40 cm H_2O by adjusting the rotary dry suction dial.
- Observe for bubbling.
  If the water in a dry-seal CDU is bubbling, it means there is an air leak.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Oxygenation

Part I. Questions to Assess Risk for Impaired Oxygenation

Demographic Data

- What is your age?
- Where do you live?
- What is your occupation?

Health History

- What healthcare problems are you currently being treated for?
- Have you ever been hospitalized or had surgery? If so, when and for what reason?
- Do you have a history of allergies or asthma?
- What medications do you currently take?
- What over-the-counter medications or alternative treatments do you use? What do you use them for?

Respiratory History

- Have you ever been diagnosed with a respiratory problem? If so, what was the diagnosis? When was the diagnosis made?
- Have you noticed any changes in your breathing?
- How often do you cough?
- When you do cough, is it productive?
- What do the secretions you cough up look like and smell like?
- How much sputum do you produce?
- How do you treat your cough? What effect did it have?
- Do you ever wheeze or feel short of breath?
- What causes you to wheeze or feel short of breath?
- Do body positions affect your breathing pattern?
- What position do you lie in when you sleep? Do you use more than one pillow?
- Do you ever wake up short of breath?

Environmental History

- Are there pets in the house?
- What response, if any, do you have to pets, dust, pollen, or plants?
- Are you exposed to smoke or fumes in the home and workplace?
- Are you exposed to respiratory irritants such as asbestos, chemicals, coal dust, fungus, molds, or soot in the home or workplace?
- What type of heating, air-conditioning, or air-filtering system do you have in the home or workplace?

(continued)

Focused Assessment

Lifestyle

- What is your current stress level? What are your major sources of stress?
- What is your usual diet? Is your current diet typical, or have you recently changed your eating habits?
- What is your usual activity level?
- What level of activity makes you feel short of breath?
- Do you smoke now, or have you ever smoked?
- If you smoke, how many packs per day and for how many years have you smoked?
- Do you smoke marijuana or use other substances?

Part II. Focused Physical Examination

Pulmonary System

- ***Inspect*** to observe respiratory patterns, signs of respiratory distress, chest structures and movement, skin and mucous membrane color, presence or absence of edema, sputum characteristics, and overall general appearance.
- ***Palpate*** skin temperature and areas of tenderness.
- ***Percuss*** over the lung fields (for consolidation or excess air pockets).
- ***Auscultate*** breath sounds and vascular sounds.
- ***Assess breathing patterns:*** eupnea, tachypnea, bradypnea, apnea, Kussmaul's breathing, Biot's breathing, and Cheyne-Stokes respirations.
- ***Assess cough and related symptoms:***

  Nasal congestion, sneezing, watery eyes, and nasal discharge suggest allergies.

  Fever, chest congention, noisy breath sounds, sputum production suggest a URI.

  Dyspnea, chest tightness, and wheezing suggest airway obstruction (e.g., asthma).
- ***Assess sputum:*** appearance, color, odor, amount, and timing.
- ***Obtain sputum samples*** as needed.
- ***Assess respiratory effort:*** Breathing should be effortless. Observe for shortness of breath, dyspnea, nasal flaring, head bobbing, retractions, use of accessory muscles during inspiration, grunting, needing to sit upright to breathe, paroxysmal nocturnal dyspnea, conversational dyspnea, stridor, and wheezing.

Key Point: *Ask every patient, not just those with oxygenation problems, whether they use tobacco and document their tobacco-use status regularly.*

DIAGNOSTIC TESTING

Diagnostic Testing

Lung Volumes and Capacities

The norms presented in this table are based on averages for a young adult man. The following are measured by spirometry.

Title	Definition	Significance
Tidal volume (V_T)	The amount of air moved into and out of the lungs with each normal breath. Normally around 500 mL.	In a healthy state, V_T increases when oxygen demand increases. Diseases that restrict lung inflation, create muscular weakness, or paralyze the diaphragm limit the ability of the body to increase tidal volume. When such disorders become severe, V_T will fall too low to support even resting oxygen demands.
Inspiratory reserve volume (IRV)	The maximum amount of air that can be inhaled above and beyond the normal tidal volume. Ranges from 2,000 to 3,000 mL.	IRV determines how much the tidal volume can increase when oxygen demands increase.
Expiratory reserve volume (ERV)	The maximum extra amount of air that can be forcefully exhaled after the end of a normal tidal expiration. Ranges from 1,000 to 1,500 mL.	Some diseases (e.g., emphysema) cause collapse of alveoli and airways, which traps extra air in the lungs. This "trapped" air cannot be exhaled and lowers ERV.
Residual volume (RV)	The amount of air remaining in the lungs after the most forceful exhalation. Ranges from 1,000 to 1,500 mL.	Diseases that reduce ERV lead to an increase in RV. As more air is trapped in the lungs and cannot be exhaled even with forceful attempts (ERV), it becomes part of the residual volume that is never completely exhaled.

Diagnostic Testing

Inspiratory capacity (IC)	The combination of the tidal volume and inspiratory reserve volume (V_T + IRV). Ranges from 2,500 to 3,500 mL.	This is the amount of air that can be inhaled with maximum effort. It reflects the capacity one has to inhale deeply.
Functional residual capacity (FRC)	The combination of expiratory reserve volume and residual volume (ERV + RV). Ranges from 2,000 to 3,000 mL. Exhalation of additional air requires effort to force more air out.	This is the amount of air that stays in the lungs at the end of a normal, passive quiet exhalation. Disorders that cause air trapping increase the FRC.
Vital capacity (VC)	The combination of inspiratory reserve volume and expiratory reserve volume (IRV + ERV). Ranges from 3,000 to 4,500 mL.	This is the maximum amount of air that can be forcefully exhaled after filling the lungs to their maximum level with the deepest possible inspiratory effort.

Diagnostic Testing

Tests Related to Oxygenation

Test	Purpose
Angiogram	A contrast dye is injected into a vein, and serial films are taken to assess patency of the vessels.
Arterial blood gases (ABG)	An analysis of arterial blood that evaluates the effectiveness of gas exchange
Bronchoscopy	Insertion of a flexible endoscope to examine the larynx, trachea, and bronchial tree
Cardiac catheterization	A catheter is passed into the heart to assess pressures, blood flow, and the size and patency of chambers.
Chest x-ray study (CXR)	Provides an anterior–posterior or lateral view of the heart and lungs, shows tissue density (e.g., to evaluate size, masses, fluid).
Creatine kinase-MB (CK-MB)	The MB isoenzyme is present only in the heart muscle. A serum measurement of the MB band is used to detect a myocardial infarction (MI). Levels rise with an acute MI.
Echocardiogram	An ultrasound evaluation of the heart that examines heart function and blood flow.
Electrocardiogram (ECG)	Electrodes placed on the extremities and chest wall conduct electrical activity from the heart. ECG illustrates heart rate, rhythm, and size and helps evaluate heart damage.
Hemoglobin (Hgb)	A serum measurement that affects the oxygen-carrying capacity of the blood. May be measured separately or as part of a complete blood count.
Holter monitor	A continuous ECG tracing used to correlate symptoms and cardiac activity. Typically the tracing lasts 48 hours to 7 days.
Pulmonary function studies	A series of tests to detect lung volume and capacity
Sputum culture	A microscopic evaluation of the sputum
Technetium scan	Technetium-99m sestamibi is injected intravenously. Approximately 90 to 120 minutes later, the heart is scanned. Areas of myocardial damage appear as "hot spots" on the scan.
Thoracentesis	Insertion of a large-bore needle through the chest wall into the pleural space to obtain fluid specimens, to instill medication, or to drain accumulations of fluid
Throat culture	A swab of the pharynx or tonsils is performed to assess pathogens present in the pharynx.
Treadmill test	Evaluates the effect of exercise on the heart and circulation via continuous ECG and vital sign monitoring during exercise.
Troponin	A serum evaluation of a complex of proteins is used to detect myocardial infarction (MI). Levels of these contractile proteins remain elevated for up to 7 days after MI.
Ventilation–perfusion scan	Used to assess for pulmonary embolus, this scan entails injection of a radioactive substance that allows blood flow to the lungs to be evaluated. A second substance is inhaled that maps out oxygen distribution in the lungs.
White blood cell (WBC) count	A serum measure to assess for the presence of infection

Diagnostic Testing

Reading a Tuberculin Skin Test Result

Size of Induration	Considered Positive For
>5 mm	People who have had recent close contact with someone with active TB
	People who have HIV or risk factors for HIV
	People with previous history of TB
>10 mm	IV drug users known to be HIV-negative
	People with medical conditions that increase the risk of progressing from latent TB to active TB (e.g., diabetes mellitus, use of steroids, chronic renal failure, some malignancies)
	Residents and employees of high-risk congregate settings: prisons, skilled nursing facilities (SNFs) and other long-term facilities, healthcare facilities, and homeless shelters
	Foreign-born persons recently arrived (i.e., within the past 5 yr) from countries having a high incidence of TB
	Low-income groups
	Children younger than 4 years of age or exposed to adults in high-risk categories
>15 mm	People who do not meet any of the above criteria

CLINICALREASONING
Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Haley, a 15-year-old female high school student, was admitted to the hospital with shortness of breath and right-sided chest pain when breathing. She states that she has had "the flu" for 3 days. She has a history of asthma since age 6, and smokes half a pack of cigarettes a day. Both her parents are heavy smokers as well. An IV was initiated, and she is receiving 800 mg of vancomycin (an antibiotic) intravenously every 12 hours. She is not on oxygen therapy, but receives 10 incentive spirometer treatments per hour while awake. Her heart rate is 80 beats/min, respiratory rate, 24 breaths/min, and blood pressure, 110/70 mm Hg. Her skin is pale but warm, and capillary refill time is 2 seconds. She has no clubbing of the fingers. She is urinating approximately 400 mL of clear yellow urine every 8 hours and maintaining a normal bowel elimination pattern. Laboratory results are:

Red blood cell count (RBCs): 3.56×10^6 (3.56 million/mm^3)
White blood cell count (WBCs): 11,800/mm^3
Hemoglobin: 11.2 g/dL
Hematocrit: 32.7%
Haley says, "I feel really tired, and too weak to even pick up a glass of water." Her cough produces white, thick sputum. Sputum culture on admission confirms a diagnosis of streptococcal pneumonia.

THINKING

1. *Theoretical Knowledge:*
   a. According to the CDC, should Haley have received a pneumonia immunization? Why or why not?
   b. What is clubbing of the fingers? You may wish to refer to Chapter 22 for review, or to a medical-surgical nursing text.
2. *Critical Thinking (Analyzing Assumptions):*
   Why is it a positive finding for Haley that she does not have clubbed fingers?

DOING

3. *Practical Knowledge:*
Twenty-four hours after the antibiotics were started, Haley's respiratory status becomes worse. She says, "It's so hard to breathe." It is decided to begin administering oxygen. Another sputum culture is prescribed. You are to collect a sputum specimen from the patient.
- **a.** What position should Haley assume for this procedure?
- **b.** What kind of protective clothing do you need for this procedure?
- **c.** You remove the lid from the specimen container. When you hand it to Haley, she touches the inside of the container with her fingers. What should you do?
- **d.** What would you tell Haley to do in order to expectorate the sputum specimen?

4. *Nursing Process (Assessment):*
In the admission data, what important information is missing with regard to her respiratory status?

CARING

5. *Self-Knowledge:*
Describe one or two patient care experiences you might draw upon to help you in caring for Haley. In what ways were those patients similar to Haley, and how might that help you?

6. *Ethical Knowledge:*
After you finish collecting the sputum specimen, what do you think Haley's biggest concern is right now?

Critical Thinking and Clinical Reasoning

1. Recall the three patients discussed in the Meet Your Patients scenario in your textbook in Volume 1:
- Mary is a 4-year-old girl with a history of asthma. Her mother, Ms. Green, has brought her in for an asthma attack. Mary is sitting on her mother's lap and breathing rapidly through an open mouth. Her cough sounds congested and wheezy. The nurse practitioner has ordered a nebulized treatment containing albuterol (Proventil) and ipratropium bromide (Atrovent).
- Mr. Chu is a 78-year-old man complaining of cough, sore throat, fatigue, and weakness. His temperature is 100.4°F (38°C), pulse is 90 beats/min, respirations are 26/min, and blood pressure (BP) is 166/82 mm Hg.
- William is a 19-year-old male who has had a sudden onset of right-sided chest pain and shortness of breath. His chest x-ray revealed a right pneumothorax, and he is currently receiving 35% oxygen by face mask while waiting for an ambulance to transport him to the hospital for further evaluation.
  - **a.** Which patients are experiencing problems with ventilation? Explain your answer.
  - **b.** Which patient appears to be experiencing problems with hypoxia? Does the problem appear to be related to oxygenation or perfusion? Explain your answers.
  - **c.** Mr. Chu has smoked two packs of cigarettes per day for 50 years. ABGs reveal a low PO_2 and a high PCO_2 consistent with chronic lung disease. He is diagnosed with an acute exacerbation of chronic bronchitis. He is placed on oral antibiotics and long-acting bronchodilators by metered-dose inhaler (MDI). What teaching could you offer to help Mr. Chu mobilize and expectorate secretions?
  - **d.** Mary receives her nebulizer treatment and markedly improves. The physician has prescribed a variety of take-home medications that you must teach her mother about. The treatment plan includes a protocol based on peak expiratory flow monitoring. Discuss how you might involve Mary in her own care.
  - **e.** William's chest x-ray film reveals a spontaneous pneumothorax. There is no apparent fluid in the pleural space. What chest tube systems can be used to treat his pneumothorax? Explain your thinking.

2. You are caring for a 68-year-old woman during the night shift. Earlier today she had an abdominal hysterectomy under general anesthesia. You note that her respiratory rate has steadily risen from 16 to 26 and that she has developed a mild, nonproductive cough. When you listen to her chest, you hear crackles throughout. She has a 40-pack-per-year cigarette smoking history. Identify an appropriate nursing diagnosis for this patient. Explain the reasons for your choice.

3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or oxygenation. Note that these are not to be merely definitions.

Ventilation	Hypoventilation
Gas exchange	Hyperventilation
Artificial airways	Supplemental oxygen
Suctioning	Pulse oximetry
Negative pressure in the chest	

What Are the Main Points in This Chapter?

- The structures of the airways, lungs, chest cavity, heart, and blood vessels function together to supply oxygen to the tissues; thus, abnormalities in any of these structures can interfere with tissue oxygenation.
- Developmental stage, environment, lifestyle, smoking, medications, and pathological factors can interfere with ventilation, circulation, or gas exchange, leading to problems with tissue oxygenation.
- A health assessment related to oxygenation includes assessment of ventilation (breathing), circulation (blood flow), and gas exchange (exchange of oxygen and carbon dioxide). The length and focus of the assessment varies with the purpose and urgency of the clinical situation.
- A physical examination related to adequacy of oxygenation includes observations of adequacy of breathing, circulation, and gas exchange.
- Pulse oximetry and arterial blood gases are used to monitor oxygen saturation.
- Small changes in oxygen saturation are associated with large shifts in the amount of oxygen available to the tissues and organs.
- Interventions to promote optimal respiratory function include deep, regular breathing, supporting smoking cessation, flu and pneumonia immunizations for at-risk individuals, frequent position changes, incentive spirometry, and preventing aspiration.
- Deep breathing, coughing exercises, and hydration promote deep inhalation and forceful expulsion of secretions.
- Supplemental oxygen is used to prevent hypoxemia. It may be delivered by a variety of methods.
- Artificial airways provide an open airway for patients who cannot maintain their own airway. The most common artificial airways are oropharyngeal, nasopharyngeal, and endotracheal.
- Airways can be suctioned to remove secretions and maintain patency. Signs that indicate the need for suctioning include gurgling sounds during respiration, restlessness, labored respirations, decreased oxygen saturation, increased heart and respiratory rates, and adventitious breath sounds during auscultation.
- Mechanical ventilation with a positive pressure ventilator requires the patient to have an artificial airway.
- Chest tubes remove air or fluid from the pleural space so that the lungs can fully expand. Chest tubes should be clamped only for changing the drainage system; clamping can lead to tension pneumothorax.
- Respiratory medications promote ventilation and oxygenation by their effects on the respiratory system. The major types of respiratory medicines include bronchodilators, corticosteroids, cough preparations, decongestants, antihistamines, and mucolytics.

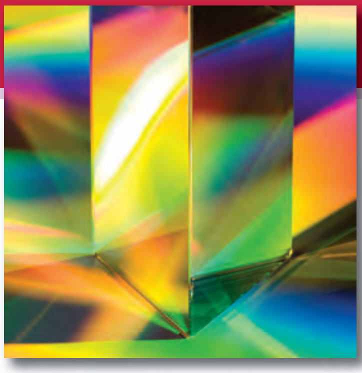
CHAPTER 37



Circulation

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 37:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Circulation (suggested readings)**
- **Concept Map of chapter content**

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 37, **Podcast—Chapter Overview,** on Davis*Plus.*

Caring for the Nguyens

Mai Nguyen, Nam's 76-year-old mother, has been complaining she feels tired all the time; she just can't do what she normally does. She describes having a hard time catching her breath as she walks up stairs and goes about her day. Nam has noticed that his mother's ankles are more swollen than he has ever seen them. So he schedules an appointment for his mother at the family clinic where you are the nurse. Mrs. Nguyen appears pale and not her usual energetic self. Nam tells you that his mom is "not right" and seems to be confused about things at home, which is not like her. She has a history of chronic congestive heart failure.

A. What additional health history data would be useful to gather at this time?

B. During her visit at the clinic, you observe that Mai has a cough. She spits a small amount of pink, frothy mucus into a tissue. Mrs. Nguyen's vital signs are as follows: BP, 142/90 mm Hg; pulse, 96 beats/min and with some irregular beats; respirations, 38 breaths/min and shallow; temperature, 97.8°F (36.5°C) oral.
- Which of these symptoms and vital signs is/are not within normal limits?
- For each abnormal finding, explain why you think it is occurring.

C. You decide to include a nursing diagnosis of Acute Confusion in Mrs. Nguyen's plan of care.
- What symptoms does she have that support this nursing diagnosis?
- What physiological changes are causing these symptoms?

D. In addition to angiotensin-converting enzyme (ACE) inhibitor, beta blocker, diuretic, and digoxin, what additional therapies do you anticipate the physician will prescribe?

E. Mrs. Nguyen asks you, "What can I do to make sure I never get this sick again?" How would you answer this question?

PracticalKnowledge knowing **how**

PROCEDURES

In this section you will find the procedures necessary for supporting oxygenation. As you perform the procedures, apply the theoretical knowledge and concepts you obtained in Volume 1. The registered nurse is responsible for assessing patients' circulation and their responses to treatments and procedures.

Procedure 37-1 ■ Performing Cardiac Monitoring

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Alcohol pads
- Gauze dressing
- Washcloth
- Shaving supplies or scissors, if necessary
- Disposable electrodes

For hardwire monitoring, add:

- Cardiac monitor
- Cable with lead wires
- Safety pin
- 1-in. tape

For telemetry, add:

- Transmitter with lead wires (with a new battery inserted before each use)
- Pouch to carry transmitter

Delegation

You should not delegate this procedure to the LPN or NAP because it requires knowledge of anatomy, physiology, and advanced assessment techniques.

Pre-Procedure Assessment

- Assess cardiovascular status, including heart sounds, pulse rate, and blood pressure, and check for the presence of pain.
- Assess skin integrity of the chest before applying electrodes.
  Skin lesions contraindicate the application of leads to the affected area.
- Assess for history of dysrhythmias.
  Early recognition of dysrhythmias allows for prompt treatment, which improves patient outcomes.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. Prepare the monitoring equipment.

For Hardwire Monitoring

a. Plug the cardiac monitor into an electrical outlet, and turn it on.
Allows the monitor to warm up while you prepare the patient for monitoring.

b. Connect the cable with lead wires into the monitor.
The cable and lead wires must be properly connected to the monitor to obtain an accurate electrocardiogram (ECG) tracing. Most are color coded.

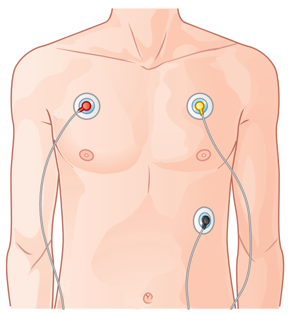
For Telemetry Monitoring

c. Insert a new battery into the transmitter.
A new battery should be inserted with each use to ensure transmitter function.

d. Turn on the transmitter.
Tests the unit to make sure that the battery is functional.

e. Connect the lead wires to the transmitter, if they are not permanently attached. Be sure to attach each one to its correct outlet.
The lead wires must be properly connected to the transmitter to obtain an accurate ECG tracing.

2. Expose the patient's chest and identify electrode sites based on the monitoring system being used and the patient's anatomy. Gently rub the placement sites with a washcloth or gauze pad until the skin reddens slightly.
The monitoring system will dictate lead placement. Sites over soft tissues or close to bone provide accurate waveforms; sites over bony prominences, thick muscles, and skinfolds can produce artifact.



3. If the patient's chest has dense hair, shave or clip the hair with scissors at each electrode site.
Hair may interfere with electrical contact, preventing accurate ECG waveform transmission.

4. With an alcohol pad clean the areas chosen for electrode placement, and allow them to dry.
Alcohol removes oil on the skin that may prevent the electrodes from adhering.

5. Remove the electrode backing and make sure the gel is moist. Discard the electrode if the gel is dry. The number of electrodes needed will depend on the monitoring system being used. It will be three to five electrodes.
A dry electrode will not conduct electrical activity.

6. Attach the lead wires to the electrodes by snapping or clipping them in place.

7. Apply the electrode to the site by pressing it firmly. Repeat with the remaining electrodes.
Pressing the electrode firmly creates a tight seal, which ensures electrical contact.

8. Secure the monitoring equipment.

For Hardwire Monitoring

f. Wrap a piece of 1-in. tape around the cable, and secure it to the patient's gown with a safety pin.
Secures the cable so leads are not disconnected with patient movement.

For Telemetry Monitoring

g. Place the transmitter in the pouch, and tie it around the patient's neck. If there is no pouch, put the transmitter into a pocket on the robe or gown.
Allows the patient independence with ambulation.

9. **Check the patient's ECG** tracing on the monitor. If necessary, adjust the gain to increase the waveform size.
The ECG tracing should be large enough to accurately assess all of the waveform components.

For Telemetry Monitoring

You may need to call a monitoring room to verify ECG tracing and rhythm.

10. **Set the upper and lower** heart rate alarm limits according to agency policy or patient condition, and turn them on.

11. **Obtain a rhythm strip** by pressing the "record" button.
You must obtain a rhythm strip to document the patient's cardiac rhythm. ➤

For Hardwire Monitoring

h. Press the "record" button on the bedside monitor.
The "record" button, located on the monitor at the bedside, allows you to print a rhythm strip immediately when cardiac symptoms occur.

For Telemetry Monitoring

i. Press the "record" button on the transmitter of the telemetry unit, or call the monitoring room to have the ECG trip printed.
The "record" button on the telemetry transmitter allows you or the patient to print a rhythm strip immediately when cardiac symptoms occur.

12. **Interpret the rhythm strip**, and then mount it (e.g., with transparent tape) in the patient's chart.
Provides a permanent record of heart activity; identifies rhythm abnormalities.

? What if . . .

- **The patient is diaphoretic?**

  Remove electrodes, clean the area with alcohol, allow the area to dry, and then reapply electrodes.
  To obtain an accurate ECG tracing.

- **The patient is receiving a cardiac medication?**

  Print a strip before and after giving medication. You may also need to call the telemetry station to have the ECG monitored.
  To assess and monitor effects of medication.

- **You are not getting a good reading on the monitor?**

  Recheck the leads; replace leads or move leads if necessary.

Evaluation

- Evaluate changes in the patient's cardiac rhythm.
- Check skin integrity, and replace the electrodes at least every 24 hours.
  Avoids skin irritation at the electrode sites. In addition, the gel begins to dry, so replacement ensures an adequate waveform.

Patient Teaching

- Explain the rationale for cardiac monitoring.
- Teach the patient that if he experiences symptoms (e.g., shortness of breath, chest pain, dizziness, palpitations) he should notify the nurse immediately so a rhythm strip can be recorded.
- Tell the patient being monitored by telemetry to remove the transmitter before showering. Ask the patient to inform you before removing it.
- Discuss home telemetry monitoring with the patient and caregiver if the patient requires telemetry monitoring after discharge.

Home Care

- Evaluate the client's and caregiver's ability to continue telemetry monitoring at home with help from an outside agency.
- Help the client and caregiver contact the monitoring agency and arrange for home telemetry monitoring.
- Explain to the caregiver and patient that the emergency medical service will be notified by the monitoring agency if a dysrhythmia develops.
- Instruct the caregiver and patient about proper lead placement and the need to rotate electrode sites to prevent skin breakdown.

Documentation

- Document the date and time that monitoring was instituted.
- Note the monitoring lead selected.
- Document a rhythm strip every 8 hours and with changes in the patient's condition according to agency policy. Label the rhythm strip (if the monitor does not label it for you) with the date, time, patient's name, and room number. Indicate on the strip when symptoms and treatment interventions occurred.
- Document the patient's response to treatment.

Practice Resources

Hancock, E. W., Deal, B. J., Mirvis, D. M., et al. (2009); Lieberman, K. (2008); Morrison, L. J., Neumar, R. W., Zimmerman, J. L., et al. (2013).

ASSESSMENT GUIDELINES & TOOLS

Focused Assessment

Assessing Circulation

Part I. Questions to Assess Risk for Impaired Circulation

Demographic Data

- What is your age?
- Where do you live?
- What is your occupation?

Health History

- Do you have current health problems? Describe.
- Do you have past health problems? Describe.
- Do you take medication for your heart, blood pressure, cholesterol, or erectile dysfunction, diabetes, breathing difficulty, or other conditions?
- Do you have chronic fatigue, heartburn, anxiety, swelling of the ankles, difficulty breathing, chest discomfort, palpitations, dizziness or fainting spells, dental problems, pain in the calf when walking that stops with rest, chronic cough or wheezing, shortness of breath, or unexplained weight loss?
- Do you take over-the-counter products, such as vitamins, supplements, or aspirin?
- Have you had surgery in the past?
- What else do you want to tell me about your physical or mental health history?

Family History

- Did your father or a brother develop coronary artery disease or have a heart attack before the age of 55?
- Did your mother or sister develop coronary artery disease or have a heart attack before the age of 65?

Cardiovascular History

- Have you ever had or been diagnosed with a heart attack, angina, coronary artery disease, peripheral artery disease, stroke, aortic aneurysm?
- Do you have high or low blood pressure? Do you feel dizzy if you stand up quickly?
- Do you have diabetes or prediabetes? Are you a normal weight?

Nutrition History

- In a typical day, how many servings of whole grains, fruits, vegetables, dairy products, eggs, nuts, and red meat or fish do you eat or drink per day?
- At how many meals per week do you east fast food or other high-fat food?
- How many sugar-sweetened soft drinks and sodas do you drink per day?
- How many meals per week do you eat out? Where?
- How many times per day do you add salt or eat salty foods?
- How many times per week do you skip a meal?

Lifestyle and Health Promotion Activities

- What is your current stress level? What are your major sources of stress? How do you relieve stress?
- What is you usual diet? Is your current diet typical, or have you recently changed your eating habits?
- What is your usual activity level? Do you exercise regularly? If so, how many minutes per week of moderate to vigorous physical activity do you get?
- Do you check your lipid profile (cholesterol and triglycerides) and blood sugar (fasting blood sugar and hemoglobin A_{1C}) on a regular basis?
- Do you smoke now, or have you ever smoked? If you smoke, how many packs per day and for how many years have you smoked?
- Do you use crack cocaine or other illicit substances?

Part II. Focused Physical Examination

Cardiovascular System

- Also review Procedure 22-13: Assessing the Heart and Vascular System.
- ***Inspect the neck*** for carotid and jugular pulsations. Palpate each carotid separately. Auscultate the carotid arteries and jugular veins for bruits and hums.
- ***Inspect the precordium*** for pulsations. Palpate for pulsations, lifts, heaves, and thrills.
- ***Auscultate for heart sounds.*** To hear examples of various heart sounds,

Go to Student Resources, **Sound Files,** on Davis***Plus.***

- ***Assess peripheral circulation:*** Palpate peripheral pulses, assess skin color and temperature, note hair distribution on extremities. Inspect for skin ulcers and edema of the feet and ankles.
- ***Inspect for venous valve competence.***
- ***Perform the capillary refill test*** anywhere you note signs of diminished blood flow.

DIAGNOSTIC TESTING

Diagnostic Testing

Tests Related to Circulation

Test	Purpose
Angiogram	A contrast dye is injected into a vein, and serial films are taken to assess patency of the vessels.
Arterial blood gases (ABG)	An analysis of arterial blood evaluates the effectiveness of gas exchange and perfusion.
Cardiac catheterization	A catheter is passed into the heart to assess pressures, blood flow, and the size and patency of chambers.
Chest x-ray study (CXR)	Provides an anterior–posterior or lateral view of the heart and lungs, shows tissue density (e.g., to evaluate size, masses, fluid).
Cholesterol, lipid profile	Indicates risk for cardiovascular disease long term.
Creatine kinase-MB (CK-MB)	The MB isoenzyme is present only in the heart muscle. A serum measurement of the MB band is used to detect a myocardial infarction (MI). Levels rise with an acute MI.
Echocardiogram	An ultrasound evaluation of the heart that examines heart function and blood flow
Electrocardiogram (ECG)	Electrodes placed on the extremities and chest wall conduct electrical activity from the heart. ECG illustrates heart rate, rhythm, and size and helps evaluate heart damage.
Hemoglobin (Hgb)	A serum measurement that affects the oxygen-carrying capacity of the blood. May be measured separately or as part of a complete blood count.
Holter monitor	A continuous ECG tracing used to correlate symptoms and cardiac activity. Typically the tracing lasts 48 hours to 7 days.
Technetium scan	Technetium-99m sestamibi is injected intravenously. Approximately 90 to 120 minutes later, the heart is scanned. Areas of myocardial damage appear as "hot spots" on the scan.
Treadmill test	Evaluates the effect of exercise on the heart and circulation via continuous ECG and vital sign monitoring during exercise.
Troponin	A serum evaluation of a complex of proteins is used to detect MI. Levels of these contractile proteins remain elevated for up to 7 days after MI.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Margarita, a 62-year-old director of management technology for a large company, was admitted to the hospital with shortness of breath, sudden and intense fatigue, and intense chest pressure that she describes as feeling like a steel band tightening around her rib cage. She reports the pain moved up to her jaw. The pain began suddenly but lasted approximately 5 to 7 minutes. During the episode, her husband tells you that Margarita acted as though she had a feeling of doom.

Margarita also has a history of sudden onset neck pain that seems to be triggered by heightened stress at work. Margarita is pale and clammy. She states she feels nauseated and has burning in her epigastric area. Her heart rate is 80 beats/minute, respiratory rate, 12 breaths/min, and blood pressure, 168/92 mm Hg. Skin is pale but warm, and capillary refill time is 4 seconds. Height is 5 ft 4 in. Weight is 156 lb. Body mass index (BMI) is 29.2. Waist circumference is 36 in.

The health history includes type 2 diabetes mellitus, high blood pressure, and tobacco use (half a pack of cigarettes a day). Margarita's mother had a heart attack in her 50s.

Lab work prior to admission:

Fasting lipids: total cholesterol, 288 mg/dL; LDL, 148 mg/dL; HDH, 44 mg/dL; triglycerides, 222 mg/dL
Serum glucose: 244 mg/dL
Hs-CRP: 3.1 mg/dL

THINKING

1 *Theoretical Knowledge:*
  a. What predisposing factors increase Margarita's risk for myocardial infarction?
  b. What does it mean to have infarcted myocardial tissue?
2 *Critical Thinking (Analyzing Assumptions):*
  Based on your knowledge of vascular causes of myocardial infarction, what are the most likely causes in this patient?

DOING

3. *Practical Knowledge:*
  After your patient's vital signs are stable and her pain is controlled, the emergency physician prescribes further diagnostic testing to determine the extent of damage to her heart.
  a. What tests would you expect your patient to have?
  b. You attempt to adhere electrodes for cardiac monitoring to Margarita's chest. The ECG tracing shows a great deal of artifact rather than a clear ECG tracing. What should you do to obtain an accurate tracing?
  c. You notice your patient is experience multiple "runs" of aberrant heartbeats. What should you do in response to the abnormal ECG tracing?
4. *Nursing Process (Assessment):*
  In the admission data, what important information is missing with regard to her cardiac status?

CARING

5. *Self-Knowledge:*
  Describe a personal experience involving someone in your own family or a friend who experienced a life-threatening event. How did you feel when your loved one was faced with a potentially life-altering heart condition? How might you draw upon this experience to help you in caring for Margarita?
6. *Ethical Knowledge:*
  a. After Margarita is finished with the last diagnostic test, what do you think her biggest concern is likely to be?
  b. Margarita tells you that she does not want anyone to know she has a heart problem. Yet her husband wants to tell other family members. How do you best respond to her concerns for privacy?

Critical Thinking and Clinical Reasoning

1. Recall the patient discussed in the Meet Your Patient scenario in Volume 1 of your textbook:
  Ms. Saunders is a 55-year-old accountant. She says she has been extremely tired, easily becomes short of breath, and is unable to complete her chores without frequent rest breaks. She is pale and seems tired. Her vital signs are as follows: temperature, 98.4°F (36.7°C); pulse, 86 beats/min; respirations, 24 breaths/min and unlabored; BP, 136/78 mm Hg; and pulse oximetry, 98% on room air. She is now waiting for her lab results, which include a complete blood count (CBC).

  Which of the following nursing diagnoses can you make, based on the patient data given here? Use a nursing diagnosis handbook and the standardized language table in this chapter of the ESG, as needed.

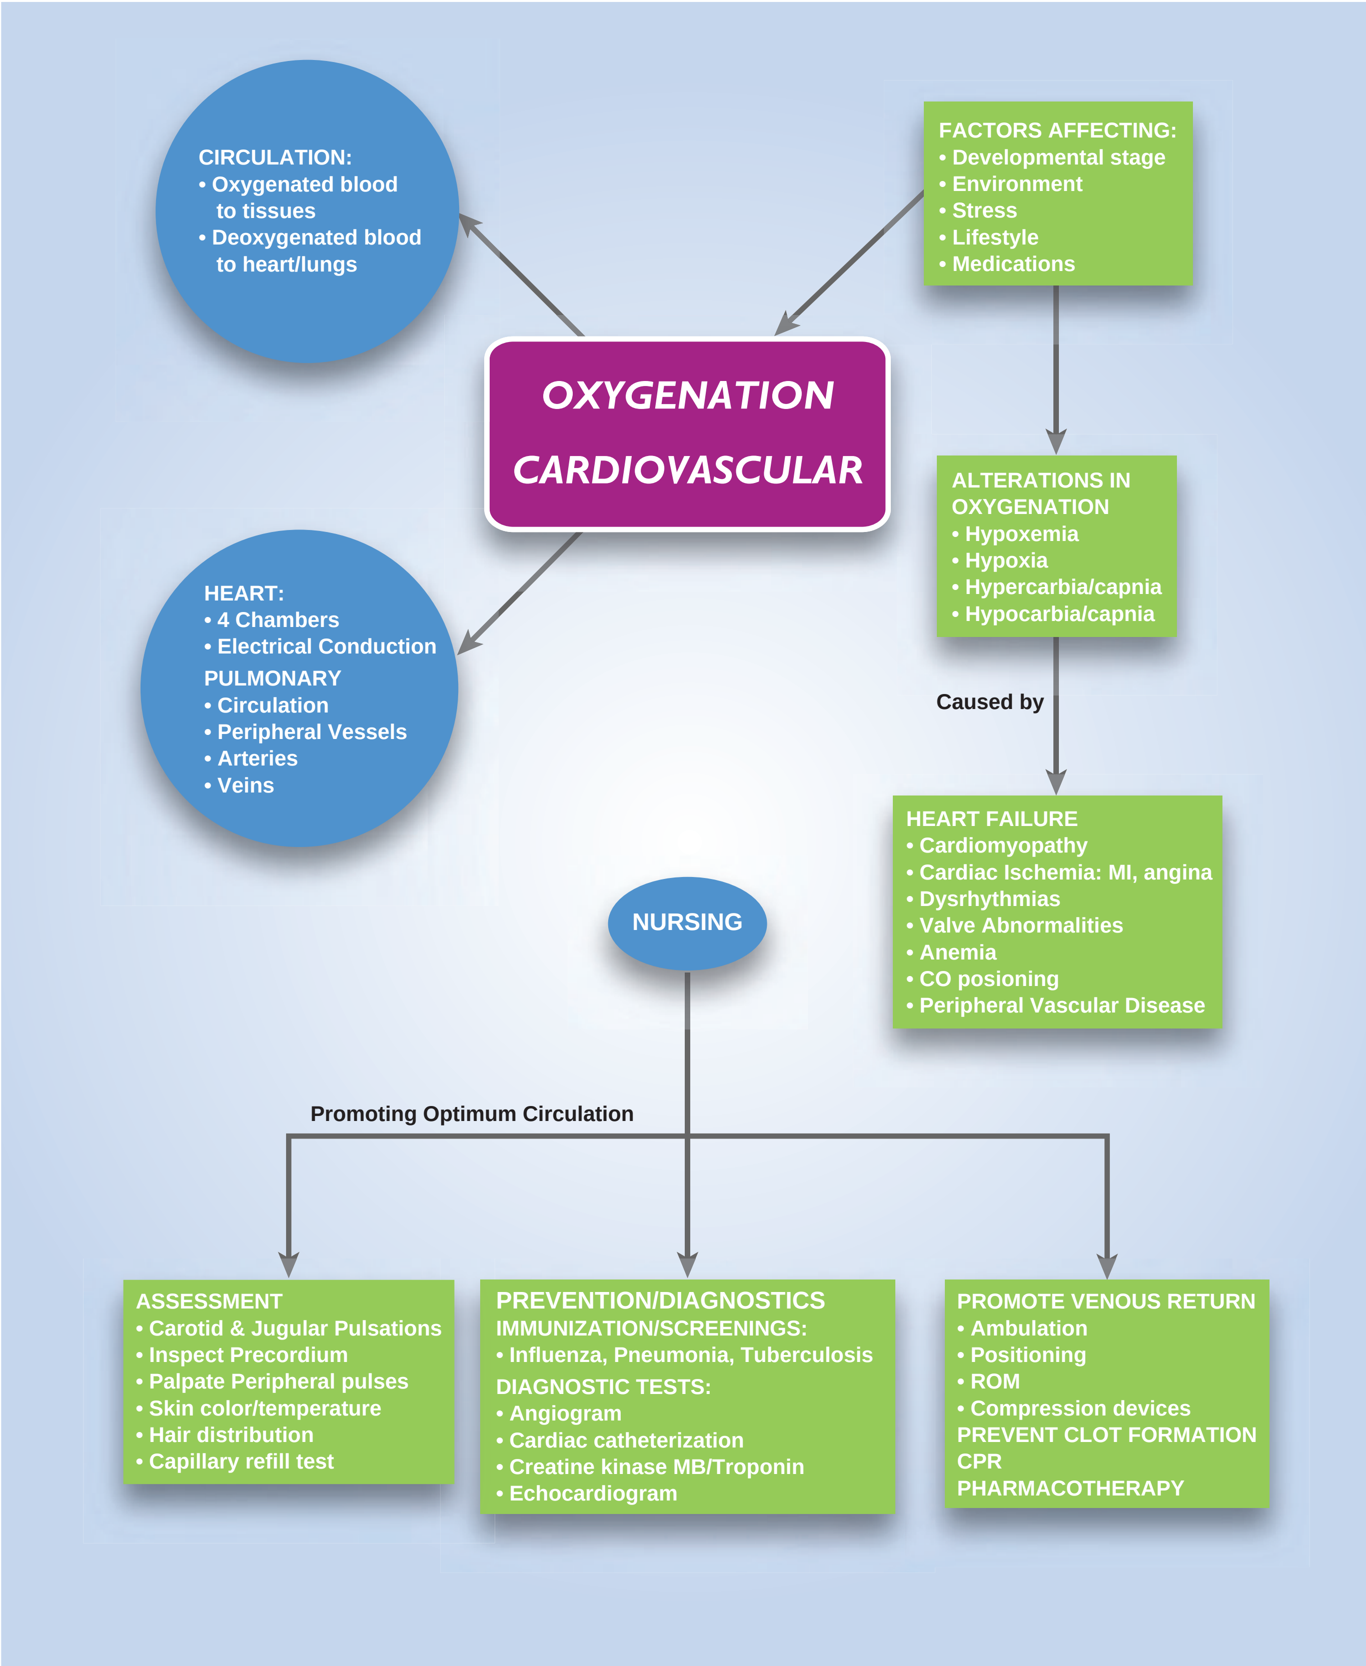
  Decreased Cardiac Output
  Risk for Decreased Cardiac Tissue Perfusion
  Ineffective Peripheral Tissue Perfusion
  Activity Intolerance
2. Ms. Saunders is diagnosed with severe anemia. She is hospitalized because her hemoglobin is 8.9 g/dL. How will this affect her oxygenation? What interventions would improve her fatigue?
3. For the following concept, use critical thinking to describe how or why it is important to nursing, patient care, or oxygenation. Note that this is *not* to be merely a definition.

  Perfusion

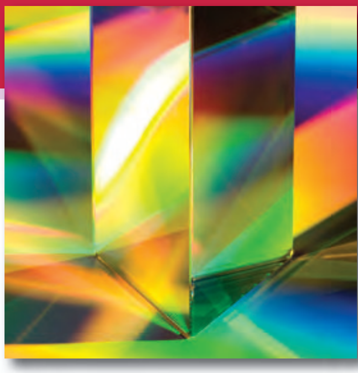
What Are the Main Points in This Chapter?

- The structures of the airways, lungs, chest cavity, heart, and blood vessels function together to supply oxygen to the tissues; thus, abnormalities in any of these structures can interfere with tissue oxygenation.
- Developmental stage, environment, individual characteristics, lifestyle, medications, and pathological factors can interfere with circulation and perfusion, leading to problems with tissue oxygenation.
- A health assessment related to circulation includes assessment of ventilation (breathing), circulation (blood flow), perfusion, and gas exchange (exchange of oxygen and carbon dioxide). The length and focus of the assessment varies with the purpose and urgency of the clinical situation.
- A physical examination related to adequacy of circulation includes observations of adequacy of circulation, and perfusion.
- Cardiovascular function is influenced by developmental stage, environment, lifestyle, substance abuse, medications, and pathophysiological conditions such as heart failure, coronary artery disease, and peripheral vascular disorders.
- The purposes of cardiac monitoring are to identify the patient's baseline rhythm and rate, recognize significant changes in the baseline rhythm and rate, and recognize life-threatening dysrhythmias that require immediate intervention.
- Promoting circulation ensures that oxygenated blood reaches tissues and organs and venous blood returns to the heart. Activities that promote venous return and peripheral arterial circulation and prevent clot formation assist with circulation.
- Cardiovascular drugs are used to enhance cardiac output, thus providing increased blood flow and oxygenation to organs and tissues. They include vasodilators, beta-adrenergic blocking agents, diuretics, and positive inotropes.

Knowledge Map



CHAPTER 38



Fluids, Electrolytes, & Acid–Base Balance

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 38:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Fluids, Electrolytes, & Acid–Base Balance (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 38, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Nam Nguyen has been prescribed the following medicines:

lisinopril (Prinivil) 20 mg PO daily
hydrochlorothiazide (Diuril) 25 mg PO daily in the a.m.
metformin (Glucophage) 500 mg PO before breakfast and lunch

Today he had blood drawn for analysis. Following are the electrolyte panel results.

Sodium	136 mEq/L
Potassium	3.0 mEq/L
Chloride	96 mEq/L
Bicarbonate	24 mEq/L
BUN	18 mg/dL
Creatinine	0.8 mg/dL

A. Review the lab results. Compare Nam's lab work with the established norms for these values. Based on the lab results, what kind of assessment questions would be appropriate to ask Nam?

B. Use your pharmacology text to review Nam's medications. Which, if any, of these medicines might be contributing to Nam's lab results?

C. What teaching would be appropriate for Nam?

PracticalKnowledge knowing how

To prevent, identify, and treat fluid, electrolyte, and acid–base problems, you will need to be skilled at initiating and managing intravenous infusions of fluids and blood, performing focused history and physical assessments, and interpreting arterial blood gas (ABG) values. When performing the procedures, apply the concepts and other theoretical knowledge you have learned.

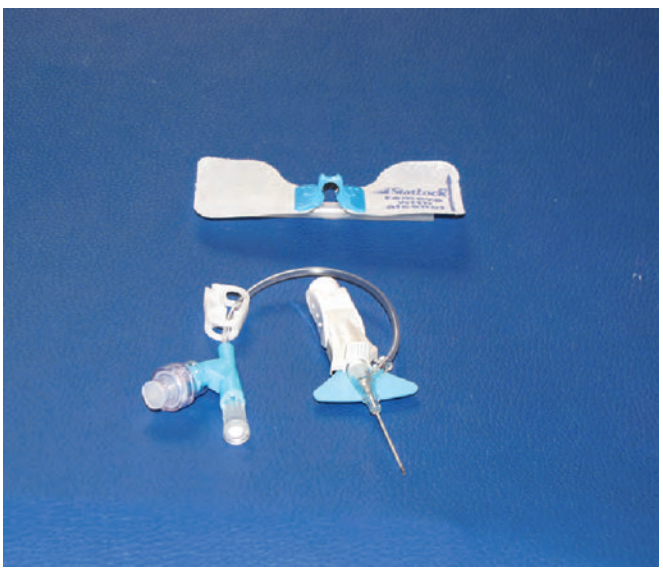
PROCEDURES

Procedure 38-1 ■ Initiating a Peripheral Intravenous Infusion

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- IV solution
- Administration set or IV lock and injection caps. (For a glass solution container, use vented tubing; for a plastic container you may use either vented or nonvented tubing.)
- Extension tubing with or without saline lock.
- Appropriately sized intravenous (IV) catheter
- Prefilled syringe to prime extension tubing.
- Clean, unsterile gloves
- Scissors
- Antiseptic swabs that contain solutions such as chlorhexidine (preferred by the Centers for Disease Control and Prevention [CDC], 2011) or 70% alcohol wipes.
- Tourniquet (non-latex, if available)
- Sterile manufactured catheter stabilization device or ½-in. tape.
- Transparent semipermeable occlusive dressing
- 1-in. nonallergenic tape, preferably clear
- Labels, time tape
- Linen-saver pad
- Arm board, if necessary



Delegation

In some states and agencies you can delegate peripheral IV catheter insertion to a licensed practical nurse (LPN) who is adequately trained in the skill.

Pre-Procedure Assessment

- Assess the patient's need for IV therapy by checking vital signs, laboratory values, urine output, skin turgor, breath sounds, and the condition of mucous membranes.
- Check for any situations that may contraindicate administering the prescribed fluids to the patient.
- Assess for allergy to tape.
- Assess the veins on the arms and hands for a potential insertion site.
  The upper extremities are preferred because of better blood flow, easier access, and less potential for complications than in other locations.
- Check the medical record for factors such as anticoagulant therapy, bleeding disorders, or low platelet count.
  These factors place the patient at risk of bleeding during IV catheter insertion.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

(continued on next page)

Procedure 38-1 ■ Initiating a Peripheral Intravenous Infusion (continued)

Procedure Steps

Note: Maintain scrupulous aseptic technique throughout this procedure.
Any microorganisms introduced can cause infection at the site, which could quickly migrate into the bloodstream and cause sepsis.

