FOR CLASSROOM AND CLINICAL SUCCESS

Watch. Do. Learn.

Davis's Nursing Skills Videos

Real nurses demonstrate essential nursing skills step by step.

All of the skills and procedures you need to master are here! Each video demonstrates a procedure, while a narrator explains clearly what to do. Procedure variations include instructions for what to do in special situations.

Watch each video from beginning to end without interruption, or watch individual sections as many times as you wish.

Select the format you need.

As new scientific information becomes available through basic and clinical research, recommended treatments and drug therapies undergo changes. The author(s) and publisher have done everything possible to make this book accurate, up to date, and in accord with accepted standards at the time of publication. The author(s), editors, and publisher are not responsible for errors or omissions or for consequences from application of the book, and make no warranty, expressed or implied, in regard to the contents of the book. Any practice described in this book should be applied by the reader in accordance with professional standards of care used in regard to the unique circumstances that may apply in each situation. The reader is advised always to check product information (package inserts) for changes and new information regarding dose and contraindications before administering any drug. Caution is especially urged when using new or infrequently ordered drugs.

Judith M. Wilkinson, PhD, CNS, APRN, Author

Judith Wilkinson taught fundamentals of nursing for 22 years, and more recently, has taught graduate-level courses in theory, research, and health policy. She also developed, and taught for many years, an LPN-to-RN transition course. She has given numerous presentations and provided consultation and faculty development workshops for nursing and other schools—primarily in the areas of critical thinking and nursing ethics, but also in standardized nursing languages, teaching strategies, testing, evaluation, and curriculum.

She obtained her PhD in Nursing from the University of Kansas School of Nursing, and master's degrees in Nursing and Education from the University of Missouri–Kansas City. Her basic nursing degree was an ADN from Johnson County Community College, followed by a BSN from Graceland College. She was granted a National Endowment for the Humanities fellowship to study nursing ethics, and a Nurses' Educational Fund (Isabel Hampton Robb) scholarship for her nursing doctoral study. Her master's thesis was a seminal work in moral distress; her doctoral dissertation also studied nursing ethics.

Dr. Wilkinson's clinical background is broad, and includes emergency, critical care, med-surg (float), and obstetric nursing. While engaged in full-time teaching, she maintained certification in inpatient obstetric nursing; her advanced practice license is in nursing care of women.

She is co-author of another fundamentals textbook, Treas and Wilkinson, *Basic Nursing: Concepts, Skills, and Reasoning.* Her other publications include a nursing process text, a nursing diagnosis handbook (each going into multiple editions and international publication), a maternal-newborn care planning book (as a co-author), and journal articles on the topics of curriculum, critical thinking, and nursing ethics. Over the years, she has contributed chapters to several textbooks and authored many ancillary materials, including test banks, learning modules, and review modules.

Leslie S. Treas, PhD, RN, CPNP-PC, NNP-BC, Author

Dr. Leslie Treas, one of the founders and former vice-president, Research and Development of *Assessment Technologies Institute™, LLC* (ATI) demonstrated leadership and expertise forecasting and directing the design and development of ATI product testing and educational product line since the formation of the company. In this role, Dr. Treas planned and implemented norming, test validation, and standard-setting studies to support data-driven product development, constructing tests with sound psychometric properties. Under her management, she produced a series of NCLEX-review books and nursing skills DVD set. She has conducted clinical and educational research, publishing in peer-reviewed journals of health and education.

Dr. Treas was involved in the start-up of a continuing education company for nurses, physicians, and allied health professionals, serving as Director of Education and Accreditation, *AcaMedic Institute™, LLC.*

Dr. Treas earned a BSN from Pennsylvania State University and an MSN degree with emphasis in maternal-child health at the University of Kansas. She obtained a PhD from the University of Kansas in the Educational Psychology and Research Department with dual areas of study of testing and measurement and nursing education. Her primary area of clinical expertise is the care of sick newborns in the NICU and labor and delivery settings in the clinical role of a neonatal nurse practitioner for 13 years. Dr. Treas obtained dual pediatric and neonatal nurse practitioner certifications at the Cleveland Metropolitan General Hospital, affiliate of Case Western University.

Her journal and textbook publications have featured various clinical topics ranging from fundamentals of nursing to care of neonatal patients. Other publications are education-based areas related to nursing licensure preparation and prediction, critical thinking, and others. She has also written articles geared to new graduate readers, addressing contemporary issues involving role change, employment, and communication.

Dr. Treas has presented for annual conferences for Sigma Theta Tau, National Association of Associate Degree Nurses, National Association of Neonatal Nurses, American Association of Colleges of Nursing, National Conference on Professional Nursing Education and Development, Association for the Advancement of Educational Research, to name a few.

She has test-writing expertise as a former item writer for the National Certification Examination for Pediatric Nurse Practitioners and Nurses, and also the National Certification Corporation for Neonatal Nurse Practitioner Exam.

Karen L. Barnett, DNP, RN, Co-author

Karen Barnett has been a nurse for more than 25 years and has held various positions in nursing, including patient care, administration, and education. Most recently, Dr. Barnett serves as Dean of Nursing for St. Vincent's College in Bridgeport, Connecticut, where she oversees more than 800 pre-nursing and nursing students in AD and RN to BSN programs. Prior to that, she taught medical-surgical nursing, professional nursing theory, and clinical education to undergraduate students and has taught advanced pathophysiology to graduate nursing students. Dr. Barnett's clinical background includes critical care, medical-surgical, and cardiac-telemetry nursing. While engaged in full-time teaching, she continues to maintain clinical competence in her role as nursing supervisor at an acute care community hospital.

Dr. Barnett earned a BSN from Southern Connecticut State University and an MSN degree with a focus in nursing administration from Sacred Heart University. She earned a DNP from the Francis Payne Bolton School of Nursing at Case Western Reserve University in 2010 with a focus in nursing education. Dr. Barnett is a member of the American Nurses Association, Connecticut Nurse Association, the National League for Nursing, and Sigma Theta Tau International Nursing Honor Society. She was honored with a Nightingale Award for Excellence in Nursing in 2013. Research interests include student learning outcomes, simulation as a learning tool, and critical thinking/clinical judgment. Dr. Barnett has contributed to chapters in several textbooks and authored other ancillary material including test banks and concept maps.

Mable H. Smith, BSN, MN, JD, PhD, Co-author

Dr. Mable Smith is the founding Dean of Nursing of the Colleges of Nursing at Roseman University of Health Sciences (formerly the University of Southern Nevada), Nevada and Utah. She has extensive experience in nursing education and has taught at all academic levels, including undergraduate courses in professional nursing, leadership and management, role transition, legal and ethical aspects of practice, and adult health nursing. Dr. Smith has published and presented in numerous arenas on legal and ethical issues in nursing education and in nursing/healthcare. Her publications have appeared in leading referred journals, and she authored the book *The Legal, Ethical and Professional Dimensions of Nursing Education,* currently in its second edition.

Dr. Smith earned a BSN from Florida State University (FSU) and an MN from Emory University, with an emphasis in education. She obtained a PhD in Higher Education Administration and JD from FSU. Dr. Smith has served on the faculties of Florida A&M

University, Old Dominion University, and the University of Southern Mississippi. Her primary area of clinical expertise is adult health nursing. Dr. Smith is a member of the American Nurses Association, Nevada Nurse Association, National League for Nursing, and the American Association of Nurse Attorneys. She was honored by the National Association of Women Business Owners as a *Woman of Distinction* for her contributions to the education field in southern Nevada and was named a Healthcare Headliner by *In Business Las Vegas*, one of southern Nevada's premier business publications. She is also a Robert Wood Johnson Executive Nurse Fellow alumna.

We dedicate this book to:

The people at F. A. Davis Company, who have supported us for many years and in many ways. To point out a few: the sales team, the marketing team, and especially the editorial team, with whom we have the closest relationships. They have allowed—even encouraged—us to think outside the box and to explore new paths without knowing for certain where they would lead.

My husband, Franklin Hiam, who relieves me of many (most) activities of daily living, and who I am sure expected me to have more free time during our "golden years."

My sons, Todd, Bryan, and Chris—for being kind, responsible men, who each in his own way makes the world a little better. They internalized my message that it's okay to march to the beat of a different drummer. They do that, and they accept people who step to a different beat from theirs.

My father, who when I was a small (literally) child, called me "Dynamite" when everyone else was calling me "JudyBug"; and said over and over, "You can do anything you think you're big enough to do." Almost, Daddy; almost.

—Judith M. Wilkinson

Judith Wilkinson

No work, however seemingly solitary, is ever produced in isolation. I'd like to heartily express my deep gratitude to the many people in my life who made it possible for me to pursue this textbook and arduously see it through to completion. Foremost to my loving husband, Randy, and our children, Megan, Bridget, and Jack, who have supported me with unwavering support in this journey from nurse practitioner to nurse entrepreneur to scholar and writer. Randy tirelessly carried the load and picked up the pieces all along the way. To my mother, who always urged me to tackle extraordinary tasks with persistence and diligence. She once said, "How do you eat an elephant? . . . One bite at a time." This book certainly was just that—one small bite after another, one step at a time, followed by a leap of faith that this important work could be, and would be done. My mother-in-law, Sandy Treas, has been an encourager and supporter, not only providing many meals for my family during these demanding times but her kindred spirit as a strong woman who has kept her eyes on the horizon, not succumbing to the challenges that pressed upon her.

To Diana Rieser, Nurse Manager of the NICU at Saint Luke's, Kansas City, who walked the walk of what it means to be a thinking, doing, and caring nurse to sick newborns and their families. She mentored "new nurses" with wisdom and care and taught them what it means to be the hands of compassion and competence. To Dr. John Callenbach, neonatologist, who was "all in" no matter what it took, day or night in addressing the needs of critically ill and convalescing infants; and who respected and relied on the nurses as the eyes and ears and the heart of quality care.

But mostly to my dear friend and respected colleague, Judith Wilkinson, who from the creation of this work has never once settled for good enough. Intent on perfection, committed to excellence, Judith's tenacity and wisdom raise the bar for teaching and learning. From the very design of this work, Judith passionately strives to draw students into the experience of learning throughout their journey from student to nurse. "Tell me and I forget, teach me and I may remember, involve me and I learn." — Benjamin Franklin

—Leslie S. Treas

Preface

We chose our book title carefully. We have used the words *theory, concepts, application, thinking, doing,* and *caring* because we believe that excellent nursing requires an equal mix of knowledge, thought, action, and caring. It is knowledge and its application—not just the tasks nurses do—that delineate the various levels of nursing. Even so, skillful performance of tasks is essential to full attainment of the nursing role.

We chose the word *fundamentals* because this text, and its concomitant course, is truly that: the foundation for all that follows. This basic content teaches essential functions that nurses will use throughout their careers, and in that sense, we believe it is of central importance. It is—or should be—the most important course students take. We want them to say, "Everything I need to know, I learned in fundamentals—all I needed to know about how to think, what to do, and how to be" (at least at a basic level). You will see those themes integrated throughout each chapter.

The thoroughly revised and updated third edition, kept fresh by the acquisition of two new co-authors, preserves the same open, user-friendly, easy-to-read style that students have been telling us they love.

ORGANIZATION

We have organized the learning package into two volumes to make it easier for on-the-go students to have at hand the material they need in either the classroom or the clinical setting. The content of Volumes 1 and 2 is comprehensive. Our chapters are self-contained and rich in cross-references so that teachers and students can use them in any order that fits their needs. The cross-references assist them to see the relationships between Volumes 1 and 2 and among the chapters, as well as to navigate easily between the two volumes.

Content within each chapter is generally organized into two major sections: Theoretical Knowledge (Knowing Why) and Practical Knowledge (Knowing How). There is some overlap in these concepts because the two types of knowledge are interdependent. We have made this general distinction because many nursing programs begin with content learned in supporting prerequisite classes and then layer on additional Theoretical Knowledge to explain the rationale for nursing actions and activities (Practical Knowledge). The distinction also affords more flexibility in teaching fundamentals. For example, it is useful to teachers who believe students are more motivated when they present first the concrete (Practical Knowledge), and then the abstract (Theoretical Knowledge); it is equally useful for those who teach from the theoretical to the practical.

Enrichment (Supplemental Material)—We have tried to write a text that meets the needs of most students and instructors and that can be used as a reference throughout the student's career—one that is comprehensive but not overwhelming. To minimize weight and bulk, and to keep the content manageable for students, we have put some enrichment material in the Electronic Study Guide on Davis*Plus* for students who need it or who wish to pursue a subject in more depth. It is all clearly cross-referenced. Instructors who believe that content to be essential can make it a reading requirement.

PEDAGOGICAL FEATURES

The book has numerous pedagogical features to facilitate student learning.

New for Third Edition

NEW!! Key Concepts and Example Problems—In the chapter opener, we have listed the key concepts. An explanation of their use (About the Key Concepts) is found at the beginning of the Theoretical Knowledge section. A Concept Map on Davis*Plus* illustrates the relationships among the key concepts and subconcepts in each chapter. Example Problem sections (e.g., Urinary Retention in Chapter 30) help students begin to think conceptually about patient care instead of trying to organize their thinking according to medical diagnoses.

NEW!! End-of-chapter box—This is another navigation tool: a list of features to remind students and help them use Davis*Plus* to their advantage. In Volume 2, the box is in the chapter opener.

NEW!! More Key Points—We know students skim the content, so we have made visible many points we want to be certain they see and remember.

Reorganized chapters—To better address the needs of many educators, we have reorganized some chapters for this edition:

- ***Life Span: Infancy Through Middle Adulthood***—To replace the summarized content contained in the second edition, we have moved and rewritten the expanded content into Chapter 9 in the book. Each stage is discussed in depth, but now more easily accessible in the book, at the request of users.

- ***Life Span: Older Adults***—Because of the recent emphasis in nursing care of the growing older adult population, we now have a separate chapter on older adults (Chapter 10). The content has been expanded in this edition.
- ***Oxygenation***—To allow students to focus better on one concept, we have divided the old Oxygenation chapter. The complex oxygenation content is now presented in Chapter 36, separate from the circulation content.
- ***Circulation***—For the same reasons, the circulation content is now presented separately, and expanded, in Chapter 37.
- ***Community & Home Health***—Because these two concepts are so interrelated, we now combine the content from the two second edition chapters (Community Nursing and Nursing in Home Care), presenting them in Chapter 43. We have not decreased the coverage of either topic – simply trimmed down redundant coverage.

Features Continued from Previous Editions

- ***Learning Outcomes (Volume 1) and What Are the Main Points in This Chapter? (Volume 2)***—These focus the student's study and provide repetition to facilitate retention of material. In addition, a cross-reference is provided to a Chapter Overview podcast on the Davis*Plus* Web site.
- ***Interactive Approach***—The text is written in an engaging style that speaks directly to the student. Recall and critical-thinking questions occur frequently in Volume 1 to break the reading up into small, manageable segments and maintain interest.
  - ***Knowledge Checks***—These questions allow students to test their recall of the material presented in the text. Answer sheets and answers are provided on the Electronic Study Guide (ESG).
  - ***Think Like a Nurse Exercises***—Thought-provoking questions in both volumes facilitate critical thinking and clinical reasoning and allow the student to synthesize content and explore personal beliefs. Response sheets are provided on the Electronic Study Guide; suggested responses are found on the Instructors' Guide on Davis*Plus*.
- ***Meet Your Patient***—This chapter-opening feature in Volume 1 introduces one or more patients. The scenario is used throughout the chapter to illustrate theoretical points and make the content come alive. These patients are often followed in the clinical reasoning activities in Volume 2. This facilitates contextualizing information rather than learning facts in isolation.
- ***Safety Features***—To emphasize and help students remember important aspects of safe care, we have specially marked the most important points about safety to make them visible and memorable. They are color-shaded, with an icon to draw attention to them. We do, of course, have an entire chapter on promoting safety.
- ***Knowledge Maps***—In Volume 2 every chapter now has a Knowledge Map of the Volume 1 theoretical content. This serves as a content review and helps students learn visually how chapter concepts relate.
- ***Care Plans***—Seventeen care plans integrating NANDA-I, NIC, and NOC are found in Volume 1 and on Davis*Plus*. They are based on case studies that allow students to see the nursing process in action. Evidence-based rationales support interventions.
- ***Care Maps***—For each care plan, a Care Map allows visual learners to grasp the connection between the phases of the nursing process and illustrates an alternative method of care planning.
- ***Care Planning and Care Mapping Exercises***—Several Volume 1 chapters link students to the Student Resources on the Davis*Plus* Web site for practice in constructing care plans, both in columnar format and as concept maps, using the Concept Map Generator on the Web site.
- ***Practice Documentation***—Several Volume 2 chapters link students to Practice Documentation exercises on Davis*Plus*.
- ***Highlights of Procedures Boxes***—This Volume 1 box contains the highlights of all chapter procedures presented in Volume 2. These boxes serve as a reference when studying the Practical Knowledge content in Volume 1, or as a quick review just before performing a procedure in the clinical area.
- ***Caring for the Nguyens***—This is an ongoing case study that begins every chapter of Volume 2. It allows students to become familiar with a single family and to experience vicariously the continuity of care they may encounter in outpatient settings. As with all exercises in the two volumes, response sheets are provided on the Davis*Plus* Web site.
- ***Applying the Full-Spectrum Nursing Model***—In Volume 2, these clinically based exercises guide students to safely apply their thinking skills to chapter content. At the same time, they reinforce the full-spectrum model concepts of thinking, doing, and caring introduced in Volume 1.
- ***Critical Thinking and Clinical Reasoning***—This set of clinically based exercises (in Volume 2) guides students to safely practice critical thinking in preparation for doing so in the clinical area. Frequently, these clinical exercises make use of material related to the Meet Your Patient scenario in Volume 1.
- ***Thinking About the Procedure***—Procedures in Volume 2 include a cross reference to Davis*Plus* for exercises that require students to watch the associated Davis's Nursing Skills Videos to answer the questions. Answers are provided on Davis*Plus*.
- ***What If . . .***—Volume 2 procedures include a section to aid students in knowing what to do in special situations that require decisions during a procedure. For

example, what if you perform a fingerstick to monitor blood glucose, and the monitor shows a very unusual result or an error message? What should you do? We provide the answer. What If's are placed after the procedure steps so they will not distract from the steps while the student learns the procedure.

- *Diagnostic Testing Boxes*—These are found in Volume 2, and on Davis*Plus* in applicable chapters. We believe it is more meaningful to place the diagnostic test information near the related content rather than in an isolated chapter containing all the diagnostic testing content. If students need a more comprehensive reference, we recommend a diagnostic testing book.

THEMES

At least 20 themes are important in professional nursing. Our book weaves these almost seamlessly through the content of both volumes of the book. The following themes that are stressed throughout—some of them in every chapter:

- ***Safety.*** Safety is a central focus in nursing and healthcare. To emphasize and help students remember important aspects of safe care, we have key safety points marked for high visibility. We also have an entire chapter on Promoting Safety.
- **New for Third Edition. *PICOT Boxes.*** We have added this feature to most chapters to facilitate the skill of inquiry, especially as it relates to evidence-based practice.
- **New for Third Edition. *More QSEN Boxes.*** To promote competency-focused learning, we have introduced the Quality and Safety Education for Nurses (QSEN) competencies in the early chapters of Volume 1, and reinforced them where relevant throughout the text. To remind students that these competencies have practical implications, approximately 30 of the chapters have a QSEN box, providing an example of how a particular competency is related to a chapter concept and expressed in practice.
- **New for Third Edition. *Gerontology.*** To allow for an in-depth discussion of aging and gerontology, provided by an expert on this topic, Chapter 10 is entirely devoted to the older adult developmental stage. Assessments and interventions specifically for the young-old, middle-old, oldest-old, and frail elderly are provided. We have also included interventions specific to older adults in clinical chapters where they apply (e.g., assessing for pain, in Chapter 31; variations for older adults in the health assessment procedures in Chapter 22). Content specific to older adults is marked with a distinctive icon, and the beginning and end of the section are indicated by a colored bar. You will also find that many features and exercises use an older adult as the patient.
- **New for Third Edition. *Developmental Stages.*** The Theoretical Knowledge in most chapters devotes a section to discussing the effects of life span on the chapter topic. In Volume 2, procedures include variations for children and older adults. The thorough discussion of life span considerations for all age groups, formerly on Davis*Plus*, has been moved to Chapters 9 and 10 by request of users.
- ***Critical Thinking.*** We emphasize critical thinking and clinical reasoning in various ways. The following are two examples.
  - In addition to the critical-thinking questions and exercises in Volumes 1 and 2, concepts in Volume 1 are often presented in an inductive manner, or pose a question to the student (e.g., "What would happen if . . . ?").
  - **The full-spectrum model of nursing** (presented in Chapter 2) is a comprehensive approach to care that uses critical thinking in all aspects of care. It is not rigidly used to structure the chapters. Instead, the full-spectrum model is reinforced in every chapter of Volume 2 with a set of exercises (Applying the Full-Spectrum Nursing Model) that require students to use the model concepts of thinking, doing, and caring to structure their thinking. Because students cannot focus on everything at once, different model parts are stressed at different times. Sometimes they ask, "What theoretical knowledge do you need to . . . ?" In other instances they might ask, "What biases do you have that might interfere with . . . ?"
- ***Toward Evidence-Based Practice Boxes.*** In every chapter, we describe research related to the chapter topic and pose critical-thinking questions for students to examine these findings. The concept of evidence-based practice is introduced in Chapter 6 (Nursing Process: Planning Interventions), further explained in Chapter 8 (Evidence-Based Practice: Nursing Theory & Research), and mentioned frequently in other chapters as well.
- ***Nursing Process.*** Nursing process is a common framework for nursing thinking. Chapter 2 relates nursing process and critical thinking. Chapters 3 through 7 are a comprehensive presentation of the nursing process, which is presented as reflexive rather than linear. The Practical Knowledge sections of Volume 1 are organized according to the nursing process phases; the procedures in Volume 2 have assessment and evaluation components. In addition, many of the questions and exercises provide opportunity for students to apply the nursing process.
- ***Standardized Languages: NANDA-I, NIC, and NOC.*** Because these are important for electronic health records, the book includes a thorough discussion of these taxonomies in the nursing process and other chapters. NOC outcomes and NIC interventions are included in every chapter of Volume 1; many are presented in tables in Volume 2 or on Davis*Plus*. The Omaha System and the Clinical Care Classification are also used in the community and home health chapters.

- ***Caring.*** Caring is integrated throughout many chapters and is a part of the Volume 2 book title. Chapter 1 provides historical examples of nursing as a caring profession. Chapter 8 describes the important caring theories. Watson's theory is used throughout the chapter to illustrate how theory is applied in nursing. As well, the Applying the Full-Spectrum Nursing Model exercises in Volume 2 all have questions involving caring (one of the model concepts).
- ***Wellness.*** Many examples and scenarios in this text refer to people who are not ill. Chapter 11 emphasizes health; Chapter 42 talks about the nurse's role in health promotion.
- ***Culture.*** Cultural diversity is highlighted throughout the text in clinical scenarios, illustrations, and theoretical discussion. Chapter 15 focuses on culturally sensitive nursing care. The *Caring for the Nguyens,* an ongoing case study throughout Volume 2, features an extended family; ethnic variations are described in procedures, as applicable.
- ***Spirituality.*** Chapter 16 is probably the most extensive presentation of spiritual care available in a fundamentals text. Spirituality is integrated within various chapters in scenarios, examples, and exercises.
- ***Documentation.*** All chapters include reference to documentation, where relevant. The procedures in Volume 2 all have guidelines for and examples of how to document the procedure. In addition, we have included some Practice Documentation exercises on Davis*Plus*. Chapter 18 contains a thorough presentation of documentation and reporting.
- ***Delegation***. Delegation is introduced early, in the nursing process chapters, and is a thread in most Volume 1 chapters. Chapter 40, Leading & Managing, also discusses delegation. In Volume 2, all procedures have guidelines for delegating.
- ***ANA Standards***. Nursing and other healthcare standards (e.g., The Joint Commission, Medicare) are frequently referenced. Links to pertinent Web sites are given so students can keep up with changes to standards.
- ***Ethics.*** In addition to the extensive treatment in Chapter 44, ethical knowledge is an aspect of our full-spectrum model. As such, many of the critical-thinking exercises ask students to grapple with ethical issues. Good examples are found in Chapter 6, Volume 2, and in the Applying the Full-Spectrum Nursing Model in every chapter.
- ***Legal Issues.*** Chapter 45 is devoted to legal issues that nurses face in their practice. Legal issues are integrated in many other chapters as well (e.g., licensing in Chapter 1; end-of-life legal considerations in Chapter 16).
- ***Community and Home Healthcare.*** Chapter 43 is devoted exclusively to these topics. In other chapters, clinical scenarios and examples involve nurses in these settings. Procedures in Volume 2 have sections for adapting skills to home care; Volume 1 has special feature boxes:
- ***Home Care Boxes***—These provide guidelines for safely modifying care for delivery in the home.
- ***Teaching: Self-Care Boxes***—Self-Care boxes appear throughout Volume 1. They are similar to the traditional "teaching boxes," but focus on equipping patients to perform self-care.
- ***Complementary Therapies.*** The book conceptualizes nursing as holistic. Chapter 46 (on Davis*Plus*) is devoted exclusively to complementary and alternative therapies. Several chapters in Volume 1 (e.g., Chapter 15, Culture & Ethnicity) contain material related to this topic. For example, you will find Complementary & Alternative Modalities (CAM) boxes in several chapters. Some describe a complementary therapy related to the chapter topic. Others present research concerning a particular complementary therapy (e.g., intercessory prayer in Chapter 16).
- ***Contemporary Issues.*** In Chapter 23, we include extensive information about bioterrorism, multidrug-resistant organisms, and emerging infectious diseases, and healthcare-related infections. Those topics are also included in Chapter 43 as relevant to Community Nursing. The safety chapter includes ways to assess for and cope with violence in the healthcare setting.
- ***Nursing Informatics.*** Chapter 41 is an excellent introduction to nursing informatics. Standardized languages and electronic care planning and documentation are interspersed throughout the book (for example, in the nursing process and medications chapters), and especially in standardized language tables in Volume 2 and on Davis*Plus*. We also emphasize electronic documentation in Chapter 18 and in our illustrations for documenting some procedures in Volume 2. We further encourage use of technology by providing students with links to material on Davis*Plus* and other Web sites related to the chapter topic.

THE TEXT AS A RESPONSE TO CHANGE

This book was developed to address the needs of today's nursing students and in response to the following changes in nursing education and practice.

Changes in Students

- **Nontraditional Students.** Students range from younger students just out of high school to older, second-career students. Many have work or family responsibilities that compete with school for attention. To address this change, we have followed two principles of adult learning: that learning must be relevant, efficient, and meaningful to the person. *Efficiency:* Volume 1 is intended for classroom use, while Volume 2 is for clinical use.

- *Technology:* The Electronic Study Guide on Davis*Plus* delivers enhancements to the printed text, developed with the knowledge that highly motivated students will welcome the chance to use technologies to maximize their learning.
- *Meaningfulness/Relevance:* To make the content more meaningful, each chapter opens with a patient scenario or story of a practicing nurse. This story is woven throughout the chapter to provide context for factual information and to show how concepts are applied and how nurses think.
- *Practical Application:* We stress practical application throughout the text because adults want to apply knowledge in real-life circumstances. The Nguyen family case, in all chapters of Volume 2, is a prime example of this.

- **Variety in Learning Styles.** Students learn in different ways. To address this, we have used more than 1,400 photos and many diagrams and concept maps to assist visual learners. Podcasts, animations, and sound files of body sounds and other clinical assessment findings are included on Davis*Plus* for auditory learners. To teach psychomotor skills, we have, in addition to step-by-step procedures, included skills videos and checklists that students can print out for practicing procedures or for teachers to use in evaluations.
- **Reading Comprehension.** Whether because of changes in admission requirements, or because English is a second language, or for other reasons, some schools are finding students' reading abilities to be lower than in the past. We addressed this change by writing in an informal style, addressing the student directly ("you will . . ."). We have not made the content more superficial, but have made reading about it more inviting and user-friendly. We define new terms at their first use in each chapter, and include a glossary on Davis*Plus* for additional unfamiliar terms.
- **The Technology Generation.** The newer generations of students are accustomed to using technology and multitasking. To hold their attention, in addition to our easy-to-read style, we present information in an interactive manner, and in relatively short segments interspersed with review questions and critical-thinking questions. For this same reason, the text frequently directs students to find related information on Davis*Plus* and on the Internet, often in the form of podcasts or sound files. eBooks offer the convenience of accessing the book from wherever the student has Internet access without having to lug around heavy books.

Changes in Curricula

- **Teachers say they do not have enough time to "cover the content."** One way to address this problem is not to re-teach material students have had in other classes. We provide, for example, just enough anatomy and physiology in each chapter to aid students who need to review A&P, or who are taking A&P concurrently with nursing courses. You should not need to "cover" it in class.
- **Understanding and retention continue to be a problem.** To aid in retention, we have interspersed knowledge checks and critical-thinking questions throughout Volume 1 to allow students to check their recall and understanding of the content as they progress through the chapters. Recognizing that repetition aids retention, we provide Learning Outcomes at the beginning of each chapter in Volume 1. In addition, chapters in Volume 2 include a list titled *What Are the Main Points in This Chapter?* and a full-page Knowledge Map of the chapter content. To accompany each chapter, there is also a podcast on the Davis*Plus* Web site that overviews chapter content. And finally, the Student Resources contain an Audio Glossary.
- **Some curricula have de-emphasized mental health.** Mental health may be taught in other (e.g., medical-surgical) clinical areas, with no separate mental health course in the curriculum. In response to pleas from educators, we include expanded mental health content and tools for psychosocial assessment. In addition to the usual concepts of self-concept and self-esteem, Chapter 13 includes basic assessments and interventions for the Example Problems of anxiety and depression, which students will encounter commonly in all areas, not just on mental health units. In Chapter 21, the communication chapter, we have excellent content on the nurse-patient relationship and communication techniques that mental health teachers find so essential. Chapter 12, Stress & Adaptation, includes information about defense mechanisms.
- **The curriculum does not include separate pharmacology, nutrition, ethics, or nursing process courses.** Because all nurses need grounding in these topics, we have provided extensive coverage of these topics, both in Volume 1 and on Davis*Plus*. The medications chapter provides in-depth pharmacology information. Chapter 27, Nutrition, provides a foundational understanding of patients' nutritional needs. Chapter 44 is a comprehensive look at nursing ethics. We have, arguably, the most useful and thorough presentation of nursing process available in a fundamentals text. These chapters, as well as most others, will be a valuable reference for students when they take other clinical nursing courses.

Changes in Nursing and Healthcare

- **The nursing role is increasingly complex, requiring management, decision-making, delegation, and supervision skills early in the career.**
  To address this change, we have included a comprehensive discussion of leadership and management in Chapter 38. The critical-thinking exercises, especially in Volume 2, and the Nguyens feature help students to develop clinical decision-making skills. Delegation is presented early, in the nursing process chapters, and

stressed in the rest of the chapters in Volume 1, as applicable. Each clinical procedure in Volume 2 contains a Delegation section.

- **Healthcare has moved increasingly from the hospital to the home and community.**
  To address this change we have included a provocative discussion about the evolving healthcare system in Chapter 1. In addition, Chapter 43 discusses Community and Home Care. Those concepts are also integrated throughout Volume 1 (e.g., *Healthy People 2020* goals are cited where they are relevant to content); and the procedures in Volume 2 include home-care adaptations, as well as patient-teaching points that enable patients and caregivers to assume more responsibility for care.
- **Nurses need to be critical thinkers and life-long learners.**
  To address this change, we have organized the text around a model of Full-Spectrum Nursing, a comprehensive approach to care that uses critical thinking in all aspects of care. The model is reinforced in each chapter of Volume 2 in the feature Applying the Full-Spectrum Nursing Model. Critical thinking is integrated throughout both volumes of the text, both in discussion and in critical-thinking exercises. Discussion of this model follows.

THE FULL-SPECTRUM MODEL OF NURSING

We believe that nursing knowledge is a fusion of theoretical knowledge, practical knowledge, self-knowledge, and ethical knowledge. To function at the highest level, nurses use critical thinking and the nursing process to blend thinking and doing to put caring into action. We refer to this blend as *Full-Spectrum Nursing*. We have organized our learning package to reflect this philosophy. This model is presented in Chapter 2 and referred to and used throughout the text.

THE LEARNING PACKAGE

This is a well-integrated and cross-referenced package containing a two-volume text; an Electronic Study Guide on Davis*Plus* (Chapter Resources); and instructors' materials provided on Davis*Plus*. Although any item can be used either in classroom or clinical settings, Volume 1 will usually be used in the classroom setting, whereas Volume 2 will usually be used in the clinical setting or learning laboratory. You can also purchase a set of skills videos, a book of procedure checklists, and a *Fundamentals Skills Notes* pocket guide.

Volume 1

Volume 1 contains all the theoretical and conceptual material typically present in a fundamentals text, presented in a clinically focused, user-friendly manner, and incorporating many examples. This presentation allows students to see how the content will be useful to them. In Chapters 8 through 46, the nursing process is used as the model to organize the Practical Knowledge section.

Unit 1—focuses on how nurses think. It begins by showing how nursing history relates to our present healthcare system. Chapter 2 focuses on critical thinking, and Chapters 3 through 7 provide an extensive treatment of the nursing process. This unit prepares students to follow the organization of subsequent chapters and provides the thinking tools and processes they need to apply the content of the other chapters. Chapter 8 contains an overview of the processes of theory building, nursing research, and evidence-based practice as they relate to the nurse in practice.

Unit 2—is about the internal and external factors that affect an individual's health (e.g., family, culture, spirituality, and life stage). Internal factors are personal beliefs or attributes that influence how the client views health, healthcare, and nursing. A groundbreaking feature is Chapter 11, which describes the health-illness-wellness continuum in an experiential way, encouraging self-knowledge, personal growth, and affective learning of that content.

Unit 3—examines essential nursing interventions. We consider these skills "essential" because nurses use some or all of these skills in *all* areas of nursing, regardless of setting or patient diagnosis. The unit begins with documentation and includes communication, teaching, taking vital signs, physical assessment, asepsis, safety, hygiene, and medication administration.

Unit 4—concentrates on nursing care that supports physiological function. We examine broad categories of physiological function (e.g., nutrition, elimination, oxygenation) and discuss related nursing care.

Unit 5—explores diverse nursing functions. For example, we look at leadership and management, the use of technology and informatics, and health-promotion activities. Chapter 41 is a more thorough introduction to informatics than you will usually find in a fundamentals text.

Unit 6—looks at the context for nurses' work. This includes chapters on community and home care, as well as the ethical and legal contexts for nursing work. And we are especially proud of Chapter 46 (on the Davis*Plus* Web site), which provides a deeper treatment of holistic healing than you will typically find. We believe that a fundamentals book, overall, provides all concepts needed for a holistic view of the patient—just scan our chapter titles to see what we mean by that. We went one step further with Chapter 46.

Volume 2

Volume 2 is designed primarily, but not exclusively, for use in the skills lab and clinical setting. As does Volume 1, it includes thinking, doing, and caring. The critical-thinking exercises require students to use their thinking skills and the nursing process to apply theoretical knowledge to specific patient situations. The clinical procedures, assessment tools, clinical forms, diagnostic testing information, and standardized language tables make up the practical knowledge sections. Throughout Volume 2, students have access to a simulated experience known as *Caring for the Nguyens*, an ongoing case study through which they learn about the nursing role, the healthcare system, and the real-world application of the content in Volume 1.

Student Resources on DavisPlus

Sometimes referred to as an Electronic Study Guide (or ESG), the Student Resources on the Davis*Plus* Web site at **DavisPl.us/Wilkinson3** contains expanded discussions of some of the Volume 1 material, mastery questions, answers to the Volume 1 Knowledge Checks, a panel of NCLEX-style and chapter review test questions for practice, a glossary, additional care plans and care maps, and procedure checklists. Also included are forms that students can print out to write their answers to Knowledge Checks, Critical Thinking questions, and Mastery questions as well as the Volume 2 critical-thinking exercises. It also provides other types of forms that students can print out and use in clinical settings, for example, some assessment tools. The questions themselves have expandable space so that answers can be typed in on the electronic form and then printed out. The large glossary provides definitions of all bolded terms used in the text as well as supplementary terms that may be helpful to students.

Procedure checklists can be used to study for skills lab or clinical, or as a means to assess skill mastery. Checklists are provided in two formats: One is a detailed list of steps for each procedure; another is a generic, principles-based list that instructors can use to evaluate all procedures.

Other Resources on DavisPl.us/Wilkinson3

- ***Podcasts***—For audio learners, podcasts for each chapter summarize the main ideas for convenient prep for class or review for quizzes or exams. There are 12 "stress buster" podcasts: one for each month. You will also find 24 clever and revealing test-taking tips to give you the "one-up" on getting a better test result.
- ***NCLEX-style and chapter review questions for students***—We have added more questions to help students right from the beginning of their nursing studies to become comfortable answering NCLEX-style questions while reviewing chapter content.
- ***eBook***—Tired of lugging around heavy books? Now you can access this two-volume textbook electronically. Log on to the Davis*Plus* site for on-screen reading—just as though you were turning pages in your own book.

INSTRUCTOR'S GUIDE

The Instructor's Guide contains everything in the Student Resources plus additional features to assist faculty. These include an image bank of illustrations from the book, PowerPoint lecture outlines with illustrations, "clicker" questions, and a critical-thinking question.

New for Third Edition. The PowerPoint lecture outlines now include notes you can refer to when lecturing from the slides.

New for Third Edition. The Lesson Plans have been replaced by a new feature called Flipping the Classroom. These are presented as Word files so teachers can add to or delete from them to meet their unique needs.

Also included are teaching strategies to accompany each chapter, suggested responses for the critical-thinking exercises in Volumes 1 and 2, instructions for using concept mapping, and a test bank of more than 2,300 NCLEX-style and chapter review questions, including the newer NCLEX formats. The number of learning strategies has been significantly increased.

HOW TO USE THIS LEARNING PACKAGE (FOR TEACHERS)

You are fortunate to be working with students at perhaps the most formative point in their nursing education: the fundamentals course. We are certain that each of you will bring your own special style to the teaching of this most-important-of-all nursing courses, and that you will find new and creative ways to use the many teaching and learning features we have provided. We hope your enjoyment of this new and improved learning package is equal to our pride in it.

For suggestions about how to use this integrated learning package (in both text and podcast format),

Go to How to Use This Learning Package in the Instructor's Resources on the Davis*Plus* Web site, at **DavisPl.us/Wilkinson3.**

Go to Getting the Most Out of This Learning Package podcast on the Davis*Plus* Web site.

Schools that adopt our textbook also have access to a PowerPoint slide presentation and a podcast explaining how to use the learning package. You can use this and/or the podcast to orient new teachers and students so they can easily navigate and make best use of the entire learning package.

GETTING THE MOST OUT OF THIS LEARNING PACKAGE (FOR STUDENTS)

For ideas about how to use your textbooks and the Electronic Study Guide (Student and Chapter Resources) to get the best results from your studying, Go to Getting the Most Out of This Learning Package on the Davis*Plus* Web site.

For those times when you'd rather listen than read, we offer podcasts that describe ways for you to use the different components of your learning package—that is, your two-volume book set, nursing skills DVD set, your online Chapter Resources, NCLEX-style practice and chapter review questions, animations, documentation exercises, care mapping exercises, concept map generator, and many more, worthwhile learning tools.

Go to Getting the Most Out of This Learning Package podcast on the Davis*Plus* Web site.

We also know that being a student in a nursing program is hard work and can be overwhelming. Log on to the Davis*Plus* Web site for 12 useful strategies to reduce your stress while you are on your journey to becoming a nurse.

Go to Stress Busters podcast on the Davis*Plus* Web site.

Your goal is to do well in your courses. Knowing testing is an important part of your experience while in school, we now offer clever, test-taking tips to help you to take tests with excellence and show what you know!

Go to Test-Taking Tips podcast on the Davis*Plus* Web site.

Contributors to Third Edition

The following people contributed material that was used in creating this learning package. We are grateful for their assistance.

Pennie Sessler Branden, PhD, CNM, RN
Assistant Professor
Sacred Heart University, School of Nursing
Fairfield, Connecticut
Item Writer, Teacher Testbank

Stephanie Scovill Bronsky, RN, MSN Ed
Clinical Educator
Grand Canyon University
Chapter Contributor, Nutrition
PICOT feature

Patricia-Ann Calarco, RN, MSN
Assistant Professor
College of Nursing
Roseman University
Henderson, Nevada
Item Writer, Teacher Testbank

Lu Ann Connor, RN, BSN, MBA
Team Leader of Inpatient Adult Behavioral Health
SSM DePaul Health Care at St. Vincent's Hospital
Saint Louis, Missouri
Area Clinical Director/Home Care Director of Clinical Operations
Alere Health, Inc.
Saint Louis, Missouri
Chapter Contributor, Community & Home Health Nursing

Susan Johnson Garbutt, DNP, CIC, CNE
Simulation Coordinator in Nursing
University of Tampa
Tampa, Florida
Chapter Contributor, Promoting Asepsis & Preventing Infection

Kathleen C. Jones, RN, MSN, CNS
Associate Professor of Nursing
Walters State Community College
Morristown, Tennessee
Chapter Contributor, Wounds & Skin Integrity

Patricia A. Koral, RN, MSN, CNE
Associate Professor
Good Samaritan College of Nursing and Health Science
Cincinnati, Ohio
QSEN feature

Karen LoCascio, MS, RN-BC
Nursing Lab Coordinator
Southern Maine Community College
South Portland, Maine
Chapter Contributor, Urinary Elimination

Jacqueline Patton Mayer, RN, MSN
Associate Professor
Good Samaritan College of Nursing and Health Sciences
Cincinnati, Ohio
QSEN feature

Debra S. McKinney, RN, MSN/MBA/HCA
Nursing Faculty
Grand Canyon University, Ottawa University, and University of Phoenix
Item Writer, Teacher Testbank

Phyllis Puckett, RN, MS
Assistant Director of Nursing Program
Northern Wyoming Community College District
Sheridan, Wyoming
Contributor, Instructor Lectures

L. Jane Rosati, EdD, MSN, RN
Professor, School of Nursing
Daytona State College
Daytona Beach, Florida
Instructor's Guide Contributor, Classroom enrichment strategies

Melanie H. Simpson, PhD, RN-BC, OCN, CHPN
Pain Management Resource Team
The University of Kansas Hospital
Kansas City, Kansas
Chapter Contributor, Pain

Acknowledgments

We wish to extend sincere thanks to the exceptional team that helped us create this learning package, and especially to the following people:

- **Lisa Deitch**, Acquisitions Editor and friend, for her vision and forward thinking for the first edition, and for her continued support throughout its revisions.
- **Adrienne Simon**, Senior Content Project Manager, deserves extraordinary thanks. She joined the team midway through this edition. With almost no learning curve time, she quickly grasped and managed the many interlocking details of this complex project and worked incessantly to keep this project on track. Her untiring efforts and attention to detail enabled us to better focus on content and didactic issues.
- **Shirley Kuhn**, Developmental Editor, for tirelessly facilitating communication between the authors and all elements of the production team. We dearly appreciate her integrity, work ethic, and sense of humor.
- **Jamie Elfrank**, Project Editor, for her amazing ability to organize and retrieve information and files, all the while churning out a mountain of work during the time she was with us. She kept chaos at bay, made our lives easier, and never let us down.
- **Darlene Pedersen**, Director of Content Development, for working her magic behind the scenes to support our project. We heartily thank her for throwing us a lifeline, when needed, to make things just a little bit easier.

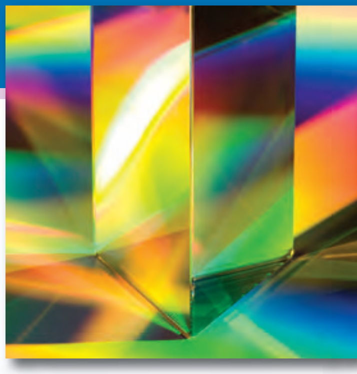
How Nurses Think

CHAPTER 1



Evolution of Nursing Thought & Action

Learning Outcomes

After completing this chapter, you should be able to:

- Define *nursing* in your own words.
- Discuss the transitions nursing education has undergone in the last century.
- Differentiate among the various forms of nursing education.
- Explain how nursing practice is regulated.
- Give four examples of influential nursing organizations.
- Name and recognize the four purposes of nursing care.
- Describe the healthcare delivery system in the United States, including sites for care, types of workers, regulation, and financing of healthcare.
- Name nine expanded roles for nursing.
- Discuss issues related to healthcare reform.
- Delineate the forces and trends affecting contemporary nursing practice.

*If you were assigned the Expanded Discussion on the Davis*Plus*, you should also be able to demonstrate the following outcomes:*

- Identify the factors that led to the change of nursing from a vocation of men and women to a predominantly female profession.
- Describe the various images of nurses through history.
- Describe the role of religion in the development of nursing.
- Explain the role of the military in the development of the nursing profession.

Key Concepts

Nursing
Nursing history
Contemporary nursing education
Contemporary nursing practice
Healthcare delivery system

See the Concept Map on Davis*Plus*.

This volume contains only a brief introduction to nursing history. For more detailed information,

Go to Student Resources, Chapter 1, **Evolution of Nursing Thought and Action—Expanded Discussion,** on Davis*Plus*.

Nurses Make a Difference . . .

Then & Now

Time: 1854, Üsküdar (now part of Istanbul, Turkey) in the Crimea

The hospital tent is set up away from the battlefield. The injured and dying soldiers are lying upon the bare earth, soiled and covered with crusted blood. Outside the air is cool, yet the tent is stifling with the rank odor of disease and death. Scanning the scene, Florence Nightingale gathers her staff of 38 nurses. They review the environmental condition of the hospital tent, the health problems of the soldiers, and the supplies and equipment they have to work with. First, they open the tent to allow in fresh air. Then they clean the tent, bathe the wounded, and provide clean bedding. They assess and dress the wounds, feed the soldiers a nutritious meal, and comfort those dying or in pain. They offer encouragement and emotional care to the healthier soldiers and help

(Continued)

Nurses Make a Difference . . . (continued)

them to write letters home. Within a brief period of time the mortality rate drops from 47% to 2% and morale improves immeasurably.

Time: 2012, Your Local Hospital

While standing at the bedside mixing an antibiotic solution, Susan listens to the ventilator cycle. She notes that her patient has begun to trigger breaths on his own. In the background she hears the cardiac monitor sounds, which have become more irregular over the past hour. She mentally runs through her patient assessment. "Why is his heart so irritable?" she wonders. She calls the lab for the morning blood work results. When the lab technician e-mails the results to the unit, Susan notes that the potassium level is low (2.9 mEq/L). She notifies the physician of the lab results and the cardiac irritability. Susan tells the physician, "The patient's potassium is low from the diarrhea he's had since we began the antibiotics." Together they develop a plan to administer intravenous (IV) potassium chloride to raise the serum potassium level and to check it every 8 hours. Several hours later Susan documents that the *ectopy* (irregular heartbeat) has decreased to less than 2 beats/min.

Time: 2030, A Local Home

Yesterday, Mr. Samuels underwent cardiac surgery. He was discharged home this morning and is now under your care. As a home health nurse, your role is to assess his condition; provide skilled care; teach Mr. Samuels how to care for himself; instruct his family about his care; and coordinate any required additional services. You have been monitoring his condition remotely (telehealth) since discharge before the visit. Mrs. Samuels greets you at the front door. She tells you that her husband is in a lot of pain and that the chest drainage system appears full. She looks frightened as she says, "When my father had cardiac surgery 25 years ago, he spent 4 days in the hospital. I don't understand why my husband got sent home so quickly." You explain that changes in technology and the healthcare system allow you to take care of clients in the home who would previously have been in the hospital. As you begin your assessments, you tell Mrs. Samuels, "After I've gathered more information, we'll make a plan that will make all of us more comfortable."

In each of these scenarios, the nurses engaged in *full-spectrum nursing;* that is, they used their minds and their hands to improve the client's comfort and condition. As the scenarios illustrate, nursing roles have changed over time. Yet nursing remains a profession dedicated to client care.

ThinkLike a Nurse 1-1

The Quality and Safety Education for Nurses (QSEN) project and the Institute of Medicine (IOM) have identified quality and safety competencies for nurses: (1) patient-centered care, (2) teamwork and collaboration, (3) evidence-based practice, (4) quality improvement, (5) safety, and (6) informatics (Cronenwett, Sherwood, Barnsteiner, et al., 2007). Which of these did Florence Nightingale demonstrate? Explain your thinking.

ABOUT THE KEY CONCEPTS

The overarching concept for this chapter is **nursing**. As you come to understand key concepts (i.e., nursing history, contemporary nursing education, contemporary nursing practice, healthcare delivery system) you will grasp how nursing has emerged from historical influences to become today's contemporary nursing practice.

HISTORICAL CONTEXT OF NURSING

Key Point: ***An understanding of the past can lend insight into the customs, values, and future of nursing.*** When exploring history, it becomes apparent that societal beliefs, Christianity, and the military had strong influences on the evolution and images of professional nursing.

Early civilizations had numerous health practices, including massages, hydrotherapy, acupuncture, Roman baths, quarantines, prayer, and dances, to name a few. Their practices were related to societal beliefs about health and illness, as are today's practices. The following are examples:

- In the prehistoric period, illness was thought to be caused by evils spirits that had invaded the body. Care was aimed at removing the evil spirits through ceremonial rituals.
- Early Egyptians prayed to various gods and goddesses to remove illness and maintain health. Women assumed the role of nursing, providing comfort and supportive care to the sick.

Images of Nursing

As you think of each of the three scenarios at the opening of this chapter, what images of the scene and of the nurse do you see? Does each of these images reinforce nursing's legacy of caring? What is your image of yourself as a nurse?

The following are images of the nurse that have developed throughout history—and which persist to a greater or lesser extent even now.

Angel of Mercy This image grew out of the influence of religion and the risks inherent to the practice of nursing. Images of the angel-nurse are usually serene and content, with a halo or other religious symbol.

Battle-Ax The image of the nurse as a battle-ax emerged, as science and philosophy grew popular during the 17th century, when religious orders became less common. A more recent historical example is found in the 1975 film *One Flew Over the Cuckoo's Nest*, in which Nurse Ratched personifies the nurse as the battle-ax or torturer, treating her patients with cruelty and disdain.

Nurse as Professional The battle-ax image of an unprofessional nurse remained until transformed by Florence Nightingale (Fig. 1-1). Florence Nightingale kept meticulous notes and statistics that were used for advocating and obtaining changes in healthcare. She used her political connections and social standing to return nursing to a respectable profession. The Nightingale School for Nurses was opened in 1860 and is considered the first official nursing program.

Naughty Nurse The image of the sexy, risqué nurse arose in the early part of the 20th century with burlesque shows and still persists. For example, in many television programs such as *M*A*S*H* and *Grey's Anatomy*, nurses are portrayed as sexy, mindless, irrelevant, or simply potential dates for bright and talented surgeons.

Military Image Throughout the last century (the 1900s), nurses were frequently portrayed in uniform providing support at the battlefield, and nurses are still often characterized as warriors fighting disease. The impact of wars has had positive influences on the development of nursing as a profession. Nurses took the lead in providing care to the sick, wounded, and dying soldiers in each of the following wars, which highlighted the need for nurses to be trained: American Civil War, Spanish American War, World Wars I and II; and the Korean, Vietnam, Iraq, and Afghanistan conflicts.

FIGURE 1-1 Florence Nightingale (1820–1910).

Handmaiden Image This stereotype portrays the male physician in the dominant role, with the female nurse merely assisting the doctor, or perhaps supporting the patient at the bedside. This image grew out of the nurse's early limited role in healing, from the legal and financial authority of physicians, and from the nurse's work position as an employee.

Nursing Today: Full-Spectrum Nursing

Nurses today are highly trained, well educated, caring, and competent professionals. They are essential members of the healthcare team. The complexity of the healthcare delivery requires that nurses use their critical thinking, communication, organizational, leadership, advocacy, and technical skills to ensure that patients receive safe and effective care.

Key Point: ***Nurses apply knowledge from the arts and sciences in their various roles to provide patient-centered care (Table 1-1).***

Nurses use clinical judgment, critical thinking, and problem-solving as they care for patients. (You will learn more about full-spectrum nursing in the section in Chapter 2, What Is Full-Spectrum Nursing?)

To provide safe care, nurses must carefully consider their actions and think carefully about the patient, the treatment plan, the healthcare environment, the patient's support system, the nurse's support system and resources, and safety.

Clinical judgment involves observing, comparing, contrasting, and evaluating the client's condition to determine whether change has occurred. It also involves careful consideration of the client's health status in light of what is expected based on the client's condition, medications, and treatment. These actions, collectively known as nursing process, are discussed in Chapters 3 through 7 and in each of the clinically focused chapters.

Critical thinking is a reflective thinking process that involves collecting information, analyzing the adequacy and accuracy of the information, and carefully considering options for action. Nurses use critical thinking in every aspect of nursing care. Critical thinking is discussed at length in Chapter 2 and applied in every chapter in this text.

Problem-solving is a process by which nurses consider an issue and attempt to find a satisfactory solution to achieve the best outcomes. You will often use problem-solving in your professional life. The nursing process (see Chapters 2–7) is one type of problem-solving process.

Table 1-1 ➤ Roles and Functions of the Nurse

ROLE	FUNCTION	EXAMPLES
Direct care provider	Addressing the physical, emotional, social, and spiritual needs of the client	Listening to lung sounds Giving medications Patient teaching
Communicator	Using interpersonal and therapeutic communication skills to address the needs of the client, to facilitate communication in the healthcare team, and to advise the community about health promotion and disease prevention	Counseling a client Discussing staffing needs at a unit meeting Providing HIV education at a local school
Client/family educator	Assessing and diagnosing the teaching needs of the client, group, family, or community. Once the diagnosis is made, nurses plan how to meet these needs, implement the teaching plan, and evaluate its effectiveness.	Preoperative teaching Prenatal education for siblings Community classes on nutrition
Client advocate	Supporting clients' right to make healthcare decisions when they are able to voice their opinions and protecting clients from harm when they are unable to make decisions	Helping a client explain to his family that he does not want to have further chemotherapy
Counselor	Using therapeutic communication skills to advise clients about health-related issues	Counseling a client on weight-loss strategies
Change agent	Advocating for change on an individual, family, group, community, or societal level that enhances health. The nurse may use counseling, communication, and educator skills to accomplish this change.	Working to improve the nutritional quality of the lunch program at a preschool
Leader	Inspiring others by setting an example of positive health, assertive communication, and willingness to improve	Florence Nightingale Walt Whitman Harriet Tubman
Manager	Coordinating and managing the activities of all members of the team	Charge nurse on a hospital unit (e.g., assigns patients and work to staff nurses)
Case manager	Coordinating the care delivered to a client	Coordinator of services for clients with tuberculosis
Research consumer	Applying evidence-based practice to provide the most appropriate care, to identify clinical problems that warrant research, and to protect the rights of research subjects	Reading journal articles Attending continuing education; seeking additional education

In the three scenarios in Nurses Make a Difference . . . Then & Now, what image of nursing predominates: thinking or doing?

CONTEMPORARY NURSING: EDUCATION, REGULATION, AND PRACTICE

As a student about to enter your new professional life, you need to realistically grasp the nature and demands of your chosen career. To help better acquaint you with nursing today, the remainder of this chapter discusses the current state of nursing, nursing education, and the trends affecting nursing. You will also be introduced to the healthcare delivery system.

How Is Nursing Defined?

As you have seen, there are many images of nursing. These images are only loosely based on fact and sometimes conflict. They make it difficult for the public to know the reality of nursing—and they are confusing to nurses and other members of the healthcare team as

Quality and Safety Education for Nurses

What Are QSEN Competencies?

Competencies: *Patient-Centered Care, Teamwork and Collaboration, Evidence-Based Practice, Quality Improvement, Safety, Informatics**

The QSEN (pronounced cue-zen) competencies are six areas of expertise that nursing students are expected to acquire before graduation. Each competency includes a list of associated knowledge, skills, and attitudes (KSAs) that operationalize the concepts. The six competencies and their definitions are:

- **Patient-centered Care:** Recognize the patient or designee as the source of control and [a] full partner [when] providing compassionate and coordinated care based on respect for patient's preferences, values, and needs.
- **Teamwork and Collaboration:** Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.
- **Evidence-based Practice:** Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal healthcare.
- **Quality Improvement (QI):** Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safe of HC systems.
- **Safety:** Minimizes risk of harm to patients and providers through both system effectiveness and individual performance.
- **Informatics:** Use information and technology to communicate, manage knowledge, mitigate error, and support decision making.

*To see the KSAs for the QSEN competencies,

Go to the QSEN Web site, at **http://www.qsen.org/ksas_prelicensure.php**

Source: Cronenwett, Sherwood, Barnsteiner, J., et al. (2007).

well. In addition, the constantly changing nature of nursing, healthcare, and society further complicates the definition of nursing. **Key Point:** ***Therefore, it is important for nurses to articulate clearly, for themselves and for the public, what nursing is and what nurses do.*** The following sections articulate the views of two important nursing organizations in answer to the question, "What is nursing?"

International Council of Nurses Definition

In 1973 the International Council of Nurses (ICN), an organization representing nurses throughout the world, defined nursing according to the beliefs of respected theorist Virginia Henderson:

> *The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge. (Henderson, 1966, p. 15)*

In the decades since the adoption of this definition, nursing throughout the world has changed. Advances in healthcare have altered the type of care required by clients. Nurses have taken on expanded roles, and once again there is interest in providing care outside the hospital. To reflect these changes, the ICN has revised its definition of nursing, as follows:

> *Nursing encompasses autonomous and collaborative care of individuals of all ages, families, groups and communities, sick or well and in all settings. Nursing includes the promotion of health, prevention of illness, and the care of ill, disabled and dying people. Advocacy, promotion of a safe environment, research, participation in shaping health policy and in patient and health systems management, and education are also key nursing roles. (ICN, 2010)*

Think**Like a Nurse** 1-3

Look at the three scenarios of Nurses Make a Difference . . . Then & Now. What nursing actions did the nurses perform that are represented in the ICN definition of nursing?

American Nurses Association Definitions

You can see similar changes in the approach of the American Nurses Association (ANA). In 1980, the ANA defined nursing as "the diagnosis and treatment of human responses to actual and potential health problems" (p. 2). Attempts to refine this definition have been difficult. Nurses are a widely varied group of people with varying skills. They perform activities designed to provide care ranging from basic to complex in a growing number of settings. Therefore, it is not easy to describe the boundaries of the profession.

In 2010, the ANA acknowledged five characteristics of registered nursing:

- Nursing practice is individualized.
- Nurses coordinate care by establishing partnerships (with persons, families, support systems, and other providers).
- Caring is central to the practice of the registered nurse.
- Registered nurses use the nursing process to plan and provide individualized care to their healthcare consumers.
- A strong link exists between the professional work environment and the registered nurse's ability to provide quality healthcare and achieve optimal outcomes. (ANA, 2010, pp. 4–5)

As a result, the ANA redefined professional nursing as:

The protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations. (ANA, 2010, p. 1)

Why Is a Definition Important?

Nursing organizations and leaders have pushed for accurate definitions to (1) help the public understand the value of nursing, (2) describe what activities and roles belong to nursing versus other health professions, and (3) help students and practicing nurses understand what is expected of them within their role as nurses.

From a brief review of nursing history, you can see that nursing has undergone tremendous change, from a role limited to providing kindness and support to full-spectrum work that is based in science but still focuses on care and nurturing. Undoubtedly, nursing will continue to change as nursing knowledge increases and society changes. Box 1-1 lists several additional definitions of nursing for you to consider.

BOX 1-1 ■ What Is Nursing?

- I use the word nursing, for want of a better word. It has been limited to signify little more than the administration of medicines and the application of poultices. It ought to signify the proper use of fresh air, light, warmth, cleanliness, quiet, and the proper choosing and giving of diet—all at the least expense of vital power to the patient. (Nightingale, 1876, p. 5)
- Events that give rise to higher degrees of consideration for those who are helpless or oppressed, kindliness and sympathy for the unfortunate and for those who suffer, tolerance for those of differing religion, race, color, etc.—all tend to promote activities like nursing which are primarily humanitarian. (Dock & Stewart, 1938, p. 3)
- Nursing has been called the oldest of the arts and the youngest of the professions. As such, it has gone through many stages and has been an integral part of societal movements. Nursing has been involved in the existing culture—shaped by it and yet helping to develop it. (Donahue, 1985, p. 3)
- Nurses provide care for people in the midst of health, pain, loss, fear, disfigurement, death, grieving, challenge, growth, birth, and transition on an intimate front-line basis. Expert nurses call this the privileged place of nursing. (Benner & Wrubel, 1989, p. xi)
- Nursing: The care and nurturing of healthy and ill people, individually or in groups and communities. [*Taber's* also includes as a part of the definition the ANA "essential features" involving holism, use of subjective and objective data, application of scientific knowledge, and provision of a caring relationship.] (Venes, D. *Taber's Cyclopedic Medical Dictionary*, 2013)
- Nurses provide and coordinate patient care, educate patients and the public about various health conditions, and provide advice and emotional support to patients and their family members. (Bureau of Labor Statistics, 2012c)

As a student entering nursing, you can use definitions and descriptions to understand what is expected of you. To aid you in this task, refer to Table 1-1 and review the essential components of the nursing role. While in the clinical setting, you will observe nurses functioning in each of these capacities. Nursing is a flexible career that requires you to move effortlessly among these areas to meet the needs of the patient. Nursing requires certain skills and competencies, which you will learn throughout this book. Box 1-2 identifies several qualities that are essential for safe nursing practice.

KnowledgeCheck 1-1

- What factors make it difficult to define nursing?
- Based on the ICN definition of nursing, what does a nurse do?

Is Nursing a Profession, Discipline, or Occupation?

One strategy used to describe a field of work is to categorize it as a profession, discipline, or occupation.

Profession Although the term *profession* is freely used, a group must meet certain criteria to be considered a **profession** (see Table 1-2). Nursing appears to meet all criteria of a profession as defined by Starr (1982) and Miller, Adams, & Beck (1993).

Discipline To be considered a **discipline**, a profession must have a domain of knowledge that has both theoretical and practical boundaries. The **theoretical boundaries** of a profession are the questions that arise from clinical practice and are then investigated through research. The **practical boundaries** are the current state of knowledge and research in the field—the facts that dictate safe practice (Meleis, 1991). A case can be made that nursing is both a profession and a discipline:

- It is a scientifically based and self-governed *profession* that focuses on the ethical care of others.
- It is a *discipline*, driven by aspects of theory and practice. It demands mastery of both theoretical knowledge and clinical skills.

Occupation In spite of meeting criteria for both designations (profession and discipline), nursing is often described as an **occupation**, or job. Unlike physicians, most of whom are in control of their practice environment, working conditions, and schedule, most nurses are hourly wage earners. The employer, not the nurse, decides the conditions of practice and the nature of the work. Nurse practice acts do not prevent nurses from functioning more autonomously, however.

Rather than continuing to develop arguments to "prove" that nursing is a profession, the following actions might do more to improve the status of nursing:

- Standardizing the educational requirements for entry into practice
- Enacting uniform continuing education requirements

BOX 1-2 ■ Important Qualities for Nurses

Critical-Thinking Skills

Required Action: Monitor the patient, note changes, and take actions to ensure safe and effective care.

Example: Call the physician to get a stronger pain medication for a patient who, 2 hrs after receiving pain medication, rates his pain 7 out of 10.

Caring and Compassion

Required Action: Show kindness, concern, and warmth that shows patients that you care and are concern about their well-being.

Example: Sit with and hold the hand of a patient who has just been told that he has a terminal illness.

Detail Oriented

Required Action: Pay attention to details to prevent and identify errors in care that may be harmful to the patient.

Example: Seek clarification and correct a dosage that is written as 7 mg that should be 0.7 mg.

Organizational Skills

Required Action: Prioritize the needs of your patient and meet the needs of the most critical patients first.

Example: Care for the patient with difficulty breathing prior to performing a dressing change on a postoperative patient.

Speaking Skills

Required Action: Communicate correct and pertinent information to patients and members of the healthcare team.

Example: Teach the patient how to perform a dressing change at home after discharge from the hospital.

Listening Skills

Required Action: Listen to patients' concerns and take verbal or telephone orders from providers.

Example: The provider telephones you and gives you orders to implement for your patient.

Patience

Required Action: In stressful situations in the work environment, think clearly and take the correct actions.

Example: Remains calm when a patient's condition deteriorates, provides the needed care, and transfers the patient to the ICU.

Competence

Required Action: Knowledge and skills to ensure safe, quality patient outcomes.

Example: Recognize that the correct dose for the drug is 0.10 mg rather than 10 mg.

Adapted from Bureau of Labor Statistics (2012c). How to become a registered nurse. http://www.bls.gov/ooh/healthcare/registered-nurses.htm#tab-4

Table 1-2 ➤ Nursing: Is It a Profession?

STARR CRITERION	EXAMPLES IN NURSING
The knowledge of the group must be based on technical and scientific knowledge.	■ Entry-level nursing education requires coursework in basic and social sciences as well as humanities, arts, and general education. ■ Nursing education and practice are increasingly based on research from nursing and related fields.
The knowledge and competence of members of the group must be evaluated by a community of peers.	■ State or provincial regulatory bodies have defined the criteria that nurses must meet to practice, and they monitor members for adherence to standards.
The group must have a service orientation and a code of ethics.	■ Nursing is clearly focused on providing service to others. ■ The major professional organizations have developed ethical guidelines to guide the practice of nursing.

- Encouraging the participation of more nurses in professional organizations
- Educating the public about the true nature of nursing practice

Evaluate the status of nursing. Is nursing a respected profession? Give examples to support your opinion.

How Do Nurses' Educational Paths Differ?

The transition into the nursing profession involves formal and informal processes. **Formal education** consists of completing the initial and continuing education required for licensure. **Informal education** involves a gradual progression in skill and clinical judgment that allows the nurse to advance in the profession.

Formal Education

When the patient calls out "Nurse!" who can respond? To legally use the title *nurse,* a person must be a graduate of an accredited nursing education program and have successfully passed the National Council Licensure Examination (NCLEX). Students may enter nursing through two paths: as a practical nurse or a registered nurse. Other personnel may respond to the patient's call, but they cannot legally be considered nurses.

Practical and Vocational Nursing Education

Practical nursing education prepares nurses to provide bedside care to clients. Practical nurses are known as licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) in a few states. In the United States a student who wishes to become an LPN/LVN may attend one of approximately 1,200 approved programs given at technical schools and community colleges. Educational programs for LPN/LVNs offer both classroom and clinical teaching and usually last 1 year. After completing the practical nursing education program, the student must pass the NCLEX-PN exam. Practical nurses provide basic care and work under the direction of the registered nurse (RN) or the primary care provider. The majority of LVN/LPNs work in nursing care facilities. Their job growth is expected to grow 21% between 2008 and 2018 based on the increased growth of the aging population (Bureau of Labor Statistics, 2012a).

Registered Nursing Entry Education

Currently, five educational pathways lead to licensure as a registered nurse (RN). Graduates of all these programs must successfully complete the NCLEX-RN exam to practice as RNs.

- **Diploma programs**. These hospital-based programs are the oldest type of nursing education. They were modeled after the Nightingale Schools of Nursing apprenticeship style of learning. This method of preparing nurses was the mainstay of nursing education from the mid-1800s to the 1960s. The typical program lasts 3 years and focuses on clinical experience in direct patient care. Since the 1960s the number of diploma programs has steadily decreased. In 2011, only about 4% of nursing schools were diploma programs (Kaufman, 2012). About 20% of RNs in the United States reported receiving their initial education in a diploma program in 2008 compared with 63% in 1980 (Health Resources and Services Administration, 2010). The number of diploma programs decreased from 75 in 2007 to 69 in 2008 (National League for Nursing, 2010).
- **Associate degree programs.** This type of program, conceptualized by Mildred Montag, emerged during the nursing shortage following World War II. Most associate degree (AD) programs are offered in community colleges. Although the nursing component typically lasts 2 years, students are required to take many other courses in the liberal arts and sciences. In 2008, 45% of RNs in the United States reported receiving their initial education in an AD program (Health Resources and Services Administration, 2010). The student is prepared to provide direct patient care. The number of AD programs increased from 1,023 in 2008 to 1,031 in 2009 (NLN, 2010).
- **Baccalaureate degree programs.** Students in baccalaureate (BSN) programs pursue a course of study like that of other undergraduate students. The course of study lasts for at least eight semesters. Students are prepared to address complex clinical situations, provide direct patient care, work in community care, use research, and enter graduate education (Bureau of Labor Statistics, 2012c). In 2008, BSN graduates accounted for 34% of RNs in the United States (Health Resources and Services Administration, 2010). The number of BSN programs increased by two in 2008 to 683. Many AD graduates enter RN-to-BSN (or RN "completion") programs to obtain a baccalaureate degree in nursing. The length of time required to complete the BSN varies according to the program and the number of credits each student can transfer. The goal is to increase the proportion of baccalaureate-prepared nurses to 80% by the year 2020 (Institute of Medicine, 2011).
- **Master's entry programs.** The typical student in these programs has a baccalaureate degree in another field and has entered nursing as a second career. Programs usually are completed in 3 years of full-time study, with the first year devoted to basic nursing content. At the completion, the student is eligible to take the licensing exam and is awarded a master's degree in nursing.
- **Doctoral entry.** This is the most unusual entry pathway into nursing. The nursing doctorate (ND) path parallels the pathway through which physicians enter the healthcare field. This entry path has very limited enrollment.

For several decades, nursing leaders have debated about the most appropriate educational pathway for entry into the profession. For an overview of this debate,

Go to Chapter 1, **Expanded Discussion: Nursing History, Entry Into Practice Debate,** on Davis*Plus*.

Graduate Nursing Education

Graduate nursing education prepares the RN for advanced practice, expanded roles, or research. **Master's degree programs** prepare RNs to function in a more independent and autonomous role, such as nurse practitioner, clinical specialist, nurse educator, or nursing administration. It typically takes 2 years or longer to complete the master's degree. **Doctoral programs** in nursing offer professional degrees. Typically the student has completed a baccalaureate and master's degree before entry into a doctoral program. Doctoral degree programs in nursing offer the Doctor of Nursing Practice (DNP) or the Doctor of Nursing Science (DSN/DNSc). The DNS/DNSc focuses on nursing research and the DNP is a practice doctorate. The popularity of the DNP has created concerns that the growth of nursing research will decline. Some nurses obtain a Doctor of Philosophy (PhD), another research degree. For additional discussion on expanded nurse roles, see the section on Expanded Career Roles later in this chapter.

Other Forms of Formal Education

Advances in healthcare have a strong influence on nursing practice. Since nurses must keep current in their practice, you will be socialized to the concept of "nurses as lifelong learners." This means that you must engage in continuing education to enhance your intellectual and practical knowledge throughout your nursing career.

- **Continuing education** is a professional strategy to help you stay current in your clinical knowledge. Continuing education programs are available at work sites, at local colleges and universities, through privately operated educational groups, on the Internet, and in professional journals. In many states, renewal of the nursing license requires successful completion of a specified number of continuing education courses. Some states allow nurses to take any approved coursework, while others have specific requirements in special areas, such as HIV/AIDS, bioterrorism, and domestic violence. The regulations for continuing education change frequently. Your state board of nursing (SBN) will notify you of continuing education requirements, if any, when you receive your initial nursing license. Thereafter, the SBN will notify you by e-mail or postal mail of any changes in the requirements. For an overview of the continuing education requirements for license renewal in the United States,

Go to Chapter 1, **ESG Table 1-1, Continuing Education Requirements for Nurses,** on Davis*Plus*.

- **In-service education** is another form of ongoing education. It is offered at the work place, and usually does not count toward meeting the continuing education requirement for license renewal. In-service education is typically institution specific and product specific, and provides information on pertinent changes in nursing. For instance, in-service education might focus on the use of new equipment, the introduction of new policies, or it may resemble traditional continuing education programs. It is designed to enhance your continued competence in knowledge, skills, and attitude.

Informal Education

In addition to formal programs of study, education also requires socialization into the profession. **Socialization** is the informal education that occurs as you move into your new profession. It is the knowledge gained from direct experience, observation in the real world, and informal discussion with peers and colleagues. **Key Point:** ***Professional socialization begins when you enter the educational program and continues as you gain expertise throughout your career.*** Informal education complements formal education to create clinical competence.

Benner's Model

Patricia Benner (1984) described the process by which a nurse acquires clinical skills and judgment. As this process shows, expertise is not merely a demonstration of skilled application of knowledge, but rather a personal integration of knowledge that requires technical skill, thoughtful application, and insight. This is what we mean in this text when we use the term *full-spectrum nursing*. Expertise requires both thinking and doing skills.

- ***Stage 1: Novice***. This phase begins with the onset of your education. The novice nurse has little nursing experience and is at the first stage of acquiring clinical knowledge. At this stage, you are task oriented and focus narrowly on "learning the rules." For example, when performing a sterile dressing change, you may be so concerned with following the steps in the skills checklist that you forget to assess the patient's reaction to the procedure.
- ***Stage 2: Advanced beginner***. A new graduate usually functions at this level. An advanced beginner begins to focus on more aspects of a clinical situation, use more facts, make more sophisticated use of the rules, and recognize similarities in situations. The nurse can distinguish abnormal findings, but cannot readily understand their significance. For example, a new graduate assesses that her postoperative abdominal surgical patient's blood pressure has decreased and his pulse rate has increased, and he has become more restless during the last 2 hours. An advanced beginner will report these as changes, but does not recognize that these signs/symptoms may indicate early blood loss. After considerable exposure to clinical situations, nurses improve in performance and, through repeated experiences or mentoring, begin to recognize the elements of a situation.
- ***Stage 3: Competence.*** Nurses achieve competence after 2 to 3 years of nursing practice in the same area. Competent performers have gained additional experience and wrestle with more complex concerns. They are able to handle their patient load and prioritize situations. They are also more involved in their caregiving role and may be emotionally involved in the clinical choices made. Although competent nurses manage clinical care with mastery, they often do not fully grasp the overall scope and most important aspects. The competent nurse would immediately connect the changes in the vital signs with the surgical procedure, recognize possible early signs of shock, and conduct a more in-depth assessment.
- ***Stage 4: Proficient***. The proficient nurse is able to quickly take in all aspects of a situation and immediately give meaning to the cluster of assessment data, and serves as a resource for less experienced nurses. Proficient nurses are able to see the "big picture" and can coordinate services and forecast needs. For example, they would immediately recognize a patient's symptoms as a possible heart attack, pulmonary embolus, or brain attack (stroke) and immediately gather the resources to initiate treatment. They are much more flexible and fluent with their role and able to adapt to nuances of various patient situations. Proficient nurses plan intuitively as well as consciously.
- ***Stage 5: Expert.*** Expert nurses are able to see what needs to be achieved and how to do it. They trust in

and use their intuition while operating with a deep understanding of a situation, often recognizing a problem in the absence of the classic signs and symptoms. They have expert skills and are often consulted when others need advice or assistance.

Benner's model deals with the development of clinical wisdom and competence. Keep in mind that this progression is not automatic. Nurses do not simply move through the stages as they gain experience. Instead, this model assumes that to improve in skill and judgment, nurses must also be attuned to each clinical situation. This requires an ability to take in information from a variety of sources and to notice subtle variations. Although expertise (Stage 5) is a goal, not everyone can achieve this level.

Nursing Organization Guidelines

The ANA and other organizations are also involved in helping nurses to continue to improve their practice (e.g., by setting standards and articulating nursing values). For example, in the Code for Nurses, the ANA provides guidelines for nurses to conduct themselves in their day-to-day practice. These guidelines describe acceptable and unacceptable professional behaviors and identify values to help improve your practice and participation in the profession. Box 1-3 presents some values and behaviors associated with nursing. See Chapter 44 for further discussion of nursing values and the ANA Code for Nurses.

KnowledgeCheck 1-2

- Compare and contrast formal and informal education.
- Name and describe five educational pathways leading to licensure as an RN.

How Is Nursing Practice Regulated?

Nursing practice in the United States is regulated by laws and professional organizations' standards of practice.

Nurse Practice Acts In the United States, each state enacts its own **nurse practice act**—laws that regulate nursing practice. The state board of nursing is the agency responsible for regulating nursing practice. The board is charged with protecting the health, safety, and welfare of the general public. Although there are minor variations, each board of nursing is responsible for:

- Approving nursing education programs
- Defining the practice of professional nursing
- Establishing criteria that allow a person to be licensed as a registered nurse (RN) or licensed practical or vocational nurse (LPN/LVN)
- Defining professional practice, which determines the nurse's scope of practice or those activities that nurses are expected to perform (and by implications, those they may not)
- Developing rules and regulations for guidance to nurses
- Enforcing the rules that govern nursing

BOX 1-3 ■ Nursing Values and Behaviors

- The nurse's primary concern is the good of the patient.
- Nurses ought to be competent.
- Nurses demonstrate a strong commitment to service.
- Nurses believe in the dignity and worth of each person.
- Nurses constantly strive to improve their profession.
- Nurses work collaboratively within the profession.

Key Point: ***To practice nursing, you must be licensed as a nurse. Licenses are issued by the state.*** All states require graduation from an approved nursing program and successful completion of the National Council Licensure Exam (NCLEX). To receive licensure in another state, the nurse simply applies for licensure by endorsement (reciprocity) or follows the guidance of the mutual recognition model. For further details about licensing and the regulation of nursing practice, see Chapter 45.

Standards of Practice Nursing is also guided by standards of practice, which "describe a competent level of nursing practice and professional performance common to all registered nurses. . . . They are authoritative statements of the duties that all registered nurses, regardless of role, population, or specialty, are expected to perform competently" (ANA, 2010, p. 2). Standards provide a guide to the knowledge, skills, and attitudes (KSAs) that nurses must incorporate into their practice to provide safe, quality care. Standards are used by individual nurses, employers of nurses, professional organizations, and other professions.

As a student of nursing, you may use the ANA standards of nursing practice to get a better understanding of nursing (Table 1-3). Practicing nurses use the standards to judge their own performance, develop an improvement plan, and understand what employers expect of them. Employers incorporate the standards into annual evaluation tools at hospitals and health facilities. Professional organizations use the standards to educate the public about nursing, to plan for continuing education programs for nurses, and to guide their efforts at lobbying and other activities that advocate for nurses. Finally, other professions read the standards of practice to examine the boundaries between nursing and other health professions.

ThinkLike a Nurse 1-5

What additional information have you learned about nursing from your review of the ANA standards of practice?

What Are Some Important Nursing Organizations?

Numerous organizations are involved in the profession of nursing. Some of the most influential are discussed here.

Table 1-3 ➤ American Nurses Association: Scope and Standards of Clinical Nursing Practice

STANDARDS OF CARE		
Standard 1	Assessment	The registered nurse collects comprehensive data pertinent to the healthcare consumer's health and/or the situation.
Standard 2	Diagnosis	The registered nurse analyzes the assessment data to determine the diagnoses or issues.
Standard 3	Outcome Identification	The registered nurse identifies expected outcomes for a plan individualized to the healthcare consumer or situation.
Standard 4	Planning	The registered nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes.
Standard 5	Implementation	The registered nurse implements the identified plan.
Standard 5A	Coordination of Care	The registered nurse coordinates care delivery.
Standard 5B	Health Teaching and Health Promotion	The registered nurse employs strategies to promote health and a safe environment.
Standard 5C	Consultation	The graduate-level prepared specialty nurse or advanced practice registered nurse provides consultation to influence the identified plan, enhance the abilities of others, and effect change.
Standard 5D	Prescriptive Authority and Treatment	The advanced practice registered nurse uses prescriptive authority, procedures, referrals, treatments, and therapies in accordance with state and federal laws and regulations.
Standard 6	Evaluation	The registered nurse evaluates progress toward attainment of outcomes.
STANDARDS OF PROFESSIONAL PERFORMANCE		
Standard 7	Ethics	The registered nurse practices ethically.
Standard 8	Education	The registered nurse attains knowledge and competency that reflects current nursing practice.
Standard 9	Evidence-Based Practice and Research	The registered nurse integrates evidence and research findings into practice.
Standard 10	Quality of Practice	The registered nurse contributes to quality nursing practice.
Standard 11	Communication	The registered nurse communicates effectively in all areas of practice.
Standard 12	Leadership	The registered nurse demonstrates leadership in the professional practice setting and the profession.
Standard 13	Collaboration	The registered nurse collaborates with healthcare consumer, family, and others in the conduct of nursing practice.
Standard 14	Professional Practice Evaluation	The registered nurse evaluates his or her own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.
Standard 15	Resource Utilization	The registered nurse utilizes appropriate resources to plan and provide nursing services that are safe, effective, and financially responsible.
Standard 16	Environmental Health	The registered nurse practices in an environmentally safe and healthy manner.

American Nurses Association (2010). *Nursing: Scope and Standards of Practice* (2nd ed). Silver Spring, MD: Nursebooks.org.

American Nurses Association

The American Nurses Association (ANA) is the official professional organization for nurses in the United States. The ANA was formed in 1911 from an organization previously known as the Nurses' Associated Alumnae of the United States and Canada. Originally, the ANA focused on establishing standards of nursing to promote high-quality care and work toward licensure as a means of ensuring adherence to the standards.

The ANA continues to update its standards. Representatives are elected from the local branches of the state organizations to bring their concerns to the national level. As such, they track healthcare legislation, serve as liaisons with national government representatives to inform them of how current and proposed legislation will affect nursing, and develop and sponsor legislation that will have a positive effect on nursing and on patient care. The ANA publishes educational materials on nursing news, issues, and standards. The official publication of the ANA is *The American Nurse*.

National League for Nursing

Originally founded as the American Society of Superintendents of Training Schools for Nurses in 1893, the National League for Nursing (NLN) was the first nursing organization with a goal to establish and maintain a universal standard of education. The NLN sets standards for all types of nursing education programs, studies the nursing workforce, lobbies and participates with other major healthcare organizations to set policy for the nursing workforce, aids faculty development, funds research on nursing education, and publishes the journal *Nursing Education Perspectives*.

International Council of Nursing

The International Council of Nursing (ICN) represents more than 13 million nurses on a global level. It is composed of a federation of national nursing organizations from more than 130 nations. The ICN aims to ensure quality nursing care for all, supports global health policies that advance nursing and improve worldwide health, and strives to improve working conditions for nurses throughout the world.

National Student Nurses Association

The National Student Nurses Association (NSNA) represents nursing students in the United States. It is the student counterpart of the ANA. Like the ANA, this association comprises elected volunteers who advocate on behalf of student nurses. The NSNA sponsors yearly conventions to address the concerns of nursing students. Local chapters are usually organized at individual schools. The NSNA also publishes *Image,* a journal dedicated to nursing student issues.

Sigma Theta Tau International

Sigma Theta Tau International (STTI) is the international honor society for nursing. Membership includes the clinical, education, and nursing research communities and senior level baccalaureate and graduate programs. The goal of this organization is to foster nursing scholarship, leadership, service, and research to improve health worldwide. The official publication of STTI is the *Journal of Nursing Scholarship.*

Specialty Organizations

Numerous specialty organizations have developed around clinical specialties, group identification, or similarly held values. Here are some examples:

- ***Clinical specialty.*** Association of Operating Room Nurses (AORN), Association of Nurses in AIDS Care (ANAC), Emergency Nurses Association (ENA)
- ***Group identification.*** National Organization for Associate Degree Nursing (NOADN), National Association of Hispanic Nurses (NAHN), American Assembly for Men in Nursing (AMN)
- ***Similar values***. Nurses Christian Fellowship (NCF), Nursing Ethics Network (NEN)

To explore Web sites of a variety of nursing organizations,

Go to Chapter 1, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

Nursing Practice: Caring for Clients

Look again at the definitions of nursing you have read in this chapter (e.g., see Box 1-1). Notice that they all agree that nursing is about caring for clients. Recent studies show that when the proportion of RNs increases in an agency, quality of care rises, death and infection rates drop (Potera, 2007), and length of stay is shorter by at least 30% (Kane, Shamliyan, Mueller, et al., 2007). Studies also show that smaller nurse-to-patient ratios (i.e., when each nurse cared for fewer patients) were related to positive patient outcomes, lower patient mortality, improved detection of pre-discharge infections, less nurse burnout, and higher job satisfaction for nurses (Aiken, Sloane, Cimiotti, et al., 2010; Penoyer, 2010; Unruh & Zhang, 2012).

Who Are the Recipients of Nursing Care?

The recipients of nursing care may be individuals, groups, families, communities, or societies. They can be referred to as patients, clients, or persons. **Direct care** involves personal interaction between the nurse and clients (e.g., giving medications, dressing a wound, or teaching a client about medicines or care). Nurses engage in **indirect care** when they work on behalf of an individual, group, family, or community to improve their health status (e.g., restocking the code blue cart [an emergency cart], ordering unit supplies, arranging unit staffing, or serving on an ethics committee). A nurse may use independent judgment to determine the care needed or may work under the direct order of a primary care provider.

As a nurse, however, you should not view patients as passive recipients of care. Nurses should respect and actively support patients' right to make decisions about their healthcare, and facilitate their participation as collaborative members of the healthcare team.

What Are the Purposes of Nursing Care?

Nurses provide care to achieve the goals of health promotion, illness prevention, health restoration, and end-of-life care. Together these aspects of care represent a range of services that cover the spectrum from complete well-being to death. Nurses plan patient care to ensure consistency of care over time, individualize care according to patient needs, ensure that holistic care is provided, and collaborate with the interdisciplinary health team for optimal patient outcomes.

Where Do Nurses Work?

As a nurse you will have the opportunity to work in a variety of settings. During your education you will have assignments in many clinical units and environments that will allow you to see some of the options available to you upon graduation. Approximately 62% of nurses work in hospitals. The remaining 38% work in extended care facilities, ambulatory care, home health settings, public health, or nursing education (Health Resources and Services Administration, 2010).

What Models of Care Are Used to Provide Nursing Care?

Nursing care is structured in a variety of ways. The organization of the nursing team reflects the philosophy and beliefs of the institution, as well as the prevailing views on nursing. The structure of the team is often referred to as the *model of care*. The most common models include the following:

Case Method The **case method**, also called *total care*, is one-to-one care; one nurse provides all aspects of care for one patient during a single shift. An inpatient may have a different nurse on each shift. Although this method may be satisfying for patients and nurses, high costs limit its use. The case method is used in intensive care, labor and delivery, and private duty care. In this method, the patient's needs are quickly met, the nurse and patient work more closely together, and the nurse has a greater degree of autonomy.

Functional Nursing In **functional nursing**, care is compartmentalized, with each task assigned to a staff member with the appropriate knowledge and skills. For example, the nursing assistant may give bed baths and make beds, the LPN/LVN may distribute medications, and the RN may be in charge and perform ordered treatments. This approach requires a clear understanding of what tasks are required to deliver care in each unit. Although this approach is economical and efficient when the unit is short staffed, it can easily lead to fragmentation of care—meaning that it is difficult for the nurse to fully grasp the patient's "whole picture."

Team Nursing The **team approach** is an efficient arrangement for delivering nursing care and maintains the cost saving of functional nursing while attempting to limit fragmentation. In team nursing, a licensed nurse (RN or LPN/ LVN) is paired with a nursing assistant or nursing assistive personnel. The team is then assigned to a group of patients. Teams led by RNs are assigned to high-acuity patients. Team nursing is popular during times of nursing shortages (Holt, 2011; Wood, 2007).

Primary Nursing In **primary nursing**, one nurse manages care for a group of patients. The primary nurse assesses the patient and develops a plan of care. When she is at work, she provides care for the patients for whom she is responsible. In her absence, associate nurses deliver care and implements the plan developed by the primary nurse.

Differentiated Practice **Differentiated practice** is a variation of primary nursing. It recognizes that education and experience lead to differences in the care delivered by nurses. For this system to work, each nursing unit must identify the types of expertise needed by its patients, and the nursing competencies required to deliver that care. Once this has been developed, individual nurses put together a portfolio to demonstrate their competencies. Nurses who have the necessary competencies care for patients.

HEALTHCARE DELIVERY SYSTEM

The healthcare delivery system in the United States is a unique and complex collection of patients, providers, facilities, vendors, and rules. The rest of this chapter is designed to help you gain a beginner's understanding of the U.S. healthcare system. You will need to know the various components of the system to understand the continuum of healthcare patients receive, providers involved in that care, and factors that influence the type and amount of care patients receive.

Where Is Healthcare Provided?

Patients can receive treatment in a variety of environments based on their needs. Hospitals, extended care facilities, ambulatory care centers, and home healthcare agencies are the most visible sites for delivery of healthcare. A patient who has been admitted to a healthcare facility is an **inpatient**. An **outpatient** is a person who receives treatment at a facility, but does not stay overnight. Inpatient services occur in various hospital settings.

Hospitals

Hospitals are the most expensive and the most frequently used site for care. They provide a broad range of services to treat various injuries and disease processes (Fig. 1-2). Hospitals vary in size, ownership, and the

FIGURE 1-2 Emergency rooms have become the primary source of healthcare for the uninsured.

services provided. Small rural facilities may have only 8 to 12 beds. In contrast, large metropolitan medical centers might exceed a 1,200-bed capacity. Small hospitals offer basic services, whereas larger medical centers usually offer additional and specialty services. Basic services include inpatient beds, radiology, and laboratory services. Hospitals usually have an emergency department, diagnostic centers, and various units such as intensive care, medical, surgical, pediatrics, and maternal newborn.

A large percentage (62%) of RNs are employed in hospitals (Health Resources and Services Administration, 2010). Hospitals are distinguished from other healthcare facilities because they employ nurses, allied health therapists, physicians, case managers, pharmacists, and many other persons to ensure the acute care needs of the patient are met around the clock. The length of stay is limited to the amount of time that the patient requires 24-hour observation.

As a result of research and technology, many hospitals have sophisticated equipment to deliver the highest quality healthcare available. This progress has lengthened life spans in many cases but has at the same time increased the costs of care. Technological advances and efforts to control costs have had the following effects:

- *Larger Hospitals.* The number of community hospitals and hospital beds has declined, and larger regional facilities have emerged in their place.
- *Specialty Hospitals.* Hospitals may specialize in order to reduce redundancies in healthcare within a local community. For example, one hospital might be the regional tertiary cardiac care center, while another provides oncology (cancer) services. Specialization minimizes expense from duplicating costly specialized equipment and specially trained personnel for each individual site.
- *Shorter Length of Stay.* Patients' length of stay has decreased overall. For example, in the 1950s a patient having surgery for gallbladder removal would remain in the hospital for at least 10 days. Now, this surgery is usually performed on an outpatient basis. Only those patients who require 24-hour care are hospitalized. Even after cardiac surgery, a typical patient remains hospitalized for only 4 days. As soon as the patient is stabilized, she is relocated to home or less expensive sites of care, such as extended care facilities or rehabilitation centers.

Extended Care Facilities

Extended care facilities provide care for clients for an extended period of time—usually longer than 1 month. As the length of stay in hospitals has declined, extended care facilities have begun to deliver services that were previously provided in the hospital. These facilities include nursing homes, skilled nursing facilities (also known as convalescent hospitals), and rehabilitation facilities. The distinction among them is based primarily on whether they provide skilled or custodial care.

Skilled care includes services of trained professionals that are needed for a limited period of time after an injury or illness. These "skilled" services include wound care, infusions, teaching, and ongoing monitoring of patient status. Skilled care patients are those who can be expected to improve with treatment. For example, a patient who no longer needs hospitalization may transfer to a skilled nursing facility until she is able to return home. Many extended care facilities have designated units, often called subacute units that provide post-hospitalization skilled care.

Custodial care consists of help with activities of daily living: bathing, dressing, eating, grooming, ambulation, toileting, and other care that people typically do for themselves (e.g., taking medications, monitoring blood glucose levels).

Residents in extended care facilities are most commonly older adults, but clients of any age who require assistance with self-care activities, such as hygiene, toileting, and dressing, may live in these facilities. Because of the aging population and increased longevity of patients with traumatic injuries and chronic diseases, the number of patients requiring long-term care, as well as the number of facilities providing these services, is expected to increase.

Nursing Homes A **nursing home** provides custodial care for people who cannot live on their own but are not sick enough to require hospitalization. It provides a room, custodial care, and recreation and may be a permanent residence for people who require continual supervision to ensure their safety. A physician for each patient supervises care. In the United States approximately 15,690 nursing homes provide care for approximately 1.7 million residents (Centers for Medicare & Medicaid Services, 2010).

Rehabilitation Centers Rehabilitation centers provide extended care and treatment for patients with physical and mental illness. Types of services include alcohol and drug rehabilitation, physical rehabilitation services for patients who have experienced traumatic injuries, and rehabilitation of patients after stroke or heart attack. Rehabilitation services may be inpatient, outpatient, or a combination. Nurses work in direct patient care, counseling, and coordination of care. Because of the lengthy time frame for this care, nurses at rehabilitation centers have an ongoing relationship with their patients. Rehabilitation often involves a multidisciplinary, collaborative approach with weekly team and family conferences to discuss the treatment plan. A variety of providers and therapists are involved in the patients care to help them reach their optimal level of functioning. These are discussed later in the chapter.

Assisted Living Facilities **Assisted living facilities** were designed to bridge the gap between independence and institutionalization for older adults who have a decline in health status and cannot live alone independently. Residents of these facilities are able to perform self-care activities, but require assistance with meals, housekeeping, or medications. Nurses have a limited presence at assisted living sites because residents typically travel from their homes to the physician and other service providers.

Ambulatory Care Centers

Ambulatory care centers are used by people to get same-day cost-effective healthcare. Ambulatory care is synonymous with *outpatient care* and provides services for clients who are able to come and go from the facility. Clients live at home or in nonhospital settings and come to the site for care. Ambulatory care sites include private health and medical offices, clinics, and outpatient therapy centers. Low-cost, walk-in, retail clinics have expanded rapidly—in shopping centers, pharmacies, and other retail sites. Typically they treat only common ailments and refer complex or serious illnesses to specialized physicians or emergency rooms (Darcé, 2007). To keep the cost of healthcare down, more and more services are being provided in ambulatory facilities, such as chemotherapy or outpatient surgeries. Ambulatory centers may be connected to hospitals (Fig. 1-3).

Home Healthcare Agencies

Home healthcare agencies provide continuing care to patients after hospitalization. Home care is provided (a) when clients are homebound or unable to get to ambulatory care centers for services; (b) when the client or family prefers to receive care in the home—particularly when the client is terminally ill; and (c) when a client still requires skilled care but is discharged from the hospital because his reimbursable length-of-stay has expired. Services are usually coordinated by a home health or visiting nurse service and include nursing care as well as various therapies and home assistance programs. Chapter 43 provides further discussion on home health nursing.

FIGURE 1-3 The shift to outpatient care is a cost-saving strategy.

Community/Public Health Centers

Community or public health centers are community-based centers that provide care for the community at large. Community health nurses provide services to at-risk populations and devise strategies to improve the health status of the surrounding community. Examples of community health programs include healthcare for the homeless and school-based programs designed to decrease the incidence of teen pregnancies.

Community care is a comprehensive term that describes the care provided to client groups at various sites, such as church, schools, shelters, the workplace, and public clinics. Care focuses on populations (e.g., older adults, pregnant women, employees at a manufacturing plant), neighborhoods, and at-risk groups (e.g., pregnant teens, victims of domestic violence, substance abusers). Chapter 43 provides further discussion of community healthcare.

Independent Living Facilities

Also known as retirement homes, **independent living facilities** are designed for seniors 55 years or older who (a) are independent in all aspects and (b) want to live in a community with other senior citizens. They may not want the responsibilities associated with owning a home, such as maintenance and yard work. Other benefits to this style of community living include a peer support network that provides socialization opportunities, structured recreational activities, transportation arrangements, fitness centers, pools, and quiet environments. Living facilities range from apartment-style homes to smaller separate residential homes. Nurses may provide periodic health screening and health information.

How Is Healthcare Categorized?

Because the boundaries of care have become fluid, it is useful to look at the system in a different light. The complexity of care no longer is a predictor of where care will be delivered. Instead, regulators, finances, and the patient's support system dictate where a patient will be located in the system. On a basic level, healthcare is categorized by degree of complexity into primary, secondary, and tertiary services.

Primary Care

Primary care services focus on health promotion, preventive services, health education, and screening for the early detection of healthcare problems. Services are directed toward keeping the patient well by preventing illness and by treating acute episodic problems. General or primary care providers provide most of the care at this level. Most of these services are offered in the community at physicians' offices, clinics, and diagnostic centers. However, hospitals may also offer primary care services. Health promotion and illness prevention by nurses are examples of primary care.

Nursing and Health Promotion In 1948, the World Health Organization (WHO) defined health as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." The definition has not been amended since that time (WHO, 2007). Health promotion activities foster the highest state of well-being of the recipient of the activities. This inclusive definition can be applied to individuals, groups, families, communities, or societies. The following are examples:

- *Individual level*—Counseling a pregnant client about the importance of adequate prenatal nutrition to promote health for the client and baby.
- *Group and family level*—Teaching about nutrition during pregnancy in family education programs.
- *Community level*—Activities that focus on reaching a larger number of people, for example, advocating for prominent billboards highlighting the importance of prenatal care and nutrition, posting signs in grocery stores recommending food sources for pregnant women, and lobbying for labeling of substances that should be avoided in pregnancy.
- *Societal level*—Working with international partners to establish worldwide prenatal nutrition standards.

Nursing and Illness Prevention *Illness prevention* focuses on avoidance of disease, infection, and other comorbidities. Activities are targeted to decrease the risk of developing an illness or to minimize the risk of exposure to disease. For example, pneumonia causes many deaths every year. It affects society's most vulnerable: the very young, the very old, and the very ill. Some nursing activities to decrease the risk of pneumonia include:

- Teaching the importance of hand hygiene to decrease the transmission of infection
- Advocating for and administering pneumonia immunizations to those at high risk
- Promoting smoking cessation
- Promoting adequate nutrition to include a diet high in vitamin C

Secondary Care

Secondary care consists of services to diagnose and treat illness, disease, and injury. Historically, we have thought of this as hospital-based care, but increasingly these services are being performed in surgery centers, offices, and outpatient centers. The trend away from the hospital is related to containing costs, increasing specialization of hospitals, and growing evidence that hospitals often harbor medication-resistant infections.

Nursing and Health Restoration **Health restoration** activities foster a return to health for those already ill. To restore health, the nurse provides direct care to ill individuals, groups, families, or communities. Direct care is what most people think of when they envision the nursing role. Recall that health has physical, mental, spiritual, and social dimensions. When you engage in health-restoration activities, your care should address each of those dimensions, for example:

- Providing hygiene and nutrition for someone unable to do so independently
- Counseling individuals or groups
- Lobbying for policy changes to improve access to care for an underserved group
- Identifying the significance of cultural and/or spiritual influences

Tertiary Care

Tertiary care refers to long-term rehabilitation services and care for the dying. Historically, these services were provided in extended care facilities. Now, however, many tertiary care services are provided in the home or in outpatient settings. One nursing focus in tertiary care is to provide end-of-life care.

Nursing and End-of-Life Care Death is an inevitable destination on the journey of life. Nurses have been active in promoting the respectful care of those who are terminally ill or dying. Nursing activities for the dying are designed to promote comfort, maintain quality of life, provide culturally relevant spiritual care, maintain dignity, and ease the emotional burden of death. Nurses work with dying individuals, their family members and support persons, and organizations (hospice) that focus on the needs of the terminally ill (see Chapter 17).

KnowledgeCheck 1-3

Recall the last time that you had a cold. Identify health-promotion, illness-prevention, and health-restoration activities for individuals, families, groups, and communities in relation to the common cold.

What Healthcare Providers Will You Work With?

As a nurse, you will be part of an interdisciplinary healthcare team consisting of numerous professionals whose primary role is to ensure quality patient outcomes (Fig. 1-4). The composition of the team varies depending on the healthcare needs of the patient. Typically, for an inpatient,

FIGURE 1-4 Quality patient outcomes require the collaboration of the entire healthcare team.

the team leader is the physician, whose primary role is to make a medical diagnosis and outline the treatment plan. The registered nurse uses this plan to develop holistic, continuous, and comprehensive nursing care to the patient, which involves the licensed practical nurse and/or nursing assistive personnel in implementing the plan. The RN administers treatments and medications, provides education, and modifies the nursing care plan based on the patient responses to treatment. The role of each provider in the interdisciplinary health team is discussed below.

Physicians Physicians are licensed as medical doctors (MD) or doctors of osteopathy (DO). Their role is to diagnose and treat disease and illness through medical and surgical services. A physician may work independently, as part of a medical group, or as an employee of a health facility. Physicians may provide care in an office setting, in the hospital, or in a variety of clinics or ambulatory sites. Physicians who provide only hospital care are known as *hospitalists*. This is a growing specialty, as hospitals endeavor to reduce costs. More physicians are choosing employment in a hospital, rather than private practice because of guaranteed salary, attractive benefit packages, and limited practice hours. Other physicians are concerned this employment arrangement can lead to reduced autonomy and restrictions on their medical practice.

Physician's Assistants (PAs) PAs diagnose and treat certain diseases and injuries. Although many function in a fashion similar to nurse practitioners, they are not independently licensed. Therefore, they must practice under the supervision of a physician, in contrast to NPs, who practice independently or in collaboration with a physician, and who can provide a broader range of services. Each state varies regarding the scope of practice for nurses and PAs. Check with your state nurse practice act as well as agency policies and procedures to be certain that nurses are permitted to follow a PA's orders.

Nursing Assistive Personnel (NAP) NAP is a broad term that describes nursing assistants, aides, and technicians. NAPs provide custodial care under the direction of nurses and physicians in a variety of settings. Some NAPs introduce themselves to patients by stating, "I'm your nurse." Because they are not licensed nurses, they are making a false claim. Be sure to clarify your role and the NAP's role with all of your patients.

Therapists Allied healthcare providers are various therapists who focus on the rehabilitative needs of the patient. The goal of the rehabilitative team is to treat, maximize functioning, and/or assist the patient to adapt to limitations and achieve optimal outcomes. Types of therapists include the following:

- *Physiatrists*—as the rehabilitative team leader, collaborates with the team to manage the patient's rehabilitation outcomes.
- *Physical therapists* (PT)—focus on the rehabilitation of muscles and bones. They use heat, massage, ultrasound, electrical stimulation, and therapeutic exercise to treat clients with musculoskeletal problems. Their goal is to improve mobility and strength and teach motor skills, such as relearning how to walk after a stroke, exercising to promote flexibility after a knee replacement, or developing wheelchair skills.
- *Occupational therapists* (OT)—work closely with the PT to help patients regain function and independence. They concentrate on helping patients gain optimal functioning in self-care skills for activities of daily living and to learn how to use assistive devices. They also assist patients with disease or injury that limits their abilities to pursue diversional activities.
- *Respiratory therapists* (RT)—provide care for clients with respiratory problems. They provide oxygen therapy, set up and maintain mechanical ventilators, administer pulmonary tests, and provide respiratory treatments that have been prescribed by physicians or advance practice nurses.
- *Speech and language therapists* (SLT)—provide assistance to patients experiencing swallowing and speech disturbances. They evaluate the risk of aspiration, recommend food consistencies to reduce the risk of aspiration, work with patients to restore swallowing abilities, and assist patients in developing speech and language skills after neurological impairment.
- *Recreational therapists*—promote patients' physical, social, and emotional well-being through the use of leisure activities.
- *Marriage and family therapists*—provide counseling services to individuals, families, and groups.

Technologists Technologists perform a variety of activities in hospitals, diagnostic centers, and emergency care facilities. For example, laboratory technologists examine blood, urine, tissue, and other bodily fluids to aid in the diagnosis and treatment of patients. Radiology technologists administer x-ray and specialty radiographic-type tests. Emergency medical technologists (EMTs) work for ambulance and transport services to stabilize and transport injured and ill clients.

Nutritionists Nutritionists apply specialized knowledge about nutrition and food to promote optimal health to patients with various healthcare needs. A registered dietitian (RD) is a type of nutritionist who works with inpatients to ensure they receive the prescribed diet and learn about ways to continue to follow that diet after discharge.

Pharmacists Pharmacists prepare and dispense medications and therapeutic solutions in hospitals, community pharmacies, and various health settings. They also collaborate with nurses, physicians, and other health-team members to ensure the selection of safe and effective medications to be included in the treatment plan. They provide information about medication contraindications, side effects and adverse reactions, dosage, and administration tips. Pharmacy assistants serve as support personnel for pharmacists.

Dentists Dentists diagnose and treat disorders of the mouth, gums, and teeth. They promote dental health through therapeutic cleaning services, repair of teeth, treatment of gum disorders, inspection for oral carcinomas or infection, and correct tooth alignment disorders. Although most dentists work in community settings, some visit patients hospitalized in acute care and long-term care facilities.

Social Workers Social workers provide psychosocial support and patient services throughout the healthcare system to coordinate continuity of care. They identify the patient's need for community-based support, and help arrange for services after patient discharge. Social workers also counsel clients on financial, housing, marital, and family issues affecting healthcare. Owing to rising healthcare costs, social workers are increasingly used to help move clients through the health system.

Spiritual Care Providers In the United States, chaplains and religious clergy usually provide spiritual care. However, other leaders within various faith-based groups may also do so. Many work at healthcare facilities, but most are on call from local religious facilities. As a nurse, you will likely work with chaplains to provide spiritual services in the form of organized religious services, client visits, and family and staff support, particularly at the end of life or with serious illness.

Alternative Care Providers Alternative care providers such as chiropractors, naturopaths, and herbalists offer health services outside the traditional healthcare system. To read more about alternative healthcare practices,

Go to Student Resources, **Bonus Chapter, Chapter 46,** on Davis*Plus*.

How Is Healthcare Financed?

Payors for healthcare in the United States include individuals, individual private insurance, employment-based group private insurance, government, and charitable sources, discussed in the following sections.

Individuals

Until the latter half of the 20th century, physicians made house calls and patients paid either with cash or by bartering goods and services. Today, we refer to payments made directly by individuals as *direct payment of services* and *out-of-pocket expenses.* Many of those who do not have insurance and do not qualify for government services cannot afford healthcare if individual payment is their only means to purchase services. Those who have private insurance and government financing also bear some of these expenses through cost-sharing. **Cost-sharing** occurs in the form of insurance premiums, insurance deductibles, co-payments, costs above fixed payments, and non-covered services. **Key Point:** ***Although healthcare insurance does pay for a share of the costs, even consumers with insurance sometimes avoid or delay services because of high out-of-pocket expenses.***

Individual Private Insurance

Healthcare insurance is purchased to protect individuals from having to pay the costs associated with illness and hospitalization. The average cost of an emergency room visit was $1,319 in 2009 compared with $922 in 2008. The average annual cost of medical insurance premiums in 2012 was $5,615 for single coverage and $15,745 for family coverage. Insurance is intended to protect persons from "medical bankruptcy" associated with the costs incurred by a major medical event (Fig. 1-5).

A person with private insurance pays premiums to an insurance company. The insurance company then contracts with healthcare providers to deliver care to insured members at prearranged rates. Patients share in the cost of care through out-of-pocket expenses.

Individual private insurance began in 19th-century Europe with the establishment of voluntary benefit programs through guilds and trade associations. Monthly payments were stockpiled to provide assistance in the event of illness or death. European immigrants brought this tradition to the United States. Commercial insurance programs extended this service to individuals

FIGURE 1-5 The high cost of healthcare is a barrier to early screening and prevention.

outside of the trades. Less than 10% of healthcare in the United States is financed through this means.

Employment-Based Private Insurance

Most private insurance in the United States is employment based. Employment-based private insurance is modeled after the individual trade plans. It developed in the United States during World War II, when a labor shortage existed and wage and price controls limited salary increases. Employers financed fringe benefits, such as health insurance, to attract and reward employees as well as to improve the health of employees. Healthy employees benefit the employers with reduced sick time and a full workforce.

With employment-based insurance, the employer pays all or a portion of the costs (e.g., premiums) of providing health insurance to its employees. Increasingly, health insurance has become a source of modern labor disputes, with employers attempting to limit their cost of doing business by reducing the amount of coverage they provide. In effect, the federal government subsidizes employer-based health insurance by not taxing health insurance and allowing employers to deduct these benefits as a business expense (Bodenheimer & Grumbach, 2005).

Government (Public) Financing

Key Point: ***Government-funded programs are paid for with revenue from taxes on the citizenry. Programs include Medicare, Medicaid, children's, specialty, and categorical programs. They include federal, state, local, and jointly funded programs.***

Medicare Medicare is a federal insurance program created by Title XVIII of the Social Security Act of 1965. This Act was designed for persons aged 65 years and older. In 1972, the program was expanded to include younger people with permanent disabilities, such as end-stage renal disease. Medicare financing comes from a payroll tax levied on employers and employees and from premiums paid by Medicare subscribers (patients). The focus of Medicare reimbursement is hospital, office, and other outpatient services. Recipients can also purchase partial coverage for their outpatient medications.

Long-term care coverage is limited under Medicare. Unfortunately, as people age, the need for non-skilled care (e.g., help with bathing, dressing, and toileting) increases, yet it is not a covered benefit of Medicare, which is a program designed to care for older adults. This is a premium-based option that is available to people who are enrolled in Medicare Part A or to other eligible individuals for a monthly fee.

Medicaid Medicaid was developed under Title XIX of the Social Security Act of 1965 to provide access to healthcare services for people with low income and minimal resources. Medicaid is a joint federal and state endeavor: (1) The federal government provides the framework and guidelines for states to use in developing and administering their Medicaid program and (2) reimburses states for their Medicaid associated expenditures. The eligibility criteria for Medicaid and the range of medical services offered vary from state to state. Medicaid offers a fairly comprehensive set of benefits, including prescription drugs.

Medicaid is funded through state and federal taxes. Most states use managed care organizations, such as HMOs, which contract with providers for healthcare services at a predetermined amount. Under the Patient Protection and Affordable Care Act, beginning in 2014, more people under age 65 years whose income falls below certain percentages of the poverty level will qualify for Medicaid coverage (Natoli, Cheh, & Verghese, 2011). The Patient Protection and Affordable Care Act is frequently referred to as the Affordable Care Act.

Children's Health Insurance Program (CHIP) CHIP is a joint venture between the federal government and states to provide health insurance to millions of children whose family income exceeds Medicaid eligibility criteria, but who cannot afford private insurance and are not covered under a parent's policy. CHIP's goal is to ensure that children have health insurance and can access healthcare, either through an expansion of Medicaid or the development of a separate program. The Patient Protection and Affordable Care Act extends CHIP's funding until October 1, 2015.

Specialty and Categorical Programs Certain programs provide distinct services. For example, the federal government supports public health service hospitals, Veterans Affairs hospitals and clinics, healthcare for military personnel and dependents, and Indian Health Services. *Categorical programs* are designated by federal laws to benefit a certain category of people, such as access to healthcare for immigrants or health screening in Head Start programs. Funded programs vary based on current laws and prevailing views.

Charitable Organizations

Charitable organizations are an increasingly important funding source for healthcare. Community agencies that are funded through networks like the United Way, Salvation Army, and Red Cross provide important resources to children, poor families, the aged, and vulnerable populations, such as the homeless, mentally ill, and victims of violence. Charitable organizations provide direct services and cover the costs for some traditional health services. For example, the Salvation Army provides inpatient alcohol and drug rehabilitation services, food and clothing for the needy, and social and nutritional programs for older adults in many major cities. Most participants do not pay for the cost of these services. Instead, able-bodied participants work for the Salvation Army while in the program, and donations to this charity fund the cost of these services. Charitable organizations also donate to healthcare research and healthcare organizations.

How Are Supplies and Equipment Provided?

Suppliers are the companies and corporations that bring goods to the healthcare industry. Pharmaceutical companies and medical equipment suppliers are the largest suppliers. The costs of medications, equipment, and technology have played a major role in the rising costs of care. Suppliers argue that their costs are justified because of the enormous investment required to bring a product to the market. Research, development, and testing of pharmaceuticals and medical equipment take years. Often, numerous products are tested before a successful drug or device is available for use. The cost of insurance to protect against lawsuits, in the event the product causes unforeseen harm, is tremendous. As a result, the cost of these goods is high. On the other hand, suppliers are also launching expensive direct-to-consumer marketing campaigns that urge consumers to seek new products. All of these costs are passed on to consumers in the form of higher prices, rising insurance premiums, and increased out-of-pocket expenses.

How Is Healthcare Regulated?

Regulators are governing bodies that exert influence or control over the healthcare system. They include accrediting and licensing agencies and legislators. All health professions have accrediting bodies to ensure that entry-level programs prepare personnel to deliver safe care. The Accreditation Commission on Education in Nursing (ACEN) and the Commission on Collegiate Nursing Education (CCNE) are the accrediting bodies for nursing education. The state boards of nursing are the regulatory bodies that enforce minimum standards for licensed nurses. Other healthcare providers also have regulatory agencies that govern their practice.

The most prominent regulating body in the healthcare system is The Joint Commission. Reimbursement from government and insurance sources is dependent upon accreditation by The Joint Commission. Healthcare facilities (e.g., hospitals, rehabilitation centers) must meet and maintain standards designed to promote "best practices" for patient safety.

Legislators also affect the healthcare system. For example, legislators can redefine eligibility criteria for government-funded health plans. Most recently, some states have mandated minimum nursing staffing ratios in acute-care hospitals and several others states are considering similar actions. The most notable legislation that impacts healthcare is the Patient Protection and Affordable Care Act that was signed into law by President Obama in 2010. A major provision of the Affordable Care Act is coverage options to ensure that all U.S. citizens have health insurance.

Although accreditors, licensing bodies, and legislators are the only true regulators of healthcare, several other agencies exert enormous influence on the system. Independent watchdog groups, advisory boards, and peer review groups all have the ability to effect change.

How Do Healthcare Policy and Reform Efforts Affect Care?

The U.S. healthcare system is a paradox of excess and deprivation (Bodenheimer & Grumbach, 2005). Some individuals receive too little care because they are uninsured, unable to afford out-of-pocket expenses, or have restrictive healthcare plans that deny them access to competent providers or that are not accepted by certain providers. Others receive expensive top-of-the-line care that produces results that could have been achieved through cheaper means or that result in prolonged life of questionable quality.

Sultz and Young (1997) described the U.S. healthcare system as "focused on providing excellent care for the individuals within it, while virtually ignoring the more basic health service needs of the larger populations outside of it" (p. 46). Even though our healthcare system is the model of care for the industrialized world, access to care is not available to all. Very few can afford to pay for the tremendous costs of an illness or for the ongoing expenses of a chronic illness and long-term care when supplementary resources are limited or unavailable.

During the first quarter of 2012, 47 million persons were without health insurance (Cohen & Martinez, 2012). Without some form of coverage, people forgo needed care. The indigent and working poor have access to emergency or urgent treatment, but this can require long waits for services unless the person is very ill. But primary care—such as checkups, screenings, chronic illness follow-ups, and prenatal care—can be lacking, particularly for those above the poverty level but without government support or private insurance, thus leaving many untreated and ultimately needing more costly care.

Several variables collectively account for the current situation. These include the following:

- Increased government funding of services, creating a feeling that care is without cost to the individual
- Increased use of employer-based insurance, preventing the individual from seeing the actual cost of coverage
- Inflation, escalating the costs of all goods and services
- Rising costs of pharmaceuticals and medical devices
- Direct-to-consumer advertising of medical products, increasing the demand for and use of expensive products
- Increased use of technology, which can be costly to purchase and maintain
- Defensive medicine (practices for the purpose of preventing lawsuits and malpractice claims), resulting in excessive testing, treatments, and diagnostic studies

- Increased wages of healthcare personnel
- Population changes, particularly an increasing older population and increased longevity for those with acute and chronic illness
- Increased administrative costs due to the increased complexity of care and network institutions

Medicare and Public Policy

When Medicare was initially created, health services were reimbursed using a **retrospective system**. This means that Medicare paid hospitals based on the actual cost of providing services to individuals. With no cap on expenses, Medicare payments made to hospitals increased from $3 billion in 1967 to $37 billion in 1983. In an attempt to decrease the escalating costs of healthcare, a **prospective reimbursement system** was created under the Social Security Amendment of 1983. Hospitals were then reimbursed on a per case, flat rate basis determined by patient groups having similar needs. These groups were called **diagnostic related groups (DRGs).** If the patient's hospital costs were greater than the reimbursed ("set") amounts, the hospital lost money. If the costs were less than the rate set by Medicare, the hospital made a profit. Private insurance companies, following the lead of Medicare, reimbursed in the same manner.

The introduction of DRGs forced hospitals to consider new ways of delivering care and created a number of changes in patient care, such as the following:

- *The length of stay in hospitals decreased dramatically* as care moved away from hospitals out into the community and home. For example, formerly a patient who had a hip replacement would stay in the hospital for 10 days. Under a prospective payment system, this person is discharged after 4 days.
- *The cost of delivering nursing care became an expenditure*. As a result, team nursing with NAPs replaced the comprehensive care provided by RNs at the bedside. This transition occurred in spite of research documenting that a higher proportion of RNs on staff results in fewer adverse patient outcomes (e.g., as reported by Yang, Hung, Chen, et al., 2012).
- *Fewer choices for care resulted from corporate mergers and acquisitions* in large regional facilities. In many areas, residents have only one choice for hospital care. With less choice, there are also fewer nursing positions.
- *The cost of managing these large facilities skyrocketed*. In 2000, the Healthcare Financing Administration stated that administrative costs consumed at least 25% of all health expenditures. In 2010, administrative costs had decreased to "less than 2% of program expenditures" (Potetz, Cubanski, & Neuman, 2011).
- *Reduced staffing and higher patient acuity produced a more stressful work environment for nurses.* This fact, in combination with the growing number of career choices, has contributed to a severe nursing shortage.
- *Insurance premiums and cost-sharing increased, while availability of services decreased*. This led to a growing number of people who could not afford the care they need. As a result, most reform efforts are directed at controlling costs, improving access, and promoting appropriate distribution of resources.

Economists and policy makers agree that no matter how affluent a society is, it has limited healthcare resources—and with limited resources, rationing occurs. **Rationing** is "the limitation of access to or the equitable distribution of medical services, through various gatekeeper controls" (Farlex, 2002). Within our current system, if an individual has sufficient resources (i.e., money or insurance), then healthcare services are available. Conversely, if a person does not have the means to pay, then many services are denied. This model results in a tiered system: Those who can pay have better access to services than those who cannot pay do. The U.S. model also subsidizes healthcare via government-funded programs for some individuals who are unable to compete economically for the same services. With the passage of the Patient Protection and Affordable Care Act in 2010, the U.S. government will become more involved with funding and regulating healthcare (U.S. Department of Health & Human Services, 2010), moving toward a more European model.

In contrast, Canada, Australia, and most European countries have *socialized healthcare*, in which the government assumes responsibility for providing *necessary* services to all individuals. In a socialized model, basic services, such as office visits, prenatal care, and required surgery, are available to all. But services above the basic level, that is *desired* services, are available only to those who can afford them. In the U.S. model, rationing is implicit (hidden), whereas in the socialized model rationing is explicit (plainly visible).

Managed Care

Managed care, designed to control healthcare costs, is a competitive approach to healthcare pricing. Managed care organizations (MCOs) contract with medical providers to provide services (a) at discounted rates, or (b) based on predetermined fixed payment per individual covered under the plan (capitation). Providers treat more patients to offset their discounted rates. Employers contract with the managed care organization and select a type of health plan for its employees. There are four basic types of managed care plans:

Health Maintenance Organizations (HMOs) HMOs are a model of care based on **capitated** (per head) costs. Each HMO primary care provider receives a predetermined, fixed amount each month regardless of whether the patient receives healthcare services or not. The primary care provider coordinates all care, including referrals to specialists. Providers often choose to be a part of an HMO because of the steady income it offers. However, to compensate for the low reimbursement, they must see more patients per day, limit the number of HMO patients they are willing to provide care for, limit the number of office visits allowed, or refuse to provide care for patients with complex conditions. Patients often choose HMO coverage because they are among the most affordable insurance plans available. However, the patient sacrifices choice for affordability. The HMO will pay only for specified services, and only if the patient uses a provider on the HMO list ("in the network").

Preferred Provider Organizations (PPOs) PPOs allow patients to have greater choice among providers, medications, and devices, The PPO has many of the features of an HMO, such as a network of providers who will provide healthcare at the established contracted rate. The PPO offers patients more flexibility than an HMO, such as (a) seeing specialists within the network without having to get a referral from the primary care physician; and (b) seeing out-of-network providers, albeit at a higher cost than an in-network provider. The flexibility of a PPO comes at a financial cost, for example, the patient pays more in the form of higher premiums, deductibles, and co-insurance.

Point of Service (POS) The POS combines features from the HMO and PPO. The patient selects a physician from a list of network physicians, who will become the point of service (POS) for treatment and referrals to in-network specialists. The patient needs to see in-network providers in order to get the lower co-pays and minimal to no deductibles. There is limited out-of-network coverage, resulting in higher co-insurance and co-pay.

Integrated Delivery Networks (IDNs) Healthcare systems are moving toward a model of **integrated delivery networks**, also known as integrated delivery systems. IDNs combine providers, health facilities, pharmaceuticals, and services into one care system. Providers are employees of the facilities. They see only IDN patients, in IDN facilities, using IDN services and IDN-approved pharmaceuticals. Because all services and providers are linked, patients can be readily moved among IDN services and providers. The system is designed to promote a culture of collaboration, safety, and teamwork among the providers (Enthoven, 2009). The ability to obtain services from providers throughout the healthcare system is the chief advantage of this approach. The primary disadvantage is that care may be fragmented, as patients are rapidly moved through the system in an effort to minimize costs.

What Are the Issues Related to Healthcare Reform?

The profound changes created by the transition of the healthcare system from a retrospective open-checkbook to prospective fixed-rate payment system have created unprecedented leadership opportunities for nurse executives.

ANA Recommendations for Reform

In 1991, the ANA published *Nursing's Agenda for Healthcare Reform*, a set of recommendations to redesign the healthcare system. Although small changes were made, fragmentation of the healthcare systems, access to care barriers, and healthcare costs remained issues (ANA, 2008). The ANA recommendations were updated in the ANA document *ANA's Health System Reform Agenda* (2008), which includes the following recommendations for change:

- Provide universal access to essential healthcare services for all citizens and residents.
- Establish health policies that support safe, effective, patient-centered, timely, efficient, and fair care based on outcomes research.
- Shift the priority from illness care to health promotion, and balance between high-tech treatment and community-based and preventive services.
- Establish a single-payer system for financing healthcare.

Work Redesign

Work redesign involves looking at the level of care required and the mix of personnel necessary to achieve the best patient outcomes. Out of this redesign, a concept known as the critical pathway emerged. A **critical pathway** is a multidisciplinary approach to care that sequences interventions over a length of stay for a given case type. Using the critical pathways model, the interdisciplinary team delivers care that yields the desired outcomes in the quickest manner, hopefully to reduce the patient's length of stay. For example, using this model, a patient who has had cardiac surgery may be assisted out of bed as soon as his vital signs are stable. In the traditional model, the patient must wait to be seen by the surgeon before an order is written to get out of bed. Advocates of critical pathways state that this model allows patients to progress at their own pace. Foes of this plan state that it is a cookie-cutter approach to healthcare. (See Fig. 5-5 and Chapter 5 for more information about critical pathways.)

Another work redesign that has emerged is case management. **Case management** is the coordination of care across the healthcare system. Many hospitals, home health agencies, and insurance companies employ nurse case managers to ensure that care is efficient, cost-effective, and of high quality. Typically, nurses case manage patients with specific diagnoses. For example, a patient with diabetes may be assigned a nurse case manager in the outpatient clinic. If the patient develops complications requiring hospitalization, the case manager coordinates care so that all providers are aware of the patient's unique needs. Later, when the patient is discharged, the case manager visits the patient at home. The case manager sets goals with the patient, monitors the cost of the care, and works with all providers to eliminate duplication of service and evaluate outcomes of care.

Is Healthcare a Right or a Privilege?

A fundamental question underlying all healthcare reform is the question of whether healthcare is a right or a privilege. This question raises more questions. For example, if healthcare is a right of all citizens, should noncitizens be offered coverage? Moreover, what responsibility does an individual have to preserve her own health? Does someone who smokes or drinks excessively have a right to receive care for illnesses brought on by these lifestyle choices—especially if the care is paid for with public funds? Even if an individual leads a healthy lifestyle, should extensive and/or expensive therapies be offered if they have little likelihood of success? Finally, if you believe that healthcare should be affordable for all, are you willing to limit the salary and benefits you receive from your own employer to help control the costs of care? Are you willing to pay higher taxes? Because of the complexity of these and countless other questions, our system remains a work in progress. These fundamental questions were discussed during the debate on the Affordable Care Act. Yet, you will continue to hear these questions and others as universal healthcare continues to evolve.

- What are factors that impact your view (draw on your self-knowledge to answer this question)?

How Do Providers and Facilities Ensure Quality Care?

As you learned previously, a number of accrediting bodies inspect healthcare organizations. These inspections are designed to ensure that patients receive safe, quality care. To promote safety, regulators establish a minimum competency level that must be met for accreditation to be granted. However, most healthcare organizations and professionals declare that their goal is to deliver *excellent* care rather than merely meeting minimum standards.

Continuous Quality Improvement Programs

Continuous quality improvement (CQI) programs (also *total quality management* [TQM]) focus on quality (excellent) care as an ongoing goal rather than something that is periodically verified by audit or when a problem is identified.

Traditionally, quality assurance programs have consisted of **retrospective audit programs**, that is, material from the past (e.g., patient records) is reviewed for evidence of compliance with preselected criteria. For example, a nursing unit may set a goal of 100% compliance that nurses' notes will state the reason when any medication is held (not given). To conduct the audit, all charts within a selected time frame are then reviewed to identify times when medication had been held. The auditor then reviews the nursing notes to determine whether the nurse explained why it was held. The percentage of compliance is calculated based on the review. If it were determined, for example, that there were 50 occasions in which a medication was held during the past 3 months, and on 40 of those occasions the rationale is charted in the nursing notes, the compliance rate is 40/50, or 80%.

If the QA auditors determine that the goal for compliance has not been met, they will often launch a program to improve compliance. For the example above, mandatory in-service education may be provided. In addition, labels might be placed in the medication administration records and a computer-based medication system used to prompt staff to document the reason for holding a medication. At a later date, a second audit is conducted to determine whether compliance has improved.

Another form of retrospective quality improvement is **peer review**. Colleagues review medical records or patient satisfaction data that reflect the care given by their peers. Peer review requires open, honest dialogue and a willingness to improve. Objective criteria must be set to avoid complaints of favoritism and some benefit to promote participation.

ANA Model for Quality Assurance

In 1975, the ANA developed a model for QA consisting of seven steps. This model is useful to understanding the CQI process. For the steps in the QA process and an example of how each step is applied in a clinical scenario,

Go to Student Resources, Chapter 1, **Supplemental Materials, Example of ANA Model for Quality Assurance,** on Davis*Plus*.

Quality and Safety Education for Nurses

Quality Improvement Competency

Chapter Key Concept: *Healthcare Delivery System*

Competency: *Quality Improvement**

Question: The commission on Quality and Safety Education for Nurses (QSEN) identifies quality improvement (QI) as a competency you should achieve during your nursing education. QSEN defines QI as the ability to "use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of healthcare systems." How do you think the staffing mix in a hospital might affect care quality?

Research: Recent research shows that when the proportion of RNs increases in an agency, quality of care rises and death and infection rates drop. Consider the following examples from *Critical Care* (2007), Landon et al. (2006), Tourangeau et al. (2007), and Yang et al (2012):

- Hospitals with higher proportions of RNs and baccalaureate-prepared RNs have lower patient death rates.
- Increasing the proportion of RNS on staff by 10% resulted in 6 fewer deaths per 1,000.
- Hospitals with adequate staffing had lower death rates.
- Hospitals with a higher proportion of RNs on staff performed better on a variety of performance measures.
- When the ratio of nurses to patients falls (e.g., from 1:6 patients to 1:4), risk for infection falls.

Think about it: How does the QSEN competency quality improvement relate to the chapter key concept, healthcare delivery system?

*To see the KSAs for the QSEN competencies,

Go to the QSEN Web site, at **http://www.qsen.org/ksas_prelicensure.php**

FACTORS THAT INFLUENCE CONTEMPORARY NURSING PRACTICE

Factors that influence contemporary nursing practice include (a) those outside the profession in society at large, and (b) those within nursing and healthcare.

What Are Some Trends in Society?

As you have seen, our historical roots have influenced current nursing practice and will undoubtedly continue to do so. In addition, nursing is influenced by trends in the economy—the growing number of older adults, increased consumer knowledge, legislation, the women's movement, and collective bargaining.

The National Economy

The national economy has a tremendous impact on nursing. Consider the following examples:

- *In the United States, health insurance coverage is linked to full-time employment with health insurance benefits* (although that may be changing with recent federal legislation). Thus, when unemployment figures rise, so does the number of people without insurance. Many uninsured people delay seeking treatment, and that leads to sicker patients entering the healthcare system. This taxes the system's resources and raises the level of nursing care required.
- *The healthcare industry is very expensive to operate, even in a strong economy.* Downturns in the economy affect institutional investments and profits, as well as the amount of taxes the government can collect. These in turn limit the medications and services that are available.
- *The healthcare system employs an enormous number and variety of individuals*. If you just consider that there are 2.6 million employed RNs (Health Resources and Services Administration, 2010), 798,000 active physicians (Association of American Medical Colleges, 2011), and more than 268,000 employed pharmacists (Bureau of Labor Statistics, 2012b), you begin to understand how large the healthcare system is when all other providers are added to the count. Similarly, the salaries of healthcare providers are influenced by national economic trends.

The Growing Proportion of Older Adults in the United States

A larger older adult population creates a need for more medical and nursing care. At the same time, there are fewer younger people to provide care. The growth rate for adults 65 years and older has greatly outpaced the growth of the population at 15% (40.3 million) compared with the country as a whole (9.7%). This number is expected to grow to 20% by the year 2050. The oldest old (those 85 years and older) will continue to be the fastest growing part of the population into the next century (U.S. Census Bureau, 2010). As people age, they tend to need more assistance with activities of daily living, and they experience more acute and chronic illnesses.

Changes in Healthcare Consumers

Historically, patients relied on the knowledge and decision making of the healthcare team. Now, however, consumers are demanding greater choice in the decisions that affect their health.

- *Patients have access to vast amounts of health and medical information, particularly through the Internet* (e.g., Web sites such as WebMD and PubMed). Informed consumers tend to be active participants in discussions about their health problems and therapy options. Patients need to be taught which sites are valid for information.
- *Direct-to-consumer marketing* is another form of health information, in which corporations advertise medications and therapies directed at the potential user (e.g., on the Internet and in magazines). Such advertising generates consumer interest in new products. Clients may then request their healthcare providers to prescribe specific trade name therapies they have heard about in the media. You need to be prepared to address the truthfulness of the advertisements and to present balanced information to clients, particularly as they are appropriate for individual clients' conditions. You must also be comfortable with your knowledge and not be unduly persuaded by consumers who are relying on the latest advertisement fads. Your knowledge, standards of nursing practice, and communications with the healthcare team should be the foundation for making patient-related decisions.

Legislation

Consumer interest has also generated legislation that affects nursing care. Legislation directed at the confidentiality of patient records, treating patients who need emergency care, the patient's right to know (informed consent), and the patient's right to a dignified death (living will/advance directives) all govern the care that nurses render to patients. These acts are discussed further in Chapters 44 and 45.

The Women's Movement

Historically, only unmarried women were allowed to practice nursing. As the women's movement gained momentum, women were no longer forced out of nursing if they chose to have a family. Whereas women's careers were traditionally limited to teaching, clerical work, and nursing, the women's movement opened up more choices. As a result, nursing has become just one of many options for a career, and is no longer the only career pathway. Also, societal views of nursing as a women's profession influenced the decisions of men to enter (or not enter) nursing.

Collective Bargaining

Collective bargaining is a form of negotiating that allows nurses to seek better wages and working conditions as a group rather than individually. Not all states have collective bargaining groups for nurses. A union or organization that represents the nurses usually conducts collective bargaining. Collective bargaining has resulted in significant improvements in wages, benefits, and working conditions for nurses, as well as safer conditions for patients. These improvements have made nursing more attractive as a career choice.

ThinkLike a Nurse 1-6

What effect do you think the women's movement has had on the number of women in the nursing work force? Speculate also on the ways in which women entering nursing might have been different before and after the women's movement.

What Are Some Trends in Nursing and Healthcare?

In addition to societal factors, trends in nursing and healthcare also affect contemporary practice. We discuss the most significant trends here.

Increased Use of Complementary and Alternative Medicine

The National Institutes of Health define healthcare treatments or services outside the traditional healthcare system as **complementary and alternative medicine (CAM)**. They include medical systems, such as homeopathy, naturopathy, chiropractic, and traditional Chinese medicine, as well as specific treatments, such as herbal medications, dietary changes, massage therapy, yoga, aromatherapy, prayer, and hypnotism. There is growing interest in CAM for various reasons, including costs of traditional care and increasing cultural diversity in the population. For a more extensive discussion,

Go to Student Resources, **Bonus Chapter 46, Holistic Healing,** under the heading Why Do People Use CAM, on Davis*Plus*.

Expanded Variety of Settings for Care

Nearly 40% of registered nurses now work outside the hospital setting, as compared with 20% in 1980 (ANA, 2010; Health Resources and Services Administration, 2010; Jonas & Kovner, 2008). As this trend continues, nurses must be prepared to function in alternative settings. This change requires entry-level education programs to prepare nurses for these types of work (Wilkinson, 1996). In the hospital, you have access to support personnel, consultation with other nurses and healthcare providers, ready access to equipment and diagnostic testing services, and increased access to the patient. As more care is delivered in

Toward Evidence-Based Practice

Numerous studies have found that a single approach, such as siderails, is not effective in preventing patient falls. These researchers have concluded that a multifactorial approach is needed.

Spoelstra, S. L., Given, B. A., & Given, C. W. (2012). Fall prevention in hospitals: An integrative review. *Clinical Nursing Research, 21*(1), 92–112.

This study found that intervention programs that included a multiple approach to preventing patient falls were more effective than relying on a single intervention. Fall prevention programs should include staff education, fall-risk assessments, environmental assessments and modifications, alarm systems, and patient assistance with transferring and toileting.

Capezuti, E. E., Wagner, L., Brush, B., et al. (2007). Consequences of an intervention to reduce restrictive siderail use in nursing homes. *Journal of the American Geriatrics Society, 55*(3), 334–341.

This study of more than 700 nursing home residents at four sites found that routine use of siderails does not reduce the risk of bed-related falls.

Brush, B. L., & Capezuti, E. (2001). Historical analysis of siderail use in American hospitals. *Journal of Nursing Scholarship, 33*(4), 381–385.

This study used social historical research methods to examine the pattern of siderail use, the value attached to siderails, and attitudes about raising siderails over time. Siderails on adult beds were rare until the 1930s; nurses used continual watchfulness to ensure patient safety. Initially siderails were used for temporary protection of confused patients. They were not a part of the bed, but had to be attached to it when they were needed. During the 1930s, litigation against hospitals and nurses for fall-related injuries, recurrent nurse shortages, and the move away from ward structure toward semiprivate and private rooms all promoted the use of siderails instead of nursing observation. They now have become a permanent fixture of the hospital bed. However, recent research has demonstrated that siderail-induced injuries may occur, and that sustained bedrest has negative physical and emotional consequences. In spite of these recent research-based findings, siderail use remains the norm in promoting patient safety.

1. What trends and factors currently affecting nursing might influence whether siderail use will change in the near future?

2. What additional information would you like to know before advocating for a change in siderail use?

Go to Student Resources: Chapter 1, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

outpatient, community, or home settings, you must be prepared to function more autonomously and creatively.

Telehealth nursing is practiced in a variety of settings, including rural clinics, home healthcare, corrective facilities, and physicians' offices, using communication devices such as the telephone or two-way video technology. As telehealth nursing continues to evolve, you will need to combine the use of technology with your nursing knowledge to safely care for patients remotely.

ThinkLike a Nurse 1-7

What is your nursing program doing to prepare you to work outside the hospital setting?

Interest in Interprofessional Collaboration

Nursing is changing from a largely supportive role to one of increasing responsibility. This is, in part, due to the growing role of nursing in outpatient settings, the increasing complexity of care, the limited supply of nurses, and the increased use of technology. More and more, healthcare leaders are finding interprofessional teamwork to be essential to providing safe, high-quality patient outcomes.

Collaboration is the process of joint decision making among independent parties, involving joint ownership of decisions and collective responsibility for outcomes (Disch, Bellman, & Ingbar, as cited in Sterchi, 2007). However, in a relationship in which there is a power imbalance, true collaboration can occur only if the more powerful parties are willing. Physicians and nurses tend to have different values and to place different emphases on patient care. This may contribute to strained relationships and disagreements about a patient's plan of care, which may lead to undesired outcomes for patients. True collaboration occurs when institutions enforce the goal and give recognition to those who practice it.

On a typical day, a hospitalized patient may interact with six or more individuals who are involved in his plan of care. It is essential that these care providers are talking with the patient and collaborating with each other. A primary cause of serious medical errors in healthcare facilities is communication failure, which often stems from lack of collaboration. To minimize these occurrences, healthcare providers are encouraged to use a standardized system of communication known as SBAR-R (Situation, Background, Assessment, Recommendation-Readback) (see Chapter 21).

Expanded Career Roles for Nurses

Numerous **expanded roles** extend the traditional practice of the nurse. The roles may or may not be clinical.

Advanced Practice Nurses (APNs) Registered nurses, usually with a master's degree, who work in expanded roles with a clinical focus are collectively termed *advanced practice nurses (APNs)*.

- **Clinical Nurse Specialist (CNS)—**A nurse with advanced education and expertise in an area of clinical specialization (e.g., cardiovascular, pulmonary, orthopedics). The CNS may provide direct patient care; consult on client care; engage in client, family, community, or staff teaching; and/or conduct research.
- **Nurse Practitioner (NP)—**A nurse with advanced education focused on providing primary care (comprehensive healthcare) to an age group or within a specialty area. NPs may work independently or in practice with physicians. They assess, diagnose, and treat diseases and illnesses and prescribe medications and treatments. An NP can provide approximately 80% of the care offered by a physician.
- **Certified Registered Nurse Anesthetist (CRNA)—**A nurse with advanced education focused on providing anesthesia. Nurse anesthetists conduct preoperative screening and evaluation of patients, administer anesthesia during surgery, and evaluate patients' responses to anesthesia in the postoperative period.
- **Certified Nurse Midwife (CNM)—**A nurse with advanced education focused on women's health, pregnancy, and delivery. A CNM provides prenatal care, performs uncomplicated deliveries, and provides postpartum care.

Professional and public reports (e.g., Tourangeau, Doran, Hall, et al., 2007) demonstrate high patient satisfaction with APNs; comparable, and at times superior, patient outcomes over physician-provided care; better understanding of and compliance with treatment regimen; fewer hospitalizations; and greater cost effectiveness when compared with physician providers. This positive reaction to APNs has resulted in increased acceptance and support for all nurses.

Non-Clinical Expanded Roles Expanded roles with other than a clinical focus include the following:

- **Nurse Researcher—**A nurse with advanced education at the master's or doctoral level who engages in research related to clinical practice, the discipline, or nursing education.
- **Nurse Administrator—**A nurse whose practice focuses on the management and administration of nursing care, health facilities, or health resources.
- **Nurse Educator—**A nurse with advanced education and expertise who teaches in the clinical or academic setting.
- **Nurse Informaticist—**A nurse with specialized education focused on the use of technology in healthcare and the incorporation of standardized languages and classifications into nursing practice.
- **Nurse Entrepreneur—**A nurse who has creatively created an independent or innovative business. Entrepreneurs may serve as consultants, administer a health-related business, or provide educational services.

KnowledgeCheck 1-6

Compare and contrast advanced practice clinical roles for nurses.

Increased Use of Nursing Assistive Personnel

Nursing assistive personnel (NAP) are healthcare providers who help nurses and physicians provide patient care. Common NAP roles include nurse aide, assistant, orderly, and technician. NAPs may perform simple nursing tasks (e.g., bathing, taking vital signs) under the direction of the licensed nurse. Some institutions even train NAPs for more complex tasks traditionally reserved for licensed nurses (e.g., inserting urinary catheters, giving certain medications). This redistribution of workload has prompted controversy about safety and quality of care.

Although it may be appropriate to allow the NAP to assume the simple tasks, this distances the licensed nurse from many aspects of direct patient care. The nurse retains ultimate responsibility for the patient, yet must base important patient care decisions on information obtained by the NAP. The nurse is able to use a higher level of critical thinking and a greater depth of knowledge, and is therefore likely to gather more in-depth patient data.

As you progress through your program, you will notice that nurses often gather different information from a client than does someone without nursing experience. For example, after bathing an older adult, a NAP will be able to tell the nurse that there are no open areas on the skin. However, a nurse performing the same task would be able to do an extensive client assessment while giving the bath. The nurse would be able to comment on the client's level of cognition (orientation to surroundings and self), tolerance for activity, breath sounds, heart sounds, bowel sounds, and the condition of the skin. The nurse might also use the time during the bath to teach the client about his condition or to gather information about the client's home and support system that can be used for discharge planning.

Influence of Nurses on Health Policy

Professional nursing organizations are actively involved in local, state, and national politics.

- The major professional organizations actively lobby and educate government officials about the role of nursing in healthcare.
- Nursing organizations sponsor legislation that promotes the interest of the profession and supports changes that positively influence health outcomes. Nurse-sponsored legislation has addressed safe staffing in hospitals, needle-exchange programs to decrease the transmission of HIV and other infectious diseases, and funding to increase nursing enrollment during times of nursing shortages.

As individuals, nurses should vote, lobby their elected representatives, and run for political office. Together, nurses represent the largest health professional group (more than 3.8 million); thus, when united as a voting block, they have strong political power. Many nurses organize local nursing groups to support candidates or legislation, or speak out in the community on health and nursing issues. Nurses are typically trusted and respected political candidates, running successful campaigns at the local, state, and national level. Another way to influence politics and policy is to serve on federal or state advisory panels. For example, nurse leaders serve on the National Advisory Committee for the Healthcare Research and Quality. They provide a voice from nursing on issues related to healthcare quality, safety, and evidence-based practice. You should consider all of these political activities as you move into the profession.

Divergence Between High-Tech and High-Touch

Advances in clinical knowledge and technology have contributed to improved care and a longer life for many patients who are critically ill (e.g., premature newborns and patients with advanced cardiovascular, pulmonary, or renal disease). This trend is in contrast to the concurrent trend toward holism and high-touch therapies, which often avoid technology. One of the challenges in healthcare is integrating these two divergent trends. For an excellent discussion on these colliding values, read *Holistic Health and Healing* by Mary Anne Bright (2002).

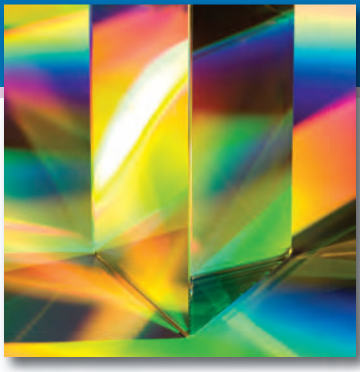
CHAPTER 2



Critical Thinking & Nursing Process

Learning Outcomes

After completing this chapter, you should be able to:

- Give one definition and one example of critical thinking.
- List at least six critical-thinking skills and attitudes.
- Review seven attitudes of the critical thinker.
- Explain ways in which nurses use critical thinking.
- List the six overlapping and interdependent phases of the nursing process.
- Describe what the nurse is doing in each phase of the nursing process.
- Explain how critical thinking is used in the nursing process.
- Explain what is meant in nursing by the concept *caring*.
- Discuss, and give examples of, the differences between practical/procedural knowledge and theoretical knowledge.
- Name the main concepts of the full-spectrum nursing model.
- Explain how nursing knowledge, nursing process, and critical thinking work together in full-spectrum nursing.

Key Concepts

Critical thinking
Full-spectrum nursing
Nursing knowledge
Nursing process

See the Concept Map on Davis*Plus*.

Explore Your Nursing Role

It's a pleasant Saturday afternoon, and you're meeting with an old friend whom you haven't seen in 2 years. She asks, "I hear you've decided to become a nurse. What made you choose that? I don't think I could be around people who are sick and in pain. Hospitals are such sad places."

She listens to your answer with interest. To respond to this statement, you will need to consider your motivation for entering nursing and your beliefs about the profession.

ThinkLike a Nurse 2-1

How would you reply to her question?

Explore Your Nursing Role (continued)

ThinkLike a Nurse 2-2

- What factors or persons influenced your decision to be a nurse?
- Have others asked you why you chose to become a nurse? How have the reactions you received before colored your explanation of your career choice?
- What makes this situation similar to or different from your prior experiences?
- What's important in this situation?
- Of the possible answers you are considering, which answer best reflects your true feelings about your career choice? Why are the other answers not appropriate?
- What beliefs and assumptions are coloring your response?

If you are able to answer these questions, then you have used critical thinking to guide your decision making. Critical thinking involves careful consideration of a situation to arrive at a solution, based on analysis of the data. Critical thinking is vital when considering important decisions. It is the kind of thinking you will use as a nurse.

ABOUT THE KEY CONCEPTS

Keep the key concepts in mind as you read this chapter. They will give you the "hooks" on which you can "hang" the other details in the chapter. As you gain understanding of **critical thinking, nursing knowledge**, and **nursing process**, you will begin to see how they all work together in **full-spectrum nursing**.

WHAT DOES NURSING INVOLVE?

Chapter 1 introduced you to nursing roles, responsibilities, and activities, and to the career of nursing. Throughout this text, you will learn much more. Thus, your view of nursing may change as you progress in your studies. To track your progress, establish a baseline by examining your current view of nursing.

ThinkLike a Nurse 2-3

What is your image of nursing? List at least five attributes a nurse should have, and at least five responsibilities that you consider to be a part of nursing.

In the preceding exercise, when you listed some nursing responsibilities, you may have mentioned activities such as "gives medications" or "performs tests and treatments." And you were correct—partially. Much of nursing is about *doing*, and nursing is activity oriented. But don't forget the importance of *caring*. And now more than ever the emphasis is on *thinking*. So, another way to describe nursing is to say that *nursing involves thinking*, *doing*, and *caring*.

The scientific basis for patient care changes constantly. Research continually uncovers new information that alters the practice of all healthcare providers. Therefore, you should know up front that you cannot possibly learn everything about healthcare and nursing in nursing school. In fact, to be a safe and competent nurse you must constantly update your knowledge and skills throughout your career. As a lifelong learner, you will need to develop and refine your critical-thinking skills. Critical thinking helps you to know what is important about each patient's situation, when you need more information, and when you need help to make the best decision.

TheoreticalKnowledge knowing why

WHAT IS CRITICAL THINKING?

If critical thinking is so important, then you might be wondering, what exactly is it? One simple definition is that critical thinking is "the art of thinking about your thinking while you are thinking in order to make your thinking better: more clear, more accurate, or more defensible" (Paul, 1990). On closer study, this definition makes an important point. It tells us that we should reflect on the thinking process we are using to figure something out: "Why did I ask those particular questions? Do I have enough information to decide, or have I jumped to a conclusion? Have I considered all the possibilities?"

Box 2-1 provides several definitions of critical thinking, or you may want to use the following more formal definition:

> ***Critical thinking*** *is a combination of reasoned thinking, openness to alternatives, an ability to reflect, and a desire to seek truth.*

There are many definitions of critical thinking because it is a complex concept and people think about it in different ways—none of them are "wrong." In fact, any situation that requires critical thinking is likely to have more than one "right" answer. You do not need critical thinking to add 2 + 2 and come up with the answer. However, you do need critical thinking to problem-solve important decisions.

Critical thinking is linked to evidence-based practice, which you will learn more about later in this book. Evidence-based practice is a research-based method for judging nursing interventions. An important aspect of critical thinking is the process of identifying and checking your assumptions—and this is also an important part of the research process.

BOX 2-1 ■ Some Definitions of Critical Thinking

- Critical thinking is the disciplined, intellectual process of applying skillful reasoning as a guide to belief or action. (Paul, Ennis, & Norris, 1996)
- Critical thinking is careful and deliberate determination of whether to accept, reject, or suspend judgment. (Moore & Parker, 2009)
- Critical thinking, as the term is generally used these days, roughly means reasonable and reflective thinking focused on deciding what to believe or do. (Ennis, 2011)
- In nursing, critical thinking for clinical decision-making is the ability to think in a systematic and logical manner with openness to questions and to reflect on the reasoning process used to ensure safe nursing practice and quality care. (Heaslip, 1992)
- Critical thinking is a purposeful, dynamic, analytic process that contributes to reasoned decisions and sound contextual judgments. (Assessment Technologies Institute, 2003)
- Critical thinking is disciplined, self-directed, rational thinking that supports what we know and makes clear what we don't know. (Wilkinson, 2011, p. 33)
- The ideal critical thinker is inquisitive, open-minded, flexible, fair-minded, well-informed, persistent in seeking the truth, wise in judgments and decision-making, logical, and honest with facing personal biases. The critical thinker uses sound reasoning and is willing to consider valid alternatives. (American Philosophical Association, 1990)

Critical thinkers are flexible, nonjudgmental, inquisitive, honest, and interested in seeking the truth. They possess intellectual skills that allow them to use their curiosity to their advantage, and they have critical attitudes that motivate them to use those skills responsibly.

What Are Critical-Thinking Skills?

Skills in critical thinking refer to the cognitive (intellectual) processes used in complex thinking operations such as problem-solving and decision making. In this example, the skills are italicized, and the complex thinking processes are in bold type:

> *When planning nursing care, nurses* gather information *about the client and then* ***draw tentative conclusions about the meaning of the information*** *to* identify the client's problems. *Then they* think of several different actions *they might take to help* ***solve or relieve the problem***.

The following are a few examples of critical-thinking skills:

- Objectively gathering information on a problem or issue
- Recognizing the need for more information
- Evaluating the credibility and usefulness of sources of information
- Recognizing gaps in one's own knowledge
- Listening carefully; reading thoughtfully
- Separating relevant from irrelevant data and important from unimportant data
- Organizing or grouping information in meaningful ways
- Making inferences (tentative conclusions) about the meaning of the information
- Visualizing potential solutions to a problem
- Exploring the advantages, disadvantages, and consequences of each potential action

What Are Critical-Thinking Attitudes?

Attitudes are not the same as intellectual skills. They are more like feelings and traits of mind. Your attitudes and character determine whether you will use your thinking skills fairly and with an open mind. Without a critical attitude, people tend to use thinking skills to justify narrow-mindedness and prejudice, and to benefit themselves rather than others. The following are some critical-thinking attitudes (Paul, 1990):

- **Independent thinking.** Critical thinkers do not believe everything they are told; they do not just go along with the crowd. They listen to what others think and they learn from new ideas. They do not accept or reject an idea before they understand it. Nurses should challenge actions and policies with little logical support.
- **Intellectual curiosity.** Critical thinkers love to learn new things. They show an attitude of curiosity and inquiry, and frequently think or ask, "What if . . . ?" "How could we do this differently?" "How does this work?" or "Why did that happen?"
- **Intellectual humility.** Critical thinkers are aware that they do not know everything, and they are not embarrassed to ask for help when they don't know. They are not too proud to seek the wisdom of mentors with knowledge, skill, and ability. They reevaluate their conclusions or actions in light of new information and are willing to admit when they are wrong.
- **Intellectual empathy.** Critical thinkers try to understand the feelings and perceptions of others. They try to see a situation as the other person sees it.
- **Intellectual courage.** Critical thinkers consider and examine fairly their own values and beliefs, as well as beliefs of others, even when this is uncomfortable. They are willing to rethink, and even reject, previously held beliefs that are not well justified. Without intellectual courage, people become resistant to change.
- **Intellectual perseverance.** Critical thinkers don't jump to conclusions or settle for the quick, obvious answer. Important questions are usually complex, and critical thinkers give them serious thought and research, even when this takes a great deal of effort and time.
- **Fair-mindedness.** Critical thinkers try to make impartial judgments. They treat all viewpoints

fairly, realizing that personal biases, customs, and social pressures can influence their thinking. They examine their own biases each time they make a decision.

Critical thinking can be used in all aspects of your life. Whenever you are trying to reach an important decision, reasoned action (critical thinking) is called for. Everyday uses of critical thinking might include deciding where you should live, choosing which nursing programs you should apply to, and deciding among several job offers. The rest of this chapter shows you why critical thinking is important to you in your chosen career, nursing.

KnowledgeCheck 2-1

- Define *critical thinking* in your own words.
- List five skills or attitudes that reflect critical thinking.

WHY IS CRITICAL THINKING IMPORTANT FOR NURSES?

Nurses use complex critical-thinking processes (e.g., problem-solving, decision making, and clinical reasoning) in every aspect of their work (Box 2-2). Because nurses care for a variety of patients with a multitude of concerns, a patient's response to therapy may not always be apparent. Nurses constantly assess their patients and determine how they are responding to nursing interventions and medical treatments. Reasoning and reflection are required for the nurse to decide what interventions to use, determine whether they worked, and, if not, figure out why.

BOX 2-2 ■ Complex Thinking Processes

Problem-Solving

Identifying a problem and finding reasonable solutions to it. Requires critical-thinking skills such as organizing data, identifying relevant and important data, making inferences, making decisions, projecting consequences of actions, and applying theoretical knowledge to a specific patient context. The nursing process is a problem-solving process.

Decision Making

Choosing the best action to take. In nursing, this is usually the action likely to produce the desired patient outcome. Requires thinking skills such as making judgments (e.g., about what is important) and making choices. Important in problem-solving; however, many decisions are made that are not related to problem-solving.

Clinical Reasoning

Reflective, concurrent, creative thinking about patients and patient care. Clinical reasoning is used in the nursing process. Reasoning is logical thinking that links thoughts together to create meaning.

Nurses Deal With Complex Situations

Critical thinking is important for nurses because they deal with complex situations daily. One such situation is that of caring for clients with **comorbidities** (more than one health problems occurring at the same time). For example, if a healthy 9-year-old fell and broke his right arm, he would experience pain and discomfort. However, with proper casting of the arm and time to heal, the child would recover. While recovering, he may have to eat using his left hand or limit the use of his injured arm. The child would likely be discharged home from the emergency department or clinic in the care of his parent(s) or guardian(s). The nurse's primary interventions would be to teach the home caregivers the care needed by the child.

The adjustments would be quite different for an older adult who has had a stroke (a comorbidity) that limits the use of his left arm. With decreased function in the left arm, a right-arm fracture would severely affect the older person's ability to care for himself. The nurse would need to evaluate whether the adult requires care in the hospital or in a skilled-care facility and what support services he will need as he convalesces. In the inpatient setting, nursing interventions might initially include assisting the client with eating, bathing, and toileting.

Clients Are Unique

Critical thinking is important because each client is unique. Their differences (e.g., type of illness, culture, and age) make it impossible to provide strict rules for all client care.

Individual Differences Research-based care plans and protocols identify guidelines for providing care; however, nurses must evaluate and modify these guidelines to be sure they are appropriate for each client.

Consider the following example: You have undoubtedly been told to drink plenty of fluid when you have a cough, to keep the secretions moist. Now imagine you are caring for a client in renal failure. Your client no longer urinates and is being considered for dialysis. You notice that this client has a persistent cough. Should you encourage the client to drink as much fluid as possible? Do you see how you could cause harm to a client by unthinkingly doing as you have been told? Nurses must always think, "How will that work in *this* instance?" "How is this like or different from similar situations?"

Client's Culture Ethnic and cultural differences affect a person's view of health and the healthcare system, as well as his responses to health problems. Cultural beliefs influence how people define sickness, at what point they seek healthcare, what type of healthcare provider they see, and the type of treatment they consider acceptable. Critical thinking enables the nurse to assess the client's and family's cultural beliefs and adapt care so that it is culturally sensitive and responsive to their needs.

Client's Roles A person's roles also influence when, how, and why she seeks healthcare. A single mother with young children may ask to be discharged from the hospital early to meet the needs of her family. Clients with extensive support from family or friends may be willing to take more time to convalesce when they are ill. Nurses take these things into consideration, for example, when determining why a nursing intervention was (or was not) successful.

Other Factors In addition, the following factors may influence how a person responds to illness or to healthcare intervention:

- *Age*. Each of us was raised with a set of beliefs, values, and knowledge that was strongly influenced by the prevailing views of our times.
- *Personal bias*. Clients may have fixed beliefs about health and illness.
- *Personality*. Individuals have unique personalities. This means every person is different; all have individual ways of responding to stress, fear, illness, and pain. Some are hardy and show an attitude of strength, endurance, and high threshold to pain. Others are less tolerant and may outwardly express pain or other conditions associated with illness, hospitalization, and death.
- *Previous experience* with healthcare problems. For example, a boy who has experienced a painful injection in the past may be terrified when he sees the nurse approach with a syringe.

Nurses Apply Knowledge to Provide Holistic Care

In addition to the need to individualize care for each patient, there are some aspects of nursing itself that require the nurse to be a critical thinker.

- *Nursing is an applied discipline.* Nurses deal with complex, ill-defined, and sometimes confusing problems—not well-defined, straightforward problems such as you find in a math book. This means that nurses must *apply* their knowledge, not just memorize and regurgitate facts.
- *Nursing uses knowledge from other fields.* Nurses use information from chemistry, physiology, psychology, social sciences, and other disciplines to identify and plan interventions for patient problems. Nursing plays an important role within a multidisciplinary approach to patient care.
- *Nursing is fast-paced*. Nurses often deal with demanding situations. A patient's condition may change hour to hour or even minute to minute, so knowing the routine may not be adequate. You will need critical thinking in order to respond appropriately under stress.

ThinkLike a Nurse 2-4

Write a short scenario (story) about a nurse that illustrates one of the reasons why nurses need to be critical thinkers.

A MODEL FOR CRITICAL THINKING

A **model** is a set of interrelated concepts that represents a particular way of thinking about something—much in the same way that the shape of a lens affects what you see. For example, you would look through a telescope to view a distant star. Looking at the star through reading glasses or a magnifying glass would give a different view. You will learn more about models in Chapter 8.

The critical-thinking model used throughout this book provides one way of making sense of critical thinking. This model organizes critical thinking into five major categories. Table 2-1 defines each category and provides questions to help you focus your thinking in patient care situations. You can use some of the questions when deciding what to think about and do; you can use others when analyzing a situation after it happens (reflecting). Figure 2-1 is a simpler representation of the model, relating it to the nursing process, which is introduced later in this chapter.

This model is not meant to be all-inclusive; there is much more to critical thinking than just the questions listed in Table 2-1. Use it as a guide when you are faced with clinical decisions or unfamiliar situations. The questions can help you to "think about your thinking" as you apply principles and knowledge from various sources to a current problem. This should help you to achieve good outcomes for your patients. You do not need to ask yourself every question in every situation—just those that are relevant. And you should not proceed from top to bottom in the table. The processes do not occur "sequentially," so you may jump back and forth among them.

Let's apply the model to a situation faced by all nursing students. Soon you will begin your clinical rotations, if you have not already done so. Many students find clinical experiences exciting, yet somewhat intimidating. How could you use the five points of the critical-thinking star to approach your first clinical day so that you will be well prepared and able to function safely?

Contextual Awareness One of the first things you need to consider is your usual response to new experiences. How do you react to change? What other tasks or assignments do you have that will dictate the timing of your preparation? Have you had any previous experiences that will aid or hamper you in your preparation? As you consider these questions, you are addressing the star point of contextual awareness.

Table 2-1 ➤ Critical-Thinking Model

THINKING PROCESS	DESCRIPTION	QUESTIONS FOR FOCUSING THINKING
Contextual awareness (deciding what to observe and consider)	An awareness of what's happening in the total situation, including values, cultural issues, interpersonal relationships, and environmental influences	■ What is going on in the situation that may influence the outcome? ■ What factors may influence my behavior and that of others in this situation (e.g., culture, roles, relationships, economic status)? ■ What about this situation have I seen before? What is different? ■ Who should be involved in order to improve the outcome? ■ What else was happening at the same time that affected me in this situation? ■ What happened just before this incident that made a difference? ■ What emotional responses influenced how I reacted in this situation? ■ What changes in behavior alerted me that something was wrong?
Inquiry (based on credible sources)	Applying standards of good reasoning to your thinking when analyzing a situation and evaluating your actions	■ How do I go about getting the information I need? ■ What framework should I use to organize my information? ■ Do I have enough knowledge to decide? If not, what do I need to know? ■ Have I used a valid, reliable source of information (e.g., patient, other professionals, references)? ■ Did I (do I need to) validate the data (e.g., with the client)? ■ What else do I need to know? What information is missing? ■ Are the data accurate? Precise? ■ What's important and what's not important in this situation? ■ Did I consider professional, ethical, and legal standards? ■ Have I jumped to conclusions?
Considering alternatives	Exploring and imagining as many alternatives as you can think of for the situation	■ What is one possible explanation for what is happening or what happened? ■ What are other explanations for what is happening? What is one thing I could do in this situation? ■ What are two more possibilities/alternatives? ■ Are there others who might help me develop more alternatives? ■ Of the possible actions I am considering, which one is most reasonable? Why are the others not as reasonable? ■ Of the possible actions I am considering, which one is most likely to achieve the desired outcomes?
Analyzing assumptions	Recognizing and analyzing assumptions you are making about the situation and examining the beliefs that underlie your choices	■ What have I (or others) taken for granted in this situation? ■ Which beliefs/values are shaping my assumptions? ■ What assumptions contributed to the problem in this situation? ■ What rationale supports my assumptions? ■ How will I know my assumption is correct? ■ What biases do I have that may affect my thinking and my decisions in this situation?

continued

Table 2-1 ➤ Critical-Thinking Model—cont'd

THINKING PROCESS	DESCRIPTION	QUESTIONS FOR FOCUSING THINKING
Reflecting skeptically and deciding what to do	Questioning, analyzing, and reflecting on the rationale for your decisions	■ What aspects of this situation require the most careful attention? ■ What else might work in this situation? ■ Am I sure of my interpretation of this situation? ■ Why is (was) it important to intervene? ■ What rationale do I have for my decisions? ■ In priority order, what should I do in this situation and why? ■ Having decided what was wrong/happening, what is the best response? ■ What might I delegate in this situation? ■ What got me started taking some action? ■ What priorities were missed? ■ What was done? Why was it done? ■ What would I do differently after reflecting on this situation?

Sources: Model based on Brookfield, S. D. (1991). *Developing critical thinkers.* San Francisco: Jossey-Bass; McDonald, M. E. (2002). *Systematic assessment of learning outcomes: Developing multiple-choice exams.* Boston: Jones & Bartlett Publishers; Paul, R. W. (1993). *Critical thinking: What every person needs to survive in a rapidly changing world* (3rd ed.). Santa Rosa, CA: Foundation for Critical Thinking; Raingruber, B., & Haffer, A. (2001). *Using your head to land on your feet.* Philadelphia: F.A. Davis; and Wilkinson, J. M. (2011). *Nursing process and critical thinking* (5th ed.). Upper Saddle River, NJ: Prentice Hall.

Using Credible Sources You need to gather information about the clinical experience. It is important to use inquiry based on credible sources as you gather data. For example, you may ask your instructor for guidance on how to best prepare. Or you might consult a student who has successfully completed the same course. You will need to obtain accurate information about clients who have been assigned to you for care. You could use the client's chart and your textbooks to prepare. Use only knowledgeable, reliable sources of information—for example, nursing texts and nursing journals, not popular (nonscholarly) magazines (such as *Parents* magazine) or certain Internet sites. After you have more information, you should go back and analyze your response to the situation. You may find that you are feeling less anxious already! All of this is a part of inquiry.

Exploring Alternatives and Analyzing Assumptions Now that you know something about the clinical experience, you can plan your day. You need to consider alternatives and analyze your assumptions about the experience. What is expected of you? What do you expect from the experience? How should you approach your client? How will you introduce yourself? What skills do you have? How will you apply them to caring for your client?

Reflecting and Deciding After you feel that you have addressed these concerns, you need to quickly review your preparation (reflective skepticism). Have you gathered enough information to feel comfortable in the situation? Have you left anything out? Do you need more information?

This was a demonstration of how you might apply the critical-thinking model to a real experience. In this example, you also used theoretical, practical, personal, and ethical knowledge, which are explained in the next section.

KnowledgeCheck 2-2

In the preceding example, identify the actions that demonstrate use of each of the four types of knowledge.

WHAT ARE THE DIFFERENT KINDS OF NURSING KNOWLEDGE?

Critical thinking does not occur in a vacuum—you must have something to think about: your knowledge base. Nurses use various kinds of knowledge: theoretical, practical, personal, and ethical. Every chapter of this text is designed to help you gain practical knowledge and theoretical knowledge. Put very simply, that is *knowing what* (to do) and *knowing how* (to do it). In fact, the chapters are organized according to those two types of knowledge.

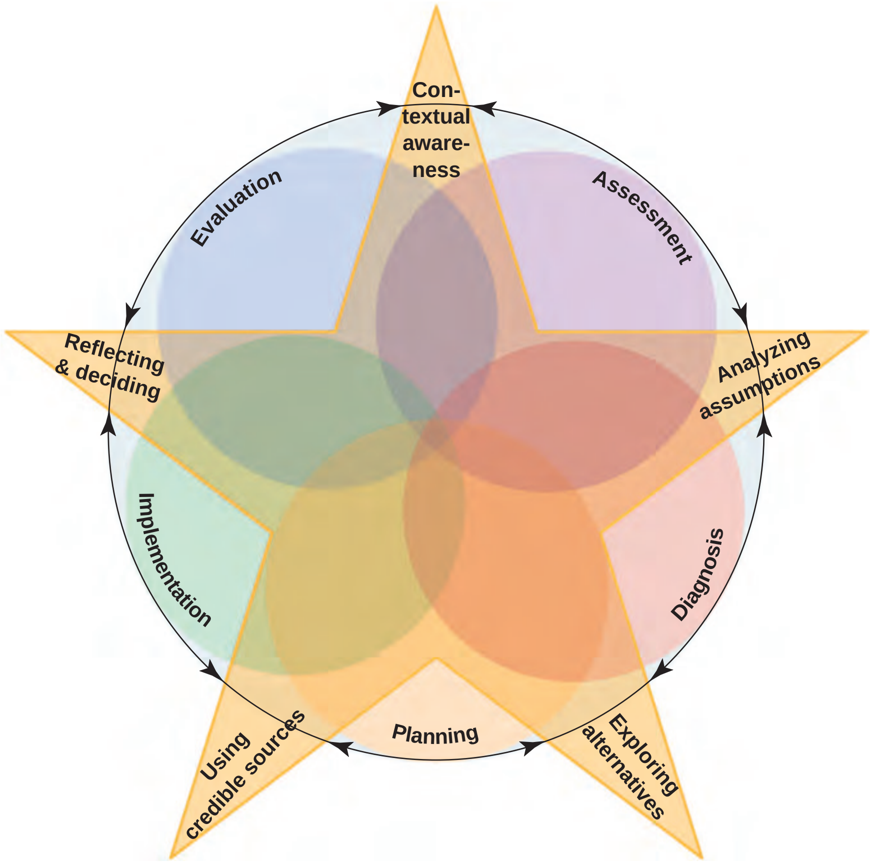

FIGURE 2-1 Model of critical thinking and nursing process.

Theoretical Knowledge Each chapter begins by presenting theoretical knowledge. Theoretical knowledge consists of information, facts, principles, and evidence-based theories in nursing and related disciplines (e.g., physiology and psychology). It includes research findings and rationally constructed explanations of phenomena. You will use it to describe your patients, understand their health status, explain your reasoning for choosing interventions, and predict patient responses to interventions and treatments.

Practical Knowledge Each chapter then provides the practical knowledge that enables you to apply your theoretical knowledge to caring for patients. Practical knowledge—knowing what to do and how to do it—consists of processes (e.g., the decision process and the nursing process) and procedures (e.g., how to give an injection), and is an aspect of nursing expertise.

Self-Knowledge In addition to theoretical and practical knowledge, nurses use self-knowledge—that is, self-understanding. To think critically, you must be aware of your beliefs, values, and cultural and religious biases. This kind of knowledge helps you to find errors in your thinking and enables you to tune in to your patients. You can gain self-knowledge by developing personal awareness—by reflecting (asking yourself), "Why did I do that?" or "How did I come to think that?"

Ethical Knowledge Finally, nurses use ethical knowledge, that is, knowledge of obligation, or right and wrong. Ethical knowledge consists of information about moral principles and processes for making moral decisions. Ethical knowledge helps you to fulfill your ethical obligations to patients and colleagues. Chapter 44 will help expand your ethical knowledge.

PracticalKnowledge knowing **how**

WHAT IS NURSING PROCESS?

Nursing process is a systematic problem-solving process that guides all nursing actions. It is the type of thinking and doing nurses use in their practice. In fact, the American Nurses Association (ANA) organizes its standards of care around the nursing process (ANA, 2010).

Think**Like a Nurse** 2-5

Practice your critical thinking. What questions should you ask about the last paragraph you have just read? For hints, look at Figure 2-1 and Table 2-1.

When evaluating the preceding paragraph, you should ask about the credibility of the sources cited, and you should ask yourself whether you have enough information about them to judge their credibility. Do you know what the ANA is? What they do? Who are their members? What are standards of practice, and who decides what will be included in them? What effect do they have on what you will be doing as a nurse? Those are the kinds of questions you should ask when you see such statements. If you have read Chapter 1, you can probably answer most of these questions. You will see standards of care and practice quoted in chapters throughout this book, beginning in Chapter 3.

All nurses apply nursing process, to well and ill clients alike, in many settings (e.g., homes, clinics, hospitals). The purpose of the nursing process is to help the nurse provide goal-directed, client-centered care. The nursing process, like nursing itself, involves both thinking and doing. Nurses must have good psychomotor and interpersonal skills, and they must use a sound knowledge base and good judgment to use the nursing process effectively.

What Are the Phases of the Nursing Process?

Nursing process consists of six phases (or steps): assessment, diagnosis, planning outcomes, planning interventions, implementation, and evaluation (Wilkinson, 2011). A model illustrating these phases is shown in Figure 2-2. Note, though, that experts organize the phases in different ways. Many have a five-step process, combining outcomes and interventions into one planning phase. Some even have a four-step process; they combine assessment and diagnosis into one phase that they call "assessment." There is no "right" way to do it, and experienced nurses do not use the steps separately anyway. Your text presents them as distinct and separate only to make it easier for you to learn how the process works.

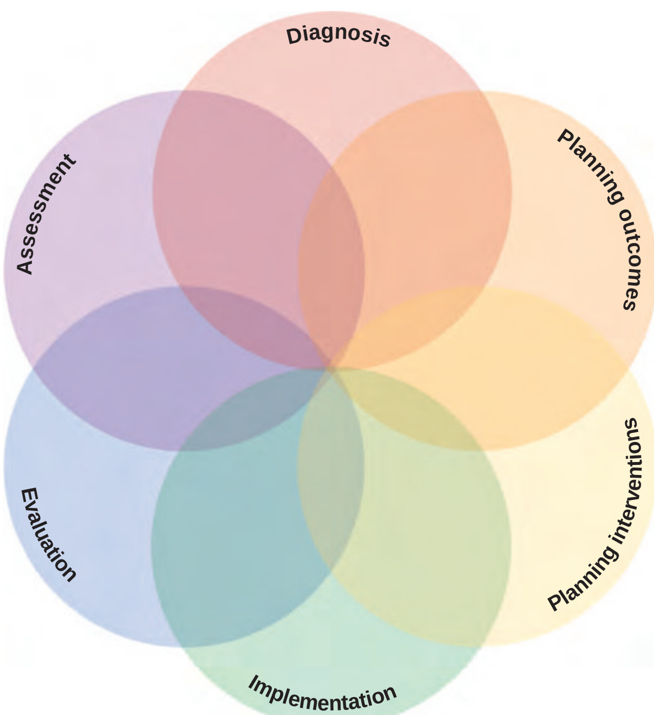

FIGURE 2-2 The phases of the nursing process.

Assessment The first phase of the nursing process—the data-gathering stage—is assessment. You will obtain information from many sources: the client via history or physical exam, the client record, lab or test results, other health professionals, the client's family or support system, and the professional literature. In this phase, your purpose is to gather data that you will use to draw conclusions about the client's health status.

Diagnosis This is the second phase of the nursing process. In this step you will identify the client's health needs (usually stated in the form of a problem) based on careful review of your assessment data. You need to analyze all your data, synthesize and cluster information, and hypothesize about your client's health status. The term *diagnosis* has been thought of as being medical, such as a diagnosis of cancer or diabetes. However, nursing diagnoses reflect the client's responses to actual or potential health problems and are different from medical diagnoses, as you will discover in Chapter 4.

Planning The third and fourth steps of the nursing process both involve planning. Planning can be divided into two phases: planning (predicting) outcomes and planning interventions. The finished product of the planning phases is a holistic nursing care plan, individualized to reflect the client's problems and strengths. A care plan is a written or electronic document containing detailed instructions for a client's nursing care (see Fig. 5-2).

- In the **planning outcomes** step you work with the client to decide goals for your care—that is, the client outcomes you want to achieve through your nursing activities. These outcomes will drive your choice of interventions. The following is an example of an outcome statement you might find in a care plan:

  Nutritional status will improve as evidenced by a weight gain of 3 lb (1.4 kg) by July 1.

  See Chapter 5 for more about goals and outcomes.
- In the **planning interventions** phase you develop a list of possible interventions based on your nursing knowledge and then choose those most likely to help the client to achieve the stated goals. The best interventions are evidence based; that is, supported by sound research. See Chapter 6 for more about interventions.

Implementation This is the action phase. During implementation you will you carry out or delegate the actions that you previously planned. You may delegate an action to another member of the healthcare team only if it is an action that may safely and legally be carried out by that team member. Delegation is discussed further in Chapters 7 and 40. In the implementation phase, you also document your actions and the client's responses to them.

Evaluation The final phase of nursing process is evaluation. In this phase, you determine whether the desired outcomes have been achieved, and judge whether your actions have successfully treated or prevented the client's health problems. You then modify the care plan as needed. For example, if a problem has been resolved, you delete it from the care plan; if outcomes have not been achieved, you determine why. It may be that a new intervention is needed. If so, you add it.

Key Point: ***Notice that the nursing process is not intended to be linear (one step rigidly following another). Instead it is a cyclical process that follows a logical progression***. You can see that the evaluation step requires you to begin again using all the other steps. You will find that you go back and forth between the steps, especially as you gain nursing experience. In addition to being cyclical, the steps may be *concurrent*. That means that some of the steps may occur at the same time. For example, while inserting a urinary catheter (implementation step), the nurse also observes the urine that returns through the tube (assessment step). You will learn about each nursing process phase in depth in Chapters 3 through 7.

KnowledgeCheck 2-3

- List the six phases of the nursing process.
- In which stage does the nurse collect data?
- Which stage involves problem identification?
- What does the nurse do in the evaluation step?

How Is Nursing Process Related to Critical Thinking?

Key Point: ***Critical thinking and nursing process are interrelated, but not identical.***

- Nurses use critical thinking for decisions unrelated to the nursing process (e.g., to decide how many nurses are needed to staff the unit).
- Some nursing activities (e.g., applying a cardiac monitor, inserting a urinary catheter), although they must be done skillfully, do not require reflective critical thinking.

Nursing process is essentially a problem-solving process. As such, it is one of the *complex critical-thinking skills* (see Box 2-2). Complex thinking skills, such as the nursing process, make use of many different critical-thinking skills (see Table 2-1 and Fig. 2-1). The following sections illustrate how nurses use critical thinking, as well as nursing knowledge, in each phase of the nursing process.

WHAT IS CARING?

Caring involves personal concern for people, events, projects, and things. It allows you to connect with others and to give help as well as receive it. One aspect of self-knowledge is to be aware of what and whom you care about. Knowing what the patient cares about reveals what is stressful for the patient, because only things that matter can create stress. Caring also enables the nurse to notice which interventions are effective.

A caring perspective highlights each person as unique and valued, so caring is always specific and relational for each nurse–person encounter. It is not an abstraction. That is, you don't just care for "suffering humankind," but you respond compassionately to *this* patient's needs right now, in the moment, even if you are busy and tired. Caring involves thinking and acting in ways that preserve human dignity and humanity, and does not treat people as objects. For example, a caring nurse drapes a patient for privacy when inserting a urinary catheter. A caring nurse's actions are never routine or impersonal.

Caring has at least five components:

- *Knowing.* Striving to understand what an event (e.g., an illness) means in the life of the patient
- *Being with.* Being emotionally present for the patient (e.g., making eye contact, actively listening)
- *Doing for.* Doing what the patient would do for himself if he could (e.g., bathing)
- *Enabling.* Supporting the patient through coping with life changes and unfamiliar events, such as hospitalization
- *Maintaining belief.* Having faith in the patient's ability to get through the change or event and to find fulfillment and meaning (Swanson, 1990)

Caring is the central concept in several nursing theories. You will learn more about them in Chapter 8.

KnowledgeCheck 2-4

List all the characteristics of caring that you can remember.

WHAT IS FULL-SPECTRUM NURSING?

Key Point: **Full-spectrum** ***nursing is a unique blend of thinking, doing, and caring.*** It is performed by nurses who fully develop and apply nursing knowledge, critical thinking, and the nursing process to patient situations for the purpose of effecting good outcomes.

What Concepts Are Used in Full-Spectrum Nursing?

When we put concepts (ideas) together to explain something, it is called a **model**. You'll learn more about concepts in Chapter 8; for now, think of them as ideas. The four main concepts that describe full-spectrum nursing are *thinking*, *doing*, *caring*, and *patient situation* (or *context*) (Table 2-2).

In order to think, you must have something to think about. When nurses think, they use the nursing knowledge that they have stored in their memory. In addition, they think about the patient situation, which they acquire through use of the nursing process. Situation, or context, refers to the context for care, the patient's

Table 2-2 ➤ Full-Spectrum Nursing Concepts

THINKING	DOING	CARING	PATIENT SITUATION
Critical Thinking Enables you to fully use your knowledge and skills	**Practical Knowledge** Skills, procedures, and processes (including the nursing process)	**Self-Knowledge** Awareness of your values, beliefs, and biases	**Patient Data** Physical, psychosocial, spiritual
Theoretical Knowledge Principles, facts, theories; what you have to think *with*	**Nursing Process** ***Assessment and Evaluation:*** Everything you know about the patient including context ***Planning and Implementation:*** What you do for the patient	**Ethical Knowledge** Understanding your obligations; sense of right and wrong	**Patient Preferences and Context** Context for care, environment, relationships, culture, resources, supports

environment outside the care setting, relationships, resources available for patient care, and so on. Figure 2-3 is a simple, visual model of full-spectrum nursing. You can see that the concept's full model involves everything you have learned in this chapter—critical thinking, nursing knowledge, and nursing process—but organized under the simple concepts of thinking, doing, caring, and patient situation.

Let's see how the model concepts work together for a full-spectrum nurse. They are all interrelated and overlapping, but we divide them into simple categories to help you understand and remember them. You can see that a full-spectrum nurse needs excellent thinking skills because there is so much to think *about* and so much to *do.*

KnowledgeCheck 2-5

- What are the four main concepts of the full-spectrum model of nursing?
- Where do the four types of nursing knowledge fit into the full-spectrum model?
- What is the ultimate purpose of full-spectrum nursing?

How Does the Model Work?

The full-spectrum nursing model is used throughout this text, so it is important that you understand how it works. Nurses use critical *thinking* in all steps of the nursing process. They also apply critical thinking to the four kinds of nursing knowledge, and when they are *doing* for the patient. *Caring* motivates and facilitates

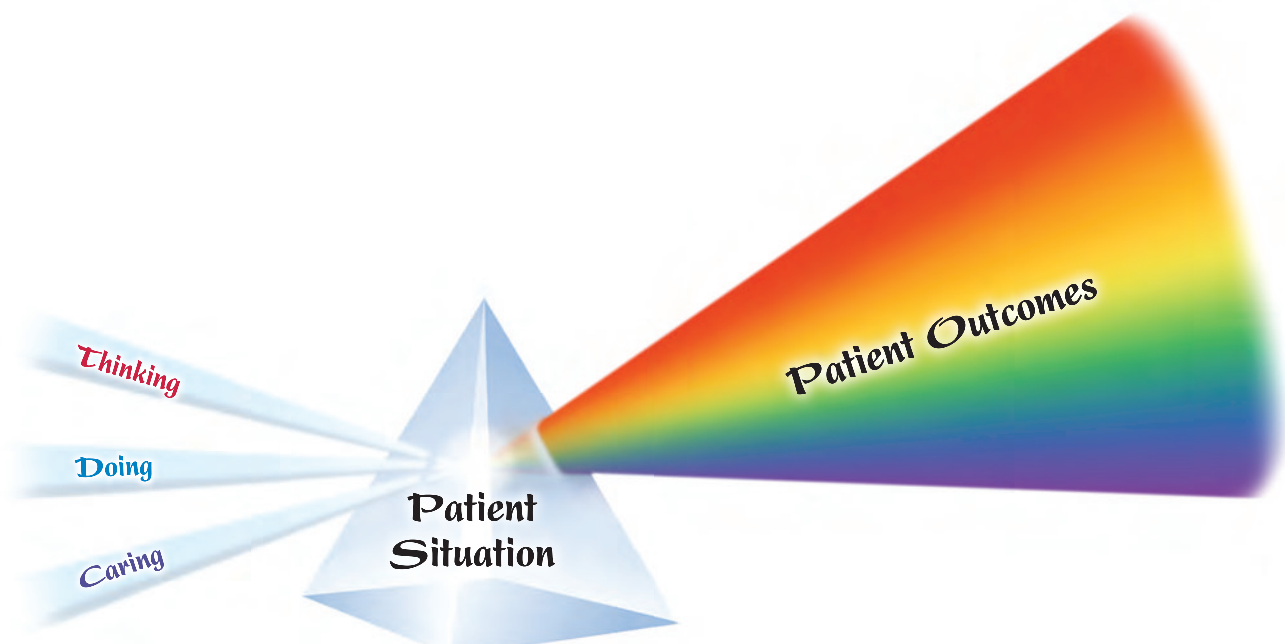

FIGURE 2-3 Model of full-spectrum nursing.

the thinking and doing. The goal of all this is to have a positive effect on a patient's health outcomes.