1. **Place the patient in** a comfortable position, the bed at a comfortable working height, and supplies within reach. Explain the procedure to the patient.
Makes the procedure safer, easier, and decreases the risk for the nurse to develop back problems from improper body mechanics.

2. **Prepare the IV solution** and administration set or IV lock.
   a. Following the "rights" of medication administration, check the IV solution to make sure that you have the proper solution with the prescribed additives.
   IV solution is considered medication, and you should check it carefully to avoid administration and compatibility errors.
   b. Check the expiration date on the IV solution. Do not use IV solution after the expiration date.
   c. Check the IV solution for discoloration or particulate matter.
   Indicates contamination and should not be used.
   d. Label the IV solution container with the patient's name, date, and your initials. Place a time tape on the solution container with the prescribed infusion rate, time the infusion begins, and the time it is to be completed.
   Policies govern when solution containers, administration sets, dressings, and IV catheters need to be changed to avoid complications such as infection. Although not all agencies require a time tape, labeling infusion rates on the solution containers in this manner will alert others and makes it easy to see at a glance whether the solution is infusing on time.

   e. Take the administration set from the package and close the roller clamp by rolling it downward. Label the tubing with the date and time.
   Ensures that fluid does not flow through inadvertently after the bag is spiked.
   f. Remove the protective cover from the solution container port.
   g. Remove the protective cover from the spike on the IV administration set, keeping the spike sterile. Insert the spike into the port of the solution container.

When Using a Glass Bottle
Clean the rubber stopper on the top of the bottle with an alcohol pad. Then insert the spike of the administration set through the stopper.

   h. Be certain the tubing is clamped. Hang the IV solution container on an IV pole.
   Clamping prevents leakage of fluid.
   i. Lightly compress the drip chamber, and allow it to fill up halfway.
   Overfilling the drip chamber will impair your ability to see the drips and adequately regulate the IV flow rate.

When Not Using Extension Tubing
Prime the tubing by opening the roller clamp and allowing the fluid to slowly fill the tubing. When tubing is filled, close the clamp.

When Using Extension Tubing
Either attach it to the end of the administration set now and prime it with the rest of the IV line, or prime it separately, as follows:

(1) Scrub the injection port of the extension tubing with an antiseptic pad and let it dry.
(2) Attach a flush syringe filled with normal saline to the injection port or to the non-luer-lock end and slowly push the fluid through the tubing until completely primed. (Consult packaging instructions for the amount of saline needed to flush the tubing.)
(3) Leave flush syringe attached to the extension tubing.
IV extension tubing makes it easier to convert an IV to a saline lock without disturbing the IV dressing and catheter. Manipulation of the IV catheter increases the risk of complications such as phlebitis, inflammation, infection, and infiltration.

j. **Inspect the tubing for air.** If air bubbles remain in the tubing, flick the tubing with a fingertip to mobilize them into the drip chamber. Recap the end of the tubing firmly.
Air in the tubing creates the potential for air embolism.

3. **Place a linen-saver pad** under the patient's arm.
Protects the bed from soiling during venipuncture.

4. **Place the patient's arm** in a dependent position.
Gravity helps fill and dilate the vein, making venipuncture easier.

5. **Apply a tourniquet** 10 to 20 cm (4 to 8 in.) above the selected site. Palpate the radial pulse. If no pulse is present, loosen the tourniquet, and reapply it with less tension.
Occluding the arterial flow diminishes venous filling, making venipuncture difficult.

6. **Locate a vein for inserting the IV** catheter. Select the best most distal vein on the hand or arm. Check with the medical provider before using an arm or hand that contains a dialysis graft or fistula, or the affected arm of a patient who has undergone a mastectomy. See Clinical Insight 38-3 for more guidelines.
Choose the most distal veins on the hand or arm so that you can perform subsequent venipunctures proximal to the previous site. This preserves veins for long-term therapy and prevents extravasation of fluid and medicines.

7. **Palpate the vein and press it** downward, making sure that it rebounds quickly. If the vein is not adequately dilated, ask the patient to open and close his fist; apply heat (e.g., a warm towel, a warming mitt); lightly tap the vein site; or stroke the extremity from distal to proximal, beginning below the selected venipuncture site. If available in your agency, use an infrared or other visualization device to assist in locating a vein.
These maneuvers bring blood to the local area to dilate the vein, making it easier to locate and making venipuncture easier.

8. **Loosen the tourniquet.** If excessive hair is present at the venipuncture site, clip it with a scissor.
Loosening the tourniquet restores blood flow and allows for patient comfort while preparing for venipuncture. Clipping the hair helps the dressings to adhere after catheter insertion. Shaving is not recommended because it may abrade the skin, providing a portal of entry for pathogens.

9. **Don clean nonsterile gloves.**
Provides protection from inadvertent exposure to blood. Note that some nurses don gloves routinely, even when preparing supplies and equipment. However, there is no risk for coming in contact with body fluids before this step, so strictly speaking, CDC standard precautions require gloves only from this step forward.

10. **Select an IV catheter** appropriate for the size of the vein, the solution to be infused, and the expected duration of therapy. Using aseptic technique, open the package touching only the outside of it.
Reduces the risk of extravasation and phlebitis. Always use the smallest diameter and shortest catheter that will deliver the desired solution flow. For most adults this will be a 20- to 24-gauge to minimize venous irritation and promote blood flow around the catheter. Aseptic handling reduces the risk of infection.

11. **Gently reapply the tourniquet** and scrub the site, using an antiseptic swab that contains chlorhexidine gluconate (preferred, CDC, 2011); if this is not available, use 70% alcohol wipes. Cleanse for 30 seconds, using friction.
Removes microorganisms from the skin so that they do not enter the venous system during venipuncture. Working "clean to dirty," or from the venipuncture site outward, avoids moving microorganisms toward the puncture site.▼

12. **Allow the antiseptic to air-dry.** Do not fan.
The antiseptic promotes adherence of the dressing. Fanning can cause contamination of the skin.

13. **Pick up the catheter and inspect the tip.**
There should be no burrs (rough spots, ridges) on the needle or peeling of the catheter material.

14. **Inform the patient** that you are about to insert the catheter and that it may be uncomfortable.
Keeping the patient informed promotes cooperation and lessens anxiety.

If Using a Wing-Tipped Catheter (Butterfly)

Grasp the catheter by the wings, using the thumb and forefinger of your dominant hand, making sure that the bevel is up. Remove the protective cap from the needle.
Stabilizes the catheter for insertion. Inserting the needle bevel up makes it less likely that you will pierce both vein walls (go "through" the vein) as well as making piercing the skin less painful for the patient.▼

If Using an Over-the-Needle Catheter

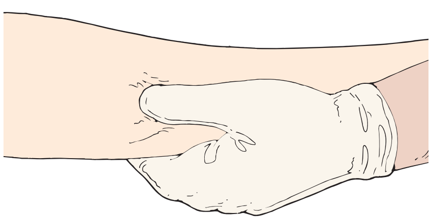
Grasp the catheter by the hub, using the thumb and forefinger of your dominant hand, making sure that the bevel is up.

(continued on next page)

Procedure 38-1 ■ Initiating a Peripheral Intravenous Infusion (continued)

See Step 14 variation for an over-the-needle catheter, preceding.

15. Using your nondominant hand, stabilize the vein by continuously pulling the skin taut below the puncture area (pull downward toward the hand or fingers). Do not press too hard, and make sure not to contaminate the insertion site.
Stabilizing the vein eases insertion and prevents damage to the underside of the vein as well as preventing the vein from rolling. Pressing too hard compresses blood flow in the vein and causes it to collapse.



16. Holding the catheter at a 30° to 45° angle, pierce the skin directly over the vein. Penetrate all layers of the vein with one quick, smooth motion.
A 30° to 45° angle allows you to pierce the skin without inadvertently passing through the vein, and allows backflow of blood into the catheter.

17. Look for a flashback of blood into the chamber of the catheter or the tubing of the winged catheter.
The flashback of blood indicates that the vein has been entered, but only by the needle when using an over-the-needle catheter.

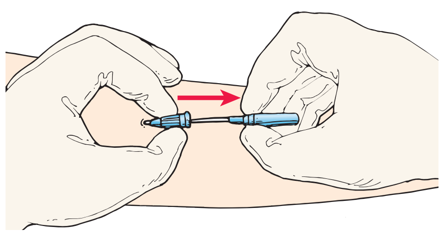
18. Lower the angle of the catheter and needle to skin level and advance them into the vein.

For a Wing-Tipped Catheter
Fully advance the catheter.

For an Over-the-Needle Catheter
Still maintaining traction on the skin with your nondominant hand, hold the catheter hub with your thumb and middle finger, and use your index finger to advance the catheter to at least half of its length before you begin withdrawing the needle. When a steady backflow of blood occurs, partially withdraw the needle while advancing the catheter fully into the vein. For an animated illustration of an over-the-needle IV catheter,

Go to **Animations: Insertion of an Over-the-Needle IV Catheter,** on Davis*Plus*.

Withdrawing the needle too early will result in the catheter not fully entering the vein, only the needle. There will be no bleeding from the catheter and infiltration will occur when starting the IV solution. The patient will also experience pain.



19. While holding the catheter in place with one hand, release the tourniquet and remove or retract the needle.

For an Over-the-Needle Catheter
Hold the catheter in place by placing light pressure on the catheter, away from the hub and venipuncture site.

> Never attempt to reinsert the needle after it is withdrawn. This can damage the catheter and even cause bits of it to break off within the vein.

For a Winged Needle
Place a finger lightly on the same area plus a finger farther along the vein away from the needle so the needle does not go through the vein.
Releasing the tourniquet restores full circulation to the patient's extremity and prevents injury. Placing light pressure on the catheter or vein minimizes bleeding from the catheter or needle while you complete the procedure.

20. Quickly connect the administration set to the IV catheter, using aseptic technique.
To minimize bleeding and prevent infection.

If Using a Peripheral IV Lock
Once the lock is connected, flush with normal saline and then disconnect the flush. A common amount is 1 to 2 mL, but tubing varies, so check package instructions for the exact amount needed.
Flushing the catheter both clears it and keeps it sterile.

21. While still holding the catheter in place, slowly open the roller clamp. Observe that flow is achieved. Adjust the drip to the prescribed flow rate.

22. Secure the connection between the tubing and the catheter. Many sets have luer-lock connections, so no further securing is needed. If not using luer-lock tubing, clasping devices and threaded devices can be used. Do not use tape.
Secure the connection to prevent separation of tubing from the hub.

> Taping is not recommended because the junction is not visible under tape; therefore, the tubing could separate from the catheter without being discovered, possibly leading to air embolism, bleeding, or infection.

23. Stabilize the catheter. Use an agency-approved device. Catheter stabilization devices include manufactured devices (such as StatLok), or tape.

When Stabilizing With Tape
Place a narrow (¼-in.) strip of tape under the catheter hub and crisscross the ends over the hub to form a chevron. Apply tape only to the catheter hub, not to the catheter itself, and do not apply tape

directly to the site where the catheter enters the skin.
Luer-locks are designed to prevent accidental disengagement of tubing and catheter; they do not stabilize the catheter. Catheter stabilization is important to minimize catheter movement and help prevent complications such as phlebitis, inflammation, infiltration, and infection.

24. Dress the site, following agency policy. If needed, clean the site with an antiseptic swab and allow it to dry before applying the dressing.

If Using a Transparent Dressing (Preferred)

a. Open the package containing the dressing. Remove the protective backing from the dressing, making sure not to touch the sterile surface.
b. Cover the insertion site and the hub or winged portion of the catheter with the dressing. Do not cover the junction with the administration tubing.

c. Gently pinch the transparent dressing around the catheter hub to secure the hub further. Smooth the remainder of the dressing so that it adheres to the skin.

If You Must Use a Gauze Dressing

a. Fold a 2 in. × 2 in. sterile gauze dressing in half, cover it with 1-in. tape (about 3 in. long).
b. Place under the tubing/hub junction and press down on the tape.
Raises hub off the skin and prevents pressure on the skin.
c. Place a sterile gauze pad over the insertion site and catheter hub—but not over the catheter–hub junction.
d. Secure all edges with tape.

25. Label the dressing with the date and time of insertion, catheter size, and your initials.
A label lets nurses see at a glance how long the dressing has been in place.

26. Secure the IV administration tubing by looping and taping the tubing to the skin.
Helps prevent the IV catheter from becoming dislodged and decreases movement of the catheter, thereby decreasing the risk of phlebitis, inflammation and infiltration.

27. Place an arm board under the joint and secure it with tape, if the insertion site is located near a joint.
An arm board stabilizes the joint and helps prevent the catheter from becoming dislodged. However, avoid inserting an IV near a joint when possible, as there is increased potential for movement of the IV catheter, leading to an increased risk of complications. IVs placed in the antecubital fossa are difficult to assess for infiltration. Arm boards are not widely used because of the high acuity of inpatients, many of whom have central lines instead of peripheral IVs.

28. Dispose of all supplies, including sharps, into appropriate receptacles; raise the siderail; lower the bed; and be sure the patient call system is within reach. Wash your hands.
Prevents infection and ensure patient and staff safety.

? What if . . .

- **The patient is an older adult?**

Do not scrub skin too vigorously.
This can damage fragile surface tissue, creating a portal for pathogens.

Use a softer tourniquet and do not apply tightly; for well-dilated veins, do not use one at all.
This decreases the risk of rupture of fragile veins.

Use the smallest catheter possible to meet the infusion needs.
Insert the needle at an almost flat angle (10° to 20°).
In most older adults, veins are close to the skin surface.

Before penetrating the skin, apply traction to the vein below the insertion site.
For comfort and ease of insertion.

Insert the catheter on top of the vein; do not use the side access technique. If bleeding occurs, hold gentle pressure longer than for younger patients.
A clot may take longer to form.

- **The patient is an infant younger than 2 months old?**

Allow the antiseptic to air-dry on the skin. Do not fan.
Increases the antiseptic's effectiveness; promotes patient comfort on puncture of the skin; promotes adherence of dressing. Fanning increases exposure to airborne microbes.

- **The patient is allergic to iodine or shellfish?**

Use 70% alcohol or chlorhexidine for 30 seconds to cleanse the site (not povidone-iodine or iodine).

- **You are not successful with the first venipuncture attempt?**

Use a new cannula and make a second attempt on the other arm; or if unsuccessful, higher up on the same arm. Do not make more than two attempts without seeking assistance.

- **When you insert the needle and catheter and connect the tubing, you see bright red blood quickly appear and start to advance up the tubing?**

You may have entered an artery. Remove the catheter and apply direct pressure for at least 5 minutes. Notify the primary care provider. Monitor the extremity distal to the insertion site for pulses, color, and temperature.

(continued on next page)

Procedure 38-1 ■ Initiating a Peripheral Intravenous Infusion (continued)

Evaluation

- Monitor the IV site and flow rate regularly (many agency standards require hourly) while IV fluid is infusing. Check for signs of infiltration, inflammation, and phlebitis.
- Monitor the patient's tolerance of IV therapy by auscultating breath sounds and monitoring vital signs, urine output, laboratory values, and neck vein distention. Report to the primary provider any signs of fluid overload, such as crackles, edema, shortness of breath, diminished urine output, increased blood pressure, increased heart rate with bounding pulse, and distended neck veins. Fluid overload can lead to pulmonary edema and heart failure.

Patient Teaching

- Instruct the patient about IV therapy.
- Teach the patient the importance of notifying staff immediately if the catheter or administration set becomes dislodged; the insertion site becomes tender, red, or swollen; or the patient notices moisture or fluid leakage.
- Explain the desired and adverse effects of IV therapy, and tell the patient to notify staff if he develops discomfort or breathing difficulty.
- Teach the patient measures to avoid dislodging the catheter.

Home Care

- Explain home IV therapy to the client and caregiver, and teach them how to identify complications.
- Provide the client with the name and phone numbers of people to contact in case problems arise with the catheter site or if there is a change in level of comfort.

Documentation

- Date and time of insertion, gauge and type of catheter, number of attempts, and location of the insertion site
- Tourniquet use (or nonuse)
- Blood return in catheter; whether the IV flushes, type and amount of flush solution used
- Dressing and tape type used
- Method of securing or stabilizing the IV line
- Type and rate of the IV fluid infusing
- Patient's tolerance of the procedure, any adverse reactions to the insertion or IV therapy, and the interventions required
- Patient teaching
- Often, IV care is documented on a flowsheet. Fluids infused are documented on the I&O record as well.

Sample documentation

06/07/16 0200. 20-gauge, winged catheter inserted in cephalic vein, with tourniquet, without difficulty on first attempt. Obtained blood return. Catheter flushed easily. Dressed site with a transparent, semipermeable dressing and clear tape. Catheter stabilized with fixation device. 1 L of D_5/NS hung at 125 mL/hr. Patient tolerated venipuncture with no difficulty. Instructed to notify nursing staff immediately if pain or swelling occurs at the site. Also instructed about precautions to take to avoid dislodging IV catheter and importance of notifying staff immediately should it become dislodged. ———S. Jiminez, RN

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Initiating a Peripheral Intravenous Infusion.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 38-2 ■ Regulating the IV Flow Rate

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- IV solution hanging on an IV pole and attached to an administration set
- Watch with a second hand or digital seconds
- Time tape

Delegation

Refer to your state nurse practice act and agency policy regarding delegation of this task to an LPN.

Pre-Procedure Assessment

- Assess the IV catheter for patency and date of insertion before starting the infusion and then regularly (many agencies specify hourly) while the IV fluid infuses.
  Decreases risk of complications related to incorrect infusion rate, expired infusion solution, tubing, or catheter dwell time.
- Assess the IV site for signs of phlebitis, infiltration, infection, or inflammation.
  You must change the IV catheter before regulating the flow rate if any of these complications occur.

- Confirm the patient's need for IV therapy by verifying the order and checking laboratory values, urine output, vital signs, and breath sounds.

Ensures that the patient still needs IV fluids and that the solution is correct. Laboratory values and assessment findings monitor the IV treatment plan. IV therapy creates a risk for fluid overload.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Follow all the "checks" and "rights"** of medication administration, including verifying the prescription. Check the solution to make sure that you have the proper IV fluid hanging with the prescribed additives, and that there is no discoloration of or particles or crystallization in the fluid. Also verify the infusion rate.
IV solution is considered medication, and you should check it carefully to avoid administration and compatibility errors. Do not simply pull a bag of fluid from a shelf assuming that the shelf is labeled properly, as bags are often misplaced and this is a potential source of error.

2. **Calculate the hourly rate** if it is not specified in the order. Divide the volume to be infused by the number of hours it is to be infused. For example, if the physician prescribes 1,000 mL to run over the course of 4 hours, the infusion rate is 250 mL/hr.
You must carefully calculate the infusion rate to ensure that the patient receives the correct volume of fluid.

Note: If you are using a volume-control pump, you can omit Steps 3 and 4.

3. **Calculate the drip rate** by multiplying the number of milliliters to be infused in 60 minutes by the drop factor in drops [gtts]/per milliliter; then divide by 60 minutes:

$$\frac{\text{Hourly rate in mL} \times (\text{gtts/mL})}{60 \text{ minutes}} = \text{drip rate}$$

For example, an hourly rate of 100 mL multiplied by 15 gtts/mL and divided by 60 minutes equals 25. Therefore, the drip rate equals 25 gtts/minute. Each administration set has a drip factor that is determined by the manufacturer. The ***drip factor*** *is the number of drops necessary to deliver 1 mL of solution. Microdrip tubing has a drip factor of 60 gtts/mL; blood administration tubing typically has a drip factor of 10 gtts/mL; macrodrip tubing has a drip factor of 15 gtts/mL.*

4. **Verify your calculations.**
To prevent dosage errors, either have a second person verify your calculations or check them a second time yourself.

5. **Apply a time tape** when hanging a new bag to the IV solution container next to the volume markings. Mark the time tape with the time that the infusion was started. Continue to mark 1-hour intervals on the time tape until you reach the bottom of the container.
The time tape allows all nurses to accurately monitor the rate of administration.

6. **Open the roller clamp** so that IV fluid begins to flow (when hanging a new bag).
The roller clamp must be opened to allow the flow of fluid.

7. **Set the rate.**

For Gravity Drip

Using a watch placed next to the drip chamber, count the number of drops entering the drip chamber in 1 minute. Adjust the roller clamp by increasing or decreasing the flow until you achieve the prescribed drip rate.
Timing the drip rate for 1 minute helps to accurately achieve the correct drip rate and having the watch next to what you are counting will ensure that you do not miss seeing any drops.

For a Volume-Control Pump

Program the ordered rate into the pump.
IV solution is considered a medication and must infuse at the prescribed rate.

8. **Monitor manually regulated** infusion rates closely for the 15 minutes after you begin an infusion; then monitor at least hourly by counting drops per minute or reading the numbers on the pumps.
Changes in the patient's position may speed up or slow down the infusion rate; frequent monitoring of the infusion rate ensures that the correct volume of fluid infuses over the correct length of time.

(continued on next page)

Procedure 38-2 ■ Regulating the IV Flow Rate (continued)

? What if . . .

- **The prescription for the IV flow rate changes?**
  Recalculate the new flow rate and adjust the drops/minute to obtain the desired new flow rate. Also, remove the old time tape and place a new time tape with the new rate of infusion.
- **When you check the rate, you discover that the IV has been running too slowly for the past hour?**
  Adjust to the correct rate, but do not attempt to catch up by adjusting the flow to a rate higher than prescribed. *Too rapid IV infusion can lead to fluid overload for patients with congestive heart failure or other cardiopulmonary problems.*
- **When you check the rate, you discover that the IV has been running too fast for the past hour?**
  Slow the rate and assess the patient for signs of fluid volume excess.

Evaluation

- Evaluate the patient's response to IV therapy by checking for signs of excessive or deficient fluid volume.
- Evaluate the IV site for signs of infiltration, inflammation, infection, and phlebitis.
- Check laboratory studies to help evaluate the effectiveness of IV therapy.
- Monitor for correct IV rate at least hourly.
- Evaluate the tubing for kinks, or patient lying on the tubing. *Kinked tubing will interfere with the flow rate.*

Patient Teaching

- Explain the desired and adverse effects of IV therapy.
- Discuss the importance of notifying staff immediately if the catheter or administration set becomes dislodged; if the insertion site becomes tender, red, or swollen; if the patient notices moisture or fluid leakage; or if he has difficulty breathing.
- Teach safety measures if the patient is permitted to ambulate while the IV is infusing.

Home Care

- Explain home IV therapy to the client and caregiver, and teach them how to identify complications.
- Provide the client and caregiver with the name and phone numbers of people to contact in case problems arise with the catheter, insertion site, or level of comfort.

Documentation

Often IV care is documented on a flowsheet, and includes the following.

- Date and time the infusion was started
- Type of IV fluid, rate of infusion, and IV catheter site
- Whether rate is manual or pump controlled
- Patient's tolerance of IV therapy, any complications, and the interventions taken
- Document the volume infused on the I&O record.

Practice Resources

INS (2011a); Phillips, L. (2010); Shlamovitz, G. (updated 2013a).

Procedure 38-3 ■ Setting Up and Using Volume-Control Pumps

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonsterile gloves
- Alcohol wipes or chlorhexidine/alcohol antiseptic product
- Volume-control pump and IV pole
- Administration set appropriate for the pump
- IV fluid or medicated solution
- Tape for IV fluid solution time tape

Delegation

You can delegate the task of setting up a volume-control pump to an LPN who is specially trained in IV therapy, if covered by the agency's policy. Do not delegate this task to nursing assistive personnel (NAP). Do, however, instruct the NAP to notify you of any pump alarms that sound.

Pre-Procedure Assessment

- Confirm the patient's need for IV therapy by checking vital signs, laboratory values, urine output, skin turgor, breath sounds, and the moisture of mucous membranes.
  IV therapy creates a risk for fluid overload and electrolyte imbalance, which may be revealed by assessment data.
- Assess the existing IV catheter for patency.
  Occlusion of the IV catheter prevents the infusion of IV fluid. If not patent, you will need to change the IV.
- Assess the IV site hourly for signs of phlebitis, infiltration, infection and inflammation.
  Complications of IV therapy retard the therapeutic benefit of the fluids, as well as increase medical concerns and treatment cost for the patient. You must change the IV catheter and site if any of these complications occur.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Calculate the infusion rate** by dividing the volume to be infused by the number of hours it is to be infused. For example, if the order states 1,000 mL to run over 8 hours, divide 1,000 mL by 8 hours to determine the infusion rate of 125 mL/hr.
This ensures that the patient receives the correct dose. Pumps are usually programmed in milliliters per hour instead of drops per minute.

2. **Verify your calculations.**
To prevent dosage errors, either ask a second person to verify your calculations or check them a second time yourself.

3. **Attach the pump to the IV pole**, and plug it into the nearest electrical outlet.

> Check to be sure that the infusion pump has a safety sticker on it and that the cord and plug are intact.

Volume-control pumps need regular maintenance checks. Using an electrical outlet saves battery power if needed for transport or electrical outage. As with gravity flow, the IV solution container needs to remain above the pump to prevent occlusion and for proper drainage of the container.

4. **Take the administration set** from the package, and close the clamp on it.
To prevent inadvertent loss of fluid.

5. **Attach a filter to the end** of the administration set, if required.
Filters are sometimes used to filter minute particles from the solution.

6. **Remove the protective covers**, and spike the port of the solution container with the administration set, maintaining sterility. Label the IV tubing and solution container with the date and time, and place a time tape on the solution container. Hang the container on the IV pole.
Labeling the administration set with the date and time informs the nursing staff when the administration set should be changed. The time tape allows you, and other nurses, to see at a glance whether the correct volume is infusing.

7. **Compress the drip chamber** of the administration set, and allow it to fill halfway. Consult the manufacturer's instructions for setup, as pumps differ. (On older gravity pumps, place the electronic eye on the drip chamber between the fluid level and the origin of the drop.)
Prepares the administration set for priming and prevents air from entering the tubing with the solution. Infusion pumps compress the tubing to move fluid; they measure the amount internally. On older gravity-type pumps, an electronic eye counts the number of drops to ensure the proper rate.

8. **Prime the administration set** with fluid by opening the roller clamp and allowing the fluid to flow slowly through the tubing. Recap the tubing and close the clamp.
Priming removes air from the tubing to prevent air embolus.

9. **Inspect the tubing** for air. If air bubbles remain in the tubing, flick the tubing with a fingertip to mobilize the bubbles into the drip chamber.
Air bubbles in the administration tubing interrupt flow and they can cause air emboli, which can be dangerous to the patient if they accumulate in the circulation.

10. **Turn on the pump, and load** the administration tubing into the pump according to the manufacturer's instructions.
Pumps differ. Consult the manufacturer's instructions.

11. **Program the pump** with the prescribed information: total hours, infusion rate (hourly rate) and the volume to be infused (usually the total amount in the IV bag). *Note: Some pumps have only total hours and volume to infuse and do not have a feature that allows you to program in the infusion rate.*

12. **Don clean nonsterile gloves,** check the IV site for patency, and scrub all surfaces of the primary line injection port or needleless connector, including the threads, with an antiseptic pad for at least 15 seconds. Allow it to dry.

(continued on next page)

Procedure 38-3 ■ Setting Up and Using Volume-Control Pumps (continued)

Clean nonsterile gloves protect from exposure to body fluids when you connect the tubing to the IV catheter or port. Scrubbing the port helps prevent infection.

13. **Connect the administration set** adapter to the injection port, keeping the connecting ends sterile.
Aseptic technique decreases the risk for contamination.

14. **Unclamp the administration set** tubing (open the roller clamp all the way), and press the start button on the pump.
Allows the IV fluid to flow through the administration set.

15. **Make sure the alarms** are turned on and audible.
The alarms must be functioning so that the pump can alert you of problems, such as kinks, air in the tubing, or catheter occlusion.

Key Point: ***Do not depend completely on the pump alarms to indicate IV patency. Pumps can infuse fluid, even if the line is clogged or infiltrated into the surrounding tissue.***

16. **Check the pump regularly** to make sure the correct volume is infusing. Checks are commonly done hourly.
Infusion pumps sometimes malfunction, so frequent monitoring is essential.

17. **At the end of your shift** (or at the time specified by your healthcare facility), clear the pump of the volume infused and record the volume on the patient's I&O form.
This helps the oncoming shift accurately monitor the fluid infused during their shift.

? What if . . .

- **In later evaluation you find the IV free flowing and not running via the pump setting?**

Immediately slow the IV fluid down. At the same time, begin assessing the patient: vital signs, mental awareness, lung sounds, pulse oximetry. Depending on the type of fluid running, you may need to make other assessments. Calculate the amount of IV fluid actually infused compared with the prescribed amount. Notify the provider and write out an occurrence report. If the pump is malfunctioning, set it aside, label it as "not working," and notify biomedical engineering so they can repair it.
Labeling the pump will prevent others from using it, until it can be repaired.

Evaluation

- Monitor the correct functioning of the pump regularly, perhaps hourly.
- Assess the IV site hourly for signs of phlebitis, infiltration, infection, and inflammation.
Complications of IV therapy interfere with the therapeutic benefit of the fluids and increase medical concerns, and treatment costs for the patient. You must change the IV catheter and document if any of these complications occur.

Patient Teaching

- Explain use of the IV infusion pump to the patient.
- Teach the patient the importance of notifying staff immediately if the infusion pump alarm sounds; the catheter or administration set becomes dislodged; the insertion site becomes tender, red, or swollen; or the dressing becomes wet.
- Teach the patient safety measures if he is able to ambulate while the infusion pump is in use.

Home Care

- Explain home IV infusion pump use to the client and caregiver, and teach them how to identify complications. Most home infusion pumps are smaller than institutional pumps.
- Provide the client with the name and phone numbers of people to contact in case problems arise with the catheter, insertion site, IV infusion pump, or other equipment.

Documentation

- Type and volume of IV fluid infusing, along with the infusion rate
- Use of the infusion pump, and patient's tolerance of IV therapy
- Any complications of IV therapy and the interventions taken
- Document volume infused on the patient's I&O record and/or an IV flowsheet.

Sample documentation

07/26/16 0600 Patient admitted from the ED with dehydration. NSS infusing at 250 mL/hr via infusion pump through an 18-gauge catheter. No signs of infiltration. No tenderness, redness, or swelling at the insertion site. Temp 102.6°F orally. HR 118 beats/min, RR 24 breaths/min, and BP 90/46 ——————————R. Brill, RN

Practice Resources

Cummings, K., & McGowan, R. (2011); Phillips, L. (2010).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **Setting Up and Using Volume-Control Pumps.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 38-4 ■ Changing IV Solutions and Tubing

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Nonsterile gloves
- Administration set
- IV solution
- IV pole
- Antiseptic swabs that contain solutions such as 70% alcohol or 2% chlorhexidine (chlorhexidine is not recommended in infants younger than age 2 months). You may use iodine-based products if alcohol or chlorhexidine are contraindicated and the patient is not allergic to iodine.
- 1-in. nonallergenic tape
- Time tape
- Watch with a second hand or digital seconds

Delegation

You can delegate the tasks of changing IV solutions and tubing to an LPN who is specially trained in IV therapy. The task should not be delegated to a NAP. However, do instruct the NAP to notify you of any problems that occur with IV therapy, such as the disconnecting of the administration set; catheter dislodging; or complaints of pain, swelling, or redness at the insertion site.

Pre-Procedure Assessments

- Assess the IV catheter for patency before changing the solution container or administration set.
- Assess the IV site for signs of phlebitis, infiltration, infection, or inflammation.
  If any of these complications occur, discontinue the IV and start a new IV at a different site.
- Check IV catheter insertion date.
  IV catheters are replaced per agency guidelines, which are based on the CDC recommendations of changing a peripheral IV site when clinically indicated (e.g., signs of phlebitis, infiltration, irritation).

Procedure 38-4A ■ Changing the IV Solution

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Following the rights** of medication administration, prepare and label your next container of IV solution at least 1 hour before the present infusion is scheduled to finish.
   Preparing the next IV solution container reduces the risk of the present container running dry, thereby causing clots to form that would occlude the catheter.
2. **Close the roller clamp** on the infusing administration set.
   Prevents air from entering the tubing while changing the IV solution container.
3. **Wearing clean nonsterile gloves**, remove the old IV solution container from the IV pole. Remove the spike from the bag, keeping the spike sterile.
   The spike must remain sterile to prevent contamination of the new IV fluid. Clean nonsterile gloves protect you from exposure to body fluids.
4. **Remove the protective cover** from the new IV solution container port.
5. **Place the spike into the port** of the new solution container.

For a Glass Bottle

First scrub the rubber stopper on the top of the bottle with an antiseptic pad; then, insert the spike of the administration set through the rubber stopper.
Cleansing the stopper removes particulate matter and microbes.

6. **Hang the IV solution** container on the IV pole.
   Allows the fluid to infuse by gravity.
7. **Inspect the tubing** to be sure that it is free of air bubbles and the drip chamber remains half-filled. Flick the tubing with a finger to mobilize the bubbles into the drip chamber.
   Prevents air from entering the system as the new solution is hung. If the drip chamber becomes too full, it will be difficult to impossible to count the drip rate properly and regulate the IV.
8. **Open the roller clamp** and adjust the drip rate, as prescribed.
   IV solution is considered a medication and must infuse at the prescribed rate for therapeutic effect and to prevent fluid overload.
9. **Affix the time tape** to the new IV solution container, if practiced within your agency. Mark the tape with the time the infusion was started, and mark 1-hour intervals on the tape until you reach the bottom of the container.
   The time tape allows you and other nurses to monitor the rate of administration easily.
10. **Dispose of used supplies** into appropriate receptacles, according to agency policy in line with CDC guidelines.

(continued on next page)

Procedure 38-4 ■ Changing IV Solutions and Tubing (continued)

Procedure 38-4B ■ Changing the IV Administration Tubing and Solution

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Prepare the IV solution** and tubing as you would when initiating a new IV. (See Procedure 38-1, Step 2.)
2. **Hang the new administration** set on the IV pole.
3. **Close the roller clamp** on the old administration set.
   Stops the flow of fluid from the old container.
4. **Disconnect the old tubing**
   a. Wearing clean nonsterile gloves, place a sterile swab under the catheter hub.
   The swab absorbs any leakage from the catheter hub when you disconnect the tubing.
   b. Apply pressure to the vein about 3 inches above the insertion site, using the fourth or fifth finger of your nondominant hand. Hold the catheter hub firmly with the thumb and index finger of that hand, but do not apply downward pressure.
   Prevents blood from leaking out of the catheter during the tubing change. Holding the hub firmly keeps the catheter from moving about and traumatizing the vein.
   c. Then carefully remove the device securing the connection between the catheter and tubing. This may be as simple as unscrewing a luer-lock. The connection should not be covered by tape, but if it is, remove it so you can access the connection.
5. **Remove the protective cover** from the distal end of the new administration set.
   Cover keeps the distal end sterile until you are ready to connect it to the IV catheter.
6. **Continue to stabilize the IV** catheter with your nondominant hand while applying pressure over the vein.

7. **Gently disengage the used** tubing from the IV catheter, and place it in a basin or other receptacle. Quickly insert the new tubing into the catheter hub.
   The CDC recommends IV tubing should be changed at 96-hours interval, but at least every 7 days, depending on agency policy and solution. Certain solutions (e.g., blood, blood products, fat emulsions) require more frequent tubing changes. Change it quickly to prevent microorganisms from entering the IV catheter.
8. **Open the roller clamp** on the new administration set, and allow the IV solution to infuse.
   This clears the IV catheter of blood, preventing catheter occlusion.
9. **Program and turn on** the volume-control pump. Or, for a gravity drip, use the roller clamp to adjust the flow to the prescribed rate.
   IV solution is considered a medication and must infuse at the prescribed rate.
10. **Cleanse the IV site** and secure the IV catheter and tubing connection.
   Removes microorganisms and media for growth; helps preserve the integrity of the intact line; and prevents air and microorganisms from entering the line.
11. **Loop and tape tubing** to patient's skin.
   Helps minimize catheter movement, which contributes to phlebitis.
12. **Label tubing and solution** with date, initials, rate, and time tape.
   Alerts staff to when tubing and solution was changed and to when they will need to be changed again to decrease the incidence of infection.
13. **Dispose of used supplies** into appropriate receptacles according to agency policy in line with CDC guidelines.

? What if . . .

- **The drip chamber becomes too full (over half) so that drops cannot be adequately counted?**
  Close the roller clamp, invert the bag or bottle, and squeeze the excess fluid back into the bag/bottle.
- **The tubing will not separate from the catheter connection when you attempt to disconnect it?**
  If the lock does not twist off, gently try using a hemostat ("mosquito" clamp) to twist the lock. Do not lock the hemostat; merely use it lightly as a grip. After the lock is off, if the tubing will not separate, use the hemostat to gently twist the tubing back and forth. If the catheter needs to be stabilized, wear a sterile glove or use a sterile hemostat.

Evaluation

- Assess the IV insertion site for signs of infiltration, inflammation, infection, and phlebitis.
- Evaluate the effectiveness of IV therapy by assessing the patient's hydration status or expected effect of the intravenous medication/solution.
- Monitor the IV rate regularly (usually hourly).

Patient Teaching

- Discuss the importance of notifying staff immediately if the catheter or administration set becomes dislodged; if the insertion site becomes tender, red, or swollen; or if the IV dressing becomes wet.

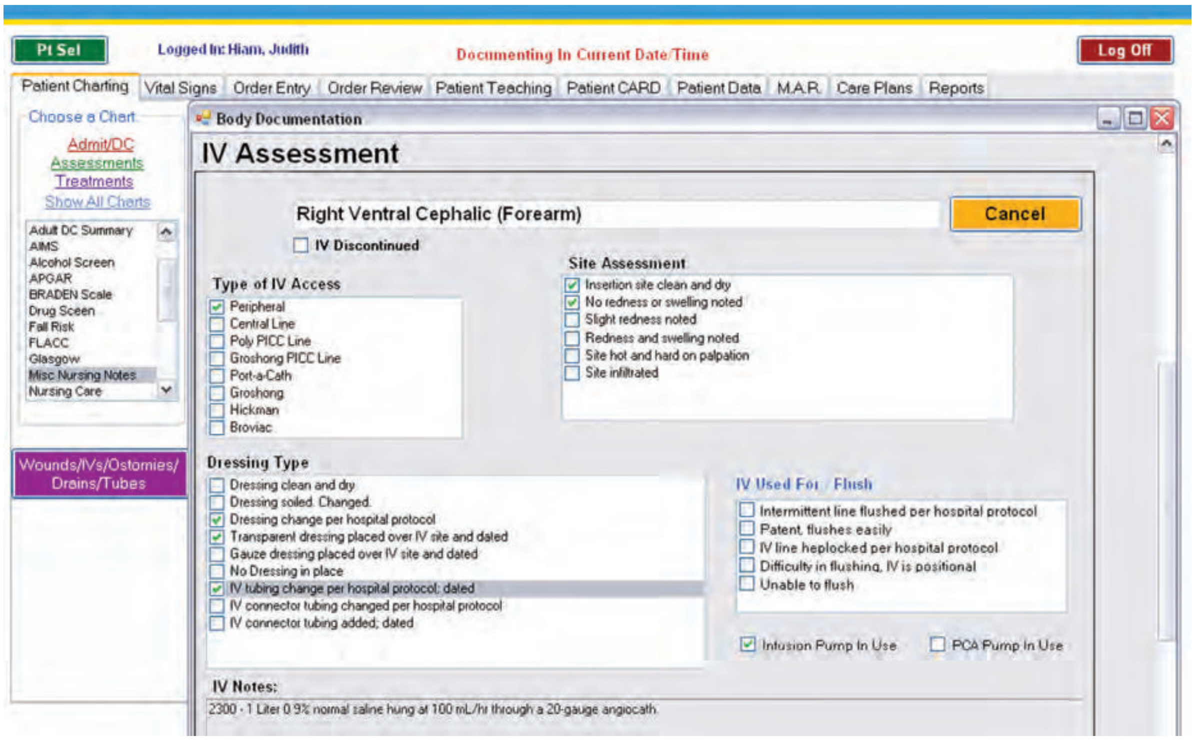
Home Care

- Explain home IV therapy to the client and caregiver; teach them how to identify complications.
- Obtain a return demonstration to ensure the caregiver is able to perform fluid and tubing changes, when necessary.

Documentation

- Fluid and tubing changes are usually documented on a flowsheet.
- Document the date and time the IV fluid and tubing were changed; type of IV fluid and rate of infusion; and the location and condition of the IV catheter insertion site.
- Any complications of IV therapy and the interventions taken.

Sample documentation



Practice Resources

CDC (2011b); INS (2011a).

Procedure 38-5 ■ Changing IV Dressings

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover. For this procedure, also refer to Clinical Insights 23-1 through 23-6 if you need to review information about medical and surgical asepsis.

Equipment

Peripheral IV Dressings

- Clean nonsterile gloves
- Sterile transparent semipermeable dressing or dressing specified by institution
- Antiseptic swabs: alcohol or chlorhexidine (*Note: Use iodine-based products only if the preferred antiseptics cannot be used. Chlorhexidine is not recommended in infants younger than age 2 months.*)
- 1-inch nonallergenic tape or manufactured stabilization device

Central Line Dressings

- Clean nonsterile gloves
- Central line dressing kit. It should include sterile gloves, a mask, a sterile transparent semipermeable dressing, sterile tape, an antimicrobial agent, and a sterile catheter stabilization device. If it does not, obtain them. *Note: It is acceptable to use povidone-iodine followed by alcohol as the antimicrobial if the preferred chlorhexidine is contraindicated.*
- A sponge containing the antimicrobial agent chlorhexidine gluconate may be used as a part of the dressing, as well.
  To reduce the risk for catheter-related infection
- Mask for patient (possibly)

Note: Some institutions do not include this in their procedure and a few patients cannot tolerate wearing a mask.

Delegation

You can delegate the tasks of changing dressings to an LPN who is specially trained in IV therapy. The task should not be delegated to a NAP. Do, however, instruct the NAP to notify you of any problems that occur with dressing such as soiling, blood, leakage, or loosening.

Pre-Procedure Assessments

- Assess the IV catheter for patency before changing the dressing.
  Ensure that the IV is still working properly.
- Assess the IV site for signs of phlebitis, infiltration, infection, or inflammation.
  If any of these complications exist, the current IV will need to be discontinued and a new IV started.
- Assess for allergy to tape.
- Assess IV catheter start date.
  IV catheters are replaced per agency guidelines which are based on the CDC recommendations of changing a peripheral IV site at 96-hour intervals, but at least every 7 days. Changing more often than recommended actually increases the risk of infection.

Procedure 38-5A ■ Peripheral IV Dressings

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure is usually performed at the same time the IV tubing is changed because the old dressing may need to be removed to do that. The CDC recommends that dressing be changed when damp, loosened, or visibly soiled. You should follow your agency's policy.

Procedure Steps

1. **Wearing clean nonsterile gloves,** stabilize the catheter with your nondominant hand, avoiding direct pressure on the catheter/hub junction, and carefully remove and discard the dressing and the catheter stabilization device.
   Remove the dressing gently to avoid dislodging the catheter.
2. **Inspect the insertion site.** Look for erythema and drainage, and note any tenderness. Remove procedure gloves and perform hand hygiene.
   If signs of infection, phlebitis, or infiltration are present, you must remove the IV catheter.
3. **Don a clean pair of nonsterile gloves.**
4. **Cleanse the insertion site**, and then allow the antiseptic to dry on the skin. Do not fan.

If Using Chlorhexidine

Apply using a back-and-forth motion and friction for at least 30 seconds. (Avoid using chlorhexidine in infants younger than age 2 months.)

If Using Alcohol or 2% Tincture of Iodine

Using a circular motion, start at the insertion site and work outward 2 to 3 inches. Do not go back over any cleansed area.
Removes microorganisms from the skin to minimize the risk of their entering the venipuncture site. Allowing the antiseptic to dry increases its effectiveness.

5. **Perform hand hygiene** and change procedure gloves. Apply a new sterile catheter stabilization device and dressing. For illustrations, see Procedure 38-1.

If Using a Transparent Dressing

a. Open the package containing the sterile, semipermeable, transparent dressing. Remove the protective backing from the dressing, making sure not to touch the sterile surface.

b. Cover the insertion site and the hub or winged portion of the catheter with the dressing. Do not cover the junction with the tubing of the administration set.

c. Gently pinch the transparent dressing around the catheter hub to secure the hub. Smooth the remainder of the dressing so that it adheres to the skin.
Pinching the dressing around the hub prevents pressure of the hub on the underlying skin.

If You Must Use a Gauze Dressing

d. Fold a 2 in. × 2 in. sterile gauze dressing in half, cover it with 1-inch tape (about 3 inches long).

e. Place under the tubing/hub junction and press down on the tape.
Raises the hub to prevent pressure on the skin.

f. Place a sterile gauze pad over the insertion site and catheter hub—but not over the catheter/hub junction

g. Secure all edges with tape.

6. **Secure the connection between** the catheter and the tubing, but do not cover the catheter-tubing junction with tape.
Securing the connection helps maintain a closed system and prevents entry of microorganisms. You should not cover the junction with tape because removing the tape may interfere with your ability to disconnect the tubing from the hub quickly, should you need to do so. Removing tape requires much manipulation; the more the catheter is manipulated, the higher the risk for infection.

7. **Secure the IV administration** tubing by looping and taping the tubing to the skin.
Looping the tubing provides slack to prevent the IV catheter from becoming dislodged.

8. **Label the dressing with the date** and time of insertion, catheter size, and the date the dressing was changed and your initials.
Peripheral IV catheters should be replaced as clinically indicated (e.g., phlebitis, infiltration, irritation) to prevent complications. Labeling the dressing with the date and time of insertion helps communicate to other nurses the date of the IV insertion and dressing change.

9. **Discard all supplies** in the appropriate containers according to agency policy in line with CDC guidelines.

? What if . . .

- **The patient is immunocompromised? Or the peripheral midline catheter must be in the same site for an extended time?**

  Use sterile gloves and a mask when changing the dressing and giving site care.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Peripheral IV Dressings.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 38-5B ■ Central Line Dressings

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ *Note:* This procedure focuses on dressing change. Refer to Clinical Insight 38-4 for assessments and maintenance of CVCs.

Procedure Steps

1. **Obtain a sterile central line** dressing kit (or equivalent supplies if there is no kit) and mask for the patient, if one is needed.
Because central lines have direct access to the central circulation, the risk of systemic infection is greater. Therefore, the procedure uses aseptic technique. All supplies must be sterile.

2. **Place the patient** in a semi-Fowler's position, if tolerated. Lower the siderail and adjust the bed to working height.
Semi-Fowler's position and bed adjustments facilitate site cleansing and dressing application and reduce strain on the nurse's back.

3. **Explain the procedure** and ask the patient to turn his head to the opposite side from the insertion site. If he cannot cooperate, place a mask on the patient.
Explanation may reduce anxiety and enhance cooperation; turning helps prevent contamination of the insertion site.

4. **Put on your mask** and clean nonsterile gloves. Carefully remove the old dressing and catheter stabilization device, if present.