The following patient situations illustrate how the three main dimensions of full-spectrum nursing work together. As you read, notice the overlapping of concepts. For example, recall that nursing process and problem-solving are themselves complex critical-thinking skills. Also notice how the nurse uses critical thinking with nursing knowledge and nursing process.

Patient Situation 1

When taking a patient's oral temperature, a nurse sees a glass of ice water on the overbed table. Realizing that a cold drink can reduce the accuracy of the temperature reading, she questions the patient, "How long since you've taken a drink of water?" The nurse is busy and tired, but she returns to take the patient's temperature again at a later time.

Thinking

Theoretical knowledge. The nurse realized that a cold drink can lower the temperature reading. The nurse used interviewing principles to get more information from the patient.

Critical thinking. The nurse recognized relevant information and identified the need for more information. She used the patient's answer to decide what to do. Being aware of context is also critical thinking. The context in this scenario includes ice water within the patient's reach and that the patient was physically capable of reaching it.

Doing

Practical knowledge. The nurse used a psychomotor skill when she measured the patient's temperature to acquire more patient vital sign data and a communication process to question the patient.

Nursing process (Assessment). The nurse observed the glass of ice water on the table. The nurse asked, "How long since you've taken a drink of water?" The nurse also observed the environmental data (e.g., ice water at the bedside). *(Implementation)* The nurse took the patient's temperature.

Caring

The scenario does not say this, but a caring nurse, even a very busy one, would not be annoyed with the patient for the inconvenience of having to come back again to take the temperature. Self-knowledge might include the nurse's awareness that she is tired and feeling irritable. Ethical knowledge would tell her that she has an obligation to get an accurate temperature from the patient rather than thinking, "Oh, I'll just record the reading a degree or two higher, as it doesn't matter that much."

Patient Situation 2

Thirty minutes after giving a pain medication, a nurse checks with the patient to see whether the pain has been relieved. The nurse is using the desired outcome ("States pain relief is adequate . . .") as a criterion for evaluating the effectiveness of the nursing activity. The patient says, "I don't think that medicine is helping a bit." On a scale of 1 to 10, the patient reports her pain as 9. The nurse notifies the primary care provider to request an increase in the dosage of pain medication. She then gives the new medication to the patient and, even though it is the end of her shift, she sits with the patient to help him use guided imagery and deep-breathing strategies to reduce his pain until the medication takes effect.

Thinking

Theoretical knowledge. The nurse had theoretical knowledge of the interval needed for the medication to take effect. She also knew facts and principles about pain rating scales and strategies to relieve pain without medication.

Critical thinking. Criterion-based evaluation is a critical-thinking skill. The nurse applied knowledge of the medication's action to know when to evaluate the patient's response to it. She realized she needed more data about the patient's pain scale. She was also able to generate more interventions, such as requesting an adjustment in the dosage of medication and using guided imagery and deep breathing.

Doing

Practical knowledge. The nurse undoubtedly used practical knowledge when administering the medication (e.g., knowledge of how to administer the medication) and helping the patient with guided imagery and deep breathing to distract him from his pain.

Nursing process. The nurse had apparently previously assessed the patient, identified a nursing diagnosis of Acute Pain, set a desired outcome, implemented an intervention, and then evaluated its effect based on new patient data. She also implemented care when she called the primary provider, administered the medications, and used guided imagery and deep breathing. In addition to data about the pain, you might assume that the nurse knew the following about the context: From the way the goal is stated, we can assume that the patient can speak. The patient is most likely hospitalized because he is not administering his own medication, and the nurse plans to check on him in 30 minutes. Certainly the nurse had all that contextual information.

Caring

Ethical knowledge. The nurse served as a patient advocate when she telephoned the care provider for a new prescription. She cared enough about the patient to stay with him and help him reduce the intensity of his pain using nonpharmacological methods until the new medication took effect, even though this meant working late.

Self-knowledge. Perhaps this nurse values a stoic, "tough it out," response to pain. Knowing this about herself, she could put this aside and see the reality of suffering for the patient and how the experience of pain is individual and personal.

As a full-spectrum nurse, you will apply thinking, doing, and caring to patient situations to help benefit patients and bring about good outcomes.

Toward Evidence-Based Practice

Catlett, S., & Lovan, S. (2011). Being a good nurse and doing the right thing: A replication study. *Nursing Ethics, 18*(1), 54–63.

The purpose of this qualitative study was to examine nurses' perceptions of what it means to be a good nurse and to do the right thing. Researchers used open-ended questions to interview nurse subjects. They identified four categories that related to being a good nurse and doing the right thing: (1) personal traits and attributes; (2) technical skills and management of care; (3) work environment and coworkers; and (4) caring and caring behaviors.

1. What examples of full-spectrum nursing can you see in the four categories identified?

2. Based on this abstract, which of the following questions might this study answer satisfactorily for you? Explain your reasoning.
   a. What is a good nurse?
   b. Did the nurse-subjects demonstrate critical thinking?
   c. How did the nurse-subjects describe a good nurse?

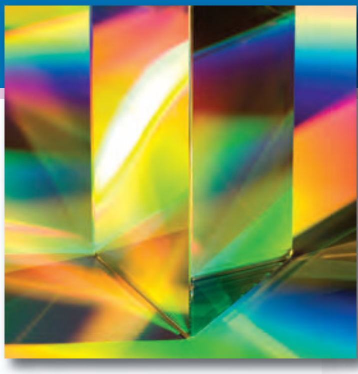
CHAPTER 3



Nursing Process: Assessment

Learning Outcomes

After completing this chapter, you should be able to:

- Define *nursing assessment*, including the four features common to all its definitions.
- Explain how assessment is related to each of the other steps of the nursing process.
- State the ANA position on delegating assessment.
- Name three requirements of The Joint Commission regarding patient assessment.
- Use assessment skills to gather data during a nursing assessment.
- Define initial, ongoing, comprehensive, and focused assessment.
- Explain the importance of discharge planning assessment.
- List five special needs assessments and state when or why you would use them.
- Identify the following types of data: subjective, objective, primary source, secondary source.
- Identify at least four components of a nursing health history and state the purpose of each.
- Describe the differences between directive and nondirective interviewing.
- Compare and contrast open-ended and closed questions, including definitions, uses, advantages, and disadvantages.
- Discuss how to prepare for and conduct an interview.
- Describe three circumstances in which you should validate data.
- Use nursing frameworks to organize data.
- State four guidelines for documenting data.
- Compose three questions to ask yourself when you are evaluating the quality of your assessments.

Key Concepts

Assessment

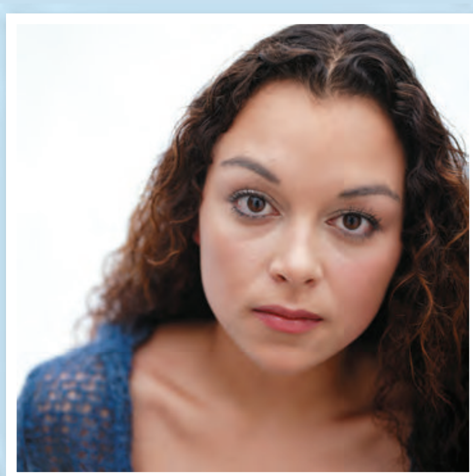
Meet Your Patient

As the intake nurse in a community-based clinic in Miami, Florida, your role is to complete a comprehensive nursing assessment and initiate a plan of care for the clients. Your first client is a 24-year-old single woman, Sami, who is requesting clinic services for her general healthcare needs. Sami is Cuban American and lives alone in a one-bedroom apartment. She works as a fitness trainer at the local fitness club while attending college part-time. Her family lives in Tampa, Florida. Sami's earnings place her below the poverty level. She realizes that she must have healthcare to prevent health problems and to detect and receive treatment of illnesses should they arise. You will be asked to apply full-spectrum thinking to Sami's case throughout the chapter as you learn the concepts of assessment.



Theoretical Knowledge knowing why

In this section, you will learn about the role of assessment in the nursing process and collaborative care; about sources of data; and about various types of assessment.

ABOUT THE KEY CONCEPTS

Assessment is a key concept because it is so integral to the nursing role. It is closely tied to another key concept: *data*. The related concepts in this chapter will enable you to fully understand the notion of assessment and to see how they all fit together.

ASSESSMENT: THE FIRST STEP OF THE NURSING PROCESS

Assessment is the systematic gathering of information related to the physical, mental, spiritual, socioeconomic, and cultural status of an individual, group, or community. Although various definitions exist, all definitions of assessment include the following features: collecting data, categorizing data, recording data, and using a systematic and ongoing process.

The purpose of assessment is to obtain enough data to allow you to help the patient. The nursing interview and the physical assessment findings become a part of the **patient database** (all the pertinent patient data obtained by nurses and other health professionals). You will use the facts, impressions, and contextual information obtained in your assessment to develop a plan of care.

How Is Assessment Related to Other Steps of the Nursing Process?

Assessment is the first phase of the nursing process. Data must be accurate and complete, because the remainder of the nursing process rests on this foundation of data. Assessment is related to other nursing process steps as follows (Fig. 3-1):

- *Diagnosis*—Assessment provides the data necessary for identifying the client's health problems and strengths.
- *Planning outcomes*—Data about the patient's motivation, family, and available resources help you formulate realistic goals.
- *Planning interventions*—Assessment data help you to choose the interventions most likely to be acceptable to and effective for the client.
- *Implementation*—As you perform nursing actions, you will also gather data by observing the client's responses. For example, while helping a client ambulate, you might observe that she becomes short of breath. If this is new information, you might then identify a new diagnosis of Activity Intolerance.

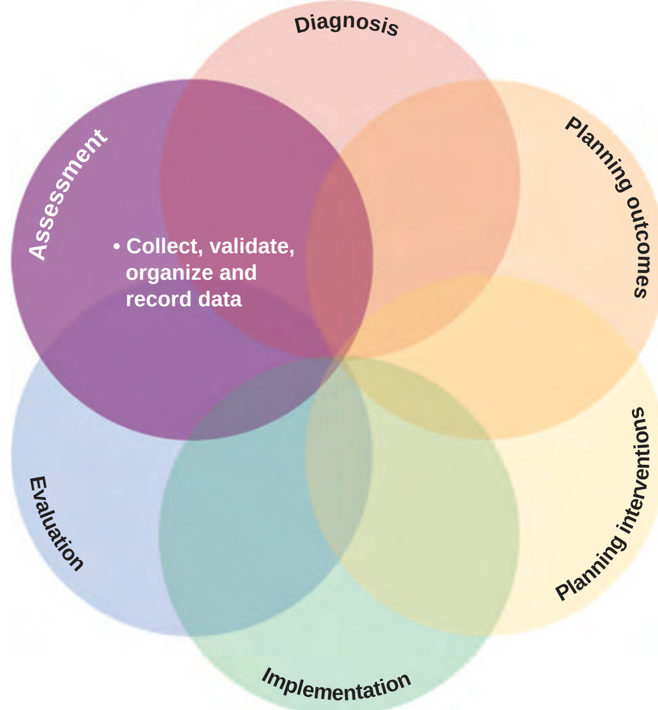


FIGURE 3-1 Nursing process: Assessment phase.

- *Evaluation*—After performing interventions for existing diagnoses, you assess the client's responses. This *reassessment* provides the basis for changes in the care plan.

How Does Nursing Assessment Fit Into Collaborative Care?

As a nurse, you will focus on your clients' *responses* to illness, which include their physical responses; their understanding of the illness and how it affects their lives and ability to care for themselves; and their emotional responses and concerns. You will also use assessment with healthy clients to help identify ways they can maintain their current level of wellness and prevent disease. This is different from traditional medical assessments, which focus on identifying disease.

Other healthcare professionals can access the database created from the nursing assessment findings. In some settings, the nurse looks at the database and delegates or makes referrals to other professionals with expertise in a particular area of healthcare. This helps ensure that clients receive the proper care by qualified individuals at the time it is needed.

Sami's case illustrates this. Sami has not had a gynecological (female) examination for 5 years. In the interview, she tells you that her mother has had breast cancer and that her sister is being treated for endometriosis. You first ask whether, because of any religious or other beliefs, Sami would be offended by an open discussion. Then you ask about her sexual activity, assuring her that you will keep all information confidential. As a result of this interview, you encourage Sami to get a women's health examination as soon as possible. She agrees, and you refer her to a women's clinic, where she will be billed according to her ability to pay.

What Do Professional Standards Say About Assessment?

Complete, skillful, and timely assessment of all clients is an important skill for nurses in all healthcare settings. Standards of governmental agencies, professional organizations, and accrediting bodies, such as the following, all address assessment.

The American Nurses Association (ANA) standards for clinical practice, which apply to all nurses, identify assessment as a professional responsibility (Box 3-1).

BOX 3-1 ■ Professional Standards for Assessment

American Nurses Association Standards of Nursing Practice[1]

Standard 1. Assessment

The registered nurse collects comprehensive data pertinent to the healthcare consumer's health and/or situation.

Competencies

The registered nurse:

- Collects comprehensive data including but not limited to physical, functional, psychosocial, emotional, cognitive, sexual, cultural, age-related, environmental, spiritual/transpersonal, and economic assessments in a systematic and ongoing process while honoring the uniqueness of the person.
- Elicits the healthcare consumer's values, preferences, expressed needs, and their knowledge of the healthcare situation.
- Involves the healthcare consumer, family, and other healthcare providers, as appropriate, in holistic data collection.
- Identifies barriers (e.g., psychosocial, literacy, financial, cultural) to effective communication and makes appropriate adaptations.
- Recognizes the impact of personal attitudes, values, and beliefs.
- Assesses family dynamics and impact on healthcare consumer health and wellness.
- Prioritizes data collection based on the healthcare consumer's immediate condition, or the anticipated needs of the healthcare consumer or situation.
- Uses appropriate evidence-based assessment techniques, instruments, and tools.
- Synthesizes available data, information, and knowledge relevant to the situation to identify patterns and variances.
- Applies ethical, legal, and privacy guidelines and policies to the collection, maintenance, use, and dissemination of data and information.
- Recognizes the healthcare consumer as the authority on her or his own health by honoring their care preferences.
- Documents relevant data in a retrievable format.

Source: American Nurses Association. (2010). *Nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Nursebooks.org.

Nurse practice acts regulate the practice of nurses in individual states. The National Council of State Boards of Nursing (2006, Article II, Section 2) *Model Nursing Practice Act* also asserts that the scope of nursing includes surveillance and comprehensive assessment of the health status of individuals, families, groups, and communities.

The Joint Commission (2012, pp. PC-1–PC-20), in its standards for "Provision of Care, Treatment, and Services," identifies assessment as an essential element of patient care. In agencies with an RN on staff, an RN must assess patients' needs for nursing care within 24 hours of inpatient admission (p. PC-7). The Joint Commission includes standards that require agencies to provide evidence that:

- Assessments are written, comprehensive (physical, psychological, and social status), and used to identify and assign priorities for care.
- Agency policy designates (1) when each patient is to be reassessed and (2) which disciplines can make which assessments.
- All patients are assessed for pain.

KnowledgeCheck 3-1

- What are the four features common to all definitions of assessment?
- How is a nursing assessment similar to a medical assessment?
- How is it different?

Can I Delegate Assessments?

For data to be reliable, someone with education and experience must perform the assessment. **Key Point:** ***Nurse aides or other nursing assistive personnel (NAP) may collect information such as temperature, height, and weight. However, as a nurse, it is your responsibility to assign those tasks, validate the data collected, conduct the interview, and complete the physical assessment.*** The ANA's *Code of Ethics for Nurses*, Provision 4 (2001) states: "The nurse . . . determines the appropriate delegation of tasks consistent with the nurse's obligation to provide optimum patient care." Also see Chapters 7 and 40 for a thorough discussion of delegation of tasks to NAPs. The following resources can guide you in deciding which caregivers are qualified to perform parts or all of an assessment.

- *State nurse practice acts*. Each state nurse practice act specifies which portions of the assessment can legally be completed by individuals with different credentials. Look for statements related to delegation. For example, the definitions in the National Council of State Boards of Nursing's (NCSBN) *Model Nursing Practice Act* (2011) differentiate between assessments by RNs and LPNs/LVNs (Box 3-2).
- *Agency policies/procedures*, such as those stating which caregivers can collect and document specified data, can provide guidelines.
- *Accrediting agencies*, such as The Joint Commission, also provide guidelines on who can perform and document assessments.

BOX 3-2 ■ NCSBN Model Nursing Practice Act (2011), Selected Definitions Related to Nursing Assessment

Comprehensive Assessment by the RN

An extensive data collection (initial and ongoing) for individuals, families, groups, and communities:

Addressing anticipated changes in client conditions as well as emerging changes in a client's health status

Recognizing alterations to previous client conditions

Synthesizing the biological, psychological, and social aspects of the client's condition

Evaluating the impact of nursing care

Using this broad and complete analysis to make independent decisions and nursing diagnoses

Planning nursing interventions

Evaluating need for different interventions

Communicating the need to communicate and consult with other health team members.

Focused Assessment by the LPN/LVN

An appraisal of an individual's status and situation at hand, contributing to comprehensive assessment by the registered nurse, supporting ongoing data collection, and deciding who needs to be informed of the information and when to inform.

ThinkLike a Nurse 3-1

Think about the following situations, then answer the questions. More than one answer may be acceptable. Compare your ideas with those of other students or nurses, or consult your instructor.

- Suppose you are a nurse in a healthcare setting in which the policy states that nursing assistive personnel (NAPs) can take vital signs (blood pressure, pulse, temperature, and respirations). You have a patient who is critically ill and whose condition is changing rapidly. Would you measure the vital signs or delegate the task to the NAP? Why?
- Imagine that you are a nurse in the same hospital on a different day. All but one NAP have called in sick today because of an influenza outbreak. This NAP is inexperienced and overwhelmed by her tasks. Would you bathe the patients in your caseload (even though that is usually done by a NAP), or would you ask the NAP to do it? Why?

It is obvious from the previous examples that you must use good judgment when applying standards and policies and deciding when to delegate assessments.

Sources of Data

Subjective data (*covert data, symptoms*) are the information communicated to the nurse by the client, family, or community. Subjective data reveal the perspective, thoughts, feelings, beliefs, and sensations of the person giving the data. Thus, subjective data from two different people can vary. For example, people with insomnia often report getting much less sleep than their sleep partner says they do. You can use subjective data to clarify objective data (e.g., "How did you get this scar?"). Some people (e.g., infants, adults with mental illness) are unable to provide subjective data. Others can give subjective data, but you might question its accuracy. For example, how credible is a diabetic patient's response that she complies with a diabetic diet and medication regimen when the blood sugar level is markedly elevated? What could you do to double-check the subjective data?

Objective data (*overt data, signs*) are gathered through a physical assessment or from laboratory or diagnostic tests. They can be measured or observed by the nurse or other healthcare providers. Examples are vital signs, x-ray results, skin color, and urine output. You sometimes need to use objective data to validate subjective data. In the preceding example, if you thought the report of dietary intake and insulin use was inaccurate, you would measure the blood sugar and ask for a dietary journal.

You may also use objective data to verify subjective information that seems accurate. For example, when Sami told you her family and sexual history, you learned that she has significant risk factors for breast and cervical cancer and referred her for a gynecological exam. The results of the breast exam and Pap smear (Papanicolaou test, a smear of cervical cells) provide objective data related to these risk factors.

Primary data are the subjective and objective data obtained from the client: what the client says or what you observe. **Secondary data** are obtained "second-hand," for example, from the medical record or from another caregiver. A client's husband may say, "She seems more confused than usual." Or the NAP may report, "Mr. Atlas's heart rate was 100 beats per minute this morning." If you count the heart rate yourself, though, it would be primary data. Table 3-1 provides further examples of types and sources of data.

KnowledgeCheck 3-2

During Sami's appointment at the women's clinic, she has a Pap smear, breast exam, and blood work. She also informs the nurse that her menstrual flow is heavy and that she experiences severe abdominal cramping. These data are added to the database as references for future visits. Sami's Pap smear results and breast exam are normal, but she is moderately anemic. When the lab results indicate a low hemoglobin level, the nurse practitioner suspects that Sami's heavy flow may be causing her anemia. According to clinic protocol, she prescribes birth control pills for Sami to control her menstrual symptoms and provide contraception. Ongoing assessment will include visits every 6 months to manage her birth control pills and monitor the

Table 3-1 ➤ Examples of Data Types

DATA TYPES	
Subjective Data	**Objective Data**
"I have been having a lot of pain in my abdomen."	Suprapubic area firm to light palpation. Lower abdomen semisoft
"My throat hurts when I swallow."	White patches noted at the back of the throat and tonsillar area reddened and swollen
"Our children have no place to go after football games. That is why they get into so much trouble."	In a windshield survey, no public facility was open after football games to allow young people to socialize under supervision.
DATA SOURCES	
Primary Source (Client)	**Secondary Sources (Everything Else)**
Pulse rate 100 beats/min	From chart: WBC count 14,000/mm^3.
States feeling short of breath	In transfer report, nurse states that the surgical dressing is dry.
Abdomen tender on palpation	Client's wife states that he has been tired a lot lately.

anemia. State whether the following data are primary or secondary, subjective or objective:

- You see in Sami's health record that her breast exam was normal.
- Sami tells the nurse practitioner that she experiences cramping with her menstrual cycle. *For the nurse practitioner*, would this would be primary or secondary, subjective or objective data?
- The nurse practitioner tells you that Sami is anemic.
- You check the result of the Pap smear on the computer and see that it is normal.

Types of Assessment

Key Point: ***Assessment can be broad and general or very specific. The type of assessment you do depends on the client's status.*** In acute care settings, such as the emergency department, the assessments are rapid and focused on the presenting problem. In inpatient settings, you may perform an initial comprehensive assessment at admission and other, more focused assessments over time, according to the client's needs.

Initial and Ongoing Assessments

An **initial (admission) assessment** is completed when the client first comes to the healthcare agency. First obtain data related to the person's reason for seeking nursing or medical assistance. Then complete a comprehensive assessment if the client's condition permits. Data gathered from the initial assessment provide guidance for care and determine the need for further assessment. Initial assessment data tend to be static; for example, demographic data (marital status, occupation) are not likely to change often.

Ongoing assessment is performed as needed, at any time after the initial database is completed. Ideally, you will make at least some observations at every contact with a client. You use data from ongoing assessments to identify new problems or to follow up on previously identified problems. In comparison with the initial assessment, ongoing assessment reflects the dynamic state of the client. For example, vital signs may change rapidly and serve as important indicators of developing or resolving health problems.

Comprehensive Assessments

A **comprehensive assessment** (also called a *global assessment, patient database,* or *nursing database*) provides holistic information about the client's overall health status. It includes subjective and objective data about the client's body systems and functional abilities, emotional status, spiritual health, and psychosocial situation, including information about the family and community. It enables you to identify client problems and strengths. You need comprehensive data to enhance your sensitivity to a patient's culture, values, beliefs, and economic situation. Figure 3-2 shows what information is gathered in an initial comprehensive assessment (database) and how it fits into the broad concept of assessment in the nursing process. To see an example of a form for recording a comprehensive assessment,

Go to Chapter 3, Assessment Guidelines and Tools, **Nursing Admission Data Form,** in Volume 2.

Nurses collect data through the use of all their senses. Whether assessment is initial or ongoing, comprehensive, or focused, you will use the skills of observation, physical examination, and interviewing.

Observation

Observation refers to the deliberate use of all of your senses to gather and interpret patient and environmental data. All that you see, hear, feel, or smell becomes data in the context of assessment. You should try to use the same sequence of observation at each patient contact. By making systematic observations each time you are with a patient, you are less likely to miss an assessment area. The mnemonic (memory aid) in Box 3-3 may help you.

Physical Assessment

Physical assessment (or *physical examination*) produces primarily objective data and makes use of the following techniques, which are described in detail in Chapter 22.

- **Inspection.** Observation and visual examination of the client, as well as use of equipment such as an otoscope or ophthalmoscope
- **Palpation.** Light touch, progressing to deeper touch, using the pads of the fingers
- **Percussion.** Striking a body surface with the tip of a finger, which produces different vibrations and sounds

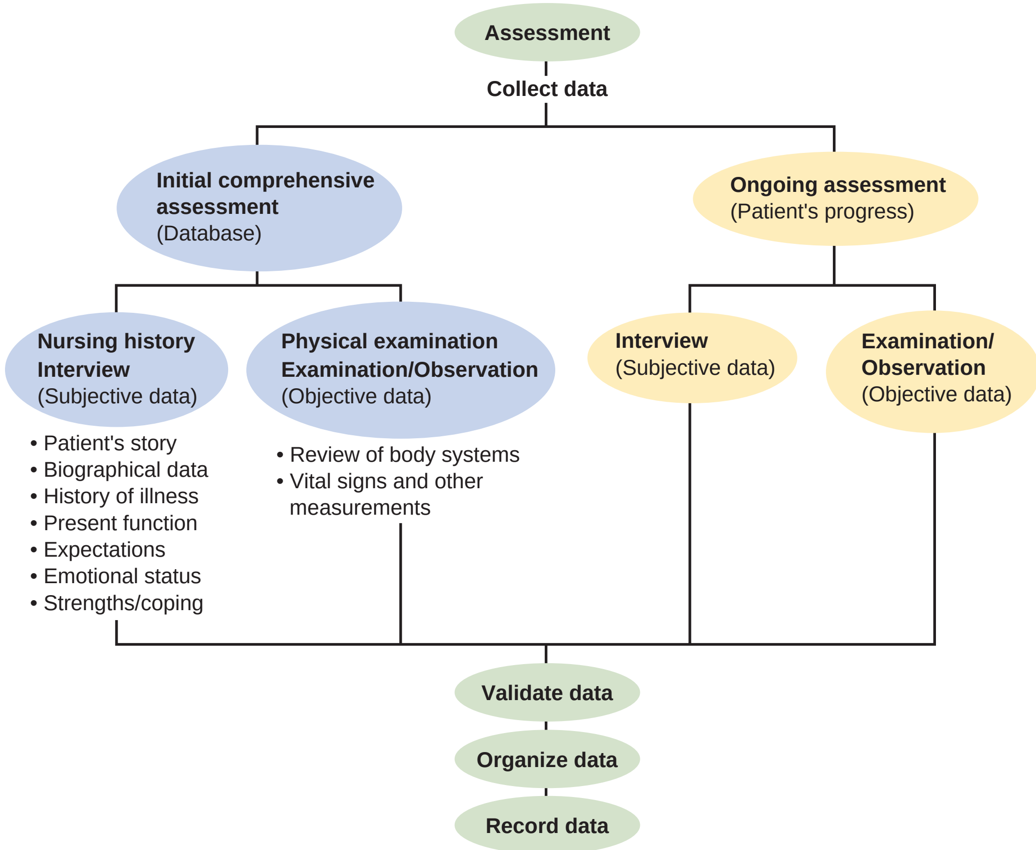

FIGURE 3-2 Overview of assessment content and methods. (*Source:* Wilkinson, J. M. (2012). *Nursing process and critical thinking* (5th ed.), p. 78. Reprinted by permission of Pearson Education, Inc., Upper Saddle River, NJ.)

depending on what is under the area that is tapped (air, fluid, or solid)

- **Auscultation.** Listening with the unaided ear for sounds made by the client (*direct auscultation*) and listening with the use of a stethoscope (*indirect auscultation*) for normal and abnormal sounds within the body

The Nursing Interview

A **nursing interview** is purposeful, structured communication in which you question the patient to gather subjective data for the nursing database (Fig. 3-3). The admission interview is planned, but during ongoing assessment, the interview may be informal, brief, and narrowly focused.

BOX 3-3 ■ Mnemonic for Systematic Observing

Use the first letter of each word to help you observe systematically as you enter a patient's room.

HELP!!

Help. Observe first signs the patient may need help. Look for signs of distress (e.g., pain, pallor, labored breathing)

Environment and equipment. Next look for safety hazards (spills, equipment cords, sharps). Check to see that all equipment is working: IV line running? Catheter draining? Oxygen working?

Look more closely. Examine the patient thoroughly for appearance, breathing, condition of dressings, correct positioning, skin color and condition, odors, condition of linens, and any other clues that might indicate a need for care.

People. Who are the people in the room? Family? Other caregivers? What are they doing?

KnowledgeCheck 3-3

Give at least two more examples of data you might obtain with each of the following senses. One example is provided for each.

- Touch (e.g., bladder distention)
- Vision (e.g., facial expression of pain)
- Smell (e.g., fecal odor)
- Hearing (e.g., bowel sounds)

Focused Assessments

A **focused assessment** is performed to obtain data about an actual, potential, or possible problem that has been identified or is suspected. It focuses on a particular topic, body part, or functional ability rather than on overall health status. For example, focused assessments can center on pain, nutrition, spiritual health, social support, lifestyle, and family assessment. These specialized assessments add to the database created by the comprehensive initial assessment.

- An ***initial focused assessment*** is used to follow up on client-reported symptoms or unusual findings during the first exam (e.g., on admission to a hospital). For example, when the nurse asks Mr. Jacobs why he has come to the clinic today, he replies, "I can't get rid of this pain in my foot." The nurse asks questions to get

FIGURE 3-3 The nurse conducts an informal interview.

in-depth information about this symptom: When did it begin? On a scale of 1 to 10, how severe is it? What makes it worse? What do you do to make it feel better? She also examines the foot for joint mobility, redness, edema, and tenderness to touch.

- *An **ongoing focused assessment*** is used to evaluate the status of existing problems and goals. For examples, after surgery, Ms. King has a nursing diagnosis of Acute Pain secondary to abdominal incision. The nurse assesses her pain level at least every 2 hours and before and after administering pain medication.

ThinkLike a Nurse 3-2

- Give examples of each type of assessment (initial, ongoing, comprehensive, focused) using patients you have observed or cared for or your own personal experiences as a patient.
- How might age and developmental stage make a difference in your assessment of a patient?
- Suppose you are the triage nurse at the community clinic in the Meet Your Patient scenario. What kind of assessment do you perform at Sami's first visit (initial, ongoing, comprehensive, focused)? What type will the care provider at the women's clinic perform?

Special Needs Assessments

A **special needs assessment** is a type of focused assessment. It provides in-depth information about a particular area of client functioning and often involves using a specially designed form. The Joint Commission requires certain special needs assessments (e.g., of nutrition status and pain) for all clients. In some settings, such as hospice, home health, and rehabilitation settings, other special needs assessments (e.g., of functional abilities) are also required. You should perform a special needs assessment any time assessment cues suggest risk factors or problems in an area of client functioning.

Self-Care

Teaching Self-Assessment

As you learned in Chapters 1 and 2, it is essential for nurses to provide information that will help clients to care for themselves. One important aspect of self-care is performing regular self-assessments to detect symptoms of disease.

Important assessments every person needs to know:

- Breast self-exam or testicular self-exam—monthly (Note that this is not at present recommended by all care providers or all best practice guidelines.)
- Skin assessment—daily but at least weekly
- Feet assessment—daily if diabetic or elderly, otherwise weekly

Before you begin teaching:

- Assess the readiness and willingness of your client to learn some type of assessment.
- Assess current knowledge or understanding of the topic to be discussed.

See Chapter 22 for details of these assessments.

Special needs assessments can be quite lengthy; therefore, you need to think carefully about when and how to use them. You need enough data to provide holistic care, but you must balance this need against the need not to intrude on the client's privacy. Obtain only the data you need to enhance the care provided to the client and add to the comprehensive assessment. The following are some special needs assessments:

Functional Ability Assessment Health problems and normal aging changes often bring a decline in functional status. Functional ability is especially important in discharge planning and home care. Future rehabilitation needs are derived from initial and ongoing functional ability assessments. The Joint Commission (2012, p. PC-6) requires an initial functional ability assessment "based on the patient's condition." These three functional assessment tools are commonly used:

- **The Katz Index of ADL scale (1963).** This instrument is one of the best for assessing independent performance in very basic areas. It assigns one point for independence in each of the following areas: bathing, dressing, toileting, transfer, continence, and feeding (Shelkey & Wallace, revised 2012). Nurses often use the data to plan staffing and appropriate placement of clients. See Box 3-4 for questions to use when assessing activities of daily living (ADLs). For a link to the Katz scale,

Go to Chapter 3, **Resources for Caregivers and Health Professionals,** on Davis*Plus.*

- **Lawton Instrumental Activities of Daily Living (IADL) scale (1969).** This easy-to-use tool is particularly helpful in assessing a person's ability to independently

BOX 3-4 ■ Questions for Assessing Independence in Activities of Daily Living

Mobility

Does the client require devices (e.g., cane, crutches, walker, wheelchair) for support?

Transfer

Can the client get in and out of bed and in and out of a chair without assistance?

If not, how much help does the client need?

Is the client completely confined to bed?

Bathing

Can the client perform a sponge bath, tub bath, or shower bath with no help?

If not, specifically what assistance does the client need?

Dressing

Can the client get all necessary clothing from drawers and closets and get completely dressed without help?

If not, specifically what assistance does the client need?

Feeding

Can the client feed self without assistance?

If not, specifically what assistance does the client need (e.g., help with cutting meat, tube feeding)?

Toileting

Can the client go to the bathroom, use the toilet, clean self, and rearrange clothing without help?

If a night bedpan or commode is used, can the client empty and clean it independently?

If the client needs help with these activities, specifically what does it include?

Continence

Does the client independently control urination and bowel movements?

If not, how often is the client incontinent of bladder or bowel?

Does the client require an indwelling urinary catheter?

perform the more sophisticated tasks of everyday life, such as shopping. Identifying early functional decline is important for discharge planning.

The Lawton scale is especially useful for older adults, who may begin to experience functional decline within 48 hours of hospital admission (Graf, 2008; Lawton & Brody, 1969).

- To see the Lawton scale,

Go to Chapter 3, Assessment Guidelines and Tools, **Patient Assessment Tool—Lawton IADL,** in Volume 2.

- **The Karnofsky Performance scale (Karnofsky & Burchenal, 1949).** This tool is used primarily in palliative care settings to assess functional abilities at the end of life. To see this tool,

Go to Chapter 3, Tables, Boxes, Figures; **Box ESG 3-1, Karnofsky Performance Scale,** on Davis*Plus*.

Nutritional Assessment Perform a nutritional assessment when data suggest that the client is undernourished, is at risk for Imbalanced Nutrition, or requires nutritional therapy as an intervention (as for a person newly diagnosed with diabetes). In addition to information about food intake, it includes information related to personal, psychosocial, and economic problems that may affect nutrition. See Chapter 27 for more information about nutritional assessment.

Pain Assessment In addition, good nursing care and accrediting agency standards require you to perform a thorough pain assessment on all patients during the initial assessment and in ongoing assessments (The Joint Commission, 2012). For more information on pain assessments, see Chapter 31.

Cultural Assessment Awareness of cultural influences should guide your assessment and nursing care, but be careful not to stereotype clients based on culture. To be culturally competent, you must be able to assess and honor the diversity among all clients. For content included in a cultural assessment, see Chapter 15.

Spiritual Health Assessment For ill persons, spirituality can be a problem or a source of support. To gather useful information, you must do more than ask the client's religious preference. Spiritual health assessment provides insight into how a client interprets life events and health. See Chapter 16 for more detailed information.

Psychosocial Assessment A psychosocial assessment includes data about lifestyle, usual coping patterns, understanding of the current illness, personality style, previous psychiatric disorders, recent stressors, major issues related to the illness, and mental status (Gorman & Sultan, 2008). Perform a focused psychosocial assessment if initial assessment data indicate that social and emotional needs are not being met (e.g., if the client is very anxious or exhibiting symptoms of stress), or if sociocultural factors (e.g., unemployment) present a risk to health (see Chapter 13).

Wellness Assessment Health promotion focuses on activities of a well person to achieve a higher level of health. Well people can usually identify their own health needs, so most assessment tools are self-administered. A wellness assessment includes data about spiritual health, social support, nutrition, physical fitness, health beliefs, and lifestyle, as well as a life-stress review. See Chapter 42 for a more detailed discussion of assessing wellness.

Family Assessment Health behaviors and beliefs generally have their beginnings in family interactions. Therefore, a family assessment provides a better understanding of the client's health-related values, beliefs, and behaviors (see Chapter 14).

Community Assessment Community assessment provides information about community demographics, resources, health concerns, points of referral, environmental risks, and community norms and values (see Chapter 43).

ThinkLike a Nurse 3-3

Based on the data you have so far about Sami, consider the need to perform any of the special-purpose assessments. What is your rationale for using or not using a special needs assessment?

PracticalKnowledge knowing how

In this chapter, practical knowledge involves your skill in using structured and unstructured methods of data collection, as well as validating, organizing, and documenting your assessment findings.

Interviewing to Obtain a Nursing Health History

Suppose that an elderly man has a fractured hip. The physician is interested in the cause of the fracture, the extent of the injury, and any preexisting health problems that suggest the client is a poor surgical risk. As the nurse, you too would ask about the cause of the injury. However, you would also want to (1) know what effect the injury has on the man's ability to perform everyday activities, and (2) identify supports and strengths to begin planning for his eventual discharge and self-care. **Key Point:** ***So you see, the nursing health history covers some of the same topics as the medical history, but the reason for the questions is different.***

Health history forms vary among agencies and according to purpose (e.g., inpatient, clinic, surgery, medical, emergency department, or newborn care), but most include the subjective information found in Table 3-2.

ThinkLike a Nurse 3-4

The Quality and Safety Education for Nurses (QSEN) competency definitions identify assessment as a necessary skill for competency in patient-centered care: Elicit patient values, preferences, and expressed needs as part of a clinical interview (Cronenwett, Sherwood, Barnsteiner, et al., 2007). Where do you think this type of patient information fits into the preceding components of a nursing health history? Why?

Types of Interviews

Interviews may be directive or nondirective. Use **directive interviewing** to obtain factual, easily categorized information (e.g., age, sex), or in an emergency situation. In this type of interview, you control the topics and ask mostly closed questions to obtain specific information. **Closed questions** are those that can be answered with a "yes," "no," or other short, factual answer. They usually begin with *who, when, where, what, do (did, does),* and *is (are, were).* Closed questions are useful for patients who are very anxious or who have communication difficulties.

When you want to promote communication, build rapport, or help the patient to express feelings, use **nondirective interviewing.** This means that you allow the patient to control the subject matter. Your role is to clarify, summarize, and ask mostly open-ended questions that facilitate thought and communication. **Open-ended questions** specify a topic to be explored, but phrase it broadly to encourage the patient to elaborate. Ask open-ended questions when you want to obtain subjective data.

Directive interviewing is efficient but may cause you to miss topics important to the patient. Nondirective interviewing allows you to find out what is important to the patient, but it is time consuming and can produce much irrelevant data. A successful interview includes both closed and open-ended questions. Use broad, open-ended questions to guide the patient to talk about certain topics. From the answers to the broad questions, you can decide which topics to clarify or follow up with specific and closed questions. Part of the interview with Sami might have gone like this:

NURSE When was your last physical examination? *(closed question)*
SAMI I had a female exam about 5 years ago.
NURSE What problems have you had in that area? *(open-ended question)*
SAMI None, really.
NURSE What about other women in your family? *(open-ended question)*
SAMI Well, my mother had breast cancer about the same time that I went for my checkup. She's OK now though.
NURSE Go on . . . (*open-ended question*)
SAMI And my sister has been taking some pills for endometriosis. She hasn't been able to get pregnant because of that.
NURSE Are you sexually active? *(closed question)*
SAMI Yes.
NURSE Tell me about that. (*open-ended question*)

See Table 3-3 for other examples of closed and open-ended questions.

Preparing for an Interview

While you are learning, you may feel uncomfortable interviewing patients. You may have one of the following concerns:

- **You are imposing on the patient, who clearly needs rest more than you need information.** This may be because you believe a "real nurse" has already obtained the information, or because you don't have a clear idea of how the information will be used to help the patient.
- **The patient won't be receptive to answering personal questions from a stranger (you).** To help set the tone for the interview, be sure to tell your patients that the information given will be kept confidential and that they can refuse to answer any question.

Table 3-2 ➤ Components of a Nursing Health History

COMPONENT	DESCRIPTION
Biographical Data	Relatively unchanging information, such as name, address, age, gender, race, religion, marital status, and occupation. Responses to these questions reflect mental status and ability to communicate.
Chief Complaint (Reason for Seeking Healthcare)	The client's perception of or reason for seeking medical or nursing advice. From this, you will be able to target your assessment to gather the most relevant and important data. Ask, for example, "Tell me why you have come to the hospital today." The client might respond, "I just don't feel right," or "I'm having chest pain." Follow up by asking him specifically what caused him to seek help (e.g., chest pain, a checkup). Be sure to document the answer in the client's words.
History of Present Illness	An in-depth exploration of the client's chief complaint. Find out when the illness or problem began, whether the onset was sudden or gradual, how often it occurs, what makes it worse, what the person does to relieve it, how the client's health has changed from his usual status, and what effect the illness has had on his daily life.
Client's Perception of Health Status and Expectations for Care	Includes the client's knowledge about his illness and its potential effects on his life. For example, does a client with arterial insufficiency believe his foot will be "normal" again? Also, ask the client what he expects will be done for him (e.g., does he understand that his foot will be amputated)? And what does he want the nurses to do to help (e.g., leave a light on at night, bring his medication)?
Past Health History (sometimes called *medical history*)	Includes childhood diseases and immunizations, previous hospitalizations, and previous surgeries. The past health history helps guide your assessment and helps you to understand some of the data you obtain. For example, if Sami tells you she had her appendix out when she was 5 years old, you would expect to find a scar on her abdomen.
Family Health History	Includes data on first-degree blood relatives such as mother, father, siblings, and maternal and paternal grandparents. It includes data about diseases they have had, their current state of health and chronic disease, whether or not they are alive, and cause of death if they are not. Risk factors for various illnesses and disorders (e.g., hypertension, allergies) are often tied to multigenerational health problems. Refer to the genogram in Chapter 14.
Social History	Includes information about family and other relationships, economic status, occupations, exposure to toxic materials, home and neighborhood conditions, and ethnicity. Also includes data about tobacco, alcohol, and drug use; and exercise habits.
Medication History and Device Use	Past and current medication usage may uncover some medical history the client has forgotten to disclose. Also ask about nutritional supplements, herbs, and other alternative medicines. As you continue with the assessment, you can direct questions toward previous episodes of medical treatment and use of medical devices, such as braces, inhalers, and home oxygen therapy. Data about current medications are essential because (1) they may interact with newly prescribed medications and (2) some may affect certain body symptoms, causing abnormalities in your assessment findings (e.g., skin color, laboratory values).
Complementary/Alternative Modalities (CAM)	Therapies used instead of or in addition to the allopathic therapies recommended by physicians—for example, chiropractics, homeopathy, aromatherapy, music therapy, massage therapy, energy work (therapeutic touch, Reiki), and acupressure or acupuncture. Such therapies can complement or interfere with conventional therapies, so this is important information.
Review of Body Systems and Associated Functional Abilities	Subjective data regarding body systems (e.g., Do you have a productive cough?). It includes functional abilities (e.g., difficulties with dressing, bathing, eating, and elimination). You can obtain these data during the physical assessment as well as in the interview.

Remember the patient is free to choose what to tell and what to withhold from you. Also, be aware that the patient may have been feeling the need to talk about something, has not known how to bring it up, and is actually relieved you have introduced the topic.

- **Some of your questions will upset the patient—the person might cry or become angry.** Remember that patients usually feel better after releasing their emotions. Expressions of strong emotion may cause you discomfort, but you must learn to accept them. You will have large gaps in your data if you avoid difficult topics, and your patients will not get the help they need.

Your interviews will go more smoothly if you take time to prepare yourself, your patient, and the interview space before you begin asking questions. To learn how

Table 3-3 ➤ Examples of Closed and Open-Ended Questions

CLOSED QUESTIONS	OPEN-ENDED QUESTIONS
Are you having any pain?	Tell me about your pain.
Do you ever drink excessively?	Tell me about your use of alcohol.
Why did you come to this clinic?	I am glad to see you here today. Could you tell me a little bit about why you decided to come see us?
Do you have any family history of heart disease?	Tell me about your family members and what kind of experiences they may have had with heart disease or problems with circulation.
Are there any parks where you can walk safely?	Tell me about safe places here in your community where you might go to take a walk.

to do that, and for tips on conducting and closing an interview,

Go to Chapter 3, **Clinical Insights 3-1, 3-2, and 3-3,** in Volume 2.

KnowledgeCheck 3-4

- What are the 10 components of a nursing history and why are they important?
- What are two things you should do to prepare yourself before an interview?
- List several things you could do to be sure the client is comfortable before the interview. To review this information,

Go to Chapter 3, **Clinical Insight 3-2,** in Volume 2.

- State four guidelines that will help you to obtain complete and accurate data when conducting an interview (these are also in Chapter 3, Volume 2).

HOW AND WHEN SHOULD I VALIDATE DATA?

Suppose a patient has told you that he has never had high blood pressure (BP), but you obtain an abnormal BP reading of 180/98 mm Hg. What would you do? Would you record the 180/98 mm Hg reading, or would you:

- Ask the patient some more questions, such as, "What do you mean when you say you have never had high blood pressure?" or "What have you been doing in the last 15 minutes?"
- Ask another nurse to double-check your findings?
- Check when the sphygmomanometer was last calibrated?
- Retake the BP using a different sphygmomanometer?
- Compare the reading with previous entries in the chart?
- Check the BP in the patient's other arm?
- Wait a few minutes and take the reading again in the same arm?

All of those are ways to **validate** your data—to verify it or double-check it. Validating data helps to ensure that they are accurate, complete, and factual and that you have not jumped to conclusions. If the patient tells you that he was running late and has just jogged the two blocks from the parking lot, you would know that 180/98 mm Hg does not reflect his usual BP and that you need to check it again.

Not all data must be validated. You can usually assume, for example, that laboratory results are correct and that the patient has given you correct information about data such as height, weight, and birth date. You should validate data under the following circumstances (Wilkinson, 2012):

- Subjective and objective data do not agree, or do not make sense together.
  Example: In the preceding situation, the subjective data was "never had high BP," but the objective data, BP 180/98 mm Hg, is a high reading.
- The patient's statements differ at different times in the interview.
  Example: A patient tells you he follows a low-cholesterol diet. However, later when describing his usual daily food pattern, he includes eggs for breakfast, a cheese sandwich for lunch, and a hamburger for dinner.
- The data fall far outside normal range.
  Example: A patient has no symptoms of infection or high fever, but you obtain an elevated oral temperature reading of 106°F (41.1°C). (Hint: Ask him whether he has just had something warm to drink.)
- Factors are present that interfere with accurate measurement.
  Example: The patient has very thin arms, and there are no appropriately sized BP cuffs available. Therefore, because the BP will probably not be accurate, you should measure it again after you can obtain appropriate equipment.

HOW CAN I ORGANIZE DATA?

Professional standards require systematic data collection (see Box 3-1). This means you collect and record data in predetermined categories, not just at random. Data in most initial (e.g., admissions) assessments are categorized by the agency's data-collection form. For ongoing assessments, you may need to provide your own organizing structure (framework). Because a **framework** represents a particular way of thinking about clients and health, it indicates which information is significant and guides you in deciding which patient data to observe. The major concepts of a

Toward Evidence-Based Practice

Moore, K., & Fortner, B. (2010). Utility of routine nurse assessment of the risk of chemotherapy-induced febrile neutropenia. *Canadian Oncology Nursing Journal, 20*(2), 75–79.

This study assessed the usefulness of having nurses routinely assess for the risk of febrile neutropenia (FN) in cancer patients prior to beginning chemotherapy. Using a standardized assessment tool, 15 nurses assessed 150 patients. In 94% of the patients studied, nurses detected risk factors, and interventions were provided to reduce the incidence of FN. When interviewed, 67% of the nurses said the use of a standardized tool helped them to identify patients at risk for FN.

Which of the following inferences can you make (based on this summary alone)? State whether the study summary provides *extensive, limited,* or *no evidence* to support each inference.

1. These positive results occurred because the nurses used a standardized assessment form.
2. Most of the patients in the study did not experience FN.
3. Ten of the 15 nurses in the study said the standardized tool was helpful.
4. A unit policy should require all cancer patients to be assessed with this standardized tool.
5. Assessment is faster and more efficient using a standardized assessment tool.

Go to Chapter 3, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

model/framework help you to cluster data and find patterns. If you don't understand what a framework is, refer to Chapter 8.

Nonnursing Models

ANA professional standards state that nursing data collection should be holistic. Many agencies use a **body systems (medical) framework** for at least a section of the assessment form. This model is useful for identifying medical problems, but it needs to be combined with other models (e.g., a nursing model or Maslow's Hierarchy of Needs) to provide the holistic data you need to identify both nursing and medical problems.

Maslow's Hierarchy of Needs (Maslow, 1970; Maslow & Lowery, 1998) groups data according to human needs. It states that the basic needs must be met before higher needs can be addressed. Maslow's categories of needs, from most basic to highest, are:

Physiological. Basic survival needs (e.g., oxygen, water, food, and shelter)
Safety and security. The need to be safe and comfortable (e.g., safe from falls and treatment side effects as well as the need for psychological security)
Love and belonging. The need for love and affection (e.g., family, social supports)
Esteem and self-esteem. The need to feel good about oneself (e.g., body image, pride in achievements, admiration from others)
Cognitive. The need for knowledge, understanding, and exploration
Aesthetic. The need for symmetry, order, and beauty
Self-actualization. The need to achieve one's potential; the need for growth and change (e.g., extent to which goals are achieved, role performance)

See Chapter 8 for a more complete discussion of Maslow's model.

Nursing Models

Nurse theorists have developed many different theories and models for thinking about nursing, clients, health, and the environment. Nursing models produce a holistic database that is useful in identifying nursing rather than medical diagnoses. Several nursing theories are described in Chapter 8. Table 3-4 identifies the major concepts of five models frequently used to structure nursing assessments. The concepts are the categories that you would use to gather and cluster data.

HOW SHOULD I DOCUMENT DATA?

The ANA *Nursing: Scope and Standards of Practice* (2010) and The Joint Commission standards (2012) stress the importance of documenting patient information, including assessment data, in a retrievable format. Accurate, timely, and clear documentation of all assessment findings benefits patients by providing the basis for planning effective nursing care. Furthermore, since the nursing database is a permanent part of the client's record, documentation protects you, the nurse, by establishing that you actually performed the needed assessments. Malpractice suits are not unusual in our society, and court cases may be presented years after you provide care for a patient. Your documentation is the only evidence supporting the care you gave. The assumption in malpractice cases is, "If it isn't documented, it wasn't done."

Guidelines for Recording Assessment Data

Follow these guidelines when recording assessment data:

- *Document as soon as possible* after you perform the assessment.
- *Write neatly, legibly, and in black ink* or record electronically.

Table 3-4 ➤ Assessment Models: Major Concepts

MODEL	MAJOR MODEL CONCEPTS
Gordon's Functional Health Patterns	Describe common patterns of behavior that can be functional or dysfunctional. Gordon intended the model for nursing assessment. The functional health patterns are major model concepts: Health perception/health Management Nutritional/metabolic Elimination Activity/exercise Cognitive/perceptual Self-perception/self-concept Sleep/rest Role/relationship Coping/stress tolerance Value/belief
Source: Adapted from Gordon, M. (1994). *Nursing diagnosis: Process and application* (3rd ed.). St. Louis, MO: Mosby, p. 70.	
The NANDA-International Nursing Diagnosis Taxonomy II	Consists of functional patterns and is a modified version of the Gordon model. It is intended as a model for categorizing nursing diagnoses, not as a fully developed theory of nursing. The following are the NANDA-I domains (categories): Health Promotion Nutrition Elimination and Exchange Activity/Rest Perception/Cognition Self-Perception Role Relationships Sexuality Coping/Stress Tolerance Life Principles Safety/Protection Comfort Growth/Development
Source: Adapted from NANDA International. (2012). *Nursing diagnoses definitions & classification 2012–2014.* Ames, IA: Wiley-Blackwell.	
The Taxonomy of Nursing Practice (NANDA-I/NOC/NIC)	Intended as a model for categorizing nursing diagnoses, client outcomes, and nursing interventions. It consists of four domains and 28 classes. *Functional Domain* Activity exercise, comfort, growth and development, nutrition, self-care, sexuality, sleep/rest, values/beliefs *Physiological Domain* Cardiac function, elimination, fluids and electrolytes, neurocognition, pharmacological function, physical regulation, reproduction, respiratory function, sensation/perception, tissue integrity *Psychosocial Domain* Behavior, communication, coping, emotional, knowledge, roles/relationships, self-perception *Environmental Domain* Healthcare system, populations, risk management
Source: Dochterman, J. M., & Jones, D. A. (Eds.). (2003). *Unifying nursing languages: The harmonization of NANDA, NIC, and NOC.* Washington, DC: American Nurses Association, NursesBooks.org.	
The Roy Adaptation Model	Conceptualizes patients as adapting constantly to internal and external demands within a biological and psychosocial context. Using this model, you would look at the person's ability to achieve balance in the following "adaptive modes": Activity and rest Nutrition Elimination Fluid and electrolytes Oxygenation Protection Temperature regulation Regulation of the senses Physical self-concept Personal self-concept Role function Interdependence
Source: Adapted from Roy, C., & Andrews, H. (1991). *The Roy adaptation model: The definitive statement.* Norwalk, CT: Appleton & Lange, pp. 15–17; and Roy, C., & Andrews, HA (1999). *The Roy adaptation model* (2nd ed.). Norwalk, CT: Appleton & Lange.

Table 3-4 ➤ Assessment Models: Major Concepts—cont'd

MODEL	MAJOR MODEL CONCEPTS
Orem's Self-Care Model	Conceptualizes health as the ability to perform self-care. Using this model, you would gather data to identify the following universal self-care deficits that require nursing assistance: Maintenance of a sufficient intake of air, water, and food Maintenance of a balance between activity and rest Maintenance of a balance between time alone and time with others Provision of care associated with elimination processes and excrements Prevention of hazards to human life, functioning, and well-being Promotion of human functioning and development within social groups in accord with human potential, limitations, and desire to be normal (as determined by science, culture, and social values)

Source: Adapted from Orem, D. (1991). *Nursing: Concepts of practice* (4th ed.). St. Louis, MO: Mosby-Year Book, p. 126.

- *Use acronyms sparingly,* using only agency-approved abbreviations.
- *Write the patient's own words, when possible*, in quotation marks. If the comments are too long, summarize what the patient says (e.g., Patient states that he is sleepy).
- *Record only the most important patient words*. If you record everything the patient says, the narrative will probably be too long and contain irrelevant data. For example, write "Patient states, 'I hardly slept at all last night,'" even though what the patient actually said was, "I hardly slept at all last night. I tossed and turned and people kept waking me up. Then the thunder and lightning came, and then I had to get up to go to the bathroom, and my wife called early this morning."
- *Use concrete, specific information* rather than vague generalities such as *normal, adequate, good,* and *tolerated well.* For example, what does it mean to say, "Patient slept well"? Did she fall asleep easily and sleep for 6 hours? Did she fall asleep with difficulty, but sleep for 8 hours? Did she sleep only 4 hours, but state that she feels well rested? It is much better to write, "Patient fell asleep before 2100 hr and slept until 0600 hr. She states that she woke up only once during the night and feels rested now. Observed sleeping three times during the night."
- *Record cues, not inferences*. **Cues** are what the client says and what you observe. **Inferences** are judgments and interpretations about what the cues mean. In other words, "just the facts, Jack (or Jill)." When recording cues, you do not need to "waffle" with the words *appears* and *seems.* Don't write "Incision seems red" or "edges appear separated." For example:

Cues	*Inferences*
Incision red, draining pus, edges separated.	Incision is infected.
Tearful. States that father died of a heart attack. Trembling.	Anxious about scheduled cardiac catheterization.
States, "I hate my mother. I wish I was dead."	Patient is angry and suicidal.

Tools for Recording Assessment Data

Each organization has its own forms and formats for documenting initial and ongoing assessments. You will record data on a variety of documents, including nurses' notes and the following:

- *Graphic flow sheet*. Includes vital signs such as blood pressure, pulse, respirations, and temperature so trends over time can be seen clearly (Fig. 3-4).
- *Intake and output (I&O) sheet*. May be on the graphic sheet, as in Figure 3-4, or separate document. This form has spaces for all intake: oral, intravenous, and tube feedings. There is also space to record all output: urine, fluid from drainage tubes, wound drainage, and bowel movements.
- *Nursing admission assessment*. Although agency forms differ in organization, all collect similar data as specified by The Joint Commission for standards for initial assessment. For an example of an admission assessment form,

Go to Chapter 3, **Assessment Forms: Nursing Admission Data Form,** in Volume 2.

- *Nursing discharge summary*. This may be a part of the initial assessment form because data obtained at admission are used for discharge planning.
- *Special-purpose forms*. Examples are diabetic flow sheets and medication administration forms.
- *Electronic documentation*. In some facilities, initial data and ongoing assessment data are entered into a computer program for organization, shared communication, and easy retrieval (Fig. 3-5).

REFLECTING CRITICALLY ABOUT ASSESSMENT

After gathering and recording patient data, use critical thinking to help you evaluate the quality of your assessment. See Chapter 2 for a review of critical thinking, as

needed. The following are questions to guide your final judgments about your data.

1. Are my data complete?
   - Have I completed all areas of the assessment form?
   - Is there anything else I need to know to identify or rule out a nursing diagnosis?
   - Have I collected holistic data: physical, emotional, interpersonal, spiritual, and cultural?
2. How do I know the data are accurate?
3. Have I recorded data rather than conclusions (cues, not inferences)?
4. Did I validate any data that do not make sense? Do any of the data conflict with other data?
5. Did I record the data in clear, specific terms, using the patient's own words, when possible, for subjective data? Did I avoid vague terms such as "normal," "good," and "slept well"?
6. Have I followed up with in-depth special needs assessments when appropriate?
7. Have I included only relevant data, taking care to protect the client's privacy?
8. The assessment interview:
   - Did I use therapeutic communication during the assessment?
   - Did I avoid asking too many questions and using too many closed questions?
   - How comfortable was I during the interview?
   - What signals did I get from the client in response to my questions? Did I follow up?
9. Physical assessment, observation, and examination:
   - Did I miss something in the environment?
   - How did the client and significant others respond to me verbally and nonverbally?
   - Did I pay attention to detail?
   - Were my assessment techniques performed skillfully (palpation, percussion, auscultation, inspection)?
10. Memory:
    - Did I have to ask questions in the sequence found on the forms?
    - Did I have to depend on the forms for all aspects of the assessment?
    - Did I have to repeat any area of assessment because I could not remember what I saw, heard, smelled, or felt?

If you have followed the recommended processes and reflected critically on your assessment, you should have the data necessary to create a holistic plan of care individualized to meet the client's needs.

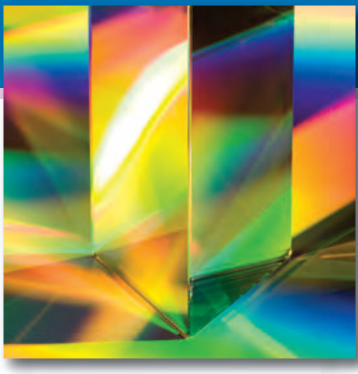
CHAPTER 4



Nursing Process: Diagnosis

Learning Outcomes

After completing this chapter, you should be able to:

- Define the following terms: diagnosis, nursing diagnosis, diagnostic reasoning, diagnostic label, defining characteristics, related factors, risk factors, health problem.
- Explain how nursing diagnosis is related to other phases of the nursing process.
- Differentiate between nursing diagnoses, medical diagnoses, and collaborative problems.
- Explain the differences between actual, risk, possible, syndrome, and wellness nursing diagnoses.
- Describe the diagnostic process.
- Explain why an etiology is always an inference.
- Describe at least two frameworks for prioritizing nursing diagnoses.
- Describe errors of theoretical and self-knowledge that may occur in diagnostic reasoning.
- Use standardized nursing language to write nursing diagnoses.
- Use collaborative problem statements appropriately.
- Explain the relationship between nursing diagnoses and goals/interventions.
- State at least five criteria for judging the quality of a diagnostic statement.
- Discuss issues associated with the NANDA-I diagnostic labels and with standardized language.

Key Concepts

Nursing diagnosis

Diagnostic process (diagnostic reasoning)

Diagnostic format

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patient

On your unit at an acute care facility, you will be admitting a client, Todd, from the emergency department (ED). Todd's ED nurse telephones you to give a report on his status. Todd's admitting medical diagnosis is chronic renal failure. He is married, 58 years old, employed, and has a longstanding history of type 2 diabetes mellitus (DM). In the past 3 days, he has developed decreased sensation in his bilateral lower extremities with slight mobility impairment.

You still have many questions concerning Todd's immediate and long-term needs. You will need to ask Todd about his medication regimen, his compliance with his diabetes treatment plan, and the extent to which his family is involved. You will also need to find out what laboratory tests have been completed and how severe his renal dysfunction has become. After you obtain necessary data, you need to organize and analyze it to form some initial impressions about what it means. For example:

- Admitting diagnosis is chronic renal failure; anticipate a problem with fluid balance.
- Admitted to the hospital and is acutely ill; therefore, he may be anxious and fearful.
- Decreased sensation in lower extremities; patient may have a mobility and a safety problem.

(continued)

Meet Your Patient (continued)

- Diabetes; patient is at risk for impaired skin and tissue integrity.
- Diabetes and renal failure require complex regimens and patient self-care; therefore, it is possible that Todd may not be managing his therapy effectively, because he either is not motivated to do so or he lacks the knowledge he needs to comply with treatment.

When Todd and his family arrive on your unit, you begin gathering additional data. Using your comprehensive data, you then make a list of Todd's health problems, in order of priority. These actions illustrate the diagnosis phase of the nursing process. The purpose of diagnosing is to identify the client's health status, from which you will create an individualized plan of care.

Theoretical Knowledge knowing why

Professional standards of nursing practice, as well as many state nurse practice acts, identify diagnosing as the unique obligation of the professional nurse (Box 4-1). Although many nursing activities may be delegated, diagnosis cannot. To meet practice expectations and professional obligations as a registered nurse, you will assume the role of diagnostician and make clinical judgments. Most state nurse practice acts limit the role of the licensed practical nurse (LPN/LVN) to gathering data that will be analyzed by the RN. However, LPN roles vary among states and agencies, and they are subject to change. Furthermore, LPN and RN roles are becoming more closely linked through statewide career ladder programs. Therefore, all clinicians need to stay current with updates in practice acts and standards.

BOX 4-1 ■ Professional Standards for Diagnosing

American Nurses Association Standards of Nursing Practice

Standard 2. Diagnosis

The registered nurse analyzes the assessment data to determine the diagnoses or issues.

Competencies

The registered nurse:

- Derives the diagnoses or issues from assessment data.
- Validates the diagnoses or issues with the healthcare consumer, family, and other healthcare providers when possible and appropriate.
- Identifies actual or potential risks to the healthcare consumer's health and safety or barriers to health, which may include but are not limited to interpersonal, systematic, or environmental circumstances.
- Uses standardized classification systems and clinical decision support tools, when available, in identifying diagnoses.
- Documents diagnoses or issues in a manner that facilitates the determination of the expected outcomes and plan.

Note: There are additional measurement criteria for advanced practice registered nurses.

Source: American Nurses Association. (2010). *Nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Nursebooks.org.

ABOUT THE KEY CONCEPTS

Nursing diagnosis is the single concept in this chapter that ties all the other concepts together.

The *diagnostic process* (also called *diagnostic reasoning*) represents the thinking aspect of nursing diagnosis, and the *diagnostic format* is the concrete product. Other, related, concepts will clarify what is *not* a nursing diagnosis, explain various types of nursing diagnoses, and expand on the concept of diagnostic format.

DIAGNOSIS: THE SECOND STEP OF THE NURSING PROCESS

After gathering the data you will use your critical-thinking skills to analyze the data—that is, identify patterns in the data and draw conclusions about the client's health status. This describes **nursing diagnosis,** the second step of the nursing process. As in all phases of the nursing process, involve the patient and family as much as possible.

Overlapping As you can see in Figure 4-1, diagnosis overlaps with the other nursing process steps. Most nurses actually begin diagnostic reasoning during the assessment phase. For example, you probably formed your initial impressions about Todd while you were still gathering data. On learning the medical diagnosis, chronic renal failure, you would have immediately considered the diagnosis Risk for Imbalanced Fluid Volume, but you would have obtained more data before actually recording that as a nursing diagnosis. So your tentative diagnostic conclusion would actually lead you to collect more data: *Is he still producing urine? What is his oral intake? Does he have edema?* Do you see how you would move back and forth between assessment and diagnosis? The two stages are not separate at all, but we present them that way to make it easier for you to learn.

Diagnosis is critical because it links the assessment step, which precedes it, to all the steps that follow it (Fig. 4-2). Assessment data must be complete and

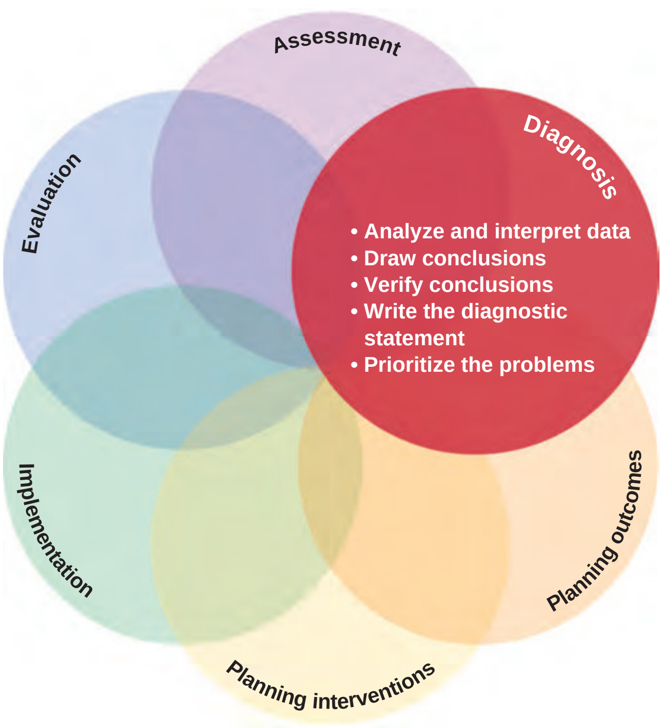


FIGURE 4-1 Nursing diagnosis: Second phase of the nursing process.

accurate for you to make an accurate nursing diagnosis. **Key Point:** ***Nursing diagnosis is the basis for planning client-centered goals and interventions, so accuracy is essential.***

Terminology The term **diagnosis** is used in the nursing literature to refer to:

- The second phase of the nursing process
- The reasoning process used in interpreting assessment data
- A formal diagnostic statement of the client's health status, containing both the problem and etiology (factors contributing to the problem)
- The list of standardized terms (labels) used to write diagnostic statements. Those terms are actually problem labels; you must add a second part (etiology) in order to create a complete diagnostic statement. To see the entire list of NANDA-I diagnostic labels,

Go to Student Resources: Student 4, **Standardized Language, NANDA-I Taxonomy II: Domains, Classes, and Diagnoses (Labels),** on Davis*Plus*.

Table 4-1 summarizes and provides examples of how we use nursing diagnosis terminology in this text.

What Are the Origins of Nursing Diagnosis?

Before the 1950s, nurses assisted physicians by collecting data to help them diagnose and treat disease. Nursing care was thought of as a set of tasks and organized as a list of things to do. The term *nursing diagnosis* was first used in 1953 to differentiate nursing from medicine, when Fry (1953) stated that a nursing diagnosis identifies the client's needs for nursing rather than for medical care. Until the early 1970s, nursing diagnosis was not widely used in nursing practice, but two major events in 1973 spurred change:

- The First Conference on Nursing Diagnosis was held (Gebbie, 1976). A national task force was formed to begin developing a language to describe the health problems treated by nurses.
- The American Nurses Association (ANA) *Standards of Nursing Practice* included nursing diagnosis as an expectation of professional nurses.

In 1980, the ANA published *ANA Social Policy Statement*, which characterized nursing as "the diagnosis and treatment of human response to actual or potential health problems" (ANA, 1980, p. 2). As a result of this definition and the work of the nursing diagnosis task force, most state nurse practice acts began to designate nursing diagnosis as an exclusive responsibility of registered nurses. Nursing diagnosis is now widely used in nursing education and practice. **Key Point:** ***The formal list of nursing diagnostic labels describes health problems that can be addressed by independent nursing actions and, in that sense, forms the body of knowledge that is unique to nursing.***

Since the first conference, the nursing diagnosis group has continued to meet every 2 years. In 1982 it adopted the name North American Nursing Diagnosis Association (NANDA). In 2002 the organization changed its name to NANDA International (NANDA-I), to reflect its large number of members from countries outside the

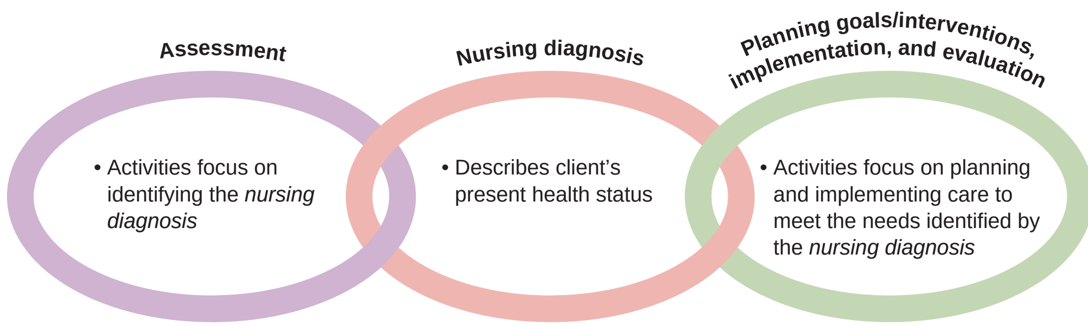

FIGURE 4-2 Diagnosis links the assessment phase to the rest of the nursing process.

Table 4-1 ➤ Nursing Diagnosis Terminology

TERM AND EXISTING MEANINGS	TERMINOLOGY USED IN THIS BOOK	EXAMPLE
Diagnosis		
1. The second phase of the nursing process 2. The reasoning process used in identifying patient problems and strengths	1. Diagnosis 2. Diagnostic process, diagnostic reasoning, or diagnosing	With Todd (Meet Your Patient), you used *diagnostic reasoning* to *diagnose* and list his problems. This was the *diagnosis phase* of the nursing process.
Nursing Diagnosis		
1. The end product of the diagnostic reasoning process: a full diagnostic statement describing client health status. It contains both problem and etiology. 2. A standardized problem label from the NANDA-I taxonomy (e.g., Anxiety)	1. Nursing diagnosis, diagnostic statement 2. Label, NANDA-I label, problem label, diagnostic label	For Todd, you might have made a *nursing diagnosis* of Excess Fluid Volume secondary to renal failure. To write that statement, you would have used the *NANDA-I label* Fluid Excess Volume.

United States and Canada. NANDA-I continues to review and refine the diagnostic labels and to discuss new and revised labels at each biannual conference. The diagnoses on the official list are approved for clinical use and further study; the list is not intended to represent a finished product, because many of the diagnoses are only partially substantiated by research. NANDA-I encourages individual nurses and nursing organizations to submit new and revised diagnoses.

KnowledgeCheck 4-1

- Why is the diagnosis step so critical to the other phases of the nursing process?
- Which two nursing organizations have been responsible for making diagnosis a part of the professional nursing role?

What Are Health Problems?

A **health problem** is any condition that requires intervention to promote wellness or to prevent or treat disease or illness. After you identify a health problem, you must decide how to treat it: independently or in collaboration with other health professionals. The answer determines whether it is a nursing diagnosis, a medical diagnosis, or a collaborative problem. See Table 4-2 for a comparison of these problem types.

Recognizing Nursing Diagnoses

A **nursing diagnosis** is a statement of client health status that nurses can identify, prevent, or treat independently. It is stated in terms of **human responses** (reactions) to disease, injury, or other stressors, and it can be either a problem or a strength. Human responses can be biological, emotional, interpersonal, social, or spiritual. For example, in the Meet Your Patient scenario, Todd's medical diagnosis is chronic renal failure. A *physical response* to renal failure might be Excess Fluid Volume. Admission to the ED is also a stressor, to which his *emotional response* might be Anxiety or Fear. What other actual or possible responses were identified for Todd in the situation? Take a moment to write them down.

Recall that Todd has decreased sensation in his lower extremities. This is a stressor, to which he has responded with slightly impaired mobility. Perhaps you identified that because of diminished feeling in his feet, Todd might be at risk for falling (safety), impaired skin or tissue integrity, and ineffective management of his therapy. All of those are responses to disease, illness, or stressors. Also note that in addition to being a stressor, the decreased sensation in Todd's lower extremities can be considered a physical response to type 2 DM. Was this response on the list you just made?

ThinkLike a Nurse 4-1

Imagine that you have been in an automobile accident. You have internal injuries and broken bones and will be hospitalized for at least 2 weeks, right before your final exams. What human responses (physical, emotional, interpersonal, social, spiritual) would you have?

NANDA-I officially defines *nursing diagnosis* as "a clinical judgment about individual, family, or community experiences/responses to actual or potential health problems/life processes. A nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse has accountability" (approved at the ninth NANDA conference; amended in 2009) (NANDA-I, 2012, p. 514). This definition emphasizes the clinical judgment aspect of diagnosing.

Recognizing Medical Diagnoses

Todd has two medical diagnoses: chronic renal failure and type 2 DM. A **medical diagnosis** describes a disease, illness, or injury. Its purpose is to identify a pathology so that appropriate medical treatment can be given. A medical diagnosis is more narrowly focused than is a nursing diagnosis.

Table 4-2 ➤ Comparison of Nursing Diagnoses, Medical Diagnoses, and Collaborative Problems

	NURSING DIAGNOSIS	MEDICAL DIAGNOSIS	COLLABORATIVE PROBLEM
Definition	A clinical judgment about individual, family, or community responses to a health problem	Disease, illness, injury, or condition validated by signs and symptoms and medical diagnostic studies	Certain potential physiological complications that are always associated with a disease, test, or treatment
Focus	The individual/person	Disease, pathology, and medical treatments/procedures	Pathophysiology (complications caused by the disease process)
Characteristics	Holistic; describes physiological, psychological, social, interpersonal, and spiritual responses	Describes disease or pathology; does not consider the broader range of human responses	Describes potential physiological complications only; not holistic
Who Diagnoses?	Professional nurse	Physicians, advanced practice nurses, physician's assistants	Nurses
Who Orders Treatment?	Professional nurse, primarily	Physician, advanced practice nurse, physicians' assistants	Physician prescribes primary interventions; however, the nurse can order some as well.
Problem Status	Can be actual, potential, or possible	Actual or possible (rule out)	Always potential; if the problem actually develops, it is then a medical diagnosis.
Purpose of Nursing Interventions	Treat or prevent the problem; relieve the symptoms	Carry out medical prescriptions for treatment; monitor for improvement or worsening of the condition.	Monitor for development of the complication; institute some, but not all, preventive interventions.
Example of Diagnostic Statement	Ineffective Denial related to difficulty coping with new diagnosis of "heart attack"	Myocardial infarction	Potential Complication of myocardial infarction: congestive heart failure
Example of Data to Support the Diagnosis	Waited more than 6 hours before coming to hospital. Minimizes symptoms, refuses pain medications. States, "I've got to get back to work. I can't stay in the hospital." Laughing, joking, saying, "It's nothing."	Cardiac enzyme levels elevated; has had severe chest pain; elevated white blood cell count; electrocardiogram (ECG) and echocardiogram diagnostic of cardiac muscle ischemia	58-year-old man with diagnosis of myocardial infarction (MI); acknowledges chest pain; ECG and lab work diagnostic of MI

Key Point: ***Except for advanced practice nurses, nurses cannot legally diagnose or treat medical problems.*** Your assessment data will help the medical team to identify disease states and evaluate the effects of medical therapies. For example, if your assessment indicates that a medication does not adequately relieve a patient's pain, you would inform the primary care provider, who would prescribe a different medication or dosage. You need to know the pathophysiology of the patient's illness to understand and evaluate the effects of medical treatments and to know how to focus your assessments. The following are differences between medical and nursing diagnoses:

- **You cannot predict a patient's nursing diagnoses just by knowing his medical diagnosis or pathology.** Nursing diagnoses are human responses, which are complex and unique to each person. A medical diagnosis, in contrast, remains the same as long as a particular injury or pathology is present. In the Meet Your Patient scenario, Todd's medical diagnosis of type 2 DM will not change, because the fact that his body cannot use glucose normally will not change. This is not true for nursing diagnoses. Suppose Todd has a nursing diagnosis of Noncompliance with diabetic diet r/t (related to) lack of knowledge about food groups. If he learned about the foods and began following his diet, he would no longer have this nursing diagnosis. But he would still have the medical diagnosis of type 2 DM.
- **A medical diagnosis, disease, or pathological condition can have any number of nursing diagnoses associated with it.** For example, in response to his type 2 DM, Todd might have nursing diagnoses of Noncompliance and Risk for Impaired Skin Integrity.
- **Clients with the same medical diagnosis may have different nursing diagnoses.** Another client with type 2 DM may not have a diagnosis of Noncompliance,

but instead may have a diagnosis of Ineffective Denial because he simply cannot accept that he truly has diabetes. Other patients with type 2 DM might have diagnoses of Anxiety, Deficient Knowledge, Disturbed Body Image, and perhaps others, depending on their unique responses to the stressor, type 2 DM.

Recognizing Collaborative Problems

Collaborative problems are "certain physiologic complications [of diseases, medical treatments, or diagnostic studies] that nurses monitor to detect onset or changes in status" (Carpenito, 2006, p. 19). They have the following characteristics:

- **All patients who have a certain disease or medical treatment are at risk for developing the same complications.** That is, the collaborative problems (complications) are determined by the medical diagnosis or pathology. Consider these examples:
  Todd, because he has type 2 DM, has the collaborative problem Potential Complication of type 2 DM: hyperglycemia and/or hypoglycemia. All other patients with type 2 DM also have those potential complications.
  All patients having surgery have the collaborative problem Potential Complication of surgery: infection.
  Use your theoretical knowledge of anatomy, physiology, microbiology, pathophysiology, and so on as the basis for identifying the complications associated with a particular disease or treatment.
- **A collaborative problem is always a potential problem.** If it becomes *actual,* then it is no longer a collaborative problem, but a medical diagnosis requiring physician interventions. Consider what would be needed if the preceding potential complications became actual problems:
  Actual hyperglycemia (high blood glucose) or actual hypoglycemia (low blood glucose)
  Actual infection of a surgical incision
  Either condition would require medical intervention to prevent serious harm to the patient.
- **If you can prevent the complication with independent nursing interventions alone, it is not a collaborative problem.** Collaborative problems require both medical and independent nursing interventions to prevent them or minimize the complications. The purpose of independent nursing interventions is primarily to monitor for onset of the complication, although nurses can provide some independent preventive measures.

See Figure 4-3 for an algorithm to help you differentiate nursing diagnoses from medical diagnoses and collaborative problems.

KnowledgeCheck 4-2

State whether each of the following represents a nursing diagnosis, medical diagnosis, or collaborative problem:

- After giving birth, all women are at risk for developing postpartum hemorrhage.
- A patient has signs and symptoms of appendicitis, which must be treated with surgery and antibiotics.
- A client is at risk for constipation because he postpones defecation and also does not consume enough dietary fiber and fluids. The problem can be prevented by patient teaching, which the nurse is licensed to do.

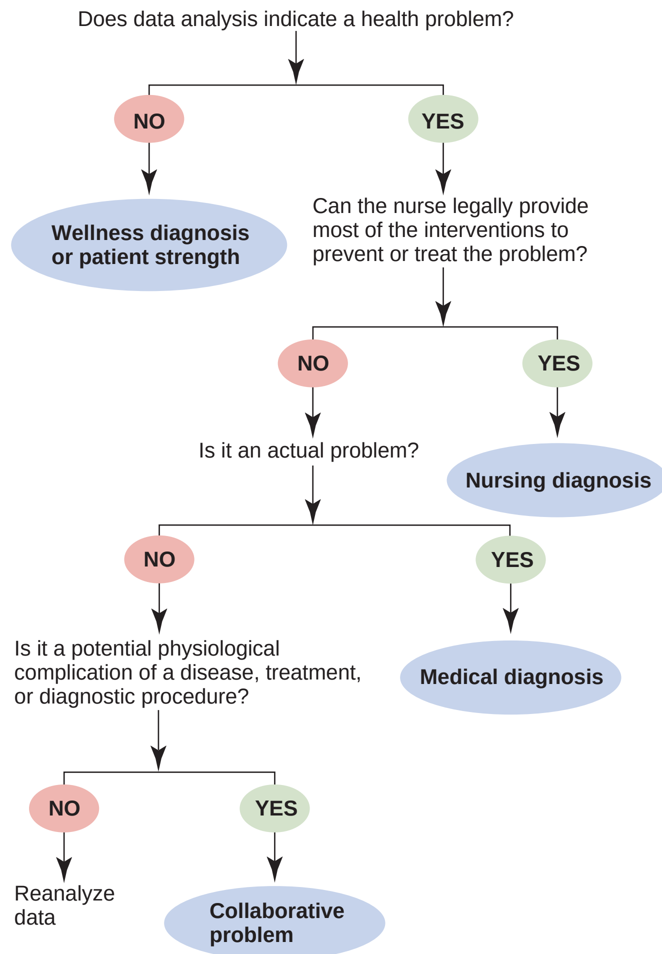

FIGURE 4-3 Algorithm for distinguishing among nursing, medical, and collaborative problems.

Types of Nursing Diagnoses

You must determine the status, or type, of each nursing diagnosis: Is it an actual, risk (potential), possible, syndrome, or wellness nursing diagnosis? Figure 4-4 provides an algorithm for determining the type of diagnosis, and Table 4-3 compares the diagnosis types. Identifying the type is important because each status requires (1) different wording in the diagnostic statement and (2) different nursing interventions.

KnowledgeCheck 4-3

- What are the five types (statuses) of nursing diagnoses?
- What type of nursing diagnosis is each of the following?
  a. Jane Thomas regularly engages in exercise but tells you she would like to increase her endurance.
  b. Mrs. King has several of the signs and symptoms (defining characteristics) of the nursing diagnosis Ineffective Coping.

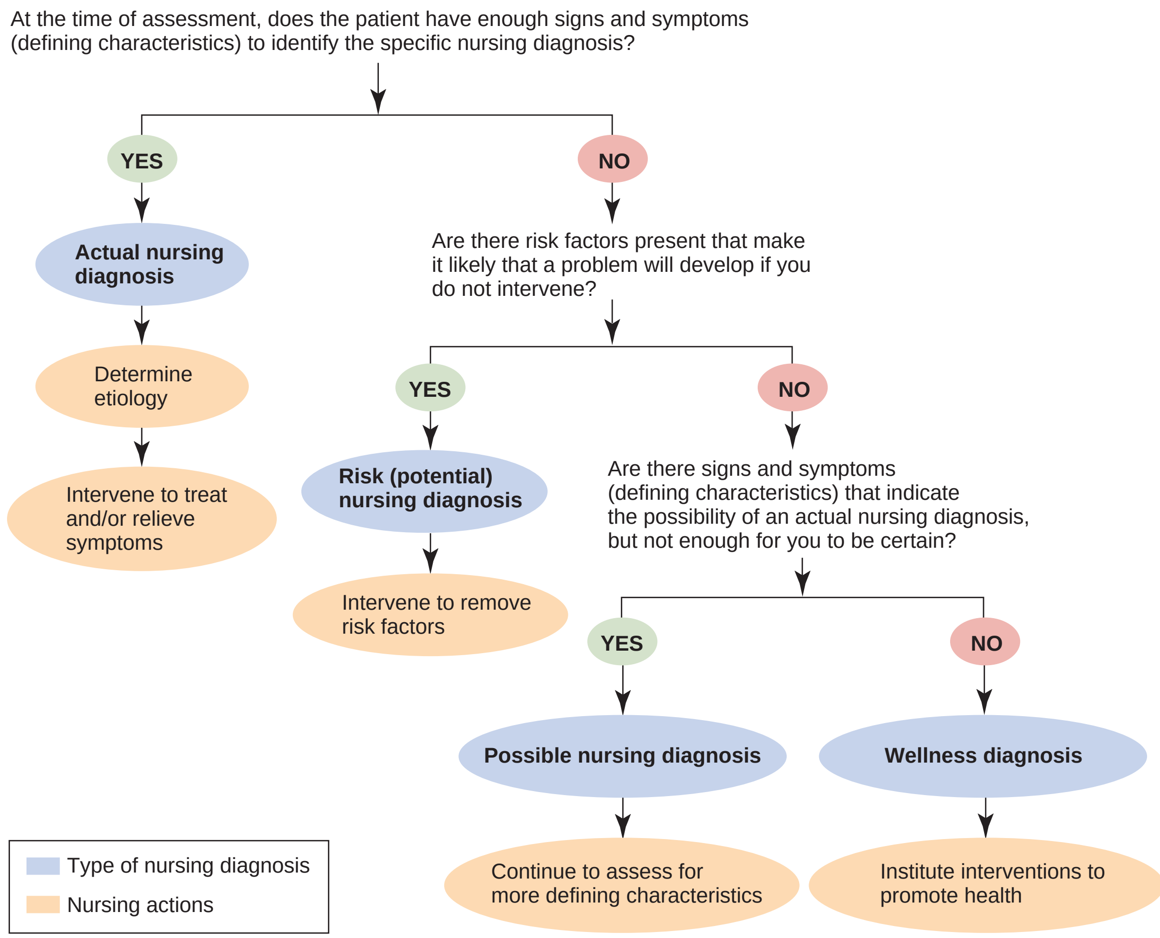

FIGURE 4-4 Algorithm for determining whether a nursing diagnosis is an actual diagnosis, a risk (potential) diagnosis, a possible diagnosis, or a wellness diagnosis.

c. Alicia Hernandez seems anxious, but you are not sure whether she actually is. You would like to have more data in order to diagnose or rule out a diagnosis of Anxiety.
d. Charles Oberfeldt has no symptoms of constipation. However, he reports that he does not include many fiber-rich foods in his diet and drinks few liquids. In addition, he is now fairly inactive because of a back injury. These are all risk factors for a diagnosis of Constipation.

WHAT IS DIAGNOSTIC REASONING?

A comprehensive patient assessment produces a great deal of data. **Diagnostic reasoning** is the thinking process that enables you to make sense of it. This text presents diagnostic reasoning (also referred to as **analysis**) in separate steps so that it is easier to learn, but that is not the way it really occurs (Fig. 4-5). When you first begin to use diagnostic reasoning, follow the steps in the order presented so that you will not miss anything. But just as you move back and forth between assessing and diagnosing, you will soon find yourself moving back and forth among the steps of diagnostic reasoning, skipping steps, returning to previous steps, and doing some steps simultaneously.

In diagnostic reasoning, you will use your critical thinking to analyze and interpret data, draw conclusions about the patient's health status, verify problems with the patient, prioritize the problems, and record the diagnostic statements.

Analyze and Interpret Data

As you analyze and interpret the data, you will gradually narrow the quantity of data you must deal with. But even as you narrow the field of data to the significant points and patterns, you will note the need for new information and further assessments. To analyze and interpret data, follow three steps: (1) Identify significant data, (2) cluster cues, and (3) identify data gaps and inconsistencies.

Step 1. Identify Significant Data

Significant data (also called **cues**) are data that influence your conclusions about the client's health status. A cue should alert you to look for other cues that might be related to it (form a pattern). You may be thinking, "How will I recognize a cue?"

Table 4-3 ➤ Types of Nursing Diagnoses: Actual, Risk, Possible, Syndrome, and Wellness

DIAGNOSIS TYPE	DEFINITION AND CHARACTERISTICS	MEET YOUR PATIENT OR OTHER EXAMPLE
Actual Nursing Diagnosis: Problem Is Present	▪ A problem response that exists at the time of the assessment ▪ Signs and symptoms (cues) that are present	Todd (Meet Your Patient) may have at least one actual nursing diagnosis (Impaired Walking or perhaps Impaired Physical Mobility), related to his lack of peripheral sensation; however, no signs and symptoms were given in the scenario to support that diagnosis.
Risk (Potential) Nursing Diagnosis: Problem May Occur	▪ A problem response that is likely to develop in a vulnerable patient if the nurse and patient do not intervene to prevent it ▪ No signs/symptoms of the problem, but the risk factors are present that increase the patient's vulnerability ▪ The patient is more susceptible to the problem than others in the same or a comparable setting (e.g., one who is undernourished or who has a compromised immune system).	1. Todd's (MYP) loss of lower limb sensation is a risk factor for a diagnosis of Risk for Falls even though Todd has no symptoms or history of falling. 2. All surgical patients have at least some risk for developing infection, so do not routinely write Risk for Infection on every surgical care plan. Instead, write Potential Complication of surgery: infection (incision and systemic).
Possible Nursing Diagnosis: Problem May Be Present	▪ Use when your intuition and experience direct you to suspect that a diagnosis is present, but you do not have enough data to support the diagnosis. The main reason for including this type of diagnosis on a care plan is to alert other nurses to continue to collect data to confirm or rule out the problem.	Todd (MYP) has a symptom, mildly impaired mobility. This could indicate the diagnoses Impaired Physical Mobility, Impaired Walking, or Risk for Falls. You need more data to decide which nursing diagnosis is appropriate, so you might write a nursing diagnosis of Possible Risk for Falls related to decreased sensation in both legs.
Syndrome Nursing Diagnosis: Several Related Problems Are Present	▪ Represents a collection of nursing diagnoses that usually occur together. ▪ Use when you notice that the patient has more than one nursing diagnosis with the same etiology (cause, contributing factors).	The NANDA-I label Risk for Disuse Syndrome is used to represent all the complications that can occur as a result of immobility (e.g., pressure ulcer, constipation, stasis of pulmonary secretions, thrombosis, body image disturbance).
Wellness Nursing Diagnosis: No Problem Is Present	▪ Describes health status, but does not describe a problem; can apply to an individual, family, group, or community ▪ Use when the client is in transition from one level of wellness to a higher level ▪ Two conditions must be present: 1. The client's present level of wellness is effective. 2. The client wants to move to a higher level of wellness.	Suppose that Todd (MYP) tells you that he prays, participates in religious activities, and trusts in God, but he would like to feel even closer to God. He asks to meet with the minister from his church. You might make a diagnosis of Readiness for Enhanced Spiritual Well-Being.

A cue is usually an unhealthy response. One way to recognize cues is to draw on your theoretical knowledge (e.g., of anatomy, physiology, psychology) and compare each piece of data with standards and norms. For example, suppose you have noted that a woman's pulse rate is 110 beats/min. Is this an unhealthy response—a cue? You would of course use as one standard the average rate (80 beats/min) and normal range (60–100 beats/min) for an adult pulse. But this woman is a long-time cigarette smoker who also drinks coffee and caffeinated energy

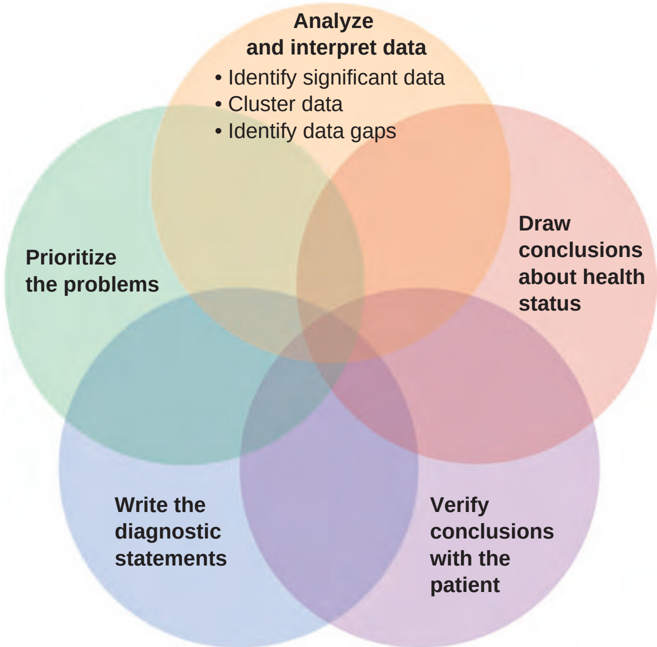

FIGURE 4-5 The process of diagnostic reasoning.

drinks. These habits increase pulse rate, so 110 beats/min may be a normal finding for this client. See Box 4-2 for other indications of cues.

KnowledgeCheck 4-4

- What is a cue?
- What are five ways you can recognize a cue?

Step 2. Cluster Cues

A **cluster** is a group of cues that are related to each other in some way. The cluster may suggest a health problem. To help ensure accuracy, you should always derive a nursing diagnosis from data clusters rather than from a single cue.

Consider this example: Alma was transferred to the hospital from a long-term care facility. Because of a CVA (cerebrovascular accident, or stroke), Alma can make sounds but cannot speak; and because of joint contractures, she cannot use her hands and arms. Alma is frequently incontinent of urine, so the nurses have diagnosed Overflow Urinary Incontinence and are resigned to the idea that Alma will not be able to control her urine. Because Alma makes loud vocal noises, they have placed her in a room near the nurses' station. When a nursing student is assigned to the care for Alma, the student looks for cues in addition to urinary incontinence. The student notices that Alma is often incontinent after loud vocalizing. She sees a pattern in these cues: urinary incontinence, cannot use hands and arms, and cannot communicate verbally. The student changes the nursing diagnosis to Self-Care Deficit: Toileting related to immobility and inability to communicate the need to void. After the student provides a call device that fits under Alma's arm, Alma is able to press the device and call the nurse when she needs to void. She is no longer incontinent of urine.

BOX 4-2 ■ Recognizing Cues

The following may indicate cues.

A deviation from population norms

Example: For a well-conditioned athlete who is not a smoker, a baseline heart rate of 120 beats/min would probably be an unhealthy response (cue). But remember that in addition, you must always consider whether the response is normal for the patient or the situation.

Changes in usual health patterns not explained by developmental or situational changes

Example: What change has Todd (Meet Your Patient) experienced in the 3 days before admission to the ED? Is there any developmental or situational explanation for his decreased sensation and mobility? No. It is an unhealthy response: a cue.

Indications of delayed growth and development

Example: A 17-year-old girl has not yet experienced menses, her breasts are just barely developed, and she has very scant pubic and underarm hair.

Changes in usual behaviors in roles or relationships

Example: During her first year at college, a previously successful student begins to skip classes. She stays up late partying and sleeps most of the day. She no longer keeps in contact with her friends, and despite a previous close relationship with her parents, she barely talks to them when they contact her.

Nonproductive or dysfunctional behavior

This may or may not be a change in behavior. It could be a long-standing dysfunctional behavior.

Example: A man has been abusing alcohol for many years, even though it is causing many problems with his family and job and has begun to damage his liver.

Source: Adapted from Gordon, M. (1994). *Nursing diagnosis: Process and application* (3rd ed.). St. Louis, MO: C.V. Mosby.

ThinkLike a Nurse 4-2

For each of the following cue clusters, decide whether the cues represent a pattern; that is, are all the cues related in some way? If so, explain how they are related. If not, state which cue does not fit. If you do not have enough theoretical knowledge to know for sure, draw on your past experiences and discuss the clusters with other students.

a. Dry skin, abnormal skin turgor (more than 4 seconds), thirst, and scanty, dark yellow urine
b. Pain and limited range of motion in knees, uses walker, medical diagnosis of osteoarthritis
c. Hard, painful bowel movement about every 3 days; does not exercise regularly; eats very little dietary fiber; skin is dry.

Clustering data forces you to think about the relationships between the cues. For item (c) in the preceding example, you would think, "What might cause hard, painful bowel movements? I know that dietary fiber promotes peristalsis, so lack of fiber might contribute to constipation. And I remember that lack of exercise is associated with constipation. I don't see how dry skin would be related to constipation."

Step 3. Identify Data Gaps and Inconsistencies

As you cluster and think about relationships among the cues, you will identify the need for data that was not apparent before. In Think Like a Nurse item (c), you have enough data to support a diagnosis of Constipation. However, you still need to identify factors contributing to the problem. You have two: lack of dietary fiber and lack of exercise. But you should also ask about other causes of Constipation. Does the patient postpone defecation? Does he have a history of relying on laxatives? How much fluid does the client drink? (For example, Todd's skin is dry [Meet Your Patient]. Could that be because he is fluid deficient?)

Data Gaps As another example, look again at Todd's data. Except for medical diagnoses, there are very few data. The following data gaps exist:

- His admitting diagnosis, chronic renal failure, suggests the possibility of fluid imbalance; however, there are no other data to support that. What is his intake? His output? His skin turgor? The appearance of his urine? Does he have edema? Does he complain of thirst? What are his hemoglobin and hematocrit levels?
- Admission to the ED could cause Anxiety. To pursue that line of thinking, observe for physical and verbal symptoms of Anxiety.
- Decreased sensation in his lower extremities might create mobility or safety problems. You would need to know the degree of sensation loss and the exact meaning of "slight loss of mobility" to determine whether to focus on the mobility or the safety issue.
- The effect of diabetes on circulation and skin certainly places Todd at risk for skin problems. However, you need more data to determine whether he has any actual skin problems (e.g., presence or history of sores on his feet).

Inconsistencies In addition to missing data, look for inconsistencies in the data. Suppose a client tells you, "I really don't eat much. Three meals a day, and I don't snack between meals." However, she is 5 ft tall and weighs 190 lb. This seems inconsistent because your theoretical knowledge tells you that obesity is often caused by excessive intake of calories. Even though there are many causes for overweight, you wonder if someone could be so much overweight without "eating much." You would need more specific data about what this client actually eats, so consider having her keep a food diary of everything she eats for a week or two. What else would you want to know? For example, does she have any medical problems that might cause obesity (e.g., hypothyroidism)? Is there any reason she might not want to tell you the truth about her eating pattern? Does she know the number of calories in various foods? Is she actually aware of how much she is eating? More data will help answer your questions.

Draw Conclusions About Health Status

After clustering cues and collecting any missing data, the next step is to begin drawing conclusions about the patient's health status—strengths as well as problems. Decide which one of the following the cluster represents:

- *Nursing Diagnosis: Possible, actual, risk, or wellness* (see Table 4-3)
- *Medical diagnosis.* Nurses are not licensed to make medical diagnoses. If you recognize signs and symptoms suggestive of a medical diagnosis, refer the patient to a physician for diagnosis and treatment.
- *Collaborative problem.* The client's medical diagnosis or treatment indicates the need to monitor for development of complications and to take some measures to prevent the complication, but you cannot prevent or treat the problem independently.
- *Patient strength.* If data seem to meet standards and norms, you can conclude the patient has a strength in that area. For example, Todd's strengths might be his marital status, family involvement, and employment status.
- *No problem.* If data seem to meet standards for normal and no nursing interventions are needed, you can conclude no problem exists in that area. If, in addition, the patient expresses the wish to achieve a higher level of wellness, you would make a wellness diagnosis.

Step 1. Make Inferences

Making inferences is a critical-thinking skill. Recall that cues are facts (or data), whereas inferences are conclusions (judgments, interpretations) that are based on the data. An inference is not a fact, because you cannot directly check its truth or accuracy. For example:

Fact:	Patient is crying. (You can observe that directly.)
	Patient is trembling. (You can observe that directly.)
Inference:	Patient is anxious. (You cannot observe anxiety, but you know that crying and trembling may be signs of anxiety.)

Even though you can never be completely sure that an inference is accurate, clearly some inferences are supported by more complete and reliable data than others. In the preceding example, suppose you said to the patient, "You seem upset. Can you tell me what's going on?" And the patient replied, "I've never been in the hospital before. So much has been happening, I guess I'm just anxious about everything." Now you have enough data to support your inference, and you can be reasonably sure that it is accurate (valid). But remember, you can't be absolutely certain. For example, although it is unlikely, the patient might be exaggerating or not telling you the truth. Perhaps she is crying because her husband said hurtful things to her, and she is too embarrassed to share that with you. Or perhaps she is a spy and is trying to divert your attention while an accomplice finds the hospital's hidden secrets. Yes, that is far-fetched, but that exaggerated example should convince you that an inference—even one that appears to be more valid than this one—is not a *fact*.

Key Point: ***Nursing diagnoses, because they are inferences, are only your reasoned judgment about a patient's health status. So try not to think of a diagnosis as being right or wrong, but instead as more accurate or less accurate. Realize that you can never construct a perfect diagnosis, but strive to make your diagnostic statements as accurate as possible. Incorrect diagnoses result in ineffective care.***

KnowledgeCheck 4-5

- What are the possible conclusions you can draw about a client's health status (e.g., that no problem exists)?
- What is the difference between a cue and an inference?
- How can you be satisfied that you have made a valid inference?

Step 2. Identify Problem Etiologies

An **etiology** consists of the factors that are causing or contributing to the problem. Etiologies may be pathophysiological, treatment related, situational, social, spiritual, maturational, or environmental. It is important to correctly identify the etiology because it directs the nursing interventions. Consider this nursing diagnosis:

Constipation related to inadequate intake of dietary fiber

The etiology suggests that you encourage the client to eat more high-fiber foods. You might also teach the client about foods that are high in fiber. But what if that etiology is incomplete? What if you overlooked the fact that the client does not drink enough fluids? Or that he gets very little exercise? And what if you didn't realize that he often postpones defecation because he is a kindergarten teacher in a crowded, bustling classroom, and he simply cannot leave the children unattended except at scheduled times? In that case, your efforts to increase intake of high-fiber foods would probably not help relieve the client's constipation.

To identify the etiology of a health problem, use your theoretical knowledge (e.g., of psychology, physiology, disease processes) and the patient data to answer questions such as the following:

- What factors are known to cause this problem?
- What patient cues are present that may be contributing to this problem?
- How likely is it that these factors are contributing to the problem?
- What past experiences do I have that support my judgment that these factors are linked to the problem?
- Are these cues *causing* the problem, or are they merely *symptoms* of the problem?

Key Point: ***An etiology is always an inference because you can never actually observe the "link" between etiology and problem.*** For example, in the preceding Constipation diagnosis, you could measure (observe) the person's fiber intake. You could also observe infrequent, hard stools (Constipation). But you cannot observe that the lack of fiber is the cause of the Constipation. You have to infer that link based on your knowledge of normal elimination and your experiences with other patients.

ThinkLike a Nurse 4-3

- How would your nursing interventions be different for the following diagnoses?
  a. Constipation related to lack of knowledge about laxative use
  b. Constipation related to weak abdominal muscles secondary to long-term immobility
- How would your nursing interventions be different for the following diagnoses?
  a. Ineffective Breastfeeding related to lack of knowledge about breastfeeding techniques
  b. Ineffective Breastfeeding related to inability of infant to latch on to the breast and to coordinate sucking and swallowing, secondary to prematurity

Verify Problems With the Patient

After identifying problems and etiologies, verify them with the patient. A diagnostic statement is an interpretation of the data, and the patient's interpretations may differ from yours. For example, if you have diagnosed Ineffective Breastfeeding related to lack of knowledge about breastfeeding techniques, you might verify it by saying, "It seems to me you are having difficulty breastfeeding your baby because you are not sure how to position him and get him to latch on to your breast. Does this seem accurate to you?" The woman might confirm your diagnosis, or she might say, "No. I *do* know how to do it; I am just tired and a little nervous with you watching me." Think of nursing diagnoses as tentative, and remain open to changing them based on new data or insights from the patient.

Prioritize Problems

Up to this point, the diagnostic process has focused on identifying and validating health problems. However, clients often have more than one problem, so you must use nursing judgment to decide which ones to address first and which it is safe to address later. This is **prioritizing**. Prioritizing places the problems in order of importance, but it does not mean you must resolve one problem before attending to another.

You will usually prioritize problems when you are recording them. You can indicate the priority by designating each problem as high, medium, or low priority or by ranking all the problems in order from highest to lowest (i.e., 1, 2, 3, and so on). For example:

Labeling Each Problem	*Ranking the Problems*
Pain (high)	1—Risk for Falls
Risk for Falls (high)	2—Pain
Chronic Low Self-Esteem (low)	3—Imbalanced Nutrition
Imbalanced Nutrition (medium)	4—Chronic Low Self-Esteem

Notice that risk problems can have a higher priority than actual problems. In this example, it is more urgent to prevent falls than to treat low self-esteem.

Problem priority is largely determined by the theoretical framework you use (e.g., whether your criteria are human needs, problem urgency, future consequences, or patient preference).

Maslow's Hierarchy of Human Needs

Even though it is not a nursing framework, many nurses use Maslow's hierarchy to prioritize nursing diagnoses (Fig. 4-6). In Maslow's model, basic needs must be met before a person can focus on higher needs. Maslow (1970) ranks human needs on eight levels, beginning with the most basic needs. Table 4-4 shows examples of nursing diagnoses at various levels of Maslow's hierarchy. For further information on the Maslow theory, see Chapter 8.

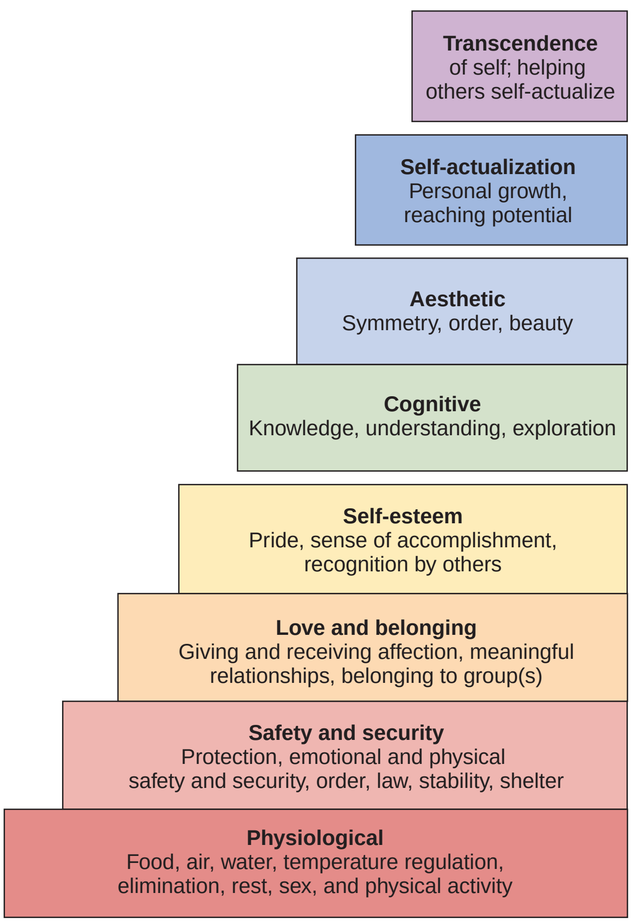

FIGURE 4-6 Maslow's Hierarchy of Human Needs can be used for prioritizing problems. Most nursing diagnoses fall at the cognitive and lower levels. (*Source:* Adapted from Maslow, A. (1971). *The farther reaches of human nature.* New York: The Viking Press; and Maslow, A., & Lowery, R. (Eds.). (1998). *Toward a psychology of being* (3rd ed.). New York: John Wiley & Sons.)

Think**Like a Nurse** 4-4

Prioritize the following nursing diagnosis labels (problems) based on the Maslow framework. (1) First assign each diagnosis a high, medium, or low priority. Some may have the same priority. (2) Next rank them in order of importance, with 1 being most important and 5 being least important; use each number only once.

_______ Ineffective Airway Clearance
_______ Ineffective Breathing Pattern
_______ Diarrhea
_______ Risk for Falls
_______ Impaired Memory

Problem Urgency

If you use problem urgency as your ranking criteria, you would rank the problems according to the degree of threat they pose to the patient's life or to the immediacy with which treatment is needed. Assign:

High priority to problems that are life threatening (e.g., Ineffective Airway Clearance) or that could have a destructive effect on the client (e.g., substance abuse)

Medium priority to problems that do not pose a direct threat to life, but that may cause destructive physical or emotional changes (e.g., Ineffective Denial, Unilateral Neglect)

Low priority to problems that require minimal supportive nursing intervention (e.g., Risk for Delayed Development, Interrupted Breastfeeding, mild Anxiety)

Future Consequences

Even though a problem is not life threatening, and even though the patient does not see the problem as a priority, it may result in harmful future consequences for the patient. For example, suppose that Todd (Meet Your Patient) is hospitalized for 5 days and undergoes inpatient dialysis. His physician prescribes a renal diet and insulin (instead of his previous oral medications) to treat the diabetes. Todd announces that he would like to go home as soon as possible. "I need to get back to my job and my family," he tells you. He resists learning about his medicines and how to administer his insulin. "Just give me a list of my medicines, and I'll take them when I get home," he says. You are aware that his renal failure is secondary to uncontrolled DM and that he often neglected to take his medication in the past. You suspect that he has not been taking his medicines because he is in denial about his health problems. Clearly his Ineffective Denial may lead to further problems with his treatment plan. You would assign high priority to this problem and address it before attempting to provide teaching for his nursing diagnosis of Deficient Knowledge (insulin).

Table 4-4 ➤ Using Maslow's Hierarchy to Prioritize Diagnoses

BASIC NEEDS (MOST BASIC TO HIGHEST)	EXAMPLES OF HUMAN NEEDS	EXAMPLES OF NURSING DIAGNOSES
Physiological	Food, air, water, shelter, sleep and rest, elimination, activity, temperature regulation	Imbalanced Nutrition: Less Than Body Requirements Impaired Gas Exchange
Safety and Security	(Includes both physical and psychological safety); law, order, shelter, stability	Risk for Falls Fear Risk for Self-Directed Violence
Love and Belonging	Roles, relationships, the need to give and receive affection, the feeling of belonging	Impaired Social Interaction Ineffective Sexuality Pattern Risk for Impaired Attachment
Self-Esteem	Feelings of confidence, capability, and independence; respect, recognition, and appreciation from others	Chronic Low Self-Esteem Social Isolation
Cognitive	Knowledge, understanding, exploration	Acute Confusion Impaired Memory Delayed Growth and Development
Aesthetic	Symmetry, order, beauty	(It is unusual for nursing diagnoses to fall into this, or the two higher, categories.)
Self-Actualization	Personal growth, reaching one's highest potential	
Transcendence	Connecting to something beyond self, helping others reach their potential	Readiness for Enhanced Spiritual Well-Being Spiritual Distress (and Risk for Spiritual Distress)

Sources: Adapted from Maslow, A. (1971). *The farther reaches of human nature.* New York: The Viking Press; and Maslow, A., & Lowery, R. (Eds.). (1998). *Toward a psychology of being* (3rd ed.). New York: John Wiley & Sons.

Patient Preference

Give high priority to problems the patient thinks are most important, provided that this does not conflict with basic/survival needs or medical treatments. Patients cooperate more fully with interventions they consider important. In addition, they may be more motivated to work on other problems after their own priorities are addressed.

Consider this example. Mr. Amani has had a major surgery within the past 24 hours. His main concern is to obtain pain relief. He refuses to turn, deep-breathe, and cough (TDBC) because it causes pain. However, as his nurse, you realize that these activities are essential for preventing Ineffective Airway Clearance, so you cannot safely support Mr. Amani's priorities. You should of course provide pain medication before helping him TDBC, but it may be impossible for him to be entirely pain free during these activities. You would explain your actions and continue to emphasize the importance of TDBC. When you explain the importance of your priorities, patients often come to agree with them.

ThinkLike a Nurse 4-5

Suppose that on Todd's transfer from the ED (Meet Your Patient), you made the following nursing diagnoses for him. Using problem urgency as your criterion, assign each of these diagnoses a low, medium, or high priority. You may not have much theoretical knowledge about type 2 DM and chronic renal disease, but use the information provided in the scenario and in the etiologies to prioritize as well as you can. Discuss the case with your classmates and your instructor.

- Risk for Imbalanced Fluid Volume secondary to renal failure
- Risk for Falls related to decreased sensation and mobility in legs
- Anxiety r/t unknown prognosis of renal failure and ED environment
- Deficient Knowledge (renal disease process) r/t new diagnosis of renal involvement secondary to type 2 DM

Computer-Assisted Diagnosing

Many institutions use computers for planning and documenting patient care. Some expert (knowledge-based) systems allow you to enter assessment data, and the computer program will generate a list of possible problems. After you choose a problem label, the computer will provide a screen with the definition and defining characteristics of the problem so you can compare them to the actual patient data. After you "accept" the diagnostic label, you complete the problem statement by choosing etiologies from the next computer screen. To see examples of such computer screens,

Go to Student Resources: Chapter 4, **Tables, Boxes, Figures: ESG Figures 4-1 and 4-2,** on Davis*Plus*.

KnowledgeCheck 4-6

List the steps in the diagnostic process.

REFLECTING CRITICALLY ON YOUR DIAGNOSTIC REASONING

Diagnostic reasoning is complex and vulnerable to error. Therefore, after prioritizing your list of problems, you need to evaluate the list for accuracy. With the implementation of electronic health records, there is an even greater need for accuracy of nursing diagnoses (Häyrinen, Lammintakanen, & Saranto, 2010; Lunney, 2008). When diagnosing, you apply critical thinking to your theoretical and self-knowledge and to the patient data and situation (recall the full-spectrum nursing model in Chapter 2).

Critical thinking + Knowledge + Data =
Statement of health status

Think About Your Theoretical Knowledge

The better your knowledge base is, the better is your diagnostic reasoning. Ask yourself the following questions:

- Is this diagnosis based on sound knowledge (e.g., of pathophysiology, psychology, nutrition, and other related disciplines)?
- Do I have sound knowledge about the defining characteristics associated with various nursing diagnoses?
- Do I feel reasonably sure I have interpreted the data correctly?
- Have I identified the problem type correctly—that is, can this problem be treated primarily by nursing interventions?
- Am I qualified to make this diagnosis, or should I consult with a more experienced nurse or other member of the collaborative healthcare team?

To avoid diagnostic error, build a good knowledge base and learn from your clinical experiences. If you lack knowledge in an area, review the literature. Solid theoretical knowledge will help you (1) to recognize cues and patterns, (2) to associate patterns with the correct problem, (3) gain confidence in your ability to reason, and (4) keep from relying too much on authority figures (Wilkinson, 2011).

Think About Your Self-Knowledge

Realize that your beliefs, values, and experiences affect your thinking and can be misleading. For example, imagine that a nurse in a labor and delivery unit believes it is important to be strong and uncomplaining, even when experiencing severe pain. When this nurse cares for a woman in early labor who cries out and complains of pain, the nurse sees it as a problem of either Anxiety or Ineffective Coping, not as a problem of Pain. Can you see how that changes the focus of the nurse's care? Ask yourself the following questions (Wilkinson, 2011):

What biases and stereotypes may have influenced my interpretation of the data? A **bias** is the tendency to slant your judgment based on personal opinion or unfounded beliefs, as the nurse did in the preceding example. **Stereotypes** are judgments and expectations about an individual based on the personal beliefs you have about this group (e.g., men are unemotional; Asians are intelligent; teenagers are irresponsible). Referring to patients by their diagnosis or developmental group is a form of stereotyping (e.g., "the elderly man in room 110"; "the broken hip in 288"). You form stereotypes by making flawed assumptions when you have little or no actual experience with a person or group.

Did I rely too much on past experiences? This is like stereotyping in that you draw conclusions about an individual based on what you know about people in similar situations. Consider, for example, a nurse who has cared for many first-time mothers (primiparas) during labor. Most of these women experienced moderate anxiety even during early labor. Now each time the nurse cares for a primipara, she expects to see anxiety, and she tends to identify cue clusters as Anxiety, failing to check for other explanations such as Pain or Deficient Knowledge.

Did I rely too much on the client's medical diagnosis, the setting, or what others say about the client instead of on the data? Medical diagnoses and statements from others can help you to think of possible explanations for your data, but they can also bias your thinking and prevent you from gathering your own data. For example, Ms. Grayson has cancer. She returned to the unit last evening after undergoing a total colectomy and colostomy (removal of the colon and creation of an artificial opening for removal of stool). She had expected her surgery to be only an exploratory laparotomy to evaluate abdominal symptoms. This morning in report, the night shift nurse stated, "Ms. Grayson is aware that she has cancer and is coping well." While bathing Ms. Grayson, you begin to talk to her about her colostomy. She seems shocked. "I didn't know they did that! What's wrong with me?" As you answer her questions, you realize that she has been very groggy from the anesthesia and pain medication and does not recall being told about her surgery and cancer.

Think About Your Thinking

After reflecting on your knowledge, think about how you used the diagnostic process. Be sure your analysis of the data was thorough, that you have accurately identified the patient's problems, and that they are logically linked to the etiologies. Review your interactions with the patient: Do the diagnostic statements reflect his perceptions and priorities, or did he just give you the answers he thought you wanted? Use the questions in Box 4-3 to critique your thinking during the diagnostic process.

KnowledgeCheck 4-7

To help you fix them in your mind, list at least 10 questions to ask yourself when evaluating your diagnostic reasoning. Refer to Box 4-3 if you need help preparing this list.

Practical knowledge knowing how

After you have completed the diagnostic reasoning process, the final activity in the diagnosis step is to record patient strengths and problem statements. Practical knowledge regarding nursing diagnosis involves selecting the correct standardized problem labels and writing the diagnostic statements. The remainder of this chapter will help you learn to apply the concepts you learned in the Theoretical Knowledge section.

STANDARDIZED NURSING LANGUAGES

In order to communicate, people need a shared language. A **standardized language** is one in which the terms are carefully defined and mean the same thing to all who use them. One example is the periodic table for chemical elements. When a chemist in the United States writes Fe or Zn, all other chemists in the world know that she means iron or zinc. Moreover, they know exactly what is meant by iron and zinc, because each is defined by its own atomic number, atomic mass, number of protons, number of neutrons, and so on. There is no confusion. **Standardized nursing languages** are a comparatively recent attempt to bring such clarity to communication about nursing knowledge and nursing thinking. Nurses need clear, precise, consistent terminology when referring to the same clinical problems and treatments. A standardized language can do the following:

- Support electronic health records.
- Define, communicate, and expand nursing knowledge.

BOX 4-3 ■ Critiquing Your Diagnostic Reasoning Process

Data Analysis

Did you:

- Identify all the significant data (cues)?
- Omit any important cues from the cluster?
- Include unnecessary cues that may have confused your interpretation?
- Try more than one way of grouping the cues?
- Consider the patient's social, cultural, and spiritual beliefs and needs?
- Identify all the data gaps and inconsistencies?

Drawing Inferences and Interpretations of the Data

- Did you consider all the possible explanations for the cue cluster?
- Is this the best explanation for the cue cluster? Remember that a variety of explanations may be possible.
- Did you have enough data to make that inference? If not, suspend judgment until you gather more data.
- Did you look at patterns, not single cues?
- Did you look at behavior over time, not just isolated incidents?
- Did you jump to conclusions? Or did you take the time to carefully analyze and synthesize the data?

Critiquing the Diagnostic Statement (Problem + Etiology)

- Is the diagnosis relevant, and does it reflect the data?
- Does the diagnostic statement give a clear and accurate picture of the patient's problem or strength?
- When identifying the problem and etiology, did you look beyond medical diagnoses and consider human responses?
- Did you consider strengths and wellness diagnoses?
- Can you explain how the etiology relates to the problem—that is, how it would produce the problem response?
- Does the complete list of problems fully describe the patient's overall health status?

Verifying the Diagnosis

- Did the patient verify this diagnosis?
- When you verified the diagnosis are you certain the patient understood your description of his health status?
- Did you obtain feedback from the patient, or did you merely assume that the patient agreed?
- Did you keep an open mind, realizing all diagnoses are tentative and subject to change as you acquire more data?

Prioritizing

- Considering the whole situation, what are the most important problems?
- What aspects of the situation require immediate attention?
- Did you consider patient preferences when setting priorities? If not, was there a good reason?

- Increase visibility and awareness of nursing interventions.
- Facilitate research to demonstrate the contribution of nurses to healthcare and influence health policy decisions (Shever, 2011).
- Improve patient care by providing better communication among nurses and other healthcare providers and facilitating the testing of nursing interventions.

For a full discussion of the benefits of a uniform nursing language,

Go to Student Resources, Chapter 4, **Supplemental Materials: Why Do We Need a Standardized Nursing Language?** on Davis*Plus*.

What Is a Taxonomy?

A **taxonomy** is a system for classifying ideas or objects based on characteristics they have in common. Classifications are created and used for various reasons. As mentioned earlier, the periodic table classifies elements according to their atomic mass, number of protons, and so on. Medications are classified in various ways; one way is to classify them according to their use (e.g., analgesics, antibiotics). The following classification systems are widely used in healthcare:

- The American Psychiatric Association's (APA) *Diagnostic and Statistical Manual (DSM-5)* describes mental disorders (e.g., bipolar disorder, schizoaffective disorder) (APA, 2013).
- The *Manual of the International Classification of Disease and Related Health Problems (ICD-10)* names and classifies medical conditions (World Health Organization [WHO], 1992).
- The *Current Procedural Terminology: CPT 2010*, used for reimbursement of physician services, names and defines medical services and procedures (American Medical Association [AMA], 2010).

The following are classification systems that the American Nurses Association (ANA) has recognized for describing nursing diagnoses (some describe outcomes and interventions as well):

- *NANDA International*. The first use of standardized nursing language began in the 1970s, with the NANDA classification of nursing diagnoses. This taxonomy includes more than 200 diagnostic labels with etiologies, risk factors, and defining characteristics. Most chapters of this textbook use NANDA-I terminology.
- *Clinical Care Classification (CCC).* Similar to the NANDA-I system; includes nearly 200 labels. Contains interventions as well as nursing diagnoses. The CCC was developed for home health use, but can be used in any setting.
- *Omaha System*. Contains about 42 nursing diagnosis "concepts" (also interventions and outcomes). The Omaha system is primarily for community health use, but can be used in other settings.
- *Perioperative Nursing Data Set (PNDS)*. For use in perioperative nursing only. Consists of 64 nursing diagnoses (also includes nursing interventions and patient outcomes). This was the first nursing language developed by a nursing specialty.
- *International Classification for Nursing Practice (ICNP).* Includes diagnoses, outcomes, and nursing actions. The ICNP intends to provide a common language for nurses in various clinical settings worldwide (International Council of Nurses, 2011).

NANDA-I Taxonomy of Diagnostic Terminology

Which of the following could you group together? In what ways are the grouped objects similar?

a five-dollar bill	a penny
weeds (still growing)	new grass
an iron skillet	a needle

You could make these groupings:

A $5 bill and a penny (because they are both money).
A penny, an iron skillet, and a needle (because they are all metal).
A $5 bill, grass, and weeds (because they are all green).

Maybe you thought of other groupings, too. Any number of principles can be used to classify things and to organize a taxonomy.

The first NANDA taxonomy was simply an alphabetical list. To see that taxonomy,

Go to Additional Resources: **NANDA-I Nursing Diagnoses, 2012-2014 Alphabetical List,** on Davis*Plus*.

NANDA's *Taxonomy II* categorizes nursing diagnoses into 13 domains and 47 classes (NANDA-I, 2012). A **domain** is an area of activity, study, or interest (e.g., health promotion, nutrition). A **class** is a subdivision of a domain (e.g., health awareness is a class under health promotion; digestion is a class under nutrition). To see Taxonomy II,

Go to Student Resources: Chapter 4, **Standardized Language, NANDA-I Taxonomy II: Domains, Classes, and Diagnoses (Labels),** on Davis*Plus*.

One strength of the NANDA taxonomy is that it has been developed by nurses from the areas of administration, education, practice, and research, and from all specialties (e.g., maternity, mental health, medical-surgical, community). Because they represent the thinking of a broad spectrum of nurses, the diagnostic labels can be used in any setting or specialty.

What Are the Components of a NANDA-I Nursing Diagnosis?

Each nursing diagnosis in the NANDA-I taxonomy has four parts: label, definition, defining characteristics, and related or risk factors. You must consider all four parts when formulating a nursing diagnosis.

Diagnostic Label The **diagnostic label** (**title** or **name**) is a word or phrase that represents a pattern of related cues and describes a problem or wellness response, such as Disturbed Body Image or Readiness for Enhanced Nutrition. Some labels include descriptors for time, age, and other factors (e.g., acute, deficient, delayed). For the complete list of descriptors for NANDA-I nursing diagnoses,

Go to Chapter 4, **Descriptors for NANDA-I Nursing Diagnoses,** in Volume 2.

Definition The **definition** explains the meaning of the label and distinguishes it from similar nursing diagnoses. For example, for a patient with a sleep problem, would you label the problem Sleep Deprivation or Disturbed Sleep Pattern? The following definitions can help you to decide:

Sleep Deprivation: Prolonged periods of time without sleep

Disturbed Sleep Pattern: Time limited disruption of sleep amount and quality

Defining Characteristics The cues (signs and symptoms) that allow you to identify a problem or wellness diagnosis are called **defining characteristics**. To use a problem label appropriately, a cluster of defining characteristics must be present in the patient data. For example, you cannot decide to use the label Sleep Deprivation merely by reading the definition. You must be sure the patient actually has some of the defining characteristics for Sleep Deprivation.

Related Factors The cues, conditions, or circumstances that cause, precede, influence, contribute to, or are in some way associated with the problem (label) are called **related factors**. They can be pathophysiological, psychological, social, treatment related, situational, maturational, and so on. NANDA-I lists the related factors that are most often associated with each problem label, but keep in mind that:

- *The list is not exhaustive*. Factors other than those listed by NANDA-I could also be associated with the problem. For example, imagine the vast number of factors that might cause someone to have Chronic Low Self-Esteem.
- *The problem may have more than one related factor*. Human beings are complex, and their problems rarely have one single cause. Nursing diagnoses may have multiple factors as their etiology.
- *An individual patient's etiology will not include all the related factors* that NANDA-I lists for the diagnosis.

Risk Factors Events, circumstances, or conditions that increase the vulnerability of a person or group to a health problem are called **risk factors**. They can be environmental, physiological, psychological, genetic, or chemical. For example, ignoring the urge to defecate and being pregnant increase the risk a person will become constipated. The diagnostic statement would be: Risk for Constipation r/t pregnancy and habitually ignoring the urge to defecate.

For potential (risk) nursing diagnoses, risk factors function as the defining characteristics. They must be present to make the diagnosis, and they almost always form at least a part of the etiology of the diagnostic statement. If **related factors** are present, an actual, rather than potential, problem exists.

Key Point: ***To help you remember, as a rule:***

Related factors are similar to signs and symptoms (of actual problems)

Risk factors are similar to etiologies (of potential problems)

KnowledgeCheck 4-8

- What are the four parts of a NANDA-I nursing diagnosis?
- What purpose does each part of the nursing diagnosis serve for directing the care of the client?

How Do I Know Which Label to Use?

For the following sections, you will need access to the NANDA-I labels, definitions, and so on, as well as to *Taxonomy II*. You can use either a NANDA-I handbook or a nursing diagnosis handbook; or if you wish, print out NANDA-I *Taxonomy II* and use that,

Go to Student Resources: Chapter 4, **Standardized Language, NANDA International—Approved Nursing Diagnoses (2012–2014), Taxonomy II: Domains, Classes, and Diagnoses (Labels),** on Davis*Plus*.

During the diagnostic process, you will already have determined the general topic of the problem and perhaps even have some tentative problem labels in mind. Follow these steps:

1. ***First, identify the broad topic (or domain) that seems to fit the cue cluster.*** You can look at the NANDA-I taxonomy to see which domain the problem seems to fit. For example, suppose that after further assessment, you find that Todd (Meet Your Patient) has the following defining characteristics:
   Intake exceeds output.
   Oliguria (low volume of urine)
   Generalized edema
   Recent rapid weight gain
   Which of the following NANDA domains are suggested by those cues?

Health Promotion	Role Relationships
Nutrition	Self-Perception
Elimination	Activity/Rest

   The most logical guesses would be Nutrition and Elimination. However, you would need to read the domain definitions in the table, NANDA International—Approved Nursing Diagnoses (2012–2014), Taxonomy II: Domains, Classes, and Diagnoses Labels (on the ESG); also look at the classes to be sure.
2. ***Narrow your search (to the class or most likely labels).*** In the NANDA-I taxonomy, read the definitions for the Nutrition and Elimination domains. Then look at the classes in each. Under Elimination,

you will find that Class 1 is Urinary Function. Because Todd has renal failure, you may think that his nursing diagnosis will be found in this class. However, remember that renal failure is a pathology or pathological condition; you are looking for Todd's *responses* to renal failure. On examining the diagnosis labels in the Urinary Function class, you will see none of those really represents Todd's defining characteristics.

Now look at the Nutrition domain. You will see the classes Ingestion, Digestion, Absorption, Metabolism, and Hydration. Look at the diagnostic labels listed for the class Hydration. All five of those labels describe fluid balance. You can easily eliminate both risk labels because Todd has an actual problem (he has symptoms). You can eliminate Readiness for Enhanced Fluid Balance because it is a wellness diagnosis. So, you must choose between Deficient Fluid Volume and Excess Fluid Volume. From this point, you simply compare Todd's cue cluster to the defining characteristics and definitions of those two labels and choose the best match.

3. ***Using a nursing diagnosis handbook, compare definitions and defining characteristics of the diagnostic labels to your cue cluster.*** A brief look at a NANDA-I alphabetical list should convince you that you cannot know exactly what a diagnostic label means from the label name alone. For example, suppose you have a patient who is not sleeping well at night. As a result, she is too tired to concentrate during the day. Which label would you use to describe this problem: Activity Intolerance, Fatigue, or Acute Confusion? You can answer that question only if you know the definition and defining characteristics of those nursing diagnosis labels.

Not all of the defining characteristics need to be present, but recall that the more data you have when you make an inference, the more certain you can be that your inference is correct. For example, NANDA-I lists 14 defining characteristics for Ineffective Thermoregulation, including the following:

- Fluctuations in body temperature above and below normal range
- Cyanotic nailbeds
- Pallor
- Slow capillary refill
- Tachycardia

You could diagnose Ineffective Thermoregulation on the basis of the first defining characteristic alone, but you might be more certain of your diagnosis if the other cues were also present.

ThinkLike a Nurse 4-6

- In the preceding example, what if the first defining characteristic (temperature fluctuations) were not present and you had only cyanotic nailbeds, pallor, and slow capillary refill as cues? Could you conclude that Ineffective Thermoregulation is causing those signs? What other explanations might there be for cyanotic nailbeds, pallor, and slow capillary refill?
- What if the tachycardia was present without fluctuations in body temperature above and below normal range? What could cause tachycardia? Do you see the importance of using clusters rather than individual cues?

WRITING DIAGNOSTIC STATEMENTS

A diagnostic statement consists of a problem and an etiology linked by a connecting phrase.

Problem The **problem** describes the client's health status (or a human response to a health problem) and identifies a response that needs to be changed. Use a NANDA-I label when possible. As noted earlier, many NANDA-I labels include a descriptor such as acute, impaired, or deficient. You will see them arranged in alphabetical lists with the descriptor after the main word (e.g., Physical Mobility, Impaired). However, you should record them as you would say them; for example:

Incorrect: Physical Mobility, Impaired r/t pain in left knee

Correct: Impaired Physical Mobility r/t pain in left knee

Etiology As discussed earlier, the **etiology** contains the factors that cause, contribute to, or create a risk for the problem. The etiology may include a NANDA-I label, defining characteristics, related factors, risk factors, or other factors. Remember that an etiology may consist of several factors.

- *The etiology will help you to individualize nursing care because etiologies are unique to the individual.* For example, suppose two patients have the following nursing diagnoses:

  John: Anxiety r/t lack of knowledge of the treatment procedure

  Janet: Anxiety r/t prior negative experiences and lack of trust in health professionals

  The problem, Anxiety, has the same definition for both patients. They probably share some of the same defining characteristics, and you would use some of the same interventions for both John and Janet. For example, for all anxious patients, regardless of etiology, a calm, reassuring approach is important. However, to prevent the anxiety from recurring, you would need to treat its cause. To relieve John's anxiety, you would teach him what to expect from the impending procedure. But teaching would do nothing to relieve Janet's anxiety. For her, you would need to spend time building a relationship that demonstrates you can be trusted. You would also encourage her to talk about her fears and feelings.
- *Because the etiology directs the nursing interventions, include only factors that are influenced by nursing interventions.* For example, do not use a medical diagnosis or treatment as an etiology, because you cannot write nursing orders to change it. As another example, there are no independent nursing actions that would change

the etiologies in the following diagnosis: Deficient Fluid Volume related to medical order of NPO (nothing by mouth).

- *Most NANDA-I-related factors are listed in nonspecific terms, so you will usually need to individualize them to reflect each person's unique problem etiology*. For example, one of the related factors for Impaired Skin Integrity is "extremes in age." To plan care, you need to know whether this means very old or very young; even better, you should specify the exact age. You would write the diagnostic statement as Impaired Skin Integrity r/t very young age (2 days).

Connecting Phrase (related to) Most nurses use **related to (r/t)** to connect the problem and etiology, believing that the phrase *due to* implies a direct causal relationship. Because humans are complex, there are usually many factors that combine to "cause" a problem, so it is nearly impossible to prove an exact cause. In fact, even if you eliminate the etiological factors, the problem might remain. For example, even if Janet begins to trust health professionals, she may become anxious for another reason.

Formats for Diagnostic Statements

A diagnostic statement should describe the client's health status as specifically as possible. The format will vary depending on the type of problem you are describing (Table 4-5).

Basic Two-Part Statement

The two-part statement is used for actual, risk, and possible diagnoses. The format is:

Problem	r/t	Etiology
Or		
NANDA-I label	r/t	related factors

For actual diagnoses, the etiology consists of related factors; for risk diagnoses, it consists of risk factors. For example, for a client with excessive vomiting you might write Risk for Deficient Fluid Volume r/t excessive losses through vomiting.

Basic Three-Part Statement

The three-part statement is also called the **PES format** (problem, etiology, and symptom). Some nurses use *AEB (as evidenced by)* whereas others use *AMB (as manifested by)*. The format is:

Problem r/t etiology as manifested by (AMB) signs or symptoms

This format adds the patient signs or symptoms that led you to make the diagnosis. For example:

Constipation r/t inadequate intake of fluids and fiber-rich foods AMB painful, hard stool and bowel movement every 3 or 4 days.

This is a good method for students because it helps to ensure that you have enough data to support the problem you have identified.

Although ideally the problem and etiology should thoroughly describe the patient's health status, you can sometimes make the description more clear and useful by including the cues in the statement. However, this method can create a long, unwieldy statement. For example:

Decisional Conflict (whether to accept chemotherapy) r/t desire to protect family from financial hardship of a lingering illness AMB verbalizing uncertainty about what to do and feelings of distress; indecision about having and not having chemotherapy; exhibiting physical signs of anxiety (increased heart rate, restlessness); questioning personal values and beliefs ("I'm not sure what to do. I hate to leave them any sooner than I have to, but I don't want to ruin them financially, either").

For such situations, you can record the cues in the nurses' notes instead of in the diagnostic statement. Another alternative is to list the signs and symptoms below the nursing diagnosis on the care plan instead of including it as part of the statement, as in the following example:

Decisional Conflict (whether to accept chemotherapy) r/t desire to protect family from financial hardship of a lingering illness

Subjective cues: Verbalizes uncertainty about what to do and feelings of distress; vacillates between having and not having chemo; questions personal values and beliefs ("I'm not sure what to do. I hate to leave them any sooner than I have to, but I don't want to ruin them financially, either").

Objective cues: Exhibits physical signs of anxiety (increased heart rate, restlessness)

Obviously you cannot use the PES format for risk nursing diagnoses, because symptoms are not present with risk diagnoses.

One-Part Statement

You can omit the etiology from certain kinds of diagnostic statements:

Syndrome Diagnoses Recall that a syndrome diagnosis is a label that represents a collection of several nursing diagnoses. A syndrome diagnosis usually does not need an etiology.

Wellness Diagnoses As a rule, NANDA-I wellness diagnoses are one-part statements beginning with the phrase Readiness for Enhanced (e.g., Readiness for Enhanced Parenting). Because the wellness label does not describe a problem, no etiology ("cause") is needed.

Very Specific Labels A few NANDA-I labels are so specific that they imply the etiology, or the only possible etiology is a medical diagnosis (e.g., Death Anxiety, Latex Allergy Response). For Latex Allergy Response, it would be redundant to write Latex Allergy Response

Table 4-5 ➤ Examples of Diagnostic Statements

FORMAT	PROBLEM TYPE	PROBLEM (CLIENT RESPONSE; NANDA LABEL)	ETIOLOGY (RELATED OR RISK FACTORS)	DEFINING CHARACTERISTICS OR "SECONDARY"
Basic One-Part	Wellness diagnosis	Readiness for Enhanced Nutrition	None	
	Syndrome diagnosis	Disuse Syndrome	None	
	Very specific label	Death Anxiety	None	
Basic Two-Part	Actual problem	Impaired Social Interaction	r/t self-consciousness following amputation of bilateral lower extremities	
	Potential problem	Risk for Impaired Attachment	r/t separation from infant at birth because of mother's illness	
	Possible problem	Possible Impaired Attachment	r/t separation from infant at birth because of mother's illness	
Basic Three-Part	Actual Problem	Impaired Social Interaction	r/t self-consciousness following amputation of bilateral lower extremities	AEB avoidance of others, social isolation, blaming others for current condition
	Possible Problem	Impaired Social Interaction	r/t self-consciousness following amputation of bilateral lower extremities	AEB blaming others for current condition
Variations	(Specify)	Decisional Conflict (whether to accept chemotherapy)	r/t desire to protect family from financial hardship of a lingering illness	Secondary to diagnosis of terminal cancer
	Secondary to	Decisional Conflict (whether to accept chemotherapy)	r/t desire to protect family from financial hardship of a lingering illness	Secondary to side effects of chemotherapy
	Two-part NANDA-I label	Imbalanced Nutrition: Less Than Body Requirements	r/t loss of appetite from nausea	Secondary to residual effects of stroke
	Adding words to the label	Impaired Physical Mobility: Inability to turn self in bed	r/t generalized weakness	
	Unknown etiology	Parental Role Conflict	r/t unknown etiology or possibly r/t recent divorce	
	Complex etiology	Chronic Low Self-Esteem	r/t complex etiology	
Collaborative Problems	Potential complications of disease, test, or treatment	Potential Complication of preeclampsia: renal failure	None	

AEB = as evidenced by

r/t sensitivity to latex. The etiology adds nothing to your understanding of the problem, nor does it suggest interventions different from those suggested by the problem label. The same is true for Death Anxiety.

Format Variations

The following are some variations of the basic two- and three-part formats.

"Specify" You will see the word *specify* in some NANDA-I labels, for example, Decisional Conflict (specify). This means that the label is useful only if you describe the problem more specifically (see Table 4-5 for an example).

"Secondary to" When the defining characteristics are vague (e.g., Chronic Pain r/t chronic physical disability) you may need to add a second part to the etiology following the words *secondary to* (2°). This second part is usually a pathophysiology or disease process (e.g., Chronic Pain r/t chronic physical disability secondary to rheumatoid arthritis). As a rule, you should avoid using pathophysiology or medical diagnoses in the etiology because they cannot be addressed by independent nursing interventions. The words *secondary to* make it clear the nurse is not ultimately responsible for the pathophysiological part of the etiology. Do not use this phrase routinely. Use it only if it adds to the understanding of your diagnostic statement.

Two-Part NANDA-I Label Some NANDA-I labels have two parts. The first part describes a general response; the second part, following a colon, makes it more specific (see Table 4-5).

Adding Words to the NANDA-I Label The problem phrase must describe the client's health status precisely because general categories are not useful for planning nursing care. For example, what do you think the problem label Impaired Physical Mobility means? Does it mean that the patient cannot grasp objects with her hands, or that she cannot walk, or that she cannot move at all? For such labels, you will need to add your own words to the label to make it more descriptive (see example in Table 4-5).

Other labels that often need to be clarified include: Acute Pain, Chronic Pain, Risk for Infection, and Risk for Injury. Think carefully about whether the clarifying words belong in the problem or the etiology. For example, you may see a pain diagnosis written as: Acute Pain r/t surgical incision. However, surgical incision is a medical treatment and should not be used as the etiology. It would be better to write: Acute pain (abdominal incision) r/t turning and moving secondary to abdominal surgery.

Key Point: ***The "rule" for adding words is to first try to make the statement specific or descriptive by writing a good etiology, using the PES format, or adding secondary to. If that does not fully describe the health status, add descriptive words to the problem label.***

Unknown Etiology Sometimes you will be able to identify the patient's problem but not know the etiology. For example, your patient might have defining characteristics for Parental Role Conflict, but you may need more information to determine the cause. Perhaps there is an impending divorce; perhaps she has just had to take on the care of an elderly parent, and so on. In this case, you could write Parental Role Conflict *r/t unknown etiology*. Later, when you obtain more data, you will be able to complete the etiology. A similar situation exists when you have some, but not enough, information about the etiology. In this case you would write Parental Role Conflict *possibly r/t* recent divorce.

Complex Etiology Some problems have too many etiological factors to list, or the etiology is too complex to explain in a brief diagnostic statement. For example, imagine the number of factors that might contribute to problems such as Chronic Low Self-Esteem, Disabled Family Coping, and Adult Failure to Thrive. For such problems you can replace the etiology with the phrase *complex factors* (e.g., Disabled Family Coping r/t complex factors).

Collaborative Problems

A collaborative problem is always a potential problem (e.g., a complication of a disease, test, or medical treatment). The disease, test, or treatment is actually the etiology of the problem. Because you cannot treat the etiology with independent nursing interventions, you should not use the problem + etiology format. The focus of your interventions is monitoring for and preventing the complication. The format is:

Potential Complication of thrombophlebitis: Pulmonary embolism

Can you see that the word(s) following the colon represent the problem you are monitoring and trying to prevent?

Key Point: ***In actual practice, you would not write an etiology for a collaborative problem.*** However, as a student, you may wish to do so when it clarifies your diagnostic statement or when it helps to suggest nursing interventions (Wilkinson, 2011). For example, a student statement might be:

Potential Complication of magnesium sulfate therapy: Respiratory depression r/t increased blood levels of magnesium because of decreased kidney function secondary to preeclampsia (a pregnancy-related disorder with hypertension as a major pathology).

In addition to alerting you to monitor for respiratory depression, this statement might remind you to monitor the serum magnesium level, assess for other data related to kidney function, and monitor blood pressure.

KnowledgeCheck 4-9

Write an example of each of the following diagnostic statement formats, using the listed components—mix and match:

Problem labels: Anxiety, Pain (lower back)

Etiologies: Unknown outcome of surgery; muscle strain and tissue inflammation

Cues: Exhibits physical manifestations of anxiety (e.g., hands shaking); states pain is 9 on a scale of 1 to 10.

- Basic two-part statement
- Basic three-part statement
- Basic two-part statement, using "secondary to" (create your own disease/pathology)
- Statement with unknown etiology
- Possible nursing diagnosis
- Risk nursing diagnosis

How Does the Nursing Diagnosis Relate to Outcomes and Interventions?

Key Point: ***As a general rule, the problem suggests goals, and the etiology suggests interventions.*** Keep in mind that there are exceptions to this rule.

The Problem Suggests Goals

The problem describes a health status that needs to be changed. From the problem, you can determine the patient outcomes for measuring this change. Consider the following diagnostic statement: Risk for Impaired Skin Integrity r/t complete immobility 2° spinal cord injury.

- *The goal, or outcome, is the opposite of the unhealthy response:* Skin will remain intact and healthy.
- *The goals suggest assessments*, which are actually a type of nursing intervention. For example, the diagnosis Risk for Impaired Skin Integrity tells you to monitor the patient's skin condition.
- *If the problem is not an accurate statement of health status, then your goals and resulting assessments will be wrong*. If you incorrectly identified the previous problem as Impaired Physical Mobility 2° spinal cord injury, then the goal would suggest that you monitor the patient's mobility—which would not improve—and you might miss a developing skin problem.

The Etiology Suggests Interventions

Key Point: ***The aim of the nursing interventions is to remove or alter the factors contributing to the problem.*** In the preceding example, Impaired Physical Mobility 2° spinal cord injury, you could not cure the spinal cord injury or restore the patient's ability to move about. However, you could provide some mobility by turning and repositioning the patient frequently. This would help prevent Impaired Skin Integrity (which is the best diagnosis).

If the etiology is incorrect or incomplete, you might omit important nursing interventions. For the diagnosis Risk for Impaired Skin Integrity *r/t complete immobility 2° spinal cord injury*, you would focus on supporting mobility in order to prevent Impaired Skin Integrity. However, what if that etiology is incomplete, and the diagnosis should have been Risk for Impaired Skin Integrity *r/t poor nutritional status and complete immobility 2° spinal cord injury*? Now you can see that interventions that focus only on supporting mobility would not be adequate to prevent Impaired Skin Integrity.

REFLECTING CRITICALLY ABOUT DIAGNOSTIC STATEMENTS

Just as you critiqued your diagnostic reasoning process, you must reflect on the content, format, and meaning of your diagnostic statements. In this section, you will also begin to reflect on the nature of standardized language and the NANDA-I taxonomy of nursing diagnoses.

Guidelines for Judging the Quality of Diagnostic Statements

After you have written your diagnostic statements, use the following criteria to judge their quality (Wilkinson, 2011).

In choosing a NANDA-I label, do not rely on the label definition alone. Always compare patient data with the defining characteristics of the label as well as with the definition. Consider the diagnosis Parental Role Conflict:

Definition: Parental experience of role confusion and conflict in response to crisis

Defining Characteristics: Include "Reluctant to participate in usual caretaking activities"

Notice that you cannot actually observe role confusion and conflict in a patient; however, the defining characteristics for this label include more specific cues to help you make the diagnosis.

Include both problem and etiology, with cause and effect stated correctly. A quick check of this is to read your statement backward: "Etiology causes problem," and see if it makes sense.

Correct example: Ineffective Breastfeeding r/t Deficient Knowledge (positioning infant at breast)

Read backward, this statement says deficient knowledge about positioning the infant at breast "causes" Ineffective Breastfeeding. This makes sense.

Incorrect example: Deficient Knowledge r/t Ineffective Breastfeeding (incorrect positioning infant at breast)

Read backward, this statement says Ineffective Breastfeeding causes deficient knowledge. This does not make sense.

Be sure that the etiology does not merely restate the problem.

Incorrect example: Impaired Physical Mobility r/t inability to walk

Correct example: Impaired Physical Mobility: Inability to walk r/t weakness and pain in legs

In the incorrect example, inability to walk is the specific impaired physical mobility. The etiology should state the factors that are causing the inability to walk.

Avoid using medical diagnoses and treatments as etiological factors. The nurse should be able to provide interventions to change or remove the etiological factors. What could the nurse do to change the following etiology?

Incorrect example: Risk for Impaired Skin Integrity (ulcers, infection) r/t diabetes mellitus

The answer, of course, is that the nurse can do nothing to change or get rid of the DM. Try the following approaches to reword the diagnosis:

- Reword the etiology in terms of something the nurse can change, as follows:
  Correct example: Risk for Impaired Skin Integrity (ulcers, infection) r/t lack of knowledge of self-care measures for inspecting feet and trimming toenails
- If you cannot reword the etiology in terms of something the nurse can change, you may have identified the problem incorrectly; perhaps it is merely the stimulus for another patient problem that you can address independently. In the following example, Risk for Impaired Skin Integrity is one possible response to the stimulus, Impaired Physical Mobility.
  Incorrect example: Impaired Physical Mobility (total) r/t paralysis secondary to high spinal injury
  Correct example: Risk for Impaired Skin Integrity (pressure ulcers) r/t Impaired Physical Mobility (total) secondary to high spinal injury
- If none of these seem to work, you can resort to using "secondary to" instead of "related to," as in the following example: Risk for Deficient Fluid Volume secondary to prescribed NPO.

Write the statement clearly. The statement should give a clear picture of the client's health status, and other health professionals should be able to understand it readily. Avoid abbreviations and jargon as much as possible. For example, do you know what the first statement below means?

Incorrect example: Imp. Phys. Mobility (inability to get OOB w/o assist.) r/t muscle weakness and pain in LL
Correct example: Impaired Physical Mobility (inability to get out of bed without assistance) r/t muscle weakness and pain in left leg

Write the statement concisely. A wordy statement is likely to be unclear. The following will help limit statement length:

- Use "complex etiology" instead of listing numerous etiological factors.
- If there are numerous signs and symptoms, either do not use PES format, or describe the signs and symptoms in the nurses' notes.
  Incorrect example: Constipation r/t habitually ignoring the urge to defecate, insufficient exercise, weak abdominal muscles, side effects of iron medications, insufficient intake of fluids and fiber, and longstanding reliance on laxatives.
  Correct example: Constipation r/t complex factors (see nurses' notes)

Be sure the statement is descriptive and specific. A vaguely stated problem and/or etiology cannot provide guidance for formulating goals and nursing interventions. Follow this guideline even if it means the statement is not as concise as you'd like. You can make the NANDA-I labels more specific by doing the following:

- Include all appropriate etiological factors.
- Review the label definition. Do not write the definition, but when you know the meaning of the label, you may find that it is descriptive enough.
- Use PES format to add the patient's signs and symptoms.
- Add qualifying words (e.g., mild, severe, occasional, or constant) to the label.
  Example: Severe Neck Pain r/t muscle spasms 2° herniated intervertebral disc
- Add "secondary to" to the etiology.
  Example: Severe Neck Pain r/t muscle spasms 2° herniated intervertebral disc
- Add a colon and descriptors to the label.
  Example: Impaired Physical Mobility: Inability to walk r/t weakness and pain in legs

State the problem as a patient response.

- **A problem is not a patient need.** As a rule, avoid using the word *need* in a problem statement. A need may cause a problem, but it is not a human response.
  Incorrect example: Needs increased fluids related to . . .
  Correct example: Risk for Deficient Fluid Volume, or Deficient Fluid Volume related to . . .
- **A problem is not a medical test, treatment, diagnosis, or equipment.**

Incorrect examples	***Correct examples***
Starting on diabetic diet	Deficient Knowledge, Ineffective Denial
Foley catheter in place	Risk for Infection, Urinary Retention
Risk for pneumonia	Risk for Ineffective Airway Clearance
Traction to left leg	Impaired Physical Mobility

- **A problem is not a nursing goal, a nursing problem, or a nursing action.**

Incorrect examples	***Correct examples***
Prevent urinary tract infection (nursing goal)	Risk for Urinary Tract Infection
Combative, hits (nursing problem) caregivers	Risk for Other-Directed Violence, Ineffective Coping, Acute Confusion
Provide emotional support (nursing action)	Anxiety, Decisional Conflict, Grieving

Use nonjudgmental language. If you examined your biases during the diagnostic process, your statements will probably be neutral. Look for phrases that may imply criticism of a patient, for example:

Incorrect: Risk for Infection r/t poor hygiene and housekeeping

Better: Risk for Infection r/t lack of information about sanitation and hand washing

Avoid legally questionable language. Be alert for legal implications. Look for phrases that seem to blame caregivers or patients or that refer negatively to patient care. For example, do not write: Risk for Falls r/t lack of staff to adequately supervise ambulation.

Think**Like a Nurse** 4-7

Rewrite the preceding diagnostic statement so it contains no legally questionable language. Use imaginary etiological factors if you need to.

Critiquing the NANDA-I System

Despite the potential benefits, some nurses have criticized the use of standardized language and the NANDA-I taxonomy in particular. The following are some objections and responses to counter them:

1. *Criticism:* **The labels are hard to use or not useful.**
   - They are too abstract to be useful (e.g., Ineffective Coping).
   - Some labels are merely reworded medical diagnoses (e.g., Decreased Cardiac Output).
   - Few people outside nursing know what the labels mean (e.g., "Why not just say 'tooth decay' or 'missing teeth' instead of 'Impaired Dentition'?").

   Response: These are legitimate concerns, but when you know the label definition, the term is more meaningful. Also, you can make the labels more specific and useful by adding descriptors, etiological factors, and defining characteristics to the diagnostic statement. Compared with the terminology for describing medical diagnoses, the NANDA-I system is relatively new (recall that it was begun just over 30 years ago). Consider that not long before that time, AIDS was not a medical diagnosis. All classification systems evolve and change, so many of the difficulties with individual labels will be revised as the terminology is refined.

2. *Criticism:* **The NANDA-I diagnoses have not been researched.** Historically, this has been true.

   Response:
   - An elected diagnostic review committee evaluates each submitted diagnosis to determine whether it complies with the criteria for inclusion in the taxonomy. Also, a label can be approved for testing. It must be validated by the literature, preferably research based, to remain on the approved list.
   - Research on the labels has been conducted and is continuing. In 1994, a research team at the University of Iowa (the Nursing Diagnosis Extension Classification [NDEC]) began collaborating with NANDA-I to extend and refine the NANDA-I work. They have begun to address some of the difficulties with the labels, such as specificity, clinical usefulness, and clinical testing.

3. *Criticism:* **Using a NANDA-I label to describe health status is "labeling"—it dehumanizes and stereotypes the patient.** The most serious criticisms are leveled by those who say that nurses should not use *any* standardized languages to describe nursing knowledge and nursing work.

   Response:
   - If this is true, then medical diagnoses would meet the same objection.
   - This objection ignores the fact that we must name objects and ideas in order to communicate them to other people.
   - Many of the criticisms arise out of disillusionment. It may be that nurses expect too much from nursing diagnosis. Although it is important, it is, after all, merely a process for identifying, naming, and communicating patient health status. We should not expect it to be the "magic bullet" that single-handedly cures all problems of the nursing profession and the patients.

Try not to reject the idea of standardized language just because of a few problematic labels. You do not need to use the official NANDA-I labels exclusively. If you are uncomfortable with a label, change the wording to make it more useful, or write a completely new label. **Key Point:** ***Remember, the point of a standardized language is to more clearly communicate the nature of the patient problem in nursing terms.***

For a more comprehensive critique of standardized nursing language, and the NANDA-I system in particular,

Toward Evidence-Based Practice

Müller-Staub, M., Lavin, M.A., Needham, I., et al. (2006). Nursing diagnoses, interventions and outcomes—application and impact on nursing practice: Systematic review. *Journal of Advanced Nursing, 56*(5), 514–531.

Researchers analyzed the content of 36 published studies to examine the outcomes of using nursing diagnosis. Specifically, they looked at effects on quality of patient assessments, accuracy, and completeness of nursing diagnoses, and on coherence among nursing diagnoses, interventions, and outcomes documented. They found the following:

- Nursing diagnosis use improved the quality of documented patient assessments.
- The completeness of nursing diagnoses in practice is problematic; signs and symptoms or etiology were often lacking or incompletely described.
- There was some evidence for coherent use of documented nursing diagnoses, interventions, and outcomes.
- There was some evidence that nursing diagnosis improved the quality of interventions documented.
- There was no evidence that use of nursing diagnosis improved outcomes in patients.

1. What do you think "coherence among nursing diagnoses, interventions, and outcomes" means?

2. From this study, could you reasonably infer that using nursing diagnosis would improve the quality of your nursing assessments? Why or why not?

3. From this study, could you reasonably infer that using nursing diagnosis led to nurses' documenting their interventions better? Why or why not?

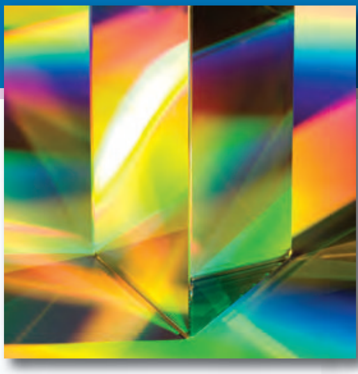
CHAPTER 5



Nursing Process: Planning Outcomes

Learning Outcomes

After completing this chapter, you should be able to:

- Describe formal, informal, initial, ongoing, and discharge planning.
- Identify patients who need a comprehensive, formal discharge plan.
- Explain the importance of a written plan of care.
- Describe the information contained in a comprehensive patient care plan.
- Compare critical pathways to integrated plans of care (IPOCs) and other standardized care-planning documents.
- Discuss the advantages and disadvantages of computerized care planning.
- Describe a process for writing an individualized care plan, making use of available standardized care-planning documents.
- Define the following terms: *goal, outcome, expected outcome, nursing-sensitive outcome.*
- Differentiate between short-term and long-term goals.
- Explain how a goal is derived from a nursing diagnosis.
- Differentiate between essential and nonessential goals.
- Write appropriate goals for actual, risk, and possible nursing diagnoses.
- Use standardized terminology to state patient goals.
- Write realistic specific, concrete, and observable goals that do not conflict with the medical plan of care and are stated in terms of patient responses/behaviors.

Patient care plan
Planning

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patient

Ben Ivanos has just been admitted to an orthopedic unit after a motorcycle accident. Mr. Ivanos is 24 years old, normally healthy, and takes no medications. He has casts and traction on both legs and a cast on one arm. He is receiving morphine sulfate intravenously via a patient-controlled analgesia (PCA) pump. Imagine that you are an orthopedic nurse and must plan care for Mr. Ivanos. You rank the following nursing diagnoses as highest priority:

1. Acute Pain secondary to musculoskeletal trauma (arms, legs, body) and muscle spasms
2. Risk for Peripheral Neurovascular Dysfunction secondary to casts/traction

Meet Your Patient (continued)

You write the following desired outcomes (goals) on the care plan:

Goals for diagnosis 1

Demonstrates correct use of PCA pump.
Rates pain not higher than 4 on a scale of 1 to 10 at all times.

Goals for diagnosis 2

Peripheral pulses palpable
Fingers and toes warm
Fingers and toes without pallor or cyanosis
No edema of fingers and toes
Capillary refill less than 3 seconds

These goals will guide you in choosing nursing interventions for relieving Mr. Ivanos's pain and preventing peripheral neurovascular dysfunction. When the nursing shift changes, the written care plan provides directions for the new caregivers so that they will continue to focus on Mr. Ivanos's most important needs.

Theoretical Knowledge knowing why

This text separates the process of planning outcomes from the process of planning interventions because, although related, they are distinctly different activities. This chapter (1) describes planning as a general process, (2) explains how to create a patient care plan, and (3) discusses how to write patient goals/expected outcomes. Chapter 6 explains how to plan nursing interventions and write nursing orders.

ABOUT THE KEY CONCEPTS

To help you understand and remember the content in this chapter, try to organize what you learn under the key concepts of **planning**, **goals** and **outcomes**, and **patient care plans**. Planning is the broad umbrella term that "covers" the rest of the chapter concepts. In this chapter, you will learn how they are all related.

WHAT IS PLANNING?

The professional nurse is responsible for care planning, and cannot delegate it. However, you should be aware that some healthcare facilities list care planning in their job description for licensed practical or vocational nurses. Certainly licensed practical (or vocational) nurses (LPNs/LVNs) can provide valuable input for registered nurses (RNs) who are planning the care. Box 5-1 lists American Nurses Association (ANA) standards that specifically identify planning as the role of the registered nurse.

Planning can be formal or informal. **Formal planning** is conscious and deliberate. It involves decision making, critical thinking, and creativity (Wilkinson, 2011). During the planning phases of the nursing process, you will work with the patient and family to derive desired outcomes from identified patient problems (e.g., nursing diagnoses) and then to identify nursing interventions to help achieve those outcomes. The end product of formal planning is a holistic plan of care that addresses the patient's unique problems and strengths.

Not all plans are written. **Informal planning** occurs while you are performing other nursing process steps. For example, while performing neurovascular checks for Ben Ivanos, you might discover that he is not obtaining adequate pain relief. Reflect on this situation. What would you do? Any response in that scenario would require some mental planning. For example, you might make a mental note (plan) to notify the patient's prescriber for an increase in the analgesic dose.

How Is Planning Related to Other Steps of the Nursing Process?

Nursing process steps are overlapping and interdependent. To develop a plan of care with realistic goals and effective nursing orders, you must have accurate, complete *assessment* data and correctly identified and prioritized *nursing diagnoses*. The *goals/desired outcomes* flow logically from the nursing diagnoses. By stating what is to be achieved, the goals then suggest nursing interventions (which are written as nursing orders in the *planning interventions* phase). The plan of care is carried out in the *implementation* phase. In the *evaluation* step, the goals/desired outcomes serve as criteria for evaluating whether the nursing care has been effective. Figure 5-1 illustrates the relationship of planning outcomes to the other stages of the nursing process.

Initial and Ongoing Planning

Initial planning begins with the first patient contact. It refers to the development of the initial comprehensive care plan, which should be written as soon as possible after the initial assessment. The nurse who performs the admission assessment has the benefit of personal contact (rather than relying completely on the written database), has the best information about the patient, and, ideally, is the one who should initiate the care plan.

BOX 5-1 ■ American Nurses Association Standards of Nursing Practice for Outcomes and Planning

Standard 3. Outcomes Identification

The registered nurse identifies expected outcomes for a plan individualized to the patient or the situation.

Competencies

The registered nurse:

Involves the healthcare consumer, family, healthcare providers, and others in formulating expected outcomes when possible and appropriate.

Derives culturally appropriate expected outcomes from the diagnoses.

Considers associated risks, benefits, costs, current scientific evidence, expected trajectory of the condition, and clinical expertise when formulating expected outcomes.

Defines expected outcomes in terms of the healthcare consumer, healthcare consumer culture, values, and ethical considerations.

Includes a time estimate for attainment of expected outcomes.

Develops expected outcomes that facilitate continuity of care.

Modifies expected outcomes based on changes in the status of the healthcare consumer or evaluation of the situation.

Documents expected outcomes as measurable goals.

Standard 4. Planning

The registered nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes.

Competencies

The registered nurse:

Develops an individualized plan in partnership with the person, family, and others considering the person's characteristics or situation, including, but not limited to, values, beliefs, spiritual and health practices, preferences, choices, developmental level, coping style, culture and environment, and available technology.

Establishes the plan priorities with the healthcare consumer, family, and others as appropriate.

Includes strategies in the plan that address each of the identified diagnoses or issues. These may include, but are not limited to, strategies for:

- Promotion and restoration of health
- Prevention of illness, injury, and disease
- The alleviation of suffering
- Supportive care for those who are dying

Includes strategies for health and wholeness across the life span.

Provides for continuity in the plan.

Considers the economic impact of the plan on the healthcare consumer, family, caregivers, or other affected parties.

Integrates current scientific evidence, trends, and research.

Utilizes the plan to provide direction to other members of the healthcare team.

Explores practice settings and safe space and time for the nurse and the healthcare consumer to explore suggested, potential, and alternative options.

Defines the plan to reflect current statutes, rules and regulations, and standards.

Modifies the plan according to the ongoing assessment of the healthcare consumer's response and other outcome indicators.

Documents the plan in a manner that uses standardized language or recognized terminology.

Note: There are additional standards for advanced practice nurses.
Source: American Nurses Association. (2010). *Nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Author.

You may sometimes need to begin care planning even though the initial database is incomplete. For example, the patient may require emergency care before assessment is complete. Or a different patient may need your immediate attention. In such situations, make a preliminary plan with whatever information you have. You can complete and refine the plan when you are able to perform a more detailed assessment.

Ongoing planning refers to changes made in the plan (1) as you evaluate the patient's responses to care or (2) as you obtain new data and make new nursing diagnoses. For example, the nurses discovered that Ben Ivanos (Meet Your Patient) had not slept well on his first night in the hospital. They identified a new nursing diagnosis for him: Disturbed Sleep Pattern r/t unfamiliar environment and pain. They then developed a plan for addressing this problem. Ongoing planning allows you to decide which problems to focus on each day that you care for the patient.

Discharge Planning

If the recommended length of stay for patients with surgical reduction of fractures is 2 days, then Ben Ivanos will still have casts on his arm and both legs when he leaves the hospital. Obviously, he will not be able to manage his own activities of daily living (shopping, cooking, bathing, etc.). What questions come to your mind when you think about how he will manage after he leaves the hospital? Stretch your mind—take a moment now to jot down your ideas.

You may have thought of some questions: Is there anyone who can help Mr. Ivanos with his personal care? Will he need to go up and down stairs? Who will drive him home from the hospital? Can he be discharged home or will he need to go to a rehabilitation facility? How soon does he need to see his primary care provider? Can he get to the provider's office? How will he manage his pain at home; what will he use in place of the PCA narcotics?

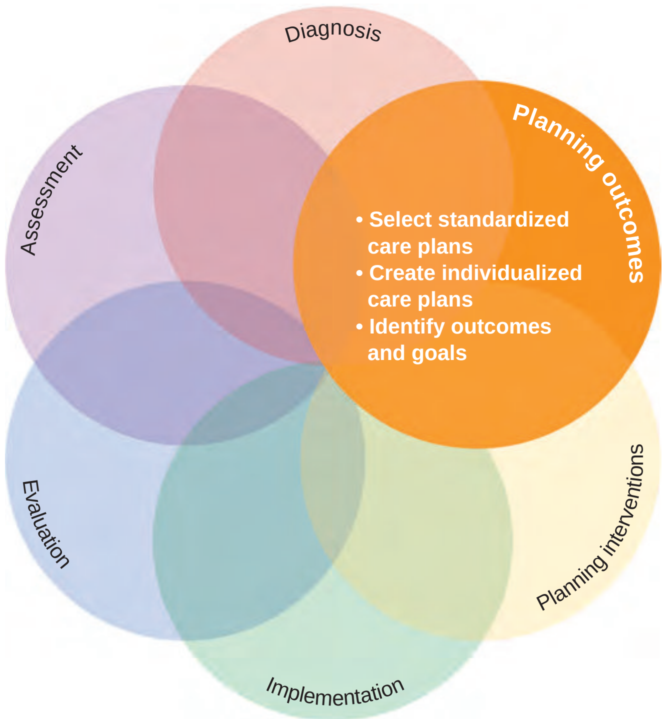

FIGURE 5-1 Nursing process phases: Planning outcomes.

Discharge planning is the process of planning for self-care and continuity of care after the patient leaves a healthcare setting. Ben Ivanos's case is not unusual. In the United States, outpatient surgeries and short hospital stays are the norm. Many patients are discharged despite ongoing need for nursing care and complex treatments. Therefore, nurses must prepare family members to perform tasks such as bathing, changing sterile dressings, and monitoring intravenously administered medications. If family members are not available or if skilled nursing care is needed, arrangements must be made for home healthcare or transfer to a skilled nursing or rehabilitation facility. Sometimes a case manager is assigned, but often staff nurses must plan and coordinate services. If appropriate services are not provided or if family members perform care incorrectly, the patient may experience delayed recovery or complications that require further treatment or hospital readmission.

To learn more about the process of discharging patients from an institution, refer to the section Maintaining Trust During Transitions in Chapter 11 and

Go to Chapter 11, **Procedure 11-4, Discharging a Patient from the Healthcare Facility,** in Volume 2.

Discharge Planning Begins at Assessment

Because patients are in the surgery center or hospital for such a short time, discharge planning must begin at the initial assessment, which should include the following patient data:

- Physical condition and functional and self-care limitations
- Emotional stability and ability to learn
- Financial resources (e.g., personal finances, insurance, community resources such as food stamps, Medicaid)
- Family or other caregivers available
- Caregiving responsibilities the patient may have for others
- Environment, both home and community (e.g., stairs, space for supplies and equipment, availability of transportation to healthcare services)
- Use of community services before admission
- Estimated date of discharge. Some agencies require this be done at the time of admission, except for situations such as admission from the emergency department or a critical care unit. This may require collaborative effort.

Written Discharge Plans

All patients need at least some discharge planning, but you will not always need a separate, written discharge plan. For example, a middle-aged patient who has been hospitalized for deep vein thrombosis (a blood clot in a major vein, usually the lower leg) will be able to care for herself independently when she goes home. For this patient, you could simply write on the comprehensive care plan a nursing order to teach her about the side effects of the warfarin (Coumadin, an anticoagulant) she will be taking at home. In contrast, you will probably need a comprehensive, formal discharge plan if the patient is an older adult or has one or more of the following (Jweinat, 2010; NSW Department of Health, 2011; Walker, Hogstel, & Curry, 2007):

- *Personal characteristics that interfere with self-care, such as the following:*
  - Difficulty learning or a memory deficit
  - Emotional or mental illness
  - Poor mobility
  - Self-care deficits (e.g., dressing, feeding, bathing, toileting)
  - Incontinence
- *Disease or treatment characteristics; coexisting illness*
  - Terminal illness
  - Complicated major surgery
  - Complex treatment regimen or more than three medications to continue at home
  - An illness with an expected long period of recovery
  - A newly diagnosed or multiple chronic health problems (e.g., diabetes, chronic pain)
  - Preexisting wound
  - Malnutrition
- *Social or family factors*
  - Inadequate services available in the community

Inadequate financial resources
No family or significant others to help provide care

For an example of a discharge planning form,

Go to Chapter 5, **Discharge Planning Form,** in Volume 2.

Discharge Planning for Older Adults

The percentage of older adults in hospitals is quite high, and they tend to have complex needs when discharged. Therefore, when an older adult is hospitalized, it is especially important to start discharge planning at the initial admission assessment. This means that assessment of functional abilities, cognition, vision, hearing, social support, and psychological well-being must be a part of the initial assessment so that you can identify needed services at discharge. A comprehensive discharge process for older adults should help to achieve the following objectives:

- Maintain functional ability.
- Lengthen the time between rehospitalizations.
- Involve all concerned parties in decision making.
- Improve interagency communication (e.g., hospital to nursing home).
- Emphasize client and family involvement and interdisciplinary collaboration (Walker, Hogstel, & Curry, 2007).

Discharge Planning Requires Collaboration

Comprehensive discharge planning involves significant collaboration. Ideally, it is done *with,* not *for,* the patient—patient involvement is important for achieving desired outcomes. In addition, a patient's postdischarge needs often call for services from a multidisciplinary team, which may include home care service personnel; private-duty nurses; physical therapists; social service professionals; speech, occupational, and hearing therapists; physicians; and members of the patient's family.

KnowledgeCheck 5-1

- What does the nurse do in the planning phases of the nursing process?
- What is the purpose of initial planning? Ongoing planning? Discharge planning?

PATIENT CARE PLANS

The **comprehensive patient care plan** (also called *nursing care plan*) is the central source of information needed to guide holistic, goal-oriented care to address each patient's unique needs. It is a document—usually several documents—that specifies dependent, interdependent, and independent nursing actions necessary for care of a specific patient. It usually combines both standardized and individualized approaches to care.

Why Is a Written Patient Care Plan Important?

A well-written comprehensive care plan benefits the patient and the healthcare institution by:

- **Ensuring that care is complete.** Specific written directions are less likely to be overlooked by busy caregivers (e.g., "Turn patient hourly").
- **Providing continuity of care.** This helps ensure that when an effective intervention is found, all caregivers will use the same approach with the patient. For example, suppose a child who is dehydrated refuses to drink any liquids. The day nurse discovers the child will eat red, and only red, popsicles. If he fails to note that on the care plan, the night nurse may be unable to persuade the child to take oral liquids and may have to administer fluids intravenously to prevent further dehydration.
- **Promoting efficient use of nursing efforts.** Specific, written instructions help to ensure that nurses do not waste time on ineffective approaches. In the preceding example, the night nurse may waste a great deal of time trying to persuade the child to drink liquids.
- **Providing a guide for assessments and charting.** Nursing orders and goals/expected outcomes on the care plan can help you plan your activities and ensure nothing is omitted from your documentation.
- **Meeting the requirements of accrediting agencies.** The Joint Commission and professional standards review organizations (PSROs) require a patient-specific plan of care.

What Information Does a Comprehensive Patient Care Plan Contain?

Regardless of their format, comprehensive care plans include directions for four different kinds of care and include both medical and nursing interventions:

1. *Basic needs and activities of daily living (ADLs).* This includes the routine assistance that the patient needs with hygiene, nutrition, elimination, and so on, regardless of her nursing diagnoses.
2. *Medical/multidisciplinary treatment.* Nurses need to know the medical orders for each patient (e.g., prescriptions for IV fluids and medications) and the nursing activities necessary for carrying out those orders.
3. *Nursing diagnoses and collaborative problems.* This section may be referred to as the *nursing diagnosis care plan.* It contains goals and nursing orders for the patient's nursing diagnoses and collaborative problems.
4. *Special discharge needs or teaching needs.* Finally, the plan should contain instructions for formal discharge planning and special teaching if they are needed.

What Documents Make Up a Comprehensive Patient Care Plan?

You will use a variety of documents to create a care plan. Care plans vary widely in format, appearance, and use. In most healthcare organizations, caregivers use preprinted, standardized plans that can be adapted to meet individual needs. Figure 5-2 shows the documents that are most commonly included in a comprehensive patient care plan.

Form for Client Profile and Basic Needs

Some essential client data either do not change or are used or updated often. This includes the client's profile (e.g., age, providers, drug allergies, and so on), basic needs (e.g., for hygiene, nutrition, and elimination), and diagnostic tests and treatments (e.g., laboratory tests, radiology procedures, and respiratory therapy). To provide quick and easy access, such information is usually recorded on standardized forms and not organized according to medical or nursing diagnoses (see Fig. 5-2A). These are often in electronic format, but may be printed on cardstock and kept in a central location easily accessible to all care providers. For an example of a printed Kardex,

Go to Student Resources: Chapter 5, **Tables, Boxes, Figures: ESG Figure 5-1,** on Davis*Plus*.

For clients who require more than routine attention to their basic needs, you may need to write a nursing diagnosis care plan. Examples include a client with no appetite and the nursing diagnosis Imbalanced Nutrition: Less Than Body Requirements, or an immobile client with the diagnosis Risk for Impaired Skin Integrity.

Preprinted, Standardized Plans

As shown in Figure 5-2B, a comprehensive care plan usually includes one or more preprinted, standardized documents. It would be too time consuming to handwrite a complete care plan for every patient. Standardized plans save nursing time, promote consistency of care, and help ensure that nurses do not overlook important interventions. You will find standardized instructions for patient care in a variety of documents. A document may (1) contain nursing or multidisciplinary interventions and (2) prescribe care for one or more nursing diagnoses (e.g., Anxiety) or a disease or medical condition (e.g., pneumonia). The following are examples of standardized, preprinted instructions for care.

Policies and Procedures

Policies and **procedures** are similar to rules and regulations. When a situation occurs frequently or requires a consistent response regardless of who handles it, management develops a policy to govern how it is to be handled. You should consider individual needs and use critical thinking to interpret policies in a caring manner. For example, in some critical care units a patient is allowed one visitor for 10 minutes each hour. Imagine, though, that a patient is expected to die soon, and that his daughter has come from a distant state

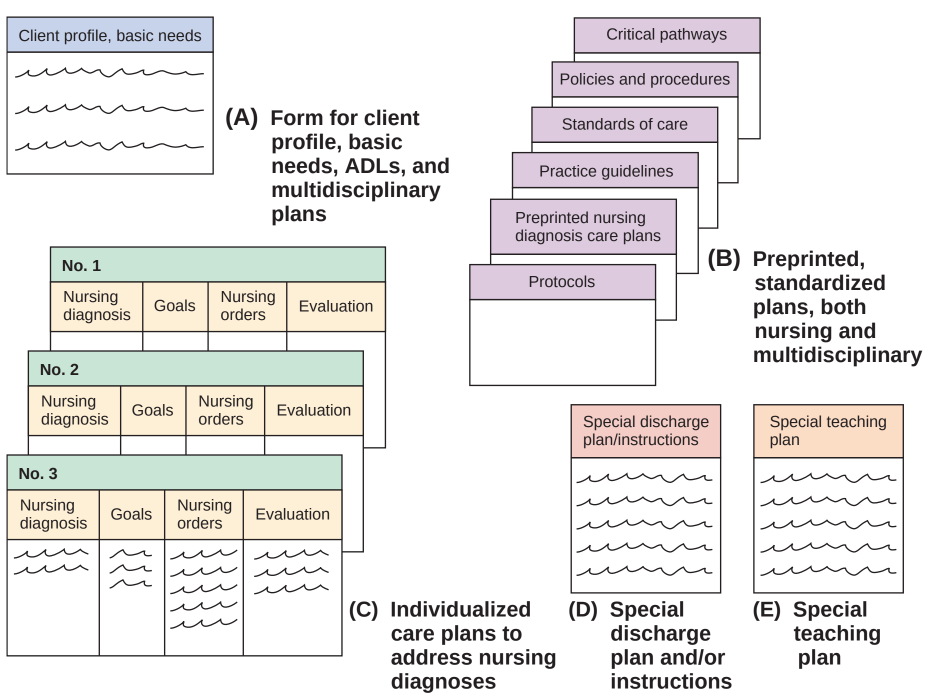

FIGURE 5-2 Components of a patient care plan. *A*, Form for client profile, basic needs, ADLs, and multidisciplinary plans. *B*, Preprinted, standardized plans, both nursing and multidisciplinary. *C*, Individualized care plans to address nursing diagnoses. *D*, Special discharge plan and/or instructions. *E*, Special teaching plan.

and brought her three children for one last visit. Would you tell the daughter to take the children in to see their grandfather? Would you insist that she follow the rule and send them in without her, one at a time over a period of 3 hours?

Protocols

Protocols cover specific actions usually required for a clinical problem unique to a subgroup of patients. For example, not every patient on a medical-surgical unit is at risk for falls, but many are. Therefore the nurse would add a falls protocol to the care plan for a patient in that subgroup, such as in Figure 5-3. Protocols may be written for a particular medical diagnosis (e.g., seizure), treatments (e.g., administration of oxytocin to induce labor), or diagnostic tests (e.g., barium enema). They contain both medical and nursing orders. Some include definitions and rationales for interventions.

Unit Standards of Care

Unit standards of care describe the care that nurses are expected to provide for all patients in defined situations (e.g., all women admitted to a labor unit or all patients admitted to the critical care unit). In this way, they are similar to protocols. Unlike protocols, however, they (1) apply to every patient in a defined situation, rather than a subgroup; (2) do not become part of the patient's care plan but are kept on file on the unit; and (3) do not usually include specific medical orders. Instead of describing ideal care, standards of care describe the minimum level of care the nurses are expected to achieve given the institution's resources and the client population. Unit standards of care usually are not organized according to nursing diagnoses and they usually resemble a list of "things to do" (e.g., complete comprehensive assessment within 2 hours of admission) rather than detailed instructions for care.

A Seventh-day Adventist Community Service

Patient Care Protocol

Title: Fall or Injury/Disruption of Care, Care of the Patient at Risk for **Effective Date:** mm/dd/yyyy

Expected Outcome: The patient at risk for falls will be identified and preventive measures initiated. The patient will not pull out indwelling devices.

Relevant Information: Initiate this protocol for adult patients who have a Conley Fall Scale score of $\geq$3.

Assessment:
1. The Conley Fall Scale will be administered on admission to adult inpatients. Further assessment will be based on patient population and identified patient need.

Interventions: Make alterations in environment, such as:
- Avoiding clutter in room.
- Moving patient closer to Nursing Station if indicated.
- Making sure call light, telephone, and other personal items are within reach

Educate patient and family about:
- The possibility that family and friends may be called upon to stay with patient with high risk for fall or injury or who attempts to pull out indwelling devices.
- The possibility that, if the above measures are not successful in reducing the patient's fall risk or preventing attempts to pull out indwelling devices, alternative measures such as the use of restraints may have to be considered.

Evaluation:
1. Evaluate frequently to determine whether expected outcome is being met. Change strategies as needed to reduce fall risks or to prevent disruption of indwelling devices.
2. **Criteria for initiation of Restraint Protocol:**
   - If interventions have been implemented and patient continues to be at risk of falling or disrupting medical treatment, the protocol Care of the Patient in Restraint for Medical/Surgical Management is initiated.
   - The CRN/Supervisor is notified at the time the restraint is initiated for med/surg management and reviews the need for restraint.

FIGURE 5-3 Portion of Patient Care Protocol for patient at risk for falls. (*Source:* Courtesy of Shawnee Mission Health System, Shawnee Mission, KS, 66204.)

ThinkLike a Nurse 5-1

- Think of some other "defined situations" for which unit standards of care might be useful.
- Suggest some other subgroups for which a protocol might be appropriate.

Standardized Patient Care Plans

Standardized (model) patient care plans detail the nursing care that is usually needed for a particular nursing diagnosis or for all nursing diagnoses that commonly occur with a medical condition. Figure 5-4 is a standardized care plan for a single nursing diagnosis. Although similar to unit standards of care, model care plans are different in that they usually:

- Provide more detailed interventions. They may add to or delete from unit standards of care.
- Are organized by nursing diagnosis and include specific patient goals and nursing orders.
- Are a part of the patient's comprehensive care plan and become a part of the permanent record.
- Describe ideal rather than minimum nursing care.
- Allow you to incorporate addendum care plans.
- Include checklists, blank lines, or empty spaces so that you can individualize goals and interventions.

Students sometimes purchase model care plan books. You can use them as guides, but be aware that they do not address a client's individual, specific needs. For this reason, they may lead you to focus on the common, predictable problems and overlook an unusual—and perhaps more important—problem the person is experiencing. Beginning with the standardized plan may stifle your creativity. It is best to first use the process for writing a patient care plan (see What Is the Process for Writing an Individualized Patient Care Plan? later in this chapter) and then consult the model plan to see whether you have missed anything.

Critical Pathways

Critical pathways are often used in managed care systems. They are outcomes-based, interdisciplinary plans that sequence patient care according to case type. They specify predicted patient outcomes and broad interventions for each day, or in some situations, for each hour (Fig. 5-5). They describe the minimal standard of care required to meet the recommended length of stay for patients with a particular condition or *diagnosis-related group* (*DRG*; e.g., postpartum, myocardial infarction, or total hip replacement). An agency usually develops critical pathways for its most frequent case types or for situations in which standardized care can produce predictable outcomes. Although critical pathways are developed by a multidisciplinary team, they tend to emphasize medical problems and interventions. Because critical pathways describe the expected outcomes of multidisciplinary care, they do not provide a way to judge *nursing* effectiveness—you will learn about *nursing-sensitive outcomes* later in the chapter.

Integrated Plans of Care

Integrated plans of care (IPOCs) are standardized plans that function as both care plan and documentation form. Therefore, there is a different form—or sometimes a different column—for each day of care. Many critical pathways are designed as IPOCs; however, IPOCs do not necessarily (1) organize care according to diagnosis, (2) describe minimal standards of care, or (3) specify a timeline for interventions and outcomes. For an example of an IPOC,

Go to Chapter 5, **Tables, Boxes, Figures: ESG Figure 5-2,** on Davis*Plus*.

Individualized Patient Care Plans

Nurses use individualized patient care plans to address nursing diagnoses unique to a particular client (Fig. 5-2C). These care plans reflect the independent component of nursing practice, and therefore best demonstrate the nurse's critical thinking and clinical expertise. In addition to including goals and nursing orders that you write specifically for a patient, a complete individualized care plan may contain standardized single-problem care plans (see Fig. 5-4).

Standardized plans focus on the common problems and interventions needed by most patients. They do not address unusual problems and may not meet a patient's individual needs. You should always adapt standardized plans by adding the necessary nursing diagnoses, goals/outcomes, and nursing orders they do not include. For example, a standardized plan for a client with a myocardial infarction (heart attack) would undoubtedly prescribe care for the nursing diagnosis Pain and the potential complication of heart failure. However, it might not address the needs of a person who is not complying with treatments because he is in denial about his illness (nursing diagnosis: Ineffective Denial). An individualized plan for resolving the patient's denial would improve the likelihood that the rest of the plan will be successful.

You may sometimes include medical orders in a nursing diagnosis or collaborative problem care plan, especially in a student care plan. For example, for a client with a nursing diagnosis of Deficient Fluid Volume, you might list the medical prescription for intravenously administered fluids in the Nursing Orders column.

Nursing Diagnosis	*Nursing orders*
Deficient Fluid Volume related to vomiting and diarrhea	1. Check skin turgor q4hr 2. Medical order: IV normal saline, 150 mL/hr

Special Discharge or Teaching Plans

A nursing plan of care may also contain one or more discharge or teaching plans (see Fig. 5-2D). These are sometimes referred to as *special-purpose* or *addendum* care plans. You can address routine discharge planning and teaching needs by using standardized plans or by

PATIENT PLAN OF CARE - GENESIS MEDICAL CENTER - Davenport, Iowa

PAIN, ACUTE: Experience of an unpleasant sensory and emotional sensation for a duration of less than 6 months.
SIGNS & SYMPTOMS: Observed or reported (select at least 2)

- ☐ Change in BP
- ☐ Patient's self-report of pain
- ☐ Change in respiratory pattern
- ☐ Restlessness
- ☐ Diaphoresis
- ☐ Whimpering
- ☐ Grimacing
- ☐ Increased muscle tension
- ☐ Whining
- ☐ Crying
- ☐ Change in pulse rate

OUTCOME SCORING

RELATED FACTORS	OUTCOMES	ADM				DC	INTERVENTIONS
☐ Physical injuring agent ☐ Psychological injuring agent	4 Pain-control behavior – Recognizes causal factors – Uses non-analgesic relief measures – Uses analgesics appropriately – Reports pain controlled 3 Pain level – Oral/facial expressions of pain – Change in respiratory rate, heart rate, BP – Restlessness – Reported pain 3 Comfort level – Reported satisfaction with symptom control – Expressed satisfaction with pain control – Reported physical well-being						☐ Pain management ☐ Analgesic administration ☐ Patient-controlled analgesic (PCA) assistance ☐ Analgesic administration: Intraspinal ☐ Environmental management: comfort ☐ Anxiety reduction ☐ Transcutaneous electrical nerve stimulation (TENS) ☐ Heat/cold application ☐ Distraction ☐ Simple relaxation therapy ☐ Simple massage ☐ Developmental care ☐ Preparatory sensory information ☐ Positioning

Definition of scoring scales	**1**	**2**	**3**	**4**	**5**
Pain control — Personal actions to control pain	Never demonstrated	Rarely demonstrated	Sometimes demonstrated	Often demonstrated	Consistently demonstrated
Pain level — Severity of reported pain	Severe	Substantial	Moderate	Slight	None
Comfort level — Extent of physical and psychological ease	None	Limited	Moderate	Substantial	Extensive

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA

TOTAL LOWER JOINT (HIP/KNEE)
CLINICAL PATHWAY

ELIGIBILITY CRITERIA: All primary unilateral total hip or total knee replacements

EXPECTED LOS: 3 Days

ADDRESSOGRAPH

CLINICAL KEYS:

1. Pain managed midpoint on painscale
2. Transfer to chair/commode with assistance POD 1; Ambulate in room, bathroom POD2
3. DVT precautions
4. Discharge plan completed by POD2
5. Patient verbalizes knowledge of hip or knee precautions
6. Knee motion 10 to 70 or better (TKA patients only)

	PACU	IMMED. POST- OP	POD 1	POD 2	POD 3-4
ASSESSMENTS	• NV checks with VS q1h × 4 • Pain • Effects of narcotics/ tolerance • 1 & 0 × 24hr • Pulse Ox q8 if on O2	• NV check / VS q 4hr → → • S/S DVT →	→ → → → • Pulse Ox × 1 on RA • Dsg/wound status q4	• NV check / VS q 8hr → → → • D/C pulse ox if O2 D/C • Dsg/wound status q8	→ → → → →
CONSULTS		• PT • PMR	→ (If not done already) → (If not done already)		
TESTS	• A/P hip X-ray (THA) • A/P knee X-ray (TKA)		• CBC	→ • INR (if on warfarin)	• A/P hip X-ray →
TREATMENTS	• O2	• D/C O2 if sat 94% • Incentive spirometry • Order walker (hip chair, elevated commode if needed) • Pneumatic compression device (ankle for knees, calf for hips)	→ → • D/C foley • Dressing change (1st dsg change by MD) →	→ → • Dressing change q day and pm →	→ → →
MEDICATIONS	• PCA or epidural	→ • Anticoagulation	• IV heplock → • Consider conversion to oral pain meds	• D/C heplock → • D/C PCA/PCEA • PO pain meds	→
ACTIVITY	• Bedrest • Hip precautions if THA • CPM for total knee	→ → →	• OOB to chair BID → → • Weight bear per order • Ambulate with assistive device	• OOB TID → → → → • PT ×2	→ → → → → →
NUTRITION	• NPO	• NPO → ice → advance to full as tolerated	• Regular	→	→
EDUCATION / D/C PLANNING	• Deep breathing exercises	• Pain management • Initiate d/c plan	→ • Home vs rehab decision • Anticoagulation if indicated	→ • S/S wound infection • Medications • Activity level • D/C plan in place	→ → → • Car transfer

<u>Transfer to rehab when:</u>
1. Able to participate in care
2. Tolerating 2 physical therapy sessions
3. Not requiring IV pain medicine
4. Blood values are stable
5. Motivation is commensurate with projected functional status

<u>Discharge to home when:</u>
1. Mobility and ADL's appropriate for degree of assistance at home and home environment
2. Appropriate assistive device and necessary adaptive equipment is used
3. Independent with hip/knee precautions
4. Independent with home exercise program or ongoing PT in the home or outpatient

**IF D/C TO HOME, ENSURE APPROPRIATE CONSULTS TO ARRANGE HOME CARE FOLLOW-UP AND EQUIPMENT

including teaching as part of the nursing orders on an individualized care plan. For example, a care plan for the diagnosis Acute Pain might include the nursing order, "Teach patient to splint incision when turning in bed." Chapter 19 shows an example of a teaching plan for the diagnosis Deficient Knowledge.

Computer Plans of Care

Many healthcare organizations use electronic health records, including *computer-generated care plans.* The computer stores standardized plans (e.g., for nursing diagnoses, medical diagnoses, or diagnosis-related groups [DRGs]). When you enter a diagnosis or a desired outcome, the computer generates a list of suggested interventions. You then choose appropriate interventions from the list, individualize by choosing from checklists, or type in your own interventions and strategies.

Computer prompts help ensure that you consider a variety of actions and keep you from overlooking common and important interventions. After the initial learning curve, they also reduce the time spent on paperwork. However, computerized planning requires constant use of a step-by-step thinking process, which may cause a decrease in intuition, insight, ability to care, and nursing expertise (Harris, 1990; Kossman & Scheidenhelm, 2008). You must resist the temptation to accept "one size fits all" solutions. Always look for creative approaches that might be more effective for a particular individual. Think, "What would work for *this* person?"

ESG Figure 5-3 at Davis*Plus* shows a computer screen displaying a care plan for the nursing diagnosis Impaired Mobility. Most computer programs allow you to print the plan.

Go to Student Resources: Chapter 5, **Tables, Boxes, Figures: ESG Figure 5-3,** on Davis*Plus*.

KnowledgeCheck 5-2

- In addition to care related to the patient's basic needs, what other types of information does a comprehensive care plan contain?
- How are critical pathways different from other standardized care plans?
- What is the main disadvantage of computerized and standardized care plans?

ThinkLike a Nurse 5-2

Suppose a nurse sees one of your student care plans and says to you, "You're wasting your time writing those things. We never use the nursing process in the real world." Take a few minutes to write how you might respond.

Student Care Plans

You may have noticed that the care plans you see in clinical settings look different from the ones you create as a part of your clinical preparation. This is because student care plans are a learning activity as well as a plan of care. They are designed to help you learn and apply concepts from the nursing process, physiology, and psychopathology. For this reason, they may contain more detailed nursing orders as well as other information the instructor requires (e.g., information about lab tests, medications, and assessment data to support the nursing diagnoses). Some instructors may ask you to write rationales and cite references to support them. **Rationales** state the scientific principles or research that supports nursing interventions. Writing rationales helps ensure that you understand the reasons for the interventions. **Key Point:** ***Understanding why you do what you do is one aspect of functioning as a professional.*** For an example of a student care plan,

Go to Student Resources: Chapter 5, **Student Care Plan Example,** on Davis*Plus*.

Mind-Mapping Student Care Plans

Mind-mapping is a technique for showing relationships among ideas and concepts in a graphical, or pictorial, way. Mind-mapping is thought to stimulate "whole-brain" and critical thinking, and to foster the development of holistic plans of care (Mueller, Johnston, Bligh, & Wilkinson, 2002). A mind-mapped care plan uses shapes and pictures to represent the parts of the nursing process (i.e., assessment data, nursing diagnoses, patient goals, interventions, and evaluation), as well as the patient's pathophysiology, medications, and other pertinent information. For complete information about mind-mapping,

Go to Student Resources: Chapter 5, **Supplemental Materials: Mind-Mapping Student Care Plans,** on Davis*Plus*.

PracticalKnowledge knowing **how**

The rest of this chapter will help you learn how to apply your knowledge of the key concepts, *goals, outcomes, patient care plan, and planning*, as well as the many related concepts you have learned.

WHAT IS THE PROCESS FOR WRITING AN INDIVIDUALIZED PATIENT CARE PLAN?

In this section, you will need to use your theoretical knowledge of concepts related to care planning (e.g., standardized plans, protocols, individualized patient care plans. Writing an individualized patient care plan follows in natural sequence from the assessment and diagnosis phases of the nursing process:

1. ***Make a Working Problem List***. Earlier in the nursing process, you will already have developed and prioritized a list of the patient's nursing diagnoses, collaborative problems, and strengths. Suppose that after

assessment you prioritized Ben Ivanos's (Meet Your Patient) problems as follows:

A. Acute Pain secondary to musculoskeletal trauma (arms, legs, body) and muscle spasms
B. Risk for Peripheral Neurovascular Dysfunction secondary to casts/traction
C. Self-Care Deficit (Bathing, Dressing, Feeding, Toileting) r/t immobility secondary to casts, especially cast on dominant right arm
D. Potential Complication of fracture: delayed, union, malunion, or nonunion of bone

2. ***Decide which problems can be managed with standardized care plans or critical pathways.*** What institutional documents are available? Suppose that the hospital unit has a critical pathway for "Patients with Casts and/or Traction." This critical pathway would contain goals and interventions to guide the care for problems B and D above. It would specify regular neurovascular assessments and management of the traction apparatus, for example.
3. ***Individualize the standardized plan as needed.*** Cross out any instructions that do not apply to your patient, and add or adapt nursing orders as appropriate. For example, the plan might say "Perform neurovascular checks q_____." You would fill in the frequency of the assessment according to Mr. Ivanos's needs.
4. ***Transcribe medical orders to appropriate documents.*** For example, you might write orders for pain medications on a special medication administration record. Details about Mr. Ivanos's traction would probably go on a Kardex or special section of the critical pathway.
5. ***Write ADLs and basic care needs in special sections of the Kardex, care plan, or computer screen.*** For Ben Ivanos, you might note on the Kardex that he requires a complete bed bath and help with eating.
6. ***Develop individualized care plans for problems not addressed by standardized documents***. For Ben Ivanos, you would need to write a plan for problems A and C above. The critical pathway probably contains some expected outcomes and basic interventions for problem A, Pain, but you might need to individualize them to make them more effective. If your unit had a Pain protocol, similar to the Falls protocol in Figure 5-3, you would add it to Mr. Ivanos's care plan. If not, you would hand-write goals and interventions for the Pain diagnosis.

Problem C, Self-Care Deficit, would be partially addressed in the basic care section of Mr. Ivanos's Kardex, but he has special needs. For example, he will need teaching and therapy to increase his ability to care for himself. So you would need to hand-write a plan for this nursing diagnosis.

KnowledgeCheck 5-3

Briefly describe a process for creating a comprehensive, individualized care plan that incorporates collaborative care and standardized planning documents.

PLANNING PATIENT GOALS/OUTCOMES

In this section you will learn about the key concepts of goals and outcomes, and also about a number of related concepts that will expand your understanding of goals and outcomes (e.g., short-term and long-term goals). Then you will learn how to apply your knowledge of goals and outcomes in creating a patient care plan.

After assessment and diagnosis, the next step in individualized care planning is to formulate goals for improving or maintaining the patient's health status. **Goals** (also called **expected outcomes, desired outcomes,** or **predicted outcomes**) describe the changes in patient health status that you hope to achieve. **Nursing-sensitive outcomes** are those that can be influenced by nursing interventions. The rest of this chapter discusses individualized care planning and nursing-sensitive outcomes.

Importance of Goals The purposes of precise, descriptive, clearly stated goals/expected outcomes are to:

- Provide a guide for selecting nursing interventions by describing what you wish to achieve.
- Motivate the client and the nurse by providing a sense of achievement when the goals are met. This is especially important when the client must make difficult lifestyle changes.
- Form the criteria you will use in the evaluation phase of the nursing process.

Nursing Responsibility Goal/expected outcome formulation is the responsibility of the professional nurse (see Box 5-1). You should involve the client as much as possible in goal setting, because goal achievement is more likely if the client believes the goals are important and realistic. Of course, the client must be alert and independent enough to participate. If physical or mental impairments prevent active participation, the nursing team acts on the client's behalf to develop client-centered goals.

How Should I Use the Terms Goal and Outcome?

Many nurses use the terms *goal* and *outcome* interchangeably. In this text, we usually use the Nursing Outcomes Classification (NOC) terminology: the word *outcome,* used alone, means *any* patient response (positive or negative) to interventions (e.g., the pain could become better or worse; both are outcomes). When referring to desired (positive) patient responses, we use *goals, expected outcomes, desired outcomes,* or *predicted outcomes.* For example:

Outcome	Decision Making
Goals/expected outcomes	Participates in decisions about own care.
	Chooses between two or more alternatives.

Some nurses use the term *goal* to mean a broad, nonspecific statement about the desired results of nursing activities. They use *outcomes* (and other outcome terms such as *expected outcomes*) to mean the more specific, observable responses you would use to judge whether the goal has been met. When goals are defined in this way, you must include both goals and expected outcomes on the care plan because a broad goal does not provide enough guidance for evaluating patient responses to care. You can combine the broad goal and specific expected outcome into a single statement by writing, "as evidenced by," as in the following example:

Broad statement (goal)	Constipation relieved
Specific expected outcome (evaluation criteria)	Will have soft, formed bowel movement within 24 hours
Combined statement (goal + outcome)	Constipation will be relieved *as evidenced by* soft, formed bowel movement within 24 hours

Key Point: ***Use of broad goals on the care plan is optional; however, expected outcomes are not optional. You must include them on the care plan.***

How Do I Distinguish Between Short-Term and Long-Term Goals?

Short-term goals are those you expect the patient to achieve within a few hours or days. They are important:

- In situations in which the patient may be discharged before you can evaluate progress toward long-term goals (e.g., as in a same-day and outpatient surgery).
- For providing positive reinforcement to clients who are working toward long-term goals.

Long-term goals are changes in health status that you wish to achieve over a longer period—perhaps a week, a month, or longer. They describe the optimal level of functioning you expect the patient to achieve, given health status and available resources. Ideally, this is a return to normal functioning, but that is not always possible. See Table 5-1 for a comparison of short-term and long-term goals.

KnowledgeCheck 5-4

Refer to Meet Your Patient, at the beginning of the chapter. State whether each of Mr. Ivanos's goals was a short-term or long-term goal.

What Are the Components of a Goal Statement?

Every expected outcome/goal statement must have the following parts:

Subject The subject is understood to be the client, but it can also be a function or part of the client. For example:

[Mrs. Johnson] Will walk to the doorway with the help of one person by 12/13/15.
Lung sounds will be clear to auscultation within 2 days after receiving antibiotics.

Assume that the subject is the client unless otherwise stated. Think, "Client will . . ." to help you phrase the goal statement correctly, but do not write it. For example, in the first goal, you should not write "Mrs. Johnson."

Action Verb Use an action verb to indicate the action the client will perform: what the client will learn, do, or say (e.g., Will *walk* to the doorway). Use concrete verbs

Table 5-1 ➤ Comparison of Short-Term and Long-Term Goals

	DEFINITION	SITUATIONS FOR USE	EXAMPLES
Short-Term Goals	▪ Can be achieved in a few hours or a few days.	▪ Acute care ▪ Day surgery ▪ Clinics ▪ Focus on immediate needs ▪ Students ▪ Evaluation of progress toward long-term goals	▪ Describes pain as < 3 on a 1–10 scale within 30 min after receiving analgesic. ▪ Limits food intake to 1,500 calories per day.
Long-Term Goals	▪ Expected changes that occur over a week, a month, or more ▪ Optimal level of functioning given health status and resources	▪ Home healthcare ▪ Extended-care facilities ▪ Rehabilitation centers ▪ Chronic illness ▪ Conditions that are managed, not cured	▪ Infant will double birth weight within 5 months. ▪ Within 3 months after physical therapy treatments, will dress self except for buttons.

(i.e., describing actions that you can see, hear, smell, feel, or measure), such as the following:

apply	explain	report
choose	eat	select
demonstrate	list	transfer
describe	measure	turn
drink	prepare	verbalize

Performance Criteria These are the standards for evaluating the client's performance. They describe the extent to which you expect to see the action or behavior. Write them in concrete, observable terms because they indicate what you need to measure in order to evaluate outcomes. Performance criteria specify:

(a) How, what, when, or where something is to be done
(b) Amount, quality, accuracy, speed, distance, and so forth

The following example specifies the distance the client is expected to walk: [Client] Will walk *to the doorway* with the help of one person by 12/13/16.

Target Time This is the realistic date or time by which the performance/behavior should be achieved. The target time is the "when" part of the performance criterion: [Client] will walk to the doorway with the help of one person *by 12/13/16*.

Other examples of target times are *by discharge, within 24 hours, at the next visit, each hour, at all times*. For risk (potential) nursing diagnoses, the desired outcome is that the problem will never occur. You assume that the desired response should occur "at all times," but you may wish to schedule times for evaluating the outcome. For example:

Nursing diagnosis: Risk for Constipation r/t inadequate fluid intake
Expected outcome: Bowel movements will be of normal frequency and consistency.
Target time: At all times
Evaluate: Daily

Special Conditions These describe the amount of assistance or resources needed or the experiences/treatments the client should have to perform the behavior. Include special conditions when it is important for other nurses to know them. For example:

[Client] Will walk to the doorway *with the help of one person* by 12/13/16.
After two teaching sessions, [client] will be able to identify foods to avoid on a low-fat diet by 3/1/15.

KnowledgeCheck 5-5

In the following predicted outcomes, identify the subject, action verb, performance criterion, target time, and special conditions (if any). State which components are assumed, if any.

- Will walk to the doorway with the help of one person by 12/13/16.
- After two teaching sessions, [client] will be able to identify foods to avoid on a low-fat diet by 3/1/16.
- Bowel movements will be soft and formed and of his usual frequency.
- Lungs clear to auscultation at all times.

How Do Goals Relate to Nursing Diagnoses?

Expected outcomes are derived directly from the nursing diagnosis. Therefore, they will be appropriate only if you identify the nursing diagnosis correctly. The problem clause (the clause at the left) of a nursing diagnosis describes the response or health status you wish to change. A desired outcome states the *opposite* of the problem and implies this response is what the interventions are intended to achieve (Table 5-2).

ThinkLike a Nurse 5-3

Answer the following questions for Ben Ivanos's nursing diagnosis of Acute Pain secondary to musculoskeletal trauma (arms, legs, body) and muscle spasms:

- What would be the opposite, healthy response to his problem?
- What changes should you see in appearance, body functions, symptoms, knowledge, and emotions?
- If the problem is prevented or solved, how will Mr. Ivanos look or behave? What will you be able to observe (e.g., see, hear, smell, taste, or touch)?
- What should Mr. Ivanos be able to do to demonstrate a positive change? How well, or how soon, should he be able to do it?

Table 5-2 ➤ Comparison of Nursing Diagnoses and Goals

NURSING DIAGNOSIS (PROBLEM SIDE)	GOAL/EXPECTED OUTCOME
Problem response	Opposite of problem response
Present health status	Desired health status
Response that you hope to change	Response that you hope to achieve
Example:	*Examples:*
Ineffective Airway Clearance →	Lungs clear to auscultation
r/t ineffective cough secondary to incision pain →	Coughs productively

After thinking about those questions, you might have said that the opposite response to pain would be absence of (or relief from) pain, but you couldn't really observe that. "Absence of pain" might serve as a broad goal statement. But how about more specific, observable expected outcomes? How would you know that Mr. Ivanos's pain was relieved? Specific, observable behaviors that demonstrate absence of pain include the following: Relaxed body posture, relaxed facial expression, states that his pain is relieved, rates pain as less than 3 on a scale of 1 to 10.

Essential Versus Nonessential Goals

In general, the problem side of the nursing diagnosis suggests the goals, and the etiology suggests nursing interventions. You can also derive some goals from the etiology; however, the **essential patient goals** flow from the problem side of the nursing diagnosis (see the bold print in Table 5-3) because the problem side describes the unhealthy response you intend to change.

Notice in Table 5-3 that the goals derived from the etiology may help resolve the problem, but they could also be achieved without resolution of the problem. Suppose that for a patient with Ineffective Airway Clearance you had written only the goals in regular type. If the patient coughs forcefully and effectively, rates pain as less than 3, and splints his incision while coughing, you might discontinue the interventions for Ineffective Airway Clearance. However, the problem might still exist. Even a client who demonstrates all three of those responses might not be coughing productively enough to clear the airways and might still not have clear lung sounds. This means you should follow this rule:

Key Point: ***For every nursing diagnosis, you must state one goal that if achieved would demonstrate resolution or improvement of the problem.***

Goals for Actual, Risk, and Possible Nursing Diagnoses

You will develop expected outcomes to promote, maintain, or restore health, depending on the status of the nursing diagnosis. See Table 5-4 for explanations and examples. Review Chapter 4 as needed.

Goals for Collaborative Problems

Recall that collaborative problems are physiological complications of diseases (e.g., diabetes) or medical treatments (e.g., cardiac catheterization) that nurses monitor to detect onset or changes in status. The desired outcome is always that the complication will not develop. However, unlike outcomes for nursing diagnoses, these outcomes are not nurse-sensitive; that is, they do not result primarily from nursing interventions. They occur as a result of interventions by several disciplines. Consider the following example:

Collaborative problem: Potential Complication of abdominal surgery: paralytic ileus (paralysis of the ileum of the small intestine)

Goal: Patient will not develop paralytic ileus

Suppose that 36 hours after the surgery, the patient's bowel sounds are absent, his abdomen is distended and painful, and he begins vomiting. What could the nurse have done to prevent this situation? What can the nurse do to relieve the ileus and bring about return of peristalsis? Very little, actually. The primary interventions are medical, and if there is obstruction, probably surgical. Therefore, it would not be appropriate to include a goal for this problem on a patient care plan, because that would imply that nurses are primarily accountable for the outcome.

Collaborative goals are appropriate on multidisciplinary care plans and critical pathways. However, all goals on a patient care plan should be nursing-sensitive goals. For collaborative problems, instead of a patient outcome, you might wish to write a *nursing goal* such as "Early detection of complication, should it occur." See Table 5-4.

On student care plans, to aid your learning, you can write the symptoms of the complication or the normal physiological response you hope to observe (e.g., Bowel sounds present within 24 hours; no abdominal distention; no vomiting), but these are not appropriate on an institutional care plan.

Table 5-3 ➤ Deriving Goals and Interventions From Nursing Diagnoses

NURSING DIAGNOSIS	GOALS/EXPECTED OUTCOMES	NURSING ACTIVITIES
Problem: → *Ineffective Airway Clearance* r/t	**Lungs clear to auscultation.** → **Coughs productively.** **Respirations 12–20/min.** **No pallor or cyanosis.** **No dyspnea or shortness of breath (SOB)**	Teach deep breathing and coughing. Auscultate lungs q4hr. Assess respiratory rate, breathing, and skin color q4hr.
Etiology: → *Ineffective cough secondary to incisional pain*	Coughs forcefully/effectively. → Rates pain as < 3 on 1–10 scale. Splints incision while coughing.	Teach to splint incision while coughing. Turn, cough, and deep-breathe (TCDB) hourly. Medicate for pain 30 min before TCDB.

Table 5-4 ➤ Expected Outcomes for Various Problem Types

TYPE OF PROBLEM	EXAMPLE OF DIAGNOSIS	EXPLANATION OF DIAGNOSIS	EXAMPLE OF EXPECTED PATIENT OUTCOME	FOCUS OF NURSING INTERVENTIONS
Actual Nursing Diagnosis	Constipation r/t inadequate dietary fiber and fluids	Symptoms of constipation present (e.g., no bowel movement [BM]).	Will have normal, formed BM within 24 hours after receiving stool softener.	Resolution or reduction of problem; prevention of complications
Risk (Potential) Nursing Diagnosis	Risk for Constipation r/t inadequate dietary fiber and fluids	Risk factors present (e.g., not drinking enough or eating adequate fiber).	Will have bowel function within normal limits for patient (e.g., daily bowel movement with no need for stool softener or laxative).	Prevention and early detection of problem
Possible Nursing Diagnosis	Possible Constipation r/t suspected inadequate intake of dietary fiber and fluids	Not enough data (e.g., no BM for 2 days, but no data on intake or on his usual bowel habits).	No patient goal. The nursing goal is "Confirm or rule out the problem."	Confirm or rule out problem.
Collaborative Problem	Potential Complication of abdominal surgery: ileus	Medical treatment creates risk for complication that is prevented by collaborative care.	None. Patient responses depend on collaborative care. The broad nursing goal is early identification of the problem.	Primarily detection; prevention is collaborative.
Wellness Diagnosis	Readiness for Enhanced Nutrition	Bowel habits and dietary intake within normal limits, but can be improved	Reports increased intake of dietary fiber and fluids; reports bowel functioning within normal limits.	Maintain or promote higher level of health.

How Do I Use Standardized Terminology for Outcomes?

In Chapter 4, you learned about the NANDA-I standardized terminology for nursing diagnoses. The ANA has also approved several standardized vocabularies for describing client outcomes. The one used throughout most of this book is the Nursing Outcomes Classification (NOC) (Moorhead, Johnson, Maas, et al., 2013).

The NOC is a standardized vocabulary of 385 nursing-sensitive outcomes developed by a research team at the University of Iowa. In the NOC vocabulary, an **outcome** is "an individual, family, or community state, behavior, or perception that is measured along a continuum in response to nursing interventions" (Moorhead, Johnson, Maas, et al., 2013, p. 2). Thus, the NOC is versatile because it is appropriate for use in all specialty and practice areas.

Components of an NOC Outcome

Each NOC outcome consists of an outcome label, indicators, and a measurement scale.

Outcome Label The **outcome label** (usually referred to as *the outcome*) is broadly stated (e.g., Decision Making, Mobility Level, Concentration). It is a neutral label (a variable), to allow for positive, negative, or no change in patient health status. Because NOC outcomes are linked to NANDA-I nursing diagnoses, you can look up a nursing diagnosis to see the list of outcomes suggested for it (Box 5-2). You can find suggested outcomes for each NANDA-I diagnosis in the NANDA/NIC/NOC "linkages" book (Johnson, Moorhead, Bulechek, et al., 2012). You can find Additional Associated Outcomes for each diagnosis in Part IV of the *Nursing Outcomes Classification (NOC)* (Moorhead, Johnson, Maas, et al., 2013).

Indicators The **indicators** are the observable behaviors and states you can use to evaluate patient status. In Table 5-5 the indicators are in the first (left) column. The first one is "Identifies relevant information." This indicator helps you evaluate whether Decision Making (the broad outcome) is being achieved. For each outcome, you select the indicators that are appropriate to the patient. You can add to the list of indicators if necessary.

Measurement Scale For each outcome, NOC has a five-point **measurement scale** (the numbers in Table 5-5) for describing patient status for each indicator. As a rule, 1 is least desirable and 5 is most desirable. If you are using

BOX 5-2 ■ Outcomes Linked to NANDA-I Diagnosis

Nursing Diagnosis

NOC, you do not need to write traditional goal statements. You simply write the label, choose the appropriate indicators, and assign a number from the measurement scale. In your initial assessment, you assign the number that represents the patient's present health status. To form the "goal," you assign the scale number that the patient can realistically achieve after the interventions. Using Table 5-5, you might assign the following numbers:

(NOC Outcome) **Decision Making**
Goals (Indicators + measurement scale)
Identifies relevant information (4, mildly compromised)
Identifies alternatives (4, mildly compromised)
Identifies potential consequences of each alternative (5, not compromised)

For a list of the NOC measurement scales,

Go to Chapter 5, **Standardized Language,** in Volume 2.

KnowledgeCheck 5-6

Figure 5-4, a patient plan of care for Acute Pain, uses NOC language.

- What outcomes did the nurse choose for this patient?
- List two indicators for each of the outcomes.
- For which outcome does the nurse expect the highest level of functioning to occur after interventions? (Note that in this care plan the measuring scale has been applied to the outcomes rather than to the indicators.)

ThinkLike a Nurse 5-4

In Figure 5-4, what do you think the nurse expects to happen? Why do you think she ranked the outcomes this way?

Using NOC With Computer Care Plans

Standardized language (e.g., NOC) is especially useful in computerized care systems. To see computer screens for locating and choosing NOC outcomes and for choosing NOC indicators, respectively,

Go to Student Resources: Chapter 5, **Tables, Boxes, Figures: ESG Figures 5-4 and 5-5,** on Davis*Plus.*

In those figures, the nurse chose Circulation Status as a patient outcome, and the program provided the definition and the NOC indicators for that outcome. The nurse would then check the indicators that apply to the patient.

Key Point: ***The computer does not think for you. You are responsible for deciding which outcomes and indicators to use for each patient, and for identifying a target time.*** Most electronic health records have a screen that allows you to type in your own goals as well.

How Do I Write Goals for Groups?

Home and community health nurses are especially likely to write goals for aggregates (groups), such as families and communities. **Community health goals (public health goals)** are those you would use to specify and evaluate the health of groups, aggregates, or populations. They tend to emphasize health promotion, health maintenance, and disease prevention outcomes. The following are examples.

The U.S. Public Health Service (USPHS) has proposed four group goals—the following broad, overarching goals for improving the health of the nation by a target date of 2020 (*Healthy People 2020*, 2010):

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.

Table 5-5 ➤ Example of an NOC Outcome

Decision Making (0906)

Source: Moorhead, S., Johnson, M., Maas, M., et al. (2013). *Nursing outcomes classification* (5th ed.). St. Louis, MO: Mosby/Elsevier.

- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

NOC currently includes 16 outcomes targeted to Community Health, which they define as "outcomes that describe the health, well-being, and functioning of a community or population" (Moorhead, Johnson, Maas, et al., 2013, pp. 66–67). Two examples are Community Competence and Community Risk Control: Lead Exposure. NOC also has 14 outcomes that describe the health of a family as a unit. Two examples are Family Coping and Family Health Status. NOC outcomes can be used in all settings, including home and community nursing. For further explanation, see Chapters 14 and 43. Also, search for Nursing Outcomes Classification on the Web or

Go to the NOC Web site at http://www.nursing.uiowa.edu/excellence/nursing_knowledge/clinical_effectiveness/index.htm

The Clinical Care Classification (CCC) was developed by Virginia Saba, a nurse-researcher, for use in home health nursing. In the CCC, you form goals by adding modifiers to the nursing diagnoses. This system has four nursing diagnoses that are clearly for family units: Family Coping Impairment, Compromised Family Coping, Disabled Family Coping, and Family Processes Alteration. The CCC includes one diagnosis specifically for communities: Community Coping Impairment. For a complete description of the CCC system,

Go to the CCC Web site at http://www.sabacare.com

The Omaha System was developed specifically for community health nursing. In that system, you must label all nursing diagnoses as *individual, family,* or *group*. You can write aggregate outcomes by specifying a *family* or *group* diagnosis and then creating a goal from it, by using terms in a Problem Rating Scale for Outcomes, as in the following example.

Omaha Nursing Diagnosis: Personal Hygiene. Family. Deficit (Actual Problem)

Present status	*Expected outcome*
Minimal knowledge of family personal hygiene	Adequate knowledge of family personal hygiene

For a complete description of the Omaha System, and to see the Problem Rating Scale for Outcomes,

Go to the Omaha System Web site at http://www.omahasystem.org

- Which standardized classification system was designed specifically for home healthcare?
- Which standardized classification system was designed for use in all areas and specialties of nursing?

How Do I Write Goals for Wellness Diagnoses?

Whether standardized or individualized, expected outcomes for wellness diagnoses describe behaviors or responses that demonstrate health maintenance or achievement of an even higher level of health. For example: "Over the next year, [Mr. Needham] will continue to eat a balanced diet with more emphasis on including whole grains and fiber." By using the highest number (5) on the rating scale, you can use the NOC to write wellness outcomes. For example:

Nursing diagnosis: Readiness for Enhanced Nutrition
Expected outcome: Nutritional Status: (5) Not compromised

In addition, many NOC outcomes can be used to measure health (e.g., Activity Tolerance, Child Development, Growth, Nutritional Status). See Chapter 42 or go to the NOC Web site for a complete list of wellness outcomes.

Outcomes for Special Teaching Plans

As discussed earlier, some patients need a special teaching plan to address learning needs. Expected outcomes are written in the same way as any other type of care plan, but they are usually called teaching objectives. **Teaching objectives** describe what the patient is to learn and the observable behaviors that will demonstrate learning; they should state whether learning is to be cognitive, psychomotor, or affective. Consider the following examples:

Cognitive: By May 1, will list four foods to avoid on a low-fat diet.
Affective: By May 1, will verbalize feeling less anger about diet limitations.
Psychomotor: By May 1, will demonstrate how to use grasp extender to obtain food from the top shelf.

For further information about teaching objectives, see Chapter 19.

REFLECTING CRITICALLY ABOUT EXPECTED OUTCOMES/GOALS

After writing the expected outcomes for a client, use the full-spectrum nursing model to help you evaluate their quality. Use the following questions as a guide.

For each nursing diagnosis:

1. ***Is there at least one goal that, when met, would demonstrate problem resolution;*** that is, does at least one goal flow from the problem clause?
2. ***Do the predicted outcomes completely address the nursing diagnosis?*** If you have written outcomes in very specific, measurable terms, you may need several for a single nursing diagnosis. Review Table 5-3.

For each expected outcome:

3. ***Is the outcome appropriate for the nursing diagnosis?*** If not, a new nursing diagnosis should be written rather than adding a not-quite-related goal to the existing plan. In Table 5-3, for example, "Obtains 8 hrs sleep at night" would not be appropriate for the nursing diagnosis Ineffective Airway Clearance, because it does not flow from either the problem or etiology clause.
4. ***Is each outcome derived from only one nursing diagnosis?*** That is, does it describe only one patient response? Consider the following outcomes for a diagnosis of Diarrhea.

Examples:
Incorrect: Will have no diarrhea in the next 12 hours, and skin will be intact and without redness in the perianal area. (*Explanation:* Even though diarrhea may cause excoriation of perianal skin, obtaining a good skin outcome would not tell you anything about the status of the Diarrhea diagnosis.)

Correct: Will have no diarrhea in the next 12 hours.
Correct: Then write a new diagnosis of Impaired Skin Integrity, and a goal, "Skin will remain intact and without redness in the perianal area."

5. ***Does each outcome describe only one patient response or behavior?*** Look at the "correct" example in item 4, preceding, for the new Impaired Skin Integrity diagnosis. How many patient responses does it contain? It has two responses: Skin will remain intact, and skin will not be red. So our "correct" example meets the criteria for item 4 but not for item 5.

ThinkLike a Nurse 5-5

Why is it not a good idea to write the Skin Integrity outcome as shown in Item 4?

6. ***Is the outcome stated as a patient behavior, not a nurse activity?***
Incorrect (nurse activity): Prevent skin irritation.
Correct (patient response): Skin will not show signs of irritation.
7. ***Is the outcome stated in positive terms?*** When possible, state what you intend to occur, rather than what should not occur. For example, use "incision dry," rather than "no incision drainage." This is not always possible, especially for potential problems. It is better, for example, to write "No redness" (even though it is negative) than to write "Skin color normal," because "normal" is too vague. For potential problems, a negatively worded outcome is actually a list of the patient responses you are trying to prevent.
8. ***Is the outcome measurable or observable?***
Correct: Explains the actions and side effects of Coumadin, by 8/11/16.
Incorrect: Understands the actions and side effects of Coumadin, by 8/11/16.
There is no way to observe someone's understanding, so you could not use the second (incorrect) goal to evaluate client progress. Use action verbs; think, "What do I want to see, hear, feel, or smell?"
9. ***Are the performance criteria specific and concrete?*** Avoid words such as *normal, sufficient, enough, more, less, adequate, increased.* Vague words can be interpreted differently by different people. Does "*adequate* sleep" mean that the patient will sleep 8 hours per night, will fall asleep within an hour of going to bed, will feel rested in the morning, or will not become sleepy during the day?
10. ***Does each goal include all the necessary parts?*** Is there a subject (implied or actual), action verb, performance criterion, target time, and special condition (when needed)?
11. ***Is the expected outcome realistic and achievable by this patient, given the available resources?*** People usually will not work toward goals unless they believe they are possible to achieve. The outcome "Will rest for an hour twice a day" may not be realistic for a single mother with several small children and no help at home. Be sure to consider the patient's support system, financial status, available community services, and physical and mental status. Also consider institutional resources. For example, there is no point in writing, "Will express anxieties freely to the nurse" if staffing is not adequate to allow the nurse to spend time with the patient to develop a relationship.
12. ***Does the outcome conflict with the medical or other collaborative treatment plan?*** For example, an outcome of "Ambulated to end of hall" would not be compatible with the medical treatment plan for a patient who is sleepy and lethargic from the side effects of medications.
13. ***Does the patient, family, or community value the outcome?*** The care plan is more likely to be effective if the goal is important to the client. You may, for example, believe that smoking cessation is an important goal for the patient. However, the patient might not be motivated to stop smoking, even when given all the related information. When your goals conflict with the patient's, explore the patient's thinking. Explain your reasoning and try to find a compromise or an alternative approach.
14. ***Does the goal conflict with any religious or cultural values?*** You may know that early ambulation (e.g., "Ambulates to bathroom within 4 hours after birth of the baby") helps to prevent thrombophlebitis. However, in some cultures, childbirth is viewed as an illness, and the mother expects to remain in bed for several days with family members taking care of her needs. When a patient is "noncompliant," the reason may be that she is complying with her cultural beliefs rather than the caregiver's plan of care.

KnowledgeCheck 5-8

List at least eight questions you could use to critically evaluate the quality of your goal/outcome statements.

Toward Evidence-Based Practice

Scherb, C. A., Stevens, M. S., & Busman, C. (2007). Outcomes related to dehydration in the pediatric population. *Journal of Pediatric Nursing, 22*(5), 376–382.

The purpose of this pilot study was to (1) determine whether there was a meaningful difference (in statistical terms) in nursing-sensitive patient outcome ratings from admission to discharge and (2) to describe nursing interventions used for children (younger than age 18 years) admitted with a primary diagnosis of dehydration. During the study period, researchers examined 29 patient care records that were a part of a computerized clinical documentation system in a Midwestern hospital. The documentation system used the standardized nursing languages of NANDA-I, NOC, and NIC.

Standardized care plans (also using NANDA-I, NOC, and NIC) were initiated upon a child's admission, and individualized as needed. NOC outcomes were rated upon admission and at discharge. Examples of outcomes on the care plan include Nutritional Status, Fluid Balance, and Urinary Elimination. Of the eight outcomes on the care plan, seven had statistically significant changes (showing the child's improvement).

1. If you had to decide on the basis of this study alone, would you be for or against using standardized nursing languages for documentation and patient care plans in your organization? Explain your reasoning.

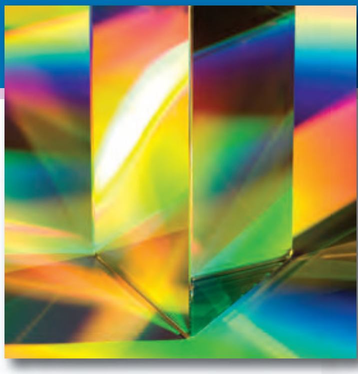
CHAPTER 6



Nursing Process: Planning Interventions

Learning Outcomes

After completing this chapter, you should be able to:

- Define the term *nursing intervention.*
- Compare and contrast independent, dependent, and interdependent (collaborative) nursing interventions.
- Explain how theories, research, and evidence-based practice influence the choice of nursing interventions.
- Explain how nursing interventions are determined by problem status (i.e., actual or potential problem).
- Describe a process for generating nursing interventions for a client.
- Explain how to use a standardized vocabulary for nursing interventions and activities.
- Give one example of a standardized wellness (health promotion) intervention and one individualized nursing order for performing that intervention.
- Give one example of a standardized spirituality intervention and one individualized nursing order for performing that intervention.
- Write complete, detailed nursing orders, in correct format, for patients.
- Give examples of some questions for reflecting critically about nursing orders you have written.

Key Concepts

Evidence-based practice
Nursing interventions

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patient

Ben Ivanos, whom you met in Chapter 5, is confined to bed after a motorcycle accident. He has casts and traction for both legs and a cast on one arm. Since admission to the hospital 3 days ago, he has been receiving narcotic analgesics for severe pain. He has a new nursing diagnosis today: Constipation related to immobility and decreased gastrointestinal (GI) motility secondary to narcotic analgesics. The nurse enters the diagnosis into a care-planning program. In addition to a list of suggested assessments, the computer database generates the following list of suggested treatment interventions:

1. Institute a program to establish a regular pattern of bowel movements.
2. Administer laxative or stool softener, as prescribed.
3. Administer enema.
4. Remove stool manually.
5. Encourage increased fluid intake, including warm liquids.
6. Instruct about and encourage a high-fiber diet.
7. Encourage a regular program of activity and exercise.
8. Perform manual reduction of rectal prolapse.

Which interventions should the nurse choose? Which can he eliminate, based on the information provided? You may not yet have enough nursing knowledge to be sure about your answers to these questions, but before reading on, try to think it through with the information and life experience available to you.

The nurse eliminated interventions 1, 3, 4, 7, and 8. Take a few moments to see if you can explain the nurse's reasons for deleting these interventions.

Theoretical Knowledge knowing why

Compare your explanations to the following reasons given by the nurse in the Meet Your Patient scenario. The nurse eliminated the following interventions:

- **1**—because it is useful for patients who are constipated as a result of irregular bowel habits, whereas Mr. Ivanos's problem is caused by immobility and narcotic side effects.
- **3 and 4**—because Mr. Ivanos's symptoms did not seem severe enough to warrant an enema or manual removal of stool.
- **7**—because it is not practical: Mr. Ivanos cannot exercise in his present condition.
- **8**—because it is not relevant: Mr. Ivanos does not have rectal prolapse.

The nurse chose the following interventions to include in the care plan:

- **2**—because it directly addresses the problem, Constipation.
- **5 and 6**—because they address the etiology of the problem. Fluid and fiber soften the stool and help to stimulate bowel activity.

The nurse also reasoned that because narcotics cause constipation, it would be good to administer them less frequently to Mr. Ivanos if other satisfactory pain-relief measures could be found. So he added the following nursing orders to the care plan:

Assist to change position every 1–2 hours.
Encourage distraction (e.g., watching TV, reading, listening to music).
Assist with relaxation and visualization techniques.
Obtain medical prescription for nonnarcotic analgesics to enhance nonpharmacological pain-relief measures.
Assess effectiveness of nonpharmacological interventions for pain.
Give prescribed narcotic analgesics if other measures are ineffective.

The nurse knows people are often self-conscious or embarrassed about using a bedpan, especially in the presence of others. So he also added the following to the care plan:

Encourage Mr. Ivanos to summon the nurse when he feels the urge to defecate (place call light within reach). If he does not, then ask at least every 4 hr whether he needs the bedpan.
Warm the bedpan and provide privacy. Pull the bed curtain; turn on the TV or radio if he has a roommate; explain that you will leave the room and that he should call when he is ready for you to return; and shut the door.

As you can see, to develop interventions to meet Mr. Ivanos's needs, the nurse needed to do more than just look at a list and follow physician orders. He thought critically about (1) his theoretical knowledge (of narcotics, bowel elimination, and psychological needs), (2) his past experiences with similar patients, and (3) the patient situation (the data about Mr. Ivanos and the factors contributing to his problem). By thinking of interventions to meet the client's specific needs, this nurse may prevent Mr. Ivanos's constipation from worsening. A nurse with less knowledge and experience might have used only the interventions in the computer database, failing to effectively meet the desired outcomes (goals) for Mr. Ivanos.

ABOUT THE KEY CONCEPTS

As you study this chapter, try to think about how related concepts (such as theories, standardized language, nursing orders, and so on) are linked to the key concepts of **evidence-based practice** and **nursing interventions**. This should help you to understand and remember chapter content. The deeper your understanding, the better you will be able to apply your knowledge in caring for patients.

WHAT ARE NURSING INTERVENTIONS?

Nursing interventions are actions, based on clinical judgment and nursing knowledge, that nurses perform to achieve client outcomes. Interventions are also referred to as *nursing actions*, *measures*, *strategies*, and *activities*. This chapter uses those terms interchangeably except when referring to the Nursing Interventions Classification (NIC) standardized labels (discussed later in the chapter), which are always called *interventions*. Figure 6-1 shows how planning interventions relates to the other phases of the nursing process.

No matter what term is used, nursing interventions include a broad range of activities.

- **Direct-care interventions** are performed through interaction with the client(s). Examples are physical care, emotional support, and patient teaching.
- **Indirect-care interventions** are performed away from the client but on behalf of a client or group of clients. They include advocacy, managing the environment, consulting with other members of the healthcare team, and making referrals.

ThinkLike a Nurse 6-1

- Give one example of a direct-care intervention.
- Give one example of an indirect-care intervention.

Nurses work collaboratively with other healthcare providers. Some things you do for patients will require a physician's order; many will not. Sometimes the activities of care providers overlap. For example, physicians, nurses, and respiratory therapists may all measure a client's blood pressure; and a nurse and a dietitian may both teach the client about a diet to help manage hypertension. Nursing

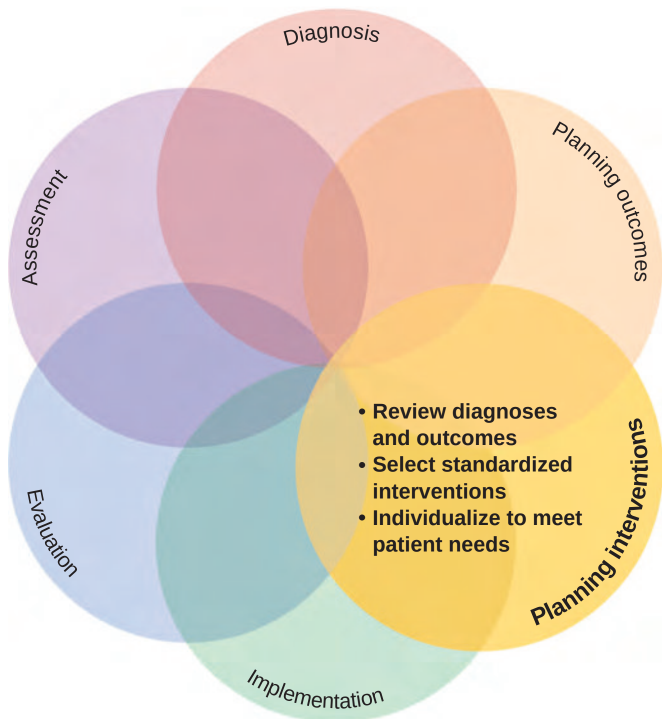


FIGURE 6-1 Nursing process: Planning interventions.

interventions may be independent, dependent, or collaborative (interdependent).

Independent Interventions *Nurse A makes a nursing diagnosis of Anxiety related to deficient knowledge about barium enema; she writes a nursing order to teach the patient what to expect from the upcoming diagnostic test.* This is an **independent intervention**—one that registered nurses are licensed to prescribe, perform, or delegate based on their knowledge and skills. It does not require a provider's order. Knowing how, when, and why to perform an activity makes the action **autonomous** (independent). As a rule, nurses prescribe and perform independent interventions in response to a nursing diagnosis. Understand you are **accountable** (answerable) for your decisions and actions with regard to nursing diagnoses and independent interventions. If patient teaching did not relieve the patient's anxiety in this example, it might be that the nurse misdiagnosed or chose an ineffective intervention.

Dependent Interventions *Nurse B reads a physician's prescription in a patient's chart: Give cephalothin sodium (Keflin) 1 g IV [through the intravenous line] before surgery, and then every 6 hr for 24 hr. She prepares and administers the medication.* This is a **dependent intervention**—one that is prescribed by a physician or advanced practice nurse but carried out by the bedside nurse. Dependent interventions are usually orders for diagnostic tests, medications, treatments, IV therapy, diet, and activity. In addition to carrying out medical prescriptions, you will be responsible for assessing the need for the prescription, explaining the activities to the patient, and evaluating the effectiveness of the order. For example, after giving the Keflin (an antibiotic), Nurse B observes that the patient has developed a severe rash. Suspecting an allergic reaction, she contacts the prescriber so that the prescription can be changed and antibiotic prophylaxis can be continued after surgery without danger to the patient.

You may write nursing orders to individualize a medical order, based on the patient's condition. For example, the provider may prescribe, "Give oral fluids up to 3,000 mL every 24 hours." You might individualize the order to give 1,500 mL on the day shift, 1,000 mL on the evening shift, and 500 mL during the night, so that the patient will not have to be awakened frequently during the night.

Collaborative (Interdependent) Interventions *Nurse C notes that a client newly diagnosed with diabetes has been seen by a dietitian, who taught and provided materials about a diabetic diet. The nurse observes the client's menu choices. She notes that the client is eating candy brought by visitors. She explains to the client how concentrated sugar affects his diabetes; she also communicates her assessments and teaching to the dietitian.* This is an **interdependent (collaborative) intervention**—one that is carried out in collaboration with other healthcare team members (e.g., physical therapists, dietitians, and physicians). Because nurses care for the whole person, their responsibilities often overlap with those of other team members.

ThinkLike a Nurse 6-2

- What are some other examples of independent interventions?
- What are some other examples of dependent interventions?
- What are some other examples of collaborative interventions?

HOW DO I DECIDE WHICH INTERVENTIONS TO USE?

To review American Nurses Association (ANA) (2010) standards of care related to care planning and interventions, refer to Box 5-1, Standard 4, in Chapter 5. Use the ANA standards to guide you in selecting interventions appropriate for the client's nursing diagnoses (or collaborative problems) and the desired outcomes. In addition to these standards, a variety of theories, nursing research, and the client's problem status will all influence your choice of interventions.

Key Point: ***As a nurse, you will be responsible for choosing nursing interventions. You cannot delegate this responsibility to nursing assistive personnel.***

As a rule, licensed practical/vocational nurses (LPN/LVNs) give care according to a plan created by the RN. In many situations, the LPN/LVN contributes to the plan by providing data or by giving feedback about the effectiveness of the interventions. For more information about delegation, see Chapter 7.

How Do Theories Influence My Choice of Interventions?

A **theory** is a set of interrelated concepts (ideas) that describes or explains something—nursing, for example.

A theory, like a lens, influences your perspective: What you notice, what you consider to be a problem—and how you define a problem—more or less determine what you choose to do about it. For example, suppose a patient is pale and fidgeting and has sweaty palms and a rapid pulse. If you looked at this person through the lens of psychological theory, your first thought might be that the patient is anxious. Your first intervention, then, would probably be to assess for the cause of his anxiety. If you were using a physiological lens, you might suspect pain. Your first intervention, then, might be to ask the patient whether he is having pain. For more information about nursing theories, see Chapter 8.

How Does Nursing Research Influence My Choice of Interventions?

Although much nursing and medical practice is still based on tradition, experience, and professional opinion, this is not an ideal basis for choosing an intervention. Ideally, a nurse should choose an intervention because of firm evidence that it is the best possible approach for the patient. You would expect that such interventions should be those that were developed from a sound body of scientific research.

American Nurses Association (ANA) Standards Standard 9 of the ANA Scope and Standards of Practice, Nursing (ANA, 2010, p. 51), states that the registered nurse:

- Utilizes current evidence-based nursing knowledge, including research findings, to guide practice decisions.
- Incorporates evidence when initiating changes in nursing practice.
- Participates, as appropriate to education level and position, in the formulation of evidence-based practice through research.
- Shares personal or third-party research findings with colleagues and peers.

To see if you have the most current ANA standards,

Go to http://www.nursingworld.org/, or more directly, go to http://www.nursingworld.org/MainMenuCategories/ThePracticeofProfessionalNursing/NursingStandards.aspx

QSEN Competencies According to the Quality and Safety Education for Nurses (QSEN) group, one competency you should achieve in nursing school is to differentiate clinical opinion from research and evidence summaries. To see an expanded discussion of this competency,

Go to **the Cronenwett, et al. (2007) reference, in** Student Resources: Chapter 6, **Reading More About Nursing Process: Interventions,** on Davis*Plus*
or

Go to http://qsen.org/competencies/pre-licensure-ksas/

Types of Research-Based Support

Research-based support for an intervention includes single studies, critical pathways and protocols, clinical practice guidelines, systematic reviews of the literature, and evidence reports. In Chapter 8, you will learn how to ask "PICOT" questions that help you use evidence to decide which interventions to use.

Single Studies It is not difficult to find individual studies that give you an idea of the effectiveness of an intervention. Research reports are available in research journals, and they are often interpreted and published in such widely circulated journals as the *American Journal of Nursing (AJN)*, *Nursing*, and *RN*, as well as online sites. Unfortunately, there may be only one or two studies of an intervention, and they may have included only a small number of patients. Thus, single studies may not be reliable. To see several examples of single intervention studies,

Go to Student Resources: Chapter 6, **Reading More About the Nursing Process: Planning Interventions,** on Davis*Plus*.

Critical Pathways and Protocols **Critical pathways** (also called *clinical pathways* and *collaborative care plans*) are standardized plans of care for frequently occurring conditions (e.g., total hip replacement) for which similar outcomes and interventions are appropriate for all patients who have the condition. They are tools developed by an organization for its own use and are intended to guide best practice at the local level. However, they may not be based on research if the practitioners who develop them are reluctant to change traditional practices they believe to be effective. Furthermore, issues of cost to the organization influence the decision to include an intervention in the plan of care. Nevertheless, critical pathways have, at the very least, been developed on the basis of expert opinion. So they do provide some guidance for nursing interventions. See Chapter 5 for discussion and examples of critical pathways and protocols.

What Is Evidence-Based Practice?

You can feel more confident about an intervention if several studies have supported it. **Evidence-based practice (EBP)** is an approach that uses firm scientific data rather than anecdote, tradition, intuition, or folklore in making decisions about medical and nursing practice. In nursing it includes blending clinical judgment and expertise with the best available research evidence and patient characteristics and preferences. The goal of evidence-based practice is to identify the most effective and cost-efficient treatments for a particular disease, condition, or problem. Steps in the EBP process include the following:

1. Formulating an answerable question about prevention, diagnosis, prognosis (likely outcome), and interventions
2. Conducting a systematic review of published evidence (research) to find studies that shed light on the desired topic

3. Evaluating or grading the quality of the evidence obtained. Quality involves *validity* (closeness to the truth), *applicability* (usefulness), and *impact* (extent of the effect). Figure 6-2 lists evidence from strongest to weakest. For more information about "levels of evidence," or how evidence is evaluated,

Go to Student Resources: Chapter 6, **Supplemental Materials, Levels of Evidence,** on Davis*Plus*.

4. Compiling and analyzing the data to prepare a structured report of the review
5. "Translating" the evidence into guidelines for practice
6. Integrating the guidelines and evidence with clinical expertise and the patient's preferences and characteristics

A number of healthcare organizations and groups are devoted to compiling study results that provide evidence to use in formulating guidelines for medical and nursing practice. Online examples include The Joanna Briggs Institute and the Cochrane Database of Systematic Reviews. You will find such compiled information in clinical practice guidelines, evidence reports, and sometimes in local healthcare agency tools (e.g., clinical pathways and protocols). For full discussion on the importance of research and evidence-based nursing practice, see Chapter 8.

Evidence Reports

Evidence reports are state-of-the-art, systematic reviews of clinical topics for the purpose of providing evidence for practice guidelines, quality improvement, quality measures, and insurance coverage decisions (Cronenwett, 2002). Evidence reports are usually developed by scientists rather than by clinicians, patients, and advocacy groups. One source of such reports is the Evidence-Based Practice Center (EPC) Program of the federal Agency for Healthcare Research and Quality (AHRQ). The EPC uses explicit grading systems to review studies and rank the strength of their evidence. For free access to online reviews,

Go to the AHRQ Web site at http://www.ahrq.gov/clinic/epcindex.htm

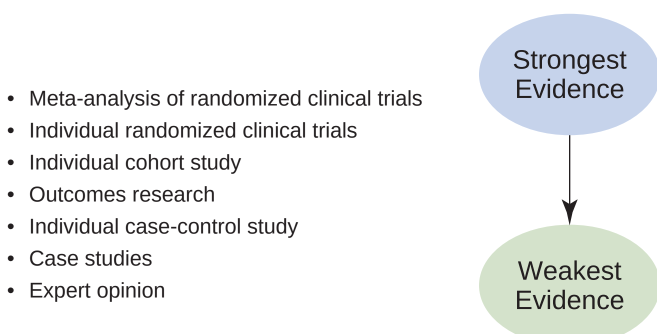

FIGURE 6-2 Hierarchy of research evidence. (*Source:* Courtesy of Fain, J. A. (2008). *Reading, understanding, and applying nursing research: A text and workbook* (3rd ed., p. 279). Philadelphia: F. A. Davis.)

Clinical Practice Guidelines

Evidence reports often form the basis for developing clinical practice guidelines. **Clinical practice guidelines** are statements developed by a systematic review of evidence and an assessment of the benefits and harms of care options. They include recommendations made to assist practitioners and patients in making decisions about appropriate healthcare for a particular disease or procedure (Field & Lohr, 1992; Institute of Medicine, 2011). Clinical practice guidelines are usually developed by clinicians, patients, and advocacy groups and are published by specialty organizations, universities, and government agencies. The following are examples:

- The Joanna Briggs Institute *Best Practice* information sheet on Topical Skin Care in Aged Care Facilities (JBI, 2007)
- University of Iowa research-based guidelines for care of the elderly (Titler, Mentes, Rakel, et al., 1999)
- National Guideline Clearinghouse, initiative of the Agency for Healthcare Research and Quality (AHRQ), U.S. Department of Health and Human Services, is a comprehensive database of guidelines for health professionals (http://www.guideline.gov/)

Clinical practice guidelines form the basis for nursing interventions. One example of clinical practice guidelines is found in Box 6-1. For years, relying on conventional

BOX 6-1 ■ Portion of a Clinical Practice Guideline on Pressure Ulcer Formation

Note: This is not the complete practice guideline.

Assessment*

- Use a reliable and standardized tool for doing a risk assessment, such as the Braden Scale.
- Risk assessment documentation on admission to a facility and whenever the client's condition changes and based on patient care setting (e.g., acute care, every 48 hr)

Nursing Care Strategies and Interventions

Do not massage bony prominences.

- Use pressure-reducing devices (static air, alternating air, gel, water mattresses). (Evidence Level II)
- Raise heels of bedbound clients off the bed; do not use donut-type devices. (Evidence Level III)
- Avoid hot water and soaps that are drying when bathing elderly. Use body wash and skin protectant. (Evidence Level III)

*"Strength of evidence" is an AHRQ ranking (I to VI) of the amount and quality of research supporting the guideline. The best ranking is I.

Source: Agency for Healthcare Research and Quality (AHRQ). (2003; updated June 2008). Guideline summary. Preventing pressure ulcers and skin tears. In: *Evidence-based geriatric nursing protocols for best practice*. Retrieved July 13, 2012, from http://www.guideline.gov/content.aspx?id=12262&search=pressure+ulcer#Section442

wisdom and word of mouth, nurses tried to prevent pressure ulcers by writing the nursing order, "Massage skin over bony prominences." They reasoned that because poor circulation can contribute to the formation of pressure ulcers, improving circulation to the area would prevent them. But as you can see in Box 6-1, research-based practice guidelines show that massage may actually be harmful. This report would certainly motivate you, as a full-spectrum nurse, to remove this "standard" intervention from your practice.

KnowledgeCheck 6-1

- Explain how theory influences your choice of nursing interventions.
- Why does a clinical practice guideline provide better support for an intervention than does a single study?
- Why does a clinical practice guideline provide better support for an intervention than does an agency's critical pathway?

How Does Problem Status Influence Nursing Interventions?

Nursing interventions include activities for observation/assessment, prevention, treatment, and health promotion. As you can see in Table 6-1, the status of the problem (i.e., whether it is a collaborative problem or an actual, potential, possible, or wellness nursing diagnosis) determines which types of activities are required (to review problem status, see Chapter 4).

A nursing strategy can be a preventive measure in one situation and a treatment in another. For example, you might write the nursing order, "Teach the importance of adequate fluids," to treat a patient with an actual diagnosis of Constipation or to help prevent the problem for a woman with a diagnosis of Risk for Constipation.

KnowledgeCheck 6-2

Review problem status (actual, potential, or possible nursing diagnosis; collaborative problem; or wellness diagnosis) in Chapter 4. For which type(s) of problem(s) would you write the following:

- Nursing orders for observation/assessments?
- Nursing orders for treatments?
- Nursing orders for health promotion interventions?
- Preventive nursing orders?

What Process Can I Use for Generating and Selecting Interventions?

As you can see from the case of Ben Ivanos (Meet Your Patient), there are usually several nursing measures that might be effective for any one problem. The idea, of course, is to select those most likely to achieve the

Table 6-1 ➤ Relationship of Problem Status to Intervention Type

PROBLEM STATUS	INTERVENTION TYPE			
	Observation	**Prevention**	**Treatment**	**Health Promotion**
Actual nursing diagnosis	To detect change in status (improvement, exacerbation of problem).	To help keep the problem from becoming worse.	To relieve symptoms and resolve etiologies (contributing factors).	
Potential (risk) nursing diagnosis	To detect (1) progression to an actual problem or (2) an increase or decrease in risk factors.	To remove or reduce risk factors in an effort to keep the problem from developing.		
Possible nursing diagnosis	To obtain more data to confirm or rule out a suspected nursing diagnosis.			
Collaborative problem	To detect onset of a complication for early provider notification.	To implement nursing and medical orders to help prevent development of a complication.	To implement nursing and medical orders for relieving or eliminating the underlying condition for which complications may develop.	
Wellness diagnosis	To assess a client's wellness practices.	To prevent specific diseases (e.g., giving immunization).	Clients usually manage their own wellness treatment.	To support a client's health promotion efforts and achieve a higher level of wellness.

desired goals. In doing that, you must consider the patient's abilities and preferences; the education, experience, and capabilities of the nursing staff; the resources available (e.g., time, equipment); medical orders; and institutional policies and procedures. When generating interventions, you will use critical thinking skills.

For example, imagine you are caring for a hospice patient who has cancer and is dying. She has told you that she is experiencing significant pain, but also that she wants to spend her last hours with her husband and two daughters, who are staying with her. Critical thinking skills you might use include the following:

- *Making interdisciplinary connections* (e.g., "What did I learn in psychology class that might help me here?")
- *Predicting* (e.g., "If I give morphine to the patient, it should relieve her pain, but she will probably become drowsy.")
- *Generalizing* (e.g., "I have used touch to relieve anxiety many times in similar situations; perhaps it will also help for this patient.")
- *Explaining* (e.g., "The morphine causes drowsiness by depressing the central nervous system.")
- *Therapeutic judgment* (e.g., "The patient wants to spend quality time with her family before she dies. Because the morphine will make her drowsy, I should find out if she wants me to give a smaller dose, even though it will not provide good pain relief, along with some nonpharmacological measures.")

You must always rethink an intervention for each patient. You cannot assume a strategy that was useful in the past will be effective in every situation. Mr. Ivanos's nurse may have used distraction successfully to relieve the pain of other patients in the past. However, if Mr. Ivanos has severe pain, or if he has difficulty concentrating, then distraction may not be effective. A full-spectrum nurse takes such details into account before choosing an intervention. The following five-step process will help you to select the best interventions (Wilkinson, 2011):

1. Review the Nursing Diagnosis

The etiology of a nursing diagnosis describes the factors that contribute to the unhealthy response. Choose strategies you expect will reduce or remove the etiological factors of actual problems, or that will reduce or remove risk factors for potential problems.

- ***When it is not possible to change the etiology***, choose strategies to treat the patient's symptoms (the AMB part of a diagnosis referred to in Chapter 4). For example, if the cause of pain is a surgical incision, you cannot suddenly "cure" the incision. Your nursing actions should focus on measures to relieve the pain.
- ***You may not always know the etiology of the problem***. However, some interventions may relieve a problem regardless of its cause. For example, when you have a client with Anxiety, regardless of its cause, it is helpful to approach the patient calmly; and when you have a client with Constipation, regardless of its cause, it is always appropriate to assess the characteristics of the stool. Consider the nursing diagnosis and interventions for Mr. Ivanos in Figure 6-3.

Obviously, some people with constipation do not have pain. The pain-relief nursing order, which flows from the etiology of the problem, is specific to Mr. Ivanos's needs. Administering a stool softener and laxative, however, is a common strategy for constipation, whatever its cause.

Key Point: ***As a rule, standardized interventions (care common to all patients with a particular condition) flow from the problem side of a nursing diagnosis; individualized interventions, from the etiology.***

ThinkLike a Nurse 6-3

For the following nursing diagnoses, write one intervention to address the problem and one for the etiology of the problem.

- Ineffective Airway Clearance r/t thick secretions and decreased chest expansion secondary to dehydration and pain
- Self-Care Deficit: Bathing and Dressing r/t fatigue secondary to disturbed sleep pattern

2. Review the Desired Patient Outcomes

Desired outcomes (goals) suggest nursing strategies that are specific to the individual patient. For example, Table 6-2 shows some goals and outcomes for Mr. Ivanos's Constipation diagnosis. For each goal on the care plan, ask, "What intervention(s) will help to produce this patient response?" As you can see in the table, there may be one or more interventions for each goal. There is no

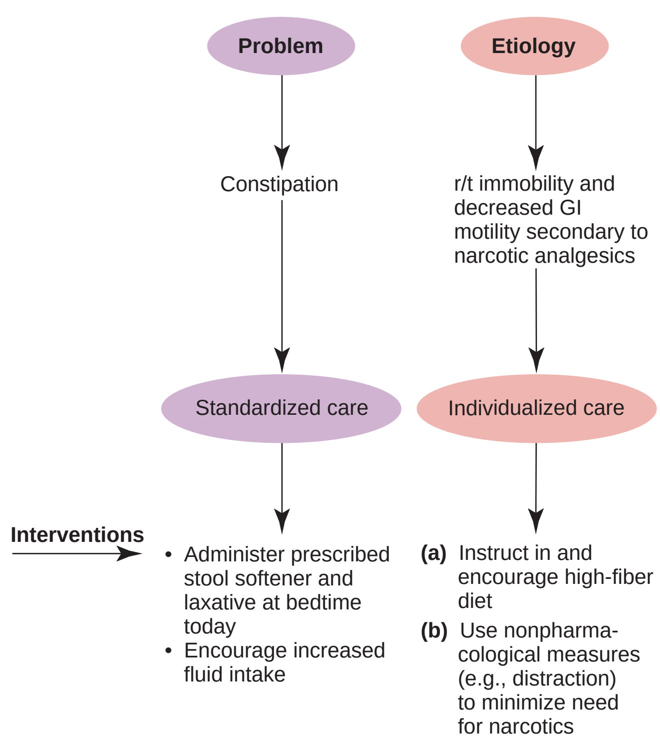

FIGURE 6-3 Nursing interventions flow from the nursing diagnosis.

Table 6-2 ➤ Interventions Flow from Desired Outcomes

GOALS/OUTCOMES	STRATEGIES SUGGESTED BY GOALS
1. **Will have bowel movement within 12 hours after receiving stool softener and laxative.**	A. **Administer prescribed stool softener and laxative at bedtime today.**
2. Will have daily soft, formed bowel movement during rest of hospital stay.	B. Instruct in and encourage high-fiber diet. C. Encourage increased fluid intake.
3. Within 24 hours, will need narcotics to manage pain < 2x/day.	D. Use nonpharmacological measures (e.g., distraction) to minimize need for narcotics.
4. *Calls nurse when urge to defecate is felt; does not delay defecation.*	E. *Encourage Mr. Ivanos to summon the nurse when he feels the urge to defecate.* F. *Provide privacy (e.g., pull the bed curtain, turn on the TV, leave room).*

Discussion:

Strategy A would help to achieve goal 1; but because the effects of these medications are short lived, it would do nothing to achieve goals 2 through 4.

Strategies B and C both help to achieve goal 2.

Strategy D (minimize narcotics), in contrast, directly addresses goal 3 and indirectly helps to achieve goal 2.

Strategies E and F both directly address goal 4 and indirectly address goal 2.

***Note:* Dotted lines indicate indirect contribution to goal.**

strict one-to-one correspondence between goals and interventions.

3. Identify Several Interventions or Actions

The next step in choosing interventions is to think of several nursing activities that might achieve the desired outcomes. Don't try to narrow your list at this point; include unusual and creative ideas. You can refer to a standardized list of interventions (e.g., the Nursing Interventions Classification list on Davis*Plus*) or choose interventions from standardized care plans and agency protocols. Alternatively, you can generate the interventions yourself, based on your knowledge; experience; and use of nursing texts, journal articles, and professional nurses. To get started, ask yourself: For this nursing diagnosis, (1) What assessments/observations do I need to make? (2) What do I need to do for the patient? Include both dependent and independent activities as appropriate.

4. Choose the Best Interventions for the Patient

The best interventions are those you expect to be most effective in helping to achieve client goals. When possible, choose interventions based on research and scientific principles. Use the following critical-thinking questions from the full-spectrum nursing model (in Chapter 2) to help you determine the best actions.

Contextual awareness

- Is this intervention acceptable to the client (e.g., congruent with the patient's values and wishes)?
- Is this intervention culturally sensitive?
- What is going on in the patient's life (e.g., family, work situation, financial status) that may enhance or interfere with the effectiveness of the intervention?
- What is going on in the patient's health status (e.g., knowledge, abilities, resources, severity of illness) that may enhance or interfere with the effectiveness of the intervention?

Credible sources

- Have I used valid, reliable sources of information to identify this intervention (e.g., patient, other professionals, references)?
- Did I consider professional, ethical, and legal standards?
- What is the research basis for this intervention, if any?

Considering alternatives

- Is there adequate rationale for this intervention (e.g., principles, theory, facts)?
- Which action(s) is (are) most reasonable? Why are the others not as reasonable?
- Which action(s) is (are) most likely to achieve stated goals?

Analyzing assumptions

- What beliefs, values, or biases do I have that may affect my thinking and my choice of interventions?
- Do I feel any discomfort with this intervention?

Reflecting skeptically

- Are there other interventions I have overlooked?
- What might be the consequences of this intervention?
  - "What will happen if . . .?"

- Does it have any potential ill effects? If so, how will we manage them?
- Is this intervention feasible? For example, is it cost effective, are the time and personnel available for it? Can the patient or family manage it at home?
- How will the intervention interact with medical orders? For example, you cannot order "elevate head of bed" to facilitate breathing if there is a medical order to keep the patient flat to improve circulation to the neck and head.
- In priority order, what should I do in this situation and why?
- Do I have the knowledge and skills needed for the intervention, or do I need to consult with someone more qualified in this area?
- What might I delegate in this situation?

5. Individualize Standardized Interventions

Practice guidelines, systematic reviews of the literature, protocols, critical pathways, and even textbooks describe interventions that are appropriate for most people or the average person. However, they cannot take into account all the individual factors that contribute to a problem or that might affect the effectiveness of an intervention. You must always consider how an intervention can be used with a particular person. For example, after Ben Ivanos's nurse decided which of the computer-generated list of interventions to use, he adapted them to fit Ben's unique needs and preferences. Table 6-3 provides examples of standardized and individualized interventions for Mr. Ivanos.

KnowledgeCheck 6-3

Describe a five-step process for generating and choosing nursing interventions.

Computer-Generated Interventions

Most electronic care planning programs will generate a list of suggested interventions when you enter either a problem (nursing diagnosis, medical, collaborative) or an outcome (Fig. 6-4). You then choose the interventions appropriate for the patient (as in the case of Ben Ivanos) or type in nursing actions of your own. Computer prompts provide a wide range of interventions for your consideration. However, you must resist the temptation to settle for the ready-made solutions. Always look for other, perhaps more effective, strategies based on the patient data. Always think, "Are there other interventions I have overlooked? How should I adapt this for *this* patient?"

To see a computer screen showing how an intervention (Pain Control Techniques Education) is converted to nursing orders,

Go to Student Resources: Chapter 6, **Tables, Boxes, Figures: ESG Figure 6-1,** on Davis*Plus*.

Table 6-3 ➤ Individualizing Nursing Actions for Ben Ivanos

STANDARDIZED INTERVENTIONS	INDIVIDUALIZED NURSING ORDERS
1. Encourage increased fluid intake.	1. Remind patient to drink a glass of water every hour; also keep ice and tea available at the bedside.
2. Instruct on and encourage a high-fiber diet.	2. Assist with menu choices to obtain more fiber; encourage family to bring salads and fruits from home for snacks.
3. Encourage distraction (e.g., watching TV, reading, listening to music).	3. Provide books from hospital library (he does not enjoy TV); have family bring radio, iPad, or tablet and headphones from home.
4. Give prescribed narcotic analgesics if other measures are ineffective.	4. Give Tylenol #3 every 4 hr if relaxation, visualization, and distraction are not effective. If orally administered Tylenol #3 is not effective, advise patient to administer IV morphine via patient-controlled analgesia pump.

HOW CAN I USE STANDARDIZED LANGUAGE TO PLAN INTERVENTIONS?

As a review before reading this section, you may wish to read the discussion of standardized language in Chapter 4 (NANDA-I for nursing diagnoses), and in Chapter 5 (NOC for patient outcomes).

Recall that standardized nursing terminologies are important for electronic health records (EHR), for research, and for clear, precise, consistent communication among nurses and with other disciplines. The American Nurses Association (ANA, 2006) has recognized 12 standardized vocabularies for recording and tracking the clinical care process. Those most commonly used for describing nursing interventions are the Nursing Interventions Classification (NIC), the Clinical Care Classification (CCC), and the Omaha System. NIC classifies only interventions. The CCC and the Omaha System also include nursing diagnoses and outcomes.

What Is the Nursing Interventions Classification?

Developed by a research team at the University of Iowa, the *Nursing Interventions Classification (NIC)* was the first comprehensive standardized classification of nursing interventions (McCloskey & Bulechek, 1992). The fifth edition NIC (Bulechek, Butcher, & Dochterman, et al.

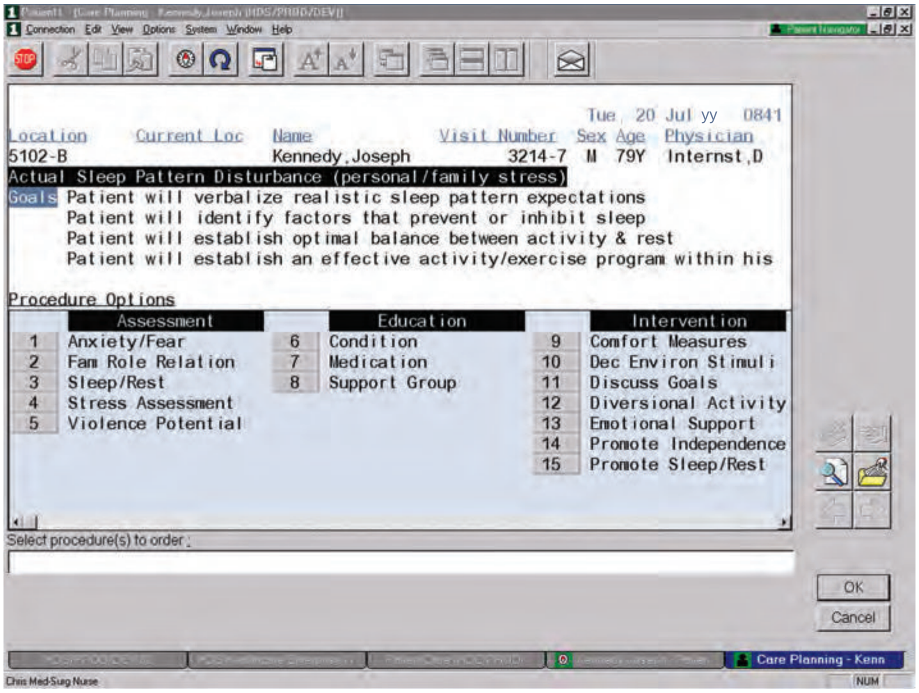

FIGURE 6-4 Computer care planning: When the nurse selects a nursing diagnosis of Sleep Pattern Disturbance, the computer database generates a list of suggested goals and "procedure options" (interventions); the nurse then chooses those best suited for the patient. (*Source:* Copyright© Ergo Partners, L.C. All rights reserved. Used with permission.)

2013) describes 554 direct and indirect-care activities performed by nurses. The NIC (pronounced "nick") is versatile—appropriate for use in all specialty and practice areas, including home health and community nursing.

Each NIC intervention consists of a label, a definition, and a list of the specific **activities** nurses perform in carrying out the intervention (Box 6-2). The **label**, usually consisting of two or three words, is the standardized terminology. The **definition** explains the meaning of the label. You are free to word the activities any way you choose in a care plan or client record. For a complete list of NIC intervention labels and definitions,

Go to Student Resources, **NIC Interventions,** on Davis*Plus*.

Locating Appropriate NIC Interventions and Activities

NIC interventions are linked to NANDA-I nursing diagnoses and NOC outcome labels in a "linkages" book, *NOC and NIC Linkages to NANDA-I and Clinical Conditions,* referred to by most nurses as the NNN linkages book (Johnson, Moorhead, Bulechek, et al., 2012). In this book, you can look up a nursing diagnosis to see the list of outcomes suggested for it and the interventions for achieving each outcome. Refer to Table 6-4 for an example of interventions linked to the nursing diagnosis Risk for Aspiration. Notice there are 5 "major" interventions and 17 "suggested" interventions from which to choose.

Once you have chosen the interventions (based on your knowledge and judgment), you then choose the

BOX 6-2 ■ NIC Intervention: Bathing

Definition

Cleaning of the body for the purposes of relaxation, cleanliness, and healing

Activities

Assist with chair shower, tub bath, bedside bath, standing shower, or sitz bath, as appropriate or desired.

Wash hair, as needed and desired.

Bathe in water of a comfortable temperature.

Use playful bathing techniques with children (e.g., wash dolls or toys; pretend a boat is a submarine; punch holes in bottom of plastic cup, fill with water, and let it "rain" on child).

Assist with perineal care, as needed.

Assist with hygiene measures (e.g., use of deodorant or perfume).

Administer foot soaks, as needed.

Shave patient, as indicated.

Apply lubricating ointment and cream to dry skin areas.

Offer handwashing after toileting and before meals.

Apply drying powders to deep skinfolds.

Monitor skin condition while bathing.

Monitor functional ability while bathing.

Source: Bulechek, B. M., Butcher, H. K., & Dochterman, J. M. (Eds.). (2013). *Nursing interventions classification (NIC)* (6th ed). St. Louis, MO: C.V. Mosby, p. 81. Used with permission from Elsevier Science.

Table 6-4 ➤ NIC Interventions Linked to NANDA-I Diagnosis, Risk for Aspiration

Aspiration, Risk for:	
The state in which an individual is at risk for entry of gastrointestinal secretions, oropharyngeal secretions, or solids or fluids into tracheobronchial passages.	
NICS Associated With Prevention of Aspiration	
Airway Management	Neurologic Monitoring
Airway Suctioning	Positioning
Artificial Airway Management	Postanesthesia Care
Aspiration Precautions	Respiratory Monitoring
Chest Physiotherapy	Resuscitation: Neonate
Cough Enhancement	Risk Identification
Dementia Management	Sedation Management
Enteral Tube Feeding	Seizure Management
Feeding	Self-Care Assistance: Feeding
Gastrointestinal Intubation	Surveillance
Mechanical Ventilation Management: Invasive	Swallowing Therapy
Mechanical Ventilatory Weaning	Tube Care: Gastrointestinal
Medication Administration: Oral	Vomiting Management

Johnson, M., Moorhead, S., Bulechek, G., et al. (2012). *NOC and NIC linkages to NANDA-I and clinical conditions* (3rd ed.). St. Louis, MO: C.V. Mosby.

appropriate activities to carry out the intervention. As you might guess from looking at Box 6-2, you will probably never need to perform all the activities for a client. Choose the best ones for the situation and individualize them to fit the client and the resources (e.g., supplies, equipment) available.

Using NIC in Electronic Care Plans

Standardized language is especially useful in electronic care systems. For a computer screen with suggested NIC interventions for a NANDA-I nursing diagnosis,

Go to Student Resources: Chapter 6, **Tables, Boxes, Figures: ESG Figure 6-2,** on Davis*Plus*.

For any NIC intervention, the program will also list the more specific nursing activities, which you can individualize as nursing orders.

Go to Student Resources: Chapter 6, **Tables, Boxes, Figures: ESG Figure 6-3,** on Davis*Plus*.

Remember that you, not the computer, are responsible for choosing which interventions to use for each patient, when to use them, and which activities to write as specific nursing orders. You can reject *all* of the suggested interventions if they do not fit the patient's unique needs. Most computer programs have a field that allows you to type in your own interventions and activities.

Standardized Languages for Home Health and Community Care

The NIC includes interventions applicable in all settings, including home health and community nursing. However, the following taxonomies were created specifically for those uses:

- **The Clinical Care Classification (CCC).** Previously called the *Home Healthcare Classification*, the CCC was developed for use in home healthcare (Saba, 1995, 2006). In addition to terminology for nursing diagnoses and outcomes, the CCC has 198 interventions. For a complete description of the CCC system, see the nursing process section of Chapter 43 and

Go to the CCC Web site at http://www.sabacare.com

- **The Omaha system.** The Omaha system was developed for community health nurses to use in caring for individuals, families, and **aggregates** (community groups or entire communities) (Martin, 2005). It includes terminology for diagnoses, outcomes, and interventions. For a complete description of the Omaha system, and for NIC community interventions, see the nursing process section of Chapter 43 and

Go to the Omaha system Web site at http://www.omahasystem.org

KnowledgeCheck 6-4

- Name and describe three standardized intervention vocabularies recognized by the ANA.
- In the NIC system, what is the difference between interventions and activities?

Does Standardized Language Interfere With Holistic Care?

Some nurses have criticized standardized terminologies for focusing on illness and physical interventions. However, NIC, Omaha, and CCC do include interventions to address health promotion and cultural and spiritual needs. If you have a holistic attitude, you will give holistic care. Using a common language should help rather than hinder your choice of interventions. CAM performed and documented according to one of the standard taxonomies makes clear that the techniques are appropriate as nursing interventions (Frisch, 2001). For further discussion of holistic nursing care,

Go to Student Resources: Chapter 46, on Davis*Plus*.

The following sections discuss interventions focused on wellness, spiritual needs, and culturally sensitive care.

Wellness Interventions When you are caring for a healthy client, the client is the primary decision maker. You will function mainly as a teacher and health counselor. Frequently, the nursing orders outline lifestyle modification or behavior changes the client wants to make, along with self-rewards to reinforce the behaviors. For example:

Specific behavior change: I will consume fewer than 1,400 calories per day for the next week.
Self-reward: I will reward myself with an evening out to hear my favorite band.

The NIC contains most of the wellness interventions you will need. However, they are not all grouped together in one class. Some examples are Decision-Making Support, Exercise Promotion, and Health Screening. For more information on using standardized languages to describe wellness interventions, see Chapter 42.

Spiritual Care Interventions NIC, CCC, and the Omaha system all include terminology to describe spiritual interventions. The following are just a few examples:

NIC: Spiritual Growth Facilitation, Religious Ritual Enhancement
CCC: Spiritual Care, Coping Skills
Omaha: Spiritual Support, Bereavement Support

Chapter 16 provides full discussion of standardized nursing interventions to address spiritual needs. As you will see, you could also use most of those interventions (e.g., Coping Skills) for other than spiritual problems.

Culturally Sensitive Care Except for the NIC Culture Brokerage intervention, there are no standardized interventions that are unique to culturally based needs. All standardized interventions will result in culturally sensitive care if they are delivered by a culturally competent nurse.

PracticalKnowledge knowing how

WHAT ARE NURSING ORDERS, AND HOW DO I WRITE THEM?

Nursing orders are instructions that describe how and when nursing interventions are to be implemented. They are usually written on a patient care plan. Other nurses and nursing assistive personnel (NAP) are responsible and accountable for implementing nursing orders.

ThinkLike a Nurse 6-4

Suppose you are caring for a patient 24 hours after a major surgery. You see the following order on the nursing care plan: Ambulate 24 hours postoperatively.

- When you care for the patient, how will you go about implementing this nursing order?
- What else do you need to know to effectively carry out this order?

Components of a Nursing Order

Did you have trouble answering the preceding questions? Even experienced nurses would, because this nursing order is incomplete. As you see from this example, nursing orders must be specific and detailed because many caregivers will use the care plan, and they need to be able to interpret the orders correctly. A well-written nursing order, whether on paper or as an electronic care plan, contains the following components:

- ***Date.*** Indicate the date the order was written. Change the date each time you review or revise the order. Why do you think it is important to have the date?
- ***Subject.*** Nursing orders are instructions to nurses, so they are written in terms of *nurse* behaviors. Therefore, the subject of the order is "the nurse." Because anyone reading the care plan should understand this, you do not actually need to write "the nurse" in your orders. For each order, think, but do not write, "The nurse will . . ." or "The nurse should . . ." This will help you to state the order properly so that it doesn't sound like a goal statement. Goals state patient behaviors; nursing orders state nurse behaviors. For example:

Goal/expected outcome	*Nursing order*
(Patient) Drinks 100 mL fluids per hour	(Nurse will) Offer 100 mL water or juice per hour on day shift

- ***Action verb.*** This tells the nurse what action to take—what to do. Examples of action verbs are *assist, assess, auscultate, bathe, change, demonstrate, explain, give, teach,* and *turn.* The following nursing orders show the action verbs in italics:

Teach the components of a healthy diet, 9/15, day shift
Offer 100 mL water every hour
Administer acetaminophen 500 mg orally at least 30 min before dressing change

- ***Times and limits.*** State when (e.g., which shift, what day), how often, and how long the activity is to be done. Consider the unit routines (e.g., visiting hours, mealtimes), the patient's usual rest times, scheduled tests and procedures (e.g., chest x-ray), and treatments (e.g., physical therapy). The following nursing orders show times and limits

Teach the components of a healthy diet *on 9/15, day shift.*
Offer 100 mL water *every hour between 0700 and 1900.*
Administer acetaminophen 500 mg orally *at least 30 min before dressing change.*

If you omit specific times, such as "day shift," the order may not be followed. It is easy for a nurse to think, "Perhaps someone else will do it (or has done it)."

- ***Signature.*** The nurse writing the order should sign it. A signature indicates that you accept legal and ethical accountability for your orders and allows others to know whom to contact if they have questions or comments about the order. If interventions are chosen on an electronic care plan, there may not be an actual signature. However, the name of the nurse who chose the intervention should be indicated in some manner.

KnowledgeCheck 6-5

List the five components of a nursing order.

Reflecting Critically About Nursing Orders

After writing the nursing orders, reflect on the interventions you have chosen. If you followed the process in the section What Process Can I Use for Generating and Selecting Interventions? you will already have thought critically and made some considered decisions as you were choosing the interventions and activities. The following are questions to guide your final judgments about the plan of care.

1. ***Is the set of orders complete?*** That is, do they address all aspects of the problem?
   — Do they address the etiology of the problem?
   — If the etiology cannot be changed, do the orders focus on the symptoms of the problem?
   — Have I considered physical, emotional, interpersonal, spiritual, and cultural needs?
2. ***Is each order technically complete?*** That is, does it contain all the required components?
3. ***Are the orders clear, specific, and precise?*** If you have included all the required components, the orders will usually provide specific enough directions (e.g., when, how often, and so on) to be useful to other nurses. Avoid vague language. For example, "Offer emotional support" is too general to provide direction for care. One nurse might think this means to ask the client about his family, another might sit quietly with the patient, and still another might use a therapeutic statement such as, "This must be difficult for you." Ask yourself, "Would all nurses interpret this order in the same way? Would they all do the same thing after reading it?"
4. ***Is the order individualized for this particular patient?*** For example, even if you have written an order to "Offer 100 mL fluids every hr," it is even better if you make a note of the kinds of fluids the patient likes or can tolerate.

Toward Evidence-Based Practice

Paradis, V., Cossette, S., Frasure-Smith, N., Heppell, S., & Guertin, M-C. (2010). The efficacy of a motivational nursing intervention based on the stages of change on self-care in heart failure patients. *Journal of Cardiovascular Nursing, 25*(2), 130–141.

It is known that adherence to self-care recommendations is not optimal in heart failure patients. This study evaluated the effect of a specific type of motivational interviewing based on the stages of change (MISC). Thirty patients were randomly assigned to an experimental (EG) or control group. The EG patients each received one in-person intervention and two phone interventions. The effect of the interventions was evaluated on five self-care outcomes specific to heart failure. In the group receiving the interventions, significant results were obtained regarding patients' confidence in performing self-care specific to heart failure. Researchers concluded that an MISC intervention is useful in increasing patients' confidence in self-care and has the potential to improve self-care.

1. Based on this brief report, what facts do you know about the 30 patients who took part in the study?
2. Which of the following statements is most accurate based on the information in this report?
   a. The MISC intervention increased patient confidence in self-care.
   b. The MISC intervention increased patient confidence in self-care related to heart failure
3. If you wanted to begin using the MISC intervention to increase confidence in self-care for all heart failure patients on your unit, which of the following additional information would be most important to know?
   a. Did the same nurse provide the interventions to all the EG patients?
   b. How many patients were men and how many were women?
   c. Does increased confidence in self-care actually result in better performance of self-care?
4. Which of the following questions would be the best to use as the basis for a future related study? Why?
   a. Did the same nurse provide the interventions to all the EG patients?
   b. How many patients were men and how many were women?
   c. Do increased confidence in self-care actually result in better performance of self-care?

Go to Student Resources: Chapter 6, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

5. ***Are the orders concise?*** Long, complex statements may be unclear. Keep the orders as brief as possible without sacrificing clarity and specificity. If the patient requires complex procedures (e.g., insertion of a urinary catheter), don't write the details of the procedure on the care plan. Simply refer to the source of instructions for the procedure: perhaps an agency procedure manual, or a list of instructions to be found at the bedside. You will, however, need to write in the care plan any modifications to a procedure (e.g., "Do not use alcohol; client's skin is very dry").
6. ***Which orders have priority?*** Which nursing orders must be implemented immediately? Which must be done on this shift? Which must be done today? If possible, write them in priority order. In Chapter 4 you learned about frameworks for prioritizing nursing diagnoses (e.g., Maslow's hierarchy, problem urgency, future consequences, and patient preference). You can use these same frameworks to help you prioritize nursing orders.

If you have followed the recommended processes and reflected critically on your interventions, you should have a holistic plan of care individualized to meet the client's needs.

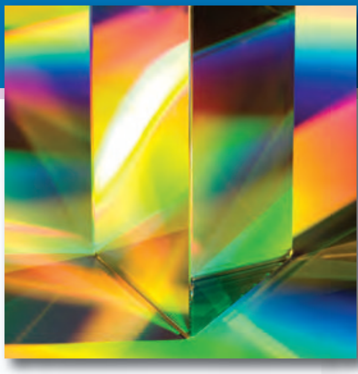
CHAPTER 7



Nursing Process: Implementation & Evaluation

Learning Outcomes

After completing this chapter, you should be able to:

- Define implementation.
- State the three broad phases of the implementation process (doing, delegating, recording).
- Describe what nurses do in the implementation phase of the nursing process.
- Define the terms *delegation* and *supervision.*
- Identify and describe the "five rights" of delegation.
- Explain how standards and criteria are used in evaluation.
- Explain how structure, process, and outcomes evaluation are related.
- Distinguish between ongoing, intermittent, and terminal evaluation.
- Describe a process for evaluating client health status (outcomes) after interventions.
- Describe a process for evaluating the effectiveness of the nursing care plan.
- List variables that may influence the effectiveness of a nursing intervention; state which ones the nurse can and cannot control.
- Discuss the importance of nurses' involvement in evaluating the quality of care in an organization.

Meet Your Patients

Patient 1. Jeannette Wu is a frail 80-year-old woman who is in the hospital after surgical repair of a fractured hip 4 days ago. Because of her overall fragile health and some postsurgery confusion, her recovery is slower than usual. One of her nursing diagnoses is Self-Care Deficit (Bathing, Dressing, and Toileting) related to weakness, pain, confusion, and decreased mobility. Her nursing orders (NIC) include Bathing and Self-Care: Activities of Daily Living (ADLs). As the nurse is helping a nursing assistive personnel (NAP) with Mrs. Wu's bath, she notices a reddened area on Mrs. Wu's sacrum. Realizing that this may be the beginning of a pressure ulcer, the nurse observes closely and notes a small skin excoriation (abrasion) in the reddened area. She repositions Mrs. Wu to prevent further pressure on her sacrum. After finishing the bath, the nurse records her findings and enters on Mrs. Wu's care plan a nursing diagnosis of Impaired Skin Integrity related to impaired bed mobility and minimal subcutaneous tissue. She writes nursing orders, including an order to observe skin over bony prominences every 4 hours, and then delegates to the NAP the task of turning and repositioning Mrs. Wu every 2 hours. The nurse also sends a consultation request to a wound care nurse specialist.

Patient 2. Patsy Jimenez is a healthy 25-year-old woman with no medical problems. She eats a balanced diet but does not exercise much. She and the nurse have created a plan to help her increase her physical activity. Ms. Jimenez will try

(continued)

Meet Your Patients (continued)

to walk for 30 minutes at least 5 days a week. Each week she is successful, she plans to reward herself with a movie or a milkshake, which she usually avoids because of the fat content. The nurse would prefer that Ms. Jimenez not reward herself with food, but respects her decision and realizes that if it is to serve as motivation, the reward must be something that Ms. Jimenez values.

ThinkLike a Nurse 7-1

- For Jeannette Wu, which parts of the scenario illustrate *doing* by the nurse?
- For Jeannette Wu, which parts of the scenario illustrate *thinking* by the nurse?
- For Patsy Jimenez, who will be implementing (carrying out) the plan of care?

ABOUT THE KEY CONCEPTS

As you study this chapter, keep the key concepts of **implementation, evaluation**, and **quality improvement** in mind. Everything in the chapter relates to those concepts in some way and as you read, you will begin to understand how they are related to each other and to your role as a nurse.

IMPLEMENTATION: THE ACTION PHASE OF THE NURSING PROCESS

Implementation is the action phase of the nursing process. Of course, it involves thinking, but the emphasis is on doing. During **implementation**, you will perform or delegate planned interventions—that is, carry out the care plan. The implementation phase ends when you document the nursing actions; it evolves into evaluation as you document the resulting client responses (Fig. 7-1). In short, implementation is doing, delegating, and documenting. For professional standards relating to implementation see Box 7-1.

As in all phases of the nursing process, think of the client as a collaborative partner. Encourage the client and family to participate as much as possible in the client's care. When Mrs. Wu is less confused and better able to move about, for example, the nurse will encourage her to help with her own bath. Keep in mind that clients vary in their ability and desire to participate. In the opening scenarios, Mrs. Wu was able to participate very little, but Patsy Jimenez participated fully. Typically, the client implements health-promotion interventions, with little or no involvement by the nurse.

How Is Implementation Related to Other Steps of the Nursing Process?

Nursing process phases are interdependent (see Fig. 7-1). Each phase affects and is affected by other phases. Without the assessment, diagnosis, and planning steps, implementation would reflect only dependent functions, such as carrying out policies, protocols, and medical orders. The autonomous nursing activities performed during implementation are built on the nurse's reasoning in the previous three steps. Implementation overlaps in some way with every other phase of the nursing process.

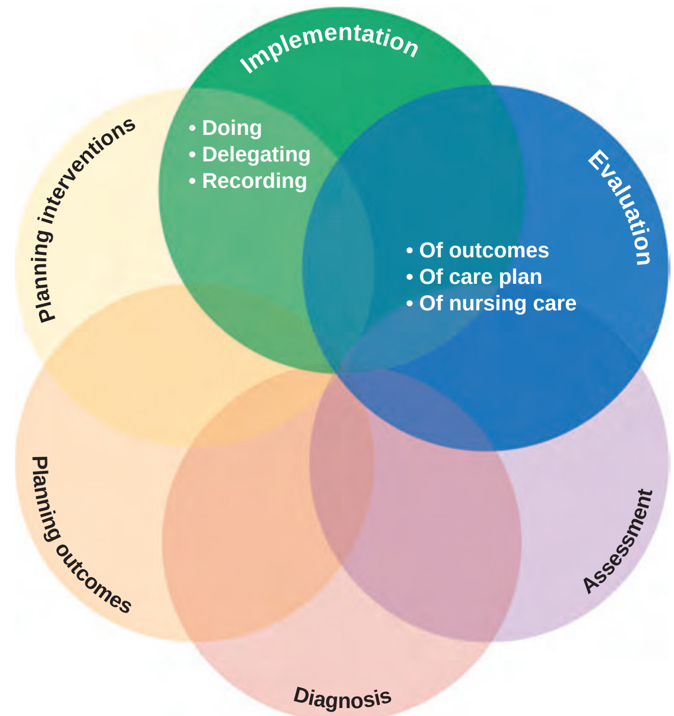

FIGURE 7-1 Nursing process phase: Implementation and evaluation.

Implementation Overlaps With Assessment Nurses use assessment data to individualize interventions for a specific person rather than just giving "routine care." For example, a nursing order may read, "Offer clear liquids hourly; patient likes tea." When taking the tea to the patient, you may discover that she prefers it without ice. This information allows you to individualize the nursing order further. Implementation also provides the opportunity to assess your patients at every contact. In Meet Your Patients, what data did the nurse obtain while bathing Mrs. Wu? When performing an ordered ongoing assessment, you are both

BOX 7-1 ■ American Nurses Association Standards of Practice for Implementation

Standard 5. Implementation

The registered nurse implements the identified plan.

Competencies

The registered nurse:

Partners with the person, family, significant others, and caregivers to implement the plan in a safe, realistic, and timely manner.

Demonstrates caring behaviors towards healthcare consumers, significant others, and groups of people receiving care.

Utilizes technology to measure, record, and retrieve healthcare consumer data; implement the nursing process; and enhance nursing practice.

Utilizes evidence-based interventions and treatments specific to the diagnosis or problem.

Provides holistic care that addresses the needs of diverse populations across the life span.

Advocates for healthcare that is sensitive to the needs of healthcare consumers, with particular emphasis on the needs of diverse populations.

Applies appropriate knowledge of major health problems and cultural diversity in implementing the plan of care.

Applies available healthcare technologies to maximize access and optimize outcomes for healthcare consumers.

Utilizes community resources and systems to implement the plan.

Collaborates with healthcare providers from diverse backgrounds to implement and integrate the plan.

Accommodates for different styles of communication used by healthcare consumers, families, and healthcare providers.

Integrates traditional and complementary healthcare practices as appropriate.

Implements the plan in a timely manner in accordance with patient safety goals.

Promotes the healthcare consumer's capacity for the optimal level of participation and problem solving.

Documents implementation and any modifications, including changes or omissions, of the identified plan.

Standard 5A: Coordination of Care

The registered nurse coordinates care delivery.

Competencies

The registered nurse:

Organizes the components of the plan.

Manages a healthcare consumer's care in order to maximize independence and quality of life.

Assists the healthcare consumer in identifying options for alternative care.

Communicates with the healthcare consumer, family, and system during transitions in care.

Advocates for the delivery of dignified and humane care by the interprofessional team.

Documents the coordination of the care.

Standard 5B: Health Teaching and Health Promotion

The registered nurse employs strategies to promote health and a safe environment.

Competencies

The registered nurse:

Provides health teaching that addresses such topics as healthy lifestyles, risk-reducing behaviors, developmental needs, activities of daily living, and preventive self-care.

Uses health promotion and health teaching methods appropriate to the situation and the healthcare consumer's values, beliefs, health practices, developmental level, learning needs, readiness and ability to learn, language preference, spirituality, culture, and socioeconomic status.

Seeks opportunities for feedback and evaluation of the effectiveness of the strategies used.

Uses information technologies to communicate health promotion and disease prevention information to the healthcare consumer in a variety of settings.

Provides healthcare consumers with information about intended effects and potential adverse effects of proposed therapies.

Standard 15. Resource Utilization

The registered nurse utilizes appropriate resources to plan and provide nursing services that are safe, effective, and financially responsible.

Competencies

The registered nurse:

Delegates elements of care to appropriate healthcare workers in accordance with any applicable legal or policy parameters or principles.

Modifies practice when necessary to promote positive interaction between healthcare consumers, care providers, and technology.

Assists the healthcare consumer and family in identifying and securing appropriate services to address needs across the healthcare continuum.

implementing and assessing. What ongoing assessment was ordered for Mrs. Wu?

Implementation Overlaps With Diagnosis Nurses use data discovered during implementation to identify new diagnoses or to revise existing ones. What new nursing diagnosis did the nurse make for Mrs. Wu after bathing her?

Implementation Overlaps With Planning Outcomes and Interventions Patient responses to interventions provide the data you need for revising the original goals and nursing orders. As you care for a client, you begin to know her better, and her unique needs become more apparent.

Implementation Overlaps With Evaluation When evaluating patient health status and progress toward goals, you will compare the responses you observe during implementation to the existing goals (which were written in the planning outcomes phase).

Preparing for Implementation?

Implementation involves some preparation. Although the care plan will already have been developed in the planning stages of the nursing process, you should do some more planning just before implementing the plan—as explained in the following sections. Notice how important critical thinking and nursing knowledge are to this "doing" phase of the nursing process. To see how the concept *preparation* is related to the key concept *implementation*,

Go to the **Knowledge Map**, at the end of Chapter 7, in Volume 2.

Check Your Knowledge and Abilities

Before beginning a nursing activity, review the care plan and reflect critically on the nursing and medical prescriptions. As a nurse, you are obligated ethically and legally to clarify or question orders that you believe to be unclear, incorrect, or inappropriate. At the same time, you must decide whether you are qualified to carry out the orders.

You should ask for help when:

- You do not have the knowledge or skill needed to implement an order (e.g., when administering an unfamiliar medication, or when you have never performed an ordered procedure).
- You cannot perform the activity safely alone (e.g., helping an obese, weak patient to ambulate).
- Performing the activity alone would cause undue stress for the patient (e.g., giving back care to a patient with multiple fractures).

For a decision tree to help you check whether you are ready to implement care,

Go to Student Resources: Chapter 7, **Resources for Caregivers and Health Professionals,** and follow the link for **"Decision Tree,"** on Davis*Plus*.

Organize Your Work

Because you will be providing care for more than one patient on each shift, you will need to make a time-sequenced work plan (worksheet) to prioritize your patient care for the day. Because of the need to control healthcare costs, you must work efficiently. To make the most of every patient contact, think ahead which interventions you can perform at the same time. Mrs. Wu's nurse performed a skin assessment while she was giving a bed bath. As another example, you might conduct patient teaching while assisting with breathing exercises. While changing a dressing, you might also use that time to show interest and concern for an anxious patient. Many institutions have forms for this type of scheduling, or you may need to write your own list of "things to do" in the order you need to do them. For a worksheet you can print and use in clinical,

Go to Student Resources: Chapter 7, Tables, Boxes, Figures: **ESG Figure 7-1, Worksheet for Organizing Nursing Care,** on Davis*Plus*.

At first, you may also need to make a time-sequenced list, the size of a 3×5 card, to help you organize your day. For example, it might read in part:

0700—Assessments, all patients, begin with Room 310.
0730—Ambulation: 315, 318
0800—Change IV, meds 310; check intake
0815—Meds 315, 318, 319; check intake
0845—Toilet and bath, 310

Key Point: ***Room numbers take up less space than names on the form, but do not fall into the habit of thinking of your patients by room number or diagnosis. They are people, with names.***

Establish Feedback Points

You cannot assume you will be able to carry out a nursing order in exactly the way it was written. For example, suppose the nursing order states, "Help to ambulate in the hall bid." When you help the patient to stand, he becomes pale, dizzy, diaphoretic, and short of breath. Would you still carry out the order? Of course you would not. You must always be ready to alter the activity on the spot as the patient's responses demand. This means that you must look for **feedback** (how the patient is responding to the activity) as you perform care. In a sense, this is evaluating. However, because it is done before the intervention is complete, we call it *feedback*.

When organizing your work, identify points in each intervention where you want to pause for feedback. For example, if you are assisting with range-of-motion exercises, you might plan to assess for pain during movement of each joint and to assess for activity intolerance after exercising both arms and again after exercising the legs. Feedback is not always verbal; it could be a change in vital signs, skin color, or level of consciousness.

Key Point: ***Notice how the concept of feedback relates to the concept organization, and how they both relate to the key concept, implementation.***

Prepare Supplies and Equipment

Gather all the supplies and equipment you need before you go to the patient's room. This allows you to work efficiently by eliminating the need to go to the supply room for items you have overlooked. Also, it prevents the stress to your patient that occurs when you interrupt a procedure to go get a needed item.

Suppose that when you insert an intravenous (IV) catheter, you "blow" the vein. You discover that you do not have another IV catheter; you have used the last one. What are your options at this point? Are there any *good* options?

The answer is that there are no good options. You might call another busy caregiver (provided that one is available) to bring you a sterile IV catheter. Or you could interrupt the procedure and get it yourself, making it necessary to leave the patient, and don another pair of gloves to prep another site. Either way, time and money would be lost, as might your patient's confidence in you. You may not be able to prevent "blowing" an IV; but by preparing ahead, you can prevent inefficiency and waste. In this case, that would mean being sure your IV tray is fully stocked before beginning the procedure.

Prepare the Patient

Before performing a nursing activity, identify the patient and reassess him to make sure the activity is still necessary and the patient is physically and psychologically ready for the intervention.

Check Your Assumptions This is just good critical thinking. Don't assume that an intervention is still needed simply because it is written on the care plan. For example, on postoperative day 6 after Jeannette Wu's surgery, the NAP is preparing to give her a bed bath, as instructed on the care plan (Table 7-1, section of plan dated December 18). However, Mrs. Wu has regained some of her strength and is able to sit in a chair. So the nurse and the assistant agree that, with help, Mrs. Wu can bathe at the sink instead of requiring a complete bed bath.

Assess the Patient's Readiness To obtain the most benefit from an intervention, a client must be physically and psychologically ready. The hospital's critical pathway for hip fractures recommended a "help bath" on postoperative day three. The nurse did not assume Mrs. Wu was ready to progress just because the critical pathway dictated it, and a complete bed bath was given, as indicated by Mrs. Wu's physical condition. The following are more examples of ensuring readiness:

- Because her patient was anxious about his test results, a nurse postponed a teaching session until he was feeling calmer.
- While preparing to perform a painful dressing change, a nurse discovered the patient had visitors. The nurse waited until the visitors had gone to do the procedure.

Explain What You Will Do and What the Patient Will Feel Clients are not merely passive recipients of your care. Many interventions require their participation or cooperation. Caring nurses take time to explain because

Table 7-1 ➤ Portions of the Care Plan for Jeannette Wu

NURSING DIAGNOSIS	DESIRED OUTCOMES	NURSING ORDERS	EVALUATION
Date: 12/16/15 Care Plan Before Implementation on Post-Op Day 4			
12/16/15 Self-Care Deficit (Bathing/Hygiene, Dressing/Grooming, and Toileting) related to weakness, pain, confusion, and decreased mobility	By post-op day 6 (12/18/15) will assist with bath and oral hygiene.	■ Complete bed bath daily in a.m. ■ Give prescribed analgesic ½ hr before bath. ■ Assist with range-of-motion exercises.	
Date: 12/16/15 Care Plan After Implementation on Post-Op Day 4			
NURSING DIAGNOSIS	**DESIRED OUTCOMES**	**NURSING ORDERS**	**EVALUATION**
12/16/15 Self-Care Deficit (Bathing/Hygiene, Dressing/Grooming, and Toileting) related to weakness, pain, confusion, and decreased mobility	By post-op day 6 (12/18/15) will assist with bath and oral hygiene.	■ Complete bed bath daily in A.M. (NAP) ■ Give Tylenol #3, tabs i by mouth, ½ hr before bath ■ Assist with range-of-motion exercises tid. (RN).	12/16/15 Too soon to evaluate
12/16/15 Impaired skin integrity (sacrum) r/t pressure 2° immobility	***By 12/23/15, skin healed over sacrum; skin intact and normal color over all bony prominences***	■ ***Turn and reposition q2hr; do not place supine (NAP).*** ■ ***Observe skin over bony prominences q4hr (RN).***

Date: 12/18/15 Care Plan After Implementation on Post-Op Day 6

NURSING DIAGNOSIS	DESIRED OUTCOMES	NURSING ORDERS	EVALUATION
12/16/15 Self-Care Deficit (Bathing, Dressing, and Toileting) related to weakness, pain, confusion, and decreased mobility	By post-op day 6 (12/18/15) will assist with bath and oral hygiene.	■ ~~Complete bed bath daily in A.M.~~ *12/18/15 NAP help with bath at sink daily in A.M. Patient can wash hands and face and perform oral hygiene.* ■ Give prescribed analgesic ½ hr before bath. ■ Assist with range-of-motion exercises tid (RN).	*12/18/15 Goal met. Sat in chair for help with bath. Performed oral hygiene and washed hands and face.*
12/16/15 Impaired skin integrity (sacrum) r/t pressure 2° immobility	By 12/23/15, skin healed over sacrum; skin intact and normal color over all bony prominences	■ Turn and reposition q2hr; do not place supine (NAP). ■ Observe skin over bony prominences q4hr (RN). ■ *12/18/15 Requested foam and fatty mattress pad.* ■ *12/18/15 Refer to nutritionist for evaluation.*	*12/18/15 Skin excoriation over sacrum is larger: now 2 cm × 2 cm, and about ½ cm deep*

it helps to motivate the person and gives him the information he needs to participate. Knowing what to expect helps to relieve anxiety, enables the person to cope with unpleasant or painful sensations, and promotes a trusting relationship.

KnowledgeCheck 7-1

- Why is it important to organize your work before implementing care?
- In addition to organizing your work, what other preparations should you make before implementing care?

ThinkLike a Nurse 7-2

Suppose your patient, Jeannette Wu, has become incontinent of bowel and bladder. Because she already has Impaired Skin Integrity, the physician writes a new prescription to insert an indwelling urinary catheter (a drainage tube inserted through her urinary meatus into her bladder). Urinary catheterization is a sterile technique. You have practiced this procedure in the skills lab, but you have never actually performed it on a patient.

- As a student, what should you do?
- If you were a licensed nurse, what are some things you could do to ensure that both you and the patient are prepared for the procedure?

Implementing the Plan: Doing or Delegating

After both you and the patient are prepared, it is time to act. Nursing actions include both those you do yourself and those you delegate to others; and they may be collaborative, independent, or dependent (see Chapter 6 if you do not recall the meaning of these terms). During implementation, you will coordinate and carry out both the nursing orders on the nursing care plan and the medical orders that relate to the patient's medical treatment.

What Knowledge and Skills Do I Need?

There is almost no limit to the number and kinds of nursing interventions you might perform. The *Nursing Interventions Classification* (Bulecheck, Butcher, & Dochterman, et al., 2013), for example, lists 554 broad interventions (e.g., Hypothermia Treatment), each of which includes approximately 15 to 20 specific activities. For example, one activity for Hypothermia Treatment is to "remove patient's cold, wet clothing" (p. 224). During implementation, then, you can expect to use all the types of knowledge presented in Chapter 2: theoretical, practical, personal, and ethical knowledge, as well as knowledge about the patient situation.

You will also use various combinations of cognitive, interpersonal, and psychomotor skills to perform nursing activities (thinking, doing, caring). For example, when you are inserting an IV catheter, you need cognitive knowledge of sterile procedure, interpersonal skills to reassure the patient, and psychomotor skills to apply the tourniquet and insert the IV catheter.

ThinkLike a Nurse 7-3

Use the examples provided in the preceding paragraph to help you write a definition for each of the following terms:

- Cognitive skills
- Interpersonal skills
- Psychomotor skills

How Can I Promote Client Participation and Adherence?

Different interventions require differing levels of participation. However, even a nurse-initiated intervention, such as inserting a urinary catheter, goes more smoothly if the patient participates at least to the extent of holding still while you perform the procedure. Many interventions (e.g., instituting a low-calorie diet) depend almost entirely on the patient's adhering to the therapy. In the case of Ms. Jimenez (Meet Your Patient), implementation of the intervention, walking for 30 minutes five times a week, depends entirely on the client.

People fail to follow therapeutic regimens for various reasons: pain, lack of understanding of the routines or their rationale, cultural objections, lifestyle difficulties (e.g., no time to exercise), fear of failure, embarrassment, or hesitation to ask questions of a "busy" nurse or physician. You can promote cooperation with treatments and therapies by following these guidelines:

- **Assess the client's knowledge.** Assess the client's understanding of his illness and the treatments and provide the necessary information.
- **Provide teaching.** Be as specific as possible with your instructions. Keep instructions simple and clear, and provide a written copy.
- **Assess the client's supports and resources.** You cannot assume that every patient has transportation to the healthcare facility. Even if they wish to follow the therapy, some people do not have enough money for food or medicine; some people cannot read printed instructions; some do not have family or friends to help with their care at home, and so on.
- **Be sensitive to the client's cultural, spiritual, and other needs and viewpoints.** For example, regardless of the need for dietary protein, some people do not like the taste of meat, poultry, or fish. Others might have religious or cultural objections to eating these foods. You will need to modify your recommendations to reflect client preferences and beliefs.
- **Realize and accept that some attitudes cannot be changed.** For example, regardless of the effects of obesity on blood pressure, a client will not lose weight simply because you tell him it is important. The client must *want* to lose weight.
- **Key Point:** ***Information alone will not change a person's behavior.***
- **Determine the client's main concerns.** For example, you may be concerned that lack of exercise makes it difficult to regulate a client's blood sugar; the client's main concern may be that exercise makes her joints hurt.
- **Help the client to set realistic goals.** Clients usually more readily accept small, rather than drastic, behavioral or lifestyle changes. Perhaps a client with a child who has asthma cannot even imagine that she could stop smoking. But you may be able to convince her it would be better for her child if she would smoke outdoors rather than in the house or in the car (U.S. Environmental Protection Agency [EPA], 2009).
- **Talk openly and regularly about adherence.** Let the client know you understand how difficult treatment can be and that others struggle with adherence as well.

After reading this section, can you define the concept of *adherence*? Can you explain how this concept relates to the key concept, implementation?

What Should I Know About Collaborating and Coordinating Care?

For successful implementation, you need the skills of collaboration and coordination.

Collaboration As discussed in Chapter 6, **collaboration** simply means working with patients and other caregivers (e.g., physicians, respiratory therapists) to plan, make decisions, or perform interventions. Unlike delegated activities (discussed in the following section) true collaboration requires shared decision making.

According to the Quality and Safety Education for Nurses (QSEN) project, one of the competencies you should acquire in nursing school is the ability to function and collaborate on an interdisciplinary team, as well as with other nurses. This means, in part, that you will learn to be assertive in discussions about patient care. At the same time, you should recognize the differences in authority and power that exist on interdisciplinary teams and choose your communication style carefully, taking that into account (Cronenwett, Sherwood, Barnsteiner, et al., 2007).

Coordination Coordinating care includes scheduling treatments and activities with other departments (e.g., laboratory, physical therapy, radiology), but it is more than that. In the hospital, nurses are the professionals who have the most frequent and continuous contact with the patient, so they have the most complete picture of the person. Most other caregivers focus on only a very specific aspect of the patient (e.g., breathing, eating, surgical incision). You will be expected to put together the bits and pieces of information (e.g., the patient's response to physical therapy, dietary intake, emotional status, and vital signs) to provide a holistic view of the person. You will need to read the reports of other professionals; help interpret the results for the patient and family; and make rounds with other professionals to be sure that everyone sees the whole picture.

Outside the hospital, the health professional who has the most contact with the client usually assumes the coordination role. For example, if a client is receiving episodic care for ongoing health problems, the primary care provider (e.g., physician or advanced practice nurse) may coordinate care. For a client discharged home after a hip fracture, the physical therapist may coordinate care.

KnowledgeCheck 7-2

- What are some reasons that a client may not follow a recommended treatment regimen?
- List at least four things you can do to promote client participation in care or adherence to recommendations for treatment.

What Should I Know About Delegation and Supervision?

Delegation is the process of directing another person to perform a task or activity; it is a transfer of authority or responsibility. The person delegating retains accountability for the outcome of the activity (American Nurses Association [ANA] & the National Council of State Boards of Nursing [NCSBN], 2006). As a registered nurse, you will frequently delegate patient care activities to licensed vocational (or practical) nurses (LVN/LPNs) and NAPs, although in some states LVN/LPNs are considered accountable for their actions because they are licensed.

Delegating Is Not the Same as Assigning You may also *assign* tasks to other registered nurses (RNs) (e.g., as a nurse in charge tasks making unit assignments for the day). However, this is not delegation because those RNs are accountable for the outcome of their activities. **Key Point:** ***Remember, you can only delegate down in the chain of command.***

Understand That You Cannot Delegate Nursing Care Decisions You can delegate only the responsibility for performing a defined activity in a particular situation. So, even though the nurse has delegated to the NAP the task of turning Mrs. Wu (Meet Your Patients) every 2 hours, it is *the nurse* who must assess her skin condition and take action if it does not improve.

Use NAPs Appropriately In some healthcare settings, NAPs are used inappropriately to perform functions that are legally nursing functions (e.g., administering medications) (Dickens, Stubbs, & Haw, 2008). Many nurses are concerned that inappropriate delegation is a threat to patient safety. Nurses may find themselves in a difficult position of caring for sicker patients, using new technologies, administering medications, and juggling these activities with overseeing delegated work. According to the ANA, any nursing intervention that requires critical thinking or professional judgment cannot be delegated. However, the ANA takes the position that RN delegation and direction of specific tasks to NAPs in accordance with state nurse practice acts is appropriate, safe, and resource-efficient (ANA, 2007). Standard 15 of *Nursing: Scope and Standards of Practice* (2nd ed.) (ANA, 2010) states that the registered nurse "delegates elements of care to appropriate healthcare workers in accordance with any applicable legal or policy parameters or principles."

The Five Rights of Delegation

When deciding whether to delegate tasks, think critically about the task, the circumstance, the person, the direction or communication, and the supervision and evaluation. For a checklist to help you consider these five critical elements, or "five rights" of delegating,

Go to Chapter 7, **Implementation and Evaluation Tools, The Five Rights of Delegation—Checklist,** in Volume 2.

Right Task

The first question to ask is, "Can I delegate this task?" As a rule, you should delegate an activity only if it meets *all* of the following criteria (ANA, 1996; ANA/NCSBN, 2006). The activity:

- Is within your scope of practice to perform and delegate, as defined by your state nurse practice act.
- Is within the LVN/LPN's or NAP's scope of practice.
- Is in accordance with agency policies, if they exist.
- Is performed according to an established sequence of steps and requires little or no modification from one situation to another.
- Does not require ongoing nursing assessments, interpretation, or decision making.
- Occurs frequently in the daily care of patients on the unit.
- Has reasonably predictable results.
- Does *not* require independent or specialized nursing knowledge, skills, or judgment.
- Is *not* health teaching or counseling.
- Does not endanger a client's life or well-being.

Examples of tasks you might assign to a NAP are bathing a stable patient, ambulating steady patients, obtaining routine vital signs, changing linens, assisting patients with meals, clerical duties, and transporting non-acute patients and specimens.

LPNs can usually provide care to medically stable patients according to an established plan of care; they can give you feedback about patient responses for patients who are expected to respond predictably. Tasks you can usually assign to an LPN include administering some medications (except for IV medications and some controlled substances), starting an IV infusion and administering plain IV solutions, and assisting with identification of blood units for transfusion. You would not assign an

LPN to start a blood transfusion, administer chemotherapy, administer or monitor parenteral nutrition, give IV push medications, or create and modify nursing care plans (Ayers & Montgomery, 2008).

Key Point: ***Remember that you are assigning staff members to a task, not to a patient. You cannot delegate the responsibility for total patient care; and you cannot allow a NAP to delegate care to other NAPs.***

Right Circumstance

NAPs are being used in settings in which acuity and technology have increased while length of stay has decreased. This means they are caring for sicker patients. Even tasks such as bathing, feeding, and turning patients may not be appropriate if the patient is seriously ill. Before deciding to delegate, assess your patient to be certain that her needs match the abilities of the NAP or LPN. It is best if the patient is relatively stable (e.g., with a chronic rather than an acute condition) and does not need extensive help with self-care activities. If the client is very ill or if the results of the task are unpredictable, the task should probably not be delegated. For a tool to help you make appropriate delegation decisions,

Go to Chapter 7, Implementation and Evaluation tools, **NCSBN Delegation Grid**, in Volume 2.

Right Person

You must also be sure that the LPN or NAP is competent to perform the task and that his workload allows time to do the task properly. Consider the person's experience, training, and cultural competence. The following are evidence of competence:

- The facility has documented proof that the person has demonstrated competence.
- The NAP has performed the task often or has worked with patients with similar diagnoses.

If evidence is lacking, you need to establish the NAP's competence. For example, you might observe and evaluate his performance, or you might ask the NAP, "How many times have you done this procedure?" or "Will you need help with this procedure?" Only a professional nurse can evaluate an LPN's or NAP's ability to perform a nursing task.

Right Communication

Right communication means that when you delegate, you should communicate clearly and specifically about each task. You can communicate orally or in writing, but leave no room for misinterpretation.

- **Explain exactly what the task is.** Include what to do and what not to do. For example, "Empty the catheter bag, and measure the amount of urine using the clear, marked plastic container"—not just, "Measure the urine."
- **Include specific times and methods for reporting.** For example, "Come tell me the patient's temperature every hour."
- **Explain the purpose or objective of the task.** For example, "Change Mrs. Wu's position every 2 hours to prevent bedsores; she is not able to turn by herself."
- **Describe the expected results or potential complications to expect.** For example, "She will probably cry out when you turn her, but that is more from fear than from pain," or "I have given her medications, so her temperature should be below 100°F by 0900. If not, let me know immediately."
- **Be specific in your instructions.** For example, "Let me know whether Mrs. Wu has any red spots or broken skin areas when you turn her"—not "Tell me what her skin looks like."

Right Supervision

Supervision is the process of directing, guiding, and influencing the performance of the delegated task. When you delegate tasks to a NAP or LVN/LPN, you or another RN must be available to answer questions and provide help, if necessary. You are responsible for providing supervision and evaluating the outcomes. This includes the following:

- **Monitor the NAP/LVN/LPN's work.** This is important to be sure it complies with agency policies and procedures and standards of practice. For example, after the NAP bathes a patient, you could check to see whether the patient is clean; or you might choose to observe for a few minutes while the NAP is working. Make frequent patient rounds and get regular reports from those you have assigned to do tasks.
- **Intervene, if necessary.** Many NAPs receive little training, so you may need to demonstrate some caregiving activities.
- **Obtain and provide feedback from the worker.** Give positive, as well as negative, feedback often. If performance is not acceptable, speak privately with the NAP to explain the specific mistakes that were made. Listen to the NAP's view of the situation. For example, there may have been too many tasks to complete in the time allowed.
- **Evaluate client outcomes.** Evaluate both the physical response and the relationship with the NAP. Ask the client for input after the care is given.
- **Ensure proper documentation.** Some agencies permit NAPs to record vital signs and other patient data. You are responsible for seeing that all necessary data are recorded and that they are accurate.

KnowledgeCheck 7-3

- List the five rights of delegation.
- List at least four characteristics of a "right task"—that is, a task that would be acceptable to delegate.
- As an RN, how could you establish that a NAP is competent to perform a task?
- List at least three ways to help ensure that the NAP will understand clearly what she needs to do when you delegate a task.
- List at least three things you should do when providing supervision to an unlicensed caregiver.

ThinkLike a Nurse 7-4

For your patient, Jeannette Wu:

- Which activity did the nurse delegate to someone else?
- What collaborative activities should the nurse consider?

Documenting: The Final Step of Implementation

After giving care, you will record the nursing activities and the patient's responses. Documentation is a mode of communication among the members of the health team, and it provides the information you need to evaluate the patient's health status and the nursing care plan. For a thorough discussion of documenting, refer to Chapter 18.

Reflecting Critically About Implementation

During the implementation phase, perhaps more than at any other time, nurses combine thinking and doing. You should always be prepared to modify the activity based on the patient's responses. Afterward, when you have some time to reflect, you can think critically about what happened (good or bad) and why. Use the following questions, or refer to the critical thinking model. (See Chapter 2, Table 2-1 if you would like other ideas.)

- What was done? Why was it done? What were the patient's responses?
- Did I forget to do anything?
- What was going on in the situation that may have influenced the outcome?
- What factors influenced my behavior (or others' behavior) in this situation?
- Would the activity have been more successful if I had had more knowledge or skill? If so, why did I not realize that ahead of time, and how can I avoid such lack of insight in the future?
- What assumptions or biases (mine or the patient's) contributed to the problem in this situation?
- Did I communicate clearly to the patient?
- Did I convey respect and caring?
- What could I have delegated? What did I delegate that I should *not* have? Why?
- After reflecting on it, what would I do differently in this situation?

Refer to Table 7-2 for examples that demonstrate how the reflection questions might be used in a clinical situation.

Toward Evidence-Based Practice

Read about the following studies, and then answer the questions at the end of the box.

Potter, P., Deshields, T., & Kuhrik, M. (2010). Delegation practices between registered nurses and nursing assistive personnel. *Journal of Nursing Management, 18*(2), 157–165.

The authors of this qualitative study conducted a series of small-group, semi-structured interviews with ten RNs and six NAPs. They asked participants to describe their experiences of delegation practices on their units, and then analyzed transcripts of the interviews. Participants described conflict as a central theme. Researchers concluded that successful delegation depends on the quality of RN and NAP working relationships, timely ongoing communication, initiative, and a willingness to collaborate.

Standing, T., & Anthony, M. K. (2008). Delegation: What it means to acute care nurses. *Applied Nursing Research, 21*(1), 8–14.

The authors of this qualitative study conducted 17 in-depth interviews with acute care nurses, both novice and experienced, to examine the nature of delegation. Nurses expressed frustration that they were being held accountable for the NAPs' tasks, while the NAPs themselves were not. Several nurses described NAPs' resentment of RNs. They indicated that the RN-NAP relationship and good communication are at the heart of delegation. The RNs recognized the importance of acknowledging the contribution of the NAP. The RNs pointed out that one negative aspect of delegation is that the NAP sometimes did not perform tasks well, or at all, and sometimes communicated improperly with patients. A positive aspect is that delegation allows the RN time to monitor patient changes, review charts, and focus on "more important things." They concluded nursing education should provide more content on communication and interpersonal relationships.

1. What similarities do you see between the methods used in the two studies?
2. What differences do you see in the participants in the two studies?
3. What similarities in results are reported?
4. With your answer to question 3 in mind, what skill(s) do you think you need to learn and practice to prepare for working with and delegating to NAPs?

Go to Student Resources: Chapter 7, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

Table 7-2 ➤ Examples of Reflecting Critically About Implementation

SITUATION	QUESTION FOR REFLECTION	WHAT MIGHT HAVE HAPPENED?
The nursing order read, "Assist to ambulate to the end of the hall. . . ." However, the patient was able to walk only about half that distance before becoming too weak to stand.	What was going on in the situation that may have influenced the outcome?	Perhaps the patient was weak because he had not slept well the night before; or perhaps he had just had a long, tiring session of physical therapy.
When the patient became too weak to walk, the nurse called for help. Why did she do that instead of helping the patient to sit where he was, or instead of helping him back to the room by herself?	What factors influenced the nurse's behavior in this situation?	Perhaps the patient was very large and the nurse realized she was not strong enough to provide support. Can you think of other reasons that the nurse might have chosen that action?

EVALUATION: THE FINAL STEP OF THE NURSING PROCESS

Evaluation, the final step of the nursing process, is a planned, ongoing, systematic activity in which you will make judgments about:

- The client's progress toward desired health outcomes.
- The effectiveness of the nursing care plan.
- The quality of nursing care in the healthcare setting.

How Is Evaluation Related to Other Steps of the Nursing Process?

The patient outcomes stated in the *planning outcomes* stage must be concrete, observable, and appropriate for the patient in order to be useful as evaluation criteria. Appropriate outcomes, in turn, depend on complete and accurate *assessment* data and *nursing diagnoses.* You will observe and evaluate client responses during *implementation* in order to make on-the-spot changes in activity. And, of course, *interventions* must be *planned* and *implemented* to produce the patient behaviors that you evaluate. Evaluation overlaps greatly with the assessment step—both involve data collection.

Key Point: ***The difference is in when you collect and how you use the data.***

- *Assessment data* are collected before interventions are performed to determine initial or baseline health status and to make nursing diagnoses.
- *Evaluation data* are collected after interventions are performed to determine whether client goals were achieved.

Why Is Evaluation Essential to Full-Spectrum Nursing?

Evaluation is a key concept in this chapter, and it is an essential part of the full-spectrum nursing role for the following reasons:

- **The patient is the nurse's first priority.** The aim of all nursing activity is to achieve positive outcomes for patients. Evaluation lets you know whether your interventions are helping the patient as intended, and guides your next actions. No matter how carefully and conscientiously you implement, if the intervention does not help the patient achieve desired outcomes, you may need to revise the plan of care.
- **Evaluation helps nurses to conserve scarce resources.** Healthcare resources are limited and fewer nurses are hired to care for more and sicker patients. Workloads are heavy. Therefore, nursing time must be used wisely. Evaluation allows you to discard interventions that are not working well and focus on more effective, and perhaps more cost-effective, ones.
- **Professional standards of practice require evaluation.** For an example, see the ANA practice standards in Box 7-2.
- **The ANA Code of Ethics requires evaluation.** "The nurse's primary commitment is to the recipient of nursing and healthcare services—the patient—whether the recipient is an individual, a family, a group, or a community. . . . The nurse has a responsibility to implement and maintain standards of professional nursing practice. The nurse should participate in planning, establishing, implementing, and evaluating review mechanisms designed to safeguard patients and nurses, such as peer review processes or committees, credentialing processes, quality improvement initiatives, and ethics committees" (ANA, 2001, Section 2.1 and Standard 3.4).
- **The Joint Commission and professional standards review organizations (PSROs) require evaluation.** These organizations use outcomes and performance measures to evaluate the quality of care in healthcare institutions. They conceptualize quality of care as the degree to which health services increase the likelihood of desired health outcomes.
- **Evaluation helps demonstrate the value of nursing.** Linking nursing interventions to achievement of client outcomes demonstrates the value of nursing. In today's competitive healthcare market, that is essential for ensuring continued funding for nursing services, education, and research.

BOX 7-2 ■ ANA Standards of Practice for Evaluation

Standard 6. Evaluation

The registered nurse evaluates progress toward attainment of outcomes.

Competencies

The registered nurse:

Conducts a systematic, ongoing, and criterion-based evaluation of the outcomes in relation to the structures and processes prescribed by the plan of care and the indicated timeline.

Collaborates with the healthcare consumer and others involved in the care or situation in the evaluation process.

Evaluates, in partnership with the healthcare consumer, the effectiveness of the planned strategies in relation to the healthcare consumer's responses and attainment of the expected outcomes.

Uses ongoing assessment data to revise the diagnoses, outcomes, the plan, and the implementation, as needed.

Disseminates the results to the healthcare consumer, family, and others involved, in accordance with federal and state regulations.

Participates in assessing and assuring the responsible and appropriate use of interventions in order to minimize unwarranted or unwanted treatment and healthcare consumer suffering.

Documents the results of the evaluation.

Source: American Nurses Association. (2010). *Nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Author.

- **Evaluation demonstrates caring and responsibility**. Without evaluation, you would not know whether your care was effective. Examining outcomes implies that you care about how your activities affect your clients.
- **Quality and Safety Education for Nurses (QSEN).** This task force includes quality improvement, which involves evaluation, as one of the competencies to be achieved during your education in nursing.

How Are Standards and Criteria Used in Evaluation?

In a broad sense, evaluation is the systematic process of judging the quality or value of something by comparing it with one or more standards or criteria. In our daily lives, we evaluate many things: for example, a meal, a TV program, an insurance policy we are thinking of buying. **Key Point:** ***However, for formal evaluation, you must decide* in advance *which standards and criteria you will use.***

As you learned in Chapter 1, **standards** represent expected or accepted levels of performance; they provide a model of what ought to be done. In nursing, standards are used to describe quality nursing care. The ANA's standards of practice are a good example of broadly written standards (see Boxes 7-1 and 7-2).

Notice that each of the ANA standards includes a set of measurement criteria, called competencies, to help describe the standard. **Criteria** are measurable or observable characteristics, properties, attributes, or qualities. They describe the specific skills, knowledge, behaviors, and attitudes that are desired or expected. Judges at a diving competition, for example, might evaluate a dive by using criteria for difficulty, technique, and style.

The patient goals and outcomes discussed in Chapter 5 are also examples of criteria. As you learned there, these criteria should be concrete and specific enough to serve as guides for collecting evaluation data. In addition, they should be reliable and valid. A criterion is **reliable** if it yields consistent results—that is, the same results every time, regardless of who uses it. For example, suppose you and another nurse measure a patient's temperature by (1) using an oral thermometer and (2) placing the back of your hand on the patient's forehead. Which method would probably give the same (or nearly same) results every time? As you probably concluded, the oral thermometer is more reliable.

A criterion is **valid** if it is really measuring what it was intended to measure. For example, fever is often used as a criterion for concluding that a person has an infection. However, if used alone, it is not a valid indicator because (1) other conditions, such as dehydration, can cause a fever and (2) elevated temperature is not present in all infections. However, validity of that criterion is increased when you use additional criteria (e.g., elevated white blood cell count, presence of signs of infection, such as redness and pus).

ThinkLike a Nurse 7-5

- The outcome "Patient will not complain of pain" by itself is not a valid criterion for measuring pain. Why? What would be a more valid criterion for pain?
- A criterion reads, "Measures client vital signs once per shift, or as prescribed." For which of the following standards would it be valid (that is, which conclusion could you draw if you knew that a nurse measured the vital signs once per shift, or as prescribed)?
  Follows unit policies.
  Performs skills accurately.

What Are the Types of Evaluation

Evaluation is categorized according to (1) what is being evaluated (structures, processes, or outcomes) and (2) frequency and time of evaluation.

Evaluation of Structures, Processes, and Outcomes

Structures, processes and outcomes all work together to affect care; however, each requires different criteria and methods of evaluation.

Structure evaluation focuses on the setting in which care is provided. It explores the effect of organizational characteristics on the quality of care. It requires standards and data about policies, procedures, fiscal resources, physical facilities and equipment, and number and qualifications of personnel. Examples of criteria for structure evaluation include the following:

At least one registered nurse is present on each unit at all times.
A resuscitation cart is available on each floor.

Process evaluation focuses on the manner in which care is given—the activities performed by nurses (and other personnel). It explores whether the care was relevant to patient needs, appropriate, complete, and timely. Your instructor uses process evaluation to evaluate your clinical performance. Your clinical evaluation describes what you did and how well you did it. As a rule, it does not describe the *results* of your activities. Examples of criteria for process evaluation include the following:

Protects patient's privacy when performing procedures.
Washes hands before each patient contact.

Outcomes evaluation focuses on observable or measurable changes in the patient's health status that result from the care given. Although structure and process are important to quality, the most important aspect is improvement in patient health status. The evaluation step of the nursing process uses outcomes evaluation. Examples of outcomes criteria include the following:

Patient will walk, assisted, to end of hall by postoperative day 5.
Patient reports pain less than 4 on a scale of 1 to 10 within 1 hour after analgesic administration.

Outcomes evaluation is also used when evaluating quality of care in an organization. When used for that purpose, the criteria also state the percentage of clients expected to have the outcome when care is satisfactory—as in the following example:

Post-catheterization urinary tract infection does not occur.
Expected compliance: 100%

This means that the criterion would be met only if no patients developed a urinary tract infection after being catheterized.

Ongoing, Intermittent, and Terminal Evaluation

Evaluation begins as soon as you have completed the first nursing activity and continues during each client contact until all goals are achieved or the client is discharged from nursing care. The client's status determines how often you evaluate. A critically ill patient may need a nurse constantly at the bedside; after a patient undergoes surgery, you may measure vital signs every 15 minutes; as the patient nears discharge, you may evaluate once a day. In long-term care settings, in contrast, residents often have chronic health problems that require evaluation over an extended period of time. Most care is provided by LVN/LPNs and NAPs, and the RN may participate in weekly care conferences to evaluate the resident's response to the current plan of care.

You will perform **ongoing evaluation** while implementing, immediately after an intervention, and at each patient contact. In contrast, **intermittent evaluation** is performed at specified times. Both kinds of evaluation enable you to judge the progress toward goal achievement and to modify the care plan as needed. Goals and expected outcomes should designate times for collecting evaluation data. For example:

Will rate pain as < 3 on a scale of 1 to 10 *within 1 hr after medication*.
Will lose 1 lb *per week* until weight of 125 lb is achieved.
By the second home visit, mother will demonstrate proper techniques for breastfeeding.

Terminal evaluation describes the client's health status and progress toward goals at the time of discharge. Most institutions have special discharge forms for terminal evaluation that also include instructions about medications, treatments, and follow-up care.

As in all phases of the nursing process, collaborate with the patient and family in the evaluation to the extent they are able. As the nurse, you are responsible for drawing evaluative conclusions; however, you should use input from the patient, the family, NAPs and other caregivers (see Box 7-2).

ThinkLike a Nurse 7-6

For each of the following goals, when or how often should the nurse collect evaluation data?

- Will rate pain as < 3 on scale of 1 to 10 within *1 hr after medication*.
- Will lose 1 lb *per week* until weight of 125 lb is achieved.
- *By the second home visit*, mother will demonstrate proper techniques for breastfeeding.

KnowledgeCheck 7-4

- Explain what is evaluated in each of the following types of evaluation (i.e., the focus of each type of evaluation): structure, process, and outcomes.
- Identify what is evaluated using the following criteria: structure, process, or outcomes.
  In the Emergency Department the time from patient sign-in to assessment by a healthcare worker will be less than 15 minutes.
  A fire extinguisher is located in an accessible spot on each unit.
  No patients with indwelling urinary catheters will develop urinary tract infection.
- Define the following: ongoing evaluation, intermittent evaluation, terminal evaluation.

How Do I Evaluate Patient Progress?

Evaluation does not "end" the nursing process. It merely provides the information you need to begin another cycle. After giving care, you compare patient responses to the desired outcomes (goals) and use that information to reflect critically on (1) the care plan and (2) each step of the nursing process as it applies to that patient. When evaluating patient progress, you review the desired outcomes, collect reassessment data, judge whether goals have been met, and record the evaluative statement (Wilkinson, 2011). Figure 7-1 illustrates the relationship of the evaluation phase to the rest of the nursing process.

Review Outcomes

First, review the goals/outcomes on the patient's care plan. The goals and indicators you identified in the planning outcomes phase suggest the kind of assessments you need to make and provide criteria by which to judge the data.

Collect Reassessment Data

Next, assess client responses to the interventions. To minimize confusion, assessments made for the purpose of evaluation may be called **reassessment**. Reassessments are always focused assessments (see Chapter 3). As already mentioned, the care plan goals determine their focus.

- Suppose, for example, that the nursing care plan lists the following goal: "By 8/24/16, will walk, unassisted, to the end of the hall without pallor or shortness of breath." What kind of assessments would you make to know whether this goal has been met?
- Suppose the care plan includes the following goal: "By 8/24/16, will notify nurse as soon as pain begins." How would you obtain the data you need to evaluate this goal?

For the first example, you would observe the patient's skin color as he walked, observe and count his respirations, and ask him whether he felt short of breath at any time. The second example is a little less obvious. If the patient doesn't call you, you cannot assume this means there is no pain. You would need to ask him whether he has had pain (e.g., "I notice that you have not put your call light on. Have you had any pain at all today?"). If the patient does call you, you still cannot assume it is because of pain, or that he called as soon as the pain began. You must question to clarify, for example, "How can I help you?" "Are you in pain?" "When did it start?"

ThinkLike a Nurse 7-7

In the examples in the preceding paragraph, which aspects of critical thinking (in the full-spectrum nursing model in Chapter 2) did you use in order to decide what data you needed?

Goals can be cognitive, psychomotor, or affective, or they may refer to body appearance and function. The nature of the goal determines the kind of data you need to collect. See Table 7-3 for examples of goal types and the kind of reassessment data they require. As in the assessment phase, you will collect data from the client, family, friends, and health team members, as well as from the client's chart (e.g., laboratory results). The RN is responsible for evaluating goal achievement, even though someone else may have supplied the data.

Judge Goal Achievement

Next, compare the reassessment data with the patient's goals. Are the responses (actual outcomes) the same as the expected or desired outcomes? If so, the goal has been met. As always, get the patient's input. Ask her whether she thinks the goals have been achieved. You can draw the following conclusions about a goal or outcome:

- *Achieved.* The actual responses are the same as the desired outcome.
- *Partially achieved.* Some, but not all, of the desired behaviors were observed, or the desired response occurs only some of the time (e.g., the desired heart rate is < 100 beats/min, a goal that is achieved except for one or two episodes a day, when it is 110 beats/min).
- *Not achieved.* The desired response did not occur (actual outcome does not match desired outcome or goal).

Record the Evaluative Statement

Professional standards require that you record your evaluations. You may write an evaluative summary in the nursing notes or on the care plan, depending on the procedure specified by the institution. An evaluative statement should include:

- The conclusion about whether the goal was achieved
- Reassessment data to support the judgment

An evaluative statement for the pain goal "By 8/24, will notify nurse as soon as pain begins" might be:

> 8/25/16, 0100. Goal not met. Has not used call light at all this a.m. Restless and grimacing with movement during a.m. care. When asked, described pain as 8 on a scale of 1 to 10. ——— J. Hiam, RN

When using standardized outcomes (e.g., Nursing Outcomes Classification [NOC]) or electronic care plans, your evaluative statements may be different. In the NOC system, each outcome (label) has a scale and indicators (specific patient responses), numbered 1 through 5, which you can use to write goals (see Chapter 5). For example, a patient with a problem of decreased peripheral circulation might have this goal: "Circulation status not compromised." Using standardized language from NOC, you might write a goal (*desired* status) of:

> *Goal:* Circulation Status: 5 (5 means "no deviation from normal range" in the NOC scale).

Each of the indicators could also be made into a goal by adding the desired scale numbers, as follows:

> Systolic BP in expected range: 5
> Diastolic BP in expected range: 5
> Mean BP in expected range: 5

Table 7-3 ➤ Reassessments for Different Types of Goals

TYPE OF GOAL	INVOLVES	EXAMPLE OF GOALS	REASSESSMENT TECHNIQUES
Cognitive	Increases in patient knowledge	■ By 8/24/16 accurately describes schedule for taking medications. ■ By 8/25/16 correctly describes the procedure for pouring liquid medications.	Ask the person to repeat information or to apply new knowledge (e.g., to describe to you the schedule for taking her medications).
Affective	Changes in feelings, values, beliefs, and attitudes	■ By 8/24/16 expresses positive feelings for the newborn. ■ By 8/24/16 states he is only mildly anxious about changing his own dressing.	Observe client behavior reflecting values and beliefs; talk to the client about feelings and beliefs; observe nonverbal expression of feelings (e.g., laughing, crying).
Psychomotor	Patient's ability to perform skills	■ By 8/24/16, performs own dressing change, using proper aseptic technique. ■ By 8/24/16, measures liquid medication accurately.	Ask the person to demonstrate the new skill (e.g., change a dressing, measure a liquid medication).
Body appearance and function	Changes in body systems and functions	■ Heart rate will be 100 beats/min after ambulation to end of hall. ■ By 8/24/16 can dress self and fasten own zipper.	Observe functioning, examine the body, perform measurements, read laboratory reports (e.g., measure vital signs, observe skin color, assess for pain).

Evaluation statements are written exactly the same as goals, but the scale number describes the patient's *actual* status. So, if on reassessment the patient's blood pressure is quite low and he has orthostatic hypotension, the evaluative statement might be:

Evaluative Statement: Circulation Status: 3 (3 means "moderately compromised" on this NOC scale)

Figure 7-2 is a computer screen showing the NOC outcome of Acceptance: Health Status. The Initial Scale shows the initial assessment; the Expected Scale is the goal; and the Outcome Scale is the evaluative statement after intervention and reassessment. Did the interventions achieve the desired effect, or not? If you want to see a computer screen showing a single NOC outcome with a definition and indicators,

Go to Student Resources: Chapter 7, **Tables, Boxes, Figures: ESG Figure 7-2,** on Davis*Plus*.

KnowledgeCheck 7-5

Using the following outcomes and reassessment data, determine whether each goal has been met, partially met, or not met.

Goal: By 8/24/16, will walk, unassisted, to the end of the hall without pallor or shortness of breath.
Reassessment data: 8/24/16. Walked, unassisted, to end of hall; states no shortness of breath, but skin color was noticeably pale.

Goal: By 8/24/16, will walk, unassisted, to the end of the hall without pallor or shortness of breath.
Reassessment data: 8/23/16. Walked, unassisted, to end of hall. Skin color pink; respirations 14/min; no dyspnea observed; states no shortness of breath.

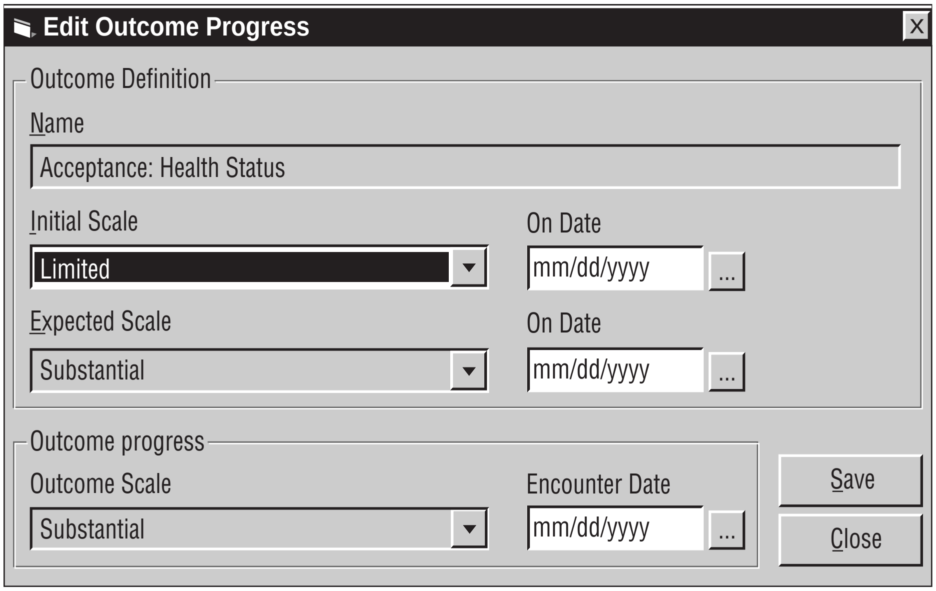
Goal: By 8/24/16, will walk, unassisted, to the end of the hall without pallor or shortness of breath.
Reassessment data: 8/25/16. Walked halfway to end of hall before becoming pale and short of breath.

How Do I Evaluate Collaborative Problems?

If a patient's collaborative problem is Potential Complication of myocardial infarction: congestive heart failure (CHF), the logical goal is that CHF will not occur. Clearly, nursing actions alone cannot prevent CHF. Collaborative efforts are required.

Because collaborative problems are the responsibility of the entire healthcare team, goals for collaborative problems are not included on the nursing care plan, and the evaluation process is slightly different. The desired outcome for all collaborative problems is that no complication will occur. To evaluate, you will compare the reassessment data with established norms (e.g., normal temperature, normal electrocardiogram patter) and determine whether data are within an acceptable range. If the data indicate the client's condition is worsening, notify the medical provider.

Example: If a patient with the collaborative problem, Potential Complication of myocardial infarction: CHF, develops fatigue, dyspnea, a productive cough, or abnormal lab results (e.g., elevated blood urea nitrogen [BUN] and creatinine levels), you would suspect CHF and notify the provider.



Explanation of Figure

Computer field	Nursing process terminology	Represents	Status recorded on computer
Initial scale	Initial assessment	*Actual* status *before* intervention	Limited acceptance of health status
Expected scale	Goal	*Desired* status *after* intervention	Substantial acceptance of health status
Outcome scale	Evaluative statement	*Actual* status *after* intervention	Substantial acceptance of health status

FIGURE 7-2 Computer screen showing outcome progress, using NOC. (*Source:* Courtesy of Ergo Partners, L.C., Boulder, CO. Used with permission.)

If the reassessment data are within normal limits, this does not mean that the collaborative problem is resolved—only that the complication has not occurred. As long as the patient has the medical condition (e.g., myocardial infarction), the collaborative problem (e.g., CHF) still exists. See Chapter 4 if you need to review collaborative problems.

Evaluating and Revising the Care Plan

After evaluating patient progress, you will use your conclusions about goal achievement to decide whether to continue, modify, or discontinue the care plan.

Relate Outcomes to Interventions

Even when goals have been met, you cannot assume that the nursing interventions caused the patient outcomes. You need to use critical reflection to identify factors that might have supported or interfered with the effectiveness of an intervention. Recall that organizational structures and processes can also affect patient care. The following are variables that can affect the ability of an intervention to produce the desired outcome:

- The client's ability and motivation to follow directions for treatment
- Availability and support from family and significant others
- Treatments and therapies performed by other health-care team members
- Client failure to provide complete information during assessment
- Client's lack of experience, knowledge, or ability
- Staffing in the institution (ratio of licensed to unlicensed caregivers; number of patients for whom a nurse is responsible)
- Nurse's physical and mental well-being

Identifying these factors allows you to reinforce or change them. For example, if Jeannette Wu does not achieve a goal of "Intact skin over sacrum" even after being turned every 2 hours by the NAP, you may discover Ms. Wu's skin is more fragile than expected because her hydration and nutrition are not adequate. You could then take measures to support her intake of food and fluids, increasing the effectiveness of the turning intervention. Notice, though, that you cannot control all the variables that might affect the success of an intervention (e.g., the client's lack of experience, staffing in your institution).

Draw Conclusions About Problem Status

Whether you retain or remove a nursing diagnosis from the care plan depends on whether or not goals were met, as follows:

Goals met: If all goals for a nursing diagnosis have been met, you can discontinue the care plan for that diagnosis.

Goals partially met: If some outcomes are met and others not, you may revise the care plan for that problem;

or you may continue with the same plan but allow more time for goal achievement.

G*oals not met:* If goals are not met, you should examine the entire plan and review all steps of the nursing process to decide whether to revise the care plan.

For an example of electronic evaluation of problem status for a client with multiple nursing care needs,

Go to Student Resources: Chapter 7, **Tables, Boxes, Figures: ESG Figure 7-3,** on Davis*Plus*.

Revise the Care Plan

To decide how to revise the care plan, you must review each step of the nursing process. You cannot merely discontinue the ineffective interventions and try new ones. The interventions may not need to be changed at all. When goals have not been met, errors in other steps of the nursing process may be the reason. To find a checklist you can use to evaluate the care plan and the process by which it was developed (Wilkinson, 2011),

Go to Chapter 7, Implementation and Evaluation Tools, **Evaluation Checklist,** in Volume 2.

1. ***Review of assessment.*** Review all initial and ongoing assessment data. All steps of the nursing process depend on complete and accurate data. So if there are errors or omissions, you may need to revise any or all sections of the care plan (i.e., nursing diagnosis, outcomes, nursing orders). Also, the data may have changed since the care plan was written: The client's condition may have changed, or new data may have been identified.
2. ***Review of diagnosis.*** Even if there were no assessment errors, you may need to revise or add new nursing diagnoses. Perhaps the nurse who wrote the diagnostic statement did not communicate the patient's condition clearly, or perhaps it was not validated with the patient. This might have caused an incorrect focus for outcomes and interventions.
3. ***Review of planning outcomes.*** You will probably need to revise the outcomes if you have added data or revised the nursing diagnosis. If assessment and diagnosis are satisfactory, perhaps the outcomes were unrealistic, written too broadly, or had unrealistic target times. Or perhaps the client's priorities have changed, or the outcomes did not address all aspects of the patient's problem.
4. ***Review of planning interventions.*** You will probably need to modify nursing orders (a) if you determine that interventions were not effective or (b) if you have revised nursing diagnoses or outcomes.
5. ***Review of implementation.*** It could be that goals were not met because of a failure to implement the nursing orders or because of the manner in which they were implemented. Get input from the client, significant others, other caregivers, and the client records to find out what went wrong. For example, the person implementing care may have been tired, in a hurry, or abrupt with the client; or maybe he did not have the necessary skills. See Delegating and Supervising Care, earlier in this chapter, if you need a review.

Reflecting Critically About Evaluation

After evaluating the patient's health status and the nursing care plan, you should think critically about your thinking during the evaluation process. That's right: Think about your thinking, not just about your actions. The critical thinking model from Chapter 2, Table 2-1, suggests some questions you might use for reflection.

Inquiring

Is my evaluation statement clearly stated (goal met or not met, plus supporting data)?

Were my information sources reliable (e.g., was the patient being honest or merely trying to please me)?

Did I jump to conclusions about goal achievement? Do I need any other data to validate my conclusion?

Noticing context

What was going on either before or during evaluation that might have influenced my ability to gather data or draw conclusions (e.g., Was I in a hurry? Did the patient have visitors?)

What emotional responses influenced my conclusions about goal achievement (e.g., Would I feel as though I had failed if the goal was not met?)

Analyzing assumptions

What biases do I have that may have affected my ability to reassess or evaluate goal achievement?

Reflecting skeptically

Did I make evaluating a priority? Did I schedule time for it, the same as I do for interventions?

Could I have done it better?

What would I do differently next time?

The most common errors of evaluation are failing to:

- Evaluate systematically.
- Record the results.
- Use the reassessment data to examine and modify the care plan.

Because nurses are action oriented, it is easy for most to make a plan and take action. And most nurses regularly observe the patient's responses to the actions. But you will need determined effort to make time to *observe regularly and systematically* and *document the patient's responses* to your actions. Only in that way can you be sure the care has met the client's needs.

Evaluating the Quality of Care in a Healthcare Setting

As a nurse, you may be involved in evaluating and improving the overall quality of nursing care in an organization or a geographical area. At a minimum, your documentation will provide data that regulatory agencies (e.g., The Joint Commission, state boards of

Quality and Safety Education for Nurses

Learning About the Outcomes of Care

Chapter Key Concept: *Quality Improvement*

Competency: *Quality Improvement (Knowledge, Skill, Attitudes)**

Situation. Quality improvement (CQI) is an essential element of everyday nursing practice. You are in a unique position to identify problems in the patient populations for which you provide care, but first you must be able to quantify (measure) the outcomes and determine the cause (or root) of the outcome. For example, suppose you suspect that the number of central line infections has increased on your pediatric unit. You have noticed a lot of variation in how different nurses provide central line care. Knowing that variation in treatment often leads to variations in outcomes, what data do you need to support your suspicions? What outcome must you measure? What root cause should be assessed (i.e., what nursing practice may be causing the infections)?

Actions. If you identified the *outcome* as rate of central line infection, and the *nursing practice* as how central line dressing changes are performed, you are correct. Now, how can you obtain data about those two factors? Sources might include databases kept by QI, safety, and/or infection control departments. Some patient care units also track quality measures. The medical records department can develop electronic reports or you can review charts, or collect data prospectively.

Improving the quality of care is possible only with clear measurements. They provide insight into the problem and a baseline against which practice changes can be judged.

Think about it. Do you see how this box relates to the QSEN competency of QI? Notice that this QSEN competency is one of the key concepts of this chapter.

nursing) use to determine whether nursing care meets nursing standards.

QSEN Competency Quality improvement is one of the QSEN competencies. That means that by the time you graduate, you should be able to "use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of healthcare systems (Cronenwett, Sherwood, Barnsteiner, et al., 2007).

Quality Assurance (QA) Programs **QA programs** are specially designed programs to promote excellence in nursing. Variations of quality assurance are quality improvement (QI), continuous quality improvement (CQI), total quality management (TQM), and persistent quality improvement (PQI). Whatever the approach, the goal is to evaluate and improve the care provided in an agency or for a group of patients. One hospital reports reduction in patient falls and medication errors, as well as improvement in nursing documentation after implementation of a QI program chaired by a staff nurse (Johnson, Hallsey, Meredith, et al., 2006). For more information about quality assurance, refer to Chapter 1.

Summary

This chapter has described (1) outcomes evaluation of *client progress* and (2) process evaluation of the *effectiveness of the nursing care plan*. Quality improvement involves evaluation of structures, as well as outcomes and processes. All are important because structures and processes affect patient outcomes. Adequate structures (e.g., staffing, money) and processes (e.g., policies and procedures) do not guarantee desired patient outcomes; however, without them, it is very difficult to obtain good outcomes. For example, a unit could be well staffed (structure) and follow infection-control procedures carefully (process), yet have a higher-than-average rate of urinary tract infections (outcome). The reason may be that most of the patients treated on that unit have compromised immune systems, making them especially susceptible to infection. For more discussion of QSEN QA/QI evaluation, see Chapter 1.

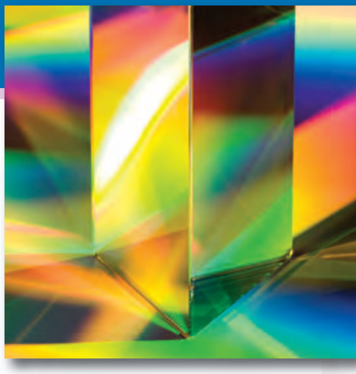
CHAPTER 8



Evidence-Based Practice: Theory & Research

Learning Outcomes

After completing this chapter, you should be able to:

- Define *nursing theory.*
- List four components of a theory.
- Describe how a nursing theory is developed.
- List the four essential concepts in a nursing theory.
- List three ways nurses can use nursing theory.
- Name three predominant thinkers who proposed theories of caring.
- Describe three nonnursing theories and their contributions to nursing.
- Define *nursing research.*
- Describe the significance of evidence-based nursing practice.
- Compare and contrast quantitative and qualitative nursing research.
- List three components of the research process, and explain their importance.
- Name three priorities in the process of protecting research participants, and explain the significance of these to the nursing research process.
- Describe the PICOT method of formulating a question to guide a literature search.
- Discuss the process of analytical reading of research reports, and explain its significance to the appraisal of research.
- Describe how to use nursing research in nursing practice.

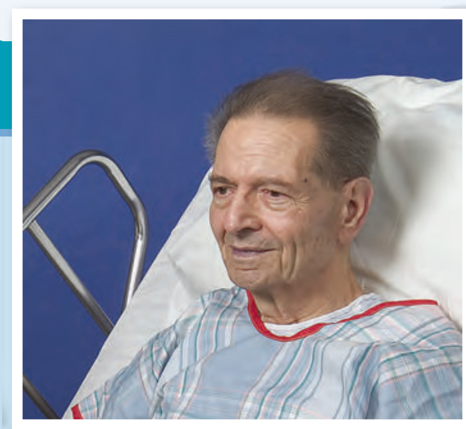
Meet Your Patient



Imagine you are the charge nurse on the night shift at a long-term care facility. You hear the certified nursing assistant (CNA) and another person speaking loudly down the hall. You immediately go to see what has happened. You are startled by what you see. An older patient, Mr. Wilkey, is sitting on the bed of another patient, Mrs. Fredrickson, who is crying and shouting, "Get out! Get out!" Mr. Wilkey is tearful and looks frightened. He keeps repeating, "Where is Momma? Where is Momma?" The CNA is visibly upset and is grabbing at Mr. Wilkey in an effort to get him off the bed.

What are you going to do, and why do you think it will help? Don't be concerned if you don't think you know enough to answer this question. Before you read on, try to answer it based on the knowledge and experience that you *do* have.

There are two general ways to approach this problem. One way is to be upset with Mr. Wilkey and take him from the room immediately, explaining sternly that his behavior is not acceptable and he must stay in his room. Another possibility is to ask the CNA to calm Mrs. Fredrickson while you talk quietly to Mr. Wilkey and gently guide him out of the room, not rushing him. While you are talking to him, you might ask, "Who is Momma? What does she look like? Do you miss her?" By the time you lead him to his room, you might realize he is exhibiting stage II dementia. You infer that he probably woke up scared and confused and began looking for his long-dead mother. Seeing Mrs. Fredrickson, Mr. Wilkey thought he had found his mother and crawled into her bed.

If you chose the first approach in the scenario, you were demonstrating **mechanistic nursing**, which is based on getting the tasks done. If you chose the second solution, you based your behavior on **holistic nursing**, which requires meeting the needs of the whole person. This scenario demonstrates the powerful impact of nursing theory and research on your daily practice as a nurse.

ABOUT THE KEY CONCEPTS

The overall goal of this chapter is for you to understand the concepts of **nursing theory, nursing research, and evidence-based practice** well enough to see how they are related and how they form the foundations for patient care.

Think of full-spectrum nursing as a jigsaw puzzle of concepts (Fig. 8-1). Initially, a nurse has an idea, which usually comes out of experiences in practice (the first puzzle piece). Perhaps the idea is something simple like: "Why don't I slow down and spend more time with the patients' families? It would really help them if I took more time." After seriously considering the new idea, the nurse may decide the idea is worth investigating with *research* (the second puzzle piece). The research question might be: "How does spending more time with family members affect the quality of care the patient receives?" If the research supported the nurse's idea, she could then use the research findings to develop a **theory** (the third puzzle piece). The nurse could even take the research results to nursing administrators to determine whether the theory could be put into practice in the organization—perhaps as a policy or in a standardized care plan. That would be the beginning of what is called a **clinical practice theory**, a theory that is immediately applicable in the clinical setting. All of these concepts are essential to **evidence-based practice**.

You will also need a grasp of the related concept, *caring*. This chapter uses theories of caring to illustrate key points because we believe caring is central to nursing and influences all the actions that nurses take. You may recall that it is an important concept in the full-spectrum model introduced in Chapter 2.

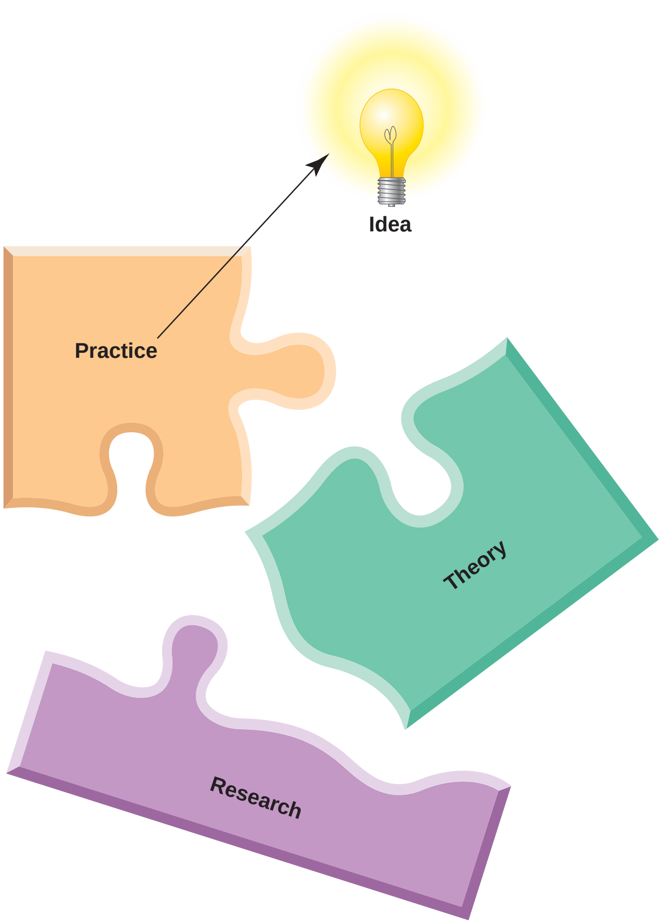


FIGURE 8-1 Practice, theory, and research are interrelated: A nurse has an idea, conducts research to test the idea, and finally develops a theory.

TheoreticalKnowledge knowing **why**

This chapter introduces you to nursing theory and research and how they form the foundations for patient care. It draws heavily on caring theory for examples. However, you will find other theories that pertain to specific aspects of practice in later chapters. For example, developmental theories are discussed in Chapter 9, theories of self-concept in Chapter 12, and family theories in Chapter 14.

Go to Student Resources: Chapter 8, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

THE IMPORTANCE OF NURSING THEORY AND RESEARCH

Following are three examples that demonstrate how important theory and research are to the foundations for patient care.

The Framingham Heart Study The Framingham Heart Study is a longitudinal, multidisciplinary research project (*longitudinal* means done over a long period of time). It consisted of several studies carried out over 50 years (from 1948 to 1998) to identify the health and healthcare practices of one specific community: Framingham, Massachusetts. The results of the various Framingham studies influenced healthcare practices for diabetes mellitus, breast cancer, heart disease, osteoarthritis in older adults, and other disease entities. For example, one commonly accepted practice that came out of the Framingham study is the use of mammography to screen for breast cancer. There was a time when mammography was considered unreliable and unimportant. The Framingham project changed that attitude and, as a result, improved the healthcare of women.

Watson's Science of Human Caring Dr. Jean Watson (Fig. 8-2) developed a nursing theory called the **Science of Human Caring** (Watson, 1988). This theory describes what *caring* means from a nursing perspective. It may not seem that nurses need to be taught how to care, but Dr. Watson and other nursing theorists found they did. Before the "caring theorists," nurses were somewhat mechanistic in the work they did, much like the first alternative for dealing with Mr. Wilkey (Meet Your Patient). A mechanistic nurse has a list of things to do, completes the list, and does nothing more. The "something more" behaviors often are the caring behaviors, such as singing to a frightened child or taking the time to teach a new mother for the second time how to bathe her baby.

This is not to say that nurses didn't care about their patients before Watson. The point is that a theory of caring (such as Watson's) changes the *focus* of nursing. Certainly Nightingale must have cared about the soldiers who were her patients. But what she wrote about and what she taught the nurses was a set of "things to do." Nurses were valued for the tasks they performed in patient care. Caring theories demonstrate the value of the non–task-oriented aspects of nursing.

Benner's "Novice to Expert" Dr. Patricia Benner, in the book *From Novice to Expert* (1984), proposed a theory that should be of special interest to you. This theory, which was explained in Chapter 1, describes the progression of a beginning nurse to increasing levels of expertise. You are a **novice**, or a beginning nurse, simply because you are new to the nursing profession. Benner's theory provides the information necessary to understand how you learn and perform your nursing responsibilities. Benner's theory of caring is discussed later in this chapter.

- Briefly describe the Framingham Heart Study, and list three diseases for which this study influenced care.

NURSING THEORIES

Florence Nightingale (1859/1992) stated that nursing theories describe and explain what is and what is not nursing. Therefore, it is helpful to learn them in the beginning of your nursing education. Before focusing on nursing theory, though, you need to learn a little more about theory in general. Exactly what *is* a theory? And how is a theory created?

A **theory** is an organized set of related ideas and concepts that helps us:

- Find meaning in our experiences (such as nursing)
- Organize our thinking around an idea (such as caring)
- Develop new ideas and insights into the work we do

Put simply, a theory answers the questions: *What is this? And how does it work?* Although a theory is based on observations of facts, the theory itself is *not* a fact. A theory is merely a way of viewing phenomena (reality); it defines and illustrates concepts and explains how they are related or linked. Theories can be, and are, changed.

What Are the Components of a Theory?

Theories are made up of assumptions, phenomena, concepts, definitions, and statements (or propositions). You can think of these as the building blocks of a theory.

Assumptions **Assumptions** are ideas that we take for granted. In a theory, they are the ideas that the theorist or researcher presumes, or takes for granted, to be true and does not intend to test with research. They are statements about concepts or relationships between concepts. For example, Watson assumed nursing had its own professional concepts and that one of them was caring. Assumptions may or may not be stated in a theory. For example, most nursing theorists assume but do not state that human beings are complex. One exception is Martha Rogers (1970), who states outright that human beings are unified wholes that are more than and different from the sum of their parts.

Phenomena Aspects of reality that you can observe and experience are called **phenomena**. They are the subject matter of a discipline (when used in this sense, they are often called *phenomena of concern*). Think of phenomena as marking the boundaries (*domain*) of a discipline—making one discipline unique from another. For example, for pharmacists, the phenomena of concern are medications: their chemical composition and their effects on the body. For nurses, the phenomena of concern are human beings and, more specifically, their body-mind-spirit responses to illness and injuries. It may seem a subtle difference, but Watson's theory of caring gave us the words and ideas for describing the nursing phenomena of concern in terms of *human beings in their environments.*

Concepts A **concept** is a mental image of a phenomenon. It is formed by generalizing an abstract idea from your experiences and observations of events, objects, and properties, and it exists as a symbol (e.g., a word or picture) in your mind. For example, what does the word *fever* bring to mind? From your own experience with fever, you know the subjective feeling that fever produces. You have the theoretical knowledge that it is an elevated body temperature; you know the physiology of temperature regulation, so you know what is going on in the body. You may have the visual image of a thermometer or someone who is warm to the touch and possibly perspiring. The word *fever* is a symbol for all of those ideas and images. It is a concept.

Concepts range from simple to complex and from fairly concrete to very abstract. Simple, concrete concepts are those you can observe directly (e.g., height, weight, gender, body type). More abstract and complex concepts are those you observe indirectly (e.g., hematocrit, brain activity, nutritional status). Abstract concepts are those you must infer from many direct and indirect observations (e.g., self-esteem, wellness).

A theory usually contains several concepts. For example, Watson includes ten "caring processes" in her original theory (Box 8-1). Each of those is a complex concept. To see how those caring factors have evolved in her theory,

BOX 8-1 ■ Watson's Ten Caring Processes

1. Forming a humanistic–altruistic system of values
2. Instilling faith and hope
3. Cultivating sensitivity to self and others
4. Forming helping and trusting relationships
5. Conveying and accepting the expression of positive and negative feelings
6. Systematic use of the scientific problem-solving method that involves caring process
7. Promoting transpersonal teaching–learning
8. Providing for supportive, protective, and corrective mental, physical, sociocultural, and spiritual environment
9. Assisting with gratification of human needs
10. Sensitivity to existential–phenomenological forces

Go to Student Resources: Chapter 8, **Tables, Boxes, Figures: ESG Table 8-1, Watson's Caritas Processes,** on Davis*Plus.*

Definitions A **definition** is a statement of the meaning of a term or concept that sets forth the concept's characteristics or indicators—that is, the things that allow you to identify the concept. A definition may be general or specific. A **theoretical definition** refers to the conceptual meaning of a term, whereas an **operational definition** specifies how you would observe or measure the concept (e.g., when doing research). For example, for pain:

Theoretical definition: Pain is an unpleasant sensory and emotional experience associated with actual or potential tissue damage.

Operational definition: Pain is the patient's verbal statement that he is in pain.

Statements (Propositions) **Statements**, or propositions, systematically describe the linkages and interactions among the concepts of a theory. The statements, taken as a whole, make up the theory. In Maslow's theory, for example, two concepts are *physiological needs* and *self-esteem needs.* An example of a statement in that theory would be: "*Physiological needs* must be met to an acceptable degree before a person can attempt to meet his *self-esteem needs.*"

Theory, Framework, Model, or Paradigm?

In any discussion of nursing knowledge, you may hear the terms *theory, framework, model,* or *paradigm.* It may be difficult for you to differentiate among these terms because (1) they are so abstract, (2) they are defined differently by theorists, and (3) you may hear them used interchangeably in general conversation among nurses. As you progress in your career and education, you will need to pay more careful attention to the similarities and differences among these terms. For now, you can use the following basic definitions (*theory* was defined earlier):

A **paradigm** is the worldview or ideology of a discipline. It is the broadest, most global conceptual framework of a discipline. It includes and guides the values, philosophy, knowledge, theories, and research processes of the discipline. It is a way of thinking that is shared by a community of scholars who are studying and working on the same phenomena. Compare the two following examples:

- *The medical paradigm* views a person through a lens that focuses on identifying and treating disease. This lens causes you to look in depth at the person's "parts" (e.g., cells, organs).
- *The nursing paradigm* views the person through a lens that focuses more broadly on the entire person and how he responds to isolated changes in his cells and organs.

Key Point: ***Paradigms are not theories; they are just "how we see things."***

A **conceptual framework** (also referred to as a *theoretical framework*) is a set of concepts that are related to form a whole or pattern. Frameworks (and models) tend to be broader and more philosophical than theories. As a rule, frameworks are not developed using research processes and have not been tested in practice. The relationships among the concepts are described in less detail than in a theory, and assumptions are not stated. Don't be alarmed if you can't tell the difference between a theory and a theoretical framework. The experts don't always agree, either. Many theorists, for example, classify the early nursing theories (e.g., Orem's self-care deficit theory and others presented in this chapter) as conceptual frameworks; others classify them as theories.

A **model** is a symbolic representation of a framework or concepts—a diagram, graph, picture, drawing, or physical model. The plastic body parts you have seen in anatomy class are models of the real human body; Figure 8-1 is a simple model of the relationships between nursing practice, theory, and research, for example. Many models are more complex than Figure 8-1.

A **conceptual model** (sometimes referred to as a *conceptual framework*) is a model that is expressed in language—the symbols are words. Figure 2-3 is a model of full-spectrum nursing. In comparison, the *description* of the full-spectrum model in Chapter 2 is a conceptual model or framework. In one sense, all models are "conceptual" because they all represent ideas.

For now, it is enough for you to remember these three points:

1. The terms *theory, model,* and *framework* all refer to a group of related concepts.
2. The terms differ in meaning, depending on the extent to which the set of concepts has been used and tested in practice and on the level of detail and organization of the concepts.
3. A theory has a higher level of research, detail, and organization of concepts than do models and frameworks.

Do you think this is a theory, a conceptual framework, or a model?

KnowledgeCheck 8-2

- Name the five building blocks of a theory.
- How is a paradigm different from a theory?

How Are Theories Developed?

To begin developing a theory, a nurse has an idea that seems worth exploring through research. As an example, Dr. Jean Watson had an idea about caring behaviors toward patients. Once the idea was clear in her mind, she performed research to see whether her ideas made sense. She validated her ideas to develop her theory. Once she had a research-based theory, she shared it with others, and it changed nursing practice.

Theories are developed through a specific way of thinking called logical reasoning (Alligood & Marriner Tomey, 2009). Generally, you can think of **reasoning** as connecting ideas in a way that makes sense. The purpose of **logical reasoning** is to develop an argument or statement based on evidence that will result in a logical conclusion. Nursing theories cannot be based on guesswork; they must be developed on a solid foundation of logical reasoning. The most commonly used types of logical reasoning are inductive and deductive reasoning.

Inductive reasoning is often used in nursing process. If you walk into a person's room and note that the patient has a temperature of 101°F (38°C), a pulse of 104 beats/min, and respiration rate of 20 breaths/min, you could reasonably *induce* (conclude) that the person is ill, possibly with an infection. Induction moves from the specific to the general. You gathered separate pieces of information, recognized a pattern, and formed a generalization. Remember induction by thinking, "IN-duction: I have specific data 'out there,' and I bring the data 'IN' to make the generalization" (Fig. 8-3).

Deductive reasoning is the opposite of inductive reasoning. Deduction starts with a *general premise* and moves to a *specific deduction*. Suppose you receive a call from the emergency department stating they will be receiving a new patient with acute pyelonephritis (kidney infection). Because you know what is involved in the general premise (pyelonephritis), you deduce the patient will probably have an elevated temperature and back pain. You have the "big picture" about what is true in general, and from that you can figure out logically what is likely to be true for a particular individual.

Understanding logical thinking, even on this basic level, will help you understand the thinking that goes into both nursing theory and nursing research.

ThinkLike a Nurse 8-2

- Your patient is grimacing, groaning, and holding his hands over his abdominal incision. You induce that the patient is having incision pain. How could you be sure your induction is factual (true)?
- In the example of deductive reasoning (above) you deduced that your emergency department patient with pyelonephritis will have a temperature and back pain. How confident are you that this is actually so? How could you be more certain your deduction is correct?

The preceding exercise should demonstrate that inductions and deductions are not "facts" or "truth," but rather that they point you in the direction to go in seeking truth (reality). They also allow you to make connections between ideas when you are developing a theory. The more

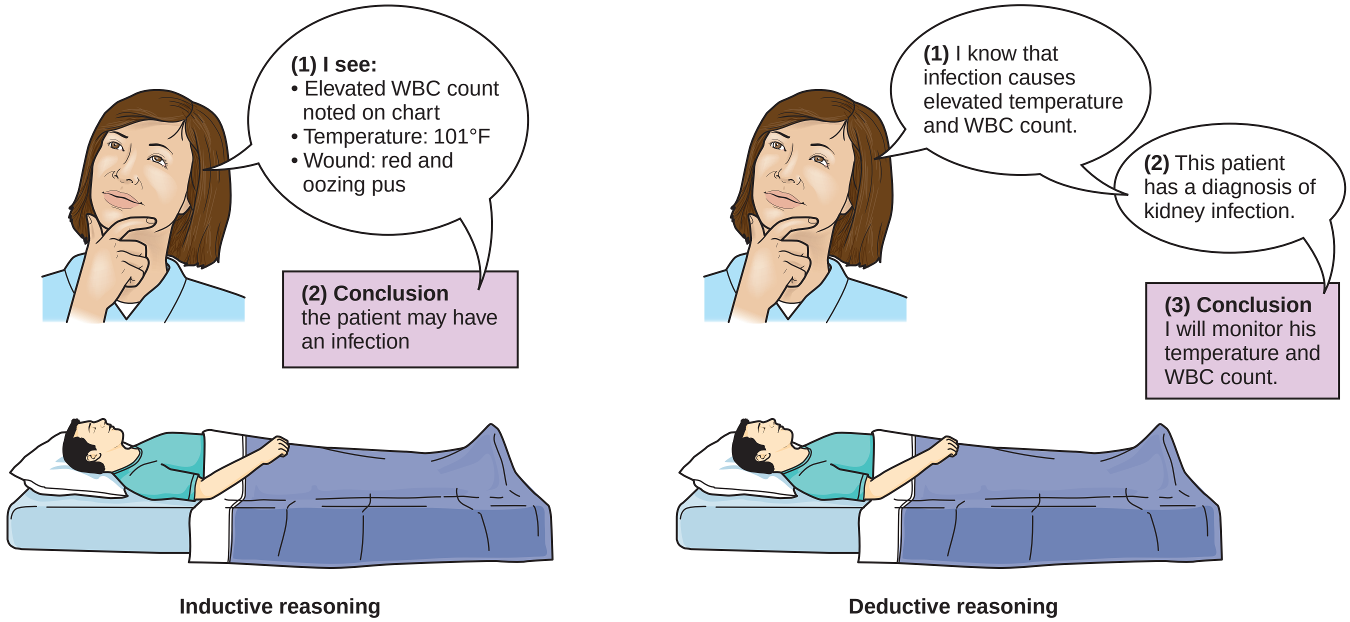

FIGURE 8-3 A comparison of inductive and deductive reasoning. Theorists and nurses in practice use both types of reasoning.

information you have to support your conclusions, the more confident you can be that they are correct.

What Are the Essential Concepts of a *Nursing* Theory?

Any nursing theory should address the four basic concepts that are said to be the phenomena of concern for nursing: **person, environment, health,** and **nursing** (Yura & Torres, 1975). Notice that these concepts further divide the puzzle piece for nursing theory into four more pieces (Fig. 8-4).

A meaningful nursing theory defines these four puzzle pieces and explains how they are related to each other. Consider a theory that does not include the concept of person. Such a theory would describe the needs of the *nurse* and the condition of the *environment*, as well as the *health* of the person. However, it would not deal with the *person's* reaction to her health or lack of health. As a result, the person's learning needs, fears, family concerns, or discharge arrangements would not be considered. That sounds quite mechanistic, doesn't it?

The following illustrates how Watson (1988) viewed the four basic concepts. In her science of human caring, she explored the concept of *caring* as it relates to the person, environment, health, and nursing. Watson focused heavily on the *person* and the *nurse*. She talked about the "transpersonal" caring moments that exist between the two. She presented the *environment* as another way to show caring: by keeping it clean, colorful, or quiet or including whatever promotes health for the person. All of the caring behaviors (see Box 8-1) listed in Watson's theory focus on improving the *health* of the person.