5. **Inspect the site** for signs and symptoms of infection and other complications.
If a complication is suspected, notify the person who placed the central line.

(continued on next page)

Procedure 38-5 ■ Changing IV Dressings (continued)

6. **Remove and discard your gloves**, along with the soiled dressing. Wash your hands.

7. **Set up a sterile field** and open the dressing kit.
To prevent contamination of the insertion site and the sterile supplies.

8. **Don the sterile gloves** contained in the kit and arrange sterile supplies as needed.

9. **Scrub the insertion site** and surrounding skin with an antiseptic swab.

If Using Chlorhexidine
Use a back-and-forth motion with friction and scrub for at least 30 seconds.

If Using Povidone-Iodine and Alcohol
The kit should contain three swabs of each. Beginning with a povidone-iodine swab, start at the insertion site and work outward several inches ("dirty to clean"). Repeat with the other two povidone-iodine swabs. Then, using the same method, clean with the three alcohol swabs. With each swab, do not "go back over" an area you have just cleaned with that swab.
To rid the site of any potential infectious microorganisms, work "from clean to contaminated."

10. **Scrub the sutures (if any)**, and the catheter from insertion site to the hub or bifurcation, for at least 15 seconds with an alcohol swab or chlorhexidine/alcohol antiseptic product.

11. **Allow the site to dry**—do not fan.
Allows the antiseptic time to work completely and allows the dressing to stick properly. Povidone-iodine requires 1 minute to air-dry completely; chlorhexidine requires 30 seconds.

12. **Apply a new catheter** stabilization device, if one is used.

13. **Apply the transparent dressing** that comes in the kit.

If You Place Gauze Under the Catheter Hub
You may first place a small piece of folded sterile gauze under the catheter hub.
To reduce pressure on the skin under the hub.

If Chlorhexidine Gluconate Sponge Is Part of the Dressing
Apply the sponge directly over the catheter insertion site, ensuring that the sponge is in full contact with the skin. Then apply the transparent dressing over the sponge.
Reduces the risk for catheter-related infection, especially in units with high infection rates or in high-risk patients (CDC, 2011a; Timsit, Schwebel, Boudma, et al., 2009).

14. **Remove the drape**, if you used one.

15. **Loop the catheter gently** and secure it with tape to the skin. Avoid securing it to the dressing. Or, depending on type of CVC, place a piece of clear tape across the ends of the catheter lumens, near but not on the hubs.
Ensures that accidental tugging on the catheter does not dislodge the catheter. Do not cover the hubs, as you may need to access them.

16. **Label the dressing** with the date changed, time, and your initials.
Alerts staff to when the next dressing change will be due.

17. **Place the patient in** a comfortable position, raise the siderail, and be sure the call light is accessible.

18. **Remove your mask and gloves** and the patient's mask.

19. **Dispose of supplies** into the appropriate receptacles according to agency policy in line with CDC guidelines.

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Central Line Dressings.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*

Procedure 38-5C ■ PICC Line Dressings

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Obtain a sterile PICC** (central) line dressing kit (or equivalent supplies if there is no kit) and mask for the patient, if one is needed.
Because central lines have direct access to the central circulation, the risk of systemic infection is greater. Therefore, this procedure uses aseptic technique, even though the insertion site is peripheral. All supplies must be sterile.

2. **Place the patient in a** semi-Fowler's position, if tolerated. Lower the siderail and adjust the bed to working height.
Semi-Fowler's position and bed adjustments facilitate site cleansing and dressing application and reduce strain on the nurse's back.

3. **Explain the procedure** and ask the patient to turn his head to the opposite side from the insertion site. If the patient cannot cooperate, place a mask on him, if consistent with agency policy.
Explanation may reduce anxiety and enhance cooperation; turning helps prevent contamination of the insertion site from nasal and oral airborne secretions.

4. **Inspect the site** for signs and symptoms of infection and catheter migration.
5. **Put on your mask and** clean nonsterile gloves and carefully remove the old dressing by pulling towards the insertion site and catheter stabilization device, if present. Discard your gloves with the dressing.
   The mask helps prevent contamination of the insertion site from the nurse's nasal and oral airborne secretions. Pulling toward the insertion site minimizes the possibility of dislodging the catheter.
6. **Perform hand hygiene**, open the kit, and remove and don the sterile gloves.
7. **If the kit contains a sterile drape,** unfold it and establish your sterile field**.** Transfer items from kit to your sterile field.
   Ensures that strict sterile technique is maintained.
8. **Use a sterile tape measure** to compare the external length of the PICC with the baseline insertion length (if consistent with agency's policy).
   Detects catheter migration, which may indicate that the PICC line is not in the correct location.
9. **Scrub the insertion site** and surrounding skin with an antiseptic solution. Ensure that blood or encrustations are removed from the site and catheter. (Refer to Procedure 38-5B: Central Line Dressings, Steps 9 and 10).
   Minimizes the proliferation of microorganisms.
10. **Allow the site to air-dry.** If you are using a chlorhexadine gluconate sponge as part of the dressing, apply it directly over the catheter insertion site, ensuring that it is in direct contact with the skin.
11. **Apply a commercial stabilization** device, if applicable.
12. **Apply a transparent dressing** over catheter site.

13. **Label the dressing** with the date, time, and your initials.
    Used to identify the next scheduled dressing change.
14. **Loop and anchor the catheter, as needed;** secure it with tape.
    Reduces the risk of accidental dislodgement.
15. **Place the patient** in a comfortable position, raise the siderails, and place the call light so it is accessible to patient.
16. **Dispose of used supplies** into the appropriate receptacles according to agency policy and consistent with CDC guidelines.

Evaluation

- Evaluate the IV insertion site and surrounding tissue for signs of infiltration, inflammation, infection, and phlebitis.
- Monitor the dressing for dampness, blood, soiling, or loosening.
  If these occur, the dressing must be changed.

Patient Teaching

- Explain the importance of notifying staff if the IV dressing becomes soiled, dampened, or loosened.
- Remind the patient to notify staff immediately for bleeding, pain, or swelling around the catheter or dressing area or discomfort in the hand, arm, or shoulder on the same side as the catheter.

Home Care

- Explain home IV therapy to the client and caregiver; teach them how to identify complications.
- Obtain a return demonstration by the client or caregiver to ensure competent performance of fluid, tubing, and dressing changes when necessary.

(continued on next page)

Procedure 38-5 ■ Changing IV Dressings (continued)

Documentation

- Chart the date and time the dressing was changed. Document the location and condition of the IV catheter insertion site.
- Document any complications of IV therapy and the interventions taken.
- Document the dressing change on your IV record. Often, IV care is documented on a flowsheet.

Sample documentation

mm/dd/yyyy 2300 *New transparent semipermeable dressing applied over PICC insertion site in left forearm. No redness, tenderness, swelling, or exudates at the site.*
———————— Mary Ramirez, RNC

Practice Resources

CDC (2011a); Hadaway, L. (2010); INS (2011a); Institute for Healthcare Improvement (IHI) (2012); The Joint Commission (2012); National Guideline Clearinghouse (NGC) (2011); Pronovost, P., Goeschel, A., Colantuoi, E., et al. (2010); Timsit, J-F., Schwebel, C., Boudma, L., et al. (2009).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos,* **PICC Line Dressings.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions and Suggested Responses** on Davis*Plus.*

Procedure 38-6 ■ Converting a Primary Line to a Peripheral IV Lock

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Clean nonsterile gloves
- Peripheral intermittent IV lock adapter
- Two syringes containing saline solution (one syringe with dilute heparin solution, if required by agency policy)
- Linen-saver pad
- Transparent semipermeable dressing
- Alcohol or chlorhexidine/alcohol or other antiseptic swab

Delegation

You can delegate the task of converting a primary IV line to an intermittent lock device to an LPN who is specially trained in IV therapy. The task should not be delegated to a NAP. However, you should instruct the NAP to notify you of any problems with the intermittent lock device, such as dislodging of the catheter or client complaints of pain, swelling, or redness at the insertion site.

Pre-Procedure Assessment

- Assess the patient's readiness to have the IV fluid discontinued (e.g., tolerating oral fluids, adequate urine output, and laboratory values within normal limits).
  If the patient's condition indicates that he still requires IV fluids, notify the primary care provider and do not discontinue the IV line.
- Assess for allergy to tape.
- Assess the IV site for signs of phlebitis, infiltration, extravasation, or infection.
  If complications are present or the IV has been in place longer than 96 hours or at least 7 days, remove the IV catheter instead of converting it to an intermittent lock.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ Maintain sterility of supplies and equipment (e.g., do not touch catheter opening or ends of the IV lock; keep flush syringe connector sterile).

Procedure Steps

1. **Help the client assume** a comfortable position that provides access to the IV site.
   Promotes cooperation and facilitates your ability to perform the procedure.
2. **Lower siderails, raise the bed** to working height, and place linen-saver pad under extremity with the IV.
   Protects linens from blood and fluid that might leak from the vessel during catheter removal and ensures good body mechanics.
3. **Don clean nonsterile gloves**. Remove the IV lock from the package and flush the adapter with the first syringe of saline or dilute heparin, according to agency policy. Place the lock back loosely inside the sterile

package, keeping it sterile. **Continue with Step 5.**
Removes air from the lock.

Procedure Variation for Primary Tubing Set-Up With Extension Tubing With a Lock
Merely discontinue the IV solution and disconnect the primary tubing from the extension tubing with lock. Then, flush extension tubing per agency policy and **skip to Step 13.**

4. **Carefully remove the IV dressing** and the tape that is securing the tubing.
Provides access to the IV catheter.

5. **Close the roller clamp** on the administration set.
Prevents loss of IV fluid during the procedure.

6. **With the side of your** nondominant hand, apply pressure over the vein just above the insertion site but not directly on the catheter–hub junction. At the same time, stabilize the catheter hub with your thumb and forefinger.
Applying pressure over the vein stops blood from flowing from the catheter as you change the administration tubing.

7. **Gently disengage the used** tubing from the IV catheter. If the tubing does not separate from the catheter, see the What If . . . section at the end of Step 13.

8. **Quickly insert the lock adapter** into the IV catheter and turn it to lock it in place.
Insert the adapter quickly to prevent bleeding from the IV catheter.

9. **Scrub the injection port** of the adapter with an antiseptic pad.
Cleaning the port with antiseptic helps prevent contamination by microorganisms when the adapter is flushed.

10. **Insert the second syringe** containing saline or dilute heparin into the injection port of the adapter. Flush the catheter using the method recommended in your agency (e.g., push-stop-push or a slow, steady push).
Some experts recommend a turbulence (push-stop-push method) on the theory that turbulence ensures patency of the IV catheter by clearing the catheter and helping prevent reflux of blood back into the catheter. Others believe this method has undesired effects and recommend, instead, a steady, slow push. There is no evidence to support the turbulence theory (INS, 2011a). In the meantime, follow agency policy regarding the flushing technique.

11. **Using aseptic technique**, cover the insertion site and catheter hub with a sterile transparent semipermeable dressing. Do not cover the junction of the catheter hub and the IV lock. See Procedure 38-5A for review of dressings.
Secures the IV catheter and prevents contamination of the site.

12. **Label the dressing** with the date changed and your initials.

13. **Discard used supplies** into appropriate receptacles according to agency policy in line with CDC guidelines.
Discarding used equipment properly keeps the healthcare environment safe.

? What if . . .

- **At Step 7, the tubing will not separate from the catheter?**

First, if it is a luer-lock connection, be sure you have twisted the luer-lock "open." If so, place a hemostat ("mosquito" clamp) on the IV tubing and gently twist back and forth to loosen the connection. Then if the IV tubing still does not come loose, use the hemostat to gently twist the lock back and forth to loosen the connection. Do not lock the hemostat; merely use it lightly as a grip.
Use of hemostat may help loosen tubing from the catheter, but placement is critical so that the IV catheter and connector are not damaged.

- **At Step 7, the IV catheter becomes dislodged while trying to disconnect the tubing?**

If you can see as much as three-fourths of the catheter emerging from the site, you must remove it and start a new IV at a different site.
Trying to re-advance the catheter might cause it to pierce through the vein as well as increase the risk of infection from reinserting a catheter that is no longer sterile. It also causes tissue trauma and increases the risk of phlebitis from catheter manipulation.

(continued on next page)

Procedure 38-6 ■ Converting a Primary Line to a Peripheral IV Lock (continued)

Evaluation

- Assess the patency of the catheter before each use according to institutional policy. Patency check and flushing are usually done every 8 to 24 hours.
- Evaluate the patient's tolerance to intermittent IV therapy.
- Inspect the insertion site for signs of complications.

Patient Teaching

Explain the importance of notifying staff if the IV site becomes red, painful, or swollen; or if the dressing becomes soiled, damp, or loosened (indicating that the catheter has become dislodged or the connection is loose). Include the family in the teaching, as the patient may not be able to assess his own IV therapy.

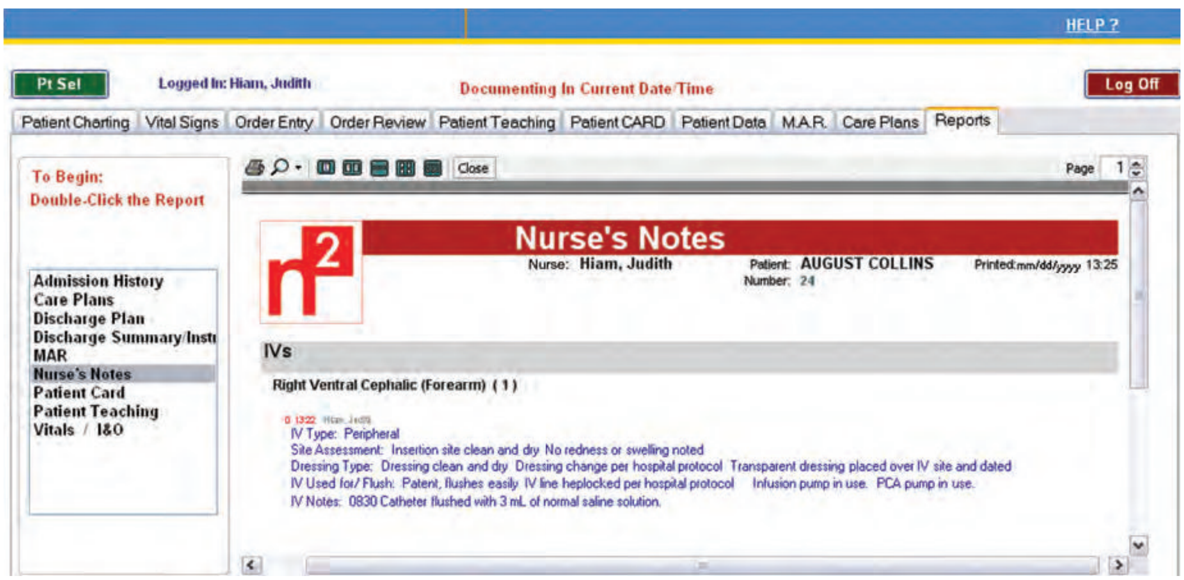
Home Care

- Explain home use of the intermittent lock to the patient and caregiver. Teach them how to flush the catheter before and after administering prescribed medications.
- Provide the patient and caregiver with the name and phone numbers of people to contact in case problems arise with the catheter or insertion site.

Documentation

- Chart the date and time the IV line was converted to an intermittent lock device.
- Note the size and location of the catheter, as well as the type and amount of flush solution used.
- Record on the I&O record the amount of IV fluid infused.
- Document the condition of the IV site and any complications noted.
- Often, IV care is documented on a flowsheet or the electronic patient record.

Sample documentation



Practice Resources

CDC (2011); Hadaway, L. (2010); INS (2011a).

Procedure 38-7 ■ Discontinuing a Peripheral IV

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Clean nonsterile gloves
- Sterile 2 in. × 2 in. gauze dressings
- 1-in. tape or transparent semipermeable dressing
- Linen-saver pad

Delegation

You can delegate the task of discontinuing an IV to an LPN who is specially trained in IV therapy. The task should not be delegated to a NAP. However, you should instruct the NAP to notify you of any bleeding from the insertion site.

Pre-Procedure Assessment

- Assess the patient's readiness to have the IV fluid discontinued and verify the order. For example, determine whether he is tolerating oral fluids and has adequate urine output and whether laboratory values are within normal limits.
  If the patient's condition indicates that he still requires IV fluids, notify the physician and do not discontinue the IV line.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Assist the client to a** comfortable position and raise the bed to working height.
   Helps ensure patient cooperation with the procedure; supports good body mechanics for the nurse.

2. **Place a linen-saver pad** under the extremity with the IV.
   Protects linens from blood and fluid that might leak from the vein during catheter removal

3. **Don clean nonsterile gloves**, and close the roller clamp on the administration set.
   Closing the roller prevents IV fluid from spilling onto the bed or client during catheter removal. Procedure gloves protect you from body fluid exposure.

4. **Carefully remove the IV dressing**, catheter stabilization device, and the tape that is securing the tubing.
   Removing tape and dressings can be painful especially if over hair or sensitive or thin skin.

If the IV Is Running Through an Extension Tubing or a Saline Lock

Disconnect the administration set tubing and close the slide clamp on the extension tubing.

5. **Scrub the catheter–skin junction** with an alcohol prep pad or chlorhexidine/alcohol antiseptic product for at least 15 seconds.
   Removes microorganisms from the skin entry site.

6. **Apply a sterile 2 in. × 2 in. gauze** pad above the IV insertion site and gently remove the catheter, directing it straight along the vein. Do not press down on the gauze pad while removing the catheter.
   Directing the catheter along the vein prevents vein injury while you are removing the catheter.

7. **Immediately apply firm pressure** with the gauze pad over the insertion site. Hold pressure for 1 to 3 minutes; hold longer if bleeding persists.
   This typically stops bleeding by hastening clot formation.

8. **Remove the soiled 2 in. × 2 in.** gauze pad, and replace it with a sterile 2 in. × 2 in. gauze pad folded over to form a pressure dressing. Secure it with 1-inch tape or a transparent semipermeable dressing.
   Protects the site from contamination.

9. **Return the bed to a low position.** Discard all supplies in the appropriate receptacles according to agency policy in line with CDC guidelines.

(continued on next page)

Procedure 38-7 ■ Discontinuing a Peripheral IV (continued)

Evaluation

- Assess the integrity of the removed catheter; compare the length with the original insertion length to ensure the entire catheter is removed. If a catheter defect is noted, report to the manufacturer and regulatory agencies and complete an incident report according to agency policy.
- Evaluate the patient's response to oral fluids after IV therapy is discontinued.
- Monitor for changes in the patient's condition to assess whether IV therapy should be re-established.

Patient Teaching

- Instruct the client and family to notify staff if bleeding or discomfort occurs at the insertion site.
- Teach the importance of drinking adequate amounts of fluid, within the prescribed treatment plan, to prevent dehydration. (Some patients have fluid restrictions.)

Documentation

- Chart the date and time that IV therapy was discontinued.
- Note the condition of the site, including the presence of any complications. If complications are present, document your interventions, including physician notification.
- Often you will record this procedure on a flow sheet or in the electronic patient record.

Sample documentation

mm/dd/yyyy 2100 RA#2, 22-gauge catheter discontinued. Site without redness, swelling, tenderness, or exudates. Pressure applied to site for 3 minutes. Bleeding stopped and sterile 2 × 2 gauze dressing applied. Informed patient to notify staff if bleeding or discomfort occurs.
S. Horowitz, RN

Practice Resources

CDC (2011); INS (2011a).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Discontinuing a Peripheral IV.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 38-8 ■ Administering a Blood Transfusion

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Clean nonsterile gloves
- Blood product
- Normal saline IV solution, 250 mL
  Key Point: ***Normal saline solution is the only solution that is compatible with blood products; other IV solutions cause hemolysis of blood cells.***
- Blood administration set (with a 200-micrometer filter and luer-lock connection). If there is no filter on the tubing, you must attach one.
- IV pole
- Watch with a second hand or digital seconds
- Thermometer
- Blood pressure cuff with sphygmomanometer
- Stethoscope

Delegation

Do not delegate this procedure to the LPN or NAP, because blood product administration requires advanced assessment and critical-thinking skills. The LPN and NAP can assist by monitoring vital signs. Instruct both about the complications associated with blood product administration, and instruct them to inform you if any occur.

Pre-Procedure Assessment

- Confirm the patient's need for blood products by assessing vital signs, urine output, and laboratory studies.
  Blood products may cause life-threatening complications; therefore, they should be administered only when needed.
- Check the patient's history for previous blood transfusions and reactions and verify her blood type.
  If the patient has a history of a blood transfusion reaction, precautions must be taken before she receives additional transfusions. For example, she may need premedication with acetaminophen, a corticosteroid, and diphenhydramine; specially treated blood products; and the use of a specialized administration set with greater filtering capabilities.
- Assess patency of the existing IV catheter, and make sure that it is the proper size for blood product administration.
  Nurses often use a 20-gauge catheter for blood administration. However, for routine transfusion, a 22-gauge or even a 24-gauge catheter can be used. You would need an 18- or 20-gauge catheter when large amounts of blood must be transfused rapidly. The primary consideration should be the size of the patient's veins and not an arbitrary catheter size.
- Assess for allergy to tape.

Procedure 38-8A ■ Administering Blood and Blood Products

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Verify that informed consent** has been obtained.
Informed consent is required for blood product administration, as for any invasive or risk-bearing procedure.

2. **Verify the medical prescription,** noting the indication, rate of infusion, and any medications. If there are any pretransfusion medications, administer them as prescribed.
Helps prevent administration errors.

3. **Obtain a blood administration set** and 250 mL of IV normal saline solution.

4. **Obtain infusion pump**, if possible, and blood warmer, if necessary
Having all supplies and equipment on hand minimizes delays in starting the transfusion.

5. **Obtain the blood product** from the blood bank, according to your institution's policy. Wear clean nonsterile gloves whenever handling blood products.
Some blood banks require a pickup slip that verifies the presence of a functioning IV catheter, signed informed consent, and a prescription, because blood must be discarded after it has been out of refrigeration for 30 minutes.

6. **Verify that the blood product** matches the prescription. Inspect the blood. If you note any of the following abnormalities, return the blood to the blood bank and obtain a new bag:
   a. Pink plasma indicates hemolysis.
   b. The red cells should be red, not purple or black.
   c. There should be no large clots visible.
   d. There should be no leakage.

7. **Verify the patient and blood** product identification with another qualified staff member (as deemed by your institution).
Only one of the staff members is required by The Joint Commission to be qualified to administer blood products; however, agency policies may specify those requirements.
   a. Use two patient coidentifiers (e.g., ask the patient to tell you her full name and date of birth) and compare it with the name and date of birth located on the blood bank form and patient ID band.
   Allowing the patient to confirm her identity and comparing the information against the blood bank form is a safety measure to ensure that the correct patient is receiving the correct blood product.
   b. Compare the patient name and hospital identification number on the patient's identification bracelet with the patient name and hospital identification number on the blood bank form attached to the blood product.
   Verifies that the correct patient is receiving the correct blood product.
   c. Compare the unit identification number located on the blood bank form with the identification number printed on the blood product container.
   Verifies that the blood bank has dispensed the correct blood product.

   d. Compare the patient's blood type listed on the blood bank form with the blood type listed on the blood product container.
   Verifies that the blood type of the product matches the patient's blood type.
   e. If all verifications are in agreement, both staff members should sign the blood bank form attached to the blood product container.

Contact the blood bank immediately if any discrepancies occur during the identification process. If there are any discrepancies, do not administer the blood product.

   Signing the blood bank form confirms that the blood product was identified and verified by two qualified staff members.
   f. Document on the blood bank form the date and time that the transfusion was begun.
   Blood cannot be infused past the expiration time; documenting the start time alerts the nurse of the expiration time.
   g. Make sure that the blood bank form remains attached to the blood product container until administration is complete.
   Ensures product identity should a transfu sion reaction occur.

8. **Remove the blood** administration set from the package, and label the tubing with the date and time. Then, close all clamps on the administration set.
Labeling the administration set with the date and time informs the nursing staff when the administration set should be changed.

9. **Remove the protective covers** from the normal saline solution container port and from one of the spikes located on the "Y" of the blood product administration set. Place the spike into the port of the solution container.

10. **Hang the normal saline solution** container on the IV pole.

11. **Compress the drip chamber** of the saline administration set, and allow it to fill halfway.
Prevents air from entering the tubing with the solution.

12. **Open the roller clamp** and prime the administration set tubing with normal saline.
Removes air from the tubing.

(continued on next page)

Procedure 38-8 ■ Administering a Blood Transfusion (continued)

13. Close the roller clamp. Inspect the tubing for air. If air bubbles are in the tubing, flick the tubing with a fingertip to mobilize the bubbles up into the drip chamber.
Air bubbles in the administration tubing can cause an air embolus.

14. Gently invert the blood product container several times, but do not shake the bag.
Mixes the blood product with the preservatives that are added to the container without causing trauma (lysis) to the cells.

15. Remove the protective covers from the blood spike on the blood tubing and the blood product port. Carefully spike the blood product container through the port.
Prevents inadvertent puncturing of the container.

16. Hang the blood product bag on the IV pole, prime the short blood tubing by allowing the saline to backflow into the blood bag drip chamber. Then thread the line through the infusion pump.
Enables the blood to flow by gravity.

17. Obtain and record the patient's vital signs, including temperature, pulse, and blood pressure, before beginning the transfusion.
Establishes a baseline to help monitor for transfusion reactions.

18. Using aseptic technique, attach the distal end of the administration set to the IV catheter.
Prevents contamination of the IV catheter and administration set.

19. Slowly open the roller clamp closest to the blood product.
Allows the blood product to slowly fill that side of the "Y" of the administration set tubing.

20. Set the infusion rate. Start the rate slowly until 50 mL have infused; if there is no reaction, set it to prescribed rate.
A unit of blood cannot hang for more than 4 hours (some guidelines say 6 hours); otherwise, bacterial growth may occur.

For a Volume-Control Infusion Pump
Program the rate. Push "Start." Start the rate slowly until 50 mL have infused; if there is no reaction, set it to the prescribed rate.

For Gravity Flow
Using the roller clamp, adjust the drip rate. Keep in mind that blood administration sets have a drip factor of 10 gtts/mL. *Note: When using a 24-gauge needle, you will usually (but not always) use gravity infusion instead of a pump.*
Forcing red blood cells through a smaller size catheter could result in some cell damage. Allowing the blood to flow by gravity allows time for the cells to change shape as they naturally do when flowing through small capillaries. However, only pumps that have been approved for blood transfusions should be used, because they prevent hemolysis (Galvey, Ibey, McConnell, et al., 2011).

21. Remain with the patient during the first 5 minutes, and then obtain vital signs.
Most severe blood transfusion reactions occur during the transfusion of the initial 50 mL of blood.

22. Ensure that the patient's call device is readily available, and have her alert you immediately of any signs or symptoms of a transfusion reaction, such as back pain, chills, itching, or shortness of breath.
If the patient alerts you immediately, you should be able to stop the transfusion in time to prevent serious complications.

23. Obtain vital signs again in 15 minutes (follow agency procedures), then again in 30 minutes, and then hourly while the transfusion infuses. Blood and blood product infusions must be completed within 4 to 6 hours.
Frequent monitoring alerts you to detect early signs of transfusion reaction or fluid overload.

24. After the unit has infused, close the roller clamp to the blood product container, and open the roller clamp to the normal saline solution to flush the administration set with normal saline solution.
Flushing the tubing with normal saline solution clears the tubing of any blood and avoids wasting any of the blood product.

25. Close the roller clamp to the normal saline, and then disconnect the blood administration set from the IV catheter, if an additional unit of blood has not been prescribed.

26. If another unit of blood is required, you may hang the second unit with the same administration set. However, administration sets and add-on filters need to be changed every 4 hours.
The same administration set can be used for two units of blood or per agency policy.

27. Discard the empty blood container and administration set in a biohazard receptacle, according to your institution's policy.
Promotes a safer healthcare environment.

? What if . . .

■ **Two individuals are not available to verify that the blood and the patient are a match, and the blood must be hung now?**

In this instance, if it is available, an automated identification technology (e.g., bar coding) may be used.

Procedure 38-8B ■ Managing a Transfusion Reaction

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **If signs or symptoms of a** transfusion reaction occur, stop the transfusion immediately. Do not flush the tubing.

   Flushing the tubing causes the patient to receive the blood that remains in the tubing.

2. **Disconnect the administration** set from the IV catheter. Call for help. Obtain vital signs, and auscultate heart and breath sounds.
   Severe transfusion reactions may cause respiratory distress and shock; early recognition and treatment improve patient outcomes.

3. **Maintain patency of the IV** catheter by hanging a new infusion of normal saline solution, using new tubing.
   Maintaining a patent IV catheter with normal saline solution provides IV access in which emergency medication can be administered if necessary.

4. **Notify the primary provider** as soon as you have stopped the blood, assessed the patient, and hung the new normal saline solution.

5. **Place the administration set** and blood product container, with the blood bank form attached, inside a biohazard bag. Send the bag to the blood bank immediately.
   The remainder of the blood must be sent to the blood bank, where it can be analyzed to help determine the cause of the reaction.

6. **Obtain blood** (in the extremity opposite the transfusion site) and urine specimens according to your institution's policy.
   Blood banks typically require (1) a specimen for a type and crossmatch to compare with the pretransfusion type and crossmatch, (2) a specimen for free hemoglobin, and (3) a specimen for serum bilirubin level. A urine sample should also be sent to check for hemoglobinuria, a sign of acute hemolytic reactions.

7. **Continue to monitor vital signs** frequently, at least every 15 minutes.
   To quickly detect worsening of the patient's condition.

8. **Administer medications**, as prescribed.
   Medications will vary depending on the type of transfusion reaction.

? What if . . .

- **At Step 3, you do not have a new bag of normal saline to hang?**

  Clamp the normal saline line until you can obtain a new bag of normal saline, then disconnect the old normal saline. Do this as quickly as possible.
  Preserves the patency of the IV catheter.

Evaluation

- Evaluate the patient's response to the blood transfusion by checking for changes in blood pressure and oxygenation, improvement in color, or for signs of fluid overload.
- Monitor for signs and symptoms of transfusion reaction.
- Assess the IV insertion site for signs of infiltration, phlebitis, infection, or inflammation.
- Monitor laboratory studies, such as complete blood count, to help evaluate the effectiveness of therapy and/or transfusion reaction.

Patient Teaching

- Explain the signs and symptoms of transfusion reactions, and tell the client and family to notify staff immediately should they occur.
- Warn the client or family to notify staff immediately if tenderness, redness, or swelling occurs at the IV catheter insertion site.
- Explain the importance of notifying staff immediately if the administration set becomes disconnected from the IV catheter or the IV catheter becomes dislodged.

Documentation

- Chart the date, time, and reason the transfusion was started.
- Document transfusion vital signs according to institution policy (many institutions have a special form for transfusion vital signs).
- Record the amount of blood transfused on the I&O record.
- Chart any complications and the interventions taken.

Sample documentation

Mm/dd/yyyy 0600 1 unit (250 mL) PRBCs was hung at 0300 and infused through 20-gauge catheter in LA, for Hbg 8.3 mg/dL. Pretransfusion vital signs: T 98.9°F, BP 100/68 mm Hg, HR 114 beats/min, and RR, 22 breaths/min. See frequent vital sign sheet for other transfusion vital signs. Breath sounds remained clear throughout the transfusion. No evidence of reaction. Post-transfusion lab due at 1200. ——— L. Gilmore, RN

Procedure 38-8 ■ Administering a Blood Transfusion (continued)

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Administering Blood and Blood Products.**

For questions and suggested responses,

Go to Chapter 38, **Thinking About the Procedure Questions** and **Suggested Responses** on Davis*Plus*.

Procedure 38-9 ■ Assisting With Percutaneous Central Venous Catheter Placement

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Sterile gloves (two or three pairs)
- Masks, hats, barrier gowns
- 10-mL vials of normal saline (three or four)
- Syringes with 1-in. needle (two or three)
- 25-gauge ⅝-in. and 18-gauge 1½-in. needles (two or three of each)
- Central venous catheter (CVC) kit containing: an introducer, antiseptic solution/swabs, sterile drapes, 10-mL syringe, 1% or 2% Xylocaine without epinephrine, suture, sterile scissors and needle holder, CVC kit (single- or multilumen)
- Injection caps
- Alcohol wipes

Delegation

Do not delegate this procedure because complex assessment and support skills are needed. The nurse must be alert to changes in the patient's condition and signs of developing complications. CVC placement at the bedside is associated with pneumothorax, hemothorax, cardiac tamponade, and air emboli.

Pre-Procedure Assessments

- Obtain baseline vital signs.
- Verify that informed consent has been given.
- Assess for allergy to tape.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Explain the procedure** to the patient.
To relieve anxiety and increase the patient's ability to cooperate with the procedure.

2. **Verify informed consent** and obtain vital signs.

3. **Gather supplies and perform** meticulous hand hygiene.
Promotes efficiency; removes contaminants to help prevent infection.

4. **Set up the sterile field** and add supplies. Position the table so it is easily accessible by the physician or advanced practice nurse (APN) during the procedure.
Promotes efficiency and makes the procedure faster and therefore less burdensome for the patient.

5. **Position the patient** to facilitate the procedure, usually in the Trendelenburg position with a rolled towel between the shoulders.
To prevent air embolism and dilate neck veins.

6. **Offer mask, gown, and sterile gloves** (and possibly hat, depending on agency policy) to the physician or APN after she performs hand hygiene.
Maximum barrier precautions are required for central line placement.

7. **Don mask and then sterile gloves.**
To prevent contamination of sterile areas and of the insertion site as you cleanse it. Don mask first to keep gloves sterile.

8. **Prep the marked site** with 2% chlorhexidine gluconate in 70% alcohol applicators, using a friction scrub.
   a. Use a back-and-forth motion to scrub an area at least 20 to 25 cm (8 to 10 in.) in diameter. Do not go back over an area with the same applicator.
   b. Repeat with three applicators. Total scrub should take at least 30 seconds (2 minutes for a moist site such as the femoral vein).
   c. Allow site to air-dry completely (about 2 minutes). Never wipe or blot dry.
   Insertion kits and agency policies may vary. Follow agency policy. If it does not conform to evidence-based guidelines, work for policy change.

9. **Drape the insertion site** with a large sterile drape, exposing only the prepared skin area. Use other large drapes to cover the patient from head to toe. If your agency does not have a policy that the patient wear a mask, have the patient turn his head in the opposite direction of insertion site.
Creates a sterile field and decreases the chance of contamination by the patient's exhalations. Turning the head to the opposite side also helps to make it easier to advance the catheter when it passes through the subclavian site.

10. **Observe while the physician** or APN performs the following steps:
    a. Anesthetizes the area with lidocaine.
    b. Primes the central venous catheter with saline.
    c. Performs venipuncture with the insertion needle (in the internal jugular or subclavian site). The femoral site may be used in emergencies, but it is associated with a higher rate of complications than other sites.
    d. Attaches a syringe to the needle and aspirates for blood.
    To ensure the needle is in the vein.
    e. After obtaining blood return, removes syringe from the needle and inserts a guidewire through the needle.
    The guidewire guides the flexible catheter into the vein.
    f. Aspirates all air out of the catheter lumens and then flushes them with normal saline.
    To reduce the risk of air embolism.
    g. Places injection caps on each lumen.
    To prevent blood loss and maintain sterility of the lumens
    h. Sutures the catheter in place.
    To minimize movement and prevent catheter migration (in or out).
11. **Apply sterile transparent dressing** over the site after the physician or APN is finished.
    Minimizes contamination of the site. The most common route of infection is via migration of skin organisms at the insertion site into the cutaneous catheter tract with colonization of the catheter tip. Transparent dressing allows for observation of the site without removing the dressing and manipulating the catheter.
12. **If there are clamps** on the lumens, close them.
13. **Place tape over the lumens** near the ends, but not on the injection caps.
    To minimize movement of the catheter that increases the risk of dislodgement.
14. **Remove sterile drape** and assist the patient to a comfortable position.
15. **Dispose of used supplies** and equipment in the appropriate receptacles according to agency policy in line with CDC guidelines.
16. **Remove and dispose of mask** and gloves. Perform hand hygiene.
    Observes standard precaution guidelines.

Guidelines

- The patient and all staff in the room should wear a mask.
- A health professional who has received appropriate education (e.g., a nurse) should observe the CVC insertion to ensure that aseptic technique is maintained.
- This person should stop the procedure if aseptic technique errors are made.
- A central line checklist should be used during the procedure. You may be responsible for auditing the procedure and completing the checklist.

? What if . . .

- **In Step 9, a large sterile drape is not available?**

  Use two small drapes to cover the patient from head to toe.
  Evidence-based guidelines advise maximal barrier precautions for insertion of CVCs.

Evaluation

- Obtain vital signs.
- Auscultate the lungs and assess for respiratory distress, sharp chest pain, and coughing. Monitor for 24 hours for these signs.
  To detect pneumothorax or cardiac tamponade.
- Obtain a chest x-ray.
  To verify correct location of catheter tip in the distal third of the superior vena cava, as well as absence of thorax and cardiac puncture.
- Assess the patient daily to determine continuing need for the CVC.
  Risk of infection is closely related to the length of time the CVC is in place.
- For further evaluation and follow-up, refer to Clinical Insight 38-4: Caring for Patients With a Central Venous Access Device (CVAD): CVC and PICC, and Procedure 38-5B: Central Line Dressings.

Documentation

- Date and time of catheter insertion
- Catheter type and size
- Site location
- Assessments and interventions performed at insertion and immediately after
- Patient's tolerance of procedure (subjective and objective data)
- X-ray verification of catheter placement

Practice Resources

CDC (2011); Dumont, C., & Nesselrodt, D. (2012); INH (2011); Institute for Healthcare Improvement (IHI, 2012); Pronovost, P., Goeschel, C., Colantuoni, E., et al. (2010); Rhoads, J., & Meeker, B. (2008).

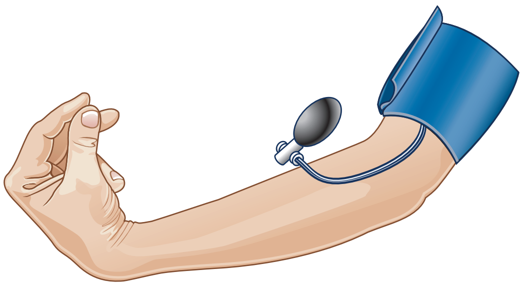
CLINICAL INSIGHTS

Clinical Insight 38-1 ➤ Assessing for Trousseau's and Chvostek's Signs

Positive Trousseau's and Chvostek's signs are signs of hypocalcemia. To check for these signs, follow these instructions.

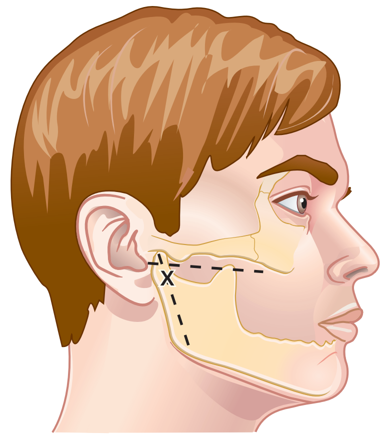
Trousseau's Sign

Inflate a blood pressure cuff above systolic pressure. Flexion of the wrist and hand constitutes a positive sign.



Chvostek's Sign

Tap the face in front of the ear and below the zygomatic bone (cheek bone). Facial twitching constitutes a positive sign.



Clinical Insight 38-2 ➤ Guidelines for Measuring Intake and Output (I&O)

General Guidelines

Assessing

- Identify factors that can affect the patient's fluid intake or output (e.g., surgery, medical condition, or medications such as diuretics).
- Enlist the patient's help in keeping track of I&O if she is able.
- If you delegate the task of recording intake and output:
  - Be sure the assistive person understands its importance and knows how to perform the procedure correctly.
  - Be certain to evaluate the totals and the fluid sources. A patient or NAP can collect the data, but an RN must make the assessments.
- For accuracy, use a graduated container and hold it at eye level when measuring fluids.

Recording

- You will usually record measurements on a bedside I&O form and transfer the 8-hr total to a graphic sheet or the 24-hr I&O on the patient's record. You may sometimes need hourly measurements.
- Document your findings in milliliters (mL). Describe any fluid restrictions and the patient's compliance with them.

Measuring Intake

It is most accurate to premeasure fluids before they are consumed. However, if that is not possible, you can use the following estimates:

Equivalents

1 oz = 30 mL
1 teaspoon = 5 mL
1 tablespoon = 15 mL
1 home measuring cup of fluid = 8 oz (240 mL)
1 pint of fluid = 16 oz (480 mL)
1 quart of fluid = 32 oz (960 mL)

Various Containers

Record ice chips as fluid at half their volume (1 cup ice = ½ cup fluid)
Bowl (soup) = 180 mL
Creamer (small) = 30 mL
Custard cup = 100 mL
Drinking cup = 180 mL
Coffee mug = 240 mL
Gelatin cup = 100 mL
Ice cream serving = 120 mL
Juice glass = 120 mL
Paper cup, large = 200 mL

Clinical Insight 38-2 ➤ Guidelines for Measuring Intake and Output (I&O)—cont'd

Paper cup, small = 120 mL
Water glass = 200 mL
Water pitcher = 1,000 mL

Examples of fast-food drinks:
Child-size drink = 12 oz
Small drink = 16 oz
Medium drink = 21 oz
Large drink = 32 oz

Assessing

- Fluid intake includes the following:
  - Oral fluids, including the liquid in prepared foods
  - Soups
  - Everything that melts into liquid at room temperature (e.g., gelatin, custard, ice cream, and ice)
  - Liquid medications and fluids used to take tablets or capsules
  - IV fluids
  - Enteral or parenteral nutrition fluids
  - Instillations into the GI tract
  - Bladder irrigations
- Measure oral fluids according to agency policy.
- For increased accuracy, use a graduated cup to measure and record fluid amounts before the patient consumes them. Subtract from the total any fluid that the patient throws away or saves for future consumption.
- Wash the measuring cup after each use, except after measuring water.
- Measure and teach the patient to measure and record the amount of fluid he drinks with each meal, with medicine, and between meals.
- In the home, cups come in many different sizes, so do the following:
  - Use a measuring cup to measure how much the drinking cups and glasses hold.
  - Always use the same drinking cup or glass.
  - Explain that the labels on cans and bottles will help to determine precise fluid amounts.

Recording

- At least every 8 hours, record the type and amount of all fluids the patient has received and indicate the route (oral, parenteral, rectal, or enteric tube).
- Record all forms of intake except blood and blood products.

Measuring Output

Assessing

- Refer to Procedure 28-1 to review how to measure urine.

Fluid output includes everything that leaves the body in fluid form: urine, watery stool, vomitus, wound drainage, surgical drains, NG tubes, chest tubes, and any fluid aspirated from a body cavity.

- Use a calibrated container to measure fluids. Observe it at eye level and take the reading at the bottom of the fluid meniscus.
- Use a different graduated container for each patient; clean after use.
- Teach the patient to keep toilet paper out of the urine for accurate measurement.
- If irrigating an NG tube or the bladder, measure the amount instilled and subtract it from total output.
- You will need to empty wound drains or other devices to measure this volume.
- If a wound is draining, but the fluid is not collected in a drainage device, you may measure the amount of fluid lost by weighing dressings before and after they are applied. If measuring the exact volume is not crucial, you may evaluate the degree of saturation of the dressing.

Recording

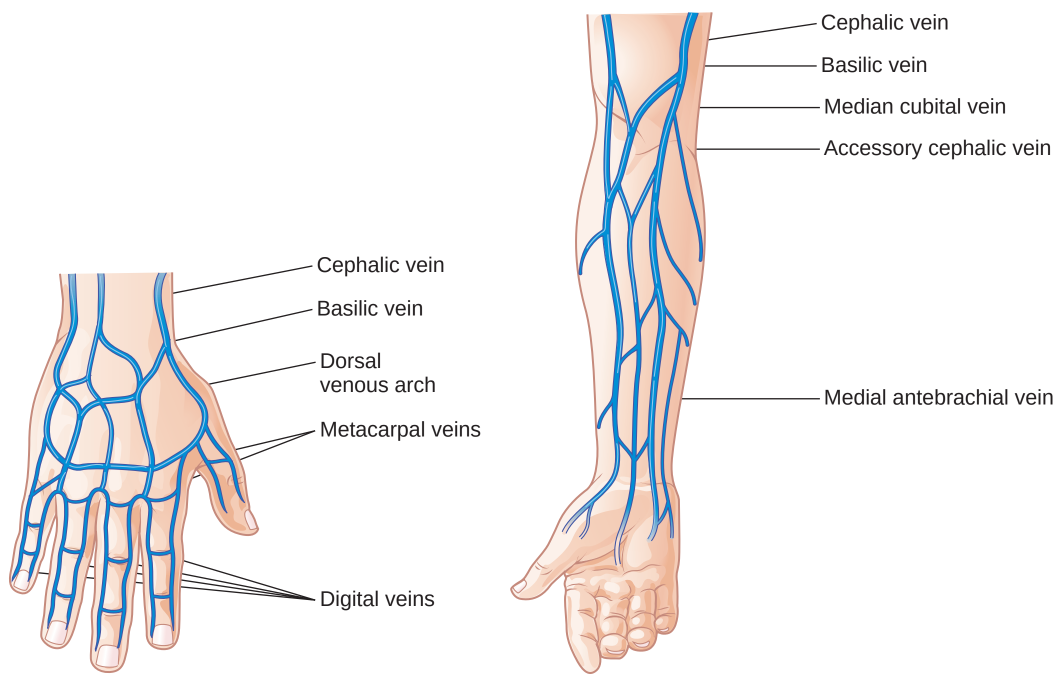
- Record the type, route, and amount of all fluids the patient loses.
- Insensible fluid losses can't be easily quantified. However, unusual losses (e.g., saturated dressing, excessive perspiration, rapid breathing patterns, and large burn areas) should be objectively described in narrative charting.

Tips for Analyzing I&O

- Measure and record all intake and output.
- Determine if output is more or less than intake.
- Evaluate trends over for a period of 24 to 48 hours.
- To identify problems, when evaluating total urine output, ask how many times the patient voided. For example, was a total of 300 mL obtained from 2 voids, or from 10 voids of 30 mL each?
- Evaluate patterns and values outside the normal range (e.g., frequent voiding, infrequent voiding), keeping in mind the normal range for 24-hour intake and output.
- The amount of output is important, but consider color, color changes, and odor.
- Analyze intake and output holistically. Take into account the patient's usual pattern and amounts, age, medical problem, and type of surgical procedure.
- You must correlate I&O with daily weights to accurately determine overall fluid status (Collins & Claros, 2011; Crawford & Harris, 2012b).

Clinical Insight 38-3 ➤ Guidelines for Selecting a Peripheral Venipuncture Site

- As a general rule, select the most distal vein on an upper extremity.
- If available, use visualization technologies, such as portable ultrasound or imaging devices.
  This minimizes the number of needlesticks the patient must undergo.
- For adults, you will usually use veins in the hand or arm; for infants, veins in the scalp or dorsum of the foot can also be used.
- If possible, select a vein on the patient's nondominant hand or arm.
  Helps to preserve functional ability.
- Look for a vein that has a firm, round appearance with a relatively straight pathway. Do not use a red, hot, or hard vein.
- Avoid veins that are highly visible; they tend to roll.
- The cephalic vein of the arm is one of the best veins to use because it is relatively large, and the forearm provides a natural splint
- The dorsal veins of the hand are easy to access and are splinted by the metacarpals, but these veins are often quite small and fragile.