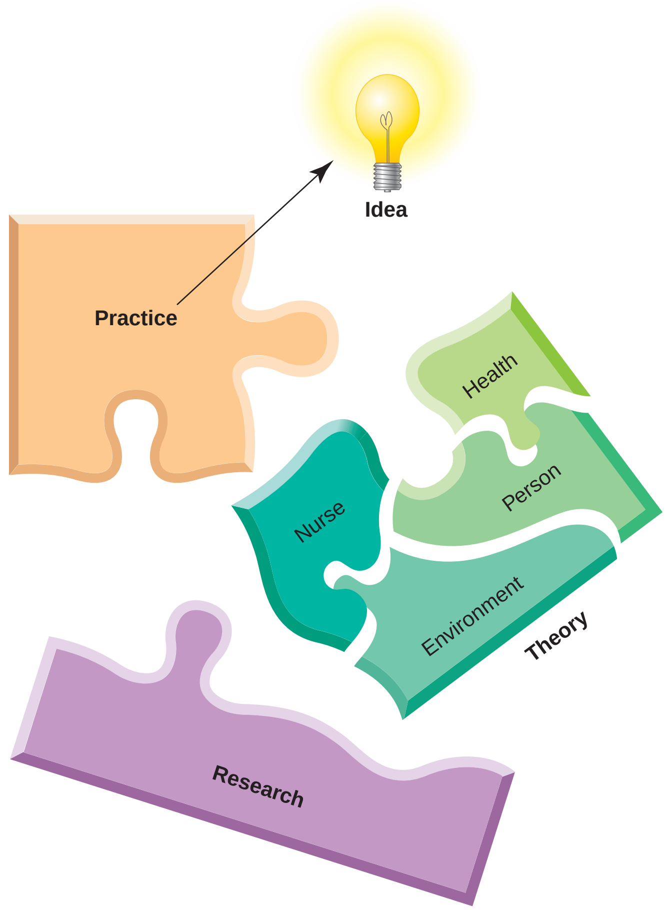

FIGURE 8-4 The four components of a nursing theory are person, nurse, health, and environment.

Observing nursing situations within the framework of the four components of nursing theory will help you understand the importance of each. This is very important because the finished puzzle reflects excellent (full-spectrum) nursing care.

ThinkLike a Nurse 8-3

Think of an experience you have had in clinical. Perhaps it was taking vital signs or bathing a confused patient. Describe how each of the four components of a nursing theory occurred in your clinical situation. Share your thinking with a classmate or coworker.

- Who was the *person(s)* involved (*person* refers to the patient or resident or the family and support persons)?
- What was the *environment*? A community center? A bathing room in a nursing home? The person's bedside in a hospital?
- What was the *health* condition of the person? For example, was the person seeking information for self-care? Critical? In pain? Ready for discharge?
- How was *nursing* involved? For example, was the nurse compassionate? Angry? Efficient? A novice or an expert?

KnowledgeCheck 8-3

- What are the four essential concepts in a nursing theory?
- What is the title of Dr. Watson's theory?
- Caring processes are critical to her theory. What is the purpose of the caring processes?

How Do Nurses Use Theories?

Nursing theories try to describe, explain, and predict human behavior. The case of Mr. Wilkey (Meet Your Patient) shows how the use of a certain theory might guide the nurse to more compassionate care. Think of a theory as a lens. You can see the stars more clearly if you look at them through a telescope than you can by using binoculars. As another metaphor, the lenses of your sunglasses remove glare, allowing you to see more clearly in bright sunlight but decreasing your ability to see in dim light. Theories offer a lens for looking at nursing, and in this way they affect your entire perspective. The theory you use influences what you look for, what you notice, what you perceive as a problem, what outcomes you hope to achieve, and what interventions you will choose.

In Nursing Practice

Nursing theories serve as a guide for assessment, problem identification, and choice of nursing interventions. They help nurses communicate to other members of the health team what it is that makes nurses unique and important to the interdisciplinary team.

Clinical practice theories very specifically guide what you do each day. They are limited in scope—that is, they do not attempt to explain all of nursing. A theory on human interaction directs nurse–client communication; another theory provides a guide for teaching people how to be self-reliant. The following are other examples:

1. Nightingale's theory emphasized the importance of the environment in the care of patients. Her work affected the design and building of hospitals for decades.
2. Dr. Imogene Rigdon developed a theory about bereavement of older women after noticing (and having an idea!) that older women handled grief differently from men and younger women (Rigdon, Clayton, & Dimond, 1987). Hospice organizations all over the country now use this theory to work with older women who have lost a significant other.
3. Nola Pender's theory on health promotion (see Chapter 42) is the basis for most health promotion teaching done by nurses (Pender, Murdaugh, & Parsons, 2011).
4. Dr. Katharine Kolcaba (1994) developed a theory of holistic comfort in nursing, which provides a more holistic view than earlier theories of pain and anxiety.

In Nursing Education

Some schools of nursing use theories to guide curriculum planning, programs, and projects. These are frequently grand theories, such as Watson's theory of caring or Rogers's science of unitary human beings. A **grand theory** covers broad areas of concern within a discipline. A grand theory is usually abstract and does not outline specific nursing interventions. Instead, it tends to deal with the relationships among nurse, person, health, and environment.

A school using Watson's theory, for example, would include aspects of her theory in each class. A course might even be organized around the caring factors listed in Box 8-1. As another example, an inservice education director in a nursing home may choose a narrower and more specific theory (*mid-range* or *practice theory*) of comfort, using it to create policies and procedures and design educational programs.

In Nursing Research

Theories help generate new knowledge by suggesting questions for researchers to study. Researchers also use theories and models as a framework for structuring a study. Theories provide a systematic way to define the questions for study, identify the variables to measure, and interpret the findings. For example, Kolcaba tested her statement that comfort interventions, as defined in her theory, would improve the health of the whole person.

Who Are Some Important Nurse Theorists?

You will need to thoroughly understand the theories you use in practice and the one (or more) used by your school of nursing. As an educated nurse, you should also have at least a nodding acquaintance with the nurse theorists who have influenced nursing practice. The first three theorists below, along with the caring theorists that follow, are presented in detail because of their historical significance. The description of their theories is simple and applicable to what you do every day as a nurse.

Florence Nightingale

As you learned in Chapter 1, Florence Nightingale revolutionized nursing. When she went to the hospital in Scutari during the Crimean War, the soldiers slept on mats on the floor, where rats scampered and raw sewage flowed. Nightingale's "idea" was that *more men would survive if they had a clean and healthy environment and nutritious food (so that the body could heal itself)*. That may not seem remarkable to you, but consider that the germ theory of infectious disease had not yet been identified.

Nightingale also was an outstanding researcher. She stayed awake late at night to keep records of what was happening at the hospital before and after she introduced her ideas (research). She used her research to develop her theory that a clean environment would improve the health of patients. Because of her theory and research, Nightingale dramatically reduced the death rate of the soldiers and changed the way the entire British Army hospital system was managed (Dossey, 1999). For links to more information about Nightingale,

Go to Student Resources: Chapter 8, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

Virginia Henderson

Virginia Henderson began her career as a U.S. Army nurse in 1918. She also was a visiting nurse in New York City and then a teacher of nursing. Her pamphlet, *Basic Principles of Nursing Care*, published in 1960 by the International Council of Nursing, has been translated into 20 languages.

While a nursing student at Walter Reed Army Hospital, Henderson began to question the mechanistic nursing care she was taught to give, as well as the fact she was expected to be the physicians' handmaiden. As a teacher of nursing, she came to recognize there was no clear description of the purpose and function of nursing. She was the first nurse to identify that as a concern. Her "idea" was that *nurses deserve to know what it means to be a nurse.*

Henderson's 1966 book, *The Nature of Nursing*, described her theory of nursing's primary, unique function. She identified 14 basic needs that are addressed by nursing care (Box 8-2). Although the simple things on that list are commonplace today, they had not been identified as components of nursing care until Virginia Henderson did so. Henderson's (1966, p. 3) definition of nursing states: "The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to a peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge. And do this in such a way as to help him gain independence as rapidly as possible." Henderson defined what nursing was in the 20th century. If you would like more information on Henderson,

BOX 8-2 ■ Virginia Henderson's List of Basic Needs

1. Breathe normally.
2. Eat and drink adequately.
3. Eliminate body wastes.
4. Move and maintain desirable posture.
5. Sleep and rest.
6. Select suitable clothes—dress and undress.
7. Maintain body temperature within normal range by adjusting clothing and modifying the environment.
8. Keep the body clean and well groomed, and protect the integument.
9. Avoid dangers in the environment and avoid injuring others.
10. Communicate with others in expressing emotions, needs, fears, or opinions.
11. Worship according to one's faith.
12. Work in such a way that there is a sense of accomplishment.
13. Play or participate in various forms of recreation.
14. Learn, discover, or satisfy the curiosity that leads to normal development and health and use of the available health facilities.

Hildegard Peplau

Hildegard E. Peplau was born in 1909 to immigrant parents in Pennsylvania. She was a psychiatric nurse and contributed much to nursing in general. She influenced the advancement of standards in nursing education, promoted self-regulation in nursing through credentialing, and was a strong advocate for advanced nursing practice.

Dr. Peplau's "idea" was that *health could be improved for psychiatric patients if there was a more effective way to communicate with them.* You may feel this is an unnecessary theory because nurses communicate with patients all the time. But remember that in the early 1900s actually talking to and developing a personal relationship with psychiatric patients simply was not done. Psychiatric patients did not have the benefit of psychotropic drugs currently available to manage their symptoms. They were often agitated and extremely difficult to communicate with.

Peplau's research showed that developing a relationship with psychiatric patients does make their treatment more effective. She developed the theory of interpersonal relations, which focuses on the relationship a nurse has with the patient. This is a theory you use every day without even knowing it existed. For more information on Peplau's theory,

Go to Student Resources: Chapter 8, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

The Caring Theorists

It could be argued that the three leading caring theorists in nursing are Dr. Jean Watson, Dr. Patricia Benner, and Dr. Madeleine Leininger. We have been using Watson's ideas to illustrate principles and concepts of theory. In this section, we discuss Benner and Leininger.

Patricia Benner

Caring is the central concept in Benner and Wrubel's *primacy of caring model.* The nurse's caring helps the client cope. Moreover, it offers opportunity for the nurse to connect with others and to receive as well as give help (Benner & Wrubel, 1989). Caring involves personal concern for persons, events, projects, and things. Therefore, it reveals what is stressful for a person (because if something does not matter to a person, it will not create stress) and provides motivation. Caring also makes the nurse notice which interventions are effective. This theory stresses that each person is unique, so that caring is always specific and relational for each nurse–person encounter.

In Chapter 1, we discussed another of Benner's theories. A critical care nurse, she wanted to find out *what makes an expert nurse*. In this case, the idea took the form of a question. An example of an expert nurse, for her, was an intensive care unit (ICU) nurse who "knew" intuitively when it was time to extubate a critical patient. Benner wanted to know what makes a nurse expert enough to know that and other critical information. She therefore interviewed ICU nurses and, from her research, identified five stages of knowledge development and acquisition of nursing skills. As you may recall, the first level is that of a novice nurse (you). The others are advanced beginner, competent, proficient, and expert nurse (see Chapter 1 if you need to review).

Let's see whether this novice-to-expert theory addresses the four components of a nursing theory. *Person* and *nurse* are very clearly points of focus. Knowing the *nurse's* skill level (novice, advanced beginner, competent, proficient, or expert) provides for an intelligent way to match the nurse's skill with the patient's (*person*) acuity. This is the basis of the theory. The theory also indicates the nurse contributes to the person's *health* according to her skill level.

The *environment* is clearly stated as the ICU. Benner's theory does meet the criteria of the four components of a theory, although some are emphasized more than others. Differences in emphasis are typical of theories, by the way.

Madeleine Leininger

Leininger is the founder of transcultural nursing and was the first nurse in the United States to earn a doctoral degree in cultural and social anthropology. Her theory focuses on caring as **cultural competence** (using knowledge of cultures and of nursing to provide culturally congruent and responsible care). Her "idea" came from working with children from diverse cultures who were under her care in a psychiatric hospital: *Would the psychotherapy for the children be more effective if delivered within the framework of the child's culture* (Alligood & Marriner Tomey, 2006)?

Leininger performed the research to confirm her idea that culturally competent care made a difference, and then she developed her theory. She followed the pattern of the puzzle pieces referred to throughout this chapter. The *person* in Leininger's theory is an individual with cultural beliefs that are specific to herself and that may differ from the beliefs of others. Human beings can feel concern for others, but ways of caring vary across cultures. The *nurse* is the professional who values the cultural diversity of the person and is willing to make cultural accommodations for the health benefit of the person. This requires specialized cultural knowledge. The *environment* is wherever the nurse and the person are together in the healthcare system. *Health* is defined by the person and may be culturally specific in its definition. You will learn more about Leininger's theory in Chapter 15.

You may be thinking, "This is all about culture; what does that have to do with caring?" Leininger's theory brings together the cultures of the *person,* the *nurse,* and the *healthcare system* (indeed, there is a culture of healthcare, as you will discover in Chapter 15) to improve healthcare delivery and its effectiveness. For example, as a nurse, you may need to welcome the Shaman from a Native American tribe who has been asked to perform a sacred dance in the hospital room. This is one way to demonstrate caring and respect for the person who is ill.

A nurse tells a true culture-care story. It is an example of applying a theory directly to the needs of an ill person.

> *As a young nurse, I was caring for a monk who had just had surgery, and he would not take any pain medication. He wanted to "offer the pain up to God." That was a serious values clash for me because I believed the patient was jeopardizing his health, yet I did respect his right to live his cultural beliefs. We worked out a compromise. The monk agreed to take pain medication every 8 hours (instead of the prescribed every 3–4 hours), and I made sure to ambulation, hygiene, and his other needs during the times the medication was in effect.*

Other Selected Nurse Theorists

You will find a list of selected nurse theorists and a brief description of their theories in Table 8-1. For a more complete discussion of those theories, you could see the Web sites listed there, and

Go to Student Resources: Chapter 8, **Supplemental Materials: Other Selected Nurse Theorists,** on Davis*Plus*.

Table 8-1 ➤ Selected Nurse Theorists

THEORIST	DATE	THEORY
Peplau, Hildegard E.	1952	Interpersonal relations model: Interpersonal communication can improve mental health.
Henderson, Virginia	1955	14 basic needs addressed by nursing care; definition of nursing; do for the patient what he cannot do for himself.
Abdellah, Faye G.	1960	21 nursing problems; deliver care to the whole person.
Orlando, Ida Jean	1961	Interpersonal process; nursing process theory.
Wiedenbach, Ernestine	1964	The purpose of nursing is to support and meet patients' needs for help. Nursing is a helping art.
Levine, Myra	1967, 1973	Conservation model; designed to promote adaptation of the person while maintaining wholeness, or health.
Johnson, Dorothy	1968, 1980	The behavioral system model: Incorporates five principles of systems thinking to establish a balance or equilibrium (adaptation) in the person. The patient is a behavioral system consisting of subsystems.
Rogers, Martha	1970	The science of unitary human beings focuses on the betterment of human kind through new and innovative modalities. Maintaining an environment free of negative energy is important.
Orem, Dorothea	1971	The self-care deficit nursing theory explains what nursing care is required when people are not able to care for themselves. Goal is to help client attain total self-care.
King, Imogene	1971	First of two theories was the interacting systems framework, designed to explain the organized wholes within which nurses are expected to function, i.e., society, groups, and individuals. The first theory led to the theory of goal attainment, which focuses on mutual goal setting between a nurse and patient and the process for meeting the goals.
Neuman, Betty	1972	Neuman systems model is based on general system theory (a nonnursing theory) and reflects the nature of living organisms as open systems.
Roy, Sr. Callista	1974	Adaptation model was inspired by the strength and resiliency of children. The model relates to the choices people make as they adapt to illness and wellness.
Leininger, Madeleine M.	1978, 1984	Cultural care diversity and universality theory. Caring theory.
Newman, Margaret	1979	Theory of health as expanding consciousness describes nursing intervention as nonintervention, where the nurse's presence helps patients recognize their own pattern of interacting with the environment.
Watson, Jean	1979	Caring theory. Nursing is an interpersonal process.
Parse, Rosemarie Rizzo	1981	Theory of human becoming focuses on the human–universe–health process and knowledge related to human becoming (or reaching one's potential).
Benner, Patricia, and Wrubel, J.	1989	Primacy of caring model. Caring is central to the model and helps the client cope with stressors of illness.

For more information on these theorists,

Go to Chapter 8, **Supplemental Materials,** on Davis*Plus*.

KnowledgeCheck 8-4

Define in a brief conceptual form or title the nursing theory of each theorist listed below:

- Florence Nightingale
- Virginia Henderson
- Hildegard Peplau

How Do Nurses Use Theories From Other Disciplines?

Theory development is relatively new in nursing. Except for Nightingale (1859/1992), it was not until the mid-1950s that nursing leaders began to publish their theories about nursing. The profession relied heavily on the theories of other disciplines. Nurses still use knowledge from other disciplines as a part of their scientific knowledge base. The following are a few of the many "borrowed" theories you will use in nursing.

Maslow's Hierarchy of Basic Human Needs

One of the classic theories still used in most nursing education and practice settings is Maslow's Hierarchy of Needs (1970). Maslow observed that certain human needs are common to all people, but some needs are "more basic" than others. The lower-level (e.g., physiological) needs must be met to some degree before the higher needs (e.g., self-esteem) can be achieved (Fig. 8-5). For example, if you sit down to study but the room is cold, you will likely decide to put on a sweater or turn up the heat before opening your books. Nevertheless, a person may consciously choose to ignore a lower-level need in order to achieve a higher need. For example, the rescuers at the World Trade Center on 9/11 and in Haiti after the 2010 earthquake ignored their need for safety and security to help others (transcendence of self). In daily life, most people are partially satisfied and partially unsatisfied at each level.

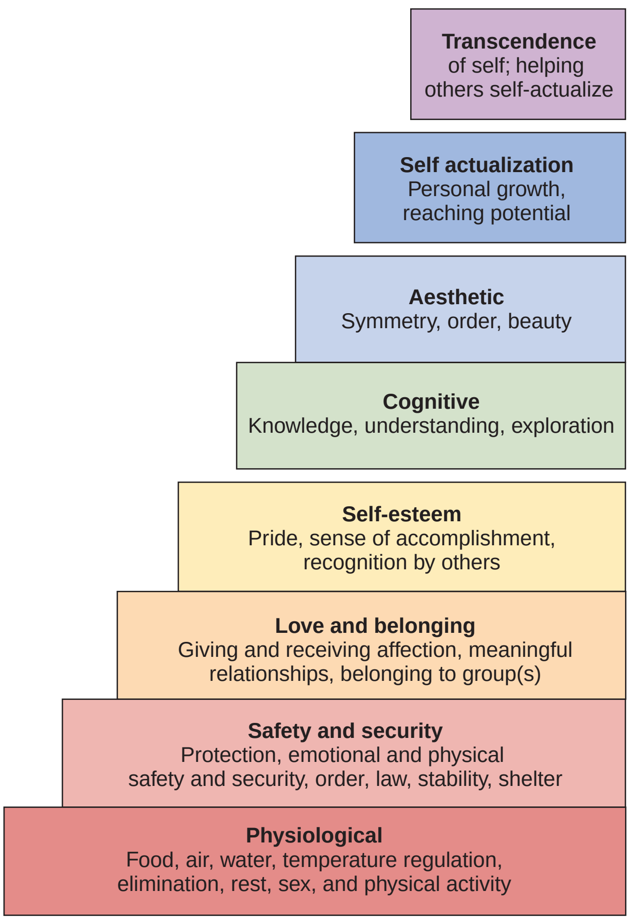

FIGURE 8-5 Maslow's Hierarchy of Human Needs is a theory nurses use every day. (*Sources:* Adapted from Maslow, A. (1971). *The farther reaches of human nature.* New York: Viking Press; and Maslow, A., & Lowery, R. (Eds.). (1998). *Toward a psychology of being* (3rd ed.). New York: John Wiley & Sons.)

Everyone has a dominant need, but it varies among individuals. For example, a teenager may have a (self-esteem) need to be accepted by a group. A heroin addict needs to satisfy her cravings for heroin and will not worry much about being accepted by others.

Physiological Needs Physiological needs, the most basic, are those that must be met to maintain life. They include the needs for food, air, water, temperature regulation, elimination, sleep and rest, sex, and physical activity. Most healthy adults meet their physiological needs through self-care. However, many of your nursing interventions are intended to support patients' physiological needs.

Safety and Security Needs The needs for safety and security are the next priority. Safety and security may refer to either physical or emotional needs. *Physical safety and security* mean protection from physical harm (e.g., falls, infection, and effects of medications) and having adequate shelter (e.g., housing with sanitation, heat, and safety). *Emotional safety and security* involve freedom from fear and anxiety—feeling safe in the physical environment as well as in relationships. We need the security of a home and family. If there is an abusive husband, for example, the wife will spend most of her time and energy trying not trigger episodes of violence or abuse. This leaves little attention for meeting self-esteem needs, for example.

Love and Belonging Needs Needs for love and belonging are sometimes called social or affiliation needs. When they dominate, the person strives for meaningful relationships with others. Everyone has a basic need to love and be loved, give and receive affection, and have a feeling of belonging, (e.g., in a family, peer group, or community). When these needs are not met, a person may feel isolated and lonely and may withdraw or become demanding and critical.

Self-Esteem Needs People who have begun to satisfy the need to belong may begin to feel the need for self-esteem. Self-esteem comes through a sense of accomplishment and recognition from others and brings confidence and independence. As we discuss in Chapter 13, illness can affect self-esteem by causing role changes (e.g., inability to perform one's job), or a change of body image (e.g., loss of a body part). When recognition cannot be obtained through positive behaviors, the person may resort to disruptive or irresponsible actions.

Self-Actualization Needs The highest level on Maslow's original hierarchy, self-actualization refers to the need to reach your full potential and to act unselfishly. At this level, a person develops wisdom and knows what to do in a variety of situations. Maslow studied self-actualized people to develop a list of their characteristics. To see this list,

Go to Student Resources: Chapter 8, **Tables, Boxes, Figures: ESG Box 8-1,** on Davis*Plus*.

In his later work, Maslow identified two growth needs that must be met before reaching self-actualization (Maslow & Lowery, 1998):

1. *Cognitive needs* to know, understand, and explore
2. *Aesthetic needs* for symmetry, order, and beauty

Transcendence of Self Later research led Maslow to identify another, even higher need (Maslow, 1971): the need for *transcendence of self.* This is the drive to connect to something beyond oneself and to help others realize their potential. Some people include spirituality at this level, which is also the basis for acts of self-sacrifice (for example, donating a kidney so that another person can live).

Applying Maslow's Theory

The following example illustrates how you might use Maslow's theory when teaching patients. Suppose you have been assigned to teach your patient, Mrs. Gallegos, about her colostomy before her discharge. Because she speaks little English, you put a great deal of effort into obtaining materials in her primary language, and you have arranged for an interpreter in case she has some questions you can't understand or answer. As you walk in the door to begin teaching, you immediately observe that Mrs. Gallegos seems to be in a great deal of pain. What will you do?

Maslow's Hierarchy of Needs tells you clearly that until the pain (a physiological need) is controlled, Mrs. Gallegos cannot learn. (Maslow considers pursuit of knowledge a self-actualization need.) You arrange for pain medication to be administered and reschedule the teaching session. If you went ahead with the teaching, the experience would be for the sole purpose of "crossing it off your list" (remember mechanistic nursing?) rather than actually teaching Mrs. Gallegos.

Validation Theory

Validation theory (Feil, 2003) arises from social work and provides for a way to communicate with older people with dementia. The theory asks the caregiver to *go where the demented person is in his own mind*. For example, if Mr. Wilkey (Meet Your Patient) is talking about his mother, who has been dead for many years, you would ask questions about her rather than tell him that she is dead. Learning of his mother's death would be a shocking and traumatic experience, which he would relive each time he heard the news. So instead of telling him that she is dead, you would go where Mr. Wilkey is in his own mind by asking him, for example, about the color of his mother's eyes, what songs she sings to him, or other personal questions that will likely stimulate meaningful conversation about the mother.

Stress and Adaptation Theory

Hans Selye (1993) developed the stress and adaptation theory. There are many theories about stress, but Selye's was the forerunner of them all. His theory states that a certain amount of stress is good for people; it keeps them motivated and alert. However, too much stress, called *distress,* results in physiological symptoms and eventual illness. Does that happen to you at the end of the semester when you are "distressed" over the number of papers due and the difficulty of the tests for which you are studying? Generally the human body will respond to distress with an illness, such as a cold, that will force the body to slow down or simply go to bed. Selye's theory is discussed more in Chapter 12.

Developmental Theories

Developmental theories look at stages through which individuals, groups, families, and communities progress over time. The following are some important examples:

- Erickson's psychosocial developmental theory (discussed in Chapter 9)
- Theories of family development (discussed in Chapters 13 and 14)
- Kohlberg's and Gilligan's theories of moral development (discussed in Chapters 9 and 44).

These theories are useful in nursing practice because they identify norms and expectations at various stages of development and help you identify activities and interventions that are appropriate for your client.

System Theory

Ludwig von Bertalanffy created system theory in the 1940s (von Bertalanffy, 1976). He intended it to be abstract enough to use for theory and research in any discipline. Today the understanding of systems has evolved to the point that many of the concepts are a part of our everyday language (e.g., healthcare system, body systems, information systems, family systems).

One of the premises of systems theory is that all complex phenomena, regardless of their type, have some principles, laws, and organization in common. A **system** is made up of separate components (or **subsystems**), which constantly interact with each other and with other systems. For example, the cardiovascular and renal systems are subsystems of the body; the cells are subsystems of those systems. All of those systems and subsystems exchange processes and information with each other and with systems outside the body.

A system maintains some organization even though it is constantly facing internal and external changes. All systems have some common elements. The goal (function) of any system is to process **input** (the energy, information, or materials that enter the system) for use within the system or in the **environment** (everything outside the system) or both. Other common elements include the following:

- **Throughput** consists of the processes the system uses to convert input (raw materials) into output (products to be used by the system or environment). Examples are thinking, planning, sorting, meeting in groups, sterilizing, hammering, and cutting.

- **Output** is the product or service that results from the system's throughput. Examples of output are documents, money, nursing diagnoses, and cars.
- **Feedback** is information about some aspect of the processing that is used to monitor the system and make its performance more effective (e.g., evaluation in the nursing process: how the patient responded to the interventions).
- **Open systems** exchange information and energy freely with the environment. Open systems are capable of growth, development, and adaptation. Examples of open systems include people, body systems, hospitals, and businesses.
- **Closed systems** have fixed, automatic relationships among their components and little give-and-take with the environment. One example is a rock. A nursing example is a family that is isolated from the community and resists outside influences.

Several nursing theories have been built on system theory, for example, Johnson's (1968, 1980) behavioral system model, King's (1971) interacting systems framework, and the Neuman systems model (Neuman & Young, 1972), to name a few. If you need more information about these theorists,

Go to Student Resources: Chapter 8, **Supplemental Materials: Other Selected Nurse Theorists,** on Davis*Plus*.

KnowledgeCheck 8-5

- Name four theories nurses "borrow" from other disciplines.
- What are the five original levels of Maslow's basic human needs (not including cognitive needs, aesthetic needs, and transcendence)?

PracticalKnowledge knowing how

Practical knowledge about theory means using theories to guide you in your use of the nursing process. Recall the lens metaphor: A theory's concepts and principles determine what you look for and what you notice. In the assessment step of the nursing process, your theory tells you what to assess and provides the rationale for the assessments. Its major concepts serve as categories for organizing the data. In the diagnosis step, your theory guides you in defining patient problems; in fact, it determines whether you will even recognize a cluster of cues as a problem. The theory helps you to generate appropriate, achievable client outcomes, to choose effective nursing interventions, and to provide rationales for your actions.

There is no reason to read about theory in this book unless you can apply the information. To show you how, this section applies caring theory to the planning of nursing interventions. Of course you can use *any* theory for this purpose. We use caring theory because of the powerful and positive impact it can have on your nursing care. In reading this chapter, you should have become familiar with two well-known caring theories. Test your recall by writing the theorists' names and basic ideas. If you have difficulty, be sure to review the information about caring theorists before proceeding.

ThinkLike a Nurse 8-4

Write a paragraph describing a clinical experience in which you applied or observed one or both of the caring theories. Record your thinking on a piece of paper, and be prepared to share it with your classmates. You may title it "My Experience in Caring."

Planning Theory-Based Interventions/ Implementation

The Nursing Interventions Classification, or NIC (Bulechek, Butcher, Dochterman, et al., 2013), introduced in Chapter 6, is theory development in an early stage. Each of the standardized intervention labels (e.g., Exercise Promotion, Infection Control) is a concept, and defining or describing concepts is an important step in theory development. In this section, we use nine key concepts of Watson's caring theory to describe important nursing activities and approaches.

1. **Holistic Nursing Care.** The basis of modern nursing, holistic nursing care allows nurses to examine the entire person and the person's world when making healthcare decisions. It goes beyond just giving the medication or dressing a wound. These are important tasks, but try to see nursing as giving care to the entire person and all that this entails (e.g., family, friends, fears, cultural beliefs).
2. **Honoring Personhood.** None of the three caring theorists refers to the person in the healthcare system as a patient unless they need to for clarification. They believe the "patient" is someone who deserves to be honored for individuality in behavior as well as needs. If you accept the need to honor personhood, you will learn the names of the people in your care and will refer to them by name instead of "Room 331," or "the kidney infection down the hall." Honoring personhood requires you to control the fast pace of nursing and hurried care and take time with your patients. You need to look at, talk to, and touch the person to understand what his personhood is.
3. **Transpersonal Caring Moments.** The concept of transpersonal caring is a moral ideal rather than a task-oriented behavior. Transpersonal caring moments occur when an actual caring occasion or caring relationship exists between the nurse and the person. This can be a challenge! The current healthcare environment moves people rapidly through the system. How can you find the time to develop authentic caring relationships? The first step is to make a commitment to be a caring nurse: to go to

work with the thought, "Today I will be authentic (genuine, real) with the people in my care." Or you might think, "I will focus on creating transpersonal caring moments instead of rushed and harried ones." As a student, you might think, "Today I will practice changing sterile dressings, starting intravenous solutions, or giving intramuscular injections." However, developing the ability to have transpersonal caring moments is just as important. Think about Mr. Wilkey (Meet Your Patient). Where did opportunities for transpersonal caring moments with him arise?

4. **Personal Presence.** Another phrase for being authentic and in the moment is *personal presence*. The concept of presence suggests that you, the nurse, are emotionally and physically *with* the person for the time you are there. You are not thinking about a medication you need to give or medical orders you need to get. If the person in the bed is fearful, you should be fully present, recognize the fear, and support the person experiencing it. Your support may take the form of answering simple questions or providing more in-depth education. It may simply be staying with the person for 2 or 3 minutes while quietly listening and holding the person's hand. As your psychomotor and nursing process skills become second nature to you, you will find it easier to remain in the moment.
5. **Comfort.** Some nurses think of comfort as the relief of pain, but it is much more. In Kolcaba's (1994) theory, comfort occurs in four contexts: physical, psychospiritual, social, and environmental. For example, is the person comfortable with you as the caregiver? Some women, especially from Middle Eastern or Asian cultures, are uncomfortable with male nurses. Other questions to consider are whether
   - the patient's modesty is being respected.
   - there is too much or too little environmental stimuli.
   - the room temperature is neither too cold nor too warm.
   - the patient needs more rest periods in order to heal.
   - the patient needs someone to spend a transpersonal caring moment with him so he can express fears and anxiety.

   This is the complex picture of comfort.
6. **Listening.** Listening requires you to quiet your mind and truly listen with your mind *and* heart. The caring theorists also talk about listening from within yourself. Some call that *intuition*. Benner believes it is intuition that allows nurses to advance to expert level practice.
7. **Spiritual Care.** Spiritual care is a critical aspect of holistic nursing care (see Boxes 8-1 and 8-2). You need to know what an individual's spiritual needs are and make appropriate plans to meet them. If the person does not want to talk about or deal with her spirituality, you will listen and follow her instructions. However, generally the opposite is true. People who are ill often want to talk about their spiritual needs, but they may be uncomfortable doing so. Helping someone to meet spiritual needs may be as simple as offering to call a clergy member or praying with the person who is sick. Chapter 16 provides more information about spiritual care.
8. **Caring for the Family**. All nurses who base their practice on caring theories recognize the importance of including the family of the person who is receiving care. Nontraditional family structure (e.g., a same-sex couple, a polygamist family) is not a reason to withdraw support, even if it conflicts with your values. What about an older family member with dementia? This person deserves to know what is happening to his loved one even though he most likely will forget the information. If he does forget, patiently repeat what he needs to know. You will find more information about family care in Chapter 14.
9. **Cultural Competence.** This was discussed in the explanation of Leininger's cultural care theory. Also see Chapter 15 if you want more information.

Do you see the value of each of these nine abstract concepts? From them flow very real, concrete nursing actions that make a difference in the lives of patients. Theory is not just "pie in the sky." Understanding nursing theories and applying them throughout your career are essential to full-spectrum nursing care. To perform the essential clinical tasks of nursing within the framework of caring is the highest possible performance of the profession.

KnowledgeCheck 8-6

List and explain three ways to incorporate caring theory into your nursing care.

NURSING RESEARCH

You now have a good beginning (novice) background in nursing theory. Remember the puzzle pieces (Fig. 8-2)? A nurse has an idea, does research to determine whether the idea is a valid one, and then develops a nursing theory. It is now time to study the research piece of the puzzle.

TheoreticalKnowledge knowing why

Many people, including some nurses, do not know that nurses do research. They see nurses as people who work in hospitals, wear scrubs, and carry a stethoscope in their pocket. Were you aware of the research done in the field of caring before reading this chapter? Most novice nurses would not be. Remember the Framingham Heart Study, which changed medical and nursing practice? Had you heard of that before? To be an effective professional nurse in the 21st century, you need to understand the basic principles of nursing research and their powerful impact on healthcare and the nursing profession. This section of the chapter is designed to show you what research is and how to incorporate it into your practice.

Although there are many definitions of nursing research, this chapter defines **nursing research** as the systematic, objective process of analyzing phenomena of importance to nursing (Nieswiadomy, 2008). Its purpose is to develop knowledge about issues that are important in nursing. Nursing research encompasses all clinical practice arenas, nursing education, and nursing administration.

Nurse researchers currently are making important contributions to the evidence-based practice necessary for professional nursing. Consider this example: When you are in the clinical setting, you will notice that when a nurse discontinues an intravenous (IV) fluid infusion, she sometimes replaces it with a lock, or plug, to maintain a route for IV medications, even though the patient no longer needs the fluids. Not many years ago, she would periodically flush the plug with heparin to keep blood from clotting and blocking the IV catheter. But heparin is a drug, and it has side effects. Nurses and other professionals performed several studies to see whether saline (which has no side effects) would work just as well. Goode and others (1996) performed a meta-analysis of those studies showing that saline was indeed just as effective; that is now the standard of care in most institutions. (A **meta-analysis** combines and analyzes the data from several different studies.)

Why Should I Learn About Research?

The best reason, of course, is that the ability to read and use nursing research enhances your ability to give quality patient care. Like theory, research affects you every day you are a nurse. Full-spectrum nurses participate in research by:

- Identifying ideas that should be examined through the research process
- Assisting in, designing, and/or performing research
- Using research as a basis for their practice

In fact, educational and practice standards require that you acquire a degree of research competence.

ANA Standards

The position of the American Nurses Association (ANA) is that all nurses share a commitment to the advancement and ethical conduct of nursing science. The following two items from The ANA Standards of Practice (2010) include the ability to use research in planning care:

Standard 4, Planning—Measurement Criterion: The registered nurse integrates current trends and research affecting care in planning.

Standard 5, Implementation—Measurement Criterion: The registered nurse utilizes evidence-based interventions and treatments specific to the diagnosis or problem.

The ANA Standards of Professional Performance include a separate research standard (Standard 9, Evidence-Based Practice and Research). Four criteria for it follow. The registered nurse:

- Utilizes current evidence-based nursing knowledge, including research findings, to guide practice decisions.
- Critically analyzes evidence-based practice and research findings for application to practice.
- Participates in the development of evidence-based practice through research activities. Participation levels occur appropriate to the nurse's education and position.
- Shares research activities and/or findings with peers and others.

Educational Competencies

The Quality and Safety Education for Nurses (QSEN) project has identified competencies for nurses. One important competency is evidence-based practice, the ability to "integrate the best available current evidence with clinical expertise and patient/family preferences and values for delivery of optimal healthcare" (Cronenwett, Sherwood, Barnsteiner, et al., 2007, pp. 122–131). To achieve this competency, you will need a basic understanding of nursing research. If you would like to see a description of the knowledge, skills, and attitudes you need for achieving this competency,

Go to Student Resources: Chapter 8, **ESG Table 8-2** on Davis*Plus*,

or

Go to the QSEN Web site at **http://www.qsen.org/ksas_prelicensure.php**

What Is the History of Nursing Research?

The records Florence Nightingale kept while nursing soldiers in the Crimea were the beginning of formalized nursing research. As she developed schools of nursing throughout Britain and the United States, Nightingale urged her students to do clinical research. Yet because she had passed on to them the authoritarian tradition of her time, she found they were not prepared to perform it. Authority-based education does not promote intellectual inquiry or critical thinking, two characteristics essential for research. This is one reason nursing research was slow to develop.

As baccalaureate, master's, and doctoral programs grew in number, so did the number and quality of research projects nurses performed. Nursing research is now supported by federal funds and private grants, and results are reported in a growing number of nursing (and other) research journals. Nurses present their research at national and international conferences and publish their results in national and international journals.

The preparation of doctoral-level nurses with a strong background in research has enhanced the quality and diversity of nursing research.

How Are Priorities for Nursing Research Developed?

Nursing research provides evidence on which to base nursing care. Ideally, all nursing interventions should be validated through research to show their safety and effectiveness. Professional organizations, such as the ANA and specialty organizations (e.g., the Oncology Nurses Association), have established research priorities that will assist nursing to build a strong knowledge base in areas of importance to society. In the present healthcare system, which emphasizes the need for cost-effective interventions, it is likely that nursing research will continue to be focused on clinical issues. The National Institute of Nursing Research (NINR), a federally funded agency that is a part of the National Institutes of Health (NIH), periodically identifies research themes and priorities for funding (NINR, n.d., 2006, 2010). For more information about nursing research priorities,

Go to Student Resources: Chapter 8, **Supplemental Materials: What Are the Priorities for Research in the 21st Century?** on Davis*Plus*.

KnowledgeCheck 8-7

- Define *nursing research*.
- According to the text, why has nursing research been slow to develop?

What Educational Preparation Does a Researcher Need?

At each level of educational preparation, nurses function in different roles in the research process.

Associate Degree and Diploma Nursing At this educational level, there are three research roles you can fulfill. You can (1) be aware of the importance of research to evidence-based practice, (2) help identify problem areas in nursing, (3) help collect data with a more experienced nurse researcher, and (4) use evidence-based practice in planning nursing interventions.

Baccalaureate Degree in Nursing If you are a baccalaureate-prepared nurse, you should be able to (1) critique research for application to clinical practice, (2) identify nursing research problems and help implement research studies, and (3) apply research findings to establish sound, evidence-based clinical practice.

Master's Degree in Nursing Nurses with graduate degrees should be able to (1) analyze problems so that appropriately designed research can be used to solve the problem, (2) through clinical expertise, apply evidence-based practice to nursing care situations, (3) provide support to ongoing research projects, and (4) conduct research for the purpose of assuring quality nursing care.

Doctoral Degree in Nursing or Related Field Doctorally prepared nurses are specifically educated to be nurse researchers. They are qualified to (1) conduct nursing research, (2) serve as leaders in applying research results to the clinical arena, and (3) develop ways to monitor the quality of nursing care being administered by nurses (adapted from ANA, 1981). In addition, they should disseminate their research findings via publications and conferences.

PracticalKnowledge knowing how

No one expects you to have a sophisticated understanding of research at this point in your career. However, you do need some basic practical knowledge, including information about the scientific method, types of research design, the research process, how to find practice-related research articles, how to identify researchable problems, and how to critique research reports.

How Do We Gain Knowledge?

Recall that in Chapter 2 you learned the different kinds of nursing knowledge: theoretical, practical, ethical, and self-knowledge. There are also various ways to *gain* knowledge.

Trial and Error Plus Common Sense Suppose a patient has been medicated but is still in pain. You might try repositioning him. If that doesn't help, you might try distraction or visualization techniques. And so on. If visualization provides some relief, you would probably try that technique first when a similar situation occurs with another patient.

Authority and Tradition This means to rely on an expert or to do "what has always been done." For the patient with unrelieved pain, this would mean you might ask a more experienced nurse what to do. Or you could consult a procedure manual.

Intuition and Inspiration Intuition is a "feeling" about something—an inner sense. Nurses say, "I just had a feeling something was wrong with the patient, but I can't explain why." For the patient in pain, you might "have a feeling" that a complication was developing, that the pain was due to more than just ineffective pain medication. However, as a novice, you should always check with a more experienced nurse before acting on your intuition.

Logical Reasoning Using your knowledge and the facts available, you form conclusions (refer to How Are Theories Developed?). For the patient in pain, you might think, "This man weighs 300 lb, but I gave him only the standard dose of medication. Probably he needs a higher dose."

Scientific Method Research is based on the scientific method (or scientific inquiry). **Scientific inquiry** is the process in which the researcher, through use of the senses, systematically collects observable, verifiable data to describe, explain, or predict events. The goals of scientific inquiry are to find solutions to problems and to develop explanations of the world (theories). The scientific method has two unique characteristics that the other ways of gaining knowledge do not:

- *Objectivity*, or *self-correction*. This means that the researcher uses techniques to keep her personal beliefs, values, and attitudes separate from the research process.
- *The use of empirical data*. Researchers use their senses to gather empirical data through observation. They attempt to verify the information gathered through a variety of methods so that the research conclusions are based in "reality" rather than on the researcher's beliefs, biases, or hunches.

Box 8-3 summarizes the characteristics of the scientific method.

BOX 8-3 ■ Characteristics of the Scientific Method

Begins with an identified problem or need to be studied.

Uses theories, models, and conceptual themes that have been empirically tested.

Uses systematic, orderly methods to acquire empirical evidence to test theories.

Uses methods of control for ruling out other variables that might affect the relationships among the variables they are studying.

Avoids explanations that cannot be empirically tested.

Prefers to generalize the findings (knowledge) so that it can be applied in cases other than those in the study.

Uses built-in mechanisms for self-correction.

Source: Adapted from Wilson, H. S. (1993). *Introducing research in nursing* (2nd ed.). Redwood City, CA: Addison-Wesley Nursing.

What Are Two Approaches to Research?

The scientific method makes use of a variety of procedures and study designs aimed to increase the chances that the data collected will be reliable, relevant, and unbiased. You should recognize the two major categories of research design: quantitative and qualitative. Each category has within it several specific types of research methodologies; however, for now you need to understand only the basic differences (Table 8-2). For an expanded discussion,

Go to Student Resources: Chapter 8, **Supplemental Materials: Quantitative Research and Qualitative Research,** on Davis*Plus*.

Quantitative Research

The main purpose of **quantitative research** is to gather data from enough **subjects** (people being studied) to be able to generalize the results to a similar population. **Generalizing results** means that you think, "What I found to be so for this group of people will probably be the same for all people who are similar" (e.g., "My findings for *this* group of women over age 40 in the United States will probably be useful for *all* women over age 40 in the United States"). In quantitative research, researchers carefully control data collection and are careful to maintain the objectivity of the process. Quantitative data are reported as numbers. The Framingham Study is a classic example of a quantitative study—actually of several quantitative studies. To read more about this landmark research,

Go to the Framingham Study Web site at http://www.framinghamheartstudy.org/index.html

Another classic example of quantitative nursing research is the Conduct and Utilization of Research in Nursing (CURN) project, which was intended to increase the use of research by direct-care nurses (Horsley, Crane, Crabtree, et al., 1983). Many of the protocols (procedures)

Table 8-2 ➤ Comparison of Quantitative and Qualitative Research

	QUANTITATIVE RESEARCH	QUALITATIVE RESEARCH
Data	Numerical data, e.g., questionnaires, number of incidents, or reactions to a medication	Nonnumerical data; data may consist of words from interviews, observations, written documents, and even art or photos.
Persons Studied	Large numbers of *subjects* so it can be generalized to other similar populations	Often uses small numbers of *participants*; is not designed with the intent to generalize.
Hypothesis	Has a hypothesis	No hypothesis because it is the research of the "lived experience" of the person or persons being studied; study may be guided by research questions.
Environment	Can be in a laboratory setting; needs to be a controlled environment	Is often done in the "natural" setting (i.e., the person's home or work setting).
Analysis	Objective data, tested with statistical methods	Subjective data; identifies themes; sometimes converted to numerical data (e.g., by counting categories).

developed from these studies are used today with some modification. The following are some CURN protocol examples:

Clean intermittent catheterization
Intravenous cannula change
Distress reduction through sensory preparation
Preventing decubitus ulcers

Qualitative Research

Qualitative research focuses on the lived experience of people. The purpose is not to generalize the data, but to share the experience of the person or persons in the study. There is no need for large numbers. A case study of one person can examine the lived experience, for example, of a 19-year-old single mother of triplets or a middle-aged woman with HIV. Qualitative research uses words, quotations from persons interviewed, observations, and other nonnumeric sources of data. The Nun Study, a long-term, multidisciplinary project involving a convent of Catholic nuns in Minnesota, included some qualitative research (e.g., data obtained by interviews and reported in the nuns' own words, and samples of writing from the nuns' diaries, reports, and letters). For an example of research from the Nun Study,

Go to the University of Minnesota Web site, **The Nun Study,** at http://www.apa.org/pubs/journals/releases/psp805804.pdf

KnowledgeCheck 8-8

- Define *quantitative research*. Name one study presented as an example in this chapter.
- Define *qualitative research*. Name one study presented as an example in this chapter.

What Are the Phases of the Research Process?

At the novice level, you will be using but not performing research. But in order to evaluate the research you read, you should have a general idea of the steps for conducting valid, reliable research. The research process is a problem-solving process, similar to but not the same as the nursing process. Different study designs require different steps, and you will find some variation in how different authors present the research process steps. However, in general, the steps include the following five phases (Fain, 2013):

1. Select and define the problem.
2. Select a research design.
3. Collect data.
4. Analyze data.
5. Use the research findings.

If you need a more detailed description of those phases,

Go to Student Resources: Chapter 8, **Supplemental Materials, What Are the Steps of the Research Process?** on Davis*Plus*.

ThinkLike a Nurse 8-5

Take 10 minutes to sit quietly and think about nursing research. Do you have an idea or a problem you would like to see investigated with a research project? If nothing comes to mind quickly, then ponder for a few moments more. Write the information on a sheet of paper. Take the time to do your best thinking. Then share what you have written with your instructor and other students.

- What would you like to have more information about in nursing? Explain why it is a problem or what brought about your idea.
- If you were the research assistant on a nursing research project on your topic, what one-sentence problem statement would you write regarding your research idea?
- What is the purpose of doing this research project? Why should it be done?

You may struggle with this assignment and wonder about its value to you, yet one of the most important things that nurses do is identify problems. Here is your chance to practice.

What Are the Rights of Research Participants?

Every nurse has a moral and legal responsibility to protect research participants from being harmed during the research process. Although research is crucial to the development of the profession, it should never be held in higher regard than the rights of the individuals being studied.

The current ethical standards for research, from all disciplines, are a direct result of the atrocities committed in the name of research in the German prison camps during World War II. After the trials for war crimes committed at that time, the Nuremberg Code was developed in 1949 to protect research participants from unethical behavior. The Nuremberg Code prompted many other codes and standards for performing ethical research (Code of Federal Regulations, 2009; Ghooi, 2001; The Nuremberg Code, 1949). The United States government, through the Department of Health and Human Services (DHHS), has a complex set of standards that all researchers must follow.

Informed Consent

As a rule, **informed consent** must be obtained from every participant in a study. Consent is obtained by discussing what is expected of the participant, providing written information on the project to the participant, and obtaining the participant's written consent to be a subject. The following critical concepts are part of the informed consent.

- *Right to not be harmed.* The information given to the participant outlines the safety protocols of the study. If at any time preliminary data indicate potential harm to the participant, the study must be stopped immediately.
- *Right to full disclosure.* Participants have a right to answers to such questions as: What is the purpose of this

research? What risks are there? Are there any benefits? Will I be paid? What happens if I get sick or feel worse? Whom do I contact with questions and concerns?

- *Right to self-determination.* This refers to the right to say no. At any time in a study, the participant has the right to stop participating, for any reason. As the nurse, you are responsible to support a participant during the process of withdrawing from a study. Do not allow anyone to coerce the participant into remaining in the study.
- *Rights of privacy and confidentiality.* All research participants have the right to have their identity protected. Generally they are given a code number rather than being identified by name. Once the study is completed and the data are analyzed, the researcher is responsibility for protecting the raw data (such as questionnaires and taped interviews).

Institutional Review Boards

The mechanism for overseeing the ethical standards established by the U.S. DHHS is the Institutional Review Board (IRB). Every hospital, university, and other healthcare facility where federal funds are involved has an IRB. It consists of healthcare professionals and people from the community who are willing to review and critique research proposals. The two main responsibilities of the IRB are to (1) protect the research participants from harm and (2) ensure that the research is of value.

KnowledgeCheck 8-9

- List the phases of the research process.
- List four critical concepts that make up informed consent.

How Can I Base My Practice on the Best Evidence?

Recall from Chapter 6 that research provides the data for evidence-based practice. When there is a body of research on a topic, experts and professional groups evaluate the quality of the research reports and translate them into guidelines for practice. In your own evidence-based practice, you should use research findings and practice guidelines when they are available. When they are not, you will need to rely on the research reports themselves. Similar to the phases of research, the following process should assist you in finding the best evidence for your own interventions:

- Identify a clinical problem.
- Formulate a searchable question.
- Search the literature.
- Evaluate the quality of the research you find in the literature.
- Integrate your findings into your practice.

Identify a Clinical Nursing Problem

Even as a novice nurse, you should be prepared to identify clinical problems for research. Identifying a clinical nursing problem comes from being alert and interested in what you are doing each day in your clinical setting. How do you think the tympanic thermometer came into being? Someone became frustrated with the discomfort patients experienced when temperatures were taken rectally. At the same time, there was a great deal of concern over the inaccuracy of axillary temperatures. Someone noticed the problem and wondered: "Is there a better way to do this?"

Common sources of clinical problems are experience, social issues, theories, ideas from others, and the nursing literature (Polit & Beck, 2007). Most of these sources are relevant whether you are identifying a problem for a research study or for doing a literature search.

Experience As you go about your work, you will notice interventions that may not be working or that require a great deal of effort for the minimal good they do. You will wonder, "How could we do this better?" Or you may notice that for clients with a particular health problem, the outcomes are often not good. You will wonder, "How could we improve the care so the patient's health improves?" Other questions might be, "Why do we do this procedure this way? "What do I need to know in order to plan new interventions for patients with this health problem?" If you are curious about why things are done and about what might happen if changes were mad, you will find plenty of problems—for example, problems to staffing, equipment, nursing interventions, or coordination among health professionals.

Social Issues You may be concerned about broader social issues that affect or require nursing care, such as issues of gender equity, sexual harassment, and domestic violence. You may be concerned about patients who do not have access to healthcare or about the health problems of a particular group or subculture.

Theories Recall that theories must be tested in order to be useful in nursing practice. You might want to suggest research to test a theory you are interested in. If the theory is accurate, what behaviors would you expect to find, or what evidence would you need to support the theory?

Ideas From Others Your instructor may suggest a topic to research, or perhaps you might brainstorm with nurses or other students. Agencies and organizations that fund research often ask for proposals on certain topics (e.g., the ANA and the NINR).

Nursing Literature Read widely in your field of interest. You may identify clinical problems by reading articles and research reports in nursing journals. This may occur in one of the following ways:

- An article may stimulate your imagination and interest in a topic.
- You may notice a discrepancy in what staff nurses are doing and what the literature recommends.

- You may notice inconsistencies in the findings of two different studies on the same topic.
- You may read a study on a topic of interest to you (e.g., a technique for measuring blood pressure) and wonder whether the results would be the same if the study had been done in a different setting (e.g., a clinic instead of a hospital) or with a different population (e.g., healthy instead of ill people).

Formulate a Searchable Question

When you have found a topic of interest, the next step is to state it in such a way that you can find it in the vast amount of nursing literature that is published. Stated too broadly, the search may yield thousands of irrelevant results. Stated too narrowly, you may get no results. Using the acronym PICO enables you to search efficiently. The acronym stands for ***P***atient or problem, ***I***ntervention, ***C***omparison intervention, ***O***utcomes, and ***T***imes. You may not always need a comparison intervention (C), and sometimes not a (T) (Box 8-4).

Search the Literature

Once you have stated your guiding question, the next step is to look for research articles related to the question (or problem statement). You may be thinking, "Where do I look for research articles?" As previously stated, evidence reports and practice guidelines may already exist for your clinical problem, so look first for those. If there are none, proceed to search for your topic in research reports in scientific journals.

Indexes and Databases

Obviously you need to go to a library or online and search a database or index for appropriate journal references. A **database** is an electronic bibliographic file that can be accessed either online or on a CD-ROM. The best database for you, as a novice nurse, is the Cumulative Index to Nursing and Allied Health Literature (CINAHL). This is a comprehensive database that includes nearly 3,000 nursing and allied health journals. Generally, you will be able to find in CINAHL whatever you are looking for in clinical nursing. Most university libraries have access to CINAHL and other indexes online. If you are an online user, it will be worth your time to get information from the library about conducting online searches. In the library, you will find the printed version of CINAHL in a set of large books in the reference section.

Once you have access to CINAHL in either format, select words that relate to your topic (e.g., dementia or nursing ethics). The index or database will list journal articles related to the key words. Sometimes, you will get a large number of articles (more than 1,000) that carry that word. A PICO question should help you narrow your search, but you may need to ask the librarian for assistance. It is beyond the scope of this chapter to provide detailed instructions for literature searches. For more information about literature databases, see Chapter 41.

BOX 8-4 ■ PICOT Questions

	Sample Questions	Example
P—Patient Population, or Problem	What is the medical diagnosis, nursing diagnosis, patient problem, symptom, situation, or need that requires an intervention? How would you describe a group of similar patients?	For patients with Impaired Skin Integrity (perineum) related to urinary incontinence
I—Intervention, treatment, cause, contributing factor	Which intervention are you considering? Specifically, what might help the problem (improve the situation, etc.)?	Would applying a barrier cream help?
C—Comparison Intervention, control	What other interventions are being considered or used?	As compared with washing with soap and water, rinsing well, and air-drying?
O—Outcome	What effect could the intervention realistically have? What do you hope to achieve?	Prevent or achieve less perineal excoriation? Are there any expected undesired effects associated with the intervention?
T—Time	How often, or when, will the outcome be measured? How often or how long will the intervention or treatment be administered?	After incontinent episodes?

KnowledgeCheck 8-10

Where can you go to use CINAHL?

Journals

It also is easy to search in a specific journal for articles. The title of a journal provides clues to the content. The critical care journals will have, obviously, articles about critical care. Oncology, orthopedics, and other specialty journals carry information specific to their own specialty. Looking for such journals is another way to do a casual search for articles of interest.

You will find the best research articles in refereed journals. **Refereed journals** are professional journals (not lay magazines, such as *Men's Health* or *Fitness*) in which professionals with expertise in the topic review each article and then recommend whether the article should be published. The easiest way to identify a refereed journal is to see whether it has an extensive editorial board listed in the front of the journal. Refereed journals meet a higher standard for publishing, which makes the information you read more credible (and therefore more useful to your work). Two examples of refereed nursing research journals are *Advances in Nursing Science* and *Nursing Research.* For a more extensive list,

Go to Chapter 8, **Supplemental Materials: Nursing Research Journals,** on Davis*Plus.*

How can you tell whether the article you retrieve is a research article? Simply look for the steps in the research process described earlier in this chapter. Does the article have a problem statement and a purpose? Is there a section on the sample and site of the research? And so on.

If your focus is clinical practice, you should not overlook specialty journals, such as *Geriatric Nursing* or the *Journal of Gerontological Nursing*, if you really want information on, say, older adults with dementia. They are not research journals, but they generally have one or two research articles in each issue. If you do not have a specialty interest, review the *American Journal of Nursing, Nursing,* or *RN* for articles of general interest. Again, remember that it is up to you to identify whether the article is research or another form of information sharing.

Evaluate the Quality of the Research

As mentioned previously, you may be fortunate enough to find clinical practice guidelines related to your topic. If so, the related research has already been evaluated by experts, and should have a notation about the level of evidence supporting the guideline. For a description of the different levels of evidence described by guidelines panels,

Go to Student Resources: Chapter 6, **Supplemental Materials, Levels of Evidence,** on Davis*Plus.*

If no practice guidelines are available, you will need to critically appraise the individual research articles you find. You can do this by reading analytically and performing a careful appraisal of the research you read.

Analytical Reading

You cannot expect to do a sophisticated critique of a research report at this stage of your education, or probably even on graduation from your basic education. However, you need to know enough to help you decide which articles are worthy of using in your practice. You will make that decision after you have examined the research to determine whether it is well done and meaningful to your work. Begin this process by learning to read analytically. Wilson (1993, p. 25) says that **analytical reading** occurs when you "begin asking questions of what you are reading so that you can truly understand it." For questions to use when reading analytically, see Box 8-5.

Research Appraisal

Not all research is good research. Some published studies contain serious flaws, and you need to be able to recognize them. An effective strategy for conducting a research appraisal is to read the entire article, using the four "analytical reading" questions in Box 8-5 and making notes of questions you have. Then go back and evaluate the article section by section, thinking critically about each (Wilson, 1993).

- ***Researcher qualifications*** are an easy place to start. Was the researcher qualified as an expert on the study topic? Try to determine whether the author's credentials and background "fit" with the topic.
- ***The title*** should be concise and clear. Key words in the title should provide clues to the research topic.
- ***The abstract*** is a brief (perhaps 500 words) summary of the study. It should be interesting and usually describes at least the purpose, methods, sample, and findings of the study.
- ***The introduction*** should catch your interest and set the stage for the rest of the report. The introduction

BOX 8-5 ■ Reading Analytically

When reading analytically, ask yourself the following questions:

1. ***What is the book, journal, or article about as a whole?*** That is, what is the theme of the article, and how is it developed?
2. ***What is being said in detail, and how?*** What are the author's main ideas, claims, and arguments? In a research article, you will find this mainly in the abstract and the conclusions.
3. ***Is the book, journal, or article "true" in whole or part?*** You must decide this for yourself. The strategies in the section, Research Appraisal, may help you to determine the truth of a research report.
4. ***What of it?*** Is it of any significance? Is there any way to use the information to improve patient care, education, or other areas of nursing?

may contain the *review of the literature, theoretical (conceptual) framework, assumptions, and limitations.* At this stage of your expertise, you should primarily just check that these are present; however, some explanation follows.

- ***Review of the literature*** should be thorough and relevant. The references should logically pertain to the study topic and methods and consist primarily of research and theory articles. The references should support the researcher's variable definitions, methodology, and choices of data-collection tools; it should also present background work on the topic being studied.
- ***Identify the study assumptions.*** Recall that assumptions are beliefs that you "take for granted" as true but that have not been proved. For example, you assume that when people are in bed, they sleep; and you assume that study participants answer truthfully to the researcher's questions. Assumptions should be clearly stated to avoid confusion regarding the study.
- ***Recognize the limitations of the study.*** Every study has limitations or weaknesses. Look for the author to admit the things that could not be controlled. For example, a study may test a population of people that would not generalize to other populations, (e.g., testing only Caucasian students instead of testing a variety of students who represent the ethnic diversity of the university).
- ***The purpose*** should be stated clearly. It should give the reasons for doing the study. Ask these three questions to help you judge it: Will the study (1) solve a problem relevant to nursing, (2) present facts that are useful to nursing, or (3) contribute to nursing knowledge?
- ***The problem statement*** should be presented early in the report, and it should be "researchable"; that is, it (1) is stated as a question, (2) involves the relationship between two or more variables, and (3) can be answered by collecting empirical data.
- ***Definition of terms*** is essential in a formal research report. However, it often is not included in a published article because of the lack of space.
- ***The research design*** indicates the plan for collecting data. As a novice, you probably cannot judge the adequacy of the design, but you should be sure the researcher names and describes it and discusses its strengths and weakness. The researcher should include an explanation of what was done to enhance the validity and reliability of the study. To oversimplify, **validity** means the study actually measures the concept it claims to measure. **Reliability** refers to the accuracy, consistency, and precision of a measure. That is, if someone else repeated the study using the same design, would they obtain similar results? For example, if you weighed the same item on a scale each day and obtained the same weight each time, you could say that the scale is reliable—but a scale would not give you a valid measure of body fat.
- ***Identify the setting, population, and sample.*** The researcher should identify the type of setting where the data was collected, describe the population and sample, and state the criteria that were used for choosing study participants. This section may also contain information about how informed consent was obtained.
- ***Data-collection methods*** answer the basic questions of what, how, who, where, and when. Data-collection instruments are the "tools" used to gather the data (e.g., questionnaires or a laboratory instrument). The researcher should provide evidence (pilot tests, literature) that the tools used were reliable and valid.
- ***Determine the data analysis used.*** A quantitative report would include statistical analyses of the data. A qualitative report would include quotes from the participants. The analyses of both types of data are very specific and beyond the scope of this textbook.
- ***Discussion of findings and conclusion*** are the sections of a research report that you may find most interesting. They are the "So what was learned?" sections. All findings should be presented in an objective manner, and compared with information found in the literature. The easiest errors for you to recognize with your present knowledge level are that the researcher:
  1. Generalizes beyond the data or the sample. For example, the sample may have been young adult women in a clinic setting, but the researcher might have suggested that the same intervention be used for all women in the clinic, regardless of age.
  2. Does not mention any limitations that might have influenced the results.
  3. Does not present findings in a clear, logical manner (i.e., you have trouble figuring out what the findings actually are).
- ***Implications and recommendations*** are the final pieces of the research critique. The implications are the "shoulds" of the research. In essence, the researcher says, "Now we know this fact; therefore, nurses should . . ." For example, the research "should" be replicated with another population, or the instrument "should" be revised and retested, or that nurses "should" use the study intervention in their practice.

When you read a research article, examine it for each of the preceding items. Although you have limited knowledge and experience, every time you review an article thoroughly, you will learn more about the research process. As you learn, you will be better able to determine the quality of research you will accept as a basis for changing your nursing practice.

KnowledgeCheck 8-11

- Explain the difference between analytical reading and research appraisal.
- What are the parts of a PICOT question?

Integrate the Research Into Your Practice

True evidence-based practice requires that after discovering and critiquing the best available evidence, nursing expertise must be applied to see how the recommended interventions fit into the practice setting and whether they are compatible with patient preferences. If the intervention is to involve more than just an individual nurse, nurse managers must consider costs, barriers to change, facilitators for change, and staff education before deciding to implement the clinical practice guideline in their unit or hospital.

Research is more than just an exercise that nurses engage in to earn master's and doctoral degrees. The ultimate reason for conducting research is to establish an evidence-based practice or to gain greater understanding of a phenomenon. This means that nurses in practice have a responsibility for finding and using the research that others do. Remember the discussion of authority-based practice during Florence Nightingale's era? Even in the 21st century, much nursing practice is still based on authority and tradition. That is not acceptable for full-spectrum professional nurses. You must have reasons for what you do. Research can provide those reasons.

Although there are barriers (see Box 8-6), you can use nursing research to enhance your practice by acting on the information in this chapter. Read and talk about research with your colleagues and instructors. Once you have a research-based idea clear in your mind, try it out in your clinical setting (with approval from the nurse manager or instructor). Then discuss it with others. You can learn to effectively read and use research, and then you can motivate others to do the same.

BOX 8-6 ■ Barriers to Using Research

According to Nieswiadomy (2008), there are five reasons nurses *do not* use research as the basis for their practice:

1. Lack of knowledge of nursing research
2. Negative attitudes toward research
3. Inadequate forums for disseminating research
4. Lack of support from the employing institution
5. Study findings that are not ready for the clinical environment

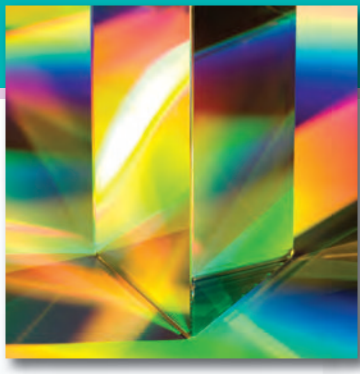
Factors Affecting Health

CHAPTER 9



Life Span: Infancy Through Middle Adulthood

Learning Outcomes

After completing this chapter, you should be able to:

- Discuss the principles of growth and development.
- Compare and contrast developmental task theory, psychoanalytic theory, cognitive theory, and the psychosocial theory of growth and development.
- Outline the major principles involved in moral and spiritual development.
- Identify conditions that influence growth and development at all ages.
- Discuss the cognitive and psychosocial challenges for each age group, infant through middle age.
- Identify common health problems seen in each stage of development.
- Describe special assessments unique to each age group.
- Discuss age-appropriate interventions for each age group.
- Incorporate developmental principles into nursing care.

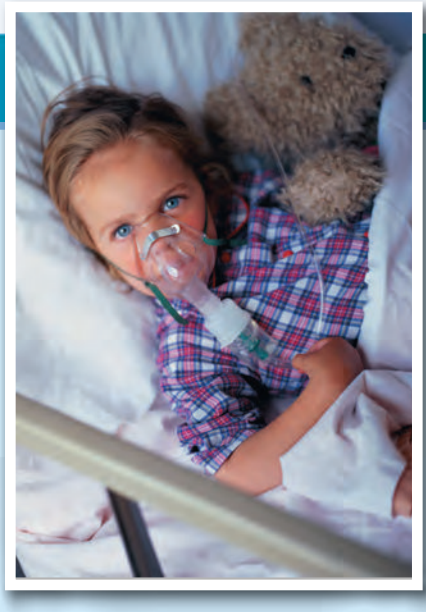
Substance abuse

Meet Your Patients

At the end of your first clinical day on the pediatric unit, you reflect on your experiences. You provided care for three children who were diagnosed with pneumonia:

- Tamika, a 3-year-old, lives with her grandparents. Her grandmother is present only during afternoon visiting hours because she must care for her husband, who suffers from numerous health problems.
- Miguel, a 2-month-old, lives with his mother. Since his admission yesterday, Miguel's mother has stayed at his bedside and provided most of her son's care.
- Carrie, a 13-year-old, lives with her parents. Both parents are able to visit only during evening visiting hours, when they leave work.
- You think back to another clinical day when you were assigned to care for Ms. Lowenstein, a middle-aged patient with pneumonia who lives alone.



Each of these patients is unique. Although they share the same medical diagnosis, their needs and your nursing care differ dramatically. These differences stem from a variety of factors, one of the most significant of which is each patient's developmental stage. Throughout the life span, human beings are in a constant process of physical, cognitive, and emotional change, whether or not it is visible to the eye.

Theoretical Knowledge knowing **why**

In this chapter, you will learn principles and theories of growth and development that can form the foundation for planning and delivering effective patient care. You will also find a discussion of normal growth and development across the life span. A fundamentals course or textbook can provide only a basic foundation covering infant and child development. For situations in which you need more in-depth or specialized knowledge, refer to a child development or pediatric nursing textbook.

ABOUT THE KEY CONCEPTS

Development refers to the process of adapting to one's body and environment over time, which is enabled by increasing complexity of function and skill progression. A few examples of development are a child who comes to recognize right from wrong, an adolescent who decides on a vocation, and an older adult who recognizes the nearness of death. **Growth** refers to physical changes that occur over time, such as increases in height, sexual maturation, or gains in weight and muscle tone. Growth is the physical aspect of development; the rest is behavioral. As you read this chapter, you will see how the key concept of **stages** is intertwined with the concepts of growth and development.

HOW DOES DEVELOPMENT OCCUR?

The Greek philosopher Heraclitus said, "Nothing is permanent but change." We readily see this truth in the dramatic physical, cognitive, and emotional growth that children undergo from one month to another, but it is true also for adults. **Key Point:** ***Change is constant throughout the life span.***

What has been the most important force in your becoming the person you are now: characteristics that you inherited from your parents, or the environment in which you were raised?

For centuries, scientists have debated the effects of nature versus nurture on growth and development. **Nature** refers to genetic endowment, whereas **nurture** is the influence of the environment on the individual. The birth of a child can be compared to the planting of a tulip. Within the bulb is nearly everything it needs to sprout; but whether it reaches its full potential—that is, grows into a flowering plant—also depends on the environment. Is the soil rich in nutrients? Is there adequate sunshine? Water? Similarly, the joining of ovum and sperm forms chromosomes that determine appearance, characteristics, and affect how the child will grow and develop. However, environmental factors, such as access to food, love, affection, and education, also affect how the child develops and thrives.

Principles of Growth and Development

Important principles of growth and development include the following.

Growth and Development Usually Follow an Orderly, Predictable Pattern However, the timing, rate of change, and response to change are unique for each individual. For example, all children learn to sit before they walk. One child may learn to sit at 6 months of age and walk at 10 months; another child may first sit at 7 months and not walk until 15 months. Each of these children is developing in the same pattern, and progressing within a normal time frame.

Growth and Development Follow a Cephalocaudal Pattern, Beginning at the Head and Progressing Down to the Chest, Trunk, and Lower Extremities To illustrate cephalocaudal *growth*, when an infant is born, the head is the largest portion of the body. In the first year, the head, chest, and trunk gain in size, yet the legs remain short. Growth of the legs is readily apparent in the second year. An example of cephalocaudal *development* is the tendency of infants to use their arms before their legs.

Growth and Development Proceed in a Proximodistal Pattern beginning at the center of the body and moving outward. Proximodistal *growth* occurs in utero, for example, when the baby's central body is formed before the limbs. As an example of proximodistal *development*, the infant first begins to focus his eyes; then lifts the head; later pushes up and rolls over. As the infant gains strength and coordination distally, he will crawl and later walk.

Simple Skills Develop Separately and Independently Later they are integrated into more complex skills. Many complex skills represent a combination of simple skills. For example:

- Feeding yourself requires the ability to find your mouth, grasp an object, control movement of that object, coordinate movement of the hand from the plate to the mouth, and swallow solid food.
- If you have ever tried to learn to play a musical instrument, you are familiar with this principle. You must master simple steps before you are able to play a tune.

Each Body System Grows at its Own Rate This principle is readily apparent in fetal development and at the onset of puberty. In the years leading up to puberty, the cardiovascular, respiratory, and nervous systems grow and develop dramatically, yet the reproductive system changes very little. Puberty is a series of changes that leads to full development of the reproductive system and also triggers growth in the musculoskeletal system.

Body System Functions Become Increasingly Differentiated Over Time Have you ever seen a newborn respond to a loud noise? The newborn's startle response involves the whole body. With maturity, the response becomes more focused, for example, covering the ears. An adult is often able to state the location of the sound and distinguish the origin of the sound.

Theories of Development

Theories of development describe and explain patterns of development common to all people. Such theories provide a basis for your nursing interventions and clinical decision making. The needs of a 6-year-old differ greatly from those of a 25-year-old or a 65-year-old, even though they all may have the same medical diagnosis (e.g., asthma) or even the same nursing diagnosis (e.g., Anxiety). Understanding the tasks associated with a person's developmental stage (1) provides a basis for assessing whether behaviors are as expected or if they need further assessment, and (2) suggests specific ways in which to support and encourage the person's progress through the developmental stage.

Each developmental theory examines how humans develop and divides the life span into stages. Each stage represents a period of time that shares common characteristics. Most theories also identify tasks that are usually accomplished in each stage. An understanding of the following key developmental theories is essential to full-spectrum nursing practice.

Developmental Task Theory

Robert Havighurst theorized that learning is a lifelong process. He believed that a person moves through six life stages, each associated with a number of tasks that must be learned. Havighurst characterizes **developmental task** as "midway between an individual need and societal demand. It assumes an active learner interacting with an active social environment" (1971, p. vi). Failure to master a task leads to imbalance within the individual, unhappiness, and difficulty mastering future tasks and interacting with others. Table 9-1 presents the tasks associated with each stage of life. It is easy to evaluate a client's completion of Havighurst's broadly written tasks, but the nonspecific time frame limits this theory's usefulness for assessing whether an individual is developing within an expected range.

ThinkLike a Nurse 9-1

Which stage in Havighurst's developmental task theory contains the most complex tasks and would be the most difficult to master? Why?

Psychoanalytic Theory

Sigmund Freud was a pioneer in the science of human development. His psychoanalytic theory focuses on the motivation for human behavior and personality development. Freud believed human development is maintained by instinctual drives, such as libido (sexual instinct), aggression, and survival (Sadock & Sadock, 2010). Different drives predominate, depending on the age of the individual. Psychoanalytic theory became the foremost theoretical foundation of early 20th century psychotherapy. However, Freud developed his theory in the Victorian era, when societal norms were very strict. Sexual repression and male dominance over female behavior were the cultural standard. Many of today's social scientists question whether his theory should be applied to life in the 21st century.

In Freud's theory, the personality consists of the id, ego, and superego—different "parts" that develop at different life stages. Each factor, or force, has a unique function.

- The **id** represents instinctual urges, pleasure, and gratification, such as hunger, procreation, pleasure, and aggression. We are born with our id. It is dominant in infants and young children, as well as in older children and adults who cannot control their urges.
- The **ego** begins to develop around 4 to 6 months of age and is thought to represent reality. It strives to balance what is wanted (id) and what is possible to obtain or achieve.
- The **superego** is sometimes referred to as the conscience. This force develops in early childhood (age 5 or 6) as a result of the internalization of primary caregiver responses to environmental events.
- The **unconscious mind** is composed of thoughts and memories that are not readily recalled but unconsciously influence behavior.

In the mid-1950s, Freud's daughter, the psychologist Anna Freud, identified a number of **defense mechanisms**, which she described as thought patterns or behaviors that the ego makes use of in the face of threat to biological or psychological integrity (Townsend, 2011). In other words, defense mechanisms protect us from excess anxiety. For example, after receiving a failing grade in chemistry, a student might refuse to think about it, intellectualize reasons why she failed, blame her teacher, or compensate by emphasizing her A grade in psychology. All people use defense mechanisms to varying degrees. For a comprehensive discussion of defense mechanisms, see Chapter 12 and Table 12-1.

Freud identified five stages of psychosexual development (Table 9-2). He believed that human development is perpetuated by instinctual drives, such as libido (sexual instinct), aggression, and survival (Sadock & Sadock, 2010). These drives have varying emphases, depending on the age of the individual.

KnowledgeCheck 9-1

- According to Freud, which motivator of personality is based in reality?
- Which is referred to as our conscience?
- What is the purpose of defense mechanisms?

Cognitive Development Theory

Swiss psychologist Jean Piaget studied his own children to understand how humans develop **cognitive abilities** (i.e., the ability to think, reason, and use language).

Table 9-1 ➤ Havighurst's Developmental Task Theory

STAGE	TASKS
Infants & Toddlers	**Physical Development** ■ Walking ■ Taking solid foods ■ Talking ■ Controlling bowel and bladder elimination ■ Learning sex differences and sexual modesty **Cognitive & Social Development** ■ Acquiring psychological stability ■ Forming concepts; learning language ■ Getting ready to read
Preschool & School Age	**Physical Development** ■ Learning physical skills necessary for ordinary games **Cognitive & Social Development** ■ Building wholesome attitudes toward oneself as a growing organism ■ Learning to get along with age-mates ■ Learning masculine or feminine social role ■ Acquiring fundamental skills in reading, writing, and calculating ■ Developing concepts necessary for everyday living ■ Developing a conscience, morality, and a scale of values ■ Achieving personal independence ■ Acquiring attitudes toward social groups and institutions
Adolescents	**Physical Development** ■ Accepting one's physique and using the body effectively **Cognitive & Social Development** ■ Achieving new and more mature relations with age-mates of both sexes ■ Achieving a masculine or feminine social role ■ Developing emotional independence from parents and other adults ■ Preparing for future marriage and family life ■ Preparing for a career ■ Acquiring a set of values and an ethical system to guide behavior; developing an ideology ■ Aspiring to and achieving socially responsible behavior
Young Adults	■ Choosing a mate ■ Achieving a masculine or feminine social role ■ Learning to live with a partner ■ Rearing children ■ Managing a home ■ Establishing an occupation ■ Taking on community responsibilities ■ Finding a compatible social group
Middle Adults	**Physical Development** ■ Adjusting to the physiological changes of middle age

Table 9-1 ➤ Havighurst's Developmental Task Theory—cont'd

STAGE	TASKS
	Cognitive & Social Development ▪ Assisting teenage children to become responsible and happy adults ▪ Achieving adult civic and social responsibility ▪ Reaching and maintaining satisfactory performance in one's occupational career ▪ Developing adult leisure-time activities ▪ Relating oneself to one's spouse as a person
Older Adults, refer to Chapter 10.	

Source: Havighurst, R. J. (1971). *Developmental tasks and education* (3rd ed.). New York: Longman.

Table 9-2 ➤ Freud's Stages of Psychosexual Development

AGE	STAGE	DESCRIPTION
Birth–18 mo	Oral	The infant's primary needs are centered on the oral zone: lips, tongue, mouth. The need for hunger and pleasure are satisfied through the oral zone. Trust is developed through the meeting of needs. When needs are not met, aggression can manifest itself in the form of biting, spitting, or crying.
18 mo–3 yr	Anal	Neuromuscular control over the anal sphincter allows the child to have control over expulsion or retention of feces. This coincides with the child's struggle for separation and independence from caregivers. Successful completion of this stage yields a child who is self-directed, cooperative, and without shame. Conversely, the anal child will exhibit willfulness, stubbornness, and need for orderliness.
3–6 yr	Phallic	The focus is on the genital organs. This coincides with the development of gender identity. Unconscious sexual feelings toward the parent of the opposite sex are common. Children emerge from this stage with a sense of sexual curiosity and a mastery of their instinctual impulses.
6–12 yr	Latency	Ego functioning matures, and sexual urges diminish. The child focuses his energy on same-sex relationships and mastery of his world, including relationships with significant others (teachers, coaches).
13–20 yr	Genital	Puberty causes an intensification of instinctual drives, particularly sexual. The focus of this stage is the resolution of previous conflicts and the development of a mature identity and the ability to form adult relationships.

According to Piaget, cognitive development requires three core competencies: adaptation, assimilation, and accommodation. **Adaptation** is the ability to adjust to and interact with one's environment. To be able to adapt, one must assimilate and accommodate. **Assimilation** is the integration of new experiences with one's own system of knowledge. **Accommodation** is the change in one's system of knowledge that results from processing new information. For example, an infant is born with an innate ability to suck. Presented with the mother's nipple, the infant is able to assimilate the nipple to the behavior of sucking. If given a bottle, the infant can learn to accommodate the artificial nipple. However, the baby may adapt by accepting the artificial nipple only from the father, crying and fussing if the mother offers a bottle instead of her breast.

According to Piaget, cognitive development occurs from birth through adolescence in a sequence of four stages: sensorimotor, preoperational thought, concrete operations, and formal operations (Table 9-3). A child must complete each stage before moving to the next. The rate at which a child moves through the four stages is determined by the inherited intellect and the influence of the environment. Piaget does not address cognitive development after adolescence.

KnowledgeCheck 9-2

- According to Piaget, what core competencies are necessary for cognitive development?
- During which stage is the child the most egocentric?
- When does abstract thinking develop?

Table 9-3 ➤ Piaget's Stages of Cognitive Development

STAGE	AGE	CHARACTERISTICS OF DEVELOPMENT
Sensorimotor	Birth–2 yr	■ Learns the world through the senses. ■ Displays curiosity. ■ Shows intentional behavior. ■ Begins to see that objects exist apart from self. ■ Begins to see objects as separate from self.
Preoperational	2–7 yr	■ Uses symbols and language. ■ Sees himself as the center of the universe: egocentric. ■ Thought based on perception rather than logic.
Concrete operations	7–11 yr	■ Operates and reacts to the concrete: What is perceived is actual. ■ Egocentricity diminishes, can see from others' viewpoints. ■ Able to use logic and reason in thinking. ■ Able to conserve: to see that objects may change but recognizes them as the same. (e.g., water may change to ice, or a tower of blocks is the same as a long fence of blocks).
Formal operations	11–adolescence	■ Develops the ability to think abstractly: to reason, deduce, and define concepts in a logical manner. ■ Some individuals do not develop the ability to think abstractly.

Psychosocial Development Theory

In the 1950s Eric Erikson introduced his theory of psychosocial development. He was strongly influenced by Freud but believed that personality continues to evolve throughout the life span as the person interacts with the social world. He hypothesized that individuals must negotiate eight stages as they progress through the life span. Most people successfully move from stage to stage; however, a person can regress during times of stress to earlier stages or be forced to face tasks of later stages because of unforeseen life events, such as terminal illness. Failure to successfully move through a stage leads to maladjustment. Erikson's theory is widely used in nursing and healthcare. Below are Erikson's eight stages.

Stage 1: Trust Versus Mistrust (Birth to About 18 Months) The child develops a sense of trust in himself and the external world as a result of having his needs consistently met. This is the beginning of self-confidence. An infant who does not have his needs met develops a sense of mistrust and suspiciousness in others that will affect future interpersonal relationships.

Stage 2: Autonomy Versus Shame and Doubt (About 18 Months to 3 Years) The goal is for the child to develop self-control and independence while maintaining self-esteem. This requires an ability to cooperate and express feelings and thoughts. Failure to successfully complete this stage will lead to an adult who lacks self-confidence and feels controlled by others and who may exhibit extreme compliance (self-restraint) or defiance.

Stage 3: Initiative Versus Guilt (3 to 5 Years) The focus of this stage is to develop initiative by gradually assuming responsibility and developing self-discipline. During this stage, the superego (conscience) develops, and the child learns to manage impulses. Failure to develop initiative leads to guilt, limited creativity, lack of self-confidence, and pessimism.

Stage 4: Industry Versus Inferiority (6 to 11 Years) In this stage, the child learns that recognition comes through achievement and completion of tasks. This success occurs primarily in school. The adult who has not fulfilled the tasks of this stage will demonstrate a sense of inadequacy in all areas of life.

Stage 5: Identity Versus Role Confusion (11 to 21 Years) This stage coincides with puberty. The adolescent develops a sense of self and begins to make decisions about the future. Social groups serve as a place to test out ideas and behaviors. Healthy role models facilitate the development of identity. A person who fails to recognize his abilities and sense of self is unable to experience a solid place in the world. This is manifested by dysfunctional interpersonal relationships and occupational performance. Delinquent and rebellious behavior may be prominent when the task of identity formation is not met.

Stage 6: Intimacy Versus Isolation (21 to 40 Years) Erikson (1963) defines intimacy as "the capacity to commit himself to concrete affiliations and partnerships and to develop the ethical strength to abide by such commitments" (p. 263). Isolation is the avoidance of intimacy. The task at this stage is to develop a commitment to work and relationships. Failure to do so will result in impersonal relationships and difficulty with maintaining a job.

Stage 7: Generativity Versus Stagnation (40 to 65 Years) The goal of this stage is to be creative and productive. Often this is accomplished through work or relationships, such as raising healthy, functional children or contributing to society by developing a distinguished career, for example in nursing. The person who fails to achieve generativity (the desire and motivation to guide the next generation) may manifest stagnation in the form of superficial relationships and self-absorption.

Stage 8: Ego Integrity Versus Despair (Over 65 Years) The task of this stage is the acceptance of one's life, worth, and eventual death. Ego integrity reflects a satisfaction with life and an understanding of one's place in the life cycle. In despair, a sense of loss, discomfort with life and aging, and a fear of death are seen.

ThinkLike a Nurse 9-2

Review the case study in the Meet Your Patients section of the chapter. Based on Erikson's psychosocial development theory, what kind of behavior would you anticipate from Carrie?

Moral Development Theory: Kohlberg

Lawrence Kohlberg (1968) developed his theory of moral development by studying the development of 84 boys over a period of 20 years. Observing their responses to moral dilemmas, Kohlberg hypothesized that a person's level of moral development can be identified by analyzing the rationale he gives for action in a moral dilemma. In this theory, moral reasoning appears to be somewhat age-related, and moral development is based on one's ability to think at progressively higher levels. Increased maturity provides some degree of higher-level thinking but does not guarantee the ability to function at the highest cognitive or moral levels. Kohlberg described the following levels; each has two stages (Kohlberg, 1968, 1981; Waugh, 1978). Not all people are able to achieve the higher levels. To see a table with expanded information about the stages,

Go to Student Resources: Chapter 44, **ESG Table 44-1, Stages of Moral Development: Kohlberg,** on Davis*Plus.*

Level I. Preconventional The person conforms to cultural rules and labels of good and bad, but interprets them in terms of punishment and reward or in terms of the physical power of those who enforce the rules. Children ages 4 to 10 years are usually at this level; some adults are, as well.

Stage 1—punishment–obedience orientation (right action is that which avoids punishment)
Stage 2—personal interest orientation (right action is that which satisfies personal needs)

Level II. Conventional The person perceives that meeting the expectations of the family, group, or society is valuable in its own right, regardless of the consequences of the actions. More than just conforming, the person is loyal to the social order and identifies with those involved in it. Others set the standards, but motivation to follow them is internal.

Stage 3—"good boy–nice girl" orientation (right actions are those that please others)
Stage 4—law-and-order orientation (right action is following the rules)

Level III. Postconventional, Autonomous, or Principled The person makes an effort to define moral values and principles that have validity apart from society, groups, or persons in power. At this level it becomes possible for conflict to occur between two socially accepted standards, and the person attempts to decide rationally between them. Both the standards and the decision are internal.

Stage 5—legalistic, social contract orientation (right action is decided in terms of individual rights and standards agreed upon by the whole society)
Stage 6—universal ethical principles orientation (right action is determined by conscience and abstract principles such as the Golden Rule)

Moral Development Theory: Gilligan

Although all of his research subjects were male, Kohlberg claimed that his sequence of stages applies equally to everyone. The validity of his theory for women has been sharply criticized, most prominently by Carol Gilligan (1982, 1993). To address the moral development of women, Gilligan proposed an alternative theory that incorporates the concepts of caring, interpersonal relationships, and responsibility. She described a three-stage approach to moral development.

Stage 1: Caring for Oneself In this stage, the focus is providing for oneself and surviving. The individual is egocentric in thought and does not consider the needs of others. When concerns about being selfish begin to emerge, the individual is signaling a readiness to move to stage 2.

Stage 2: Caring for Others At this level, an individual recognizes the importance of relationships with others. The person is willing to make sacrifices to help others, often at the expense of her own needs. When she recognizes the conflict between caring for oneself and caring for others, the individual is ready to move to stage 3.

Stage 3: Caring for Self and Others This represents the highest stage of moral development. In this stage, care is the focus of decision making. The individual carefully balances her own needs against the needs of others to decide on a course of action.

See Chapter 44 for more discussion of moral development.

Spiritual Development Theory

James Fowler, a minister, defined faith as a universal human concern and as a process of growing in trust. He noticed that his congregants had very different approaches to faith, depending on their age. Basing his studies on the work of Piaget, Erikson, and Kohlberg, he developed a theory of faith development, which includes a pre-stage (stage 0) and six stages of faith (Fowler, 1981).

- ***Stages 0, 1, and 2*** are closely associated with evolving cognitive abilities. In these stages, faith depends largely on the views expressed by the parents, caregivers, and those who have significant influence in the life of the person.
- ***Stage 3*** coincides with the ability to use **logic** and **hypothetical thinking** to construct and evaluate ideas. At this point, faith is largely a collection of conventional, unexamined beliefs. Fowler's studies demonstrated that approximately one-fourth of all adults function at this level or lower.
- ***Stages 4, 5, and 6*** represent increasing levels of refinement of faith. With each increase in level there is decreasing likelihood that an individual can attain this stage of development. Fowler found that very few people achieve stage 6.

To see more details about Fowler's stages,

Go to Student Resources: Chapter 9, **ESG Table 9-1, Fowler's Theory of Faith Development,** on Davis*Plus*.

The rest of this chapter describes the human life span as a series of developmental stages: physical, cognitive, and psychosocial. Development and common health problems are discussed for each stage. To simplify organization, you will find nursing assessments and interventions included with each stage rather than together in a single Practical Knowledge section.

THE GESTATIONAL PERIOD: CONCEPTION TO BIRTH

The time between conception and birth is called the **gestational period.** Human gestation (pregnancy) is calculated from the first day of the mother's last menstrual period and lasts approximately 40 weeks (280 days). Full discussions of pregnancy and childbirth are beyond the scope of a fundamentals text. If you need more information, refer to a maternal–child health textbook.

Fetal Development During Gestation

Pregnancy is usually divided into three trimesters, each lasting about 13 weeks.

First Trimester The first 8 weeks is known as the **embryonic phase**. It begins when an egg released from a woman's ovary unites with a sperm cell, usually in one of the woman's fallopian tubes. This is called **fertilization** (or conception). Continual cell division leads to the development of a tiny ball of cells called the **morula**, which travels toward the woman's uterus for a period of about 7 days before implanting there as a multicelled **blastocyst**. Upon implantation, three primary germ layers begin to differentiate, and the **embryo** begins to resemble a tiny organism with a head and tail. By week 4, the brain, heart, and liver have begun to form, and tiny limb buds are present. As early as 6 to 7 weeks, you can hear the fetal heartbeat with a fetal ultrasound Doppler. By the end of week 8, all organs are formed, and the embryo is then called a **fetus**.

Second Trimester Rapid fetal growth and further development of the body systems characterize the second trimester. At about 16 to 20 weeks of pregnancy, the mother can feel her fetus move, a sensation called *quickening*. At the end of the second trimester, the fetus has all organs and body parts intact that will develop during the last trimester. The kidneys are intact and begin to produce urine, although they do not effectively concentrate it until late in the third trimester. The lungs are formed, but they do not contain enough of the substance to keep air sacs open after birth until late in the third trimester.

Third Trimester The fetus continues to grow in size and add subcutaneous fat. Body systems mature in preparation for extrauterine life. If born prematurely during this trimester, the newborn may be able to survive with intensive care. By week 37, the fetus is considered full term; after 41 weeks it is considered post-term. A normal full-term baby weighs, on average, 5 lb 8 oz to 8 lb 13 oz (2,500 to 4,000 g) and is 20 in. (50 cm) long. If you would like to see a concise timeline of fetal growth,

Go to Chapter 9, **Tables, Boxes, Figures: ESG Table 9-2,** on Davis*Plus*.

Maternal Changes During Pregnancy

A woman's health during pregnancy is essential for healthy, sustained growth and development of the fetus. It is important for young women to develop good health practices well before conception, including exercise, a balanced diet, smoking cessation, avoidance of alcohol, and regular dental checkups. The growing fetus depends entirely on the placenta for oxygen and nutrition. Therefore, many of the physical changes that the woman experiences during pregnancy are for the purpose of increasing blood flow through the placenta to the baby. A pregnant woman's heart enlarges slightly and the chest wall expands so that respiratory rate and cardiac output increase significantly. In fact, the woman's normal blood flow increases by about 30% by the 35th week of pregnancy.

First Trimester Menses typically cease. Hormone shifts, primarily in progesterone and estrogen, may cause the pregnant women to experience morning sickness, fullness in the pelvic area, breast enlargement and tenderness, urinary frequency, and fatigue.

Second Trimester The uterus enlarges and hyperpigmentation of the skin occurs, often creating a dark line from the umbilicus to the symphysis pubis and causing the nipples to darken. Other common changes include mottling of the cheeks and forehead, swelling and bleeding of the gums, and "stuffiness" from swelling in the mucous membranes in the nose. The woman begins to feel the fetus moving and may experience mild contractions (called Braxton Hicks).

Third Trimester Fetal movement is the predominant feature of the latter period of pregnancy. The breasts begin to produce and secrete colostrum in preparation for lactation. Pressure from the enlarged fetus may cause shortness of breath and urinary frequency.

Psychosocial Challenges As the birth of a child is a life-changing condition, it is normal for women to feel ambivalent about pregnancy at first, but these feelings usually resolve in the second trimester. The pregnant woman must adapt to changes in body image, role changes, concerns about sexuality, fears about labor and delivery, concern for the baby's health and safety, planning for care of the child after delivery, financial pressures, and stresses involving employment during pregnancy.

Common Health Problems During Gestation

Blood circulating through the placenta carries nutrients and oxygen to the fetus and toxins and metabolic wastes away from the fetus. Other substances also cross the placenta. For example, **teratogens** are substances that interfere with normal growth and development.

Key Point: ***Because the brain and other vital organs develop during the first trimester, this is the time when the fetus is most vulnerable to teratogens.***

- *Alcohol* can cause birth defects, growth retardation, developmental delay, and impaired intellectual development.
- *Nicotine* interferes with the transport of oxygen to the fetus, contributing to premature birth, low birth weight, and learning disabilities.
- *Morphine, heroin, methadone, and other narcotics,* when used during pregnancy, cause the newborn to suffer from withdrawal at birth. Symptoms include tremors, restlessness, hyperactive reflexes, poor temperature control, vomiting and diarrhea, high-pitched cries, seizures, and sometimes death.
- *Cocaine, including crack, and methamphetamines* are highly addictive and potentially harmful to the fetus. Infants born to cocaine users and crack users are more likely to suffer from growth retardation and to have sleep disturbances, hyperactive reflexes, irritability, feeding difficulties, attention and behavioral disorders, and learning disabilities at school age. These infants are also more likely to die from **sudden infant death syndrome (SIDS)**, the sudden, unexplained death of an infant (discussed in more detail in the section about infancy).
- *Medications*, both prescribed and over the counter, can have teratogenic effects. Examples include the acne medication isotretinoin (Accutane), tetracycline (Achromycin), phenytoin (Dilantin), and lithium (Lithobid). Pregnant women should check with their primary care provider before taking any medications or herbal remedies.

Effects of Maternal Age The risk for preterm birth, low birth weight, and fetal death is higher for babies born to adolescent mothers. The risk of fetal death is also higher for mothers over age 40 (Centers for Disease Control and Prevention [CDC], n.d.d.). Furthermore, the risk of conceiving a child with Down syndrome (trisomy 21) and other congenital anomalies increases for each year over the age of 35, but dramatically after age 42.

Effects of Maternal Health Maternal diseases, such as *rubella, syphilis, and gonorrhea*, although not common, can cause fetal blindness, deafness, or fetal loss. *Cytomegalovirus (CMV)* is a common, flu-like viral infection in adults. If the mother acquires CMV during pregnancy, the fetus can suffer intrauterine growth retardation, poor brain growth, enlarged liver (hepatomegaly) with jaundice, irritation of the lung (pneumonitis), and bleeding problems. *Toxoplasmosis* can be transmitted to the unborn fetus through handling of contaminated cat litter. If the mother experiences an outbreak of genital herpes at the time of delivery, there is risk of passing the virus to the infant. *Maternal diabetes* can result in a low blood sugar after birth and also have lasting effects on the fetus. Failure to control the diabetes may lead to neural tube and heart defects, as well as **macrosomia** (large body size).

Effects of Maternal Nutrition Even before pregnancy, nutrition is vital to the fetus. Appropriate healthy weight management before conception and appropriate maternal weight gain during pregnancy contributes to appropriate fetal birth weight and reduce the risk of fetal illness and infections. The recommended average weight gain for a pregnancy is 25 to 35 pounds. The expected weight gain is higher for underweight women and lower for overweight women.

Folic acid deficiency in the first weeks of pregnancy—typically before the woman even knows she is pregnant—is a risk factor for neural tube defects, such as spina bifida. Neural tube defects occur during the first weeks of fetal development.

ASSESSMENT

Routine prenatal visits and screenings usually take place monthly until 28 weeks, then every 2 weeks until 36 weeks, then weekly until birth. In addition to vital signs, weight, fetal heart tones, nutritional status, and other measures of maternal–fetal well-being should be assessed at each visit (Fig. 9-1).

FIGURE 9-1 After establishing a baseline weight in early pregnancy, monitor for appropriate weight gain at each prenatal visit.

Assess for common discomforts associated with pregnancy, such as nausea, fatigue, and back pain. Preexisting conditions (e.g., diabetes) must be carefully monitored. Inquire about medication use, including over-the-counter drugs (OTCs), the use of alternative therapies, and other substances. Also screen for risk factors for complications of pregnancy, such as the following:

- **Birth defects.** Women who are at higher risk for a fetus with a birth defect are those with advanced maternal age (over age 40), family history of congenital anomalies, maternal diabetes with insulin use, viral infection during pregnancy, and exposure to high levels of radiation. Blood markers and ultrasound screening are done to detect neural tube defects, abdominal wall defects, trisomy 21 (Down syndrome), and trisomy 18.
- **Gestational diabetes.** Screening for gestational diabetes is most often done between 24 and 28 weeks' gestation—earlier if there is a history of gestational diabetes with a previous pregnancy.
- **Group B streptococcus.** The Centers for Disease Control and Prevention (CDC), the American Academy of Pediatrics (AAP), and the American College of Obstetricians and Gynecologists (ACOG) recommend that pregnant women be screened for group B streptococcus between 35 and 37 weeks' gestation.

INTERVENTIONS

Key Point: ***One of the most important nursing interventions for promoting maternal and fetal health is to facilitate and teach the importance of early and continuing prenatal care.*** Early prenatal care can identify complications of pregnancy, prevent some of the effects of maternal diseases such as diabetes, and provide an opportunity for patient education.

Key Point: ***You should stress that maternal nutrition is important for a healthy baby. The mother's food intake should be well balanced.*** The recommended dietary allowances of vitamins and minerals for the pregnant woman range from 25% to 50% higher than for the nonpregnant woman. Pregnant women should increase their caloric intake by 10% to 15%. Inadequate protein affects formation of the placenta and fetal brain development. Increasing folic acid (also called folate) intake to 400 to 800 mcg daily reduces the risk of neural tube defects. Women who are of childbearing age should follow these guidelines daily rather than waiting for pregnancy to occur. This will help achieve a national goal for the year 2020 of reducing the incidence of neural tube defects (U.S. Department of Health and Human Services [USDHHS], 2010b). You can find the national goals for 2020 on the Healthy People 2020 Web site,

http://www.healthypeople.gov/

Other teaching topics include the following:

Information regarding sexually transmitted infections (STIs) and vaginal infections
Information about urinary tract infections
Exercise patterns
Child care
Fetal growth and development
Hazardous substances to avoid
Avoiding use of OTCs medication without approval from the supervising provider
Self-care measures for common discomforts of pregnancy
Danger signs that alert the woman to call her care provider
Signs of impending labor; when to go to the birthing unit

KnowledgeCheck 9-3

- What are the most common health concerns to monitor for in the gestational period?
- Identify at least four important topics for health teaching with the expectant mother.
- Why is early prenatal care so important?

THE NEONATAL PERIOD: BIRTH TO 28 DAYS

During the **neonatal period** (the first month of life), the newborn's primary task is to stabilize the body's major organ systems and adapt to life outside the uterus. Behaviors are primarily reflexive.

Physical Development of the Neonate

Growth The normal full-term newborn weighs between 2,500 and 4,000 g (5 lb 8 oz to 8 lb 13 oz). Lower birth weights are seen with prematurity, whereas higher birth weights are associated with gestational diabetes. The neonate measures between 18 and 22 in. (46 and 56 cm) in length (Fig. 9-2) and the arms are slightly longer than the legs.

At birth, the head is one-fourth the total body length, with a head circumference of 33 to 35 cm (13 to 14 in.). For a few days, it may appear asymmetrical because of molding during vaginal birth. The skull consists of six soft bones separated by sutures composed of cartilage (Fig. 9-3), with anterior and posterior **fontanels** (soft spots). These spaces allow room to accommodate the rapid growth of the infant's brain during the first months of life.

Respirations At birth, the most critical adaptation is the *establishment of respirations*. Pressure on the baby's chest during vaginal birth helps eliminate amniotic fluid from the lungs in preparation for breathing. The normal newborn's respirations are irregular, shallow, and 30 to 50 breaths/min, with brief periods of **periodic breathing** (pauses in breathing).

Cardiovascular System The cardiovascular system must also adapt to the change from placental blood flow to independent circulation. The average heart rate of a newborn is 120 to 140 beats/min, with slightly lower rates at rest and higher rates with activity or crying. Poor peripheral circulation causes a bluish coloration of the hands and feet; this is normal and usually disappears within a few hours of birth.

FIGURE 9-2 Measuring the length of a newborn.

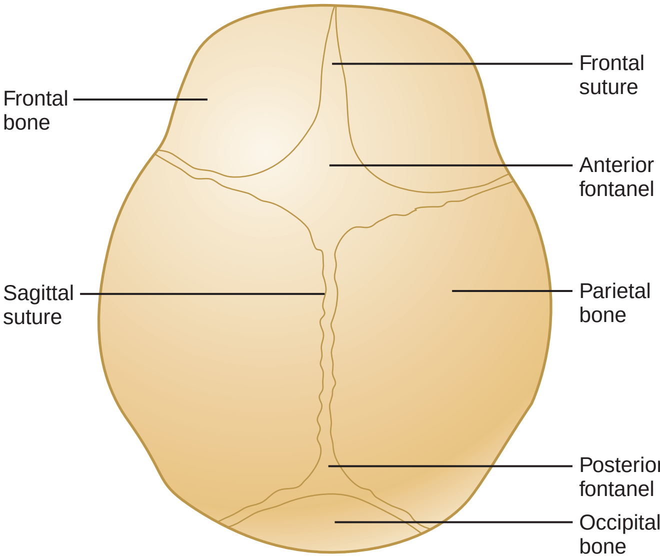


FIGURE 9-3 Sutures and fontanel of the newborn's skull.

Thermoregulation Thermoregulation is another critical task at birth. The newborn can produce adequate heat but cannot protect against heat loss. Heat may be lost by exposure to cool air temperatures, by contact with cooler solid surfaces, or by evaporation of moisture from the skin. The normal newborn's temperature is close to that of an adult. To assist in thermoregulation, it is important to keep the newborn warm and dry, with a cap on his head.

Elimination At birth, the kidneys produce 15 to 60 mL of urine per kilogram of body weight per day. During the first 24 hours, the newborn voids 5 to 25 times. Newborns have limited ability to concentrate urine. At birth, the newborn's lower intestine is filled with **meconium**, a sticky, greenish-black substance formed from amniotic fluid and intestinal secretions. Meconium is usually passed within 12 hours of birth, and the stool progressively changes in color to yellow. The full-term infant is able to swallow, digest, metabolize, and absorb proteins and simple carbohydrates. Stomach capacity varies from 30 to 90 mL, depending on the infant's weight. Normal colonic bacteria are established within a week of birth.

Epidermis and Dermis The epidermis and dermis are very thin at birth and can be easily damaged. Infants are born with varying degrees of **vernix caseosa**, a cheese-like protective covering for the skin. **Milia**, tiny white spots, may be present on the newborn's face, and the area over the sacrum may show a darkly pigmented area called a **mongolian spot**. All such features disappear spontaneously.

Neuromuscular System The neuromuscular system is not completely developed at birth. However, the following **reflexes** (automatic responses) are present at birth. Selected reflexes are illustrated in Figure 9-4.

- **Rooting.** Rooting is elicited by stroking the infant's cheek with the nipple or finger. In response, the newborn turns his head toward the stimulus, opens his mouth, takes hold and sucks. This reflex disappears by 3 to 4 months of age.
- **Sucking Reflex.** The sucking reflex is elicited by touching the infant's lips.
- **Swallowing Reflex.** The swallowing reflex is coordinated with sucking and usually occurs without gagging, coughing, or vomiting. This response is weak with prematurity or neurological defect.
- **Grasp Reflex.** The grasp reflex is triggered by placing a finger in the palm of the infant's hand (palmar) or at the base of the toes (plantar). The infant's fingers curl around the examiner's fingers, or the toes curl downward. The palmar reflex lessens by 3 to 4 months, and the plantar reflex lessens by 8 months.

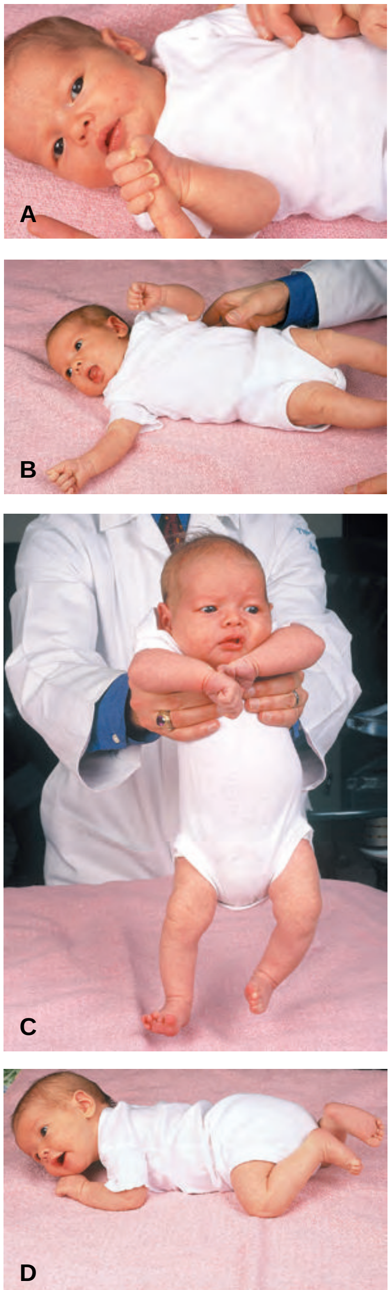

FIGURE 9-4 Several infant reflexes: *A*, the palmar grasp reflex; *B*, tonic neck reflex; *C*, stepping reflex; and *D*, crawling reflex.

- **Tonic Neck or Fencing Reflex**. The tonic neck, or fencing, reflex is elicited by rotating the infant's head to the left with the left arm and leg extended and the right arm and leg flexed. Turn the head to the right, and the extremities assume the opposite posture. The response disappears by 3 to 4 months.
- **Moro or Startle Reflex.** This reflex is elicited by placing the infant on a flat surface and striking the surface to startle the infant. Symmetrical abduction and extension of the arms are expected as an indicator of overall neurological health. The fingers fan out and form a C with the thumb and forefinger. This response is absent by 6 months.
- **Stepping Reflex**. Elicit the stepping reflex by holding the infant vertically, allowing one foot to touch a surface (e.g., tabletop). The infant will simulate walking by alternating flexion and extension of the feet during the 3 to 4 weeks of life.
- **Crawling Reflex.** The crawling reflex is noted by placing the infant on her abdomen. The newborn makes crawling movements with her arms and legs. This response should disappear by 6 weeks of age.
- **Babinski Reflex.** The Babinski reflex is elicited by stroking upward along the lateral aspect of the sole. A positive response occurs when the toes hyperextend and the great toe dorsiflexes. An infant who does not respond in this manner should undergo a neurological evaluation. This reflex disappears as the infant begins to walk or between 12 and 18 months.

Cognitive Development of the Neonate

In the first month of life, the neonate responds to stimuli in a reflexive manner. Piaget described this as the *sensorimotor phase.* Despite the newborn's limited voluntary abilities, the sensory functions are well developed.

Vision At birth, the eyes are treated with antibiotics to prevent blindness caused by gonorrhea. After the ointment has been absorbed, the newborn begins to fixate on an object. During the first few weeks of life, the infant focuses on objects, following from side to side with his gaze. The infant has visual preferences for the human face, black-and-white contrasting patterns, and large objects. Some newborns appear cross-eyed because of undeveloped ocular muscle control; this normally resolves in 3 to 4 months. Eye color varies from dark to slate gray to pale blue. Because the lacrimal apparatus is not fully developed, the newborn does not produce tears until at least week 4 of life.

Hearing and Smell Once the amniotic fluid drains from the ears, hearing is equivalent to that of an adult. Newborns react strongly to pungent odors by turning the head away from a smell and are able to distinguish their own mother's breast milk from that of other women. They will cry for their mother when her breasts are engorged and leaking.

Touch The newborn has a highly developed sense of touch, and his tactile sensation is surprisingly sophisticated, especially around the mouth, hands, and feet.

Psychosocial Development of the Neonate

The neonate calms when held or with other pacifying measures, such as a warm blanket, pacifier, and swaddling. Crying is the principal method for communicating a need or displeasure. Sometimes crying occurs simply because the neurological system is immature. Erikson identified the central developmental task of the first 18 months of life as developing a sense of trust. The neonate is completely dependent on his caretakers for all needs. Prompt responses to cries of discomfort create security and trust and promote **attachment**, emotional bonding between parent and child.

Common Health Problems of the Neonate

Respiratory Distress Respiratory distress is one of the most serious problems facing newborns. It occurs most commonly in infants born before the lungs mature, but can also be caused by aspiration of meconium during the birthing process. Newborns in respiratory distress are typically pale or mottled, with labored respirations, hypothermia, and flaccid muscle tone.

Birth Injuries Birth injuries may occur at the time of the birthing process. The following are three examples:

- **Caput succedaneum**, edema of the scalp that crosses the suture lines, results from head compression against the cervix during labor. The fluid is reabsorbed in 1 to 3 days.
- **Fracture of the clavicle** occurs with breech presentation or as a result of difficulty delivering a large baby whose shoulder gets stuck behind the mother's pelvic bones. Often no intervention is needed except for careful handling and supporting the affected bone.
- **Birth asphyxia** is a serious and potentially permanent injury resulting from perinatal events, such as a *cord prolapse* (compression of the umbilical cord), *placental abruption* (bleeding secondary to tear of the placenta), other interruptions of the blood supply between the baby and placenta, or delay in infant respiration after birth.

Congenital Anomalies Congenital anomalies (birth defects) may be visible at birth or may become apparent in the neonatal period. Treatment may be initiated, if appropriate. Congenital heart defects, fistulas, cleft lip and palate, and inborn metabolic problems are some common birth defects.

Infectious Microorganisms Infectious microorganisms that do not cause illness in older babies can cause sepsis for newborns, especially those born prematurely. Pregnant women should be screened prenatally for STIs, and treatment initiated, if possible. Newborns exposed to infections during the gestational period should be tested as soon as possible after birth.

Jaundice Jaundice is another risk for newborns. Within 48 to 72 hours after birth, the newborn's red blood cell (RBC) count normally begins to decrease. One by-product of RBC destruction is **bilirubin**, a yellowish pigment. If the newborn is not successful in eliminating the excess bilirubin, jaundice develops, giving the newborn's skin a yellowish cast. If the bilirubin level becomes too high, the newborn can suffer neurological consequences as the pigment enters the brain. Sunlight breaks down bilirubin; thus, phototherapy is a treatment of choice for jaundice.

Fetal Alcohol Syndrome Fetal alcohol syndrome may occur in infants of pregnant women addicted to alcohol. It is characterized by irregular facial features and cognitive deficits.

Women With Substance Addiction Newborns born to women who abuse substances during pregnancy are at risk for respiratory distress, behavioral abnormalities, and birth defects, as well as drug withdrawal.

ASSESSMENT

Physical assessment begins at birth. The initial assessment tool is the **Apgar scoring system**. The score is based on heart rate, respiratory effort, muscle tone, reflex irritability, and skin color. Each category is scored at 1 and 5 minutes after birth. The 1-minute score indicates how well the baby tolerated the birthing process; the 5-minute score indicates how well the baby is adapting to his new environment. A high score indicates fetal well-being. Prematurity, neuromuscular disease, and maternal sedation during the birthing process are all factors that can lower the Apgar scores. For a table to assist you with Apgar scoring,

Go to Chapter 9, **Assessment Guidelines & Tools, Apgar Scoring,** in Volume 2.

During the first 24 hours after birth, the nurse assesses the infant's transition to extrauterine life. For the first 6 to 8 hours, the newborn alternately cries and appears interested in the environment. The baby then enters the sleep stage, which lasts 2 to 4 hours. The heart and respiratory rates decrease and the infant is in a state of calm. After this restful phase, the infant is alert and responsive. The heart and respiratory rates again increase.

Shortly after birth, newborns are screened for a variety of genetic disorders. Most states require screening for phenylketonuria (PKU) (an inborn error of metabolism), hypothyroidism, galactosemia, and sickle-cell disease. You will also need to assess the following parameters:

Vital signs
Elimination (first urine and meconium)
Presence of congenital anomalies
Reflexes
Ability to breastfeed or take formula from a bottle
Skin integrity
Parent–infant attachment

INTERVENTIONS

The neonatal period is a time of transition. Feeding concerns and uncertainty about appropriate care are the primary reasons parents seek healthcare advice. Nursing interventions for the neonate are designed to smooth the transition to extrauterine life and help the neonate adjust to his new environment. Activities include the following:

- Thoroughly dry the neonate at birth and after bathing to prevent heat loss via evaporation. Also, wrap the neonate in blankets, and place her in her mother's arms or in a warmed crib.

- Assist the mother with breastfeeding or formula feeding. Often assistance is needed with the first few feedings as the newborn learns to latch on to the nipple.
- Teach parents the importance of providing warmth, nutrition, and a clean environment to prevent infection.
- Teach the caregivers about expected behavior, including crying, eating, and elimination.
- Provide circumcision care. **Circumcision** is surgical removal of the foreskin of the penis. Many male infants are circumcised a day or two after birth, although there is controversy over risks and benefits. Risks include hemorrhage, infection, and meatal stenosis. Benefits are said to include prevention of penile cancer and cervical cancer in a sexual partner. The main reason most parents elect circumcision for their infant is social, so their child looks like other family members and peers. Parental consent is required for this procedure. Care of the site depends on the procedure used. Whatever the procedure, regularly observe and teach parents to observe for hemorrhage, swelling, or oozing (signs of infection).

INFANCY: 1 MONTH TO 1 YEAR OF AGE

The remainder of the first year is known as **infancy**. This is a time associated with dramatic physical changes and acquisition of numerous skills.

Physical Development of the Infant

Growth During the first year of life, growth is very rapid. The full-term newborn loses approximately 8% to 10% of birth weight in the first days of life but will regain it by 2 weeks of age. The infant gains about 1½ pounds per month for the first 3 months. Birth weight doubles by 5 months of age and triples by 1 year. Length increases approximately 1 inch per month until 6 months of age; it then slows to 1 inch over the next 6 months. Head circumference increases by about 33% in the first year.

Eruption of Primary Teeth Eruption of teeth varies among children, but there is a distinct, predictable pattern. The first tooth typically appears between 6 and 8 months of age. First to appear are lower central incisors, followed by the upper central incisors.

Feeding Infants typically consume about 30 ounces of breast milk or formula per day by 4 months of age. Breastfeeding is recommended because it is considered the most complete nutritional source for infants up to 6 months of age. **Key Point:** ***Breastfeeding is accompanied by a lower incidence of food allergies, gastroenteritis, ear infections, and overweight in childhood, adolescence, and adulthood (Waldrop, 2008). In addition, breast milk supplies immunoglobulins that help the infant to resist infection.*** However, if breastfeeding is not possible or acceptable to the parents, the nurse should support the parents' choice of method. Most infants are physiologically ready to take solid foods between 4 and 6 months of age, but adequate nutrition can be maintained with breast milk or formula for a full year. The choices of when to begin introducing solid foods and what to use are often culturally determined, as is choice of when to wean.

Sleep Patterns Sleep patterns vary among infants. Generally by 3 to 4 months the infant has developed a night pattern of sleeping and can sleep approximately 10 hours. Infants vary in the number and length of naps they take, but the total numbers of hours they sleep per day is about 15.

Motor Development Motor development follows a predictable pattern. Box 9-1 lists typical milestones.

Cognitive Development of the Infant

Piaget describes the infancy phase of cognitive development as the *sensorimotor phase*. Although the neonate responds in a reflexive manner, the infant makes major strides in motor development and is able to vocally interact with caregivers. An infant's visual acuity and color discrimination allow her to see and explore the environment. Hearing becomes more discriminating, and infants please themselves by vocalizing with cooing, laughing, and repeating sounds they find pleasurable. By the 12th month, the infant is able to imitate sounds and understand simple words and may have a vocabulary of four or five simple words, such as "da-da."

BOX 9-1 ■ Milestones of Infant Development

- Infants can smile by the age of 3 months.
- By the age of 5 months, an infant can roll from abdomen to back.
- By 6 months, an infant can turn from back to abdomen.
- At 7 months, most infants can sit alone.
- Crawling on hands and knees occurs around 9 months.
- By the age of 10 months, the infant's pincer grasp is well enough developed to pick up finger foods; the child can move from a prone to sitting position.
- At 11 months, the infant can "cruise"—walk holding on to furniture.
- Many infants attempt their first independent steps by 12 months.
- By 12 months, many infants can pick up objects and let them go, put objects into a container, and take them out again. They typically can also find an object that has been hidden and are beginning to use objects, such as cups and combs, correctly, as when "combing dolly's hair."
- By 12 months, infants can typically respond to simple verbal requests and commands, such as "Stop!" or "No." They may also use simple gestures such as waving bye-bye or shaking their head no, and they may try to imitate adults' words.
- Psychosocial milestones include testing of caregivers to see what response is elicited by crying, refusals, and so on; anxiety with strangers; and strong preference for the primary caregiver (usually the mother).

At this stage, infants learn by doing. They develop a simple sense of cause and effect, delighting in the fact that squeezing a ball, for example, causes it to squeak, and repeating their experiment over and over again. By 12 months of age, the infant recognizes familiar objects and searches for them when they are out of sight.

Psychosocial Development of the Infant

In infancy the central task remains the development of trust. The response of the caregivers in the neonatal phase has set the tone for ongoing interaction between caregivers and child. Continued prompt responses to discomfort, cuddling, and stimulating interaction provide the infant with a sense of trust in the world.

Freud refers to infancy as the *oral stage*. The infant receives pleasure in sucking and learns to quiet herself by oral stimulation such as eating, sucking on a pacifier, or placing her hand in her mouth. At 2 or 3 months of age, infants begin to smile in response to others. At about 9 months they interact more with their environment and socialize with others. They enjoy simple games such as peek-a-boo and patty-cake.

Common Health Problems of the Infant

Common problems that cause distress for infants and their caregivers include the following.

Crying and Colic

Crying often alarms parents; however, it is a form of communication for the infant and a normal infant reaction to discomfort, cold, or hunger. A healthy infant will have "fussy" periods each day that may last up to 1 to 2 hours. Extended crying may be a sign of **colic**, a term used to describe frequent episodes of abdominal pain. The infant is often inconsolable during these episodes. The cause is unknown. Current theories include gulping of air, allergy or intolerance to formula or something that the breastfeeding mother ate, inability to digest the carbohydrates consumed, overstimulation, and parental anxiety. Colic typically disappears at about 3 months of age.

Failure to Thrive

Infants depend upon their caregivers for food, water, warmth, comfort, and love. An infant who is deprived of a comforting, responsive relationship with a mother or caregiver will not thrive even if supplied with adequate nutrition. The infant will fail to gain weight, be unable to meet age-appropriate developmental tasks, be malnourished, and may have difficulty interacting with others. This syndrome, known as **failure to thrive**, is exhibited, for example, in some infants in orphanages. Erikson believed the syndrome was proof of the essential nature of the trust versus mistrust stage. Notice, however, that failure to thrive can also stem from organic causes, such as disease or drug withdrawal.

Dental Caries

Dental caries (tooth decay) can develop as early as the end of the first year in infants allowed to sleep with a bottle containing anything other than water. Caries are caused by pooling in the back of the mouth of fluids containing sugar, such as breast milk, formula, or juice. If you need more information about dental problems, see Chapter 25.

Example Problem: Abuse, Neglect, and Violence

We have chosen abuse, neglect, and violence as the classic example of a problem of development because they form a problem that occurs in all developmental stages. You will read about it again and again in sections about other developmental stages, where we discuss how it manifests in those stages and suggest appropriate nursing interventions.

About 1 in 50 infants in the United States are neglected or abused, according to a national study (Brodowski, Nolan, Gaudiosi, et al., 2008). Nearly a third of the infants were 1 week old or younger when the maltreatment was reported. Child abuse may take the form of physical abuse, psychological maltreatment and neglect, or sexual abuse. Neglect is most commonly seen. Unexplained injuries, neurological defects, seizures, and respiratory difficulty are all overt signs of abuse. **Key Point:** ***Abusive head trauma (AHT) (previously known as shaken-baby syndrome), caused by violent shaking of an infant, is a form of abuse that causes severe brain injury but may not produce visible evidence of trauma. It can cause blindness and spinal cord damage, as well as broken bones.***

Factors associated with child abuse and neglect include low income status, low maternal education, nonwhite race, large family size, young maternal age, single-parent household, and parental psychiatric disturbances (National Guideline Clearinghouse [NGC], 2007; Schnitzer & Ewigman, 2008). Household composition is another risk factor: Young children living with unrelated adults, step-parents, or foster parents are at increased risk of fatal injury from maltreatment. Mothers, especially mothers in single-parent households, are two times more likely than fathers to be perpetrators of abuse (Schnitzer & Ewigman, 2008; Wilcox & Dew, 2008).

Unintentional Injury

Automobile accidents are a major cause of death in infants, often because the child was not properly restrained. Falls, burns, choking, and drowning are other common causes of accidental injury and death in infants. As infants mature, they may attempt to climb from cribs onto chairs or tables, or up or down ungated stairs. Their tendency to explore things with their mouths may lead to choking on small objects, such as bottle caps, buttons, and parts of toys. If you require more information about infant safety, refer to Chapter 24.

Sudden Infant Death Syndrome (SIDS)

SIDS is the sudden death of a previously healthy infant with no explainable cause. Even postmortem examinations fail to reveal a cause of death. The peak incidence is usually around 3 to 4 months of age, although it may occur up to 12 months of age. An increased incidence is associated with prematurity, low birth weight, male gender, African American race, smoking in the household, swaddling, and putting an infant to sleep in the prone position (Fig. 9-5). Breastfeeding and offering a pacifier at naptime and bedtime are thought to be preventive measures (Adams, Good, & Defranco, 2009).

ASSESSMENT

The infant typically has regular appointments with the pediatrician or primary care provider until at least 6 months of age. As a rule, visits are timed to coincide with the immunization schedule at 2, 4, 6, and 12 months. More frequent visits may be required if problems are identified. At each visit, measure the infant's growth and development and compare against standards for height, weight, head circumference, and gross and fine motor skills.

The Denver Developmental Screening Test (Denver II, 1990) is a frequently used standardized test to assess development. The Denver II evaluates four major areas: personal-social, fine motor skills, language, and gross motor skills. It requires specialized training to administer and evaluate.

You should be aware of factors that increase the risk for child abuse, and assess for abuse any time there is an injury that is not well explained by the parent's account of how it occurred. For further discussion about assessing for abuse,

Go to Chapter 9, **Procedure 9-1: Assessing for Abuse,** in Volume 2.

Also see the accompanying Highlights of Procedures box.

FIGURE 9-5 The "Back to Sleep" campaign teaches parents to place the infant in the supine position for sleeping.

Highlights of Procedures 9-1

For steps to follow in all procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the skill. Use these Procedure Highlights later to help you review key steps.

Procedure 9-1: Assessing for Abuse

- Use a nonjudgmental approach. Do not make assumptions.
- Take a health history, assessing for physical, sexual, and psychological abuse.
- Perform a physical assessment; ensure the integrity of evidence that may be needed for criminal prosecution.
- Assess whether injuries are consistent with history.
- Observe for signs of neglect.
- If appropriate, refer for help in escaping the abusive situation.
- If appropriate, refer parent, caregiver, or partner involved in abuse to hotlines or agencies focused on stopping the abuse.
- Report abuse according to agency and state guidelines.

INTERVENTIONS

Nursing interventions for the infant focus on health promotion, safety, and growth and development.

Nutrition Teach parents about adequate nutrition, adding foods to the diet, and expected elimination patterns. If breastfeeding is not possible, or is not the parents' method of choice, commercially prepared formulas

Quality and Safety Education for Nurses

Detecting and Preventing Abuse

Chapter-Related Concepts: *Age-Specific Assessments, Age-Specific Interventions*

Competency: *Teamwork and Collaboration: (Knowledge, Skills, Attitudes)**

Detection and prevention of abuse require collaborative efforts of the healthcare team. The goal of the collaborative approach is to reduce trauma to the victims during the investigation and assessment of the patient. The team (comprising members from Child Protective Services [DCFS], Law Enforcement, State's Attorney's Office, Medical Personnel, and Mental Health Counselors) employs a multidisciplinary approach in dealing with issues of child abuse. The team approach decreases the number of interviews and invasive procedures a child must endure, thereby reducing the trauma that children face when they have been victims of sexual or physical abuse.

Think about it: Do you see how teamwork and collaboration relate to the key concepts of development and stage?

For specific Knowledge, Skills, and Attitudes,

Go to the QSEN Web site at http://www.qsen.org/

fortified with vitamins and minerals are acceptable. Cow's milk should not be used during the first year of life because infants have difficulty digesting the fat in it, and it is low in iron.

Colic Provide information about using warmth, motion, and security to relieve colic. For example, parents might try swaddling the baby, cuddling him close to their body, rocking him, placing him in a "kangaroo" pouch or a back pack, or placing him in a swinging chair.

SIDS In accordance with recommendations in *Healthy People 2020*, teach parent to place infants on their backs to sleep. Research shows that this greatly decreases the risk for SIDS. Additional interventions are discussed in Chapter 24.

Car Seats Stress the importance of car seats. Under federal law, infants must be secured in the back seat in an approved car seat every time they are in a vehicle. Because of poorly developed musculoskeletal head support, infants should be placed in a rear-facing position until 2 years of age and until they reach the height and weight recommended by the seat manufacturer (AAP, 2011). For more information about car seat restraints, refer to Chapter 24 in this book and

Go to the American Academy of Pediatrics Web site, at http://www.aap.org/family/carseatguide.htm

Immunizations Immunizations are a major aspect of health promotion for the infant. The infant receives immunizations at 2, 4, 6, and 12 months. The CDC is no longer expressing a preference for administering the combined MMRV vaccine rather than two shots (MMR for measles, mumps and rubella, and a separate one for varicella [chicken pox] [CDC, 2011a]). To see the CDC's optimal immunization schedule for children up to 6 years of age,

Go to Student Resources: Chapter 9, Tables, Boxes, Figures: **ESG Figure 9-1,** on Davis*Plus.*

Recommendations change frequently. You can always find the most current schedule on the CDC Web site, at

http://www.cdc.gov/vaccines/schedules/index.html

Unintentional Injury Stress the importance of constant supervision. As the infant gains greater mobility, potential dangers (e.g., for drowning, falls, and burns) increase. To prevent drowning, infants should never be left unattended in sinks, shallow baths, and plastic wading pools, even for a few seconds. To prevent scalding, caregivers should not drink or carry hot foods or fluids while holding the baby.

Play Encourage sensory stimulation for the infant through parental interaction and age-appropriate toys.

Interventions for Example Problem: Abuse, Neglect, and Violence

Teach parents about the dangers of shaking a baby or picking him up by an arm or leg.

If you suspect abuse, you are legally responsible for reporting your observations. As a beginning student, it is best to discuss your concerns with your instructor or the nurse assigned to the client before you make a report. Federal funds support a variety of home visit programs directed at high-risk mothers (identified on the basis of risk factors). Further information on abuse and reporting is included in Chapter 45, under Mandatory Reporting Laws.

ThinkLike a Nurse 9-3

Recall Miguel, a 2-month-old, in the Meet Your Patients scenario. How might a prolonged hospitalization affect his growth and development? What nursing actions would you take to offset developmental delays?

KnowledgeCheck 9-4

- Identify at least two reflexes present in the neonate.
- According to Erikson, what is the developmental stage of the infant?
- What teaching guideline is important in reducing the risk of SIDS?

TODDLERHOOD: AGES 1 TO 3 YEARS

The toddler period lasts from 12 to 36 months of age. This is a period of increased mobility, independence, and exploration. This is also the time of temper tantrums and negative behavior, stemming from a toddler's desire to gain autonomy.

Physical Development of the Toddler

Compared with that of infants, toddlers' *growth rate* is much slower. The average toddler gains 5 lb (2.3 kg) per year and increases in height by 3 in. (7.6 cm). Length is added mainly in the legs. By the second birthday the typical toddler weighs 27 lb (12.25 kg), is 34 in. (86 cm) tall, and has a head circumference equal to the chest circumference. Between 12 and 18 months, the anterior fontanel closes (see Fig. 9-3).

- *Respirations and heart rate* slow in comparison with infancy, but blood pressure increases.
- *The stomach* increases in size to accommodate larger portions. Toddlers typically eat about 6 times a day, in relatively small portions, and join the family at mealtimes. Most toddlers enjoy picking up food with their hands to feed themselves.
- *The physical ability to control the anal and urethral sphincters* develops between 18 and 24 months. However, the child is ready when she can signal that her diaper is wet or soiled, or is able to say that she would like to go to the potty. This usually occurs at about 18 to 24 months of age, but it is not uncommon for a child to be in diapers until 3 years of age (American Academy of Family Physicians [AAFP], 2006, updated 2010).

- *Gross motor skills* continue to be refined during toddlerhood. By 10 to 15 months, the toddler can walk using a wide stance. At the age of 24 months, many toddlers can walk up and down stairs one step at a time. At 30 months, the toddler can jump using both feet. Before the age of 3, he can stand on one foot and climb steps alternating feet.
- *Fine motor skills* also continue to be refined. By 1 year, infants can grasp small objects, yet are unable to release the object. However, by 15 months the toddler can release objects as well. By 18 months he can throw a ball overhand (Fig. 9-6). The toddler uses his new motor skills and all five senses to explore his environment, and safety continues to be an important concern.
- *Visual acuity* improves to 20/40 by the end of the toddler stage, and **strabismus** (crossed eyes) may still be seen transiently.
- *Hearing* should be fully developed by toddlerhood.

Developmental milestones of toddlerhood are listed in Box 9-2.

Cognitive Development of the Toddler

During toddlerhood the child completes Piaget's *sensorimotor phase* and moves into the *preconceptual phase.* This is a time of rapid language development and increasing curiosity. The toddler is able to name many things and begins to recognize that different objects (such as a ball, a block, and a puzzle) may be named the same thing (toys). This is the beginning of categorization and concept development. The child abandons trial and error and begins to solve problems by thinking. However, reasoning and judgment lag far behind. This discrepancy places the child at risk for accidents and injuries.

FIGURE 9-6 By 18 months, the toddler can throw a ball overhand.

BOX 9-2 ■ Milestones of Toddlerhood

- The toddler can ride a tricycle, put simple puzzles together, build a tower of six to eight blocks, turn knobs, and open lids.
- Most toddlers can copy a circle or a vertical line.
- Not only can the toddler find an object that has been hidden in his view, but also can actively search for and find a hidden object.
- By age 3, most toddlers are toilet-trained. However, it is not abnormal for toddlers to continue to experience toileting problems well into the preschool period.
- Most toddlers can play matching games, sorting games, and simple mechanical games.
- Most toddlers have only a limited understanding of jokes and hyperbole; thus, if teased, "That balloon is so big, it might fly away with you," the child may become frightened and try to give the balloon away.
- Many toddlers can speak sentences of four or five words. However, some perfectly healthy toddlers do not yet speak, whereas others can speak in sentences 10 or 11 words in length and even tell complex stories. If the toddler does speak, enunciation is good enough by the end of this period that strangers can usually understand what is said.
- Psychosocial milestones include the following: the toddler tolerates short separations from the primary caregiver, feels possessive of personal property, and openly expresses affection. Most toddlers object vehemently to changes in routine and may suffer regression following a move, change of school, or other upset.
- The toddler imitates adults, peers, and characters seen on television and videos and enjoys pretending to cook, iron, repair something broken, and mimicking other familiar adult tasks.
- In shared play, the toddler can understand the concept of "taking turns" and wait a short period of time for his or her turn.

Psychosocial Development of the Toddler

The most important psychosocial developmental task for the toddler is to initiate more independence, control, and autonomy. Erikson refers to this stage as *autonomy versus shame and doubt*. To successfully negotiate this stage, the child must learn to see herself as separate from mother, tolerate separation from the parents, withstand delayed gratification, learn to control anal and urinary sphincters, and begin to verbally communicate and interact with others.

Toddlers exert their independence by saying no to parental requests or actions or by "throwing a tantrum" to protest a parental decision they don't like. This behavior is best understood as a necessary attempt to define boundaries and test parental limits, rather than stubbornness or naughtiness. A firm but calm parental response to such "misbehavior" allows toddlers to feel secure while exploring their boundaries.

Freud defined this phase as the *anal stage.* To Freud, a successful toilet training experience accompanied by praise is necessary to becoming a well-functioning adult; difficulty in this phase leads to obsessive-compulsive behavior in adulthood. Contemporary theorists find this view somewhat narrow.

Common Health Problems of Toddlers

Unintentional Injury Drowning is the leading cause of accidental death in this age group (Reinberg, 2012). Most drowning accidents are due to unsupervised access to swimming pools or other water sources (bathtubs). Other common causes of injuries to toddlers are falls, motor vehicle accidents, burns and scalds, and choking. As toddlers gain increasing mobility, poisoning from household medications and toxic cleansers, as well as access to knives, guns, and other dangers become concern. For further discussion of safety concerns for toddlers, see Chapter 24.

Infections The shorter and wider eustachian tube in infants and toddlers increases their risk for multiple ear infections, which in turn increases the risk for hearing loss. Upper respiratory infections are common among toddlers. They no longer have the passive immunity acquired in utero, and because most breastfeeding ends before the first birthday, most toddlers no longer receive maternal antibodies in breast milk. Furthermore, as toddlers enter into more public and social settings, they are increasingly exposed to other children. Those in day care and those who have school-age siblings are particularly at risk. The most common infections are colds, ear infections, and tonsillitis. Other common infections include parasitic diseases, such as lice and tapeworms.

Immunizations The CDC (2011a) recommendations for immunization are designed to protect infants and children early in life, when they are most vulnerable and before they are exposed to potentially life-threatening diseases. Vaccines should be administered at the recommended age; but if not done, a vaccine can be administered at a later well child visit. Catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed are included in the recommendations. The CDC updates the immunization schedules periodically. To see the CDC's optimal immunization schedule for children up to 6 years of age,

Go to Student Resources: Chapter 9, **Tables, Boxes, Figures: ESG Figure 9-1,** on Davis*Plus*, or the CDC Web site, at http://www.cdc.gov/vaccines/schedules/index.html

The CDC (2011a) immunization schedule for toddlers includes the following vaccines: hepatitis A, hepatitis B, *Haemophilus influenzae,* meningococcal conjugate, tetanus and diphtheria toxoids (Td) and acellular pertussis (Tdap), pneumococcal pneumonia, inactivated poliovirus, varicella, measles/mumps/rubella (MMR), and rotavirus.

Delayed Toilet Training Although not strictly speaking a "health" problem, many parents are concerned about what they perceive as delayed toilet training. Physiologically, most children develop sphincter and neurological control by age 2, but more is involved in successful toileting. Toddlers must learn to unfasten their clothing and pull down their pants, use toilet paper effectively, dress again, and wash their hands before they are completely independent. The child also must be able to sense the need to go to the bathroom, even when preoccupied with play activities, before it is "too late." Accidents are frequent and parents should expect them.

ASSESSMENT

Children of this age are generally fearful of strangers. Thus, before beginning your assessment, you will need to establish rapport. To do so, you might engage the child in play—for example, by playing catch with a soft ball or asking the child to introduce you to the stuffed animal he may have brought along. This is also a nonthreatening way to assess language skills and motor development. Encourage parents to relieve their child's stress and anxiety by holding him during the exam and speaking to him in a calm and reassuring voice.

Toddlers need regular physical examinations. At each office visit, evaluate the child's weight, height, growth, and development against standard growth charts and by comparing his skills against age-appropriate norms. Beginning at age 3, blood pressure should be checked at least once yearly and results recorded with age/gender/height percentile and reviewed with parents (National Heart, Lung and Blood Institute, 2012).

INTERVENTIONS

Health Teaching You cannot stress safety enough to parents. Teach them how to childproof the environment. Emphasize that increasing motor skills and dexterity allow the toddler to find many dangerous areas, including stairways, windows, and electrical outlets. To prevent injury or death from such hazards, parents must provide constant supervision. They should use consistent, firm limits to help the toddler remain safe. Parents should also be vigilant about their children's toys, in light of recent recalls of toys that contained lead and other toxic substances. Toys should be larger than the diameter of the trachea in order to avoid choking accidents.

Plan ahead by teaching parents basic first aid and the choking rescue maneuver (see Chapter 24). Encourage parents to enroll in a basic life support class. You will also find a detailed list of safety measures for toddlers in Chapter 24.

Health Promotion Interventions At each wellness visit, reinforce the need for handwashing, tooth brushing, regular dental exams, and a balanced diet. This is also a time for additional immunizations and boosters. Oral health teaching should include information on brushing, fluoride, non-nutritive oral habits, and dental injury prevention (AAP, 2008). Children should see a dentist at between 12 and 36 months of age—certainly by age 3, when all teeth have erupted

Methicillin-Resistant Staphylococcus aureus (MRSA) and Vancomycin-Resistant Enterococci (VRE) These organisms have put a spotlight on the threat posed by drug-resistant bacteria. **Key Point:** ***Teach parents that antibiotics should not be used for simple colds and "flu." Explain the importance of taking the entire prescription when an antibiotic is prescribed, even after the child's symptoms resolve.*** These actions help prevent the development of drug-resistant strains of bacteria.

Remind parents that many cough and cold medicines marketed to children have not been approved for use in children, and that they should be certain that any OTC medicines are truly safe for children.

KnowledgeCheck 9-5

- According to Erikson, what is the developmental stage of the toddler?
- What is the leading cause of accidental death in toddlers?

ThinkLike a Nurse 9-4

Recall Tamika, a 3-year-old girl, in the Meet Your Patients scenario. Her grandmother, who is also caring for her ill husband, is raising Tamika. What concerns does that raise about the home environment?

PRESCHOOL STAGE: AGES 4 AND 5 YEARS

The preschooler is becoming increasingly verbal and independent and is refining gross and fine motor skills. He is able to maintain separation from parents, use language to communicate needs, control bodily functions, and cooperate with children as well as adults. These skills prepare the child to enter school.

Physical Development of the Preschooler

Growth By 4 years of age, the average preschooler weighs about 36 lb (16.3 kg) and is 40 in. (1 m) tall. By age 5, the preschooler has gained an additional 5 lb (2.3 kg) and grown 3 more in. (7.6 cm) in height. The proportions of head to trunk are somewhat closer, and the "pot belly" and exaggerated lumbar curve of toddlerhood gradually disappear. The average pulse rate is 90 to 100 beats/min, and respirations are 22 to 25 breaths/min.

Sensorimotor Development The preschooler has mature depth and color perception and 20/20 vision. Hearing is also mature. The preschooler continues to develop eye–hand coordination. Improvement in fine motor skills is most evident in artwork. Drawings become much more precise and detailed. Developmental milestones for preschoolers are listed in Box 9-3.

Cognitive Development of Preschoolers

According to Piaget, the preschooler has entered the phase of *intuitive thought.* She is able to classify objects and continues to form concepts. She still uses trial and error as a way to solve problems but increasingly uses thought to reason them out. Verbal skills expand dramatically during this phase, allowing the child to interact with more people. Preschool children are very interested in books, learning to read, and counting.

Preschoolers lack the ability to reason formally and are unable to understand that two objects that appear different may in fact be the same (e.g., two balls of clay in two different shapes). They have a limited ability to tell time or understand the passage of time, and they may say "yesterday" in describing an event of several months ago. They also retain a strong belief in magic, monsters, and mythic figures, such as Santa Claus. Preschoolers often have irrational fears, for example, of tigers lurking in the basement. Their fascination with powerful figures, such as dinosaurs and superheroes, is one way of coping with their feelings of powerlessness.

BOX 9-3 ■ Milestones of Preschool Development

- By age 5, most children can stand on one foot for 10 sec, skip, jump, hop on one foot or both feet together, climb play structures with ease, repeat simple dance steps, and begin to learn to skate.
- Most preschoolers can copy a triangle, square, and stick figure; print at least some letters; and use a fork and spoon.
- Most can dress and use the bathroom without assistance.
- Language abilities continue to be variable, but most preschoolers can tell stories, recall parts of a story told to them, and speak in sentences of more than five words. Most can state their name, age, and address, and many can repeat their home phone number. A toddler who is not speaking intelligibly by age 4 requires evaluation.
- Preschoolers can count 10 or more objects, such as buttons or coins, and may be able to name several colors and shapes. They can compare big and small, long and short, and so on, and often delight in completing simple mazes and "connect the dots" games.
- Preschoolers become increasingly aware of sex organ differences and curious about sexuality.
- Preschoolers may begin to ask about God, death, how babies are born, and other questions of a philosophical or scientific nature.
- Preschoolers typically can distinguish fantasy from reality and enjoy jokes and simple riddles.
- Psychosocial milestones include assertion of independence; pride in showing off skills, new toys and clothes, and prize possessions to friends; and a strong desire to socialize with peers.

Psychosocial Development of Preschoolers

The preschooler is in Erikson's stage of *initiative versus guilt*. In this stage, the child develops a conscience and readily recognizes right from wrong. The child becomes socially aware of others and develops the ability to consider other people's viewpoints. At this age, play is often used to teach life experiences.

The preschool child begins to fully express his personality and develop a self-concept (see Chapter 13 if you need to learn more about self-concept). He readily expresses likes and dislikes. Encouraging the child to participate in his favorite activities helps foster a positive self-concept (Fig. 9-7). Preschool children enjoy playing in small groups and use their language skills to facilitate imaginative play. Often elaborate stories, improvised costumes, and role-playing become part of the play experience. Many preschoolers have a best friend.

Freud identified the preschool years as the *phallic stage* of development. The child is aware of gender differences and often imitates the same-sex parent. The child also develops an attraction to the opposite-sex parent and may feel jealousy toward the same-sex parent.

Common Health Problems of Preschoolers

The preschooler experiences health problems similar to those of the toddler.

Communicable Diseases Communicable diseases (e.g., respiratory infections, intestinal viruses, and parasitic infections such as scabies and lice) remain a major health issue as preschoolers expand their social groups and come in contact with more children in play and structured preschool experiences. They are "hands-on," so they tend to readily transmit viruses through direct contact and airborne vectors.

FIGURE 9-7 Preschoolers typically enjoy helping a parent in the kitchen.

Poisoning Poisoning remains a significant risk for preschoolers, who often use imitation as a way to learn about new things. This predisposes the child to ingesting substances used by the adults in the house, such as prescription medicines and alcohol, or substances that look similar to these products

Enuresis Parents of preschoolers may report a concern about bed-wetting (**enuresis**), especially in boys. The causes of enuresis are not fully understood. However, it is known that in some children, the bladder is simply unable to hold a full night's output of urine until later in childhood, whereas others lack the neurological ability to waken in response to a full bladder. Most cases resolve spontaneously, with only very occasional episodes past age 6. In contrast, daytime wetting or soiling (**encopresis**) requires evaluation.

Example Problem: Child Abuse, Neglect, and Violence

Child abuse can occur at any age. It is often detected in the toddler and preschool period as children come in contact with more people outside the home. Abuse may be physical, emotional, or sexual or due to neglect. Of the confirmed cases of abuse and neglect reported to Child Protective Services, more than half are under the age of 7. Child abuse is not isolated to any one socioeconomic or education level group. The following are a few of the reasons why some people have difficulty meeting the demands of parenthood:

- **Parental characteristics:** Parents who were abused as a child are more likely to abuse their own children, especially when faced with high levels of stress and little support. Abuse can occur when parents or caregivers have unrealistic expectations of the child or unmet emotional needs of their own. Other factors include immaturity, lack of parenting knowledge, difficulty in relationships, depression, anxiety, mental health problems, and alcohol and drug addiction.
- **Characteristics of the child:** Statistical data indicate that children with a physical or mental disability and those who are born to unmarried parents or who are unwanted are more likely to suffer abuse.
- **Situational characteristics:** Crowded living space, financial difficulty, stresses of child care, employment pressures or unemployment, poor housing, domestic violence in the home, and frequent household moves are all environmental stressors that can contribute to child abuse. One recent study found that hospital visits for abuse were associated with the mortgage delinquency and foreclosure rates (Wood, Medina, Feudtner, et al., 2012). Obviously, most parents do not abuse their children, despite the presence of those characteristics. However, you should be aware

of the statistical risks. For further discussion of child abuse, refer to the section on Infancy, preceding, and

Go to Chapter 9, **Procedure 9-1: Assessing for Abuse,** in Volume 2.

ASSESSMENT

Assessments for preschoolers should include the following:

Height, Weight, and Vital Signs Gather the data and compare your findings with age-appropriate norms. Calculate and plot body mass index (BMI) at every well-child visit. To obtain information about this from the CDC Web site,

Go to "BMI—Body Mass Index," at http://www.cdc.gov/nccdphp/dnpa/bmi/index.htm

Nutrition Assess for food preferences, habits, and amount eaten. The preschool child often has strong food preferences.

Sleep Habits Assess the numbers of hours slept, bedtime rituals, and problems with night awakenings. Preschoolers are generally very active but require adequate rest. This is also the stage when children stop taking afternoon naps.

Vision Screening U.S. Preventive Services Task Force (USPSTF) (2011a) recommends vision screening for all children at least once between the ages of 3 and 5 years, to detect the presence of vision loss or its risk factors (Couser, Esmail, & Hutchinson, 2012).

Dental Hygiene During the preschool years, all deciduous teeth have erupted. Therefore, dental hygiene is very important. At each visit, ask the child about toothbrushing habits. If possible, have him demonstrate how he brushes. The child should already have made at least one visit to a dentist by age 3. *Healthy People 2020* oral health goal includes prevention and control of oral and craniofacial diseases, by providing access for all school-age children to fluoridated water, tooth sealants, and preventive oral care (USDHHS, 2010b).

Safety Risks Assess for parent and child knowledge of hazards and precautions. Because the preschool child is mobile and involved in activities such as riding a tricycle, chasing a ball, and crossing streets, accidents increase.

School Readiness A physical examination is required before the child enters school. This exam should include an assessment for "readiness"—whether the child has acquired skills such as an ability to converse with adults, follow instructions, hold a pencil, and perform a variety of motor skills, such as jump, hop, and walk a straight line. At the readiness exam, you will also need to review the immunization record. Several boosters and immunizations are due at this time. Any missed immunizations must be administered before the child enters school. For other information, refer to Common Health Problems of Toddlers earlier in this chapter. To see the CDC's Catch-Up Immunization Schedule for Persons Aged 4 Months–18 Years,

Go to Student Resources: Chapter 9, **Tables, Boxes, Figures: ESG Figure 9-2,** on Davis*Plus*, or to the CDC Web site at http://www.cdc.gov/vaccines/schedules/index.html

INTERVENTIONS

The preschool child is interactive and curious. Speak directly to the child, and include her in your teaching sessions. Teaching topics include the following:

- *Frequent handwashing to prevent the spread of disease.* Teach the child handwashing technique, and encourage parents to model frequent handwashing.
- *Proper brushing and flossing of teeth.* At this age, most children still need supervision while brushing their teeth.
- *The essentials of a balanced diet.* Encourage parents to offer a well-balanced diet and to instill healthy eating habits. By age 5 most children are willing to try new foods and are better able to sit during an entire meal. Generally, preschoolers eat half of the food portion of an adult.
- *The importance of adequate rest. The* average preschooler requires at least 12 hours of sleep each night.
- *The hazard of "stranger danger."* Increasing independence and mobility place the preschool child at risk for abduction. Teach the child to avoid talking to strangers and to never enter a stranger's home or car. This topic is explored in depth once the child is in school.
- *The importance of seat belts and car seats.* Current recommendations are to use a booster seat for children weighing between 40 and 80 lb and to continue using the seat until the child is at least 4 ft 9 in. tall.

KnowledgeCheck 9-6

- According to Erikson, what is the developmental stage of the preschooler?
- Identify at least two important assessments to make when providing care to a preschooler.

SCHOOL-AGE: AGES 6 TO 12 YEARS

The school-age child undergoes many changes; the child becomes more independent, places more importance on relationships outside the immediate family, and becomes more confident. See Box 9-4 for a summary of the developmental milestones of the school-age period.

Physical Development of the School-Age Child

Growth During the school-age years, the child grows about 2 in. (5 cm) taller and gains 4 to 7 lb (2.3 to 3 kg) per year. The child takes on a slimmer appearance, with longer legs and a lower center of gravity. Muscle mass rapidly increases and ossification of bones continues

BOX 9-4 ■ Milestones of School-Age Development

- By age 7, most children can tie their own shoelaces, print their names, and perform self-care, such as bathing and feeding themselves. Many can even prepare simple meals.
- By age 8, improved fine motor skills allow the child to begin to write, learn to knit or crochet, and/or take up a musical instrument.
- By age 9, motor development approaches that of an adult.
- School-age children understand the concept of payment for work and the value of money.
- Fears of ghosts and monsters may continue through age 7 but give way to more realistic fears, such as of school failure or divorce of parents, by age 8 or 9.
- By age 6, the child has a vocabulary of 3,000 words and usually can read. By the end of the school-age period, the child can write complex compositions with appropriate grammar, spelling, and accurate description.
- Psychosocial development includes team play, peer friendships, and ability to look beyond family members for social support.

throughout this stage. Strength and physical abilities rapidly improve, and the child gains more poise and coordination. The brain and skull grow slowly, and facial characteristics mature. The gastrointestinal system matures and stomach capacity increases, although caloric demands decrease. As the immune system develops, the school-age child begins to produce antibodies and antigens. Initially boys and girls vary little in size. Toward the end of the school-age phase, marked differences become apparent. Girls grow rapidly in the latter school-age years, as puberty begins. They experience onset of puberty approximately 2 years before boys do.

Visual Acuity Visual acuity improves with age. Because children do not complain of visual difficulties, the AAP (2003) recommends visual acuity measurement (vision screening) beginning at age 3 years. AAP Vision Screening Guidelines specify that all children over age 8 should be able to achieve 20/20 visual acuity using their best eyeglass correction. Younger children should be referred to an ophthalmologist if there is a difference between the right and left eyes of two or more lines on a Snellen chart evaluation (Broderick, 1998).

Dentition School-age children begin to lose their primary teeth (baby teeth) at about age 6 or 7, and the permanent teeth appear soon after. Their large size in relation to the remaining primary teeth and the child's jaw, as well as the gaps left by teeth not yet replaced, can make even the most beautiful children look somewhat awkward at this stage.

Cognitive Development of the School-Age Child

School-age children use their thought processes to experience actions and events. Piaget describes this as *concrete operations.* The child's thinking is concrete and systematic; magical beliefs are gradually replaced with a passion to understand how things really are. He is also able to see another person's point of view and develops an understanding of relationships. The school-age child learns to classify objects according to similarities, and enjoys learning by handling and manipulating objects. The child learns to tell time and gains an experiential understanding of the length of days, months, and years. He reads independently and does numerical calculations without representative objects such as fingers or beads. By the end of this stage, mental capacity develops to the point where the child is able to think through a task and understand it without actually performing the task.

Psychosocial Development of the School-Age Child

Erikson describes this stage as a time of *industry versus inferiority*. During this stage, the child is able to work at more complex projects independently. Through participation in school, she is recognized for achievements and accomplishments. For the child to progress through this stage, the parent must also provide praise for accomplishments. This recognition builds self-confidence. The child will develop a sense of inferiority and lack of self-worth if her accomplishments are met with a negative response.

Peers take on increasing importance, influencing the child's choices of what to eat, wear, and do. Friendships during the school-age years are usually with children of the same gender and may be intense but short-lived (Fig. 9-8). However, some children have one best friend throughout their childhood. In the later school-age years, friendships become more reciprocal with each child recognizing the unique qualities of the other.

Common Health Problems of School-Age Children

School-age children are at risk for problems similar to those of preschoolers, including upper respiratory tract infections, parasitic infections such as scabies and lice, and dental caries. Although violence, bullying, smoking, and

FIGURE 9-8 Same-gender friendships are important to school-age children.

experimentation with alcohol, drugs, and sex are more common among adolescents, these problems are also seen toward the end of the school-age years. The presence of a gun in the home significantly increases the risk of accidental death, even in the school-age population.

Childhood Obesity

Obesity among school-age children has become a growing health concern. In 1994, 11% of children ages 6 to 11 were obese (defined as being in the 95th percentile of body mass index); by 2006, that figure had risen to 17%, to what is viewed as epidemic proportions (American Heart Association, 2012). Nutrition and lifestyle are primarily responsible. Children spend much less time playing outside than in past generations, and more time watching television and playing on electronic devices. They consume more fast food, bigger portions, and fewer vegetables. Thirty percent of all meals are taken outside of the home and fast food contributes to 10 percent of overall calorie intake (American Heart Association, 2010). As a result of the obesity epidemic, prevalence of obesity-related diseases, such as type 2 diabetes mellitus (type 2 DM), hyperlipidemia, and hypertension, have risen in children.

Type 2 DM is an endocrine disorder characterized by insulin resistance; that is, insulin fails to effectively transfer glucose from the bloodstream into the body's cells. Treatment involves dietary changes, weight loss, and exercise. Medications are required if these lifestyle changes are not sufficient to control blood sugar.

Childhood Asthma

Asthma, a chronic inflammatory disorder of the airways, affects about 6.8 million children in the United States. From 2001 through 2009 asthma rates rose most among African American children, increasing almost 50% (CDC, 2006, 2010a). Asthma is the leading cause of school absenteeism owing to chronic illness and of childhood emergency department (ED) visits. It accounts for one-third of all pediatric ED visits. Even in children who do not require emergency care, asthma can decrease attention span in school, make participation in school activities difficult, and cause social problems. For example, children are often teased and stigmatized as being "wheezers" or "lazy." Asthma has complex causes, including a strong genetic component, but poverty appears to play at least some role. Recent research has focused on indoor air pollutants, such as dust mites, mouse urine, and the decomposing corpses of cockroaches as significant triggers.

Unintentional Injuries in School-Age Children

School-age children experience fewer injuries than do preschoolers because of their increased coordination and improved reasoning abilities. Nevertheless, they do have a high incidence of fractures, sprains, strains, cuts, and abrasions. Falls are the most common form of nonfatal injury for children ages 6 to 12 years, while the leading cause of death from unintentional injury is motor vehicle and traffic injury (54% of the deaths for this group) (CDC, 2012a).

Concussions are one of the most commonly reported injuries in children and adolescents who participate in sports and recreation activities. Most sports- and recreation-related concussions seen in EDs each year (65%) occur among youth ages 5 to 18. While many of these injuries may be considered mild, they can result in health consequences such as impaired thinking, memory problems, and emotional or behavioral changes (USDHHS, 2007–2008). Injuries also occur from riding bicycles on the street, skiing, skateboarding, sledding, and the use of trampolines. If you would like more information about unintentional injuries, see Chapter 24.

ASSESSMENT

The school-age child should have a routine health maintenance visit every 1 or 2 years. Many children participate in sports, so annual physical exams are scheduled for them. Allow time to meet with the child alone as well as time with the caregiver present. School-age children often have questions about puberty and the changes their bodies are undergoing. Private time with the child may encourage the child to be more open as you explore these concerns.

Nursing Interview The nursing interview should cover the following topics:

- **Nutrition.** Assess the child's nutrition, including intake of key nutrients such as calcium, vitamin D, and iron.
- **Allergies.** Ask the child whether he ever experiences difficulty breathing or feels too tired to play. Ask about allergy symptoms, including clear nasal discharge, frequent sneezing, or watery eyes. Listen to breath sounds, and observe for allergy symptoms.
- **Dental hygiene.** Determine the child's knowledge of dental hygiene. Inspect the mouth for secondary teeth eruption according to expected patterns, as well as for tooth decay and gum disease.
- **Sleep pattern.** Assess the child's sleep pattern. To remain healthy and function well at school, the school-age child needs 9 to 10 hours of sleep each night.
- **Safety.** Determine the child's awareness of safety. Be sure to assess risk-taking behavior. Has the child tried smoking? Does he have friends who are smoking? What is the child's experience with alcohol and drugs? Has he tried them? What does his peer group think about drinking and drugs? Has he ever been sexually active? Does he have friends who are sexually active? Has the child engaged in fistfights or fights with knives or other weapons? Is there a gun in the home? Does the child have access to it? Although these concerns are seen with greater frequency in adolescence, you should assess for them among school-age children.

BMI At each visit, assess the child's vital signs, height, weight, and developmental skills. After weighing the child, correlate your measurements with growth charts. The American Heart Association (2012) BMI classifications are as follows:

- At 85th percentile—mild to moderately overweight
- At or above the 95th percentile—obese

Because health risk increases with degree of obesity, at-risk and obese school-age children should be identified and counseled. For more information about BMI for children,

Go to **BMI—Body Mass Index, at http://www.cdc.gov/nccdphp/dnpa/bmi/index.htm**

Vision Screening Many school systems have regular vision screening programs that are carried out by volunteer professionals, school nurses, and/or properly trained laypersons. Screening can be done quickly, accurately, and with minimal expense by one of these individuals.

Scoliosis Screening **Scoliosis** is an abnormal spinal curvature that affects primarily females. Screening is done in the preadolescent period, usually in the 6th grade. Refer to an orthopedic surgeon for evaluation and follow-up if an abnormal curvature is discovered.

Immunizations Review the immunization record. Although immunization against hepatitis B is recommended in infancy, many parents skip these immunizations. Several states require students to complete the hepatitis B series prior to entry into 7th grade. The child must begin the series at or before 12 years of age to complete it in time for 7th grade. The CDC (2011a) recommends the following vaccines for school-age children: tetanus, diphtheria, and pertussis booster; human papillomavirus; meningococcal; pneumococcal; influenza; hepatitis A; hepatitis B; inactivated poliovirus; measles, mumps, and rubella; and varicella. To see this schedule,

Go to the CDC, **2012 Recommended Immunizations for Children from 7 Through 18 Years Old,** at http://www.cdc.gov/vaccines/who/teens/downloads/parent-version-schedule-7-18yrs.pdf

Also refer to the section Common Health Problems of Toddlers.

INTERVENTIONS

The *Healthy People 2020* campaign focuses on preventing injury rather than on treating illness. Your efforts in patient teaching will help promote the national *Healthy People 2020* population objectives (USDHHS, 2010b). Use age-appropriate teaching materials and methods.

Teaching for Safety

To help prevent injury in the school-age child, educate the child and parents on safety and the proper use of equipment and gear. Teach them to wear seat belts at all times. Encourage parents to be firm about the use of helmets for bicycle safety, stressing that head injury is the most common cause of death in this group. Also stress the importance of warming up before playing sports, using safety equipment that is properly fitted, and avoiding overtraining.

Teaching About Nutrition, Exercise, and Overweight

Counsel overweight and obese children about nutrition for weight loss. Encourage them to develop good eating habits by choosing nutritious foods and snacks. For example, they should avoid junk foods, and instead of sodas choose milk, calcium-fortified orange juice, or plain water. If the diet is severely restrictive, and if it has none of the child's favorite foods, it is likely to fail. Focus on making small but permanent changes. Refer for further counseling, if indicated.

Recommend 60 minutes of moderate-intensity exercise 7 days per week (American Heart Association, n.d., updated June 2012). USDHHS guidelines recommend even more exercise: 1 hour or more of vigorous aerobic physical activity every day. Explain how important exercise is to weight loss—diet alone will not achieve it for them. Exercise does not necessarily need to be structured. For example, it might consist of family walks in the community, bike riding, skateboarding, or swimming in a neighborhood pool. Even table tennis requires more activity than watching television. The AAP (2006) recommends the following:

- Limit TV viewing and video game playing to 2 hours a day.
- Boys should take at least 11,000 steps daily.
- Girls should take at least 13,000 steps daily.

You could suggest that parents buy a pedometer so the child can track the number of steps.

Teach children about self-regulation of impulse control, decision-making skills, and social competence. The most effective programs for preventing obesity focus on children, rather than their parents. However, management of obesity does involve the whole family. Parents can help by modeling healthy eating. Recommend group-based or family-based counseling. Many parents do not perceive that their child is overweight, and they must come to recognize this if they are to cooperate with needed changes.

Work with the community to involve the schools in obesity prevention. Many schools have removed soda from their campuses and are now offering healthy menus in their cafeterias. In addition, physical education in public schools has been mandated in many U.S. states.

Teaching About Asthma

Teach parents and children about indoor environmental asthma triggers, such as secondhand smoke, dust mites (in mattresses, carpets, and furniture), mold, cockroaches, pets, and nitrogen dioxide (a gas that is a byproduct of indoor fuel-burning appliances such as gas stoves, fireplaces, or wood stoves (U.S. Environmental Protection Agency [EPA], last updated October, 2010)).

Provide and help fill out, as necessary, an asthma action plan card for the child to carry when away from home. An action plan should include (1) the child's asthma triggers, (2) instructions for asthma medicines, (3) what to do if the child has an attack, (4) when to call the doctor, and (5) emergency telephone numbers. To obtain a plan form from the EPA's Asthma home page,

Go to http://www.epa.gov/asthma/pdfs/asthma_action_plan.pdf

Intervention for Example Problem: Violence

At the community health level, school violence can be addressed through psychological counseling, weapons-screening devices, schoolwide educational programs, and policies calling for the suspension or expulsion of students who are caught intimidating other children or participating in fights on school property. The school-age period also offers many opportunities to educate children about the hazards of smoking, drinking, and using drugs, which often contribute to violence.

Helping the Hospitalized Child

Finally, help children express their fears so you can respond to specific needs. Hospitalized children may fear the unknown, the strange environment, and strange professionals. They are afraid of tests and treatments (e.g., operations, needles), pain, and dying. They miss the comforts of home: their mother's cooking, their own room, and so on. They are bothered by separation from family and friends and by loss of control over their personal needs. You can help by maximizing their contact with friends and school. Offer children choices, when possible, to restore some sense of control (e.g., whether to have a tub or shower bath or what they'd prefer to eat for meals). Encourage parents to bring familiar items from home to personalize their space. Involve parents in their care, and provide them accurate information so they can relieve children's anxieties.

KnowledgeCheck 9-7

- What important physical changes occur in the school-age group?
- According to Piaget, what is the cognitive developmental stage of the school-age child?

ADOLESCENCE: AGES 12 TO 18 YEARS

Adolescence marks the transition from child to adult. **Puberty** refers to the beginning of reproductive abilities. In this period, the child experiences progressive physical, cognitive, and psychological change.

Physical Development of Adolescents

Physical and hormonal changes are readily apparent during the adolescent years. Developmental milestones of adolescence are summarized in Box 9-5.

BOX 9-5 ■ Milestones of Adolescent Development

- The adolescent reaches adult height and about 90% of peak bone density by the end of this stage.
- Menarche occurs by age 14 in most girls, who develop adult primary and secondary sex characteristics by about age 16.
- Boys have developed adult primary and secondary sex characteristics by about ages 17 to 19.
- Motor development is equal to that of adults.
- Maturation of the central nervous system allows formal operational thought processes, logic, and abstract reasoning.
- Psychosocial development includes the teen's increasing reliance on peers, ambivalent feelings toward family, anxiety over and/or preoccupation with sex and sexuality, and determination of sexual orientation.

Growth *Females* undergo a growth spurt between 9 and 14 years of age. Height increases 2 to 8 in. (5.1 to 7.6 cm), and weight gain varies from 15 to 55 lb (6.8 to 24.9 kg). By the onset of menstruation, females have attained 90% of their adult height. *Males* undergo a growth spurt between the ages of 10 and 16 years. Height increases by 4 to 12 in. (10.2 to 30.5 cm), and weight increases by 15 to 65 lb (6.8 to 29.5 kg). Boys continue to grow until 18 to 20 years of age. Bone mass continues to accumulate until about age 20.

In both males and females, the blood pressure and the size and strength of the heart increase. The pulse rate decreases. By the end of adolescence, blood values are that of the adult. Respiratory rate, volume, and lung capacity also reach the adult rates. By the end of the adolescent period, all vital organs reach adult size.

Onset of Puberty The onset of puberty varies widely, but the sequences of these changes are standard (Tanner, 1962).

- In females, the time from the first appearance of breast tissue to full sexual maturation is 2 to 6 years. **Menarche** (first menstruation) occurs approximately 2 years after the beginning of puberty. The average age of menarche is 12 years, depending on race and body mass.
- In males, the onset of puberty occurs between 9 and 14 years of age. Throughout puberty, boys become more muscular, the voice deepens, and facial hair begins to grow and coarsen. It may take 2 to 5 years for the genitalia to reach adult size.

In both males and females, hormonal changes are accompanied by increased activity of the sweat (apocrine) glands, and heavy perspiration may occur for the first time. At the same time, the sebaceous glands become active, and the adolescent may experience acne. For more information about the changes in secondary sexual characteristics associated with puberty for males and females,

Go to **Procedures 22-17 and 22-18,** respectively, in Volume 2, and

Go to Student Resources: Chapter 9, **Tables, Boxes, Figures: ESG Table 9-3, Tanner Staging System,** on Davis*Plus*.

Cognitive Development of Adolescents

Piaget refers to adolescence as the period of *formal operations*. The adolescent develops the ability to think abstractly and is receptive to more detailed information. She can now imagine what may occur in the future as well as the consequences of her own decisions. Despite their more refined cognitive abilities, adolescents may still lack judgment and common sense. These develop later through life experiences.

Psychosocial Development of Adolescents

The major psychosocial task of the adolescent is to develop a *personal identity.* Teenagers shift emotional attachment away from their parents and create close bonds among their peers (Fig. 9-9). This helps the teenager to further characterize the differences between himself and his parents. The adolescent often takes on a new style of dress, dance, music, or hairstyle; develops personal values; and begins to make choices about career and further education.

Group Acceptance One of the strongest needs for teens is to feel accepted within a group of their own choosing. Acceptance onto a sports team, into a club, or into a clique or gang increases the teen's sense of self-esteem. In contrast, unpopular teens feel alienated, resentful, and antagonistic and may react with violence directed at themselves or others (Polan & Taylor, 2010).

Tattoos and Piercings Adolescents may engage in the trend of body art and piercings for a number of reasons, including a desire for social bonding, desire to look like their peers, and the wish to commemorate a friend or loved one. In the 10-year period after the mid-1990s, the number of teens who had tattoos increased from 4.5% to 14%. The average age at time of tattooing is around 17 years (Scudder, 2007). Body piercings, likewise, are not unusual. Some studies have reported a significant relationship between piercing and substance abuse, leading some to speculate that body piercing may serve as a marker of an at-risk teen (Roberts, Auinger, & Ryan 2004). Both tattoos and piercings can cause skin infections and bloodborne diseases such as HIV and hepatitis.

FIGURE 9-9 Teenagers create close bonds among their peers.

Emerging Sexual Orientation Most adolescents have a sense of their emerging sexual orientation. Approximately 4.5% of people between 18 and 44 years of age identify themselves as homosexual or bisexual (CDC, 2011b). A higher percentage report having had same-sex intercourse at least once, but consider themselves heterosexual. Some youth are bisexual, that is, attracted somewhat equally to both males and females.

Common Health Problems of Adolescents

In the United States, 77% of all deaths among young people ages 10 to 25 result from four causes: motor vehicle crashes (30%), other unintentional injuries (15%), homicide (15%), and suicide (12%). Illnesses are responsible for less than one-fourth of deaths; cancer and heart disease are the most common. Many students engage in behaviors that increase their likelihood of death or injury including: texting while driving, drinking while driving, carrying a weapon, using alcohol, and using other drugs. In a recent year, 32.8% of high school students reported having been in a physical fight (CDC, 2012b).

Example Problem: Substance Abuse

Substance abuse is the regular use of drugs or other substances for purposes other than medical use that causes physical or psychological harm to the person. Substance abuse is a major concern because of the physical, mental, and spiritual toll it takes on teens, families, and the community. Substance abuse is associated with risk-taking behaviors resulting in injury and death (e.g., car accidents, suicide).

Alcohol and Other Substances

An adolescent may try alcohol and other drugs out of curiosity or to alter the consciousness to gain a feeling of power, excitement, or confidence. Peer pressure also exerts a powerful influence. Boys and girls are starting to drink at younger ages. In a recent survey, alcohol use among those ages 12 to 17 years was 15%; youth binge and heavy drinking rates were 9% and 2%, respectively. Three out of four students have consumed more than just a few sips of alcohol by the end of high school. An estimated 11% of those in grades 9 through 12 report having driven a motor vehicle when they had been drinking alcohol (CDC, 2012b; Substance Abuse and Mental Health Services Administration [SAMHSA], 2010).

Heroin, cocaine, crack, methamphetamine, and the "designer drugs" (ecstasy, bath salts and others) may be abused. Abuse of over-the-counter and prescription drugs used by the teen's parents, such as OxyContin, is also common.

Tobacco

It is illegal to sell tobacco to minors, yet 9.5% of middle school students and 25.6% of high school students currently use some form of tobacco (American Lung Association, 2010, updated July 2011; SAMHSA, 2010) and over 54% say they have tried a cigarette. A majority of these students report that they were not asked to show proof of age when they, themselves, bought cigarettes. Tobacco use is associated with alcohol use, and acts as a "gateway drug" to using illegal drugs. Cigarette use causes an increase in the number and severity of respiratory illness, and decreased physical fitness. Smoking during childhood often forms an addiction that persists into adulthood.

Depression

Depression affects up to 8.3% of adolescents in the United States (About Teen Depression, n.d.), compared with 11% of the adult population. A government survey found an even higher rate: During the 12 months preceding the survey, 28.5% of students nationwide had felt so sad or hopeless almost every day for more than 2 weeks in a row that they stopped doing some usual activities (CDC, 2012a). Defining features of depression are the same as for adults, but the way symptoms are expressed varies with the developmental stage. Young adolescents may have difficulty identifying and describing their emotional or mood states. Instead of saying how bad they feel, they may be irritable or act out by disobeying or misbehaving, or they may use tobacco and other substances. They may sulk, be negative or grouchy, feel misunderstood, and get into trouble at school.

Risk factors for adolescent depression include a family history of depression, cigarette smoking, stress, loss of a loved one, break up of a romantic relationship, learning disorders, attention or behavioral disorders, chronic illnesses (e.g., diabetes), abuse, neglect, or other trauma. If you would like more information about depression, see Chapter 13.

Suicide

Suicide is the third leading cause of death in teenagers. It is estimated that 7.8% of high school students have attempted suicide (CDC, 2012b). Rates are higher among females (19.3%) than among males (12.5%), but because boys tend to use more lethal methods, such as guns and hanging, they are more likely to die from the attempt. Risk factors include problems at school or in romantic or family relationships, low self-esteem, social isolation, substance abuse, and depression.

Eating Disorders

Although anorexia and bulimia create nutritional problems and manifest as eating disorders, they are psychiatric disorders that require medical and psychiatric intervention.

Anorexia Nervosa A person with **anorexia nervosa** dramatically restricts food intake and may exercise excessively in an attempt to lose weight. It is the third most common chronic illness among adolescents. It occurs predominately in, but is not limited to, high-achieving adolescent females from upper-middle-class backgrounds. Anorexia is characterized by a distorted body image; often the girl sees herself as fat in spite of being markedly thin. Physical consequences include amenorrhea, bradycardia, low white blood cell count, anemia, infertility, and bone loss. Eating disorders have the highest mortality of any mental illness: 5% to 10% of patients die within 10 years of developing anorexia nervosa (Lippert, Shea, & Seagrave, 2008).

Bulimia Bulimia is another eating disorder seen in adolescent girls, as well as in boys who participate in sports that require them to maintain a specific weight. Bulimia is characterized by binge eating followed by inappropriate mechanisms to remove the food that was consumed (usually, inducing vomiting, using laxatives, or excessive exercise). Binge eating may occur every few days or as often as several times a day. People with bulimia frequently experience electrolyte imbalances, decayed teeth from gastric acid exposure, or abdominal pain from gastric overload or laxative use.

Overweight and Obesity

Overweight and obesity continue to be a concern during adolescence. The numbers are staggering. Consider these facts:

- In 1994, 11% of adolescents (ages 12 to 19) were classified as obese; by 2008, that number had reached 18% (National Center for Health Statistics, 2011a). By 2011, about 1 in 3 American children and teens was overweight (American Heart Association, 2012).
- Causes of teen obesity are similar to those of childhood obesity: sedentary lifestyles, eating larger portions, eating fast foods, and substituting high-calorie, nutrient-poor snacks for balanced meals. Even school vending machines contain junk food such as soda, snack cakes, candy, and chips, although this is changing in some areas.
- One-third of American children ages 4 to 19 years eat fast food daily. The percentage is undoubtedly higher for adolescents, who eat fewer meals at home and have more freedom to choose their own foods. Food preferences are influenced by television and other marketing strategies; on children's television shows, most of the advertising is for foods of poor nutritional value.
- Type 2 DM, hypertension, high cholesterol, and heart disease are disorders that were previously seen mainly in adults. Now that obesity has become a major health problem among youth, these disorders are occurring with increasing frequency in adolescents. Moreover,

overweight children are more likely to become overweight adults.

Risky Sexual Behaviors

Sexual activity is common among teenagers. By age 13, 3.4% of girls and 9% of boys have had sexual intercourse. This tends to increase with age, with 34% of students in grades 9 to 12 being sexually active. About 15% of students have had sexual intercourse with four or more persons (CDC, 2011b; DeNoon, 2012).

Condom Use About two-thirds of sexually active high school students report having used a condom during their most recent sexual intercourse. Child Trends (2012) reports that males are far more likely to use condoms than are females; and black males were more likely to use condoms than Hispanic males. Through its *Healthy People 2020* initiative, the federal government has set a national goal of increasing effective condom use among sexually active adolescents ages 15 to 19 years, with the goal of preventing pregnancy and providing barrier protection against disease.

Oral Sex A fairly recent trend among youth is engaging in oral sex, in the belief that it is not "real sex." In one survey of university students, 62% of females and 56% of males believed that oral sex is not "actually sex" and does not take away their virginity (Halpern-Felsher, 2008, Lindberg, Jones, & Santelli, 2008).

Web-Based Social Networking A recent study of young men (ages 16 to 24 years) who have sex with men examined the use of the Internet or Web-based social networking sites for meeting sexual partners. Forty-eight percent of the sample had sexual relations with a partner they met online. Of these, only 53% used condoms consistently, and 47% reported having sexual partners more than 4 years older than themselves. A history of unprotected anal intercourse, multiple anal intercourse partners, and engaging in sexual activity at a sex club or a bathhouse was associated with meeting sexual partners through the Internet. Researchers concluded that young men who have sex with men and who seek partners online also engage in other behaviors that place them at risk for HIV and other STIs (Garofalo, Herrick, Mustanski, et al., 2007).

Sexually Transmitted Infections (STIs) Approximately 1 in 4 U.S. teens has an STI. STIs, including HIV/AIDS, are a major health consequence associated with sexual activity, especially with unprotected sexual activity. A majority of adolescents believe that sex without a condom is not worth the risk, but most also mistakenly believe that condoms are a foolproof method of preventing STIs and HIV/AIDS. Among adolescents, trichomonal and monilial infections and human papillomavirus are common. Chlamydial infections, syphilis, and herpes simplex type II (genital herpes) occur in both males and females, and can have serious complications.

AIDS is a major cause of death worldwide, reaching epidemic proportions in some countries. It is transmitted primarily through genital, oral, or anal sexual activities, but it can be transmitted by other ways (e.g., by sharing needles with an infected person). The annual rate of AIDS diagnoses reported among males ages 15 to 19 has nearly doubled in the past 10 years (Gavin, MacKay, Brown, et al., 2009). For more information about STIs, see Chapter 33.

Adolescent Pregnancy Except for an increase between 2005 and 2007 (Gavin, MacKay, Brown, et al., 2009), teenage birth rates have declined each year since 1991. The 2010 rate of 34.3 births per 1,000 teens (ages 15 to 19) was the lowest in 70 years (CDC, 2010b). Nevertheless, rates are still high, especially among black and Hispanic teens in the South; and the United States has substantially higher teen pregnancy and birth rates than other industrialized nations (CDC, 2010b). Although a similar percentage of teens are sexually active in the United States, consistency and effectiveness of condom use are lower.

Adolescents who become pregnant face physiological risks, such as bone density loss and iron deficiency anemia, the interruption of progress in their own developmental tasks, and loss of educational opportunities. Teen mothers are less likely to complete high school and more likely live in poverty than other teens. They are less likely to be married, to receive prenatal care, and gain appropriate weight; and more likely to smoke than older mothers. This puts them and their babies at higher risk for complications of pregnancy and low-birth-weight infants.

Example Problem: Abuse, Neglect, and Violence

There is no age limit on abuse and neglect. One study of children age 13 to adulthood reported that more than 9% of the nearly 1,000 subjects had substantiated maltreatment. Maltreatment included sexual abuse, physical abuse, emotional abuse, and neglect. Abuse may be linked to later violent crimes and illicit drug use (Leeb, Lewis, & Zolotor, 2011; Mersky, Topitzes, & Reynolds, 2011). Adults often ignore symptoms and complaints of adolescent abuse. Young children are perceived as defenseless, but people tend to stereotype adolescents as provoking their own abuse. Fewer than 40% of adolescent maltreatment cases are reported to child protection agencies, compared with 76% of cases involving younger children (McFarlane & Miller, 2005).

ASSESSMENT

Adolescents should have a general health examination every 2 years. Communicating with adolescents can be challenging because they are sometimes rebellious. Try to establish rapport, and reassure the teenager that you will maintain confidentiality.

Toward Evidence-Based Practice

Perry, R., Kayekjian, K., Braun, R., et al. (2011). Adolescents' perspectives on the use of text messaging service for preventive sexual health promotion. *Journal of Adolescent Health, 51*(3), 220–225.

This study investigated the perspectives of 26 adolescents (ages 15 to 20 years) regarding a preventive sexual health text messaging service. Participants reported that they generally enjoyed receiving health-related text messages that were relevant to and directly helpful in their daily lives. They stated that receiving the text messages helped to stimulate or guide positive discussions with peers about sexual health. Findings indicated that using text messaging to relay health information to teens was convenient for the participants, did not pose financial concerns for most, and generally created a greater sense of privacy than did traditional communication tools.

Kogan, S., Yu, T., Brody, T., et al. (2012). Integrating condom skills into family-centered prevention: Efficacy of the strong African American families–teen program. *Journal of Adolescent Health, 51*(2), 164–170.

In this research study 16-year-old African American youths and their primary caregivers were randomly assigned to a group that participated in a 5-week family skills training program with a condom skills unit, or to the control group, which was not offered the condom skills unit as part of the intervention. The results of this study indicate that the intervention with its condom skills unit was effective in reducing the frequency of unprotected intercourse and increasing condom efficacy among rural African American high school students. These results suggest that integrating condom skills education into a family-centered prevention programs is effective when caregivers' input on the issue is respected.

1. What important points does the first research study make pertaining to adolescent learning needs that you could use in your preventive healthcare teaching?

2. What implications do the findings from the research studies have on how you might provide preventive services to adolescents?

Obtain a Thorough Health History Obtain information in the following areas:

- *Medications and other drugs.* Be sure to ask about use of prescription and OTC medications, tobacco, and recreational drugs. If so, find out what, how much, and for how long?
- *Psychosocial profile.* Obtain a psychosocial profile focusing on health practices and behaviors. Assess the adolescent's ability to cope with stressors. **Key Point:** ***A change in academic performance or lack of interest in school may indicate a problem such as depression.***
- *Peer relationships.* Assess the quality of the adolescent's peer relationships, to assess risk for social isolation and to determine risk for school-related and/or gang-related violence.
- *Nutrition and body image.* Ask questions about body image in relation to the adolescent's nutritional status. Assess eating patterns, as well as intake of key nutrients such as protein, iron, calcium, and vitamin D.
- *Tattoos and piercings*. The tattoo or piercing may be in a concealed location, so ask about tattoos and piercings and ask to look at them during the visit. Discuss the risks of body art and modification.
- *Activity and exercise patterns.* If the adolescent engages in activities that increase the risk for injuries, ask about the use of protective equipment, such as helmets, mouth guards, or padding. If the adolescent reports no regular physical activity, assess his or her understanding of the benefits of exercise.
- *Sleep patterns.* Teens often get little sleep during school days and sleep late on weekends. Ask whether the teen feels refreshed after a night's sleep.
- *Safety*. Determine whether the adolescent wears a seat belt. Determine whether he is aware of the hazards of driving under the influence of drugs and alcohol and while texting or talking on the phone. Other distractions, including loud music and other teens in the car, can compete with the attention and focus needed for traffic and driving safety.
- *Sexual activity*. Determine whether the adolescent is sexually active. If so, ask about condom use.
- *Review all body systems*. While doing so, keep in mind changes or problems that are specific to the adolescent.

General Survey Complete a general survey after you have gathered the subjective data. Include vital signs, height, and weight. Follow with a head-to-toe physical exam. If you identify any problems in the course of the history and physical examination, actively involve the adolescent and the parents in a plan of care.

Calculate the BMI using a BMI calculator and BMI-for-age percentiles for children and teens. Adult calculators will not give accurate results for teens. The following are the CDC weight status categories:

Underweight	Less than 5th percentile
Healthy weight	5th to less than 85th percentile
At risk of overweight	85th to less than 95th percentile
Overweight	95th percentile or greater

To use the CDC BMI Calculator for Child and Teen,

Go to the CDC Web site at http://nccd.cdc.gov/dnpabmi/

To see the CDC body mass index-for-age percentile charts for boys and girls ages 2 to 20,

Go to Student Resources: Chapter 9, **Tables, Boxes, Figures: ESG Figures 9-4 and 9-5,** in the Chapter Resources on Davis*Plus*.

INTERVENTIONS

When working with adolescents, your goal is to help the adolescent make informed decisions. Avoid scare tactics, and encourage open discussion. Often a teenager will feel more comfortable asking a nurse or other health professional about sensitive topics than asking a parent. **Key Point:** ***Reassure the adolescent that you will maintain confidentiality. However, if there is concern about suicide, explain to the adolescent that you are required to share this information with others. Provide mental health referrals immediately when an adolescent contemplates suicide.***

Focus your age-specific interventions on educating the teenager about common health problems and avoidance of injury and disease. Include the following topics in your discussions:

Preventing and Treating Obesity

Help the patient to make small but permanent changes in eating and exercise. These usually work better than a series of extreme short-term diets and exercise plans that cannot be sustained. Gradual weight loss is the healthiest approach. Even for teens, parental involvement is important, primarily to model healthy eating and physical activity.