A Superficial veins of the hand **B Superficial veins of the forearm**

- Avoid the antecubital veins if possible. If the patient flexes her arm, the IV catheter may become displaced, so you would probably need to splint her elbow to prevent that. Furthermore, if a PICC line is needed at a later time, you will still have the antecubital veins available for it.
- For these situations, you need to use the largest vein available, keeping other selection criteria in mind:
  - Hypertonic solutions, viscous solutions, or irritating medications
  - Rapid rates (also require a larger IV catheter)
- If the infusion is to be ongoing, begin the infusion with the best lowest vein and move proximal to the previous site (toward the heart) for subsequent insertions. Peripheral IV catheters are routinely changed at 96-hour intervals, but at least every 7 days. If you start the next IV below an already used site (i.e., to change the site or after a failed attempt at insertion), fluid may leak from the old site.
- Avoid areas at which the vein crosses over joints. If you must use such an area, splint the joint to limit movement.
  Splinting the joint helps preserve the vein for use, but it limits functional ability.
- Avoid areas with scarring, or with impaired circulation or neurological status (e.g., the affected arm following a mastectomy; an area with signs of infection, previous infiltration, or thrombosis; an arm with an arteriovenous fistula [shunt for dialysis]; or the affected side after cerebrovascular accident [stroke]). If you must use such an area, first obtain a medical prescription.
- Do not use veins in the legs and feet unless there is no other option.
  Peripheral circulation may not be adequate in the lower limbs, so there is increased danger of thrombus formation. In adults this location also interferes with mobility. Foot veins may be used for infants if the IV is taped securely.

Clinical Insight 38-4 ➤ Caring for Patients With a Central Venous Access Device (CVAD): CVC and PICC

Asepsis

- Use good hand hygiene and follow agency protocols for site care.
  To protect yourself and the patient.
- Use strict aseptic technique when manipulating injection ports, catheter hub and extension legs, needleless connectors, insertion site, and dressing. This includes sterile gloves and supplies, mask, and in some agencies a mask for the patient.
  To minimize line contamination and infection.
- Scrub injection ports, extension legs, and catheter hubs vigorously for at least 15 seconds, preferably with 70% alcohol or 2% chlorhexidine preparation, before accessing them.
- Appropriate antiseptics include alcohol and chlorhexidine gluconate (CHG). Do not use povidone-iodine and tincture of iodine to scrub ports unless there is some reason alcohol or CHG-alcohol combination products can't be used.
- Do not apply organic solvents, such as acetone or acetone-based products, to the skin before insertion of a catheter or during dressing changes.

Assessments

- Check the patient record for radiographic confirmation of correct tip location before beginning prescribed therapies.
- Inspect catheter–skin junction sites through the transparent dressing and palpate for tenderness daily. Do not remove transparent dressing except when dressing change is required. If site is dressed with gauze, you must remove it to inspect the site. Transparent dressings are preferred.
  A high-risk route of infection is via migration of skin organisms at the insertion site into the cutaneous catheter tract, with colonization of the catheter tip.
- Observe for excessive bleeding at the insertion site.
  You may need to obtain a prescription for a topical hemostatic agent and use with a pressure dressing.
- If symptoms of infection occur (e.g., fever without obvious cause; redness, edema, induration, exudates, or tenderness at the site), remove the dressing and inspect the site directly. Anticipate that blood cultures will be needed from both the peripheral site and the central catheter.
- Be aware that risk of infection is higher with femoral catheters and with multilumen catheters.
  Multilumen catheters require more manipulation, which encourages more colonization and bacterial growth within the catheter lumen.
- Assess for compromised catheter integrity (wet dressing; kinked, cracked, or leaking external catheter).
- Inspect catheter connections and pump function, including flow rate.
- Observe for symptoms of catheter migration to the right atrium or ventricle (i.e., mid- to lower sternal pain, dysrhythmias).
- If there are signs of complications, notify the medical provider.
- Assess the patient daily for indications that the CVC or PICC line is still needed.
  CVCs or PICC line should be removed as soon as possible because the infection rate is closely related to the length of time the catheter is in place.

Maintenance Interventions

- The site should be covered with a semipermeable transparent dressing, the catheter secured with a sterile commercially manufactured stabilizer (instead of tape), and the lumens anchored near the ports with clear tape.
- Keep dressings dry, intact, and air occlusive. Protocols generally require a dressing change every 5 to 7 days unless the integrity of the dressing is compromised (e.g., it is damp, loosened, or soiled) or if the site must be examined (e.g., because of pain or odor). A dressing change every 2 days is required if you must use gauze and tape dressings.
- Perform site care with each dressing change. Cleanse the catheter–skin junction with an appropriate antiseptic solution (e.g., 70% alcohol and CHG), apply a sterile stabilizer, and apply a new sterile dressing.
- Manipulate the catheter hub as little as possible.
  To minimize catheter movement, phlebitis, and contamination of the line. Less catheter manipulation is associated with fewer bloodstream infections.
- Flush catheters before and after any infusions or per agency protocol. This may be every 12 to 24 hours when not in use.
  - Flush volume should be twice the volume of the catheter and add-on devices (consult package label).
  - Use a syringe size recommended by the catheter manufacturer (10 mL is the smallest size recommended because of the pressure generated).
  - Type of flush solution depends on agency policy (saline versus heparin).
  - Use single-use, labeled syringes of flush solution to prevent cross-contamination.
  - If you have trouble flushing, the catheter may be kinked or malpositioned, the inline filter may be clogged, or a clamp may need to be released. You can correct these problems.
- Never flush against resistance.
  The catheter might be clogged and you would risk dislodging a small clot. This could also rupture the catheter.
- If the patient has a PICC line, take blood pressures on the alternate arm.
  Using the arm with the PICC can cause bleeding at the site, thrombus formation, retrograde blood flow, and increased risk of catheter occlusion.

Clinical Insight 38-4 ➤ Caring for Patients With a Central Venous Access Device (CVAD): CVC and PICC—cont'd

- If the patient is receiving parenteral nutrition, reserve and label one lumen just for that purpose.

Documentation

- Document routine assessments and the condition of the catheter–skin junction site. When site care is given, also document the patient's response and any actions taken to correct or prevent adverse reactions.

Related Information

For information about dressing changes, refer to Procedure 38-5B: Central Line Dressings. For information about administering medications through a CVAD, see Procedure 26-18: Administering Medication Through a Central Venous Access Device.

References

Infusion Nurses Society (INS). (2011a). Infusion nursing standards of practice. *Journal of Infusion Nursing, 34*(1S): S1–S84; Institute for Healthcare Improvement (IHI). (2012). How-to guide: Prevent central line-associated bloodstream infection. Retrieved from http://www.ihi.org/knowledge/Pages/Tools/HowtoGuidePreventCentralLineAssociatedBloodstreamInfection.aspx

Clinical Insight 38-5 ➤ Managing Infiltration and Extravasation

- At the first sign or symptom of infiltration or extravasation, stop the IV. Symptoms include slowed or stopped flow, swelling, tenderness, pallor, hardness, and coolness at the site.
- The patient may report a burning sensation in the area.

For a Central Venous Access Device: CVC OR PICC:

- Clamp and cap the catheter hub.
- Do not remove the catheter.
- Follow agency policy when you suspect infiltration or extravasation.
- If the patient has an implanted port, aspirate, remove the port access needle, and apply a dressing.
- Notify the provider who inserted the catheter, who may order an x-ray to help determine the cause of the problem.

For a Short Peripheral Catheter:

- Disconnect the tubing from the catheter hub; attach a 3- to 5-mL syringe and try to aspirate fluid from the catheter lumen. Use aseptic technique.
- Photograph the site to create a record of its condition, if agency policy allows.
- Wearing gloves, remove the catheter and hold a dry gauze pad over the site to stop the bleeding. Apply a dry dressing. Do not apply excessive pressure to the site.
- If you are to start a new IV, start it on the other arm, if possible. If it is not possible, start it in a more proximal location on the same arm.
- Measure the circumference of the arm and compare it with the opposite arm.
- Assess capillary refill, sensation, and motion distal to the infiltrated site.
- Apply cold or warm compresses depending on which fluid has escaped into the tissues.
  - For alkaloids (e.g., vincristine) and epipodophyllotoxins (e.g., etoposide), use heat.
  - For hypertonic fluids or medications, use cold.
  - For isotonic or hypotonic fluids or medications, choose either heat or cold, or alternate them, based on patient comfort.
- Apply compresses for 15 to 30 minutes every 4 to 6 hours; continue for 24 to 48 hours.
- Estimate the volume of fluid that escaped into the tissues; notify the prescriber.
- Some medications leaked into the surrounding tissue can cause damage and even necrosis. For instance, when dopamine extravasates, you might need to give a prescribed amount of antidote (e.g., regitine injected subcutaneously) as well as hydrocortisone and an anti-inflammatory to minimize tissue damage. Be sure to check the protocol at your facility.
- Elevate the extremity and advise the patient to rest.
- Document all fluids and medications involved, equipment being used (e.g., pump), size and type of the catheter, description of the site (including location, size, and color), methods used to assess the site before administering the fluids (e.g., aspiration), patient's signs and symptoms, interventions, notifications, and patient teaching.
- Complete an occurrence (or incident) report, as required by your facility.

ASSESSMENT GUIDELINES AND TOOLS

The following questions and guidelines will help you obtain subjective and objective data about patients' fluid, electrolyte, and acid–base balance.

Focused Assessment

Assessing Fluids, Electrolytes, and Acid–Base Balance

Nursing History

Demographic Data

Age, gender, height, weight, body mass index (BMI)

Past Medical History

- Have you ever been hospitalized or had surgery? If so, when and for what reason?
- What healthcare problems are you currently being treated for?
- Have you ever been diagnosed with kidney disease, high blood pressure, diabetes, or thyroid or parathyroid problems?

Current Health Concerns

- What symptoms are you currently experiencing?
- Have you recently experienced any of the following symptoms?

  Excessive thirst
  Fever
  Excessive perspiration
  Nausea, vomiting, or diarrhea
  Dry skin or mucous membranes
  Dark, concentrated urine
  Limited amounts of urine
  Difficulty breathing
  Swelling of your hands, feet, or ankles
  Dizziness or feeling faint
  Muscle weakness
  Excessive fatigue
  Numbness, tingling, or cramping sensations

- Is your weight stable? Have you had any recent changes in your weight?
- Do you believe you have any problems with fluid loss?

Food and Fluid Intake

- How much fluid do you usually drink in a 24-hour period?
- Do you believe you drink adequate amounts of fluid?
- Describe your usual diet.
- Have you recently changed your diet or fluid intake?
- Are you following a special diet?
- Have you ever been placed on a restricted diet?
- Have you experienced any recent changes in your appetite or thirst?
- Do you salt your food?
- Do you ever use salt substitute?

Fluid Elimination

- How often do you urinate in a 24-hour period? Has that changed recently?
- How often do you get up during the night to urinate?
- Have you noticed any recent changes in the amount or appearance of your urine?
- How often do you experience vomiting, diarrhea, or constipation? Describe your experience.
- Do you have any wounds? If so, where are they, and how did they happen? What is the color of drainage and how much drainage are you experiencing?
- Do you have any breaks in your skin? If so, describe the problem, and show me the area.

Medications

- What prescribed medications do you currently take?
- What over-the-counter medications or alternative treatments do you use? What do you use them for?
- How often do you take laxatives or antacids?
- What vitamins, herbals, or supplements do you take?

Lifestyle

- What is your usual activity level?
- What type of exercise do you engage in? How often?
- How much fluid do you consume before, during, and after exercise?
- Do you drink alcohol? If so, how much do you consume in a day, a week?
- Do you smoke? If so, how much? For how long?
- Do you use any illegal medications or drugs?

Physical Assessments

Skin

Assess the skin for the following:.

- ***Color and temperature*** may be cues to the presence of fever and circulation status.
- ***Moisture content*** offers some indication of fluid status. A diaphoretic client is losing fluid at a faster rate than a client with dry skin. Dry, scaling skin may indicate a fluid deficit. Any breaks in the skin are potential areas for fluid loss.
- ***Turgor*** varies with age, weight, and skin condition but does offer information on fluid status. Pinch the skin over the sternum. Normally skin immediately returns to its usual position. In fluid volume deficit or malnutrition the skin may remain "tented" for a period of time before returning to its original position. You must, however, correlate skin turgor with context and other clinical signs. For example, the skin loses elasticity with aging, so clients older than age 65 often have decreased turgor, which is normal for them.

Focused Assessment

Assessing Fluids, Electrolytes, and Acid–Base Balance—cont'd

- ***Edema*** in dependent areas is a cue for fluid volume excess. In an ambulatory client, assess the lower extremities and hands. In a bedridden client, edema will shift as the client is turned.
- ***To grade edema*** (on a scale +1 to +4, +1 represents minimal edema and +4 represents the most severe edema),

Go to Chapter 22, **Table 22-3: Assessing Edema,** in Volume 1.

Mucous Membranes

- Inspect the tongue and buccal mucosa. Mouth breathing alone usually does not change these areas.
- Dry, cracked, or dull mucous membranes are signs of fluid volume deficit.

Cardiovascular System

- ***Assess vital signs*** (see later section).
- If you suspect fluid volume deficit, ***assess for orthostatic hypotension:***
  - Assess blood pressure while client is lying or sitting.
  - Have the client rise to a seated or standing position, and reassess the blood pressure (BP).
  - A drop in systolic BP of >15 mm Hg is a sign of orthostatic hypotension.
- ***Check capillary refill.*** Delayed capillary refill is a sign of fluid volume deficit; rapid capillary refill indicates adequate circulation and volume. If capillary refill is delayed, evaluate feet and hands bilaterally. Delays in just one area indicate impaired circulation to the extremity rather than volume changes.
- ***Assess venous filling*** by observing the jugular and hand veins. Flat jugular or hand veins indicate low fluid volume. Distended vessels are a sign of overload.

Respiratory System

- ***Assess respiratory rate, depth, and pattern.*** The respiratory system rapidly responds to changes in pH. Similarly, alterations in gas exchange at the alveolar–capillary membrane may trigger pH changes.
- ***Assess breath sounds.*** Crackles or moist rales may indicate fluid overload. Areas of consolidation indicate impaired gas exchange.

Neurological System

- Assess level of consciousness and orientation.
- Assess neuromuscular irritability.
- Assess energy level and fatigue.
- Assess reflexes.

For specific neurological cues to alterations in fluid, electrolyte, or acid–base balance,

Go to Chapter 38, **Table 38-5: Electrolyte Imbalances,** and **Table 38-7: Acid–Base Imbalances,** in Volume 1.

Vital Signs

- ***Temperature.*** An elevated body temperature increases the loss of body fluids.
- In hypernatremia, body temperature elevates because less fluid is available for sweating.
- In uncomplicated fluid volume deficit, body temperature decreases.
- ***Pulse:***
  - Tachycardia is an early sign of fluid volume deficit.
  - Pulse rate is affected by fluid status and some electrolytes (primarily sodium, potassium, calcium, and magnesium).
  - Dysrhythmias are seen with potassium and magnesium imbalances.
- The pulse volume is directly affected by fluid status. As fluid volume increases, the pulse volume also increases. Similarly, a drop in fluid volume leads to a drop in pulse volume.
- ***Respiratory rate.*** Alterations in respiratory rate may cause acid–base imbalances or be associated with compensation for a metabolic disorder.
- ***Blood pressure:***
  - Blood pressure rises and falls with fluid volume.
  - Blood pressure is elevated by hypernatremia and fluid volume excess.
  - Respiratory acidosis causes increased heart rate, resulting in BP elevation.
  - High potassium intake may lower blood pressure.

Daily Weights

- Use the same balanced scale each day to monitor fluid status accurately.
- Weigh the client at the same time of day, making sure that the client is wearing the same amount of clothing.
- For clients undergoing hemodialysis (blood cleansing through an artificial kidney), weigh the client before and after dialysis treatments.
- You may institute weight monitoring as an independent nursing order.

Fluid Intake and Output

See Clinical Insight 38-2.

DIAGNOSTIC TESTING

Diagnostic Testing

Assessing Fluid, Electrolyte, and Acid–Base Balance

Venous Blood Sample	Normal Ranges
Sodium	135–145 mEq/L
Potassium	3.5–5.0 mEq/L
Chloride	97–107 mEq/L
Bicarbonate	22–26 mEq/L
BUN	10–31 mg/dL
Creatinine	0.5–1.2 mg/dL
Serum osmolality	275–295 mOsm/kg
Urine osmolality	250–900 mOsm/kg
Hematocrit	43%–49% in men 38%–44% in menstruating women
Freshly Voided Urine Sample	
pH	5.0–9.0
Specific gravity	1.001–1.029
Arterial Blood Sample	
pH	7.35–7.45
P_{CO_2}	35–45 mm Hg
HCO_3^-	22–26 mEq/L

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Darlene Malone, age 42, has been admitted to the emergency department with complaints of fatigue, extreme weakness, and heart palpitations. She says she has not seen a healthcare provider in nearly 10 years. Suddenly, she slumps and falls over. She is not breathing, has no pulse, and does not respond to verbal stimuli. She is resuscitated with CPR and IV epinephrine, and an endotracheal tube is placed. STAT lab results show a potassium level of 7.7 mEq/L, BUN of 102 mg/dL, and creatinine of 5 mg/dL. A physician diagnoses acute renal failure. Among other interventions, an IV is started to administer 10% calcium chloride solution, 1,000 mg, by slow IV push to counteract the toxic effects of hyperkalemia on the cell membranes. The nurse used a 20-gauge over-the-needle catheter in Ms. Malone's right cephalic vein, about 5 cm (2 in.) above her wrist.

THINKING

1. *Theoretical Knowledge:*
   a. Which lab results are abnormal? Are they high or low?
   b. Which lab results directly reflect her renal failure?
   c. What term correctly describes serum potassium of 7.7 mEq/L?
2. *Critical Thinking (Considering Alternatives):*
   a. What do you think is causing Ms. Malone to have hyperkalemia? You should be able to think this through and make a reasonable guess even if you have not studied pathophysiology.
   b. Ms. Malone is to be given 50 mEq of sodium bicarbonate by slow IV push for an acid–base imbalance that is often associated with hyperkalemia. Which imbalance do you think would be treated with sodium bicarbonate: metabolic acidosis or metabolic alkalosis?

DOING

3. *Practical Knowledge:*
   a. When you prepare to administer the sodium bicarbonate (in question 2b), you notice that the IV infusion is barely flowing and that the insertion site is swollen and pale. What is the first thing you should do?
   b. You aspirate the catheter and do not obtain a blood return. Ms. Malone absolutely must have this medication. Describe what you would do in the order you would do it.
4. *Nursing Process (Planning Goals):* The NOC outcome best suited to evaluating Ms. Malone's hyperkalemia is Electrolyte & Acid–Base Imbalance. Based on the function of this electrolyte, what is the primary indicator that you could use to evaluate her goal achievement for this problem?

CARING

5. *Self-Knowledge:* Ms. Malone will need dialysis to replace her inadequate renal function and control her serum potassium level. It is likely that her renal failure was brought on by years of illegal drug abuse. She has never held a full-time job and has not worked at all for the past 7 years. Her dialysis treatments will need to be paid for by Medicaid, which is funded by tax dollars. How do you feel about this—specifically, how do you feel about the issues of (a) a person's responsibility for her own health and (b) compassion for people who cannot afford to pay for healthcare? Focus on your own feelings, not on issues of what "should" be done.

Critical Thinking and Clinical Reasoning

1. Recall the Meet Your Patients scenario in Volume 1. When you review Jackson LaGuardia's chart to prepare for the clinical day, you find that he is in the emergency department (ED) with four other members of the LaGuardia family. All of them have come to the ED complaining of nausea, vomiting, and diarrhea related to severe gastroenteritis, a viral intestinal disorder. The family members include the following:
   8-month-old Jason, grandson of Jackson
   26-year-old Susanna, Jackson's daughter and Jason's mother
   60-year-old Jackson
   58-year-old Gemma, Jackson's wife
   82-year-old Martha, Jackson's mother

   Jason, Jackson, and Martha are being admitted to the hospital. However, Susanna and Gemma have been asked to follow up tomorrow in the urgent care clinic. The following questions pertain to this scenario.
   a. Martha LaGuardia's orders call for lactated Ringer's solution with 20 mEq KCl per liter to infuse at 150 mL/hr. After 4 hours of infusion, Martha begins to complain of shortness of breath and develops a cough. What do you suspect may be happening? What actions should you take?
   b. What theoretical knowledge will you use in caring for Ms. LaGuardia's immediate problem?
   c. Jason LaGuardia has been prescribed 250 mL of 0.9% saline solution over 8 hours. What type of equipment should you consider using?
   d. Calculate the drip rate for Jason's infusion if a gravity flow device is used. What further information do you need to perform this calculation?
   e. As you may recall, Jackson LaGuardia has end-stage renal disease. His lab work reveals a hemoglobin of 7.6 mg/dL and a hematocrit of 21%. He has been prescribed two units of packed red blood cells over 8 hours. Given his condition, for what fluid balance problem is he at risk? What additional parameters should you assess while he is receiving the transfusion?
2. You are asked to administer an antibiotic intravenously via piggyback. You are not familiar with the equipment that this facility uses. As a student, what approach should you take to solve this problem?
3. Identify techniques that you have observed that may contribute to contamination of an IV site.
4. Interpret the following ABG results. Explain your thinking.
   a. pH 7.47 P_{CO_2} 45 mm Hg HCO_3^- 32 mEq/L
   b. pH 7.32 P_{CO_2} 50 mm Hg HCO_3^- 25 mEq/L
   c. pH 7.30 P_{CO_2} 41 mm Hg HCO_3^- 18 mEq/L
   d. pH 7.45 P_{CO_2} 30 mm Hg HCO_3^- 22 mEq/L

5. For each of the following concepts, use critical thinking to describe how or why it is important to nursing; patient care; or fluids, electrolytes, and acid–base balance. Note that these are not to be merely definitions.
   Homeostasis
   Selectively permeable membranes
   Fluid imbalance
   Electrolyte imbalances
   Acid–base imbalances
   Parenteral fluid and electrolyte replacement

What Are the Main Points in This Chapter?

- Water is the largest single constituent of the body. Total body water content varies with age, gender, and the number of fat cells.
- Intracellular fluid (ICF) is contained within the cells. It is essential for cell function and metabolism and accounts for approximately 40% of body weight.
- Extracellular fluid (ECF) consists of three types of fluid: interstitial, intravascular, and transcellular fluid. ECF carries water, electrolytes, nutrients, and oxygen to the cells and removes the waste products of cell metabolism. ECF accounts for 20% of body weight.
- Electrolytes that carry a positive charge are called cations. These include sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+}). Electrolytes that carry a negative charge are called anions.
- Potassium and magnesium are the major cations in the ICF. Phosphate and sulfate are the major anions.
- The major electrolytes of ECF are sodium, chloride, and bicarbonate. Albumin is also present in the ECF.
- The functions of the major electrolytes include the following:
  - Sodium is essential to regulate fluid volume.
  - Chloride works with sodium to regulate osmotic pressure, and with the bicarbonate buffer system to regulate acid–base balance.
  - Potassium is essential for cellular metabolism.
  - Calcium is responsible for bone health and neuromuscular and cardiac function, and is an essential factor in blood clotting.
  - Magnesium is a mineral used in more than 300 biochemical reactions in the body.
  - Phosphorus is important in the formation of bones and teeth and has an inverse relationship with calcium.
- Osmosis, diffusion, filtration, and active transport are mechanisms used to maintain a balance between fluids and solutes in the body.
- General recommendations for total fluid intake are 2,700 mL per day for women and 3,700 mL per day for men.
- When the body is in a healthy state, fluid losses through urine, skin, insensible losses, and feces are equivalent to fluid intake.
- Fluid volume deficit occurs when there is a proportional loss of water and electrolytes from the ECF.
- Fluid volume excess involves excessive retention of sodium and water in the ECF.
- Bicarbonate is important in acid–base regulation and is regulated by the kidneys to maintain pH.
- The amount of acid or base present in a solution is measured as pH. The pH is reported on a scale of 1 to 14, with 1 to 6.9 being acidic, 7 neutral, and 7.1 to 14 basic, or alkaline. Normal blood pH is slightly alkalotic, between 7.35 and 7.45.
- A buffer system consists of a weak acid and a weak base. These molecules react with strong acids or bases to keep them from altering the pH by either absorbing free hydrogen ions or releasing free hydrogen ions. The principal buffer system in the ECF is the carbonic acid (H_2CO_3) and sodium bicarbonate ($NaHCO_3^-$) system.
- When the serum pH falls below 7.35, the patient is acidotic. When the serum pH increases above 7.45, the patient is alkalotic. Arterial blood gases (ABGs) are used to monitor acid–base balance.
- When the serum pH is too acidic (pH is low), the lungs remove carbon dioxide through rapid, deep breathing. If the serum pH is too alkaline (pH is high), the lungs try to conserve carbon dioxide through shallow respirations.
- The kidneys affect pH by regulating the amount of bicarbonate (base) that is kept in the body.

- Assessment of a client's fluid, electrolyte, and acid–base balance includes history; laboratory data; physical examination of the skin, mucous membranes, and neurological status; and assessment of cardiovascular and respiratory systems.
- Intake and output (I&O) are monitored to assess fluid status. To monitor, measure all fluids consumed and excreted in a 24-hour period.
- Tests used to monitor fluid, electrolyte, and acid–base balance include serum electrolytes and osmolality, complete blood count, urinalysis, and measurement of arterial blood gases.
- Nursing interventions for patients experiencing alterations in fluid, electrolyte, or acid–base balance include preventing imbalances modifying oral intake, providing parenteral replacement, and transfusing blood products.
- Intravenous fluids are classified as isotonic, hypotonic, and hypertonic solutions, based on their comparison to the osmolality of blood serum.
- Vascular access devices may provide access to peripheral or central veins.
- Intravenous equipment consists of the IV catheter, an administration set, extension tubing, and the IV solution.
- Nurses are responsible for using established formulas to calculate and maintain the correct rate of flow and for monitoring the client's response to the infusion.
- Assess for local IV site complications (e.g., infiltration, extravasation, infection, thrombus, and thrombophlebitis) and systemic complications (e.g. fluid volume excess, sepsis, and embolus).
- Meticulous aseptic technique is required for initiation and care of intravenous infusions, to prevent bloodstream infection.
- Blood products are infused when the client has experienced significant blood loss, diminished oxygen-carrying capacity, or a deficiency in one of the blood components.
- Nurses must administer the correct blood type to patients to prevent a hemolytic reaction.

Knowledge Map

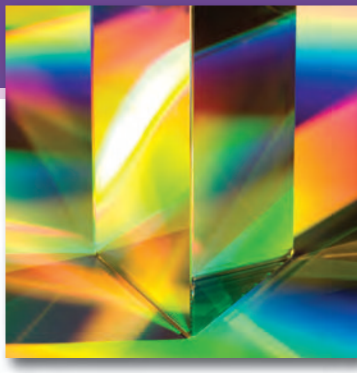
Nursing Functions

CHAPTER 39



Perioperative Care

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus*, at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 39:
- **Response Sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Perioperative Care**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 39, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Mai Nguyen, the 76-year-old mother of Nam Nguyen, has been experiencing blurred vision and decreased visual acuity. A local ophthalmologist diagnosed bilateral cataracts. The ophthalmologist has recommended cataract removal in the left eye, with insertion of an intraocular lens. He told Mrs. Nguyen to schedule the surgery "at your convenience" and explained that the surgery would be performed on an outpatient basis. The ophthalmologist gave Mrs. Nguyen a list of activities to prepare for the surgery, containing the following information:

- Schedule a date for your surgery. My receptionist will set up a time for your surgery. All surgeries are

(Continued)

Caring for the Nguyens (continued)

performed at Western Medical Center Same-Day Surgery Department.
- Please arrange to be seen by your primary care provider 1 to 2 weeks prior to the surgery to receive clearance for surgery.
- Make an appointment with the Preoperative Center at Western Medical Center Same-Day Surgery Department 1 to 2 days before surgery.
- Arrange to have a ride to and from the surgery.

A. What preoperative testing is Mrs. Nguyen likely to undergo? Explain your rationale.

B. The preoperative list states that the client must be seen by the primary care provider to receive clearance for surgery. Why is this an essential part of the preoperative period?

C. What theoretical knowledge do you need to perform preoperative teaching for Mrs. Nguyen? How could you obtain that information? Be specific about your sources.

D. What content would you include in Mrs. Nguyen's preoperative teaching?

E. The ophthalmologist has planned anesthesia via conscious sedation. What factors, if any, might keep Mrs. Nguyen from receiving this form of anesthesia? What additional information do you need to answer this question?

PracticalKnowledge knowing how

Perioperative care requires you to use the nursing process to ensure that the patient is in the best possible condition for surgery, is safe during surgery, and has the best possible outcomes postoperatively. Perioperative nursing care includes procedures and techniques designed for prevention and early detection of complications. Recall that full-spectrum nursing involves thinking, doing, and caring—all are equally important, in perioperative as well as other settings.

PROCEDURES

The procedures in this section will help you to prevent postoperative complications. Preoperative teaching of coughing, deep breathing, moving in bed, and leg exercises help to prevent thrombophlebitis, atelectasis, and pneumonia. Antiembolism stockings and sequential compression devices are designed to promote peripheral circulation and prevent thrombus formation. Gastrointestinal suction is used to relieve or prevent abdominal distention.

Procedure 39-1 ■ Teaching a Patient to Deep-Breathe, Cough, Move in Bed, and Perform Leg Exercises

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

For Teaching Deep Breathing and Coughing

- Folded blanket or a pillow (if teaching will include splinting of a surgical incision site)
- Tissues

For Moving in Bed

- Small pillow or folded blanket
- Pillows

Delegation

You or another RN should perform the initial teaching. You may delegate reinforcement of the teaching to a licensed vocational nurse (LVN), licensed practical nurse (LPN), or nursing assistive personnel (NAP).

Pre-Procedure Assessments

- Assess the patient's cognitive level and level of consciousness. *Helps assess the patient's ability to understand and follow directions and select the appropriate teaching method.*

- Assess the patient's pain level.
  Even preoperatively, pain must be well controlled to ensure full patient participation.
- Determine whether the surgical procedure and/or a physical disability will limit the patient's participation.
  For example, a fractured arm that has not yet been repaired will impair the patient's ability to hold a pillow for splinting.
- Determine whether the surgical procedure may entail special exercises or equipment. In addition, assess for any special equipment, such as braces, slings, or abductor wedges that may be needed when turning a patient in bed.

Knee and hip surgeries often involve special exercises or equipment postoperatively. Consult the surgeon before teaching the patient any leg exercises. Spinal and neurological surgeries often limit movement in the postoperative period. For example, some spinal surgeries require the patient to logroll (move from head to toe as one unit). Some neurological procedures require limiting the amount of time the patient's head of bed is above 30°. Identify these restrictions preoperatively, and inform the patient and family about them during your teaching session.

- Assess the patient's belief about the ability of the surgical incision to remain intact.
  If the patient believes that the incision will not stay together if he coughs or moves, he is less likely to comply.

Procedure 39-1A ■ Teaching a Patient to Deep-Breathe and Cough

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Deep breathing and coughing expand the lungs, improve ventilation, promote gas exchange, and help prevent atelectasis and pneumonia. Coughing after deep breathing mobilizes secretions, which keeps airways and alveoli open and provides greater surface area for gas exchange.

Procedure Steps

1. **Assist the patient to a Fowler's** or semi-Fowler's position, with the shoulders relaxed.
   Allows for best chest and lung expansion.
2. **Assist the patient who will have** a chest or abdominal incision to practice splinting the site with a folded blanket or pillow (see the photo in column 2).
   Counterpressure supports the incision and decreases pain. ➤

3. **Teach the patient diaphragmatic/** deep breathing. Tell the patient to:
   a. Place her hands anteriorly, along the lower end of the rib cage. The tips of the third fingers should touch at the midline.
   b. Slowly take a deep breath in through the nose. Tell the patient that she should feel her chest expanding as the diaphragm moves down.
   c. Hold her breath for 2 to 5 seconds.
   Stimulates surfactant production and helps prevent alveolar collapse.
   d. Slowly and completely exhale the breath through her mouth.
4. **Teach the patient to cough** in conjunction with diaphragmatic breathing. Instruct her to:
   a. Complete two or three cycles of diaphragmatic breathing.
   b. On the next breath in, have the patient lean forward and cough rapidly, through an open mouth, using the muscles of the abdomen, thighs, and buttocks. Cough several times on that breath.
   This information helps the patient to distinguish coughing from merely clearing her throat.

For a Patient Experiencing Weakness
If the patient is too weak to perform this maneuver, have the patient inhale deeply, bend forward slightly, and perform three or four "huffs" against an open glottis to move secretions forward.

Procedure 39-1B ■ Teaching a Patient to Move in Bed

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Moving in bed promotes blood circulation, stimulates respiratory function, and helps mobilize gas in the intestines.

Procedure Steps

1. **Start with the patient in** supine position, bedrails up. Then instruct the patient as follows.
2. **To turn to the left side:** Bend the right leg, sliding the foot flat along the bed and flexing the knee.
   Enables the patient to push herself over to the opposite side.

(continued on next page)

Procedure 39-1 ■ Teaching a Patient to Deep-Breathe, Cough, Move in Bed, and Perform Leg Exercises (continued)

3. **Reach the right arm across** the chest, and grasp the opposite bedrail.
Helps the patient to turn, reduces the need to use the abdominal muscles for turning, and minimizes incision pain.

4. **Breathe deeply**, **and practice** splinting any potential abdominal or chest incisions. Provide as much assistance as the patient needs.
Facilitates comfort during movement.

5. **Pull on the bedrail** while pushing off with the right foot.
Assists patient to turn to the left.

6. **If the patient cannot maintain** this position independently, place a folded pillow or blanket along her back for support.

7. **Teach the patient to change** positions every 2 hours, repeating the turning process with the opposite arm and leg. For patients who need pillows placed for support, you will need to assist with turning.

Procedure 39-1C ■ Teaching Leg Exercises

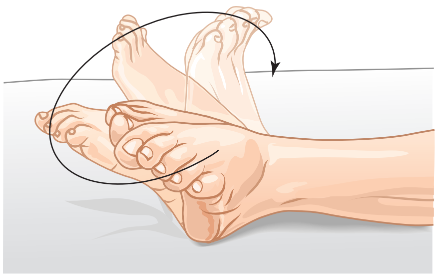
➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Leg exercises flex and extend the leg muscles to increase peripheral circulation and help prevent thrombus formation. Thrombus formation is a common postoperative complication.

Procedure Steps

1. **Instruct the patient to lie supine** in the bed.
Note: Although these exercises can be done when the patient is up in a chair, the effect will be diminished by the effects of gravity.

2. **Perform ankle circles.** Instruct the patient to:
   a. Start with one foot in the dorsiflexed position.
   b. Slowly rotate the ankle clockwise.
   c. After three rotations, repeat the procedure in a counterclockwise direction.
   d. Repeat this exercise at least three times in each direction, then switch and exercise the other ankle.



3. **Perform ankle pumps.** Instruct the patient to:
   a. Start with one foot, leg extended.
   b. Point the toe until her foot is plantar flexed.
   c. Pull the toes back toward her head until the foot is dorsiflexed; at the same time, press the back of the knee into the bed.
   d. Make sure she feels a pull, or a stretch, in the calf.
   e. Repeat the alternation between plantar and dorsiflexion several times.
   f. Repeat the cycle with the other foot.

4. **Perform leg exercises.** Instruct the patient to:
   a. Lie supine in the bed.
   b. Slowly begin bending one knee, sliding the sole of the foot along the bed until the knee is in a flexed position.

   c. Reverse the motion, extending the knee until the leg is once again flat on the bed.

   d. Repeat several times.
   e. Repeat using the opposite leg.

What if . . .

■ **The patient has had knee, hip, or back surgery?**
Leg exercises may be contraindicated in patients having knee, hip, or back surgery. Check the surgeon's prescriptions and/or collaborate with the physical therapist.

■ **The patient has had nasal, ophthalmic, or neurological surgery?**
Coughing and deep-breathing exercises are contraindicated.
To avoid increasing intracranial pressure.

Evaluation

Make sure that the patient performs correctly a return demonstration of the procedures taught.

Documentation

In many healthcare facilities, checklists and charts have special areas in which to document patient teaching. Documentation should identify the person who completed the teaching, the person to whom the procedures were taught, what procedures were taught, and whether the patient understood the teaching. Also include the name and type of any printed materials given.

Sample electronic documentation

Note that because this is just one screen of a documentation system, not all of the information is visible. For example, you cannot see the date or the name of the nurse.

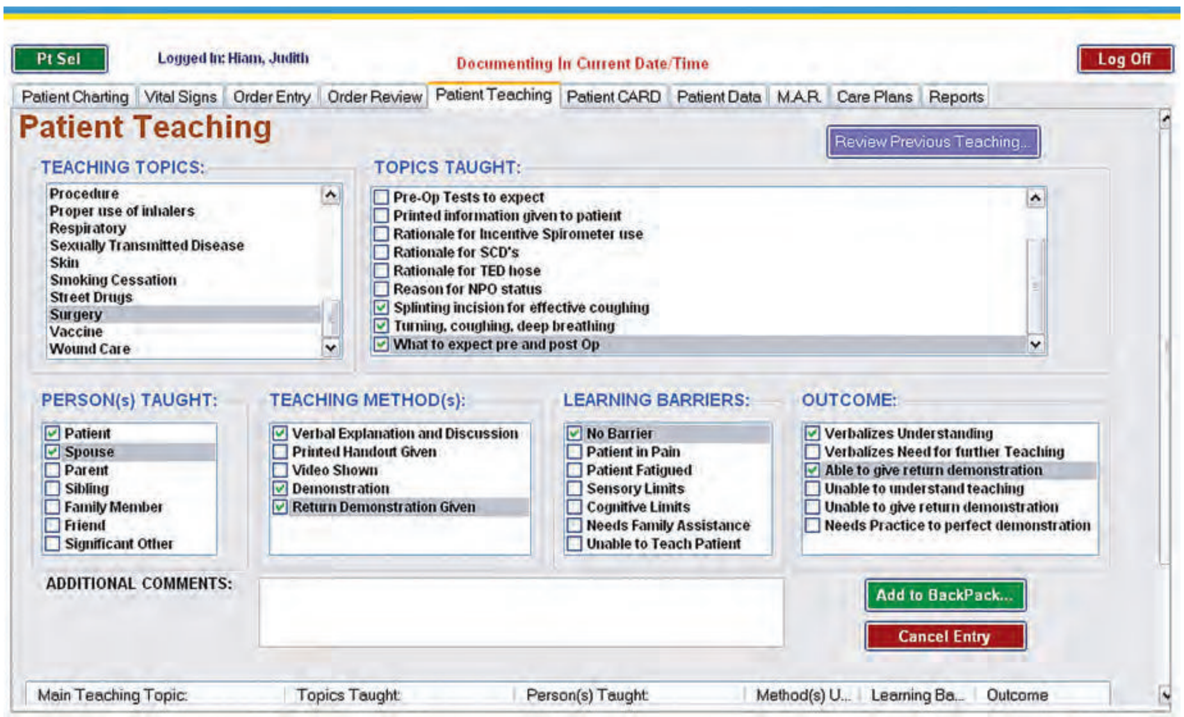
Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Teaching a Patient to Deep-Breathe and Cough, Teaching a Patient to Move in Bed,** and **Teaching Leg Exercises.**

For questions and suggested responses,

Go to Chapter 39, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus.*



Procedure 39-2 ■ Applying Antiembolism Stockings

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

- Measuring tape
- Antiembolism stockings
- Washcloth and towel (if needed to cleanse legs)
- Talcum powder (optional: check manufacturer's recommendations)

Delegation

You can delegate application of antiembolism stockings to nursing assistive personnel who have been trained in the task. Instruct the NAP as follows:

- Report the presence of any abnormalities on the lower extremities, such as lesions, sores, or redness, before applying the stockings.
- Instruct the patient to maintain a recumbent position for at least 15 minutes before applying the stockings.
- Do not massage the legs.
- Make sure there are no wrinkles in the stockings once they have been applied.

(continued on next page)

Procedure 39-2 ■ Applying Antiembolism Stockings (continued)

Pre-Procedure Assessment

- Assess the level of consciousness and cognitive ability.
  If the patient is unconscious or confused, you will need to call for assistance to hold and stabilize the lower extremities as you apply the stockings.
- Assess for signs and symptoms of severe peripheral arterial disease, such as weak or absent pulses, discoloration or cyanosis, or gangrene.
  Antiembolism stockings should not be used in patients with any of these findings because stockings compress the vessels and, therefore, further impede the already compromised arterial flow.
- Assess skin condition. Note lesions, dermatitis, or major edema, as evidenced by shiny, taut skin.
  If skin is overstretched by edema, antiembolism stockings may irritate or worsen skin conditions and cause skin breakdown.
- Note the patient's position and length of time she has been in that position.
  Place the patient supine for at least 15 minutes before stocking application. This prevents trapping of pooled venous blood.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

➤ If possible, apply stockings in the morning, before the patient gets out of bed.

Prevents venous distention and edema that occur when the patient is sitting or standing.

Procedure Steps

1. **Measure the patient's lower extremities** to obtain the correct size stockings. This is critical to their effectiveness.
   Stockings must be sized correctly in order to apply the correct amounts of pressure at the ankle, mid-calf, and upper thigh. If they are not tight enough, they will not improve venous return effectively. If they are too tight, they may compress the veins and impair circulation to the skin.

For Thigh-High Stockings

Note: Thigh-high elastic stockings have not been proved to be more effective in preventing thromboembolism than knee-high ones, and should probably be avoided because of the tendency to roll and have a tourniquet effect (Perry, Borchert, Burke, et al., 2012)

   a. Measure the circumference of the upper thigh at the gluteal fold.
   The manufacturer of TED stockings recommends that thigh-high stockings not be applied if the thigh circumference exceeds 82 cm (32 in.). Use knee-high stockings instead.
   b. Measure the calf circumference at the widest section.
   c. Measure the distance from the gluteal fold to the base of the heel.

For Knee-High Stockings

   a. Measure the circumference of the calf at the widest section.
   b. Measure the distance from the base of the heel to the middle of the knee joint.
   Evidence is not conclusive, but increasingly supports the use of knee-high instead of thigh-high hose.

2. **Assist the patient to a supine** position, and instruct him to maintain that position for at least 15 minutes before you apply the stockings.
   Prevents trapping of pooled venous blood by the antiembolism stockings.
3. **Cleanse the patient's legs and** feet if necessary. Dry well.
   Removing surface dirt and bacteria will decrease the likelihood of infection and odor.
4. **Lightly dust the legs and feet** with talcum powder to ease the application of the stockings, if recommended by the manufacturer. **Key Point:** ***Do not use powder if the patient is or is likely to become diaphoretic. Powder eases the application of the stockings, but perspiration will cause the powder to clump.***
5. **Holding one stocking at the top** cuff in your dominant hand, slide your nondominant arm down and into the stocking until your hand reaches the heel of the stocking.
6. **Grasp the center of the heel** with your hand inside the stocking, and then slowly turn the stocking inside out to the level of the heel with your other hand.
   The elastic in the stockings is very strong; this method is the easiest way to fit it over the foot and calf.

7. **Ask the patient to point his toes** as you grasp the turned foot of the stocking and ease it onto his foot and heel (like putting on a sock). Center the patient's heel in the heel of the stocking.
   Ensures that the pressure of the stocking is over the correct anatomical areas.
8. **Gradually pull the remainder** of the stocking up and over the leg,

turning it right side out as you proceed. Be certain the stocking is straight.

For Knee-High Stockings

a. Pull up to 2.5 to 5 cm (1 to 2 in.) below the knee

For Thigh-High Stockings

a. Pull up to the gluteal fold of the thigh, rotating inward so the gusset is centered over the femoral artery, slightly toward the inside of the leg.
Stockings apply varying amounts of compression between ankle, calf, and thigh areas. Keeping the stocking straight ensures that the pressure occurs over the correct areas.

9. **Smooth out any excess** material; keep stockings free of wrinkles and bunching.
Decreases the risk of skin breakdown and areas of inappropriate and potentially dangerous constriction.

10. **If the stockings have closed** toes, tug gently on the stocking toe to create a small space between the end of the toes and the stocking.
Prevents compression of small vessels in the toes, which may impede circulation.

11. **Repeat the procedure** on the other leg.

12. **Remove the stockings** and bathe and dry the legs daily.

13. **Launder the stockings** at least every 3 days; dry them on a flat surface.
Soiled stockings can irritate the skin; dry flat to prevent stretching.

? What if . . .

- **Both legs do not measure the same?**
Order two different sizes of stockings and use one from each package to make two pairs.

Evaluation

- Evaluate patient comfort.
Severe, continuous discomfort may indicate that the stockings are the wrong size.
- Check the stockings for wrinkles and/or rolling down at the top, especially when sitting.
Wrinkles and rolling down can cause skin breakdown and areas of constriction.
- Evaluate and monitor skin condition.
Elastic stockings should be removed for 20 to 30 minutes every 8 to 12 hours to allow you to inspect the patient's skin and evaluate the adequacy of his circulation.
- Evaluate the patient's ability to ambulate.
It is important to reduce the time the patient is immobile due to pain, sedation, mechanical ventilation, and so on.
- Re-measure the legs regularly.
To prevent complications related to swelling and weight gain.

Home Care

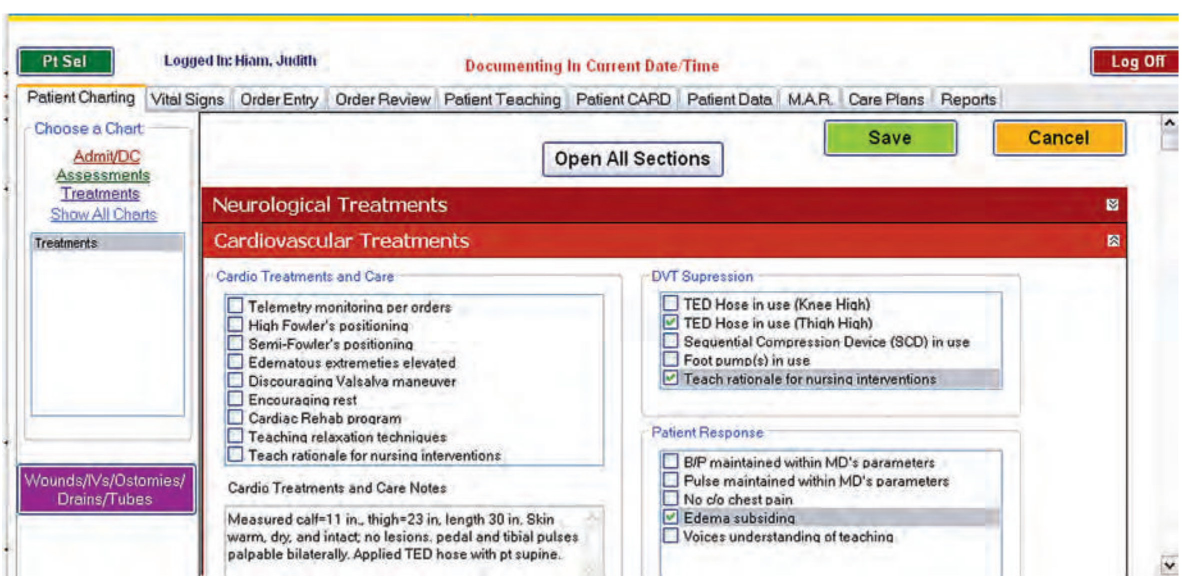
- Teach the client and/or caregiver to apply the stockings.
- Encourage the client to have two pairs of stockings on hand so that one pair can be used while the other is being laundered.
- Instruct the client to follow the manufacturer's directions for washing the stockings.
- Teach the client not to roll down the tops of the stockings.