Calorie Intake Reducing calorie intake is usually the easiest change to make. As a rule, avoid highly restrictive diets that forbid favorite foods. It is important to encourage strong support from parents and others involved in buying and preparing food. Teach the teen how to choose highly nutritious foods at school, to replace junk foods with healthier choices as snacks, and to limit fruit juices and sodas. Recommend eating a balanced diet, but with smaller portions.

Physical Activity Stress the importance of regular physical activity. Suggest walking to school instead of driving or taking a bus. If this is not practical, involve the family in planning regular physical activities, for example, a long walk after dinner. Even mild exercise, such as shooting hoops or swimming, provides more activity than watching television or playing computer games. You might start with the following goals:

- *Limit television and video game use* to 1 or 2 hours a day. Discourage use before school, during homework, and late at night. Keep the television off during family mealtimes.
- *Engage in 30 minutes of outdoor activity every day*, no matter how mild the activity. Then work up to an hour a day of more strenuous exercise.

Intervention for Example Problem: Substance Abuse

Discuss with the adolescent the effects of drugs, alcohol, and tobacco and the hazards associated with their use. If your assessment has identified drug or alcohol use, make appropriate referrals.

Provide information on smoking cessation programs, if appropriate. Remind teens that the earlier a person begins smoking, the harder the addiction is to break. Stress the unattractive physical effects, such as bad breath, stained teeth and fingers, and a long-term cough, not to mention the expense and inconvenience of purchasing cigarettes. More and more teens are using smokeless tobacco products, and some have the mistaken idea that these are safer than smoking.

Preventing Pregnancy and STIs

One of the *Healthy People 2020* national goals is to increase the percentage of adolescents who either abstain from sex or use condoms with hormonal or intrauterine contraception. To see the *Healthy People 2020* objectives,

Go to the *Healthy People 2020* Web site at http://www.healthypeople.gov/2020/default.aspx

Abstinence is the only 100% effective way to prevent pregnancy and STIs. However, if the adolescent is sexually active, explain that using condoms can greatly reduce, although not eliminate, the risk of STIs and unwanted pregnancies. Be sure he understands that STIs can be transmitted orally and anally, as well as vaginally, so it is important that he uses a condom, regardless of the type of sexual activity.

A practice guideline from the AAP (2005) recommends that schools make condoms available for adolescents and, with community involvement, develop a comprehensive sequential sexuality education as a part of a K–12 health education program. Some parents may worry that sex education and condom availability encourage teenage sex but data show that making condoms available does not increase the rate of sexual activity (Agency for Healthcare Research and Quality, 2008). School and community collaboration is essential to promote sexual responsibility by increasing the use of condoms.

Breast Self-Exam

Currently there is some controversy about whether or not we should continue to encourage breast self-examination (BSE). The American Cancer Society (n.d., updated 2012) advises that monthly BSE is optional for women under age 30. BSE is recommended by certain medical groups, such as the ACOG (2009; NGC, 1998, revised March 2012), but not by the USPSTF (2009). Some studies indicate that BSE does not reduce death rates from breast cancer (National Cancer Institute, 2008); however, others found that more cancers are discovered and that the cancers detected are smaller in groups who perform BSE (Gemignani, 2011; Kösters & Gøtzsche, 2004, updated October 8, 2009; Meissner, Klabunde, Han, et al., 2011).

There is a trend away from teaching BSE and toward promoting *breast self-awareness*, defined as women's awareness of the normal appearance and feel of their breasts. Breast self-awareness can include BSE, and if patients choose to perform BSE, they should be trained in proper technique to avoid false-negative findings (ACOG, 2009; USPSTF, 2009; NGC, 1998, revised March 2012). To see how to perform a BSE,

Go to Chapter 9, **Assessment Box: Breast Self-Exam,** in Volume 2.

Testicular Self-Exam

Males over the age of 14 should perform a testicular self-examination once a month. This is an effective way to become familiar with the body and to detect testicular cancer early, when it is most curable. However, the USPSTF (2011b) recommends against routine screening, even though they acknowledge that most testicular cancers are discovered by TSE. They concluded that screening does not reduce the deaths population-wide from testicular cancer sufficiently to merit routine TSE. If your patient chooses to perform TSE, advise him to perform the exam after a warm bath or shower (heat relaxes the scrotum, making it easier to find abnormalities). To learn how to do a testicular self-exam,

Go to Chapter 9, **Assessment Box: Testicular Self-Exam,** in Volume 2.

To find information about testicular self-examination,

Go to the Testicular Cancer Resource Center Web site at http://tcrc.acor.org/tcexam.html

Immunizations

For adolescents ages 13 to 17, none of the *Healthy People 2010* objectives for vaccinations were met. Fewer than half have current tetanus, diphtheria, and pertussis immunization. About double that number have been vaccinated for hepatitis B, measles, mumps, and rubella. To see the national goals for 2020,

Go to the *Healthy People 2020* Web site at http://www.healthypeople.gov/2020/topicsobjectives2020/default

For the recommended immunization schedule for adolescents,

Go to Student Resources: Chapter 9, **Tables, Boxes, Figures: ESG Figure 9-3,** on Davis*Plus*. Also go to Immunizations Recommended for Children Ages 7 to 18 years, on the CDC Web site, at http://www.cdc.gov/vaccines/schedules/Schedulers/adolescent-scheduler.html

Other Health Promotion Activities

Other nursing activities include promoting adolescent health and safety.

- *Rest.* Explain the importance of adequate rest. Teens need 8 hours of sleep a night for maximum performance in academics and sports.
- *Nutrition.* Stress the importance of adequate nutrition, including intake of 1,300 mg of calcium and 400 IU of vitamin D daily to reach maximum bone density during this critical period of rapid increase in growth and bone mass. Teach teens how to include fruits, vegetables, cereal and grains, lean meats, chicken, fish, and low-fat dairy products in their diet, and to avoid foods and drinks that are high in sugar, fat, or caffeine.
- *Dental Hygiene.* Advise parents that the adolescent should have a preventive dental care visit once a year. Teach the teen to brush twice a day with a soft toothbrush, and to floss daily.
- *Safety.* Remind teens to wear a seat belt when riding in the car, and avoid distractions while driving (e.g., talking or texting on a cell phone, changing a radio station). Ask them *never* to drive under the influence of alcohol or drugs. Remind them to wear a helmet and protective gear for activities such as bicycling, in-line skating, and skateboarding. Teach the importance of sun safety (e.g., applying a sunscreen of at least SPF 15, avoiding tanning beds, wearing sunglasses when in the sun).

Think**Like a Nurse** 9-5

Recall Carrie, a 13-year-old, in the Meet Your Patients scenario. Carrie is hospitalized for pneumonia. What effect might this have on her behavior? As her nurse, how might you intervene?

YOUNG ADULTHOOD: AGES 19 TO 40 YEARS

Young adulthood is the time of transition to independence and responsibility. This transition involves important life events, such as high school graduation, entering college or starting a career, and leaving home and functioning independently. The 20s are spent exploring occupations, marriage, or alternative relationships.

Physical Development of Young Adults

Young adulthood is usually the healthiest stage of a person's life. Maturation of the body systems is complete. Peak bone density is achieved for both females and males by age 25. Vision and hearing are typically acute. For women, the ages between 20 and 30 years are the optimal years for childbearing. For men, male hormone levels that surged in adolescence begin to slowly decrease and stabilize around age 24.

Cognitive Development of Young Adults

According to Piaget, cognitive development terminates in adolescence around age 15. At this point, thought processes and mental abilities are well established. Learning continues throughout life but patterns of thinking do not alter.

Contemporary psychologists have proposed an additional stage of cognitive development called *post-formal operations*. In the *formal operations* phase, one is able to think rationally, predict outcomes, and hypothesize about the future. *Post-formal operations* add a dimension of complexity. In this phase, the young adult is able to accept contradictions and fine points in thinking. For example, the post-formal thinker recognizes that her opinion on a social controversy has aspects of two opposing viewpoints. She sees merit in both parts of the argument and is comfortable with the discrepancy.

Psychosocial Development of Young Adults

Young adults begin to explore options for careers and intimate relationships. They strive to become less dependent and more self-sufficient. Around age 30, most young adults experience a period of self-evaluation. This often results in job, career, or relationship changes. Erikson describes this period as the stage of *intimacy versus isolation*. Successful completion of this phase requires establishment of lasting friendships and associations. Freud described this phase of life as the *genital stage*. He believed that young adults are instinctively driven to form a sexually intimate relationship.

Common Health Problems of Young Adults

Young adults are generally active and in good physical health. Health problems may include STIs, unplanned pregnancies, traumatic injury, suicide attempts, substance abuse, domestic violence, obesity, diabetes, and hypertension.

Sexually Transmitted Infections

Sexual experimentation often continues in this stage. Among adults 15 to 44 years of age, nearly all have had vaginal intercourse and most have had oral sex with an opposite-sex partner. More than one-third of women and 44% of men have had anal sex with an opposite-sex partner. Twice as many women ages 25 to 44 (12%) reported any same-sex contact in their lifetime, compared with men (5.8%) (Chandra, Mosher, & Copen, 2011). Some common STIs include chlamydia, genital warts (condyloma acuminata), gonorrhea, and genital herpes. Also, the large majority of newly diagnosed cases (nearly 39%) of acquired immunodeficiency syndrome (AIDS) are among young adults (CDC, 2008, 2010b, revised 2011). For more information about STIs, see Chapter 33, and

Go to Chapter 9, **Supplemental Resources, Sexually Transmitted Infections,** on Davis*Plus*.

Example Problems: Substance Abuse and Violence

Drug abuse is commonly thought of as an adolescent problem; however, cocaine use is on the rise among young adults with families and careers. In the young adult years, there is a strong emphasis on "getting ahead," establishing a career and family, and becoming independent. These tasks are emotionally difficult. Substance abuse and mental health problems, particularly depression and suicide, may result from the tensions that arise. Substance abuse is often associated with acts of violence.

Unintentional injury is the leading cause of death in young adults (National Center for Health Statistics, 2011b). Suicide, a potential result of untreated depression, is another cause of death among young adults. Roughly 40,000 people a year die from firearm injuries; most of these are suicide and homicide rather than accidental injury. This is a rate of about 1 death per 10,000 people. The male death rate is about 7 times that for females (Heron, Hoyert, Murphy, et al., 2009).

Example Problem: Intimate Partner Abuse, Neglect, and Violence

Domestic violence is the abuse of power and control within an intimate relationship, most often between spouses or domestic partners. The CDC recognizes four categories of intimate partner violence (IPV), including physical violence, sexual violence, threat of physical or sexual violence, and psychological or emotional abuse.

Incidence Surveys typically report that 1 in 3 U.S. women is physically assaulted by a spouse or partner at some point in their lives—an estimated 1 to 5 million each year. About half of these incidents result in injury (Moracco, Runyan, Bowling, et al., 2007; Nelson, Bougatsos, & Blazina, 2012; U.S. Department of Justice, 2000). Many victims do not report the abuse, so survey results vary. Violence against women and girls is a worldwide epidemic. Globally, 1 in every 3 women has been assaulted, coerced into sex, or otherwise abused at some point in her life. More often than not, the abuser is a spouse or domestic partner, but it is sometimes another family member.

Risk Factors Abuse occurs in all ethnic and socioeconomic groups. Factors associated with intimate partner violence include young age, low income status, pregnancy, mental health problems, alcohol or substance abuse by victims or perpetrators, separated or divorced status, and history of childhood sexual or physical abuse (Nelson, Bougatsos, & Blazina, 2012). Females 16 to 24 years of age are the most vulnerable to nonfatal violence. In the United States, women are 7 to 14 times more likely to be abused than are men. About 31% of female murder victims are killed by an intimate, compared with 3% of male victims.

Health Consequences Intimate partner violence has negative consequences for physical, sexual, and psychological health. Abuse victims can suffer acute and chronic pain, disability, damage to the eyes, sleep disorders, miscarriage, STIs, poor self-esteem, depression, anxiety, and even suicidal behavior.

Obesity

Obesity rates have increased during the past 25 years. It has now become a public health crisis. In 2010, 35.7% of U.S. adults were obese, with no difference between men and women. With the increase in obesity, the incidences of type 2 DM and hypertension have grown dramatically among young adults (National Center for Health Statistics 2011a; Ogden, Carroll, Kit, et al., 2012).

ASSESSMENT

Young adults should have an annual physical examination, including assessment of physical health, mental health, and lifestyle. Be sure to assess diet, exercise, smoking, drinking, and drug use. For women the exam should include a pelvic examination.

Screening Screening for diabetes and hypertension is very important in the young adult years, especially for those who are overweight or who have a family history of these disorders.

The American Cancer Society recommends a clinical breast examination at least once every 3 years. The USPSTF (2011b) no longer recommends clinical testicular exams because there is not enough evidence to show that screening reduces the deaths population-wide from testicular cancer. Nor do they recommend monthly TSE.

Example Problem: Assessment—Violence Screening

Intimate partner violence (IPV) is common, but often remains undetected, so the USPSTF recommends that clinicians screen women of childbearing age for abuse or domestic violence, and provide or refer women who screen positive to intervention services (Smith & Segal, 2012; USPSTF, 2012a). If there is any reason to suspect abuse, conduct a thorough assessment.

If a patient discloses domestic violence, act immediately. Ask the patient whether she would like you to contact the agency's domestic violence advocate (if there is one). If not, provide contact information for community domestic violence programs. Patients are often fearful, isolated, and in real danger, but they may refuse help the first time it is offered. For further information on abuse assessment and reporting,

Go to **Procedure 9-1,** in Volume 2.

Also see Mandatory Reporting Laws, in Chapter 45, Legal Issues.

INTERVENTIONS

Nursing interventions for the young adult are similar to those for the adolescent. As a newly independent person, the young adult is establishing health patterns, including how she will interact with healthcare providers. Reinforce the teaching that was begun in the earlier age group. Stress the importance of health promotion activities such as Papanicolaou (Pap) test (for cervical cancer) every 3 years for women between the ages of 21 and 30 (NGC, 2012a; USPSTF, 2012b).

Breast Cancer Prevention Teach BSE if the client chooses to do it for early detection of cancer (see the section Breast Self-Exam in the part of this chapter on adolescents, preceding). Self-exam does not replace screening mammograms, and women younger than 40 who have risk factors for breast cancer should ask their healthcare provider whether they need mammograms. Risk factors include personal and family history of breast cancer, having the first child late in the childbearing cycle, having the first menstrual period before age 12, and certain breast changes (e.g., cells that look abnormal under a microscope). Studies have shown no link between abortion, or miscarriage, and breast cancer (National Cancer Institute, 2009). For a BSE procedure,

Go to **Assessment Guidelines & Tools, Assessment Box: Breast Self-Examination (BSE),** in Volume 2.

Exercise Recommend that adults engage in 2½ hours a week of moderate-intensity or 75 minutes a week of vigorous-intensity aerobic physical activity. Increasing exercise to 300 minutes a week provides even more health benefits (USDHHS, 2008).

KnowledgeCheck 9-9

- According to Erikson, what is the developmental stage of the young adult?
- What is the leading cause of death for this age group?
- What gender-specific assessments should be emphasized with this age group?

MIDDLE ADULTHOOD: AGES 40 TO 64 YEARS

The middle adult years are a time when people realize the difference between their early aspirations and their actual achievements. For families with children, this is a time when the children mature and leave the home. As a result, many middle adults and their children feel a need to redefine family roles.

Physical Development of Middle Adults

Physiological changes that occur during the middle adult years include graying hair, decreases in elasticity of the blood vessels, muscle tone, skin moisture and turgor, and gastrointestinal (GI) motility. A decrease in bone mass often causes a slight loss of height.

Menopause One of the principal changes that middle-adult women experience is **menopause**, the cessation of menstrual periods for at least 12 months. The ovaries no longer produce eggs on a cyclical basis, and reproductive ability is lost (although some women do become pregnant after not having menses for a year). The average age of menopause is 51 years. Most women experience a transition that takes place over several years. *Perimenopausal symptoms* are related to a decline in estrogen levels and may precede menopause by as much as 5 to 7 years. These symptoms include hot flashes, a decrease in breast size, changes in the length of the menstrual cycle and menstrual flow, vaginal dryness, nighttime awakenings, and moodiness.

Hormone replacement therapy (HRT) has been used extensively in the past to treat these symptoms, but recent studies have raised questions about the safety of hormone therapy to treat a naturally occurring phenomenon. HRT can relieve symptoms such as hot flashes and vaginal dryness. It may also protect against osteoporosis and age-linked eye disease. Some studies show that it may help prevent dementia; others show that it does not. Risks of HRT include increased risk of heart disease, breast cancer, stroke, and blood clots. The National Heart, Lung, and Blood Institute (National Institutes of Health, 2008) concludes that the risks of long-term combination hormone (estrogen and progestin) therapy outweigh the benefits for postmenopausal women. Women should be advised to consult their physician about estrogen-alone therapy, bioidentical therapies, and certain natural remedies that can provide symptom relief.

Andropause Men do not experience such a clear-cut transition as do women; however, many men do experience a transitional period known as andropause. **Andropause** is characterized by a decline in testosterone production, a lower sperm count, and a need for more time to achieve an erection. Andropause does not result in an inability to reproduce but does limit reproductive abilities.

Cognitive Development of Middle Adults

Piaget theorizes that the middle adult moves freely between formal operations, concrete operations, and problem-solving as the task demands. The middle adult is able to reflect on the past and anticipate the future. Creativity may reach its peak during this stage. Memory is intact, but reaction time begins to diminish because of diminishing nerve impulses.

Psychosocial Development of Middle Adults

Erikson describes middle adulthood as a stage of *generativity versus stagnation. Generativity* is the process of guiding the next generation or improving the whole of society. *Stagnation* occurs when development ceases: A stagnant middle adult cannot guide the next generation or contribute to society. Erikson believes that an inability to meet the developmental tasks of the middle adult years results in lack of preparedness for the final life stage of old age.

Middle adults often complain of declining energy and competing demands as they raise children, care for aging parents, and work at the peak of their career (Fig. 9-10). These stressors in combination with visible signs of aging may produce a **midlife crisis**—a recognition that youth is over and that life is limited. Coping skills learned in earlier years are important predictors of how the middle adult reacts to these changes.

Common Health Problems of Middle Adults

In the middle adult years, chronic diseases emerge as a major health problem. The most common chronic diseases are cancer, obesity, diabetes, hypertension, and cardiovascular disease. Many interventions for younger age groups are directed at preventing the development of these disorders.

FIGURE 9-10 Middle adulthood is a time of competing demands.

Cancer Cancer is the second leading cause of death in this age group. The majority of cancer diagnoses occur in the middle and older adult years. Cancers of the lung, breast, colon, prostate, and bladder are among the most common. A man's risk of **prostate cancer** increases as he ages. Nearly 65% of prostate cancer cases occur after the age of 65. Other factors that increase the risk of developing prostate cancer are family history, race (African American men have the highest rate), and possibly diet. There is some evidence that a diet high in animal fat may increase the risk.

Obesity As we have seen, obesity is a major health problem in all age groups. It often triggers development of type 2 DM, hypertension, joint pain, and cardiovascular diseases, such as coronary artery disease, atherosclerosis, and venous insufficiency. Diet and exercise must be consistently used together to combat obesity. Ironically, obesity leads to a variety of problems that make it even harder to exercise.

Hypertension Hypertension (high blood pressure) is a complex disorder. As the elasticity of the vascular system declines with each passing year, the incidence of hypertension increases. If there is a strong family history of hypertension, the likelihood of needing treatment escalates sharply. Except for age and family history, factors that increase the risk of hypertension are under the patient's control. They include excess weight, sedentary lifestyle, high sodium intake, high fat intake, smoking, and the ingestion of more than 1.5 ounces of alcohol per day. For further discussion of hypertension, see Chapter 20.

Cardiovascular Disease Cardiovascular disease (CVD) is often the end product of poor lifestyle choices. Atherosclerotic plaque develops in the peripheral vascular system, the heart, major vessels, or any combination of these areas. CVD is the result of inadequately treated hypertension, ongoing weight gain or obesity, an aftermath of poorly controlled type 2 DM, and an outcome of sedentary lifestyle. Smoking and excess alcohol use are additional risk factors, as is long-term hormone replacement therapy for women. CVD is among the leading causes of death in the middle adult years.

Example Problem: Domestic Abuse, Neglect, and Violence.

Although younger women are more likely to experience nonfatal violence, women ages 35 to 49 are the most at risk for intimate murder (U.S. Department of Justice, n.d., last reviewed 2012). Also see Common Health Problems of Young Adults and the Example Problem: Intimate Partner Abuse, Neglect, and Violence, preceding. The assessments and interventions for middle adults are similar to those for young adults.

ASSESSMENT

Middle adults should undergo an annual physical exam. In addition to height, weight, BMI, and vital signs, the exam should include the following:

- *Lipid panel screening*; total cholesterol, triglycerides, high-density lipoprotein (HDL), low-density lipoprotein (LDL), and ratios.
- *Blood glucose screening.*
- *Clinical breast and pelvic examination* for women. There is still controversy about whether to encourage BSE (*The Guide to Clinical Preventive Services 2010–2011;* NGC, 1998, revised 2012); however, many clinicians believe it to be useful. See Breast Self-Exam, in the section on adolescents. Women older than age 30 should have a Pap test every 3 to 5 years based on health history and discussion with their primary care provider.
- *Annual or biannual mammogram* for women (American Cancer Society, n.d.b, last revised June 2012; NGC, 1998, revised March 2012).
- *Digital rectal exam for prostate evaluation* in men should be offered but not routinely done (American Cancer Society, n.d.b). An enlarged prostate can indicate either benign prostatic hypertrophy or prostate cancer. In men, serum prostatic specific antigen (PSA) level is a sensitive indicator of prostate disorders. Recommendations vary. Some caution against routine screening; however, the American Cancer Society (n.d.b, revised June 2012) says this test should be given beginning at age 45 to men who want to be screened, and at age 40 for those who are at higher risk.
- *Annual eye exam*. Visual changes are common in this age group and include the development of presbyopia (far-sightedness) and the onset of glaucoma and cataracts.
- *Colorectal cancer screening.* Regular screening, beginning at age 50, is the key to preventing colorectal cancer. The USPSTF and an NGC Guideline Summary recommend screening for colorectal cancer using stool for occult blood testing, and sigmoidoscopy or colonoscopy beginning at age 50 years (or at age 40 for high-risk patients) and continuing until age 75 years (NGC, 2012b; Qaseem, Denberg, Hopkins, et al., 2012; USPSTF, 2008). The frequency of repeat exams depends on the findings.
- *Osteoporosis screening* at or prior to menopause for at-risk women who elect it. Most guidelines recommend assessing all adults age 50 years and older for risk factors (e.g., smoking, low body weight), with bone density measurement (e.g., a DXA test) based on the risk profile (NGC, 2008, revised 2012).

INTERVENTIONS

Care for middle adults focuses on identifying risk factors and promoting a healthy lifestyle. At each annual exam and at periodic health visits, you should discuss the hazards of alcohol and tobacco use, stress-management techniques, and safety, as well as the following three topics. You will also need to add teaching interventions if any chronic problem is discovered.

Nutrition For menopausal women, encourage daily intake of 12,00 milligrams of calcium and 600 IU of vitamin D, as well as regular weight-bearing exercise, to promote optimal bone density (Institute of Medicine, Food and Nutrition Board, 2010, updated 2012; Office of Dietary Supplements, National Institutes of Health, 2011). There is growing consensus that even this amount may be too low. Many clinicians are prescribing higher doses, especially in cases of known deficiency.

Exercise Although the usual recommendation is for 60 minutes of exercise daily, and that amount brings the most health benefits, researchers now suggest that even smaller amounts of exercise can improve the quality of life for sedentary, overweight or obese postmenopausal women. Even just 10 to 30 minutes a day can improve in social functioning and decrease limitations in work and other activities due to physical or emotional problems (American Heart Association, 2011).

Immunizations Review the patient's immunization record regularly. Middle adults often require periodic boosters, for example, for tetanus. For clients who have a chronic disease, recommend an annual flu vaccination. Strongly encourage clients with respiratory problems to receive pneumonia vaccination as well.

KnowledgeCheck 9-10

- According to Erikson, what is the developmental stage associated with middle adulthood?
- Identify at least five appropriate topics for health teaching during middle adulthood.

PracticalKnowledge knowing how

This section of the chapter focuses on using standardized nursing language for nursing diagnoses, patient outcomes, and interventions for patients in infancy through middle-adulthood. Specific assessments and interventions were discussed within each of the developmental stages in the Theoretical Knowledge section.

ANALYSIS/DIAGNOSIS

Although most NANDA-I diagnoses can be used for any age group, the following focus specifically on growth and development (NANDA-I, 2012):

Adult Failure to Thrive
Delayed Growth and Development
Risk for Delayed Development
Risk for Disproportionate Growth

Refer to the clients in the Meet Your Patients scenario. You would, of course, consider their growth and development needs in your assessments and care. However, they are unlikely to experience any of the four growth and development diagnoses. Short-term illness does not usually lead to delays in growth and development. Growth and development problems are more likely to be caused by family dysfunction, inadequate nutrition, or severe or long-term illness (e.g., Risk for Delayed Development r/t inadequate stimulation secondary to parental substance abuse).

Delayed growth and development is more often a part of the defining characteristics (signs and symptoms) of a problem rather than the diagnosis (e.g., Impaired Parenting r/t mother's chronic disability and absent father, as evidenced by height, weight, and verbal skills behind norms for age group).

When used to describe a client's *problem,* Delayed Growth and Development is too broad to suggest nursing actions. For example, the label is not useful for a mentally handicapped child (e.g., do not write, Delayed Growth and Development r/t Down syndrome). Instead, write a nursing diagnosis describing the specific functional task(s) the child cannot perform (e.g., Toileting Self-Care Deficit r/t inability to recognize the urge to void in time to ask for help secondary to Delayed Growth and Development). This label is also not appropriate for a child with failure to thrive. Instead, use one of the family functioning diagnoses (e.g., Impaired Parenting) or Imbalanced Nutrition: Less Than Body Requirements (Wilkinson, 2013).

Although there are only four NANDA-I diagnoses that specifically address growth and development, some other NANDA-I diagnoses do address age-specific problems. Because they provide more specific direction for nursing care than the growth and development diagnoses, use these when possible. Those diagnoses are as follows:

- Ineffective Breastfeeding
- Ineffective Infant Feeding Pattern
- Interrupted Breastfeeding
- Readiness for Enhanced Breastfeeding
- Disorganized Infant Behavior
- Risk for Disorganized Infant Behavior
- Readiness for Enhanced Organized Infant Behavior
- Risk for Impaired Attachment
- Impaired Parenting
- Readiness for Enhanced Parenting
- Risk for Impaired Parenting
- Parental Role Conflict

PLANNING OUTCOMES/EVALUATION

NOC outcomes specifically related to growth and development include the following; however, many other NOC outcomes may be appropriate depending on the

NANDA-I label you use (e.g., Imbalanced Nutrition, Self-Care Deficit).

- Child Development: (specify 2 Months, 4 Years, and so on)
- Fetal Status: Antepartum
- Fetal Status: Intrapartum Growth
- Newborn Adaptation
- Physical Aging
- Physical Maturation: Female
- Physical Maturation: Male
- Will to Live

Individualized goals/outcome statements for the other NANDA-I growth and development diagnoses might include the following examples:

- *Diagnosis*: Risk for Disproportionate Growth
  Goal: The child will continue to gain weight and length as measured at the next well-child check.
- *Diagnosis*: Risk for Delayed Growth and Development
  Goal: The child will continue to gain weight and length and meet developmental milestones as measured at the next well-child check.

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC standardized interventions associated with growth and development diagnoses include the following:

- Coping Enhancement
- Developmental Care
- Hope Inspiration
- Parent Education: Childrearing Family
- Risk Identification
- Self-Care Assistance
- Self-Responsibility Facilitation
- Teaching: Infant Nutrition, Infant Safety, Safe Sex, Sexuality, Toddler Nutrition, Toddler Safety

PUTTING IT ALL TOGETHER

Recall the case of 3-year-old Tamika, who is being raised by her grandmother and has been hospitalized with pneumonia (Meet Your Patients scenario). Imagine that Tamika has been abandoned by her mother, who is addicted to heroin. If you observe that Tamika is small for her size and has not met developmental milestones appropriate for a 3-year-old, you could write the following *diagnostic statement*:

Delayed Growth and Development r/t abandonment by mother, recent change in living status, and gestational heroin exposure as evidenced by underweight status, short stature, limited verbal skills, and onset of walking at 36 months of age

To address Tamika's diagnosis you might use the following *outcomes*:

NOC outcome: Child Development: 3 Years
Individualized goal: Tamika will achieve growth between the 35th and 65th percentiles for her age group and be able to walk up steps, verbalize with 2- to 3-word sentences, and eat a variety of foods within 6 months.

Tamika will need care that helps her catch up developmentally and allows her to establish a strong relationship with her grandmother. Because the grandmother is also caring for an ailing spouse, you may need to refer this family to community support services for ongoing help.

NIC interventions appropriate for Tamika are as follows:
Developmental Care
Teaching: Toddler Nutrition and Toddler Safety
Specific interventions for Tamika might include therapeutic play with age-appropriate toys, reading stories, and engaging in conversation, as well as teaching the grandmother about these activities. This family may need counseling to assist with this transition.

CHAPTER 10 Life Span: Older Adults

Learning Outcomes

After completing this chapter, you should be able to do the following:

- Discuss the relationship of life expectancy and livable communities.
- Discuss the developmental challenges for each older adult age group.
- Identify common health problems seen in each group and for all older adults.
- Describe any special assessments unique to each group of older adults.
- Discuss age-appropriate interventions for older adults and for each group.
- Incorporate developmental principles of aging into nursing care.

Meet Your Patient

Ethel Higginbotham, an 80-year-old woman, is in the hospital with pneumonia. She lives alone. Her son tells you that she began to lose weight rapidly, complains of no appetite, and became withdrawn after the death of her husband. At a recent visit to her home, he found his mother confused, with a productive cough, and with small open lesions on her lower legs. This led to her hospitalization. Even though she is no longer receiving oxygen, you observe that she is very thin and weak, sleeps most of the time, and refuses to eat. "I just want to die," she tells you.

Theoretical Knowledge knowing why

Why should you learn about older adults? One very important reason is that most of your patients are likely to be older adults. Half of all hospitalized patients are older adults, and because older adults are more likely to have disabilities and chronic health problems, they will make up a sizeable number of the patients you see in clinics, home care, and other settings, as well. This chapter presents the most important topics and issues about aging and the development of older adults.

ABOUT THE KEY CONCEPTS

You may have thought of **developmental stages** as something that applies mostly to children. However, as you learned in Chapter 9, developmental changes occur throughout life, even in **older adulthood.** Many normal changes occur in **older adulthood**. You will learn how normal changes, as well as illness, can affect **functional status**—a major focus in caring for older adults.

PERSPECTIVES ON AGING

Older adulthood is the fastest growing age group in developed nations. To understand this, you will need to look at some statistics. In 1900, a mere 4.1% of the U.S. population was 65 or older. By 2008, life expectancy had increased, and older adults made up 13% of the population. It is expected that by 2050 one-fifth of the population will be over 65.

This chapter examines aging from different angles. We will discuss the concepts of life expectancy, distribution of age groups, life-span perspective, and percentage of total population. All of these concepts require you to think about numerical descriptions of population characteristics.

Life Expectancy

Life expectancy, measured at birth and at age 65, is one way to view aging. Around the world, people in developed countries are living longer and having fewer children. Consider the following data from the National Center for Health Statistics (2012).

- **Life expectancy at birth** has risen dramatically in the United States:
  In 1900, average life expectancy was 49.2 years.
  In 2009, average life expectancy was 78.5 years.
- **Life expectancy measured at age 65** has risen as follows:
  In 1900, a 65-year-old person could expect to live 11.9 more years.
  In 2009, a 65-year-old person could expect to live 19.2 more years.

This means that a baby born in 2009 could expect to live for nearly 78.5 years, whereas a 65-year-old person in 2009 could expect to live another 19.2 years, to age 84. Those numbers reflect the average life expectancy for both sexes and all ethnic/racial groups. However, differences in life expectancy emerge when you examine sex and ethnic group data.

Gender Disparities For infants born in 2009, the average total life expectancy for females is 80.9 years (life expectancy at birth). For males it is only 76 years. This difference is especially noticeable in the 85-years-and-older population, in which women greatly outnumber men. Life expectancy measured at age 65 was nearly the same for men and women in 1900; however, women had a lead of about 5 years over men in 2009, narrowing the gap as men age. So the longer men live, the longer they *will* live.

Racial Disparities In 1900, race defined U.S. life expectancy at birth. As of 2009, the picture was less clear (as you can see in the following data from National Center for Health Statistics, 2012).

- *Life expectancy at birth:* White females continued to have the highest life expectancy at birth but following closely behind were white males and black females. In 2009, the life expectancy of black males at birth was a little over 10 years less than for white females.
- *Life expectancy at age 65*: White women led life expectancy with 20 years, followed closely by black women at 19.3 and white men at 17.7 years, whereas black men at age 65 had the lowest life expectancy (15.8). Notice, though, that the gap for ethnicity decreases as a person ages.
  A black baby boy born in 2009 can expect to live to about age 71.
  A black man at age 65 in 2009 can expect to live another 15.8 years, to age 81.

The future population of older adults will be more ethnically and racially diverse, with minority groups (everyone except non-Hispanic, single-race whites) representing 54% of the population in 2050. The non-Hispanic white population—66% of the population in 2008—is projected to decrease and to compose only 46% of the total population in 2050 (U.S. Census Bureau, 2008).

Migration and Distribution of Age Groups

In addition to life expectancy, in-migration and out-migration within countries and between countries contribute to the distribution of age groups within each country and the median age of a population. For example, between 1995 and 2000, five states had the highest in-migration of newly retired persons: Nevada, Arizona, Florida, North Carolina, and Delaware. By 2020, these five states will begin to face an accelerated growth in the

85+ population. In 2010, the median age (years) (U.S. Census Bureau, 2008):

Of the U. S. population	was	37.2
Of the state of Maine	was	42.7
Of the state of Utah	was	29.2

The median age of the population in the United States is increasing:

In 2005, the median age of the U.S. population was 37.2 years.

In 2050, the median age of the U.S. population is expected to be 39 years.

KnowledgeCheck 10-1

- About what percentage of people over age 65 live in nursing homes?
- What percentage of people over 85 years old live in nursing homes?
- Who has the longer life expectancy, women or men?

Percentage of Total Population

Yet another way to view aging is by the *percentage of total population* each age group represents. In the United States, older adults composed approximately:

4.1% of the population in 1900
13% of the population in 2010
21% of the population in 2050 (projected by the U.S. Census Bureau, 2008)

Age distribution of a population is often illustrated in a pyramid with the youngest age group (0–4) at the base and the oldest age group (85+) at the peak, men on the left of the figure and women on the right. The shape of a population pyramid changes to that of a rectangle in developed countries with fewer births and increased life expectancy. To view a population pyramid that illustrates the projected age distribution of the U.S. population in 2025 and 2050, see Figure 10-1.

Notice that also that the percentage for centenarians almost doubles from 2025 to 2050. The Census Bureau reports the following in total number of centenarians (U.S. Census Bureau, 2006, 2008, 2011):

53,000 centenarians—actual total number in 2010
600,000 centenarians—projected total number in 2050

ThinkLike a Nurse 10-1

- What factors do you think account for the overall increase in life expectancy?
- What effect will the distribution of the population by age within your state have on your nursing practice?
- Refer to Figure 10-1 to answer the following three questions.
  In the 85 to 89 age group in the 2025 data, what percentage of the population are men? What percentage are women?
  In the 85 to 89 age group in the 2050 data, what percentage of the population are men? What percentage are women?
  In the 85 to 89 age group, which group increases the most between 2025 and 2050: women or men?

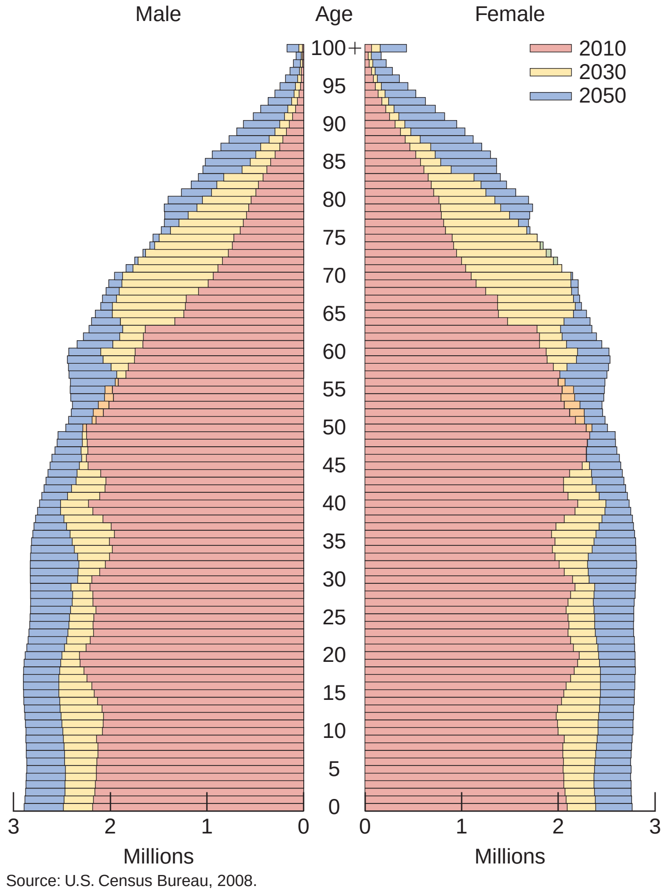

FIGURE 10-1 **Age and sex structure of the population for the United States: 2010, 2030, and 2050.** (*Source:* Retrieved December 9, 2012, from http://www.census.gov/prod/2010pubs/p25-1138.pdf.)

Life-Span Perspective

Another way to view aging is from a *life-span perspective*. In this perspective, *genes* inherited at conception, *behaviors* expressed throughout a lifetime and *environments* within which a person lives, works, and plays interact with each other over time. The cumulative effect of these interactions is seen in older adulthood.

Think of the genetic–behavior–environment interaction as a survival mechanism of aging. Attending to healthy behaviors (e.g., daily exercise) and avoiding unhealthy behaviors (e.g., tobacco use) is a lifelong process. A lifetime of positive health behaviors interacting with a healthful environment has the potential to shift effects of a harmful genetic trait—that is, a person may have the genetic trait for a particular disease but never show signs of the disease.

Remember the Nun Study discussed in Chapter 8? Some of the nuns demonstrated no symptoms of Alzheimer's disease during their lifetime, yet upon autopsy scientists discovered the typical neurological changes associated with Alzheimer's disease (Snowdon, 2003). The Nun Study results illustrate strong evidence of the power of behaviors and the environment over genes, resulting in centenarians who are cognitively intact and asymptomatic for Alzheimer's disease.

ThinkLike a Nurse 10-2

Plot your birth year on a time line that extends in 10-year increments through your 65th and 100th year. What is the projected distribution of age and gender when you are an older adult? What genetic, environmental, and behavioral attributes will influence your life expectancy and state of health as an older adult?

AGING IN PLACE AND ALTERNATIVES

Contrary to popular belief, most older adults live independently (Houser, Fox-Grage, & Gibson, 2012). **Aging in place** means that as they age, persons live in their own residences and receive supportive services for their changing needs, rather than moving to another type of housing. Aging in place requires an elder-friendly residence and an elder-friendly or livable community that provides maximum accessibility, minimal barriers, and adequate resources and services to maintain independence for as long as possible. The goal of an elder-friendly residence is safe daily interaction with a living environment for persons with normal changes of aging.

Elder-Friendly Residences Among the considerations for an *elder-friendly residence* are the following:

- Ground-level entry or no-step entry
- One-level living area
- Wide doorways to allow for assistive devices such as walkers and wheelchairs
- Lever-style door and faucet handles for easy grasp
- Grab bars, shower seats, and elevated toilet seat in bathrooms
- Kitchen appliances, cabinets, and surfaces no higher than 48 inches above the floor
- Shelves no more than 10 inches deep, for easy accessibility
- Adequate light in all areas inside and outside the residence
- Walking areas free of clutter, including area rugs.

Elder-Friendly Communities Livable communities (also referred to as *elder friendly*) "actively involve, value, and support older adults" (Alley, Liebig, Pynoos, et al., 2007, p. 1). To illustrate the need for elder-friendly communities, consider these facts about older adults in 2007 (Houser, Fox-Grage, & Gibson, 2009):

1 in 3 persons age 75+ lived alone

A little less than half the persons age 65+ lived at or below 250% of the poverty line (about $27,000 for a single person or $36,000 for a family of two)

Nearly 1 in 5 persons age 65+ had a bachelor's degree or higher

37% have a sensory, physical, mobility, self-care, or cognitive disability

Many older adults spent at least 30% of their income on housing (Harrell, 2011). This includes the approximately 48% who owned their own homes, and the 59% of older adults who were renters.

Livable communities offer:

- Affordable and appropriate housing for all ages
- Supportive services and features
- Dependable and affordable transportation and housing
- Resources that facilitate individual independence and socialization of residents (AARP Public Policy Institute, 2011)
- Affordable and accessible healthcare
- Safe, low-crime environment
- Community engagement

Naturally Occurring Retirement Communities

When persons "age in place" within a specific apartment building or a community/street of single-family homes, that area is referred to as a **naturally occurring retirement community (NORC)**. Persons within a NORC have aged together. More often than not, they have, over the years, developed access to services needed to maintain the highest quality of life for all within the NORC. When one neighbor needs assistance, others pitch in to help or to obtain help. The U.S. Administration on Aging provides competitive funding to support the development and maintenance of services within a NORC.

Retirement Communities

Some housing developments are built specifically as **retirement communities**. They are planned to provide elder-friendly dwellings and environments for independent living and allow older adults to "downsize" into a house that has less than 2,000 square feet in single-level, livable space. Purchase of a home in a retirement community usually includes, for an annual association fee, services such as home maintenance and repair; landscaping; snow, leaf, and trash removal; some home utilities; security; home fire and theft insurance; recreational amenities, such as pool, spa, walking track, and golf and tennis facilities; and planned activities. They usually have a minimum age restriction of 55, 60, or 62 either for one of the residents in a household or for all occupants. Age restriction may be problematic if grandparents become the primary care providers for a grandchild.

Continuing Care Retirement Communities

Continuing care retirement communities (CCRC), or *life care communities*, offer a wide range of living accommodations from residential living (e.g., cottages, cluster homes, apartments), assisted living, skilled nursing care, rehabilitation, and dementia care on a large campus-like setting. CCRCs include many amenities, ranging from golf courses, pools, and indoor sport facilities to a full range of hobby and clubrooms and personal services. A CCRC is another example of aging in place, except that an older adult must first move to it. So in that sense, it is not a NORC.

Entrance requirements include physical, mental, and financial health evaluations. CCRCs are usually expensive, requiring a contract, an entrance fee, and monthly fees that may increase with annual cost-of-living estimates. Depending on the contract, monthly fees may cover a set number of meals per month, transportation, housekeeping, unit maintenance, laundry service, health monitoring, some utilities, coordinated social activities, emergency call monitoring, and round-the-clock security. A health clinic is usually on site. Healthcare providers may include a registered nurse, nurse practitioner, physician, dentist, and physical therapist.

CCRCs vary by their affiliation (e.g., ethnic or religious group, university, corporation) and whether the living space is rented or purchased. University-affiliated CCRCs incorporate all aspects of academic life into the lives of residents and provide opportunities for cross-generation interactions on the CCRC and university campuses. These interactions are especially important for students interested in careers in gerontology, because they have an opportunity to work or conduct research with CCRC residents in areas that fit their disciplinary focus.

Assisted-Living Facilities

Assisted-living facilities (ALFs) are congregate residential settings that provide or coordinate personal services, 24-hour supervision and assistance (scheduled and unscheduled), activities, and health-related services. ALFs are *not* aging in place environments. State regulations and level of services do not allow residents to stay in an ALF when their needs become greater than the resources and services provided can handle. ALFs are designed to:

- minimize the need to move
- accommodate individual residents' changing needs and preferences
- maximize residents' dignity, autonomy, privacy, independence, and safety
- encourage family and community involvement (Total Living Choices, 2000–2012)

There are multiple definitions and goals of ALFs and no common physical size, design, or model. ALFs might be self-standing or housed within a CCRC as one level of housing and service. Each ALF has its own culture, rules, norms, values, and rituals that are created by the residents (Al Omari, Kramer, Hronek, et al., 2005). An ALF may have limitations such as reduced consumer choice, little flexibility, and an illusion of certainty (Zimmerman & Sloane, 2007).

Nursing Care Facilities (Nursing Homes)

Nursing care facilities, or nursing homes, provide skilled and unskilled nursing care for older adults and adults with disabilities. To understand the scope of nursing care facilities in the overall picture of aging, consider the following facts. In 2009:

- About 1.5 million residents lived in more than 16,000 U.S. nursing facilities.
- Only 3.1% of persons age 65+ lived in nursing facilities; however, this rises to 10.4% for people over 85 years.
- Nearly half of the residents of nursing homes had dementia, and one-fifth had other psychological diagnoses (Houser, Fox-Grage, & Gibson, 2009).
- Women composed more than 70% of the nursing home population.
- Nearly 75% of residents are age 75 or older; the median age is 83.2 (U.S. Census Bureau, 2007, revised September 19, 2012).
- Medicaid is the primary source of payment for most (65%) of the residents; Medicare pays for about 13%, primarily for short stays; and individual long-term care insurance or private sources pay for 22% (Houser, Fox-Grage, & Gibson, 2009).

What is the difference between a retirement community and a continuing care retirement community (CCRC)?

ThinkLike a Nurse 10-3

How elder-friendly is the community in which you live?

THEORIES OF AGING

There is no single explanation for how the body ages, but four groups of physiological theories predominate. Despite wide debate on these theories, most scientists consider aging to be a combination of factors, including inherited traits and the cell's response to environmental stressors.

Wear-and-Tear Theory This theory of aging proposes that repeated insults and the accumulation of metabolic wastes eventually cause cells to wear out and cease functioning.

Genetic Theories Genetic theories of aging propose that cells have a preprogrammed, finite number of cell divisions. Hence, the time of death is determined at birth. The genetic messages within the various body cells specify how many times the cell can reproduce, thus defining the life of that cell.

Cellular Malfunction These theories hypothesize that a malfunction in the cell causes changes in cellular DNA, leading to problems with cell replication. The cellular malfunction can be the result of a chemical reaction with the DNA (cross-linking theory), an abundance of free radicals that damage cells and impair their ability to function normally (free-radical theory), or a buildup of toxins over time that causes cell death (toxin theory).

Autoimmune Reaction This theory hypothesizes that cells change with age. Over time the changes result in the immune system's perceiving some cells as foreign substances and triggering an immune response to destroy the cells.

STAGES OF OLDER ADULTHOOD

Most references use 65 years as the age when older adulthood begins. The stages of older adulthood are typically referred to as the *young-old* (age 65 to 74), *middle-old* (age 75 to 84), and *oldest-old* (age 85 and older). The fastest growing segment of older adults is the oldest-old, some of whom are the frail elderly and *centenarians* (people older than 100 years). For more in-depth information about aging and older adults, refer to a life-span development or gerontology book.

Young-Old: Age 65 to 74

Physical and psychological adaptations to retirement are paramount in this age group. At retirement, a person's usual social contacts and structure for daily activities may change markedly. A newly retired older adult may be searching for new interests outside of the previous work environment. One key indicator of well-being is use of leisure time. On an average day, young-old persons spend most of their time (57%) watching television; 18% in solitary activities of reading, relaxing, and thinking; 11% socializing and communicating; 3% participating in sports, exercise, and recreation; and the remaining time in other activities, including related travel (Federal Interagency Forum on Aging Related Statistics, 2010).

By the time they reach age 65, young-old persons are already experiencing the effects of chronic illnesses that began in middle adulthood, along with the effects of lack of time to care for self because of the demands and stressors of work during that period. Retirement frees up time for the young-old to make up for these effects and focus on health-promoting behaviors to help prevent the decline of health as they age. However, young-old persons face barriers to health, such as a lack of supplemental insurance for health screening or physicals that are not covered under Medicare, self-perception of aging, changes in physical activity, and being in a deconditioned state by not participating in exercise in earlier life stages. There is some evidence that physical activity declines as early as age 63 for some, and by age 70 for most people (Wilson & Palha, 2007).

Middle-Old: Age 75 to 84

The developmental challenge of middle-old persons is an increasingly solitary, sedentary lifestyle. This age group spends one-fourth of their leisure time reading, relaxing, and thinking—more than their younger cohort. They spend only 3% of their time participating in sports, exercise, and recreation—less than their younger cohort (Federal Interagency Forum on Aging Related Statistics, 2010). Without physical activity, the risk of disability associated with chronic conditions increases during the middle-old years.

Adapted Physical Activity (APA) programs are group exercise programs designed for persons with chronic conditions, to correct sedentary lifestyle and prevent disability secondary to the disease. The focus of APA programs is on functional ability rather than disability, and they are beneficial throughout the older adult years. Even after critical incidents such as a stroke, APA can prevent further disability, maximize function, increase quality of life, and curtail the side effects of social isolation and depression (Macko, Benvenuti, Stanhope, et al., 2008).

Senior centers are beginning to offer APA programs as they update their programming for the active baby-boomer generation. Some health and fitness facilities may also offer senior health programs that include adapted strategies for lifelong walkers and marathon runners. Although physical activity declines in the middle-old group overall, there is some evidence that older adults represent the fastest-growing segment of participants in competitive sports, with a rise in the 80-plus-year-old finishers at road races such as the New York City Marathon (Futterman, 2008).

Oldest-Old: Age 85 and Older

The developmental challenges of the oldest-old are sensory impairments, oral health, inadequate nutritional intake, and functional limitations. The following incidence figures are from 2010 (Federal Interagency Forum on Aging Related Statistics, 2010):

- *Hearing.* Nearly half of older men and more than one-third of older women reported difficulty hearing. This was higher for the 85+ age group than it was for the young-old and the middle-old.
- *Vision.* 27% of the 85+ age group reported trouble seeing.
- *Edentulism.* 34% of those over 85 years old reported **edentulism** (having no natural teeth). This tends to be income related: 42% of older adults below the poverty line reported edentulism, whereas for those above the poverty line, incidence was only 23%.
- *Nutrition.* Edentulism compromises an already inadequate nutritional intake of older adults and fosters a diet of "soft" foods that may be higher in fats, carbohydrates, and calories. For the oldest-old, this occurs at a time when they need to decrease intake of these foods to combat obesity and counter decreased activity levels.
- *Functional limitations.* Ability to stoop/kneel, reach overhead, walk two or three blocks, and lift 10 pounds

are common parameters for determining functional abilities of older adults. Forty percent of men and more than half of women in the oldest-old group reported they were unable to perform at least one of these activities. There were minimal to no differences across ethnic and racial groups.

Centenarians People aged 100 years and older (**centenarians)** are a subgroup of the oldest-old. It appears that surviving to an extreme old age is the result of favorable interactions between genetic composition, environment, and lifestyle (behaviors). The most significant factor may be the presence of a loved one in the life of the older adult. One genetic variation of centenarians has been linked with longevity, but mapping the centenarian genome is essential to determine whether they do, in fact, carry a so-called longevity gene (Perls, 2006; Perls, Silver, & Lauerman, 1999). Among the characteristics of centenarians are that 12% live independently, 90% are cognitively intact into their 90s, and their commitment to community is linked to their longevity.

Example Problem: Frail Elderly

As humans age, they are gradually less able to adapt to challenges from internal (disease) and external (injury) environments. Frailty was at first used to mean the oldest-old, believing they were the least able to adapt and survive. However, as the oldest-old population increased and more is known about their survival, **frailty** has been distinguished in the following ways:

- A syndrome, or a set of characteristics, that describes a heightened state of vulnerability for developing adverse health outcomes.
- A multisystem reduction in the person's physiological capacity.
- The point at which the human organism is believed to have its least capacity for survival, and will fail in response to a minor internal or external insult. For example, a frail older adult might die merely as a result of falling ill to an upper respiratory infection (such as a cold).

KnowledgeCheck 10-3

- Name and give the age ranges for the four stages of older adulthood.
- Name and briefly describe four theories of aging.

DEVELOPMENTAL CHANGES OF OLDER ADULTS

Although not all people age at the same pace, there are predictable patterns of physical, cognitive, and psychosocial change. Older adults also have several, often chronic, health problems in common.

Physical Development of Older Adults

Although there is variation among individuals, patterns of change can be predicted in each body system. Table 10-1 presents an overview of changes seen with aging as well as corresponding areas for assessment.

Cognitive Development of Older Adults

Reaction time slows in older adults, and short-term memory declines; it takes longer to respond to a stimulus, and it takes more time to process incoming information. Thus, older adults learn new material more slowly. **Key Point:** ***However, there is no loss of intelligence as a person ages.*** Loss of short-term memory is more common than loss of long-term memory; thus, older adults may remember incidents from many years ago in vivid detail but may have trouble recalling what they did earlier in the day.

Physical health problems or medications may also affect memory. Research indicates that an active social life with complete engagement and participation in the community delays memory loss with aging (Ertel, Glymour, & Berkman, 2008). Regular mental exercises (e.g., crossword puzzles, conversation) appear to stimulate the brain and enhance memory. Other factors that slow memory loss are getting adequate sleep and rest, eating a nourishing diet, and avoiding drugs and alcohol.

Psychosocial Development of Older Adults

Rather than explaining how the body ages, psychosocial theories of aging attempt to explain the psychological and social adjustment associated with aging.

Disengagement Theory (1961) Cumming and Henry hypothesized that the older adult and society gradually and mutually withdraw or disengage from each other. Mandatory retirement, chronic illness, the deaths of relatives and friends, and poverty are among the factors that may contribute to this phenomenon. As the interaction between a person and his world decreases, there is (a) more time for reflection and (b) freedom from societal roles. Power transfers to younger members of society as the older adult withdraws. Disengagement is not the norm for the current generation of older adults in America, nor is it universally true for cultures that value older adults' advice as essential for family decision making.

Activity Theory (1963) Activity theory posits that the individual should stay as active and engaged as possible to enjoy the highest life satisfaction. On retirement, another activity, such as travel, sports, hobbies, or volunteering, replaces time spent at work. The more engaged the older adult is, the greater his life satisfaction will be (Fig. 10-2). Havighurst's theory is the counterpart of disengagement theory. According to Havighurst

Table 10-1 ➤ Age-Related Changes and Areas for Assessment

	NORMAL AGING CHANGE	AREAS FOR ASSESSMENT
Musculoskeletal	Decreased muscle strength, body mass, bone mass, joint mobility Increased fat deposit	■ Activity/exercise tolerance ■ Joint pain, range of motion ■ Gait, balance, posture, change in height ■ Susceptibility to falls ■ Ability to perform ADLs
Cardiovascular	Decreased cardiac output Increased peripheral resistance, systolic blood pressure	■ Activity tolerance ■ Blood pressure ■ Orthostatic hypotension ■ Susceptibility to arrhythmia
Respiratory	Decreased elasticity of chest wall, intercostals muscle strength, cough reflex Increased anteroposterior diameter of chest, rigidity of lung tissue	■ Cough reflex ■ Use of accessory muscles ■ Gas exchange ■ Mouth breathing
Gastrointestinal	Decreased saliva production, GI motility, gastric acid production	■ Ability to chew ■ Dentition ■ Pattern of elimination ■ Frequency/size of meals
Integument	Decreased skin elasticity, nail growth Increased dryness of skin, thinning of skin layers, nail thickening, hair thinning	■ Susceptibility to hypo/hyperthermia ■ Intact skin, bruising ■ Dry skin ■ Bathing pattern
Genitourinary	Decreased glomerular filtration rate, blood flow to kidneys, bladder capacity, vaginal lubrication, hardness of erection	■ Continence ■ Urgency, frequency, nocturia ■ Hydration status ■ Drug levels ■ Sexual pattern
Nervous	Decreased nerve cells, neurotransmitters, REM sleep, blood flow to CNS	■ Diminished reflexes ■ Sleep pattern ■ Depression
Endocrine	Decreased insulin release, thyroid function, estrogen and testosterone	■ Change in weight ■ Libido ■ Energy level
Sensory	Decreased visual acuity (presbyopia, or impaired near vision) and depth perception, tear production, pupil size, accommodation, acuity of smell and taste, hearing of high-frequency sound, sense of balance changes in pain sensation Increased glare sensitivity, thickening of lens of the eye, changes in pain sensation	■ Adequate lighting with a glare-free bulb ■ Cerumen buildup ■ Home safety ■ Pain sensation ■ Driving ability ■ Environmental stimulation

Table 10-1 ➤ Age-Related Changes and Areas for Assessment—cont'd

	NORMAL AGING CHANGE	AREAS FOR ASSESSMENT
Cognition	Decreased short-term memory Increased reaction time, information-processing time	▪ Memory changes ▪ Learning barriers ▪ Adaptive coping
Personality	Increased cautiousness Retirement, widowhood, grandparenthood	▪ Sources of social support ▪ Social network

CNS = central nervous system; REM = rapid eye movement.

FIGURE 10-2 Many older adults are able to remain active and engaged well into their later years.

(1971), the following are physical, cognitive, and social developmental tasks of older adults:

Adjusting to decreasing physical strength and health
Adjusting to retirement
Adjusting to a lower income
Adjusting to death of a spouse
Establishing an open affiliation with one's age group
Adopting and adapting flexible social roles
Establishing satisfactory physical living arrangements

Psychosocial Development Theory (1963) Erikson's developmental theory identifies *ego integrity versus despair* as the task of the older adult. This stage of development has as its cornerstone the acceptance that one's life has had meaning and that death is a part of the continuum of life. This outlook allows a person to accept the inevitable changes in health and life circumstances. The basic virtue gained at this stage is wisdom. Recall that Erikson's theory is discussed in Chapter 9.

Psychosocial changes in this age group are many and significant. The older adult must face multiple losses, including the death of a spouse or partner, family members, and friends, as well as challenges to health, independence, and youthful vitality. Loss of independence and the ability to live without assistance often have a negative psychological affect on the older adult. Loss is discussed in detail in Chapter 17.

Common Health Problems of Older Adults

The 10 leading causes of death for older Americans are as follows (Murphy, Xu, & Kochanek, 2012):

1. Heart disease
2. Cancer
3. Chronic lower respiratory diseases
4. Stroke
5. Alzheimer's disease
6. Diabetes mellitus
7. Influenza and pneumonia
8. Nephritis, nephritic syndrome, and nephrosis
9. Accidents
10. Septicemia

Six of the seven leading causes of death among older adults are chronic diseases. Heart disease, cancer, stroke, and diabetes not only are among the most common but also are the most costly health conditions. These are long-term illnesses that are rarely cured, but many can be prevented or modified with healthy behavioral interventions. Prevalence of chronic conditions differs by race and ethnicity. For example, consider the different prevalence in diabetes in older adults in 2007–2008 (American Diabetes Association, 2011; Federal Interagency Forum on Aging Related Statistics, 2010):

Non-Hispanic blacks	30%
Hispanics	27%
Non-Hispanic whites	16%
Asian Americans	8.4%

In addition, an estimated 10 million Americans have *osteoporosis*, a loss in bone mineral density that increases the risk of fracture. In advanced cases, bones become so porous that they fracture spontaneously, merely from the stress of bearing the person's weight. The risk increases with age and is much greater for women, in part because of their normal bone density is less than that of men, but also because of hormonal changes at menopause and inadequate calcium intake. Cigarette smoking, moderate to heavy alcohol consumption, and lack of weight-bearing exercise also increase risk.

Example Problem: Dementia

Key Point: ***Dementia is not a normal result of aging.*** **Dementia** is an irreversible, progressive decline in mental abilities that affects about 1 in 5 adults older than age 70. Dementia involves both memory impairments and a disturbance in at least one other area of cognition such as the following:

- Aphasia (loss of ability to communicate)
- Apraxia (loss of ability to carry out purposeful movements)
- Agnosia (impaired ability to recognize or identify objects). Agnosia can lead to the inability to recognize family members or even one's own reflection in the mirror.
- Disturbance in executive functioning (ability to organize, manage, and make decisions)

Dementia makes it more and more difficult for the older adult to remember things, think clearly, communicate with others, or take care of himself. In addition, dementia can cause mood swings and even change a person's personality and behavior.

Risk factors for dementia include old age, family history, cardiovascular disease, and environmental factors such as a head injury or alcohol abuse (Fletcher, 2012). The U.S. Preventive Services Task Force (USPSTF) (2003a) does not recommend for or against routine screening for dementia, but does recognize that early diagnosis allows clinicians to anticipate future problems the patients may have (Registered Nurses' Association of Ontario, 2010). Table 10-2 includes information that may help you distinguish between normal changes in older adults as compared with changes resulting from dementia.

Table 10-2 ➤ Distinguishing the Changes of Typical Aging From Dementia

TYPICAL AGING	DEMENTIA
Independence in daily activities preserved	Dependent on others for key independent-living activities
Complains of memory loss but able to provide considerable detail regarding incidents of forgetfulness	May complain of memory problems only if specifically asked; unable to recall instances in which memory loss was noticed
Patient is more concerned about alleged forgetfulness than are close family members	Close family members much more concerned about incidents of memory loss than patient
Recent memory for important events, affairs, conversations is intact	Notable decline in memory for recent events and ability to converse
Occasional word-finding difficulties	Frequent word-finding pauses and substitutions
Does not get lost in familiar territory; may have to pause momentarily to remember way	Gets lost in familiar territory while walking or driving; may take hours to eventually return home
Able to operate common appliances even if unwilling to learn how to operate new devices	Becomes unable to operate common appliances; unable to learn to operate even simple new appliances
Maintains prior level of interpersonal social skills	Exhibits loss of interest in social activities; exhibits socially inappropriate behaviors
Normal performance on mental status examinations, taking education and culture into account	Abnormal performance on mental status examination not accounted for by education or cultural factors

Source: Adapted from Agency for Healthcare Research and Quality. (1996, November). *Clinical practice guidelines*. No. 19. Publication #97-0702, Washington, DC: U.S. Department of Health and Human Services. Retrieved October 25, 2012, from http://www.dartmouth-hitchcock.org/dhmc-internet-upload/file_collection/111609_aging_vs_dementia_table.pdf

Alzheimer's disease is the primary form of dementia and is considered progressive. Increasing age is the greatest known risk factor for Alzheimer's disease. The odds of developing Alzheimer's disease double about every 5 years after age 65. About half the adults age 85 and older have Alzheimer's disease (Alzheimer's Association, 2008).

Other dementias may be treatable—for example, those resulting from medication toxicity, sensory deficits, and some physiological problems. The diagnosis of dementia is often complicated by the fact that older adults may have comorbidities. It is important to differentiate dementia from acute confusion or delirium that may be precipitated by dehydration, infection, or a medication side effect or overdose. If you need more information about differentiating dementia, delirium, and depression, see Chapter 13.

Polypharmacy

Polypharmacy, the use of multiple medications, is a risk factor for acute confusion, delirium, and depression in older adults (see Chapter 26). The mapping and continued growth in knowledge about the human genome has accelerated the field of **pharmacogenomics** (the discipline that blends pharmacology with genomic capabilities); therefore, the future of drug therapy for older adults will take into consideration DNA variants and individual responses to medical treatments to identify particular subgroups of older adults and develop drugs customized for those subgroups. This technology is expected to increase the efficiency of the drug industry and result in cheaper, more effective drug therapies for older adults.

Depression

Medical problems can cause depression in older adults either directly or as a psychological reaction to the illness. Any chronic medical condition, particularly if it is painful, disabling, or life threatening, can lead to depression or make depression symptoms worse. In 2008, 17% of older women reported depressive symptoms compared with 10% of older men, numbers that have remained fairly stable for nearly a decade and may be related to appropriate antidepressant drug treatment for older adults (Federal Interagency Forum on Aging Related Statistics, 2010).

Depression not only affects mood but also impacts energy, sleep, appetite, and physical health. Many of the symptoms of depression are similar to those of dementia (memory problems, sluggish speech and movements, and low motivation) so it may be difficult to tell the two apart. Symptoms of depression can also be the side effect of many commonly prescribed drugs, especially if the person is taking multiple medications. Older adults are more sensitive to mood-related side effects of prescription medication because, as they age, their bodies become less efficient at metabolizing and processing drugs.

Example Problem: Elder Abuse

Elder abuse takes many forms, including the following:

- Battering
- Inappropriate use of drugs and physical restraints
- Force-feeding, physical punishment
- Nonconsensual sexual contact
- Treating an older person like an infant, including infantilizing communication (also referred to as *elderspeak*)
- Giving an older person the "silent treatment"
- Enforced social isolation
- Demeaning an older adult
- Neglect
- Abandonment
- Financial or material exploitation, such as illegal or improper use of an older adult's funds, property, assets, or Social Security checks
- Risk of abuse is higher for women and those with physical and cognitive vulnerabilities (Laumann, Leitsch, & Waite, 2008; Williams, Herman, Gajewski, et al., 2008)

Like domestic violence, elder abuse is seen in all cultures and socioeconomic groups. Risk factors for elder abuse include the following: advanced age; physical, functional, or cognitive impairment; mental illness, alcoholism, or drug abuse in elder or caregiver; social isolation or poor social network; dependence on others; past history of abusive relationships; low income status; financial or other family problems (of elder or caregiver); inadequate or unsafe housing; depression; low self-esteem; poor health of patient or caregiver; caregiver stressed or frustrated with difficult caregiving tasks.

Keep in mind that if there an older adult has an injury such as maxillofacial trauma, dental trauma, subdural hematomas, periorbital and laryngeal trauma, rib fractures, or upper extremity injuries, along with a wasted and unkempt appearance, there is the possibility that it was inflicted (Lowry, 2012). **Key Point:** ***If you suspect abuse, your care priority is to assure the client is safe and cared for. Next, suspicion of elder abuse must be reported to adult protection services and/or the authority designated by law in each state to investigate and prosecute elder abuse.*** For some elder abuse resources,

Go to the National Center on Elder Abuse (NCEA) **(http://www.ncea.aoa.gov)** and the Clearinghouse on Abuse and Neglect of the Elderly (CANE) **(http://www.cane.udel.edu).**

To assess for elder abuse, see the Assessment section, and

Go to **Procedure 9–1**, in Volume 2.

Ageism

Ageism is age-based discrimination. Negative expectations for older adults can cloud nursing assessments, planning, and interventions. Box 10-1 presents a quiz to test your knowledge of aging. Take the quiz so that you can be prepared to best assist your older adult clients. For answers,

Go to Chapter 10, **Supplemental Materials: Answers to "What's Your Aging IQ?"** on Davis*Plus*.

KnowledgeCheck 10-4

- Name two age-related changes seen in older adults.
- According to Erikson, what is the developmental stage of the older adult?
- What are the top two causes of death among older adults?

PracticalKnowledge knowing how

You would expect differences in functioning in older adults who are relatively healthy and those who have one or more illnesses. You will, of course, base nursing care on individual needs, not on a person's age category. And yet, in general, you would expect a patient's needs to be different at age 65 than at age 85. **Key Point:** ***Remember, though, that an individual's health status and needs are affected by many more variables than just his or her age (e.g., chronic illness, stressors).***

ASSESSMENT

This section presents information to use in caring for all older adults, as well as interventions specific to the young-old, the middle-old, the oldest-old, and the frail elderly.

Assessment for All Older Adults

Recommend to older adults that they have an annual physical and dental examinations. The exam should include the same categories as in middle adulthood (see Chapter 9), as well as screening for mood, cognition, and ability to perform activities of daily living (ADLs) (e.g., bathing and dressing), and instrumental activities of daily living, or IADLs (e.g., shopping, doing laundry). A focused nutritional assessment becomes increasingly important for those in the old-old category. Table 10-1 summarizes the areas for physical assessment related to the aging process. **Key Point:** ***Expect frequent changes to recommendations for screening exams (e.g., for breast, cervical, and colon cancer).***

- *Vital signs*. When assessing vital signs, keep in mind that the normal ranges for vital signs are slightly different for older adults (see Chapter 20). The average body temperature, for example, is lower.
- *Height measurement.* Compare with previous height (a screen for osteoporosis). This begins to be especially important past age 65.
- *Weight and body mass index (BMI) calculation.*

BOX 10-1 ■ What's Your Aging IQ?

The following quiz is adapted from one created by the National Institute on Aging to test your knowledge of aging.

1. Which of the following age groups is one of the fastest growing segments of the American population?
   (a) Babies and children under age 5
   (b) Children age 15 to 19
   (c) People over age 85
2. You can be too old to exercise. True/False
3. Diet and exercise reduce the risk for osteoporosis. True/False
4. Heart disease is a much bigger problem for older men than for older women. True/False
5. Screening older people for cancer is not beneficial because they can't be treated. True/False
6. Everybody gets cataracts. True/False
7. People who are older than 80 years should stop driving a car. True/False
8. Most older people are depressed. True/False
9. The older you get, the less you sleep. True/False
10. Everyone becomes confused or forgetful if they live long enough. True/False
11. If your parents had Alzheimer's disease, you will inevitably get it. True/False
12. Older people take more medications than younger people. True/False
13. People should control their weight as they age. True/False
14. People begin to lose interest in sex around age 55. True/False
15. Older adults are not at risk for HIV/AIDS. True/False
16. Families do not take responsibility for care of their older relatives. True/False
17. As your body changes with age, so does your personality. True/False
18. Older people can accept urinary accidents as a fact of life. True/False
19. Falls and injuries "just happen" to older people. True/False
20. "You can't teach an old dog new tricks." True/False
21. Extremes in environmental heat and cold can be especially dangerous for older people. True/False
22. Suicide is most often a risk among teens. True/False

Source: Adapted from U.S. Department of Health and Human Services, Public Health Service, National Institutes of Health. (2003). *What's your aging IQ* (Reprinted 2006). Retrieved September 18, 2012, from \http://www.nia.nih.gov/sites/default/files/AgingIQ_web.pdf

- *Lipid panel screening*. Total cholesterol, triglycerides, high-density lipoprotein (HDL), low-density lipoprotein (LDL), and ratios.
- *Blood glucose screening*.
- *Annual clinical breast and pelvic examination* for women (American Cancer Society, 2010).
- *Breast self-examination (BSE).* There is still controversy about whether to encourage BSE. There is insufficient research evidence to support BSE (National Cancer Institute, 2008, last modified January, 2011; *Guide to Clinical Preventive Services, 2010–2011*, 2010), but many clinicians believe it to be useful until at least age 85 (American College of Obstetricians and Gynecologists [ACOG], 2009; Flaherty, Morley, Murphy, et al., 2002; Gemignani, 2011, updated 2009; Meissner, Klabunde, Han, et al., 2011; Smith, Cokkinides, Eyre, et al., 2003).
- *Annual or biannual mammogram or thermography* for women over age 65. A woman should have mammograms as long as she is in good health and would be a candidate for treatment. Age alone is not a reason to stop having mammograms (American Cancer Society, 2010). The USPSTF (2002, updated 2009, 2009b) does not recommend biannual mammograms after age 74. However, other guidelines recommend them even beyond age 80 or 85 if the woman is in good health (ACOG, 2011; Flaherty, Morley, Murphy, et al., 2002; Smith, Cokkinides, Eyre, et al., 2003).
- *Pap test.* Some guidelines do not recommend a routine Pap test for women past age 65 (National Guideline Clearinghouse [NGC], 2012; USPSTF, 2012, but the American Cancer Society recommends that they be continued until age 70. The ACOG (2012) recommends that women stop cervical cancer screening at age 65 if they've had three or more normal Pap results in a row and no abnormal Pap in the previous 10 years.
- *Colon cancer screening.* The USPSTF recommends screening for colorectal cancer (CRC) using fecal occult blood testing, sigmoidoscopy, or colonoscopy in adults, beginning at age 50 years and continuing until age 75 years. Intervals for recommended screening strategies include (USPSTF, 2009a):
  - Annual screening with high-sensitivity fecal occult blood testing
  - Sigmoidoscopy every 5 years, with high-sensitivity fecal occult blood testing every 3 years
  - Screening colonoscopy every 10 years
- *Screening CT colonographies*, or "virtual colonoscopies," are particularly safe for older adults as a noninvasive test that does not require sedation or anesthesia. The American Cancer Society considers CT colonography, as a first-line colon cancer screening test, to be as effective as the traditional colonoscopy.
- *Digital rectal exam* for prostate evaluation in men. An enlarged prostate can indicate either benign prostatic hypertrophy or prostate cancer. The USPSTF (2012b) recommends against routine screening for prostate cancer.
- *Serum prostatic specific antigen (PSA) level* (for men) is a more sensitive indicator of prostate disorders than is digital rectal exam. Some guidelines encourage yearly screening for men over age 50; some caution against routine screening; others make decisions on an individual basis. The USPSTF recommends that regardless of age, men without symptoms should not routinely have the PSA blood test to screen for (USPSTF, 2012b). However, at this writing, Medicare does provide coverage for an annual PSA test for all men age 50 and older.
- *Eye exam every 2 years* if there are no problems; otherwise annually, particularly if the older adult has chronic conditions such as hypertension, cardiovascular disease, or diabetes. Macular degeneration is a problem that may occur in older adults that an eye exam can pick up.
- *Bone density scan* is recommended for all women age 65 and older as a routine screening for osteoporosis and for women at increased risk for osteoporotic fractures (postmenopausal, tobacco smoking, history of fragility fracture, low body weight) screening should begin at age 60 years (NGC, 2008, April, revised November 2012). The test is also recommended for men older than age 70.

Think**Like a Nurse** 10-4

To determine whether Mrs. Higginbotham's pneumonia is resolving (Meet Your Patient), you are monitoring her vital signs. Her oral temperature is 98.9°F (37.2°C). What do you need to keep in mind when evaluating the meaning of this reading? Do you think this represents a fever?

Assessing Functional Status

Functional status is the ability to perform self-care and other activities of daily living (ADLs) and instrumental activities of daily living (IADLs).

- **Activities of Daily Living.** You can use the Katz Index of Independence in Activities of Daily Living to assess for ADLs. It allows you to rate a client's independence in bathing, dressing, toileting, transferring, continence, and feeding (Katz, Down, Cash, et al., 1970; "Katz Index," 2007). To use the Katz assessment tool,

Go to http://consultgerirn.org/uploads/File/trythis/try_this_2.pdf

- **Instrumental Activities of Daily Living. IADLs** are the activities needed to maintain one's immediate environment, for example, shopping, using the telephone, housekeeping, managing money, preparing food, and managing one's medications. Loss of ability to perform IADLs frequently marks a need for assisted living, nursing home placement, or the aid of family or homemaker services to allow an older adult to age in place. For a tool to help you assess IADLs,

Go to Chapter 3, Assessment Guidelines & Tools, **Lawton Instrumental Activities of Daily Living,** in Volume 2.

Assessing for Depression

For more information about depression in older adults, see Chapter 13, Example Problem: Depression, as well as the entire section entitled Assessment: Depression. To assess for depression, you may wish to use the Geriatric Depression Scale (GDS), a 30-item questionnaire that screens for depression. It is tailored to the concerns that older adults face. To see the Geriatric Depression Scale,

Go to Chapter 10, **Resources for Caregivers & Health Professionals** on Davis*Plus*, and click the links under **Web Sites for Mental Status Exams.**

Assessing Cognitive Status (Example Problem: Dementia)

The Mini Mental State Exam (MMSE) (Folstein, Folstein, & McHugh, 1975) and other similar tools are used to obtain a baseline of cognitive function and to evaluate any interventions. The MMSE assesses various aspects of cognition, including short-term memory. A total score of 30 is possible. Typically, a score of 25 or lower indicates some degree of cognitive impairment. Further work-up is required to determine the stability and cause of the impairment.

The "Sweet 16" is a newer cognitive assessment screening tool that is useful for identifying problems in thinking, learning, and memory in older adults who might need further evaluation by a specialist (Fong, Jones, Rudolph, et al., 2010). It consists of 16 items that test orientation, registration, sustained attention, and short-term memory. It is easy to use and correlates highly with the MMSE. For a step-by-step procedure for assessing mental status, see Procedure 22-16, Assessing the Sensory-Neurological System. To see the MMSE and the Mini-Cog (a mental status assessment for older adults),

Go to Chapter 9, **Resources for Caregivers & Health Professionals** on *DavisPlus*, and click the links under **Web Sites for Mental Status Exams.**

Assessing for Example Problem: Abuse

It is important to assess older adults for abuse routinely and any time there is a possibility that an injury may have been inflicted rather than accidental (USPSTF, 2012c). For a screening tool and a procedure to aid you in assessing for abuse,

Go to Chapter 9, **Procedure 9-1,** in Volume 2.

Assessment (Young-Old)

Assessments focused on young-old patients should include the following:

- Assess daily routines, social interactions, and short- and long-term goals. This will help determine the degree to which the person has adapted to retirement.
- Determine the level of fitness and the level of effort for physical activity. This and the following point are essential before beginning a program of routine exercise.
- Gain an understanding about how a chronic condition affects the client's ability to do regular physical activities safely.
- Assess the client's barriers to exercise.
- Assess the client's self-confidence in her ability to maintain an exercise program.

Assessment (Middle-Old)

It is critical for you to assess the function, support system, social network, and mental health of the middle-old client. Observe for cues to triggers that the client is entering a *spiral of vulnerability*. For example, a decrease in an older adult's mobility and the use of an assistive device such as a cane may indicate prolonged inactivity associated with physiological changes. These may be associated with an unsteady or slow gait and slower response and reaction times—all resulting in deliberate, slow actions. Thus begins a spiral of vulnerability: The older adult may become a victim of abuse, fall, and sustain an injury; the injury may require hospitalization, giving rise to the potential complications of infection and pressure ulcers and the need for rehabilitation. The impact of this spiral of vulnerability is felt in psychological and financial costs to the client and society, as well as loss of client independence. It is easier to intervene and stop the spiral if cues are found early (Fig. 10-3).

Some research indicates that regular mammography or thermography for women over 80 years of age is associated with diagnosing cancer at an earlier disease

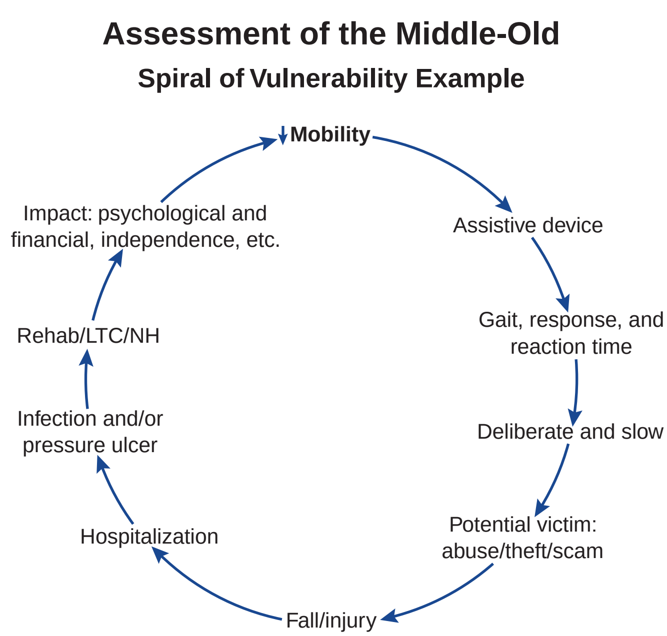

FIGURE 10-3 A seemingly small event for a middle-old adult may trigger a spiral of vulnerability. (Courtesy of V. Rempusheski, PhD.)

stage, and with fewer positive lymph nodes at surgery. However, only about 1 in 5 women of this age actually have regular mammograms (Badgwell, Giordano, Duan, et al., 2008).

Assessment (Oldest-Old)

The oldest-old need similar assessments as the middle-old. Keep in mind that assessment of physical, psychosocial, and cognitive abilities and social engagement and living conditions are crucial for the oldest-old. Psychosocial and environmental factors may be the cues for frailty when subtle physiological changes are not obvious.

Assessing for Example Problem: Frail Elderly

Assess older adults for risk factors and characteristics associated with frailty. Frail older adults are weak, have little ability for independent living, and often need assistance with ADLs. They may have impaired mental abilities. Most are women, are older than 80 years, and receive care from an adult child. To be considered frail, a person must have three or more of the following characteristics:

- Low physical activity
- Muscle weakness
- Slowed performance
- Fatigue or poor endurance

Recall an earlier discussion of genetic–behavior–environment interaction as a survival mechanism of aging. Psychosocial and behavioral factors, including depression, caregiver problems, and housing conditions, are important to a person's interactions with the environment and are believed to predict vulnerability (frailty) and ability to survive (Martin & Brighton, 2008; Rockwood, 2005; Woodhouse & O'Mahony, 1997). Other risk factors include smoking and being underweight.

ANALYSIS/DIAGNOSIS (ALL OLDER ADULTS)

Although most NANDA-I diagnoses can be used for any age group, the following NANDA-I diagnoses focus specifically on growth and development:

Risk for Disproportionate Growth
Adult Failure to Thrive
Delayed Growth and Development
Risk for Delayed Development

An understanding of age-related changes can help older adults identify normal changes, adapt their routine, and report alterations in ADLs and IADLs that are outside the expected changes for their age. Many such changes signal conditions that are treatable. Consider these examples:

- Frequent falls or loss of balance is not the result of normal age-related changes but could signal a neuropathology such as Parkinson's disease or early symptoms of dementia and should be reported to a healthcare provider.
- Urinary incontinence is not the result of usual age-related changes. It may signal a urinary tract infection, a prostate problem, excessive urogenital drying, or the need for in-home assistance.

OUTCOMES/EVALUATION (ALL OLDER ADULTS)

Nursing goals for all older adults should be to maintain the person's ability to function independently for as long as possible, arrange for appropriate care, and teach clients and caregivers how and when to call for professional help.

INTERVENTIONS/IMPLEMENTATION

As you already know, interventions depend on the nursing diagnoses that you identify for each individual. This section presents interventions specific to each of the older-adult age groups, as well as interventions that apply to all older adults.

Interventions (Young-Old)

Young-old adults may need support for positive retirement, identifying and overcoming barriers to health promotion, evaluating methods for introducing health promotion for positive long-term change, and describing short- and long-term benefits of health promotion (Wilson & Palha, 2007). Providing resources for social and civic engagement will help a new retiree reestablish a satisfying and rewarding retirement.

It is also important to teach and help the client plan for physical exercise. Research indicates that a sedentary lifestyle increases the risk of aging-related diseases and premature death. DNA changes occur partly as a result of stress and oxidative damage to cells. By reducing stress, exercise may slow some of these oxidative changes and thereby the aging process (Cherkas, Hunkin, Kato, et al., 2008). More research is needed.

The Centers for Disease Control and Prevention (CDC) (2011) recommends the following activities for older adults:

- *Regular aerobic physical activity.* Encourage clients to engage in 150 minutes a week of moderate-intensity aerobic exercise. Alternatively, they can engage in 75 minutes a week of vigorous-intensity activity. Each episode of activity should last for at least 10 minutes, and the client should spread the exercise throughout the week. Advise clients that additional benefits can be obtained by gradually increasing the amount of exercise (perhaps up to 300 minutes a week).
- *Muscle-strengthening activities*. Clients should perform moderate or high-intensity muscle-strengthening activities on 2 or more days a week. The weight-bearing and toning exercises should involve all major muscle groups.

- *Balance activities.* These are especially important for older adults at risk for falls.
- *Adapted physical activities.* Encourage older adults with chronic conditions to be as physically active as abilities and conditions allow. Help them to make adaptations that allow them to do so, or refer them to an exercise therapist.

Key Point: ***Some activity is better than none; and more is better.*** Remind clients that doing some activity at least 3 days a week produces health benefits and helps avoid excessive fatigue. Some practical suggestions for exercising include the following:

- A brisk 15-minute walk twice a day, every day of the week would easily meet the minimum guidelines for aerobic activity.
- Muscle-strengthening activities at least 2 days a week can include use of exercise bands, handheld weights, digging, lifting and carrying as part of gardening, carrying groceries, and some yoga and tai chi exercises.
- Inactive older adults or those with a very low level of fitness should begin with 10 minutes of walking and increase minutes and intensity slowly with subsequent walks.

You can provide support for the client's exercise regimen by suggesting a range of choices and a list of community resources (e.g., parks, organizations, recreation centers). Also, teach the client how to walk, as needed, and safety considerations. Help the young-old adult institute self-monitoring methods to help her see her progress (e.g., a graph, a chart, a step counter), and reinforce personal progress, such as decreased fatigue and weight loss.

Interventions (Middle-Old)

Older adults who have maintained healthy behaviors throughout their lifetime are likely to remain vital and actively engaged. However, the occurrence of a health crisis and even a short period of restrictive activity will lead to decreased functional ability and the need for encouragement, support, and a planned program of limited activity progressing to optimal function for clients in this age group.

Interventions (Oldest-Old)

The goal of interventions for the oldest-old is to maximize function and prevent loss of function or disability, thus ensuring independence for as long as possible. Broad interventions important for the oldest-old include the following:

- Supportive environments and conditions that allow a person to function are vital.
- Modified adapted activity may include walking, flexibility exercises, yoga, tai chi, and water aerobics.
- Nutrition should include whole grains, dark green and orange vegetables and legumes, all types of fruits and vegetables, and fat-free and low-fat milk and milk products. These are among the food groups most needed in the diet of the oldest-old to combat obesity and inactivity.

Interventions/Implementation for Example Problem: Frail Elderly

Prevention of frailty and care of the frail elderly are complex and specialized. The following are examples of

PICOT

Physical Activity and Well-Being of Older Adults

Situation: While caring for patients in the rehab unit, the nurse notes that there is a wide range of health among the elderly patients, and that not all 75-year-old clients heal at the same rate.

PICOT Components:

P	Population/patient	=	Older adults
I	Intervention/indicator	=	Regular exercise and physical activity
C	Comparator/control	=	No regular exercise, sedentary
O	Outcome	=	Improved well-being into aging
T	Time	=	None

Seachable Question: Do __________ (P) who receive/are exposed to __________ (I) demonstrate __________ (O) as compared with __________ (C) during __________ (T)?

Example of Evidence: Advances in healthcare have increased the life span as well as the quality of life for many people. Physical fitness as a younger adult may improve the physical and emotional well-being later in life. One of the specific goals of *Healthy People 2020* is to increase physical activity, with the expectation that it will slow the decline in physical functioning associated with age. This should help to improve the quality of life in later adulthood, promote faster recovery time, and therefore help decrease the dollars spent each year on medical care.

Practice Change: The nurse emphasizes to all her patients the importance of regular exercise, and helps them think of ways they might incorporate more activity into their present routines. She also discusses with the unit manager the possibility of incorporating this nursing action into unit routines.

Reference: Tahmaseb-McConatha, J., Volkwein-Caplan, K., & DiGregorio, N. (2011). Culture, aging and well-being: The importance of place and space. *International Journal of Sport & Society*, 2(2), 41–48.

research that support some preventive measures that may give you some ideas for positive interventions:

- Frail and non-frail elderly who participated in an exercise-training group demonstrated significant improvement in physical capacity, cognitive performance, and quality of life. Benefits were equivalent between frail and nonfrail participants (Langlois, Vu, Chassé, et al., 2012). One study found that for obese frail older persons, a combination of weight loss and exercise therapy improved their physical status (Villareal, Chode, Parimi, et al., 2011).
- Malnutrition, impaired mobility, and care dependency are potential reversible factors related to falls (Meijers, Halfens, Neyens, et al., 2012). Sixty-seven frail elders who lived alone were provided Internet access. They maintained physical and cognitive status, whereas the control group declined significantly in both (Tomita, Mann, Stanton, et al., 2007).

Advise caregivers and older adults to take the following measures that are thought to prevent or slow the progression of frailty (National Health Information Center, 2012):

- Engage in daily physical activity to the extent possible: walking and weights to build aerobic fitness, build muscle, and improve joint stiffness and pain.
- Eat a balanced diet, including enough protein, fiber, and fluids.
- If you smoke, stop.
- Get regular checkups.
- Keep the mind active by socializing, working puzzles, reading, or playing games.

Interventions for All Older Adults

Some interventions are appropriate for all older adults.

Preserving Functional Abilities Focus on preserving functional abilities, including the ability and motivation to function in the patient's own environment. Look for simple things you can do to promote better functioning. For example, if the patient cannot see to sort his medications, you might try turning on more lights, or having a brighter light installed. For all interventions and interactions, ask yourself, "Does this promote the client's dignity and self-esteem?"

Teaching for Safety Teach older adults about age-related changes and what these changes mean for their daily routine. For example, age-related changes diminish stamina, conditioning, reflexes, and the speed of processing information. Therefore, when multitasking or performing seemingly non-thinking physical activities, older adults need to be very purposeful in their actions and attend to the details of the task or activity. Failing to do so could result in missteps, injury, or exhaustion.

Illness Prevention Although the risks for disease and disability increase with age, poor health need not always occur. Known prevention measures can help older adults avoid many illnesses and disabilities associated with chronic diseases. Stress the importance of a healthy lifestyle (e.g., healthy eating; regular physical activity; avoiding tobacco use; screening for breast, cervical, and colorectal cancers). Older adults who engage in progressive aerobic training can maintain their independence longer and delay the aging process perhaps by as much as 10 years (Shephard, 2008).

Immunizations Health-promotion activities for all older adults include teaching and facilitating immunizations for varicella, influenza, pneumonia, herpes zoster (shingles), and tetanus/diphtheria/pertussis (Fig. 10-4).

Empowerment Many older adults have Internet savvy. You can empower them by suggesting Web sites offering resources to help them understand and cope with the unknowns of their situation. Some good resources include the following:

www.nihseniorhealth.gov—Developed by the National Institute on Aging and the National Library of Medicine, this site provides up-to-date information on a variety of topics, such as arthritis, depression, and exercise. It includes videos and quizzes. New topics are added regularly.

http://www.alz.org/we_can_help_we_can_help.asp— The Alzheimer's Association designed this site to help families find care for family members with Alzheimer's disease. Use of the site is free.

www.lotsahelpinghands.com—This is an online service to help family caregivers to organize and communicate with other family members and significant others to coordinate visits and help with meals, transportation, and so on.

Communicating With Older Adults

Many normal changes of aging affect communication. For example, older adults tend to process information more slowly, so speak slowly and allow time for the patient to form an answer.

Until you know there is no hearing deficit, look at the patient as you speak to allow for lip reading. But do not assume that all older adults are deaf or that they do not understand the meaning of your communication. And remember, you need to speak slowly, not loudly. Of course you should check for sensory deficits at the beginning of your interaction.

You will need to rely on body language more than usual. Notice nonverbal communication, such as fidgeting, hand-wringing, tearfulness, or quivering lips. Memory deficits make it difficult for some older adults to find the words to express what they mean.

Appropriate speech may be accompanied by inappropriate affect. For instance, a client may speak coherently and make sense while telling you that she was able to walk to the bathroom today, and then begin crying for no apparent reason. Nevertheless, the information about her ambulation may be credible.

Recommended Adult Immunization Schedule—United States - 2013

Note: These recommendations must be read with the footnotes that follow containing number of doses, intervals between doses, and other important information.

VACCINE ▼ AGE GROUP ▶	19-21 years	22-26 years	27-49 years	50-59 years	60-64 years	≥ 65 years
Influenza [2,*]	1 dose annually					
Tetanus, diphtheria, pertussis (Td/Tdap) [3,*]	Substitute 1-time dose of Tdap for Td booster; then boost with Td every 10 yrs					
Varicella [4,*]	2 doses					
Human papillomavirus (HPV) Female [5,*]	3 doses					
Human papillomavirus (HPV) Male [5,*]	3 doses					
Zoster [6]					1 dose	
Measles, mumps, rubella (MMR) [7,*]	1 or 2 doses					
Pneumococcal polysaccharide (PPSV23) [8,9]	1 or 2 doses					1 dose
Pneumococcal 13-valent conjugate (PCV13) [10,*]	1 dose					
Meningococcal [11,*]	1 or more doses					
Hepatitis A [12,*]	2 doses					
Hepatitis B [13,*]	3 doses					

*Covered by the Vaccine Injury Compensation Program

For all persons in this category who meet the age requirements and who lack documentation of vaccination or have no evidence of previous infection; zoster vaccine recommended regardless of prior episode of zoster

Recommended if some other risk factor is present (e.g., on the basis of medical, occupational, lifestyle, or other indication)

No recommendation

Report all clinically significant postvaccination reactions to the Vaccine Adverse Event Reporting System (VAERS). Reporting forms and instructions on filing a VAERS report are available at www.vaers.hhs.gov or by telephone, 800-822-7967.
Information on how to file a Vaccine Injury Compensation Program claim is available at www.hrsa.gov/vaccinecompensation or by telephone, 800-338-2382. To file a claim for vaccine injury, contact the U.S. Court of Federal Claims, 717 Madison Place, N.W., Washington, D.C. 20005; telephone, 202-357-6400.
Additional information about the vaccines in this schedule, extent of available data, and contraindications for vaccination is also available at www.cdc.gov/vaccines or from the CDC-INFO Contact Center at 800-CDC-INFO (800-232-4636) in English and Spanish, 8:00 a.m. - 8:00 p.m. Eastern Time, Monday - Friday, excluding holidays.
Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

The recommendations in this schedule were approved by the Centers for Disease Control and Prevention's (CDC) Advisory Committee on Immunization Practices (ACIP), the American Academy of Family Physicians (AAFP), the American College of Physicians (ACP), American College of Obstetricians and Gynecologists (ACOG) and American College of Nurse-Midwives (ACNM).

FIGURE 10-4 Recommended Adult Immunization Schedule, United States, 2013. (*Source:* Centers for Disease Control and Prevention (CDC), Department of Health and Human Services. Retrieved September 18, 2013, from http://www.cdc.gov/vaccines/schedules/downloads/adult/adult-schedule.pdf.)

Conversely, inappropriate affect and incoherent speech do not always indicate lack of understanding. For example, a client may laugh appropriately at something funny, but not be able to speak clearly or find the words to ask you what time it is.

Be aware that some older adults are confused at one time and not another. A client may begin by giving you credible information, but as the conversation progresses, he may lose track of the topic or talk about something irrelevant. When a client seems confused, use focused assessment to determine his mental status. If you conclude that his communication is unreliable, you can always finish the talk later, when he is less confused.

Key Point: ***The ability to speak does not always reflect the person's ability to understand; and what the patient says may or may not match what she is feeling.***

Interventions for Example Problem: Dementia

Dementia is an irreversible, progressive decline in mental abilities. Individuals with moderate to severe dementia or Alzheimer's disease often require special care, including supervision (sometimes 24 hours a day), specialized communication techniques, and management of difficult behavior. They may need help with ADLs such as bathing, eating, getting out of bed to a chair or wheelchair, toileting, and other personal care. Most often this care falls on a family member or caregiver in the home (see the section Providing Caregiver Support later in the chapter).

Communicating With Persons With Cognitive Deficit.

In addition to the normal changes of aging, many older adults have more severe problems with memory and at least one other cognitive ability (e.g., judgment, thinking, language, or coordination). Because of their decline in mental abilities, people with dementia have difficulty speaking and understanding. In addition to the general approaches for all older adults, the following are some ideas to help you communicate with people with cognitive deficits:

- Use simple, short sentences, with one idea at a time: "Where does it hurt?" rather than "Please describe the quality and location of your pain."
- Avoid vague comments (e.g., "I see," "Um-hmm," "Yes, yes, okay"). The patient will not be able to interpret these responses. Instead, echo the patient's comment and state your response directly and simply: "You are hungry. I will bring your lunch."
- If the patient doesn't understand what you say, repeat your words exactly. Under other circumstances, you

usually rephrase your sentences when someone doesn't understand, but for patients with dementia, giving new information just adds to their confusion.

- Try to understand that the patient's reality is distorted and he is behaving in the only way he is able. When the patient is conversing superficially and seems comfortable, it may seem he is competent.

Promoting Independence and Maintaining Function

Focus your care on maximizing independent activity and enhancing function. Often this will involve helping older adults to adapt and develop new skills so they can continue to take part in activities they enjoy. Consider any environmental modifications that might aid independence, including assistive technology. Facilitate and encourage physical exercise in order to help improve continence and help prevent further loss of mobility. Exercise also improves strength, balance, and endurance, and aids in falls prevention.

Electronic technology is increasingly being used to deliver care "remotely" and support older adults in their own homes. *Telehealth technologies* involve such things as electronic reminder systems, video conference visiting, and remotely controlled security sensors (Gellis, Kenaley, McGinty, et al., 2012; Stall, Nowaczynski, & Sinha, 2013; Young, Foster, Silander, et al., 2011).

Promoting Cognitive Function

The National Institute for Health and Clinical Excellence (NICE) (2006) identified a link between improving cognitive symptoms and ability to maintain day-to-day functioning. You can promote cognitive function by providing older adults with activities and materials that are engaging and involve some degree of cognitive processing (e.g., reading, playing board games, playing a musical instrument, dancing). Activities should be person-centered and appropriate to the age group. An emphasis on social activities will improve participation. In addition, reality orientation, life review, and reminiscence are simple interventions that can be used to promote cognitive functioning.

Providing Caregiver Support

A diagnosis of dementia can be traumatic and devastating. Family members are often the primary caregivers (either through choice or necessity). Caregivers of any patient are more likely than noncaregivers to be at risk for depression, heart disease, high blood pressure, and other chronic illnesses, even death. Caring for a person with dementia puts them at even higher risk.

Most caregivers of those suffering from dementia are also older adults who themselves have special needs. It is not uncommon for the caregiver to feel abandoned and unsupported, not only by services but also by family and friends. Exhaustion and despair can quickly follow. In order to assist and support caregivers the following approaches are suggested (Brodaty, Green, & Koschera, 2003):

- education about dementia
- supportive counseling
- psychotherapy
- rapid support in crisis
- support from other caregivers (respite)
- faith-based spiritual assistance

Interventions such as these can contribute to physical and psychological well-being, help maintain hope, and reduce caregiver burden.

Toward Evidence-Based Practice

Smith, G. E., Lunde, A. M., Hathaway, J. C., et al. (2007). Telehealth home monitoring of solitary persons with mild dementia. *American Journal of Alzheimer's Disease and Other Dementias, 22*(1), 20–26.

Quantitative and qualitative outcome data were collected from eight persons with mild dementia. Two-way interactive video technology was used to monitor medication compliance and findings revealed that medication compliance was 81% in the video-monitored group compared with 66% in the control group. Video-monitored participants' compliance remained stable while unmonitored patients' compliance fell 12 percentage points, consistent with expectations for older adults with dementia. Qualitative interviews with the caregivers found that there was a strong feeling that the intervention prevented relocation of the patient to extended care facilities.

Chumbler, N. R., Mann, W. C., Wu, S., et al. (2004). The association of home-telehealth use and care coordination with improvement of functional and cognitive functioning in frail elderly men. *Telemedicine Journal & E-Health, 10*(2), 129–137.

Investigators evaluated the extent to which home-telehealth technology use was associated with improvement in functional and cognitive status for 176 male elderly veterans as compared with a group of 226 frail elderly men not receiving home-telehealth. Over a 12-month period, the investigators found greater improvements in both IADL and ADL independence in the home-telehealth group than in the control group. Elders in the home-telehealth group also experienced significantly greater improvements in cognitive status. This evidence suggests that the use of home-telehealth has the potential to improve the functional and cognitive status of frail older individuals.

1. What ideas does each study give you for ways in which you might help an older adult with dementia who is living at home?

2. What benefits does the use of home telehealth technology provide for caregivers of patients with dementia?

ThinkLike a Nurse 10-5

What factors contribute to a community of functionally active older adults?

PUTTING IT ALL TOGETHER

Recall Ethel Higginbotham, in the Meet Your Patient scenario. She is very thin and frail and refuses to eat. She says, "I just want to die." Do you feel ready to plan her nursing care now?

You might diagnose Ms. Higginbotham with Adult Failure to Thrive. An appropriate *NOC outcome* would be Will to Live. An *individualized goal* might be "Ms. Higginbotham will gain 1 pound and participate in at least one daily group activity by the first of next month." Interventions depend on the diagnosis and its etiology.

Ms. Higginbotham will need care that helps her adjust to widowhood, provides adequate nutrition, and offers activities that provide interaction with others. *NIC interventions* appropriate for Ms. Higginbotham are as follows: Coping Enhancement, Hope Instillation, Self-Care Assistance, Spiritual Support.

Individualized interventions for Ms. Higginbotham include grief counseling, nutritional support, and working with her and her family to determine whether it is appropriate for her to continue to live independently.

As a full-spectrum nurse, you should assess the developmental stage of each of your clients. In maternity and pediatric care, this is a routine part of nursing care. However, growth and development continue to be important throughout the life span. To assess growth and development you must gather data such as the client's age, height, and weight; activities the client engages in; and the client's communication skills. You should also perform age-specific assessments, such as those discussed in previous sections.

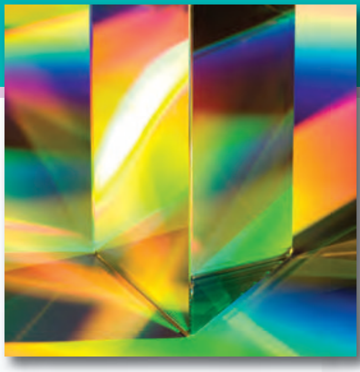
CHAPTER 11



Experiencing Health & Illness

Learning Outcomes

After completing this chapter, you should be able to:

- Explore the concepts of health and illness from a holistic perspective.
- Compare and contrast three models of health and illness.
- Describe the various ways that people experience health and illness.
- Identify factors that disrupt health.
- Describe the five stages of illness behavior.
- Differentiate between acute and chronic illness.
- Identify factors that influence individuals' responses to illness.
- Apply the concepts presented in this chapter to a variety of patient care situations.
- Explain what the concepts in this chapter mean to you as you work toward becoming a full-spectrum nurse.

Key Concepts

Health
Health experience
Illness
Illness experience

Meet Your Patient

Evelyn is 87 years old and has lived in a long-term care facility for the last 5 years. She suffers from congestive heart failure, hypertension, diabetes, macular degeneration resulting in near blindness, a severe hearing deficit, urinary incontinence, and immobility resulting from a hip fracture.

Evelyn was married nearly 60 years to Lloyd, who died 6 years ago. They have 5 children, 17 grandchildren, and 14 great-grandchildren. In these last few years, she has experienced the loss of her husband, home, vision, hearing, mobility, and bladder control. Despite these limitations, she keeps current in the lives of all of her extended family and friends.

She is the confidante of the facility staff and knows about their children, their romances, and the gossip around the institution. She is an avid Minnesota Twins fan and also keeps track of the televised high school basketball tournaments. Whenever there is an election, she makes sure that she votes. She "reads" every talking book she can get her hands on. Recently Evelyn was admitted to the hospital in severe congestive heart failure. She told her pastor, "I don't want to die yet. I'm having too much fun!"

Evelyn's situation is a far cry from what most people would picture as "good health." However, as you consider the ideas of health presented in this chapter, you might conclude that she is a reasonably healthy person from many standpoints.

Theoretical Knowledge knowing why

Every day there is something in the news about health or illness. Politicians talk about their desire to improve our health and reorganize healthcare. Schools want students to eat healthy, exercise, and receive regular immunizations. In an attempt to reduce health insurance claims, employers open on-site fitness centers and employ nurses and counselors to work with employees to improve employee health. Everyone says they want to be healthy.

As a nursing student, you have probably already cared for clients in various stages of health and illness. But have you ever considered what those terms mean? Our understanding of health and illness is influenced by our family, culture, health history, and a host of other factors. As you evolve as a nurse, you'll find that your understanding of these concepts evolves, too. Here we examine some ways that you and your clients might define health and illness and some ways that full-spectrum nurses have come to understand these terms through their thinking, doing, and caring.

You may find this chapter a little different from other chapters in this book and other textbooks. That is because the goal of the chapter is not so much to help you learn facts about health and illness, but to understand how people experience them. Even the language of the chapter is designed for that purpose. Relax and flow with the chapter. Instead of agonizing over each detail, read it in a way that will help you see the "big picture."

ABOUT THE KEY CONCEPTS

You will need to understand the abstract concepts of **health** and **illness** to help you appreciate the **experience of health and illness**, as lived by real, not abstract, people. Strive for an overview of factors that are disruptive to health and factors that nourish health. Try to understand the subconcept of hardiness as it relates to patients, and healing presence as it relates to your work as a nurse.

HOW DO WE UNDERSTAND HEALTH AND ILLNESS?

First let's examine the key concept, **health**. What is your image of health? Here are some ideas.

The "Body Beautiful" Being a "picture of health" can depend on whether you were born in the right era—or in the right country. Styles of beautiful bodies come and go. For instance, much Indian, African, Greek, and European art portrays ideal women as well-rounded creatures. The perfect body view of health also denies the possibility of health to people who use wheelchairs, prosthetics, or even eyeglasses and hearing aids. Yet many full-spectrum nurses working with disabled clients would indeed describe their clients as healthy.

Not Having an Illness In describing healthy people, would you disqualify someone with a cold, dandruff, or athlete's foot? What about diabetes, heart disease, or cancer? Doing so would reflect another view of health: that is, not having an illness. This view unfairly and unrealistically restricts health to those who do not have some kind of physical impairment.

Something You Can Buy Another popular view is that health is something you can buy: an exercise bicycle, membership in a health club, medicine, liposuction, coronary bypasses, and so on. In this view, health does not come from within. It's something "out there" that is available if you have enough money or insurance.

Ideal Physical and Mental Well-Being Health can also be described as an ideal state of physical and mental well-being: something to strive for, but never to attain. In this view, good health is never actually reached, because there is always something more to be achieved. Health is the goal itself, the end instead of one of the means to fulfilling life's purposes.

The Ability of the Soul to Cope Theologian Jürgen Moltmann (1983) described health in a different way: "True health is the strength to live, the strength to suffer, and the strength to die. Health is not a condition of my body; it is the power of my soul to cope with the varying condition of that body" (p. 142). Similarly, novelist and poet Robert Louis Stevenson wrote of health, "It is not a matter of holding good cards, it's playing a poor hand well." For more traditional definitions of health, refer to Box 11-1.

Nurses Understand Health and Illness as Individual Experiences

If you were the nurse caring for Evelyn in the Meet Your Patient scenario, would you understand health as a perfect body or the absence of disease? Probably not. **Key Point:** ***Nurses understand health and illness as individual experiences, emerging from each patient's unique responses. The person with an illness rarely perceives the experience as a medical diagnosis. Instead, people describe their illness in terms of how it makes them feel.***

Think back to the last time you were ill. How did you feel? Did you feel pain, sadness, fatigue, loss? Did you feel overwhelmed? These responses are disruptions to health and, as such, constitute the lived experience of illness. **Lived experience** is unique to each patient: Just as Evelyn might describe herself as "raring to go," another patient who is 10 years younger and on half as many medications may describe herself as "exhausted all the time" and "just waiting to die." In short, nurses honor the client's understanding of his or her state of being. For many years, nurses have recognized that, like Evelyn, some clients strive to maintain a state of optimal health even when coping with chronic and even terminal disease. Many experience this state as wellness: "a way of life oriented toward optimal health and well-being in which

BOX 11-1 ■ What Do the Experts Say About Health?

- *The World Health Organization (WHO)* initially defined health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1948).
- *In 1986 WHO* redefined health as "a resource for everyday life, not the objective of living. Health is a positive concept emphasizing social and personal resources, as well as physical capacities" (The Ottawa Charter for Health Promotion, 1986).
- *Traditional Chinese medicine* considers health to be a balance between the opposite energy forces of *yin* and *yang*.
- *Ayurveda,* an ancient Indian medical system, describes health as the trinity of body, mind, and spiritual awareness (Sheinfeld-Gorin & Arnold, 2006).
- *Florence Nightingale* believed that health was prevention of disease through the use of fresh air, pure water, efficient drainage, cleanliness, and light (1859/1992).
- *Nursing theorist Jean Watson* (1979) believes that health implies at least three elements: (1) a high level of overall physical, mental, and social functioning; (2) a general adaptive–maintenance level of daily functioning; and (3) the absence of illness (or the presence of efforts that lead to its absence). To Watson, health is a matter of perception. Even an individual with a terminal illness may be considered healthy if he has a high level of functioning, is coping with the diagnosis, and is actively making efforts to improve his status.

body, mind, and spirit are integrated by the individual to live more fully within the human and natural community" (Myers, Sweeney, & Witmer, 2000, p. 252). This perspective acknowledges the influence of attitude and lifestyle choices on the client's state of being. It also implies that nursing interventions in support of wellness are important for clients who are illness free, but also for those who are experiencing disease, or even facing death.

ThinkLike a Nurse 11-1

What qualities are essential to your own personal definition of health? How do you define illness?

KnowledgeCheck 11-1

- Provide at least two common definitions of health.
- Explain how full-spectrum nurses define health and illness.
- Define *wellness* in your own words.

Nurses Use Conceptual Models to Understand Health and Illness

You can use a variety of models to understand health and illness. Each emphasizes somewhat different aspects of these complex experiences. Nurses have found the following models particularly useful.

The Health–Illness Continuum

Most of us recognize that our health status changes frequently. For example, although today I feel pretty good and yesterday I was exhausted, I believe I was healthy on both of those days. I know that my exhaustion was related to staying up late enjoying the company of good friends. My medical record states that I have diabetes and hypertension, but I keep both diseases in control. I take multiple medications, read food labels, exercise aerobically 5 days a week, and lift weights 3 days a week. Am I healthy, ill, or a health nut?

The preceding example illustrates the complex and dynamic nature of human health. In an effort to describe this complex state, many theorists speak of a **health–illness continuum**, that is, they see health and illness as a graduated spectrum that cannot be divided—except arbitrarily—into parts. A person's position moves back and forth on the continuum with physiological changes, lifestyle choices, and the results of various therapies. As shown in Figure 11-1, the number 1 represents a state of being gravely ill, and 10 represents excellent health, a person in peak form. Notice, however, that a client like Evelyn (Meet Your Patient) may view herself at various points on this continuum according to how she feels on any particular day. In other words, the continuum is personal and dynamic: Health changes over the course of time.

Dunn's Health Grid

Dunn (1959) created a health grid that plots a person's status on the health–illness continuum against environmental conditions (Fig. 11-2). Many nurses use this grid to help them predict the likelihood that a client will experience a change in health status. For example, Evelyn (Meet Your Patient) has several health problems. On a scale of 1 to 10, an observer who does not know Evelyn

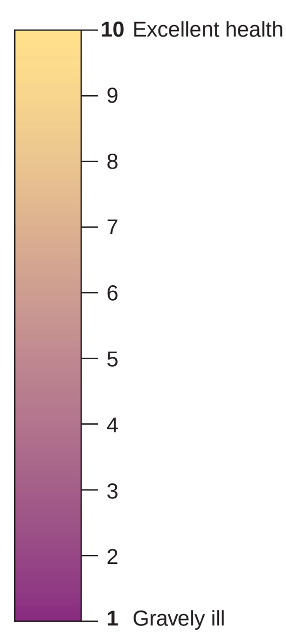

FIGURE 11-1 Over a lifetime, an individual moves up and down on the health–illness continuum.

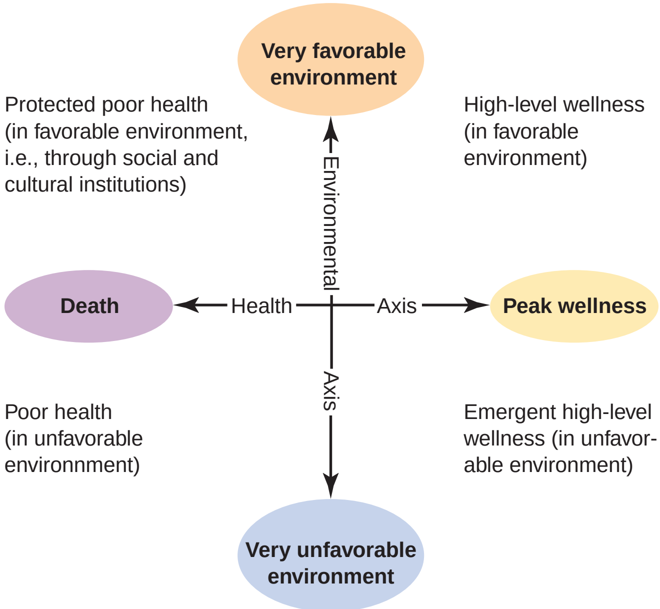

FIGURE 11-2 **Dunn's health grid: Health is affected by an individual's status on the health–illness continuum as well as environmental conditions.** (*Source:* Adapted from Dunn, H. L. (1959). High level wellness for man and society. *American Journal of Public Health, 49*(6), 786–788.)

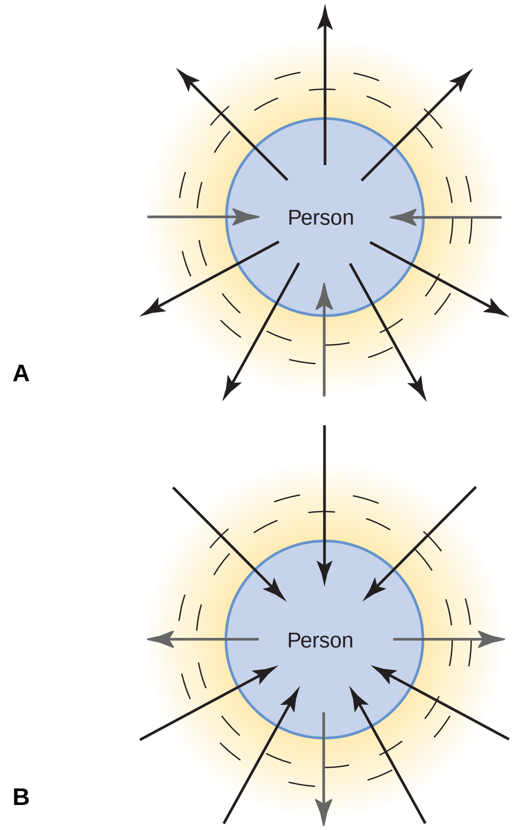

FIGURE 11-3 **Neuman's continuum: A balance of input and output. *A*, When energy output exceeds input, illness results. *B*, Wellness occurs when more energy is generated than is expended.** (*Source:* Neuman, B. (1995). *The Neuman systems model.* In B. Neuman, *The Neuman systems model* (3rd ed., pp. 3–61). East Norwalk, CT: Appleton & Lange.)

well might rate her health as a 3. However, Evelyn has a positive outlook and tells her pastor, "I don't want to die yet. I'm having too much fun!" She also has excellent support from her friends, family, and the facility staff. Clearly, Evelyn is in a favorable environment. This positive setting protects her from harm and provides a good quality of life. On Dunn's grid, Evelyn would probably fall in the area of "protected poor health."

Neuman's Continuum

Nursing theorist Betty Neuman (2002) views health as an expression of living energy available to an individual. The energy is displayed as a continuum with high energy (wellness) at one end and low energy (illness) at the opposite end (Fig. 11-3). The person is said to have varying levels of energy at various stages of life. When more energy is generated than is expended, there is wellness. When more energy is expended than is generated, there is illness—possibly death. Although Evelyn (Meet Your Patient) has several clearly identified health problems, she is engaged in life and active with her family, friends, and long-term care facility staff. We might not all agree on where to place her on Neuman's continuum, but certainly her activity and energy counterbalance her physical frailty.

HOW DO PEOPLE EXPERIENCE HEALTH AND ILLNESS?

In envisioning health and illness as a continuum, full-spectrum nurses promote wellness regardless of the circumstances a client faces now or in the future. This approach requires the holistic understanding that health is multidimensional. The following are some of the many dimensions of health that we experience along the health–illness continuum. An understanding of these dimensions should broaden your concept of health.

Biological Factors

Although biological factors are not entirely within our control, most people consider them when they describe themselves as "well" or "ill." A healthy genetic makeup and freedom from debilitating age-related changes are certainly desired states, and they tip the scale toward the wellness end of the health–illness continuum.

Genetic Makeup For example, the risk of breast cancer increases dramatically in women who have a family history of a mother, sister, or daughter with breast cancer. Recently, a genetic marker for this type of breast cancer has been discovered—that is, some people inherit a tendency to develop breast cancer.

Gender Many diseases occur more commonly in one gender than in another. For example, rheumatoid arthritis, osteoporosis, and breast cancer are more common in women, whereas ulcers, color blindness, and bladder cancer are more common in men.

Age and Developmental Stage Age and developmental stage influence the likelihood of becoming ill. Certain health problems can be correlated to developmental stage. For example, more than 75% of new breast cancer cases are diagnosed in women older than age 50. As another example, adolescent boys have much higher rates of head injury and spinal cord injury than the general public because of their tendency toward risk-taking behaviors. For further discussion of growth and development, see Chapters 9 and 10 in this book. Developmental stage influences coping ability and perceptions, hence their experience of health and illness.

- **Developmental influences on coping ability.** Developmental stage influences a person's ability to cope with stressors that tend to move him toward the illness end of the continuum. Infants or children who are ill, frightened, or hurt have a limited repertoire of experiences, communication ability, and understanding to help them in their responses. As we progress through the stages of development, we develop understanding and skills to help us deal with illness.
- **Developmental influences on perceptions.** When disease, loss, or other disruptions occur at a younger age than expected, they change our perception of the event and may present a greater challenge to our coping skills than disruptions that are expected. For example, a child's death may seem more tragic than that of an older adult. It is important, though, not to discount the impact of disruptions that occur during the period of a person's life when they might be expected.

For example, the death of a spouse is no less traumatic for an older adult than it would be for a young spouse. Losing someone with whom one has spent most of one's life is an incredible loss, whether or not it is "expected" at that stage of life.

Nutrition

Health requires nourishment, and the most obvious form of nourishment is food. The influence of diet on human health is undeniable: Nutrient-deficiency diseases, such as scurvy and night blindness, are unknown in people who consume a nutritious diet. In addition, many chronic diseases, such as type 2 diabetes mellitus and heart disease, are influenced by our diets, and nutrition appears to play at least a moderate role in a variety of other diseases, such as osteoporosis and some forms of cancer (Thompson & Manore, 2012). As more studies look at the protective properties of some foods (e.g., antioxidants) and the hazards of others (e.g., refined carbohydrates, *trans*-fatty acids), the phrase "You are what you eat" seems more accurate each day. Chapter 27 discusses nutrition in greater detail.

Physical Activity

Healthy people are usually active people. When they are unable to maintain previous levels of activity, they may perceive themselves as less healthy. Studies support the benefit of moderate physical activity in reducing the risk of chronic disease and promoting longevity (Thompson & Manore, 2012). As little as 30 minutes of gardening or 15 minutes of jogging on most days of the week can lead to these benefits. In addition, certain types of exercise have been shown to reduce the risk of specific diseases, such as osteoporosis and heart disease. For example, weight training has been shown to increase bone density and reduce the risk of osteoporosis in women older than age 40, and aerobic activity, such as walking, decreases the risk of heart disease. Physical activity is discussed more fully in Chapter 32.

Sleep and Rest

Sleep nourishes health. Most of the body's growth hormone, which assists in tissue regeneration, synthesis of bone, and formation of red blood cells, is released during sleep. Sleep is also important to mental health because it provides time for the mind to slow down and rejuvenate. In controlled studies, people kept awake for 24 hours experienced difficulty concentrating and performing routine tasks. With increasing levels of sleep deprivation, sensory deficits and mood disturbances occurred. Outside the laboratory, mild but chronic sleep deprivation is common, particularly among students, mothers of infants and young children, and people in pain. Sleep and rest are discussed in more detail in Chapter 34.

Meaningful Work

Many people find that work is a healthy way to cope with stressors. Psychologist Victor Frankl, who survived internment in a Nazi concentration camp, observed in *Man's Search for Meaning* (1959, 1962, 1984, 2004) that engaging in meaningful work promotes health and, even in the midst of horrific stressors, can defend against physical and mental breakdown. The definition of meaningful work varies, but many share the view offered by Morrie Schwartz in *Tuesdays With Morrie:* "You know what really gives you satisfaction? Offering others what you have to give. . . . [D]evote yourself to your community around you, and . . . to creating something that gives you purpose and meaning. You notice, there's nothing in there about a salary" (Albom, 1997).

People also experience meaningful work as a dimension of wellness. For many people, volunteering, pursuing hobbies, and engaging in pleasurable activities can be forms of meaningful work. For example, some find that singing, playing a musical instrument, or listening to music is particularly healing. For others, it may be literature, art, playing basketball, knitting, gardening, hiking in the wilderness, or even shopping. Remember that being healthy is not all about denying yourself the pleasure of ice cream and French fries. Healthful activities can be fun, too. By supporting clients' life work, hobbies, and personal interests, you help them nourish their health in their unique way.

Lifestyle Choices

People who consider themselves healthy are usually those who make healthy lifestyle choices. They are aware of the threats to health created by cigarette smoking, alcohol consumption, drug abuse, unprotected sex, and other risky behaviors. Consider the following examples:

Tobacco Tobacco use increases recovery time from other illnesses, injuries, and surgery. Smoking also increases the risk of diabetes, infertility, low birth weight and preterm babies, and perinatal death.

Alcohol Studies have indicated that drinking a glass of red wine each day can reduce the risk of heart disease and slow bone loss. In contrast, excessive alcohol consumption damages the brain, liver, pancreas, intestines, and neurological system and can lead to malnutrition. It has also been implicated in several forms of cancer and in fetal alcohol syndrome in newborns.

Finally, excessive alcohol consumption is implicated in about half of all motor vehicle accidents and other injuries.

Other Substances Abuse of alcohol and illicit drugs leads to deterioration in health, functioning, and relationships. Even prescription drugs can be abused. Substance abuse is a risk factor in many diseases. For example, people who inject illegal drugs are at increased risk of hepatitis and HIV.

You will learn more about effects of lifestyle choices on wellness and safety in Chapters 9, 24, and 42.

Personal Relationships

Living in a healthy family is an important dimension of wellness. Moreover, the family influences a person's view of himself as well or ill. Look at Table 11-1. Of the five pairs of families listed there, which family in each pair would you expect to experience a higher level of wellness?

Especially when clients are coping with life-threatening disease, family relationships can provide critical sustenance and preserve optimal wellness during the experience. Weeks before his death from amyotrophic lateral sclerosis (ALS), a neurological disease, sociologist Morrie Schwartz stated, "It's become quite clear to me as I've been sick. If you don't have the support and love and caring and concern that you get from a family, you don't have much at all." (Albom, 1997, p. 91). You will learn more about the role of family in human health in Chapter 14.

When illness occurs, some people prefer to be totally independent, priding themselves on never asking for or accepting help. But the reality is that during times of disruption, support from others (e.g., family, friends, coworkers, pastors, counselors) is crucial, even for rugged individualists. Knowing that support is available, and being willing to accept the support, can greatly affect a person's response to disruptions.

Culture

The healthcare culture has traditionally responded to illness with specific therapies aimed at treating a biophysical disorder, whereas nursing, as part of the culture of holism, responds to the physical, emotional, mental, and spiritual dimensions of illness. The culture of a region, a neighborhood, a school or work environment, affluence or poverty, or a religious group, can also influence individual and family health. Culture affects the experience of illness in the following ways:

- **It influences health decisions, behaviors, perceptions, and view of self as well or ill.** For example, the cultural group may share health-promoting values, such as a nutritious diet or regular physical activity. This is not to say that individuals can be "defined" by their culture. Some, either consciously or unconsciously decide to break away from culturally conditioned responses.
- **It influences responses to illness.** Our response to illness is also partly determined by our culture. For example, people who belong to fundamentalist religions may interpret illness as a punishment from God and may bear their symptoms stoically (i.e., hide their

Table 11-1 ➤ Family Personal Relationships

Which family would likely experience a higher level of wellness?

Family A: Places a high priority on health promotion	OR	**Family B:** Responds to health issues only in times of serious illness
Family C: Encourages adventure and risk taking	OR	**Family D:** Emphasizes caution in new situations
Family D: Is very open about expressing feelings and disagreements	OR	**Family E.** Squelches personal feelings to avoid conflict in the family
Family F: Views the family as capable and successful	OR	**Family G:** Views them as powerless victims
Family H: Teaches good negotiation skills, builds a network of family support, while encouraging the development of independence	OR	**Family I:** Parents do not have a large repertoire of coping and communication skills to share with their children

symptoms) to try to pay for their sins (retribution). People who identify themselves with the New Age movement may believe that illness is a lesson we give ourselves to teach us something we need to learn for our spiritual evolution. If you need more information about the influence of culture on health and illness, see Chapter 15.

Religion and Spirituality

Religion and spirituality are closely tied to culture, and clients' religious beliefs and practices can influence their healthcare choices. For example, some people believe that spiritual beliefs influence the mind–body connection to promote wellness and healing. A dramatic example is seemingly spontaneous recovery after a religious rite, as when, for example, a Native American with crippling arthritis is visited by the "false faces" (shamans wearing masks depicting spirits) and then recovers enough to walk across the room. When healing is not possible because of terminal illness or external circumstances beyond our control, spiritual reserves can help maintain our view of ourselves as "well." You will learn more about the influence of spirituality on health in Chapter 16.

Environmental Factors

The environment can also nourish wellness. For institutionalized clients, a little corner of the room that is uniquely "theirs," with photos and other mementos, can be healing. Other clients may be soothed by the quietness of a chapel, a walk in the park, or even a trip to a shopping mall. Spending time in any place where they feel harmony and peace and draw strength can promote clients' health.

On the other hand, environmental pollutants are a common cause of illness. For example, exposure to secondhand smoke causes an estimated 3,000 deaths from lung cancer among American adults each year (Centers for Disease Control and Prevention [CDC], 2010a). Carbon monoxide and lead poisoning, mold, radon, chemicals (e.g., insecticides), and other pollutants also cause serious disease. See Chapter 24 for more information about environmental pollutants.

Finances

It is often said that money doesn't buy happiness. Certainly this is true. However, money does buy access to healthcare and healthcare choices and thus nourishes wellness. In the United States, health insurance is often tied to employment or income level, and health insurance dictates which providers you have access to and what services are available to you. Even in countries with national health programs, such as Canada and some European countries, the standard care available may not include all the services or medications a person desires. The same is true in the United States, for example with Medicare.

Sometimes healthcare providers wonder why people do not take advantage of services that are available to them. Why do they let things go so long before seeking help—or fail to follow up with recommended treatment plans? **Key Point:** ***A client's apparent lack of concern or lack of compliance to a treatment regimen may be, in reality, a problem of access to healthcare. Any one or more factors may keep individuals and families from getting the help that they need (e.g., distance from the resources, knowledge of available resources, trust in the available resources, financial status, and lifestyle adjustments such as a change in employment).***

WHAT FACTORS DISRUPT HEALTH?

We spend much of our lives trying to maintain good health—eating, sleeping, keeping our bodies at a comfortable temperature—in general, tending to our high-maintenance bodily needs. It's a continual process because of the many disruptions to health we face. Not all of these disruptions are incapacitating, but all challenge our ability to function and enjoy our everyday lives, and they tend to move us toward the illness end of the health–illness continuum. What are **health disruptions**? Let's explore the concept by learning about some specific examples.

Physical Disease

Disease disrupts our lives in so many ways. It may reduce our ability to perform our life roles effectively or to engage in activities we enjoyed before the illness. The diagnosis of a chronic or life-threatening disease may bring shock, fear, anxiety, anger, or grief: Will I become disabled? How will I support my family? What did I do to deserve this? And finally, it may also cause clients to question the meaning and purpose of their lives, to become more inwardly focused, or to embrace life even more fully. When she first learned of her diagnosis of breast cancer at age 36, Treya Killam Wilber wrote, "Strange things happen to the mind when catastrophe strikes. . . . I was so stunned that it was as if absolutely nothing had happened. A tremendous strength descended on me, the strength of being both totally jolted and totally stupefied. I was clear, present, and very determined" (Wilber, 2000).

Injury

Injury can cause the same symptoms and emotions as disease, but perhaps its most disruptive aspect is its suddenness. In *Still Me,* actor Christopher Reeve (Superman) described his thoughts in the first days after he recovered consciousness following his cervical spinal cord injury: "The thought that kept going

Quality and Safety Education for Nurses

Chronic Illness and Self-Management Through Telehealth

Chapter Key Concepts: *Health, Illness*

Competency: *Informatics (knowledge, skills, attitudes)**

Background: Telehealth encourages patients to be in more control of their health and to take ownership of their condition (Pearce, 2012). Healthcare is transitioning to a focus on patient self-management. Telecommunication provides a strategy for self-management by empowering patients and helping them feel more secure in monitoring and managing their care (Kim, Kim, Kim, et al., 2012). In chronic conditions there is a window of opportunity for remote monitoring to detect health changes sooner and to initiate earlier interventions (Kim, Kim, Kim, et al., 2012).

Scenario: A patient with long-standing chronic obstructive pulmonary disease (COPD) frequently experiences exacerbations requiring hospital admission. Because the patient lives in a remote rural area he often delays seeking healthcare. At the last clinic visit the nurse provided the patient with home monitoring devices that connected him to telehealth services.

Think about it:

- What advantages can telehealth provide for a patient with chronic illness?
- How might telehealth increase the patient's self-care management of COPD?
- Discuss how informatics (specifically telehealth) can impact an individual's position on the health–illness continuum.

Go to the QSEN Web site at http://qsen.org/competencies/pre-licensure-ksas/

*As reference for your QSEN log box, the QSEN KSA that is most pertinent is: *Describe examples of how technology and information management are related to the quality and safety of patient management.*

through my mind was: I've ruined my life. I've ruined my life, and you only get one. There's no counter you can go up to and say, 'I dropped my ice cream cone; could I please have another one?'. . . . Why isn't there a higher authority you can go to and say, 'Wait a minute, you didn't mean for this to happen to *me*'" (Reeve, 1998).

Mental Illness

Clients with mental illness and their families experience a level of pain, suffering, and chronic sorrow that is difficult for healthy people to fully appreciate (Godress, Ozgul, Owen, et al., 2005; Kokanovic, Petersen, & Klimidis, 2006). In addition, if the illness affects work ability, they experience loss of income and altered role relationships, accompanied by the costs of various therapies.

Mental illness carries with it a stigma that may be diminishing slowly, but is highly visible to those who suffer from its effects (Townsend, 2012). This stigmatization can also disrupt the health of family members. Families must adjust to a major upheaval in their lives, as they experience the pain associated with the loss of a once promising child or relative to the spiral of mental illness (Townsend, 2012). Family members may also live in constant fear that their loved one hurt herself or even commit suicide.

Pain

Whether mild or severe, temporary or long lasting, pain is a disruption. It's not that we can't live with pain—many people do, every day of their lives. However, pain disrupts the smooth operation of our lives; it can change personality, erode coping skills, and interfere with healthy communication. It's hard to concentrate on what we are trying to accomplish when pain is competing for our attention. Pain can interfere in life at all levels, particularly when it is chronic or severe.

Pain that is easily remedied with over-the-counter (OTC) medications or that is short lived serves only as a minor disruption in our lives. However, pain that is all-encompassing permeates a person's entire existence. Sometimes that pain is physical, sometimes psychological. One young mother of a profoundly mentally disabled 14-year-old girl spoke of "hurting so bad that my bones hurt."

As you know, some of our nursing interventions inflict pain. We ask patients to turn, deep-breathe, and cough after surgery, even though it hurts—a *lot*! We put needles in them, catheterize them, and get them out of bed when they would rather sleep. We pull off tape. We invade their physical personal space. We ask them questions about personal things, such as their bowel movements. It is a challenge to be a comforting, healing presence when we have to do things that cause discomfort.

Loss

Loss is a disruption that cuts to the core of who we are—whether the loss of a job; the end of a romantic relationship; the death of a loved one; or the loss of youth, beauty, functioning, or identity. Most of us cling to a unique identity, which usually does *not* include gaining weight or getting wrinkles and gray hair, let alone being a "patient" or losing major bodily functions. When such a loss occurs, the resulting period of significant disintegration may continue until the person either finds a way to cope with the loss or succeeds in reinterpreting the loss in a meaningful way. Toward the end of her battle with cancer, Treya Killam Wilber lost her near vision. One way she coped with this loss was by replacing her passion for reading with sitting at her window contemplating the mountains beyond (Wilber, 2000).

Loss of Sense of Self Many have written about the indignities people suffered in concentration camps, including nakedness, exposure to human excrement, and being treated like children, incapable of thoughtful judgment (Bettelheim, 1979; Frankl, 1959, 1962, 1984, 2004; Valladares, 2001). Those three indignities are crucial threats to a person's sense of self. Sadly, patients in healthcare institutions may also suffer those indignities. Think how patients feel who have to don a hospital gown and allow their body to be exposed for various tests or procedures, or how it feels to lose control of bladder or bowel function. One woman who was paralyzed as the result of a lesion on her spine indicated that one of the toughest things she had to deal with was having her daughter give her enemas and clean her up as if she were a baby. **Key Point:** ***As healthcare providers, we may easily forget how humiliating such "routine procedures" may be for the patient. You can help relieve the disruption of disease and injury when you respect patients' dignity, provide for privacy, and allow them to make choices regarding their care.***

Permanent Loss If temporary losses are difficult, what about those that are permanent? C. S. Lewis (1961) wrote about his response to the death of his wife: "I know that the thing I want is exactly the thing I can never get. The old life, the jokes, the drinks, the arguments, the lovemaking, the tiny, heartbreaking commonplace" (p. 22). As nurses, we would like to "fix" everything. Though we can't "fix" the holes that are left when a person suffers a loss, we can be open and sensitive to his heart's cry.

Impending Death

It is easy for most of us to ignore that we have a 100% chance of dying and live as though death were only a remote possibility. Lifton and Olson (1974) state that during middle age, even without the presence of life-threatening illness, people tend to become more aware of the compelling reality of death: "One's life is suddenly felt to be limited. . . . It also becomes apparent that . . . there will not be time for all one's projects" (p. 63).

As a nurse, you will care for clients who are living in disruptions of the shadow of death. Some may be aware of their condition; others may choose to deny it, ignore it, or "fight it to the end" by trying a series of conventional and alternative therapies. Caring for dying clients makes us painfully aware of our own frailty and is one of the most difficult experiences you will face as a nurse. Chapter 17 provides further discussion of loss, grieving, and dying.

Competing Demands

Even in the normal flow of life, there are many competing demands. Taken independently, they may be easy to handle. Taken together, the cumulative effect wears us down. In times of illness, the other competing demands continue. Children need to be cared for. Aging parents may need care. Bills still need to be paid. Job responsibilities press in. One man with depression reported, "[T]he whole thing bundled together—one caused the other which caused more and it was just a degenerative loop. . . . [O]ne thing feeds another which feeds another and so forth until you just constantly go down" (Smith, 1992, p. 104).

Sometimes people ignore health issues because the competing demands are too great. Symptoms may even go unnoticed because attention is scattered in so many directions and there is not enough time and energy to research one's symptoms, schedule a doctor's appointment, or follow through with treatments.

When an illness is acute, such as a broken bone, the stress is usually bearable because it usually lasts for a set amount of time. Bettleheim (1979) states: "The worst calamity becomes bearable if one believes its end is in sight" (pp. 3–4). But when the illness is chronic, the competing demands can take a heavy toll. One woman who took care of her husband who lived at home on a respirator recounted the overwhelming burden she felt when, after 2 years, he was "no better and no worse. This could go on forever!" Although people came in to help, she felt she had to maintain constant alertness in case something went wrong with his ventilator, and she still had to meet many other demands and challenges each day.

As nurses, we sometimes find it easy to criticize how people deal with their situations. But it is so important to realize that the short amount of time that you spend with someone in a hospital or clinic or in a home visit is only one tiny fragment of the cumulative experience that patients and their families experience, sometimes unrelentingly for years on end.

ThinkLike a Nurse 11-3

How might you assist your patient to maintain normalcy in spite of illness?

The Unknown

Even normal life changes present challenges. For example, most parents bringing their first baby home from the hospital are in for plenty of surprises. With some unknowns, there is time to investigate the potential problem and prepare. For example, if an expectant couple learns via amniocentesis (a prenatal test) that their child has a genetic defect, then during the remaining months of pregnancy they can read about the disorder and meet with other parents who have had children similarly affected. But injuries and illnesses can happen abruptly, with no chance to prepare ourselves for new realities. A woman described her experience of finding out she had cancer of the lung with metastasis: "It was on a . . . Friday—I got to feeling kind of bad—kind of like you had the flu or something, you know? . . . so I went to the doctor. . . . And he sent me to the hospital. . . . they started doin' tests on me—all kinds of tests—and found out I had cancer" (Smith, 1992, p. 107).

Imbalance

Our sense of justice tells us that when we are good, good things should happen. When we are bad, bad things should happen. The Buddhist concept of karma suggests that there is a fair balance between what one gives to life and what one receives. Thus, when we perceive that life has violated this rule, we experience that as a disruption, as in these examples:

- **Death of a child.** Our sense of balance is perhaps most dramatically disturbed by the death of children. Such deaths are sometimes referred to as "out of order" because children (of any age) "should" not die before their parents.
- **Treatment failure.** Balance is also disrupted when patients, expecting that their painful and harrowing treatments "should" help them get better, do not get better. One young woman under treatment for advanced cancer described it like this: "It's just—you've been working hard . . . . you're doin' what you're supposed to be doin' and focusing and all this and that—and your body is still not responding" (Smith, 1992, p. 111).

Have you seen the bumper sticker "Life is hard. And then you die"? Cynical perhaps, but we do not have to live long before we realize that as much as we would like for everything to be fair, it is not going to happen. Knowing this intellectually, however, does not necessarily reduce the disruptive effect of the imbalance.

Isolation

How many times have you thought, "No one knows what I'm going through!"? A sense of isolation or aloneness seems to accompany suffering. C. S. Lewis (1961) states, "You can't really share someone else's weakness, or fear or pain" (p. 13). Vanauken (1977), in writing about the death of his young wife, reveals that it was not only suffering his loss, but having to go through the experience *without* her that made it so difficult: "Along with the emptiness . . . I kept wanting to *tell* her about it. We always told each other—that was what sharing was—and now this huge thing was happening to me, and I couldn't tell her" (p. 181).

The sense of aloneness reported by seriously ill clients is related in part to their actual physical separation from loved ones during treatments, hospitalizations, or clinic visits. But it also stems from their feeling that there is no one who is really "in their world." Having someone physically present does not necessarily remove the sense of aloneness:

> *When I lay here it's lonely—very, very lonely. Because [my daughter] can't just sit here and talk to me all the time. She's got wash to do, fold and all that stuff. And then the kids to worry about. . . . The worst thing I've found about this whole disease is the loneliness. . . . Because your family can be with you and if they don't come and sit down and talk to you about different things, you're lonely. It's the loneliness that makes you sad inside. . . . It's like everybody's afraid of you or something. They're afraid that maybe they're gonna catch what you got or something. (Smith, 1992)*

KnowledgeCheck 11-2

Identify at least four factors that disrupt health.

ThinkLike a Nurse 11-4

- What impact do disruptions have on your life?
- How could you apply the information about disruptions to the health of a community? To the health of a nation?

WHY DO PEOPLE EXPERIENCE ILLNESS DIFFERENTLY?

Earlier in this chapter, we mentioned that people vary greatly in terms of their response to life situations. Why is this so? Why do some people react to seemingly insurmountable problems with calmness and grace, while others fall apart over seemingly "small" disruptions? The human experience is so complex and interactive that it is impossible to make neat little categories that we might add up to determine a score predicting how a person will respond to a given situation. There are several factors, however, that may influence an individual's responses to illness. Focus now on the concepts of illness stage; acute and chronic illness; hardiness; and the intensity, duration, and multiplicity of the disruption.

Stages of Illness Behavior

Illness can be viewed as a social role, in which both the patients and caregivers have duties and expectations that are shaped by the society in which they live. Therefore, how people react to an illness depends in part on their illness stage. Suchman (1972) identified five stages of illness behaviors that people move through as they cope with disruptions to health: experiencing symptoms, sick role behavior, seeking professional care, dependence on others, and recovery.

Experiencing Symptoms Symptoms are a signal that illness has begun. If the symptoms are recognizable, such as a runny nose, sneezing, and a cough, you may identify the problem as a common cold and turn to previously used remedies. Common problems rarely progress beyond this stage. However, if the symptoms are unusual, severe, or overwhelming, you may progress to the next stage.

Sick Role Behavior When you have identified yourself as ill, you assume the sick role. The sick role relieves you of normal duties, such as work, school, or tasks at home. In Western biomedical culture, the prevailing view is that sick persons are not responsible for their illnesses and that a curative process outside the person is needed to restore wellness. We believe that the sick person has the duty to try to get well, to seek healthcare, and to cooperate with the care providers (Cockerham, 2011). The severity of the symptoms and anticipated length of illness determine whether you will progress further along the stages of illness.

Seeking Professional Care The next stage is seeking professional care. To reach this stage, you must determine that you are ill and that professional care is required to treat the illness. Persons who seek professional care are asking for validation of their illness, explanations for their symptoms, appropriate treatment, and information about the anticipated length of illness. Healthcare professionals often bypass this stage, relying on themselves to identify and treat the problem. This is not always the best course of action because it is difficult to be objective when examining yourself.

Dependence on Others When you accept the diagnosis and treatment of the healthcare provider you typically also accept the need to depend on others. The severity of the illness and the type of treatment determine the extent of dependence. This may be limited to listening to the provider's instructions, filling the prescription, and following directions given in the office. However, illness that requires hospitalization is often associated with dependence on nursing staff and hospital personnel for activities of daily living (ADLs), medications, and treatments. Some people easily make the transition to dependence; others remain as independent as possible even in the face of severe illness. Personal characteristics and values play a large role in determining how each of us will respond to the challenges of being dependent.

Recovery The final stage of illness is called **recovery**. The person gradually resumes independence and returns to normal roles and functioning. In minor illness, this is usually a return to the status quo. Severe illnesses may require a newly defined level of optimal function. The greater the change, the more difficult this transition will be. Learning to manage a chronic illness is the equivalent of a cure in an acute illness (Parsons, 1975). Both represent the recovery stage.

The Nature of the Illness

The nature of the illness (e.g., whether the illness is chronic or acute) affects the way persons react to disruptions and respond to illness.

Acute Illness An **acute illness** occurs suddenly and lasts for a limited amount of time. Acute illnesses, such as a cold, flu, or viral infection, may be minor and require no formal healthcare. Some acute illnesses, such as strep throat, may require a visit to a healthcare provider for treatment or even hospitalization or surgery, as in cholecystitis (gallbladder inflammation secondary to gallstone formation) or pyelonephritis (infection of the kidney). Although hospitalization and surgery can be quite traumatic, in each case the person is expected to recover. In acute illness, a person may experience the disruptions of pain, competing demands, and the unknown. However, an end is in sight. Relief is expected.

Chronic Illness In contrast, **chronic illness** lasts for a long period of time, usually 6 months or more, often for a lifetime. Chronic illness requires the person to make life changes. These changes might be regular visits to the clinic or hospital, daily medications, or lifestyle modifications such as a low-fat diet or smoking cessation. Common chronic illnesses include AIDS, diabetes mellitus, rheumatoid arthritis, and hypertension. Because of the lengthy period of illness, people with chronic disease often experience periods of remission or exacerbation. A **remission** occurs when symptoms are minimal to none. An **exacerbation** ("flare-up") occurs when symptoms intensify. Clients with chronic illness often complain about the unrelenting nature of their health problems. A person with chronic illness may experience virtually all of the disruptions identified earlier. Box 11-2 identifies some interesting facts about chronic conditions.

Hardiness

Why does one client who drinks, smokes, overeats, and avoids exercise live into his 90s, yet another client who

BOX 11-2 ■ Facts About Chronic Conditions

- More than 90 million Americans live with chronic conditions.
- Chronic conditions account for about 70% of all deaths in the United States.
  - About 80% of older adults have at least one chronic condition; 50% have at least two.
  - Approximately 6% of adults older than age 65 have a diagnosable depressive illness.
- The top three risks for functional decline are cognitive impairment, depression, and disease burden.
- The largest declines in functional abilities are associated with these physical conditions: arthritis of the hip or knee; sciatica; and chronic pulmonary diseases.
- Arthritis affects 1 in 5 U.S. adults; for more than 40% of those, arthritis limits their activities.
- About 32% of the adult population and 17.1% of children and adolescents were obese in 2003–2004.
- In a large sample of Medicare beneficiaries, the following were the most frequent chronic physical conditions:

Hypertension (56%)	Depression (13%)
Hyperlipidemia (47%)	Osteoporosis (12%)
Ischemic heart disease (32%)	Atrial fibrillation (8%)
	Alzheimer's disease (11%)
Diabetes (27%)	Any cancer (other than skin cancer) (7%)
Arthritis (21%)	
Heart failure (18%)	Emphysema, asthma, or COPD (11%)
Chronic kidney disease (13%)	Stroke (5%)

Sources: Centers for Disease Control and Prevention (CDC) (2002, 2010a, n.d.); Centers for Medicare & Medicaid Services (2011); Peikes, D., Chen, A., Schore, J., et al. (2009); Wiktorsson, S., Runeson, B., Skoog, I., et al. (2010); Stuck, A. E., Walthert, J. M., Nikolaus, T., et al., 1999.

"follows all the rules" dies of a sudden heart attack at age 39? Our bodies do not react to the same stressors in the same way. One factor that may contribute to this difference is the person's hardiness.

Will to Live **Hardiness** has been described as developing a very strong positive force to live—and enjoying the ride (Fig. 11-4)! A man with heart problems said, "I guess everybody that's in the situation, who has to fight to live, and has learned the mental wizardry of it, you know, to make yourself want to live on. But if you want to, you develop this—this very, very strong positive force to make it go" (Smith, 1992, p. 131). Seigel (1986) reported a study by London researchers that revealed a 10-year survival rate of 75% "among cancer patients who reacted to the diagnosis with a 'fighting spirit,'" compared with a 22% survival rate "among those who responded with 'stoic acceptance' or feelings of helplessness or hopelessness" (p. 25).

Adapting to Change Another aspect of hardiness is the willingness to draw on resources within oneself or from others to break out of old patterns of living when life situations change. When disruption hits, some people don't have the cognitive, communicative, creative, and spiritual resources they need to make life changes, and they just give up. Hardy individuals are willing to seek out information and take initiative in dealing with life situations rather than sitting back and letting someone else control their lives. Ironically, some people survive and thrive during times of adversity. Those who see themselves as hardy tend to approach changes with an "I can deal with this" attitude.

FIGURE 11-4 Hardiness has been described as developing a very strong positive force to live—and enjoying the ride!

The Intensity, Duration, and Multiplicity of the Disruption

Everyone has limits. For healthcare providers, too many demands over too long a period of time can lead to "burnout," a feeling of being overwhelmed and demoralized. For clients and their families, dealing with the cumulative effect of illness and other life disruptions can break down what might otherwise be excellent coping skills. Therefore, their responses may not be typical of what they usually have demonstrated.

- Identify the factors that affect how a person responds to the disruptions of illness.
- Define *hardiness*.

Toward Evidence-Based Practice

Rodin, D., & Stewart, D. E. (2012). Resilience in elderly survivors of child maltreatment. *SAGE Open*, 2(2), 1–9.

This study of older adults was conducted to better understand the factors that contribute to resilience (positive adaptation of individuals, despite exposure to adversity) in the elderly population. In this qualitative study of nine survivors of childhood abuse, resilience was found to be high, despite earlier trauma and the subsequent challenges of old age. The authors found that active engagement in relationships and in valued activities were the most often mentioned contributors to resilience.

Jaser, S. S., & White, L. E. (2011). Coping and resilience in adolescents with type 1 diabetes. *Child: Care, Health and Development*, 37(3), 335–342.

Thirty adolescents between the ages of 10 and 16 with type 1 diabetes and their mothers completed questionnaires on adolescents' coping strategy use, competence, and quality of life. Greater use of coping strategies (such as problem-solving and emotional expression) was associated with higher social competence scores, better quality of life, and better metabolic control. Adolescents who reported a lack of coping strategies (instead using withdrawal or denial) reported lower social competence and poorer metabolic control of their diabetes.

1. How do the results of these studies apply to the concept of health as presented in this chapter?

2. Identify ways in which the methods and findings could be applied to other populations.

Go to Chapter 11, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

Practical Knowledge knowing how

In the preceding section, you have learned how people experience health, wellness, and illness. In this section, we look at how this information can be applied to your nursing practice.

USING THE NURSING PROCESS TO PROMOTE HEALTH

Throughout this textbook, you will learn to use the nursing process to help clients deal with a variety of health problems. But how does the nursing process relate to the broader aspects of health and illness described in this chapter? Overall, it involves helping clients—regardless of the type of health problem—to look within themselves to develop creative ways to deal with the realities they are facing.

Patients may fail to comply with a proposed healthcare regimen if healthcare providers develop a plan of care that has no cultural or personal relevance for the patient (or family). Perhaps the plan does not consider the knowledge level of the patient or caregiver; or perhaps it is not feasible in terms of available support, time, energy, finances, or location. Patients may leave a hospital setting *against medical advice* (AMA), thereby endangering their chances of recovery. They may believe that the treatment offered them will not help or that the illness is preferable to the proposed treatment. Noncompliance often occurs because the effort, inconvenience, or pain involved with a therapeutic plan of care is too much for them to handle.

Remember that people probably do not refuse to carry out a plan of care simply out of stubbornness, hostility toward healthcare providers, or wanton disregard for their own welfare. The challenge for nurses is to develop an individualized plan of care in collaboration with patients, based on mutual goals and respect.

ASSESSMENT

In looking at an individual's health status, it is easy to focus on the measurable aspects. Physical needs obviously are crucial, but competing issues may be present and cause the client to view the therapeutic interventions as irrelevant or even disruptive.

What Does It Mean to Communicate Care and Concern?

Key Point: ***Obtaining data about the psychosocial, emotional, and spiritual aspects of health requires a level of communication that goes beyond a neat list of skills. Communicating genuine care, concern, and sensitivity comes from who you are as a person, not from assuming a professional persona (putting on your "nurse's hat").*** The following are aspects of a high level of communicating:

Settling In Your initial approach to a patient creates a climate that determines the level of communication that takes place. The patient is probably in a new environment, and your tone, words, and facial expressions can bring comfort and ease. Nurses can be in new situations too, and taking a few moments to settle in to the situation can be helpful in establishing a therapeutic relationship and facilitating communication.

Attuning Being maximally attentive is another key factor in facilitating communication. Most people are hungry for someone to listen to them. So often, listeners are so busy thinking about what they want to say that they fail to really listen. Try to focus on what the patient or family has to say instead of thinking ahead to what you want to ask next.

Acceptance Another vital aspect of communicating is acceptance—acceptance of appearance, lifestyles, ways of coping, and values. You might ask, "How can I be accepting when there are aspects of this person that go against my entire value system?" Accepting is not the same as "agreeing with." You can accept people as valued, creative, unique individuals, despite their differences from your own ways of being. This view of acceptance does not mean that people will not be held accountable for their actions, for example, in cases of domestic violence and child abuse. It does mean, though, that in your role as a caregiver, you must convey an attitude of accepting the intrinsic value of life—in whatever form that life takes.

Enjoying Perhaps even more difficult than accepting is enjoying. You will come into contact with a wide array of individuals, many of whom are different from people you have grown up around and have come to know and enjoy. A challenge for you is to broaden the repertoire of people you enjoy: to see and enjoy commonalities among individuals seemingly so different and to recognize and appreciate the pathos of suffering in the unique experience of each person.

How Can I Be a Better Communicator?

Settling in, attuning, respecting, and enjoying—certainly this is not a step-by-step process, but each is vital to creating a climate for the openness and communication needed for assessment.

Take Time to Communicate You might argue that the healthcare environment does not allow time for such a high level of attentiveness. Consider, though, how much time is spent in delivering nursing care. As a full-spectrum nurse, you will assess patients continually while thinking, doing, and caring for your patients. In fact, the physical contact involved in carrying out nursing procedures seems to break down barriers of communication. Nurses hold a unique opportunity in "being with" individuals during difficult life situations. Indeed, Benner and Wrubel (1989) state that expert nurses call this the "privileged place of nursing" (p. xi).

Identify the Patient's Main Concern One way to approach assessment, whether in outpatient, acute care, long-term care, or home settings, is to ask the patient, "What is the biggest concern you are dealing with today?" You may have a plan of care that addresses areas that you know to be important, but it may fall far short of meeting your patient's needs if you have not addressed the concern that is fundamental to your patient.

Develop Your Observation Skills In addition to communicating, developing your observation skills will enable you to assess your patients more fully. Watching your patient's responses to you and your care; observing the presence or absence of visitors and the effect on your patients; and observing signs of religious or cultural practices that have significance all provide important information about your patient's strengths and needs.

ANALYSIS/NURSING DIAGNOSIS

Several of the nursing diagnosis labels identified by NANDA International relate to health issues discussed in this chapter. Some examples are Anxiety, Caregiver Role Strain, Deficient Knowledge, and Spiritual Distress. An analysis of the assessment data that you gather should also provide the information needed to describe related causal factors, such as Spiritual Distress related to fear of impending death, or Situational Low Self-esteem related to loss of job secondary to frequent absences for chemotherapy.

KnowledgeCheck 11-4

Compare and contrast attuning, acceptance, and enjoying.

PLANNING OUTCOMES/EVALUATION

Goals and outcomes should be both realistic and valued by the patient and family. When you set goals in the broader dimension of health and illness (as in this chapter), it is much harder to be specific in describing expected outcomes and time frames. As a nurse, your role is to help the patient (or family member) envision acceptable outcomes and to set smaller, realistic goals so that the patient recognizes progress. For example, an older woman caring for a spouse with Alzheimer's disease may have a nursing diagnosis of Caregiver Role Strain related to care of spouse with dementia. Together you would establish acceptable goals and break them down into realistic steps. You also would identify outcomes to indicate that the caregiver actually experiences a reduction in strain, such as being able to sleep or having time to pursue meaningful activities.

PLANNING INTERVENTIONS/IMPLEMENTATION

The ideal approach is to draw on patient and family strengths to help achieve the desired outcomes. In the preceding example of the older adult caregiver, you would discuss with her the options available to provide support, but she would identify which options were acceptable to her and her spouse. In the stress of illness, patients and families may not recognize the strengths and creative abilities that they bring to a situation. **Key Point:** ***Part of the art of nursing is to envision strengths and potential in patients and families, just as an artful teacher might recognize a "spark" in a child and encourage that child to learn and grow.***

ThinkLike a Nurse 11-5

- How can you use the concepts of health when you are admitting a patient to a hospital setting? To a clinic? To an emergency department? To a rehabilitation or long-term care setting? In initiating home care?
- What questions can you ask or what observations can you make to help you gain information about individuals' health strategies, disruptions to health, and factors contributing to their responses to disruptions?
- How would you consider health concepts in planning for patients' discharge from healthcare settings?

How Can I Honor Each Client's Unique Health/Illness Experience?

As a nurse, you can be an instrument of healing in a hurtful world. However, being an instrument of healing does not come automatically with your nursing license. Nor does it allow you the luxury of learning just one approach and applying it to every client. It means cultivating a healing presence by listening, being maximally attentive, being aware of your own gifts and limitations of communication, being willing to learn from those in your care, recognizing and respecting others' ways of coping, and enjoying others for who they are.

Patients may be impressed by your skill and knowledge and amazed by the healthcare technology used to diagnose and treat their illnesses. However, what they most often remember, perhaps through the rest of their lives, is that person who connected with them in a very special way. One man, quadriplegic for 26 years following a car accident in his teens, spoke of a senior nursing student who cared for him during his initial hospitalization. He said that after 26 years, he not only still remembered her, but also still could sense the warmth of her caring presence.

During times of vulnerability, people seem acutely attuned to those who are helpful to them and also to those who slight them in hurtful ways, whether intentionally or not. What a challenge this creates for a nurse! In this section, we discuss steps you can take to prepare yourself for responding to your clients in ways that are meaningful and healing to them.

Examine Life's Uncertainties

Wellness is a balancing act between living in the mostly known present and the mostly unknown future. Encourage your clients to make active decisions that positively affect their future. You do not have control over a drunk driver who sails across the median and hits you head-on, but you do have control over getting the brakes on your car fixed or wearing your seat belt. Likewise, you do not know whether you will develop cancer or heart disease, but you can take responsibility for learning and practicing prevention and detection of problems.

Making health-promoting lifestyle choices is important, but it cannot protect us from risk. Significant life experiences, such as getting married, having children, investing in friendships, venturing into business, and selecting a profession all involve risk. Making a commitment to *anything* is a risk. Each person has a different "risk–comfort range." Some are willing to risk little, have fewer disappointments, and less sparkling achievements. To others, security is not as important, and they are comfortable taking greater risks.

In *A Severe Mercy*, Sheldon Vanauken (1977) writes about finding and losing a great love. He reasons: "The joy would be worth the pain—if, indeed, they went together. If there were a choice . . . between, on the one hand, the heights and the depths and, on the other hand, some sort of safe, cautious middle way, he, for one, here and now chose the heights and the depths" (p. 9). He did, indeed, find a great love, and when he lost his wife at an early age, he was able to accept their time together as one of his life's greatest blessings. As a nurse, you will face many uncertainties and dilemmas. You will certainly face new experiences and challenges, situations you thought *you* never would have to deal with. You will observe pain, suffering, and death. You may never understand the apparent unfairness of it all. But often life brings new meaning when it takes a different direction from the one planned. For example, a couple formerly embittered over their third miscarriage found joy in adopting two children with disabilities.

You will also be privileged to witness many joys. Some might even qualify as minor triumphs: a patient taking his first steps after major surgery, a pathology report that isn't as bad as feared, or even a peaceful death that brings closure to a grieving family. As you move from novice to expert, you may find that such witnessing causes you to stop questioning life's uncertainties and instead to start treasuring them.

ThinkLike a Nurse 11-6

- What uncertainties have you struggled with?
- What approaches have proved effective for you in dealing with uncertainties?

Envision Wellness for Your Clients and Yourself

Wherever there is a dream, there is someone there to tell you it can't be done, or at least not by you. There is something to be said, however, for "envisioning" wellness for your clients and yourself. Remember Evelyn (Meet Your Patient)? If her nurses had labeled her as debilitated and close to death, how would that have affected her? In contrast, their acceptance of her vision of herself as well and full of life supports her and aids her healing. In the same way, think of how you view your own health. Is the life you envision for yourself characterized by zest and vigor? What are your family relationships like? What are your values? Does your work give meaning and purpose to your life? The wellness that you envision for yourself can be the blueprint for what you want to become. The skeptic in you might say, "What if I do everything that I know to do to maintain a healthy life and still have a heart attack at 45?" As we have seen, life is full of uncertainties. That does not mean that you have to stop envisioning. Instead, use *flexible envisioning*, adjusting your goals and dreams to each new reality. Health does not mean always getting your first choice. Part of health is being able to dream a new dream, starting over if you need to, but always envisioning that there is something worth striving for.

Establish Trust at Your First Patient Contact

When patients are admitted to a hospital or ambulatory care facility, you will need to support them in their transition from wellness to illness, in dealing with the unknown, and in adjusting to a new environment. The relationship and trust you establish in your first contact with patients can go a long way toward relieving their anxiety and preserving the energy needed for healing. Take time to get to know your client. Try to set a tone of caring, respect, and understanding.

You can make the transition smoother for patients if you are prepared. The following activities should be incorporated into your nursing care.

- ***Prepare the room.*** A room that is prepared for the client conveys a message of acceptance. Room preparation depends on the type of unit or facility, the client's needs, and the anticipated treatment.

Go to Chapter 11, **Clinical Insight 11-1: Preparing the Room for an Admission,** in Volume 2.

- ***Greet the client.*** Gather basic information ahead of time, such as name, diagnosis, and anticipated length of stay. Imagine how it might feel if you were a new patient and you heard the staff say, "Who's this? I didn't know we were getting an admission. How am I supposed to take care of this one, too?"
- ***Introduce yourself to the client and family.*** Explain who you are. Don't be afraid to tell a client that you are a nursing student. Many clients are aware that students have more time to spend with them.
- ***Orient the client to the room and the unit.*** Make sure the client knows how to use the bed, the call light, and any equipment that you expect him to use. Show the client the location of the restroom. If you will be measuring the client's intake and output, tell him so during your orientation. If the client is alert, he may be able to assist you with these measures. Remember that one of the disruptions associated with illness is anxiety

about the unknown. If you tell your client what to expect, you help to minimize his anxiety.

- ***Gather a health history.*** In Chapter 3, you learned about assessment. Chapter 22 provides a step-by-step approach to physical assessment. Be sure to include in your health history the client's expectations and concerns.
- ***Establish a relationship with the client.*** Take time to get to know your client. Try to set a tone of caring, respect, and understanding.

For detailed directions on how to admit a client to a hospital unit,

Go to Chapter 11, **Procedure 11-1: Admitting a Patient to a Nursing Unit,** in Volume 2.

Provide a Healing Presence

Part of what you do as a healing presence will never show up in a written care plan. However, your healing presence may be the most important aspect of care that you have to offer. A statement by a young woman undergoing chemotherapy illustrates the difference the healing presence of a nurse made:

> *The nursing care I got was in response to the physical symptoms I showed. If I was not feeling good, they were sympathetic with me, you know. . . . But it was nothing further than that. There was no exploration of feelings or anything like that.*
>
> *Some of them were—seemed to be very caring. I remember [one nurse] . . . but she was just a really nice person. And I remember one time that I was throwing up dreadfully. . . . I rang for her and I said, "I'm sorry," and she was almost crying and she said, "No, I'm sorry you have to do this—you must feel awful." And she was just very empathetic with it, and I felt like, you know, I wasn't infringing upon her to make her empty my emesis basin or anything like that. (Smith, 1992, pp. 233–234)*

Maintain Trust During Transitions

Just as you help patients transition into illness, your support is important in helping them transition to other units within the agency, other agencies, or home. As discussed in Chapter 5, planning for discharge begins with the admission assessment and continues until the patient is well enough to go home or is transferred to another unit or facility.

Handoffs and Transfers

Patients may transfer from one unit to another when their health status changes. For example, a patient on a general nursing unit may be transferred to an intensive care unit when he develops sepsis (a generalized, systemic infection that is often fatal). Patients may transfer from hospital to a long-term care facility or rehabilitation center when they no longer require an acute care hospital or when their changed health status means that family members will not be able to care for him at home. A patient residing in a long-term care facility may be transferred to a hospital when he becomes acutely ill. A patient residing in a long-term care facility may be transferred to a hospital when he becomes acutely ill.

When the patient is transferred, he must adjust to a new environment, new routines, and new caregivers. This is yet another disruption for the patient and family. You can help by ensuring the transition is smooth and that there is continuity of care. Ensure the patient's comfort and safety, provide for teaching needs, and communicate with the agency or unit sending or receiving the patient. The process at time of transfer is similar. For detailed information on transfer reports (e.g., "SBAR"), see Chapter 18. Also refer to the accompanying Highlights of Procedures box and,

Go to **Procedure 11-2, Transferring a Patient to Another Unit in the Agency, and Procedure 11-3, Transferring a Patient to a Long-Term Care Facility,** in Volume 2.

Discharge From the Healthcare Facility

As much as patients usually look forward to being discharged, this, too, is a disruption. Patients are discharged when the outcomes of care are met. However, they are often dependent on family members for care and treatments they cannot manage alone. Inability to assume self-care can be stressful and anxiety producing. Successful discharge planning must begin at first patient assessment, on admission to the facility. The same conditions that require a formal discharge plan frequently also indicate the need for referrals for posthospital care in the community. Review Discharge Planning in Chapter 5, as needed.

Procedures for discharge vary among agencies. There may be a discharge planner or case manager to coordinate the transition to another agency or to home, but often you will need to manage the discharge. You can help by communicating and coordinating care and services, and by teaching the patient and caregivers about the continuing care the patient needs. For more information, see the accompanying Highlights of Procedures box and,

Go to **Procedure 11-4, Discharging a Patient From the Healthcare Facility; Forms, Discharge Assessment/Instructions;** and **Patient Education Form,** in Volume 2.

KnowledgeCheck 11-5

Explain how you can promote patient trust during admissions, transfers, and discharges.

Is a Healthy Life Attainable?

The concepts suggested in this chapter as ways to live a healthy life did not come from people who had easy lives. These themes were teased from literature, autobiographies, and interviews with people who were dealing with life situations that would be viewed as difficult from anyone's standpoint. However, in the midst of their circumstances, they were very much involved in

Highlights of Procedures 11-1 Through 11-4

For steps to follow in all procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the skill. Use these Procedure Highlights later to help you review key steps.

Procedure 11-1 Admitting a Patient to a Nursing Unit

- Begin the admission: Introduce yourself, assist the patient into a hospital gown, weigh him, assist him into the bed.
- Validate patient identity.
- Obtain a translator, if needed.
- Complete the nursing assessment, including vital signs; validate the admission list of medications.
- Provide information: Room, equipment, routines, Health Insurance Portability and Accountability Act (HIPAA), nurse call system, and advance directives.
- Answer any questions.
- Provide printed information.
- Complete nursing admission paperwork according to agency policy.
- Complete or ensure that admission orders have been completed.
- Inventory the patient's belongings; send home or lock up valuables.
- Finish the admission process.
  - Ensure patient comfort (water, positioning, pain).
  - Make one last safety check: call light, bed position, siderails.
  - Ask: "Is there anything else I can do for you?"

Procedure 11-2 Transferring a Patient to Another Unit in the Agency

- Make a final, brief, focused assessment.
- Plan ahead the amount of help needed.
- Schedule time of the transfer.
- Make appropriate notifications.
- Gather and label patient medications.
- Gather the patient's belongings, supplies, and treatment equipment.
- Bring the transfer vehicle to the bedside.
- Transfer the patient to the new room.
- Give oral handoff report and make final nursing notes entry.

Procedure 11-3 Transferring a Patient to a Long-Term Care Facility

- Plan in advance: Notify the patient and family of the impending transfer.
- Prepare the patient's records; copy for the new facility if needed.
- Pack personal items and treatment supplies.
- Coordinate the transfer with the receiving facility and other hospital departments.
- Make the final assessment; document and sign.
- Move the patient to the transportation vehicle.
- Give an oral or telephone report to the receiving nurse; use standardized form if available.
- Notify the long-term care facility if the patient is colonized or infected with methicillin-resistant *Staphylococcus aureus* (MRSA) or other contagious microorganisms.

Procedure 11-4 Discharging a Patient From the Healthcare Facility

- Notify the patient and family well in advance of the discharge.
- A day or two before discharge:

  Arrange for or confirm: transportation and services and equipment needed at home.

  Make referrals.

  Provide teaching about the patient's condition and medications.

  Provide training in use of equipment.

  Ask the caregiver to bring clothing for the patient to wear home.
- Day of discharge:

  Make and document final assessments.

  Confirm that the patient has house keys, heat is turned on, and food is available.

  Make final notifications (community agencies, transportation).

  Gather and pack the patient's personal items and treatment supplies.

  Label and give take-home medications to the patient.

  Give the patient prescriptions, instruction sheets, and appointment cards.

  Review discharge instructions with the patient.

  Answer questions.

  Document the final nursing note and complete the discharge summary.

  Accompany the patient out of the hospital.

  Notify Admissions of the discharge.

  Ensure records are sent to the medical records department.

living. Ripples or even waves of disruption or despair came into their lives, but through it all they evolved an overriding sense of life worth pursuing. This can be true for you as a nurse and also for those privileged to be under your care.

As a nurse, you offer your personal health and strength to your patients and their families every day. If you barely have enough physical, emotional, and spiritual strength to manage your own stressors, you will not have much available to offer others who are depleted. This is why it is so important for you to nurture yourself in all aspects of your life, to balance learning how to care for others with caring for yourself, to develop yourself as a healing presence in this world.

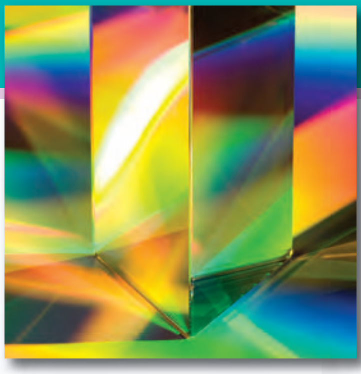
CHAPTER 12



Stress & Adaptation

Learning Outcomes

After completing this chapter, you should be able to:

- Define *stress*.
- Explain the difference between adaptive and maladaptive coping strategies.
- Explain the relationship between stressors, responses, and adaptation.
- Describe physical changes occurring during the three stages of Selye's general adaptation syndrome (GAS).
- Explain how Selye's local adaptation syndrome (LAS) is different from the GAS.
- Discuss the inflammatory response: What triggers it, and what physiological changes occur?
- Explain how anxiety, fear, and anger relate to stress.
- Provide examples and definitions of specific ego defense mechanisms.
- Describe the effects of prolonged stress and unsuccessful adaptation on the various body systems.
- Briefly describe: hypochondriasis, somatization, somatoform pain disorder, and malingering.
- Compare and contrast crisis and burnout.
- State three ways in which you could assess for each of the following: (1) stressors and risk factors, (2) coping methods and adaptation, (3) physiological responses to stress, (4) emotional and behavioral responses to stresses, (5) cognitive responses to stress, and (6) adequacy of support systems.
- Describe several interventions or activities for preventing and managing stress.

Meet Your Patients

Gloria and her husband, John, live in a residential community from which John commutes to work in a nearby city. Gloria runs an accounting business from their home. They have two teenage boys who are active in sports, church activities, Boy Scouts, and the school band. The boys need transportation to activities. Gloria and John teach Sunday school and are Boy Scout leaders. Gloria's mother needs knee replacement surgery and so cannot take care of Gloria's father, who has early-stage Alzheimer's disease. In addition to her own home responsibilities, Gloria must go to her parents' home to prepare meals and to provide care for them during the day. Gloria's sister comes at 8:00 p.m. to sleep in the parents' home during the night.

Theoretical Knowledge knowing why

Everyone experiences stress as a part of daily life, but we each perceive and respond to stress in our own unique way. Our responses are holistic—that is, physical, psychological, spiritual, and social. Stress has been directly linked to heart disease (Richardson, Shaffer, Falzon, et al., 2012), stroke, injury, suicide, and homicide. Indirectly, it is also linked to cancer (Ohio State University, 2013), chronic liver disease, chronic bronchitis, and emphysema (Quick, Saleh, Sime, et al., 2006). As a nurse, you need to understand stress to help your clients cope effectively and adapt to the stressors of illness and caregiving. In addition, you will encounter many stressful situations in your career, so you must develop healthful ways of responding.

ABOUT THE KEY CONCEPTS

The two overarching concepts for this chapter are *stress* and *adaptation*. To help you grasp those concepts, we will present definitions and examples, as well as numerous sub-concepts that relate to health and illness in various ways. Another important concept is *coping*. The stressors of illness and caregiving include *anxiety* and *fear*. As a nurse, you need to understand stress and related concepts in order to help your clients cope effectively with anxiety and fear.

WHAT IS STRESS?

Stress is any disturbance in a person's normal balanced state. A **stressor** is a stimulus that the person perceives as a challenge or threat; it disturbs the person's equilibrium by initiating a physical or emotional response. When stress occurs, it produces voluntary and involuntary **coping responses** aimed at restoring equilibrium (balance, or homeostasis). The changes that take place as a result of stress and coping are called **adaptations**. We can also define adaptation as an ongoing effort to maintain external and internal equilibrium, or **homeostasis**.

Stress is not necessarily bad. It can keep you alert and motivate you to function at a higher performance level. On the one hand, when you are preparing for an examination, your desire to succeed can create just enough anxiety to motivate you to study. On the other hand, if you become too anxious, you may be unable to focus on the task or think clearly.

Types of Stressors

The sources of stress are infinite; however, stressors are commonly categorized in the following ways:

Distress/Eustress **Distress** threatens health, and **eustress** (literally "good stress") is protective. A passionate kiss can produce as strong a stress response as a slap in the face. On the Holmes–Rahe stress scale, for example, marriage and divorce receive similarly high scores. To see this scale,

Go to Chapter 25, **Assessment Guidelines and Tools, The Holmes–Rahe Social Readjustment Scale,** in Volume 2.

External/Internal Stressors may be **external** to the person, for example, death of a family member, a hurricane, or even something as simple as excessive heat in a room. Stressors may also be **internal**, for example, diseases, anxiety, nervous anticipation of an event, or negative self-talk.

Developmental/Situational **Developmental stressors** are those that can be predicted to occur at various stages of a person's life. For example, most young adults face the stress of leaving home and beginning a career, and many middle-aged adults must adjust to aging parents and accepting their own physical changes. In a sense, developmental stressors may be easier to cope with because they are expected and the person has some time to prepare for them. For theoretical knowledge about developmental stages, refer to the theories of Erikson and Havighurst in Chapter 9 of Volume 1. Also see Box 12-1 for examples of developmental stressors.

Situational stressors are unpredictable. For example, you cannot predict if you will experience an automobile accident, a natural disaster, or an illness. Situational stressors can occur at any life stage and can affect infants, children, and adults equally.

Physiological/Psychosocial **Physiological stressors** are those that affect body structure or function. You can categorize them as follows; a few examples are given for each category.

- Chemical—poison, medications, tobacco
- Physical or mechanical—trauma, cold, joint overuse
- Nutritional—vitamin deficiency, high-fat diet
- Biological—viruses, bacteria
- Genetic—inborn errors of metabolism
- Lifestyle—obesity, sedentary lifestyle

Psychosocial stressors are external stressors that arise from work, family dynamics, living situation, social relationships, and other aspects of our daily lives. The Holmes–Rahe Scale in Volume 2 contains examples of psychosocial stressors.

KnowledgeCheck 12-1

Refer to the Meet Your Patients scenario.

- What are Gloria's stressors? Classify each of them as follows: (1) Are they physiological or psychosocial? (2) Are they developmental or situational?
- What are John's stressors?

Models of Stress

Some theorists conceptualize stress as a complex, dynamic, and reciprocal transaction between person and environment. Other theorists view stress solely as a

Toward Evidence-Based Practice

Hamer, M., Kivimaki, M., Stamatakis, G., et al. (2012, June 18). Psychological distress as a risk factor for death from cerebrovascular disease. *Canadian Medical Association Journal.* doi:10.1503/cmaj.111719. Retrieved September 6, 2012, from http://www.cmaj.ca/content/early/2012/06/18/cmaj.111719.full.pdf+html

Researchers found psychological distress influences not only coronary disease but also other types of cardiovascular (CV) diseases, such as stroke. They obtained data from 68,652 adults with no know CV disease. Data showed the risk of death from ischemic heart disease was 59% greater in patients with psychological distress, including anxiety, depression, and sleep disturbance. The risk for stroke was even higher (69%) as compared with those without psychological distress and after controlling for confounders, such as body mass index (BMI), blood pressure, and diabetes.

Job strain, job insecurity, and incident cardiovascular disease in the women's health study: Results from a 10-year prospective study of America. *PLoS One,* 7(7), e40512. Retrieved September 6, 2012, from http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3399852/?tool=pubmed

In a large study of more than 22,000 women healthcare workers over a period of 10 years, researchers looked for associations between job strain and job insecurity and cardiovascular disease (CVD) among women. They found women with high stress in the workplace were 38% more likely to experience a non-fatal CVD event, such as myocardial infarction, as compared with women who reported low levels of job strain. No evidence supported an association between job insecurity and long-term CVD risk.

Fagundes, C. P., Glaser, R., Johnson, S. L., et al. (2012, June). Basal cell carcinoma: Stressful life events and the tumor environment. *Archives of General Psychiatry, 69*(6), 618–626. doi:10.1001/archgenpsychiatry.2011.1535

This retrospective study examined the effect of stress on the immune system's response in either progressing or regressing tumors among 91 adults with a history of basal cell carcinoma (BCC). Researchers found that people who were emotionally maltreated by parents (especially mothers) in childhood and who also had a recent, severe life event had a poorer immune response to the BCC tumor as compared with those did not experience these stress triggers.

1. Hans Selye (1974, 1976) found that physical, emotional, psychological, and spiritual stressors, or the anticipation of stressors can initiate a physiological stress response. What might the underlying mechanism be linking psychological stress and researchers' findings of stroke and nonfatal myocardial infarction in people experiencing high levels of stress?
2. What other physiological response to emotional distress was demonstrated in the study conducted by Fagundes and associates?

PICOT

Stress and Multiple Responsibilities

Situation: The nurse is preparing to meet with a mother who has two children: one a 9-year-old with some behavior problems at school, and another a 5-year-old with Down syndrome. The mother reports she and her husband work alternate work shifts, although she also has total responsibility for childcare and household responsibilities.

PICOT Components:

P Population/client	=	Siblings of Down syndrome children
I Intervention/indicator	=	Parents with less satisfactory relationships
C Comparator/control	=	Parents with psychosocial well-being
0 Outcome	=	Behavior problems
T Time	=	During school

SEARCHABLE QUESTION: Do ________ (P) who receive/are exposed to ________ (I) demonstrate ________ (O) as compared with ________ (C) during ________ (T)?

Example of Evidence: Healthcare providers caring for families with a Down syndrome child look to the literature to gain understanding about ways to improve sibling adaptation. While reports show there seems to be greater intimacy among siblings of children with DS, there are other factors that influence sibling adaptation negatively. One study associated the degree of adaptation in two groups of siblings (DS, TD) to the level of parental distress. Parents who were depressed and had less satisfactory marital relationships tended to have less well-adapted children than those with psychosocial well-being. These children were more likely to show deviant behavior problems both at home and in school.

Choi, H., & Riper, M. (2013). Siblings of children with Down syndrome: An integrative review. *MCN, The American Journal of Maternal/Child Nursing, 38*(2), 72–78.

BOX 12-1 ■ Stressors Throughout the Life Span

The following are common developmental stressors. Of course not everyone will experience these stressors.

Childhood

School-age children may also experience stressors at school or among peers; however, children's stressors occur primarily in the home:

- Absence of parental figures
- Failure of parents to meet needs for safety, security, love, and belonging
- Failure of parents to meet basic physiological needs for oxygen, food, elimination, rest, and cleanliness

Adolescence

- Exposure to an expanded environment and a wider circle of friends and acceptance by peers
- Rapid changes in body appearance
- Need for academic achievement, sports performance, or demonstration of other talents
- Peer pressure
- Maintaining self-esteem while searching for identity
- Decisions about the future in the areas of school, work, and relationships
- Conflicts between standards for behavior and the sex drive
- Decisions about and involvement with alcohol and drugs

Young Adult

- Separation from family, starting college or a job
- Making the transition from youth to adult responsibilities
- Preparing for careers: graduation from college, learning a trade
- Establishing career goals and planning how to achieve success and career stability
- Financial stressors around relationships and providing a home for self or family
- Parenting children
- Conflicts between responsibilities for work and family or other relationships

Middle Age

- Concern with career achievement and continuing career challenges
- Continuation of child rearing; marriage of the children; grandparenting
- Changes in appearance and health due to aging
- Dealing with too many responsibilities: e.g., children, work, elderly parents, community activities
- Empty-nest syndrome when the children leave home
- Being "sandwiched" between caring for aging parents as well as children or grandchildren
- "Mid-life crisis" (wanting to escape from one's present life): The person regresses and unrealistically tries to recapture youth, for example, by buying a new sports car that is too small to hold the entire family, making a geographic move, taking an exotic vacation that strains the budget, engaging in an affair, daydreaming excessively about the ideal life in retirement, "partying" and overuse of alcohol and illicit drugs, engaging in "workaholic" behavior, or unhealthy "addiction" to cosmetic surgery. Any one of these behaviors does not necessarily signal mid-life crisis, but they are all examples of behaviors someone might use as an escape.

Older Adults

- Loss of family and friends due to illness or death, resulting in loneliness and isolation
- Changes in physical appearance and functional abilities, including mobility
- Major life changes (e.g., retirement, loss of life partner)
- Health problems (e.g., chronic diseases) with accompanying discomfort or pain
- The cost of healthcare
- Learning to live on a fixed, perhaps inadequate, income
- Adjusting to loss of independence
- Reduction in social status
- Alcohol abuse or dependence symptoms is a problem for about 12% of adults age of 50 to 64, and 7% of those older than 65 years (Wang & Andrade, 2013). These adults are more likely to engage in binge drinking and prescription drug misuse (Blazer & Wu, 2011).

stimulus that causes psychological or physiological responses that in turn increase vulnerability to disease. This chapter uses the **response-based model** of Hans Selye (1974, 1976), and our distinction between *stressors* and *stress* stems from this model. Selye found that physical, emotional, psychological, and spiritual stressors, or the anticipation of a stressor (as in anxiety), can initiate nonspecific physiological *responses*. Selye defined these responses as stress.

For more information about the transaction and stimulus models of stress,

Go to Chapter 12, **Supplemental Materials: Models of Stress,** on Davis*Plus*.

ThinkLike a Nurse 12-1

- Make a list of your own stressors in the following areas: work, school, family, and living situation.
- What physiological stressors do you have?

HOW DO COPING AND ADAPTATION RELATE TO STRESS?

Coping strategies are the thinking processes and behaviors a person uses to manage stressors. Some examples are problem-solving, daydreaming, making changes in lifestyle (e.g., exercising more, eating less), sleeping, and consulting others for support or advice. Coping strategies can be adaptive or maladaptive.

Adaptive (effective) coping consists of making healthy choices that reduce the negative effects of stress (e.g., exercising to relieve tension, engaging in a favorite hobby, consulting others for support or advice). Sometimes the difference between effective and ineffective coping is in the degree to which a technique is used (for examples, see the section Ego Defense Mechanisms later in this chapter).

Maladaptive (ineffective) coping does not promote adaptation. Unhealthful coping choices include overeating, working too much, excessive sleeping, and substance abuse. Although a maladaptive behavior may temporarily relieve anxiety, it may have other harmful effects. For example, a person who smokes to relieve the tensions of a stressful work situation may experience an immediate decrease in anxiety. However, the person is doing nothing to change or adapt to the stressful situation, and, over time, is increasing her risk of cardiorespiratory disease.

Three Approaches to Coping Are Commonly Used

People use three approaches to cope with stress, at different times and in various combinations:

Altering the Stressor In some situations, a person takes actions to remove or change the stressor. For example, Gloria (Meet Your Patients) might remove one of her stressors by resigning her position as a Scout leader.

Adapting to the Stressor It is not always possible to remove or change a stressor. Adapting involves changing one's thoughts or behaviors related to the stressor. Gloria cannot change the fact that her father needs ongoing care and her mother needs surgery, but as she gains experience as a caregiver, she may find easier, more efficient ways to care for her parents. This would give her a little more time to relax or attend to other responsibilities.

Avoiding the Stressor Sometimes it is healthful to avoid a stressor. For example, you may find that being with a certain person is stressful for you, even though you have tried many times to change the dynamics of the relationship. In that case, it may be best to minimize or end your relationship with the person. In other situations, avoidance may be maladaptive. For example, a woman who discovers a lump in her breast becomes anxious that she may have cancer. She copes with her anxiety by putting it out of her mind and avoids seeking medical care. As a result, if the lump is cancerous, it would not be treated at an early stage.

The Outcome of Stress Is Either Adaptation or Disease

Stress results in either adaptation or disease. Successful adaptation allows for normal growth and development and effective responses to changes and challenges in daily life. The outcome depends on the balance between the strength of the stressors and the effectiveness of the person's coping methods (Fig. 12-1). In the following equation, **E** is the event (stressor), **R** is the person's response (which is determined in part by past experiences, perception of the stressor, and coping methods used), and **O** is the outcome.

E	+	*R*	=	*0*
stressful event		response (experience, perception, coping methods)		outcome (adaptation or disease)

Some events produce more stress than others. However, a person with good coping skills can usually adapt to a single stressful event, even a demanding one. But suppose several stressors occur in a short period of time. Gloria (Meet Your Patients) has many stressors, so her coping abilities may be taxed to the limit. When there are many stressors or when stressors continue for a long period of time, adaptation is more likely to fail.

Personal Factors Influence Adaptation

Why do some people succumb to overwhelming stress while others adapt and thrive? Fortunately, successful adaptation does not depend entirely on being able to alter or avoid stressors. Various personal factors also influence the outcome:

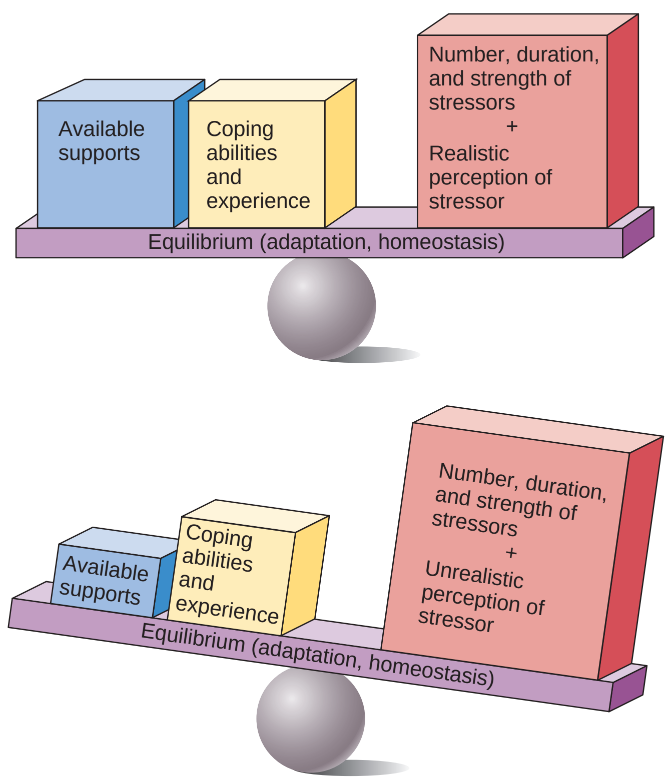

FIGURE 12-1 Adaptation occurs when a person has supports and coping abilities adequate to enable him to deal with the stressors. A realistic perception of the stressful event promotes adaptation, whereas an unrealistic perception makes adaptation more difficult.

Perception of the Stressor A person's perception may be realistic or exaggerated. Suppose two women with similar coping skills and support systems both must have a mastectomy. Mrs. King thinks, "Yes, I am losing a part of my body, but I am more than just a breast. This will be a difficult adjustment, but I am so grateful to be alive." Mrs. Alan thinks, "I will be so ugly. My husband won't want to touch me. I won't be much of a woman now. This is the worst thing that could ever happen." Which woman do you think is more likely to adapt successfully to this change in her body?

Overall Health Status On the one hand, stressors may actually cause a healthy person to engage in constructive adaptive behaviors that improve health. A person who has just discovered that he has hypertension may react by modifying his diet and exercising to lower his blood pressure and prevent complications. On the other hand, if a person with hypertension also has been coping for years with pain and immobility from arthritis, he may be too overwhelmed and exhausted to take any actions to lower his blood pressure.

Support System A **support system** may include friends, family, counseling groups, church groups, or other like-minded people who share common interests. A good support system can help a person adapt to stress, provide emotional support, encourage expression of feelings, and help the person solve problems. It may also provide financial and other concrete types of support, such as a place to live, meal preparation, household help, child care, and transportation.

Hardiness People who thrive despite overwhelming stressors tend to have a quality that has been termed **hardiness**. They maintain three key attitudes that help them weather adversity: commitment, control, and challenge. *Commitment* lets them seek to be involved with ongoing events, rather than feeling isolated. *Control* enables them to struggle and try to influence outcomes instead of becoming passive and feeling powerless. Challenge allows them to perceive stressful changes as opportunities for learning (Maddi, 2002; Maddi, Koshaba, Fazel, et al., 2009).

Other Personal Factors Age, developmental level, and life experiences (e.g., learning which coping methods have worked for you) all affect a person's response to stress. For example, infants and the very old may lack the physiological reserves to adapt to physical stressors, such as temperature extremes, dehydration, or illness.

Even with a positive attitude and good coping skills, excessive amounts of stress can lead to maladaptation and disease. Some people succumb to illness after experiencing only a few stressors, whereas others seem to adapt to multiple, intensely difficult stressors. Each person has a different ability to tolerate stress, but everyone has a breaking point at which stress becomes overwhelming.

KnowledgeCheck 12-2

- True or false: The difference between adaptive and maladaptive coping is that maladaptive coping does not relieve stress.
- In addition to avoiding the stressor, what are two other approaches to coping?
- (Complete the sentence.) The outcome of stress (adaptation or disease) depends on the balance among the strength, number, and duration of the stressors and ___________.

HOW DO PEOPLE RESPOND TO STRESSORS?

Although Selye's (1974, 1976) response-based model acknowledges physical, emotional, psychological, and spiritual *stressors,* his ideas about responses (*stress*) are primarily physiological. As you know, the body has various homeostatic mechanisms for regulating its internal environment to maintain homeostasis. In Selye's theory, physiological responses to stress are described by the general adaptation syndrome (GAS) and the local adaptation syndrome (LAS).

The General Adaptation Syndrome Includes Nonspecific, Systemic Responses

Would you be surprised to know that a near-miss automobile accident and kicking the winning field goal at a football game would both produce the same general body responses? It is true. Regardless of the specific stressor, the responses involve the whole body, especially the autonomic nervous system and the endocrine system. The **general adaptation syndrome (GAS)** is Selye's name for the group of nonspecific responses that all people share in the face of stressors. The GAS has three stages: (1) the initial alarm stage, (2) resistance (adaptation), and (3) the final stage of either recovery or exhaustion (Fig. 12-2).

Alarm Stage—"Fight or Flight"

Imagine yourself in this situation: It is dark. You are alone, walking to your car, when you hear footsteps behind you. You stop and look around and see no one. As you begin walking again, the footsteps return. You walk faster; the footsteps are faster. Stop reading, shut your eyes, and use your imagination. How do you feel? Pay attention to your physical and emotional reactions. If you are not feeling a response to this imaginary situation, think back to a time when something similar happened to you—when something frightened you. Is your heart pounding? Are you breathing fast? Is there a flutter in your stomach? What is the physical sensation in your muscles? Do you feel frightened? What are your emotions? Are you straining to hear the footsteps? Do you want to run away, or are you "frozen"? If someone were to walk into the room where you are studying right now, would it startle you?

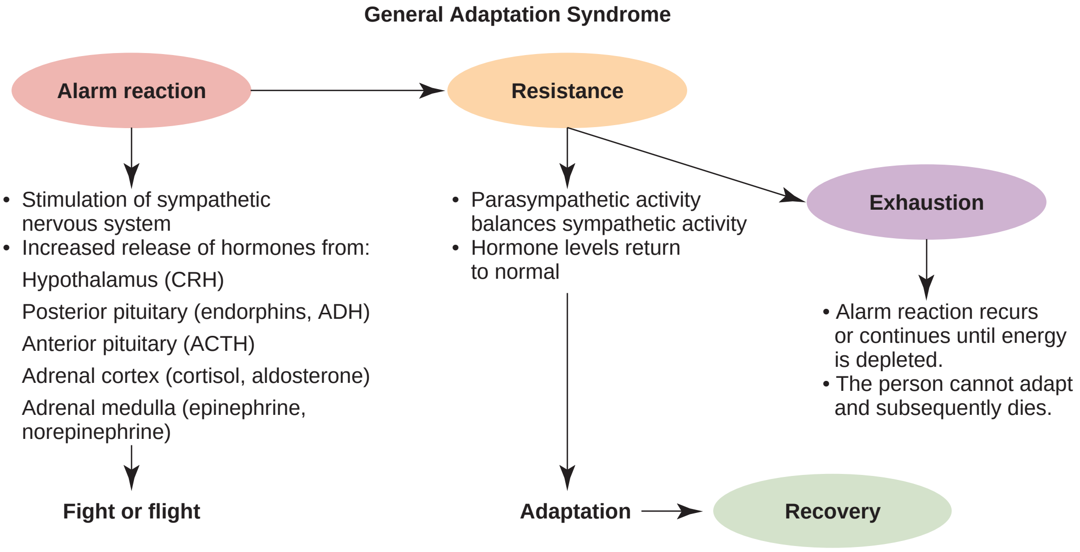

FIGURE 12-2 The stages of Selye's general adaptation syndrome (GAS) are (1) *alarm* (also called "fight or flight"); (2) *resistance* (or adaptation), in which the body enacts physical and psychological adaptive mechanisms to maintain homeostasis; and (3) either *recovery* or *exhaustion* (which usually ends in disease or death).

This scenario should help you to imagine the experience of the alarm stage, during which the body prepares for "*fight or flight*." The alarm stage has two phases: shock and countershock. The **shock phase** begins when the cerebral cortex first perceives a stressor and sends out messages to activate the endocrine and sympathetic nervous systems. Epinephrine (adrenaline) and various other hormones prepare the body for fight or flight. The shock phase does not last long—usually less than 24 hours, and sometimes only a minute or two. In the **countershock phase**, all the changes produced in the shock phase are reversed, and the person becomes less able to deal with the immediate threat.

Endocrine System Responses

In response to a perceived stressor, the following endocrine responses occur:

1. The *hypothalamus* releases corticotropin-releasing hormone (CRH).
2. *CRH*, together with messages from the cerebral cortex, directs the pituitary gland to release adrenocorticotropic hormone (ACTH) and antidiuretic hormone (ADH).
3. *ACTH* stimulates the adrenal cortex to produce and secrete glucocorticoids (especially cortisol) and mineralocorticoids (especially aldosterone).
   Cortisol, in general, has a glucose-sparing effect. It increases the use of fats and proteins for energy and conserves glucose for use by the brain. Cortisol also has an anti-inflammatory effect. See Figure 12-3 for the effects of cortisol during the alarm reaction of the GAS.
   Aldosterone promotes fluid retention by causing the kidneys to reabsorb more sodium. In that way, it helps to increase fluid volume and maintain or increase blood pressure.
4. *ADH* also promotes fluid retention by increasing the reabsorption of water by kidney tubules. See Figure 12-4 for the effects of aldosterone and ADH.
5. *Endorphins*, secreted by the hypothalamus and posterior pituitary, act like opiates to produce a sense of well-being and reduce pain.
6. *Thyroid-stimulating hormone (TSH)* is secreted by the pituitary gland to increase the efficiency of cellular metabolism and fat conversion to energy for cell and muscle needs.

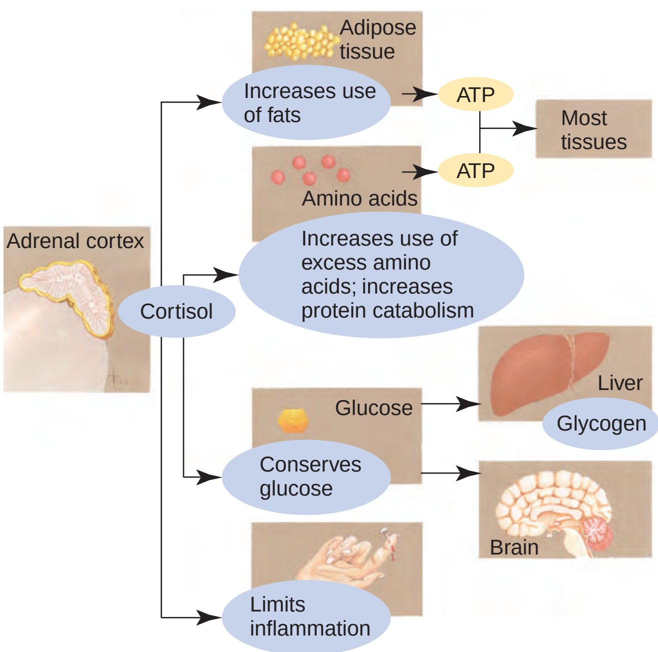

FIGURE 12-3 Functions of cortisol during the alarm stage of the GAS. (From Scanlon, V., & Sanders, T. (2011). *Essentials of anatomy and physiology* (6th ed.). Philadelphia: F. A. Davis, p. 241.)

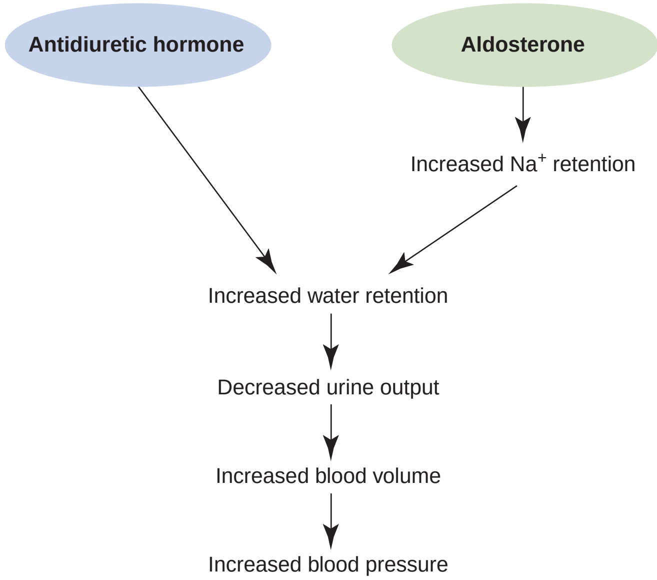

FIGURE 12-4 The release of ADH (from the posterior pituitary gland) and aldosterone (from the adrenal cortex) leads to sodium and water retention, increases blood volume, and increases blood pressure.

Sympathetic Nervous System Responses

The cerebral cortex also sends messages via the hypothalamus to stimulate the sympathetic nervous system. The sympathetic nervous system then stimulates the adrenal glands to secrete adrenaline and norepinephrine, which increase mental alertness. This allows the person to assess the situation and aids in a decision to stand and fight or run away in flight. Adrenaline also increases the ability of the muscles to contract and causes the pupils to dilate, producing greater visual fields. See Figure 12-5 for the effects of adrenaline during the alarm reaction of the GAS.

Other Body System Responses in the Alarm Stage

The following are some body system responses that occur in the alarm stage as a result of endocrine and sympathetic nervous system activity. Refer to Figures 12-2 through 12-5 to see how these changes are produced.

- *Cardiovascular system.* The heart rate and contraction force increase. Peripheral and visceral vasoconstriction increase blood flow to vital organs (e.g., brain, lungs) and to muscles preparing for flight. Blood volume and blood pressure also increase, and the blood clots more readily.
- *Respiratory system.* The bronchioles dilate, thereby increasing the depth of respiration and tidal volume. This makes oxygen available for diffusion to muscle, brain, and cardiac cells.
- *Metabolism.* The metabolic rate increases. The liver converts more glycogen to glucose (*glycogenolysis*), making it available for energy. Except in the brain, the body uses less glucose for energy. The use of amino acids and the mobilization of fats for energy (*lipolysis*) increase.

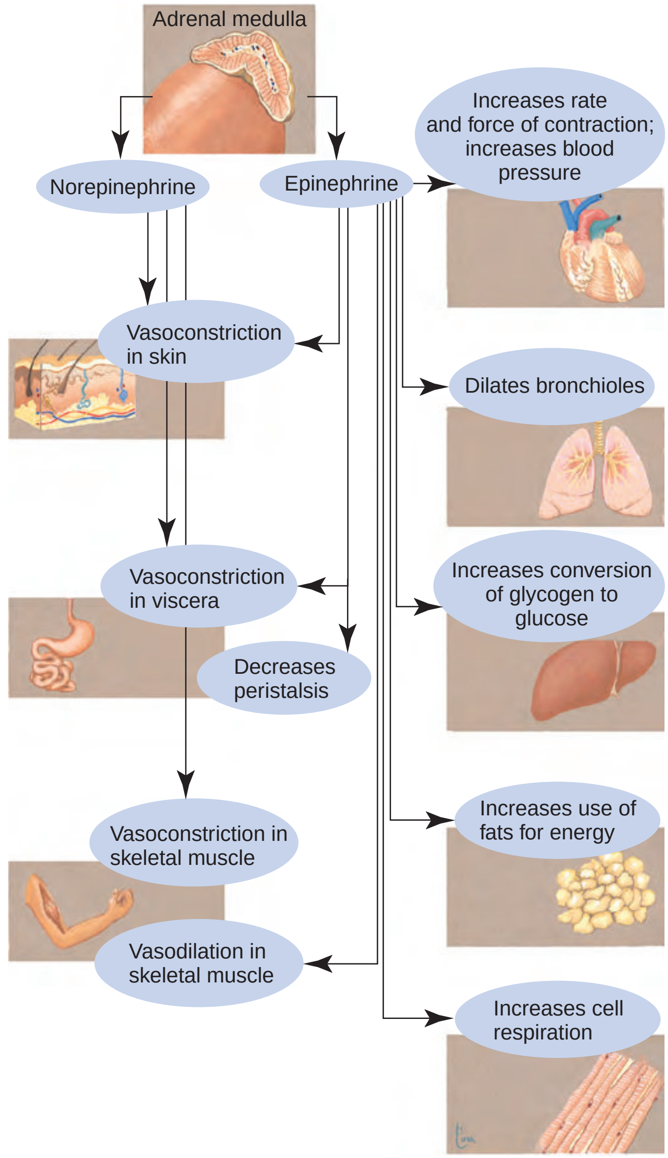

FIGURE 12-5 Functions of epinephrine and norepinephrine during the alarm stage of the GAS. (From Scanlon, V., & Sanders, T. (2011). *Essentials of anatomy and physiology* (6th ed.). Philadelphia: F. A. Davis, p. 239.)

- *Urinary system.* Blood flow to the kidneys decreases, and they retain more sodium and water. The kidneys secrete renin, which produces *angiotensin*. In turn, angiotensin constricts the arterioles and tends to increase blood pressure.
- *Gastrointestinal system.* Peristalsis and secretions of digestive enzymes decrease. The blood glucose level increases to fuel the energy needed for fight or flight.
- *Musculoskeletal system.* Blood vessels dilate, increasing flow of blood (and thus oxygen and energy) to skeletal muscles.

Resistance Stage—Coping With the Stressor

During the second stage of the GAS, **resistance** (or *adaptation*), the body tries to cope, protect itself against the stressor, and maintain homeostasis. Stabilization involves the use of physiological and psychological coping mechanisms. Psychological defense mechanisms for coping are discussed shortly. Physical adaptations help the heart rate, blood pressure, cardiac output, respiratory function, and hormone levels return to normal. If the person adapts successfully or if the stress can be confined to a small area (as in the inflammatory response, also discussed shortly), the body regains homeostasis. If the stress is too great (as in serious illness or severe blood loss), defense mechanisms fail, and the person enters the third phase of the GAS.

Exhaustion or Recovery Stage—Final Effort to Adapt

If stress continues and adaptive mechanisms become ineffective or are used up, a person enters the final stage, **exhaustion**. Physiological responses in this stage include vasodilation, decreased blood pressure, and increased pulse and respirations. Physical adaptive resources and energy are depleted. The body is unable to defend itself and cannot maintain resistance against the continuing stressors. Exhaustion usually ends in injury, illness, or death.

In contrast, if adaptation is successful, the final stage is **recovery**. For example, after a miscarriage, a couple participates in a support group and begins to focus more deeply on their relationship with each other. They are able gradually to resolve their grief.

KnowledgeCheck 12-3

- In general, what is the difference between the alarm stage and the resistance stage of the GAS?
- Name the gland that releases each of the following hormones in response to stress, and name each hormone's function: corticotropin-releasing hormone (CRH), antidiuretic hormone (ADH), adrenocorticotropic hormone (ACTH), aldosterone, cortisol, epinephrine, and norepinephrine.
- In the alarm stage of the GAS, what are the effects of the sympathetic nervous system on each of the following: heart, brain, glycogen stores, and skeletal muscle?
- What is the effect of Selye's resistance stage on the cardiovascular and respiratory systems? On hormone levels?

The Local Adaptation Syndrome Involves a Specific Local Response

Whereas the GAS is a whole-body response to a stressor, the **local adaptation syndrome (LAS)** is a localized body response; that is, it involves only a specific body part, tissue, or organ. It is a short-term attempt to restore homeostasis. As a nurse, the two most common LAS responses you will deal with are the reflex pain response and the inflammatory response (others include blood clotting and pupil constriction in response to light).

Reflex Pain Response

When you perceive a painful stimulus, especially in one of your limbs, you immediately and unconsciously withdraw from the source of pain. If you've ever accidentally touched a hot stove, you certainly didn't stop to ponder, "Hmmm, I think I will withdraw my hand." You pulled your hand away before you could even think about it. This is a protective **reflex** (an involuntary, predictable response). Pain receptors send sensory impulses to the spinal cord, where they synapse with the spinal motor neurons. The motor impulses travel back to the site of stimulation, causing the flexor muscles in the limb to contract. This is a local, rather than a whole-body, response.

Inflammatory Response

The **inflammatory response** is a local reaction to cell injury, either by pathogens or by physical, chemical, or other agents (Box 12-2). Regardless of the injuring agent (stressor), its mechanisms are the same, and they produce the classic symptoms of inflammation: pain, heat, swelling, redness, and loss of function. The inflammatory process includes a vascular response, a cellular response, formation of exudate, and healing.

Vascular Response Immediately after injury, blood vessels at the site constrict (narrow) to control bleeding. After the injured cells release histamine, the vessels dilate, increasing blood flow to the area (**hyperemia**). Under the influence of kinins released by the dying cells, the capillaries become more permeable, allowing movement of fluid from capillaries into tissue spaces. The tissue becomes **edematous** (swollen). After **leukocytes** (white blood cells) move into the area, localized blood flow again decreases to keep them in the area to fight infection.

Cellular Response Specialized white blood cells (**phagocytes**) migrate to the site of injury and engulf bacteria, other foreign material, and damaged cells and destroy them. Sometimes they form a "wall" around an

BOX 12-2 ■ Agents Causing Inflammatory Responses

The following agents stimulate the inflammatory response by causing cell injury:

- Autoimmune disorders
- Antigen–antibody responses
- Body substances (e.g., digestive enzymes leaking into the abdomen; accumulation of uric acid crystals in joints)
- Chemical injury (e.g., acid or alkali burns)
- Ischemia
- Neoplastic growth (i.e., cancer)
- Pathogens (e.g., bacteria, viruses)
- Physical agents:
  - Heat or cold
  - Radiation
  - Electrothermal injury
  - Mechanical trauma (e.g., abrasion, contusion, laceration, puncture, incision, fractures, sprains)

invading pathogen. The accumulation of dead white cells, digested bacteria, and other cell debris in the presence of infection is called *pus.*

Exudate Formation The fluid and white blood cells that move from the circulation to the site of injury are called **exudate.** The nature and quantity of exudate depend on the severity of injury and the tissues involved. For example, a surgical incision may ooze serosanguineous (clear or pinkish) exudate for a day or two.

Healing **Healing** is the replacement of tissue by regeneration or repair. **Regeneration** is replacement of the damaged cells with identical or similar cells. However, not all cells can regenerate (e.g., some central nervous system neurons and cardiac muscle cells cannot regenerate). Most injuries heal by **repair**, wherein scar tissue replaces the original tissue. You will find a thorough discussion of wound healing in Chapter 35.

The inflammatory response is adaptive in that it protects the body from infection and promotes healing. However, chronic inflammation, as in arthritis, is itself a stressor.

Do not confuse inflammation with infection. Inflammation is a mechanism for eliminating invading pathogens; therefore, you always see inflammation when there is infection. However, inflammation is stimulated by trauma as well as by pathogens (as in the example of a sprained ankle); thus, it can occur when there is no infection.

KnowledgeCheck 12-4

- What are four characteristics of the LAS?
- Name two LAS responses.
- What are the classic symptoms of the inflammatory process?

Psychological Responses to Stress Include Feelings, Thoughts, and Behaviors

Health professionals understand most human health disorders to be *biopsychosocial* in nature (Alford, 2007). That is, they consist of interactions among biological, psychological, and social factors. Recall that stress responses are holistic. That means we respond and adapt to stress physically, mentally, and behaviorally, and many would add spiritually.

Psychological responses are both emotional and cognitive, and they include feelings, thoughts, and behaviors (Box 12-3). They may be fleeting, as in a flash of anger that is gone in seconds; or long term, as in the avoidance of relationships by an adult whose needs for love and security were not met as a child.

As with physical responses, psychological responses can be adaptive or harmful. Consider this example case:

> Both Mr. Laslow and Mr. Harvey have had heart attacks and are both anxious about the future. To relieve his anxiety, Mr. Laslow takes a problem-solving approach, learning about diet, exercise, and lifestyle changes that he must make. Mr. Harvey uses denial; he cannot even accept that he has "really" had a heart attack. He says, "I'm not an invalid. I feel fine. I could follow all those rules and still get hit by a truck and die tomorrow." Both of these responses may relieve the person's anxiety. Which one do you think is more adaptive in the long term?

Common emotional responses to stress include anxiety, fear, anger, and depression.

BOX 12-3 ■ Psychological Responses to Stressors

Cognitive Responses

Difficulty concentrating
Poor judgment
Decrease in accuracy (e.g., in counting money)
Forgetfulness
Decreased problem-solving ability
Decreased attention to detail
Difficulty learning
Narrowing of focus
Preoccupation, daydreaming

Emotional Responses

Adjustment disorders
Anger
Anxiety
Depression
Fear
Feelings of inadequacy
Low self-esteem
Irritability
Lack of motivation
Lethargy

Behavioral Responses

Academic difficulties
Aggressiveness
Crying, emotional outbursts
Dependence
Nightmares
Poor job performance
Substance use and abuse
Sleeplessness (or sleeping too much)
Change in eating habits (e.g., loss of appetite, overeating)
Decrease in quality of job performance
Preoccupation (i.e., daydreaming)
Illnesses
Increased absenteeism from work or school
Increased number of accidents
Strained family or social relationships
Avoiding social situations or relationships
Rebellion, acting out

Anxiety and Fear

Anxiety is diffuse and not easily defined. NANDA International (2012, p. 344) defines it as a "vague, uneasy feeling of discomfort or dread accompanied by an autonomic response (the source often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. . . ." Notice that the response is not to a danger but to the *anticipation* of danger—to imagining it. An anxious person worries; feels nervous, uneasy, and fearful; may be tearful; and often has physical symptoms, such as nausea, trembling, and sweating.

Fear is an emotion or feeling of apprehension (dread) from an identified danger, threat, or pain. The danger may be real or imagined. Anxiety and fear produce similar responses; however, some experts differentiate them as follows:

- Fear is a cognitive response, whereas anxiety is an emotional response.
- Fear is related to a present event, whereas anxiety is related to a future (or anticipated) event.
- The source of fear is easily identifiable, whereas the source of anxiety may not be identifiable.
- Fear can result from either a physical or a psychological event; anxiety results from psychological conflict rather than physical threat.

Mild to moderate anxiety may be adaptive because it motivates and mobilizes the person to action. However, severe anxiety consumes energy and interferes with the person's ability to focus on and respond to what is really happening. See Chapter 13 to refresh your theoretical knowledge of anxiety and fear, including levels of anxiety.

Anxiety and fear initiate the release of epinephrine, which stimulates the sympathetic nervous system and prepares the person for fight or flight. Therefore, living with anxiety can be physically, emotionally, and spiritually exhausting.

ThinkLike a Nurse 12-2

Read the following two scenarios.

1. You are a student assigned to a 6-hour day in the clinical area. Each time you have a clinical day coming up, you feel anticipation and look forward to working in the clinical area. However, you do not know what to expect. You think: "What will my patients be like? How will the day go? Do I know enough to handle it? Do I need to practice any procedures?" It is hard to answer these questions until you are actually on the unit and see your patients.
2. Given the same situation, suppose that when you begin your clinical day, your clinical instructor tells you that he will be in the agency asking questions, supervising, evaluating your performance—and, perhaps from your perspective, making your life miserable.

In which situation are you most likely to feel fear rather than anxiety? Explain your reasoning.

Ego Defense Mechanisms When faced with a stressful situation, the ego defense systems may kick in to diminish the inner tension associated with the stressors. **Ego defense mechanisms** are unconscious mental mechanisms that make a stressful situation more tolerable by decreasing the inner tension associated with the stressors. Just as the body responds physiologically to stressors, it has psychological responses that protect the person from anxiety and assist with adaptation. When used sparingly, and for mild to moderate anxiety, defense mechanisms can be helpful. When overused, however, they become habits that give us the false illusion that we are coping. If psychological defense mechanisms (Table 12-1) are inadequate to diminish the threat and restore equilibrium, the person may develop an anxiety disorder.

Anger and Depression

Anger is a strong, uncomfortable feeling of animosity, hostility, extreme indignation, or displeasure. A person who cannot control stressors may become apprehensive (anxious about what may happen) and respond with anger. Thus, moderate anger is often a first protective response against anxiety. As anxiety increases and the person recognizes fear, he feels more threatened and may resort to bullying behavior to increase the personal feeling of power, control, and self-esteem.

Anger may be expressed in screaming or shouting, throwing things, or hitting, or more subtly with sarcastic, caustic remarks. Some people attempt to hide their emotions and soften their hurtful remarks, or make them more socially acceptable, through the use of humor and joking. When anger involves destructive behaviors such as physical or verbal abuse, it is called **hostility**. When expressed appropriately and clearly (i.e., verbally), anger can be adaptive, because it temporarily releases the person's feelings of tension. When the anger is out in the open, both parties can deal with it. Nevertheless, even verbal expressions of anger can be destructive if the anger continues after the person expresses it.

Depression is sometimes associated with unresolved anger and may result from stress. It is normal to feel depression in response to any loss or a traumatic event, but long-term depression is a reason for concern. Review Chapter 13 for information about anger and depression.

KnowledgeCheck 12-5

- In addition to ego defense mechanisms, name four common emotional responses to stress.
- Explain how mild to moderate anxiety can be adaptive.
- True or false: One difference between anxiety and fear is that the danger in anxiety may be imagined, whereas in fear the danger is real.
- What are ego defense mechanisms?

Spiritual Responses to Stress Are Multifaceted

Spiritual responses vary among individuals—as do all human responses. Many people depend on a higher power or religious community for support when coping with stress. Some search for a larger meaning in the

Table 12-1 ➤ Psychological Defense Mechanisms

DEFENSE MECHANISM	EXAMPLES	EXAMPLES AND CONSEQUENCES OF OVERUSE
Avoidance—Unconsciously staying away from events or situations that might open feelings of aggression or anxiety	"I can't go to the class reunion tonight. I'm too tired; I have to sleep."	The person becomes socially isolated because of the tension he feels when around other people.
Compensation—Making up for a perceived inadequacy by developing or emphasizing some other desirable trait	A small boy who wants to be on the football team instead becomes a great singer	Use of drugs or alcohol to gain courage to enter a social situation
Conversion—Emotional conflict is changed into physical symptoms that have no physical basis. The symptoms often disappear after the threat is over.	Feeling back pain when it is difficult to continue carrying the pressures of life; developing nausea that causes the person to miss a major exam	Laryngitis, inability to speak on the anniversary of father's death. Continued anxiety can lead to actual physical disorders, such as gastric ulcers.
Denial—Transforming reality by refusing to acknowledge thoughts, feeling, desires, or impulses. This is unconscious; the person is *not* consciously lying. Denial is usually the first defense learned.	A student refuses to acknowledge that he is barely passing anatomy, does not withdraw from the class, and is now failing a nursing course. An alcoholic states, "I can quit any time I want to."	Overuse can lead to repression and dissociative disorders (e.g., dual personalities, selective amnesia).
Displacement—"Kick the dog." Transferring emotions, ideas, or wishes from one original object or situation to a substitute inappropriate person or object that is perceived to be less powerful or threatening	Husband loses his job, goes home, and yells at his wife. (This mechanism is rarely adaptive.)	In extreme situations, this mechanism leads to verbal and physical abuse.
Dissociation—Painful events are separated or dissociated from the conscious mind.	A person who was sexually abused as a child describes the events as though they happened to a sibling.	May result in a dissociative disorder, such as multiple personality disorder.
Identification—A person takes on the ideas, personality, or characteristics of another person, especially someone that the person fears or respects.	Children play cowboy, police, firefighter, or mommy.	Assumes mannerisms, wears clothing, and arranges hair and physical appearance to match those of the other person.
Intellectualization—Cognitive reasoning is used to block or avoid feelings about a painful incident.	When her husband dies, the wife relieves her pain by thinking, "It's better this way; he was in so much pain." A person says, "I think" rather than, "I feel."	"My husband loves me, so he doesn't like it when another man talks to me; that's why he beats me."
Minimization—Not acknowledging or accepting the significance of one's own behavior, making it less important	"It doesn't matter how much I drink. I never drive when I'm drinking."	Person engages in unhealthy or antisocial behavior; there is no motivation to change behavior
Projection—Blaming others. Attributing one's own personality traits, mistakes, emotions, motives, and thoughts to another; "finger pointing."	"The clinical instructor makes me nervous, so I cannot do well." "I forgot to bake cookies because you did not tell me that cookies were due at school today."	Person cannot see his own responsibility for a situation, so he cannot make adaptive behaviors. Person criticizes habits in others that are the same as one's own bad habits.

Table 12-1 ➤ Psychological Defense Mechanisms—cont'd

DEFENSE MECHANISM	EXAMPLES	EXAMPLES AND CONSEQUENCES OF OVERUSE
Rationalization—Use of a logical-sounding excuse to cover up or justify true ideas, actions, or feelings. An attempt to preserve self-respect or approval or to conceal a motive for some action by giving a socially acceptable reason. Similar to intellectualization, but uses faulty logic.	"It was God's will that this happened to me." "If I didn't have to work, I would be a better wife."	This mechanism can lead to self-deception.
Reaction formation—Similar to compensation, except the person develops the exact opposite trait. The person is aware of her feelings but acts in ways opposite to what she is really feeling.	"It's OK that you forgot my birthday" (when it really is not OK).	Overuse can cause failure to resolve internal conflicts.
Regression—Using behavior appropriate in an earlier stage of development to overcome feeling of insecurity in a present situation	Prepares and eats a comfort food (e.g., hot fudge sundae). A 60-year-old divorcee dresses and acts like a teenager.	Can interfere with perception of reality
Repression—Unconscious "burying" or "forgetting" of painful thoughts, feelings, memories, ideas; pushing them from a conscious to an unconscious level. It is a step deeper than denial.	Having no memory of sexual abuse by sibling or father An adolescent forgets to put out the trash because being "bossed" makes him angry, but he feels guilty if he consciously chooses not to do it.	Flashbacks, post-traumatic stress syndrome, and amnesia
Restitution (undoing)—Making amends for a behavior one thinks is unacceptable, to reduce guilt	Giving a treat to a child who has been punished for wrongdoing	May send double messages. Relieves the person of the responsibility for honesty about the situation
Sublimation—Unacceptable drives, traits, or behaviors (often sexual or aggressive) are unconsciously diverted to socially accepted traits.	Anger is expressed by aggression when playing sports. A person who chooses to not have children runs a day-care center.	The "acceptable" behavior might reinforce the negative tendencies, and the person may still show signs of the undesirable trait or behavior. For example, a person indulges in child pornography to obtain sexual gratification.

Source: Adapted from Neeb, K. (2006). *Fundamentals of mental health nursing* (3rd ed.). Philadelphia: F.A. Davis.

illness or other stressor. Others may view stress as a test, a punishment, or a challenge.

Often, a first response during the alarm stage is to pray or ask for help (e.g., healing, coping). Prayer, meditation, and religious affiliation can also help during the second stage (adaptation). In the final stage, spiritual resources may be exhausted, leaving the person feeling abandoned, helpless, and hopeless. If your own spiritual life is healthy, you will be better equipped to support patients who are experiencing spiritual challenges. For more information about spiritual responses to stress, see Chapter 16.

WHAT HAPPENS WHEN ADAPTATION FAILS?

Living with continual stress strains adaptive mechanisms. This strain can lead to exhaustion and disease, which in turn can lead to more stress. Once established, this type of positive feedback loop is difficult to break. Three types of disorders that can develop when adaptation fails are stress-induced organic responses, somatoform disorders, and psychological disorders.

Stress-Induced Organic Responses

As a result of repeated central nervous system stimulation and elevation of certain hormones, continual stress brings about long-term changes in various body systems. People who use maladaptive coping strategies (e.g., overeating, substance abuse) create additional stress on the body, further contributing to disease (Table 12-2).

Somatoform Disorders

Somatoform disorders are conditions characterized by the presence of physical symptoms with no known organic cause. They are believed to result from unconscious denial, repression, and displacement of anxiety. Certain people seem predisposed to somatoform disorders—for instance, those who suffer from personality disorders and major psychiatric illness, those who do not handle anxiety well, and those who are dependent, emotionally needy, frustrated, and resentful (Neeb, 2006). The physical symptoms allow the person to avoid a situation that, if confronted, would provoke extreme anxiety. The following are examples of somatoform disorders:

- **Hypochondriasis.** The person is preoccupied with the idea that he is or will become seriously ill. The person is abnormally concerned with his health and interprets his real or imagined symptoms unrealistically, fearing that they will get worse or become incurable. The person is not "faking it"; anxiety about his health may trigger the physical sensations.
- **Somatization.** In this disorder, anxiety and emotional turmoil are expressed in physical symptoms, loss of physical function, pain that changes location often, and depression. The patient is unable to control the symptoms and behaviors, and complaints are vague or exaggerated.
- **Pain disorder.** Previously called *somatoform pain disorder*, this is emotional pain that manifests physically. Pain is the main focus of the person's life. The level of pain the person states is inconsistent with the physical condition—that is, the physical cause is either disproportionate to the pain or cannot be found at all. The pain does not change location.
- **Malingering.** Malingering is different from the other disorders because it is a *conscious* effort to escape

Table 12-2 ➤ Organic Disorders Brought About by Failure of Adaptive Mechanisms

BODY SYSTEM	PHYSIOLOGICAL RESPONSE
Cardiovascular System	Continued secretion of epinephrine may cause cardiovascular disorders including angina, myocardial infarction, cardiomegaly, and congestive heart failure, all of which lead to decreased cardiac output. As cardiac output decreases, less oxygen circulates to meet cellular metabolic demands, and the body becomes fatigued. Prolonged secretion of epinephrine and renin result in vasoconstriction, causing hypertension. ADH, aldosterone, ACTH, and cortisol create electrolyte imbalance and retention of sodium and water, thus promoting peripheral edema.
Endocrine System	Continuing high levels of blood glucose and insulin can cause diabetes. Metabolic disorders of hyperthyroidism or hypothyroidism can result as persistent demands for thyroid hormone production cause a rebound failure of the gland. Even prenatal stress can cause adaptive changes in fetal endocrine and metabolic processes that impact later adult health (Sullivan, Hawes, Winchester, et al., 2008).
Immune System	Stress reduces the ability of the body's immune cells to differentiate between self and nonself. Thus, the immune cells begin to attack body tissues, producing autoimmune illness. Common autoimmune illnesses include rheumatoid arthritis, lupus, cancer, and allergies. Research has linked stress to suppression of the immune system and even to viral replication in HIV patients (e.g., Davidson, Kabat-Zinn, Schumacher, et al., 2003; McCain, Gray, Elswick, et al., 2008).
Gastrointestinal System	The gastrointestinal system may respond to central nervous system stimulation with constipation or diarrhea, gastroesophageal reflux, colitis, or irritable bowel syndrome. Continued secretion of hydrochloric acid produces gastric hyperacidity and erosion of the gastrointestinal tract, especially in the presence of *Helicobacter pylori* (*H. pylori*).
Musculoskeletal System	Constant readiness for fight or flight produces muscle tension and pain in various body sites. Tension headache and temporomandibular joint pain result from prolonged muscle tension in the head, neck, and spine.
Respiratory System	Epinephrine and circulating hormones dilate the bronchial tubes and increase the rate of respiration. Hyperventilation can produce symptoms of alkalosis, including dizziness, tingling hands and feet, and anxiety. Distress in the respiratory system can exacerbate existing asthma, hay fever, and allergies.

unpleasant situations. The patient merely pretends to have the symptoms for personal or tangible gain (e.g., calling in sick because the person does not want to go to work).

KnowledgeCheck 12-6

- Name and describe three stress-induced organic or systemic responses to stress.
- Name and describe at least three somatoform disorders.

Stress-Induced Psychological Responses

Even if coping mechanisms are effective initially, with long-term stress, exhaustion sets in and the mechanisms begin to fail. The person may then try maladaptive ways to cope. As work and personal relationships deteriorate, the person loses self-esteem. Prolonged stress can eventually result in crisis and burnout (Fig. 12-6). More severe responses include psychiatric illnesses, such as anxiety disorders, clinical depression, and post-traumatic stress disorder (PTSD). Anxiety and depression are discussed in Chapter 13.

Crisis

A **crisis** exists when (1) an event in a person's life drastically changes the person's routine and he perceives it as a threat to self, and (2) the person's usual coping methods are ineffective, resulting in high levels of anxiety and inability to function adequately. Such events are usually sudden and unexpected (e.g., serious illness or death of a loved one, serious financial losses, an automobile accident, rape, and natural disasters) (Fig. 12-6).

Each person has a different tolerance for stress; an event that creates a crisis for one may be just a minor nuisance for another. Nevertheless, most experts agree that people experiencing crisis go through five phases (Neeb, 2006; Stuart, 2012).

1. ***Precrisis.*** In response to the event and the anxiety, the person uses her usual coping strategies; has no symptoms; denies feeling stress; and may even report a sense of well-being.
2. ***Impact.*** If the usual strategies are not effective, anxiety and confusion increase. The person may have trouble organizing her personal life and may feel the stress but minimize its severity.
3. ***Crisis.*** The person experiences more anxiety and tries new ways of coping, such as withdrawal, rationalization, and projection (refer to Table 12-1). The person recognizes the problem but denies that it is out of control.
4. ***Adaptive.*** The person redefines the threat and perceives the crisis in a realistic way. She begins to think rationally and does some positive problem-solving, regains some self-esteem, and is able to begin socializing

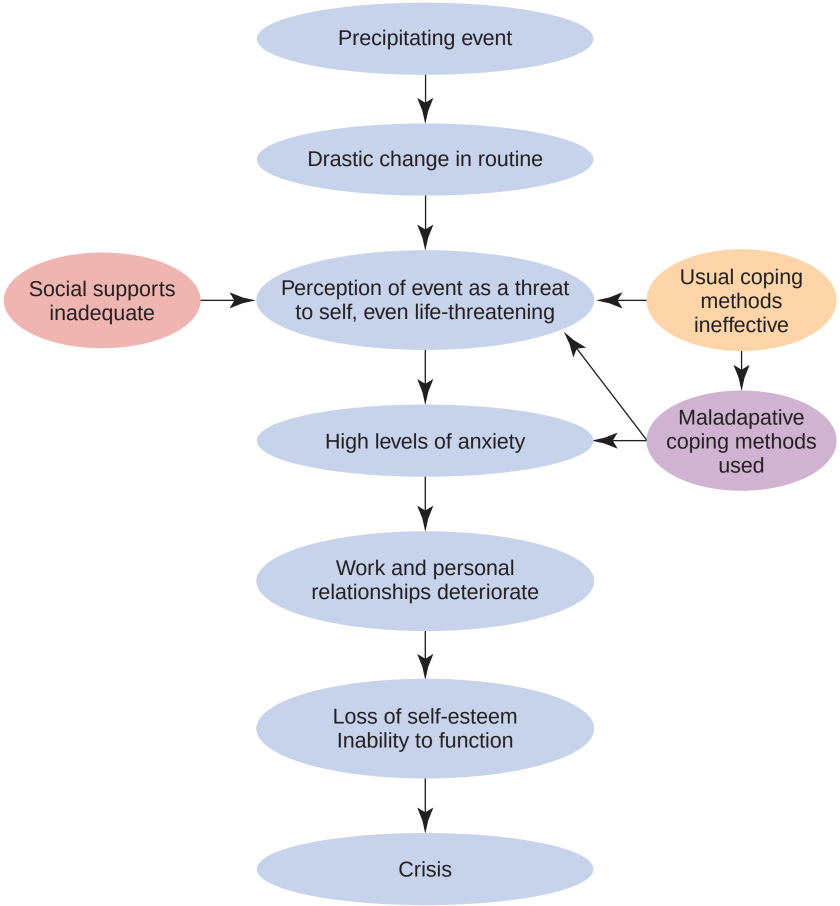

FIGURE 12-6 How a crisis develops.

again. Adaptation is more likely if the person can use effective coping strategies and if situational supports are available.

5. ***Postcrisis.*** The aftermath of a crisis may have both positive and negative effects on functioning. The person may have developed better ways of coping with stress. Or she may be critical, hostile, and depressed, and may use maladaptive strategies (e.g., overeating or substance abuse) to deal with what has happened.

People in crisis are at risk for physical and emotional harm, so intervention is essential (see Crisis Intervention later in the chapter).

ThinkLike a Nurse 12-3

Suppose you are the charge nurse on a 30-bed surgical unit. In addition, you must assume care of three patients because another nurse called in sick. It is a normal, busy day with seven postoperative patients and eight discharges. In addition, a patient went into cardiac arrhythmia and was transferred to the coronary care unit. Because the sick nurse was supposed to work a 12-hour shift and no replacement has been found, you are told you must stay and work 4 hours overtime. You had plans to have dinner with your spouse this evening because it is your anniversary. Now you will surely not be home before 8:00 p.m., and you will be exhausted.

- What would be the stressors for you in this situation?
- What thoughts and feelings would you have?
- What physical responses would you probably notice?
- What are some psychological responses that you would use to help you adapt and cope with this day?
- How would you probably react if the same thing were to happen on the following day?

Burnout

Burnout occurs when nurses and other professionals cannot cope effectively with the physical and emotional demands of the workplace. You will find examples of stressors specific to nursing in Box 12-4.

Excessive demands by an employer serve as a catalyst for burnout. In some situations, the nurse receives no respect and little support from the employer or coworkers. Filled with feelings of injustice for treatment received, the nurse may respond with anger and frustration, feel overwhelmed and helpless, and suffer low self-esteem and depression. Some nurses experience grief reactions, moral distress, and guilt feelings because the situation prevents them from performing as well as they believe they should (Badger, 2008). As a result, a nurse may develop a physical illness, a negative attitude, or may use maladaptive coping techniques such as smoking, substance abuse, or distancing from patients—"going through the motions" but not really interacting with patients in a meaningful way. Many nurses with these feeling may give up and leave nursing. You will find suggestions for preventing burnout later in the chapter.

BOX 12-4 ■ Stressors That Can Lead to Burnout

- Dealing with difficult personalities (e.g., patient, supervisors, physicians)
- Working 12-hour shifts with minimal breaks for food, water, or rest
- Frequent rotating shifts that upset the circadian rhythm of the body and lower the immune system response
- Mandatory overtime
- Being "floated" to an unfamiliar unit (e.g., a maternity nurse may be "floated" to an orthopedic unit)
- Workload: low staffing ratio (one nurse to many patients)
- Frustration with patients (e.g., who do not follow therapeutic routines)
- Need to constantly anticipate patients' needs and cope with the unexpected
- Feeling helpless against a patient's disease process or lack of healing
- Dealing with death and dying
- Lack of rewards (both intrinsic and extrinsic)
- Lack of participation in decision making
- Inability to delegate responsibilities
- Organizational philosophy that conflicts with personal philosophy

Post-Traumatic Stress Disorder

Post-traumatic stress disorder (PTSD) is a specific response to a violent, traumatizing event, (e.g., earthquake, flood, or other natural disaster) or to physical or emotional abuse, such as rape, torture, or war. The victim experiences anxiety and flashbacks that may last for months or years. Other symptoms include social withdrawal, feelings of low self-esteem, changes in existing relationships, difficulty forming new relationships, irritability and outbursts of anger for no obvious reason, depression, and chemical abuse or dependence.

Counseling, special interventions, and stress management are needed to help the person cope with and recover from the impact of the traumatic event (Bisson & Andrew, 2007).

KnowledgeCheck 12-7

Define *crisis*, *burnout*, and *post-traumatic stress disorder*.

PracticalKnowledge knowing how

People under stress may not be thinking clearly or able to communicate effectively; therefore, it is important to intervene to relieve their immediate anxiety as much as possible, demonstrate empathy, and develop rapport before beginning an assessment. Focus the patient by asking short, direct questions and then proceeding to open-ended questions that will provide you with as much information as possible (see Chapter 21 if you need to review questioning techniques).

ASSESSMENT

Assessment should explore subjective and objective data about the person's stressors, risk factors, coping and adaptation, support systems, and stress responses (psychosocial and physiological).

Assess Stressors, Risk Factors, and Coping and Adaptation

Data about the patient's stressors and risk factors should help you to:

- Determine whether the client has a realistic or an exaggerated perception of the stressors
- Identify factors that increase risk for future stress
- Identify interventions to reduce current stress and to provide anticipatory guidance to prevent future stress

You might begin gathering these data by having the patient complete a stress inventory, such as the Holmes–Rahe Social Readjustment Scale. Then follow up with questions such as those in Assessment Guidelines and Tools in Chapter 12, Volume 2. You will also find questions to help you obtain information about patients' coping methods and adaptation in those guidelines.

Go to Chapter 12, **Assessment Guidelines and Tools, the Holmes–Rahe Social Readjustment Scale** and **Assessing for Stress: Questions to Ask,** in Volume 2.

Assess Responses to Stress

When assessing responses to stress, recall that stress responses are holistic. Therefore, you will need to assess physiological, emotional, cognitive, and behavioral indicators of stress. For examples of questions to ask,

Go to Chapter 12, **Assessment Guidelines and Tools, Assessing for Stress: Questions to Ask,** in Volume 2.

Assessing Physiological Responses Because the GAS is nonspecific, you must obtain data from all body systems (for physical examination techniques, see Chapter 22). A check of vital signs for elevations in pulse, respiration, and blood pressure will indicate whether the fight-or-flight response is present. In your general survey, or overview, of the patient, you should note hygiene, grooming, facial expression, and ability to make eye contact. Box 12-5 summarizes physiological responses that indicate stress. If coping is successful, clinical signs and symptoms of stress may not be present.

Assessing Emotional and Behavioral Responses Assess for the emotional and behavioral responses to stress that are described in Box 12-3. As the client answers questions, note posture, facial expression, body tension, and other nonverbal behaviors. Also note mood and affect. Does the client seem angry, anxious, or depressed? Check the client's records, and observe for and ask the client about destructive behaviors (e.g., drug abuse, anger). The client may or may not be aware that the feelings or behaviors are related to stress.

Assessing Cognitive Responses You can assess the client's cognitive functioning as you assess other functional areas. See Box 12-3 to review examples of cognitive responses. Notice whether the person has difficulty focusing and responding to your questions. When you ask the client to describe and rate the intensity of the stressors, you can begin to assess whether he perceives the stressors realistically or in an exaggerated way. The client's responses concerning any coping strategies will give you an idea of his problem-solving abilities.

BOX 12-5 ■ Physiological Responses to Stressors

- Dilated pupils
- Muscle tension
- Stiff neck
- Headaches
- Nail biting
- Skin pallor
- Skin lesions (e.g., eczema)
- Diaphoresis, sweaty palms
- Dry mouth
- Nausea
- Weight or appetite changes
- Increased blood glucose
- Increased heart rate
- Cardiac dysrhythmias
- Hyperventilation
- Chest pain
- Water retention
- Increased urinary frequency or decreased urinary output
- Diarrhea or constipation
- Flatulence

Assess Support Systems

Recall that support systems such as family, friends, and coworkers are important to the success of a client's coping strategies. Conversely, these people may be affected by the same stressors or by the client's responses to them. For these reasons, you should determine the supports available and their ability to assist the client—that is, do the significant others have the sensitivity and skills to be supportive? For examples of questions to ask,

Go to Chapter 12, **Assessment Guidelines and Tools, Assessing for Stress: Questions to Ask,** in Volume 2.

ThinkLike a Nurse 12-4

Review the scenario of Gloria and John (Meet Your Patients). How much does it really tell you about the clients' situation?

- Which aspect of stress do you have the most information about: their stressors, their coping methods and adaptation, their responses to stress, or their support systems?
- What facts do you have about either Gloria's or John's physiological responses to their multiple stressors? What can you infer their responses might be?
- What facts do you have about the clients' emotional and behavioral responses to their stressors?
- What information do you have about how well they are adapting to stress?
- What data do you have about their support systems? What information do you need?

ANALYSIS/NURSING DIAGNOSIS

Stress is nonspecific, so there is almost no limit to the number of nursing diagnoses that could be stress induced. Your theoretical knowledge of the holistic nature of stress should lead you to identify diagnoses in the physical, behavioral, cognitive, emotional, interpersonal, and spiritual domains. The following are some examples.

Physical	Constipation r/t decreased peristalsis secondary to stress
Behavioral	Ineffective Health Maintenance r/t use of denial as an ego defense mechanism to relieve anxiety
Cognitive	Impaired Short-Term Memory r/t overwhelming number and severity of stressors
Emotional	Anxiety r/t uncertainty about the future and ineffectiveness of usual coping mechanisms
Interpersonal	Impaired Parenting r/t maladaptive use of alcohol to cope with recent stress of divorce
Spiritual	Hopelessness r/t perceived lack of support and ability to change the present situation

For a more extensive list of stress-related nursing diagnoses,

Go to Chapter 12, **Standardized Language, NANDA-I Nursing Diagnoses Associated With Stress,** in Volume 2.

It is important to correctly identify the etiology of the diagnosis so that you can choose interventions to remove or modify the stressor. For example, if you believe a patient's Diarrhea is being caused by stress, you would intervene by modifying the stressor, helping the patient to perceive the stressor differently, and so on. If, instead, the Diarrhea were being caused by a gastrointestinal virus, your interventions would not have been helpful.

KnowledgeCheck 12-8

- How might you identify and assess Gloria and John's stressors (Meet Your Patients)?
- List three questions you could ask to find out how Gloria is coping and adapting to stress.
- List three questions you could ask to assess Gloria's physiological responses to stress. What observations might you also make?
- List three questions you could ask to assess Gloria's emotional and behavioral responses to stress.
- How might you determine whether stress is affecting Gloria's cognitive functioning?
- You know Gloria's sister is providing some support. How could you find out more about the extent of Gloria and John's support system?

PLANNING OUTCOMES/EVALUATION

NOC standardized outcomes are outcomes that if achieved demonstrate resolution of the problem stated by the nursing diagnosis. For example, if you make a diagnosis of Anxiety related to the client's perception that he will not be able to fulfill family responsibilities, you might use the NOC outcome Anxiety Control. For a list of NOC outcomes to use for stress diagnoses,

Go to Chapter 12, **Standardized Language, Standardized Outcomes and Interventions for Stress-Related Nursing Diagnosis,** in Volume 2.

Individualized goal or outcome statements are also specific to each nursing diagnosis. Broad, general goals for clients experiencing stress are to (1) reduce the strength and duration of the stressor, (2) relieve or remove responses to stress, and (3) use effective coping mechanisms. Examples of specific outcome statements you might write include the following:

- Reports (or physical exam reveals) reduction in physical symptoms of stress.
- Demonstrates less physical tension in facial expression and other muscle groups.
- Verbalizes increased feelings of control in the stressful situation.
- Uses problem-solving and anxiety-reducing techniques.
- Demonstrates relaxation and stress-reducing strategies.

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC standardized interventions for stress may be linked to both the problem and the etiology of the nursing diagnosis. Using the preceding example of Anxiety related to the client's perception that he will not be able to fulfill family responsibilities, some interventions may focus on supporting the client's ability to fulfill family roles; others may focus on general techniques for relieving anxiety (e.g., Anxiety Reduction, Calming Technique). For other stress-related NIC interventions,

Go to Chapter 12, **Standardized Language, Standardized Outcomes and Interventions for Stress-Related Nursing Diagnoses,** in Volume 2.

Specific nursing activities will be individualized on the basis of the patient's needs and the etiologies of the nursing diagnoses. As you implement stress-reduction interventions, it is essential to consider compliance. Will the patient adhere to or cooperate with therapeutic suggestions? Does the person wish to use complementary or alternative care measures? How open is he to deviating from traditional Western therapies? Confer and collaborate with patients to determine what will fit most comfortably into their lifestyle. Those are the interventions that will be most effective.

Most stress-relieving interventions work by one or more of the following means:

- Removing or modifying the stressor(s)
- Supporting coping abilities (e.g., changing the person's perception of the stressor)
- Treating the person's responses to stress (e.g., symptoms such as anxiety or diarrhea)

As you read through the following interventions, see whether you can identify the rationale for the action. Look back at the list above as you need to.

Health Promotion Activities

People cannot always control the occurrence of a stressful event, and there are no high-tech treatments for coping with stress. However, a healthy lifestyle can prevent some stressors and improve the ability to cope with others. Chapter 42 provides an in-depth discussion of wellness promotion. The following suggestions are a brief guide to a healthy lifestyle.

Nutrition Nutrition is important for maintaining physical homeostasis and resisting stress. For example, adequate nutrition is essential to maintain the integrity of the immune system; and proteins are needed for tissue building and healing. In addition, overweight and malnutrition are stressors that may lead to illness. See Chapter 27 if you need detailed information about nutrition. To summarize, you should advise clients to:

- Maintain a normal body weight.
- Limit the intake of fat (especially animal fat) to no more than 30% of daily calories.
- Limit the intake of sugar and salt.
- Eat more fish and poultry and less red meat.
- Eat smaller, more frequent meals to aid digestion.
- Consume 25 grams of fiber (fruits, vegetables, and whole grains) daily to promote bowel elimination.
- Consume no more than one or two alcoholic beverages per day.

Exercise Regular exercise promotes physical homeostasis by improving muscle tone and controlling weight. It also improves the functioning of the heart and lungs and reduces the risk of cardiovascular disease. Exercise also improves emotional homeostasis by promoting relaxation and reducing tension. During exercise, the brain releases endogenous opioids (e.g., endorphins), which create a feeling of well-being. To achieve any health benefits, the client needs to exercise for at least 300 minutes per week (U.S. Department of Health and Human Services, 2008). See Chapter 32 for more specific physical activities to manage stress.

- Advise clients who are obese, chronically ill, or who have always been sedentary to consult a primary caregiver before beginning a new exercise program.
- Suggest that the client identify a variety of physical activities that he enjoys (e.g., swimming, bicycling, walking, sports) and, if possible, schedule regular sessions with one or more exercise "buddies." These strategies help the client adhere to the exercise routine.

Sleep and Rest Sleep and rest restore energy levels, allow the body to repair itself, and promote mental relaxation. Most people need 7 or 8 hours of sleep a day; however, the amount of sleep varies among individuals. Stress, pain, and illness may interfere with the ability to sleep, so some clients may need help identifying and implementing techniques for relaxing and going to sleep (see Chapter 34 for more information on sleep, as needed).

Leisure Activities Compared with exercise, which not everyone enjoys, leisure activities are any activities that provide joy and satisfaction. They may involve physical activity (after all, many people do enjoy exercising), or they may be sedentary activities, such as reading, painting, and even watching television. Leisure activities are a form of rest and, as such, are restorative.

Time Management People who manage their time efficiently and organize their life routines feel more in control and, therefore, less stressed. If clients feel overwhelmed, you can help them to prioritize tasks and make "to do" lists. It is also important that they learn to delegate responsibilities and set boundaries on the use of time. For example, a working couple with three children may need to assign each child mealtime tasks, such as setting the table, drying the dishes, and so forth. Or they may need to limit the amount of time they spend cooking, reserving elaborate meals for weekends.

Time management also includes learning to say no. Out of a need to be liked or a strong sense of responsibility to others, people sometimes try to make everyone happy by agreeing to every request for assistance: from spouse, children, parents, friends, church, school, and the community. Prompt clients to identify how much they can realistically accomplish—what is essential to do, and what would be "nice" to do.

KnowledgeCheck 12-9

Name and discuss at least four aspects of a healthful lifestyle that can help prevent or relieve stress.

Relieving Anxiety

Because anxiety is a common response to illness, medical tests, and treatments, you will use anxiety-relief interventions every day of your professional life. For example, when you tell patients what to expect before you perform a procedure or ask them to take deep breaths during a painful treatment, you lessen anxiety. If you have developed a therapeutic, trusting relationship, your very presence will help to ease the patient's anxiety. You will find specific interventions for anxiety in Chapter 13, and many of the interventions in the following sections provide anxiety relief as well (see Complementary & Alternative Modalities [CAM]: Using CAM for Stress Reduction).

Anger Management

Anger is a common response to stress. However, clients usually do not openly say, "I am angry." In fact, they may not even recognize that they are angry. Instead, they engage in angry behaviors. For example, they may become hypercritical of family members or caregivers, become verbally abusive, or become demanding. By now you have probably heard stories from nurses about the client who is "on the call light constantly." Unfortunately, such behaviors often provoke frustration or anger in others—even nurses. Be aware of how you are responding to stressed-out clients. Are you relieving your own stress, or are you relieving the client's stress? If you respond angrily to relieve your own stress, you may provoke further negative emotion in the client and even escalate the situation to the point of violence. Not only that, but anger also blocks communication and can lead to poor patient care and reduced patient satisfaction. For other tips on managing anger, refer to Box 24-8, Dealing With Violence, and

Go to Chapter 12, **Clinical Insight 12-1: Dealing With Angry Patients,** in Volume 2.

Complementary & Alternative Modalities (CAM)

Using CAM for Stress Reduction

Barrett, B., Muller, H. M., Ward, A., et al. (2012). Meditation or exercise for preventing acute respiratory infection: A randomized controlled trial. *Annals of Family Medicine, 10*(4), 337–463.

In a study designed to evaluate the potential preventive effects of meditation or exercise, 154 adults 50 years and older were randomized to one of three groups: (1) those who received an 8-week training course in mindful meditation to reduce stress; (2) a matched group involved in an 8-week training course in moderate-intensity and sustained exercise; and (3) an observational group. Researchers found fewer episodes and reduced severity of acute respiratory infection (ARI) in the meditation and exercise groups.

Gaylord, S. A., Paisson, O. S., Garland, El. L., et al. (2011). Mindfulness training reduces the severity of irritable bowel syndrome in women: Results of a randomized controlled trial. *The American Journal of Gastroenterology, 106*(9), 1678–1688.

This article reports on the successful use of alternative and complementary therapies as adjunct therapies to decrease the severity of symptoms during episodes of irritable bowel syndrome in women, often triggered by stress. Researchers found that women who trained for 8 weeks in mindfulness meditation rated their IBS symptoms as less than did women who participated in an IBS support group. The groups did not differ in quality of life, psychological stress, or anxiety related to GI sensations.

Kiecolt-Glaser, J. K., Christian, L., Preston, H., et al. (2010). Stress, inflammation, and yoga practice. *Psychosomatic Medicine, 72*(2), 113–121.

Researchers interested in the benefit of yoga to cope with stress studied the body chemistry of women practicing yoga at least twice weekly. They found markers for inflammation to be five times higher in yoga novices or those not performing yoga. Yoga experts had lower heart rates when facing stress events than did those learning yoga. Mood was also more positive in both yoga novice and expert groups than in those using other interventions (walking, video).

Stress Management Techniques

It is important to teach your clients about relaxation and other stress management techniques. Most such techniques focus on discharging tension or simplifying one's life to modify stressors or control stress responses. **Relaxation** is a state of reduced physical and mental arousal. It is an important intervention because it reverses some stress responses. By elongating muscle fibers, relaxation reduces neural impulses sent to the brain and decreases the activity of the brain and other body systems. Blood pressure, heart rate, respiratory rate, and oxygen consumption decrease, while peripheral skin temperatures and brain alpha wave activity increase.

Many of the techniques in this section are complementary or alternative therapies that require special training, and which are discussed in detail in other chapters. If you would like to have detailed information about CAM, refer to Chapter 46. For 12 weeks of daily suggestions for coping with stress,

Go to Chapter 12, **Tables, Boxes, Figures: ESG Box 12-1,** on Davis*Plus*.

Exercise Exercise is used to treat, as well as prevent stress. It reduces stress because it releases tension held in muscles, improves muscle tone and posture, expresses emotions, and stimulates the secretion of endorphins, thus creating a feeling of well-being and relaxation.

Relaxation Techniques Relaxation techniques involve teaching the patient to relax individual muscle groups. **Progressive relaxation** in a quiet meditation state or lying in bed, relaxing and contracting muscle groups is much less traumatic and damaging to fragile joints and muscles than active exercise. Therefore, it may be used even by people who are not in good health. **Passive relaxation**, in which the person relaxes the muscle groups without first contracting them, is even less traumatic and requires even less energy.

Meditation Managing stress through meditation involves heightening one's attention or awareness. Regular meditation increases harmony among mind, body, and spirit, thereby reducing anxiety and giving the person control. See Chapter 42 for further information. For a script to lead a client through a guided meditation to reduce stress,

Go to Chapter 12, **Tables, Boxes, Figures: ESG Box 12-2, Script for Visualization,** on Davis*Plus*.

Visualization or Imagery Visualization (imagery) techniques are often used to complement the effects of relaxation techniques. They are explained in Chapter 46.

Biofeedback Techniques of biofeedback use electronic instruments to measure neuromuscular and autonomic nervous system activity and provide information about those responses to the person. The immediate feedback helps the person become aware of and learn how to voluntarily control certain physiological responses, such as those produced by stress (Olson, 2003). Biofeedback practitioners require special training, and most are credentialed in biofeedback. For more information, see Chapter 46.

Acupuncture **Acupuncture** involves insertion of a needle into "meridian points" to regulate the flow of energy or life force throughout the body. It can modify pain perception and restore normal physiological functions (e.g., decrease the heart rate). Special training is required to use this intervention (see Chapter 31).

Chiropractic Adjustment Misalignment of the vertebrae is thought to lead to pain, loss of function, and illness. Chiropractic adjustment is the manual realignment of the vertebrae to free energy, release muscle tension, and improve body function and health. Chiropractors undergo special education and training before they are qualified to perform adjustments. See Chapter 46 for more information.

Touch Therapies **Healing touch, Reiki,** and **therapeutic touch** are focused on energy modulation. Healing energy is channeled through a practitioner's hands to improve well-being, reduce pain, and accelerate healing. Further studies are needed for use in children and conditions other than pain (So, Jiang, & Qin, 2008, online 2012, August 15). See Chapters 31 and 46 for more information.

Massage Through manipulation of the soft tissues, massage relaxes muscles, releases body tension, improves circulation, and allows energy and blood to flow through muscles and soft tissues more readily. See Chapters 31 and 42 for more information. For instructions on how to give a back rub,

Go to Chapter 34, **Procedure 34–1: Giving a Back Massage,** in Volume 2.

Reflexology Reflexology is the application of pressure to specific points on the feet, hands, or ears, which are thought to correspond with certain organs of the body. The goal is to relieve blockage, promote the flow of energy, and reduce tension—thus, reflexology may be helpful in treating stress-related illnesses. Reflexology requires special training. See Chapter 46 for more information.

The following are simpler activities you can recommend to most clients to aid in relaxation and stress reduction:

- **Humor.** Laughter releases endorphins and relieves feelings of stress (Fig. 12-7). It enhances respiration and circulation, oxygenates the blood, suppresses the stress-related hormones in the brain, and activates the immune system. Some medical centers have begun implementing in-house humor programs (Bennett & Lengacher, 2007; Cousins, 1979; du Pré, 1998; Johnson, 2002).
- **Listening to Music.** Music soothes and relaxes when its vibrations are in harmony with body frequencies. Listening to tranquil music can also relax the mind.
- **Engaging in Art Activities.** Painting, working with clay, and engaging in other art activities help to express emotions and release endorphins.
- **Dance and Sports.** Like other forms of exercise, movement and physical activity release pent-up physical tension and emotions. Steady-state exercises, such as running or swimming at a consistent pace, offer stress relief in a meditative manner through sustained deep breathing and repetitive motion. Physical activity can also enhance self-esteem and help people feel better by the simple act of accomplishing a personal goal.
- **Journal Writing.** Expressive writing can help a person reduce stress and anxiety by venting emotion and reflecting on experiences. Journaling can provide insights into causes of stress and ways to modify stressors.

FIGURE 12-7 Laughter releases endorphins and helps relieve stress.

Changing Perception of Stressors or Self

Recall that altering one's perception is one way to improve adaptation to stress. For clients who have an unrealistic perception of the stressor and can imagine only negative outcomes, a technique, called **cognitive restructuring**, may be helpful. With this technique, you help clients to recognize their negative focus and to restructure their thinking in more positive and realistic ways. For example, you might encourage a working mother with demanding family members to take a single positive step, such as saying no to someone at least once a day.

You can also help clients to identify positive aspects of themselves and their coping abilities. This promotes self-esteem and helps them to recognize and use the resources they have for coping with their stressors. **Positive self-talk** is another method for increasing self-esteem. Each time you hear negative self-talk, stop the client, and ask him to rephrase the statement so that it is positive.

Identifying and Using Support Systems

You can facilitate successful adaptation by helping clients to identify and contact people and groups who offer various supports (e.g., listening, encouragement, advice, problem-solving, help with household tasks, financial support). Be aware of the groups available in your community (e.g., Weight Watchers, Alcoholics Anonymous, Parents Without Partners, Reach for Recovery). You may need to teach socialization skills to clients who are socially isolated so that they can begin to build a support system.

Reducing the Stress of Hospitalization

Illness and hospitalization are stressful for patients and their families. In addition to being sick, patients find themselves in unfamiliar surroundings, with little privacy, and a certain loss of control. Promote patient-centered care in the healthcare agency as much as you can. Involving patients and families actively in their care helps them adapt to the stressors of hospitalization. Teach patients what to expect from hospitalization, and give them a few tips to help plan ahead to minimize the stress they experience (See Self-Care: Teaching Clients How to Reduce the Stress of Hospitalization).

Providing Spiritual Support

In addition to helping clients obtain spiritual support from church groups and clergy, you can help to strengthen the client spiritually. You may wish to:

- Pray for or with clients, if they desire, and if you are comfortable doing so. Prayer can help reduce their feelings of powerlessness and loneliness.
- Help clients to define their values and set boundaries that honor themselves and uphold those values.
- Teach clients to silently recite an affirming mantra (e.g., on inhalation, say, "I am free." Exhale and say, "Stress, leave me.")

For other ways to provide spiritual support, see Chapter 16.

Self-Care

Teaching Clients How to Reduce the Stress of Hospitalization

Share the following tips with clients, preferably before hospitalization:

- Bring what you need from home. Make a list of necessities and pack carefully before you go. For example, bring your own soap, toothpaste, lotion, pajamas, and slippers—or your favorite tea bags and sweetener. Having familiar things can make your stay more pleasant for you.
- If you will feel well enough, bring your computer, reading material, crossword puzzles, or whatever you like to do that can help prevent boredom and depression. You might want to bring a few family photos for your nightstand.
- Bring a notepad and pencils so that you can take notes about what your primary care providers tell you (e.g., about diagnostic tests, instructions for care, and so on).
- Do *not* bring jewelry, cash, credit cards, or other valuables.
- Do not bring clothing that is not washable or that is uncomfortable or tight.
- Do not allow family or friends to visit if they are ill.
- It helps to ask family or friends to stay at the bedside, particularly when the physician is "making rounds." They can advocate for you and help you feel confident that everything will go well. You may not feel well enough to ask for what you need, but a family member can do that for you.
- Your family members or friends can also help you interpret and remember information and instructions that you will receive from nurses, physicians, and other care providers. There may be 30 people in your room each day, and when you are ill or taking certain medications it is hard to keep track of everything.
- Keep a bottle of hand sanitizer by your bed or insist visitors, including family members and care providers, use a hand hygiene product at the door when entering the room, just as you do.
- Know the name of your primary nurse (or nurses) on each shift, and ask as many questions as you need to.
- Even though some things seem to not make sense (e.g., taking your temperature at 3 a.m.), there is likely a medical reason for it. Try to be as patient and cheerful as possible.

Crisis Intervention

As an entry-level nurse in acute and ambulatory care settings, you are more likely to see patients in the first three phases of crisis and not be present for the adaptive and postcrisis stages. The goals of crisis intervention at an entry level of practice include the following (Brammer & MacDonald, 2003; Neeb, 2006):

1. Assess the situation.
2. Ensure the patient's safety.
3. Defuse the situation.
4. Decrease the person's anxiety.
5. Determine the problem.

6. Decide on the type of help needed.
7. Return the person to precrisis level of functioning.

For further explanation and to learn how to intervene when a patient is in crisis,

Go to Chapter 12, **Clinical Insight 12-2: Crisis Intervention Guidelines,** in Volume 2.

Crisis centers often rely on telephone counseling ("hotlines"). If telephone counseling is not adequate, or if observations of the home environment are needed, home visits may be necessary.

KnowledgeCheck 12-10

- Describe at least five specific interventions for dealing with an angry person.
- What is cognitive restructuring?
- What is the purpose of positive self-talk?
- List the seven steps of crisis intervention.
- Why is relaxation an important stress intervention?

Stress Management in the Workplace

You will need to pay attention to your feelings, your body, and your personal responses to stress. Do you notice that you are eating more than usual or have lost your appetite? Are you feeling edgy or impatient with family or coworkers, or not sleeping well? Check your body. Do you feel tired or often have headaches or gastrointestinal distress? Are the muscles in your face and shoulders tense? Do you often take work home with you? Are you unable to stop thinking about work, even when you are at home? Do concerns about finances or personal situations consume your thinking and create a sense of doom? If so, you probably need to start managing your stress. You can better manage workplace stress and avoid burnout by following the advice you give your patients. For some tips,

Go to Chapter 12, **Tables, Boxes, Figures: ESG Box 12-1,** on Davis*Plus*.

When stressors arise from the workplace, the following actions are especially important:

- Set realistic expectations of yourself and others. Don't be overcritical; most people, including you, are doing the best they can.
- Ask for help. Seeking the support of others does not indicate weakness or incompetence. It can even make others feel good by giving them an opportunity to practice collegiality.
- Offer support to colleagues who need help with tasks or with their feelings. This adds to the overall good feeling on a unit and improves the efficiency of performing many tasks.
- Be proactive about the things you can change and accept the things that you cannot change. Get involved in constructive efforts to change a particular stressor (e.g., staffing, overtime, and safety practices). If you cannot effect the changes, and if you cannot accept things as they are, you may need to think about removing yourself from the situation. Complaining and negative talk add to your own stress and that of others.
- Join and support professional organizations that address workplace issues (e.g., the National Student Nurses Association [NSNA] and the ANA).
- Strive for balance in these six key areas: family, financial responsibilities, health, social contributions, career, vocation or education, and spirituality or faith. Focus on the most important items and task; remember, work affects life, but your life also affects your work.
- Obtain counseling for stress that exceeds your ability to cope.

Making Referrals

This chapter has presented many assessments and interventions for reducing stress. Remember, though, you are not yet an expert nurse and no one, not even an experienced nurse, is an expert in all areas. It is important not to "get in over your head" with clients who are under stress and showing maladaptive coping. You can help by recognizing your limitations and by referring the client to the appropriate professionals as needed (e.g., a spiritual leader, a counselor, a social worker, a practitioner of complementary therapies, a physician, a psychologist, or a psychiatrist).

ThinkLike a Nurse 12-5

Sally is an RN seeking employment at a local nursing home. She left her previous employer because of stress and frustration with agency policy, for which the bottom line was financial gain rather than quality patient care. What can Sally do to help ensure that she will not experience the same problem in the new agency?

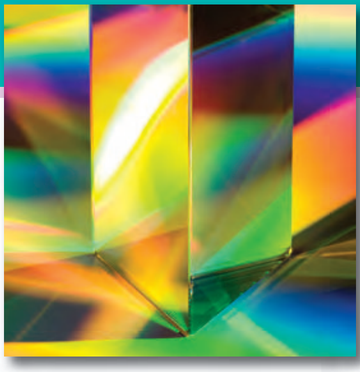
CHAPTER 13



Psychosocial Health & Illness

Learning Outcomes

After completing this chapter, you should be able to:

- Explain the relationship of psychosocial factors to overall health and development.
- Identify the factors that influence the development and stability of self-concept.
- List the four interrelated components of self-concept.
- Develop a nursing care plan for patients exhibiting disturbances in self-concept and self-esteem.
- Identify nursing diagnoses, outcomes, and interventions specific to body image disturbance.
- Describe interventions for preventing depersonalization.
- List the psychological and physiological effects of anxiety.
- Recognize the levels and symptoms of anxiety that are severe enough to merit referral to a mental health professional.
- Devise a nursing care plan for the nursing diagnosis of Anxiety.
- Differentiate between mild depression and that which should be referred to a mental health professional.
- Assess older adults for manifestations of depression.
- Plan outcomes and nursing interventions for patients who are depressed.
- Plan outcomes and nursing interventions for patients with a diagnosis of Risk for Suicide.

Meet Your Patient

You are caring for a 16-year-old patient named Karli who is suffering from fractures to both arms and several ribs, as well as extensive first- and second-degree burns to 30% of her body, following a motor vehicle accident. Karli was driving her parents' car home from her part-time job when she lost control of the car and crashed into a wall. The car exploded in flames. A passerby quickly reported the accident, and fast action by the emergency response team saved Karli's life.

Karli is suffering from a moderate amount of shock and pain. She alternates among outbursts of anger, self-directed sarcasm, and despondence. She tells you that she cannot understand how the accident happened, that one moment she was adjusting the car radio, and the next moment she awoke in the hospital. Then suddenly she explodes. "It's not fair! I just took my eyes off the road for a second; that's all!" She bursts into tears. Picking at her bandages, she sobs, "No one will ever love me the way I'm going to look. My life is over. I hate myself! You take her hand. "I used to be pretty," she says, "but now I'll look like a freak! What did I do to deserve this? I know plenty of kids who drive drunk or high all the time. I wasn't doing anything wrong! Why did this happen to me?"

Before reading on, jot down a list of the multiple physical, psychological, and social issues that you would need to consider in developing a comprehensive care plan for Karli. You can revisit your list throughout this chapter to compare your answers.

ThinkLike a Nurse 13-1

Review Chapter 9 as needed.

- What theoretical knowledge about Karli's developmental stage will assist you in determining nursing diagnoses, interventions, and outcomes?
- Considering that Karli will need a significant amount of assistance for activities of daily living (ADLs) because of her fractures and burns, how might you use the time to develop your therapeutic relationship?

ABOUT THE KEY CONCEPTS

This chapter introduces you to the key concepts of **psychosocial health, self-concept, anxiety,** and **depression**. As you study the related topics and terms in the chapter, you will gain a more complete understanding of the four key concepts. All of these will help you organize the content in your memory.

TheoreticalKnowledge knowing why

This chapter is designed to help you provide basic psychosocial care for patients in general practice settings.

PSYCHOSOCIAL HEALTH

The interactions of the mind and body are continuous and complex. One of the strengths of nursing is that we can go beyond a *biomedical* (disease-oriented) focus to care for the whole person. Nurses recognize that patient responses to illness are influenced not only by the physical pathology but also by the person's psychosocial health and its relationship to her overall wellness.

The term *psychosocial* encompasses both psychological and social factors: A person's psychological state interacts with his social development and position within society to contribute to his overall—or biopsychosocial—well-being (Fig. 13-1). Figure 13-2 illustrates the interlocking psychosocial influences on health and personal development.

Keep in mind that any human dimension may dominate health needs at a given time. For example, a patient suffering from a severe flare-up of psoriasis (a skin disease characterized by red, scaly patches) may require physiological interventions during the acute stage. He may not be ready to deal with body image issues (psychological dimension) until his skin lesions are better. Remember, though, that your patients' psychosocial needs are just as important as, for example, their dietary requirements or their level of pain.

What Is Psychosocial Theory?

You can think of **psychosocial theory** as a method of understanding people as a combination of psychological and social events. Of the many theories of psychosocial development, the works of the German psychologist Erik Erikson (1902–1994) are foremost. Using Erikson's theory, you can assess for successful completion of developmental tasks. Refer to Chapter 9 for more information about Erikson's theory. For a summary of developmental tasks,

Go to Chapter 13, **Tables, Boxes, Figures: ESG Table 13-1,** on Davis*Plus*.

Chapter 12 presents another important psychosocial theory that is relevant for healthcare providers: psychologist Abraham Maslow's theory of self-actualization and self-transcendence. Maslow (1968) developed a widely accepted hierarchy of human needs and motivations, in which essential needs (e.g., air, water, and food) must be met before higher needs (e.g., learning, creating, understanding, and self-fulfillment). Recall that, in order from most basic to highest need, Maslow's hierarchy includes

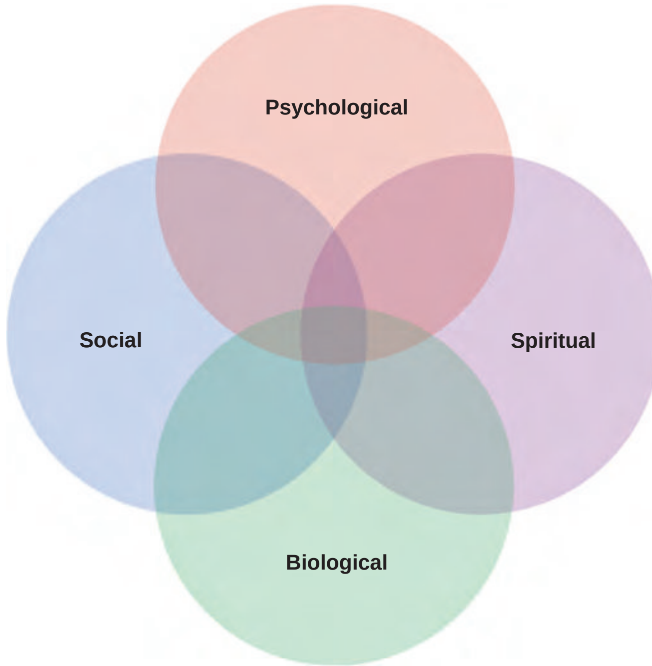

FIGURE 13-1 In the biopsychosocial view of health, biological, psychological, social, and spiritual factors interact to contribute to health.

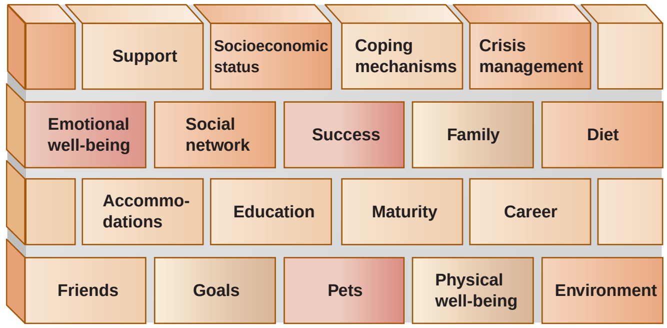

FIGURE 13-2 Interlocking psychosocial influences.

physiological, safety and security, love and belonging, self-esteem, and self-actualization needs. For more information about psychosocial theories,

Go to Chapter 13, **Supplemental Materials: Psychosocial Theory,** on Davis*Plus*.

KnowledgeCheck 13-1

- Why is psychosocial theory relevant to healthcare?
- What does the term *biopsychosocial* mean?
- Explain the implication of Maslow's hierarchy of human needs for working with a homeless man with gangrene.

What Is Self-Concept?

Self-concept is one's overall view of oneself. It is your complete and unique answer to the question, "Who do you think you are?" (e.g., "I am a student"; "I am successful and competent").

Key Point: ***Self-concept forms out of a person's evaluation of his physical appearance, sexual performance, intellectual abilities, success in the workplace, friendship and approval from others, problem-solving and coping abilities, unique talents, and so on. A person with a healthy self-concept has a mostly positive perception of these evaluations of self.***

Self-concept both influences and is influenced by social functioning. For example, Karli's self-concept is that she is no longer pretty and that she "looks like a freak." If this self-concept continues, it may cause her to withdraw from social interaction and make it difficult to form new relationships (social functioning). Equally, if others—for example, prospective employers—*do* see her as hideously ugly, she may have difficulty finding a place in society.

The "Dynamic Self" The self forms and changes in response to our environment.

Anthropologist Margaret Mead (1934) states that we discover who we are through a lifelong process of differentiating from and comparing our self to others. As we experience life events, we continually reconstruct and develop our understanding of who we are. Dickstein (1977) called this idea the **dynamic self,** meaning that who we are (the self) is subject to change through social and environmental influence. But if our concept of self is changeable, what factors cause it to change? Can it be harmed, and how? And how does it first develop? These questions are explored next.

How Is Self-Concept Formed?

Humans are not born with a concept of self; rather, it begins to develop during infancy and childhood as the child interacts with family members, peers, and others. The broad steps of self-concept formation are as follows:

Infant—Learning that the physical self is different from the environment: "me; not me."

Child—Internalizing others' attitudes about the self, primarily parents and peers: "Who do *they* say that I am?"

Child and adult—Internalizing standards of society: "How do I compare to others?"

Adult—Self-actualization and self-adjustment: "This *is* who I am and who I will continue to be."

Change occurs gradually, and the steps overlap. Also, the age at which the stages occur varies widely among individuals. For a summary of the growth of self-concept through the various developmental stages,

Go to Chapter 13, **Tables, Boxes, Figures: ESGTable 13-2,** Development of Self-Concept on Davis*Plus*.

ThinkLike a Nurse 13-2

- Explain how each of Maslow's five basic needs is related to psychosocial development; that is, how might each of the needs affect psychosocial health if met or not met?
- To what extent do social relationships help or hinder a person in meeting each need?

What Factors Affect a Person's Self-Concept?

Some factors affecting a person's self-concept cannot be changed, for example, gender and developmental level. Others, such as socioeconomic status and family relationships, can be changed to a degree, but are not fully under the person's control—and certainly not during childhood, when the self-concept is forming. Understanding that such factors are not within a patient's control may help you provide more sensitive, compassionate care to patients experiencing impaired self-concept.

Gender

Certain aspects of self-concept differ by gender. Some of the differences appear to be related to the role expectations of boys and girls rather than any actual difference in ability. For example,

Girls typically rate teamwork and cooperation as important to their sense of self, whereas most boys place a higher value on individual achievement.

Physical appearance seems more important to girls, and they may be less satisfied and more self-conscious throughout life because of this.

As role expectations and career choices for both men and women expand, these gender-based differences in self-concept may fade.

Developmental Level

As we mature, our self-concept becomes more inner-guided. That is, others (e.g., friends, the media) have less influence on our ideas about who we are. We become less likely to view our failures and shortcomings as evidence of worthlessness and more likely to see them as challenges common to humans everywhere.

Family and Peer Relationships

The family strongly influences a child's developing self-concept. As an infant's sense of self permanence develops and becomes stable, categories of self begin to emerge. These include notions of gender, values, and a sense of having a distinct "place" among family members (Feiring & Taska, as cited in Bracken, 1996). Social identity is first fostered by interactions between infants and their parents and broadens in toddlerhood through relationships with siblings, grandparents, and extended family members. For older children, peers become more important than family in this respect.

Locus of Control

Whereas the preceding external influences contribute to the *formation* of our self-concept, internal influences help us to *moderate* it. For example, biochemical brain processes influence perceptual acuity, interpretation abilities, and level of insight and judgment.

- **Internal Locus of Control.** People who allow their inner "voice" to influence their self-concept have what is called an **internal locus of control**. Such people feel they can exert control over their lives. They take appropriate responsibility for their life experiences and for their responses to them. This enables them to interpret unexpected adverse events (e.g., injuries and illnesses) in a more positive light.
- **External Locus of Control.** In contrast, people who have an **external locus of control** attribute control of their situation to factors outside themselves, including other people, institutions, and God. They may feel they lack the ability to change what happens to them.

KnowledgeCheck 13-2

- When does self-concept become stable?
- What factors have been determined to have an impact on our self-concept?

What Are the Components of Self-Concept?

Self-concept embraces four interrelated components: body image, role performance, personal identity, and self-esteem.

Body Image

How often do you hear someone say something like the following?

"Look at the muscles on that man. He looks good!"
"Look at her pigging out. She needs that candy like I need a hole in my head."

You probably grew up overhearing similar statements. Such preoccupations with food, weight, and appearance have led to a prejudice against people who do not have perfect bodies. No wonder people engage in unhealthy behaviors in order to be thin or that patients like Karli have difficulty coping with disfiguring accidents or with surgeries such as limb amputation and mastectomy.

Body image is your mental image of your physical self, including physical appearance and physical functioning. Both cognitive understanding and sensory input influence body image. Our cognitive understanding is in turn influenced by family, social, ethnic, and cultural norms; education; and exposure to alternative values. The American media portray the ideal male as young, tall, and muscular; nevertheless, many older, short, slender men maintain a positive body image because their cognitive understanding indicates they are in good health, are attractive to their partners, and so on.

Ideal, Perceived, and Actual Body Image People do not always see their own bodies as objectively as others see them. Some psychological disorders interfere with the ability to interpret sensory data objectively. For example, people with the eating disorders anorexia nervosa and bulimia nervosa see themselves as fat even when their mirror reflects, and other people see, a normal or even an emaciated body. The closer the match between a person's ideal body image and sensory input about his or her body (perceived body image), the more positive the person's body image is likely to be.

For Janalee, thick, luxurious hair is an important component of her ideal body image. Amy hardly thinks about her hair at all; she keeps it very short so that it is easy to care for. Both women have been receiving chemotherapy to treat their cancer, and both are experiencing severe hair loss. Which person do you think will be more likely to experience body image disturbance because of this?

Appearance and Function Influence Body Image Not surprisingly, a physical disability, such as blindness, deafness, or paraplegia, can interfere with the development of a positive body image. Children born with a physical disability are at risk for poor self-concept and depression. Risks are partially created by social values and the child's resulting difficulty in forming adequate social relationships, but it may also relate to the person's perception that he has low social value. In contrast, an attractive appearance and superior functioning, whether in a career, sports, or academics, make it easier to develop a positive body image. Nevertheless, cognitive understanding can increase self-concept even in people who are average in appearance or achievement. For instance, people of average appearance who learn to value integrity, honesty, teamwork, and other social values equally with physical attractiveness or success in sports are less likely to suffer from body image disturbance.

Gradual Versus Sudden Body Changes Gradual changes in physical appearance occur naturally throughout life as the body matures and grows old. Most people adapt to such changes relatively easily, especially because their friends and colleagues are aging, too. In contrast, when changes in appearance or functioning occur abruptly (e.g., following an acute illness or an accident, as happened to your patient, Karli), they are much more difficult to accept. Denial, anger, self-hatred, and despair are a few of many reactions that can follow such an abrupt change in body image.

Influence of Body Image on Health Body image influences health and health behaviors. A negative body image has been associated with:

- Depression (Cargill, Clark, Pera, et al., 2012; McCabe & Ricciardelli, 2012; Muehlenkamp, & Brausch, 2012)
- Initiation of smoking among adolescents (Cargill, Clark, Pera, et al., 2012)
- Increased risk for unintended pregnancy and sexually transmitted infections, including HIV infection (Larson, Clark, Robinson, et al., 2012; Woertman & van den Brink, 2012)
- Increased incidence of being bullied (Brixval, Rayce, Rasmussen, et al., 2012)

In contrast, a positive body image was found to be a major contributor to overall life happiness in adult women (Walters-Brown & Hall, 2012). There is not yet enough evidence to determine how much of the effect is due to body image alone and how much to body image in combination with other psychosocial issues.

Role Performance

Before you began your nursing program, what were your expectations? What activities did you imagine yourself engaged in, and what behaviors did you think would be expected of you? Together, these expectations make up your conception of the *role* of nursing student. In addition to being a student, you probably play several roles, such as parent, sibling, friend, breadwinner, caregiver, volunteer, and so on.

Role performance can be defined as the actions a person takes and the behaviors he demonstrates in fulfilling a role. Instead of expectations, role performance is the reality. If you expected that you would sail through your nursing program and instead you find yourself so overwhelmed that lately you have begun to skip classes, then you are experiencing **role strain**, a mismatch between role expectations and role performance. In addition, your ideas about how to perform the nursing student role may be very different from those of your instructors. When that type of mismatch occurs, you are experiencing an **interpersonal role conflict**. Other types of role conflict are also common. For instance, what if you are a single parent and your child's sudden illness causes you to miss a week of classes and clinicals? When two roles make competing demands on an individual, **interrole conflict** occurs.

Personal Identity

How would you describe yourself to others? Make a list of 10 words or short phrases that describe who you are (e.g., student, motorcycle rider, woman). Then list them in order, with the most important one first. Are you happy with your list? Are you satisfied with who you are? Compare your list with a friend's list. Could you identify her based on her list of identifying labels? Could she identify you?

Your **personal identity** is your view of yourself as a unique human being, different and separate from all others. Identity develops over time, beginning in childhood when you identified with your parents, and then later with teachers, peers, and others. Unlike body image, which is expected to change over time, personal identity is relatively constant and consistent. It is culturally determined and learned through socialization.

People with a strong sense of personal identity are less likely to compare themselves to others or to be unduly influenced by them. They tend to appreciate the unique perspective and contributions of others, yet value their own perspectives and contributions. In contrast, people with a weak sense of personal identity have difficulty distinguishing their boundaries from those of others. They may interpret events in the environment personally, or they may interpret their personal experiences as belonging to everyone. For example, a patient with a weak personal identity may insist that a breakdown in the hospital's air-conditioning system is a punishment for his complaint that his room was too cold.

Patients may experience an impaired sense of identity when they are challenged by a serious or chronic illness (e.g., cancer, AIDS, or rheumatoid arthritis). They then place too many limitations on their activities or interpret the responses of others in light of their illness. For instance, a woman with osteoporosis (loss of bone density) might say, "I used to enjoy going bird-watching, but I don't go anymore because I might trip and fall."

ThinkLike a Nurse 13-3

Think about Karli in the Meet Your Patient scenario. If you asked Karli to list 10 labels to identify herself, what do you think they would be? (You may not have enough information to come up with 10, but think of as many as you can.)

Self-Esteem

Self-esteem is, in the simplest terms, how well a person likes himself. It is the difference between the "ideal self" and "actual self," that is, between "what I think I ought (or want) to be" and "what I really am." The area of overlap in Figure 13-3 illustrates the extent of self-esteem. The more overlap there is, the higher the self-esteem.

The balance between our self-expectations and our true abilities can be precarious. When we succeed beyond our ambitions, we experience a high sense of self-esteem; but when we aim for an ideal self beyond our capabilities, we risk loss of self-esteem.

It is not difficult to imagine how a sudden, disfiguring accident such as Karli's might provoke a crisis in self-esteem, because Karli's ideal self is currently out of her reach. Even mild illnesses and minor setbacks can cause some people to question their self-worth. This is especially true if the problem is interpreted as one incident in a continuing pattern—for example, a couple hoping to become parents who experience a third pregnancy loss.

As another example, if as a nursing student you find that you are more successful than you expected to be when you enrolled in your nursing program, that is a

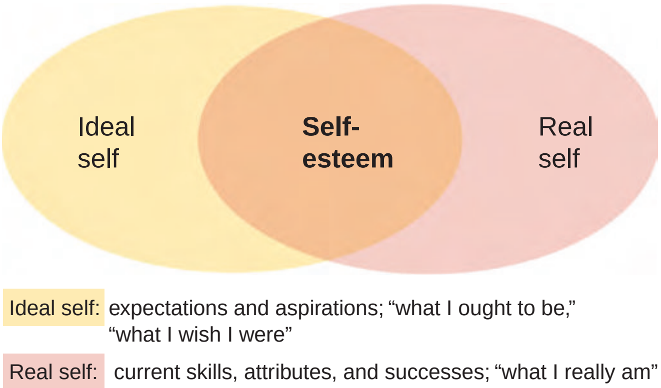

FIGURE 13-3 Self-esteem is determined by the relationship between an individual's ideal self and real self.

boost to your self-esteem. If, however, your expectations of being a skillful nurse outweigh your current abilities, then lower self-esteem is likely.

ThinkLike a Nurse 13-4

What if a person does not have any aspirations to success, but is content to meet each day as a learner, vitalized by her daily discoveries? How do you think a high score on an exam would affect her self-esteem? How do you think a poor score on a clinical skills test would affect her self-esteem?

KnowledgeCheck 13-3

- What four components contribute to an individual's self-concept?
- What is self-esteem?

PSYCHOSOCIAL ILLNESS: ANXIETY AND DEPRESSION

Think about the advertisements you've seen recently on TV or in newspapers and magazines. How many times do you recall seeing an ad for a medication for anxiety or depression? These two problems are not confined to mental health settings. They are woven into the fabric of our everyday lives. As a nurse, you should be prepared to recognize and provide care for anxious and depressed patients in all practice settings.

Example Problem: Anxiety

I wake up in the middle of the night with a knot in my stomach and thinking about work. I go over and over my day and worry about my decisions and what I should have done instead. I replay the meetings in my head and think, "I know what that person said, but what did she mean by that?" I wonder whether I can handle the responsibility. My neck and shoulders are so tense that I get headaches. But when I try to relax and watch TV, I can feel my heart racing, and I feel shaky. I can't concentrate well enough to read.

Anxiety is a common emotional response to a stressor. It is a "vague, uneasy feeling of discomfort or dread accompanied by an autonomic response (the source often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. It is an alerting signal that warns of impending danger and enables the individual to take measures to deal with threat" (NANDA International, 2012 p. 344). An anxious person worries; feels nervous, uneasy, and fearful; may be tearful; and often has physical symptoms such as nausea, trembling, and sweating. Anxiety and fear produce similar responses; however, some experts differentiate them as follows:

Fear is a specific, cognitive response to a known threat. It is related to a present event, either physical *or* psychological.

Anxiety is a vague, emotional response to a known or unknown threat. It is related to anticipation of a future event and is the result of psychological conflict rather than physical threat.

Key Point: ***Anxiety is so common that mild anxiety is considered normal and even necessary for our survival. No matter what area of nursing you work in, nearly every patient you meet will have at least some degree of anxiety. Chronic anxiety has been associated with physical problems, such as the risk of heart attack (Compare, Germani, Proietti, et al., 2011; Wittstein, 2010).***

Patients encounter anxiety-producing situations in healthcare settings because of threats to their basic needs (Stuart, 2012). Consider the following examples:

- Physiological—anxiety in anticipation of or in response to a diagnosis of cancer
- Safety and security—an upcoming surgery or diagnostic test, such as cardiac catheterization
- Love and belonging—anxiety over potential or actual loss of a loved one
- Esteem—anxiety over potential or actual loss of ability or appearance
- Self-actualization—anxiety over lack of self-fulfillment

Levels of Anxiety

Anxiety ranges from normal to abnormal, depending on its **intensity** and **duration—**how much anxiety is present and how long it has been present.

- **Normal anxiety** is an essential reaction to a realistic danger or threat to our physical or psychological integrity. In other words, it enables us to survive and, when the threat is no longer present, to move on. For example, anxiety when hiking on a rocky and narrow mountain trail heightens your awareness and quickens your responses, thereby reducing the likelihood of falls.
- **Abnormal anxiety** is out of proportion to the situation and lasts long after the threat is over, perhaps causing the person to alter her lifestyle. For example,

after breaking her ankle in a fall down a short flight of stairs, a young woman moves to a ground-floor apartment. Five years later, she still refuses to use stairs.

You should determine a patient's level of anxiety as accurately as possible because each requires different nursing actions. Peplau (1963) described the four levels found in Table 13-1.

Coping With Anxiety

People use a variety of coping behaviors to relieve mild anxiety, such as exercising, talking with others, engaging in pleasurable activities, deep-breathing, or using relaxation programs (Bourne, 2011). Less adaptive behaviors include excessive sleeping, eating, smoking, crying, pacing, fidgeting, drinking, laughing, cursing, nail biting, or finger tapping.

Table 13-1 ➤ Levels of Anxiety

DEFINITION OR DESCRIPTION	SYMPTOMS
Mild Anxiety	
This is normal anxiety, experienced in response to the events of day-to-day living. It heightens perception, sharpens the senses, enhances learning, and enables the person to function at his optimal level.	If present, symptoms may include muscle tension, restlessness, irritability, and a sense of unease. The person usually does not experience distress.
Moderate Anxiety	
As anxiety increases, the perceptual field narrows, and the person begins to focus on self and the need to relieve his discomfort.	▪ Less alert to environmental events ▪ Distracts easily ▪ Shorter attention span ▪ May need help with problem-solving but can attend to his needs with direction ▪ Physical symptoms may include: Increased heart and respiratory rates Increased perspiration Gastric discomfort Increased muscle tension ▪ Rapid, loud, and higher pitched speech
Severe Anxiety	
Perceptual field is so narrow that the person can focus on only one particular detail or may shift focus to many extraneous details. Focus is totally on self and the need to relieve the anxiety.	▪ Concentration and attention span are severely limited, so the person has difficulty completing simple tasks. ▪ Anxiety prevents problem-solving and learning. ▪ May report feelings of dread, confusion, and other unpleasant emotions. ▪ Physical symptoms may include headaches, palpitations, tachycardia, insomnia, dizziness, nausea, trembling, hyperventilation, urinary frequency, and diarrhea.
Panic Anxiety	
The person becomes unreasonable and irrational and is unable to focus on even one detail in the environment. He may misperceive environmental cues or lose contact with reality (e.g., experience hallucinations or delusions).	▪ May react wildly (e.g., shouting, screaming, running about, clinging to something) or withdraw completely. ▪ Cannot function or communicate effectively (e.g., may speak incoherently or be unable to speak). ▪ May feel terror and impending doom, believe he has a life-threatening illness, or that he is "going crazy." ▪ Physical symptoms include dilated pupils, labored breathing, severe trembling, sleeplessness, palpitations, diaphoresis, pallor, and muscular incoordination (Townsend, 2010).

When anxiety is more severe, the person attempts to counteract the anxiety in some way. Each person develops unique patterns of coping with anxiety, called **defense mechanisms**, which are used consciously or unconsciously to relieve the anxiety. Examples of defense mechanisms are **denial** (refusing to acknowledge the existence of a real situation or associated feelings) and **displacement** (transferring feelings from one target to another that seems less threatening—for example, kicking the dog when you are angry at your boss). See Chapter 12 for further discussion of defense mechanisms.

When overused, defense mechanisms can be maladaptive and lead to psychological disorders such as phobias, obsessive–compulsive disorders, and dissociative disorders (e.g., amnesia). Excessive or unrelieved anxiety may also contribute to **psychosis**, which is a loss of ability to differentiate self from nonself or by impaired reality testing (that is, knowing what is real and what exists only in one's mind), often accompanied by hallucinations and delusions. Examples of psychotic responses to anxiety include schizophrenia and delusional disorders. These disorders are beyond the scope of this book. If you need more information, refer to a mental health text.

KnowledgeCheck 13-4

- What is anxiety?
- When is anxiety a normal response to life?
- Identify at least three healthcare scenarios that might trigger anxiety in patients.

Example Problem: Depression

Others imply that they know what it is like to be depressed because they have gone through a divorce, lost a job or broken up with someone. But these experiences carry with them feelings. Depression, instead, is flat, hollow, and unendurable.
—Kay Redfield Jamison (1997, p. 218), An Unquiet Mind

The term **depression** is commonly used to describe a feeling of sadness or "the blues." But to psychologists, nurses, and other healthcare professionals, it refers to a specific condition with characteristic symptoms and often devastating consequences if left untreated (Steptoe, 2007; Suls & Howren, 2012). Depression occurs in all age groups, even in very young children. It affects about 9.1% of the adult population in the United States, and is one of the top three risks for functional decline. The incidence is higher in women than in men (*Morbidity and Mortality Weekly Report*, October 1, 2011). See Table 13-2 for common truths and myths about depression.

Criteria established by the American Psychiatric Association (APA) (2013) for **major depressive disorder** include:

- Depressed mood most of the day nearly every day for at least 2 weeks, typically accompanied by markedly diminished interest or pleasure in activities the person previously enjoyed
- Insomnia or hypersomnia
- Loss of energy
- Feelings of worthlessness
- Diminished ability to concentrate
- Recurrent thoughts of death (APA, 2013)

Unlike the feeling of true sadness, such as might accompany a divorce, death, or other loss, the depressed mood is typically marked by a sense of emptiness. This contributes to the depressed person's tendency to withdraw from social contacts and also explains the characteristically flat affect (Fig. 13-4).

Table 13-2 ➤ Depression: Truths and Myths

TRUE	FALSE
Depressive disorders are more common among women than men (2:1).	"Getting on with life" will cure depression.
Spiritual distress is associated with depression.	Everyone likes to talk about how they feel.
Depression can be defined as a maladaptive emotional response.	Medication is the answer to depression.
Low socioeconomic circumstances and social isolation correlate with depression.	Once depression has been cured, it does not return.

FIGURE 13-4 Depressed affect.

Depression in Older and Middle Adults

The incidence of depression is slightly higher for older adults than for the population as a whole. Of adults 65 to 74 years old, 10% reported that they had feelings associated with depression (sadness, hopelessness, worthlessness, and feeling that everything is an effort) "all or most of the time." For adults 75 and older, this was 12%. The incidence is much higher if you count the people who reported having those feelings only "some of the time" (Schiller, Lucas, Ward, et al., 2012, Table 14).

We typically think of older adults as being at higher risk because of their many losses and multiple physical illnesses (Touhy & Jett, 2009). However, at least one recent large, international study found that people in their late 40s are approximately twice as likely to be taking antidepressants as individuals—with the same characteristics—who are under the age of 25 or over the age of 65 (Blanchflower & Oswald, 2012), and that happiness and sense of well-being reach their lowest in the 40s. This study remains controversial, and more research is needed, but the findings are interesting.

What Causes Depression?

Are our genes responsible for the development of depression? Is depression "anger turned inward"? Depression theories fall into four groupings:

- *Physiological theories* relate depression to biochemical imbalances stemming from hormonal, neurological, or genetic factors.
- *Psychodynamic theories* relate depression to loss, abandonment, and emotional detachment and to diurnal and seasonal mood variations.
- *Cognitive theory* relates depression to negative thinking.
- *Social/environmental theories* relate depression to poor family relationships, difficult interpersonal relationships, and socioeconomic and political factors.

Research has shown that the following factors increase the risk for depression:

Family history of depression
Hormonal or nutritional imbalance
Inability to externalize anger
Low self-esteem
Negative thinking
Learned helplessness and hopelessness
Prior success or failure in coping mechanisms
Traumatic loss
Catastrophic stressors (e.g., unemployment)
Chronic disease
Female gender

How Is Depression Treated?

People who are clinically depressed cannot just "snap out of it." If untreated, the symptoms may continue for weeks or even years. The physiological theory of depression predominates in the medical community, and current evidence shows that biochemical processes determine moods, thought, cognition, and perception. Therefore, treatment of serious depression relies more heavily on antidepressant medication than on psychotherapy. However, the medications have a number of unpleasant, and even serious, side effects, and some patients say that they do not effectively elevate their mood. Psychotherapists acknowledge that individual tolerance of symptoms, coping resources, education, and social support networks all have an important effect on outcomes and treatment.

Of course, you will not be conducting psychotherapy with depressed patients in your general practice. However, you *will* care for patients who are taking antidepressant medications and who have situational or even clinical depressions. Even without being a "psych nurse," there is much you can do to make your care of these patients more effective.

KnowledgeCheck 13-5

- What distinguishes clinical depression from feelings of sadness?
- How might a child manifest depression?
- Why is the nurse–patient (therapeutic) relationship important when caring for depressed individuals?

PracticalKnowledge knowing **how**

Practical knowledge in this chapter consists of planning, implementing, and evaluating care to promote clients' mental health and provide support when they experience psychosocial and psychological problems. Remember, the physical body is only one dimension of a person. What patients are thinking and feeling may be equally important to their healing process.

As a nurse generalist, your independent role is to assess and document the patient's behavioral state as it relates to his medical-surgical condition, rather than to diagnose and treat mental illnesses. Clients who are anxious, for example, may not understand or recall instructions for self-care; and those who are depressed may not have the energy or motivation to follow a medical regimen or keep appointments with their healthcare providers.

NURSING CARE TO PROMOTE PSYCHOSOCIAL HEALTH

Physical illness may be particularly stressful when it occurs in combination with psychosocial issues. For example, think of Karli (Meet Your Patient). Might her condition have been less complicated if (1) she had no disfiguring injuries or (2) she were an older adult at a developmental stage when appearance is generally less crucial?

ASSESSMENTS: PSYCHOSOCIAL

No matter what the patient's medical diagnosis, you need to perform accurate and ongoing psychosocial assessments to develop holistic nursing diagnoses and interventions. Most admission assessment forms have a few questions to screen psychosocial status. If any of the answers indicate risk for a problem, you may need to conduct a more comprehensive special needs (or system specific) assessment. For an example of a psychosocial assessment tool,

Go to Chapter 13, **Tables, Boxes, Figures: ESGFigure 13-1,** on Davis*Plus*.

A comprehensive psychosocial assessment should include the following categories:

- Biological details
- Recent life changes or stressors (both positive and negative)
- Lifestyle and relationships with the wider social environment
- History of psychiatric disorders
- Functional abilities (behavioral performance)
- Self-efficacy (the belief that you can influence your own behaviors and outcomes)
- Family relationships
- Social resources and network
- Usual coping mechanisms
- Interpersonal communication
- Understanding about current illness
- Major issues raised by current illness
- Health priorities
- Spirituality (see the HOPE assessment tool in Chapter 16)

After interviewing the patient, assess her *personality style*. That is, identify any personality traits that may affect her care or compliance, such as a tendency to be dependent, hostile, dramatic, or critical (Gorman & Sultan, 2008).

Psychosocial information is personal and sometimes sensitive. To encourage patients to share this information, you will need to use your developing communication skills. For example:

- Be aware of your own biases and discomforts that could influence your assessment.
- Use active listening through eye contact and verbal response. Be sensitive, though; eye contact is uncomfortable for some people.
- Proceed from general details ("How do you get along with your parents?") to the specific ("Does your mother ever hit you?").
- Use an open and positive voice tone, facial expression, and body language (e.g., avoid frowning, criticizing, or expressing shock).
- Keep the focus on the patient.
- Be respectful and sensitive to cultural and gender-specific details.
- Use open-ended questions (questions that cannot be answered with a yes or no).
- Follow the patient's cues by using reflection and restating.
- Be flexible and use humor as appropriate.
- Provide empathetic feedback and touch as appropriate.

You will learn more about interviewing and communication skills in Chapter 21.

ThinkLike a Nurse 13-5

Psychologically, Karli is worried about the unfairness of her situation, and is probably struggling with body image issues. In addition, what do you think her *social* concerns might be?

ANALYSIS/NURSING DIAGNOSIS: PSYCHOSOCIAL

Psychosocial issues involve nearly all areas of patient functioning, so there is overlap between what we are calling "psychosocial" diagnoses and those used in the rest of the chapter to describe the more specific problems of self-concept, anxiety, and depression. That is, you may use some of these psychosocial diagnoses for clients who have problems of self-concept, anxiety, and depression. It would be impossible to list every possible psychosocial diagnosis; the following are but a few.

- *Family Coping [Compromised and/or Disabled].* Usual support (comfort and assistance) from a significant other is either compromised (insufficient or withdrawn) or disabled (competing or maladapted), causing a significant health challenge.
- *Parental Role Conflict.* A parent shows significant role confusion and/or conflict in response to crises.
- *Ineffective Coping*. The patient fails to comprehend and effectively judge stressors, when he perceives incorrect or dangerous life choices as normal, and when there is an inability to use available resources. Inability to identify strengths and resources may be secondary to low self-esteem.
- *Post-Trauma Syndrome*. There is a maladaptive learned response to a traumatic and distressing event.
- *Risk for Loneliness.* The person is separated from persons, culture, objects, or environments to which a person may have ongoing attachments.
- *Social Isolation.* The person experiences significant aloneness that has a negative impact on health, or perceives the isolation as a threat to health.
- *Risk for Other-Directed Violence.* Situations in which a person threatens or uses aggression or violence to harm others. The intention of harm may not be limited to physical harm.

Psychosocial issues can be a problem, a symptom of a problem, or the etiology of a problem. It is important for you to determine what is cause and what is effect, although this can be hard to unravel at times. What you identify significantly affects your choice of goals and nursing activities (Table 13-3).

PLANNING PSYCHOSOCIAL OUTCOMES/EVALUATION

As always, the outcomes you identify will serve as guidelines for ongoing assessment and as criteria for evaluation of your patients' responses to care.

Individualized goal/outcome statements will depend on the nursing diagnoses used, client input, and realistic

Table 13-3 ➤ Implications of Identifying a Psychosocial Issue as Problem, Etiology, or Symptom

	AS PROBLEM	AS ETIOLOGY	AS SYMPTOM
Nursing Diagnosis	**Interrupted Family Processes** r/t tumult from parental divorce	Delayed Development r/t lack of stimulation **secondary to Interrupted Family Processes** (parental divorce)	Ineffective Individual Coping (Mother) r/t poor judgment and impaired reality perception, **as manifested by Interrupted Family Processes** and risk-taking behaviors
Sample Goals (based on problem)	***NOC Outcome*** Family Functioning	***NOC Outcome*** Child Development: 4 years	***NOC Outcomes*** Coping, Decision Making, Role Performance, Social Support, Impulse Control
	Goals Members perform expected family roles. Family cares for dependent members.	***Goals*** Child demonstrates age-appropriate motor activities. Child uses four- and five-word sentences.	***Goals*** Identifies coping strategies that have been effective in the past. Discusses the implications of decision alternatives with family.
Sample Interventions and Activities (based on etiology)	***NIC Interventions*** Family Integrity Promotion Family Process Maintenance Normalization Promotion	***NIC Interventions*** Developmental Enhancement: Child Parent Education Health Screening	***NIC Interventions*** Coping Enhancement Decision-Making Support Impulse Control Training Family Involvement Promotion Support Group Support System Enhancement
	Specific Activities Promote parental involvement in healthcare. Assist the family with skills and education of conflict resolution, coping skills, and problem-solving. Link the individual and family to the appropriate support and education services.	***Specific Activities*** Establish time for one-on-one care. Provide for creative play (e.g., clay, blocks, painting). Teach parents appropriate stimulation. Teach parents about developmental milestones and expected behaviors. Assess changes in family processes.	***Specific Activities*** Identify and discuss alternative behaviors. Encourage delaying decision-making when under stress. Help the mother solve problems constructively. Assist her to evaluate her own behavior. Identify and discuss past successful coping behaviors she has used.

expectations of what the client can achieve and agrees to. For example, for Compromised or Disabled Family Coping, examples of goal statements are, "Involves family members in decision making" and "Expresses feelings and emotions freely." If the nursing diagnosis is Impaired Social Interaction, goal statements may call for the client to develop the skills of "engagement, assertiveness, compromise, confrontation, and consideration."

The Psychosocial Health domain of the NOC taxonomy includes approximately 30 *NOC standardized outcomes* to describe psychological well-being, psychosocial adaptation, self-control, and social interaction. The following are a few examples:

Abusive Behavior Self-Restraint
Coping
Child Adaptation to Hospitalization
Psychosocial Adjustment: Life Change
Role Performance
Social Interaction Skills

Examples from other domains include Family Coping, Family Functioning, and Family Resiliency.

Other NOC domains also include useful psychosocial outcomes. The following are only a few examples (Moorhead, Johnson, Maas, et al., 2013):

Family Coping
Family Functioning
Family Participation in Professional Care
Family Resiliency

PLANNING PSYCHOSOCIAL INTERVENTIONS/IMPLEMENTATION

Psychosocial nursing interventions and activities will be determined by the nursing diagnoses you identify, especially by the etiologies.

NIC standardized interventions for psychosocial diagnoses are found primarily in the Behavioral and Family domains of the NIC system. The following are some examples from the Behavioral domain:

Anger Control Assistance
Anxiety Reduction
Coping Enhancement
Decision-Making Support
Socialization Enhancement

The following are examples of interventions from the Family domain:

Family Involvement Promotion
Family Support
Family Therapy
Parenting Promotion (Bulechek, Butcher, & Dochterman, 2012)

Specific, individualized nursing activities used to help patients maintain a sense of personhood are discussed in the following section, Preventing Depersonalization. For nursing activities in which the nursing goal is to provide conflict mediation, enhance socialization, or strengthen the family,

Go to Student Resources: Chapter 13, **Supplemental Materials, Psychosocial Nursing Interventions,** on Davis*Plus*.

Preventing Depersonalization

Illness, and especially hospitalization, can have a depersonalizing effect that alters the self-concept. The ill person may feel that she has become an object to be examined, poked, prodded, and discussed. You can help patients maintain a sense of personhood by using a caring approach:

- Introduce yourself if the patient does not know you.
- Address the patient by her preferred name each time you enter the room, and always speak respectfully.
- Listen actively when the patient speaks.
- Do not talk *about* the patient to others in the room (e.g., do not say, "He seems to be better today, don't you think?"). Speak *to* the patient.
- Use eye contact and touch, keeping in mind that people vary in their desire to be touched.
- Always offer an explanation before beginning a procedure, and warn the patient before you touch him ("I'm going to touch your leg now").
- Move, turn, and position the patient gently.
- Provide for privacy when performing procedures or discussing something personal or sensitive.

Nursing Care for Example Problems Self-Concept Disturbance and Low Self-Esteem

As is true for psychosocial issues, self-concept and self-esteem issues are a part of the holistic care of well and ill patients in all settings.

ASSESSMENT: SELF-CONCEPT AND SELF-ESTEEM

Psychological tests are typically administered by a clinical psychologist or licensed social worker. However, if you were working in a mental health agency, you might collect in-depth information regarding self-concept by using a psychological measurement tool, to be interpreted by a clinical psychologist or licensed social worker. For an all-purpose assessment you might use screening in any setting,

Go to Chapter 13, **Clinical insight 13-1: Assessing Self-Concept Problems,** in Volume 2.

Observe for behaviors and comments specifically associated with low self-esteem. People with low self-esteem tend to avoid eye contact and have a stooped posture. They may move slowly and have poor grooming. Their verbal behaviors include speaking hesitantly, being overly critical of others and of self ("I never do anything right."), not accepting positive comments about self ("Oh, anybody could have done it."), apologizing frequently, and verbalizing feelings of powerlessness ("Whatever you say is fine with me."; "It doesn't matter what I do; it won't change anything."). To assess specifically for the self-esteem dimension of a person's self-concept, you can

Go to Chapter 13, **Clinical Insight 13-2: Performing a Self-Esteem Inventory,** in Volume 2.

Key Point: ***If you suspect serious problems with self-concept, document the patient's responses in your nursing notes and refer the patient for appropriate psychological testing.***

Think**Like a Nurse** 13-6

In the Meet Your Patient scenario, Karli perceives herself as unlovable "looking this way." You should not assume that you know exactly what Karli means by this. Also from the scenario: Picking at her bandages, she sobs that no one will love her looking as she does, that her life is over, and that she hates herself. "You take her hand. 'I used to be pretty,' she says, 'but now I'll look like a freak!'"

- Which of her words do you need to clarify with her?
- What might you say to her to get her to provide more information about the psychosocial meaning of her statement?

ANALYSIS/NURSING DIAGNOSIS: SELF-CONCEPT AND SELF-ESTEEM

Psychosocial and self-concept issues can be a problem, a symptom of a problem, or the etiology of a problem. It is important for you to determine what is cause and what is effect, although this may not always be clear. As you can see in Table 13-3, your analysis significantly affects your choice of goals and nursing activities.

When analyzing data for self-concept problems, keep the following two guidelines in mind:

- *Avoid seeking simplistic cause-and-effect relationships*. Instead, recognize the complexity of human responses. For example:

  Molly, a 19-year-old student, has just been admitted to your unit and is presenting with clinical depression and low self-esteem. Is Molly depressed because she has low self-esteem? Or is longstanding low self-esteem causing her to feel depressed? Or are the two interrelated?
- *Avoid confusing low self-concept with clinical emotional and/or behavioral psychiatric diagnoses*. There is no recognized diagnosis describing self-concept disorder in the APA's *Diagnostic and Statistical Manual of Mental Disorders*, 5th ed., Text Revision (*DSM-5*, 2013). Self-concept (particularly self-esteem) plays a secondary role in a number of disorders but is not a primary disorder itself.

Self-Concept or Body Image as a Problem

You can diagnose a body image or self-concept problem when it is the result of a particular condition and might not exist if not for the condition (e.g., a profoundly deaf adolescent develops self-worth problems). The following nursing diagnoses may be useful for patients with either low overall self-concept or difficulties in specific domains of self-concept (e.g., self-esteem):

Chronic Low Self-Esteem The person expresses ongoing and longstanding overall self-dissatisfaction and negative self-appraisal (i.e., wide differences between "ideal" and "actual" or "perceived" self). *Etiologies* include but are not limited to depression, mismatch in ideal and perceived self, dysfunctional family, anxiety, or failure to adapt to a change in physical appearance or functioning.

Situational Low Self-Esteem The person exhibits self-disapproval and negative self-evaluations as a specific reaction to loss or change. *Etiologies:* See Chronic Low Self-Esteem, preceding.

Disturbed Personal Identity Negative and incorrect assessment of self-identity and inability to determine boundaries between self and others. *Etiologies* include but are not limited to distorted perceptions of self, such as occur in certain mental illnesses; loss of health, limb, physical appearance, or functioning; or dysfunctional family.

Ineffective Role Performance A person experiences or perceives difficulty in fulfilling a usual role, or there is a mismatch between role expectations and role performance (either perceived or societal expectations). *Etiologies* include but are not limited to job demands exceeding abilities, inadequate resources or support system, family conflicts, domestic violence, unrealistic role expectations, lack of a role model, substance abuse, cognitive deficits, illness or disease, low self-esteem, pain, fatigue, and cognitive deficits.

Disturbed Body Image An individual has a confused image of his physical self or negatively evaluates his body or an aspect of it. *Etiologies* include but are not limited to loss of functioning or appearance (e.g., acne, scars, breast removal, amputation), eating disorder, gender conflict, or personality disorder.

ThinkLike a Nurse 13-7

- Refer to Karli in Meet Your Patient. Look at the preceding five NANDA-I labels for self-concept problems (Chronic Low Self-Esteem, Situational Low Self-Esteem, Disturbed Personal Identity, Ineffective Role Performance, Disturbed Body Image). Which one most clearly applies to Karli? Explain your thinking.
- Write a nursing diagnosis (problem r/t etiology) for the problem you chose.

Self-Concept or Body Image as Etiology

Self-concept problems are an etiology when they precede a condition such as depression and play a central role in the condition (e.g., low self-esteem causing and maintaining depression or leading to an anxiety disorder). The following are examples of nursing diagnoses with self-concept (e.g., self-esteem) as the etiology:

- *Impaired Adjustment* should be used where a patient experiences difficulties adapting perception and evaluation of self after changes in health status.
- *Complicated Grieving* may develop in anticipation of or following body changes (e.g., hysterectomy) or loss of key roles (e.g., resulting from death of a spouse).
- *Deficient Knowledge* of a healthcare situation may occur because of low self-esteem and lack of confidence in ability to learn or to manage care. Low self-esteem diminishes the motivation to learn.
- *Hopelessness* may occur because of overwhelming role demands, external locus of control, or lack of confidence in abilities.
- *Impaired Social Interaction* may occur when the person's low self-esteem and external locus of control cause him to fear criticism or lack of acceptance from others.

- *Ineffective Health Maintenance* may occur as a result of low self-esteem: not perceiving one's self as capable, or feeling there is no point to making the effort.
- *Sexual Dysfunction* or *Ineffective Sexuality Pattern* may result from negative body image brought about by changes in body structure or function (e.g., pregnancy, medications, surgery, trauma, diseases such as arthritis, or treatments such as radiation).

PLANNING OUTCOMES/EVALUATION: SELF-CONCEPT AND SELF-ESTEEM

You will choose outcomes based on the client's specific nursing diagnosis. For example:

Nursing Diagnosis: Chronic Low Self-Esteem
NOC Outcome: Quality of Life
Individualized Outcome: Expresses pleasure in participating in activities

Nursing Diagnosis: Disturbed Body Image
NOC Outcome: Body Image
Individualized Outcome: Verbalizes positive aspects of body

To see a more extensive list of *NOC standardized outcomes* and indicators for selected self-concept problems, as well as *individualized goal/outcome statement* examples,

Go to Chapter 13, **Standardized Nursing Language, Self-Concept Diagnoses: Selected Standardized and Individualized Outcomes,** on Davis*Plus*.

When self-concept is the etiology of other problems (e.g., Sexual Dysfunction related to negative body image), choose outcomes based on the problem label (e.g., Sexual Abuse Recovery, Sexual Functioning, Body Image). The overall goal, in all cases, is that the patient's self-concept (or some aspect of it) will improve.

PLANNING INTERVENTIONS/IMPLEMENTATION: SELF-CONCEPT AND SELF-ESTEEM

Common NIC standardized interventions for self-concept and self-esteem diagnoses include Anticipatory Guidance, Behavior Modification, Decision-Making Support, and Self-Esteem Enhancement. For a more extensive list, along with examples of nursing activities,

Go to Chapter 13, **Standardized Nursing Language, Self-Concept Diagnoses: Selected NIC Interventions and Nursing Activities,** on Davis*Plus*.

Although not all-inclusive, those examples should give you an idea of the types of care needed to support self-concept.

Specific, individualized nursing activities used frequently for patients with psychosocial and self-concept diagnoses are discussed in the text that follows. They include supportive measures to promote self-esteem, self-concept, positive body image, and role satisfaction.

Promoting Self-Esteem and Self-Concept

The dependence that often accompanies illness and aging can bring about loss of self-esteem. Although the foundation for self-esteem is laid in childhood and affected by many sociocultural variables, your nursing approach can help preserve and enhance a patient's self-esteem. Your efforts to preserve self-worth of course promote self-esteem.

Identifying Patient Strengths It is important to help the client identify past achievements and areas of strength. One way to do that is to point out areas of strength that you observe, such as the following:

Emotional strengths might include the ability to express emotions, to "feel" for others.
Relationship strengths include being sensitive to others' needs and being a good listener.
Spiritual strengths may include faith in God and participation in church activities.

Evaluate the client's sense of humor, which can also be a strength—and be sure the client considers special aptitudes, such as cooking, arts and crafts, sports, work, and education.

It is important to help the client identify past achievements and areas of strength. One way to do that is to point out areas of strength that you observe. Be sure the client considers special aptitudes, such as cooking, arts and crafts, sports, work, and education. Other emotional strengths might include the ability to express emotions, to "feel" for others, to give and receive affection. Relationship strengths include being sensitive to others' needs, being a good listener, and making people feel comfortable.

Other Interventions The following are other nursing actions specific to self-esteem:

- Establish a therapeutic nursing relationship emphasizing trust, consistency, honest communication, and unconditional positive regard.
- Encourage the client to be as independent as possible (e.g., by performing self-care).
- Monitor for and discourage self-criticism and negative self-talk.
- Teach the client to substitute positive self-talk for negative self-talk. For example, the client says, "I know my blood sugar is high, but I can't seem to stay on my diet. I ate way too much again today." You might remind the client that she exercised today and has been following her exercise program religiously. Eventually, she should learn to cue herself.
- Use positive and reaffirming language.
- Be supportive and accepting, but do not invade the client's personal space.
- Help the client develop realistic goals that provide achievable challenges (no-fail situations).
- Encourage the client to take part in activities that offer opportunities for success.

- Role-model communications skills that will help the person develop interpersonal relationships. Provide opportunities for practice.
- Refer to self-help and support groups, as needed.
- When possible, ask the client's advice (e.g., "How do you usually do this dressing change?")
- Point out good health practices and healthy aspects of the client's body functions.
- Refer to the Self-Care box for suggestions about teaching parents about promoting self-esteem in their children.

Promoting Positive Body Image

You can help parents promote a positive body image in their children, and you can help patients develop a different attitude toward their body. The following suggestions may be useful.

- Examine your own attitudes about what constitutes a healthy body, and pay attention to the messages you convey to others.
- Encourage patients to discuss body changes resulting from their illness, surgery, or trauma.
- Provide the opportunity to interact with people who have had similar body changes.

Teach clients the following, some of which are the same as for developing self-concept and self-esteem.

Healthy Does Not Mean Perfect Help clients to accept that healthy bodies come in a wide range of shapes and sizes. Fashion magazines portray an ideal body that is unrealistic and unhealthy for most people. If they make you feel bad by comparison, don't read them!

Focus on Activity and Healthy Eating Encourage clients to be active and focus on healthy eating rather than starving and depriving themselves to lose weight.

Don't Make Negative Comments About Your Body Monitor for negative comments about body functions, weight, or size. Advise the client not to talk negatively about body weight, size, or deformity. Urge clients to be kind to themselves, and point out when they are being unrealistically critical of their body.

Keep a List Suggest that the client keep a list of things he likes about his body and refer to it when he is feeling down.

Accept Compliments Provide the client with practice in accepting positive comments about his appearance. Coach his responses as needed (e.g., say, "Thank you" after a compliment).

Challenge Critical Comments Teach the client to challenge critical comments from others about her appearance.

Surround Yourself With Positive People Support the client in surrounding herself with positive people who support the changes she is trying to make in her image of her body, and avoid people who are critical.

Use a Counter Suggest that the client buy a counter and click it each time he makes a deliberate effort to accept positive feedback about his body or engages in positive body behaviors.

To see a Care Plan and Care Map for Disturbed Body Image,

Go to Chapter 13, **Care Plan and Care Map,** on Davis*Plus*.

ThinkLike a Nurse 13-8

- Which of the preceding body image interventions would be most appropriate for Karli's nursing diagnosis?
- For the interventions you did not choose, explain why.

Self-Care

Teaching Parents to Promote Self-Esteem in Children

Demonstrate love and acceptance by doing the following:

- Spending some one-on-one time with the child as often as possible: read, play, or just be together
- Being free with touches: a hug, a pat on the back
- Refraining from frequent negative criticism
- Providing nearly total acceptance of the child

Provide security by:

- Having clearly defined limits and consequences for breaking rules
- Being firm and consistent in applying the rules
- Being sure the rules are reasonable
- Allowing some latitude for individual actions within defined limits
- Treating the child with respect
- Establishing routines, such as bedtime activity, homework before play, dressing for school before breakfast in the morning, and so on
- Clearly defining every family member's role

Promote competence by:

- Setting realistic expectations about behaviors
- Assigning a few chores that are within the child's capability (e.g., picking up toys, making the bed)
- Role-modeling values, such as respect for others, honesty, and responsibility
- Providing positive feedback
- Helping the child accomplish goals
- Providing a stimulating and responsive environment
- Providing support in meeting challenges

Facilitating Role Enhancement

Sometimes the difficulty with self-concept centers on an inability to fulfill one's usual or desired role. Specific actions to enhance role satisfaction include the following:

- Help the client distinguish between ideal and actual role performance.
- Help the person to identify her past, present, and future roles. For older adults, encourage reminiscence.
- Discuss boundaries, expectations, and management defined by lifestyle and family networks.
- Facilitate communication between client and significant other regarding the sharing of role responsibilities to accommodate role changes of the ill person.
- Help the client describe realistic roles and expectations tailored to specific health changes.
- Compare realistic roles with previous and less functional roles.
- Help the client examine the difference between previous roles and current role by providing education and a learning environment that focuses on positive and supportive change.
- Help the client identify and role-play behaviors needed in new roles.

KnowledgeCheck 13-6

Without looking back at the preceding material, see whether you can:

- List three interventions for preserving self-worth.
- List three interventions for promoting self-esteem.
- List three interventions for fostering positive body image.
- List three interventions for promoting role enhancement.

Nursing Care For Example Problem: Anxiety

In general practice, the focus of nursing care for clients with anxiety is (1) to differentiate between mild anxiety and that which is severe enough to require referral to a mental health professional and (2) to provide interventions to relieve anxiety.

ASSESSMENT FOR EXAMPLE PROBLEM: ANXIETY

Your patient assessment should identify the *presence, level,* and *cause* of anxiety. It should include data about the following:

- **Observable behaviors**—poor eye contact, restlessness (e.g., pacing, wringing the hands, fidgeting, shuffling the feet), crying, trembling, rapid speech
- **Cognitive changes—**confusion, difficulty concentrating, forgetfulness
- **Objective physical data—**sweating, rapid pulse and respirations, dilated pupils
- **Subjective data**—shortness of breath, nausea, insomnia, worry

As we have said, most ill patients will have at least some level of anxiety. Anxiety becomes a problem when it escalates to a level that interferes with the ability to meet basic needs. You must determine whether the anxiety is normal and adaptive or whether it is severe enough to require nursing interventions, consultation, or referral to a mental health professional. For a checklist to help you make this determination,

Go to Chapter 13, Assessment Guidelines and Tools, **Focused Assessment: Anxiety Assessment Guide,** in Volume 2.

Severe Anxiety If you suspect severe or disabling anxiety, document the patient's responses in your nursing notes, and refer the person to a physician or mental health clinician. Involve a mental health professional immediately (same day) if you discover any of the following:

- Suicidal thoughts and/or plans that make you uncertain of the patient's safety
- Assaultive or homicidal thoughts and/or plans that make you uncertain about the safety of the patient or others
- Loss of touch with reality (psychosis)
- Significant or prolonged inability to work and care for self or family

Physical Assessment Consider a comprehensive physical assessment for anxious patients, to rule out underlying disease or disorders. For example, a patient who suffers from heart palpitations when anxious may be found to have significant cardiac arrhythmias. Other medical conditions that may mimic anxiety symptoms include hormone imbalance, nutritional deficiencies, electrolyte imbalance, and central nervous system disorders. Most anxious patients, even those with diagnosed obsessive–compulsive disorder or panic attacks, are not admitted to the hospital just for their anxiety. You will encounter them more often in community settings or when they are hospitalized for other illnesses.

ANALYSIS/NURSING DIAGNOSIS FOR EXAMPLE PROBLEM: ANXIETY

For severe anxiety (neuroses, psychoses), medical treatment includes anti-anxiety medications and perhaps psychotherapy. The following five NANDA-I labels represent anxiety problems for which nursing interventions may be effective:

- ***Anxiety*** is a vague, uneasy feeling of discomfort or dread, accompanied by some of the symptoms listed in the preceding Assessment section. Anxiety may be unconscious; that is, the patient may not recognize that he is anxious (e.g., "My heart is pounding, and I can't seem to get my breath. What is wrong?").
- ***Death Anxiety*** is apprehension, worry, or fear related to death or dying.
- ***Decisional Conflict*** describes a person who is uncertain about what action to take when the choice among

the alternatives involves risk, loss, or challenge to personal life values.

- ***Fear*** is a response to a perceived threat that is consciously recognized as a danger (e.g., "My father died of this same surgery. Truly, I'm scared to death."). Fear is difficult to differentiate from Anxiety because many of the symptoms are similar.
- ***Ineffective Denial*** occurs when the person consciously or unconsciously rejects the knowledge or meaning of an event (e.g., a client having a heart attack says or thinks, "They have made a mistake. It's just sore muscles or pleurisy. I'll go back to work this afternoon.").

Anxiety can be the etiology or a symptom of many other nursing diagnoses, such as Deficient Knowledge, Self-Mutilation, Ineffective Sexuality Pattern, or Insomnia.

KnowledgeCheck 13-7

- List five NANDA-I labels you could use to describe a problem of anxiety.
- List four observations that would alert you that anxiety is severe enough to merit referral to a mental health professional.

PLANNING OUTCOMES/EVALUATION FOR EXAMPLE PROBLEM: ANXIETY

You will use outcomes developed in the planning stage as criteria for evaluating patient progress and the success of your nursing interventions. Whether anxiety is a symptom, a problem, or the cause or etiology of a problem, one of the desired outcomes is that the anxiety will be relieved.

For selected NOC standardized outcomes and indicators for anxiety-related diagnoses,

Go to Chapter 13, **Standardized Nursing Language, Anxiety-Related Diagnoses: Selected NOC Outcomes and NIC Interventions,** in Volume 2.

Individualized goal/outcome statements should relate the patient's specific nursing diagnosis, stating behaviors that will indicate that the problem is resolving. The following are some examples.

For Anxiety:
Plans coping strategies for anxious situations.
Uses relaxation techniques as required.
Reports absence of physical and psychological manifestations of anxiety.

For Death Anxiety:
Reports feeling less fearful.
Discusses funeral arrangements with family.

For Decisional Conflict:
Identifies relevant information about the decision and its consequences.
Recognizes how various alternatives conflict with others' desires.

For Fear:
Uses effective coping strategies.
Maintains social relationships and control over life.

For Ineffective Denial:
Verbalizes understanding of the complications that may occur if the disease is not treated.
Follows prescribed regimen for treatments and medications.

ThinkLike a Nurse 13-9

Go to Chapter 13, **Standardized Nursing Language, Anxiety-Related Diagnoses: Selected NOC Outcomes and NIC Interventions,** in Volume 2.

Notice that Anxiety Control is listed as a possible outcome for each of the nursing diagnoses. Explain how anxiety relates to each of the diagnoses: Is it a problem, a symptom, or an etiology?

PLANNING INTERVENTIONS/IMPLEMENTATION FOR EXAMPLE PROBLEM, ANXIETY

Interventions for anxious clients will depend on the cause of the anxiety; however, for *all* anxious clients, regardless of the etiology, the nursing goals in most situations are to help the client to:

- ***Recognize that the client is anxious.*** Because the symptoms may be varied, subtle, and physical, a person may demonstrate anxious behaviors without even realizing why he is doing so. Or he may attribute his symptoms to a physical illness.
- ***Identify the source of the client's anxiety.*** This may require a more extended relationship than you might have with a hospitalized client, because it involves the uncovering of emotional conflicts. Nevertheless, a more permanent relief can be obtained once the client recognizes the conflict and can use his conscious, rational mind to deal with it.
- ***Deal with the symptoms of the client's anxiety.*** For example, you may use massage, relaxation techniques, and so forth.

For *NIC standardized interventions* and selected activities for anxiety-related diagnoses,

Go to Chapter 13, **Standardized Nursing Language, Anxiety-Related Diagnoses: Selected NOC Outcomes and NIC Interventions,** in Volume 2

Specific nursing activities for reducing anxiety include the following:

- Provide a calm and safe environment, including a quiet, reassuring approach to communication and nursing activities. This will help the person remain centered and focused.
- Establish a relationship of trust, caring, and unconditional positive regard (i.e., don't make promises you

can't keep; don't make any "judgment" statements such as, "You ought to . . ." or "You shouldn't . . .").

- Be present and stay with the individual to help allay fears, create trust, and promote safety.
- Help the person identify triggers and situations that create anxiety.
- Use clear and factual knowledge tailored to the individual's circumstances.
- Explain and, if necessary, explore details of all healthcare procedures.
- Develop coping strategies and behavior modification techniques.
- Encourage enjoyable, nonstressful activities to give the person an opportunity to think about something other than the anxiety-producing situation.
- Advise regular physical exercise unless contraindicated by a physical condition.
- Control the environment by removing anxiety-provoking equipment and people.
- Administer and monitor anti-anxiety medication when required.
- Assist the patient in relaxation methods, such as biofeedback, meditation, and therapeutic touch. For specific information about these methods,

Go to **Chapter 46, Holistic Healing,** on Davis*Plus*.

- In addition, interventions specific for Death Anxiety include the following (also refer to Chapter 17):
  - Stay physically close to the patient when he is fearful.
  - Obtain spiritual support for the patient and family, as needed.
  - Inquire about the patient's and family's specific requests for care.

Nursing Care For Example Problem: Depression

The nurse–patient relationship is vital when you work with a depressed person. Whereas an anxious patient may actively seek your assistance, a depressed person is likely to avoid your approach and may even feel unworthy of your time and effort. Establishing a nurse–patient bond requires a specific, empathetic approach involving warmth, acceptance, and understanding (unconditional positive regard) even in the face of an unresponsive, even angry, patient response.

ASSESSMENT FOR EXAMPLE PROBLEM: DEPRESSION

You should be alert for risk factors and signs and symptoms of depression in all healthcare settings. If cues are present, you will need to perform a more thorough screening or comprehensive assessment, such as the following:

Go to Chapter 13, **Depression Assessment Guide: Patient Health Questionnaire (PHQ-9),** in Volume 2.

Risk Factors Specific to Older Adults For older adults, risk factors for depression include dementia, cancer, alcohol and substance abuse, stroke, myocardial infarction, functional disability, being widowed, being a caregiver, and social isolation (Kurlowicz, 2008). Presence of risk factors should alert you to the need for a system-specific (or special needs) assessment to determine whether depression is present.

Symptoms of Depression

Because there are so many symptoms, categorizing them may help to you to remember them. Depression is expressed by changes in feelings, cognition, and behaviors, as well as physical symptoms and changes in lifestyle. Symptoms may differ in some ways in children and older adults. When assessing for depression, observe for symptoms in the following areas:

Feelings (Affect) Depression is characterized by a flat affect; difficulty concentrating; and **anhedonia,** a loss of interest or pleasure in previously enjoyable activities (Steptoe, 2007). Finally, the person may feel worthless, guilt-ridden, or suicidal. Observe for anger, anxiety, guilt, helplessness, powerlessness, hopelessness, sadness; verbalizing lack of feeling; inability to enjoy previously enjoyable activities, low self-esteem, and worthlessness.

Cognition (Thoughts) The person may be preoccupied with loss (e.g., of job, of function); may experience self-blame, ambivalence, guilt, confusion, inability to make decisions; or blame others. You may observe, or the person may report, slowed thinking, poor concentration, preoccupation with bodily changes, and inability to accept positive comments,

Behavior The person may be unable to sleep, or sleep too much, dreading the moment when he has to get out of bed and face family members or responsibilities. Some people lose interest in eating and, therefore, lose weight; others eat frequently but without pleasure in an attempt to keep their "emptiness" at bay. Some people become agitated and restless; others experience slowed thinking and lethargy. Many experience fatigue or feelings of exhaustion throughout the day. Depression may be expressed in children by irritability, tantrums, or not eating. Look for persistently sad expression, poor eye contact, tearfulness, regression, restlessness, agitation, psychomotor retardation, withdrawal, poor grooming/hygiene, decreased sexual interest, past or current alcohol or substance abuse, and past history of suicide attempts.

Lifestyle Effects Social isolation is common. Depression may be masked by attempts to "self-medicate" with alcohol, over-the-counter (OTC) drugs, or illegal substances; or by disordered eating, participation in dangerous sports, or other forms of reckless behavior. In children, depression may manifest in skipping school or difficulty with relationships with others.

Physiological Effects Like all mental illnesses, depression carries a social stigma; thus, patients who are unwilling to admit—even to themselves—that they might be depressed may present with a physical complaint such as persistent fatigue or a fear of cancer. In such cases, skillful psychosocial assessment is critical. Physical conditions that might accompany depression include dizziness, headache, migraines, joint aches and pains (e.g., back pain), stomach ulcers and digestive upsets, chest pain, lethargy, constipation, sleep deprivation or hypersomnia, fatigue, anorexia or overeating, and weight changes.

Assessing Older Adults: Depression, Dementia, or Delirium?

Unfortunately for older adults, cognitive difficulty and depression continue to be under-recognized and undertreated. You will find more information about dementia in Chapter 10.

Delirium Also called *acute confusion*, **delirium** is an acute and potentially reversible disturbance of consciousness and cognition in response to underlying medical or mental illnesses, drug toxicity, and a variety of other causes. An estimated 30% to 40% of cases of delirium are preventable (Fong, Tulebaev, & Inouye, 2009). In fact, the Agency for Healthcare Research and Quality (2003, reaffirmed July, 2012) identified delirium as a marker of quality of care and patient safety. Many aspects of the care you will be providing, such as medication administration, evaluation of complications, and assessment of dehydration, nutrition, and sleep, are factors that can be modified to prevent the development of delirium.

Dementia **Dementia** is an irreversible decline in mental abilities. APA (2013) defines dementia as part of **neurocognitive disorders (NCDs),** a group of disorders in which the primary clinical deficit is in cognitive function. NCDs are acquired rather than developmental and may be associated with Alzheimer's disease; vascular disease; Parkinson's disease; traumatic brain injury; HIV infection; or substance/medication-induced NCD. Dementia affects about 22% of adults 71 years and older. Dementia prevalence increases with age: The rate is about 40% in those older than age 85. Confusion may be present in patients with depression, as well as those who have dementia or delirium.

The Geriatric Depression Scale is especially useful in screening for depression in older adults. It requires minimal training to use, and will help you decide whether the patient needs further assessment.

To see a short form of the Geriatric Depression Scale,

Go to Chapter 13, **Tables, Boxes, Figures: ESG Figure 13-2,** on Davis*Plus*.

For a comparison of the symptoms of depression and dementia,

Go to Chapter 13, **Assessment Guidelines and Tools, Differentiating Depression and Dementia,** in Volume 2.

When Should I Refer the Patient to a Mental Health Specialist?

Because depression is so common, many of the patients you see (e.g., medical-surgical, maternity, clinics) will have at least some degree of depression. It will be important for you to differentiate among temporary, situational sadness, low energy, and a psychiatric diagnosis (clinical depression). Figure 13-5 illustrates the continuum of mild to severe depression incorporating aspects of mood, behavior, thoughts, and physical symptoms.

The presence of any of the following should alert you to make a referral. If you suspect severe depression, document the patient's responses in your nursing notes, and refer the patient to a mental health specialist.

- Personal history of recurrent depression or bipolar disorder
- Family history of recurrent depression or bipolar disorder
- Personal history of recurrence of depression within 1 year after stopping effective treatment
- Episode of major depression before age 20
- Severe, sudden, or life-threatening depressive episode (i.e., suicide attempt). If you believe there is a risk for suicide, make the referral immediately (Box 13-1).

For two alternative methods you can use to identify patients who should be referred to a mental health specialist for evaluation and/or treatment of depression,

Go to Chapter 13, **Clinical Insight 13-3: Identifying Depressed Patients Who Should Be Referred for Evaluation,** in Volume 2.

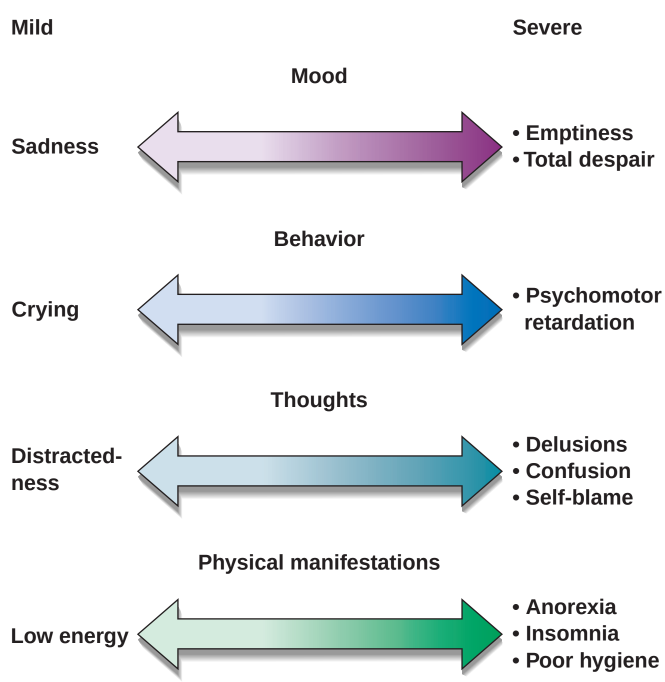

FIGURE 13-5 Depression assessment continuum incorporating mood, behavior, thoughts, and physical state.

BOX 13-1 ■ Cues Indicating a Possible Risk for Suicide

Risk Factors

- Alcohol substance abuse
- Family history of mental disorders or substance abuse
- Family history of suicide
- Firearms in the home
- Family violence, including physical or sexual abuse
- A significant medical illness, such as cancer or chronic pain
- Compulsive gambling
- Recent losses: Physical, financial, personal
- Age, gender, race (elderly or young adult, unmarried, white, male, living alone)
- Recent discharge from an inpatient psychiatry unit

Warning Signs

Patients with risk factors who exhibit any of the following warning signs clearly raise a red flag and merit immediate referral.

- Withdrawal from social contact
- Desire to be left alone
- Preoccupation with death and dying, or violence
- Risky or self-destructive behavior, such as drug use or unsafe driving
- Changes in routine, sleeping patterns
- Changes in eating habits
- Giving away belongings or getting affairs in order
- Personality changes, such as becoming very outgoing after being shy
- Saying goodbye to people as if they won't be seen again
- Talking about suicide (e.g., "I'm going to kill myself," I wish I were dead," or "I wish I hadn't been born.")

Source: Maybury, B. C. (2008, March 10). Suicide prevention: Every nurse's responsibility. Nurse.com. Retrieved January 10, 2013, from http://news.nurse.com/article/20080310/NY02/80305017

ANALYSIS/NURSING DIAGNOSIS FOR EXAMPLE PROBLEM: DEPRESSION

Depression is a psychiatric diagnosis, so you will not make that diagnosis. Nevertheless, you will need to describe associated problems that are appropriate for nursing intervention. The NANDA-I taxonomy does not have a specific diagnosis that uses the term *depression;* however, the following nursing diagnoses may be useful in describing the feelings and moods of patients who are depressed:

- ***Hopelessness*** may apply to a person who is unable to seek or comprehend opportunities, options, and alternatives because of a distressed emotional and unmotivated state. Note that research shows hopelessness to correlate highly with suicide (Cheung, Law, Chan, et al., 2006; Goldston, Reboussin, & Daniel, 2006; Nekanda_Trepka, Bishop, & Blackburn, 2011).
- ***Powerlessness*** may be diagnosed when a person's perception of control over situations and life events is significantly impaired and externally based.

Risk for Suicide must always be considered when a patient is depressed, especially when the person has a history of prior attempts or is verbalizing the desire to die or the intent to kill himself.

Remember that depression can cause a variety of physical and behavioral problems, such as the following:

Activity Intolerance
Adult Failure to Thrive
Constipation
Imbalanced Nutrition: Less than Body Requirements
Imbalanced Nutrition: More than Body Requirements
Impaired Social Interaction
Ineffective Health Maintenance
Ineffective Therapeutic Regimen Management
Insomnia
Noncompliance
Self-Care Deficit (Bathing/Hygiene, Dressing/Grooming)
Self-Neglect

The diagnoses of Situational and Chronic Low Self-Esteem are also useful because depressed clients often experience low self-esteem. These diagnoses were presented in the preceding section, Analysis/Nursing Diagnosis: Self-Concept and Self-Esteem.

PLANNING OUTCOMES/EVALUATION FOR EXAMPLE PROBLEM: DEPRESSION

You will use outcomes developed in the planning stage as criteria for evaluating the patient's progress and the success of your nursing interventions.

For selected NOC standardized outcomes and indicators for depression-related diagnoses,

Go to Chapter 13, **Standardized Nursing Language, Depression-Related Diagnoses: Selected NOC Outcomes and NIC Interventions,** in Volume 2.

Individualized goal/outcome statements should relate to the patient's specific nursing diagnosis, stating behaviors that will indicate that the problem is resolving. The following are some examples:

For Depressed Mood:

Affect is appropriate to the situation.
Reports feeling less sadness and depression.
Interacts willingly and appropriately with others.
Eats a well-balanced diet to prevent weight loss.
Bathes, washes and combs hair, dresses—maintains grooming and hygiene.

For Hopelessness:

Expresses positive belief in self, others, and meaning of life.
Demonstrates interest in life/activity.
Maintains spiritual belief system or religious affiliation.

For Powerlessness:

Participates in healthcare decisions to the extent possible.
Sets realistic goals for self.

For Risk for Suicide:

Verbalizes any suicidal ideas to staff.
Trusts staff enough to disclose any specific plans for suicide.

PLANNING INTERVENTIONS/IMPLEMENTATION FOR EXAMPLE PROBLEM: DEPRESSION

For *NIC standardized interventions and selected activities* for depression-related diagnoses,

Go to Chapter 13, **Standardized Nursing Language, Depression-Related Diagnoses: Selected NOC Outcomes and NIC Interventions,** in Volume 2.

Individualized nursing activities for depression-related diagnoses focus on altering the problem etiologies and relieving symptoms of depression. In general, care of the depressed person involves (1) developing a therapeutic relationship through effective communication and (2) promoting nutrition, exercise, and personal hygiene.

- Use therapeutic communication:
  - Be honest and open.
  - Be patient.
  - Be consistent.
  - Do not use false reassurance ("You'll feel better soon").
  - Avoid phrases such as "Cheer up" or "Think how lucky you are to have a good family."
  - Do make comments such as, "I like the way you look in that dress."
  - Do not be overly cheerful.
  - Encourage the client to express feelings, including anger.
  - Be accepting and nonjudgmental when the client expresses feelings.
  - Encourage communication that explores reality, grief, and personal loss.
- Promote activity. Activities in small groups can help build self-esteem.
- Promote and teach good nutrition and hydration.
- Provide support as needed for self-care and decision making, while promoting as much independence as possible.
- Assess for and provide information about use of complementary and alternative therapies for depression (see Complementary & Alternative Modalities (CAM): Depression & Anxiety: Teaching for CAM Use).
- Monitor for suicide risk. Ask directly: "Have you thought about harming yourself? If so, what do you plan to do?"
- Institute measures to build self-esteem (see Promoting Self-Esteem and Self-Concept in this chapter).
- Provide information on support and educational groups.
- Encourage the person to maintain his religious affiliations.

Nursing Interventions for Older Adults

Remember that depression is not a normal part of aging. As mentioned previously, it is important to identify depression in older adults and not mistake it for dementia or "signs of old age."

Team Communication If you identify signs of depression, be certain to communicate that to other members of the staff and to the primary care provider. You and the other nurses may be the only ones who have repeated contact with the patient, so you might be able to observe cues that are missed by other providers.

Medications Because metabolism changes with aging, the risk of adverse medication effects is high for older adults. Closely supervise patients being treated with antidepressants because severe side effects are possible. When a patient is admitted to a hospital there is a risk that self-administered medications may be overlooked. If one of those medications is an antidepressant, missed doses combined with a physical illness may cause depression symptoms to worsen.

Reminiscence Use reminiscence and life review as an intervention. Encourage the patient to talk about significant positive and negative experiences that have occurred during her life.

Suicide Risk **Key Point:** ***Keep in mind that depression is a significant predictor of suicide in older adults.***

As an example, the suicide rate among white men age 85 and older is almost double that of the U.S. general population (National Institute of Mental Health, 2010). Older adults often succeed in their suicide attempts. To illustrate: Among adults older than age 75 years, there is one suicide for every four attempts; among young adults, there is one suicide for every 100 to 200 attempts (Centers for Disease Control and Prevention [CDC], 2012a).

Complementary & Alternative Modalities (CAM)

Depression & Anxiety: Teaching for CAM Use

Many people use herbal therapies to relieve symptoms of anxiety and depression. Patients may self-treat, or herbal therapies may be prescribed by CAM practitioners. You should assess for CAM use to be sure the method is not contraindicated and that the patient has informed the primary care provider about its use.

DEPRESSION

Ginkgo Biloba

Can take 6–8 weeks for patient to feel any better.

Mixing with some fruits and nuts could produce poison ivy–like reaction.

Patients using anticoagulants must use with caution.

Should not be used by patients with peptic ulcer disease, children, or women who are pregnant or breastfeeding.

Ginseng

There are many kinds of ginseng; patient should look up the specific type he is using.

Should not be used by patients who are anticoagulated or who have hypertension, hypotension diabetes, cardiovascular disease; or by women who are pregnant or breastfeeding.

Kava

May experience symptom relief within 1 week.

Significant adverse reactions may occur.

Kava enhances the effects of alcohol and central nervous system (CNS) medications (e.g., alprazolam and CNS depressants).

Should not be used by women who are pregnant or breastfeeding.

Because of liver toxicity, the CDC has cautioned consumers against using kava (CDC, 2002). Its use is severely limited and regulated in Australia (Therapeutic Goods Administration, 2005).

St. John's Wort

Patients who are depressed should not take this herb without medical supervision.

Should not be taken by children or women who are pregnant or lactating, nor by those who use monoamine oxidase inhibitors (MAOIs), selective serotonin reuptake inhibitors (SSRIs), alcohol, or OTC cold and flu medications.

S-Adenosyl Methionine (SAMe)

Patients with bipolar disorder should not use this supplement unless under direct supervision of their physician.

Use enteric-coated forms to decrease gastric irritation.

For more in-depth information about CAM use for depression and anxiety,

Go to Chapter Resources: Chapter 13, **Tables, Boxes, Figures: CAM Box. Teaching for Patients Who Use CAM for Depression and Anxiety,** on Davis*Plus*.

Professional Help Encourage the patient to seek professional help. Older adults are likely to try to "handle it themselves," or even not think of depression as a health problem. Many think that it is normal to be depressed as they grow older

Suicide Prevention Interventions

It is not only patients on psychiatric units who commit suicide. They may be the same patients you care for on a medical-surgical unit or in their homes. Illnesses such as advanced cancer and AIDS are often accompanied by uncontrolled pain and delirium. Because of the suffering and dependency they cause, they are associated with higher suicide rates.

Key Point: ***Your most important intervention is assessment. Be alert for risk factors and warning signs that may indicate the possibility of suicide (see Box 13-1).***

Remember that about 80% of those who attempt suicide give some prior verbal or indirect cues.

- Evaluate the patient's medications (e.g., certain antihypertensive agents, steroids, cancer chemotherapeutic agents, and amphotericin-B can cause depression).
- If risk factors are present, put them prominently on the care plan and report them to other caregivers.
- Do not avoid the patient because you fear saying the wrong thing. Talking about suicide does not increase the risk.
- Be aware of your personal feelings and anxieties regarding suicide.
- If the patient mentions suicide specifically, be direct. Ask whether he is having thoughts of harming himself.
- If he answers yes, do not leave him. Have someone contact his primary care provider so that a psychiatric consult can be ordered, and possibly transfer to a psychiatric unit if the patient is physically stable.

- Ask if the patient has a plan for suicide, and if so, what it is.
- Remove items that might be used for self-harm (e.g., razor blades and other sharp objects, shoelaces, belts, intravenous tubing, telephone cords, pills, and glasses). Search the room and the bathroom.
- Make sure the windows cannot be opened.
- Follow agency policy for continuous monitoring, moving to a room close to the nurses' station, and so on. (Gorman & Sultan, 2008; Maybury, 2008; Valente, 2010).

Key Point: Most of all, never attempt to work with a suicidal patient by yourself. Involve other members of the team immediately.

Toward Evidence-Based Practice

(Study A) Piderman, K., Lapid, M., Stevens, S., et al. (2011). Spiritual well-being and spiritual practices in elderly depressed psychiatric inpatients. *Journal of Pastoral Care & Counseling: JPCC, 65*(1–2), 3–31.

Researchers studied 45 elderly psychiatric inpatients to examine associations among spirituality, depression, and quality of life (QOL). They found that patients with spiritual well-being reported a higher QOL and those with poor spiritual well-being had a higher incidence of depression. During hospitalization, participants with increased spiritual well-being reported peacefulness and reduced hopelessness, worthlessness, and guilt.

(Study B) Judson, P., Dickson, E., Argenta, P., et al. (2011). A prospective, randomized trial of integrative medicine for women with ovarian cancer. *Gynecologic Oncology, 123*(2), 346–350.

This pilot trial evaluated the usefulness of complementary or integrative medicine (CM-IM) in women with ovarian cancer and evaluated its effects on QOL, chemotherapy toxicity, and immunological profiles. Forty-three women with newly diagnosed ovarian cancer requiring chemotherapy were randomized to the experimental group who received hypnosis, therapeutic massage, and healing touch with each cycle of chemotherapy and the control group who received chemotherapy without complementary or integrative therapy.

The researchers concluded that women who received CM-IM demonstrated no improvement in QOL or chemotherapy toxicity.

(Study C) Lin, P. C., Lin, M. L., Huang, L. C., et al. (2011). Music therapy for patients receiving spine surgery. *Journal of Clinical Nursing, 20*(7–8), 960–968.

This study compared the effects of music therapy with a quiet, uninterrupted rest period on pain intensity, anxiety, and physiological parameters after spinal surgery. A total of 60 patients receiving spinal surgery were randomly assigned to listen to selected music from the evening before surgery to the second day after surgery. The control group did not listen to music. Researchers found that patients who listened to music experienced a significant reduction in anxiety and pain, but that there was no effect on blood pressure, heart rate, or cortisol levels. They concluded that patients recovering from spinal surgery may benefit from music therapy.

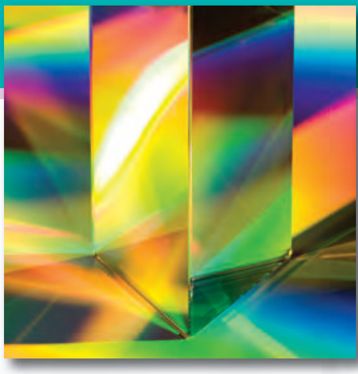
CHAPTER 14



The Family

Learning Outcomes

After completing this chapter, you should be able to:

- Distinguish among different family structures.
- Describe approaches to working with various types of families to provide optimal care to both well and ill clients.
- Explain how family theories provide a framework to understand family functioning.
- Identify family risk factors in five different stages of the family life span.
- Discuss how economic factors influence nursing practice, family care, and access to services.
- Present ways that chronic, life-threatening illness can affect families.
- Identify populations most at risk for homelessness.
- Demonstrate an understanding of family violence.
- Conduct a family assessment.
- Identify common health beliefs and communication patterns among families.
- Identify appropriate nursing interventions when a family member is ill.
- Review how risk factors, such as illness and death, substance abuse, violence, mental health disorders, financial hardship, unemployment, and other issues, can change a family's structure, communication, and coping strategies.
- Discuss the sandwich generation and assessment and intervention strategies for caregiver burnout.

Example Problem

Caregiver role strain

Meet Your Patient

J. B. is an 80-year-old man who is hospitalized for end-stage renal disease. His wife died 4 years ago. His remaining family includes two married daughters and four grandchildren. J. B. has several siblings, but they live far away and rarely phone or visit.

J. B. has lived in the same neighborhood for more than 55 years. When he and his wife, Pamela, first moved into the neighborhood, they lived across the street from Mike and Lena. The two couples socialized, raised their children, and enjoyed many holidays and festivities together. After the children were grown, the two couples sold their homes and each moved into a townhouse near the center of town. They lived next door to each other and continued to spend time together. A year after Pamela died, Mike's wife, Lena, died from liver cancer.

Meet Your Patient (continued)

J. B. and Mike decided to share an apartment to reduce living expenses. They also want the security, support, and companionship that come with a roommate situation. Before starting their daily activities, they like to read the newspaper over breakfast—the local one for J. B. and the national one for Mike. They have season tickets to the baseball games and watch sports together on TV. "Thank goodness we have each other," says Mike. Mike comes to the hospital every morning. He brings both papers and breakfast muffins for J. B., himself, and the nursing unit staff. He spends the day at the hospital and leaves shortly after dinner.

Theoretical Knowledge knowing why

ABOUT THE KEY CONCEPTS

This chapter is about contemporary families and how they differ from those of the past. As you study the chapter, you will begin to see how **family, family nursing,** and other related concepts apply to J. B. and Mike (Meet Your Patient). The key concepts are the basis of the theoretical knowledge to which you will apply the nursing process and your nursing judgment, as you learn to meet the challenges of family health as a full-spectrum nurse.

WHAT IS A FAMILY?

Traditionally, people have thought of a family as consisting of a husband, wife, and their children. However, with increasingly cultural diversity and changes in social traditions and lifestyles, the concept of family has become broader. A family is formally defined as two or more people related by birth, marriage, or adoption residing in the same household (Lofquist, Lugaila, O'Connell, et al., 2012). A more holistic definition of **family** is "two or more individuals who provide physical, emotional, economic, or spiritual support to each other." They may or may not be related by blood, but maintain involvement in each other's lives. Most often, people who consider themselves to be family live in the same household; however, adult children living apart from their parents continue to be part of a family unit, which may also include siblings, aunts, uncles, and cousins. In short, families come in many forms, living arrangements, and emotional connections.

Changes in Family Structures

We continue to see significant changes in the living arrangements of families in the United States as a result of socioeconomic factors, an aging population, cultural influences, increasing average age at first marriage, high divorce rates, improvements in the health and financial status of the older population, and changing residential preferences. Although family householders (the householder, his/her spouse, and children) accounted for 87% of the population, the number of nonfamily households increased 16% from 2000 to 2010. During this time, we also saw an 18% increase in female householders with no spouse, a 31% increase in male householders with no spouse, a 41% increase in unmarried couple households, and an increase in the number of multigenerational households (Lofquist, Lugaila, O'Connell, et al., 2012). Conversely, the number of husband–wife households, in relation to the total number of households, continues to show a downward trend, from 55.2% in 1990 to 48.4% in 2010.

Traditional Families In the past, the majority of American families consisted of married couples with at least one child, the husband in the labor force, and a wife not employed outside the home. U.S. Census Bureau data collected in 2010 show that 20.2% of American households consisted of a husband–wife household with children as compared with 23.5% in 2000. Asian children are more likely to live in a two-parent household (87%), followed by White non-Hispanic (75%). Black children were least likely to live with both parents (37%), followed by Hispanic children (67%) (Kreider & Ellis, 2011). The vast majority of "stay-at-home" parents are still women (5.0 million) while only 154,000 fathers "stay at home" (U.S. Census Bureau, 2012).

Grandparent Families When parents are unable or unwilling to assume the parenting role, grandparents will raise their grandchildren to prevent them from going to foster care or other alternate placement. In households without a parent, 64% of Black, 61% of Hispanics, 55% of White, and 35% of Asian children live with grandparents (Kreider & Ellis, 2011).

Married Adults Without Children Once only a small number in American society, this group now accounts for 28% of households (Lofquist, Lugaila, O'Connell, et al., 2012).

Dual-Earner Families A dual-earner family has both parents in the workforce. Parents of older children (6–11 years) were more likely to have jobs (1.9 million) than parents with younger children under 3 years of age (1.4 million) (U.S. Census, 2012b).

Single-Parent Families Single-parent families result from divorce, from the death of a partner, or from partners who choose not to marry or live together. In 2009, 27% of children lived with one parent. Most single-parent families are headed by women (15.3 million); however, the number of men raising children without a spouse has increased in recent years to 5.8 million in 2010. The percentage of single-parent households in the United States varies among geographic areas and ethnic groups.

Blended and Stepfamilies A **blended family** is established when single parents marry and either or both have children from a previous relationship. The nonbiological partner becomes the stepparent and a stepfamily is created. Blended families can include stepsiblings, half-siblings, or stepparents (Kreider & Ellis, 2011). Commonly, biological parents who are not living together in the child's home alternate the responsibilities and the child will have two mother or father figures (biological and step).

Extended Families In many cultural groups, it is not unusual for extended family members (e.g., grandparents, aunts, uncles, cousins) to live within a single dwelling or in close proximity and be considered immediate family. A less formal view of extended family incorporates close friends and other non-relatives. Consider, for example, the Meet Your Patient scenario. Although J. B.'s siblings are members of his extended family, they do not live with him, and he would not view them as his immediate family because his emotional bond and daily involvement is with Mike.

Sandwich Families The growing number of older adults has created **sandwich families** (Petrovich, 2008; Schumacher, MacNeil, Mobily, et al., 2012), in which middle-aged adults who still have children at home must care for and share their household with aging parents. The more affluent adults (household income > $100,000/year) and Hispanics are more likely to be in sandwich families (Parker & Patten, 2013). Although competent in the caregiver role, they feel personally overwhelmed and emotionally conflicted, but report being as happy as the non-sandwiched families.

Other Family Structures In addition to families bound by marriage and bloodlines, increasingly other family types exist, such as *heterosexual individuals* who may reside in a common household, or *gay and lesbian couples with or without children.* Although *individuals or couples who adopt children* are not biologically related, nonetheless, they are very much a family as they are emotionally attached and participate in the care and experiences in each other's lives. **Cohabiting adults** choose to live together and not marry or live together as a "trial run" prior to marriage. Cohabiting couples who marry have a higher rate of separation than their counterparts who do not live together before marriage, although this trend is declining (Copen, Daniels, Vespa, et al., 2012).

Recall that a family is a group of individuals who provide support and assistance to each other. In the Meet Your Patient scenario, J. B. and Mike are not blood relatives, yet they provide strong support for each other. Many refer to this type of bond as **kith**, persons with a kinship bond. For some people, this bond is stronger than those created through bloodline.

Approaches to Family Nursing

Family nursing refers to nursing care that is holistically directed toward the whole family as well as to individual members (Fig. 14-1). Knowing the family unit is affected by acute or chronic illness, hospitalization, or healthcare interventions, the nurse best cares for the family by involving them in patient care decisions. For J. B. (Meet Your Patient) the nurses would support Mike's daily visits, and Mike is listed on the Health Insurance Portability and Accountability Act (HIPAA) form for communication of patient information. The staff would involve Mike and J. B.'s adult children in his care, discharge planning, and follow-up care at home. They would also teach Mike about J. B.'s medications and treatments so that he can assist J. B. in his activities of daily living (ADLs).

Three perspectives on family nursing include the family as (1) context, (2) unit of care, and (3) system. Family nursing is a specialty; to work with the family as a unit of care or as a system, you may need additional preparation.

Family as the Context for Care As a graduate nurse, you should be prepared to work, at least, with the family

FIGURE 14-1 Family nursing refers to nursing care that is holistically directed toward the whole family as well as to individual members.

as the context for care of an individual person. Your focus in this approach is on the ill individual. From this perspective, you view the family as either a resource or a stressor to your patient. Using this knowledge, you would recognize the importance of J. B.'s friend and roommate, Mike, who is J. B.'s primary source of support. Before discharge, you would ask J. B., "Will Mike or will your daughters be able to help you when you go home?"

Family as the Unit of Care A slightly more complex approach views the family as the unit of care. Wellness of each member is critical to promoting family health. In this approach, you would view the family as the sum of all individual members and provide assessment and care for all family members; however, you might direct interventions to individual family members rather than the family as a whole. For example, you might provide teaching on nutrition and physical activity to all family members to promote their health. Or, to use our earlier example, you might check Mike's blood pressure when he visits J. B.

Family as a System The third perspective is the family as a system. In this approach, you focus on the family as a whole and as an interactional system. Using this perspective, you direct your assessment and intervention to communications and interactions between family members. The systems approach sees the family as embedded in and interacting with a larger community. Using this approach, you might ask, for example, "How has your family's relationship within the senior's group at your townhouse complex changed since your illness?"

KnowledgeCheck 14-1

- What are two topics that the nurse can discuss with the family as a unit?

ThinkLike a Nurse 14-1

- How can you promote family cohesion for a family whose members live great distances from each other?

WHAT THEORIES ARE USEFUL FOR FAMILY CARE?

Several theories have been proposed to help us understand family functioning. Four such theories are general systems theory, structural–functional theories, family interactional theory, and developmental theory.

General Systems Theory

General systems theory (see Chapter 8) focuses on interactions between systems and the changes that result from these interactions. The family is considered an open system because the members function as individuals, are interdependent, and operate as a family unit (a *whole*, in systems language). Interaction can occur between members of the family or between multiple families. Healthy families strive to maintain a balance between external stress and internal relationships.

Changes in the behaviors or attitudes of an individual member affect the family unit, and changes in family structure and functioning affect individual members. It may help to think of a system as a mobile; if one piece of the mobile is moved, that movement sets the whole mobile in motion.

Other systems surround the family unit (e.g., the community, the city, the state, the healthcare system). Because these systems are broader than the family, they are referred to as **suprasystems.** Smaller components that fit within the family system (e.g., the mother, the marital couple) may be viewed as **subsystems.** Each system has a particular function. For example, one family member might be viewed as the decision maker, another as the peacekeeper, and yet another, the worker, and another as the disciplinarian for the children.

Structural–Functional Theories

Structural–functional family theories are based on the developmental theories of Freud, Erikson, and Havighurst (see Chapter 9 for review) and include the concepts of family roles and interactions. According to Parsons and Bales (1955), the structural–functional approach includes the following assumptions:

- A family is a social system with functional requirements.
- A family is a small group possessing certain features common to small groups.
- The family accomplishes functions that serve both the individual and society.
- Individuals act according to internalized norms that are learned through socialization.

Although they view the family as a social system, structural–functional theories, unlike systems theory, focus on *outcome* rather than process. You would use this theory to assess how well the family functions, both internally among family members and externally with outside systems. Examples of family functions include socialization of children; meeting the physical, financial, and emotional needs of family members; caring for older members; and being productive members of society.

Family Interactional Theory

Family interactional theory views the family as a unit of interacting personalities (Hill & Hansen, 1960). The major emphasis is on family roles. This approach to understanding families de-emphasizes the influence of the external world on what occurs within the family. Nurses working from an interactional perspective focus family healthcare on the interaction and communication between family members; their roles and power; family coping; and relationships with other people outside the direct family unit.

Developmental Theories

Developmental theories focus on the stage of family development. Theorists typically identify eight stages in the family life cycle according to the ages of the children and parents: beginning family, childbearing family, family with preschool children, family with school-age children, family with teenagers and young adults, family launching young adults, postparental family, and aging family. Each stage is associated with developmental tasks the family needs to achieve. Most family development theories do not identify stages and tasks for families who remain childless throughout their lives. To learn about developmental tasks associated with family stages, including those for families without children,

Go to Chapter 14, **Assessment Guidelines and Tools, Assessing Family Developmental Tasks,** in Volume 2.

Generally the stages follow one another in a linear progression; however, some families may be in more than one stage at a time or may revert to previous stages. This overlap or reversion is most common in families that have children spaced far apart, in blended families, and in stepfamilies. See Chapter 9 for developmental theories applicable to individual family members.

KnowledgeCheck 14-2

- Which type of theory focuses on interactions among families, family members, and groups in the environment?
- What is the name of the theory that views families as a social system with a focus on outcomes?
- What are some examples of family functions as defined by structural–functional theories?

ThinkLike a Nurse 14-2

- Using systems theory, you could view J. B., his siblings, his children, and his grandchildren as a system. Refer to the section on family structures—how would you categorize this family structurally?
- Again using systems theory, what or who are the subsystems in the family system described in the preceding question?
- Considering J. B. alone, at what developmental stage is his "family"?

WHAT ARE SOME FAMILY HEALTH RISK FACTORS?

Many health risk factors are the same for families as for individuals, and they are similar across age groups and family types. Basically, destructive behaviors remain destructive behaviors, regardless of who is performing them. For a more complete discussion of this topic,

Go to Chapter 14, **Supplemental Materials: What Are Some Family Health Risk Factors?** on Davis*Plus*.

For specific topics as they relate to families, also see Chapters 9 and 10 covering growth and development, Chapter 12 on stress and adaptation, Chapter 19 on teaching clients, and Chapter 21 on communication.

Childless and Childbearing Couples

Adapting to new roles within the home creates stress for newly married couples, couples who are trying to become pregnant, and new parents who are inexperienced in the challenges and responsibilities of raising a healthy, happy, and safe child (Fig. 14-2). Use of maladaptive coping mechanisms can lead to health problems and deterioration in relationships. For example, someone who uses alcohol to deal with stress is at risk for addiction, self-injury, and liver disease, and the family may possibly suffer the harmful effects of neglect and family violence. In addition to health risks related to pregnancy (e.g., miscarriage), abuse of alcohol could lead to congenital malformations and genetic defects in the child.

Families With Young Children

Finding safe, nurturing, and affordable childcare can be a major source of family stress for parents working outside the home. Common parenting concerns center on the child's development, socialization, education, discipline, nutrition, sleeping, toileting, and safety. In addition, the demands of work and child rearing mean less time is available to nurture the couple's relationship, leaving them at increased risk for marital discord.

FIGURE 14-2 Newly married couples, couples who are trying to become pregnant, and new parents are vulnerable to stress as they adapt to new roles.

Injuries and illness create risks to family health. For example, those receiving group childcare or attending school are exposed to other children who might have contagious diseases that can spread to other family members. To reduce the risk for serious infectious diseases (e.g., mumps or hepatitis B), parents need to be aware of the importance of adhering to the recommended childhood immunization schedule. Research shows that the percentage of parents who refuse immunizations for their children continues to increase each year. Parents report various concerns, including personal perceptions and healthcare system issues (Luthy, Beckstrand, Callister, et al., 2012). For families who live with a chronic illness (e.g., asthma or type 1 diabetes) or a developmental or learning disability (e.g., autism), the stress related to compromised health, falling behind in school, financial burdens, and even day-to-day living can become overwhelming.

Families With Adolescents

Families with adolescents are often concerned about teen risk-taking behaviors. Some specific risk-taking behaviors include using tobacco, alcohol, and other illicit drugs; engaging in extreme stunts and accepting dares; rebelling against authority; and being sexually promiscuous.

Adolescents may participate in risky behaviors to impress others, to feel cool or important, or to experience a feeling of power. Developmentally, adolescents typically do not feel the threat of real danger. Other contributing factors include family expectations of not completing school and being in a large family (Homer, Rew, & Brown, 2012).

Families with adolescents may also be dealing with aging parents or grandparents (Fig. 14-3). Parents may become "sandwiched" between the needs of the growing adolescents and the needs of their aging parents. Women are particularly at risk for stress in these situations because they are usually the ones who provide the additional care for older relatives.

FIGURE 14-3 In families with adolescents or young adults, the parents may become "sandwiched" between the needs of the growing adolescents and the needs of their own parents.

Families With Young Adults

Young adults commonly move out of the parental home as their school years end, taking on full-time jobs, many for the first time. This is a time when many marry and begin childbearing and rearing. Some confront such problems as tight finances, inability to find meaningful work, nontherapeutic personal relationships, or other life challenges.

Financial strain might influence a young adult, alone or with a newly formed family, to move back with his parents until he can "get back on his feet." This return to the nest, although sensible, can nonetheless be a stress on the family. Role strain and poor communication are common. Although young adults returning to the home of origin can represent a new opportunity for family attachment, the presence of another person in the household commonly changes family dynamics.

Not every transition is a permanent accomplishment or marker of social success. Newly found autonomy and independence is exhilarating for some and anxiety-provoking for others. The boundary between adolescence and adulthood is blurred by societal forces (e.g., a contracting economy, changing labor force expectations, and expanding opportunities for women). As this continues, roles within the family will evolve and families will need to find healthy ways to adapt.

Families With Middle-Aged Adults

The middle years are a time of examining life goals and coping with aging and the empty nest. This can be a satisfying time of role fulfillment, career success, financial security, and social comfort. The quality of the spousal relationship might take on a new importance. The middle-aged adult may experience a new sense of freedom and need for self-exploration and personal growth. Without the time demands of raising children, adults have more time available to pursue other personal interests or professional paths.

The middle years can also be a time of self-doubt triggered by the changes of aging, menopause, an empty nest, care or death of parents, heightened career demands, or change in career life or relationships, all of which can cause emotional strain. Some adults suffer a **mid-life crisis**, which is a period of intense questioning about the meaning and direction in life, asking what brings personal fulfillment. Adults battling mid-life crisis might display signs of depression, anxiety, or rebellion from the status quo.

The effects of long-standing unhealthy behaviors often become apparent in middle adulthood. For example, people who have used tobacco for many years may now begin to notice an increase in cough and chest congestion or those who have consumed high-fat diets may develop high blood pressure or elevated cholesterol levels. Remember, individual health impacts family health.

Families With Older Adults

Falls and trauma are a common health risk for families with older adults. For more information about this, see Chapters 10 and 24. Older adults are also at risk for social isolation and loneliness because of the loss of relationships that occurs with aging. Family dynamics change as the older person copes with the death of a spouse, sibling, friends, or other loved ones. Loss and grief can deeply affect an elderly person's quality of life, clarity of thinking, and physical and emotional well-being. Families should maintain frequent contact and communications to offset feelings of isolation and loneliness.

Although retirement can bring the simpler life that many people desire, retired individuals must deal with the loss of daily contact with colleagues in the workplace and, for some, a reduced sense of responsibility or purpose. Friends can be a significant source of support (Fig. 14-4), but functional losses may cause the person to limit physical activity, volunteer work, church attendance, and other social activities. Elderly adults have an increased risk for depression.

Maintaining good nutrition and hydration becomes more difficult as a person ages, particularly for the frail elderly. The following are situations that may compromise the nutrition of older adults:

- Forgetting to eat (especially those who live alone)
- Inadequate or unreliable transportation to shop for food
- Lack of money to buy food
- Physical changes that alter taste (e.g., reduced sensitivity in the taste buds and less saliva for taste and swallowing)
- Loss of appetite
- Poorly fitting dentures
- For more information about nutrition, see Chapter 27.

Memory and problem-solving abilities change with aging. Forgetfulness and confusion can pose risks to safety for older adults, particularly for those living alone or with other aging adults whose mental status is compromised. When older adults, and especially frail elderly, lose their ability to reason, they are vulnerable to physical harm. The demands of keeping the aging adult safe can lead to caregiver role strain and family stress.

It is easy to understand from the above scenarios the cascading effect that one deficit, such as lack of transportation, can have on the health of an older adult and her family. Be sure to educate them about the availability of community resources, such as Meals on Wheels and home health aides, as many may not be aware that help is available.

FIGURE 14-4 Friends play an important role in the support system of older people.

ThinkLike a Nurse 14-3

- What developmental stage is your family in? How do you know?
- What basic attitudes, values, or beliefs influenced you in your childhood family?
- How were decisions made in your childhood family? Were people's feelings and individuals' needs considered?
- Can you remember good times and laughter that bonded you together as a family? In your present family life, how often do you laugh together?
- In the Meet Your Patient scenario, what health risks do J. B. and Mike face, considering their age and health?