Documentation

- Document leg measurements and size of the stockings used, to provide a baseline.
- Document the time and date applied.
- Note the condition of the skin, including any abnormalities.

Sample electronic documentation

Note that because this is just one screen of a documentation system, not all of the information is visible. For example, you cannot see the date or the name of the nurse.



(continued on next page)

Procedure 39-2 ■ Applying Antiembolism Stockings (continued)

Practice Resources

American Association of Critical-Care Nurses (2010); Joanna Briggs Institute (2008a); Larry, C. (2003); National Guideline Clearinghouse (2008b); National Institute for Health and Clinical Excellence (NICE) (2007); Perry, D., Borchert, K., Burke, S., et al. (2012); Winslow, E., & Brosz, D. (2008).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Applying Antiembolism Stockings**.

For questions and suggested responses,

Go to Chapter 39, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 39-3 ■ Applying Sequential Compression Devices

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

Note: Sequential compression devices may be referred to by several different brand names, including SCDS (sequential compression decompression stockings), Flowtrons, and PAS (pneumatic air stockings).

- Compression pump, motor, or machine
- Connecting tubing, if applicable (In some devices, the tubing is preconnected to the sleeves.)
- Compression sleeve (knee-high or thigh-high, depending on the order and the type of device)
- Elastic stockings (if also prescribed)
- Washcloth and towel as needed to cleanse the lower extremities
- Measuring tape

Delegation

You may delegate the application of the sequential compression device to a NAP who has had training in that task. Instruct the NAP to report any redness, irritation, or open areas on the lower extremities. Instruct the NAP to ensure that all cords and connecting tubing are in a place that will not create a fall risk for the patient or visitors. SCDs should not be removed for long periods of time because they are needed to support the patient's peripheral circulation.

Instruct the NAP to ensure that all cords and connecting tubing are in a place that will not create a fall risk for the patient or visitors.

Pre-Procedure Assessment

- Assess cognitive level and level of consciousness.
  Patients with altered cognition may be at higher risk for falls related to the presence of the connecting tubing and attachment to the compression pump. Patients who are unconscious will not be able to report a device that is creating too much pressure.
- Assess signs and symptoms of severe peripheral arterial disease, such as weak or absent pulses, discoloration or cyanosis, or gangrene.
  Increased compression of vessels by the sequential device may further impede arterial flow.
- Assess skin condition. Note lesions, dermatitis, or major edema, as evidenced by shiny, taut skin.
  If skin is overstretched by edema, the sequential compression sleeve may irritate or worsen skin conditions and cause skin breakdown.

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Cleanse the lower extremities**, if necessary.
   Removes surface dirt and bacteria to decrease the likelihood of infection and odor.
2. **Apply elastic stockings** if they have been ordered in conjunction with the sequential compression device, following the steps in Procedure 39-2.
3. **For thigh-high SCD sleeves**, measure the circumference and length of both thighs to ensure that the sleeves are of the proper size. Follow the manufacturer's instructions.
4. **Position the patient supine.**
   Prevents venous pooling. Allows for easier application of the compression sleeve.
5. **Place the compression device** pump in a location near an electrical outlet so that the cord will not pose a fall risk.
   Plug in the pump.
   Note: Many compression pumps come equipped with hangers so you can hang the device at the bottom of the patient's bed.

6. **Apply the compression sleeve.**

For Flowtron Brand (available in knee-length only)

a. Open the Velcro fasteners on the sleeve.

b. Place the sleeve under the lower leg below the knee, with the "air bladder" side down on the bed.

c. Bring the ends of the sleeve up, and wrap them around the lower leg, leaving one to two fingerbreadths of space between the leg and the sleeve.
Prevents excess pressure and overcompression.

For SCDS/PAS Brands

a. Open the Velcro fasteners on the sleeve.

b. For thigh-high sleeves, place the opened sleeve under the leg, ensuring that the knee opening is at the level of the knee joint and that the fastener will close on the anterior surface.
Ensures that compression occurs over the correct structures. Prevents restricted range of motion (ROM) of the knee joint.

c. Bring the ends of the sleeve up, and wrap them around the leg, leaving one to two fingerbreadths of space between the leg and the sleeve.
Prevents excess pressure and overcompression.

7. **Connect the sleeve** to the compression pump.

8. **Turn the pump on** and, if applicable, set the compression pressure on the pump device to the manufacturer's recommended setting. *Note: In some facilities, the compression pressure amount is preset and can be changed only by the central supply/equipment department.*

Evaluation

After applying the device, make the following ongoing assessments:

- Inflation and deflation of the sleeve
  Ensures that the device is actually working.
- Kinking or pinching of the connecting tubing
  Interferes with inflation of sleeves and may cause overheating or malfunction of the unit.
- Circulation, sensation, and motion of the foot, including skin color, pulses, temperature, capillary refill, motion, and sensation
- Patient comfort
  Increasing discomfort may indicate excess or incorrect pressure.
- Skin condition. Remove the compression sleeves at intervals so that you can inspect skin and evaluate the adequacy of circulation. *Note: If elastic stockings are being used in conjunction with the sequential compression device, follow the recommendations in Procedure 39-2.*
- Signs and symptoms of deep vein thrombosis
  Even with sequential compression device therapy, a patient can still develop thrombi.

Patient Teaching

Teach the patient to call for assistance when disconnecting the tubing from the compression pump to ambulate.
Prevents patient falls. The SCD tubing is a tripping hazard, and injuries from falls involving SCDs are likely to be more severe than injuries associated with general patient falls (Johnston & Davis, 2008).

Documentation

- Document the date and time you applied the device.
- Note the type and size (if applicable) of the compression sleeve used.
- Document the skin condition, including any abnormalities.

Sample documentation

11/11/16 1100. Knee-high SCD applied per order. Skin warm, dry, and intact at time of application. Peripheral pulses palpable. Pt's wife instructed on use of SCD. Pt unresponsive. No evidence of discomfort, no grimace or movement with application. ——————S. Bee, RN

Practice Resources

Johnston, J., & Davis, M. (2008); Markel, D., & Morris, G. (2002); Nelson, E. A., Mani, R., Thomas, K., et al. (2011).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Applying Sequential Compression Devices**.

For questions and suggested responses,

Go to Chapter 39, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

Procedure 39-4 ■ Managing Gastric Suction

➤ No Author. (2007). *Best practices: Evidence-based nursing procedures* (2nd ed). Philadelphia: Lippincott.

➤ For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover.

Equipment

Procedure 39-4A Initial Equipment Setup

- Nonsterile procedure gloves
- Suction source (either a portable machine or piped-in wall source)
- Suction container and tubing
- Stopcock (to connect the NG tube to suction tubing)

Procedure 39-4B Emptying the Suction Container

- Clean nonsterile procedure gloves
- Graduated container

  To measure gastric output when emptying the suction container. Not needed if suction canister is marked for measuring.
- Alcohol wipes or chlorhexidine/alcohol antiseptic product

Procedure 39-4C Irrigating the Nasogastric Tubing

- Nonsterile procedure gloves
- Irrigating set (basin and bulb syringe or catheter-tipped syringe)
- Normal saline irrigant (unless another irrigant is prescribed)
- Linen-saver pads

Procedure 39-4D Providing Comfort Measures

- Nonsterile procedure gloves
- Emesis basin, cup, and water for mouth care
- Water-soluble lubricant
- Cotton-tip applicators
- Tissues or damp washcloth

Note: This procedure assumes an NG or other enteric tube is already in place and that its correct placement has already been verified. If you need to insert an NG tube or check placement, refer to Chapter 27. Tubes for gastric decompression are typically large-lumen tubes such as a Salem sump or Levin tube. See the table at the end of this procedure for more information about tubes.

Portable suction source. (Courtesy of Allied Healthcare Products, St. Louis, MO.)

Delegation

A registered nurse should do the initial setup and any subsequent irrigation. You may delegate a NAP to empty and measure drainage and perform comfort measures. You must monitor equipment functioning and the patient's responses to the decompression. Instruct the NAP about observations that should be reported to you.

Pre-Procedure Assessments

- Determine that the NG tube has been inserted and placement has been verified.
- Verify the prescriber's order for type of tube and whether it is to be placed to suction or a drainage bag; also verify the type of suction to be used (low, high, continuous, intermittent).
- Auscultate for bowel sounds.
- Assess the patient's ability to cooperate with the procedure and understand explanations.
- Refer to the Evaluation section of this procedure. This procedure assumes an NG tube is already in place, so assessments are ongoing.

Wall suction unit.

Procedure 39-4A ■ Initial Equipment Setup

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

Procedure Steps

1. **Place the collection container** in the holder (either on the portable suction machine or on the wall). Plug the power cord into a grounded outlet if using a portable suction machine.

2. **Connect the short tubing** between the container and the suction source. In some systems, the port will be marked "vacuum."

3. **Connect the long suction tubing** to the container (it may be marked "patient"); if one is available, connect a stopcock to the open end nearest the patient.

4. **Don nonsterile procedure gloves.**
   Helps prevent transfer of microorganisms.

5. **After the NG tube has been** inserted and placement verified, attach the end of the NG tube to the suction tubing.
   See Chapter 27 to review importance of tube placement. You must be certain the NG tube is in the stomach, not in the esophagus or airways.

6. **If the patient has a double-lumen** tube (e.g., Salem sump), instill 10 to 20 mL of air into the vent lumen to make sure it is patent. This should create a soft hissing sound.

7. **Check that the NG tube is secured** to the client's nose and gown (see Chapter 27 to review).
   Minimizes movement of the tube, helping to prevent irritation of the nares or other insertion site, as well as helping to keep the tube from migrating up out of the stomach.

8. **Turn on the suction source** to the prescribed amount. In an emergency when there is no order, always use low suction. Note the direction of the arrows and open the stopcock.

9. **Observe that drainage appears** in the collection container.
   It may take up to 5 minutes for air to be removed from the canister before the stomach contents will drain.

Procedure 39-4B ■ Emptying the Suction Container

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

1. **Don clean nonsterile gloves.**
   Limits the transfer of microorganisms; protects your hands from contact with body secretions.

2. **Turn off the suction source** and close the stopcock on the tubing (or clamp the tubing, if there is no stopcock).
   Prevents suction flow during emptying of the container.

3. **Empty the suction canister.**

For a suction container marked with measurements.
Note the amount, color, and odor of the contents. Empty and rinse the container.

For a suction container not marked incrementally.
Remove the cap from the lid of the suction container and pour the drainage into a graduated measuring container. Note color, odor, and amount.
A container with graduated markings enables you to monitor intake and output (I&O) accurately. Rinsing removes organic material that could be a reservoir for microorganisms.

4. **Wipe the port of the suction** container with an alcohol wipe. Place the suction container back in its holder and close the stopper on the lid.

5. **Turn on the suction source** to the prescribed amount. Note the direction of the arrows and turn the stopcock to the "On" position. If there is no stopcock, unclamp the tubing.

6. **Observe for proper functioning** of the suction and patency of the tubing.
   Prevents complications that would result from malfunction.

7. **Remove and discard your gloves.** Perform hand hygiene.

(continued on next page)

Procedure 39-4 ■ Managing Gastric Suction (continued)

Procedure 39-4C ■ Irrigating the Nasogastric Tubing

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

1. **Place a linen-saver pad** on the bed under the NG tube.
2. **Open the irrigation set** and pour saline into the basin.
   Water is not used because it may cause electrolyte imbalances.
3. **Place patient at a 30° to 45°** elevation (unless contraindicated or not tolerated)
   This position helps avoid gastric reflux of irrigant.
4. **Don clean procedure gloves.**
   Limits the transfer of microorganisms; protects your hands from contact with body secretions.
5. **Check for correct placement** of the NG tube using at least two bedside methods (see Chapter 28 as needed).
   Prevents accidental instillation of irrigant into the airways.
6. **Fill the syringe with 10 to 30 mL** of saline and place it on the linen-saver pad.
7. **Clamp the NG tube** or turn off the stopcock connecting to the suction tubing. Then disconnect the NG tube from the suction tubing.
   Prevents backflow of drainage and soiling of linens and clothing.
8. **Hold the drainage tubing up** until suction clears it. Then place it on the linen-saver pad or hook it over the suction machine.
   Keeps secretions from soiling the bed linens or clothing.
9. **Turn off the suction machine.**
10. **Unclamp the NG tube** or turn on the stopcock.
11. **Unpin the NG tube** (or remove tape) from the patient's clothing.
12. **Attach the syringe and instill** the irrigant slowly into the NG tube. Do not force the solution. Be careful not to instill fluid into the air vent.
    Clears the NG tube of gastric contents to keep it patent and helps keep the tube from adhering to the gastric mucosa. Partially digested food, clotted blood, or tissue debris may clog the tube and prevent effective drainage.
13. **Lower the end of the NG tube** and then release the syringe bulb (or, depending on the type of syringe, pull back the plunger) to withdraw fluid. Instill and withdraw until fluid flows in and out freely.
    Uses the force of gravity with negative pressure to withdraw instilled fluid and gastric contents.

For a Double-Lumen NG Tube

Draw 30 mL of air into the syringe and inject it into the "pigtail" (the smaller-bore tube). Follow agency policy for this.
This clears the air-vent tube of any secretions. It must be patent in order to equalize pressure and prevent gastric tissue trauma at the drainage ports. The air also keeps the tube from draining fluid out of the stomach by capillary action.

14. **Reclamp the NG tube** or turn off the stopcock.
    Prevents backflow of drainage.
15. **Reconnect the NG tube** to the suction tube. Then release the clamp or turn on the stopcock.
16. **Reattach the NG tube** to the patient's clothing (with a pin or tape—see Chapter 27 as needed).
    Prevents pulling on and irritating the patient's nostril.
17. **Provide comfort measures** (e.g., mouth care).
18. **Remove and discard gloves**. Perform hand hygiene.

Procedure 39-4D ■ Providing Comfort Measures

➤ When performing the procedure, always identify your patient according to agency policy, using two identifiers, and be attentive to standard precautions, hand hygiene, patient safety and privacy, body mechanics, and documentation.

1. **Don clean nonsterile procedure gloves**.
2. **Provide mouth care** (see Procedures 25-6, 25-7, and 25-8 if you need to review). Use mouthwash as desired. Avoid using lemon-glycerine swabs. Apply water-soluble lubricant to the lips if they become dry and crusty.
   The patient most likely has a dry mouth from not receiving oral intake and from mouth breathing. Lemon-glycerine swabs cause even more drying of tissues.
3. **Remove nasal secretions** with a tissue or a damp washcloth. Moisten a cotton-tip applicator and wipe the inside of each nostril. If secretions are encrusted, moisten the applicator with hydrogen peroxide, then follow with an applicator moistened with water.
   To soften, dissolve, and remove secretions and prevent tissue irritation.
4. **Apply a small amount of** water-soluble lubricant to the inside of each nostril.
   Soothes and softens dried skin. Avoid petroleum-based lubricants, as complications may occur if they are inhaled.
5. **Check that the tape or tube** fixation device is secure. If it is not, replace it (see Procedure 27-2 as needed).
   Prevents irritation of the nasal skin and mucosa. Helps prevent migration of the NG tube from the stomach.

? What if . . .

- **Resistance is met when you irrigate the NG tube?**

  Check the tubing for kinks or evidence of obstruction. Have the patient turn to the left side.

  Turning to one side changes the position of the distal tip of the NG tube.

- **The patient complains that the NG tube is pulling against her nostril?**

  The tube may not be properly anchored to her clothing. Reattach the safety pin (or tape) closer to the nose so that there is more slack in the tube.

- **The NG tube causes excoriation of the nares?**

  Remove the tape or fixation device from the nose. Remove the residual adhesive from the skin. Apply skin sealant and anchor the tube so that the adhesive touches in a different place on the skin. Keep the excoriated areas clean and dry.

- **The NG tube does not drain?**

  Check tubing for kinks or blockage. Check the suction apparatus. If the collection container is higher than the patient's abdomen, lower it. If these aspects are working properly, irrigate the tube (see Procedure 39-4C, preceding). If the tube still is not draining and the patient is uncomfortable, document and notify the primary care provider. Encourage the patient to relax and breathe slowly through her nose. If the patient has abdominal distention, pain, or vomiting, notify the provider immediately.

  If the container is too high, the negative pressure of low suction may not be enough to overcome the force of gravity. Abdominal distention, pain, or vomiting may mean the system is not working. Continued distention creates undue strain on the suture line. You should notify the care provider of these symptoms even when the mechanical aspects of the suction seem in working order.

Gastric Decompression Tubes

TYPE	LUMEN(S)	USE	MANAGEMENT	DISCUSSION
Levin	1, unvented	Decompression, feedings, or irrigation	Use low intermittent suction; may require irrigation.	If the tube opening(s) rest(s) against the gastric mucosa, the suction may irritate or injure the tissue.
Salem Sump	2	Decompression, suction, gastric lavage	Vented. May use high continuous suction.	The air vent helps keep the tube away from the gastric mucosa during suction.
Sengsten–Blakemore	3	Decompression; treatment of active bleeding from esophageal or gastric varices	Use low intermittent suction.	Gastric or esophageal balloons hold the tube in place.
Cantor	1, unvented	Decompression	Use intermittent suction.	Distal end is weighted with a balloon. Used in bowel obstruction. Rarely used because of the hazard posed by the mercury in the weighted balloon.
Miller–Abbott	2	Decompression	Use intermittent suction	Distal end weighted with a balloon. Used in bowel obstruction. Rarely used because it contains mercury in the weighted balloon.
Ewald or other very large-bore tube	May be passed orally for emergency evacuation of stomach contents to prevent absorption of ingested medications, poisons, or products. A piston tip syringe is placed on the end of the tube for manual suction. Typically the stomach is washed repeatedly with saline and all contents are withdrawn. Because of its large diameter, this type of tube is not tolerated by patients who are alert, and is not left in place after lavage is completed.			
Weighted Small-Bore Tubes (e.g., Keofeed)	For feedings only. Suction collapses the tube.			

(continued on next page)

Procedure 39-4 ■ Managing Gastric Suction (continued)

Evaluation and Maintenance

- Periodically assess placement of the tube by a combination of methods (i.e., checking pH of aspirate, by listening over the stomach with a stethoscope while injecting air into the tube, and by reviewing radiographic reports). See Chapter 26 for review, as needed.
- Monitor patency of the tube and the effectiveness of the suction. Check tube connections.
- Monitor patient comfort (e.g., sore throat).
  The continuing presence of a tube in the nose and throat is bothersome to patients. The major nuisance is the pressure of the tube against the internal mucous membranes, irritating the nostril, pharynx, and esophagus.
- Auscultate for bowel sounds; turn off suction while auscultating.
  Bowel sounds indicate the return of peristalsis and the success of gastric decompression. You may hear the sound of the suction apparatus and misinterpret it as bowel sounds.
- Monitor for gastric distention, vomiting, and abdominal pain.
  These symptoms probably indicate the suction is not working effectively. See the What If . . . section, preceding.
- Examine skin and mucous membranes around the insertion site (e.g., nares, abdomen).
- Follow agency policy or the primary care provider's prescription for irrigation of the gastric tube. It is common to irrigate with 10 to 30 mL of normal saline every 3 to 4 hours.
- Monitor the color of the drainage (should be green to gold). If there is blood in the drainage, notify the primary care provider.
- For clients undergoing prolonged GI suction, observe for signs and symptoms of hyponatremia and hypokalemia (i.e., fatigue, lethargy, confusion, seizures, muscle weakness, paresthesia, and cardiac dysrhythmias). Review lab results and report any symptoms to the primary care provider.
- Assess the patient's ability to move about in bed while attached to the suction source.

Patient Teaching

- Instruct the patient to notify you of any discomfort, and to not tug on or try to reposition the NG tube if it becomes uncomfortable.
- Instruct the patient to notify you if feeling nauseated.
  This could mean the tube is blocked and not draining effectively.

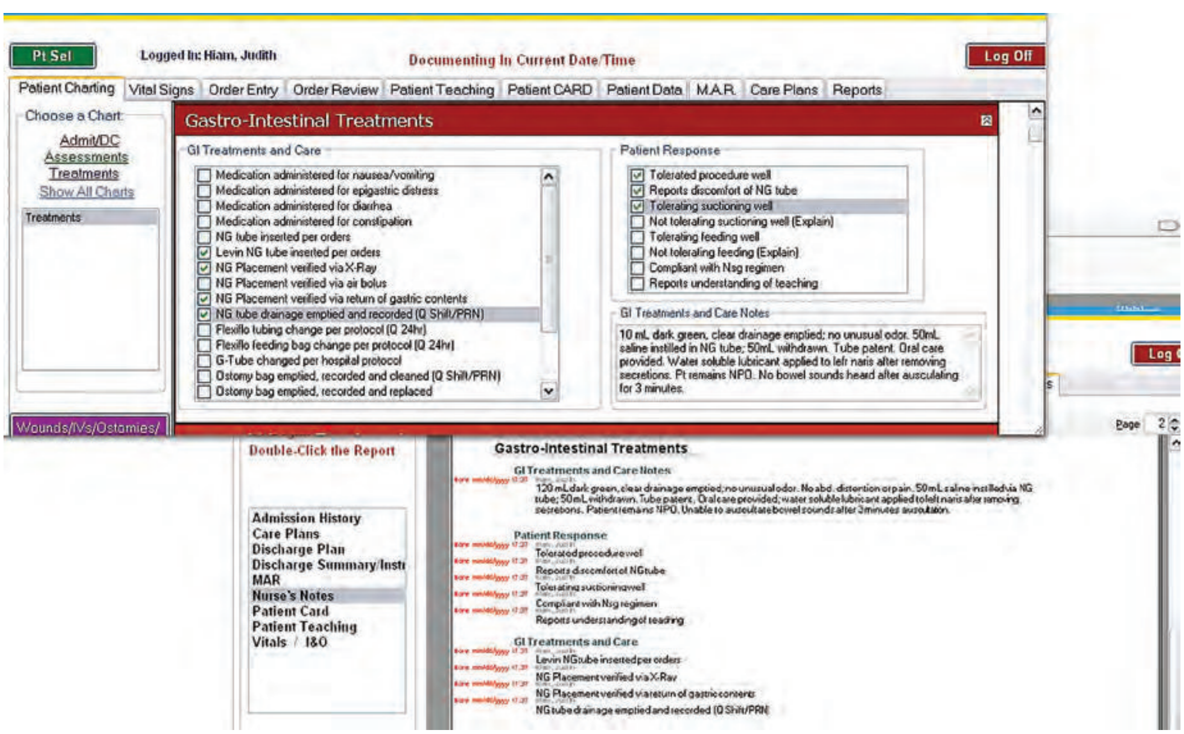
Home Care

Usually, gastric suction is performed in a hospital. If the client is to go home with gastric suction (e.g., a terminally ill person who has a bowel obstruction and wants to be in his or her own home), teach the family how to use the device before the person is discharged. Also arrange for home healthcare.

Documentation

- Record all drainage as output on the I&O record.
- Record the time, type, and volume of irrigations and the drainage returned.
- Be sure to include irrigation fluids as input on the I&O record.
- Note color, odor, and consistency of drainage.
- Document patient's emotional and physical responses to NG intubation.
- Document any evidence of tube or equipment malfunction.
- Document epigastric pain, discomfort, distention, or vomiting.

Sample electronic documentation



Practice Resources

Allied Healthcare Products, Inc. (n.d.); Bankhead., R., Boullata, J., Brantley, S., et al. (2009); *Best Practices* (2007); Green, S., Harris, C., & Singer, J. (2008); Sarasota Memorial Hospital (2008, reviewed 2011).

Thinking About the Procedure

To practice applying clinical reasoning to this procedure,

Go to *Davis's Nursing Skills Videos*, **Managing Gastric Suction: Initial Equipment Setup, Emptying the Suction Container, if Irrigating the Nasogastric Tubing.**

For questions and suggested responses,

Go to Chapter 39, **Thinking About the Procedure Questions and Suggested Responses,** on Davis*Plus*.

CLINICAL INSIGHTS

Clinical Insight 39-1 ➤ Preoperative Teaching

Explain What to Expect Before Surgery

- Explain the planned preoperative testing—lab tests, x-ray studies, ECG, and so on.
- Discuss skin preparation, including preoperative wash with an antibacterial product if this is included in the treatment plan.
- Discuss prescribed preoperative medications.
- Outline activities that will occur before surgery, such as insertion of an IV, placement of a urinary catheter, or cardiac monitoring.
- Review the preoperative restriction of fluid and food. Often the patient is to be NPO for at least 8 hours before the planned start of surgery. Some guidelines indicate that most children can drink clear liquids until 2 hours before surgery (Crenshaw, 2011, Joanna Briggs Institute, 2008a; "Practice Guidelines for Preoperative Fasting," 2011).
- If the patient is having surgery on the gastrointestinal (GI) tract, an additional bowel prep may be ordered (e.g., a low-residue diet beginning 1 week before surgery, and a liquid diet for the 48 hours preceding surgery). Patients having GI surgery also may have enemas before surgery. (If you need to review special diets, refer to Chapter 27.)
- Explain the need to remove jewelry, makeup, hearing aids, glasses, contact lenses, and any removable dental prostheses before being transported to the operating suite. It is best to have a family member take valuable belongings home for safekeeping.
- Tell the patient that a member of the anesthesia team will speak with him about the proposed anesthesia before surgery.
- Give the patient and family a tentative schedule for the operative day, including the time to arrive at the hospital or surgery center.

Explain What to Expect in the Operative Suite

- Inform the patient and family where they can go to wait during surgery.
- Discuss the preoperative holding area and activities that may occur there.
- Describe the operating room and the activities that the patient may anticipate before the surgery.
- Explain that the anesthesiologist or nurse anesthetist will monitor the patient and is responsible for keeping him comfortable with medications throughout the procedure.
- Describe the types of people who may be present in the operative suite. This is particularly important if the patient is not receiving a general anesthetic.

Explain What to Expect After Surgery

- Explain that the patient will initially be cared for in the postanesthesia care unit. After a period of observation, he will be transferred to the surgical unit. Note that some patients may be transferred directly to a critical care unit after surgery. If this is expected, tell the patient and family about this preoperatively.
- Family may visit after the patient has been admitted and assessed on the surgical unit.
- Tell the patient what to expect in terms of dressings, equipment, and monitoring devices.
- Describe the types of assessments that will be performed.
- Explain that pain medication will be given to keep the patient comfortable. If he experiences pain, he should tell the nursing staff.
- Discuss the usual progression of recovery, including activity level, deep breathing, coughing, leg exercises, and dietary intake.
- Discuss the anticipated length of stay.
- Teach the importance of deep breathing and coughing, especially after general anesthesia. Demonstrate how to splint the incision to facilitate deep breathing and coughing. Refer to Procedure 39-1A.
- Teach the patient how to move into and out of bed after surgery.
- Teach and emphasize the importance of leg exercises to minimize the risk of thrombus formation. Refer to Procedure 39-1C.
- If decreased activity or prolonged bedrest is anticipated, explain the use of antiembolism stockings or sequential compression devices.

Note: If the patient is to be discharged the day of surgery, inform him in advance about what to wear to the facility, and explain that he must arrange for a responsible adult to drive him home.

Clinical Insight 39-2 ➤ Preparing a Room for a Patient's Return From Surgery

In many institutions, the patient is transported to surgery using the bed that is in his hospital room, so these steps may vary.

- Put clean linens on the bed, including pads to protect the linen from drainage.
- Fold the linens back to the end of the bed.
- Raise the bed to stretcher height, and lock the wheels.
- Move furniture and equipment so that the stretcher can be placed directly against the bed.
- If needed, set up suction, oxygen, or other special equipment.
- Place the following equipment in the room:
  Stethoscope, manometer, thermometer (to measure vital signs)
  IV pole
  Emesis basin
  Tissues
  A clean gown, washcloth, and towel
  Extra pillows for positioning the patient

Clinical Insight 39-3 ➤ Creating an Operative Field

- A nonsterile team member (usually the circulating nurse) performs a surgical prep, using a scrub agent and "paint," to cleanse the operative site. Antiseptic agents must be approved by the U.S. Food and Drug Administration and by the agency's infection control professional. Chlorhexidine and povidone-iodine solutions are most commonly used.
- The area surrounding the operative site is then covered with sterile drapes so that only the operative area is exposed.

In the intraoperative period, sterile team members are the only persons allowed to enter the sterile field. The sterile field encompasses the patient and the area immediately surrounding the client. Creation of the sterile field proceeds as follows:

- Don head covering and shoe covers before entering the surgical suite.
- Perform a surgical scrub.
- Don sterile gown, gloves, and other surgical attire (e.g., mask).
- Cover the area surrounding the operative site with sterile drapes so that only the patient's operative area is exposed.
- Place sterile draping over the remainder of the patient's body.
- (In most cases) suspend a vertical drape at neck level so the client's head and airway are accessible to the anesthesiologist or nurse anesthetist (who is not sterile). For neurosurgery, even the head is draped, and the anesthesiologist or nurse anesthetist sits to the side of the head.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Preoperative Assessment Topics

Include the following information in your preoperative assessment.

Health History—Discuss current and chronic health problems and prior hospitalizations or surgeries.

Physical Status—Identify any mobility concerns, and determine whether the client uses hearing aids, glasses, or contact lenses. Identify risk factors for venous thromboembolism (AORN, 2009, updated 2011):

- Venous stasis (such as occurs with bedrest, lengthy surgery, varicose veins, and heart failure)
- Vascular wall injury, which initiates clotting (e.g., surgery, IV catheter, irritating IV drugs, prior deep vein thrombus, smoking).
- Hypercoagulability (e.g., estrogen therapy, oral contraceptive use, cancer, dehydration, pregnancy)
- Older adults, especially those with other risk factors

Allergies—Check allergies to medications, food, tape, soaps, latex, or other substances.

Medications—Ask what prescribed medications and over-the-counter, herbal, or natural remedies the client takes (e.g., echinacea, ephedra, garlic, ginkgo biloba, ginseng, and St. John's wort). For more details about herbal products,

Go to Student Resources: Chapter 39, **Tables, Boxes, Figures: ESG Box 39-1, Examples of Risks Associated With Herbal Products,** on Davis*Plus*.

Mental Status—Note whether the client is able to respond to questions and offer a health history. Is he oriented? Does he appear anxious?

Knowledge—Understanding of the surgery and anesthesia. Ask the client to explain in his own words the planned surgery and postoperative course. Reinforce accurate statements, and correct any misconceptions.

Cultural and Spiritual Factors—Identify any cultural practices or spiritual beliefs that bring comfort to the client. Discuss how you can integrate these practices into the client's surgical experience.

Access to Social Resources—Identify the client's support network. Who is available to assist the client after surgery? Whom does the client rely on? Are those people aware of the client's upcoming surgery and condition?

Coping Strategies—Ask the client to identify the strategies he uses to cope with stress.

Use of Alcohol and Recreational Drugs—Inquire about the amount and frequency of alcohol use. Discuss the use of pain medications and recreational drugs. If the client uses these substances, identify the amount and frequency.

Focused Assessment

Intraoperative Care Questionnaire

Common nursing interview questions include the following:

- What is your name?
- What type of surgery are you going to have today?
- Is someone here with you?
- Are you allergic to any medications, latex, or tape?
- When is the last time that you had anything to eat or drink?
- Do you have false teeth, contact lenses, or any other prostheses that need to be removed?
- Have you taken any medications today?
- Do you have any implants, such as metal plates or a pacemaker?
- Do you have any scratches, bruises, or other wounds on your body at this time?
- Are there any parts of your body that are painful, such as a stiff shoulder or leg?

Also see the WHO Surgical Safety Checklist, preceding.

Focused Assessment

Postanesthesia Assessment: Essential Elements

The postanesthesia care nurse performs a quick, focused initial assessment of the surgical patient in the presence of the anesthesia provider and circulating RN. After that, the nurse assesses the patient every 5 to 15 minutes. The AORN (2009, updated 2011) has identified the essential elements of assessment in the PACU.

- ***Vital signs***
  - Blood pressure, cuff or arterial
  - Respiratory rate, respiratory competence, and breath sounds
  - Respiratory adequacy, including skin color and condition
  - Temperature (record type of measurement used, for example, skin, tympanic, oral)
  - Pulse (apical and peripheral)
  - Oxygen saturation (e.g., pulse oximeter reading)
- ***Peripheral circulation*** (postoperative tissue perfusion), for example, peripheral pulses and sensation at extremities
- ***Neurological status***, including pupil response and intracranial pressure (if indicated)
- ***Mental status***, including level of consciousness, alertness, lucidity, orientation

Older adults make up nearly 40% of surgical patients, and dementia is among the most common surgical complications, including postoperative delirium.

- ***Intravenous therapy***, including patency, location of sites, rates of solution(s), and/or blood products infusing
- ***Allergies and sensitivities***
- ***Pain***
- ***Motor abilities***, including return of sensory and motor control in areas affected by local or regional anesthetics
- ***Skin integrity***
- ***Temperature regulation***
- ***Positioning***
- ***Surgical incision site***, including condition of suture line(s) if visible
- ***Nausea and vomiting***
- ***Fluid and electrolyte balance***
- ***Safety needs*** (e.g., siderails raised)
- ***Central venous pressure (CVP), pulmonary wedge pressure***
- ***Airway***: patency, presence of artificial airway, mechanical ventilator settings
- ***Condition of dressing(s)***
- ***Drainage***, including type; patency; and amount and type of drainage from dressings, tubes, and catheters

DIAGNOSTIC TESTING

Diagnostic Testing

Common Preoperative Screening Tests

Test	Uses
Urinalysis	To detect urinary tract infections (UTIs) and the presence of glucose or protein in the urine, which may indicate poorly controlled diabetes or renal disease
Complete blood	To detect irregularities in hemoglobin (Hgb) and count (CBC) hematocrit (Hct) A low Hgb level is an indication of anemia, which may place the client at risk if significant blood loss occurs Measures white blood cell (WBC) count as an indicator of immune function Measures platelet count, which affects clotting ability
ECG	To detect cardiac dysrhythmias (electrocardiogram) and other cardiac pathology
Chest x-ray	To detect for or evaluate underlying cardiopulmonary disease that examination may lead to postoperative complications
Blood type and crossmatch	To identify blood type in the event that blood transfusion is needed
Serum electrolytes	To detect sodium, potassium, chloride, magnesium, calcium, and pH imbalances, which affect cardiac and other organ function and fluid balance
Fasting blood sugar	To detect diabetes or poorly controlled diabetes
Comprehensive metabolic panel	Includes electrolytes, blood glucose, liver function tests (ALT, AST), serum albumin and protein, and renal function tests (BUN and creatinine); used to detect underlying health problems that may affect surgical risk or outcome

Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions

NURSING DIAGNOSES	OUTCOMES AND GOALS	NURSING INTERVENTIONS AND ACTIVITIES
These interventions are not routinely done for all patients. They are specific to patients who have the defining characteristics of each nursing diagnosis.		
Activity Intolerance r/t pain, the surgical procedure, and stressors of surgery	***NOC outcomes:*** Activity Tolerance Endurance Energy Conservation Psychomotor Energy ***NOC goals:*** ➤ O_2 saturation, heart rate, respiratory rate, systolic and diastolic blood pressure not compromised with activity ➤ Ease of breathing with activity not compromised ➤ Walking pace and distance not compromised ➤ Ease of performing activities of daily living (ADLs) not compromised ➤ Ability to speak with physical activity not compromised ➤ Energy restored after rest, not compromised ➤ Uses naps to restore energy, often demonstrated. ➤ Exhibits concentration, consistently demonstrated.	***NIC interventions:*** Activity Therapy Energy Management Exercise Promotion: Strength Training ***Nursing activities:*** ➤ Collaborate with [other disciplines] in planning and monitoring an activity program, as appropriate. ➤ Assist patient to choose activities . . . consistent with capabilities. ➤ Assist patient to focus on abilities rather than weaknesses. ➤ Encourage creative activities. . . . ➤ Instruct patient and family how to perform desired or prescribed activity. ➤ Refer to community centers, programs as appropriate. ➤ Arrange physical activities to reduce competition for oxygen supply to vital body functions (e.g., avoid activity immediately after meals). ➤ Avoid care activities during scheduled rest periods. ➤ Assist patient to sit on side of bed ("dangle"), if unable to transfer or walk. ➤ Monitor location and nature of pain during activity. ➤ Teach activity organization and time management techniques to prevent fatigue.
Acute Pain r/t (1) inflammation or injury in the surgical area, (2) abdominal distention secondary to decreased peristalsis, (3) muscle pain secondary to positioning and tension	***NOC outcomes:*** Pain Control Pain Level ***NOC goals:*** ➤ Consistently rates pain as controlled ➤ No moaning and crying ➤ No facial expressions of pain ➤ Describes causal factors, often demonstrated ➤ Uses preventive measures, consistently demonstrated. ➤ Uses nonanalgesic relief measures, often demonstrated. ➤ Uses analgesics as recommended, consistently demonstrated. ➤ Reports changes in pain symptoms to a health professional, consistently demonstrated. ***Other goals:*** No guarding of incision	***NIC interventions:*** Analgesic Administration Pain Management Patient-Controlled Analgesia Assistance ***Nursing activities:*** ➤ Perform a comprehensive assessment of pain to include location, characteristics, onset/duration, frequency, quality, intensity or severity of pain, and precipitating factors. ➤ Observe for nonverbal discomfort cues. ➤ Assure the patient attentive analgesic care. ➤ Consider cultural influences of responses to pain. ➤ Utilize developmentally appropriate assessment method. . . . ➤ Determine the needed frequency of making a pain assessment and implement monitoring plan. ➤ Provide information about the pain, such as causes, how long it will last, and anticipated discomforts from procedures. ➤ Control environmental factors that may influence the client's response to discomfort (e.g., room temperature . . . , noise). ➤ Provide the person optimal pain relief with prescribed analgesics.

Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions—cont'd

NURSING DIAGNOSES	OUTCOMES AND GOALS	NURSING INTERVENTIONS AND ACTIVITIES
		➤ Implement patient-controlled analgesia as appropriate. ➤ Use pain control measures before pain becomes severe. ➤ Encourage patient to use adequate pain medication. ➤ Medicate before activity to increase participation, but evaluate the hazard of sedation. ➤ Teach nonpharmacological pain relief measures (e.g., guided imagery, progressive muscle relaxation). ➤ Utilize multidisciplinary approach to pain management.
Anxiety r/t change in health status, hospital environment	***NOC outcomes:*** Anxiety Level Anxiety Self-Control ***NOC goals:*** ➤ Consistently uses effective coping strategies. ➤ Often seeks information to reduce anxiety. ➤ Consistently uses relaxation techniques to reduce anxiety. ➤ Often maintains concentration. ➤ Verbalizes that anxiety is mild. ➤ Minimal restlessness, hand wringing, muscle tension, facial tension, difficulty concentrating. ➤ Mild changes in vital signs; no dilated pupils, sweating or dizziness ➤ Controls anxiety response consistently.	***NIC intervention:*** Anxiety Reduction ***Nursing activities:*** ➤ Use calm, reassuring approach. ➤ Assess for verbal and nonverbal signs of anxiety. ➤ Explain all procedures, including sensations likely to be experienced during the procedure. . . . ➤ Provide factual information concerning diagnosis, treatment, prognosis. ➤ Administer back rub or neck rub as appropriate. ➤ Listen attentively. ➤ Create trusting atmosphere. ➤ Help patient to identify situations that precipitate anxiety. ➤ [Assist the client to recognize that she is anxious]. ➤ Determine patient's decision-making ability. ➤ Encourage verbalization of feelings, perceptions, and fears [related to the surgical procedure]. ➤ Encourage family to stay with patient, as appropriate. ➤ Support use of appropriate defense mechanisms. ➤ Instruct the patient on the use of relaxation techniques.
Risk for Bleeding r/t side effects of surgery	***NOC outcomes:*** Blood Loss Severity Circulation Status ***NOC goals:*** ➤ (4) Systolic and diastolic blood pressure, mild deviation from normal. ➤ (5) Mean blood pressure not compromised. ➤ (5) Central venous pressure not compromised. ➤ (4)Urine output mildly compromised. ➤ (5) Hemoglobin and hematocrit are not compromised. ➤ (4) Mild Orthostatic hypotension present.	***NIC interventions:*** Bleeding Precautions Incision Site Care Surveillance ***Nursing activities:*** ➤ Monitor patient closely for hemorrhage. ➤ Note hemoglobin and hematocrit levels before and after blood loss as indicated. ➤ Monitor orthostatic vital signs, including blood pressure and pulse. ➤ Note characteristics of any drainage. ➤ Monitor the healing process at the incision site. ➤ Monitor for signs and symptoms of fluid and electrolyte imbalance. ➤ Monitor tissue perfusion, as appropriate. ➤ Activate rapid response team if indicated by patient bleeding or vital signs.

Standardized Language

Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions—cont'd

NURSING DIAGNOSES	OUTCOMES AND GOALS	NURSING INTERVENTIONS AND ACTIVITIES
Nausea r/t manipulation of gastrointestinal tract, decreased peristalsis secondary to anesthesia	***NOC outcomes:*** Nausea & Vomiting Control Nausea & Vomiting: Disruptive Effects Nausea & Vomiting Severity Nutritional Status: Food & Fluid Intake ***NOC goals:*** ➤ (5) Reports nausea, retching, and vomiting controlled. ➤ (4) Mild or no intolerance of odors ➤ (4) Mild or no intolerance of movement ➤ (5) Recognizes onset of nausea. ➤ (5) Recognizes precipitating stimuli. ➤ (4) Frequency, intensity, and distress of nausea are mild. ➤ (5) Uses preventive measures often. ➤ (4) Only mild decrease in food and fluid intake ➤ (5) No weight loss ➤ (5) Reports bothersome side effects from antiemetics. ➤ (5) Reports failure of antiemetic treatment.	***NIC interventions:*** Nausea Management Medication Management ***Nursing activities:*** ➤ Provide information about the causes of nausea and how long it will last. ➤ Teach patient and/or family members the expected action and side effects of the [antiemetic] medication. ➤ Monitor recorded intake for nutritional content and calories. ➤ Encourage to monitor own nausea experience, including use of a symptom diary. ➤ Encourage patient to learn strategies for managing own nausea. ➤ Perform complete assessment of nausea, including frequency, duration, severity, and precipitating factors. . . . ➤ Observe for nonverbal cues of discomfort. . . . ➤ Evaluate past experiences with nausea (e.g., pregnancy and car sickness). ➤ Identify strategies that have been successful in relieving nausea. ➤ Teach the use of nonpharmacological techniques (e.g., guided imagery, self-hypnosis, relaxation, biofeedback, music therapy, distraction, acupressure) to manage nausea. ➤ Use frequent oral hygiene to promote comfort, unless it stimulates nausea. ➤ [Keep tissues and water to rinse the mouth nearby.] ➤ Give cold, clear liquid, odorless and colorless food, as appropriate. ➤ Instruct in high-carbohydrate and low-fat foods, as appropriate. ➤ Encourage eating small amounts of food that are appealing to the person. ➤ Encourage to drink cola, but not too cold; suck on an ice cube, sorbet, or a piece of frozen fruit. (non-NIC) ➤ Have the client sit in an upright position for 30 to 45 minutes after eating. (non-NIC) ➤ Control environmental factors that may evoke nausea (e.g., odors, sound, and unpleasant visual stimuli). ➤ Ensure that effective antiemetic drugs are given to prevent nausea when possible. . . .
Constipation r/t decreased activity, decreased food or fluid intake, decreased peristalsis secondary to anesthesia, pain medication	***NOC outcome:*** Bowel Elimination ***NOC goals:*** ➤ Elimination pattern not compromised ➤ Reports ease of stool passage not compromised.	***NIC interventions:*** Bowel Management Constipation/Impaction Management ***Nursing activities:*** ➤ Monitor for signs and symptoms of constipation. ➤ Note date of last bowel movement.

(continued)

Standardized Language

Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions—cont'd

NURSING DIAGNOSES	OUTCOMES AND GOALS	NURSING INTERVENTIONS AND ACTIVITIES
	➤ Bowel sounds not compromised ➤ Muscle tone to evacuate stool not compromised ➤ Passes soft, formed stool in amount appropriate for diet. ➤ No pain with passage of stool ***Other:*** ➤ Bloating not present (non-NOC)	➤ Monitor bowel sounds. ➤ Monitor frequency, consistency, shape, volume, and color of bowel movements. ➤ Teach the patient about specific foods that assist in promoting bowel regularity. ➤ Insert a rectal suppository (or enema or irrigation), as appropriate. ➤ Evaluate medication profile for GI side effects (e.g., narcotic analgesics). ➤ Give warm liquids after meals, as appropriate. ➤ Encourage increased fluid intake, unless contraindicated. ➤ Instruct the client in foods high in fiber, as appropriate.
Urinary Retention r/t anesthesia, preoperative medications (anticholinergics), pain, fear, unfamiliar surroundings, client's position	***NOC outcome:*** Urinary Elimination ***NOC goals:*** ➤ Empties bladder completely, not compromised ➤ Fluid intake not compromised ➤ No hesitancy with urination ***Other:*** ➤ Bladder not palpable ➤ Reports subjective feeling of empty bladder. ➤ 24-hour intake and output balanced	***NIC interventions:*** Urinary Catheterization Urinary Retention Care ***Nursing activities:*** ➤ Perform comprehensive urinary assessment (e.g., urinary output, voiding pattern, cognitive function, preexisting urinary problems). ➤ Provide privacy for elimination. ➤ Use power of suggestion (run water, flush toilet). ➤ Provide enough time (10 minutes) for bladder emptying. ➤ Use spirits of wintergreen in bedpan or urinal. ➤ Insert urinary catheter as appropriate. ➤ Use percussion and palpation to estimate degree of bladder distention. (non-NIC) ➤ Catheterize for residual as appropriate.
Delayed Surgical Recovery (etiologies will vary with pathology) (*Note:* This diagnosis is broad and encompasses some of the other diagnoses. If the client has Delayed Surgical Recovery, you will not, for example, need a diagnosis of Nausea on the plan of care.)	***NOC outcomes:*** Ambulation Blood Loss Severity Endurance Hydration Infection Severity Nausea & Vomiting Severity Pain Level Post-Procedure Recovery Wound Healing: Primary Intention ***NOC goals:*** ➤ Decrease in systolic or diastolic blood pressure, mild. ➤ Energy restored after rest. ➤ Tissue perfusion not compromised. ➤ Ambulation tolerance in normal range ➤ No nausea, vomiting, shivering	***NIC interventions:*** Embolus Precautions Exercise Therapy: Ambulation Incision Site Care Nutrition Management Pain Management Self-Care Assistance ***Nursing activities:*** ➤ Inspect the incision site for redness, swelling, or signs of dehiscence. ➤ Monitor for postoperative complications. ➤ Monitor the healing process in the incision site. ➤ Provide incision care as needed. (non-NIC) ➤ Teach the client and family how to care for the incision, including signs and symptoms of infection. ➤ Facilitate early ambulation postoperatively.