WHAT ARE SOME CHALLENGES TO FAMILY HEALTH?

We have already mentioned the effects of some demographic changes, such as an aging population, on families. This section examines other regional and national trends that affect families.

Poverty and Unemployment

When the economy takes a downturn, families may struggle to provide for basic needs (e.g., food and shelter) and healthcare. In 2010, 50.0 million people in the United States did not have health insurance (DeNavas-Wall, Proctor, & Smith, 2012). The Affordable Care Act, passed in 2010, has provisions to provide healthcare coverage for people who cannot obtain private or employment-funded insurance. In 2011, however, the number of uninsured people decreased to 48.6 million. Seven million children under age 18 did not have health insurance. Children in poverty had an uninsured rate of 13.8% compared with 9.4% for all children.

Families with no or inadequate health insurance do not seek preventive medical care and often come to the emergency room with acute medical conditions.

Teenage pregnancy is strongly associated with poverty, unemployment, and health risks. While teen birth rates declined in 2009, and again in 2011 (to 329,797), they still remain higher than in other developed countries (Centers for Disease Control and Prevention [CDC], 2010, updated 2012, November 21; Pazol, Warner, Gavin, et al., 2011). Infants born to teen mothers are more likely to have health problems at birth as a result of numerous factors, including late or no prenatal care. Thirty-four percent of pregnant females under age 20 failed to obtain first-trimester prenatal care compared with 28% of women between the ages of 20 and 24. In addition to the economic costs ($11 billion in 2008), teenage mothers have greater health disparities, are more likely to drop out of schools, have high unemployment rates, and their children have higher involvement in the juvenile justice system. Because of the numerous and long-lasting problems associated with teenage pregnancy, the CDC has partnered with the federal Office of the Assistant Secretary for Health (OASH) to launch a campaign aimed at reducing teenage pregnancy and addressing health disparities in teen pregnancy and birth rates (CDC, 2010, updated 2012, November 21).

Families in all socioeconomic levels can experience difficulties in an economic downturn, especially those with low reserves. Single-parent and low-income families are hardest hit. Most people who are living at or below the federal poverty level are workers with minimum-wage or seasonal jobs. In a sluggish economy, nonessential jobs may be eliminated; and many sectors of business and service suffer. This means that not only family income is compromised, but also, on a larger level, fewer workers are paying taxes. Thus, government programs supporting families in need may be underfunded. Although some people find creative solutions to family poverty (e.g., a woman who is laid off assumes childcare for another family whose members remain employed), many families experience extreme hardships when the economy is suffering.

Middle-income families are also affected by corporate downsizing or stock market fluctuations. Both skilled and unskilled laborers suffer when consumer spending and housing economies decline. Even families who were living in seeming prosperity may not have sufficient funds to cover a period of unemployment or economic recession. Many people in the United States carry significant credit card debt, a first and possibly second mortgage, car payments, a variety of insurance premiums, and perhaps school or other loans.

KnowledgeCheck 14-3

- Which socioeconomic group of families is hardest hit during poor economic periods?
- How are middle-income families affected by poor economic times?
- What concerns are associated with teenage pregnancies?

Infectious Diseases

Family health may be affected by any number of new or resistant pathogens, such as severe acute respiratory syndrome (SARS), methicillin-resistant *Staphylococcus aureus* (MRSA), West Nile virus, and H1N1 virus. The 2009 H1N1, also called swine flu, caused illness in humans, especially young children, pregnant women, people 65 years and older, and those with certain chronic diseases. Influenza A (H3N2), 2009 H1N1, and influenza B viruses were associated with the 2012–2013 seasonal flu, which caused widespread illnesses and several deaths in persons across the lifespan (CDC, 2012).

HIV infection is a devastating event that significantly impacts the family. In addition to the obvious physical and financial stressors, women who infect their infants and partners who infect the other partner with HIV bear a tremendous burden of guilt. The populations at highest risk for contracting HIV are men who have sex with men (whites, blacks, and Hispanics), followed by heterosexual black women, black males, Hispanic women, and white women (Prejean, Song, Hernandez, et al., 2011). When compared with their white counterparts, the number of new HIV cases is seven times higher for black males and 20 times higher for black females (CDC, n.d.). Some families keep the diagnosis a secret and blame each other, whereas other families support each other and manage the illness as best they can.

Advances in treating HIV infection and preventing its spread have been made through public and patient education, vaccination, antiviral therapy, and other antimicrobial treatments for HIV-related complications. The nurse should emphasize the use of proper protective precautions to minimize the spread of the disease.

Even "old" diseases, once thought to be eradicated, can threaten family health. In recent years, diseases once controlled by immunization are making a comeback (e.g., pertussis [whooping cough], polio, mumps, and smallpox). Many families either refuse or fail to comply with immunizations schedules. As a result, *herd immunity* is reduced. The outcome is high physical, social, and economic costs from illness, absent schooldays or workdays, doctor and hospital visits, and even premature deaths (CDC, 2007, updated 2012, November 21).

KnowledgeCheck 14-4

- What gender groups are experiencing the fastest rate of growth in new HIV cases?
- Name two previously eradicated diseases that have become a threat again.

Chronic Illness and Disability

Chronic illness and disability profoundly change the way families function. Family members' roles evolve over time, especially for the caregiver. Many people with chronic illness and disability require assistance with ADLs, such as getting around the home, feeding, bathing, dressing, toileting, and getting in and out of a chair or bed. Many are not able to work or generate family income, often creating financial strain or poverty. Long-term illness and disability cause mental, emotional, or physical limitations that affect family communication patterns. In addition, relationships within the family may be difficult due to caregiver strain and issues related to dependency. Long-term care of a family member may increase the risk for abuse and neglect, including maltreatment of frail elderly family members.

The Americans with Disabilities Act (ADA) Amendments Act of 2008 defines one component of disability as a physical or mental impairment that substantially interferes with a person's ability to engage in major life activities (U.S. Equal Opportunity Commission, 2008). Individuals have a disability if they meet criteria involving limitations in mobility/ambulation, hearing, vision, learning, cognitive, self-care, or independent living, to name a few. In the United States:

- 38 million (12%) of noninstitutionalized people reported one or more disabilities in 2011.
- The prevalence of disability was lowest for children under age 5 years (0.8%) and highest for those 65 years and older (36.8%).
- 6.5 million (32.6%) of noninstitutionalized people with disabilities were employed.
- The poverty rate was 31% for persons with a work disability, 28.8 % for those with a broad disability, and 28.6% for persons with both work and broad disabilities.
- Among the various types of disabilities, 10.2 million were people with ambulatory disabilities while the lowest group was those with vision disability at 3.5 million (1.8%) (Rehabilitation Research and Training, 2012).

Disabilities and other mobility limitations can lead to poor health outcomes in older adults because of limited ability to access needed resources such as fresh food and medical care. It is essential that nurses collaborate with social work/case management to ensure that older adults have the resources needed to remain independent as long as possible. Independence is associated with better long-term health outcomes.

Homelessness

Homelessness is a growing problem in many U.S. cities, not only for individuals but for also for families. Many homeless people sleep on the streets, although others live temporarily with relatives or in mission shelters. Homelessness is far more complex than lack of housing. This problem might be explained by a number of factors, such as financial crises, socially dysfunctional relationships, unemployment, lack of job skills, substance abuse, healthcare expenses, or the inability or lack of desire to live within the socially accepted norms of society. In the United States, deep poverty and homelessness often result from mental illness, disability, or misfortune.

Homeless families are often socially isolated. Many homeless children do not attend school, and those who do tend to perform poorly. Often, homeless families do not seek care for significant health problems, primarily because they don't know how to access the healthcare system and qualify for healthcare services. Homelessness threatens family relationship and emotional and physical health. The focus is on meeting basic needs of food and shelter, which according to Maslow's Hierarchy of Needs theory (Chapter 4), must be met before the family can grow.

Single women, members of minority groups, and single-parent families are particularly vulnerable to homelessness and poverty (Fig. 14-5). It is not uncommon for divorced women to end up with less income than their ex-husbands. In addition, many women also might have sole custody of their children, which creates additional expenses for them. In many states, social service departments are underfunded and unable to enforce child support laws. Some biological fathers struggle to pay child support while maintaining their own living expenses. Others may be incarcerated or their whereabouts unknown.

Violence and Neglect Within Families

Domestic violence—including physical, emotional, and sexual abuse—occurs throughout all strata of our society, among all racial, social, and economic groups. As many as one in every four women will be a victim of violence during her lifetime, and more than 3 million children each year are reported to child protective services agencies as alleged abuse victims. The National Child Abuse and Neglect Data Systems reported that 676,569 children were victims of child abuse and neglect in 2011, which represents 9.1 victims per 1,000 children (Children's Bureau, 2012). Race and ethnic data showed that 43.9% of victims were white, followed by Hispanics (22.1%) and African Americans (21.5%). The highest rate of victimization occurred in younger children (21.2%). The majority of the child victims were neglected (78.5%), followed by physical abuse (17.6%) and sexual abuse (9.1%). Children ages 12 to 14 had the highest percentage of sexual abuse (26.3%), followed by ages 15 to 17 (21.8%), and 9 to 11 (18.5%). Children age 2 and

FIGURE 14-5 Many homeless people are single women and children.

younger were the most frequent victims of fatalities (73.8%) from abuse and neglect (Children's Bureau, 2012). These children are the most vulnerable for many reasons, including their dependency, small size, and inability to defend themselves.

Any type of violence is likely to have long-lasting effects on the victims and on the family. It may result in the disintegration of the family relationships and structure (e.g., sending the children to foster care, escaping to a battered women's shelter, living with others). Health issues related to domestic violence include physical injury from the assault itself, as well as chronic health problems that emerge either as a complication of traumatic injury or as a physical response to the ongoing stress from violence or neglect. Families experiencing domestic violence have more unintended pregnancies, miscarriages, abortions, and low-birth-weight babies. They also have more sexually transmitted infections and higher rates of depression, post-traumatic stress syndrome, substance abuse, and suicide. And even though the emotional and physical pain may stop when the victim leaves the family environment, often there are long-term effects involving emotional injury, marred self-esteem, or poor-quality relationships. Victims of family violence learn patterns of ineffective coping that can be repeated in successive generations.

KnowledgeCheck 14-5

- Name two causes of homelessness.
- Name two groups of individuals who are vulnerable to homelessness.
- Name two types of violence.
- Among children, which age group is the most vulnerable to abuse and neglect?
- Describe the effects of family violence that generally endure after the physical injury has healed.

PracticalKnowledge knowing how

A holistic view of family health integrates the biological, social, cultural, and spiritual aspects of life and refers to individual members as well as the whole family. Nurses play a vital role in promoting family wellness across the life span. When working with families, you will encourage them to take responsibility for their own family health. Your interactions with families can empower them to practice behaviors that will aid in healing and maintaining good health.

ASSESSMENT

Health assessment for the family is similar to that for individuals. Gather all essential assessment information for each family member. Ensuring family privacy is essential for obtaining an accurate and comprehensive family health assessment. (See Chapter 22 for additional information on physical assessment.) In addition to the individual factors, assess the health of the family unit. For an example of a family assessment form used by a community health agency,

Go to Chapter 14, **Tables, Boxes, Figures: ESG Figure 14-1,** on Davis*Plus*.

In general, a family assessment should include the following:

- Relevant medical data, social and family history for individuals within the family
- Family composition
- Family genogram showing health issues
- Family history and developmental stage
- Description of the home environment and surroundings
- Family structure, including communication patterns and power and role structures
- Family functions
- Health beliefs, values, and behaviors
- Family strengths
- Family stressors and coping
- Abuse and violence within the family. To see an abuse assessment,

Go to Chapter 9, **Procedure 9-1: Assessing for Abuse,** in Volume 2.

For a more complete description of the context of a family assessment,

Go to Chapter 14, **Clinical Insights 14-1: Conducting a Family Assessment,** and the assessment tool, **Assessing Family Developmental Tasks,** in Volume 2.

The following sections discuss in more detail the assessment of family health beliefs, communication patterns, coping processes, and caregiver role strain.

Assessing the Family's Health History

The family history can provide clues about a person's health and susceptibility for disease. Genetic linkages have been discovered for common, complex diseases, such as breast cancer, Alzheimer's' disease, diabetes, macular degeneration, seizures, inflammatory bowel disease, lupus, and heart disease, to name a few.

Genomics is the study of human genes and their function, including the interactions among other genes and the environment. Simply said, it is about the interplay between a person's genetic makeup, and food and environmental factors such as lifestyle and stress.

How Can Genomics Be Useful? Genomics can be used to personalize a patient's plan of care by:

- Identifying at-risk individuals for certain conditions so more effective preventive care can be provided
- More accurately detecting illness, even before symptoms appear

- Tailoring healthcare to the individual, while reducing a trial-and-error approach
- Evaluating a person's response to the care, considering multiple factors

Genomics helps us to understand how people respond differently to particular drugs and medical treatments. For example, one client with a genetic predisposition for high cholesterol can benefit from a change in diet and exercise to decrease the likelihood that the genetic risk will be expressed. Another person may not respond to lifestyle measures and require cholesterol-reducing drugs.

How Is a Genogram Constructed? When assessing the family history, you can use a pictorial tool, called a **genogram**, to display the relationship of family members with pertinent health-related information (Fig. 14-6). This type of family tree can provide a quick and useful context in which to evaluate an individual's health risks.

To construct a genogram, you will note the causes of death, genetically linked diseases, and other important health problems. Use a three-generation (or more) genogram to also show environmental (e.g., toxin) and mental health issues (e.g., depression, alcohol abuse, suicide), occupational diseases (e.g., asbestos), infections (e.g., MRSA), and obesity among family members. When developing a genogram, use symbols and abbreviations to denote family members, including a key for interpretation (Box 14-1).

Assessing the Family's Health Beliefs

Health beliefs can vary widely among families and among individuals within families. The differences can be especially great among different generations of a family (e.g., between grandparents and their grandchildren). Some common health beliefs are expressed in such adages as "An apple a day keeps the doctor away," "Doctor knows best," and "Feed a cold, starve a fever." Some families may have an intense skepticism or mistrust of medical care and hospitals and may seek treatment only when absolutely necessary (e.g., when the pain becomes unbearable). Many of these beliefs are passed on from generation to generation.

Even if one family member does not share all of the beliefs of the family, you need to be aware of the family's beliefs because they may influence the individual's decision making. To illustrate this point, consider a family caring for a member who is frail elderly, confused, and immobile. Suppose one family member believes quality of life issues are more important than quantity. Yet another family member who is giving care has a fundamental disagreement with this belief and supports the right of the older adult to receive whatever care is needed for physical safety, emotional fulfillment, and

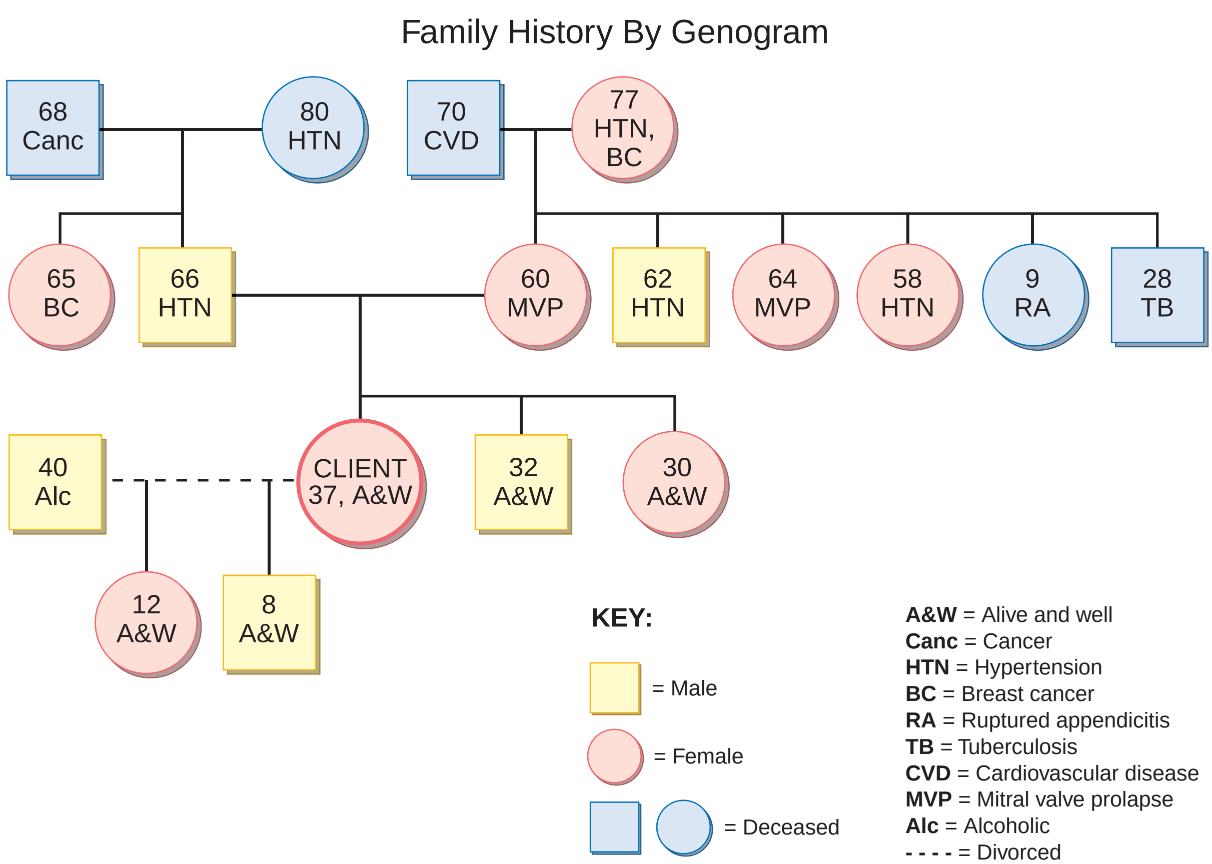

FIGURE 14-6 Family history by genogram.

BOX 14-1 ■ Family History by Listing Family Members

The following history is for a 37-year-old female patient.
Patient: Age 37, alive and well
Spouse: Age 40, divorced, alcoholism
Daughter: Age 12, alive and well
Son: Age 8, alive and well
Brother: Age 32, alive and well
Sister: Age 30, alive and well
Father: Age 66, hypertension (HTN)
Mother: Age 60, mitral valve prolapse (MVP)
Paternal aunt: Age 65, breast cancer
Maternal uncle: Age 62, HTN
Maternal uncle: Deceased age 28, tuberculosis (TB)
Maternal aunt: Age 64, MVP
Maternal aunt: Age 58, HTN
Maternal aunt: Deceased age 9, ruptured appendix
Paternal grandfather: Deceased age 68, cancer
Paternal grandmother: Age 80, HTN
Maternal grandmother: Age 77, HTN, breast cancer
Maternal grandfather: Deceased age 70, cardiovascular disease (CVD)

spiritual well-being for any length of time. In a situation like this, the family is at risk for interpersonal conflict, impaired communication, and caregiver strain. If you would like more information on health beliefs, see Chapter 42.

ThinkLike a Nurse 14-4

- As a nurse, how can you promote overall wellness in a family with a critically ill member?
- What health beliefs would you ask J. B.'s family about?

Assessing the Family's Communication Patterns

To assess family communication patterns, you will need to interview the family and also carefully observe the interactions between family members. Try to uncover the following information:

- Who is the primary decision maker in the family?
- How are family decisions made: by one individual or by family conference?
- What is the most frequent type of communication among family members (e.g., visits to the home, telephone, texting, e-mail)?

Family members who participate in dysfunctional communication patterns may not come to scheduled family meetings and may not be present during the initial interview. Additionally, when relationships among family members are strained or dysfunctional, they may distort the information they provide about a home situation or another family member.

Key Point: ***Do not rely solely on the information provided by the family members during the interview process. Families usually want to "put on the best face" for healthcare providers, so they may be careful to give socially desirable responses. Carefully observe the words people use and other cues involved in communication, such as body language, direct eye contact, and other nonverbal expressions, particularly among family members.***

PICOT

Alcohol Treatment and Family Support

Situation: The nurse is meeting with a family prior to the discharge of the husband/father from alcohol treatment. The teenage daughter asks the nurse whether her father will ever drink again.

PICOT Components:

P Population/client	=	Alcoholic adults
I Intervention/indicator	=	Family Support
C Comparator/control	=	No family support
O Outcome	=	Decreased risk of relapse
T Time	=	Over time

Searchable Question: Do __________ (P) who receive/are exposed to __________ (I) demonstrate__________ (O) as compared to __________ (C) during __________ (T)?

Example of Evidence: Alcohol abuse is a common social, family, and individual health problem. Inpatient alcohol treatment has been a common solution. Research indicates that clients who spend more time in treatment and subsequent time in an abstinence-related group home, as well as having overall family support are less likely to relapse. Family support did not need to be alcohol related; rather, support for the client in general was shown to have a positive effect on the client's sustained sobriety.

Practice Change: The nurse made certain to assess family relationships and support for this and future clients.

Reference: Groh, D., Jason, L., Davis, M., et al. (2007). Friends, family, and alcohol abuse: An examination of general and alcohol-specific social support. *American Journal on Addictions*, *16*(1), 49–55. doi:10.1080/10550490601080084

Assessing the Family's Coping Processes

The physiological manifestations of stress (e.g., anxiety, increased pulse rate) may decrease the effectiveness of interventions and negatively affect a client's health. Family members who are not coping effectively may cause the client to become stressed or anxious or have problems sleeping. Assessing family coping is a first step to helping the family develop more effective coping patterns. Observe for physical indications of stress, anxiety, or loss of sleep in the client and for relationships and communication patterns among family members. As a nurse, you can assess whether family members are irritable and "snap at" (speak harshly or curtly to) one another. Pay attention to who is visiting. Family members who are not coping well may avoid coming to visit the patient, so this may be an indicator of who is coping and who is not.

KnowledgeCheck 14-6

- Why is it important for you to ask about family health beliefs?
- What factors may impede a family's ability to cope with an individual's illness?
- What is the significance of a genogram?

Assessing for Caregiver Role Strain

Conflicts between caregiving and other responsibilities can produce tremendous family stress. The physical, emotional, and time demands involved in caring for family members who are chronically ill, disabled, or frail can create difficulties among family members and compromise relationships. Financial stress can also be a factor in family functioning. When these stressors add up, family caregivers might suffer from what NANDA-I terms Caregiver Role Strain. This is present when a person has difficulty in performing adequately in the family caregiver role.

To assess for caregiver burnout, observe for dysfunctional communication, such as abusive language and aggression. Look for physical injury to the patient, which may occur when caregivers are overwhelmed and overstressed. Alternatively, you might see the caregiver withdrawing emotionally, which could result in emotional neglect and isolation. Caregivers experiencing role strain might exhibit emotional distress, including depressive symptoms and apathy.

ANALYSIS/NURSING DIAGNOSIS

Recall in the diagnostic process you must analyze the data for cues (data that deviate from norms). Therefore, you should be familiar with the characteristics of a healthy family so you can use them as your basis for comparison (Box 14-2). For individual family members, of course, any NANDA-I diagnosis may be appropriate for describing a client's health status. **Family diagnoses**, however, are meant to describe the health status of the family as a whole. The following are examples:

Caregiver Role Strain (actual and risk for)
Family Coping: Compromised
Family Coping: Disabled
Dysfunctional Family Processes
Impaired Home Maintenance
Impaired Parenting (actual and risk for)
Ineffective Family Therapeutic Regimen Management
Ineffective Role Performance
Interrupted Family Processes
Readiness for Enhanced Family Coping

BOX 14-2 ■ Characteristics of a Healthy Family

A healthy family requires more than merely the absence of family dysfunction or disease in an individual member. Characteristics of a healthy family are listed, following:

State of family well-being
Sense of belonging and connectedness
Clear boundaries between family members where the responsibilities of adults are clear and separate from responsibilities of growing children
Sense of trust and respect
Honesty and freedom of expression, including different opinions or viewpoints
Spending time together, sharing rituals and traditions
Relaxed body language, physical touch, and frequent eye contact
Flexibility: adaptability and ability to deal with stress, openness to change
Commitment: working together to maintain the family
Spiritual well-being
Respect for privacy of individual members
Balance of giving and receiving
Positive, effective communication
Accountability, including acceptance when mistakes are made
Appreciation and affection for each other
Responding to the needs and interests of all members
Health-promoting lifestyle of individual members

Readiness for Enhanced Parenting
Relocation Stress Syndrome
Risk for Impaired Attachment
Social Isolation

For standardized definitions and terminology to describe nursing diagnoses, outcomes, and interventions for families,

Go to Chapter 14, **Standardized Language, NOC Family Health Outcomes,** and **NIC Family Interventions,** on Davis*Plus*.

PLANNING OUTCOMES AND EVALUATION

NOC outcomes specifically for families as units are found in the NOC domain Family Health, which includes the classes Family Coping, Family Health Status, Family Integrity, and Parenting Performance. Outcomes from other domains may apply as well, depending on the nursing diagnosis you have made. You will find these on Davis*Plus*, as mentioned just above.

Individualized goals/outcome statements you might write for a family include the following examples, which represent some of the traits of healthy families in Box 14-2. The family:

Teaches respect for others within and outside the family.

Observes rituals and traditions (e.g., celebrates birthdays).
Respects the privacy of each member.
Communicates effectively and openly.

Remember the outcomes you develop for the care plan serve as the criteria for evaluating your patient's responses to nursing interventions.

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC interventions for families as units are found in the NIC domain Family Integrity Promotion, which includes the classes for the Childbearing Family. Interventions from other domains may apply as well, depending on the nursing diagnosis you have made. You will find NIC family interventions on Davis*Plus,* as mentioned above.

Individualized nursing actions you might use with families include the following examples (other interventions are described in succeeding sections):

- Collaborate with family in problem solving and decision making.
- Refer the family to support groups of other families dealing with similar problems.
- Monitor current family relationships.
- Assist with family with conflict resolution.
- Encourage family to maintain positive relationships.
- Establish trusting relationship with family members.
- Counsel family members on additional effective coping skills for their own use.
- Refer for family therapy, as indicated.
- Tell family members it is safe and acceptable to use typical expression of affection when in a hospital setting.
- Encourage family members to verbalize their concerns, fears, and perceptions.

Promoting Family Wellness

Encouraging families to value and incorporate health promotion into their lifestyles will also affect the health of individual members. Health-promotion behaviors are typically learned within the family. You can promote family wellness by addressing both individual and family needs. It is important to identify both strengths and basic weaknesses of the family to adequately meet healthcare needs.

Involving the family in each phase of the nursing process promotes positive health outcomes and helps establish trust between you and the family. Wellness interventions may include contracting, health teaching, anticipatory guidance, and promoting family cohesion during a crisis (e.g., hospitalization of a family member). For specific health promotion activities, see Chapter 42.

Toward Evidence-Based Practice

Backhouse, J., & Graham, A. (2012). Grandparents raising grandchildren: Negotiating the complexities of role-identity conflict. *Child & Family Social Work, 17*(3), 306–315.

A qualitative study was conducted to identify common themes from the experiences of 27 grandmothers and 7 grandfathers who were raising their grandchildren ranging in ages from 1 to 17 years. Some of the pain and challenges described by the subjects were feelings of grief and loss regarding their children's situations, emotional and financial costs of dealing with the legal and welfare systems, inability to meet the physical activity needs of their grandchildren, and the thought of dying before the grandchildren reached adulthood. Nevertheless, the positive experiences dominated the relationships. These included the emotional bond and attachment with the grandchildren, the satisfaction of providing them with security and stability, and having more tolerance and patience with child raising experiences.

Conway, F. (2011). Emotional strain in caregiving among African American grandmothers raising their grandchildren. *Journal of Women & Aging, 23*(2), 113–128.

Researchers examined the emotional and role strain experienced by 88 African American grandmothers, ages 33 to 88, who were raising their grandchildren. Results showed that younger grandmothers experienced more emotional and caregiving strain than their older counterparts. In addition, unmarried grandmothers had more emotional and caregiving strain than married grandmothers.

Huges, M. E., Waite, L. J., LaPierre, T. A., et al. (2007). All in the family: The impact of caring for grandchildren on grandparents' health. *The Journals of Gerontology Series B: Psychological Sciences and Social Sciences, 62*, S108–S119.

Researchers were interested in knowing the effects of caring for grandchildren on the physical and psychological health of older adults. Using a sample of 12,872 grandparents ages 50 through 80, researchers found no evidence that caring for grandchildren negatively affects grandparents' health and mental well-being. In contrast, grandparents who babysit had higher levels of physical health and emotional benefits. Only a small number of grandparents may have had their health compromised by having children in the home, likely the result of infections. The findings were different when parental involvement was low: Grandmothers were more likely to experience poor health behaviors, depression, and lower self-rating of overall health. The study highlights the benefits of grandparents caring for their grandchildren.

1. Based on this research, if you were the nurse, what kinds of information would you want to gather from families in which grandparents provided custodial care to grandchildren?

2. What ways can you think of to support grandparents who assume major roles in rearing grandchildren?

Interventions When a Family Member Is Ill

When a family member is ill or hospitalized, the other family members experience a range of emotions—especially when the illness is severe or of sudden onset. Family members may display signs of stress in a variety of ways, for example, by arguing with each other or with healthcare providers, by insisting on immediate care for their loved one, by avoiding the client's room, by being critical of the care provided, or by frequently asking that information be repeated. These are normal reactions; do not take them personally.

The patient and family need to understand the medical diagnosis, the plan of care, and the recovery process. In addition, it is often the nurse who provides extensive discharge instructions to the client and family before they leave the hospital. For interventions to help the family members manage stress when a family member is ill, see Box 14-3.

Interventions for Caregiver Role Strain

Interventions specific to caregiver role strain center include the following:

- Assessing the caregiver for degree of impaired functioning (e.g., difficult sleeping, weight loss)
- Assessing for safety issues that exist for the care receiver
- Identifying causes of caregiver strain (e.g., lack of knowledge, frail client with around-the-clock care needs, complex treatments, or conflicts between caregiver and care receiver)
- Helping the caregiver to identify and express feelings, including negative ones (e.g., by use of statements such as "This must be hard for you." Or, "I hear you saying you feel angry and confused.")
- Supporting the caregiver's ability to manage the situation (e.g., by helping identify community supports, finding someone to share housekeeping activities)
- Providing information about and demonstrating caregiving skills and techniques (e.g., dealing with the client's pain)

For a list of NIC interventions for Caregiver Role Strain,

Go to Chapter 14, **Standardized Language, NOC Outcomes and NIC Interventions,** in Volume 2.

BOX 14-3 ■ Interventions to Help the Family Coping With Hospitalization

- Provide written materials explaining the client's diagnosis or condition.
- Actively involve the family in team meetings.
- Promptly follow up with family concerns or questions.
- Encourage the family to go home and rest.
- Encourage the family to call for updates when they cannot be present.
- Suggest ideas for stress-reducing activities (e.g., walking, meditating).
- Inform the family about on-site availability of a chaplain or chapel.
- Encourage the family to participate in care activities as appropriate.
- Keep the family informed of the client's progress.
- Help the family to identify sources of stress and develop strategies to work through and dissolve the root cause.
- Provide anticipatory guidance regarding outcome and expectations for discharge.

Interventions When There Is a Death in the Family

Death of a close family member is one of the most devastating life experiences. A family needs sensitive and compassionate care during this time, and such care is an appropriate focus for family-centered nursing. Interventions include facilitating the grieving process, encouraging communication, providing spiritual support, and providing compassionate care of the body after death. For more in-depth information about care of the family of a dying patient, see Chapter 17.

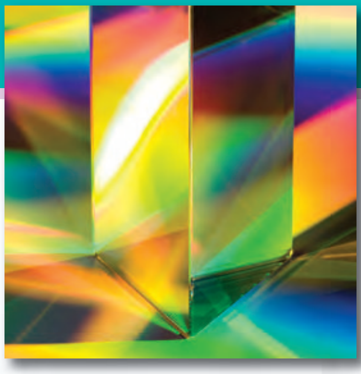
CHAPTER 15



Culture & Ethnicity

Learning Outcomes

After completing this chapter, you should be able to:

- Explain why cultural competence is important for nurses.
- Explain what is meant by *culture* and *acculturation*.
- Discuss concepts pertaining to cultural diversity in nursing.
- Identify vulnerable populations in the United States.
- Define and give an example of culture universals and of culture specifics.
- Differentiate between cultural archetypes and cultural stereotypes.
- Describe the culture of the North American healthcare system, including professional subcultures.
- Identify the phenomena of culture, including how they can affect the nursing care needs of clients and families.
- Discuss the differing views of culturally diverse clients, including biomedical, holistic, and alternative health systems, such as folk medicine.
- Explain guidelines for performing a transcultural assessment, including a cultural assessment model.
- Recognize the cultural implications inherent in nursing diagnoses.
- Describe nursing strategies that promote delivery of culturally competent care to clients and their families.
- State some techniques for communicating with clients when there is a language barrier.

Key Concepts

Culture

Cultural competence

See the Concept Map on Davis*Plus*.

Meet Your Patients

Your clinical assignment is to spend the day in a walk-in clinic with a primary care provider. Your initial job is to greet the clients and help them complete a health history form. These are the first patients you greet:

- Romano Salvatore points to his head and moans. When you ask him what is wrong, he makes a gesture to convey to you that he does not understand what you are saying. He speaks a foreign language that sounds to you like Italian.
- Rosanna is a frantic young mother, carrying her son, José, a 4-year-old who is crying and coughing. Rosanna informs you that José complains of a sore throat and has a fever. She also tells you that she has been to her *curandero,* but José is not getting any better. You notice that José is wearing a heavy coat and knit hat although it is quite warm outside. When you question Rosanna about the child's clothing, she says that José is cold.
- Lee Chan, an elderly Chinese American man, is accompanied by eight family members. Because the waiting area is small, all except his daughter Kim are asked to wait outside. Mr. Chan is quiet and does not make eye contact with you. His daughter Kim explains that her father has stomach cancer and is in a lot of pain because of disharmony. When you ask him to rate his pain, he just shakes his head and looks away. Would you wonder what *disharmony* means?

Theoretical Knowledge knowing **why**

Try to answer the following questions about the patients you have just met. You may not have the theoretical knowledge to answer them all—you will acquire that in this chapter—but do your best based on the background you now have.

ThinkLike a Nurse 15-1

- Think about Romano Salvatore.
  If you could speak Italian, what would you ask him?
- Think about Rosanna and her child.
  One question that might spring immediately to your mind is, "What is a *curandero*?" How could you find out this information?
  Why do you think that the child is dressed more warmly than you would expect for the weather?
- Think about Mr. Chan and his family.
  How would you feel about so many of his family members coming with Mr. Chan to the clinic?
  Why do you think he is not looking at or speaking to you?
  How could you communicate with Mr. Chan? Would you assume that he does not speak your language? Explain your reasoning.

ABOUT THE KEY CONCEPTS

The overarching concepts for this chapter are **culture** and **cultural competence**. The concept of cultural competence helps clarify why the concept of culture is important for nurses to understand. Related concepts, such as assimilation and culture universals, will broaden your understanding of culture and cultural competence. When you have studied the chapter, you should be able to see how all these concepts are linked to each other.

WHY LEARN ABOUT CULTURE?

The following are some reasons for nurses to learn about culture and cultural competence.

The Population Is Diverse In your practice, you will almost certainly care for patients who are not from your culture. The United States is a multicultural society. We continue to see a trend of increasing immigration from Asian and Spanish-speaking nations. The population saw a net increase of 3.4 million Asians and 13.1 million Hispanics between 2000 and 2009 (U.S. Census, 2012a). Box 15-1 shows projection data to year 2060.

Minorities will increase from 37% of the U.S. population in 2012 to 57% by 2060. Projections indicated that the United States will "become a majority-minority nation for the first time in 2043, . . . [and] no group will make up a majority" (U.S. Census, 2012b).

ThinkLike a Nurse 15-2

- With what cultural groups do you identify?
- In the neighborhood where you live, identify the cultural or ethnic groups that are different from your own. How many are there?
- In the school you are now attending, how many different cultural or ethnic groups are represented? What are they?

Health Disparities Exist Among Racial and Ethnic Groups A *Healthy People 2020* overarching goal is to eliminate disparities and improve the health of all groups (Healthy People 2020, n.d.a.)

- **Health status.** One disparity is that minority groups experience higher rates of illness and death and, in general, poorer health status compared with the white, non-Hispanic population. For example, the infant death rate among Black Americans, American Indians, and Alaska Natives is significantly higher.
- **Quality of care.** Disparities among racial groups are common. When compared with whites, blacks received worse care on 41% of quality measures; Hispanics, 39%; and Asians, American Indians, and Alaska Natives, 30% (Agency for Healthcare Research and Quality [AHRQ], 2012). For example, in nursing homes, use of physical restraints is higher among Asians than among non-Hispanic whites (AHRQ, 2012).
- **Access to care.** Lack of access to preventive healthcare and language barriers can account for differences in the health status of racial and ethnic groups (Hicks, 2012). For example, when compared with their white counterparts, black females experienced a higher rate of advanced stage breast cancer and maternal deaths. Black children received inadequate preventive asthma care, resulting in significantly higher rates of emergency room visits than other groups. Similarly, Pacific Islanders and Native Hawaiians had the highest rate of uncontrolled diabetes and hypertension when compared with white groups (AHRQ, 2012), which can lead to complications such as strokes and heart attacks. Improving access to care is one way to decrease healthcare disparities and improve health outcomes.

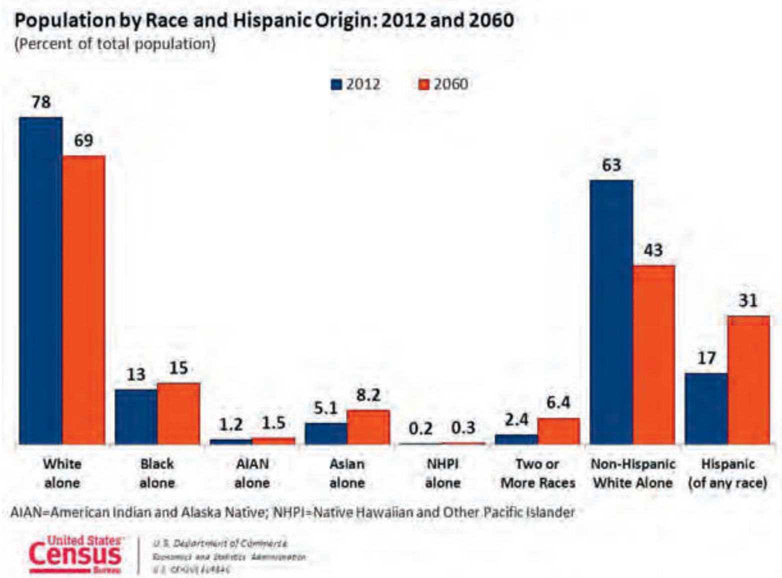
If you are interested in learning more about health disparities,

Go to Chapter 15, **Resources for Caregivers and Health Professionals,** on Davis*Plus*.

Nursing Is Challenged to Provide Culturally Competent Care In North America, the healthcare culture reflects the dominant or European American culture. However, as you saw in the Meet Your Patients scenarios, nurses care for patients from many different races and cultures. Nursing care that is appropriate for the dominant cultural group may be ineffective and inappropriate for people who have a different cultural heritage. Of course, it is impossible to know about every culture, but it is important to learn about the ones you will encounter most often in your practice. A good understanding of culture

BOX 15-1 ■ Population Projections per Racial Group, 2012–2060

Group	2012 Population (in millions)	2060 Projections (in millions)
Non-Hispanic Whites	197.8	179.0
Hispanic	53.3	128.8
Black/African American	41.2	61.8
Asian	15.9	34.4
American Indian & Alaska Natives	3.9	6.3
Native Hawaiian & Other Pacific Islander	706 (thousand)	1.4



Source: Adapted from U.S. Census Bureau (2012b). U.S. Census Bureau Projections show a slower growing, older, more diverse nation a half century from now. Retrieved February 8, 2013, from http://www.census.gov/newsroom/releases/archives/population/cb12-243.html

and ethnicity will help you in providing direct care, teaching, supervising, delegating, and role-modeling culturally competent care to other care providers.

KnowledgeCheck 15-1

- What do recent demographic trends in North America indicate?
- Why should nurses know more about the culture and ethnicity of clients?

WHAT IS MEANT BY CULTURE?

To provide care in a culturally diverse population, you need to understand the concept of *culture*. We know that culture is both *universal* (everyone has it) and *dynamic* (active). In simple terms, **culture** is what people in a group have in common and it changes over time. Formally defined, **culture** is "the totality of socially transmitted behavior patterns, arts, beliefs, values, customs, lifeways, and all other products of human work and thought characteristics of a population of people that guides their worldview and decision making" (Purnell & Paulanka, 2008, p. 404). For other definitions of culture,

Go to Chapter 15, **Supplemental Materials: Definitions of Culture,** on Davis*Plus*.

Characteristics of Culture

When you are trying to determine what is meant by *culture* or *cultural,* keep in mind the following characteristics:

- **Cultural beliefs provide identity and a sense of belonging for its members.** They do so as long as they do not conflict with the dominant culture and continue to satisfy its members.
- **Cultures consist of common beliefs and practices.** Most members of a culture share the same beliefs, traditions, customs, and practices as long as they continue to be adaptive and satisfy the members' needs. Some members of the group may deviate from cultural norms, but for a norm to be considered cultural, many members must follow it.

- **Culture exists at many levels.** Culture exists as both the material (art, writings, dress, or artifacts) and the nonmaterial (customs, traditions, language, beliefs, and practices) levels. See Figure 15-1.
- **Culture is learned and taught.** Cultural values, beliefs, and traditions are passed down from generation to generation. Learning occurs through life experiences shared with other members of the culture, either formally (e.g., in schools) or informally (e.g., in families). Some generations totally adopt the values, beliefs, and traditions of their elders; others partially accept the teachings; and some generations completely reject them.
- **Culture is dynamic and adaptive.** Cultural customs, beliefs, and practices are not static. They change over time and at different rates. Cultural change occurs with adaptation in response to the environment.
- **Culture is complex.** Reread the Purnell and Paulanka (2008) definition to review the many aspects of culture. Cultural assumptions and habits are unconscious and thus may be difficult for members of the culture to explain to others or to identify as different from another culture.
- **Culture is diverse.** Culture demonstrates the variety that exists among groups and among members of a particular group.
- **Culture is all-encompassing.** Culture can influence everything its members think and do.

ThinkLike a Nurse 15-3

Figure 15-1 depicts an example of ways members of particular cultural groups express their cultural uniqueness in dance. Can you think of other ways that people express their culture?

FIGURE 15-1 Traditional lunar New Year dancer in South Korea.

Ethnicity, Race, and Religion

People sometimes use the terms *culture*, *ethnicity*, and *race* interchangeably, but in fact they have separate, specific meanings. Distinctions between culture, ethnicity, race, and religion might seem confusing, but think of it this way: You are a member of the subculture of nursing, but you are also a member of an ethnic group (e.g., Portuguese Americans from the Azores), a racial group (e.g., white), and a religion (e.g., Roman Catholicism), each with its own sets of beliefs and values. So, your culture is a blend of all of those.

Ethnicity

Ethnicity is similar to *culture* in that it refers to groups whose members share a common social and cultural heritage that is passed down from generation to generation. Ethnicity is also similar to *subculture* in that the members of an **ethnic group** have some characteristics in common (e.g., race, ancestry, physical characteristics, geographic region, lifestyle, religion) that are not shared or understood by outsiders. Examples of ethnic groups include French Canadians, Roman Catholics, Hmongs, and Latinos.

Ethnicity may include race and Hispanic origin, but the two are separate and distinct concepts. To demonstrate, the U.S. Census Bureau (2012a) has numerous categories for *race* (see the next section). In addition, two categories are identified for *ethnicity*: (1) Hispanic, Latino, or Spanish and (2) *Not* Hispanic, Latino, or Spanish.

- **Hispanic** Americans are people who originally came from any Spanish-speaking country (e.g., Mexico, Spain). Sixty-five percent of the Hispanic population in the United States are of Mexican origin.
- **Latino**, strictly speaking, refers only to people from Central or South America.
- **Spanish** implies an origin in Spain.

If you know a client's country of origin, it is more accurate to use it when referring to the client's ethnicity (e.g., Mexican American, Colombian American) than to use either of the terms *Hispanic*, *Latino*, or *Spanish.*

Race

Unlike ethnicity, **race** is strictly related to biology. *Race* refers to the grouping of people based on biological similarities, such as skin color, blood type, or bone structure (Purnell & Paulanka, 2008; Purnell, 2012). The terms *race* and *ethnicity* overlap somewhat, because race can be a characteristic of a specific ethnic group. The U.S. Census Bureau asks people to choose the race with which they identify and divides the population into the list of racial categories following:

- White
- Black, African American, or Negro
- American Indian or Alaska Native
- Korean
- Vietnamese
- Other Asian

- Asian Indian
- Chinese
- Filipino
- Japanese
- Native Hawaiian
- Guamanian or Chamorro
- Samoan
- Other Pacific Islanders

People of Hispanic, Latino, or Spanish origin may be of any race, because the U.S. Census Bureau includes Hispanic/Latino/Spanish as a sociocultural, rather than a race category. For an explanation of each of the categories,

Go to Chapter Resources, Chapter 15, Tables, Boxes and Figures, **ESG Table 15-1, Racial Categories, Origins and/or Self-Identified Entries,** on Davis*Plus*.

Can you determine a person's race by his appearance? Frequently not. So, then, is race determined by heredity? What race is someone whose father is African American and whose mother is white? Historically, most North Americans would say that the person is African American. In some other countries (e.g., most of South America), that same person would be categorized as white. Although we commonly think of race as being based on biological characteristics, many, including the U.S. Census Bureau, believe that race is socially rather than biologically determined. As a culturally sensitive nurse, you will ask people what race they identify with and what name they prefer to use for it. For more information on race as a social construct,

Go to Chapter 15, **Supplemental Materials: Race as a Social Construct,** on Davis*Plus*.

We tend to group and categorize data to make them meaningful and useful, but we must be careful to avoid using these categories as the basis for interacting with people or providing care. When you need to designate a name for a group, be as specific as possible (e.g., Syrian American instead of white).

Religion

Religion may be confused with ethnicity because people within an ethnic group may share the same religion. For example, the Jewish culture overlaps with the Jewish faith community. **Religion** refers to an ordered system of beliefs regarding the cause, nature, and purpose of the universe, especially the beliefs related to the worship of a God or gods (Andrews & Boyle, 2007). In many cultures, religion is a high priority (Fig. 15-2).

FIGURE 15-2 Even in this tiny community of rural Appalachia, people have built a place for worship.

Concepts Related to Culture

The concept **bicultural** describes a person who identifies with two cultures and integrates some of the values and lifestyles of each into his life. The person uses more of one cultural base over another when situations call for it. Consider a Jewish man who marries an Italian Catholic woman. Their bicultural children may choose to follow Jewish tradition while still holding some of the values and beliefs of their Italian heritage. A bicultural person may experience divided loyalties or enjoy the best of both cultures.

In this chapter, **multicultural** refers to many cultures and is used to describe groups rather than individuals. Many regions of the United States are multicultural, meaning that the region is populated by individuals from many different cultural groups. The same can be said about workplace environments. Remember that culture does not always refer to the ethnicity of a group. Think of a hospital: Caregivers may be members of various ethnic, racial, and religious groups, and the nurses, physicians, physical therapists, and students each make up a different subculture. Thus, a hospital is multicultural setting.

Socialization, Acculturation, and Assimilation

Socialization is the process of learning to become a member of a society or a group. A person becomes socialized by learning social rules and roles, by learning the behaviors, norms, values, and perceptions of others in the same group or role. Your education program is socializing you into the role of a professional nurse. Families, schools, churches, peer groups, and the media are also agents of socialization and foster their members' identification with the culture.

Immigrants (new members of a group or country) assume the characteristics of that culture through a learning process called **acculturation**. A person who is acculturated accepts both his own and the new culture, adopting elements of each. Acculturation is the outgrowth of the minority group's need to survive and flourish in the new culture. Many experts theorize that it takes several years, perhaps three generations, for an immigrant group to become acculturated. Acculturation is viewed as a social determinant of health and its understanding is essential to address healthcare disparities among cultural groups (Baker, 2011).

Cultural assimilation occurs when the new members gradually learn and take on the essential values, beliefs, and behaviors of the dominant culture. Assimilation is complete when the newcomer is fully merged into the dominant cultural group. A person becomes assimilated by, for example, learning to speak the dominant language, marrying a member from the new (host) culture, and making close, personal relationships with members of the new group. For example, if you emigrated from your home in the United States to Mexico, you would take with you your own language and food preferences. But over time, you would gradually begin to eat more of the local foods and learn to speak Spanish.

Dominant Cultures, Subcultures, and Minority Groups

What do you think is the dominant culture of the United States? If you said white or Caucasian or European American, you would be only partially correct. The ancestors of most white Americans emigrated from Europe, and many were of Protestant or other Christian religions. Thus, the dominant culture in the United States and Canada is considered white Anglo-Saxon Christian of European descent. A **dominant culture** is the group that has the most authority or power to control values and reward or punish behaviors. It is usually, but not always, the largest group.

Because the white culture has been dominant in North America, most white people have been around others similar to themselves. When asked about their culture, they may reply, "I don't know; I don't think I have one." They have not been aware of their culture because they did not see it in contrast to other ways of being. Or, if they did see differences, they assumed their ways were the norm and that everyone else was culturally different.

Ethnocentrism is the tendency to think that your own group (cultural, professional, ethnic, or social) is superior to others and to view behaviors and beliefs that differ greatly from your own as somehow wrong, strange, or unenlightened. The tendency to ethnocentrism exists in all groups, not just in the dominant culture.

Subcultures are groups within a larger culture or social system that have some characteristics (e.g., values, behaviors, ancestry, ways of living) that are different from those of the dominant culture. People in subcultures have had different experiences from those in the dominant group because of status, residence, gender, sexual orientation, ethnic background, education, or other factors that unify the group (Purnell, 2012). You may be able to recognize subcultures by their speech patterns, dress, gestures, eating habits, lifestyles, and so on. Some examples of subcultures are street gangs, physicians, nurses, women, older adults, persons with disabilities, gays and lesbians, people of Appalachian heritage, rural Midwesterners, and people who abuse certain drugs.

Key Point: ***Nursing subcultures within hospitals can impact quality of care and thus patient outcomes. Nurses in specialty subcultures (e.g., intensive care units, emergency rooms) had greater control over their practice, which was associated with better quality of patient care and fewer adverse events when compared with the medical subculture (Mallidou, Cummings, Estabrook, et al., 2011).***

Minority groups are also made up of individuals who share race, religion, or ethnic heritage. They are viewed as subordinate to and usually have fewer members than the majority group. Depending on the type of group, they may or may not share beliefs, practices, or physical characteristics. The term *minority* is sometimes used to refer to a group of people who receive different and unequal treatment from others in society. You should consider that this term may be offensive to some people because it suggests inferiority and marginalization.

KnowledgeCheck 15-2

- Define *culture*.
- Give an example of each: ethnic group, race, religion.
- How does culture provide identity for an individual?
- Give an example of acculturation.

Vulnerable Populations as Subcultures

Vulnerable populations are groups that are more likely to develop health problems and experience poorer outcomes because of limited access to care, high-risk behaviors, and/or multiple and cumulative stressors (e.g., the homeless [Fig. 15-3], poor, or mentally ill; people with physical disabilities; the very young; and older adults). Some ethnic and racial minority groups are also

FIGURE 15-3 A homeless man sits on his cardboard, begging for spare change.

vulnerable. For example, among American Indians and Native Alaskans, there is a higher incidence of diabetes, notably type 2 diabetes in those under 20 years of age, which results in higher mortality rates (Centers for Disease Control and Prevention [CDC], 2011a, updated 2013, 2011b). Vulnerable populations can be considered subcultures of all of the major cultural groups.

Socioeconomic vulnerability is particularly important. Vulnerability is not limited to a particular cultural or ethnic group. People of various socioeconomic classes are found in all ethnic groups. In fact, the subculture of poverty can be found throughout the world. When caring for patients from vulnerable populations, it is important that you focus on their strengths and resources, not exclusively on their difficulties and risks.

The public health initiative *Healthy People 2020* addresses the care of vulnerable populations (Healthy People 2020, n.d.b). One of its overarching goals is to achieve health equity, eliminate disparities, and improve the health of all groups. Nursing research and literature address these inequities, such as the following:

- Oral health disparities in vulnerable populations (Carrion, Castañeda, Martinez-Tyson, et al., 2011; Lester, Henderson, & Taylor, 2012)
- Overweight and obesity among children of different ethnic groups (Long, Mareno, Shabo, et al., 2012)
- Neighborhood disparities in access to healthy foods (Hilmers, Hilmers, & Dave, 2012).

Gender as a Subculture

It should come as no surprise that some behaviors are considered acceptable for men but not for women, and vice versa; and that there are values and responses considered more typical of one sex than of the other. For example, in the dominant culture it is more acceptable for women to cry out in pain than for men to do so, who are supposed to "be strong." As another example, the U.S. culture tends to view caring and nurturing as the province of women. For this reason, historically, males were excluded from the nursing profession. Today, the number of males nurses continue to increase and research shows that they are well integrated and accepted by their peers and given fair, if not preferential, treatment in career advancement (McMurry, 2011).

Old Age as a Subculture

Older adults, especially the very old, can be thought of as a vulnerable population in some respects. You should assess for elder abuse in all cultures and not assume that indicators of abuse are a result of cultural practice. Researchers used *Promotores* (local Spanish-speaking Latinos) to assess for elder abuse among low-income Latino immigrants. Results reveal a variety of abuses, including psychological (25%), physical (11%), sexual (9%), financial (17%), and caregiver neglect (12%). Failure to report abuse may be due to mistrust of the system, protecting the family, and/or language barriers (Deliema, Gassoumis, Homeier, et al., 2012).

HOW DO CULTURAL VALUES, BELIEFS, AND PRACTICES AFFECT HEALTH?

Values are important because they help shape health-related beliefs and practices. Do you know what values are? Think for a minute about what you "value" in your own life. What are the five ideals, principles, or things that are most important to you?

You may name, for example, learning, family, independence, faith, and cleanliness. Or you may have said something entirely different. Simply put, a personal value is a principle or standard that has meaning or worth to an individual. An example is cleanliness. In contrast, a belief is something that one accepts as true (e.g., "I believe that germs cause disease"), and a practice is a set of behaviors that one follows (e.g., "I always wash my hands before preparing food"). Do you see how values, beliefs, and practices are related?

Cultural values, beliefs, and practices are the principles, standards, ideas, and behaviors that members of a cultural group share. Some values of the dominant U.S. culture are youth, beauty, success, independence, and material belongings. You should not assume a client shares your values, beliefs, and practices—nor those of the dominant culture.

Key Point: ***Remember, also, that individuals within an ethnocultural group vary widely and that learning commonalities is no substitute for careful assessment of each person.***

What Are Culture Universals and Specifics?

Culture universals are the values, beliefs, and practices that people from *all* cultures share. Leininger and McFarland (2006) refer to these as culture commonalities. In contrast, **culture specifics** (culture diversities in Leininger's theory) are those values, beliefs, and practices that are special or unique to a culture. Let's look at an example. All cultures celebrate the birth of a new baby in some way (a culture universal), but different cultures celebrate "birth rites" in different ways (a culture specific). In Belize, a baby is christened before visitors are allowed, a practice carried out to prevent the *evil eye* (bad spells cast by others); in Greece, *amulets* (objects or charms worn to protect against evil spirits) may be placed on the baby; and in Israel, Jewish male infants are circumcised on the eighth day of life. Similarly, people from all cultures practice marriage rituals in elaborate rituals that are culture specific (Fig. 15-4).

Archetype or Stereotype?

At about this point in your efforts to be culturally sensitive you might be thinking: "Wait a minute. I went to a Chinese wedding, and it was no different from my own wedding"; or "I know plenty of Greek people who don't put amulets on their babies." Of course you are correct. However, acknowledging that there are commonalities

FIGURE 15-4 People of all cultures practice marriage rituals.

within a group is not the same as saying that *all* people in the group have those characteristics. And that is, more or less, the difference between an archetype and a stereotype.

A **cultural stereotype** is a widely held but oversimplified and unsubstantiated belief that all people of a certain racial or ethnic group are alike in certain respects. Stereotypes are not always negative. Someone may think, for example, that people of a particular heritage are "naturally intelligent" or "naturally athletic." A **cultural archetype** is similar to a model, which you learned about in Chapter 8. An archetype is an *example* of a person or thing—something that is recurrent—and it has its basis in facts. Therefore, as a symbol in your mind, it may help you to remember some of the culture specifics. Unlike stereotypes, archetypes are usually not negative. For example, you might think of Mexican Americans as having brown eyes, or of European Americans as having light-colored skin. There is nothing negative about eye color or skin color.

Remember, there is probably more variation among people *within* an ethnic or cultural group than there is *between* the groups, and that much variation stems from socioeconomic differences or regional origin as much as from race or ethnicity.

Key Point: ***The general principle that should guide your practice is that each person must be seen as unique—as a member of an ethnic group, influenced by his heritage, but not defined by it.***

How Do Culture Specifics Affect Health?

Just as they influence our celebrations of births and weddings, culture specifics affect our health beliefs and behaviors. Thus, knowledge of the culture specifics of groups in your community will help explain why clients from different cultures have different expectations of healthcare. Ultimately, it will help you to provide culturally competent care. In the following sections, we will explore six culture specifics that influence health: communication, space, time orientation, social organization, environmental control, and biological variations (Giger, 2012). We will also briefly discuss several other culture specifics: religion and philosophy, politics and law, the economy, and education.

Communication

Communication is an exchange of information, ideas, and feelings. It includes verbal and nonverbal language (i.e., spoken language, gestures, eye contact, and even silences). Think how difficult it would be if you became ill in a foreign country and did not speak the language. How would you tell the caregivers your symptoms? How would you know what they were going to do to treat your illness? Language differences present one of the most difficult obstacles to providing care. Even when you and the client speak the same language, culture influences how feelings and thoughts are expressed and which verbal and nonverbal expressions are appropriate to use. Also see Chapter 21 for more on communication strategies.

Space

Space refers to a person's personal space, or the boundary lines that determine how close another person can come. A person's comfort level is related to space. A similar concept, **territoriality**, means the geographical space a person views as owned or claimed, such as an area or room (Spector, 2013). Both of these concepts are influenced by culture. If you are invading a person's personal space, a common reaction is for the person to move away from you. When personal space is protected, a person feels secure and safe, less anxious, and in control. The following are some examples of culturally influenced attitudes toward personal space (Purnell & Paulanka, 2008; Purnell, 2012):

- Americans, Canadians of Northern European ancestry, and the British keep at least 18 inches of space between themselves and the person with whom they are conversing.
- Arabs and others from the Middle East typically stand quite close when talking. They tend to keep steady eye contact, but not between men and women
- Germans usually require a great deal of space, and consider even looking into a room an invasion of privacy.

Within all cultural groups, personal space varies depending on the relationship between the people speaking: intimates versus acquaintances, people of the same versus opposite sex, and people of a different position within the social hierarchy.

Time Orientation

Time orientation varies among people of different cultures. Some persons tend to be past-, present- or future-oriented. Groups from the Far East tend to be past-oriented and value traditions and relationships over time and deadlines. In contrast, European Americans tend to be future-oriented, and Latin Americans and Filipinos are more present-oriented and enjoy living in the moment. Differences in time orientation can be important as you plan nursing interventions. For example, clients who are past-oriented may show up late (or not at all) for follow-up appointments; therefore, you should provide a written or telephone reminder of their appointment.

ThinkLike a Nurse 15-4

- Suppose you say to a client, "You will need to exercise and follow a low-calorie diet to lose weight and control your diabetes." What kind of time orientation would a client most likely have in order to follow your directions?
- Suppose a client says, "I know I need to lose weight, but I work so much, and the children take so much time. I just don't have time to shop for and cook the right foods or to exercise." What time orientation does this illustrate?

Social Organization

Social organization includes the family unit (e.g., nuclear, single-parent, or extended family) and the wider organizations (e.g., community, religious, ethnic) with which the individual or family identifies (Spector, 2013).

- *A close social organization can be found in all cultures; however, the specifics vary.* For example, in Middle Eastern and Latino cultures, the man is likely to be the dominant family member and the woman the homemaker. But many African American families are matriarchal; that is, the decision maker and family leader is a woman.
- *The social organization of your clients' cultures can provide clues as to how they will act during such life events as birth, death, illness, grieving, and mourning.* For example, imagine a patient who does not trust large institutions or government agencies, but must depend on Medicaid to pay for her healthcare. She is likely to use home remedies and delay seeing a conventional medical physician.
- *Kinship and social ties also determine who receives healthcare, and in what priority.* In the United States, for example, someone of high status (e.g., a celebrity or political figure) is likely to receive better care than a poor person who is unknown in the community. In some cultures, men receive care before women and children.

Environmental Control

Environmental control refers to a person's perception of his ability to plan activities that control nature or direct environmental factors (Spector, 2013). A person's health and illness beliefs and practices are directly related to this concept. For example, if a person does not believe he can do anything to "change things," this would negatively affect his decision to seek medical care, to take his medications, to exercise, and to eat properly. Environmental control is also illustrated in Asian Americans' perception and tolerance of pain. They do not view circumstances as something to be "controlled"; therefore, they tend to accept pain stoically, and not demand relief. Think again about Mr. Chan (Meet Your Patients). Why do you think he just shakes his head and looks away when asked to rate his pain?

Biological Variations

Biological variations are the ways in which people are different genetically and physiologically. They include body build and structure, skin color, vital signs, enzymatic and genetic variations, and drug metabolism (Purnell, 2012; Spector, 2013). Biological variations create susceptibility to certain diseases and injuries and explain differences in responses to treatment. For example, African Americans have poorer responses to certain categories of antihypertensive drugs when compared with their white counterparts (Gupta, 2010). Consequently, clinical trials (drug studies) now recommend incorporating biological variations. For more information about assessing biological variations,

Go to Chapter 15, **Clinical Insight 15-1: Assessing for Biological Variations,** in Volume 2.

To read more about biological susceptibility to diseases,

Go to Chapter 15, **Supplemental Materials: Disease Risks for Each of the Major Cultural Groups of the United States,** on Davis*Plus*.

Other Culture Specifics

The following may also be culture specifics. The first two, religion/philosophy and education, vary among subcultures in the United States, whereas technology, politics/law, and the economy exert broader effects that can be seen among different countries, but less so among subcultures within a country.

- **Religion and Philosophy.** A person's religion may determine what healthcare is acceptable to him. For example, some religions (e.g., Jehovah's Witnesses) do not accept blood transfusions, and many religions forbid abortion.
- **Education.** Education influences the perception of wellness and illness and the knowledge of options that are available for healthcare. These, in turn, affect the person's expectations for care.
- **Technology.** The availability of supplies and equipment determines what is used in the healthcare setting and what becomes culturally expected. Nurses in most of North America, for example, assume they will have bed linens, water, electricity, necessary medications, and technology such as

electrocardiography and x-ray imaging. In many parts of the world, however, these items are not available or even expected.

- **Politics and the Law.** Government policies affect healthcare, as seen in the Affordable Care Act. They determine what programs will be funded, reimbursement for providers, and acceptable functions and standards. Review Chapter 1 for an overview of governmental healthcare programs.
- **Economy.** The condition of the economy directly affects the availability of funds for publicly funded services. It also affects the individual's ability to pay for healthcare.

For more information about each of those dimensions of culture,

Go to Chapter 15, **Tables, Boxes, Figures: ESG Table 15-2,** on Davis*Plus*.

Think**Like a Nurse** 15-5

Consider this example: Mrs. Miyagi, a Japanese American, has been admitted to your care from the postanesthesia care unit (PACU), having undergone a major surgical procedure. She refuses pain medicine, although she appears to be in pain. As the hours pass, Mrs. Miyagi continues to refuse pain medication, so eventually the nurses stop asking.

- Do you assume that she is experiencing no pain?
- Are you or the other nurses stereotyping her for her cultural response to pain?
- What would you do?

KnowledgeCheck 15-3

- Explain the difference between an archetype and a stereotype.
- Identify at least six culture specifics affecting health.
- How could you use this information about culture specifics to provide better care to your clients?

WHAT IS THE "CULTURE OF HEALTHCARE"?

In any culture, two healthcare systems usually exist side by side: indigenous and professional (Leininger & McFarland, 2002, 2006). Each has its own culture.

Indigenous Healthcare System The **indigenous healthcare system** consists of *folk medicine* and *traditional healing methods,* which may include over-the-counter (OTC) and self-treatment remedies. Different groups have different folk practices (Table 15-1), but all cultural groups probably use a professional healthcare system to some degree.

Professional Healthcare System In contrast, the **professional healthcare system** is run by a set of professional healthcare providers who have been formally educated and trained for their appropriate roles and responsibilities. In North America, professional healthcare is dominated by a biomedical healthcare system that combines Western biomedical beliefs with traditional North American values of self-reliance, individualism, and aggressive action. This system is also known as Western medicine and allopathic medicine. Table 15-2 summarizes the norms of the North American professional healthcare system.

The professional healthcare system also includes practitioners formally trained in alternative healthcare, such as diet therapy, mind–body control methods, therapeutic touch, acupressure, reflexology, naturopathy, kinesiology, and chiropractic. If you would like more information about alternative healthcare, see Chapter 46 on Holistic Healing.

Conflicts may occur when the professional healthcare provider does not understand the beliefs and practices of the indigenous healthcare systems and traditional healers. The professional provider views the indigenous beliefs and practices as uncivilized and based on the supernatural, and believers in indigenous methods view the professional healthcare culture with distrust. This type of thinking benefits no one. As a nurse, you should become aware of and understand a variety of health beliefs and practices so that you can meet the needs of your clients and families.

What Are Health and Illness Beliefs?

To provide evidenced-based culturally competent care, you need to know how people in various cultural groups understand life processes, how they define health and illness, their health-seeking behaviors, and what resources are available to promote health and treat illness (Transcultural Nursing Society, 2010). Generally speaking, people follow one of three major health belief systems: scientific, magico-religious, or holistic (Andrews & Boyle, 2011). You are probably familiar with the scientific or biomedical health system. Belief in supernatural (mystical) forces dominates the magico-religious system, which is considered "alternative" or "indigenous" in the United States. One example is voodoo, which is practiced in some developing nations in Africa, Latin America, and the Caribbean, and which considers the lion a spiritual symbol (Fig. 15-5). The holistic belief system can be similar to magico-religious, but it focuses more on the need for harmony and balance of the body with nature.

Think**Like a Nurse** 15-6

- What do you do to keep yourself healthy?
- What do you do to treat minor illnesses when you do not want to see a healthcare provider?

What Are Health and Illness Practices?

In addition to knowing the values and beliefs of different cultures, you need to know what people in various cultural groups do to maintain wellness.

Table 15-1 ➤ Folk Healers and Practices

FOLK HEALERS	FOLK PRACTICES
White, European American	
Nurse Physician Chiropractor Acupuncturist Massage therapist Physical therapist Occupational therapist Respiratory therapist	Medicines (OTC and prescribed) Therapeutic or modified diets Exercise Religious healing rituals (including prayer) Sleep Cleanliness Amulets Herbal therapy Naturopathy Massage Spinal adjustment Aromatherapy
Hispanic	
Curandero/curandera *Espiritualista* (spiritualist) *Partera* *Yerbero* (herbalist) *Sabador*	"Hot" and "cold" therapies Medals and amulets Prayers Herbs and herbal teas Massage Jewelry to ward off the "Evil Eye"

(2008). *Transcultural nursing: Assessment and intervention* (5th ed.). St. Louis, MO: C.V. Mosby; Purnell, L. (2012). *Transcultural health care: A culturally competent approach* (4th ed.). Philadelphia: F.A. Davis; and Spector, R. (2013). *Cultural diversity in health and illness* (8th ed.). Upper Saddle River, NJ: Pearson Education, Inc..

Think about Mr. Chan (Meet Your Patients). If he or his daughter asked for a Chinese priest to come to his room and perform a ceremony to restore his harmony, do you think this ceremony would be harmful or helpful to him? Would you support or discourage this? What about Rosanna's dressing her child in a heavy coat and knit hat although it is quite warm outside? Is this harmful or helpful to them? Would you support or discourage this? As you think about those questions, keep in mind that cultural health practices can be any of the following (Giger & Davidhizar, 2008):

Efficacious (helpful)
Neutral (neither helpful nor causing harm)
Dysfunctional (harmful)
Uncertain (not known)

You should encourage practices that could be helpful and discourage those that may cause harm. We will

Table 15-2 ➤ Summary of Cultural Norms of the North American Healthcare System

NORM	EXAMPLES
Beliefs and Values	Standardized definitions of *health* and *illness*
	Significance of technology
	Reliance on the biomedical system
	Desire to conquer disease
	Defines health as absence or minimization of disease
Practices	Maintaining health and preventing disease through such practices as immunizations and avoidance of stress
	Annual physical examinations and diagnostic tests
Habits	Handwashing
	Use of jargon (e.g., "take your vitals")
	Use of problem-solving methods
	Documentation
Likes	Punctuality
	Neatness and organization
	Compliance (e.g., with medical "orders")
Dislikes	Tardiness
	Disorganization
	Messiness, lack of cleanliness
Customs	Use of procedures (e.g., circumcision, last rites) surrounding birth and death
	Professional respect and observance of hierarchy found in autocratic and bureaucratic systems
	Adherence to a set of ethical standards and codes of conduct
Rituals	Annual physical examination
	The surgical procedure

- As a nurse, in which of the following cultural health practices would you support your client: efficacious, neutral, dysfunctional, uncertain? Why?
- Refer to the Meet Your Patients feature. Identify an efficacious practice.

ThinkLike a Nurse 15-7

What aspects of the indigenous and professional systems have you used for yourself or your family? Give examples.

Nursing and Other Professional Subcultures

Members of the biomedical healthcare system in the United States belong to a culture with its own set of norms. That culture can be further divided into subcultures, such as those of physicians, nurses, respiratory therapists. Nursing is the largest subculture within the healthcare culture. Leininger (1978) defines the **culture of nursing** as the learned and transmitted lifeways, values, symbols, patterns, and normative practices of members of the nursing profession that are not the same as those of the mainstream culture. The nursing subculture's beliefs and values have been formed in part by the society at large, which historically has been dominated by white Anglo-Saxon Protestants. Nursing values include, in addition to those listed in Table 15-2, the following:

- Silent suffering as a response to pain
- Objective reporting and description of pain, but not an emotional response
- Use of the nursing process
- Nursing autonomy
- Caring

In this book, we add *knowledge* and *critical thinking* to the list of nursing values. Although these values may not be consistently rewarded in practice, we believe that a steadily increasing number of nurses realize their importance—that nursing is "knowledge work" and that the nurse's knowledge and thinking are essential to the well-being of patients.

As you become more socialized into the nursing culture, you should continue to examine professional values to see how strongly you identify with them and how they affect your work with patients. For example, if you value silent suffering in response to pain, how might that cause you to respond to a woman in very early labor who is screaming and crying even though her contractions are very mild on palpation? Would you dismiss her for being a "whiner"? Or scold her ("You can't be hurting that badly this early in labor")? You must be careful not to lose the ability to understand health and illness from the patient's point of view.

Review the case of Rosanna and José (Meet Your Patients). After a positive strep test, the primary care provider prescribes an antibiotic for José's fever and sore throat. You observe that Rosanna does not seem to be happy with the medicine, so you stress to her the importance of buying the medicine right away to make him better. On her way out of the clinic, Rosanna throws the prescription in the trash. Why do you think she threw away the prescription?

If you had difficulty thinking of possible answers to the question, see Table 15-3.

Also,

Go to the **Hispanic Health Cultural Specifics** in **ESG Table 15-2 (Culture Specifics Affecting Health),** on Davis*Plus.*

Some people of Mexican heritage believe that illness is caused by the body's imbalance of "hot" and "cold" (not related to temperature). The scenario doesn't tell you for sure, but it could be that Rosanna did not believe the medication would help her son, so she decided not to spend money on it. This problem could have been prevented if you or the primary care provider assessed Rosanna's health beliefs and practices and involved her in José's care by discussing treatment options with her. For example, if she considered his throat infection to be "hot," then the provider might have been able to explain that the prescribed medication would get rid of the heat and pain that José is experiencing from the infection, or perhaps find another medication that Rosanna would consider to be "cold."

This is an example of what can happen when healthcare providers are so rigidly grounded in the beliefs of the professional healthcare culture that they fail to recognize and understand the health beliefs and practices of their clients. As you may guess, this way of practicing is a barrier to culturally competent care.

KnowledgeCheck 15-5

How do the cultural norms of the North American healthcare system differ from those of other cultural groups? Refer to Tables 15-2 and 15-3 in this chapter as needed.

Traditional and Alternative Healing

As a part of your culturally competent care, you need to know how healers from various cultures cure and care for members of their group. All cultures think of their healthcare system and beliefs as "traditional"; however, we use *traditional* in this chapter to refer to alternative beliefs, those that are not of the Western, North American, biomedical, or professional healthcare systems (previously discussed). You have already learned about different healthcare beliefs and practices clients may have (e.g., biomedical or scientific, holistic, magico-religious). The following section focuses on the types of healing systems that are used in different cultures.

Folk Medicine

When you feel as if you're getting a cold or the flu, what do you do? If you said that you take aspirin or vitamin C or eat chicken soup, then you are practicing folk medicine. You most likely do what your mother or some other relative did for you in similar situations. In North America there is a "pill" for almost everything, and virtually everyone self-medicates with OTC medicines. For many cultures, folk medicine involves natural medicines, such as herbs, plants, minerals, and animal substances. Magico-religious folk medicine involves the use of charms, holy words, rituals, and holy actions for preventing and treating illnesses (Spector, 2013).

Folk medicine is defined as the beliefs and practices that the members of a cultural group follow when they are ill, as opposed to more conventional (i.e., biomedical or professional) standards (Andrews & Boyle,

Table 15-3 ➤ Values and Health and Illness Beliefs and Practices for Selected Ethnocultural Groups in North America

GROUP	DOMINANT VALUES	HEALTH AND ILLNESS BELIEFS	HEALTH AND ILLNESS PRACTICES
Native American	Bonding to family or group Acceptance of nature (Mother Earth) Tradition Sharing Belief in a spiritual power Respect of elders	Health means living in harmony with nature. Surviving under difficult circumstances Body treated with respect Illness is associated with disharmony or evil spirits. Illness is caused by an action that should not have been performed.	Rituals and ceremonies Chanting Purification Meditation Herbs
Asian and Pacific Islander	Extended family Respect for elders Group orientation Subordination to authority Conformity Self-respect and self-control Love of the land	Health is a state of physical and spiritual harmony. Illness is disharmony of basic principles: *yin* and *yang*.	Acupuncture Amulets Moxibustion Meditation Herbs
Black or African American	Family bonding Matrifocal Spiritual orientation Present-oriented	Health is harmony with nature (mind, body, and spirit). Illness is the result of disharmony or failure to eat proper foods.	Prayer Laying on of hands Magic rituals Voodoo Herbs
Hispanic or Latino	Extended family Group emphasis Fatalistic Faith and spirituality	Health is good luck or a reward for good behavior, a gift from God. Illness is body imbalance (hot or cold, wet or dry) or punishment.	Prayer Belief in miracles Wearing of religious metals or amulets Religious relics in home Herbs and spices Rituals "Hot" and "cold" therapy
White or European American	Independence Individuality Wealth Comfort Cleanliness Achievement Youth and beauty	Health is a state of physical and emotional well-being. Illness is contagion or contamination that is hereditary, psychosomatic, or supernatural	Biomedical care Home remedies Religious traditions Diet and exercise

Note: Most people in North America use a combination of biomedical and traditional (specific to their culture) healthcare practices.
Sources: Adapted from Andrews, M., & Boyle, J. (2011). *Transcultural concepts in nursing care* (6th ed.). Philadelphia: Lippincott; Giger, J., & Davidhizar, R. (2008). *Transcultural nursing: Assessment and intervention* (5th ed.). St. Louis, MO: C.V. Mosby; Munoz, C., & Luckmann, J. (2005). *Transcultural communication in healthcare*. Clifton Park, NY: Thomson Delmar; Spector, R. (2013). *Cultural diversity in health and illness* (8th ed.). Upper Saddle River, NJ: Pearson Education, Inc.; and Purnell, L. (2012). *Transcultural health care: A culturally competent approach* (4th ed.). Philadelphia: F.A. Davis.

2011). All cultures throughout the world use folk medicine. Knowledge of these treatments is passed down from generation to generation by oral, and sometimes written, tradition. Folk medicine includes both self-treatment and use of folk healers.

Why would someone want to see a folk healer rather than a professional healthcare provider? In the dominant North American culture, the folk healer *is* the professional healthcare provider (i.e., the nurse practitioner, physician, certified nurse midwife, and so on). People of other cultures may seek out folk healers because they speak their native language, share their values and beliefs, charge less money, are readily available, or make house calls. If people perceive that the professional healing system cannot meet their needs, they are likely to seek care from the folk healers within their cultures and avoid the professional system.

Key Point: ***Many folk healing traditions (see Table 15-1) are guided not only by cultural practices but also by religious beliefs and rituals. Religious rituals are often associated with births (e.g., circumcision) and deaths (e.g., who is allowed to wash the body and prepare it for burial). Although, there is a strong association between culture and religious beliefs, you should never assume that because your patient is a member of a certain culture he will also be of a certain religion. You should always ask as a part of your cultural assessment.***

Complementary and Alternative Medicine

Complementary medicine is the use of rigorously tested therapies that are outside of the mainstream medical or nursing care *to complement* those of conventional medicine (Andrews & Boyle, 2011; Buchan, Shakeel, Trinidade, et al., 2012). Examples include chiropractic care, biofeedback, and the use of certain supplements. In contrast, **alternative medicine** is defined as therapies used *instead of* conventional (i.e., biomedical) medicine, and whose reliability has not been validated through clinical testing in the United States. Examples of alternative therapies include iridology, aromatherapy, and magnet therapy.

Some complementary and alternative modalities (CAMs) are derived from the ancient and indigenous healthcare systems of people of other countries, such as traditional Chinese medicine (TCM), and **ayurveda**, the traditional healthcare system of India. Certain CAMs require a healer specially trained in their use (e.g., chiropractic, reflexology, massage therapy) and are licensed by the state (e.g., massage therapists). For a more thorough discussion on CAMs,

Go to Chapter 46, Holistic Healing, on Davis*Plus*.

KnowledgeCheck 15-6

- What is folk medicine?
- What are some common folk medicine practices?
- Why might members of some cultural groups seek out the local folk healer rather than the conventional healthcare provider?

WHAT IS CULTURALLY COMPETENT CARE?

The terms *cultural awareness*, *cultural sensitivity*, and *cultural competence* are often used interchangeably; however, they are different.

- **Cultural awareness** refers to an appreciation of the external signs of diversity.
- **Cultural sensitivity** relates to personal attitudes and being careful not to say or do something that might be offensive to someone from a different culture (Purnell & Paulanka, 2008).
- **Cultural competence** is attained on a continuum ranging from cultural destructiveness (most negative) to cultural proficiency (most positive) (Cross, Bazron, Dennis, et al., 1989) or incompetent to competent (Purnell & Paulanka, 2008). You cannot achieve cultural competence overnight because it is a developmental process. As you become more aware of and sensitive to the needs of individuals from various ethnocultural groups, you will move forward on the journey toward cultural competence: being able to use knowledge and sensitivity in practice. The following are some ideas from nursing organizations and theorist about cultural competence.

The American Nurses Association (ANA)

The American Nurses Association's publication *Nursing: Scope and Standards of Practice* (2010) states that the registered nurse should provide holistic care that does the following:

- Addresses the needs of diverse populations.
- Is provided within the context of culturally sensitive interpersonal relationships.
- Includes providing cultural assessments and formulating individualized and culturally appropriate expected outcomes and nursing interventions to foster healing.

Quality and Safety Education for Nurses (QSEN)

Several of the QSEN competencies speak to culturally competent care. For example, from the patient-centered care competency, the graduate nurse should be prepared to:

- Provide patient-centered care with sensitivity and respect for the diversity of human experience.
- Seek learning opportunities with patients who represent all aspects of human diversity.
- Recognize personally held attitudes about working with patients from different ethnic, cultural, and social backgrounds.

Purnell and Paulanka

The Purnell model for cultural competence stresses teamwork in providing culturally sensitive and competent care to improve outcomes for individuals, families, and communities (Purnell, 2000, 2002, 2012; Purnell & Paulanka, 2008). In the context of nursing, Purnell's model defines **cultural competence** as "having the knowledge, abilities, and skills to deliver care congruent with the client's cultural beliefs and practices" (Purnell & Paulanka, 2008, p. 404). The pie-shaped wedges in Figure 15-6 depict the issues all societies and humans share (e.g., pregnancy, nutrition, high-risk behavior, family organization, and death) that are expressed in ways specific to the culture. These domains provide the organizing framework for the model. The center of the model is empty and represents that which is unknown about a cultural group.

Quality and Safety Education for Nurses

How Cultural Competency Improves Patient Outcomes

Chapter Key Concepts: *Cultural Competency, Patient Outcomes, Quality Improvement*

Competency: *Quality Improvement (Knowledge, skills, attitudes)**

Background: The QSEN competency of quality improvement is applicable to culturally competent care. Cultural competence encompasses more than just ethnicity and race; it requires sensitivity to vulnerable populations and the disparities within the healthcare system (Clingerman, 2011). Kersey-Matusiak (2012) claims that becoming culturally competent is an ongoing, lifetime process requiring skill development, thoughtful reflection, and self-awareness. Furthermore the author reports that cultural competency promotes better nurse–patient communication. This contributes to a cultural partnership and sensitivity, which results in the following:

- Both nurse and patient better understand the disease process and treatment management.
- The patient is more likely to adhere to the treatment protocols.
- Patient outcomes are improved (Kersey-Matusiak, 2012).

Think about it:

What is the relationship between cultural competence and healthcare disparities?
How can cultural competence by healthcare providers impact patient outcomes?

As reference for your QSEN log box, the QSEN KSA that is most pertinent is:

Recognize that students of nursing and other health professions are parts of systems of care and care processes that affect outcomes for patients and families.

Sources: Clingerman, E., (2011); Kersey-Matusiak, G. (2012).
*For specific Knowledge, Skills, and Attitudes,

Go to the QSEN Web site at http://qsen.org/competencies/pre-licensure-ksas/

The model identifies levels of several levels of cultural competence. Think about the meaning of each level:

Unconsciously incompetent
Consciously incompetent
Consciously competent
Unconsciously competent

Increasing one's consciousness of cultural diversity improves the possibilities for healthcare practitioners to provide culturally competent care.

Leininger

Although Madeline Leininger does not use the specific term *cultural competence*, her theory fits with that concept (Leininger, 2007; Leininger & McFarland, 2006). The goal of her theory is to guide research that will assist nurses to provide *culturally congruent care* using her three modes of nursing care actions and decisions (to be explained later in the chapter). Nurses can achieve this goal by:

- Discovering cultural care and caring beliefs, values, and practices
- Analyzing the similarities and differences of these beliefs among the different cultures

For more information on Leininger's theory of culture care diversity and universality,

Go to Chapter 15, **Supplemental Materials: Leininger's Theory, and Tables, Boxes, Figures: ESG Figure 15-1, Leininger's Sunrise Model,** on Davis*Plus*.

Deardorff

Based on a recent study, Deardorff (2006, 2009) categorized intercultural competence into the following five categories:

- *Attitudes*—The key attitudes include respect, openness, and curiosity, which imply the ability to move beyond your own comfort zone.
- *Knowledge*—This includes cultural self-awareness, understanding others' perspectives, and culture-specific knowledge.
- *Skills*—These skills address the processing of knowledge. They include observation, listening, evaluating, interpreting, and relating. You need to obtain and process information; you cannot rely on knowledge alone.
- *Internal Outcomes*—"Outcome" implies change. Using your attitudes, knowledge, and skills should make you more flexible, adaptable, and empathetic. Ideally, you will be able to see from others' perspective and care for them in the ways that meet their needs.
- *External Outcomes*—External outcomes describe the ways in which you behave and communicate as a result of the preceding four categories. They answer the question of how effective and appropriate you are in intercultural situations.

WHAT ARE SOME BARRIERS TO CULTURALLY COMPETENT CARE?

Your ability to provide culturally competent care may be hampered by various prejudices, attitudes and language barriers. Self-knowledge and critical thinking are essential in helping you identify and manage them. You should avoid the following in your practice:

- **Bias**, one-sidedness: a tendency to "lean" a certain way, a lack of impartiality. A bias can be either positive or negative.
- **Ethnocentrism** is the tendency of people to be biased toward their own culture, believing their own beliefs and values are right and that those of other cultures are wrong (or at least bizarre). If you take this attitude,

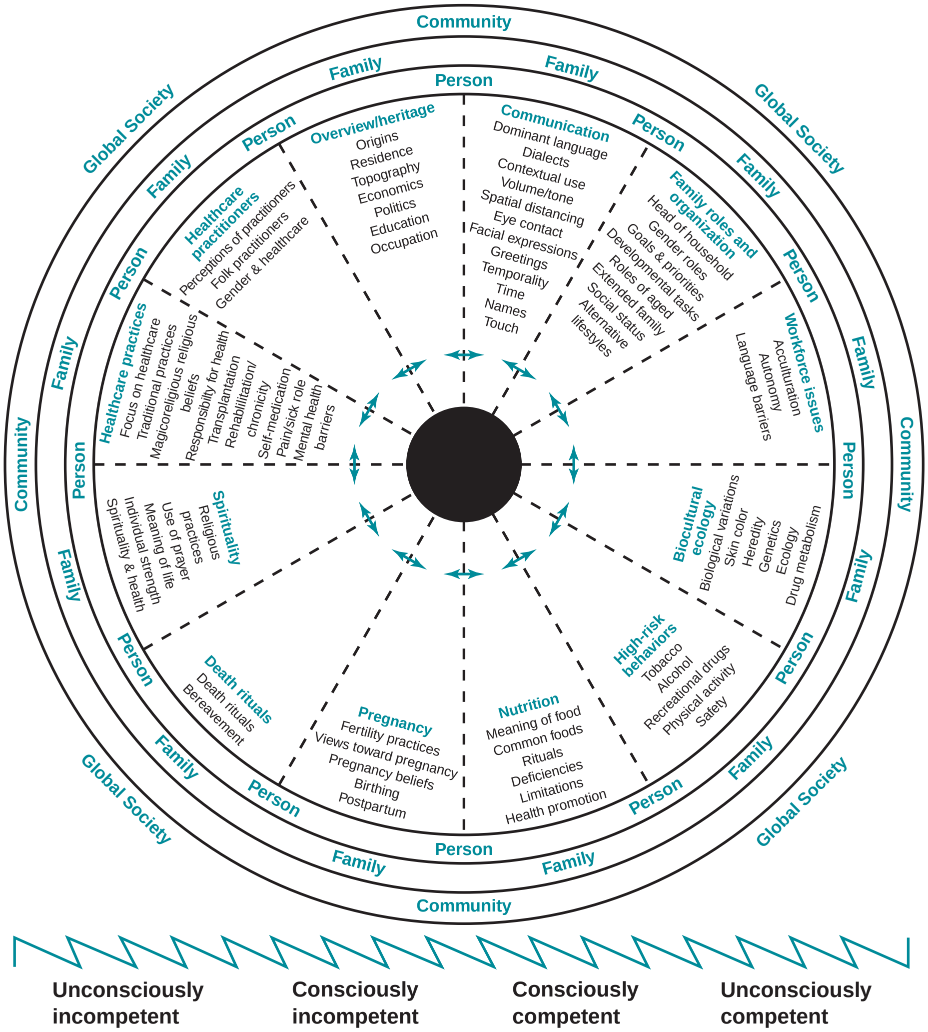

FIGURE 15-6 Purnell's model for cultural competence. (*Source:* From Purnell, L., & Paulanka, B. (2008). *Transcultural health care: A culturally competent approach* (3rd ed.). Philadelphia: F.A. Davis, p. 21. Reprinted with permission.)

your patient may feel that you disapprove of him or that you don't understand or respect him.

- **Cultural stereotyping** is the unsubstantiated belief that all people of a certain racial or ethnic group are alike in certain respects. Similar to biases, a stereotype may be positive or negative.
- **Prejudices** are negative attitudes toward other people based on faulty and rigid stereotypes about race, gender, sexual orientation, and so on.
- **Discrimination** is the behavioral manifestations of prejudice. For example, before the 1960s many U.S. hospitals refused treatment to African Americans. Slightly more subtle discrimination against minority groups still exists in housing, banking, the job market, and other areas of life.

Racism

Racism is a form of prejudice and discrimination based on the belief that (a) race is the principal determining factor of human traits and capabilities and (b) that racial differences produce an inherent superiority (or inferiority). The word *race* evokes powerful emotional responses for people who feel that they or their ancestors have been oppressed or exploited, and equally for those who deny such a responsibility. In the United States, the history of discrimination against non-whites has created a focus on differences and racial divisiveness. As a nurse, you must recognize that unconscious racism and the use of words considered "racist" can play a major role in your ability to communicate with people of other races.

Sexism

Sexism is the assumption that members of one sex are superior to those of the other sex. For example, women have been viewed as more emotional and less rational than men. Assertiveness, a trait considered positive in men, is viewed as aggressiveness and an undesirable quality in women. Similarly, male nurses must combat sexism, mainly that it is "unnatural" for men to engage in caring behaviors. Thus, male nurses may initially be rejected by their female peers and some patients.

Male chauvinism (assumption of male superiority) is common in many cultures and in healthcare settings. It may be overt or subtle. The assumption of equality, by either party, changes the way people communicate. When you have the opportunity to do so, observe a conversation between a male nurse and a male physician. You may note that the male nurse communicates more directly and uses more eye contact than female nurses do with this same physician. We are not assuming all physicians (or nurses) are chauvinistic; we are simply stating that you will probably be able to observe this kind of interchange among some professionals.

Language Barriers

About 55 million people in the United States speak a language other than English at home. Another 24.5 million speak English poorly or not at all (Shin & Kominski, 2010). Language barriers will obviously affect your ability to communicate with clients. Language barriers can involve foreign languages, dialects, regionalisms (words or pronunciation particular to a specific region), street talk, and jargon.

Recall Mr. Salvatore, in Meet Your Patients. Suppose it is found that he has a brain tumor and needs immediate surgery. You would need to get his consent for surgery even though he and his family do not speak English. You might get a certified interpreter. However, the interpreter can have difficulty understanding Mr. Salvatore completely if he uses a different dialect or slang. This is not an unusual situation. In such a case, you would need to explore the policies of your healthcare facility to obtain additional resources. If there were no other options for translation help, you would have to temporarily resort to nonverbal language and pictures to communicate. If a consent issue is involved, the hospital must ensure adequate resources to comply with informed consent requirements.

Street Talk, Slang, and Jargon These can be as challenging as a foreign language. Their meaning changes and not everyone has the same interpretations. For example, the word *bad* can mean bad or good. Ebonics (also called African American Vernacular English, or AA-VE) is a type of English that has, in the past, been spoken primarily by African Americans, but many youths of other races, enamored with hip-hop culture, now embrace Ebonics as a way to connect with street culture. Texting can be another form of jargon. Not everyone understands the abbreviations used in texting.

Healthcare Jargon Words or expressions used by a subculture, including nursing and medicine, are called jargon. In healthcare, we use our peculiar terminology and abbreviations so often we may forget that our clients do not understand them. For example, you may frighten some patients if you say to them, "I'm going to take your vitals" before assessing their blood pressure. And many patients will not know what you mean if you ask, "Have you voided today?" Even worse, patients may hesitate to ask for clarification because they don't like admitting that they don't understand a certain word. This can both distress and isolate the patient.

Other Barriers

Lack of knowledge about the cultural and ethnic values, beliefs, and behaviors of people within their community is not unusual among healthcare providers. It can cause them to misinterpret a client's behaviors. *Emotional responses*, such as fear and distrust (both yours and the client's), can arise any time members of different cultural groups meet. If you are aware this may happen, you may be able to avoid this barrier and communicate with your clients effectively. Self-knowledge is essential in removing barriers.

KnowledgeCheck 15-7

- Define *cultural competence.*
- How do the barriers of ethnocentrism and language impede nursing care of diverse populations?

PracticalKnowledge knowing how

Each phase of the nursing process presents an opportunity to provide culturally sensitive, congruent, and competent care. Regardless of the patient's cultural group, it is important to establish rapport before beginning data collection.

ASSESSMENT

Various regulating bodies (e.g., The Joint Commission and the Office of Minority Health) require healthcare organizations to integrate cultural data into a patient's health records. Cultural assessment consists of an interview and a physical assessment. When you perform a cultural assessment, you should gather data directly from your client, but if this is not possible, you may ask a friend or family member of the client to assist you.

Key Point: ***When an interpreter is needed, because of privacy concerns and legal guidelines you should not rely on a family member.***

The Health History

Regardless of the patient's cultural group, it is important for you to establish rapport before beginning data collection, especially for sensitive or personal information. To encourage clients to talk about themselves, you must convey empathy, show respect, build rapport, establish trust, listen actively, and provide appropriate feedback (Munoz & Luckmann, 2005). Ask open-ended questions when beginning a cultural assessment.

Always ask clients about their use of alternative medicine and folk remedies so their effects on traditional biomedical medications and treatments can be evaluated. Some remedies may interfere with traditional treatments; others can be dangerous. Many people use folk remedies, but they may be reluctant to tell you because they fear ridicule or disapproval.

You will not need to perform an in-depth cultural assessment on every client, but you will need to recognize situations in which this is needed. For a list of questions to help you gather essential information for a cultural assessment,

Toward Evidence-Based Practice

Reneau, M. (2013). Teaching nurses sight unseen: Comparing the cultural competency of online and on-campus BSN faculty. *Journal of Transcultural Nursing, 24*(1), 78–85.

The researcher compared the levels of cultural competency between 222 online and on-campus faculty. Results found that those teaching both online and on-campus had the highest level of cultural competency, followed by online educators. Faculty teaching on-campus had the lowest level of cultural competency. Recent cultural training was correlated with higher cultural competency scores.

Starr, S., & Wallace, D. (2011). Client perceptions of cultural competence of community-based nurses. *Journal of Community Health Nursing, 28*(2), 57–69.

Clients assessed the cultural competency of their community-based nurses in the areas of communication, interpersonal style, and decision making. The nurses self-assessed their own cultural competency. Nurses were rated by the clients as very high in all three areas. Nurses reported encountering multiple racial/ethnic groups in their practice and considered themselves as "very culturally competent."

Musolino, G., Burkhalter, S., Crookston, B., et al. (2010). Understanding and eliminating disparities in health care: Development and assessment of cultural competence for interdisciplinary health professionals at the University of Utah—a 3-year investigation. *Journal of Physical Therapy Education, 24*(1), 25–36.

A 3-year study tested the pre- and post-cultural competency learning outcomes of 2,124 Interdisciplinary Health Science students (medicine, physical therapy, nursing, pharmacy) who enrolled in a Cultural Competency and Mutual Respect course. The course consisted of four modules that focused on working and learning relationships involving different cultures. Results revealed students showed progression in the area of cultural competency for the constructs of attitudes, knowledge and skills, but did not achieve the constructs of cultural desires and cultural encounters.

Sequist, T., Fitzmaurice, G., Marshall R., et al. (2010). Cultural competency training and performance reports to improve diabetes care for black patients: A cluster randomized, controlled trial. *Annals of Internal Medicine, 152*(1), 40–46.

Increasing clinicians' awareness of racial disparities may improve communication and outcomes in patients. Researchers examined the effect of an intervention consisting of cultural competency training. Monthly reports of race stratified data on 2,699 blacks and 4,858 white diabetic patients. Primary care clinicians who received the intervention were more aware of racial differences and disparities in diabetic care among black patients, although the overall clinical outcomes did not improve.

Instructions: Staff nurses have expressed concerns that nursing students are not incorporating cultural differences in the patients' plans of care. They have asked that students receive more education on cultural care in their nursing program of study. Answer the following questions:

1. Which studies or results support the belief that education and learning activities on culture will improve cultural competence?

2. What is the importance of encounters with clients from various cultures on acquiring cultural competency?

3. Which study provides the best evidence for including cultural education in the nursing program of study?

Go to Chapter 15, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus* at **DavisPl.us/Wilkinson3.**

Go to Chapter 15, **Assessment Guidelines and Tools, Focused Assessment: Obtaining Minimal Cultural Information,** in Volume 2.

Physical Assessment

Physical assessment may reveal biocultural variations. To assess and evaluate clients accurately, you need to know the normal physiological variations among healthy members of selected populations (e.g., body proportions, vital signs, general appearance, skin, musculoskeletal system, illness, and laboratory values).

Assessing the Skin You will need to know about biocultural variations in skin because of the importance of assessing for pallor, cyanosis, jaundice, erythema, and petechiae, which may be more difficult to evaluate in dark-skinned persons, challenging you to be more observant. For helpful suggestions and for more information about assessing the skin, see Chapter 35, and

Go to Chapter 15, **Clinical Insight 15-1: Assessing for Biological Variations,** in Volume 2.

Assessing for Pain Culture influences the patient's responses to pain. Because pain and comfort are subjective responses, you need to quantify your client's pain as objectively as possible by using a pain measurement scale. Regardless of the literature descriptions of cultural responses, it is essential to investigate the meaning of pain to each individual and what they view as acceptable ways to express or cope with pain. For descriptions of some cultural responses to pain,

Go to Chapter 15, **Clinical Insight 15-2, Pain Perception in Selected Cultural Groups,** in Volume 2.

Cultural Assessment Models and Tools

Some agencies have special tools for in-depth cultural assessments. If yours does not, you can structure your assessments using any culture model, such as the following examples.

- Purnell Model for Cultural Competence (2002)
- Andrews and Boyle Transcultural Nursing Assessment Guide (2011)
- Spector's Heritage Assessment Model (2004). Instead of assessing culture specifics, this tool assesses heritage consistency: the degree to which a person's lifestyle reflects his traditional culture (country of origin, race, or ethnic group). This assessment tool also reveals the degree to which the client still identifies with his cultural origins.
- Giger and Davidhizar's Transcultural Assessment Model (2008)

For more information on the preceding cultural assessment models,

Go to Chapter 15, **Tables, Boxes, Figures: ESG Figures 15-2 and 15-3, and ESG Box 15-1 and ESG Table 15-3,** on Davis*Plus*.

For another example of a focused cultural assessment,

Go to Chapter 15, **Assessment Guidelines and Tools, Focused Assessment Cultural Assessment Using the Transcultural Model,** in Volume 2.

ANALYSIS/NURSING DIAGNOSIS

There are no NANDA-I diagnoses that specifically address culture. However, cultural factors can be the etiology of various problems. Any of the NANDA-I diagnostic labels can be used for patients of any culture, provided that the defining characteristics are present. Some possible examples include the following:

- **Risk for Imbalanced Nutrition: Less Than Body Requirements** might apply to a patient who is hospitalized and cannot obtain foods prepared in the traditional way of his ethnic group.
- **Impaired Parenting** could occur if the patient's traditional methods of discipline are not acceptable or appropriate in the dominant culture.
- **Powerlessness** might occur when the patient is unable to make healthcare personnel understand the importance of his cultural rituals or healthcare practices.
- **Impaired Verbal Communication** is sometimes used for patients who do not speak or understand the nurse's language. However, this diagnosis is of questionable value in such circumstances. In a classic study, Geissler (1991) found that Impaired Verbal Communication related more to cultural differences between the patient and healthcare provider than to the inability to communicate. The patient and nurse are equally "verbally impaired"—that is, communication is as much a problem for the nurse as it is for the patient. It is probably better to use Impaired Verbal Communication as the etiology of other diagnoses, such as Deficient Knowledge.
- **Noncompliance** can be used for clients and/or caregivers who do not follow a health-promoting or therapeutic plan the healthcare provider believes they agreed to. For example, the plan may not "fit" with the client's perception of the cause of his illness, as in the following scenario:

  Example: Suppose that a 60-year-old woman who works as a hotel maid is repeatedly admitted to your hospital for uncontrolled hypertension. You know that she does not take her medication, and you diagnose Noncompliance (failure to take prescribed medication). But do you know that a month's supply of antihypertensive medication can cost more than $100? Perhaps your patient is raising her grandchildren and paying for food, shelter, and clothing consumes her entire income. Or perhaps she believes that herbs, diet, and other practices will reduce her blood pressure.

  You should use the Noncompliance diagnosis cautiously and only after completing a cultural assessment. Geissler (1991) found that additional defining characteristics are needed before Noncompliance can be appropriately applied to clients not of the dominant U.S. culture. In fact, Geissler suggests the nurses use the term *Nonadherence* instead of *Noncompliance*.

The preceding example illustrates that standardized nursing diagnoses are not always culturally sensitive and therefore may not apply accurately to patients who are not from the dominant culture. Nursing diagnoses should describe responses that *patients* see as problematic. A nurse and patient who are from different cultures will likely have different perceptions of health and illness. This can lead to misdiagnosis. The nurse may either diagnose a problem that doesn't exist for the patient or diagnose a "real" problem but fail to describe it accurately (Wilkinson, 2011).

The following are a few examples of NANDA-I nursing diagnoses that could be interpreted differently by people from different cultures. Undoubtedly there are others.

Acute Pain	Impaired Social Interaction
Anxiety	Ineffective Coping
Decisional Conflict	Ineffective Role Performance
Readiness for Enhanced Breastfeeding	Noncompliance
Imbalanced Nutrition: More Than Body Requirements	Powerlessness

The point is to use all labels carefully and to validate nursing diagnoses with the patient to be sure that the statement describes her health status as *she* sees it.

PLANNING OUTCOMES/EVALUATION

The outcomes you choose (whether standardized or individualized) depend on the nursing diagnoses you have identified. If the diagnoses are culturally sensitive, the outcomes should be as well. However, you must involve the patient in order to be certain. For example, suppose your patient is dying. You and the patient agree that her diagnosis is Acute Pain, but your goals may be different. You might want the patient to be free from pain. However, the patient's goal may be to stay alert enough to interact with her family, even if it means she must endure some pain. When your cultures differ, it is even more important to validate the goals with the patient. Some individualized goal/outcome statements associated with cultural differences might include the following:

- Agrees to take prescribed analgesic (pain medication) before bedtime and after family leaves for the evening.
- Talks to her spiritual adviser about the possibility of a treatment plan that conflicts with her religious beliefs.
- Freely shares information about folk practices and OTC medications with the primary care provider.

PLANNING INTERVENTIONS/IMPLEMENTATION

You should become familiar with the cultural groups that are dominant in your area and that you will encounter in your nursing practice to plan culturally appropriate care.

NIC standardized interventions related to culture and the provision of culturally competent care include the following examples:

Active Listening (for Impaired Verbal Communication)
Mutual Goal Setting (for Impaired Parenting)
Self-Responsibility Facilitation (for Powerlessness)
Culture Brokerage (for Noncompliance)

Culture Brokerage, a Nursing Intervention Classification (NIC) intervention, is defined as "the deliberate use of culturally competent strategies to bridge or mediate between the patient's culture and the biomedical healthcare system" (Bulechek, Butcher, & Dochterman, 2013, p. 136).

Individualized nursing activities and focused assessments are important for all patients. However, patients from different cultural and ethnic groups may have unique needs that can be met by some of the activities included in the following discussion regarding culturally competent care.

Nursing Strategies for Providing Culturally Competent Care

When planning care for your clients, information about their cultural values, beliefs, and practices will help you identify interventions that will support these practices and incorporate them into their care as much as possible (Wilkinson, 2011). For example, when you are teaching about a specific treatment regimen ordered by the primary care provider, you should find out whether it conflicts with any of the patient's folk beliefs or alternative treatments so you can suggest necessary modifications. Remember also to identify educational methods that are most appropriate for your client's needs (e.g., translated materials and/or diagrams) and to make community referrals as necessary.

KnowledgeCheck 15-8

- Describe, in general, how the nursing process can help you provide culturally competent care.
- How can nursing diagnoses cause bias in the planning of care for clients from different cultures?

How Should I Respond to a Client's Cultural Health Practices?

Theorists describe different situations in which nursing decisions and actions are needed regarding a client's cultural health practices. A practice may be helpful, harmful, or neutral; or the effects may be unknown (Giger, 2012; Leininger, 1991; Leininger & McFarland, 2006). See Table 15-4.

Negotiation The client's perspective may differ from yours about the effects of a particular practice. Negotiation acknowledges that gap. You must negotiate when folk or traditional practices might be harmful to the client.

Example: The nurse negotiates with the client to continue seeing the curandero, but to come to the clinic every 6 weeks to have his blood pressure checked. If the client refuses all biomedical or nursing interventions, the only avenue still open is to continue monitoring the client to identify changes in his health status. If a health crisis occurs, it may be possible to renegotiate the care.

Repatterning/Restructuring This means that you attempt to change your actions or the client's lifestyle (Leininger, 1991; Leininger & McFarland, 2006). You would support and encourage the client to greatly modify his behaviors and to adopt new, different, and beneficial health behaviors, while still respecting his cultural values and beliefs.

Example 1. Change in the nurse's actions. When the client absolutely refuses to take the prescribed pain medication, the nurse uses massage, distraction, and other nonpharmacological techniques to help relieve his pain.

Example 2. Modification of the client's behaviors. A client refuses to see a biomedical doctor for her family's needs. However, when the folk healer is unsuccessful in treating her child's illness and the child becomes critically ill, the nurse convinces the client to bring the child to the emergency department.

Table 15-4 ➤ Possible Effects of a Patient's Cultural Health Practices

THE EFFECTS ARE:	EXAMPLE	NURSING APPROACH
Efficacious (Helpful)	Bringing ethnic foods that are appropriate for the client's prescribed diet.	Encourage practices that will likely improve client health and help her preserve cultural values related to health.
Neutral (Neither Helpful nor Harmful)	People of Arab heritage associate good health with eating properly and fasting to cure disease. Some may treat illness with prayers or simple foods such as dates, honey, salt, and olive oil (Purnell & Paulanka, 2008; Purnell, 2012).	There should be no harm in allowing a patient to continue a neutral health practice. You would not want to interfere with these neutral practices.
Uncertain (Unknown by You)	A client drinks a daily smoothie that consists of certain herbs and spices such as ginger, cinnamon, and basil for "good health."	You can neither encourage nor discourage these practices until you obtain more information about them. Do this as soon as possible.
Dysfunctional (Harmful)	A client may refuse to give prescribed medication to her child.	Discourage folk practices that may cause harm. In such instances, you should support and enable the client to adapt to biomedical therapies (repatterning/restructuring) or negotiate with the client to achieve satisfying outcomes.

How Do I Communicate With Clients Who Speak a Different Language?

Communicating with clients who do not speak your language can be especially challenging. The Internet and computer software allow patients to type information in their native language and translate it into English as a way to communicate with providers. However, the best way to provide culturally competent care to such clients is to use a professional medical interpreter or translator. An **interpreter** is specially trained to provide the meaning behind the words, whereas a **translator** just restates the words from one language to another. An interpreter can serve as a cultural broker by conveying the client's responses to questions and by providing general information about the client's culture. Both must meet predetermined standards to participate in translation services. Do not use family or friends as interpreters except if requested by the patient. For guidelines when using an interpreter and when an interpreter is not available,

Go to Chapter 15, **Clinical Insights 15-3: Communicating With Clients Who Speak a Different Language,** in Volume 2.

CLAS Standards

Healthcare facilities must provide language assistance services by, in order of preference, bilingual staff, face-to face interpretation by trained persons, or telephone interpreters. Healthcare interpreters should be used to obtain informed consent and to assist the patient to understand the treatment plan (U.S. Department of Health and Human Services, Office of Minority Health, 2001; Wilson-Stronks, Lee, & Cordero, 2008).

Research shows that many hospitals do provide patients with information on their rights to receive language services; however, the information is provided in English. In addition, the majority of hospitals continue to use untrained or family members as interpreters, contrary to CLAS standard 6 (Diamond, Wilson-Stronks, & Jacobs, 2010). Only 13% of hospitals surveyed met all four language-related standards. Hospitals with a diverse inpatient population, not-for-profits hospitals, and those located in affluent and competitive markets had a high degree of cultural competency (Weech-Maldonado, Elliott, Pradhan, et al., 2012). You should advocate for your clients to ensure the goal of cultural competence is met. For a complete listing of the CLAS standards,

Go to Chapter 15, **Supplemental Materials: CLAS Standards,** on Davis*Plus*.

Developing Strategies

There are several strategies for you to consider and many resources to help you develop strategies specific to various cultural groups (Box 15-2). Consider the following as you move forward on your journey toward cultural competence:

Reflect and Know Yourself

- Understand your own cultural values and practices and appreciate how they may differ from those held by people of other cultures.

BOX 15-2 ■ Being Considerate of Cultural Specifics

Consider verbal and nonverbal communication.

- Know, or find out, whether touch (e.g., a handshake) is expected or prohibited.
- Know, or find out, whether eye contact is expected or avoided. Avoiding eye contact, for some, is a sign of respect.
- Ask the client how he wishes to be addressed.
- Know, or find out, the ways people welcome each other.

Consider the person's need for personal space.

- Know the person's cultural and religious customs regarding touching and contact.
- Know the usual comfortable distance for conversing in the client's culture.

Consider body language.

- Gestures that are acceptable in one culture may be taboo in another. Know what is acceptable to the client.
- Be aware that smiling does not universally indicate friendliness.

Consider time orientation.

- Tell clients when you are coming, and be on time.
- Avoid surprise visits.
- Share your own expectations about time.
- Ask clients what they expect regarding time, appointments, and so on.
- Be sure you know the times for and meanings of the client's religious and ethnic holidays.

Consider social organization.

- Know which person in the family is the leader or decision maker.
- Know what dates are important and whether gifts are expected or not.
- Know how special events, such as births and funerals, are celebrated, whether certain colors have meaning, and what the expected rituals are.

Consider the person's perspective on environmental control.

- Find out what the client's health traditions and practices are.
- Know whether the person believes she has any ability to "change things."
- Know the general influence of the culture on perception and tolerance of pain.
- Know what foods are forbidden, what foods may or may not be eaten together, and what and how utensils are used.

- Recognize your own biases about people and groups, and consider how they may affect the care you provide.
- Learn from your mistakes, and don't make them again.

Keep Learning

- Learn as much as you can about the cultural groups in your community and work area.
- Study nursing theories and principles pertaining to culture.
- Take advantage of every opportunity to interact with persons from different cultural groups.

Accommodate and Negotiate

- Make an effort to incorporate beliefs and practices from various cultures into your nursing care and teaching materials.
- Encourage helpful or neutral cultural practices, and discourage those that are dysfunctional (harmful).
- Suggest alternatives to harmful practices.
- Accommodate cultural dietary practices when possible. For inpatients, some dietary departments can make special foods, and you can encourage families to bring food from home. In all situations, help patients and families adapt cultural foods to therapeutic diets.

Collaborate

- Work with the folk medicine practitioner in the interest of the client.
- Advocate for all of your clients, but especially for those not from the dominant culture.
- Consider the cultural role of the family member who makes the primary decisions. To ignore this person is to doom your interventions to failure.

Respect

- Consider each client as a unique individual, influenced but not defined by his culture.
- Respect your clients regardless of cultural background, and never force, pressure, manipulate, or coerce them to participate in care that conflicts with their values and beliefs.

This is by no means an exhaustive list. Most likely, you can think of other strategies. It may help you to "take a trip to BALI":

Be aware of your own cultural heritage.
Appreciate that the client is unique: influenced, but not defined by his culture.
Learn about the client's cultural group.
Incorporate the client's cultural values/behaviors into the care plan.

KnowledgeCheck 15-9

- List five factors to consider to help you develop strategies to become more culturally competent.
- What does the acronym "BALI" stand for?

How Can I Become Culturally Competent?

Of course you can't become culturally competent just by reading. People acquire cultural competence gradually, progressing through the following stages:

Unconscious incompetence—not being aware that you lack knowledge about another culture
Conscious incompetence—being aware that you lack knowledge about another culture
Conscious competence—learning about the client's culture, verifying generalizations about the culture (e.g., archetypes), and providing culture specific interventions
Unconscious competence—automatically providing culturally congruent care to clients of diverse cultures (Purnell & Paulanka, 2008, p. 6)

Theoretical knowledge can increase your awareness and appreciation of cultural differences, but you can achieve cultural competence only if you are motivated and even then only by interacting with people from cultures different from your own (Musolino, Burkhalter, Crookston, et al., 2010). Carballeira (1997) sums up this process with the LIVE and LEARN model for culturally competent family services:

Like		**L**isten
Inquire		**E**valuate
Visit	and	**A**cknowledge
Experience		**R**ecommend
		Negotiate

Key Point: ***If there were only one intervention you could use to improve your cultural competence, it should be to routinely ask patients what matters most to them in their illness and treatment.***

No matter how busy you are, you can find time to do that. You can then use that information to incorporate cultural needs into the client plan of care.

ThinkLike a Nurse 15-8

What kind of knowledge do you need to become culturally competent (theoretical, practical, self, ethical)? Explain your answer.

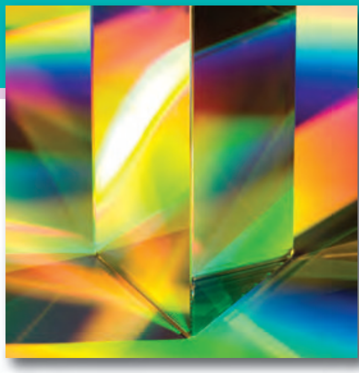
CHAPTER 16



Spirituality

Learning Outcomes

After completing this chapter, you should be able to:

- Describe the differences and similarities between religion and spirituality.
- Discuss what is meant by *spirituality.*
- For each of the religions briefly covered in this chapter, describe its major beliefs and their implications for nursing care.
- Identify five barriers to spiritual care.
- Perform a spiritual assessment.
- Recognize the differences between spiritual care diagnoses and those that may serve as etiologies of other nursing diagnoses.
- Plan nursing interventions based on the data obtained in a spiritual assessment.
- Examine your own level of comfort in terms of performing spiritual interventions.
- Describe collaborative efforts to ensure the spiritual care of the patient or family.

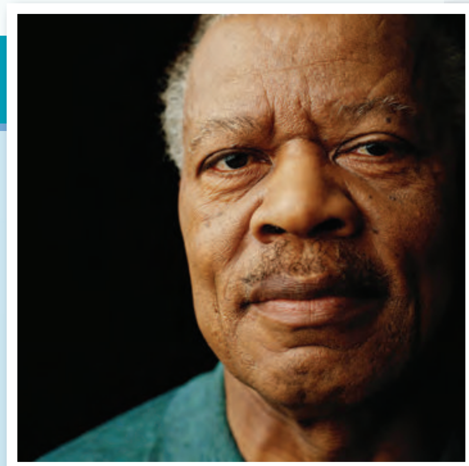
Key Concepts

Spirituality
Religion
Spiritual care

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patient



Charles Johnson is a 75-year-old African American man with newly diagnosed lung cancer. He began smoking at age 15. His physicians want to start chemotherapy to try to increase his life span. He is unsure whether he wants to have chemotherapy.

Mr. Johnson was brought up in the Baptist Church, but has fallen away from practicing his faith over the years. He has been a heavy drinker all of his adult life and, as a young man, has distanced himself from church. He explains: "Church folks are all a bunch of hypocrites, if you ask me. I choose not to be a part of any of that." Nevertheless, he says that he tries to be kind to and tolerant of others. "I've messed up my life, so I figure I don't have any business telling other people how to live. I guess I just figure that how a person lives is between him and God."

Mr. Johnson has one surviving relative, a sister, who is concerned about him. His sister is a devout Jehovah's Witness, and she has tried several times to talk to Mr. Johnson about the importance of Jehovah in her life. She continually leaves religious pamphlets and materials in his mailbox to encourage him to think about religion again.

Mr. Johnson's wife divorced him 20 years ago because of his drinking behaviors, and he has alienated his two middle-aged children, so he rarely sees his grandchildren. He lives alone, is retired, and is having some trouble making ends meet financially. He has one avid hobby: He loves to go out in a boat and fish all day with his buddy, Jim.

- Mr. Johnson clearly has some physical and psychosocial difficulties. Can you identify them?
- Assess Mr. Johnson's support system. Whom can he rely on for help?
- How might you help Mr. Johnson to add some spiritual supports to his available resources?

Theoretical Knowledge knowing why

Spirituality in nursing has multiple layers. The following layers of competing concerns must be properly balanced to minimize your confusion, frustration, and avoidance of spiritual care.

- **Spirituality of the Nurse.** Each nurse's spirituality serves as part of the guiding framework for her practice.
- **Spirituality of the Patient and Family.** Spirituality will be understood in different ways by your patients and their families. Their spirituality may be deeply ingrained or totally separate from formal religion.
- **Effects of Nursing Education.** The emphasis placed on spiritual care interventions will vary among the various nursing programs; however, many teach students to avoid imposing their spiritual beliefs, or lack of, on patients.
- **Demands of Nursing Practice.** Time constraints imposed by the day-to-day patient care activities in healthcare environments can be viewed as negatively impacting your ability to meet your patients' spiritual needs. Rely on your communication and assessment skills to establish a therapeutic nurse–patient relationship that is the foundation for meeting your patients' spiritual needs (Biro, 2012).

This chapter presents a holistic interpretation of spirituality—one that views spirituality as a component of every person's life. It also encourages you to engage your own spirituality to improve your patients' health and wholeness. It should help you to answer some of the questions posed for Mr. Johnson.

ABOUT THE KEY CONCEPTS

As you study this chapter, try to relate what you are reading to the key concepts of **spirituality** and **religion**, and try to understand how those two concepts relate to each other. This will provide you a foundation from which to work with the concept of **spiritual care**. It is that concept that links you to your patients.

HISTORY OF SPIRITUALITY IN NURSING

Through the ages, nurses and other caregivers have demonstrated deep concern for the spiritual as well as the physical and psychological needs of those who are sick and infirm.

In the pre-Christian era, caring for the sick was an expression of the values of hospitality and charity. People prayed to the god(s) for healing and as an adjunct for primitive medical procedures.

In the early Christian era, nursing the sick was honored and respected because it was one of Jesus Christ's primary teachings. Caring for the sick was a vital component of loving one's neighbor. Gradually, religious communities of women and men in the 4th through 12th centuries provided models for combining the healing arts with religious care.

During the post-Reformation period in Europe, nursing orders continued to flourish, among them the Daughters of Charity, the Sisters of Mercy, and the Kaiserswerth Deaconesses (Donahue, 1985). Florence Nightingale trained under Pastor Fliedner at his Deaconess School in Kaiserswerth, as well as under the Daughters of Charity of St. Vincent de Paul in France. For Nightingale, spirituality was at the very heart of human nature and thus was fundamental to healing. Nightingale instilled this value in her nurses, particularly during their missions in the Crimea where "the lady with the lamp" brought comfort and relief to the sick and the dying (Dolarno, 2010; McDonald, 2002).

By the mid-20th century, nursing in the United States had begun to see spiritual care as less important. As science continued to develop and expand, and as more nurses studied in university settings, nursing joined ranks with the scientific disciplines: Its spiritual underpinnings were replaced by what could be "seen and tested" by the scientific method. Only recently has nursing (and the broader health community) reclaimed the spiritual dimension as a vital part of its identity and recognized its power to influence health.

Key Point: ***Today, spiritual care cannot be the "overlooked" area of nursing practice. Professional standards of care make clear that meeting patients' spiritual needs is essential to provide holistic nursing care.*** The Joint Commission (2010) has established standards for spiritual care. In addition, the American Nurses Association's (ANA) Code for Nurses (2010) states that nurses should consider each patient's lifestyle, value system, and religious beliefs in planning care; and that nursing care measures should enable the patient to live with as much physical, emotional, social, and spiritual well-being as possible.

WHAT ARE RELIGION AND SPIRITUALITY?

Spirituality and religion are related, yet they are two distinct and different concepts, as identified in Table 16-1. For example, atheists and agnostics have no religious foundation, but may have spiritual needs (Sessana, Finnell, Underhill, et al., 2011). One way to distinguish religion from spirituality is to think of religion as a map and spirituality as a journey.

What Is Religion?

You may use a map to get to a certain location. The "map" of religion tells you what to believe and what values are essential. It provides codes of conduct that integrate beliefs and values into a way of living. The

Quality and Safety Education for Nurses

The Impact of Nurse Self-Awareness on Patient Spiritual Care

Chapter Key Concepts: *Spirituality, Patient-Centeredness, Nurse Self-Awareness*

Competency: *Patient-Centered Care (Knowledge, skills, attitudes)**

Background: Holistic nursing care includes addressing the patient's physical, psychosocial and spiritual needs. Spirituality isn't always linked with religion. Rather, spirituality is what the individual professes it to be (Schaefer, Stonecipher, & Kane, 2012). The QSEN competency of patient-centered care recognizes "the patient as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs" (Cronenwett, Sherwood, Barnsteiner, et al., 2007). To provide holistic care the nurse must understand the meaning of spirituality and have a self-awareness of her own spirituality. An awareness of one's own spirituality contributes to the ability to relate meaningfully with patients and to provide care to support patients' spiritual needs (Lee & Higgens, 2010).

Think about it:

- Describe nursing interventions that would meet the spiritual needs of the patient.
- How does providing patient-centered care attend to the spiritual needs of the patient?
- Discuss how spiritual self-awareness by the nurse might influence the spiritual care provided for the patient.

Sources: Cronenwett, L., Sherwood, G., Barnsteiner, J., et al. (2007); Lee, D., & Higgens, P. (2010); Schaefer, J., Stonecipher, S., & Kane, I. (2012).

As reference for your QSEN log box, the QSEN KSA that is most pertinent is:

Respect and encourage individual expression of patient values, preferences and expressed needs.

*For specific Knowledge, Skills, and Attitudes,

Go to the QSEN Web site at **http://qsen.org/competencies/pre-licensure-ksas/**

Table 16-1 ➤ Comparison of Religion and Spirituality

RELIGION (THE MAP)	SPIRITUALITY (THE JOURNEY)
A "roadmap" that defines: Beliefs Values Code(s) of conduct and ethics	One's journey through life; a personal quest to define meaning, fulfillment, and satisfaction in life; a will to live; a belief in self; an exploration of who you are
A tradition or system of worship that provides: Rituals Answers Norms Connection with God	A dynamic relationship with that which transcends; a capacity to know and be known (a sense of openness, expectation); connectedness with self, others, nature, and a higher power (Cavendish, Konecny, Mitzeliotis, et al., 2003); belief in a divine being, or infinite source of energy (Beckman, Boxley-Harges, Bruick-Sorge, et al., 2007).
The roadmap and tradition define: What is to be believed How beliefs affect life Self-image and identity	A lifelong process of growth (which may involve joy and/or struggle); a constant process of taking in "truth" and then adding individual insight to arrive at a way of perceiving and acting in the world
Issues: Faith, belief, trust, the nature of good and evil, the meaning of suffering, judgment, or enlightenment	Issues: Faith, hope, love

map itself may be in the form of a religious tradition (e.g., Christianity) or denomination (e.g., Baptist), which provides an identity and a "lens" for reading the world. The rituals, symbols, sacraments, and holy writings associated with religions serve as bases of authority and provide diverse ways to transcend the physical and access the divine (e.g., God) (Fig. 16-1). Regardless of their differences, many of the world religions have the following in common:

- **Theology**—that is, discussions and theories related to God and God's relation to the world
- Sacred writings that are regarded as authoritative and/or reveal the nature of the divine in some way

FIGURE 16-1 Associated with religion are various symbols and holy writings, such as this cross and Bible representing Christianity.

- Notion of created order and purpose
- Definition of *human being* that includes important life events
- Notion of sin (primarily in Western religions)
- Explanation of the origin of evil and the nature of suffering
- Conception of either salvation (in Judeo-Christian religions) or enlightenment (in Eastern religions)
- **Eschatology**, or doctrines about the human soul and its relation to death, judgment, and eternal life (primarily a Western concept)
- Explanation of the nature of reality, the higher Self or soul, the relationship between humans and the divine, and the purpose of human existence

What Is Spirituality?

If religion serves as the map, spirituality is the day-to-day, moment-by-moment journey in life and living. Like a journey, spirituality involves personal subjective experiences that take place over time. Many life events that prompt spiritual growth are fulfilling and joyful, but growth often results from painful life events that cause great internal upheaval, struggle, and challenge.

Like religion, spirituality allows various ways and means to experience the divine in our daily lives, to transcend the physical world, or simply to be still and introspective. You can also think of spirituality as the insight, value, purpose, and meaning of life derived from accumulated life experiences. They may agree or conflict with traditional religious values and cultural teachings. For example, after studying a variety of religions and traveling in Asia for several years, an American raised in the Episcopal Church may develop a spirituality that is both universal and highly individual and may feel "at home" in any place of worship in the world.

One Western model of spirituality asserts that we learn to "read" the spiritual in everyday events only when we attain a new "level of literacy." Life then is a process of recognizing everyday signs of an active Spirit in the world and understanding its meaning. This model states that we can engage this Spirit through such sources as nature, animals, leisure, creativity, and service (Brussat & Brussat, 1996).

It is critical for you to recognize and respect the different ways that patients understand religion and spirituality. You need to understand that most people are comfortable with their beliefs (or lack thereof) and that in providing spiritual care your primary goal is to support their healing, not convert them to a different view. You must also be able to recognize situations when patients may be experiencing spiritual distress and may need referral to professionals with more specialized training. These aspects of spiritual care are discussed later in this chapter.

KnowledgeCheck 16-1

- Regardless of their differences, what do many world religions have in common?
- Which can be compared to a journey: religion or spirituality?
- True or false? Both religion and spirituality allow a person various ways to access the divine.
- What is Mr. Johnson's religion (Meet Your Patient)?
- What is his sister's religion?

ThinkLike a Nurse 16-1

- What do you know, or what can you speculate, about Mr. Johnson's (Meet Your Patient) spirituality?

What Are the Core Issues of Spirituality?

By now you know that spirituality has many dimensions. We limit discussion here to three core issues. In his first letter to the Corinthians in the New Testament of the Bible, Saint Paul identified "three things that last": faith, hope, and love. Following in this tradition, a manual for nursing care of the dying (Aspen Reference Group, 2002) identifies this same trio as the three core issues of spirituality.

Faith

Faith is an evolving pattern of believing that guides and grounds us, helps us make sense of the world, and confront the challenges we face (Dyess, 2011). It allows us to trust and to maintain an optimistic perspective on life events and to find purpose in life. Like spirituality, faith represents a set of beliefs developed over time, through events that cause us to suffer and those that enable us to rejoice.

Faith struggles are common among people who experience illness and significant loss. People experiencing faith struggles might feel anger, guilt, self-judgment, and worthlessness. C. S. Lewis, a devout Christian, reveals that after the death of his wife, his grief caused him to doubt whether God exists at all, or if so, whether He is perhaps a "Cosmic Sadist" (1961, p. 35) who deliberately tortures us. Finally, Lewis came to understand that such shattering experiences are "one of the marks of His presence" (Lewis, 1961, p. 76).

People who are experiencing the *joys of faith* exhibit a sense of self, as well as insights into their gifts and talents. In his book *Callings,* Gregg Levoy (1997, p. 65) observes that our joy and our enthusiasm move us "toward a kind of divine presence because, through our passions, we are utterly present. . . . We hitch ourselves to something bigger."

Hope

Hope is a dynamic process that reflects a positive orientation towards future outcomes. It includes our basic human need to achieve, create, and to shape something of our life that will endure. If faith is expressed in terms of belief, then hope is rooted in purpose—who am I, what is my purpose, and why have I been created? People who are confronting a debilitating or terminal illness often lose hope. Research shows that support systems, attitudes of healthcare providers, and skilled nursing care are important in fostering hope in patients who experienced traumatic injuries (Warwick, 2012). After suffering a near-fatal spinal cord injury, actor Christopher Reeve struggled with hope; yet, he wrote in an essay, "Hope . . . is different from optimism or wishful thinking. When we have hope, we discover powers within ourselves we may have never known—the power to make sacrifices, to endure, to heal, and to love. Once we choose hope, everything is possible" (Reeve, 2002, p. 176).

Love

Although it is better defined as a strong affection for another, many view love as a trade: We extend our love because we hope to find that love is returned in some way. But relationships can be a source of pain. Even when our love is shared, we must inevitably face separation at our death or the death of our loved ones. Thus, while active loving in human relationships opens us up to joy and can give life meaning and purpose, it also carries with it the certainty of heartbreak (e.g., when a loved one dies).

Illness and sudden injury can prompt "struggles with love." For example, when a man with a debilitating disease loses his ability to work and requires increasing levels of caregiving, he may see himself as a "burden" and question whether his loved ones would be "better off" if he were to die. Family members are invaluable in showing their unconditional love to help restore the patient's inner integrity and self-worth. Reeve stated that the most powerful words his wife spoke to him in the first days after his injury, "the words that saved my life," were, "You're still you. And I love you" (Reeve, 1998, p. 32). This support, combined with the compassionate love transmitted by healthcare providers, can help patients to overcome negative states, increase healing, and promote better-quality outcomes (Posadzki, 2010).

Cures, Miracles, and Spiritual Healing

The patient or family may request a prayer asking God for a cure when your expertise tells you that all curative measures have been exhausted. You should not say that a cure is impossible; however, it is equally important to avoid exposing the patient and family to false hope. In such cases, it may be possible for you, as care provider and companion on the spiritual journey, to offer a way to reframe the situation. Perhaps, healing does not necessarily have to imply the elimination of all types of suffering or of the disease. Rather, it may mean a transformation in a patient's thinking or feeling or acknowledging the patient's belief in the spirit. In such instances, various forms of healing can occur, and the person may experience it as a miracle.

A **miracle** is anything that allows for the presence of the transcendent (e.g., God, a Higher Being, the experience of one's angel, or any brush with the divine). We typically think of miracles as events that break with the natural order of things; however, miracles may proceed according to natural law. After the death of her patient, a physician described the patient's long-resisted acceptance of his impending death as the miracle, which prevented fruitless interventions and unnecessary suffering (La Madrid, 2012). What makes events miracles is that they far exceed our expectations. For instance, an elderly woman, bitter for decades over the death of her daughter during childhood, "feels" her daughter's presence and dies in peace. As you can see, miracles do not always involve physical cures. Miracles can also be spiritual phenomena. As such, they are mysterious and difficult to define, explain, and comprehend. In one sense, miracles can be viewed as perfectly ordinary events; in another, they can only be explained as the act of a "deity" (McGrew, 2013). For example, a blind person suddenly can see, with no treatment or explanation.

ThinkLike a Nurse 16-2

Faith is a constant search for comprehension and meaning. What are some of your struggles with faith, and what are some of the "joys" of your faith?

How Might Spiritual Beliefs Affect Health?

Religion and spirituality have been presented as two separate and distinct constructs; however, current research on their influence on health tends to combine them into one concept, namely, religion or religious involvement. Research findings are varied in terms of the relationship of religion and/or spirituality on health outcomes and behaviors.

- One study found that religious involvement was instrumental in decreasing anxiety and depression and increasing overall quality of life (Huang, Hsu, & Chen, 2012).
- Another study found that African Americans and Hispanic Americans had a greater rate of religiosity; however, they did not experience greater mental health

benefits. In addition, only White Americans experienced better mental health benefits from attending religious services (Sternthal, Williams, Musick, et al., 2012).

- Other researchers investigated the effect of religious beliefs on health disparities (Jun & Oh, 2013). The impact of the religious/cultural belief of *fatalismo* among Hispanics and fatalism among Asians was shown to have a negative effect on compliance with preventive cancer screening. Fatalism, which is rooted in Buddhism, views fatal diseases as destined by nature and acceptance as a sign of wisdom and maturity. Likewise, *fatalismo*, with roots in Christianity, views diseases as predetermined with a predictable outcome. Both groups had high pessimistic perceptions that preventive screening would lower their risk of getting cancer.

In research on spirituality, the variables studied tend to be broadly stated and nonspecific. Most use broad measures, such as self-reports of one's own religiousness, denominational affiliation, church attendance or membership (e.g., "On a scale of 1 to 5, how religious are you?" "How often do you attend church?"). Thus, they do not allow for researchers to examine whether there might be potential harmful effects of religion. For a list of other recent studies,

Go to Chapter 16, **Reading More About Spirituality,** on Davis*Plus*.

Although some research suggests that religion has a positive influence on healthcare outcomes, it does not yet answer *how* or *why* religion has this effect. However, there is growing awareness that religion and spirituality are complex variables involving cognitive, emotional, behavioral, interpersonal, and physiological dimensions. For a description of recent research testing more specific variables (e.g., religion as a factor to live a healthy lifestyle),

Go to Chapter 16, **Supplemental Materials: Religion and Health: Recent Research Areas,** on Davis*Plus*.

Toward Evidence-Based Practice

Grudzen, C., Stone, S., Mohanty, S., et al. (2011). "I want to be taking my own last breath": Patients' reflections on illness when presenting to the emergency department at the end of life. *Journal of Palliative Medicine, 14*(3), 293–296.

Interviews were conducted with 13 patients with advanced illness who presented to the emergency department for palliative care. While many were comforted by their faith in God, they did not view themselves as controlling their fate. Although they preferred to die at home surrounded by their family, they had not discussed this with their physician. The nurse's role of advocacy will ensure that patients' wishes are known and communicated appropriately.

Yanez, B., Edmondson, D., Stanton, A., et al. (2009). Facets of spirituality as predictors of adjustments to cancer: Relative contributions of having faith and finding meaning. *Journal of Consulting and Clinical Psychology, 77*, 730–741.

In two longitudinal studies of breast cancer patients (Study 1, N = 418 breast cancer patients; Study 2, N = 165 cancer survivors), meaning/peace and faith and their interactions were examined to determine the effect on psychological adjustment. Higher meaning/peace scores were associated with a decline in depressive symptoms, an increase in vitality, improved mental health, and lower cancer-related distress. The ability to find meaning and peace in life was found to be the most influential contributor to favorable adjustment during cancer survivorship.

Buck, H., Overcash, J., & McMillan, S. (2009). The geriatric cancer experience at the end of life: Testing an adapted model. *Oncology Nursing Forum, 36*(6), 664–673.

Researchers found that the majority of variability (67%) in the quality of life factor in 403 hospice homecare patients was due to severity of symptoms and spiritual experiences. Increases in quality of life were related to increases in the spiritual experience.

Astrow, A., Wexler, A., Texeira, K., et al. (2007). Is failure to meet spiritual needs associated with cancer patients' perceptions of quality of care and their satisfaction with care? *Journal of Clinical Oncology, 25*(36), 5753–5757.

Researchers administered religion and spiritual belief and needs questionnaires to 369 outpatients at a cancer treatment facility. Results revealed an inverse relationship between fulfillment of spiritual needs and quality and satisfaction with care. Patients whose spiritual needs were not meet had lower ratings on satisfaction with and quality of care.

1. For which of the following do these studies, taken as a whole, provide the stronger support for the premise:
   a. Spirituality has a positive effect on physical factors.
   b. Spirituality has a positive effect on psychosocial or emotional factors.

Explain your reasoning.

2. Suppose you are a nursing home administrator in an institution where the focus is almost entirely on physical care. You are thinking about a program to teach and encourage your staff to integrate spiritual interventions into their care. Evaluate the findings from each of the studies to see how useful it would be in supporting your idea. Explain your thinking.

ThinkLike a Nurse 16-3

- How might religion negatively influence health?
- Has there been a pivotal moment in your life, a moment of crisis or despair that eventually provided an opportunity for spiritual growth?

Major Religions: What Should I Know?

The more you know about the differences and similarities among the world's major religions, the more you will be able to offer comprehensive and compassionate care to patients. Of course, learning about other religions requires you to be open and nonjudgmental. When you care for a patient from a known religious background, you will need to think about how the person's beliefs affect her ideas of health, healing, hospitalization, and the experience of dying. To help you make these connections, the following brief descriptions of several of the world's major religious traditions provide you with several different "worldviews." To learn about the influence of various religions on end-of-life care, see Chapter 17. For more detailed information about each religion,

Go to Chapter 16, **Supplemental Materials: Major Religions: What Should I Know?** and **Reading More About Spirituality,** on Davis*Plus*.

Judaism

Judaism is one of the Western world's oldest religions and the foundation on which Christianity and Islam were built. The Jewish Law is set down in the collective writings of the Torah. Judaism is based on the worship of one God (monotheism), obeying the Ten Commandments, and practicing charity and tolerance toward others. The degree to which Jews celebrate rituals and holy days depends on whether the person identifies with the Orthodox, Liberal, Conservative, or Reconstructionist beliefs (Oxtoby & Segal, 2007; Pawlikowski, 1990).

Jews celebrate the Sabbath from sunset on Friday to sunset Saturday evening. For Orthodox Jews, work is prohibited on the Sabbath. This includes writing, traveling, and switching on lights and appliances. During Passover (in March or April), some Jewish patients may require special foods, dinnerware, and utensils. The Day of Atonement, or Yom Kippur (in September or October), is the holiest day of the Jewish calendar. It is a special day of fasting, but fasting is not required if it would be a danger to the patient. A Jewish patient will normally wish to keep that day to pray and rest. For Orthodox patients, you might offer alternatives to oral medication (e.g., injections or suppositories).

Conservative Jews observe strict dietary laws: Only kosher foods are accepted. **Kosher foods** have been prepared under strict guidelines for how animals are slaughtered and do not contain pork, certain types of seafood, or combinations of dairy and meat. Meals are also double-packaged if kosher foods are heated in nonkosher heating units (Noble, Rom, Newsome-Wicks, et al., 2009). If possible, consult a rabbi or dietitian who is knowledgeable about Jewish dietary laws for assistance in planning dietary and activity modifications.

Orthodox Jewish women prefer to have their bodies and limbs covered. They may also prefer to keep their hair covered with a scarf and often wear a wig. Orthodox men keep their head covered with a hat or skullcap (*kappel*). Some Orthodox Jewish sects forbid contraception unless the woman's health is at risk. Nearly all Jewish boys are circumcised, usually 8 days after birth. Orthodox Judaism usually forbids organ transplants, but opinions vary and decisions may rest with the rabbinic authority.

Both Reconstructionist and Reform Judaism incorporate current societal values. Reconstructionist Judaism was founded in the 1920s by Rabbi Mordecai Kaplan and is based on Western ideas of democracy, equality, and spirituality. Followers viewed Judaism, not as a religion with rituals mandated by God, but as a spiritual path with unity and connections developed among persons (Bronstein, 2012). Likewise, followers of Reform Judaism adhere to the traditional tenets, but practice inclusion, such as the acceptance of non-Jews, members of the Gay, Lesbian & Transgender community, and women as rabbis (Union for Reform Judaism, 2011).

Christianity

Christianity is the world's largest religion. Christians worship Jesus Christ and believe that his death atoned for their sins by granting them forgiveness from God, which allows for eternal life. Their sacred text, the Bible, includes the Judaic Old Testament and the New Testament relating to the life of Christ. The many denominations within Christianity include Roman Catholicism (with allegiance to the pope in Rome), Orthodoxy (with allegiance to the patriarch of Constantinople), Protestant denominations (e.g., Lutheran, Baptist, United Methodist), and others (e.g., Jehovah's Witnesses, Christian Scientists). Rituals and practices vary among the Christian denominations.

- Many practice baptism, which is a sign of moral cleansing and correlates to being born again. The baptism of an infant, also known as "christening," indicates that the child will be raised with Christian values and influences, so when infants or children are very ill, baptism should be offered.
- Christians usually have no special dietary requirements, although some choose to abstain from eating meat on Fridays and/or during Lent and some abstain from alcohol. Others fast (abstain from food) to become closer to God, to pray for blessings, or before receiving Holy Communion. Most Christians do not

object to blood transfusion or organ transplantation. Perspectives vary on family planning using artificial birth control methods; however, natural family planning methods (e.g., rhythm) are widely accepted.

Roman Catholicism In Roman Catholicism, the **sacraments** are a means to obtain grace. A Roman Catholic who is seriously ill might wish to receive the sacrament of *anointing the sick*. This sacrament, once known as the last rites, can be repeated if the person recovers and then becomes ill at a later time. Only a priest can hear the *sacrament of reconciliation* (confession), during which God, through the agency of the priest, grants forgiveness for past sins. The *Eucharist* (communion bread), consecrated at the *mass* (a religious service), may be brought to hospitalized patients by a priest, deacon, or designated lay Eucharistic minister. Other denominations within Christianity (e.g., Episcopalians and Lutherans) observe certain sacraments as well, although the meaning and details of the rituals may vary.

Christian Science The Christian Science faith, established in 1879, is a unique form of Christianity. Christian Scientists believe that illness is caused by faulty thinking, is evil, and is not a part of God's plan, for God is good (Waldman, Perlman, & Chaudhry, 2010). Therefore, followers practice a reliance on God and prayer for healing. Although they may not believe in immunizations and vaccinations, they will follow the laws of the state (Christian Science, 2013). Although adults will probably not accept a blood transfusion, parents usually consent to transfusions and other medical care for their child if doctors consider it essential or the law so requires. You will most likely encounter followers as patients only after accidents or because of family or legal pressures.

While Christian Scientists do not oppose Western medicine, it is usually not their first choice to promote health and prevent illness. They advocate proper nutrition, adequate sleep/rest, and avoidance of alcohol and tobacco. Strict Christian Scientists may not drink tea or coffee.

Jehovah's Witnesses Many Jehovah's Witnesses adhere to the commands of God as written in both the Old and New Testaments of the Bible. A practice that can create medical concerns is their refusal to accept blood transfusions or blood products, which they view as morally wrong. Patients who adhere to this faith would accept death rather than accept blood (Dyer, 2012; Lindstrom & Johnstone, 2010). The Jehovah's Witnesses faith also does not permit autologous blood transfusions or donation or receipt of an organ through which blood flows. If blood is not involved (e.g., corneal transplants) they may accept transplantation. Consistent with this practice, meat is not acceptable if an animal has been strangled or shot and not bled properly. Some Jehovah's Witnesses do not eat raw or any meat at all. Jehovah's Witnesses abstain from tobacco and other recreational drugs. They may drink alcohol but do not condone drunkenness. Jehovah's Witnesses do not celebrate birthdays or holidays, except for the anniversary of the death of Christ. This date usually corresponds with the Christian Easter or Jewish Passover.

Mormonism The Church of Jesus Christ of Latter-Day Saints (LDS) is commonly called the Mormon Church. Mormons believe in Jesus and one God and adhere to the sacred writing the Book of Mormon (which Joseph Smith translated from ancient records written on gold plates in 1830). Mormons follow a strict health code, known as the Word of Wisdom, which advises healthful living and prohibits the use of tea, coffee, alcohol, and tobacco. Many believe in life before and after death; thus, death represents the passage into another life phrase (Waldman, Perlman, & Chaudhry, 2012).

Some Mormons (both men and women) wear a sacred undergarment (temple garments) that is "an outward expression of an inward commitment to follow the Savior" (The Church of Jesus Christ of Latter-Day Saints, 2013). The garments are only removed for purposes such as hygiene, elimination, or being intimate in marriage. Nurses may also remove it before surgery, but it must at all times be considered intensely private and be treated with respect (Keddington, 2007).

Seventh Day Adventism The Seventh Day Adventist Church is distinguished mostly by observance of Saturday, the original seventh day of the Judeo-Christian week, as the Sabbath, a day of rest and worship. To keep the Sabbath holy, Adventists do no secular work or unnecessary business on Saturday. Adventists usually practice communion, which begins with a foot-washing ceremony, four times a year. Some members believed that a healthy mind and body are an essential element of faith and worship and that both spiritual health and physical health are enhanced by good nutrition (Nath, 2010). The church also emphasizes culturally conservative principles and many Adventists refrain from body piercing, tattoos, and wearing jewelry. The following are other principles and practices:

- The church recommends a vegetarian diet and adherence to the kosher laws in the Old Testament of the Bible, which includes avoidance of pork, shellfish, and other "unclean" foods. Some Adventists, however, do eat meat.
- Most avoid alcohol, tobacco, illegal drugs, and beverages containing caffeine.
- Although the church is generally anti-abortion, in cases of serious dilemmas (e.g., threat to the woman's life or pregnancy resulting from rape or incest), women are counseled to make their own decisions. Birth control is permitted for married couples.
- The Adventist church is officially against active euthanasia but permits a passive form through withdrawal of medical support to allow the patient to die. Death is akin to sleep and the person is viewed as being in an unconscious state (Taylor & Carr, 2009).

Islam

Islam was the third monotheistic religion to emerge, following Judaism and Christianity and is now the second largest (Abdel-Khalek, 2011). The word *Islam* means submission. In particular, a Muslim is one who submits to Allah (God). Muhammad is the founder of Islam and a respected deity among Muslims. The sacred book of authority in Islam, the Koran (Holy Qu'ran), is the result of messages from the angel Gabriel sent from God to the prophet Muhammad. It contains the one common message of all faiths: There is a Supreme Being whose sovereignty is acknowledged in worship and whose teaching and commandments must be obeyed.

Muslims are forbidden to eat pork. They may eat other meat, but it has to be *halal* meat, that is, killed in a special manner stated in Islamic law. Fish and eggs are allowed, but not if they are cooked near pork or non-halal (*haram*) meat. During the month of Ramadan, a Muslim fasts between sunrise and sunset; however, those who are sick are not expected to fast. Essential drugs and medicines are allowed at all hours during Ramadan.

Muslims always wash their hands before eating and it is customary to eat with the right hand (unless prevented by injury). Patients prefer to wash in free-flowing water, so tub baths are considered unhygienic. If a shower is not available, provide a pitcher to use in the bath.

Women prefer to be treated by female staff. Some women may refuse vaginal examination by a male nurse or physician because they are forbidden to expose their bodies to or be touched by any man other than their husband. Women may wear a locket containing religious writing around the neck in a small leather bag. These are kept for protection and strength, so you should never remove them. After the birth of a baby, prayers are whispered in the baby's ear so the first thing heard are words of prayer.

There is no specific religious rule prohibiting blood transfusion or organ transplantation; however, strict Muslims will not usually agree to organ transplants. Orthodox Muslims do not approve of contraception; however, individuals vary widely in their practices. Abortion is frowned on but may be tolerated for medical reasons.

Hinduism

Hinduism, which many religious scholars believe is the oldest major religion still practiced today, does not embrace a single body of beliefs and practices. Nor does it maintain the existence of a single deity, believing that no one manifestation of God can possibly capture the limitless nature of God. Thus, Hindus may worship several or even hundreds of gods and goddesses. Even elements in the natural world, such as rivers, fire, and so forth, are considered aspects of God. Sacred Hindu texts include the *Vedas*, the *Bhagavad Gita* (Song of the Blessed One), and the *Ramayana*, the story of the life of the god Rama. Despite commonly held beliefs and texts, Hindu religious practices vary a great deal, depending on areas of origin. Hindus believe in the core concepts of Karma, Dharma, and Reincarnation (Wilkins & Mailoo, 2010). Karma teaches that every action has or causes an effect. A person who does not fulfill his destiny or given purpose in life (Dharma) will have bad karma. After death, persons begin a new life in a different body or spiritual form (Reincarnation).

Hindus practice **ayurvedic medicine**, which encompasses all aspects of life, including diet, sleep, elimination, and hygiene. Some believe in the medicinal properties of "hot" and "cold" foods—"hot" and "cold" having nothing to do with either temperature or spicy qualities. Although some Hindus will eat eggs and even chicken, most are lacto-vegetarians, consuming milk but no eggs. Many will not eat beef and avoid bovine-derived medication because of the reincarnation of certain Gods (Wilkins & Mailoo, 2010). Fasting, which may mean eating only "pure" foods such as fruit or yogurt, is common during major festivals but is not expected of the sick. Tobacco and alcohol may or may not be accepted.

Hindus prefer to wash in free-flowing water (e.g., a shower instead of a tub bath). If a shower is not available, provide a jug of water for the person to use in the bath. Women are modest and usually prefer to be treated by female medical staff. Jewelry often has a religious or cultural significance. Some Hindus wear "sacred thread" or religious jewelry around the body or wrist. Do not remove or cut these without permission from the patient or next of kin. Some Hindus may consider touching a person's feet or touching them on the head a sign of disrespect. You should always do a careful religious assessment (Wilkins & Mailoo, 2010). There is no religious objection to contraception, blood transfusion, or organ donation, as a rule.

Buddhism

The Buddha, or the "Awakened One," is revered not as a god, but as an example of a way of life (Fig. 16-2). Siddhartha Gautama was born into a royal family in 624 BCE in a part of northern India that is now in Nepal, gained enlightenment at the age of 35, and then began to teach others how to attain liberation from suffering for themselves and others.

One of the Buddha's core teachings is that suffering can be ended by following the eightfold path: right understanding, right intention, right speech, right action, right livelihood, right effort, right mindfulness, and right contemplation (Bodhi, 2007; Knierim, n.d.). **Nirvana**, similar to the Christian concept of heaven, can be attained only through an absence of desire, the achievement of perfection, and the lack of a unique identity. Buddhism is about finding spirituality within one's self. Like Hindus, Buddhists believe in karma and reincarnation.

Food is an essential component of maintaining spiritual focus, meditation, and interactions with others (Nath, 2010). Many Buddhists follow a vegetarian diet; in some cases, the diet may include both milk and eggs. Fasting customs vary by tradition. Buddhists accept

FIGURE 16-2 The Buddha is revered as an example of a way of life.

contraception but typically condemn abortion and active euthanasia. They will usually accept blood transfusion and organ transplantation.

Native American Religions

There are more than 400 federally recognized Native American nations or tribes in the United States. Although each has its own traditions and cultural heritage, some general beliefs underlie the more specific tribal ideas. The Earth is considered to be a living organism, the body of a higher individual, and humankind has an intimate relation with this organism through nature. Thus, rather than having a designated sacred place to worship, Native Americans place value in the land, mountains, rivers, and meadows (Fowler, 2009). When the Earth is harmed, humankind is harmed, and vice versa. The land belongs to life, life belongs to the land, and the land belongs to itself (Boyd, 1974).

Health is a state of harmony with nature. Whenever disharmony exists, disease or illness can occur. The traditional healer is the medicine man or woman who is wise in the interrelationships of land, humankind, and the universe. Many Native Americans believe that the treatments they receive from medicine men and women and traditional healers are far better than those rendered by the dominant healthcare establishment, which often treats Native Americans with scorn or disrespect (Fig. 16-3). You should know that for some tribes, note taking by the professional is forbidden; when you take a history or perform an exam, you must rely on your memory to record findings later. Native Americans tend to converse in a low tone of voice and may maintain long periods of silence. Be sure the setting is quiet enough to allow you to hear the patient because it is impolite to indicate that you did not hear the communications.

FIGURE 16-3 Kokopelli, the humpbacked flute player, has been a sacred figure to Native Americans of the Southwest for thousands of years. He is a legendary symbol of fertility who brought well-being to the people.

Rastafarianism

Rastafarianism is a personal religion that emphasizes dignity and a deep love of God. The authoritative writings include the Old and New Testaments of the Bible, but as a rule Rastafarians do not consider themselves to be Christian. There are no churches, services, or official clergy.

Rastafarians do not eat pork and shellfish, some are completely vegetarian, and some do not drink milk or coffee. Many prefer alternative therapies (e.g., herbalism, marijuana, or acupuncture), do not believe in contraception, and avoid any treatment that will contaminate the body. They will accept blood transfusion, but may require reassurance about its safety. The women dress modestly; however, wearing secondhand clothing is taboo, so the patient may be unwilling to wear hospital gowns that have been worn by others. You may need to provide a disposable gown or allow the person to wear her own personal nightclothes.

Atheism

Atheists do not believe in the presence of God or supernatural deities. Rather than receiving directives on living from external sources, atheists have their own personal moral code that is derived from their value systems, beliefs, and life experiences. They can be spiritual and even religious, but focus on the humanistic, secular perspectives. A nurse recalls a patient's comment that he regretted putting "Atheist" on his admission paperwork, because he would have welcomed the presence of a chaplain to discuss where he was spiritually (Mais, 2010).

Key Point: ***This comment does not imply that all atheists would react in the same way as this one. It does, however, reinforce the importance of a thorough assessment of patient needs instead of relying on categories and labels.***

KnowledgeCheck 16-3

- Which major religion believes in the anointing of the sick or dying?
- Which denomination or religion does not believe in blood transfusions?
- In terms of Native American beliefs and healthcare, who is the traditional healer or the person to be consulted in the event of "illness"?
- True or false: Most Hindus are vegetarian.

ThinkLike a Nurse 16-4

What are some ways that world religions might influence nursing care?

Self Knowledge what every nurse should know

As you have seen, your patients' spiritual and religious backgrounds may be diverse and may involve ways of thinking and doing that seem strange to you or that you do not fully understand. Before trying to understand your patients' religious or spiritual experience, you must give considerable thought to your own religious or spiritual journey. Attaining self-knowledge is an important aspect of becoming a full-spectrum nurse. This section will help you in your reflections.

What Are Your Personal Biases?

We each carry our own perspectives with us at all times. We tend to view the world through lenses we acquired in childhood, adolescence, and early adulthood. In addition, our religious education is sometimes taught with a certain flavor of "upmanship"; that is, we are taught that our religious beliefs and practices are superior to all others. When you view your own experience as the norm or as the preferred way of organizing the world, you tend to limit the range of care you provide to the patient who believes differently. Spiritual care demands nonjudgmental attitudes and an open manner of thinking that invites rather than excludes.

ThinkLike a Nurse 16-5

Consider the following examples. For each person, what moral/spiritual judgments should the nurse avoid?

- A nurse is caring for a gay man who is hospitalized with end-stage AIDS.
- A woman has come to the clinic to be treated for gonorrhea (a sexually transmitted disease). She says she has had at least six sexual partners this year.
- A man comes to the emergency department (ED) at least once a month to ask for morphine to treat his back pain. He is known to abuse drugs and to visit other EDs for the same purpose.

If you are aware of your biases, it will be easier to avoid abuses of spiritual care, such as the following:

- **Attempting to convert others to your beliefs.** For example, if a patient is near death, he and his family might be offended if their nurse inquires whether they are "saved" Christians. By remaining focused on the patient's need to talk about meaning, salvation, or other end-of-life issues, you provide full-spectrum spiritual care. In Meet Your Patient you notice that Mr. Johnson's sister seems very close to imposing her religion on him. This may alienate him further if he perceives that he is being "pushed."
- **Trying to be all things to all people,** regardless of their background or the extent of spiritual care needed. Clearly, there are times when you should refer to others with more knowledge and experience in religion and spirituality, with the patient's permission, of course. In addition, whenever a patient requests the services of a rabbi, priest, or other spiritual adviser, you should relay that request to the agency's chaplain so that all disciplines remain informed.

In summary, to work effectively with a diverse population, you must first obtain a greater degree of self-knowledge by (1) being open to the many possibilities for diverse thinking, (2) welcoming challenging experiences that allow for personal growth, and (3) taking time to think about how your actions and biases might affect the care of others. The more you know about yourself, the more effectively you care for others.

What Are Some Barriers to Spiritual Care?

Although most nurses would acknowledge that patients have a spiritual dimension, few actually identify spiritual problems or provide spiritual interventions. This may be a result of economic constraints, poor staffing, and high-tech care, which force nurses to focus only on physical needs, or the inconsistencies in the meaning of spirituality (Cavendish, Konecny, Mitzeliotis, et al., 2003; Nardi & Rooda, 2011; Swinton & Pattison, 2010). You may judge these nurses less harshly after you understand more about the barriers to spiritual interventions by nurses.

Lack of General Awareness of Spirituality

A greater awareness of spirituality in general will help you tune into the spiritual needs of patients and improve your comfort in communicating about spiritual matters. Research consistently reveals the need for more education on spiritual care. McSherry and Jamieson (2011) identified that many nurses felt inadequately trained and educated in addressing the spiritual needs of patients. One study showed that nurses could not define spirituality and related it to end-of-life care needs (Smyth & Allen, 2011). Another showed that patients at risk for spiritual distress are not identified (Blanchard, Dunlap, & Fitchett, 2012) or are inaccurately assessed (Highfield, 1992).

Lack of Awareness of Your Own Spiritual Belief System

To feel comfortable making spiritual interventions, you will need more than just theoretical knowledge. You will need introspection and an awareness of your own spiritual journey to integrate the spiritual domain into patient care. Nurses who are aware of their own spirituality are better able to incorporate spiritual care in their practice (Chan, 2010). Several steps can be taken to enhance your spiritual growth (Baldacchino, 2011; Lane, 1987):

1. Understand the differences between religion, spirituality, and spiritual care.
2. Develop an awareness of your own spirituality and how it is applied (or not) in meeting the patient's spiritual needs.
3. Open yourself by being totally present with the patient, including being an active listener.
4. Allow the patient to share his feelings and emotions without reserve and reflect in your attitude and demeanor that you care and have the time to listen.

Activities to heighten your awareness of your own spirituality, gain a broader view of spirituality, and increase sensitivity to others' spiritual needs include the following (Beckman, Boxley-Harges, Bruick-Sorge, et al., 2007):

- Increase your knowledge about spirituality.
- Develop your critical and reflective thinking abilities.
- Explore your own spirituality (e.g., reflection, discussing with others). One technique is to write your own epitaph: one or two lines summing up how you would like to be remembered.
- Reflect on your thoughts and feelings about end-of-life issues. Imagine you have only a few weeks to live; think how you would feel.
- Reflect on your personal experience with grief and loss. For example, what is the first death you can remember? What were your feelings at the time? How do you usually cope with loss? What actions by others comforted you?

You must find ways to take care of and nurture your own spiritual needs; otherwise, providing this aspect of care can be emotionally draining.

Differences in Spirituality Between Nurse and Patient

Patients and nurses can be at different levels in terms of spirituality. When a patient's spiritual beliefs are very different from your own, you must be careful not to impose your beliefs on the patient or discount the importance of the patient's beliefs and rituals. When the patient's views or beliefs are similar to yours, take care not to make false assumptions about his spiritual needs. Although you share some commonalities, this does not mean you will have the same perspectives or needs in all areas of spirituality or religion.

Think**Like a Nurse** 16-6

- How does your religion or spirituality differ from Mr. Johnson's (Meet Your Patient)?
- How is it similar?
- Can you think of problems these differences and similarities could cause you in caring for him?

Fear That Your Knowledge Base Is Insufficient

Nurses sometimes avoid giving spiritual care because they believe they lack knowledge of spirituality or of the patient's religion. This is a realistic concern. In several studies, nurses were found to be unsure of what constituted spiritual problems and spiritual interventions (Blanchard, Dunlap, & Fitchett, 2012; Smyth & Allen, 2011). In some cases they did not identify the spiritual dimension of care, or they took religious aspects into account but did not place them into a broader spiritual perspective. Your ability to incorporate spiritual care into practice will increase with experience. Ronaldson and colleagues (2012) found that the spiritual care practices of RNs working in palliative care were more advanced than those of their RN counterparts working in acute care. While both groups identified insufficient time as a barrier to spiritual care, the acute care group also identified lack of patient privacy. The palliative care RNs were older and more experienced. The good news is that spiritual care has never been more welcomed by patients. You now know the importance of and can provide care to meet your patient's spiritual needs.

Older adults, for example, have identified their spiritual needs in healthcare settings as understanding their spiritual practices; relationship with God; hope, meaning, and purpose of life; interpersonal connection; and therapeutic professional staff interactions (Hodge, Horvath, Larkin, et al., 2012).

Fear of Where Spiritual Discussions May Lead

Many nurses fear that inquiring into the spiritual domain might cause harm to the patient. For example, what if a patient asks, "Do you think active euthanasia is morally wrong? Would it jeopardize my salvation?" Here are some fears that may arise:

- You may not feel prepared to answer the questions.
- You might have an answer based on your personal religious beliefs but fear the patient may think you are imposing your beliefs on him.
- You might wonder whether communicating your own beliefs (e.g., if you favor active euthanasia) might jeopardize the patient's spiritual life if your ideas turn out to be "wrong."

The following are some ideas that may help counter your fears. Most important, the patient addressing this concern with you indicates his recognition that you are open to spiritual matters and offers an opportunity to address his spiritual domain of care. Second, the patient is concerned with issues related to euthanasia. This could lead to discussions about the patient's fears of pain, dependence, being a burden on family members, and dying alone. Third, this is an area for which you should seek collaboration with a chaplain, who is more prepared to deal with specific religious issues. You should realize that being open to the spiritual realm and assessing the patient's need for spiritual intervention does not mean that you must be a chaplain or have the extraordinary ability to deal with all spiritual or religious questions or requests. The Practical Knowledge section will provide a more detailed understanding of your role in spiritual care.

KnowledgeCheck 16-4

- What qualities can you demonstrate that may help you improve the quality of spiritual care you provide?
- What common barriers to spiritual interventions do nurses encounter?
- True or false: No matter how nonjudgmental and open we may think of ourselves, we all carry our own unique biases and prejudices that have the potential to affect patient care.

Think**Like a Nurse** 16-7

- What are some possible errors made by nurses related to spiritual care?
- What are some ways that you can develop a greater awareness of the "spirit within the self"?
- Discuss ways that nurses and patients can nurture their own spiritual needs.

PracticalKnowledge knowing **how**

Most hospital admission forms include a place to record the patient's religious preferences, and most nursing assessment forms even include questions such as, "What religious rituals do you practice?" Unfortunately, some nurses believe that by completing such forms, they have addressed the patient's spiritual needs. They may be relieved because they don't feel competent to deal any further with spirituality or because they are afraid to be perceived as imposing their own religion on the patient. However, armed with your basic theoretical knowledge of spirituality and your growing spiritual self-knowledge, you should be able to provide a level of support that extends beyond paperwork to compassion and caring.

To see a care plan and care map for a client with Spiritual Distress,

Go to Chapter 16, **Chapter Resources, Nursing Care Plan: Spiritual Distress, and Care Map: Spiritual Distress,** on Davis*Plus.*

ASSESSMENT

People of the same religion often vary greatly in the degree to which they follow religious practices. It is not enough to "fill in the religion blank" on an assessment form. You must assess each person individually to determine religious needs and practices, keeping in mind that this may be a sensitive area for some persons.

It may be difficult to obtain meaningful information on the initial admission assessment due to time constraints in completing the paperwork, collaboration with the healthcare team, and the stresses involved in getting the patient introduced to the healthcare setting. For this reason, you must at that time obtain the essential data of the patient's church preference, name of clergy, whom to call in case of emergency, dietary requirements/restrictions, and any religious implications for medical care (e.g. refusal of blood transfusions). As you have further interactions with the patient and family, trust will develop, and you will be able to obtain more sensitive, complex, and meaningful spiritual/religious information.

Sources of Spiritual Data

You can acquire information about a patient's spirituality from a variety of sources other than interviews:

- **Patient's environment.** Observe the patient's environment for hints about her spirituality (e.g., pictures of family and/or pets, the presence of sacred texts or reading materials, articles used in worship [a crucifix, rosary beads, religious medals, statues], or copies of church bulletins/sermon tapes).
- **Patient's questions.** The patient may ask questions that are indicative of spiritual comfort, longing, or distress. For example, the patient may ask if you attend church and if so, whether it provides you with a sense of comfort and meaning.
- **Patient's behaviors, moods, and feelings.** Emotional behaviors give a clear and certain indication that the patient is struggling with issues that have spiritual overtones. These warrant further assessment and nursing intervention. For example, a patient may ask you if you have ever really felt guilty about something you did as a child.

- **Nonverbal communication.** Body language may indicate hopeful or distressing times. For example, you may observe a patient praying; or when asking about spirituality, you may see the patient rolling his eyes, shaking his head, and demonstrating muscle tension.

Spiritual Assessment Tools

Some healthcare agencies have focused spiritual assessment tools tailored to their particular setting. Several others have been developed.

HOPE An easy-to-use screening method is use of the HOPE questions. Although not validated by research, they do allow for an open-ended exploration of spiritual resources and concerns (Gowri & Hight, 2001). HOPE is a mnemonic, as follows:

H—sources of Hope
O—Organized religion
P—Personal spirituality/Practices
E—Effects on medical care and end-of-life issues

JAREL The JAREL spiritual well-being scale was developed and is commonly used by nurses (Hungelmann, Kenkel-Rossi, Klassen, et al., 1996). Cutting across religious and atheistic belief systems, it assesses three key dimensions: (1) faith/belief, (2) life/self-responsibility, and (3) life-satisfaction/self-actualization.

SPIRIT The comprehensive spiritual assessment tool developed by Highfield (2000) involves an interview that is concerned with six key areas designated by the acronym SPIRIT:

SP—Spiritual/religious belief system
I—Integration within a spiritual community
R—Ritualized practices and restrictions
I—Implications for medical care
T—Terminal events planning.

To see a copy of a spiritual assessment based on this model, and for questions to use for the HOPE approach,

Go to Chapter 16, **Assessment Guidelines and Tools,** in Volume 2.

You can use the SPIRIT model with the JAREL tool and the combined assessment tool and plan of care in the ESG. To find these tools,

Go to Chapter 16, **Tables, Boxes, Figures: ESG Figures 16-1 and 16-2,** on Davis*Plus*.

Go to Chapter 16, **Assessment Guidelines and Tools,** in Volume 2.

KnowledgeCheck 16-5

What are the six areas for spiritual assessment summarized in Highfield's (2000) acronym SPIRIT?

ThinkLike a Nurse 16-8

Complete the SPIRIT assessment on yourself. Discuss it with your classmates.

ANALYSIS/NURSING DIAGNOSIS

When analyzing spiritual assessment data, you must consider the person's developmental stage. People progress through stages of spiritual development in much the same way as they develop physically and cognitively. Spiritual behaviors that seem problematic in one stage may not be so in an earlier stage. To review developmental stages, refer to Chapters 9 and 10.

Spirituality Diagnoses

Box 16-1 contains NANDA-I diagnostic labels that specifically deal with religion and spirituality. The following are examples of full diagnostic statements for spiritual problems:

- *Spiritual Distress* related to overwhelming anxiety associated with the need to have a surgical procedure that is not accepted by her religion
- *Risk for Spiritual Distress* related to unremitting pain and loss of hope for relief, as manifested by patient's question about the usefulness of prayer ("God has forgotten about me.")

A Non-NANDA–I Diagnosis Millspaugh (2005) has suggested *Spiritual Pain* as a diagnosis. When a person experiences a combination of awareness of death, loss of relationships, loss of self, loss of purpose, and loss of control, Spiritual Pain may occur. However, this combination of negative experiences can be balanced by having a life-affirming and transcending purpose and an internal sense of control (Fig. 16-4). The presence and quality of Spiritual Pain is determined by the degree to which the person is experiencing each component, and by the relationship of the components to each other.

ThinkLike a Nurse 16-9

Which of these nursing diagnoses would you use for Mr. Johnson (Meet Your Patient): Spiritual Distress, Risk for Spiritual Distress or Readiness for Enhanced Spiritual Well-Being? Why?

Spirituality as Etiology

In the spiritual realm, it is difficult sometimes to determine what is the problem and what is the etiology. Does the patient experience Spiritual Distress because of pain and hopelessness? Or did the patient first lose faith in God, which led to hopelessness and anxiety? Either way, spiritual support is needed.

Several of the NANDA-I diagnoses relate to spirituality as the problem, etiology, or symptom. Examples include Anxiety, Chronic Sorrow, Death Anxiety, Decisional Conflict, Hopelessness, Interrupted Family Processes, Noncompliance, Powerlessness, and Social Isolation. Non–NANDA-I problems include anger or resentment; feelings of guilt, shame, inadequacy, abandonment, or distrust; depression or sadness; and the inability to find meaning in life. The following are examples of diagnostic statements with spiritual etiologies:

Anxiety related to inability to reconcile decision to use birth control with religious proscriptions

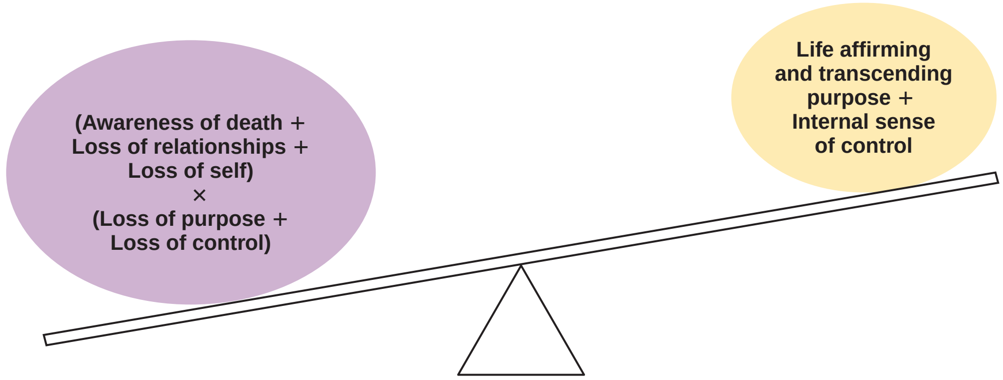

FIGURE 16-4 Components of spiritual pain. (Based on: Millspaugh, C. D. (2005). Assessment and response to spiritual pain: Part II. *Journal of Palliative Medicine, 8*(6), 1110–1117.)

Decisional Conflict related to confusion about the religious implications of the decision to forego heroic treatment measures

Hopelessness related to lack of belief in a power outside self, combined with overwhelming lack of energy

Noncompliance (with treatment regimen) related to the belief that the illness is "God's will" and that healing will occur (without treatment) for the same reason

BOX 16-1 ■ NANDA-International Spirituality Diagnoses

Moral Distress — Experienced when the person makes an ethical or moral decision, but then is unable to carry out the chosen action. Defining characteristics include anguish, powerlessness, guilt, frustration, anxiety, self-doubt, and fear over the inability to act on the moral choice.

Impaired Religiosity — Difficulty in exercising or impaired ability to exercise reliance on beliefs or to participate in rituals of a faith tradition (e.g., go to church, take communion).

Readiness for Enhanced Religiosity — The ability to increase reliance on religious beliefs and/or participate in rituals of a particular faith tradition. The patient is not experiencing a problem, but wishes to make a satisfactory situation even better.

Readiness for Enhanced Spiritual Well-Being — Describes healthy spirituality. "A pattern of experiencing and integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself that is sufficient for well-being and can be strengthened" (NANDA-I, 2012, p. 394). It is the opposite of Spiritual Distress, so you will see positive expressions of faith, hope, love, courage, acceptance, and peace; healthy connections with others and with art, music, literature, and nature; and prayer and other expressions of a connection with a power higher than oneself.

Risk for Impaired Religiosity — Occurs when risk factors are present, but symptoms are not. Risk factors may be categorized as developmental, environmental, physical, psychological, sociocultural, or spiritual. Specific examples include life transitions, lack of transportation, pain, depression, social isolation, and suffering.

Risk for Spiritual Distress — Related to unremitting pain and loss of hope for relief, as manifested by patient's question about the usefulness of prayer ("God has forgotten about me.")

Spiritual Distress — "Impaired ability to experience and integrate meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself" (NANDA International, 2012, p. 410). Defining characteristics (signs and symptoms) of this diagnosis include the following.

- *Connections to self:* Expressing a lack of hope, love, courage, acceptance, or peace; a lack of meaning and purpose in life; inability to forgive self; feelings of anger or guilt
- *Connections with others:* Refusing to see clergy; refusing to interact with family or friends; reporting lack of support system; expressions of alienation
- *Connections with art, music, literature, nature:* No interest in nature; decrease in previous interest in music, writing, art; no interest in spiritual reading
- *Connections with power greater than self:* Inability to pray, inability or refusal to participate in religious activities, feelings of abandonment by God or other deity, expressions of anger toward God or other deity, requests to see a religious leader, sudden changes in spiritual practices (increased or decreased)

Source: Adapted from NANDA International. (2012). *Nursing diagnoses: Definitions and classification 2012–2014.* Philadelphia: Wiley-Blackwell.

KnowledgeCheck 16-6

Consider the following statement: A nursing diagnosis that reflects either an actual or a potential problem may reflect religious and/or spiritual dimensions of the human condition.

- Is this statement true?
- Would it be true for a *physical* diagnosis (e.g., Disturbed Sleep Pattern)? Explain your thinking.

PLANNING OUTCOMES/EVALUATION

The outcomes you establish in the planning stage of the nursing process serve as the criteria for your evaluation of the patient's progress and the success of the nursing interventions.

NOC standardized outcomes associated with spirituality diagnoses include, but are not limited to, the following: Anxiety Level, Comfortable Death, Comfort Status: Psychospiritual, Dignified Life Closure, Hope, Loneliness Severity, Personal Resiliency, Personal Well-Being, Quality of Life, Spiritual Health, and Will to Live (Moorhead, Johnson, Maas, et al., 2013).

Individualized goals/outcome statements you might write for spiritual diagnoses include the following:

- **For Risk for Spiritual Distress—**Exhibits no signs or symptoms of spiritual distress (e.g., finds meaning in life, expresses hope and faith, follows usual religious practices).
- **For Spiritual Distress—**Returns to previous state of spiritual well-being and comfort (e.g., expresses a sense of peace, asks to see religious adviser).
- **For Readiness for Enhanced Spiritual Well-Being—**Experiences a higher level of connectedness with self, others, higher power, and/or nature.

PLANNING INTERVENTIONS/IMPLEMENTATION

Spiritual interventions are those used to treat and prevent spiritual problems related to the patient's illness. You will direct some nursing activities to resolving the problem, others at removing the etiology, and still others at relieving symptoms. You will, of course, base your nursing activities on the patient's symptoms and the problem etiologies. However, there are some nursing interventions that address spiritual problems in general.

Standardized (NIC) Spirituality Interventions

To see Nursing Interventions Classification (NIC) interventions and selected activities for the spirituality and religiosity diagnoses discussed in the preceding text.

Go to Standardized Nursing Language, **Using Selected NIC Interventions and Activities to Support Spirituality,** in Volume 2.

A few NIC standardized interventions to promote spirituality are discussed in this section. The evidence base for these is specific to older adults (Gaskamp, Sutter, & Meraviglia, 2006); however, they would seem to be indicated for other age groups, as well.

When you are performing interventions of a spiritual nature, remember that you absolutely must follow the patient's lead and be caring and respectful without inserting your own beliefs into the conversation. Choose your language carefully—words similar to *saved*, *repentance*, and *born again*, which may be a part of everyday conversation for people who follow religion, may cause some patients to feel pressured or uncomfortable. Try to mirror, and not go beyond, the patient's religious terminology. It requires knowledge, skill, and practice to provide religious support without imposing your own beliefs. The safest course of action, of course, is to offer to contact a chaplain for the patient. However, patients cannot always—or may not always want to—wait for a chaplain.

Active Listening (NIC)

The Active Listening intervention allows the nurse to establish a trusting relationship and to hear, understand, and interpret what the client is saying. Listening actively involves four NIC interventions, and one non-standardized activity.

Presence (NIC) Presence means to be with patient and family in meaningful ways. This requires not only your actual presence at the bedside, but also being open to issues and concerns of the patient and allowing the patient to lead discussions rather than setting the agenda or controlling the conversation. It involves sincere communication and being fully available to the client, and might include listening to the patient's "stories" about his illness.

Touch (NIC) Caring touch, such as hand holding or touching an arm or shoulder, facilitates communication. It conveys concern, comfort, and acceptance, especially during stressful experiences. At least one study has shown touch to improve life satisfaction and faith. Some people prefer not to be touched, so carefully observe the patient's responses.

Exploring Meaning (non-NIC) Meaning refers to a clear understanding of the illness or loss (e.g., loss of independence). It also refers to the concepts of finding meaning and purpose in life, or a sense of personal worthiness. You can facilitate the patient's search for meaning by asking probing questions, providing explanations, and reframing maladaptive interpretations of life events.

Reminiscence Therapy (NIC) Reminiscence is the recalling and sharing with another person's past life events. It promotes meaning-making through rethinking and clarifying previous experiences. As the patient reminisces, he may make spiritual links by expressing personal beliefs that helped him live through difficult life events. This intervention is more effective within a long-term relationship.

Spiritual Support (NIC)

NIC defines Spiritual Support as "assisting the patient to feel balance and connection with a greater power" (Bulechek, Butcher, Dochterman, et al., 2012, p. 353). Effective Spiritual Support is based on a focused spiritual assessment, including the person's belief system. It may include assisting with forgiveness, encouraging hope, praying, and reading scriptures or other texts the patient requests.

Forgiveness Facilitation (NIC) **Forgiveness** is the act of pardoning or being pardoned for an offense, debt, or obligation. Letting go of the resentment felt for another promotes constructive changes in a person's life, as well as a sense of renewal and reconciliation with God, church, and one's inner being. To provide this intervention, you must first assess the patient's needs for reconciliation with self, others, and God. If, like Mr. Johnson (Meet Your Patient), the patient has lost contact with family members because of disagreements, you could collaborate with the social worker and chaplain about ways to facilitate a meeting.

Forgiveness is one aspect of love. People have a spiritual need to forgive others and to be forgiven. When a person cannot forgive others, it separates him from them and interferes with giving and receiving love. When a person cannot forgive himself, he may feel the pain of shame, guilt, and anger. Or the person may be hurting because he wants forgiveness from someone he has wronged or from God. Many people interpret their illness as punishment for sins.

Some find it difficult to seek forgiveness and to believe that they have been forgiven, but this is important to achieving spiritual peace. You can help by listening when the person expresses self-doubt or guilt, providing guidance, praying with the patient if he requests it, inquiring if he is ready to forgive someone else, or offering to contact his chosen spiritual leader if intensive spiritual support is needed.

Hope Inspiration (NIC) **Hope** is a subjective state of confidence in the possibility of a better future. It includes a positive orientation, faith, and will to live. **Hopelessness** is a state in which the person perceives limited or no alternatives or personal choices. To intervene effectively, it is important to know the source of the person's hope and the factors underlying the feelings of hopelessness. As a nurse, you can encourage spiritual growth, which is thought to facilitate hope, and you can refer your patient to a support group to help in stress reduction, coping, and hope.

Prayer (Non-NIC) Prayer is an integral component of almost every religion. Research shows that the percentage of adults who use prayer for health concerns increased from 42% to 49% over a 5-year period (Wachholtz & Sambamoorthi, 2011). A recent study found that patients who received intercessory prayer had a significant improvement in spiritual and emotional well-being (Olver & Dutney, 2012). Prayer has been found "very helpful" by 69% of adults in the United States (McCaffrey, Eisenberg, Legedza, et al., 2004). So, it is quite possible that a patient or a family member may ask you to pray for him or with him.

At least 49 million older adults pray for health. African Americans and Hispanic older adults are more likely to pray for health than whites. Women are considerably more likely (97%) to pray than men and older adults at the lower income level and with chronic conditions are more likely to pray for health (Tait, Laditka, Laditka, et al., 2011). Prayer is used by older adults as a form of complementary healing treatment (84%) and to cope with stress (96%) (Dunn & Horgas, 2000). Spiritual nursing care is an integral component of quality patient care.

It is important to distinguish between *praying with* and *praying for*. If the patient asks you to pray *with* him, you must determine whether he simply wants you to be present while he or another person leads the prayer. You should ask whether he wants you to begin the prayer or whether he wants to begin the prayer. If a patient asks you to pray *for* him, assess what it is that he wants you to pray for. Often the patient is merely asking you to pray for him on your own time, as frequently as your schedule allows.

Regardless of the situation, if you feel comfortable doing so, then you should enter the experience of prayer with confidence; after all, the patient or family member has asked you to be present because he feels at ease with you and trusts in your abilities. However, if you feel at all uncomfortable about offering prayer, then you should state those feelings and offer to find someone who is comfortable with prayer. For example, you might say either of the following to the patient or family, "Thank you for asking me to pray with you; there is another nurse on the floor who is better at this than I am. May I have your permission to seek that person out for you?" Or, you might reply as follows: "I am confident that the chaplain can help you in many ways with your request. May I make a referral to the chaplain for you?"

If you do wish to pray with patients, understanding the different types of prayer may help. **Prayer** consists of those ways that we respond to and interact with the Supreme Being, whether by words, thoughts, or actions (e.g., the painting in Fig. 16-5). People tend to think of prayer in its narrowest sense as being requests for something (intercession), and this is an important and useful type of prayer. However, there are at least six other types of prayer, including adoration, praise, thanksgiving, penitence, offering, and petition (*Book of Common Prayer*, 1979). For the various types of prayers,

Go to **Figures, Tables, and Boxes, ESG BOX 16-1: Types of Prayers,** on Davis*Plus*.

FIGURE 16-5 This painting may be an expression of prayer.

The following is an excerpt from an aunt's e-mail to a distribution group of her family and friends. It movingly demonstrates a belief in the powerful nature of prayer, and is an example of the research findings that many people rely on intercessory prayer during illness.

> ***Example:*** *I would really appreciate your prayers . . . for my nephew . . . who is newly diagnosed with Hodgkin's lymphoma. We go to the clinic at 10 a.m. to get his labs and then [to] the Children's Hospital to start his chemotherapy. . . . He is very sad and scared. His chest symptoms have increased . . . [and] we know the mass is still growing. Please pray . . . for wisdom and communication with the doctors and nurses. Pray all who come in contact with my nephew give peace, comfort, and soothing touch. Pray the side effects . . . are minimal. More than anything, . . . pray the chemo targets every cancerous cell . . . and specifically for greater than 70% shrinkage. [Pray also for] no more . . . fever, night sweats, weight loss, [and] chest pain. God truly can work miracles in times of trial and we are trusting fully in Him at this great time of need. (D. Wojcik, personal communication, March 1, 2013)*

Prayer has a variety of purposes, expressions, and meanings to patients and their families, as well as to nurses. Prayer may provide for periods of intimacy with God, reveal the presence and love of God, and serve as a powerful source of comfort and hope.

Go to **Clinical Insight 16-1: Praying With Patients,** in Volume 2.

Complementary & Alternative Modalities (CAM)

Intercessory Prayer

Many people pray when they are ill, and prayer seems to have positive effects. But what about the effects of *intercessory prayer*—the prayers of people for *others* who are ill? How useful is intercessory prayer? The following studies provide little support for the use of intercessory prayer as a CAM. However, this is not an exhaustive list of studies of intercessory prayer, and research is ongoing.