Standardized Language

Postoperative Patients: Selected Standardized Nursing Diagnoses, Outcomes, and Interventions—cont'd

NURSING DIAGNOSES	OUTCOMES AND GOALS	NURSING INTERVENTIONS AND ACTIVITIES
	➤ No fever. ➤ Only mild pain ➤ No post-surgical bleeding ***Other:*** ➤ Ready for discharge within prescribed length of stay for surgery performed ➤ No postoperative complications (e.g., bleeding, infection, delayed wound healing, pneumonia)	➤ Instruct patient on diet requirements for disease state (e.g., for wound healing, encourage increased intake of protein, iron, and vitamin C, as appropriate). ➤ Determine number of calories and type of nutrients needed to meet nutrition requirements. ➤ Select and implement a variety of measures (e.g., pharmacological, nonpharmacological, interpersonal) to facilitate pain relief, as appropriate. ➤ Teach principles of pain management. ➤ Encourage independence, but intervene when the client is unable to perform.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Recall Nishad Singh (Meet Your Patient, in Volume 1). He is a 68-year-old man who came to the emergency department (ED) with sudden onset of rectal bleeding. He had been "tired and dragging for several months." The ED nurse identified nursing diagnoses of Mild Anxiety, Pain, and Risk for Bleeding. Preoperatively, his vital signs were as follows:

BP: 138/88 mm Hg
Pulse: 104 beats/min and regular; 120 beats/min; 134 beats/min
Respiratory rate: 20 breaths/min
Temperature: 36.7°C (98.0°F)
Oxygen saturation: 98%

Mr. Singh was admitted to the hospital where he received an IV of 1,000 mL of lactated Ringer's solution and a unit of packed red blood cells. He was to undergo emergency colon resection surgery; however, a left hemicolectomy including the sigmoid colon and the anus was required. He spent 4 hours in the PACU, until his vital signs stabilized. Mr. Singh now has a colostomy high in his descending colon, with a stoma on his left abdomen slightly superior to the level of his umbilicus. He also has an abdominal incision that was made for exploration. On the next day after the surgery, the surgeon informed Mr. Singh that he has widespread adenocarcinoma (cancer) of the colon with metastasis to the liver. The nurse has identified these four nursing diagnoses (among others):

Deficient Knowledge (colostomy care) r/t lack of prior experience and no preparation prior to surgery
Fear r/t diagnosis of colon cancer, liver metastasis, and possible terminal illness
Pain secondary to surgical incision and manipulation of abdominal organs during the surgical procedure
Risk for Impaired Skin Integrity r/t irritation from fecal drainage and ostomy pouch

THINKING

1. *Theoretical Knowledge:*
   a. What is a left hemicolectomy? If you do not know the answer, consult an appropriate reference.
   b. What does "metastasis to the liver" mean? If you do not know the answer, consult an appropriate reference.
2. *Critical Thinking (Inquiry):*
   a. Why might Mr. Singh have needed a colostomy instead of having his transverse colon reconnected to the remaining lower colon or rectum? State the reference you used to answer this question.
   b. Why do you think Mr. Singh has a colostomy above the level of the umbilicus and not lower down in his abdomen? State the reference you used to answer this question.

DOING

3. *Practical Knowledge:* Mr. Singh returned from surgery with knee-high antiembolism stockings.
   a. You notice that the stockings have slid down and become wrinkled between his knees and ankles. After you straighten them and pull them up, the tops reach to about 7.6 cm (3 in.) below Mr. Singh's knees. What does this probably mean, and what should you do?
   b. Which of the following instructions should you give when delegating care of Mr. Singh's antiembolism stockings to the nursing assistant? (Mr. Singh's stockings have closed toes.)
      - Remove the stockings and bathe and dry the legs every 8 to 12 hours.
      - Massage the legs after removing Mr. Singh's stockings.
      - Before reapplying stockings, report the presence of any lesions, sores, or redness of the lower extremities.
      - Instruct the patient to remain supine for at least 15 minutes after removing the stockings.
      - Make sure there are no wrinkles in the stockings once they have been applied.
      - Tug gently on the end of the stocking to create a small space between the end of the toes and the stocking.
4. *Nursing Process (Nursing Diagnosis):* List Mr. Singh's four nursing diagnoses in order of priority. List the highest priority first. Explain how you decided the priorities.

CARING

5. *Self-Knowledge:*
   c. If you were assigned to care for Mr. Singh today, what aspect of care would you feel best prepared to give? Explain your thinking.
   d. What aspect of Mr. Singh's care would you be most uncomfortable providing? Explain your thinking.
6. *Ethical Knowledge:* You want to provide culturally competent care. What is the first thing you will need to do in order to address Mr. Singh's cultural needs? Review Chapter 15 if you need to.

Critical Thinking and Clinical Reasoning

1. You are speaking with several classmates about an upcoming surgical rotation. During the rotation, you will have a opportunity to work with a circulating nurse and a scrub nurse. One of your classmates says that she is very nervous. "I don't know whether I will be able to handle this rotation. I'm afraid I might not be able to watch the surgery. I've never really seen anything gross like that before." Another classmate confides that she is worried that she will contaminate everything and put the client at risk. What advice can you give them, and what actions can you take to prepare yourself for your experience in the OR?
2. You are working on a busy surgical unit on the evening shift. There is one NAP on the unit this evening. You are caring for the following clients:
   - Mr. Singh (Meet Your Patient, in Volume 1), who underwent a colon resection and colostomy for colon cancer. He is now in postoperative day 2 and is complaining of chest pain and shortness of breath.
   - Ms. Yasmin, a 52-year-old woman admitted to the unit from PACU 1 hour ago after total abdominal hysterectomy and bilateral salpingo-oophrectomy (TAH-BSO—removal of the uterus, ovaries, and fallopian tubes)
   - Steven Stellanski, a 16-year-old with trisomy 21 who underwent an emergency appendectomy early this morning.

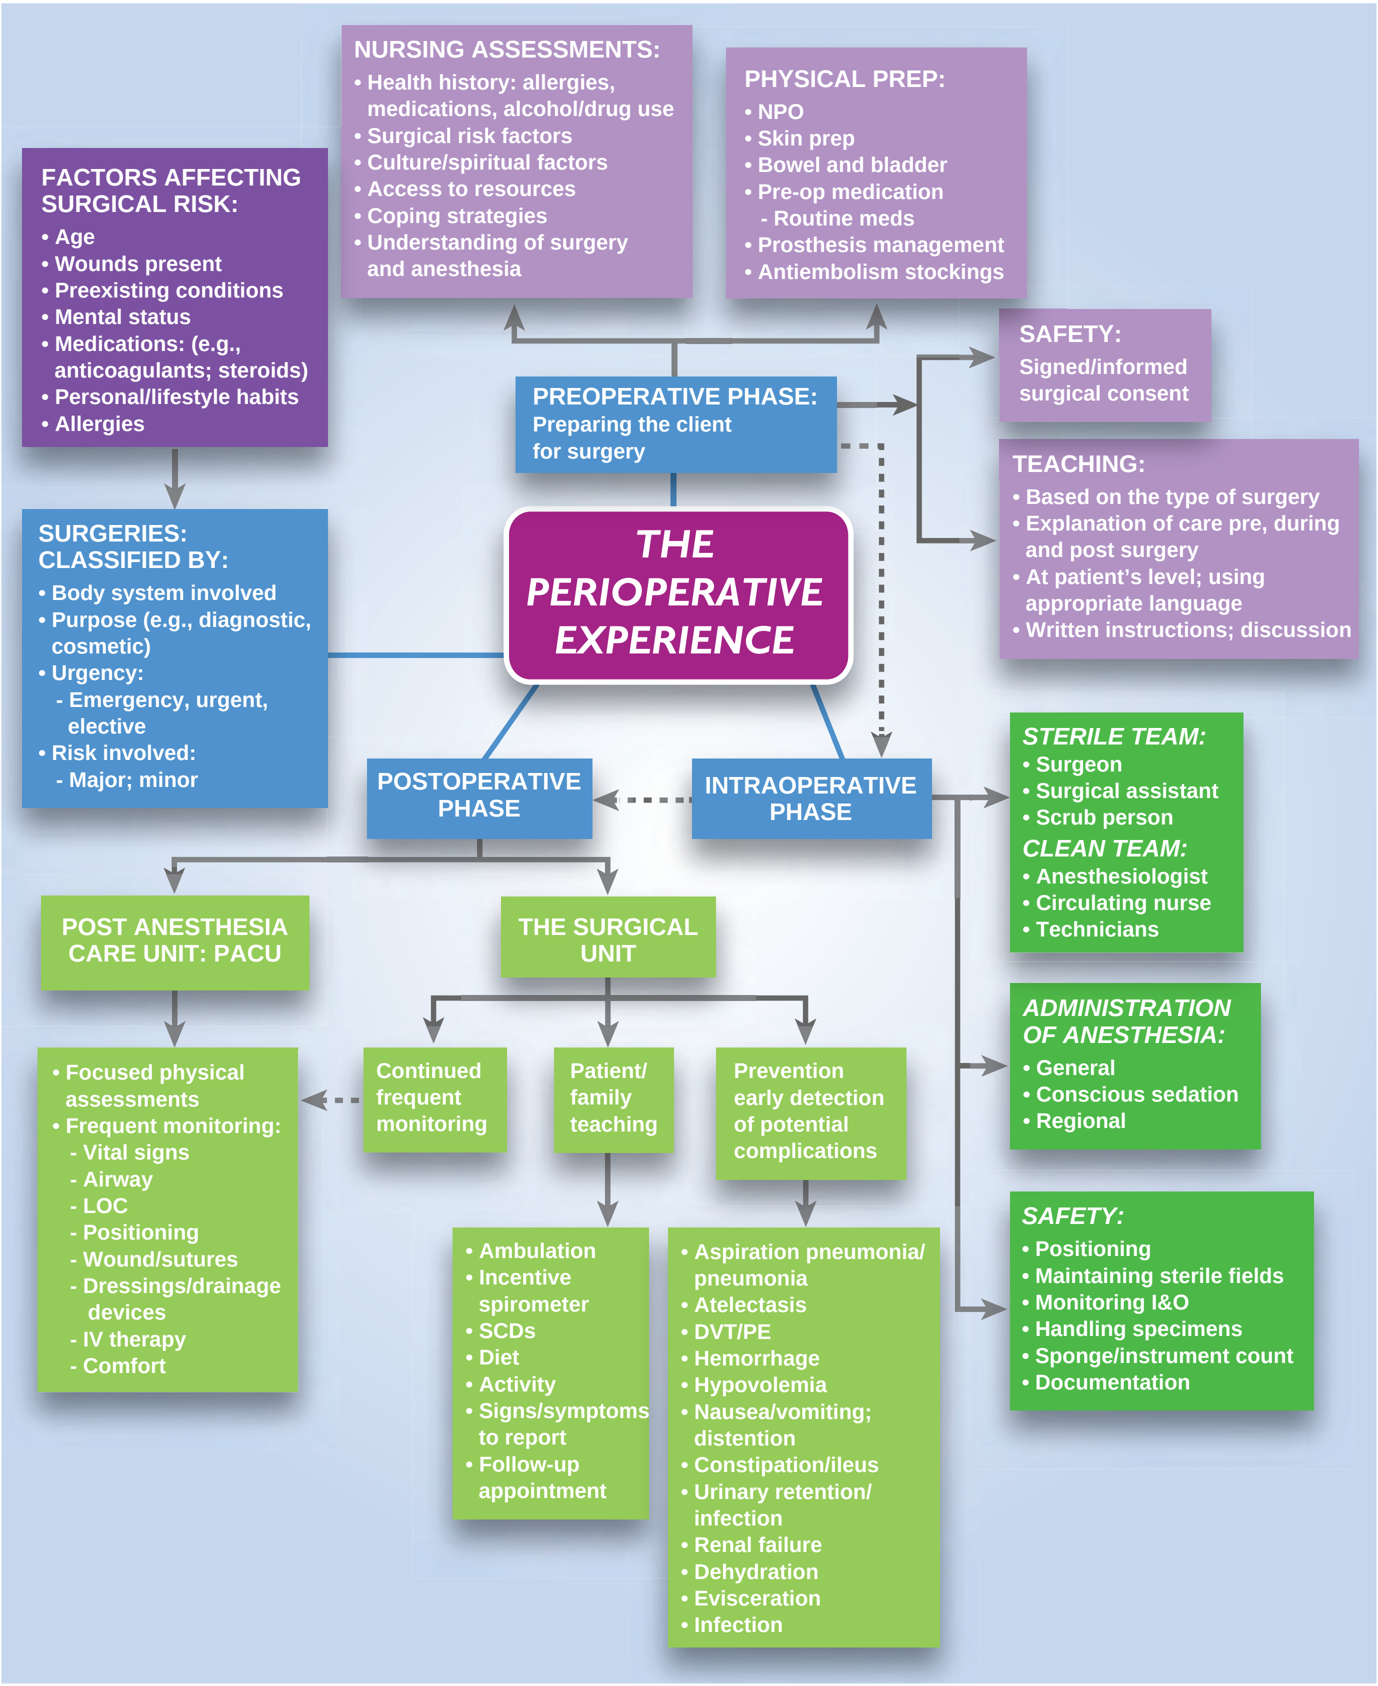
   The PACU calls to inform you that they are ready to transport Mrs. Bauer back to the unit. She is an 87-year-old woman from the local skilled nursing facility who underwent an extensive debridement of a stage IV pressure ulcer on the coccyx. The PACU nurse tells you Mrs. Bauer is confused and agitated and will need close monitoring.
   a. What problem(s) does admission of this new patient present for you? To answer this question, identify the priority nursing activity for each of the three patients you already have, as well as for Mrs. Bauer.
   b. How will you handle this situation? Identify three options, and explain their advantages and disadvantages.
3. You will be caring for a 23-year-old client who underwent emergency surgery after an automobile accident. He has had no preoperative teaching. What concerns does this raise for you? How will you address these concerns?
4. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or perioperative nursing. Note that these are *not* to be merely definitions.

Preoperative teaching	Anesthesia
Preoperative physical preparation	Postoperative complications
Intraoperative safety measures	

What Are the Main Points in This Chapter?

- Perioperative nursing includes care of patients during the preoperative, intraoperative, and postoperative phases.
- Perioperative nursing requires the systematic integration and synthesis of the nursing process with established standards of practice.
- The Association of periOperative Registered Nurses (AORN) is the organization that developed the standards of care that inform perioperative nursing and the standardized language, the Perioperative Nursing Data Set (PNDS).
- "Never Events" are serious and costly errors resulting in severe consequences for the patient, and that are mostly preventable. Medicare will not reimburse institutions for care related to complications caused by never events.
- Surgical risk is associated with the type of surgery and the condition of the patient (e.g., age, general health, personal habits).
- During the preoperative period, it is essential to determine whether the client is physiologically, cognitively, and psychologically prepared for the intraoperative and postoperative phases of surgery.
- Preoperative care includes assessment, preoperative teaching, confirming that surgical consent has been obtained; preventing wrong patient, wrong site, wrong surgery; communicating with the surgical team; preparing the patient physically for surgery; transferring the patient to the operative suite; and preparing the postoperative room on the surgical unit.
- The surgical consent form is a witnessed legal document that ensures that the surgical patient has given informed consent for the surgical procedure. The physician is legally responsible for obtaining informed consent; however, the nurse sometimes obtains the patient's signature on the form after verifying that the patient has been informed.
- A great deal of perioperative nursing care is standardized, aimed at preventing potential complications, and applicable to all patients having surgery.
- General anesthesia produces rapid unconsciousness and loss of sensation. Regional anesthesia produces loss of pain sensation without loss of consciousness.
- Intraoperative care includes skin preparation, positioning the patient for surgery, and protective measures to ensure patient safety during surgery.
- The PACU RN integrates knowledge of common complications of surgery, well-established nursing diagnoses for the postoperative client, and data from an individualized comprehensive postoperative assessment to plan and implement appropriate outcomes and interventions for the client during the postoperative stage.
- Assessments during postoperative recovery are the same as those performed in the PACU, but they can be performed less frequently.
- Antiembolism stockings and sequential compression devices may be used to help prevent thrombophlebitis.
- Incentive spirometry may be used to help prevent atelectasis and pneumonia.
- Gastrointestinal suction may be used for gastric decompression after certain surgeries to prevent gastric distention, which can increase respiratory complications, place a strain on suture lines, and interfere with wound closure.

Knowledge Map



CHAPTER 40

Leading & Managing

STUDENT RESOURCES

The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your response to the questions) on DavisPlus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 40:

- **Response sheets for all learning activities**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Leading & Managing (suggested readings)**
- **Concept Map of chapter content**

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 40, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Anh Chu, Nam's aunt, is scheduled for outpatient cataract surgery later this week at the local hospital. Nam reports to the clinic wishing to discuss the plan for his aunt's surgery "with whoever is the boss." Nam is concerned that his aunt will not be staying at the hospital. "She's having surgery. I don't understand this! She's 78 years old. She's going to need help. This doesn't make sense. You have to change things. It won't be safe to do this as planned."

Nam tells you he has discussed his concerns with the ophthalmologist. He tells you that the ophthalmologist told him he was "overreacting. We always do it this way. You just don't understand." Nam is visibly upset. He

(Continued)

Caring for the Nguyens (continued)

believes that his aunt is receiving inadequate care. He appeals to you to help him take care of his aunt. "This is where Aunt Chu gets her care. You know her. You have to change this."

Anh Chu has been seen at the family clinic several times over the past few years. She takes a medication for osteoporosis and has been counseled about the need for exercise and weight loss. She has also begun to experience problems with "accidents," that is, urine leakage. She has never had surgery in the past, and her only hospitalizations have been for childbirth. Ms. Chu's husband recently passed away, and she has been living alone since then. Devise a plan to resolve this conflict with Nam.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

ORGANIZATIONAL SITUATION

A small, not-for-profit hospice center in a small community has received a generous memorial gift from the family of a client who recently died. The family asked only that the money be "put to the best possible use." Everyone in the facility has an opinion about the best use for the money.

The administrator wants to renovate their old, run-down headquarters. The financial officer wants to put the money in the bank "for a rainy day." The chaplain wants to add a small chapel to the building. The nurses want to create a food bank to help the poorest of their clients. The social workers want to buy a van to transport clients to healthcare providers. The staff has agreed that all the ideas have merit and all the needs are important. Unfortunately, there is enough money to meet only one of them.

The more the staff members discuss how to use this gift, the more insistent each group becomes about defending its own idea. At the last meeting it is clear that some are becoming angry and frustrated. A shouting match even occurs between the administrator and the financial officer.

THINKING

1. *Theoretical Knowledge:*
   Which is appropriate at this point, a problem-solving approach or informal negotiation? Explain your answer.

DOING

2. *Practical Knowledge:*
   If you were to conduct the informal negotiation, list the steps of the plan you would follow.

CARING

3. *Self-Knowledge:*
   Which idea do you think has the most merit? Why did you select the one you did?
4. *Ethical Knowledge:*
   Which groups or individuals seem to demonstrate the value of caring for clients? Explain your thinking.

Critical Thinking and Clinical Reasoning

1. Identify a personal or professional change that you would like to see take place, and outline the steps needed to implement the change.
2. Eleanor, an LPN returning to school to obtain her associate's degree in nursing, is faced with a multitude of responsibilities. A wife, a mother of two toddlers, and a full-time staff member at a local hospital, Eleanor suddenly finds herself in a situation in which there just are not enough hours in a day. She is convinced that becoming a registered nurse is an impossible goal. You are Eleanor's mentor. When you ask where she wants to be in 5 years, she answers, "At this moment, I think, on an island in Tahiti!"
   a. Help Eleanor develop a personal time inventory. To help her determine specifically what to include, make your own personal time inventory to share with her as an example.

b. Once Eleanor has finished her time plan, how would you advise her to use it to make better use of her time? Make specific suggestions.

3. What strategies could you use to better manage your time?
4. Why is it important to learn good time management habits while you are a student?
5. This is your first semester in the nursing program. Although you have attended college to complete the prerequisite courses, this seems to be so different. All of a sudden, you have to attend clinical rotations in addition to classes. And you have to prepare ahead of time for the clinical experience, often even going to the hospital the night before to obtain information related to your patients. You feel like you are drowning! What can you do?

Go to Chapter 40, **Table 40-4: Components of Time Management,** in Volume 1.

Work through the table, asking yourself questions such as the following. Be very specific in your answers; give examples.

a. *Prioritizing:*
   - What tasks do you have to complete on a daily basis? Weekly? During the semester?
   - List the tasks in order of importance.
   - Which of the tasks do you have control over (e.g., scheduling a haircut or setting aside time to read the next assignment versus taking a test that is scheduled)?

b. *Assigning priorities:* Assign priorities to the tasks you have identified.
c. *Questioning effectiveness, efficiency:* Ask yourself, “How can I accomplish these tasks in the least amount of time but to the best of my ability?”
d. *Rechecking:* Review your plan. Mentally and physically recheck the plan. Revise the plan as needed.
e. *Self-reliance:* Carry out your plan. Use critical-thinking skills, and adapt the plan as needed so that you “go with the flow.”
f. *Treating:* Be good to yourself, but commit yourself to time management and excellence. How can you do that? What treats will you give yourself?

6. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or managing or leading. Note that these are *not* to be merely definitions.

Leadership skills	Time management
Management skills	Resolving conflicts
Becoming a mentor	Delegating appropriately
Being a mentee	Understanding the change process

What Are the Main Points in This Chapter?

- Leadership is the ability to influence other people.
- Transformational leaders communicate their vision in a way that reduces negativity and inspires commitment in people.
- Three common behavioral leadership styles are authoritarian, democratic, and laissez-faire.
- A manager is an employee of an organization who has power, authority, and responsibility for planning and directing the work of others.
- Effective managers possess a combination of qualities: leadership skills, clinical expertise, and business sense.
- A manager’s activities are generally organizational, interpersonal, and informational.
- Not all leaders should be managers, but all managers should be leaders.
- It is never too early in your career to develop a SWOT or SOAR analysis. Throughout your nursing program, revisit the analysis, and update it as you gain new knowledge and skills.
- A mentor is a role model who develops the novice nurse to be a professional by coaching, encouraging, supporting, and guiding him or her.
- Be mindful of nurses who demonstrate strong mentor qualities. Do not be afraid to ask for their support and guidance. Develop mentor qualities of your own, so you can also mentor a new student.
- At times throughout our nursing careers, we will all assume the role of follower.
- Followers need to be self-directing, actively participating experts who work on behalf of the organization.

- Sources of power include authority, reward, expertise, and coercion.
- Nurses have expertise, power, and authority over other healthcare workers. It is important that you understand your sources of power and use them wisely.
- Empowerment is the feeling of self-determination, competence, and recognition that your expertise and power within the healthcare system have meaning and positive impact.
- Evaluative feedback is a leadership responsibility that reinforces constructive and discourages undesirable behavior; provides recognition; and develops employee skills.
- Delegation of patient care tasks to other healthcare workers is one of the most important responsibilities of the registered nurse.
- Nurses must understand change and act as change agents within today's healthcare setting.
- Managing change involves recognizing and decreasing resistance.
- Conflict is inevitable, but it does not need to be destructive.
- One of a manager's responsibilities is to facilitate conflict resolution and, if necessary, function as an informal negotiator.
- Effective time management is essential to planning safe, effective patient care and demonstrating management skills.
- Time management includes goal setting and organizing and streamlining your work.
- Do not forget to get rest and "time off" when managing time.

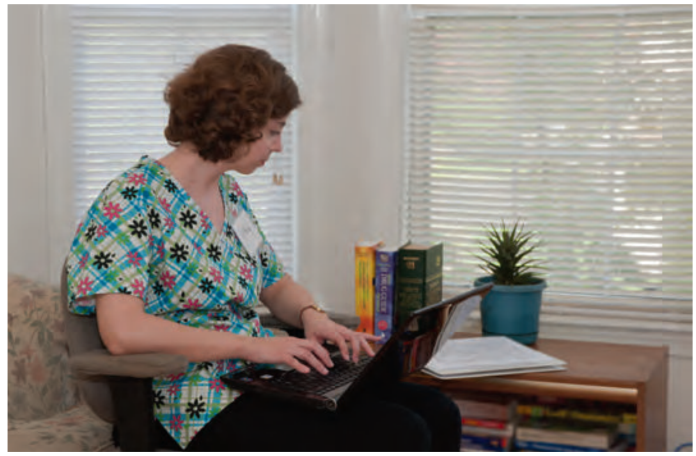
Caring for the Nguyens

Nam Nguyen, a patient you have been caring for at the Family Medicine Center, has been devastated by his recent diagnoses of type 2 diabetes mellitus and hypertension. "Oh my, this is bad. This stuff kills you. I don't understand what I did to cause this," he sighs. He is having difficulty following his medication regimen and says he doesn't understand what he is supposed to do. You have supplied him with information at each of his clinic visits as well as handouts, medication information, and a reminder sheet for his medicines. Nam asks you whether there is any information available on the Internet.



A. What advice would you give him about looking up medical information on the Internet?

B. What sources would you recommend to Nam?

PracticalKnowledge knowing how

STANDARDIZED LANGUAGE

Standardized Language

American Nurses Association Recognized Languages for Nursing

Language	Description	Recognition Date
Diagnostic Related Group (DRG)	DRG is a classification system for most health conditions to establish a standardized reimbursement system for Medicare.	1983
NANDA International	2012–2014 Nursing Diagnoses Language includes 13 Domains with diagnostic labels with etiologies, risk factors, and defining characteristics.	1992
Nursing Interventions Classification (NIC)	The sixth edition contains 554 direct and indirect interventions assigned to one of seven domains and 30 classes. Each intervention includes a concept label, definition, and activities.	1992
Clinical Care Classification (CCC)	Developed by Virginia Saba, this language is used primarily by home health agencies and community settings. This language contains nursing diagnoses and interventions developed to code, index, classify, document, track, and analyze clinical care processes.	1992
Omaha System	This language also documents care in community and home care agencies. This system consists of four levels including 42 nursing diagnoses (patient assessment and problem classification), nursing interventions (delivery of care), and a problem-rating scale for outcomes.	1992
Nursing Outcomes Classification (NOC)	The fifth edition of NOC consists of 490 outcomes, including seven family-unit and six community-level outcomes. The NOC is a comprehensive standardized language designed to help clinicians evaluate the effectiveness of nursing interventions.	1997
Nursing Management Minimum Data Set (NMMDS)	This data set describes the healthcare and nursing environment associated with the diagnosis, intervention, and outcome segments from the administrative, management, and resource management perspectives. It is composed of 17 data elements in three categories: environment, nurse resources, and financial resources.	1998

(Continued)

Standardized Language

American Nurses Association Recognized Languages for Nursing—cont'd

Language	Description	Recognition Date
Perioperative Nursing Data Set (PNDS)	The PNDS language describes perioperative nursing practice and consists of 64 nursing diagnoses, 127 nursing interventions, and 29 patient outcomes. This was the first nursing language developed by a nursing specialty.	1999
Statistical Nomenclature of Medicine Clinical Terminology (SNOMED CT)	SNOMED CT is a reference terminology that includes clinical concepts used to describe assessment, diagnosis, intervention, and outcome. Although it includes nursing concepts, it is not developed specifically for nursing, but rather for a broad spectrum of healthcare domains.	2002
Nursing Minimum Data Sets (NMDS)	This data collection establishes comparability of nursing data across population settings, geographic areas, and times. It describes the nursing care of patients or clients and their families in a variety of settings, both institutional and noninstitutional.	1999
International Classification for Nursing Practice (ICNP)	ICNP describes nursing practice in various clinical settings worldwide using common language. It includes nursing phenomena or diagnoses, outcomes, and actions.	2000

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Sarita, a nurse working in the surgical ICU, is ordering patient lab work and recording patient information in the electronic health record (EHR). While at the computer terminal, a physician walks over to her and requests an update on a postsurgery patient's condition. They go to the bedside to assess the patient's color and perfusion. Another nurse, Janelle, needs to order a STAT x-ray using the central computer in the unit. When Sarita goes back to the computer screen to order lab work and finish her documentation, Janelle has stepped in and is now accessing another patient's record.

THINKING

1. *Theoretical Knowledge:*
   a. Name five benefits of using an electronic health record for storing and retrieving patient data in a busy critical care unit.
   b. List five potential areas of difficulty in using this same electronic health record.
2. *Critical Thinking (Considering Alternatives):*
   a. Brainstorm about possible solutions for dealing with bottlenecks among staff using a centralized computer.

DOING

3. *Practical Knowledge:*
   a. Where would you look to find out who has accessed the patient record?

CARING

4. *Ethical Knowledge:*
   a. What violation has Sarita committed in this situation? What should she have done instead?
   b. What is the nurse's responsibility in protecting patient information in the electronic record? What kinds of things should the nurse do?

5. *Self-Knowledge:*
   a. Have you ever been so busy that you felt as though you just needed to take a "necessary" shortcut to save time? Describe your experience.

Go To Chapter 41, **Applying the Full-Spectrum Nursing Model Response Sheet,** on Davis*Plus*.

Critical Thinking and Clinical Reasoning

1. Refer to the following table. For each of the uses listed, what kind of information do you think the database should provide? That is, what kind of data would you need? For example, look at the first item under In Nursing Practice. For "Literature access and retrieval," you would use a database that contains information about journals, books, reports, and their content, perhaps CINAHL. For all of the following (Use in Nursing Practice), what kind of database would you use? What kind of information would you need? The first one is done for you.

   Work with your classmates. Share your knowledge and experience to answer these questions. Consult your instructor as needed.

USE	TYPE OF INFORMATION NEEDED
In Nursing Practice	
Literature access and retrieval (e.g., for evidence-based practice)	***Suggested response:*** CINAHL; information about books, journals, and their content; possibly the Internet
Care planning	***Clues:*** What information would you need for care planning? Where would you find it?
Client records (e.g., documenting, order entry, retrieving lab results)	
Telenursing (e.g., in home health)	
Case management	
In Nursing Education	
Literature access and retrieval	
Computer-assisted instruction (CAI) programs	
Classroom technology	
Distance learning	
Testing and grading	
Student records	
In Nursing Administration	
Quality assurance/improvement and utilization review	***Clues:*** What information would you need to evaluate the quality of care in your institution? Where would you find it?
Employee records (e.g., to track licenses, immunizations)	
Staffing patterns, hiring	
Buildings and facilities management	
Finance and budgets	
Accreditation reviews (e.g., monitoring quality control)	

(Continued)

USE	TYPE OF INFORMATION NEEDED
In Nursing Research	
Literature review	
Data collection	
Data analysis (both qualitative and quantitative)	
Research dissemination	
Applying for grants	

2. Search for "online nursing journals" on the Internet. Make a list of nursing journals that provide full-text articles that are available on the Internet, and at no charge. Hint:

Go to Chapter 41, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

3. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patients, or nursing informatics. Note that these are *not* to be merely definitions.

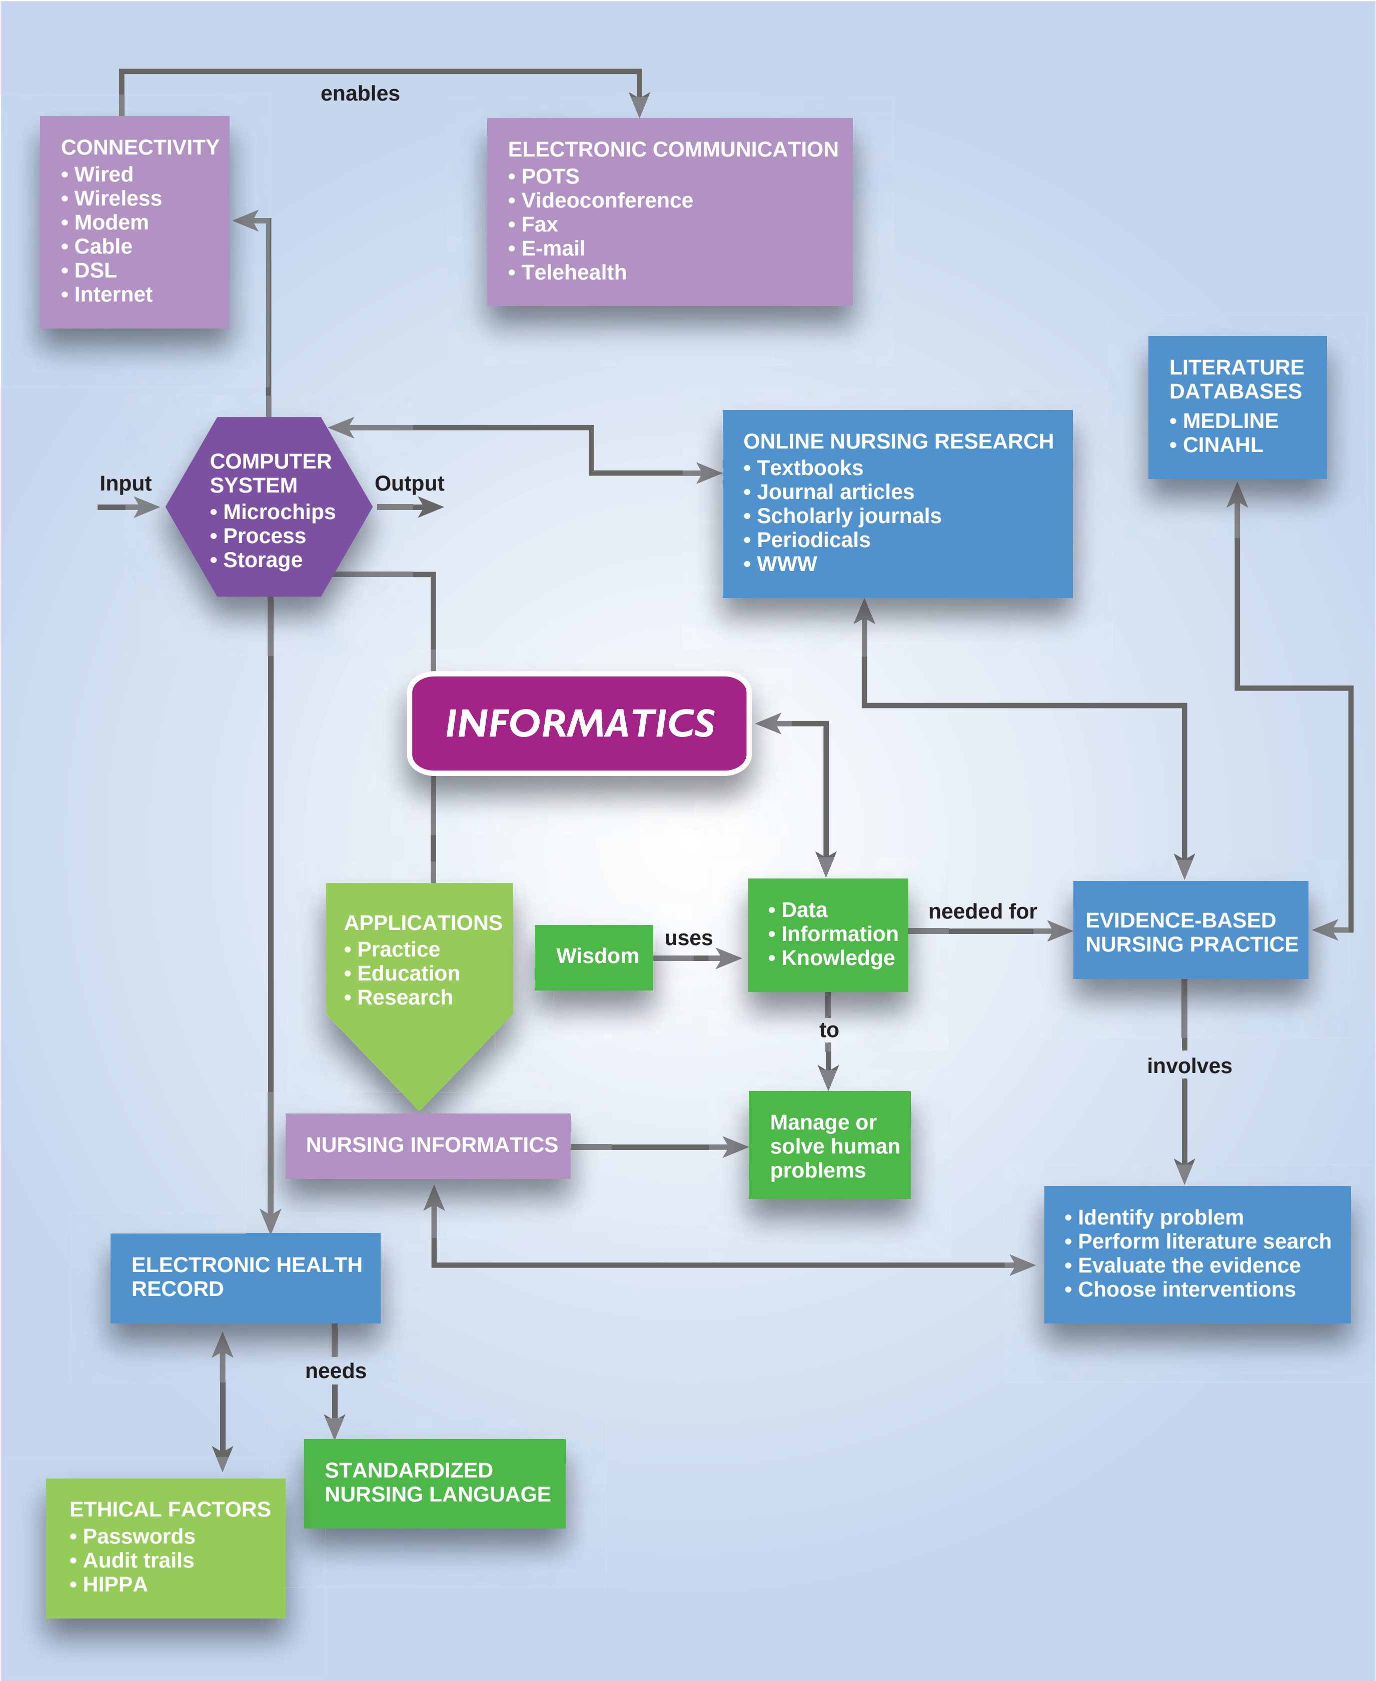
Nursing informatics	Connectivity
Data	Electronic mailing lists
Knowledge	Telehealth
Wisdom	Electronic health records
Evidence-based practice	Standardized nursing language
Computers	Literature databases
Hardware	World Wide Web
Storage media	Evaluating Web sites

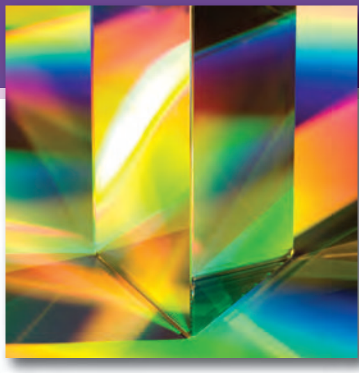
What Are the Main Points in This Chapter?

- Whatever their roles—staff nurse, administrator, educator, researcher, primary care provider—nurses use data, information, and knowledge in their daily work.
- Informatics is the processing and management of data, information, and knowledge necessary for making practice decisions.
- The nursing informatics specialist uses nursing science, computer science, and information science to manage and communicate data, information, knowledge, and wisdom in nursing practice.
- A computer has four main functions: input, processing, output, and storage. Together they are known as information processing (or data processing).
- *Connectivity* is a term referring to the ways in which computers and other hardware communicate and share information.
- Some forms of electronic communication include electronic mail and text messaging, web conferencing and webinars, electronic distribution lists, social networking, interactive gaming and virtual learning, and telehealth applications.
- Electronic health records (EHRs) are a platform for communication among the interdisciplinary healthcare team regarding patient healthcare needs, patient data, plan for care.
- EHRs allow clinicians to create, store, edit, and retrieve patient charts via the Internet or local intranet software.
- An important benefit of EHRs is reduced errors resulting from illegible handwriting.
- EHRs equip providers with clinical support tools to conveniently access information to assist with clinical decision-making.

- Standardized languages within the EHR facilitate research to improve healthcare. They also aid in billing, recordkeeping, and scheduling follow-up care.
- It is important to use and protect passwords to guard the privacy of patient records.
- Computer illiteracy and discomfort with technology is a common reason for resisting use of an EHR. Many claim documentation in the system is time consuming, especially when less familiar with the system.
- Evidence-based practice requires the ability to organize and manage information to identify a clinical problem, search the literature, evaluate the evidence, and plan an intervention.
- An information literate person seeks authoritative, current, and reliable sources of information from trusted Internet sources.
- CINAHL and MEDLINE are two important databases to search for nursing literature.

Knowledge Map





CHAPTER 42 Promoting Health

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 42, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Nam and Yen Nguyen; their 3-year-old grandson, Kim; and Mai, Nam's 76-year-old mother, are all patients at the Family Medicine Center. Zach Jackson, the family nurse practitioner at the center, asks you to devise a health promotion program for each member of the family.

(Continued)

Caring for the Nguyens (continued)

A. What information should you gather before you begin?

B. How might you obtain this information?

C. How will the plans differ for each?

D. Review Meet the Nguyens in the front of this textbook; also review Nam's physical exam findings in Chapter 22. What health promotion strategies and health screenings should you recommend to Nam?

E. How would you begin to organize and prioritize a health promotion program for Nam?

F. Using therapeutic communication, give examples of appropriate questions to ask Nam about his health beliefs.

ASSESSMENT GUIDELINES AND TOOLS

Focused Assessment

Health Promotion: Physical Fitness Assessment

Cardiorespiratory Fitness

There are many different modes of testing, such as field tests (walking or running), motor-driven treadmills, stationary bicycles, and step testing.

- **Field tests** for running are good for children. A 9-year-old child should be able to complete a 1-mile run in approximately 10 minutes, and a 17-year-old boy should be able to complete a 1-mile run in approximately 7½ minutes (www.presidentschallenge.org).
- **The step test** is appropriate for most adults. Using a 12-inch bench, instruct the participant to step up and down at a rate of 24 steps per minute for 3 minutes. At the end of 3 minutes, he should check his heart rate. Stop testing immediately if the participant experiences any chest pain, shortness of breath, or light-headedness. Results depend on age and gender and are available below.

Step Test Evaluation Charts

3-Minute Step Heart Rate Test (Men)

Physical Condition	18–25 yr	26–35 yr	36–45 yr	46–55 yr	56–65 yr	65+ yrs
Excellent	<79	<81	<83	<87	<86	<88
Good	79–89	81–89	83–96	87–97	86–97	88–96
Above average	90–99	90–99	97–103	98–105	98–103	97–103
Average	100–105	100–107	104–112	106–116	104–112	104–113
Below average	106–116	108–117	113–119	117–122	113–120	114–120
Poor	117–128	118–128	120–130	123–132	121–129	121–130
Very poor	>128	>128	>130	>132	>129	>130

3-Minute Step Test (Women)

Physical Condition	18–25 yr	26–35 yr	36–45 yr	46–55 yr	56–65 yr	65+ yr
Excellent	<85	<88	<90	<94	<95	<90
Good	85–98	88–99	90–102	94–104	95–104	90–102
Above average	99–108	100–111	103–110	105–115	105–112	103–115
Average	109–117	112–119	111–118	116–120	113–118	116–122
Below average	118–126	120–126	119–128	121–129	119–128	123–128
Poor	127–140	127–138	129–140	130–135	129–139	129–134
Very poor	>140	>138	>140	>135	>139	>134

Muscular Fitness

- **Muscle strength** measures the amount of weight a muscle (or group of muscles) can move at one time. This is recorded as a ratio of weight pushed (or lifted) divided by body weight. For example, a woman weighing 150 pounds who is able to lift 86 pounds will have a ratio of 86 divided by 150, or 0.57.

Instruct the participant warm up and stretch before the test. Weight benches are ideal sites for testing upper body and leg strength.

Focused Assessment

Health Promotion: Physical Fitness Assessment—cont'd

Compare the ratio obtained with normative standards or with previous personal scores to evaluate improvement.

- **Muscle endurance** refers to the ability of a muscle to perform repeated movements. The push-up or curl-up (crunch) test may be performed to evaluate endurance. Ask the participant to perform as many push-ups or curl-ups as possible without pausing. The number of repetitions is the score. Once again, compare scores with norms or previous performance.

Flexibility

Flexibility is the ability to move a joint through its range of motion. **The sit-and-reach test** evaluates low back and hip [trunk] flexion.

- Ask the participant to sit on a floor mat with legs fully extended and feet flat against a box. Have her extend her arms and hands forward as far as possible and hold for a count of 3.
- Using a ruler, measure the distance in inches that the client can reach beyond the proximal edge of the box. If the client cannot reach the edge, measure the distance of the fingertips from the edge, and report it as a negative number.
- Norms for trunk flexion vary among men and women. The desired range for men is +1 to +5 inches, and for women it is +2 to +6 inches (Pender, Murdaugh, & Parsons, 2010).

Focused Assessment

Lifestyle and Risk Assessment

Lifestyle refers to the manner in which a person conducts his life. You can gather this information by interview or by using a variety of questionnaires. A health risk appraisal (HRA) is a questionnaire that evaluates risk for disease based on current demographic data, lifestyle, and health behaviors. The following is an example of an HRA.

Name ________________ Age _________ Gender ______

Health View

In general, would you say your present health is?
☐ Excellent
☐ Very good
☐ Good
☐ Fair
☐ Poor

General Practices

1. **Physical activity.** How many days each week do you get at least 30 minutes of physical activity, such as brisk walking, cycling, active gardening, active dance, swimming, jogging, or active sports? __________
2. **Strength exercises.** How many days each week do you do strength-building exercises, such as weight lifting or isometric exercises? __________
3. **Smoking status.** Indicate your present smoking status.
   ☐ Current smoker ☐ Ex-smoker
   ☐ Nonsmoker, never smoked regularly.

   Environmental smoke. Do you live with or work with smokers and breathe secondhand smoke regularly?
   ☐ Yes ☐ No
4. **Alcohol.** How many drinks do you typically have on a day you drink? *One drink is a bottle or can of beer (12 oz), a glass of wine or wine cooler (3.5 oz), or a shot glass of liquor (1.5 oz).*
   ☐ Never drink.
   ☐ Have no more than one drink in a day.
   ☐ Have no more than two drinks in a day.
   ☐ Sometimes have three or four drinks in a day.
   ☐ Sometimes have five or more drinks in a day.
5. **Sleep.** How many hours of sleep do you usually get each night? __________

Eating Practices

6. **Breakfast.** How many days each week do you usually eat breakfast (more than just coffee and a roll)? _____
7. **Bread/grains.** How many servings of whole-grain breads and cereals do you eat daily? *One serving = 1 slice bread, ½ cup dry cereal, ½ cup cooked oatmeal or other whole-grain cereal or brown rice.* __________
8. **Fruits and vegetables.** How many servings of fruits and vegetables do you eat daily? *One serving = 1 medium fruit, 6 oz fruit or vegetable juice, 1 cup raw fruit or vegetables, ½ cup cooked fruit or vegetables.* __________
9. **Legumes.** How many times a week do you eat legumes (peas, beans, lentils, garbanzos)? *One serving = ½ cup cooked.* __________
10. **High-fat and high-cholesterol foods.** How often do you eat foods high in saturated fat and cholesterol (e.g., steak, hamburger, hot dog, sausage, bacon, cheese, fried chicken, French fries, ice cream, cheesecake, or other desserts)?
    ☐ Daily
    ☐ Eat these foods three or more times a week.
    ☐ Seldom or never eat these foods.
11. **Nuts/seeds.** How many servings of nuts do you usually eat each week? *One serving = 1 oz or a small handful, or 2 tablespoons of natural nut butter.* __________
12. **Refined foods.** How often do you eat highly refined foods (soda pop, snack foods, chips, refined cereals, pastry, candy)?
    ☐ Daily
    ☐ Eat these foods three or more times a week.
    ☐ Seldom or never eat refined foods.

(Continued)

Focused Assessment

Lifestyle and Risk Assessment—cont'd

13. Water. How many glasses (8 oz) of water do you typically drink each day? ________

14. Weight. How many pounds have you gained since you were 21 to 24 (enter 0 if you weigh the same, weigh less, or are younger than 21 years). ________

Mental/Social Health

15. Happiness. How happy have you been during the past month?
- ☐ Very happy
- ☐ Pretty happy
- ☐ Not too happy
- ☐ Very unhappy

16. Mood/Feelings

(a) During the past month, have you often been bothered by feeling down, depressed, or hopeless?
☐ Yes ☐ No

(b) During the past month, have you often been bothered by having little interest or pleasure in doing things?
☐ Yes ☐ No

(c) Have your feelings in the past month caused you significant distress or impaired your ability to function socially or at work (or school)?
☐ Yes ☐ No

17. Stress and coping. How much of the time do you feel stressed out and unable to cope with life?
- ☐ Seldom or never
- ☐ Occasionally
- ☐ Much of the time
- ☐ Most of the time

Social Support

18. Support. Do you have family or friends you can get help from if needed?
☐ Yes ☐ No

19. Social Interaction. Do you have frequent social contact with family or friends?
☐ Yes ☐ No

Community

20. Community Support. Do you meet regularly with a faith community or other group that gives you support, comfort, meaning, and direction in your life?
☐ Yes ☐ No

Safety

21. Seat belts. What percentage of the time do you wear seat belts when riding in a car? ________

22. Smoke alarm. Do you have a working smoke alarm on each floor of your home, including the area in which you sleep?
☐ Yes ☐ No ☐ Don't know for sure.

23. Helmet. When biking or rollerblading, do you always wear a helmet and protective gear?
☐ Yes ☐ No

24. Substance use and driving. Do you ever drive soon after drinking alcohol or taking drugs or ride with someone who has been using illicit substances, including alcohol?
☐ Yes ☐ No

Safer Sex

25. Practice safer sex.

(a) Are you in a monogamous relationship?
☐ Yes ☐ No

(b) Do you always use condoms, or abstain from sexual relations?
☐ Always ☐ Don't always practice safer sex

Preventive Exams

26. Do you keep current on recommended preventive exams (see list below) and immunizations?
☐ Yes ☐ No ☐ Don't know for sure.

Recommended Preventive Exams

- Periodic checkup, including blood pressure, height and weight, and cholesterol check as recommended by your doctor.
- Pap tests within last 1 to 3 years, for women 18 or older
- Mammogram within last 2 years, for women 40 or older
- Colorectal cancer screening for all persons 50 or older
- Prostate exam, for men 50 or older
- Flu and pneumonia immunizations, for everyone 65 or older

Height ________

Weight ________

Blood pressure ________

Blood cholesterol ________ (mg/dL)

Focused Assessment

Lifestyle and Risk Assessment—cont'd

Scoring

Your score is the number of good health indicators you meet out of the 17 possible listed (below) in this assessment. The higher your score, the healthier your lifestyle. The Average Health Style Score is 9.4

Health Indicator	Guidelines for Good Health
1. Physical activity	Get 30 or more minutes of physical activity most days of the week.
2. Strength training	Do strength-building exercises at least twice per week.
3. Not smoking	Avoid all tobacco use and frequent exposure to secondhand smoke.
4. Alcohol use	Alcohol is not recommended, but if you drink alcohol, limit to one to two drinks in a day.
5. Adequate rest	Get adequate rest, at least 7 to 8 hours of sleep daily for best health.
6. Breakfast daily	Eat a nutritious breakfast daily for optimal physical and mental performance.
7. Whole grains	Choose whole-grain breads and cereals, at least three or more servings/per day.
8. Fruits and vegetables	Eat at least five servings of fruits and vegetables daily.
9. Fats, cholesterol	Limit high-fat meats, whole milk, and butter. Vegetable oils are healthier than oils from animals.
10. Nuts	Nuts, such as almonds, contain healthy fats and protect against heart disease.
11. Healthy weight	Maintain a healthy weight by eating well and participating in regular, moderate-intensity physical activity.
12. Mental health	Develop effective coping skills, and maintain a happy, hopeful outlook.
13. Social support	Maintain good social support and frequent contact with family and friends.
14. Community	Participate regularly in a faith community or other group that provides meaning, direction, and support in your life.
15. Safety	Be safety conscious; wear safety belts in the car and helmets when biking.
16. Safer sex	Remain in a monogamous relationship, or always use condoms, or abstain.
17. Regular exams	Get regular exams, including age/gender recommended preventive exams.

Focused Assessment

Life Stress Review

Daily hassles, life events, and other stressors trigger physiological responses that may, over time, induce illness (Selye, 1976; Rahe, 1974). You will find one type of life change events assessment tool in Chapter 12, Assessment Guidelines and Tools, The Holmes-Rahe Social Readjustment Scale.

Alternatively, you might want to interview your patient to assess the following:

- His belief in his ability to control the experience (e.g., an impending decision, an illness)
- How deeply involved he feels in the activity that is producing stress (i.e., is it something he can change, or wants to change?)
- Whether he is able to view such a change as a challenge to grow

Focused Assessment

Selected Health Screening Activities

With regard to health screening guidelines, it is important to know:

1. Different agencies and groups generate different guidelines for type and frequency of screening. For example, the American Cancer Society has different Pap screening recommendations than does the U.S. Preventive Services Task Force; the American College of Obstetricians and Gynecologists may have yet another recommendation.
2. Most evidence-based guidelines make use of cost-benefit analysis to arrive at their recommendations.
3. Various third-party payors have different policies regarding the type and frequency of screening for which they will reimburse.
4. Guidelines and recommendations change often.

Clinicians must take all that into consideration when they decide which screening tests to offer to their patients.

Lipid screening. Adults age 20 years or older have a fasting lipid panel at least once every 5 years. If total cholesterol is 200 mg/dL or greater—or HDL is less than 40 mg/dL—frequent monitoring is required. Universal screening is recommended for children ages 9 to 11 years, regardless of risk factors for cardiovascular disease. (National Guideline Clearinghouse [NGC], 2011). For children age 2 to 8 years, screening is recommended if a parent, grandparent, aunt/uncle, or sibling has a history of myocardial infarction (MI), angina, stroke, coronary artery bypass graft (CABG)/stent/angioplasty, or a history of hyperlipidemia (NGC, 2011).

Dental health. Clients should have regular dental checkups to detect early signs of oral health problems such as tooth decay, gingivitis (gum disease), and oral cancers.

Colon cancer screening. Both men and women should have a fecal occult blood test every year beginning at age 50 and a screening colonoscopy based on risk factors. If there is a strong family history of colorectal cancer or polyps, screening should begin at an earlier age and be conducted more frequently (American Cancer Society, 2013).

Breast cancer screening. Breast self-examination (BSE) is an option for women 20 years and older. Women between the ages of 20 and 39 should have a clinical breast examination by a health professional every 3 years. Women who are age 40 and older should have a screening mammogram and a clinical breast examination by a healthcare professional every year. The clinical breast examination should be scheduled close to and preferably before the scheduled mammogram (American Cancer Society, 2012). Thermal mammography shows promise for breast cancer detection without using radiation.

Cervical cancer screening. A Papanicolaou (Pap) smear is used to detect cellular changes in the cervix. All women should begin cervical cancer screening at age 21. Women between the ages of 21 and 29 should have a Pap test every 3 years. They should not be tested for human papillomavirus (HPV) unless it is needed after an abnormal Pap test result. Women between the ages of 30 and 65 should have both a Pap test and an HPV test every 5 years. This is the preferred approach, but it is also okay to have a Pap test alone every 3 years. Women older than age 65 who have had regular screenings with normal results should not be screened for cervical cancer. Women who have been diagnosed with cervical pre-cancer should continue to be screened (American Cancer Society, 2013; NGC, 2013; Smith, Brooks, Cokkinides, et al. 2013).

Testicular cancer screening. Given the low prevalence of testicular cancer and the limited accuracy of self-examination, routine clinical examination is not advised in symptom-free males.

Prostate screening. Most agencies do not support routine testing for prostate cancer. However, healthcare professionals may consider offering the PSA and DRE yearly to men age 50 years and older at risk for prostate cancer and with at least a 10-year life expectancy—if there are risk factors, testing should begin at age 40 to 45 years (American Cancer Society, 2013).

Skin screening. During any health assessment or a specialized dermatological exam, a general survey of the skin using the ABCD criteria is a useful approach for assessing for skin malignancy: **A**symmetry, **B**order irregularity, **C**olor variability, **D**iameter greater than 6 mm. Rapidly changing lesions are also associated with an increased risk for cancer. Any suspicious lesions should be biopsied (U.S. Preventive Services Task Force [USPSTF], 2009).

Standardized Language

Selected NIC Health Promotion Interventions

NIC INTERVENTION	DEFINITION	EXAMPLES OF ACTIVITIES
Breast Examination	Performing activities to safeguard the health of the breasts and related areas	Advise regular mammograms as appropriate for age, condition, and risk.
Community Health Development	Assisting members of a community to identify a community's health concerns, mobilize resources, and implement solutions	Identify health concerns, strengths, and priorities with community partners.
Environmental Management: Worker Safety	Monitoring and manipulation of the worksite environment to promote safety and health of workers	Identify applicable OSHA standards and worksite compliance with standards.
Environmental Risk Protection	Preventing and detecting disease and injury in populations at risk from environmental hazards	Monitor incidents of illness and injury related to environmental hazards.
Exercise Promotion	Facilitation of regular physical activity to maintain or advance to a higher level of fitness and health	Appraise individual's health beliefs about physical exercise.
Family Planning: Contraception	Facilitation of pregnancy prevention by providing information about the physiology of reproduction and methods to control conception	Determine ability and motivation of patient and partner to correctly and regularly use contraception.
Health Education	Developing and providing instruction and learning experiences to facilitate voluntary adaptation of behavior conducive to health in individuals, families, groups, or communities	Target high-risk groups and age ranges that would benefit most from health education.
Health Policy Monitoring	Surveillance and influence of government and organization regulations, rules, and standards that affect nursing systems and practices to ensure quality care of patients	Compare requirements of policies and standards with current practices.
Health Screening	Detecting health risks or problems by means of history, examination, and other procedures	Complete appropriate Department of Health or other records for monitoring abnormal results, such as high blood pressure.
Health System Guidance	Facilitating a patient's location and use of appropriate health services	Inform the patient of accreditation and state health department requirements for judging the quality of a facility.
Immunization/Vaccination Management	Monitoring immunization status, facilitating access to immunizations, and providing immunizations to prevent communicable disease	Determine immunization status at every health care visit (including emergency department and hospital admission), and provide immunizations as needed.

(Continued)

Standardized Language

Selected NIC Health Promotion Interventions—cont'd

NIC INTERVENTION	DEFINITION	EXAMPLES OF ACTIVITIES
Oral Health Promotion	Promotion of oral hygiene and dental care for a patient with normal oral and dental health	Instruct and assist patient to perform oral hygiene after eating and as often as needed.
Parent Education: Childrearing Family	Assisting parents to understand and promote the physical, psychological, and social growth and development of their toddler, pre-school, or school-age child/children (also Parent Education: Adolescent and Parent Education: Infant)	Teach appropriate developmental tasks or goals for the child.
Patient Contracting	Negotiating and agreement with an individual that reinforces a specific behavior change	Encourage the individual to identify own goals, not those he/she believes the healthcare provider expects.
Program Development [Wellness]	Planning, implementing, and evaluating a coordinated set of activities designed to enhance wellness, or to prevent, reduce, or eliminate one or more health problems for a group or community	Assist the group or community in identifying significant health needs or problems.
Sleep Enhancement	Promoting restful sleep that meets body's needs for restoration	Determine patient's sleep/activity pattern.
Smoking Cessation Assistance	Helping another to stop smoking	Help patient identify reasons to quit and barriers to quitting.
Spiritual Growth Facilitation	Facilitation of growth in patient's capacity to identify, connect with, and call upon the source of meaning, purpose, comfort, strength, and hope in his/her life	Encourage conversation that assists the patient in sorting out spiritual concerns.
Sports-Injury Prevention: Youth	Reduce the risk of sports-related injury in young athletes	Monitor proper use and condition of safety equipment.
Substance Use Prevention	Prevention of an alcoholic or drug use lifestyle	Conduct programs in schools on the avoidance of drugs and alcohol as recreational activities.
Teaching: *Infant Nutrition* *Infant Safety* *Infant Stimulation* *Toddler Nutrition* *Toddler Safety* *Toilet Training*	Providing education to parent(s) concerning topics relevant to growth, development, and safety of infants and toddlers	*Note:* Teaching is integral to all health promotion/disease prevention activities, whether or not there is a special intervention label for the particular content.
Teaching: Safe Sex	Providing instructions concerning sexual protection during sexual activity	Create an accepting, nonjudgmental atmosphere.
Values Clarification	Assisting another to clarify her/his own values in order to facilitate effective decision making	Encourage consideration of values underlying choices and consequences of the choice.
Vehicle Safety Promotion	Assisting individuals, families, and communities to increase awareness of measures to reduce unintentional injuries in motorized and nonmotorized vehicles	Educate about the importance of proper and regular use of protective devices to decrease risk of injury (e.g., car seats, seat belts, helmets).

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Shandra Shane is a single 37-year-old woman with three children, ages 12, 15, and 17. She is raising the children on her own, although her sister occasionally helps with transportation or advice about disciplining her teenage daughters. Ms. Shane is a night-shift worker at the hospital. Her typical schedule is 3 to 4 hours of sleep in the morning soon after she gets home and then a short nap in the early evening before going back to work. She smokes 1 to 1½ packs of cigarettes per day but tells you she has been trying to smoke less around her children. Her job stress is high, as the hospital is cutting back on the number of staff. Ms. Shane also takes care of her elderly mother, who has Alzheimer's and lives with her. Ms. Shane's outlet for stress is going out with friends and drinking beer on the weekend. She is seeking your professional guidance to lose some weight (about 60 pounds) and to feel more energetic.

THINKING

1. *Theoretical Knowledge:*
   List health behaviors that negatively influence health status.
2. *Critical Thinking (Contextual Awareness):*
   What factors in this situation would you consider threatening to Ms. Shane's health and could lead to disease later in life?

DOING

3. *Nursing Process (Planning/Intervention):*
   What suggestions might you make about Shandra's diet that could help her to lose weight? Why might these actions be effective for weight loss?
4. *Practical Knowledge:*
   What areas of her daily living other than her diet might you explore further and offer recommendations for improving to promote better health and prevent illness?

CARING

5. *Self-Knowledge:*
   Have you ever been in a situation in which you felt stressed, tired, and wanting gratification offered by food, nicotine, or alcohol? Describe your experience.
6. *Ethical Knowledge:*
   In what ways could you demonstrate genuine caring for Shandra?

Critical Thinking and Clinical Reasoning

1. While working in a physician's office, a 70-year-old woman is referred to you for counseling regarding health protection activities. She is hypertensive and obese.
   a. How does her age affect your assessments and communication?
   b. What type of learning aids might be needed?
   c. What health screenings are appropriate for this client?
2. Below is a group of clients who wish to enroll in a health promotion program.
   - Jennifer Kaska is 23 years old and was diagnosed with diabetes mellitus at the age of 12 years. She checks her blood sugar and administers insulin as needed. She runs 3 miles, 3 days per week.
   - Maurice Rosenthal is 47 years old with no known illness. He is 6 feet tall and weighs 240 pounds. His body mass index (BMI) is 33 kg/m^2, indicating obesity. He takes no routine medication, only acetaminophen for occasional headaches.
   - Clara Fenton is 83 years old and has been diagnosed with hypertension, emphysema, and osteoporosis. She takes 10 prescription medications daily in addition to a multivitamin and an occasional laxative.

   Discuss the pros and cons of providing a group program that includes all three of these clients.

3. L. F. is a 50-year-old man with heart disease. He had coronary artery bypass surgery 1 month ago. He has stopped going to his prescribed cardiac rehabilitation program because of the distance he must travel to the rehabilitation center. Discuss at least two approaches for working with this client.
4. Cecelia Kent is 32 years old. She takes no medications and has annual physical exams. She walks 4 to 5 miles, 5 days per week, and lifts light weights two to three times per week. She eats a low-fat, low-salt, low-sugar diet. She has never smoked, and drinks only limited alcohol.
   a. She asks you to recommend further health promotion activities. How would you respond?
   b. How could you incorporate Cecelia into a health promotion class that includes Jennifer Kaska, Maurice Rosenthal, and Clara Fenton (from question 2)?
5. For each of the following concepts, use critical thinking to describe how or why it is important to nursing, patient care, or health promotion. Note that these are *not* to be merely definitions.

Health promotion	Hardiness
Illness prevention	Health screenings
Lifestyle	Health education

What Are the Main Points in This Chapter?

- Health promotion refers to helping clients develop an optimal state of health.
- Intention is the difference between health promotion and health protection (illness prevention).
- There are three levels of activities for health protection: primary, secondary, and tertiary prevention. *Primary interventions* are designed to prevent or slow the onset of disease. *Secondary interventions* are designed to detect illnesses in early stages. *Tertiary interventions* focus on stopping the disease from progressing and on rehabilitation.
- The *Healthy People 2020* initiative is designed to achieve four overarching goals:
  - Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
  - Achieve health equity, eliminate disparities, and improve the health of all groups.
  - Create social and physical environments that promote good health for all.
  - Promote quality of life, healthy development, and healthy behaviors all life stages.
- Pender's Health Promotion Model (HPM) identifies three groups of variables that affect health behavior: (1) individual characteristics and experiences; (2) behavior-specific cognitions and affect; and (3) behavioral outcome.
- A Wellness Wheel identifies six dimensions of health: emotional, intellectual, physical, spiritual, social/family, and occupational.
- The transtheoretical model of change identifies four stages of change: contemplation, determination, action, and maintenance.
- Health promotion activities for all age groups include nutrition, exercise, safety concerns, changing unhealthy lifestyles, immunizations, and screenings.
- Health promotion activities may be conducted in acute care facilities, the workplace, local communities, or schools.
- A health promotion assessment involves obtaining a health history, physical examination, fitness assessment, lifestyle and risk appraisal, life stress review, assessment of healthcare beliefs, nutritional assessment, and screening activities.
- Health screening activities are designed to detect disease at an early stage so that treatment can begin before there is an opportunity for disease to spread or reduce the quality of life.
- Health screening activities vary based on developmental stage and identified risk factors.
- Nurses promote health through role modeling, counseling, providing health education, and providing and facilitating support.

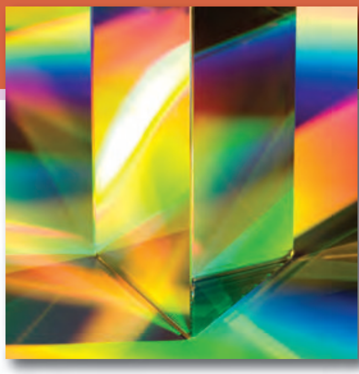
The Context for Nurses' Work

CHAPTER 43



Community & Home Health Nursing

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Community and Home Health Nursing

- **Response sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Community & Home Health Nursing (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 43, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Yen Nguyen works as preschool teacher in her community. Andre is a 4-year-old boy in her class. Over the past few months, she has noticed that Andre has many bruises in various stages of healing. He seems withdrawn and does not interact much with the other children. She is concerned that Andre might be a victim of child abuse, but she is reluctant to make that accusation, especially because her assistant doesn't seem to have noticed anything amiss.

Mrs. Nguyen talks to her husband, Nam, about her concerns: "I'm worried about a child at school, but I'm afraid to say anything. What if I'm wrong? I'd probably lose my job. But if I'm right and I don't say anything, I could still lose my job, and this boy could be hurt even worse." Nam suggests that she contact the clinic nurse at the Family Medicine Center for confidential advice on how to proceed.

A. Imagine that you are the clinic nurse. Use the full-spectrum nursing model to identify at least 10 questions that you would need to answer to investigate Yen's concerns further.

B. *Self-knowledge:* What personal values do you have that would affect the manner in which you handle this situation? Explain.

C. *Ethical knowledge:* What is the most important ethical issue in this situation? That is, what is the most important goal? Note that there may be several moral and legal issues, but you are being asked to identify the *most* important one. Note also that we are not asking you what the nurse *can* do, but rather what the nurse ideally *should* do.

D. You share the questions you have with Yen. She believes that there is a real need to investigate child abuse. You advise her to call the local child protective services (CPS) agency. Based on your knowledge of community and public health nursing, what aspects of the community health role will the nurse from CPS use as she investigates this situation?

PracticalKnowledge knowing **how**

Practical knowledge in community and home-care nursing requires you to apply the nursing process to both individuals and groups.

CLINICAL INSIGHTS

Clinical Insight 43-1 ➤ Safety Considerations in Home Care

Before the Visit

- **Plan ahead.** Know where you are headed. Use a map or global positioning system (GPS). Contact the client or family for directions if it is unclear where you are headed. File a visit plan with your office each day.
- **Dress in appropriate clothing** as dictated by your agency. Wear a nametag clearly identifying you and the agency. Wear shoes that will allow you to run if necessary.
- **Carry a cell phone.** Check to be sure it is charged. Program 911 into it in case of emergency.
- **Do not carry a purse**, multiple credit cards, or excess cash. Instead, use a waist or fanny pack and conceal it under clothing. Carry enough money for emergency transportation, telephone numbers for clients and home health agency, and emergency contact information.
- **Keep your car in good repair** and always have enough gasoline in the tank. Be prepared for inclement weather, and always carry an emergency car safety pack.
- **Do not get out of your car for any reason if driving in an area that might not be safe.** Carjacking involves minor car impact ("fender bender") as a strategy to get a person to exit the vehicle, leaving her vulnerable for attack, assault, or theft.
- **Observe your surroundings** as you drive to the visit. Notice the location of emergency services, local gas stations, and public places if help is required.
- **Carry mace or other items to aid in self-defense** in situations in which you feel threatened.
- **Park as close to your destination as possible.** If possible, park your car facing the direction you wish to go when you leave. Never enter dead-end streets or alleys.
- **Check your surroundings before you leave your car.** If you feel unsafe, leave the area immediately and call your office.
- **Lock the car. Leave no valuables in sight.**
- **Prepare your bag while you are still in the car.**
- **Carry your bag on one arm. In the opposite hand, carry your keys.** Always have them ready. You may need them if you decide to exit quickly. Also, you can use keys to defend yourself by placing the pointed ends of the keys between your fingers.
- **Walk directly to the client's house.** Walk in the middle of the sidewalk. Use common walkways. Avoid isolated and poorly lighted areas. Do not take shortcuts.
- **Knock or ring the doorbell before entering.** Never enter without being invited. If there is no answer at the door, call the patient using your cell phone, or return to a secure public pay phone and dial the client.
- **If for any reason you feel that the neighborhood is unsafe, do not get out of the car.** Instead, leave the neighborhood immediately and phone your agency.

At the Visit

- **Introduce yourself** and clearly identify your agency. Show your name badge.
- **Sit where you have access to an exit.** When you enter the home, observe all exits.
- **Notice who is present in the home. Request introductions.** This information is useful for planning care as well as for ensuring safety.
- **Leave immediately if you suspect substance use**, drug dealing, or drunken behavior.
- **Leave immediately if there is a violent domestic argument.** Do not attempt to intervene. When you return to your car, use your cell phone to dial 911, or drive to a phone booth in a safe location and place the call.
- **Request that animals be kept in another room** while you make your visit.
- **If weapons are visible, request that they be put away** immediately. Leave the home if this request is not met.
- **If household members interfere with the visit**, discuss the problem with the client. You may need to arrange a time to visit when they are not present.

After the Visit

- **Continue to observe the safety precautions** you used when getting to the visit. Do not let down your guard as you return to your car.
- **If you are in an unsafe neighborhood or poorly lighted area, leave immediately and do not consult the map** for directions to your next visit. Drive to a secure public location, and then consult the map.
- **Inform your agency** if you believe the home or neighborhood is potentially hazardous.
- **Request a security escort service** if future visits are required.
- **Document your assessments** and the care delivered.
- **Report abuse** if you suspect it in the home.

Other

You also need to protect yourself from infection and accidental injury, as you would in a hospital (see Clinical Insight 43-2).

- Use safe lifting techniques, especially because you might have to improvise more than in the hospital. There will probably be no one to assist with patient transfer, ambulation, or lifting. Mechanical lifts are likely not available.
- Do not dispose of loose sharps in household trash containers, toilets, or recycling bins. Place them immediately in a sharps disposal container. If a sharps container is not available, use a puncture- and leak-resistant plastic household container (e.g., a laundry detergent bottle or empty milk jug) (U.S. Food and Drug Administration, 2011).

Clinical Insight 43-2 ➤ Infection Control in the Home

The following suggestions can help you maintain infection control during a home visit.

Hand Hygiene

- Keep antibacterial cleanser and protective equipment approved by the Occupational Safety and Health Administration in your nursing bag.
- Perform hand hygiene using soap and warm water or an antibacterial handrub at the beginning and end of each visit and before and after any treatment.
- If the home conditions are very dirty or your hands become grossly soiled, wash your hands with soap and warm water as soon as possible after (if not during) the visit.

Supplies

- In homes that you know are not clean, limit the supplies you bring into the home. For example, leave your nursing bag in the car, and bring only the supplies you need for the visit.
- Some infection control experts believe the "bag technique" (i.e., placing a newspaper under the nursing bag before placing it on a surface) is not routinely needed, but should be used when home conditions warrant. If you use items from your nursing bag during the visit, always clean them with an approved antibacterial wipe before placing them back into your bag.
- If necessary, use a 1:10 dilution of chlorine bleach in water to disinfect surfaces or equipment in the home. Some equipment may need to be disinfected by boiling in a covered pan of water for 15 to 20 minutes. Do not boil plastic or rubber items.
- You can disinfect hard plastic items by wrapping them with a wet paper towel and placing them in a zippered plastic bag. Microwave the entire bag on high for 10 minutes.

Biohazard and Sharps Disposal

- Flush wound irrigation or potentially contaminated liquids down the toilet while wearing gloves and any other appropriate protective equipment.
- Double-bag dressings, equipment, or disposable supplies that have been contaminated with body secretions to prevent leakage. The bags should be labeled *Biohazard*.

Carry small biohazard sharps containers. Place syringes and sharps in the container without recapping. If clients or family must use syringes or sharps, you may wish to leave a sharps container in the home. An alternative solution is to have them use a metal coffee can with lid or a thick plastic milk jug with lid.

Client Teaching

- Provide instruction on home cleanliness, hygiene, handwashing, and food preparation, and instructions to avoid contact with persons who are ill, as needed.
- If the client is immunocompromised, teach the signs and symptoms of infection and the process for immediate notification of the primary care provider.

Special Situations

- If the patient has a multidrug-resistant infection or pulmonary tuberculosis, use appropriate barrier precautions. Leave reusable equipment (e.g., stethoscope, blood pressure cuff) in the home; and if possible, schedule these clients as the last appointment of the day.

STANDARDIZED LANGUAGE

This section provides guidelines for using NANDA-I, NOC, NIC, and the Omaha System to develop problem statements, goals, and nursing orders to use in planning care for aggregates and communities. If you need to review these three standardized languages,

Go to **Chapters 4, 5, and 6,** in Volume 1.

The Omaha System

The Omaha System is a problem-solving model for community health practice, education, and research. The taxonomy consists of *diagnostic labels* organized into four *domains* (categories), along with two sets of *modifiers.* Within those domains, the system classifies 42 client problems or areas of concern (see Omaha System: Domains and Examples of Problem Labels, following). As you can see, the problem labels in the environment domain are especially useful in community nursing. For the complete problem classification scheme,

Go to the **Omaha System Web site,** at http://www.omahasystem.org

Omaha Problem Classification Scheme

To create a diagnostic statement, choose an appropriate label, and add a modifier to it from each of the two sets in the accompanying box. For example, a group Environment diagnosis for workers in a meatpacking plant with lax safety standards might read *Deficit* in Group Workplace Safety. If only one worker were at risk (perhaps because of her inattention to safety rules), you could write *Potential Deficit in Individual* Workplace Safety.

Domain: Environment
Problems: Income, Sanitation, Residence, and Workplace Safety
Modifiers: (1) Health Promotion, Potential Deficit, or Deficit
(2) Family, Individual, or Group
Diagnostic Statements:
Deficit in Group Workplace Safety
Potential Deficit in Individual Workplace Safety

Omaha System: Domains and Examples of Problem Labels

Environmental Domain—The material resources, physical surroundings, and substances both internal and external to the client, home, neighborhood, and broader community

Problem (Diagnosis) Labels: Income, Sanitation, Residence, Neighborhood/Workplace Safety

Psychosocial Domain—Patterns of behavior, communication, relationships, and development.

Problem (Diagnosis) Labels: Social Contact, Role Change, Interpersonal Relationships, Spirituality, Grief, Mental Health, Sexuality, Caretaking/Parenting, Neglect, Abuse

Physiological Domain—Functional status of processes that maintain life.

Problem (Diagnosis) Labels: Hearing, Vision, Oral Health, Speech and Language, Pain, Respiration, Digestion-Hydration, Communicable/Infectious Condition

Health Related Behaviors Domain—Activities that maintain or promote wellness, promote recovery, or maximize rehabilitation potential.

Problem (Diagnosis) Labels: Nutrition, Personal Hygiene, Prescribed Medication Regimen, Sleep and Rest Patterns, Family Planning, Physical Activity

Problem Modifiers

Set 1—Health Promotion, Potential Deficit, Deficit

Set 2—Family, Individual, Group*

*Martin and Scheet (1992, p. 67) suggest that *Group* be added to these modifiers.

Source: Martin, K. S., & Scheet, N. J. (1992). *The Omaha System: Applications for community health nursing*. Philadelphia: W. B. Saunders, pp. 67–74. Used with permission.

Using the NOC and Omaha Systems to Write Aggregate Goals

NOC Outcomes

NOC standardized outcomes in the Community Health domain include the following (Moorhead, Johnson, Maas, et al., 2013):

- Community Competence
- Community Disaster Readiness
- Community Disaster Response
- Community Health Status
- Community Health Status: Immunity
- Community Risk Control: Chronic Disease
- Community Risk Control: Communicable Disease
- Community Risk Control: Lead Exposure
- Community Risk Control: Violence
- Community Violence Level

You can use these NOC labels to write goals by adding the appropriate NOC indicators and scales (see NOC Measurement Scales, in the Standardized Language section of Chapter 5, in this volume).

Omaha System Outcomes

Using the Omaha System, you will develop goals/outcomes from the words in the nursing diagnosis. Recall that all nursing diagnoses are identified as *individual, family,* or *group,* so a group nursing diagnosis will automatically indicate a group goal. For example, for the diagnosis Deficit in Group Workplace Safety, you would build the outcomes around the words “Group Workplace Safety.” The Omaha system includes a five-point Problem Rating Scale for Outcomes (see the accompanying table) that describes what you expect to achieve in terms of the client’s knowledge, behavior, and status.

Omaha Problem Rating Scale for Outcomes

CONCEPT	1	2	3	4	5
Knowledge The ability of the client to remember and interpret information	No knowledge	Minimal knowledge	Basic knowledge	Adequate knowledge	Superior knowledge
Behavior The client’s observable responses, actions, or activities fitting the occasion or purpose	Never appropriate	Rarely appropriate	Inconsistently appropriate	Usually appropriate	Consistently appropriate
Status The condition of the client in relation to objective and subjective defining characteristics	Extreme signs/ symptoms	Severe signs/ symptoms	Moderate signs/ symptoms	Minimal signs/ symptoms	No signs/ symptoms

Source: The Omaha System. (2009, May 11, updated). *Solving clinical data-information: Problem rating scale for outcomes*. Retrieved from http://www.omahasystem.org/problemratingscaleforoutcomes.html

Using the above table, you would create expected outcomes by applying this scale to Group Workplace Safety, as follows.

Creating Outcomes for the Diagnosis Group Workplace Safety

***Nursing Diagnosis:* Deficit in Group Workplace Safety**

RATING SCALE CONCEPT	PRESENT STATUS, BEFORE INTERVENTIONS	EXPECTED OUTCOME, AFTER INTERVENTIONS
Knowledge	(2) Minimal knowledge of workplace safety	(4) Adequate knowledge of workplace safety
Behavior	(2) Rarely appropriate safety behaviors	(4) Usually appropriate group safety behaviors
Status	(2) Severe signs/symptoms (e.g., frequent accidents or injuries)	(4) Minimal signs/symptoms (e.g., few accidents or injuries)

The outcomes in this table mean that after your interventions, you expect the group to have adequate knowledge of workplace safety, demonstrate usually appropriate behaviors (e.g., usually follow the safety rules), and demonstrate minimal accidents or injuries. To evaluate the client's progress, you would assign a scale number to the group's actual knowledge, behavior, and status *after interventions*.

Using the NIC and Omaha Interventions Labels for Community Health Care

The NIC Interventions Taxonomy

The NIC taxonomy includes 16 interventions specifically designed for community health (see the following box).

NIC Community Health Classes and Interventions

Class: Community Health Promotion—Interventions promote the health of the whole community

Interventions:

Case Management
Community Health Development
Fiscal Resource Management
Health Education
Health Policy Monitoring
Immunization/Vaccination Management
Program Development
Social Marketing

Class: Community Risk Management—Interventions that assist in detecting or preventing health risks to the whole community

Interventions:

Bioterrorism Preparedness
Community Disaster Preparedness
Communicable Disease Management
Environmental Management: Community
Environmental Management: Worker Safety
Environmental Risk Protection
Health Screening
Risk Identification
Surveillance: Community
Vehicle Safety Promotion

Source: Bulechek, G. M., Butcher, H. K., & Dochterman, J. M. (Eds.). (2013). *Nursing interventions classification (NIC)* (6th ed.). St. Louis, MO: C.V. Mosby. Used with permission from Elsevier Science.

The Omaha Interventions Taxonomy

The Omaha system taxonomy provides four "intervention categories" you can use in community-oriented nursing practice:

- **Health Teaching, Guidance, and Counseling.** These primary prevention activities include giving information; anticipating client problems; encouraging client action and responsibility for self-care; and assisting with coping, decision making, and problem-solving. As a community-oriented nurse, you should spend most of your time offering this level of intervention.
- **Treatments and Procedures.** These are secondary interventions directed toward preventing disease, identifying risk factors and early signs and symptoms, and decreasing or alleviating signs and symptoms.
- **Case Management.** Case management is a tertiary intervention that includes coordination, advocacy, and referral. These activities involve facilitating service delivery on behalf of the client, communicating with health and human service providers, promoting assertive client communication, and guiding the client toward appropriate community resources.

- **Surveillance.** These nursing activities include detection, measurement, critical analysis, and monitoring to indicate client status in relation to a given condition or phenomenon.

To write an intervention statement, you must combine one of those four "categories" of interventions with one of the 75 "targets" (objects of the nursing interventions), such as bowel care and nutrition. Then you must add patient-specific information to individualize the nursing order. See the accompanying box for intervention categories, examples of targets, and intervention statements (nursing orders). To see the entire set of intervention targets,

Go to the **Omaha System Web site,** at http://www.omahasystem.org/shminter.htm

You will notice that the targets can be used for individuals as well as groups. It is the designation of the nursing diagnosis as *individual, family*, or *group* that determines this.

Omaha Intervention Categories and Examples of Targets

Categories

I. Health Teaching, Guidance, and Counseling
II. Treatments and Procedures
III. Case Management
IV. Surveillance

Examples of Targets

Anatomy/physiology
Behavior modification
Communication
Discipline
Feeding procedures
Homemaking
Substance use
Wellness

Examples of Aggregate Targets

Caretaking/parenting skills
Day care/respite
Durable medical equipment
Education
Employment
Environment
Finances
Housing
Legal system
Transportation
Other community resource

Examples of Nursing Intervention Statements

Treatments and Procedures (II): Feeding procedures (Demonstrate to Mrs. Adams how to feed Mr. Adams at the next visit.)

Surveillance (IV): Feeding procedures (After teaching, observe a feeding. Monitor for choking.)

Clinical Care Classification System for Home Health Care

Clinical Care Classification: 21 Care Components (Version 2.5) Coded by Alphabetic Classes*

Code	Component	Code	Component
A	Activity	K	Physical Regulation
B	Bowel/Gastric	L	Respiratory
C	Cardiac	M	Role Relationship
D	Cognitive/NEURO	N	Safety
E	Coping	O	Self-Care
F	Fluid Volume	P	Self-Concept
G	Health Behavior	Q	Sensory
H	Medication	R	Skin Integrity
I	Metabolic	S	Tissue Perfusion
J	Nutritional	T	Urinary Elimination
		U	Life Cycle

*The Clinical Care Classification system is copyrighted, placed in public domain, and cannot be sold, but is available with written permission (Saba, V., 2012. *Clinical Care Classification (CCC) system manual.* New York: Springer, pp. 142–150).

An Example of CCC Nursing Diagnoses and Interventions

A—ACTIVITY COMPONENT *(1 of 21 Care Components)*—A cluster of elements that involve the use of energy in carrying out musculoskeletal and bodily actions.

01 Activity Alteration *(Major Nursing Diagnosis)*—Change in or modification of energy used by the body.

Subcategories that provide greater definition of the problem (of "01 Activity Alteration")

01.0 Activity Alteration

01.1 Activity Intolerance

01.2 Activity Intolerance Risk

01.3 Diversional Activity Deficit

01.4 Fatigue

01.5 Physical Mobility Impairment

01.6 Sleep Pattern Disturbance

01.7 Sleep Deprivation

Actions performed to carry out physiological or psychological daily activities:

Example: Teach Passive Range of Motion

Source: Saba, V. K. (2012.). About. Clinical Care Classification System. Version 2.5, (2nd ed.). New York: Springer. Retrieved September 13, 2013, from http://www.sabacare.com/Tables/Components.html

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Rachel, a freshman at State University, participated in a sorority rush activity during the second week of school. Nearly 150 other freshman girls attended the event to socialize in the Student Union. About 2 or 3 days later, Rachel learned six of the students at the party tested positive for the H1N1 virus and displayed signs of illness. Cite the resources you used to answer the following questions. Be sure they are of professional quality.

THINKING

1. *Theoretical Knowledge:*
   a. What is another name for the H1N1 virus?
   b. Name six common outward signs of an H1N1 infection that you might see in a college student.
2. *Critical Thinking (Contextual Awareness):*
   Why is it important to detect and treat H1N1 in a healthy population of young adults?

DOING

3. *Nursing Process (Assessment):*
   How might you assess the extent of the problem of H1N1 illness within the campus community?
4. *Practical Knowledge:*
   a. As the Community Health nurse, you design a *primary* intervention program to prevent an outbreak of H1N1 virus on campus. What might you do for this program?
   b. What interventions would you likely implement to deliver a *secondary* intervention program?
   c. Or a *tertiary* program?

CARING

5. *Self-Knowledge:*
   How would you feel if you were one of the first-detected cases or H1N1 illness spread across the college campus?

Critical Thinking and Clinical Reasoning

1. You are nearing completion of your fundamentals course. One night while you are preparing for your next clinical, the telephone rings. It is your neighbor, Tanya. Her 5-year-old daughter, Tiffany, attends kindergarten at the local public school. Tiffany came home with a letter from the school nurse stating that

another child in the class was ill with H1N1 and that all the students in the class had been exposed to this flu virus.

Tanya is concerned about the risks to Tiffany and the rest of the family. Tiffany was vaccinated against H1N1. Tanya is 8 months pregnant, and the family has no health insurance. She states that because you are a nursing student, she thought you might know what she should do or where she might go for assistance.

What are the key pieces of information (both theoretical knowledge and patient data) you need to solve your neighbor's situation?

2. You are a nurse in a public health clinic providing routine childhood immunizations. A 16-year-old mother comes into the clinic requesting "shots" for her newborn baby as well as a birth control "shot." She indicates that she has no money to pay for the shots because her 20-year-old boyfriend gave her only enough to get to the clinic. Which of the following is your nursing priority for this situation? What will you do next? Explain *how* you have chosen your priority diagnosis. On what did you base your choice?
   - Give the newborn the immunizations, and arrange for the client to meet with the social worker regarding securing healthcare coverage.
   - Educate the mother about birth control.
   - Take the client and child to a private room, and discuss the general health of the newborn and the plans for a healthcare provider to see the child. Also ask about the health needs of the mother.
   - Ask the mother whether she is being abused and report the incident if so.
3. Your assignment is to conduct a community assessment of your neighborhood. How will your membership in the community affect your assessment? What activities could you delete from the assessment?
4. You are driving home from nursing school clinical day and happen upon a car overturned along a deserted country road. You recall what you learned about the "Good Samaritan" laws. Under these circumstances, are you liable for the care you provide? What is your best course of intervention?
5. As a beginning home health nurse, you have been assigned to visit the following clients today:
   - Roland Escobar (Meet Your Patients, Volume 1), a 78-year-old man recovering from a cerebrovascular accident (stroke)
   - Sally Littlemoon, a 48-year-old woman with diabetes mellitus, blindness, and lower extremity cellulitis (a skin infection)
   - Beatrice Wayne, a 67-year-old woman who has undergone elective coronary artery bypass graft surgery (open-heart surgery)
   - Kent Churchill, an 80-year-old man with a recent hip fracture and surgical repair
   - Ms. Chana Padir, a 50-year-old woman with severe pain secondary to breast cancer with extensive metastases. She is receiving hospice care.

   a. Explore some alternatives for your schedule. How would you prepare to make these five visits in one day? How would you determine how to arrange your schedule?

   b. The report you receive from the home health supervisor includes the following information:
      - Ms. Littlemoon and Mr. Churchill require dressing changes.
      - Mr. Escobar and Ms. Wayne require teaching about their medications.
      - Mr. Escobar, Ms. Littlemoon, and Mr. Churchill require venipuncture for lab work.
      - Ms. Padir is having increasing pain.

      Based on this information, what else do you need to know and/or do before you begin your visits? What practical knowledge will you need to provide care for these clients?

   c. How might the care you deliver to Ms. Wayne differ from the care you give to Ms. Padir? To answer the question, consider the context for each woman. How are their situations different?

   d. When visiting Ms. Padir, you realize that her husband and children are very fearful of her impending death. They seem overwhelmed by the care she requires.

      What values and beliefs do you have about death and dying that might influence your care of the Padir family? (Review Chapters 15, 16, and 17 if necessary.)

      What must you consider to plan your interventions? How might you intervene?

   e. When you arrive at the home of Ms. Wayne, she is dressed and out of bed. She tells you she is able to get out of bed and ambulate about the house independently with very little pain. She can identify the medications she is receiving, their purpose, and their schedule for administration. Her chest wound is healing nicely, and her breath sounds are clear. She informs you that she is planning on going to her cabin in the mountains this upcoming weekend with her husband and children. What actions must you take with regard to continuing her home visits? Why?

      What rules/guidelines will influence your choice of action?

6. For each of the following concepts, use critical thinking and summarize how or why it is important to nursing, patient care, or community nursing. Note that these are *not* to be merely definitions.
   Community
   Aggregates
   Census tracts
   Vulnerable populations
   Healthy People 2020
   Windshield survey
   Primary intervention
   Secondary intervention
   Tertiary intervention
   Disaster preparedness
   Omaha system
7. For each of the following concepts, use critical thinking to describe how or why it is important to nurses, patient care, or nursing in the home. Note that these are *not* to be merely definitions.
   Delivering healthcare in the home setting
   Skilled services
   Caregiver role strain
   Preparing for the home visit
   Developing rapport at the home visit
   Assessment of the home environment
   Documentation of home healthcare services
   Clinical Care Classification System

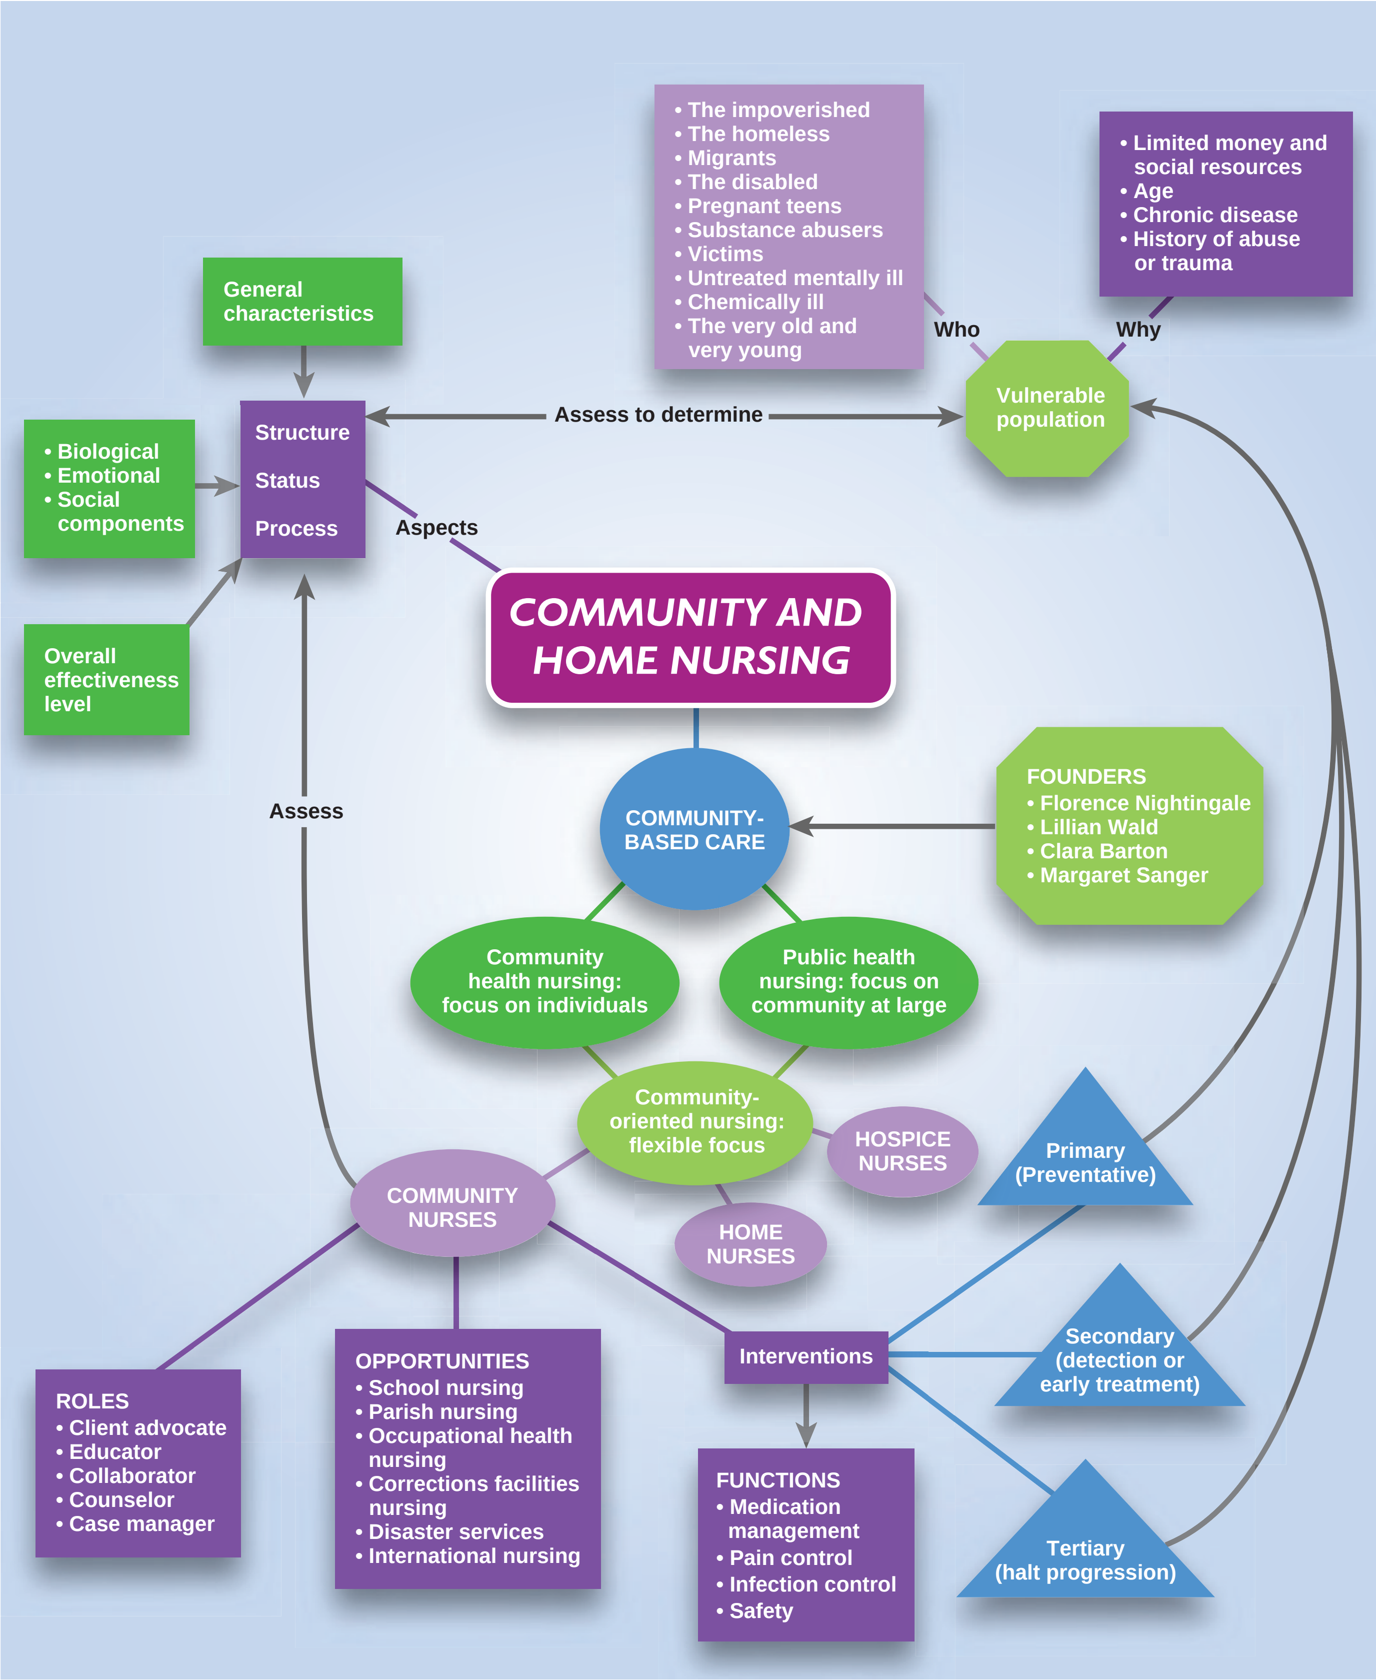
What Are the Main Points in This Chapter?

- A community can be defined as a place with defined boundaries, a group of people with a common language, rituals, or customs.
- Each community determines the meaning of health and nursing activities to promote health.
- A vulnerable population is defined as an aggregate that is at increased risk of adverse health outcomes. Members of vulnerable groups have a higher probability of developing illness.
- The community nurse assesses three general dimensions of a community: structure, status, and process.
- Common practice areas for community-based nurses include schools, churches, prison systems, disaster relief services, occupational and public health clinics, and international relief organizations.
- Community health nursing focuses on the health of individuals, families, and groups and how their individual health affects the community as a whole.
- Public health nursing focuses on the community at large and the eventual effect of the community's health status on the health of individuals, families, and groups.
- Community-oriented nursing combines components of community and public health. Nurses practicing community-oriented nursing are fluid in their approach. Their focus is a comprehensive look at the individual, family, group, and community at large. Community-based nurses function as advocates, educators, collaborators, counselors, and effective communicators.
- Community-based nurses may provide care at three levels: primary (preventive), secondary (early detection and early treatment), and tertiary (halt disease progression). The focus is on primary prevention.
- The Omaha classification system is a commonly used documentation system for generating a care plan for a community or an individual within the community setting.
- A community health nurse might practice as a school nurse, public health nurse, parish or prison nurse, international health nurse, or disaster service.
- Home health care is delivered in the community setting.
- Home health nursing fosters client and family independence and promotes self-care.
- In the home setting, many factors, such as cleanliness and noise level, are not within the nurse's control. In addition, the home health nurse works without immediate on-site access to other healthcare professionals.
- Home health agencies may be public, voluntary, proprietary, or hospital-based agencies. They may

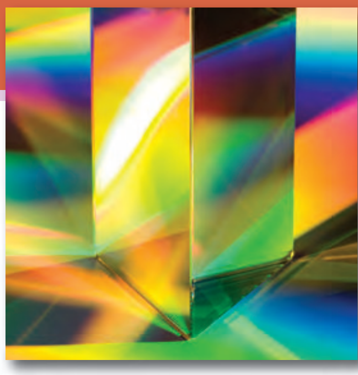
provide direct or indirect care and may specialize in certain types of clients.

- As a full-spectrum nurse working in home healthcare, you will function in the following roles: communicator, direct care provider, client/family educator, client advocate, and care coordinator (case manager).
- Hospice nurses work in hospitals, special hospice facilities, or the homes of patients who are dying. The goal of their care is to provide comfort and manage symptoms.
- Home healthcare is reimbursed by Medicare, by Medicaid, by private insurance, and through direct payment from the client. Medicare and Medicaid are the largest payors.
- To be eligible for continuing care under most government healthcare programs and private insurers, a client must be homebound and require skilled nursing care.
- Preparation for a home visit includes obtaining information from the referral, identifying the purpose of the visit, gathering required supplies, contacting the client to arrange the visit, and providing for your own safety.
- During a home visit, you will establish a rapport with the client and family, assess the needs of the client and caregivers, develop and discuss the plan of care and needed services with the client and caregivers, provide skilled care, and evaluate the need for continued services.
- Medicare requires specific client assessments using a form called the Outcome and Assessment Information Set (OASIS). It must be completed at the start of care, with each recertification (every 60 days), and at the termination of care.
- The Clinical Care Classification (CCC) system is a system of care and documentation used by most home-care agencies.
- Interventions to reduce Caregiver Role Strain include providing emotional support and arranging additional home and community services to support the client and caregiver.
- As a nurse delivering home care, you will need to follow standard precautions but recognize how infection control techniques may be modified to the home environment.
- In addition to infection control, nursing interventions usually include assisting with medication management, assessing and supporting home safety, and providing caregiver support.
- After a home visit you must document care, coordinate services for the client, and prepare for future visits.

Knowledge Map



CHAPTER 44



Ethics & Values

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 44:
- **Response sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Ethics & Values (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 44, **Podcast—Chapter Overview,** on Davis*Plus*.

Caring for the Nguyens

Mai Nguyen, Nam's mother, has hypertension. She is forgetful about taking her medicines. Since her husband died, she has experienced periods of depression. When asked about her medicines she often replies, "It doesn't really matter since my husband died. If I die, what difference will it make?"

Mai Nguyen was scheduled to have lunch with friends but did not arrive. When her friends called the house, they got no answer. At the end of lunch, one of Mai's friends decided to call Nam to inform him of her concerns about his mother. Nam found his mother unresponsive on the kitchen floor. He called 911, and she was brought to the hospital by ambulance. At the hospital, the emergency department (ED) doctor tells Nam that his mother has had a massive stroke (brain attack) brought on by uncontrolled hypertension. He asks Nam whether Mai has an advance directive or living will. Mai has neither. The physician asks Nam to consider what level of care to offer his mother. He tells Nam that comprehensive treatment would include intubation, mechanical ventilation, and tube feeding support. He feels it is unlikely that she will experience significant recovery from this stroke.

Nam tells you, "I want everything done for my mother. I lost my father this year, and I'm not going to lose her, too." Yen, Nam's wife, reminds you that Mai has been depressed since her husband died and has expressed a desire to die. Because Nam and Yen are not in agreement about the course of action, no decision is communicated. Mai's condition continues to deteriorate, and the ED physician feels he must intubate her, place her on a ventilator, and admit her to the ICU according to hospital protocol.

A. You are aware of Mai's statements and her poor compliance with treatment. What, if any, concerns do you have about this course of action?

B. Mai continues to decline. Nam is informed that the "only thing keeping his mother alive is the ventilator and IV medicines." Do you consider this heroic treatment?

C. How would you approach Mr. Nguyen to speak with him about how he is feeling?

D. Nam and Yen have asked to meet with the team providing care to Mai. They announce that they would like all the "heroic measures to end." They request that Mai be allowed to die. Could you participate in this care? What actions would you be comfortable with? What actions would you be uncomfortable with?

Practical Knowledge knowing how

Practical knowledge in nursing ethics primarily involves communication and problem-solving skills. We have included one model of ethical decision making as well as guidelines for patient advocacy for your quick reference in clinical situations.

CLINICAL INSIGHTS

Clinical Insight 44-1 ➤ Using the MORAL Model for Ethical Decision Making

- **M—Massage the dilemma.** Identify and define the issues in the dilemma. Consider the options of all the major players in the dilemma and their value systems. This includes patients, family members, nurses, physicians, religious representatives, and other interdisciplinary healthcare members. Identify the information gaps.
- **O—Outline the options.** Examine all the options, including those that are less realistic and conflicting. This stage is designed only for considering options and not for making final decisions.
- **R—Resolve the dilemma.** Review issues and options, applying basic principles of ethics to each option. Decide the best option based on the views of all those concerned in the dilemma.
- **A—Act by applying the chosen option.** This step is usually the most difficult because it requires actual implementation, whereas the previous steps allow only for dialogue and discussion.
- **L—Look back and evaluate.** Reflect on the entire process and evaluate all steps, including the implementation. No process is complete without thorough evaluation. Ensure that those involved are able to follow through on the final option. If not, a second decision may be required and the process must begin again at the first step.

Clinical Insight 44-2 ➤ Guidelines for Advocacy

The following principles will help you to function effectively as an advocate.

- **Keep the ethical principle of patient autonomy always in mind.**
- **Know and document the facts** of the case.
- **Know the arguments** of those who oppose the patient. **Use role playing** to develop a strategy for responding to the arguments.
- **Have a sound base of support for your actions.** Be familiar with any policies or laws that apply.
- **Form a coalition of allies**, if you can. Get consultation. Communicate, inform, and clarify their collaborative roles.
- **Intervene high enough in the hierarchy** to get the job done. If the difficulty is with a physician or an organizational policy, merely going to the charge nurse will not be enough. You will need to communicate with nurse administrators or other agency administrators.
- **Demonstrate to the system** how it is defeating its own goals (e.g., for patient care).
- **Avoid getting into a power struggle** if possible (use the preceding steps first). If you must, decide how far you need to go and whether you are willing to go that far. You will need to enlist people with more power in the system than you have (e.g., family members, physicians, administrators).
- **Be aware of client vulnerability.** When possible, avoid confrontation. If there is risk for the client (as in a power contest), be sure the client is aware of his risks and possible gains; then let him choose how far to take the situation.
- **Have alternative actions.** Assess risks realistically. Weigh them against potential gains.

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

Read the following summary of the Kithari and Kirschner article:

Kothari, S., & Kirschner, K. (2006). Abandoning the Golden Rule: The problem with "putting ourselves in the patient's place." ***Topics in Stroke Rehabilitation, 13*****(4), 68–73.**

A large body of evidence documents the difficulties healthcare professionals have in predicting what their patient believes or wishes. These difficulties extend from the predictions of:

- Very specific patient wishes, such as for life-sustaining therapies
- More global assessments of patients' lives as a whole (for instance, their quality of life)

One explanation for this phenomenon is that healthcare professionals, either consciously or unconsciously, adopt "Golden Rule thinking." This refers to our attempts to understand another person's situation by imagining what we would believe or want under similar circumstances, in other words, "putting ourselves in the patient's place."

Although Golden Rule thinking would seem to be a promising strategy, studies show that it actually results in inaccurate presumptions of patients' wishes or beliefs. These presumptions, in turn, have significant clinical and ethical implications. That is, they cause healthcare professionals and families to make decisions for the patient that are, in reality, *not* what the patient would want. The thinking goes:

I should put myself in the patient's place.
If I were the patient, I would want X.
Therefore, the patient probably wants X.
Because the patient probably wants X, we will do X.

This thinking process can have different results: (1) The patient really does want X, so you have met his needs. (2) The patient really wanted Y, so you did not meet his needs.

THINKING

1. *Theoretical Knowledge:* What is the Golden Rule, or what does it say?
2. *Critical Thinking (Inquiry):* What is one thing that could be done ahead of time to prevent the need for Golden Rule thinking? Explain why that would work.

DOING

3. *Nursing Process (Assessment):* If you do not know what the patient would want, instead of thinking what *you* would want, how might you get an idea of what the patient might want?

CARING

4. *Self-Knowledge:* What is your earliest memory of being taught the Golden Rule?
5. *Ethical Knowledge:* Which ethical principle does the Golden Rule seem to try to follow: autonomy, nonmaleficence/beneficence, fidelity, veracity, or justice?

Critical Thinking and Clinical Reasoning

1. Some examples of ethical issues you may encounter are end-of-life issues, abortion or other reproductive issues, breaches of patient confidentiality, and incompetent or illegal practices of colleagues. Stop for a moment and think about a time when you have witnessed an ethical challenge in the clinical area.
   a. Describe the situation.
   b. How well equipped did you feel to handle the situation?
   c. What guided your thoughts and actions?
2. At the beginning of this chapter in Volume 1, Alan (Meet Your Patients), a teenager, had been injured in a soccer game. Without a blood transfusion, he may die, but because his family is of the Jehovah's Witnesses faith, Alan's parents have refused to sign permission for his transfusion. Taking each of the abilities required

for ethical agency, state whether or not you think these people have the abilities listed below: Alan, Alan's parents, the physician, the nurse. Explain your thinking. An ethical agent must be able to:

a. Perceive the difference between good and evil, right and wrong.
   Alan
   Parents
   Physician/surgeon
   Nurse
b. Understand abstract ethical principles.
   Alan
   Parents
   Physician/surgeon
   Nurse
c. Reason and apply ethical principles to make decisions, weigh alternatives, and plan ways to achieve goals.
   Alan
   Parents
   Physician/surgeon
   Nurse
d. Decide and choose freely.
   Alan
   Parents
   Physician/surgeon
   Nurse
e. Act according to his choice; this assumes both the power and the capability to act.
   Alan
   Parents
   Physician/surgeon
   Nurse

3. Consider Alan's situation again. Analyze the situation (a) using a deontological framework and ethical principles and then (b) using a utilitarian framework. Focus on this question: Is it ethical to try hard to influence the parents to consent to allow a blood transfusion?
   a. Deontology
   b. Utilitarianism
   c. Did you reach a different conclusion depending on the framework you selected?
4. You are a busy nurse caring for a caseload of eight patients. One patient is the mother of the hospital administrator. She had surgery 3 days ago and is progressing nicely, but she is very demanding and requires a great deal of assistance to be repositioned in bed and to move from bed to chair. She has frequent visitors, including children and young grandchildren. In the next room is a young Haitian woman whose bill is paid by Medicaid. She has a history of drug abuse and had surgery this morning. She speaks little English and seems very anxious. She is experiencing nausea and pain and needs a transfusion of a unit of packed red blood cells this evening. Her boyfriend is at the desk requesting to bring her 3-year-old daughter to the unit so that she may see her mother. The visiting policy says that children must be at least 12 years old to visit the unit. Consider what aspects of justice apply to this situation and how it might be most equitably handled. Focus on the principle of justice.
5. An example of the feminist ethical approach arises in deciding whether to allocate federal healthcare resources to younger people (e.g., education, day care, free immunizations) or to older adults (e.g., prescription drug insurance, long-term care). Feminist reasoning would be as follows:
   - In the United States, older women outnumber older men.
   - Older women tend to be poorer and are more likely to be alone than are men.
   - Therefore, if healthcare for older adults were to be rationed, it would negatively affect women more than it would men.
   - Thus, more healthcare resources should be allocated to older adults, especially women.

   a. Analyze this decision using a deontological framework. Explain your reasoning, as was done above.
   b. Analyze this decision using a consequentialist framework. Explain your reasoning.
6. Deception can take different forms, from intentional lying to nondisclosure of information or partial disclosure of information. Think about your duty to tell the truth. Is there ever a time when being completely honest is not the best nursing intervention? Do you consider withholding information the same as lying?

7. Review the following scenario. Examine your self-knowledge, and work through the steps of the values clarification process (choosing, prizing, and acting). A 40-year-old couple with no other children learn that their unborn child has Down syndrome. The couple needs to make a difficult decision because the mother is 18 weeks pregnant.

a. How would you feel about this couple if they chose to have this child and insisted on doing everything possible to keep the baby alive even if it is born with severe handicaps?

b. Do you think that your professional relationship with this couple would change if they chose to terminate the pregnancy?

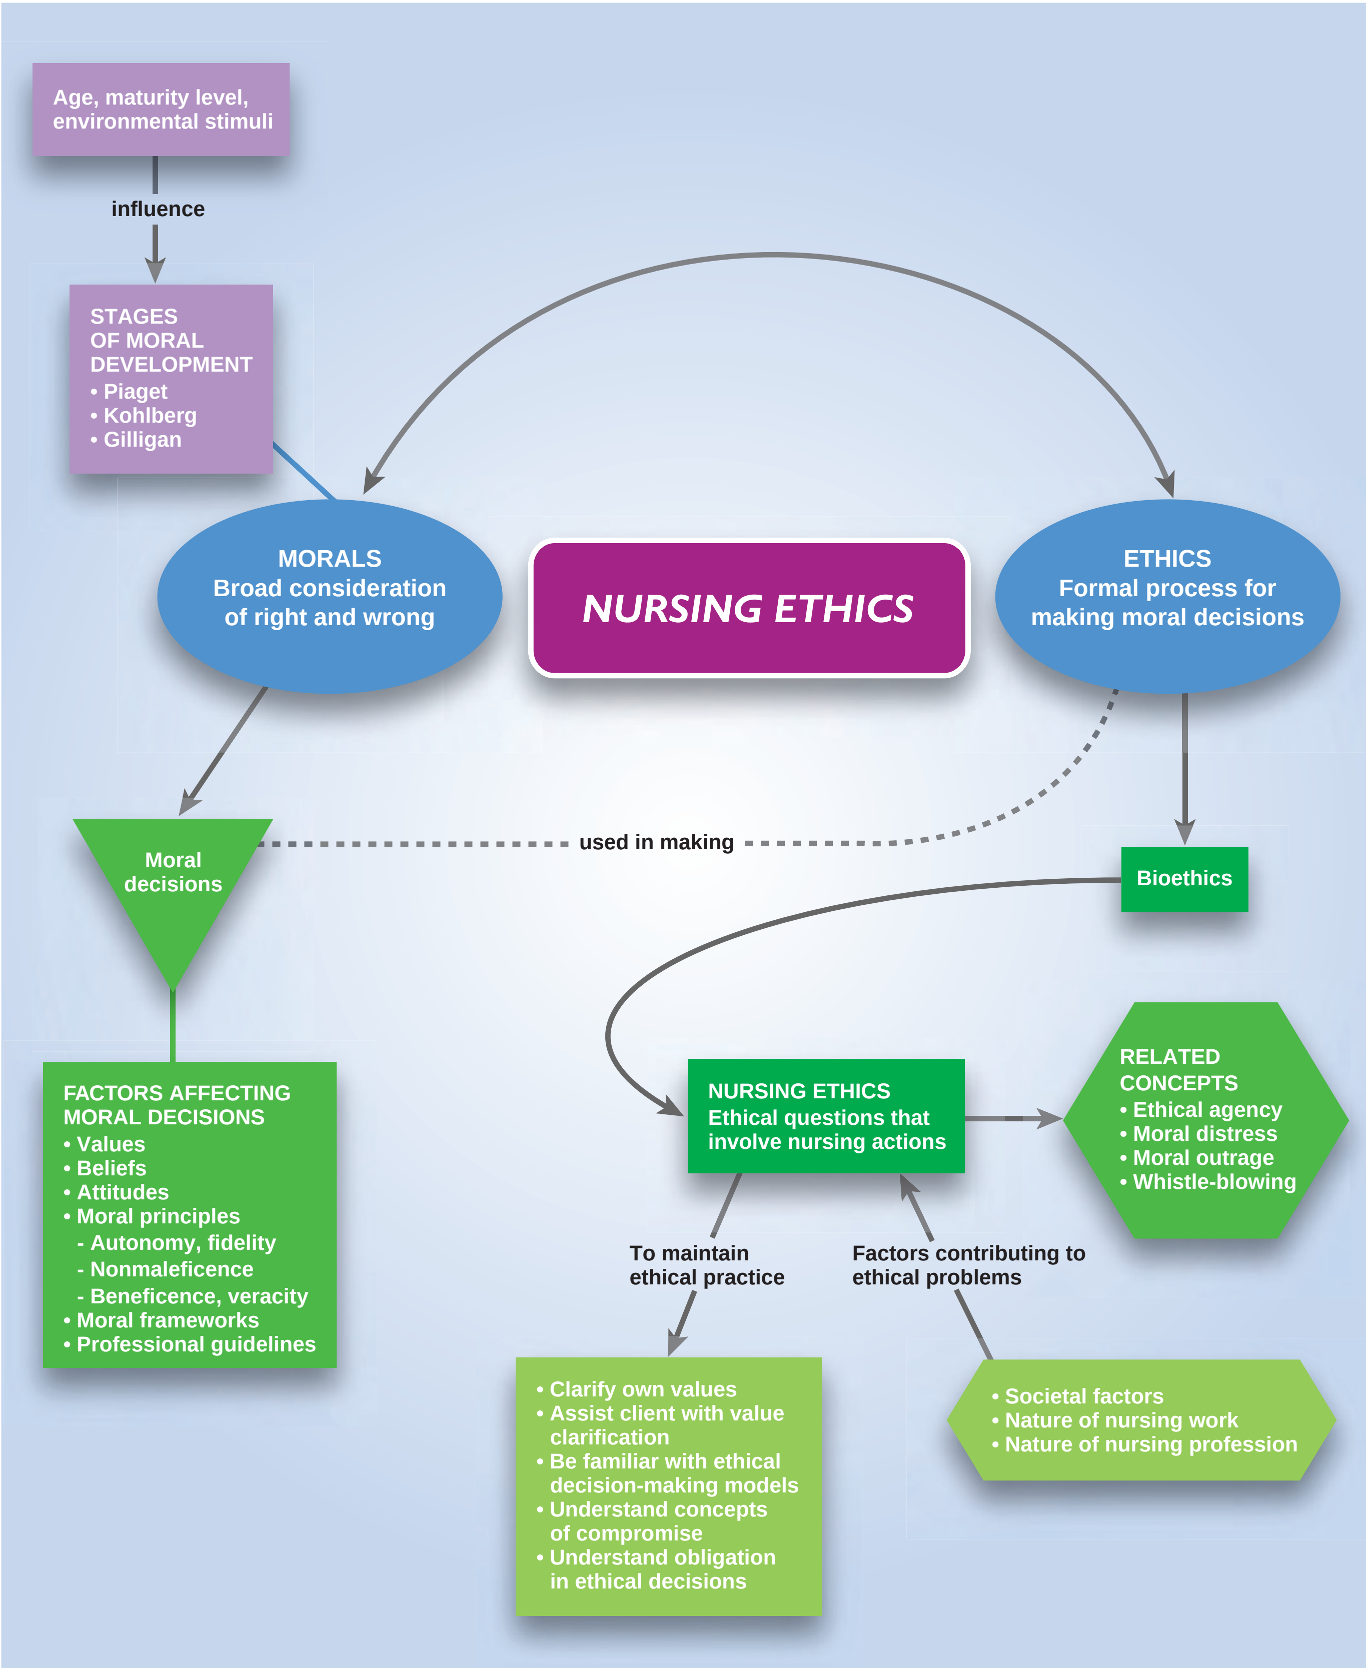
c. How can you help the couple clarify their values?
   (1) List alternatives.
   (2) Examine the possible consequences of the alternative choices.
   (3) Choose freely.
   (4) Feel good about the choice that has been made.
   (5) Affirm the choice to others.
   (6) Act on the choice.
   (7) Act with a consistent pattern.

What Are the Main Points in This Chapter?

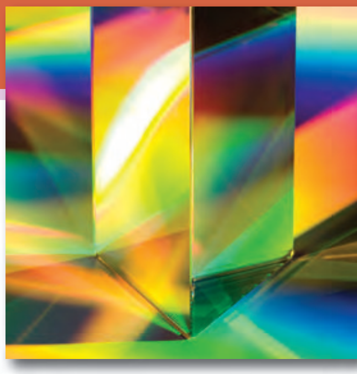
- Ethics is a formal process for deciding right and wrong conduct in situations in which issues of values and morals arise.
- Nursing ethics refers to ethical questions that arise out of nursing practice.
- Morals are learned and internalized throughout the life span. Carol Gilligan proposed that moral development and reasoning are different between men and women.
- Ethical agency is the ability to make ethical choices and to be responsible for one's ethical actions. In practice, nurses sometimes make moral decisions that they are not able to carry out.
- Moral distress is the inability to carry out moral decisions.
- Whistleblowing occurs when a person identifies in the workplace an incompetent, unethical, or illegal situation or action of others, and then appeals to someone who may have the power to stop it.
- Nursing ethics problems arise from technological advances, the needs of a multicultural population, cost containment efforts in healthcare, the nature of nursing work, and the nature of the nursing profession.
- Nurses have complex obligations and multiple complex relationships within healthcare organizations (e.g., with employers, physicians, patients, families, and other nurses).
- Ethical decisions are affected by a person's developmental stage, values, ethical frameworks and principles, and professional guidelines.
- Attitudes are mental dispositions or feelings toward a person, object, or idea.
- A belief is something that one accepts as true.
- A value is a belief that you have about the worth of something; a value is highly prized and expressed through behaviors, feelings, and decisions.
- Values are transmitted through social interaction.
- Value neutrality means that we attempt to understand our own values regarding an issue and to know when to put them aside, if necessary, to become nonjudgmental.
- Six important ethical principles are autonomy, nonmaleficence, beneficence, fidelity, veracity, and justice.
- Consequentialist theories are ethical theories in which the rightness or wrongness of an action depends on the consequences of the act, rather than on the nature of the act itself.
- The principle of utility states that a "good" act is one that produces the greatest good for the greatest number of people.
- Deontological theories consider an action to be right or wrong independent of its consequences.
- Feminist ethics asserts that focusing on deontological principles distracts one from dealing with larger social issues and that objectivity is impossible.
- An ethics-of-care directs attention to a patient's specific situation viewed within the context of his or her life narrative. It emphasizes feelings, but not at the expense of some conventional ethical principles, such as autonomy, nonmaleficence, or beneficence.
- Nurses can obtain ethical guidance from professional codes of ethics, standards of practice, and the American Hospital Association's *Patient Care Partnership.*

- The principle of autonomy underlies informed consent—clients' right to decide for themselves whether or not they will agree to a proposed procedure or treatment.
- Specific ethical issues the nurse is likely to encounter may involve AIDS, abortion, allocation of resources, issues of confidentiality, end-of-life issues (e.g., advance directives, DNAR orders, life-sustaining treatments, informed consent, organ transplantation), and reproductive technologies.
- A **value** is a belief you have about the worth of something; it serves as a principle or a standard that influences your decision making.
- Values clarification is the process of becoming conscious of and naming one's values. Nurses can assist clients with values clarification.
- Not all moral problems are dilemmas. A dilemma is a particular kind of moral problem: It is a painful situation in which a choice must be made between two equally undesirable actions. There is no clearly right or wrong option.
- One method of working through an ethical problem is to perform assessment and diagnosis, as in the nursing process; then use the mnemonic MORAL: **M**assage the dilemma, **O**utline the options, **R**esolve the dilemma, **A**ct by applying the chosen option, and **L**ook back and evaluate.
- A good compromise preserves the integrity of all parties when there is disagreement among them in an ethical situation.
- Nurses should be patient advocates because (1) their professional role requires it, (2) they have special knowledge that the patient does not have, (3) they have a special relationship with patients, and (4) one aspect of the nursing role is to defend a patient's autonomous decisions.
- The nurse's role as an advocate is to inform, support, and communicate.

Knowledge Map



CHAPTER 45



Legal Accountability

STUDENT RESOURCES

*The questions and exercises in Volume 2 allow you to practice the kind of thinking you will use as a full-spectrum nurse. Critical-thinking questions usually have more than one correct answer, so we do not provide "answers" for these features. It is more important to develop your nursing judgment than to just cover content. You will learn by discussing the questions with your peers. If you are still unsure, consult your instructor. You will find Response Sheets (for writing your responses to the questions) on Davis*Plus.

To explore learning resources for this chapter,

Go to Davis*Plus* at DavisPl.us/Wilkinson3.

Chapter Resources for Chapter 45:

- **Response sheets for all learning exercises**
- **Resources for Caregivers and Health Professionals**
- **Reading More About Legal Accountability (suggested readings)**
- **Concept Map of chapter content**

Interactive Case Studies

NCLEX-Style and Chapter Review Questions

CHAPTER OVERVIEW

For a podcast of an overview of this chapter,

Go to Student Resources, Chapter 45, **Podcast—Chapter Overview**, on Davis*Plus*.

Caring for the Nguyens

Nam and Yen Nguyen have requested an appointment with you, the nurse at the Family Medicine Clinic, to discuss advance directives. Their experience with Nam's mother, Mai, has created concerns about end-of-life care.

A. Nam asks you, "Do you think it's appropriate to create an advance directive at my age?" How would you respond?

B. Nam tells you that he believes in "natural death." He states, "I don't want extraordinary measures, and I never want to be resuscitated." Yen responds that she is extremely uncomfortable with blanket statements about treatment. "If he got hit by a car or had some accident, I would want you to do everything in your power to treat him. I couldn't carry out his wishes," she states. What actions should you take to help Nam and Yen resolve this discrepancy?

PracticalKnowledge knowing **how**

CLINICAL INSIGHTS

Clinical Insight 45-1 ➤ Using Equipment Safely

The following will help you to ensure proper and safe use of equipment:

1. Obtain appropriate training on equipment use.
2. Follow the healthcare agency's protocols, policies, and procedures on the use of the equipment.
3. Follow the manufacturer's operating instructions.
4. Be sure medical equipment has been properly inspected.
5. Perform safety checks regularly and before each use.
6. Position and use equipment properly during treatment.
7. Know how the equipment functions; be alert to signs that it is not working properly.
8. Make sure rooms are not cluttered with equipment.
9. Follow agency policies regarding equipment brought from the patient's home (e.g., hair dryers, electric shavers, radios); usually these should be inspected for proper grounding and safe cords.
10. Remove and label equipment that is malfunctioning to prevent others from using it until it can be repaired or replaced.

Practice Resources

Mattox, E. (2012).

Clinical Insight 45-2 ➤ Tips for Avoiding Malpractice

- **Develop open, honest, respectful, caring relationships** with patients and families. Patients are more likely to sue if they are angry or feel that you were not caring and professional.
- **Careful, thorough documentation** is the best defense if a lawsuit does occur:
  - Use and document all steps of the nursing process.
  - Be especially thorough when documenting care for patients who will not comply with treatments or who complain a lot.
  - Courts assume that if care is not documented, it was not given.
- **Know and follow applicable laws:** (1) federal and state laws, (2) your state's nurse practice act (perform only the activities within your scope of practice and competence).
- **Know and follow agency policies and procedures.**
- **Know and follow standards of care** set forth in the state nurse practice act, by professional organizations, in professional literature, by agency policy, and so on.
- **Follow the "rights" of medication administration** (see Chapter 26).
- **Perform falls risk assessments**, document, and take measures to ensure patient safety.
- **Recognize "problem" patients.** Try to identify the basic problem or complaint and intervene to resolve it.
- **Follow medical orders**, but clarify them as needed. Do not implement a questionable order or one you do not understand.
- **Don't blame or criticize other healthcare providers** in the presence of patients (e.g., "Sorry the night shift didn't give you your pain medicine.")
- **Maintain patient privacy and confidentiality.**
- **Don't make statements that may appear to be an admission of guilt** (e.g., "Omigosh, I forgot to shut off that IV!"). Errors should not be included on the patient's health record, but instead in an incident report.
- **Stay competent in your area of practice**; for example, attend continuing education, webinars, and in-service programs to improve your knowledge and skills.
- **Don't accept a clinical assignment that you think you are not competent to perform.** Evaluate your assignment with your supervisor if there is a question.
- **Recognize significant assessment cues**, and notify primary care providers of changes in the patient's condition or patient complaints.
- **Document the time and content of telephone conversations with other healthcare providers.**
- **Send copies only**, never originals, of records and reports requested by other professionals.

Practice Resources

Austin, S. (2008); Banford, E. & Budake, A. (2012); Reising, D. (2012).

Clinical Insight 45-3 ➤ Guidelines for Documenting Care

Complete reporting and documentation must address the following:

1. Patient status (e.g., symptoms and responses to treatments)
2. The nursing care given
3. Physician and other provider prescriptions
4. Medications and treatments
5. Patient responses
6. Consultations with other members of the healthcare team regarding patient status

When documenting care, use the F-A-C-T mnemonic:

Factual
Accurate
Complete
Timely

Another way to remember how to document is to use the 5 Cs. Charting should be:

Complete
Clear
Correct
Comprehensive
Chronological

Practice Resources

Arnold, P. (2012); Austin, S. (2011); Helm, A. (2003, pp. 1-33).

CLINICALREASONING

Applying the Full-Spectrum Nursing Model

PATIENT SITUATION

A nurse employed by a temporary agency is assigned to a neurology unit for a 12-hour shift. On arrival, she discovers that the registered nurse (RN) assigned for the shift called in sick, leaving her with two nursing assistive personnel (NAPs) to provide patient care and administer medication, including controlled substances. The nursing supervisor informs her that she will be responsible for the unit with 22 patients, 12 of whom are acutely ill and require close observation and frequent care. The nursing supervisor is not available to work on the unit and has no additional RNs to provide patient care. The nurse decides not to accept the assignment, to report the decision and reasons to her agency supervisor, and to leave the neurology unit immediately before starting the shift.

THINKING

1. *Theoretical Knowledge:*
   a. In addition to protecting her nursing license, what other factors should the nurse have considered in deciding whether to stay or leave the unit?
   b. Because the nurse decided not to accept the assignment, would this have been considered abandonment?
   c. What standards, guidelines, and laws would apply to determine whether the nurse's behavior was in accordance with standards of practice?
2. *Critical Thinking (Contextual Awareness)*:
   a. Which statements in the ANA Nurses' Bill of Rights should the nurse have considered before deciding whether to accept the assignment?
   b. What factors in this situation could create legal problems for the nurse?

DOING

3. *Nursing Process (Planning/Intervention)*: The nurse's action (leaving the unit) might be viewed, under some laws in some situations, as abandonment of patients. What are some alternative actions the nurse might have taken to avoid that risk?

CARING

4. *Self-Knowledge:* Have you ever been in a situation in which you felt a moral obligation to help out but yet knew you would be in over your head? Describe your experience.
5. *Ethical Knowledge:* In your opinion, did the nurse do the right thing when she decided not to accept the assignment and to leave the nursing unit immediately? Explain your thinking.

Critical Thinking and Clinical Reasoning

1. Think about the Meet Your Nurse Role Model scenario you read at the beginning of the chapter in Volume 1. A nurse with 3 years of experience on a medical-surgical unit arrives to work and discovers that two of her colleagues called in sick, including the charge nurse. The nursing supervisor informs her that she will need to assume the charge nurse role, in addition to assuming care for three patients. Feeling frustrated, the nurse ponders whether she should just quit and find another job, but nevertheless accepts the assignment. Two hours into the shift, one of her patients begins to experience complications, requiring blood glucose checks every 2 hours and frequent monitoring. In addition, one of the nurses becomes ill and is replaced by a float nurse from the labor and delivery unit. The nurse contacts the nursing supervisor and requests additional assistance, but is told no other nurse is available and that the supervisor is involved with an emergency situation on another unit. The nurse begins to analyze this situation from a legal perspective to determine the best course of action.

   Use the critical-thinking model to identify questions to ask yourself in reflecting and deciding what to do.

   Go to Chapter 2, **Table 2-1, Critical-Thinking Model,** in Volume 1.

   a. What questions do you need to ask about context?
   b. What knowledge do you need to make an informed and credible decision?
   c. What questions do you need to ask about considering alternatives?
   d. What questions do you need to ask about analyzing your assumptions?
   e. What questions do you need to ask about reflecting and deciding?

2. Analyze this passage:
Nursys is the national database for verification of nurse licensure, practice privileges, and disciplinary information for RNs and LVN/LPNs. The e-Notify feature of Nursys provides real-time information to employers about their nurse employees as the information is entered into Nursys (National Council of State Board of Nursing, 2012).
   - Do you think there is a need for Nursys?
   - What rights does it help protect?
3. Imagine that you are working in a large medical center in an area where there have been several robberies and assaults in the past 6 months, mostly late at night. Although the parking lot is nearly a block from the employees' exit and is not well lighted, there is only one security guard on duty outside the hospital after 2200. Despite repeated requests from employees all the way up the chain of command, no efforts are being made to improve lighting or to hire more security guards. What standards and laws might be helpful to the employees?
4. George Agnew, 75 years old, is admitted to the emergency department after being involved in a serious car accident. His wife is with him, and she is very upset—to the point of being hysterical. It is likely that Mr. Agnew will die, but physicians are considering whether he will need a ventilator in the next hour or so. You need to know Mr. Agnew's wishes on this issue, but he is not conscious. The charge nurse tells you not to ask Mrs. Agnew because it will just upset her more.
   a. What is happening in the situation that may influence the outcome?
   b. What factors may influence your behavior and others' behavior in this situation?
   c. What values or biases do you have that influence your behavior in this situation?
   d. Where might you get the information you need instead of asking Mrs. Agnew?
   e. What would you do? What legal support, if any, do you have?
5. Compare and contrast the following definitions of practical nursing and professional nursing taken from the Nurse Practice Act in Missouri and then discuss the differences in the scope of practice for the LPN/LVN and the RN. Identify two tasks/responsibilities that only the RN can perform.

   DEFINITION 1. Practical nursing is the performance for compensation of selected acts for the promotion of health and in the care of persons who are ill, injured, or experiencing alterations in normal health processes. Such performance requires substantial specialized skill, judgment, and knowledge. All such nursing care shall be given under the direction of a person licensed by a state regulatory board to prescribe medications and treatments or under the direction of a registered professional nurse. For the purposes of this chapter, the term "direction" shall mean guidance or supervision provided by a person licensed by a state regulatory board to prescribe medications and treatments or a registered professional nurse, including, but not limited to, oral, written, or otherwise communicated orders or directives for patient care. When practical nursing care is delivered pursuant to the direction of a person licensed by a state regulatory board to prescribe medications and treatments or under the direction of a registered professional nurse, such care may be delivered by a licensed practical nurse without direct physical oversight.

   DEFINITION 2. Professional nursing is the performance for compensation of any act which requires substantial specialized education, judgment, and skill based on knowledge and application of principles derived from the biological, physical, social. and nursing sciences, including, but not limited to:
   a. Responsibility for the teaching of health care and the prevention of illness to the patient and his or her family;
   b. Assessment, nursing diagnosis, nursing care, and counsel of persons who are ill, injured, or experiencing alterations in normal health processes;
   c. The administration of medications and treatments as prescribed by a person licensed by a state regulatory board to prescribe medications and treatments;
   d. The coordination and assistance in the delivery of a plan of health care with all members of a health team;
   e. The teaching and supervision of other persons in the performance of any of the foregoing. (Missouri Revised Statutes, 2013).
6. The patient was an older adult with various medical conditions and receiving multiple medications. The nurse determined the patient was a high fall risk, 8 on a scale of 0 to 10. The nurse decided to initiate the hospital's fall prevention plan, which meant raising the siderails and placing restraints on the patient without physician's orders. Hospital policy, however, did require a nurse who initiated restraints on a patient for fall prevention to notify a physician or physician's assistant within 1 hour after doing so.

   The next day another nurse, seeing that no orders for restraints had been received, removed the restraints. The patient was getting up out of bed on his own. His nursing neurological assessment showed signs of dementia and confusion. His oxygen saturation was low and his heartbeat was irregular. The physician was notified by phone but declined to order restraints. Later that evening the patient was found on the floor with a closed-head injury. He was transferred to a university hospital, where he died a few weeks later. The case was dismissed against the hospital (Sturgill v. Ashe Memorial Hosp., 2008).

a. In this case, the nurse was caring for a patient at high risk for fall but did not have a prescription to use restraints. Why do you think the court dismissed the case against the hospital?
b. What other action might the nurse have taken to prevent this patient's fall?

7. For each of the following concepts, use critical thinking to describe how or why it is important to nurses, patients, or legal issues. Note that these are *not* to be merely definitions.

Civil law
The U.S. Constitution Bill of Rights and the Patient Care Partnership
The ANA Code of Ethics; the ANA Standards of Practice; and the ANA Nurses' Bill of Rights
Patient advocacy
Battery
Vicarious liability

What Are the Main Points in This Chapter?

- The law is a binding practice, rule, or code of conduct that guides a community or society and is enforced by a controlling authority.
- Laws are primarily derived from four sources: (1) the Constitution, (2) statutes, (3) administrative bodies, and (4) the courts.
- The right of privacy comes from the Bill of Rights.
- A living will is prepared by an alert and oriented (competent) individual to give directions to others about the person's wishes regarding life-prolonging treatments if the person becomes unable to make those decisions.
- A durable power of attorney for healthcare identifies a person who will make healthcare decisions in the event the patient is unable to do so.
- State laws affecting nursing practice include mandatory reporting laws, Good Samaritan laws, safe harbor laws, and nurse practice acts.
- The ANA Code of Ethics describes the standards of professional responsibility for nurses and provides insight into ethical and acceptable behavior.
- The ANA Nurses' Bill of Rights identifies the rights nurses should expect from their workplace and work environment that are necessary for sound professional practice.
- A primary function of the medical malpractice system is to encourage healthcare providers to adhere to standards of practice and perform their responsibilities in a competent manner.
- Standards of practice look to what a reasonable and prudent nurse would do in the same or similar situation.
- Nurse practice acts are established by state boards of nursing to govern the practice of nursing.
- In most states, nurses are obligated legally to report suspected or actual patient abuse, impaired health professionals, and communicable diseases.
- State boards of nursing are empowered under the nurse practice act to approve prelicensure nursing education programs, determine the criteria for licensure, define the practice of nursing, and establish grounds for disciplinary actions against nurses.
- Criminal law deals with wrongs or offenses against society. Civil law deals with wrongs to individuals.
- Intentional torts include assault, battery, false imprisonment, fraud, and invasion of privacy.
- Quasi-intentional torts involve those actions that injure a person's reputation.
- Unintentional torts that involve healthcare professionals are negligence or malpractice.
- Negligence is a wrong committed against an individual by one who has failed to use ordinary care.
- Malpractice is negligence committed against an individual by a licensed professional involving a duty, breach of that duty, an injury, and damages.
- Litigation is the formal process where the legal issues, rights, and duties between the parties are heard and decided. The stages include (1) pleading and pretrial motions, (2) discovery, (3) alternative dispute resolution, (4) trial, and (5) appeal.
- Malpractice claims, in general, result from failure to maintain the standard of practice, including failure to assess, diagnose, plan, implement, and evaluate patient responses to care.
- Nurses can help reduce their legal risks by developing open, honest, respectful, caring relationships with patients and families; observing standards of care; and accurate documentation.
- You may witness a patient's signature on a consent form, but you are not legally responsible for explaining the treatments and options, nor for evaluating whether the provider has adequately explained them.

This illustration depicts the full-spectrum model of nursing used throughout this learning package. A full-spectrum nurse uses critical thinking and the nursing process to apply various types of knowledge (theoretical, practical, ethical, and self-knowledge) to the patient situation to bring about desired health outcomes. Truly, thinking and doing.

Universal Steps for All Procedures:
Before and Preparing

➤ You should consider the following nursing activities to be a part of every procedure:

Before Approaching a Patient

- Check the medical prescription or obtain one, if necessary.
- Refer to agency protocols unless you already know them.
- Get a signed, informed consent, if needed.
- Wash your hands. Follow agency policy and CDC guidelines for hand hygiene.
- Gather the necessary supplies and equipment.
- Obtain assistance from another healthcare worker, if it will be needed (e.g., to lift a patient).

Preparing the Patient

- Identify the patient using two identifiers (e.g., read the wrist band and ask the patient to state his or her name).
- Explain the procedure to the patient: What the patient will do, what he will feel, and what she is expected to do (e.g., "You will need to lie very still.").
- Provide privacy. For example, ask visitors to step out of the room, draw bed curtains, and close the door.
- Position the bed or treatment table to a working level; lower the near siderail.
- Make any relevant assessments (e.g., take vital signs) to ensure that the patient (1) still requires the procedure and (2) is able to tolerate it.

During and After

During the Procedure

- Wash your hands before touching the patient, before gloving, and after removing gloves. Wash them again before leaving the room.
- Maintain correct body mechanics.
- Continue to observe the patient while performing the procedure steps.

After the Procedure

- Evaluate the patient's response to the procedure.
- Leave the patient in a comfortable, safe position, with the call light within reach.
- If the patient is in bed, return the bed to its original position and raise the siderail (if the patient requires this precaution).
- Document that the procedure was done; document the patient's responses.
- Dispose of supplies and materials according to agency policy.

Remember:

All procedures are "rules of thumb." Patient care can be altered by medical orders, agency policies, and individual patient needs.

Key Point: ***Everything you do requires nursing judgment!***