- **Schlitz, Hopf, Eskenazi, et al. (2012).** Researchers explored the efforts of distant healing intention (DHI) (also known as intercessory prayer, spiritual healing, etc.) on wound healing of 72 postoperative women. The results showed that DHI did not affect wound healing or self-reported postoperative emotional or physical health. However, the women who knowingly received prayer had a significantly longer length of surgery. The groups that believed in and knowingly or unknowingly received DHI had worse physical and self-reported well-being outcomes.
- **Roberts, Ahmed, Hall, et al. (2011).** Selecting 10 trials from the literature that randomized more than 7,800 participants, researchers concluded that there was not a significant difference in outcomes for those receiving intercessory prayer and those who did not. However, researchers noted that in a trial on high risk of death, people in the intercessory group who were at a high risk of death were significantly more likely to live. Another trial found that some specific complications were significantly more likely to occur in the non-intercessory prayer group, but "certainty of receiving prayer was associated with a lower incidence of complications."
- **Benson, Dusek, Sherwood, et al. (2006).** In patients recovering after coronary artery bypass graft (CABG) surgery, this study found that intercessory prayer itself had no effect on complication-free recovery from CABG, but "certainty of receiving intercessory prayer was associated with a lower incidence of complications (p. 940)."
- **Palmer, Katerndahl, & Morgan-Kidd (2004).** Researchers studied 86 community-dwelling persons, ages 18 to 88 years. Intercessory prayer was used for 1 month to intervene with a life concern or problem the participant disclosed at the beginning. No effect on problem resolution was found. Prayer did effectively reduce a subject's level of concern, but only if the subject initially believed that the problem could be resolved. Also, better physical functioning was observed among those who had a high belief in prayer.

Other Nursing Activities

Spiritual care involves you in relationships with people who have come face-to-face with a significant life event that calls forth a new sense of meaning and purpose. Specific nursing activities, to be individualized to each client's needs, are discussed, following.

- **Make Referrals When Needed.** There are times when you should refer a patient to others with more knowledge and experience in religion and spirituality. For example, a patient may be experiencing Spiritual Distress because he believes he needs forgiveness for a past act, or a patient may refuse medical treatment because she thinks her church would not approve. For hospitalized and hospice patients, you can usually ask the chaplain's office to refer the patient and family to clergy or religious counselors in the community. If you are working in a home or community setting, use the Internet or telephone directory to find resources for you and the patient, such as local churches, priests, ministers, rabbis, or other spiritual advisers.

- **Encourage Expression of Feelings.** The best way to do this is simply to ask the patient how he is feeling or what he thinks about a particular situation.
- **Help the Patient Identify Feelings of Guilt.** You might ask the following after a patient has voiced a concern: "How do you feel about that?" or "You seem to feel sad about saying/doing that."
- **Help Significant Others Understand the Patient's Feelings and Needs.** Encourage family members to talk with the patient or simply to have a seat at the bedside. Periods of silence often lead into the most therapeutic of discussions.
- **Maximize the Patient's Comfort.** This is one of the most important spiritual activities a nurse can perform. A patient cannot think about spiritual issues when plagued with physical pain or discomfort.
- **Listen to the Patient's "Stories."** These tell the life history surrounding the person's illness and spiritual comfort or distress.
- **Assess the Patient's Needs for Reconciliation.** This may include reconciliation with self, others, and God. If, like Mr. Johnson (Meet Your Patient), the patient has lost contact with family members because of disagreements related to past events, you could collaborate with the social worker and chaplain about ways to facilitate a meeting.
- **Explore With the Client the Possible Meanings of Healing, Miracle, and Cure.** Refer to the discussion of miracles earlier in this chapter.
- **Collaborate With the Dietary Department.** Provide foods compatible with the person's religious needs. Encourage family members to bring foods from home, as appropriate.
- **Respect the Patient's Dress (and other) Requirements as Determined by His Religion.** This may include wearing religious icons, jewelry, or special clothes.
- **Do Not Make Assumptions About the Patient's and Family's Beliefs.** When a patient dies, for example, a seemingly harmless statement such as "He's gone to a better place" assumes the family believes in an afterlife. If they ask, you can briefly share your beliefs, but reflect their questions back to them (e.g., "Tell me what *you* think happens after death").

KnowledgeCheck 16-7

- What is prayer?
- What are ways can you support a patient's prayer needs?
- When a patient asks you to pray for him, what might be your most effective first response?

ThinkLike a Nurse 16-10

- A patient dying of lung cancer asks you to pray with him early one morning. You agree and ask him what he would like you to pray for. He responds: "That I may be cured of my cancer and go back home." He is on oxygen therapy, has pain medications given as prescribed, and is in a room by himself. Construct a prayer that might be meaningful and helpful.

Return to the scenario for Charles Johnson (Meet Your Patient). See whether you can answer the three questions more completely now after reading this chapter.

Complementary & Alternative Modalities (CAM)

Spiritual Care

Spiritual interventions, especially prayer, are a frequently used CAM:

- **Bekke-Hansen, Pedersen, Thygesen, et al. (2012)**—A recent study found that 76% of adult patients with acute coronary syndrome rated CAM treatments as having a positive influence on their quality of life. The most prevalent types of CAM used were dietary and exercise counseling and dietary and nutritional supplements.
- **Ben-Arye, Schiff, Vintal, et al. (2012)—**In this study researchers found that oncology patients with a higher spiritual quest had an increased use of CAM and higher expectations that providers integrate CAM into their care.
- **Ellison, Bradshaw, & Roberts (2012)**—When compared with spiritual-only, participants who were both spiritual and religious were more likely to use body–mind therapies when it included the CAM of prayer, meditation, or spiritual healing and less likely (44%) when these CAMs were removed. Religious-only participants were not inclined to use CAM.
- **Trinkaus, Burman, Barmala, et al. (2011)—**Of the 123 patients with advanced cancer on a palliative care unit, 85% had used CAM; 42% used it for curative intent. The use of CAM for cure was associated with increased spiritual faith, but low existential well-being.
- **Johannessen (2011)**—Nurses reported in interviews that self-realization and development of self were core issues in holistic nursing. They also related these to psychological and spiritual well-being.
- **Wu, Weber, Kozak, et al. (2009)**—Neurosurgeons reported acupuncture, herbs, massage therapy, prayer, and yoga as the most common CAM used by their patients. At least 38% indicated they pray for their patients and 42% believed that prayer and spirituality can affect surgical outcomes.

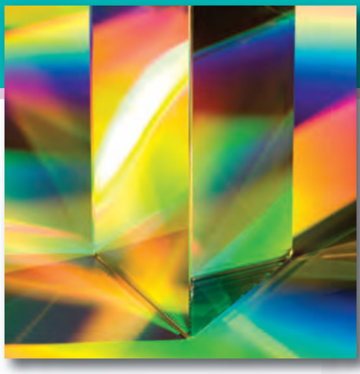
CHAPTER 17



Loss, Grief, & Dying

Learning Outcomes

After completing this chapter, you should be able to:

- Name and describe at least four types of loss.
- Identify the stages of grief as described by Engel, Worden, Rando, and Bowlby.
- Compare and contrast four types of grief.
- List and discuss at least five factors that affect grieving.
- Define *death* according to the Uniform Determination of Death Act.
- Give a definition of *higher-brain death.*
- Create a time line of the dying process, indicating the physiological signs and symptoms common to each stage.
- List and describe the Kübler-Ross stages of dying and grief.
- Define *end-of-life care*, *hospice care*, and *palliative care.*
- Identify the legal and ethical issues involved in death and dying.
- Assess, diagnose, plan, and implement care of dying patients and their families.
- Describe the responsibilities of the nurse regarding postmortem care.
- Identify nursing interventions to help clients who are grieving.

Key Concepts

Loss
Grief
Death/dying
End-of-life care

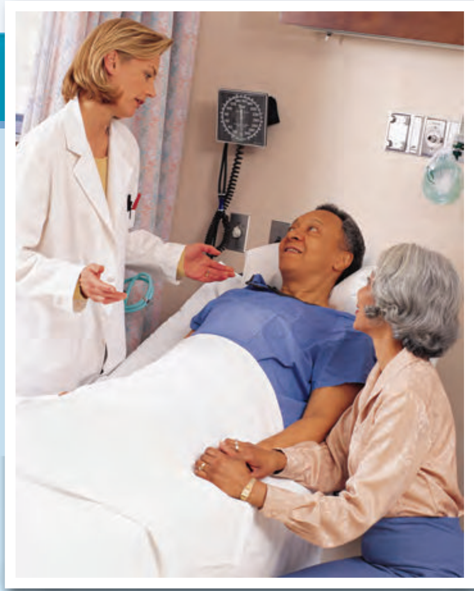
Meet Your Patient

Thomas Manning is a 47-year-old man who is in the oncology unit with end-stage cancer of the pancreas. He is married and has three children, ages 18, 15, and 13. His oldest daughter has been away at college for only 6 months. Mr. Manning's father died 3 months ago from complications of alcoholism, and his mother has been withdrawn and grieving. His wife, Mary, tells you that Thomas "just wants to die" and does not want anyone trying to revive him or "pushing on his chest" if he dies. Mary is distressed and wants him to "keep fighting."



Theoretical Knowledge knowing why

Throughout your nursing career, you will care for patients coping with loss—of youth, beauty, previous health, functioning, or quality of life. Many of your patients, like Thomas Manning, will be confronting their own approaching death, while family members will be facing loss of their loved one. As their nurse, you can help these people cope with their losses and grieve in a way that is healing, even transformative. But to do so, you need to know how to assess each patient's response to loss, plan appropriate outcomes, and intervene with skill and compassion. As a foundation, you must understand your own feelings and attitudes about loss, grief, and dying. We encourage you to increase your self- knowledge as you work through this chapter.

ABOUT THE KEY CONCEPTS

In order to provide care for patients experiencing loss, you will need to understand the key concepts of **loss, grief, death and dying**, and **end-of-life care**. Related concepts, such as stages of death, depression, and grief education, will expand the way you think about the key concepts. As you study the chapter, think often about how all the specific "parts and pieces" are related to the key concepts.

WHAT IS LOSS?

What is the first thing that comes to mind when you think of *loss*? Many people think of losing a loved one through death. Loss, however, is a daily occurrence. Our losses begin at birth when we lose the warmth and security of the womb, and end with the ultimate loss, the death of self. Loss can be defined as the undesired change or removal of a valued object, person, or situation.

Can you think of the first time you experienced a loss and what that felt like? What other losses have you undergone as you matured? For losses that are common at different developmental stages,

Go to Chapter 17, **Tables, Boxes, Figures: ESG Table 17-1,** on the Davis*Plus*.

Whenever there is change, there is loss. Because we experience many changes throughout life, we also experience much loss. Loss can be categorized in the following ways:

- **Actual versus perceived loss. Actual loss** includes the death of a loved one (or relationship), theft, deterioration, destruction, and natural disaster. Actual loss can be identified by others, not just by the person experiencing it (e.g., hair loss during chemotherapy). In contrast, **perceived loss** is internal; it is identified only by the person experiencing it (e.g., a woman diagnosed with a sexually transmitted infection may perceive herself as having lost her purity).
- **Physical loss versus psychological loss. Physical loss** includes (1) injuries (e.g., when a limb is amputated), (2) removal of an organ (e.g., hysterectomy), and (3) loss of function (e.g., loss of mobility). **Psychological losses** challenge our belief system. They are commonly seen in the areas of sexuality, control, fairness, meaning, and trust. Some losses may be mixed. For example, after removal of a prostate gland, a man may feel both the physical and psychological loss of sexuality.
- **External versus internal loss. External losses** are actual losses of objects that are important to the person because of their cost or sentimental value (e.g., jewelry, a home). These losses can be brought about by

Quality and Safety Education for Nurses

Respecting Patient and Family Needs

Chapter Key Concepts: *Loss, grief, dying, end-of-life care*

Competency: *Patient-Centered Care (Skills, Attitudes)**

Situation. Karen Litvak is a 64-year-old woman who has lived her entire life with her mother, who is 86 years old. The mother is hospitalized with pneumonia. Karen spends each day at her side. "I don't know how to help her," Karen says to the nurse. "She always took care of me." When her mother stopped breathing, a code was called and doctors, nurses, and therapists ran into the room and began aggressive resuscitation (CPR). Karen stood out of the way but did not leave the room. The chaplain asked her to come out into the hallway with him, but she refused. The chaplain continued to urge her until she said forcefully, "No, I want to stay." Karen looked to the nurses, who nodded yes, she could stay.

The CPR efforts were not successful. The nurses asked Karen if she would like to come closer while they cleaned her mother. Karen talked about her mother as the nurses washed the mother's face and hands, put a clean hospital gown on her, and folded a clean sheet up to her waist. Karen thanked the nurses and turned to go. The nurses asked her where she would go and whether she had anyone to stay with her. She said she had a sister and would stay with her for a while.

Think about it: Patient-centered care means showing respect for the patient's significant other's values and needs and the diversity of human experience.

- Should the nurses have allowed the daughter to stay during CPR? Why or why not?
- How did the nurses show respect for Karen?
- How would you describe the daughter's values and needs?

Go to the QSEN Web site at **http://qsen.org/competencies/pre-licensure-ksas/**

theft, destruction, or disasters such as floods and fire. **Internal loss** is another term for perceived or psychological loss.

- **Loss of aspects of self.** These losses include physical losses such as body organs, limbs, body functions, and/or body disfigurement. Psychological and perceived losses in this category include aspects of one's personality, developmental change (as in the aging process), loss of hopes and dreams, and loss of faith.
- **Environmental loss.** This loss involves a change in the familiar, even if the change is perceived as positive. Examples include moving to a new home, getting a new job, and going to college. These losses can be perceived or actual.
- **Loss of significant relationships.** This type of loss includes, but is not limited to, actual loss of spouses, siblings, family members, or significant others through death, divorce, or separation (e.g., military deployment).

ThinkLike a Nurse 17-1

Which kinds of loss do you think Thomas Manning is experiencing?

Why is it important to recognize loss?

WHAT IS GRIEF?

Whenever there is loss, there is grieving. Grieving requires energy, so it can interfere with health and delay healing. However, grieving is positive in the sense that it is essential to psychological healing after a loss. Consider the following losses and the different reactions of the women involved.

Both Mrs. Smith and Mrs. Jones have lost a dog. Mrs. Smith's son left his dog with her when he went away to college last year. It has died of old age. Mrs. Jones's dog has been with her for 10 years and has been her only companion since her husband died 5 years ago. Her dog was killed by a car today as they were on their morning walk. Which woman do you think will grieve her loss more? Why? Discuss this situation with a classmate. Do you both have the same opinion about this?

This exercise demonstrates that it is really impossible to decide who would feel "more" grief.

Key Point: ***The intensity of the grief depends on the meaning the person attaches to the loss.***

Both women probably felt sad. However, the meaning of and attachment to the dog are different for each one. You might have thought Mrs. Smith's loss was minor; however, her dog was owned by her son and may have represented him in her mind. Mrs. Jones's dog was a companion and a protector and may have represented security and friendship. Each woman must grieve what the loss represents to her. This is true for everyone, whether the losses are actual or perceived, physical or psychological.

Grief is the physical, psychological, and spiritual responses to a loss. **Mourning** consists of actions associated with grief (e.g., crying, wearing black clothing). These processes are normal and natural responses to a loss. The mourning and adjustment time after a loss is the period of **bereavement**. Although each person may express grief differently, some aspects of grief are shared by almost everyone.

KnowledgeCheck 17-1

What types of losses commonly occur in our lives?

Stages of Grief

There is no single, correct way to grieve, nor do people move neatly from one stage or step of grief to the next. Rather, grieving is a fluid, ongoing process. There is constant movement among stages, including recurrences of phases the bereaved person thought were resolved. The following are four major stage theorists in the field

George Engel (1961) Engel believed that uncomplicated grief has a clear onset and a predictable course, modified mainly by the abruptness and significance of the loss and how well the bereaved person was prepared for it. Uncomplicated grief is universal and does not require treatment.

John Bowlby (1982) Drawing on attachment theory, Bowlby suggested that grief occurs when the bereaved learn that the object of their attachment is lost. Some experts assert that Bowlby's theory does not take into account the individual nature of grief and that it implies loved ones can be replaced. Nevertheless, our understanding of grief is broadened by his idea that grief is a mature way of dealing with loss of attachment. He also provides a slightly different perspective on the stages of grief.

Theresa Rando (1984, 1986, 1993, 2000) Rando identified three processes of grieving (Table 17-1). Rando's (1984) stages are commonly described as the six R's of grieving:

1. *R*ecognizing the loss (awareness)
2. *R*eacting to the separation (feeling the emotions)
3. *R*ecollecting memories of the deceased (remembering, reliving)
4. *R*elinquishing the old attachment (new ways of living without the deceased)
5. *R*eadjusting to the new environment (new coping skills)
6. *R*einvesting self (energy once turned inward on grief begins to be focused outward again).

William Worden (2002) Worden described the tasks a grieving person must achieve. They progress from an initial numbness or denial through experiencing and working through pain and grief and eventually moving on with life.

Table 17-1 ➤ Theories of Grief. A Comparison

STAGES	DESCRIPTION
George Engel (1961)—Three Stages of Grief	
Shock and disbelief	Initial phase. The sufferer denies the loss in an attempt to protect himself against the shock of reality.
Developing awareness of the loss	The sufferer experiences painful feelings of sadness, guilt, shame, helplessness, hopelessness, loss, and emptiness. The person may lose interest in usual activities and experience impaired work performance. She may also experience loss of appetite, sleep disturbances, and even physical symptoms of pain or other discomfort.
Restitution and recovery	The final phase, which is prolonged and gradual. The person carries on the work of mourning and overcomes the trauma of the loss, and a state of health and well-being is reestablished.
John Bowlby (1982)—Phases of Grief	
Shock and numbness	Initial stage, in which the person experiences disorientation and feelings of helplessness
Yearning and searching	The grieving person yearns to be reconnected with the deceased and searches for connections
Disorganization and despair	The permanence of the loss becomes real. The person feels the pain and emotions of grief to their fullest and feels there is no hope of reconnection.
Reorganization	Adjusting to life without the deceased (or lost object); developing new coping skills
Theresa Rando (1984, 1986, 1993, 2000)—Three Processes of Grieving	
Avoidance	Includes shock, disbelief, denial, anger, and bargaining
Confrontation	The person actually begins to face the loss; a very emotional and upsetting time, when the person feels the grief most acutely
Accommodation	The person begins to live with the loss, feel better, and resume some routine activities
William Worden (2002)—Four Tasks of Grieving	
Accepting the reality of the loss	*Realizing that the loved one (or object) is gone.* In the hours and days after a significant loss, the grieving person typically feels numb and unable to accept the fact of the loss. This numbness is thought to be a helpful form of denial, which allows the person to "take in" only what the psyche is capable of handling at that time. So, the task of realizing the loved one or object is gone may take several days or, in the case of a sudden death, weeks.
Working through the pain and grief	*Feelings and emotions that surface are intense and can change rapidly.* This makes the person feel "out of control." People in this stage may say they feel as if they are "going crazy." This is usually the longest phase for two reasons. First, because none of us likes to be in pain; we become expert at finding ways not to feel it. We overeat, overmedicate, overwork, and drink to excess to avoid feeling the pain, and we thereby prolong the process of grief. Second, caring people do not like to see their loved ones in pain, so they make attempts to remove the pain (e.g., by distraction) rather than letting the person experience it. Like avoidance, this well-meaning behavior also prolongs the process.
Adjusting to the environment in which the deceased is missing	*Adjusting to the environment without the deceased.* This may mean performing alone activities and tasks, such as going for walks or shopping, that were once shared. Or it may include taking on roles and responsibilities that the deceased previously held. Such experiences can be extremely sad, frustrating and challenging, or very rewarding. However, once the person has established the new pattern, he or she typically feels satisfaction and increased self-esteem.
Emotionally relocating the deceased and moving on with life	*Investing emotional energy.* Initially all energy is focused on the deceased: thinking about the person, talking about him/her, reliving memories, and so on. It is nearly impossible to think of anything else. Concentration is difficult, so the grieving person finds it hard to engage in activities such as reading. When the person's energy begins to flow toward others or to different or former interests (e.g., working, socializing), the healing process is in progress.

ThinkLike a Nurse 17-2

What are some of the similarities you see in the four theories described?

Grieving as Reconstructing Meaning

Some theorists are moving away from stage models of grieving toward the idea of grieving as a process of reconstructing meaning. For example, many recognize that the sorrow of loss is always present (Boss & Carnes, 2012; Florczak, 2008), whether in the foreground or the background of a person's life. However, the meaning of the loss is constantly changing for the bereaved. The sorrow becomes "remembered" sorrow, which sometimes resurfaces and at other times sinks in to the background of other sorrows, joys, and everyday life.

Factors Affecting Grief

To begin thinking about factors affecting grieving, consider the following exercise.

ThinkLike a Nurse 17-3

Mr. Klein is an 86-year-old man whose wife died of heart disease 2 months ago. He has two adult children who regularly visit him. He also has a very supportive pastor, Mr. Owens, who meets him in the park to share stories. Mr. Owens is 30 years old and has been raising his 5-year-old daughter alone after the sudden death of his wife 6 months ago in an automobile accident. His parents and siblings live out of state. Both of these men are missing their wives very much.

- What factors do you think play a role in each man's grief?
- Who do you think will "get over it" faster?
- What are some issues that may make each man's grief uniquely difficult?

No two people ever grieve in the same manner because there are so many factors that play a role in the grieving process. They include the following:

- **Significance of the Loss.** The meaning the person has attached to the person or object lost will be different for each person. The greater the attachment, the more difficult is the grief.
- **Support System.** People with strong emotional and psychosocial support typically have less complicated grief.
- **Unresolved Conflict.** An unresolved conflict at the time of death may cause prolonged grief. For example, if a couple had an argument just before one partner's sudden death, the remaining partner's grief may be complicated by guilt.
- **Circumstances of the Loss.** Specifically, was there an opportunity to prepare for it? Was this a sudden, unexpected death, or had the person been suffering from a chronic illness? Was the death a suicide or homicide? Was the death in any sense avoidable? Was the person in pain? Is it an "ambiguous loss" or open-ended loss that occurs with the sudden disappearance of a loved one? If the circumstances of the loss leave the bereaved feeling guilty or responsible, his grieving process may be impeded. This may occur in losses other than death (e.g., loss of a job).
- **Previous Loss.** If the person has sustained more than one loss in a short period of time, the grieving process can become more complicated. In the hospital, you will frequently care for patients experiencing multiple losses. For example, consider a patient who has suffered a stroke and loss of mobility and moves to a nursing home. The patient has the compounded loss of health and functioning, independence, and the familiar surroundings of his home.
- **Spiritual/Cultural Beliefs and Practices.** Spirituality and religious beliefs can help or hinder the grieving process. One person might believe the deceased is in a place of contentment and happiness, where all suffering is over. Another may believe that the deceased person will be reborn into another form. Yet another may believe that death is final and there is no afterlife. How do you think these beliefs might influence the grieving process? Most cultures engage in rituals (e.g., funerals) that help the bereaved begin the grieving process by openly expressing their emotions and pain (Fig. 17-1). Some cultures may emphasize keeping emotions more subdued and limiting expressions of grief to private settings.
- **Timeliness of the Death.** The death of a child or a young person is almost universally more difficult to accept than the death of an older person. In addition to loss of the person, there is a sense of unfairness because of the loss of *potential*—of what the child might have become or achieved. You may hear someone ask,

FIGURE 17-1 Rituals are used to facilitate grieving.

"Why was her life cut short?" or state, "He had so much going for him, but God didn't give him a chance."

Research shows that support groups are effective in reducing the severity of grief in widowed older adults, while religious support was most effective in the reduction of grief severity (Ghesquiere, Shear, & Duan, 2013). Your care plan should incorporate support groups to minimize complicated grief and depression in older adults.

Developmental Stages and Grief

Based on Erik Erikson's stages of psychological growth, we all must achieve certain psychological milestones during a lifetime. Grief can affect the healthy development of life stages, and in turn, the person's stage of development can affect the grieving process. If you need to review Erikson's theory, review Chapter 9.

Childhood Because cognitive development is not yet complete, preschool children do not understand that death is final. They believe that death is temporary and reversible, as with cartoon characters that "die" and then "come to life" again. During early childhood, children begin to understand that death is permanent, but believe that it will never happen to them or anyone they know. Between ages 8 and 11, children recognize that death can happen to them and may be fearful (Brown, 2009).

Young children believe they are the cause of what happens around them. This is known as *magical thinking.* Such thinking may cause them to feel guilt when there is a death of someone close to them. Other responses include regressing to a previous developmental stage: "acting like a baby," demanding food and attention, becoming incontinent, and talking "baby talk."

During the weeks after a death, a child may feel immediate grief, may or may not display sadness, or may continue to believe the person is still alive. These are normal reactions.

Adolescence The bereavement and emotions felt by adolescents along with confusion regarding their identity and role can create major uncertainty. The adolescent struggles to learn who he is as a person as he breaks away from parental control. An adolescent who experiences the loss of a parent while "pushing the parent away" may feel a sense of guilt and unfinished business.

At the same time, the bereaved teen also faces psychological, physiological, social, and academic pressures. Although teens may look mature, they often lack emotional maturity. Teens are often expected to be "grown up" and support a surviving parent or younger siblings. When they feel this responsibility, they do not have the opportunity, or the permission, to mourn. Adolescents may turn to those outside of the family to discuss their feelings (Brown, 2009).

Research shows that bereaved youths who have lost a parent have a higher frequency of engaging in health risk behaviors (Hamdan, Mazariegos, Melhem, et al., 2012). Adult caregivers must be alert to these behaviors and take appropriate interventions to meet the bereavement and safety needs of children and adolescents.

Adulthood Adults are cognitively able to understand the nature of death, and they have usually experienced other types of loss by this time. Over time, they perceive loss as a normal part of living. How they respond to loss depends on factors such as the person's self-esteem and the availability of supports.

Older Adulthood A special difficulty for older adults is the cumulative effects of the many losses that they experience. Most deaths occur among older adults, so they are likely to lose friends and siblings in rapid succession, along with physical and functional losses and the loss of independence. In addition, they began the process of preparatory grief in anticipation of their own death (MacKenzie, 2011). The emotional effects may be devastating.

Research reveals that elderly adults who have suffered the loss of a child experience significant and sometimes irreparable mental and physical outcomes, accelerated disabilities, and loss of the ability to function independently. To minimize these negative outcomes, caregivers should use listening skills and metaphors and promote storytelling (Smith, Kerr, Galligan, et al., 2011).

KnowledgeCheck 17-2

- What are the main tasks of the grieving process?
- What factors affect the grieving process?

ThinkLike a Nurse 17-4

Refer to Thomas Manning and his wife (Meet Your Patient). Apply each of the preceding factors affecting grief to Thomas and to Mary (they may be different for each spouse). If the scenario does not provide enough information for you to comment, say so and then describe how you would obtain the data you need.

Types of Grief

Grief can be categorized in several ways, most of which have to do with timing and intensity.

Uncomplicated Grief (normal grief) is the natural response to a loss. The bereaved person experiences the feelings, behaviors, and cognitions that are expected in light of his culture, social status, and relationship to the lost person or object. The emotions are intense but gradually diminish over time (several months to several years). Some emotions will always be present, but the intensity will change.

Complicated Grief, also known as prolonged acute grief, is characterized by its length of time and intensity of emotion. The person's responses last longer than 6 months and are maladaptive, dysfunctional, unusually prolonged, or overwhelming (Germain, Shear, Walsh, et al., 2013). For example, the bereaved may become severely depressed, violent, or suicidal; become a "workaholic"; become socially isolated; or demonstrate addictive behavior. Or after several years the person may still be experiencing as much pain and disruption as in the first months after the loss. Complicated grief has been associated with depression, suicidal ideation, and hypertension and can be very distressing and disabling (Prigerson, Frank, Kasl, et al., 1995; Prigerson, Horowitz, Jacobs, et al., 2009). Risk factors for complicated grief include previous loss, exposure to trauma, sudden death of a significant other, emotional instability, and lack of social support (Lobb, Kristjanson, Aoun, et al., 2010). Chronic, masked, and delayed grief all are examples of complicated grief:

- **Chronic grief** begins as normal grief but continues long term, with little resolution of feelings and inability to rejoin normal life.
- **Masked grief** occurs when the person is grieving, but expressing the grief through other types of behavior. For example, a man whose wife has died may begin drinking heavily, or a couple whose child has died may find themselves engaging in violent arguments with each other. This change in behavior is part of their grief response, but they don't recognize it as such.
- **Delayed grief** is grief that is put off until a later time (e.g., "I'll think about it later; right now, I'm busy trying to keep a roof over our heads and care for my children").

Typically, complicated grief results when the grieving process has been impeded for some reason (e.g., something keeps the person "stuck" in the grief process). Usually the bereaved benefits from the assistance of a grief counselor to help establish and work through the problem areas.

Disenfranchised Grief is experienced in connection with a loss that is not socially supported or acknowledged by the usual rites or ceremonies. Some examples include a couple who experienced a miscarriage, the unplanned termination of a child's foster placement, a mistress whose lover dies, or a bereaved partner in a homosexual relationship (Lang, Fleiszer, Duhamel, et al., 2011; Riggs & Willsmore, 2012). In each of these instances, the bereaved person lacks the familial or communal support that is helpful in grieving.

Anticipatory Grief is experienced before a loss occurs. A wife caring for her husband through a long illness may grieve as she sees the vibrant man she once knew change before her eyes as she anticipates his death. Family members experience anticipatory grief as they watch the mental capacity diminish in a loved one with Alzheimer's disease and realize that the person they once knew is becoming progressively removed from them. The potential negative outcome of anticipatory grief is that the survivor may detach from a dying person too early in the dying process, leaving the person without emotional support during that period. This does not always happen, of course.

ThinkLike a Nurse 17-5

Thomas Manning (Meet Your Patient) had a strained relationship with his father for most of his life. His father was an alcoholic and constantly fought with his mother while Thomas was growing up. A few months ago, his father was hospitalized for the third time for complications of alcoholism, and Thomas visited him. He confronted his father regarding his drinking and the problems and pain it had caused him and the family. The confrontation ended in an argument. That night, Thomas's father slipped into a coma. He died a few days later, without recovering consciousness.

- What issues does Thomas have to deal with?
- Why might this be a complicated grief process?

DEATH AND DYING

Death is the ultimate loss. The dying person faces the loss of physical control and function, independence, relationships, possibilities, and ultimately life itself. In mainstream North American culture, death is not seen as a natural part of life, but rather as something to avoid at all costs. People even avoid talking or thinking about it.

How Is Death Defined?

Historically, *death* was defined as the cessation of the flow of vital bodily fluids. This evolved into the traditional definition of **heart–lung death**: the irreversible cessation of spontaneous respirations and circulation. This was later replaced with **whole-brain death**: the irreversible cessation of all functions of the brain, including the brainstem. Spontaneous respirations cannot continue once the brainstem stops functioning; however, the heart may continue to beat until it becomes oxygen starved from cessation of respirations.

In the 1970s, many practitioners began using the term **higher-brain death**, which defines death as the irreversible cessation of all "higher" brain functions (e.g., cognitive functioning, consciousness, memory, reasoning, and so on). By this definition, the brainstem can still be functioning, so both respiratory and cardiac activity may continue even though the person does not make purposive responses to external stimuli; cephalic reflexes are absent; and the electroencephalogram shows no activity.

Under those definitions, it was technically possible to keep a person "alive" indefinitely by using a mechanical ventilator. In 1981, the President's Commission for the Study of Ethical Problems in Medicine proposed the **Uniform Determination of Death Act** (Box 17-1) that provides a highly reliable means of declaring death for respirator-maintained bodies—loss of brainstem function (DeSpelder & Strickland, 1996, p. 328). For criteria for assessing brainstem functioning,

Go to Chapter 17, **Supplemental Materials: Some Criteria for Assessing Brainstem Functioning,** on Davis*Plus*.

BOX 17-1 ■ Uniform Determination of Death Act

1. [Determination of Death] An individual who has sustained either (1) irreversible cessation of circulatory and respiratory functions, or (2) irreversible cessation of all functions of the entire brain, including the brain stem, is dead. A determination of death must be made in accordance with accepted medical standards.
2. [Uniformity of Construction and Application] This act shall be applied and construed to effectuate its general purpose to make uniform the law with respect to the subject of this Act among states enacting it.

Source: President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research. (1981). *Defining death: A report on the medical, legal, and ethical issues in the determination of death.* Washington, DC: Government Printing Office, p. 73.

What Are Coma and Persistent Vegetative State?

A **coma** is a prolonged, deep state of unconsciousness lasting days or even years. The patient cannot be aroused and may or may not have decreased brainstem reflexes.

Persistent vegetative state (PVS) sometimes follows a coma, but can also occur after any event that affects cerebrovascular flow. In PVS, the person does not purposefully respond to stimuli, is unaware of the environment, and has no cognition or affective mental functions. However, the person has lost only the higher cerebral functions (see the preceding definition of higher-brain death) and so continues to have a sleep–wake cycle, may have some spontaneous movements, and may open her eyes in response to external stimuli. The person cannot speak or obey commands. Patients in a PVS may look somewhat normal and may occasionally grimace, cry, or laugh. The family may believe that the patient is responding to the environment and thus not want to give up hope for recovery. Because they cannot work through the grieving process, they continue to grieve each day.

What Are the Stages of Dying?

To help dying patients and their families understand the dying process, your theoretical knowledge base must include information on both physiological and psychological processes.

Physiological Stages of Dying

The dying process is unique to each person. However, people experience many similar symptoms as they approach the end of life. Fewer than 10% of patients die suddenly and unexpectedly, as in an accident or massive heart attack. Ninety percent die after a long illness, progressively deteriorating until an active dying phase at the end (Emanuel, Ferris, von Gunten, et al., 2008). The following time line describes the physiological responses of that group (Karnes, 1995).

One to Three Months Before Death The dying person begins to withdraw from the world and people. Sleep increases; it becomes difficult for the body to digest food, especially meats; and appetite and food intake decrease. Liquids are preferred. Anorexia and the resulting ketosis may be protective, as they can diminish pain and increase the person's sense of well-being.

One to Two Weeks Before Death A host of physical changes indicates the body is beginning to lose its ability to maintain itself. Cardiovascular deterioration brings reduced blood pressure, changes in pulse and skin color (e.g., a yellowish pallor), and extreme pallor of the extremities. Temperature fluctuates and perspiration increases. Respiratory rate may increase or decrease; during sleep, the dying person may experience brief periods of apnea. Congestion may cause a rattling sound and/or a nonproductive cough.

Days to Hours Before Death Often a surge of energy brings mental clarity and a desire to eat and talk with family members. However, as death approaches, patients tend to become dehydrated and have difficulty swallowing, which results in decreased blood volume. The tissues of the tongue and soft palate sag, and the gag reflex declines, so secretions accumulate in the oropharynx and/or bronchi. Often the mucous membranes become dry and tacky and lips become cracked. Dehydration during the last hours of dying is thought not to cause distress, and perhaps to stimulate endorphin release (Emanuel, Ferris, von Gunten, et al., 2008).

Breathing may be shallow, rapid, or irregular: Periods of apnea may lengthen to 10 to 30 seconds before breathing resumes. Congestion causes a "death rattle" that can be quite loud. **Cheyne-Stokes respirations** may occur. This is a cyclic pattern consisting of a 10- to 60-second period of apnea and then a gradual increase in depth and rate of respirations. Respirations gradually become slow and shallow, and then the cycle begins again with apnea.

Peripheral circulation decreases, and the person perspires and feels "clammy." The blood pressure decreases, and the pulse may be hard to detect. The extremities become cool and mottled, and the underside of the body may be much darker. Decreased circulation also results in reduced kidney function and decreased urinary output.

Muscles throughout the body relax, causing the face to "droop." As peristalsis slows, the patient may retain feces. Urine output decreases and urine often becomes more concentrated and foul smelling. Sphincters relax, and bowel and bladder incontinence can occur. Vision blurs; the eyes may be open or partially open, but unseeing. Instead, the patient may see things that are not visible to others.

In the final hours of life, many patients become restless and agitated. This response may be caused by medications, liver failure, cerebral hypoxia, renal failure, stool impaction, distended bladder, increased pain, or unresolved emotional or spiritual issues. Near to the time of death, some people unexpectedly become more coherent and energized for a time. Others become less communicative, quiet, and withdrawn (Pitorak, 2003). Fatigue is common.

Moments Before Death The dying person does not respond to touch or sound and cannot be awakened. Typically, there is a short series of long-spaced breaths before breathing ceases entirely and the heart stops beating (Karnes, 1995; National Caregiver Library, n.d.).

Psychological Stages of Dying

Perhaps the best known author on the psychology of dying is Dr. Elisabeth Kübler-Ross (1969). She felt that if people understood what dying patients are experiencing, they would be more competent in caring for them. From her research with dying patients, she observed that people tend to experience one or more of five psychological stages during the period from the terminal diagnosis to the actual death (Box 17-2). Her theory has become a classic for professional and lay readers alike, and has been applied to losses other than death. When you study the Kübler-Ross stages, it is important to understand that dying people:

- May not go through *every* stage.
- May not go through the stages in a linear fashion, but rather in random order.
- Do not necessarily complete one stage and move on to the next.
- May experience two or three stages simultaneously.

BOX 17-2 ■ Kübler-Ross: Stages of Dying and Grief

Stage	Defining Characteristics
Denial	■ "Not me." "This cannot be happening." "I don't believe it." Usually the person is in a state of shock. Denial is not necessarily negative; it gives the person a chance to prepare psychologically for accepting the news.
Anger	■ "Why me?" "Why is this happening?" Anger can be obvious or subtle. It is the person's response to the feeling that the situation is unfair. The person may take his anger out on people who are "safe" (e.g., family, spouse) or from whom there will be no reprisals (e.g., nurses, physician).
Bargaining	■ "If only I can live until . . ." "Yes me, but . . ." Usually this takes the form of a bargain with God or a Higher Power, in which the person asks to live to see a birth, graduation, wedding, and so forth.
Depression	■ A withdrawn sadness, not to be confused with clinical depression. This is a response to the current loss as well as to any accumulated and/or future losses.
Acceptance	■ Not necessarily *wanting* death (or the loss), but coming to terms with it and ceasing to fight it. The person may seem almost devoid of feelings.

Source: Adapted from Kübler-Ross, E. (1969). On death and dying. New York: Macmillan.

Key Point: ***Remember that it is not the nurse's responsibility to move people to the next stage so that dying patients accept death. It is our responsibility to accept and support people "where they are" and help them to verbalize their feelings. We need to understand patients, not change them.***

What Is End-of-Life Care?

When, precisely, is the end of life? There is no set, agreed-upon definition or set of criteria. A recent set of guidelines provides a working definition that includes the following three situations:

- The patient has a fatal condition.
- Death is likely with the next exacerbation of disease.
- The patient acknowledges the seriousness of the situation (Qaseem, Snow, Shekelle, et al., 2008).

In an effort to humanize healthcare, organizations such as the Institute of Medicine (2013), the American Association of Colleges of Nursing (2010, updated 2013), and the Robert Wood Johnson Foundation (2012) have undertaken initiatives to ensure that end-of-life care is delivered with compassion, sensitivity, and competency. Some of these competencies include the following (Bednash & Ferrell, 2000; End-of-Life Nursing Education Consortium [ELNEC], 2012):

- Holistic assessment of patients and families (i.e., physical, psychological, social, and spiritual)
- Acknowledging diversity in patients' beliefs and customs
- Using both traditional and complementary approaches
- Incorporating essential communication strategies that meet spiritual and cultural needs
- Applying legal and ethical principles to end-of-life care
- Demonstrating respect for the patients' views and wishes during end-of-life care
- Assessing patient, family, colleagues, and one's own success in coping with suffering, grief, loss, and bereavement at the end of life
- Providing quality postmortem care

For end-of-life nursing care competencies recommended by the American Association of Colleges of Nursing (AACN),

Go to Chapter 17, **Tables, Boxes, Figures: ESG Box 17-1,** on Davis*Plus*.

End-of-life care includes palliative care and hospice care, which are similar in that both may involve caring for dying patients, and neither focuses on cure. Some people use the terms interchangeably; however, there are subtle differences.

Complementary & Alternative Modalities (CAM)

End-of-Life Care

- **Hodgson (2013)** studied the effects of reflexology and Swedish massage on pain reduction and symptoms of agitation in 60 end-stage dementia patients. Results revealed that both CAMs promoted palliation of symptoms and pain reduction.
- **Heath, Oh, Clarke, et al. (2012)** interviewed parents of children who had died of cancer to determine the perceived efficacy of CAM and its effect on the overall end-of-life experience. The primary types of CAM used were organic foods, faith healing, and homeopathy, with 44% of respondents using more than one type. The majority (78%) reported a significant benefit from CAM use.
- **Kraft (2012)** reviewed research studies and reviews to determine the effect of CAM on depression, anxiety, grief, and other symptoms in advanced palliative care patients. Although short lived, yoga, acupuncture, aromatherapy, and some massage techniques had a positive effect on depression. These therapies also successfully treated anxiety, as did music therapy and mindfulness-based stress reduction. Acupuncture had a positive benefit on fatigue.
- **Rahim-Jamal, Sarte, Kozak, et al. (2011)** found that 81% of 49 hospice patients expressed an interest in CAM for pain relief, relaxation, and enhanced well-being. Of those, 79 % had used CAM prior to entering the hospice setting.

Palliative Care

When patients reach a stage in their illness in which cure is no longer possible, or when they refuse further treatment, they may be eligible to receive "comfort care"—meaning that no further efforts will be made to stop the disease process or prevent the patient from dying. However, the patient will receive treatment to minimize unpleasant symptoms, (e.g., nausea, pain). The correct interpretation of the term *comfort care* is, "Nothing more *can* be done to cure your loved one." However, family members sometimes interpret it to mean "Nothing more will be done." In this situation, the term *palliative care* may be more acceptable. As a specialty, palliative care is provided by a holistic team of professionals. However, many patients receive palliative care from their general practice provider, and even in acute care hospitals, especially if staff are comfortable and skilled with pain management and end-of-life care.

Palliative care is actually aggressively planned, holistic comfort care. General issues for most end-of-life care patients include the following:

- Supporting families and caregivers
- Ensuring continuity of care
- Ensuring respect for persons
- Ensuring informed decision making
- Attending to emotional and spiritual concerns
- Supporting function and survival duration
- Managing symptoms (e.g., pain, dyspnea, depression)

A patient does not necessarily have to be "actively dying" to receive palliative care. It is also provided over a long period of time for those who have slowly progressive diseases. Palliative care should not be seen as merely limiting life-sustaining treatment or allowing death. It should result in increased patient satisfaction, improved symptom control, and cost savings for hospitals (Owens, Eby, Burson, et al., 2012; Qaseem, Snow, Shekelle, et al., 2008).

Hospice Care

The hospice movement was set in motion in England by Dame Cicely Sanders, who founded the first modern-day hospice within a London hospital in 1968. More than 5,000 hospice providers in the United States alone served 1.6 million patients in 2011 (National Hospice and Palliative Care Organization, 2011). **Hospice care** focuses on holistic care of patients who are dying or debilitated and not expected to improve. For a patient to be eligible for hospice insurance benefits, a physician must certify that the patient is likely to die within 6 months. This is a primary difference between palliative care and hospice.

Hospice care is based on two key premises: (1) The quality of life is as important as the length of life, and (2) those who are terminally ill should be allowed to face death with dignity and surrounded by the comfort of their homes and families. Although you may think of hospice as "home" care, hospice is a *way* of caring rather than a setting. Some hospitals are able to devote some inpatient beds to hospice care, and freestanding hospices also exist. The purpose of admitting a patient is to provide a family with some respite for a period of time or to stabilize a patient who requires symptom management, or to care for a patient who is in the end stage of a disease (e.g., AIDS or cancer) and needs a level of expert care that family members cannot provide at home.

Treatment is holistic, addressing the patient's emotional, spiritual, and physical needs. Physical care is primarily palliative, involving symptom management. For example, pain management is considered crucial because patients must be relatively free from pain to make the most of their remaining time.

An interdisciplinary team plans care with the patient and family. Family members are encouraged to be active in the team to the extent they are able. Nursing support is available 24 hours a day and families are taught what to expect as the disease progresses. Psychosocial and spiritual care have high priority. As the patient nears death, hospice workers remain as long as necessary. After the patient dies, there is follow-up bereavement care for the families.

Legal and Ethical Considerations at End of Life

The technology of life support makes it possible to prolong bodily functions almost indefinitely, leaving patients and families struggling to decide whether prolonging life is appropriate. More clients depend on nurses for education regarding patient rights and end-of-life care choices. Each situation is unique, and you should be able to explore with clients the various options available. See Chapters 44 and 45, for more information about the ethical and legal aspects of each of the following topics.

Advance Directives

An advance directive is a group of instructions (written or oral) stating a person's wishes regarding his healthcare if he were incapacitated or unable to make that decision. An ordinary power of attorney does not give another person the right to make healthcare decisions for the patient; only a durable power of attorney for healthcare decisions can do that.

The **Patient Self-Determination Act (PSDA),** passed by Congress in 1990, requires that all healthcare providers who receive Medicare funds (e.g., hospitals, home care agencies, hospices, nursing homes) must educate staff and patients and provide an opportunity for all patients to complete an advance directive (see Chapter 45 if you want more information). The Joint Commission (2008) also requires institutions to address the wishes of the patient regarding end-of-life decisions. Laws in each state vary regarding advance directives. It is important for you to understand the federal and state laws and the policies of your institution. Two types of advance directives serve different purposes.

- A **living will** is a document that provides specific instructions about the kinds of healthcare the person would wish or would wish *not* to have in particular situations. For example, it might specify that the person does not want to be maintained on a ventilator or receive tube feedings.
- A **durable power of attorney (DPOA)**, or **healthcare proxy**, exists when another person is identified to make decisions for the individual regarding healthcare choices when he is unable to do so based on circumstances (e.g., irreversible coma, terminal illness). The individual should provide specific instructions about his desires regarding hydration, feeding tubes, medication, resuscitation, and mechanical ventilation. Since this is a legal document, it should be properly prepared (executed) and can be changed or canceled at any time by the patient. For an example of an advance directive,

Go to Chapter 17, **Tables, Boxes, Figures: ESG Figure 17-1,** on Davis*Plus*.

For details of the Patient Self-Determination Act,

Go to Chapter 17, **Supplemental Materials: Patient Self-Determination Act,** on Davis*Plus*.

Some people fear that once an advance directive is signed, no further care will be provided. It is important to explain to families and patients that these directives ensure that they will get as much or little care as *they* wish. Remind them that everyone should get advance directives while they are healthy. Such explanations are independent nursing activities, for which you are responsible.

Orders for DNAR

A **DNAR order** is an order to *not* attempt resuscitation of the patient in the event of cardiac or respiratory failure. Formerly known as *DNR (do not resuscitate)*, a DNAR must be prescribed by a physician. Some are recommending the acronym **AND** (allow natural death) to replace DNAR (Breault, 2011), because the word *death* in the acronym makes clear the intent of the provider's order (American Nurses Association [ANA], 2012). Regardless, you must pay careful attention to these orders, agency policies, and advance directives to be prepared if the patient suffers a cardiopulmonary arrest. For an example of a DNAR (DNR, AND) order,

Go to Chapter 17, **Forms, Do Not Resuscitate Orders,** in Volume 2.

In many healthcare settings, cardiopulmonary resuscitation (CPR) is performed almost automatically. This practice may be slowly changing, however, as the AHA provides guidance on the appropriate use of CPR. For example, in considering whether DNAR (DNR, AND) is appropriate, emphasis is placed on the efficacy of CPR attempts, balancing the benefits and burdens and therapeutic goals (ANA, 2012).

You should carefully explain to patients and families what CPR involves and their available options. They should know that the physician cannot write a DNAR order without their permission. They have the right to refuse CPR and may request the physician to write a DNAR (AND) order. The American Nurses Association (ANA, 2004, 2012) recommendations regarding DNAR (AND) are summarized in Box 17-3. For a complete list of the ANA recommendations,

Go to Chapter 17, **Tables, Boxes, Figures: ESG Box 17-2,** on Davis*Plus*.

There is growing evidence that strategies, such as formal and informal family meetings, daily team consensus processes, palliative care team case finding, and ethics consultation, improve communication about end-of-life decisions (Boyle, Miller, & Forbes-Thompson, 2005).

Assisted Suicide

Assisted suicide means making available that which is needed for the patient to end his own life (e.g., pharmacological agents or weapons). The patient is physically capable of ending his own life, has expressed the intention to do so, and has turned to the healthcare provider merely to supply the means. Although physician-assisted suicide is legal in a few states, the ANA (1994a, 1994b, 2013) continues to oppose assisted suicide. "ANA prohibits nurses' participation in assisted suicide and euthanasia because these are in direct violation of *Code of Ethics for Nurses With Interpretive Statements* . . . , the ethical traditions and goals

BOX 17-3 ■ Highlights of ANA Recommendations Concerning DNAR/AND

- The competent patient's choices have highest priority when there is conflict.
- When the patient is not competent, give highest priority to advance directives or the surrogate decision makers.
- DNAR orders should be discussed explicitly with the patient and significant others.
- DNAR orders must be documented, reviewed, and updated.
- DNAR does *not* mean "discontinue care" or substandard care!
- Nurses should be aware of and have an active role in developing DNAR policies in the institutions where they work; they should participate in interdisciplinary mechanisms for resolving disputes among patients, families, and healthcare practitioners concerning DNAR orders.
- Nurses should consider the acronym AND (allow natural death) because the word *death* makes the intent clear.
- Nurses have a responsibility to avoid participation in "slow codes" or "partial codes."
- Nurses have a duty to educate patients and families about technologies and termination of treatment decisions, and to encourage them to think about end-of-life preferences and make their wishes known in advance.
- Nurses have a duty to communicate relevant information and to advocate for a patient's end-of-life preferences to be honored.

Source: Adapted from American Nurses Association (ANA). (2004). Position statement: Nursing care and do-not-resuscitate decisions. Retrieved from http://ana.nursingworld.org/MainMenuCategories/EthicsStandards/Ethics-Position-Statements/Copy%20of%20dnr0414405.aspx; American Nurses Association (ANA). (2012). Revised position statement: Nursing care and Do Not Resuscitate (DNR) and Allow Natural Death (AND) decisions. Retrieved April 19, 2013, from http://www.nursingworld.org/dnrposition

of the profession, and its covenant with society" (ANA, 2013). Assisted suicide violates the ethical principle of nonmaleficence (Friend, 2011).

Some advocate the use of continuous sedation until death as an alternative to assisted suicide (Raus, Sterckx, & Mortier, 2011). The Hospice and Palliative Nurses Association promotes **palliative sedation** as the "controlled and monitored use of non-opioid medications intended to lower the patient's level of consciousness to the extent necessary, for relief of awareness of refractory and unendurable symptoms" (Hospice and Palliative Nurses Association, 2011, pg. 1).

Euthanasia

The term **euthanasia** comes from the Greek word *euthanatos*, which means "good death." It refers to the deliberate ending of the life of someone suffering from a terminal or incurable illness. **Active euthanasia** occurs as a result of a direct action (e.g., giving an overdose of medication). Active euthanasia can be *voluntary* (patient consents); *involuntary* (patient refuses); or *nonvoluntary* (patient is unable to consent, or someone else makes the decision and the patient is unaware of it). Active euthanasia goes a step further than assisted suicide. In assisted suicide, the person assisting makes available the means for the person to take his own life; in euthanasia, the assistant also serves as the direct agent of death (e.g., administers the medication).

Passive euthanasia occurs as a result of a *lack* of action (e.g., withholding medications or food necessary to sustain life). Honoring the patient's refusal of treatments is not generally considered passive euthanasia and can be ethically and legally permissible. For more information about the ethical and legal issues surrounding euthanasia, see Chapters 44 and 45, respectively.

ThinkLike a Nurse 17-6

What are your feelings about assisted suicide, continuous sedation, and euthanasia? Focus on your feelings, not on principles, explanations, and rationales.

Autopsy

An autopsy is a medical examination of the body to determine the cause of death. Autopsies have also provided relevant data about disease processes and causes. The pathologist performs a detailed internal and external evaluation of the body, removes body organs, and extracts sample tissues for further examination. The organs are then replaced in the body, and the body cavities are closed with sutures. An autopsy requires signed permission from the next of kin, except in cases in which autopsy is required by law (e.g., suspicious or unwitnessed deaths).

Organ Donation

The Uniform Anatomical Gift Act (UACA) provides guidance on tissue, eye, and organ donation (National Conference of Commissioners on Uniform State Laws, 2009). The new act specifically added language that would prevent others from overriding an individual's prior decision regarding organ donation. However, there remain ethical concerns that the new UAGA might result in donors being maintained on life support against their family's wishes.

Key Point: ***A conflict between a potential organ donor's advance directives and measures to ensure the viability of his organs (e.g., life support) must be resolved as soon as possible, by one of the following, in this order: (1) the donor (if able), (2) the surrogate decision maker, or (3) another person as authorized under state law. Until resolution, maintaining the suitability of the organs has the highest priority. You should advocate that your patient's advance directives are clear on end-of-life care and organ donation.***

The UAGA has been adopted in all but four states (as of May 2013). In general, the UAGA states the following:

- As a rule, general donors must be at least 18 years of age or an emancipated minor.

- Next of kin can donate organs when a person dies, unless an objection is known.
- Relatives cannot revoke a person's donation, even after death.
- The person making the gift can amend or revoke it at any time.

To see the UAGA major provisions in greater detail,

Go to Chapter 17, **Tables, Boxes, Figures: ESG Box 17-3, Major Provisions of the Uniform Anatomical Gift Act,** on Davis*Plus*.

Many states issue identification cards or allow driver's licenses to be amended to identify a person as an organ donor. However, even though donor cards are legal in all states, many institutions will not procure organs from the deceased if there is strong family objection (Fig. 17-2). Therefore, if a patient is planning to donate organs or tissues, be sure that he discusses these wishes with family members. If death is imminent, a healthcare team member (physician or nurse) should ask whether the patient has agreed to be an organ donor, has a donor card, or is registered with the state's donor database. In many institutions, a transplant coordinator contacts the family and makes the request for organ and tissue donation.

PracticalKnowledge knowing how

ASSESSMENT

When a patient is dying or has experienced a loss, you must carefully assess the patient and significant others for the common physical, emotional, behavioral, and cognitive grief reactions. For a list of these, along with guidelines to follow when assessing dying and grieving patients,

Go to Chapter 17, **Assessment Guidelines and Tools,** in Volume 2.

Other important areas to assess include knowledge base, history of loss, coping patterns and abilities, meaning of the loss or illness, and support systems. For dying patients, you should also make the following assessments:

- When the client and family are ready, encourage them to talk about the client's wishes for burial or cremation or tasks that the client would like taken care of (e.g., giving away valuables, calling family members).
- Determine whether the dying client has advance directives (e.g., living will, durable power of attorney for healthcare).

Is It Grief or Depression?

When you are performing a focused assessment for grief or loss, you will need to distinguish between grief and depression. Sadness and depression are an integral part of grief. However, depression that lingers beyond what is expected may be a sign that the stress of grieving has triggered a major depressive episode (Ferszt & Leveillee, 2006; Widera & Block, 2012). Although grief and depression have several symptoms in common (e.g., sadness, insomnia, poor appetite, and weight loss), grief tends to come and go—to be triggered, for example, by a holiday. For help in differentiating them,

Go to Chapter 17, **Assessment Guidelines and Tools, Assessing Grief and Loss,** in Volume 2.

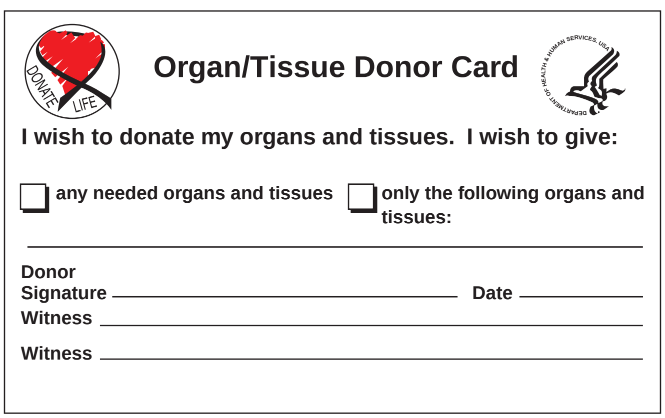
KnowledgeCheck 17-4

What assessments should you make for your terminally ill patient and his or her family?

ANALYSIS/DIAGNOSIS

When you are analyzing patient data, keep in mind that most grief is normal, not complicated or dysfunctional. You must determine whether loss and grieving are the problem or the etiology, because the etiology will influence your interventions. Also note that the same diagnoses can be used in the context of death, dying, grief, or loss.

Loss and Grieving as Problem Various nursing diagnoses may be appropriate for a person who is dying or grieving. The two most obvious ones are Grieving and Complicated Grieving. Do not use a Complicated Grieving diagnosis for every person who is grieving a loss. Complicated Grieving is disabling pain and grief, characterized by long-term grieving (perhaps years), functional impairment, and/or intense emotions. The person may deny or have difficulty expressing feelings of loss or may experience physical symptoms as a result of suppressing feelings.



Organ/Tissue Donor Card

I wish to donate my organs and tissues. I wish to give:

☐ any needed organs and tissues ☐ only the following organs and tissues:

Donor Signature ____ Date ____

Witness ____

ThinkLike a Nurse 17-7

Refer to the table in Standardized Nursing Language, NOC Outcomes and Interventions on Davis*Plus*. Answer the questions in the table. Also refer to a nursing diagnosis handbook and NIC and NOC manuals, if needed.

Loss and Grieving as Etiology Loss, grief, and dying are an etiology when they create problems in other areas of patient or family function. The following are examples of such nursing diagnoses.

- Situational or Chronic Low Self-Esteem related to inability to change the event for self or significant other; or related to dying while having "unfinished business"
- Anxiety related to inability to cope with the loss; or related to unknown outcome of situation
- Death Anxiety (or Fear) related to impending death
- Decisional Conflict related to end-of-life treatment measures (e.g., concern about the expense of "useless" procedures or their effect on the family; knowledge that the treatment may lengthen life but decrease the quality of life)
- Deficient Knowledge related to the new experience of caring for a terminally ill person
- Fatigue related to demands of caring for a dying loved one
- Spiritual Distress related to loss of trust in a loving God

PLANNING OUTCOMES/EVALUATION

Encourage the patient and family to play an active role in planning care. Involving family members helps facilitate their acceptance of the diagnosis and may put the patient more at ease. Questions such as the following will help to elicit the patient's goals for end of life (Matzo & Sherman, 2009; Weissman, Quill, & Arnold, 2010):

- "What do you still want to accomplish or do?"
- "What are the things you wish you could still do?"
- "Whom would you like to see?"
- "What would make you 'medically comfortable'?"
- "If you have pain, what would be an acceptable level for you, on a 0 to 10 scale?"
- "Where do you want to spend the rest of your life? Where are you most comfortable?"
- "If spiritual peace is important to you, what would help you achieve it?"

NOC standardized outcomes are determined by the diagnostic label you use. For examples,

Go to Chapter 17, **NOC Outcomes and NIC Interventions for Loss and Grieving Diagnoses,** on Davis*Plus*.

Individualized goals/outcome statements you might write for a grieving or dying person include the following examples. The patient and/or family will:

- Communicate openly among themselves and health-care providers (e.g., express fear, concerns, pain)
- Obtain satisfactory pain relief and symptom management
- Use all resources available to assist with coping
- Exercise control in the management of care to the extent possible

As always, you will use the goals set in the planning stage as criteria for evaluating the patient's or family's health status.

KnowledgeCheck 17-5

- List three nursing diagnosis labels you might consider when dying or grieving is the primary problem.
- List three nursing diagnosis labels that might occur as a result of dying or grieving.

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC standardized interventions associated with death, dying, and bereavement are found on Davis*Plus*.

Go to Chapter 17, **NOC Outcomes and NIC Interventions for Loss and Grieving Diagnoses,** on Davis*Plus*.

Specific nursing activities are determined by the nursing diagnosis, especially by the etiology. Your ability to help someone who is grieving or dying is largely determined by your attitude. A compassionate approach is essential but may be challenging. Watching patients struggle with pain, loss, grief, and death may stir our own deepest doubts and fears, and we may reject the challenge to respond from the heart. We may be aware that employers usually reward nurses for what they *do* rather than who they *are* as people, so it is easy to rationalize that we have other tasks to accomplish that may be equally important. When we do that, we ignore the real gift we have to offer the suffering patient is our willingness to "walk the walk" with them, if even for a short time. Full-spectrum nurses combine their psychomotor and thinking skills with compassion in ministering to those who are suffering.

Some important nursing interventions, including therapeutic communication, facilitating grief work, helping families, and specific activities involved in care of the dying person, are discussed in the following sections. Also see the Nursing Care Plan and Care Map for Grieving.

Nursing Care Plan

Client Data

Wilma Peterson is caring for her son, Henry, who has AIDS. Henry is 20 years old; his older brother, William, died at home of AIDS-related pneumonia 2 years earlier at age 24. William had left home at 18 to live in Miami and returned to his home in rural Alabama when he became too ill to manage on his own. Henry stayed home to help his mother care for William and learned he was HIV-positive just before his brother died. Henry did not tell his mother of his diagnosis until he was hospitalized for the first time with cytomegalovirus (CMV) infection. Since then, he has not followed nutritional and medical advice and has continued to stay out late and party when he feels well enough. His health has steadily declined.

You are participating in a special Caring for the Caregiver program set up by the public health nurse in your community. In this program, registered nurses visit primary caregivers to assess their needs and offer support services as needed. You are assigned to Wilma Peterson.

Ms. Peterson is initially cordial when you visit but tells you, "This is a mother's responsibility. I don't stop being his mother because he's grown up. I'm always his mother." As your discussion continues, Ms. Peterson wistfully talks about when William and Henry were boys. She says, "I didn't really understand this awful disease until William got so sick. Now, I look at Henry and I know what's waiting for him. I know we are going to lose him. Sad . . . just so sad. . . ." Her voice trails off as tears well in her eyes.

Nursing Diagnosis

Grieving related to the client's anticipating the loss of a second son, as evidenced by her previous experience caring for her other son who died at home of AIDS and by the client's stating, "I know what's waiting for him."

NOC Outcomes	Individualized Goals / Expected Outcomes
Family Coping (NOC 2600) Psychosocial Adjustment: Life Change (NOC 1305)	*(Short-term goals) At the end of the initial home visit, Ms. Peterson will:* 1. Identify community resources available to help her care for Henry at home during acute illnesses. 2. Begin to feel comfortable discussing her concerns with the nurse. *(Long-term goals) Within 6 weeks, Ms. Peterson will:* 1. Explore activities she would like to participate in once she is no longer caring for Henry. 2. Talk with Henry to learn what type of funeral he would like.

(continued on next page)

Nursing Care Plan (continued)

NIC Interventions*

Anticipatory Guidance (NIC 5210)
Coping Enhancement (NIC 5230)
Grief Work Facilitation (NIC 5290)

Nursing Activities	Rationales
1. Encourage Ms. Peterson to talk about her experiences caring for William before he died.	1. Grieving often occurs in the context of repeated caregiving (Boyle, Bunting, Hodnicki, et al., 2001) or in situations in which the caregiver has other types of previous experience with the same or a similar terminal illness. Supportive communication allows for asking questions, sharing information, and ultimately coming to terms with the loss (Ostler, 2010).
2. Ask her to relate similarities and differences between care for William and care for Henry.	2. Asking the client to discuss previous experiences allows the nurse to validate the nursing diagnosis (O'Connor & Lunney, 1998) and provides an opportunity for the client to discuss her specific needs (Kelly, Malloy, Munevar, et al., 2010).
3. Ask Ms. Peterson to describe the elements of Henry's care and to identify which she considers to be the most important.	3. Clients are holistic and consider more than just medical treatment in the care of a family member. Their actions are often based on care needed, cultural and religious beliefs, and previous experiences instead of a medically based care plan. Clients may operate on a different, parallel track from that of the healthcare providers (Boyle, Bunting, Hodnicki, et al., 2001). By asking Ms. Peterson how she prioritizes and provides Henry's care, the nurse can learn from the client rather than making assumptions based on the healthcare perspective. By showing respect for her experience as a caregiver, the nurse can build a stronger relationship with Ms. Peterson, which will facilitate future nursing interventions and anticipatory guidance (Reinhard, Given, Petlick, et al., 2008).
4. Talk with Ms. Peterson to find out what community resources she used when she cared for William and whether she has accessed them now in caring for Henry.	4. Isolation and loneliness are risk factors for sole caregivers at home. By assessing community resources, the nurse can determine whether Ms. Peterson is "connected" or isolating herself. Isolation and previous loss put her at risk for Complicated Grieving (Lobb, Kristjanson, Aoun, et al., 2010). Many community resources provide a sense of belonging and enhance and support coping strategies as well.
5. Promote shared decision making if this is acceptable to Henry Peterson.	5. Informing both Ms. Peterson and Henry about the disease, prognosis, treatment, and comfort options allows them to retain some control over their lives together, which is essential for effective palliative care (Teno, Casey, Welch, et al., 2001; Wilson, Gott, & Ingleton, 2013). Henry's permission must be obtained to preserve his autonomy.
6. Provide nonjudgmental emotional support to Ms. Peterson, and support healthy coping activities she is using.	6. Establishing a comfortable and emotionally safe environment will allow Ms. Peterson to share her concerns without fear of being judged because of her son's diagnosis (Boyle, Bunting, Hodnicki, et al., 2001; Milberg & Strang, 2011).

*Interventions are only a sample of those linked to this diagnosis by *NIC*. Activities should be individualized for each client.

Nursing Care Plan (continued)

Evaluation

Review the initial short-term outcomes and goals. Reassess your client to determine whether the goals are achieved in the stated time frame. In this case, long-term goals will fluctuate based on the progression of Henry's illness. The following occurred as the care plan was implemented:

- Ms. Peterson cried as she described the deterioration in William's health before he died. She worries that Henry will suffer and does not want him to lose his dignity the way she believes William did.
- Ms. Peterson's greatest concern is that Henry is not eating enough. Much of her self-value as a mother arises from her ability to prepare homemade meals to feed her family, and Henry doesn't have much of an appetite. This is very distressing to her.
- She has not contacted community agencies. She is holding off, hoping Henry will not be "so sick for so long. With these new drugs, he can get better."
- She remains involved in her church, which is the same one she attended as a little girl. However, she will not tell her church group that Henry has AIDS. "They talk too much," she says. Instead, she says he has leukemia.

Only one short-term goal is met at this visit—establishing a comfort level between the client and the nurse. Ms. Peterson has not identified community resources related to caring for Henry at this time.

Plan for Further Evaluation

Additional supportive visits will be needed to help Ms. Peterson understand that contacting community agencies does not mean Henry will die sooner. An important coping mechanism for Ms. Peterson is denying the need for community help; however, it is not affecting her ability to care for her son. If his condition worsens, this issue will need to be promptly addressed.

Therapeutic Communication

Therapeutic communication is critical to building a trusting relationship with the dying or **grieving** patient and their significant others (Fig. 17-3). It is most important to listen to the dying patient and to be alert for and respond to nonverbal cues. Encourage patients and family members to express their feelings, and reassure them that their feelings are normal and not "wrong." In discussions about DNAR (AND) or withholding or withdrawing treatments, it is important to find out why the patient is seeking that option: Does she wish to avoid suffering, or does she fear being a burden to loved ones?

Physicians and nurses should always work to improve their communication skills because they are essential for achieving better outcomes at end of life (Boyle, Miller, & Forbes-Thompson, 2005; Galushko, Romotzky, & Voltz, 2012). See Box 17-4 for some barriers to end-of-life communication. For tips on communicating with people who are dying or bereaved,

Go to Chapter 17, **Clinical Insight 17-1: Communicating With People Who Are Grieving,** in Volume 2.

If you need more information on communication and therapeutic relationships, refer to Chapter 21.

BOX 17-4 ■ Barriers to End-of-Life Communication

- Fear of one's own mortality
- Unresolved personal grief issues (e.g., the loss of one's own parent)
- Lack of experience with death and dying
- Fear of expressing emotion (i.e., crying)
- Fear of not knowing the answer to a question
- Not knowing whether to give an honest (and possibly unwelcome) answer to a question
- Not understanding the family's culture
- Keeping physical distance (e.g., standing away from the person or avoiding eye contact)
- Insensitivity: interrupting communication, patronizing, giving false reassurance

Facilitating Grief Work

Whether grief results from a loss of health, from an impending death, or from some other loss, you can help patients and families work through their grief by helping them express their feelings, recall memories, and find meaning in their lives. Later in this chapter, we discuss interventions for helping families after the death of a loved one. This section focuses more generally on grieving *any* loss.

Expressing Feelings

It is the family, not just an individual patient, who grieves a death or loss. Grief is a normal process, and for people and to deal with it in a healthy way they must communicate their feeling. Sometimes people are uncomfortable expressing their feeling and will hold them in. These self-contained emotions will interfere with their grief resolution, so you may need to facilitate the process, using your therapeutic communication skills (refer to Chapter 21 as needed). The following are some ways to facilitate expression of feelings:

FIGURE 17-3 The nurse encourages and accepts expression of feelings.

- Encourage questions, and respond to them within a reasonable time.
- Sit beside the head of the bed; do not appear rushed.
- When you observe the patient or family member expressing feelings, either verbally or nonverbally, encourage them to continue.
- Expect and accept a wide range of feelings, including anger, fear, and loneliness.
- Ask, "How would you like me to help?" "What do you need?"
- Be sure that everyone on the healthcare team understands and follows the care plan.
- Ask yourself what you would do if this were your family member.
- Do not compare another person's loss with your own experience. Avoid comments such as "I know how you feel." Instead, say, "Tell me how you feel."

Recalling Memories

Grieving patients and family members may need to recall memories, both good and difficult. One way to encourage recall is to go through photo albums with them and ask questions about the people in the pictures. Also look for objects of sentiment (e.g., a family heirloom) in the environment and ask the dying or bereaved person to share their significance.

Finding Meaning

Another way to facilitate grief work is to help the patient or family find meaning in their lives or in their past. Talking through this meaning is a healthy way to cope. Facilitating life review is one technique to help the patient and/or family recognize the unique contributions this person has made to family, friends, and society. You can begin by asking about the various aspects of the patient's life (e.g., "What were some of his favorite hobbies/activities?"), commenting on pictures in the room, or picking up on verbal cues that are expressed.

Bibliotherapy

Bibliotherapy is a counseling technique used when grief therapy is indicated. It uses guided reading of self-help literature or fiction to increase client awareness and understanding and promote healing. Poems, novels, and essays can help produce new insights, either as the client retells the story or is guided to discuss his feelings and thoughts about the characters in the story (Briggs & Pehrsson, 2008; Songprakun & McCann, 2012).

Think**Like a Nurse** 17-8

- What would you say to Mrs. Manning (Meet Your Patient) if you walked into a room and found her sitting in a chair and softly weeping while Mr. Manning sleeps?
- What response would you make when Mr. Manning waves his hand in the air and says, "I'm not taking any more of those damn pills" as you bring him his medications?
- A young woman approaches you in the hall and says, "I want to visit Mom and stay with her, but I just can't stand to see her like that. I feel guilty for wanting to leave." What would be your therapeutic response?

Helping Families of Dying Patients

When a patient is dying, it is important to view the family as your unit of care. If the patient is unresponsive, you may find yourself spending most of your care time with the family. This time should be spent providing education, support, and a listening ear. Observing their loved one dying can leave family members feeling confused, angry, helpless, and even devastated. Sensitive, compassionate nursing care is always essential, especially during this time. You can use the interventions in the preceding sections as you help family members to understand that what they see may be very different from what the patient is experiencing. For more specific interventions for helping families of dying patients,

Go to Chapter 17, **Clinical Insight 17-2: Helping Families of Dying Patients,** in Volume 2.

KnowledgeCheck 17-6

- Describe four ways to facilitate the grief work of a grieving or dying person.
- List two specific interventions, in addition to facilitating grief work, for helping grieving families.

Caring for the Dying Person

To effectively care for terminally ill patients, you must meet their physiological, psychological, social, sexual, and spiritual needs. Most hospitals and hospice facilities have an interdisciplinary team to provide holistic care to dying patients and their families. This team may be made up of a physician, nurse, social worker, pastoral care worker, nutritionist, physical therapist (and sometimes occupational and speech therapists), and volunteers.

Meeting Physiological Needs

Active dying usually occurs over a period of 10 to 14 days (although it can take as little as 24 hours). The "final hours" refers to the last 4 to 48 hours of life, in which failure of body systems results in death (Brennan, Prince-Paul, & Wiencek, 2011; Pitorak, 2003). In the last hours of life, most patients need skilled care around the clock. Physiological needs during this time include mobility, oxygenation, safety, nutrition, fluids, elimination, personal hygiene, and control of pain and symptoms (nausea, vomiting).

Research shows that older adults with refractory dyspnea from conditions such as heart failure or chronic obstructive pulmonary disease are not getting adequate symptom management because of fear of hastening death or other concerns. Nurses should work with members of the interdisciplinary healthcare team to ensure that patients receive the "most effective pharmacological treatment for the palliation of refractory dyspnea" (Lowey, Powers, & Xue, 2013, p. 50).

See the previous discussion of the physiological stages of dying to review signs of impending death. For specific interventions and guidelines to use when caring for a dying patient,

Go to Chapter 17, **Clinical Insight 17-3: Caring for the Dying Person: Meeting Physiological Needs,** in Volume 2.

Meeting Psychological Needs

When a patient is terminally ill, the primary provider is usually responsible for deciding what and how much to tell the person. Ideally, everyone involved with the patient should have input into this decision and you should know exactly what he and the family have been told. Most patients want to know their prognosis as soon as possible so that they can put personal affairs in order, share their feelings with family members, and come to terms with their life and death. A systematic review of research suggests that rather than protecting patients, efforts to shield patients from the reality of their situation usually create greater difficulties for them (Hancock, Clayton, Parker, et al., 2007). A "conspiracy of silence" causes fear, anxiety, and confusion, and denies people the opportunity to make needed life adaptations. However, culture may determine which family members are to be informed and how much, if any, information is given to the patient. You should seek guidance for the proper balance between cultural influences and the patient's autonomy. Also, many patients realize without being told that they are dying. For specific interventions to help meet the psychological needs of dying patients,

Go to Chapter 17, **Clinical Insight 17-4: Caring for the Dying Person: Meeting Psychological Needs,** in Volume 2.

KnowledgeCheck 17-7

- Describe six nursing interventions to use in meeting the physiological needs of a dying person.
- Describe six nursing interventions to use in meeting the psychological needs of a dying person.
- What should be the focus of your interventions when the patient is very near death?

Addressing Spiritual Needs

When a person is terminally ill, his spirituality may become very important as he searches for meaning in the illness and suffering. The person may be looking for forgiveness and/or acceptance or be reaching out to feel connected. Ways to address this need include (but are not limited to) empathetic listening, contacting pastoral care or clergy if the patient asks for this service, special rituals, praying with the patient, music, meditation, or special readings.

Information about specific religious practices may help you provide appropriate interventions at end of life. For example, after the death of an Orthodox Jewish patient, you should handle the body as little as possible if you are not Jewish. Most Christian denominations will not object to your washing and preparing the body. Remember, though, that there are wide individual differences and that you must assess each patient and family to determine how closely they adhere to the rituals of their religion. Review Chapters 15 and 16, as needed. For detailed information about a variety of religious practices surrounding death,

Go to Chapter 17, **Supplemental Materials: Addressing Spiritual Needs,** on Davis*Plus*.

Toward Evidence-Based Practice

Hancock, K., Clayton, J. M., Parker, S. M., et al. (2007). Truth-telling in discussing prognosis in advanced life-limiting illnesses: A systematic review. *Palliative Medicine, 21,* 507–517.

This was a systematic review of 46 studies related to truth-telling in discussing prognosis with patients with progressive, advanced life-limiting illnesses and their caregivers. Results revealed the following:

- Many health professionals expressed discomfort at having to inform the patient and family of limited life expectancy. Although the majority thought that patients and their caregivers should be told the truth, many either withhold information about prognosis or avoid discussing it.
- Reasons for not telling the truth include perceived lack of training, stress, no time to attend to the patient's emotional needs, fear of a negative effect on the patient, uncertainty about the prognosis, requests from family to withhold information, and feeling inadequate because further curative treatment was not available.

Fine, E., Reid, C., Shengelia, R., et al. (2010). Directly observed patient–physician discussions in palliative and end-of-life care: A systematic review of the literature. *Journal of Palliative Medicine, 13*(5), 595–603.

Researchers reviewed 20 studies that used direct observations in end-of-life/palliative communications. Several common themes emerged. Physicians tended to dominate the discussions and focused more on medical/technical aspects. Emphasis was not placed on emotional or quality of life issues. Patient satisfaction was associated with supportive behaviors by physicians.

Gramling, R., Norton, S., Ladwig, S., et al. (2013). Direct observation of prognosis communication in palliative care: A descriptive study. *Journal of Pain & Symptom Management, 45*(2), 202–412.

Researchers audio-recorded the initial visit of 71 seriously ill patients and their families who were referred for discussions of end-of-life decision making or goal clarification. Results identified these major themes: (1) Patient-focused quality of life discussions occurred more frequently than did survival discussions focused on the general population. (2) Pessimistic cues regarding prognosis occurred more often than did optimistic ones.

1. Based on these research results, do you think health professionals should inform patients when they have an advanced life-limiting (terminal) illness? What should be the focus of the communication? Explain your thinking.
2. Health professionals feared a negative effect on patients of telling them the truth about their condition. What sorts of negative effects do you think they might be anticipating?
3. What should be the goal of communications between health professionals and terminally ill patients related to end-of-life care?

Go to Chapter 17, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

Addressing Cultural Needs

Cultural values can influence a person's openness to discussions regarding death and his end-of-life health-care preferences. Researchers found that regardless of ethnicity or gender, end-of-life concerns important to most people include comfort, physician communication, having responsibilities taken care of, support, hope and optimism, and honoring spiritual beliefs. Other concerns were being cared for, love and compassion, expressing feelings, fixing relationships, saying goodbye, having choices, making plans, not being in pain or unable to breathe, and being "ready to go" (Duffy, Jackson, Schim, et al., 2006; Valente, 2010).

There is some overlap between religious and cultural practices. For example, most cultural groups engage in some type of religious ceremony that helps the bereaved begin the grieving process (Fig. 17-4). Nevertheless, some death rituals and expressions of grief may be culture based but not necessarily involve religion. For example:

- Some cultures may emphasize keeping emotions more subdued and limiting expressions of grief to private settings, whereas others gauge the value of the deceased by the amount of wailing and crying (Fig. 17-5).
- Blacks and Hispanics may be reluctant to withdraw life-sustaining treatment or to use a hospice, whereas Arab Muslims may be reluctant to prolong life unnecessarily (Duffy, Jackson, Schim, et al., 2006; Health Care Chaplaincy, updated 2013).

Despite the commonalities among groups, there are some culture-specific differences. To provide culturally sensitive care at end of life, you will need some information about specific cultural practices surrounding death. For this information,

Go to Chapter 17, **Supplemental Materials: Addressing Cultural Needs,** on Davis*Plus*.

FIGURE 17-4 After death, rituals (e.g., this Rwandan burial) are viewed as respect for the deceased and help friends and family bring closure.

FIGURE 17-5 Family openly expressing grief.

Key Point: ***As with spiritual care, remember that you cannot assume that a person follows the practices of her cultural group; you must assess to be sure.***

Think**Like a Nurse** 17-9

Reflect on this reading by Theresa Rando in *The Gift of Presence*:

> *It is one of the most difficult things in the world to do to sit and listen while another's heart is breaking with grief, to hold the hand of a dying patient who cries silently while staring into space. The gift of presence, the gift of being with those in pain, is the only gift we can give. It is the sole armor patients have against the anguish. The very most we can do for dying patients is to make it better, with our presence and concern, than it would be if we were not there. . . . We cannot "do" anything that can get rid of the psychic pain of impending loss and death. (Rando, 1984, p. 272)*

Close your eyes and visualize yourself sitting quietly beside a dying patient and holding her hand. Visualize the patient crying silently. Can you still your mind and remain silent, or do you feel you must say something to make the patient feel better?

Providing Postmortem Care

Postmortem care includes care of the patient's body after death and fulfilling any legal obligations, such as arranging transportation to the morgue or funeral home and determining the disposition of the patient's belongings. You will follow agency policies and respect cultural and spiritual preferences, along with the care that is commonly provided. In most states, the physician must pronounce death; in some areas, however, a coroner or a nurse may also perform this task.

- **Rigor mortis** (the stiffening of the body after death) is caused by contraction of the muscles from a lack of adenosine triphosphate (ATP). It occurs about 2 to 4 hours after death. Rigor mortis begins in the involuntary muscles (e.g., the heart). It appears next in the head, neck, and trunk, and finally in the extremities. It disappears about 96 hours after death.

- **Algor mortis** occurs when the blood stops circulating. The body temperature drops about 1.88°F (1°C) per hour until it reaches room temperature.
- **Livor mortis** occurs when the dependent parts of the body appear bluish and mottled. That happens when the blood stops circulating and the red blood cells break down, releasing hemoglobin.

If the family wishes to be alone with the body, straighten the bedcovers, remove all tubes (unless contraindicated), and make the patient look as natural as possible. Give family members whatever time they need before you prepare the body. Ideally, you will have already established a relationship with the family and will have begun to facilitate their grieving during the patient's dying period. And you will have prepared them as the death becomes imminent. For specific guidelines for care of the body and other immediate postmortem interventions to support family members,

Go to Chapter 17, **Clinical Insight 17-5: Providing Postmortem Care,** in Volume 2.

KnowledgeCheck 17-8

- Why is it important to position the body with a pillow under the head and shoulders soon after death?
- Why is it important to close the eyes and mouth of the deceased and position the body within at least 2 to 4 hours after death?

Providing Grief Education

Sometime after the immediate postmortem period, explain the stages of grief and point out that it may take months or even years to resolve. Explain that grief may become more intense on the anniversary of the death (or other loss) and on significant dates (e.g., birthdays).

Recall that once the bereaved person accepts that the loss is real, his feelings may be so intense that he may wonder whether he is losing his sanity. The grieving person may be fatigued from not sleeping, may be disoriented or unable to concentrate, and have numerous other symptoms. Reassure the person that such responses are expected and that there is no single right way to grieve (Egan & Arnold, 2003; Holtslander & McMillan, 2011). Also assure him that although the grief process takes time, the symptoms won't last forever.

Helping Children Deal With Loss

Some families may need information about helping children deal with grief, especially when there is a death in the family. You may need to explain that children perceive death differently from adults. See the accompanying Self-Care box for teaching surviving relatives how to help children deal with grief.

Taking Care of Yourself

When caring for dying patients, you will confront your own feelings of mortality. It is important to understand your own attitudes, fears, and beliefs concerning death, so think about these before you encounter dying patients. This will enable you to deal in a more healthy way with patients and their families. In addition, suppressing feelings associated with death of patients can take a heavy toll on you emotionally.

When you become involved with dying persons and their families at such an intimate time in their lives, you become connected to them. There is nothing wrong with this emotional involvement; it helps you to be effective in your work. But just as you care for these families, you need also to care for yourself during these times.

- Recognize that feelings of grief and loss are normal.
- Talk with other colleagues about your feelings. Nurses are known for being able to take care of everyone but themselves! Don't be afraid to ask for what you need.
- Do not be afraid to confront grief. Some nurses feel they have to be strong and tend to deny their feelings. They overwork in caring for others and underwork in caring for themselves. If you use this approach, the feelings will accumulate and begin to wear you down physically and emotionally.

Self-Care

Helping Children Deal With Loss

Teach surviving adult relatives the following:

- If a child is frightened about attending a funeral, do not force him to go. It is important, however, to include the child in some service or observance, such as lighting a candle, saying a prayer, or visiting the gravesite, at a later time.
- Spend as much time as possible with the child, making it clear that the child has permission to show her feelings openly or freely.
- Be prepared for intermittent expressions of sadness and anger from the child, over a long period of time.
- Be prepared for the possibility of regression to earlier developmental stages (e.g., talking "baby talk").
- Assure the child that he was in no way responsible for the death.
- The following warning signs may indicate the need for professional help, especially if they are prolonged:

  An extended period in which the child loses interest in daily activities and events

  Inability to sleep

  Loss of appetite

  Fear of being alone

  Extended regression

  Repeated statements about wanting to join the dead person

  Withdrawal from friends

  Refusal to attend school

  Sharp drop in school performance

- If you wish, it is appropriate for you to attend calling hours and/or funeral services when one of your patients dies. This helps you diffuse some of your feelings of loss. It also is very meaningful to family members to know that you took the time to remember them and their loved one.
- Learn how to get support for yourself and how to support your colleagues when they experience the death of a patient. One idea is a nurses' support group, or grief team, that meets regularly to talk about the feelings and to remember those who have died. If you need or want a facilitator, pastoral care workers and social workers may be available for these services.
- Do some nice things for yourself on a regular basis (e.g., facial, quiet bubble bath, massage, a sports event). Try to set aside a special spot in your home that is only for relaxation; decorate it with items that help you focus on peaceful thoughts (e.g., candles, pictures, religious objects).

Caring for the dying can be very rewarding but is also emotionally draining. To be effective in your practice, learn to care for yourself as well.

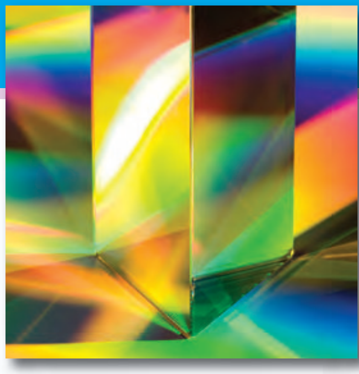
Essential Nursing Interventions

CHAPTER 18



Documenting & Reporting

Learning Outcomes

After completing this chapter you should be able to:

- Explain the purposes of documentation.
- Compare and contrast the differences between electronic and written documentation.
- Identify a variety of charting formats and their purposes.
- Describe guidelines for written and electronic documentation in the clinical setting.
- Identify approved abbreviations to use in charting.
- Follow documentation guidelines to accurately record patient health status, nursing interventions, and patient outcomes.
- Discuss the key elements of giving an oral patient report.
- Explain the process for verifying or questioning a medical order.

Key Concepts

Documentation

Oral reporting

Related Concepts

See the Concept Map on Davis*Plus*.

Meet Your Patient

Steven Stellanski is a 16-year-old male who has just been released from the post-anesthesia care unit (PACU) after an emergency appendectomy. You are to admit him to your unit. Steven is groggy but moaning in pain. "Help me, help me," he whispers. He is holding his abdomen and grimacing. The PACU nurse tells you that Steven has Down syndrome and functions at an elementary school–age level.

Steven's vital signs are as follows: tympanic membrane temperature 99.9°F (37.7°C); pulse, 104 beats/min; respirations, 24 breaths/min; and blood pressure 104/68 mm Hg. An intravenous (IV) bag of lactated Ringer's solution is infusing at 125 mL/hr. The dressing on Steven's right lower abdomen is dry and intact. An indwelling catheter is draining pale yellow urine.

The provider has prescribed a patient-controlled analgesia (PCA) pump that will deliver morphine sulfate at 1 mg every 15 minutes, up to 4 mg per hour. Steven is to remain NPO (nothing by mouth) for now. His postoperative dressing is to be changed tomorrow morning and the nurses are to institute progressive ambulation as tolerated.

Theoretical Knowledge knowing why

When you imagine yourself working as a nurse, what do you think of? Most people picture themselves at the bedside working with patients. When you look at ads for nursing jobs, they often show a nurse hanging an IV bag, listening to heart sounds, or perhaps teaching a patient. Photos rarely show the nurse charting or orally reporting care. Yet healthcare professionals rely on these two methods of communication to coordinate patient care. In this chapter, we discuss paper, electronic, and oral communication.

ABOUT THE KEY CONCEPTS

Documentation and **oral reporting** are the two broad concepts to which all other concepts in this chapter are linked. As you read, think: "What does this have to do with documentation?" and "How does this relate to oral reporting?"

DOCUMENTATION

Documentation is the act of recording patient status and care in written or electronic form, or in a combination of the two forms. Documentation is not limited to "writing nursing notes," but is the act of making a written record. The terms *documenting*, *recording,* and *charting* are often used to mean the same thing. Oral communication about a patient's status is called **reporting—**that is discussed later in this chapter.

Historically, the collection of documentation, orders, and other care information for a patient had been called the **medical record** or **chart**. However, with the present emphasis on health promotion, the medical record is now more commonly referred to as the **health record**. A patient's health record permanently documents:

- Care, in chronological order, provided by all healthcare providers
- The patient's responses to interventions and treatments
- Important facts about a client's health history, including past and present illnesses, examinations, tests, treatments, and outcomes

As a nurse, you are responsible for managing and implementing the interdisciplinary plan of care. That responsibility includes documenting the care provided and the progress made toward goals. Research shows that nurses routinely spend 15% to 25% of their workday documenting the care they give, and in some cases considerably more (Yee, Needleman, Pearson, et al., 2012).

How Do Healthcare Providers Use Documentation?

Clear, complete, concise, comprehensive and correct documentation in a client health record serves the following purposes:

Communication One important function is communication. Members of the interdisciplinary team use the health record to communicate about the patient's status and care. For example, if it is not possible to speak directly to the respiratory therapist on your shift, you can at least review the progress notes. Documentation enables healthcare professionals to plan and evaluate treatment and monitor health status over time.

Continuity of Care Communication promotes continuity of care. For example, if you are concerned that the patient is at high risk for developing an infection, you can include a nursing diagnosis of Risk for Infection on the written or electronic interdisciplinary plan of care. You would then initiate nursing orders for other nurses to regularly observe for and document signs of infection.

Quality Improvement Healthcare organizations and other agencies perform **manual chart audits** (directed reviews of client medical records) of written documentation. In electronic health record (EHR) systems, reports are run to analyze large amounts of data. Results are used to formulate strategies to improve care, decrease length of stay, control costs, and identify knowledge and practice gaps that can be addressed through inservice and continuing education. Accrediting agencies, such as The Joint Commission, review written and electronic records to ensure delivery of quality care and public safety.

Planning and Evaluation of Patient Outcomes Documentation enables physicians, nurses, and other healthcare professionals to plan and evaluate treatment and monitor health status over time.

Legal Documentation The health record will be scrutinized by legal experts if a dispute about a client's care arises. In court, the health record is legal evidence of the care given to a client, and is used to judge whether the interventions were timely and appropriate. Expert reviewers look for documentation of the client's baseline status, changes in status, interpretation of the changes, interventions implemented, and the client's responses to those interventions.

Professional Standards of Care The American Nurses Association (ANA) *Scope and Standards of Practice* (2nd ed.) (2010) includes documentation in many of its standards. By the ANA standards and competencies, the registered nurse:

- *Documents relevant data* in a retrievable format. (Standard 1, Assessment)

- *Documents diagnoses* or issues in a manner that facilitates the determination of the expected outcomes and plan. (Standard 2, Diagnosis)
- *Documents expected outcomes* as measurable goals. (Standard 3, Outcomes Identification)
- *Documents the plan* in a manner that uses standardized language or recognized terminology. (Standard 4, Planning)
- *Documents implementation* and any modifications, including changes or omission, of the identified plan. (Standard 5, Implementation)
- *Documents the coordination of the care*. (Standard 5a, Coordination of Care)
- *Documents the results of the evaluation*. (Standard 6, Evaluation)
- *Communicates effectively* in a variety of written, spoken and technological formats. (Standard 11, Communication)
- Cooperates in *creating a documented plan* focused on outcomes and decisions related to care and delivery of services that indicates communication with patients, families, and others. (Standard 14 Collaboration)

Reimbursement and Utilization Review Insurance companies, government and third-party payers, budget managers, and organization billing staff use client health records to determine the cost of care. They also use the health record for **utilization review**, the determination of whether the medical treatments and interventions were necessary and appropriate.

Education and Research As a student, you are well aware that the health record provides a snapshot of what is going on with the client, enabling you to research unfamiliar diagnoses, orders, and treatments before beginning direct care. This helps you to deliver safe care.

The health record is also used to gather data for clinical research. The increasing use of EHRs enables rapid analysis of large numbers of health records. Use of large samples of health records and clinical data sets is an essential step toward better understanding the cause and progression of disease, treatment methods, and outcomes across varied populations and diseases.

Why Are Standardized Nursing Languages Important?

Nurses have long understood the need for a standardized vocabulary for describing what nurses do and patient outcomes that result. As healthcare costs escalated, it became necessary to measure nursing's contribution to care and demonstrate the value of nursing. Standardized nursing terminology helps do that by making nursing care and its effect on patient outcomes more visible in patient records.

The ANA (2010) recommends that documentation systems use ANA-recognized terminology (e.g., NANDA-I, NIC, NOC). Standardized terminologies allow researchers to retrieve nursing data for aggregation and analysis. Through the use of standardized languages in nursing documentation, a standard for evidence-based nursing care delivery has now been established. This is a step toward closing the gap between what research shows to be the best nursing practices and the interventions nurses actually use in practice.

Standardized languages are especially important in EHR systems because computers require standardized information that can be converted to numerical codes. Several standardized nursing language models are used in nursing documentation, such as NANDA International (NANDA-I), Nursing Interventions Classification (NIC), and Nursing Outcomes Classification (NOC). To review using standardized nursing language models in your own practice, see the standardized language sections in Chapters 4, 5, and 6.

How Are Health Records Systems Organized?

A **health records system** is the overall process by which all patient records are created, stored, and retrieved in an organization. In a sense, it consists of all the EHRs in an organization. Each healthcare agency determines the health record system that is used. The nursing leaders in each organization usually determine the documentation forms that nurses will use within the records system.

Source-Oriented Record Systems

Patients in hospitals and long-term care facilities receive care from a variety of disciplines, so these institutions commonly use **source-oriented records**. Members of each discipline record their findings in a separately labeled section of the chart. In paper records, nurses chart in the nurses' notes and graphic data sections. A typical source-oriented record includes the following sections:

- *Admission data*—demographic information, insurance data, contact information
- *Advance directive*—information on client's wishes for the extent of care and medical support that should be given in the event of a life-threatening event
- *History and physical*—a detailed summary of the current health problem; past medical, surgical and social history; medications taken; allergies; review of systems, and physical examination data
- *Provider's orders*—orders for medications, treatments, and activities
- *Progress notes*—chronological charting by healthcare team members including patient exams, problem identification, and patient's response to therapy
- *Diagnostic studies*—reports detailing the findings of tests that have been performed, such as x-ray exam, ultrasound, or pulmonary function tests

- *Laboratory data*—results from diagnostic tests, such as complete blood count (CBC)
- *Nurses' notes*—documentation of patient care and response to treatment recorded by nurses (usually chronological)
- *Graphic data*—numerical data collected over time and displayed visually to allow analysis of trends. Examples include intake and output records, vital sign flowsheets, rating scales, and checklists regarding patient activity, dietary intake, and activities of daily living (ADL) tasks.
- *Rehabilitation and therapy notes*—chronological charting by therapists (e.g., physical, occupational, respiratory) about assessments, treatment plan, and patient response to therapy.
- *Discharge planning*—includes data from utilization review, case managers, or discharge planners on anticipated client needs after discharge

Advantages In source-oriented records, you can easily find the care provided by each discipline and the results of laboratory and diagnostic tests.

Disadvantages A drawback of this system is that data may be fragmented and scattered throughout the patient's record. That means that you need to review all sections of the chart to fully understand the client's condition and care. It is especially difficult with source-oriented records to track the treatments and client outcomes associated with a particular problem. For example, suppose a client with congestive heart failure is retaining fluids, causing her to be short of breath on exertion. To find the interventions for the problem, you would need to look (1) in the primary care providers' (PCP) orders to see whether cardiac drugs or diuretics were prescribed to help with the fluid retention, (2) in the respiratory therapist's notes for breathing treatments and the client's response, (3) in the nursing notes to see whether the client is being positioned with the head of the bed elevated to facilitate breathing, and (4) in the graphic section to evaluate urinary output in response to the diuretic.

Problem-Oriented Record Systems

Problem-oriented records (PORs) are organized around the patient's problems. There are no separate sections for each discipline. The POR consists of four parts: database, problem list, plan of care, and progress notes.

- The **database** consists of demographic data, the history and physical, nursing assessment data, and family and social history. As the patient's condition changes, the database is updated to reflect the patient's current status.
- The **problem list** is a concise listing of problems that have been identified from the database. Once a problem is resolved, it is noted on the problem list. If a problem changes or is redefined, the problem list is updated to reflect the change. See Figure 18-1 for an example of a problem list.

Problem number	Date entered	Date resolved	Client problem
1	mm/dd/yyyy	mm/dd/yyyy	Abdominal pain (unknown etiology) Redefined mm/dd/yyyy
1A	mm/dd/yyyy		Appendicitis resulting in emergency appendectomy
1B	mm/dd/yyyy		Acute pain r/t abdominal incision 2 appendectomy
2	mm/dd/yyyy		Down syndrome — functions at school-age level
3	mm/dd/yyyy		Risk for constipation r/t opioid use for pain control and h/o appendicitis

FIGURE 18-1 A problem list for Steven Stellanski (Meet Your Patient). Note that problem 1 has been redefined now that the cause of Steven's pain has been determined. Note also that the list contains both medical and nursing diagnoses.

- The **plan of care** includes the PCP's orders and the nursing care plan to address the identified problems. Other disciplines may also contribute to the plan.
- **Progress notes** are organized according to the problem list. Each discipline charts on shared notes. Charting is labeled according to problem number.

Advantages A common problem list allows for input from all disciplines, making it is easy to monitor the patient's progress. Because each problem is readily identified in the notes, each discipline has ready access to the findings of the other members of the health team, which promotes greater collaboration.

Disadvantages To work well, the POR system requires a cooperative spirit among health providers as well as diligence in maintaining a current database and problem list.

Charting by Exception

Charting by exception (CBE) is more than a format; it is a system of charting in which only significant findings or exceptions to standards and norms of care are charted. To use the CBE system effectively, you must know and adhere to professional, legal, and organizational guidelines for nursing assessments and interventions.

CBE uses preprinted flowsheets to record most aspects of care. CBE assumes that all standards have been met and the patient has responded normally, unless a separate entry is made (an *exception*). Normal responses for various assessments are defined on the front or back of the form. Each flowsheet has entries for expected aspects of care and thus can vary by specialty areas or diagnosis.

Advantages CBE reduces the amount of time spent on documentation, reduces repetitive charting of routine care, provides a record that is easily read and understood, and clearly highlights any variations from the expected plan of care. In many organizations, CBE records are kept at the bedside, which promotes timely documentation.

Disadvantages Inadvertent omissions are the main problem associated with CBE. Omissions may result from disagreement over what constitutes a significant variation. Research shows that some participants used either a deviation from patients' baseline or normal physiological standards to define when a finding is not "within normal limits" (WNL) (Kerr, 2013). Critics of CBE believe it: (1) requires nurses to be overly familiar with the organization's documentation standards and policies; (2) makes it difficult to capture the skilled judgment of nurses; and (3) reduces care to such rote repetitions that you may forget to chart an exception to the established standards.

CBE can lead to errors because nurses may conclude that care has been completed, when in fact it was not done. This system requires you to carefully assess and validate care provided.

Here is an example of what part of a CBE flowsheet for your patient, Steven Stellanski, might look like. Notice in the first section that the day-shift nurse merely initials that she has made an assessment or taken one of the listed actions at each of the designated times:

DATE: 04/11/16				
Hour	0800	0900	1000	1100
ACTIVITY				
Bedrest		LP		
Ambulate	LP*			
Sleeping				
BRP				
HOB elevated	LP	LP		

	DAY	EVENING	NIGHT	
Neurological		√		
Cardiovascular		√		
Pulmonary		√		
Gastrointestinal		*		Vomited 3×1, 100 mL clear yellow fluid at 0730. Given Compazine 1 mg IV with relief.

Key: √ = normal findings, * = significant finding

Notice also the second table (with the checkmarks) is a summary for the day shift. This is where the nurse describes and discusses any of the significant findings noted at the individual assessment times.

Electronic Health Record Systems

The EHR consists of records that are entered via computer. EHRs typically combine source-oriented and problem-oriented record styles, although the source-oriented system is most common. For example, a client's EHR often contains orders, clinical documentation, laboratory and other test and procedure results, as well as an interdisciplinary plan of care (IPOC), a problem and diagnosis list, and progress notes entered by physicians, nurses, respiratory therapists, and other professional providers.

Figure 18-2 is a section of an electronic form for recording intake and output in source-oriented format. As you can see, the intake and output (I&O) screen records numerical data. It also allows the nurse to add brief narrative comments in each field. Figure 18-3 is an electronic IPOC in problem-oriented format. The IPOC can be updated at the times specified by the organization, and the I&O data can be entered at any time. Both exist within the same electronic records system.

Advantages of Electronic Health Records

- **Enhanced communication and collaboration.** Communication is improved among healthcare providers.
- **Improved access to information.**
  - Multiple healthcare providers can access the same information at the same time.
  - Authorized persons can access information remotely (e.g., from a patient's home).
  - EHRs integrate client information between multiple departments so that one area can immediately see information from another. For example, when the laboratory enters a critical result, such as a clotting time, you do not need to wait for the lab to phone or to send a paper result to the nursing unit.
- **Time savings.**
  - Nurses spend up to 25% less time charting.
  - Information is stored and retrieved quickly and easily.
  - Reports can be created quickly because of the computer's ability to aggregate data (e.g., a 24-hour graph of the patient's vital signs).
  - Repetition and duplication are reduced.
- **Improved quality of care.**
  - The system can use protocols to automatically enter orders based on the client's condition. For example, most organizations have policies for making falls prevention assessments. Some EHR systems will automatically enter an order to observe and document risk of falls more often when a patient's "falls score" exceeds a certain level.
  - Embedded protocols enhance caregiver knowledge and the ability to follow clinical practice guidelines.

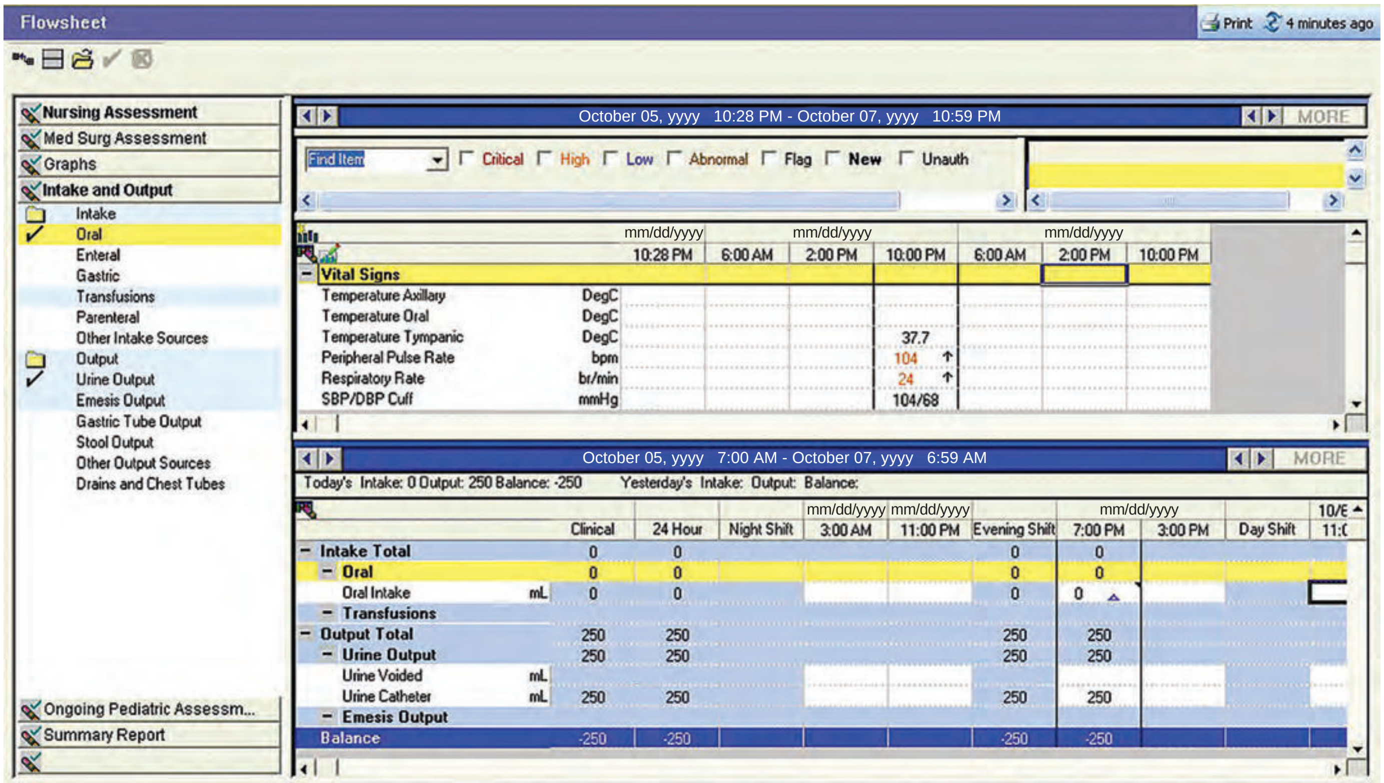


FIGURE 18-2 An electronic intake and output (I&O) entry form. (Courtesy of Cerner Corporation, Kansas City, MO.)

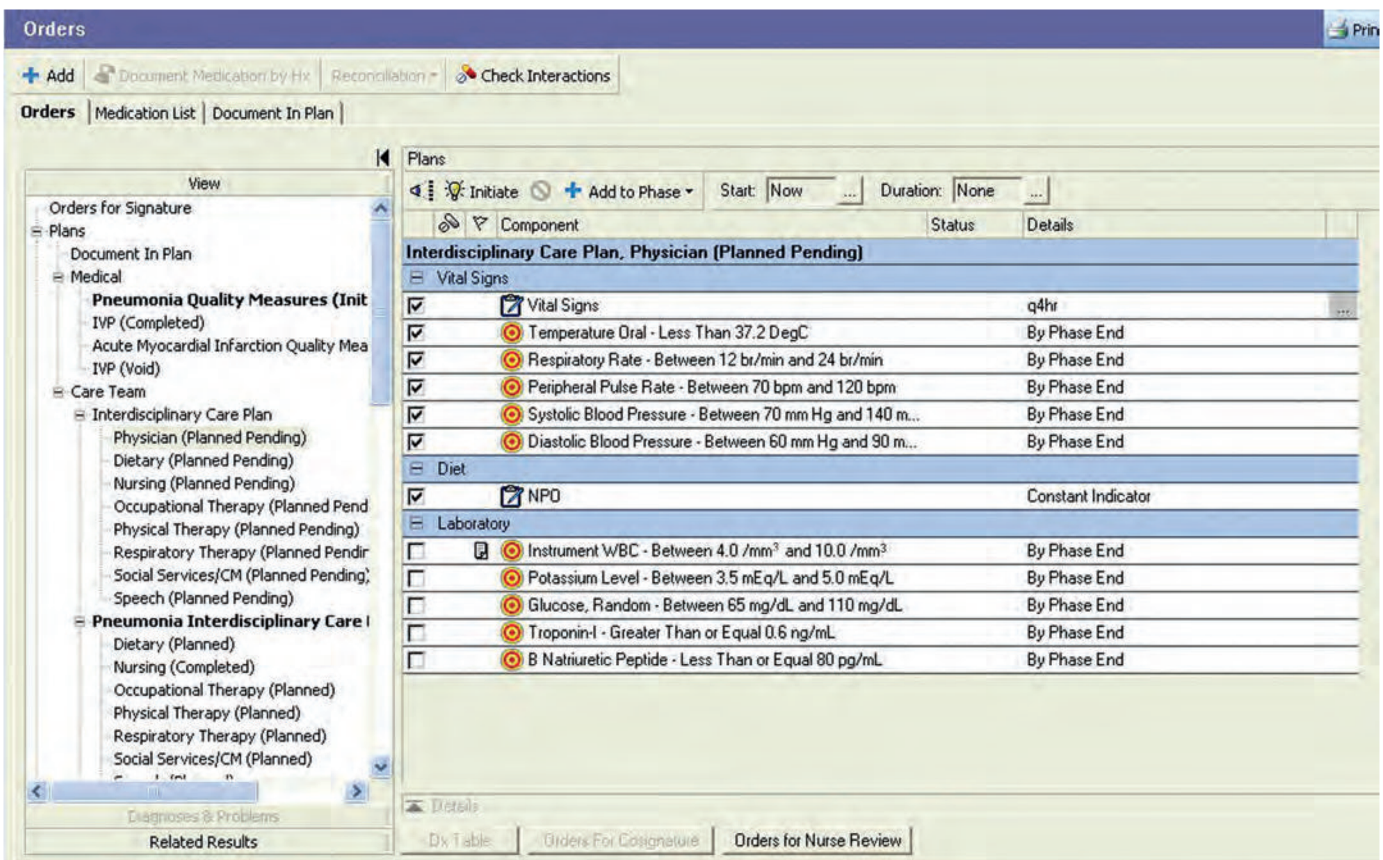

FIGURE 18-3 A portion of an electronic interdisciplinary plan of care (IPOC) form. (Courtesy of Cerner Corporation, Kansas City, MO.)

For example, suppose there is a medical prescription to administer insulin on the basis of a patient's blood glucose results. In some EHR systems, the nurse can activate an immediate link to the tables of information needed to decide how much insulin to give to the patient.

Medical errors are minimized by programmed alerts that are automatically displayed when a care provider takes an action that could be harmful (e.g., when a provider prescribes a drug to which a patient is allergic or calls for a dose that exceeds the safe range).

Data can be analyzed at the time of collection, making immediate nursing decision making possible.

EHRs facilitate evidence-based practice by making it possible to analyze thousands of records in ways that cannot be done with paper forms. With aggregated data, nursing practice can be compared across populations and geographic locations to support nursing decisions and guide professional and organization quality improvement.

- **Information is private and safe.**

  Information is permanently stored and not likely to be lost.

  Confidentiality of client information is enhanced by tracking everyone who accesses the healthcare record, proper security clearances, unique passwords, restricted access, and using front-view screen protectors.

Disadvantages of Electronic Health Records

- **Expense:** Electronic documentation systems are expensive.
- **Downtime:** Downtime processes must be in place for times when parts of the EHR are not available (e.g., because of power outages, severe weather, and system upgrades).
- **Difficulties associated change:**

  Learning to use some documentation systems can be challenging and time consuming.

  Some healthcare providers resist the change from paper to EHR.

  It is not easy to capture narrative nursing content from paper charting into an electronic format.

  Some EHRs are not user-friendly (e.g., difficult to quickly find information needed to make care decisions).

  Some systems do not control redundancy well, requiring caregivers to ask the patient for the same information over and over.
- **Lack of integration:** Most EHRs are not integrated across the different departments.

  This means sometimes a person with a legitimate reason to enter the chart cannot see entries made by other departments and must then request verbal, e-mail, or paper reports (e.g., lab results).

Advantages and Disadvantages of Paper Records

For a summary of the advantages and disadvantages of paper health records, see Box 18-1.

BOX 18-1 ■ Advantages and Disadvantages of a Paper Health Record

ADVANTAGES

- Care providers are comfortable with it because it is familiar. There is little "learning curve."
- Paper records do not require large databases and secure networks to function.
- There is no downtime for system changes, weather, and so on.
- It is relatively inexpensive to create new forms and update old ones.

DISADVANTAGES

Access may be delayed. Only one care provider can access the record at a time; and the provider must be in the same location as the chart.

Retrieving information may be slow.

- Healthcare providers may need to search through multiple pages to find needed information.
- Specific documentation is difficult to retrieve when needed, especially when files are archived in another part of the building.

Documentation is time consuming.

- Documentation may take more time because handwriting is slower than computer entry.
- Documentation is often redundant and repetitive.
- Paper records require manual audit of many charts to create reports and collect client data. This is time and resource intensive.

There is a relatively high risk for patient care error.

- Narrative documents are hard to read if the handwriting is illegible or messy. This means nurses have to take time from patient care to contact providers to clarify handwritten prescriptions.
- Papers can be lost from the chart or damaged, leading to duplicate assessments or medication errors.
- There is tremendous inconsistency in how the same client information is documented, even within the same organization. Often standardized terminology is not used.

Storage of paper records is expensive.

Confidentiality is difficult to protect. There is no way to know who may have access to the paper health record without proper authorization.

KnowledgeCheck 18-1

- Identify the purposes of the client health record.
- What are the key differences in the organization of source-oriented records, problem-oriented records, electronic documentation systems, and CBE systems?
- What are three advantages of paper health records?
- What are three advantages of EHRs?

For more information on the transition to electronic health record systems,

Go to Chapter 18, **Supplemental Materials,** on Davis*Plus.*

Documentation and the Nursing Process

The goal of all nursing documentation is a clear, concise and complete representation of the client's healthcare experience that is easily accessible and understood by all members of the healthcare team. Effective documentation allows you to help clients to make sound health decisions. It also enables use of current and consistent data, problem statements, diagnoses, goals, and strategies to support continuity of care. However, research continues to identify insufficient documentation of the steps in the nursing process (e.g., inadequate assessment information, lack of decisions based on a nursing diagnoses, inadequate evaluation and revisions in the plan of care) (Blair & Smith, 2012; Wang, Hailey, & Yu, 2011). Regardless of the type of documentation that is used, you must use or refer to the nursing process as a guideline when charting.

Assessment: Chart signs and symptoms that may indicate actual or potential client problems. At an initial assessment, document comprehensive data about all client systems.

Diagnosis/Analysis: After analyzing assessment data, document your clinical nursing judgment about the client's response to actual or potential health conditions or needs.

Outcomes/Planning: Document a measurable and achievable short-term and long-term plan of care with goals directed at preventing, minimizing, or resolving identified client problems or issues.

Implementation: After putting the plan of care into effect, record the specific interventions that were used.

Evaluation: Document client responses to nursing care; chart whether the plan of care was effective in preventing, minimizing or resolving the identified problems; and then modify the plan as needed.

What Are Some Common Formats for Nursing Progress Notes?

Nursing documentation can take many forms, including paper charts, computerized electronic documents, audio or video files, e-mails, faxes, scanned paper documents, electronically stored photographs, x-ray findings, and other images. Depending on the documentation model your organization selects, you may use one or more of the following charting formats. Choice of format is also influenced by whether your nursing documentation is written on paper, captured and stored electronically, or a blend of the two. In all formats, you must learn to use abbreviations appropriately.

Use of Abbreviations

Recall the case of Steven Stellanski (Meet Your Patient). Below is a brief admission note using narrative charting format. Underline any words or entries that you do not understand:

> *4/11/16 1600 Pt received on unit from PACU. VSS. TM temp 99.9°F (37.7°C), P 104, and BP 104.68. LOC unstable. Arouses when name called but quickly drifts off to sleep. PERRLA. Moaning, grimacing, holding abd, whispers "Help me. Help me." LR at 125 mL/hr infusing in R forearm. Urinary catheter in place, draining pale yellow urine. Drsg dry & intact. Morphine sulfate PCA ordered. Will initiate. —— —————————————— Ron Allen, RN.*

You can see from this entry that nurses use many abbreviations in their paper record charting. Every healthcare institution has a list of approved abbreviations that may and may not be used in documentation. Be sure to consult your organization's list before you chart. For a list of commonly used abbreviations in healthcare and another list of abbreviations that pertain to medication administration,

Go to Chapter 18, **Abbreviations Commonly Used in Healthcare,** in Volume 2.

Also go to Chapter 26, **Medication-Related Abbreviations,** in Volume 2.

The Joint Commission (2012a) created a "do not use" list that directs medical personnel in healthcare organizations to write out certain words, rather than use the abbreviations (see Table 18-1).

In consideration of furthering The Joint Commissions Patient Safety Goals, some institutions also:

- Write out "greater than" or "less than"—rather than using the symbols ">" or "<".
- Write drug names in full—rather than using abbreviations.
- Use metric units—instead of apothecary units.
- Write "at" or "each"—rather than use the "@"symbol.
- Write "mL" or "milliliters"—in place of the "cc" abbreviation.
- Write "mcg" or "micrograms"—instead of the "µg" abbreviation.

These actions minimize many common errors that occur in healthcare organizations.

Table 18-1 ➤ Joint Commission "Do Not Use" List

DO NOT USE THIS ABBREVIATION	WRITE OUT THE WORD OR DOSE
"U" or "u"	Unit
"IU" for	International Unit
Q.D., QD, q.d., qd	Daily
Q.O.D., QOD, q.o.d., qod	every other day
MS, MSO4, and MgSO4	either morphine sulfate or magnesium sulfate
The trailing zero for medications (X.0 mg)	X mg (e.g., 10 mg)
Lack of leading zero (.X mg)	0.X mg (e.g., 0.1 mg)

Narrative

Narrative format is used with written source-oriented and problem-oriented charts. The **narrative chart entry** tells the story of the patient's experience in a chronological format (i.e., in the order that it happens). It provides information on the details of the client's care—client status, activities, nursing interventions, psychosocial context, and response to treatment. The goal is to track the client's changing health status and progress toward goals. Narrative charting is especially useful when attempting to construct a timeline of events, such as a cardiac arrest or other emergency situations. It highlights critical thinking and captures the true art of nursing (Spoerner, 2009).

Disadvantages of narrative charting are that it may be time consuming, disorganized, contain multiple and sometimes duplicate entries, requires you to read the entire note or multiple notes to find client responses and outcomes to interventions, and does not readily identify problems and trends. Blair and Smith (2012) believe that narrative charting is not ideal in today's healthcare environment.

Problem–Intervention–Evaluation (PIE)

The Problem–Intervention–Evaluation (PIE) system organizes information according to the patient's problems and requires keeping a daily assessment record and progress notes. This eliminates the need for a separate care plan and provides a nursing-focused rather than medical-focused record.

P*roblem:* Use data from your original assessment to identify appropriate nursing diagnoses.
I*ntervention:* Record the nursing actions you take for each nursing diagnosis.
E*valuation:* Document the patient's response to interventions and treatments.

Problems are identified from the admission assessment. Subsequent entries begin with identification of the problem number. This type of charting establishes an ongoing care plan. A PIE charting entry for Steven Stellanski (Meet Your Patient) might look like this:

4/11/16 1630

P: 1B
I: Pt c̄ 1 mg doses up to 4 mg morphine/hr. Pt groggy yet c/o pain. Has not triggered PCA independently. Rates pain as 8 on scale of 1–10. PCA use reviewed with pt. Demonstrated use c̄ 1st dose at 1615.
E: Pt still moaning & grimacing. Has not initiated another dose via PCA. 2nd dose given as additional demo. Will reevaluate in 1 hr. May need continuous infusion if pt unable to use to control pain. ———————————— Ron Allen, RN

This style of charting tends to focus only on the listed problems and not on the client as a whole. However, the primary disadvantage of PIE charting is that it does not document the planning portion of the nursing process. There is no seamless flow of client data, nursing diagnosis, and interventions, such as seen in a nursing care plan.

SOAP/SOAPIE/SOAP (IER)

The SOAP format is often used to write nursing and other progress notes. It can be used in source-oriented, problem-oriented, and electronic health records. The acronyms SOAP, SOAPIE, and SOAP(IER) are explained below.

- ***S****ubjective data*—What the patient or family members tell you about the client's signs and symptoms and the reason they are seeking healthcare. Typically this is recorded by quoting the actual words said.
- ***O****bjective data*—Factual, measurable clinical findings such as vital signs, test results, and quality of breath sounds. Refer to Chapter 3 to review subjective and objective data.
- ***A****ssessment*—Conclusions drawn from the subjective and objective data, usually patient problems or nursing diagnoses. **Key Point:** ***SOAP terminology is different from nursing process terminology. In the nursing process chapters we referred to conclusions about data as inferences or problems, and stated that assessment does not include conclusions about data. When using SOAP, you should chart your conclusions about the data under "A."***
- ***P****lan*: Short-term and long-term goals and strategies that will be used to relieve the patient's problems.
- ***I****nterventions*: Actions of the healthcare team that are performed to achieve expected outcomes.
- ***E****valuation*: An analysis of the effectiveness of interventions.
- ***R****evision*: Changes made to the original care plan.

Recall that a POR is organized according to specific patient problems, and has five components: database, problem list, initial plan, progress notes, and a discharge summary. You will refer to and use the following four parts when charting in SOAP format.

Problem List A numbered list of the patient's current problems in chronological order is compiled so that you can refer to the number when entering your notes.

Initial Plan This includes expected outcomes and plans for further care interventions and teaching. There is only one initial plan so you must update and change the plan in subsequent progress notes.

Progress Notes This is where you record the SOAP(IER) information. As a rule, you enter a note for each current problem every 24 hours or when the patient's condition changes.

Discharge Summary At discharge, each problem on the list is covered and a notation made about whether it was resolved. Unresolved problems, with plans for each, are included when communicating with the patient, other facilities, and home health agencies.

Following is an example of SOAP progress notes using the admission data of Steven Stellanski (Meet Your Patient). In the previous section, these same data were used to create a narrative note. Notice that the data are similar; however, the narrative note is organized by data source. Steven's SOAP(IER) charting entry related to his postoperative nausea and pain could look like this:

04/11/16	0830	#1 – Nausea related to anesthesia **S** – Pt states "I feel sick to my stomach. Help me." **O** – Pt vomited 100 ml clear, light yellow fluid. **A** – Pt is nauseated secondary to anesthesia. **P** – Monitor nausea and give antiemetic as needed. **I** – Pt given Compazine 1 mg IV at 0830.
	0900	**E** – Pt states he feels less sick to his stomach.—Ron Allen, RN
04/11/16	0830	#1B – Acute pain related to abdominal incision 2° appendectomy **S** – States, "Help me, help me." Moaning and grimacing. **O** – Moaning and grimacing; holding abd. Drsg dry & intact. BP 104/68, P 104, Resp 24, and TM temp 99.9°F. PERRLA. **A** – Postoperative pain **P** – Give analgesic as needed. **I** – Morphine PCA initiated at 0835. Pt. instructed in use. 1st dose (1 mg) administered as demonstration.
	0900	**E** – Still moaning & grimacing even after 2nd dose given as additional demo. Still has not initiated additional PCA dose.——— *Ron Allen, RN*
	0930	**R** – Still no pain relief; still has not used PCA independently. Discussed w/ Dr. Jadu. Continuous infusion begun at 2 mg/hr. Will supplement up to 4 mg/hr prn.——— ———*Ron Allen, RN*

Disadvantages of SOAP(IE) charting are that it can be inefficient and ineffective. You may find the same interventions and responses repeated in more than one section for clients with overlapping problems. You may also find that nurses write a complete narrative rather than a single problem entry. The use of SOAP has also been shown to shift the focus from the patient to the disease, thus promoting a medical model instead of the nursing process (Blair & Smith, 2012).

Focus Charting®

The term *focus* is used to encourage you to view the client's status from a positive, rather than problem-oriented, perspective. **Focus Charting®** uses assessment data to evaluate client care concerns, problems, or strengths. It also identifies necessary revisions to the care plan as you record each entry.

The focus is often identified as a nursing diagnosis (e.g., Ineffective Breathing Pattern), a sign or symptom (e.g., shortness of breath), a client behavior (e.g., inability to follow inhaler instructions), a special need (e.g., non-English speaking), an acute change in condition (e.g., sudden appearance of chest pain), or a significant event (e.g., surgery). Focus Charting® works well in acute care settings and in areas where the same care and procedures are repeated frequently.

The first column contains the time and date. The second column identifies the focus or problem addressed in the note. The third column contains charting in a DAR format. DAR is an acronym for *data*, *action*, and *response*.

Data Subjective and objective information that supports the focus. This aspect reflects the assessment phase of the nursing process and includes other data, such as laboratory results or other diagnostic testing.

Action Describe interventions performed, such as administering medications or making calls to the physician. This aspect reflects the planning and implementation phases of the nursing process.

Response The patient's response to your interventions reflects the evaluation phase of the nursing process.

Focus Charting® is attractive because it addresses the client's concerns holistically. However, the lack of a common problem list may lead to inconsistency in labeling the focus of notes and cause difficulty in tracking patient progress. The following is an example of a Focus® note.

04/11/16 1800	Focus: developmental delay	**D:** 16 y.o. rec'd on unit at 1600 from PACU post-appendectomy. Pt w/ Down syndrome. Morphine PCA initiated. Pt unable to use PCA to control pain. Continuous infusion at 2 mg/hr begun at 1745. PERRLA. Alert, drifting in & out of sleep. PACU RN reports pt functions at elementary school–age level. **A:** Will discuss pt status w/ parents and adjust plan of care accordingly.—————————*Ron Allen, RN*
1830		**R:** Met w/ parents, who report that pt has significant developmental delays & needs supervision w/ all ADLs. Pt comfortable on 2 mg/hr infusion of morphine. Use of PCA for supplementary pain control reviewed with parents. Parents demonstrated understanding and that they will assist pt w/ PCA if add'l meds are needed.——————————*Ron Allen*, RN

FACT System

Noted for its individual elements, the FACT documentation model incorporates many charting-by-exception (CBE) principles and includes four key elements:

Flowsheets individualized to specific services
Assessment features standardized with baseline parameters
Concise, integrated progress notes and flowsheets documenting the client's condition and responses
Timely entries documented when care is given

FACT documentation includes only exceptions to the norm or significant information about the patient. It eliminates the need to chart normal findings. The disadvantages of the FACT system are the same as for CBE. The following is a FACT example for Steven Stellanski (Meet Your Patient).

DATE/TIME	04/12/16 0900	04/12/16 1330
Neurological Alert and oriented to time, place, and person. PERRLA. Symmetry of strength in extremities. No difficulty with coordination. Behavior appropriate to situation. Sensation intact without numbness or paresthesias.	√	√
Orient patient		
Refer to neurological flowsheet		
Pain No report of pain. If present, include pain scale intensity choice by patient (0–10) with location, description, duration, radiation, precipitating and alleviating factors.	Abdominal incision pain – score 10	√
Location	RLQ	
Description	Dull, constant	
Relief measures	Percocet 1 tablet by mouth	
Pain relief: Y = yes / N = no	Y	
Cardiovascular Apical pulse 60 to 100. S_1 and S_2 present. Regular rhythm. Peripheral pulses (radial, pedal) present bilaterally. No edema or calf tenderness. Extremities pink, warm, moveable within patient's ROM.		
IV Solution and Rate	lactated Ringer's at 125 mL/hr	lactated Ringer's at 125 mL/hr

Electronic Entry

The Health Information Technology for Economic and Clinical Health (HITECH) Act has been instrumental in the widespread conversion from paper to electronic health records. Electronic clinical information systems streamline documentation processes, make them more accurate and efficient, and reduce the risk of human error. This frees you to do the expert work that only nurses can do. Electronic documentation requires a shift in how you record your work.

- EHRs change documentation formats from paper to electronic.
- Documentation is done at the bedside, instead of at the nurse's station.
- Decision-making processes change from gradual to immediate.

As a nurse, you will almost certainly need to have computer skills (Fig. 18-4). You will play a crucial role in the development and evaluation of effective EHR systems that make sense to nurses. You may even participate directly in the design–implementation–redesign cycle of the EHR system in your organization.

Electronic documentation forms and flowsheets (such as Fig. 18-2) include the information that your organization has decided is important to record. Reminders to document specific kinds of information, such as overdue medications and overdue nursing interventions, display automatically to help ensure your charting is accurate. Also, the extensive use of clearly named data entry fields, drop-down menus, check boxes, and specially created templates allows you to enter your nursing documentation quickly and efficiently, usually with minimal keyboard typing.

Depending on the EHR system used and the associated charting form, progress notes may be entered electronically in prebuilt note formats. In some electronic systems, you may still need to write progress notes on lined paper, in narrative, SOAP, PIE, Focus®, or FACT formats. Transitioning from paper to electronic documentation can be challenging for some people. It usually takes a few days to know where to document your nursing care and feel confident that you haven't overlooked anything. However, EHR software is becoming more logical and user-friendly. Many organizations have printed information, classes, webinars, or Web-based tutorials that provide information about electronic documentation. Take advantage of opportunities to build your knowledge when they arise.

FIGURE 18-4 Many healthcare institutions are adopting computerized patient records.

KnowledgeCheck 18-2

Summarize the characteristics of each of the different kinds of nursing documentation formats (narrative, PIE, SOAP, Focus®, CBE and FACT, and electronic entry).

ThinkLike a Nurse 18-1

Compare the documentation examples (narrative, PIE, SOAP, Focus®, CBE and FACT, and electronic documentation). If you have had experience with charting in the clinical setting, apply this experience as well. With which charting format do you feel most comfortable? Why?

What Forms Do Nurses Use to Document Nursing Care?

Documentation forms vary by purpose, institution, and unit. However, regardless of the system or forms used, nursing documentation reflects the nursing process. You record assessments, diagnoses, planning, implementation (what you actually did), and evaluation of client responses. This section discusses the most commonly used paper and electronic forms that are used in addition to the nursing progress notes discussed in the preceding sections.

Nursing Admission Data Forms

A separate nursing admission form or a combined interdisciplinary form is completed at the time the patient enters the healthcare system. A baseline assessment is essential because it: (1) may be used as a benchmark to monitor change; (2) provides information about the client's support system and helps forecast future needs; (3) contains critical information (e.g., presenting illness or reason for admission, vital signs, allergy information, current medications, activities of daily living (ADL) status, physical assessment data, and discharge planning information). For examples of a paper admission form,

Go to Chapter 3, **Nursing Admission Data Form,** and

Go to Chapter 18, **Tables, Boxes, Figures: ESG Figure 18-1 (Adult Inpatient Admission Assessment),** on Davis*Plus*.

To see part of an electronic nursing admission data form,

Go to Chapter 18, **Charting Forms, Adult Admission History Electronic Screen,** in Volume 2.

You will use admission forms in all settings, for example, in ambulatory clinics and long-term care facilities that contain the same or similar sections. Admission forms for long-term care are similar to hospital admission forms. An ambulatory care admission form includes demographic data, allergy information, current medications, family health data, social history, and the client's past medical history. The form completed by Nam Nguyen (in Volume 2) at his first clinic visit is an example of an ambulatory care admission form. To see Mr. Nguyen's completed form,

Go to **Meet the Nguyens** at the beginning of Volume 2.

Discharge Summary

Discharge data are obtained with the admission assessment, but are often recorded on a separate form. **Key Point:** ***A general principle in nursing is that discharge planning begins on admission. Therefore, discharge needs should be evaluated when the patient first enters a healthcare facility, especially in acute care facilities.*** Ask yourself what this patient would need if he were to go home in the next few days. For example, would he need help with food preparation? Does he understand how to use his medicines?

A **discharge summary** is the last entry made in the paper chart. In the electronic chart, the discharge summary can be started any time after admission and revised throughout the hospitalization. A summary is completed when the patient is transferred within the same organization, to another facility, or discharged to home. The discharge summary may be a multidisciplinary document or each discipline may write a separate summary. The forms are different in each organization, but they contain similar data. For examples of electronic and paper discharge summaries, respectively, see Figure 18-5 and

Go to Chapter 11, **Forms, Discharge Assessment/ Instructions,** in Volume 2; also refer to **Procedure 11-4, Discharging a Patient From the Healthcare Facility,** in Volume 2.

As you can see in Figure 18-5, there is a drop-down menu in which the Nursing Discharge Note is located. It is important to clearly document the patient's condition on discharge because the discharge summary serves as baseline data for the healthcare professionals who will provide discharge care.

Flowsheets and Graphic Records

You will use flowsheets and graphic records to document assessments and care that are performed frequently, on a recurring schedule, or as a part of unit routines. For

EveryHospital Medical Center
10000 Main Street
Everyday, FM 10101
(111) 111-1111

EveryHospital would like to thank you for allowing us to assist you with your healthcare needs.
The following includes patient education materials and information regarding your injury/illness.
A copy of the record is available to the practitioner or medical organization providing follow-up care, treatment, and services. For a copy of your records to be faxed to your physician, contact Health Information at 111-111-1111.

Patient: Larson, Pat Date of Birth: mm/dd/yyyy
Date of Admission: mm/dd/yyyy Account Number: 153501 Medical Record Number: 93462

Home Medications

This is a listing of medications your physician has indicated that you take upon discharge from the hospital. If you have any questions please contact your physician for further clarification. If a medication is not listed below that you were taking before you came to the hospital, contact your physician to ask if you should or should not continue taking that medication

MEDICATION	DOSE	ROUTE	FREQUENCY	REASON FOR USE	ADDITIONAL COMMENTS
aspirin (aspirin 125 mg rectal suppository)	125 Milligram / 1 suppository(ies)	PR	Every 4 Hours		

FIGURE 18-5 A portion of an electronic discharge planning form. (Courtesy of Cerner Corporation, Kansas City, MO.)

example, most hospital units require that vital signs be taken every 8 hours for all patients. How often you perform and document care activities depends on your patient's condition and the unit policy. In the first hour after surgery, for example, you would probably record vital signs every 15 minutes; then every 30 minutes for 1 hour; and then every hour for 4 hours.

The simplest paper forms are organized with time in columns across the top and the activities or patient assessment parameters in rows down the side. On electronic forms, the areas (fields) to enter the time and activities are arranged close together. Flowsheets and graphic records allow you to see patterns of change in patient status. For instance, you may view a steady increase in the line representing a patient's blood pressure compared to his pain score on an electronically generated graph. On a paper form, you may scan across a row to see that your patient has not had a bowel movement for several days. Other types of information recorded on flowsheets include intake and output (I&O), weight, hygiene measures, ADLs, and medications administered. For examples of a paper graphic record and an electronic flowsheet, see Figure 3-4 (paper) and Figure 18-2 (electronic).

To see a flowsheet for long-term care,

Go to Chapter 18, **ESG Figure 18-5,** on Davis*Plus*.

Checklists

Assessments and care may also be recorded on paper and electronic checklists. Common normal and abnormal findings are usually organized according to body systems. Figure 18-6 is an example of a paper checklist.

Using a paper form, the nurse checks the box that reflects the current assessment findings. Some checklists include nursing actions, such as wound care, treatments, or IV fluid administration. Essentially these forms are comprehensive charting documents. Exceptions, patient care activities, and patient responses are recorded in the narrative note section of the paper form.

Using an electronic field-based checklist, the nurse enters values or text in the appropriate fields and saves the documentation. Electronic flowsheets typically contain content similar to paper checklists, but also include a greater range of potential documentation areas that can be opened as needed. This allows for a more comprehensive record of a patient's assessment, treatments, IV fluid administration, and many other parameters.

Intake and Output Records

You will sometimes use separate intake and output (I&O) paper records to document data about the patient's fluid balance. Electronic systems have flowsheet sections or I&O forms to enter I&O and save it into the patient's EHR (see Fig. 18-2). Usually these documentation forms contain data totaled by shift and by 24-hour periods. Paper forms must be totaled manually, whereas electronic systems usually automatically total I&O figures for you. For a paper I&O record,

Go to Chapter 18, **Charting Forms, Intake and Output Sheet,** in Volume 2.

I&O paper graphics may be kept at the bedside. If your patient or a family member is able to assist with measuring his I&O, teach him how to record data on the paper form. You might also complete electronic I&O documentation at the bedside using a portable or stationary computer. When appropriate, patients can still track their own intake and output on paper, but you will need to enter the patient's I&O data into the EHR. Chapter 28 provides detailed information about monitoring intake and output.

Medication Administration Records

Medication administration records (MARs) contain information about the medications that have been prescribed for the client. The information and format vary by setting, with significant differences between outpatient and inpatient facilities.

- **Inpatient facilities:** Inpatient medication records not only contain a list of prescribed medications, but also track medication administration and usage for the agency. For a comparison of the content of inpatient and outpatient MARs, see Table 18-2.
- **Outpatient facilities** (e.g., include clinics, primary care offices, and treatment facilities). Because patients do not stay at the facility, usually the MAR primarily contains information about how the patient is to use the medications prescribed. Patients retain responsibility for administering their own medications either independently or with the help of family or caregivers.

Some electronic MARs allow care providers to look up detailed information about the medication, including indications, contraindications, expected and adverse effects, and safe dosage ranges based on routes of administration. Figure 18-7 is a portion of an electronic medication record. Figure 26-7 is a paper MAR.

Terminology for Medication Administration Times. You will document medications according to the times they are given: scheduled, unscheduled, continuous, prn, STAT, and so on.

- **Scheduled medications** are medications that are to be given on a regularly scheduled basis.
- **Unscheduled medications** are medications that are to be given on call at the appropriate time. An example of an unscheduled medication is a preoperative medication to be administered immediately before the patient goes to the surgical holding area.
- **Continuous infusions** are IV fluids that are running consistently unless stopped for a blood transfusion or to give an IV medication that is not compatible with the IV fluid running.

INPATIENT MARS	OUTPATIENT MARS
■ Drug name ■ Dosage ■ Route of administration ■ Frequency ■ Duration ■ Scheduled times of administration ■ Charting of medication administration ■ Signatures (written or electronic) of nurses administering medication	■ Drug name ■ Dosage ■ Route of administration ■ Number of pills, patches, and so on to be dispensed at each prescription refill ■ Number of refills ordered ■ Directions for using the medication, including frequency and duration ■ Historical information about prescriptions, pharmacies used, and refills authorized

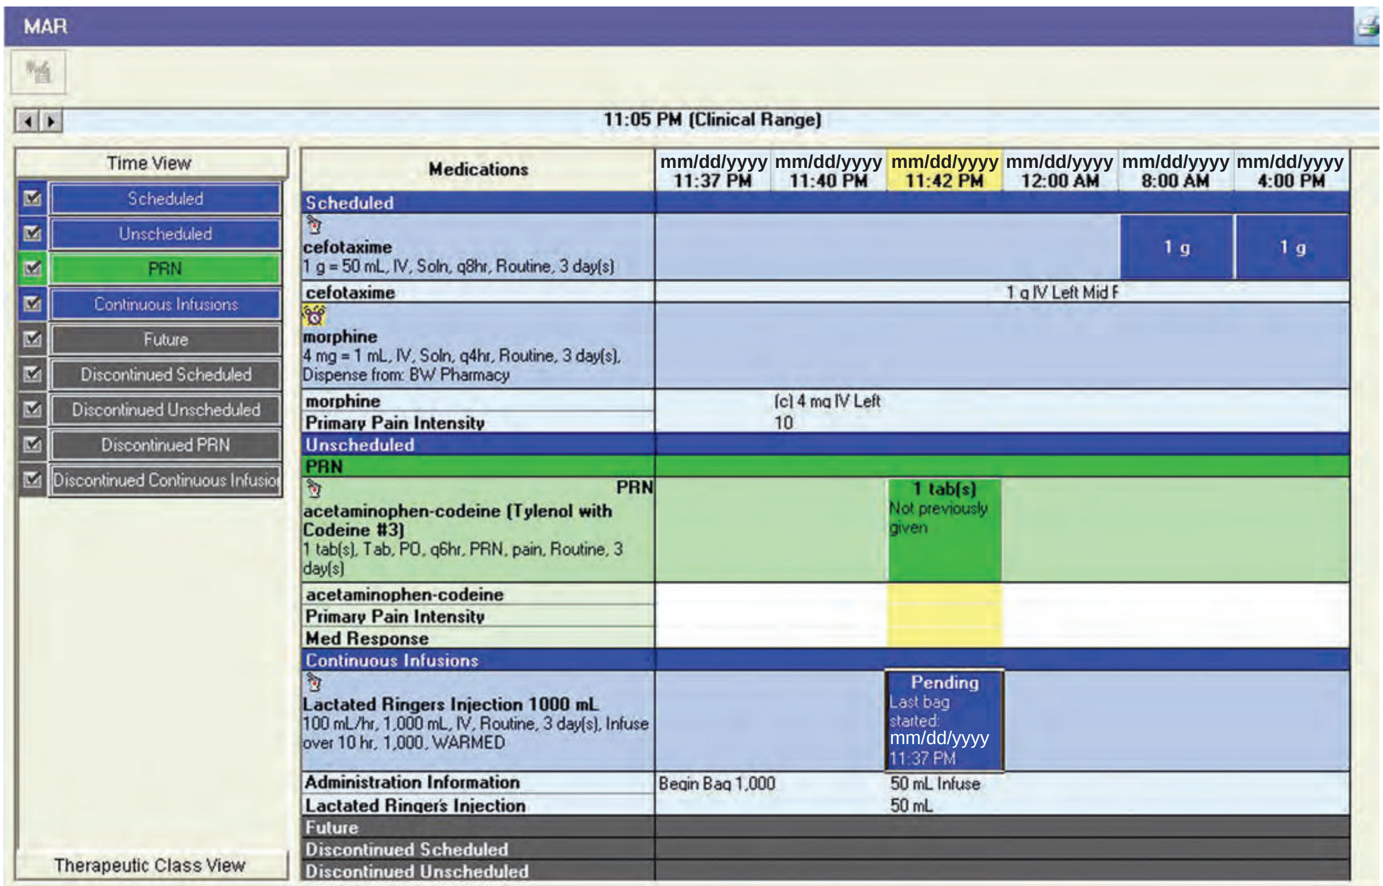

FIGURE 18-7 A portion of an electronic medication administration record. (Courtesy of Cerner Corporation, Kansas City, MO.)

- **Prn** means "as needed." It is an abbreviation of the Latin term *pro re nata.* Medications administered prn are given only when the patient meets certain conditions that were established in the medication prescription. Typically, medications are prescribed prn for relief of pain, fever, nausea, and constipation. You should administer a prn medication when you assess that the patient needs it or when the patient requests it. Document immediately after you administer the medication.
- A **STAT** medication is given and charted immediately and only once.
- A **single-order** medication is given once at a prescribed time, but not necessarily immediately.

Charting Additional Information About Medications. For scheduled medications, you may only have to initial and make a checkmark in the column that corresponds with the preprinted times at the top. In the circumstances following, you will often need to record additional information on the MAR and sometimes even in the Progress Notes.

- **Injections.** If you administer an injection, you must chart the type and the site of administration to protect the patient from repeated injections in the same location.
- **Assessment Required Before Administration.** Some medications require you to make a specific assessment before administering the drug, to ensure that it is safe to give it. You must document that assessment data on the MAR, along with the time of administration and other required information (see Chapter 26). As an example, most protocols instruct you to not give digoxin (a cardiac medication) if the heart rate is below 60 beats/min., so you must auscultate the rate before giving the drug. Blood pressure and pain medications, insulin, and anticoagulants also require assessments before administration.

- **Drug Allergies.** Drug allergies are always noted on the paper or electronic MAR. This makes them easily visible for caregivers who are prescribing or administering medication. If the patient has an allergic reaction to a medicine, you must record this response on the MAR and in the nurses' notes. Of course you would also report this to the prescriber, as discussed later in this chapter.

- **STAT, prn, Unscheduled, and Single-Order Medications.** Enter on the MAR the time the medication is given. Make a narrative note of your assessment findings and the patient's response to the medication in the appropriate location on the paper or electronic MAR. Some documented data, such as the pain score before administration of an analgesic, may automatically migrate from other documentation sources to become visible on the MAR.

  You may occasionally see a prn order that provides a range of medication to be given based on your assessment of the patient, for example, "Titrate morphine 2–3 mg IV every 1–2 hours to achieve pain control."

In the electronic MAR system, medication range orders (e.g., 1 to 2 mg) are difficult to order, so The Joint Commission and most agency protocols no longer allow dosage range orders.

- **Patient Refusal.** If the patient refuses a medication, note the refusal on the paper or electronic MAR. Your organization's policy will determine how this is recorded. On paper, you might draw a circle around the scheduled time of administration. When documenting electronically, you can click on an option offered in the MAR, such as Not Given, and then select *Patient Refused* from a drop-down field listing multiple reasons why a medication is not given.
- **Omitted Medication or Delayed Administration.** If the patient is not available or is experiencing health changes that require immediate interventions, it may be necessary to withhold a medication or delay its administration. On the paper MAR, some organizations provide a boxed section at the bottom, with a code to indicate why the medication was withheld or given at a different time. Circle the scheduled time and fill in the symbol. You will also have to chart the omission or delay in your nurses' notes. However, in the electronic MAR, often it is possible to reschedule administration times for a single dose or permanently going forward. Many systems will require you enter the reason and the action taken.

Kardex or Patient Care Summary

As discussed in Chapter 5, the Kardex is a special kind of paper form or folding card that briefly summarizes a patient's status and plan of care. Paper Kardex and electronic patient care summaries typically pull patient data from multiple areas of the health record (medical and nursing diagnoses, orders, treatments, results). Figure 18-8 is an example of an electronic patient care summary screen. To see a paper Kardex,

Go to Chapter 5, **Tables, Boxes, Figures: ESG Figure 5-1,** on Davis*Plus*.

Paper Kardexes are usually kept together in a portable file in a central location in the nurses' station to allow all team members access to patients' summary information. Each patient has a separate screen in an electronic summary. All authorized members of the care team can access the electronic care summary at the same time, even if they are away from the patient or outside the organization in a remote location, depending on the institution's permission for access. Neither the paper Kardex nor the electronic care summary is a permanent part of the patient's health record.

Integrated Plan of Care

Integrated plans of care (IPOCs) are a combined charting and care plan form. They exist in both paper and electronic formats. An IPOC maps out day-by-day patient goals, outcomes, interventions, and treatments for a specific diagnosis or condition from admission to discharge. Lab work, diagnostic testing, medications, and therapies are all included in the pathway, as well as standardized interventions captured in the plan. IPOCs help administrators predict length of stay, monitor costs of care, and can assist with staffing. They also eliminate duplicate charting, increase team effort, and enhance the nurse's teaching about what the patient can expect during the hospital stay. Figure 18-3 is an example of an electronic IPOC. For examples of complete printed IPOCs,

Go to Chapter 18, **Tables, Boxes, Figures: ESG Figure 18-2, Integrated Plan of Care,** on Davis*Plus*.

Multiple patient diagnoses can be captured easily in an electronic IPOC. However, in special situations, you may need to individualize the paper IPOC by commenting on special issues in the space provided for narrative

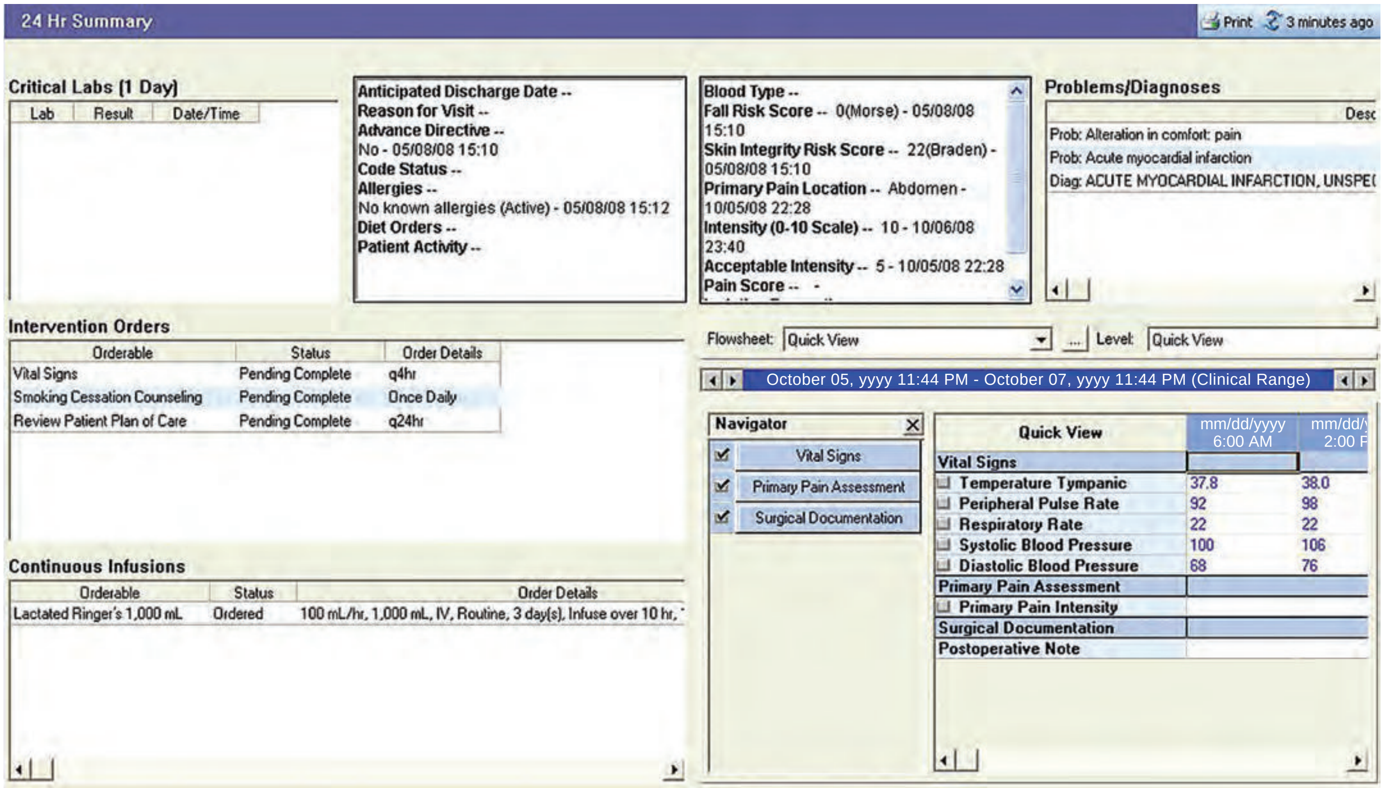

FIGURE 18-8 A portion of an electronic patient care summary screen. (Courtesy of Cerner Corporation, Kansas City, MO.)

comments (e.g., developmental delay with our patient Steven Stellanski).

Occurrence Reports

An **occurrence report**, or incident report, is a formal record of an unusual occurrence or accident. This is an organizational report that is used to analyze the event, identify areas for quality improvement, and formulate strategies to prevent future occurrences. The overall goal is to create safer processes and procedures for clients and staff. **Key Point:** ***An occurrence report is not part of the client's health record and thus should never be referenced in the nurses' notes or in other sections of the health record.*** The paper report should be sent to risk management, according to agency protocol, while the electronic form is completed on the organization's secure internal network. See Box 18-2 for examples of events that require the completion of an occurrence report.

You should report all errors, even if there was no adverse impact on the client. This is important from a safety standpoint for improving your institution's quality of care and from a legal perspective to provide defensible information. When completing an occurrence form, be sure to clearly identify the client, date, time, and location. Briefly describe the incident in objective terms. Quote the client or persons involved if possible. Identify any witnesses to the event, equipment involved, and environmental conditions. Avoid drawing conclusions or placing blame. You should document actions taken and the patient response to the interventions. Chapter 45 provides additional information on occurrence reports.

BOX 18-2 ■ Events Requiring an Occurrence Report

- Patient fall or other injury
- Medication error
- Incorrect implementation of a prescribed treatment
- Needlestick injury or other injury to staff
- Loss of patient belongings
- Injury of a visitor
- Unsafe staffing situation
- Lack of availability of essential patient care supplies
- Inadequate response to emergency situation

KnowledgeCheck 18-3

- What should you document after administering a prn medication?
- What is the purpose of an occurrence report?
- Identify four events in which you will need to complete an occurrence report.
- Identify the following abbreviations (see Volume 2):

abd	OOB	NKDA
BRP	pc	tid
DM	prn	q
fx	STD	LUQ

What Is Unique About Documentation in Home Healthcare?

Although you will perform many of the same assessments and interventions in home care that you do in other areas of healthcare, the documentation is unique. The Centers for Medicare & Medicaid Services (CMS) guidelines govern home healthcare documentation. Among the requirements for care are (1) certification of home-bound status, (2) a plan of care, and (3) ongoing assessment of the need for skilled care.

The most commonly used paper home health documentation form is known as OASIS—the Outcome and Assessment Information Set. Because of a federal government mandate that Medicare providers convert to electronic e-prescribing, many home health agencies have electronic documentation systems or plans to adopt a system. Home health nurses can use laptop computers to retrieve patient data and record progress notes in the home. The computer also allows the nurse to conveniently order needed supplies for home care and to coordinate scheduling of follow-up visits.

In home care, a monthly summary describing the patient's status and ongoing needs is required. The patient's PCP signs this form, which is submitted for reimbursement. Chapter 43 provides further information about home care.

Home health documentation includes the following:

- Your assessment highlighting changes in the client's condition
- Interventions performed (wound care, dressing changes, teaching, and other treatments)
- The client's response to interventions
- Any interaction or teaching that you conducted with caregivers
- Any interaction with the patient's PCP

If you would like to see an OASIS form,

Go to Chapter 18, **Tables, Boxes, Figures: ESG Figure 18-3, Outcome and Assessment Information Set (OASIS),** on Davis*Plus*.

ThinkLike a Nurse 18-2

Why do you think it is essential to document homebound status and the ongoing need for skilled care?

What Is Unique About Documentation in Long-Term Care?

Documentation requirements for long-term care depend on the level of care the client requires. All clients in long-term care facilities must have a comprehensive assessment at admission. Federal law requires that a resident be evaluated using the Minimum Data Set for Resident Assessment and Care Screening (MDS) within 14 days of admission. The MDS must be updated every 3 months and with any significant change in client condition. For an example of an MDS form,

Go to Chapter 18, **Tables, Boxes, Figures: ESG Figure 18-4, Minimum Data Set,** on Davis*Plus*.

Legal requirements to protect older adults mandate that you report changes in a client's condition to the PCP and to the client's family. Chart your reports in narrative notes on paper or in the appropriate areas of electronic forms. If you are caring for a client receiving Medicare-reimbursed services, such as IV therapy, wound care, or rehabilitation services, documentation is required with each shift. In addition, a summary written by a nurse must be recorded weekly. The weekly summary for adult clients must include the following:

- A summary of the client's condition
- An evaluation of the client's ability to perform ADLs
- The client's level of consciousness and mood
- Hydration and nutrition status
- Response to medications
- Any treatments provided
- Safety measures (e.g., bed rails, bed alarm, wander guard)

Long-term care facilities also provide intermediate-care services for clients who need assistance with medications, nutrition, and ADLs. These clients require a nursing care summary every 2 weeks. For a nursing assessment flowsheet used in long-term care,

Go to Chapter 18, **Charting Forms, A Flowsheet Used in Long-term Care,** in Volume 2.

KnowledgeCheck 18-4

How do home care and long-term care documentation differ from hospital-based documentation?

ThinkLike a Nurse 18-3

Why do long-term care clients require less frequent charting than clients in acute care settings?

ORAL REPORTING

The purpose of giving an oral report is to maintain continuity of care. The oral report provides an opportunity for professional communication that assists in organizing your work, and also for learning, building team relationships, and collaborating to improve patient care. Whether the source of the information shared is from a written report form, a paper Kardex, or a summary in the EHR, the quality of the report you give and receive influences how you and others plan the day's (or night's) work. Restrict your oral reports to patient-focused discussion and limit unimportant details and social conversation.

How Do I Give a Handoff Report?

The purpose of a **handoff report** (sometimes called a *change-of-shift report* or *handover report*) is to promote continuity in care. The receiving nurse is alerted to the client's status or recent changes in the client's condition; planned activities, tests, and procedures; or concerns that require follow-up. A handoff report may be given at the bedside or in a conference room, using paper notes or a mobile or desktop EHR device.

Handoff reports are usually given orally, although some organizations use written or audio-recorded reports. As a student nurse, you will receive report from either the nurse completing the shift or from the nurse assigned to the client during the shift you will be working. Report any changes to the nurse assigned to the client during your shift, and always give a report before leaving the unit.

- **A bedside report**, sometimes known as "walking rounds," allows you to observe important aspects of care, such as patient appearance, IV pumps, and wounds. With a bedside report, the outgoing nurse can introduce you to the patient and you can begin your assessment. If the patient is alert, give him the opportunity to participate in the report and ask questions. This type of report encourages continuity of care, team collaboration, and patient/family communication. Previously criticized as time consuming, Nelson and Massey (2010) reported that using an electronic template and process at the bedside decreased the time spent in change of shift report. **Key Point:** ***Ensure that the patient's privacy rights are protected when using bedside reports.***
- **A face-to-face oral report**, may involve only the outgoing and oncoming nurse or may include the entire oncoming shift. When given in a conference room, an oral report does not let you directly observe the patient, but it is time efficient and still allows interaction between nurses.
- **An audio-recorded report**, is a convenient, but sometimes time-consuming, way to transmit information. The outgoing nurse audio-records a report on the clients under her care. This method can be time-consuming, especially if you must listen to the entire unit report before hearing about your own assigned patients. A major disadvantage of an audio-recorded report is that the oncoming nurse has limited opportunity to ask questions about the client. Occasionally, audio quality is poor and the report is not clear. An advantage of this method is that the outgoing nurse continues to provide patient care while the incoming nurse receives report.

To minimize communication errors, the outgoing and incoming nurses should speak directly to each other to update information or answer any questions about the patients care. This complies with The Joint Commission Center for Transforming Healthcare (2010) recommendation that a handoff system allows for questioning between the giver and receiver of the information.

Standardized Report Formats. In more than 3,000 root-cause analyses of patient errors, communication was a primary contributor in 65% to 70% of the events (Triplett & Schuveiller, 2011). Other data indicate that "an estimated 80 percent of serious medical errors involve miscommunication between caregivers when patients are transferred or handed-off" (The Joint Commission, 2012b). No matter where or how the handoff report is given, nurses should use a consistent, structured (standardized) process that contains critical key items.

- The **PACE** format is one example of a standardized approach developed specifically to organize patient data in handoffs. The acronym stands for Patient/Problem, Assessment/Actions, Continuing/Changes, and Evaluation (Schroeder, 2006).
- The **SBAR** (Situation–Background–Assessment–Recommendation) is an easy-to-remember, concrete acronym useful for framing any conversation. Because nurses and physicians communicate in very different ways, SBAR is useful for interdisciplinary communication, especially critical situations requiring a clinician's immediate attention and action. SBAR allows for an easy and focused way to set expectations for what will be communicated and how between members of the team. The SBAR technique can be adapted for handoff reports.

For additional information about communicating with SBAR and PACE,

Go to Chapter 21, **Clinical Insight 21-3, Communicating With SBAR,** and Chapter 18, **Clinical Insight 18-1, Giving Oral Reports,** in Volume 2.

Regardless of the format used, to prepare to give a handoff report, you need to collect the following information:

- Client progress made during your shift
- Therapies and treatments administered
- Teaching done
- Consultations done or planned with other disciplines
- Status of identified desired outcomes
- Any changes in client status
- Progress made on discharge planning

KnowledgeCheck 18-5

- What data should be included in a handoff report?
- What are the types of handoff reports?

What Is a Transfer Report?

Transfer reports are given when a patient is transferred from unit to unit or from facility to facility. For information to include in an oral transfer report,

Go to Chapter 18, **Clinical Insight 18-1: Giving Oral Reports,** in Volume 2.

If the patient is being transported to another unit in the same facility, you will need to transport a paper chart with the patient. If both units are using an EHR documentation system, then the receiving unit can access the client record

Quality and Safety Education for Nurses

Handoff Reporting: Decreasing Risks for Miscommunication

Chapter Key Concepts: *Documentation, Oral reporting*

Competencies: *Safety (Knowledge, Skills, and Attitudes); Teamwork and Collaboration (Knowledge, Skills, and Attitudes)**

Think about it: How do the chapter key concepts relate to the QSEN competencies? Think about the number of patient handoffs per day among nurses and other professionals (e.g., physicians). Then consider some risks to patient safety that have been caused by miscommunication:

- Errors that have occurred because of poor *physician handoff reporting* include amputating the wrong leg, removing a healthy adrenal gland, failing to obtain serum sodium levels from a patient with diabetes insipidus, failing to act on stroke symptoms, and failing to correct electrolyte imbalances. All of these errors resulted in death or permanent brain damage.
- Potential harms in nursing *shift change handoffs* include delays in initiating critical medications or obtaining specimens; failing to initiate new treatments, communicate change in patient status, or report critical lab results; and repeating outdated information.

Causes. Factors contributing to poor quality handoffs include lack of a standardized protocol or form, relying on memory, varying levels of experience, and lack of dedicated time for reporting.

Actions. Collaborate with others in your facility to suggest the following strategies for improving quality of care, teamwork, and patient safety:

- Standardize the information (e.g., SBAR) to be conveyed but avoid giving too much or too little information.
- Include "if . . . , then . . ." statements for current problems (e.g., *if* the glucose level is still elevated, *then* call physician for insulin orders).
- Develop an electronic form or other tool to reinforce and clarify the transfer of knowledge and responsibility.
- Conduct training sessions to lessen the chance of reporting errors.

For specific Knowledge, Skills, and Attitudes

Go to the QSEN Web site **at http://qsen.org/competencies/pre-licensure-ksas/**

Source: Collins, S., Stein, D., Vawdrey, D., et al. (2011); Kitch, B., Cooper, J., Zapol, W., et al. (2008); Riesenberg, L., Leisch, J., & Cunningham, J. (2010).

electronically. Detailed information about the patient's health history can be communicated between healthcare professionals or transmitted before transfer. For transfers to other facilities, your organization will have a policy on what is to be copied and how materials should be transmitted to the receiving facility.

Research shows that older adults are vulnerable to errors in care when transitioning from one healthcare facility to another. Medication errors were dominant, resulting in increased hospital readmissions, injuries, or death. MBAR—**M**edication–**B**ackground–**A**ssessment–**R**ecommendation—was developed to provide a structured, standardized handoff that promotes medication reconciliation during handoffs and transfers (Blank, Benyo, & Glover, 2012).

For a review of transfers and discharges, see Chapter 11 in this volume and

Go to Chapter 11, **Procedures 11-2, 11-3, and 11-4,** in Volume 2.

How Do I Receive and Document Verbal and Telephone Orders?

Although licensed nurses may find it necessary to accept verbal or telephone orders on occasion, verbal and telephone orders increase the risk of hearing or writing the order incorrectly. The Joint Commission recommends the person to validate a verbal order or report of critical test results using a written and read-back process before taking any action (The Joint Commission, 2011). SBAR-R is a revised version that adds the read-back component to minimize errors and failures in communication between the nurse and provider.

Telephone Orders

Telephone orders can lead to error because of differences in pronunciation, dialect, or accent; background noise; poor reception; and unfamiliar terminology. Taking a telephone order may be acceptable when there has been a sudden change in your patient's condition and the client's PCP is not in the hospital, or the physician does not have access to placing orders electronically. Verbal or telephone orders are also acceptable in a life-threatening emergency, but you must apply the document and "read-back" safeguard. Faxes, text messages, and e-mail have reduced the need for telephone orders; however, their use may never disappear entirely.

For guidelines to use when taking telephone orders,

Go to Chapter 18, **Clinical Insight 18-2: Receiving Telephone and Verbal Orders,** in Volume 2.

The following is an example of a telephone order transcribed to a paper order sheet:

08/27/16 0805 Morphine 2 mg IV push once for pain now.——————TO Dr. Kent/S. Hogan RN

If the telephone order is entered electronically, the date/time and order remain the same, the order is marked as an electronic entry, and will go to the selected physician, Dr. Kent, for his signature.

Verbal Orders

Verbal orders are spoken directions for patient care given to you in person, usually during an emergency. Providers should never use verbal orders as a routine method of communicating orders. When recording a verbal order, include the date, time, and the written text of the order or the electronic entry of the order. If you are writing the order on an order sheet, an indicator "VO" designating verbal orders is then followed by the provider's name and your name. If you are entering the order electronically, then the order will be designated as a verbal order and be routed to the selected physician for co-signature. Follow The Joint Commission safety guidelines, above, and

Go to Chapter 18, **Clinical Insight 18-2: Receiving Telephone and Verbal Orders,** in Volume 2.

KnowledgeCheck 18-6

- What important factors should you document when receiving a telephone order?
- What is the purpose of a verbal order? When should it be used?

How Do I Question an Order?

If you feel uncertain about an order, you must question it. As a student, you will first want to discuss your concerns with your clinical instructor or the nurse you are working with during your clinical time. Remember, the goal is to provide safe care. If you have concerns, do not remain quiet—act on them.

As a nurse, you will follow your organization's policy for clarifying orders. If an order is written illegibly on a paper order sheet or is entered into the EHR missing details or order components, contact the provider directly to seek clarification. Generally, you should contact the provider who wrote the order. If the provider leaves the order as-is and you still don't feel comfortable with it or believe there is an error, you may refuse to carry it out. Inform the chain of command at your organization about your refusal. Usually you will speak with the charge nurse, who may then contact the nurse manager or nursing supervisor. The nature of the order will determine how the situation is handled.

As a new nurse, you may feel uncomfortable about questioning an order. Even experienced nurses sometimes feel uneasy with this challenge. If you are uncertain how to proceed, you can discuss your concerns with your colleagues, the charge nurse, or the supervisor before contacting the provider. Your efforts to clarify the orders help to protect your patient. If you do refuse an order, you must document your refusal and the actions you took to clarify the order.

Key Point: ***If you believe an order is inappropriate or unsafe, you are legally and ethically required to question the order.***

PracticalKnowledge knowing how

To document care effectively, you need to be familiar with the forms and requirements of your institution. Chart routine nursing actions (e.g., skin care) on the designated paper or electronic flowsheets or forms; and record your assessments, interventions, and patient responses to care in the format approved by your organization. It is important to chart accurately, completely, and consistently so that the patient's progress can be tracked and appropriate care given.

Remember that the patient's health record is permanent and that information contained in the chart is confidential. As a student, you are granted access to a client's charts for educational purposes. You have a duty to keep the information private and confidential. The Health Insurance Portability and Accountability Act (HIPAA) regulations affect access, storage, transfer, and discussion of patient information. For more information about privacy, confidentiality, and HIPAA, refer to Chapters 44 and 45.

ThinkLike a Nurse 18-4

You note that your client with asthma is having increasing difficulty breathing. You call the physician, who gives you a telephone order for an asthma medication, and then hangs up. When you enter the order electronically as a verbal order, you find out the medication is a nonformulary medication that your pharmacy does not carry.

- Is this an acceptable reason to take a verbal order?
- The physician gets irritated when you call back and says, "I prescribed what I wanted." How would you handle this situation?
- You entered the order electronically after the physician hung up. How could this situation have been avoided?

GUIDELINES FOR DOCUMENTING CARE

Key Point: ***Your documentation should convey the care that you provided to the patient during your shift.***

Thus, if you read your documentation 3 years later, as in the case of malpractice lawsuits, it should attest that the care you provided to the patient adhered to minimum standards of nursing practice. For a brief set of documentation tips, see Box 18-3. For detailed guidelines for documentation,

Go to Chapter 18, **Clinical Insight 18-3,** in Volume 2.

Guidelines for Paper Health Records

To comply with HIPAA requirements, paper health records need to be stored in designated areas to which only healthcare providers have access. To ensure your

BOX 18-3 ■ Documentation ABCs

Accurate
Bias-free
Complete
Detailed
Easy to read
Factual
Grammatical
Harmless (legally)

written paper documentation is effective, the forms used must be efficient, comprehensive, and relevant to the patient's healthcare needs. The forms should guide you to document appropriately according to your organization's policies and procedures. The following guidelines will further assist you in documenting appropriately.

- **Maintain confidentiality.** Do not provide written or verbal information to anyone not involved in the direct care of the patient without the patient's consent.
- **Ensure you have the correct form (e.g., I&O sheet, graphic record) before you begin writing.**
- **Check that the chart and documentation forms are clearly marked with the patient's name and identification number.**
- **Write legibly, neatly, and in an organized manner.** This enables others to read your entries and use them to make clinical decisions. Sloppy or illegible handwriting creates errors or, at least, leads to poor communication.
- **Always use black ink for handwritten notes (some agencies do permit blue ink).** Inks other than black or blue are not legible when a chart is photocopied. Do NOT use green or red pen. Remember that the chart is a legal document.
- **Do not leave blank lines in the narrative notes.** If you need to leave space for clarity, draw a straight line through the area and begin on the next line. Open areas leave an opportunity for later tampering.
- **Draw a line through the incorrect charting and initial it.** Never use a correction fluid, "ink over," or otherwise cover up written notes.
- **Sign all your paper charting entries with your first name, last name, and professional credentials, such as Judy Long, RN.**
- **Don't write in "shorthand" or your own abbreviated symbols.**
- **Use only abbreviations that are approved by your organization.**

Guidelines for Electronic Health Records

Well-designed nursing documentation forms and systems help you organize your work, manage your care plans, track client diagnoses and outcomes, and support decision making by healthcare providers.

How Can I Document Efficiently and Effectively?

To ensure your documentation in the EHR is most efficient and effective, keep the following in mind:

- **You must have basic computer, mouse, and software skills** to document effectively in the EHR.
- **If you are uneasy or more stressed using computers**, or unfamiliar with the software it may take you longer to make the transition to documenting in the EHR.
- **Help keep patient rooms clutter-free** so that you have a place to use a portable computer in the room for direct charting.

What Is Unique About Entering the Data?

- **Before Charting.** Before opening charting forms, you must ensure that the patient's name, identification number, and any other unique health record identifiers are correct.
- **Saving Documentation.** If your EHR allows you to save partially completed documentation before signing it, do complete the documentation and sign it as quickly as possible. In most EHR systems, saved documentation cannot be seen by others until it is signed.
- **Checklists.** Electronic forms and flowsheets are often built in a format similar to a checklist. This can make it more difficult to capture detailed patient changes and findings.
- **Errors.** If you make an error (e.g., make entries on the wrong chart or enter and sign the wrong information), you can correct it. The entry can never be completely deleted, but only the corrected information will be visible to anyone viewing the chart.

What Happens If the Computer Doesn't Work?

EHR systems can have periodic downtimes due to scheduled maintenance or network or interface problems. Client care does not stop, so you need to know the processes and procedures to follow when the EHR is offline and inaccessible. Follow organization policies regarding the amount of time the EHR needs to be "down" before you begin documenting on paper form.

How Do I Maintain Confidentiality and Data Security?

Although the specific risks to and safeguards of confidentiality differ in detail between paper and electronic records, confidentiality is equally important in both. The following safeguards are specific to EHRs:

- *When moving away from the open EHR*, close the screen and temporarily or permanently log off to ensure confidentiality and privacy. Most computer stations will automatically log-off after a specified period of inactivity. This helps keep unauthorized viewers from having access to patient information.
- *Privacy filters*—Some computer screens are equipped with privacy filters to protect patient information from the view of non-authorized viewers.

- *Create a secure password*—not something obvious, such as your birth date, Social Security number, or family members' names. Instead, you might choose a password that is at least six characters long and includes at least one capital letter (if the system is case sensitive), one number, and (if allowed by the system) one symbol. The system you are using will determine the specifications.
- *Change your password at regular intervals* even if your organization does not require it. Some systems will lock you out of the system if your password is not changed as required.
- *Do not share your personal username or password* with anyone. You are responsible for the data recorded and saved using your electronic identity. If someone else enters data or accesses charts under your identity, you will be held responsible for those actions if the patient initiates legal action.
- *Do not leave patient data displayed on the screen where others can see it.*
- *Do not leave the computer unattended after you have logged on*. This allows others access to confidential data, and to document under your name.
- *Do not leave a portable device (e.g., a laptop or PDA) unattended in a public location*, such as on a countertop in the nurses' station. This increases the possibility of theft or unauthorized access to secured patient information.
- *Never access client health records that you have no professional reason to view*. This is a severe breach of client privacy rules. Know your state and federal laws consequences for privacy violations.
- *Become familiar with your organization's policies* regarding network and patient health record information security and confidentiality.

KnowledgeCheck 18-7

Refer to **Clinical Insight 18-3, in Volume 2,** to help you answer the following questions.

- What aspects of care should be documented?
- When should care be documented?
- How is documentation on paper different from documentation in an EHR or on an electronic digital form?

Think**Like a Nurse** 18-5

You are caring for two clients on a medical-surgical unit. One of your clients is short of breath and complaining of chest pain. Your other client is recovering from abdominal surgery. He is alert, stable, and free from pain at this time. After stabilizing your first client, you realize you are 45 minutes late administering a medication to the abdominal surgery patient. You are not sure how to proceed.

- What theoretical knowledge do you need?
- You give the medicine as soon as you can (60 minutes late). How and where should you chart the medication administered?
- If you had been aware that you were going to be late with the medication, what might you have done to be sure it was given on time?

Toward Evidence-Based Practice

Cherry, B., Ford, E., & Peterson, L. (2011). Experiences with electronic health records: Early adopters in long-term care facilities. *Health Care Management Review, 36*(3), 265–274.

The implementation of electronic health records in 10 long-term care facilities revealed that administrators, nurses, managers, nurses, certified nurse aides, and other system users indicated that EHRs (1) were cost effective in improved quality of care, (2) increased documentation accuracy and implementation of evidence-based practices, (3) improved access to resident information, (4) reduced nursing overtime, and (5) resulted in an overall positive attitude among personnel working with the system.

Huryk, L. (2010). Factors influencing nurses' attitudes toward healthcare information technology. *Journal of Nursing Management, 18*(5), 606–612.

A systematic review of 13 articles on nurses' attitudes toward healthcare information technology (HIT) revealed that more positive attitudes were associated with (1) increased computer experience, (2) perceptions that HIT will enhance patient care or safety, (3) positive attitude of administrators, and (4) user-friendly and well-integrated systems. Less positive attitudes were associated with (1) perceptions of dehumanizing patient care, and (2) technological system issues/flaws. A theme of not returning to paper charting was dominant.

Kossman, S., & Scheidenhelm, S. (2008). Nurses' perceptions of the impact of electronic health records on work and patient outcomes. *CIN: Computers, Informatics, Nursing, 26*(2), 69–77.

This study addressed 46 medical-surgical and intensive care unit nurses' use of electronic health records (EHR) and their views of the impact of such records on job performance and patient outcomes. Results indicated that nurses (1) preferred EHR to paper charts and were comfortable with technology; (2) thought use of EHR impaired critical thinking, decreased interdisciplinary communication, and created a high demand on work time (73% reported spending at least half their shift

Toward Evidence-Based Practice—cont'd

using the records); (3) believed that EHR improved organization, efficiency, and information access (e.g., helpful alert screens); and (4) thought the use of EHR enabled them to provide safer care but decreased the quality of care.

1. Compare the advantages given in Advantages of Electronic Health Records with the findings in the above studies. Which EHR advantage is *not* supported by either of these studies? What is the statement in each study that conflicts with the advantages reported in your text?

2. Which study disagrees with the statement that EHR improves communication between healthcare providers? What does the study say about that?

Go to Chapter 18, **Toward Evidence-Based Practice Suggested Responses,** on the Davis*Plus*.

Can I Delegate Charting?

In some facilities, each member of the team is responsible for documenting care provided to the client. Nursing assistants or other nursing assistive personnel (NAP) often chart ADLs, activity, and I&O on graphic records. You are responsible for documenting the nursing care you provide. Never chart the actions of others as though you performed them. If an action is crucial to a chain of events, you may document that action on paper or in the EHR, referring to the person who did the action clearly. For example, "Became dizzy; assisted to chair by Nora Roverdale, NAP."

KnowledgeCheck 18-8

- Can charting be delegated?
- You are a student nurse on a medical-surgical unit. You review your client's chart and notice that the physician entered prescriptions that do not appear to be appropriate for your client. The physician is still in the area. How would you handle this situation?

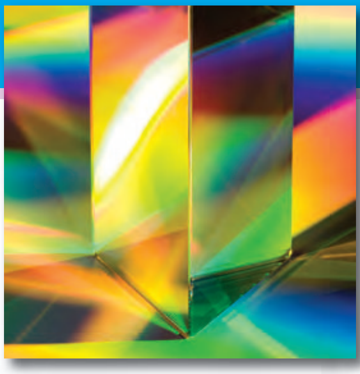
CHAPTER 19



Teaching & Learning

Learning Outcomes

After completing this chapter, you should be able to:

- Present three factors contributing to the expanding role of teaching in professional nursing.
- Describe the concepts of teaching and learning.
- Name, define, and give one example of each of Bloom's three domains of learning.
- Discuss how each of the following factors can affect learning: motivation, readiness, physical condition, emotions, timing, active involvement, feedback, repetition, environment, scheduling of the teaching session, amount and complexity of the content, communication, special needs (e.g., learning disability), developmental stage, culture, and literacy.
- List at least six barriers to teaching and learning.
- Describe some strategies for motivating learners.
- Develop strategies for working with clients with cultural or learning differences.
- Describe the content of a learning assessment.
- Discuss correct and incorrect uses of the nursing diagnosis Deficient Knowledge.
- Develop teaching plans for clients.
- List four methods for evaluating the outcomes of teaching and learning.
- Document teaching content, methods, and patient responses to learning.

Meet Your Patients

You are the student nurse assigned to Heather, a 20-year-old mother, and her 4-year-old preschooler. They have come to a family practice clinic for a well-child checkup. During the healthcare visit, you notice that the child speaks only in one- or two-word phrases. The mother's tone to her daughter is impatient and she repeatedly tells her to "stop using that baby talk."

Heather says, "I don't know what I'm doing wrong. All her friends are taller and talking more. She was even small when she was born, so I suppose it's my fault."

Your assessment shows the child is below the 5th percentile for height and weight. What health teaching could you provide that might help resolve this problem? Your nursing instructor tells you to assess for teaching needs and provide anticipatory guidance to the mother. How would you begin to address Heather's learning needs without reinforcing her feelings of self-blame?

Your anticipatory guidance should include information about safety measures for a 4-year-old, nutrition for preschool-age children, and expected growth and development. How can you evaluate whether or not the teaching has been effective and further promote Heather's retention of this new information?

By the time you finish working through this chapter, you should be able to answer these questions and provide teaching to meet the unique needs of other patients you encounter.

ABOUT THE KEY CONCEPTS

This chapter covers concepts that underlie how people take in and offer information within the healthcare environment. The overarching concepts of **teaching** and **learning** provide a "hook" on which you can hang what you learn about all the other concepts in this chapter. A firm grasp of these and other key concepts will allow you to call to mind the information you need to apply in your professional role as a patient teacher.

Theoretical Knowledge knowing why

Nurses have been teaching patients since Florence Nightingale taught both nurses and patients about the value of good nutrition, fresh air, exercise, and personal hygiene (Nightingale, 1860/1992). Since that time, teaching has become progressively more important due in part to the following:

Patients Participate in Healthcare Decisions Patients are taking responsibility for their own healthcare. Primary care providers expect patients to take an active role in making decisions about their health; patients and families need information so that they make *informed* decisions. You can help patients get answers to their questions, find resources, recognize problems, and develop self-care behaviors.

Hospital Stays Are Brief A great deal of complex care is being given in homes and the community. Patients are often sent home still needing medications, dressing changes, and skilled procedures, such as urinary catheterization. Nurses have a responsibility to teach family members how to provide care and to teach patients to care for themselves as they are able.

Healthcare Is Expensive Patient education can help to decrease the overall cost of healthcare. It does so by helping to increase patient compliance with medical and nursing regimens, which can shorten hospital stays and decrease frequency of medical treatments and admissions (Bastable, 2008).

As you might conclude from the foregoing discussion, the basic purpose of teaching and learning is to provide information that will empower clients and families to (1) perform self-care, and (2) make informed decisions about their healthcare options. Like other interventions, you can use teaching to promote wellness; prevent or limit illness; restore health; adapt to changes in body function; and facilitate coping with stress, illness, and loss.

WHO ARE THE LEARNERS?

As a nurse, your learners are clients, families, and others who care for the client. You will often provide informal one-to-one teaching while performing other nursing interventions. For example, as you give a medication, you will teach about its therapeutic and side effects. Or you may do more formal teaching to groups of people. You might demonstrate a baby bath to a class of expectant parents.

You will find your learners wherever you work: hospital, an ambulatory setting, home care, or in the community. As a community health nurse, you would be more likely to teach large groups of people; for example, you might teach a healthy lifestyles class to a group of teens.

As nurse, you will also be responsible for teaching healthcare workers whom you supervise. For example, you may instruct nursing assistive personnel (NAP) when you observe an error in technique for measuring blood pressure. Or you may help a new nurse learn how to use new equipment on the unit. Nurses in practice are also involved in clinical instruction of nursing students, new graduates, and other members of the healthcare team. Most of this teaching may be informal, although you might also present specific topics at unit meetings and conferences. For example, if there is a change in the agency's documentation system, you might teach a class to the nurses on your shift to learn the new system.

WHAT ARE MY TEACHING RESPONSIBILITIES?

Teaching is a major component of clinical practice skills and is an independent nursing function. In many states, nurses' teaching role and responsibility is defined in the Nurse Practice Act.

The American Nurses Association (ANA) The *ANA Code of Ethics for Nurses with Interpretive Statements* (2001) says that nurses are responsible for promoting and protecting health, safety, and rights of patients. Patient teaching is essential in fulfilling that responsibility.

ANA standards of practice (2010), Standard 5B, states, "The registered nurse employs strategies to promote health and a safe environment." The following are the specific measurement criteria for that standard:

- Provides health teaching that addresses such topics as healthy lifestyles, risk-reducing behaviors, developmental needs, activities of daily living, and preventive self-care.
- Uses health promotion and health teaching methods appropriate to the situation and the patient's values, beliefs, health practices, patient's developmental level, learning needs, readiness and ability to learn, language preference, spirituality, culture, and socioeconomic status.
- Seeks opportunities for feedback and evaluation of the effectiveness of the strategies used.
- Uses information technologies to communicate health promotion and disease prevention information to the healthcare consumer in a variety of settings.
- Provides healthcare consumers with information about intended effects and potential adverse effects of proposed therapies.

The Joint Commission Hospital accreditation standards require educators in healthcare organizations to consider the literacy, developmental and physical limitations, financial limitations, language barriers, culture, and religious practices of every patient. Teaching must also include any person who will be responsible for the patient's care (The Joint Commission, 2010, 2013).

The American Hospital Association (AHA) The AHA Patient Care Partnership (previously the Patient's Bill of Rights) that describes in simple language the right of patients to receive high-quality care. Patient rights include a clean and safe environment; protection of privacy; complete and current information about disease/condition, diagnosis, treatment, and prognosis; information communicated in ways patients can understand; and the right to be informed of hospital policies and practices that relate to them (American Hospital Association [AHA], 2003).

WHAT ARE SOME BASIC LEARNING CONCEPTS AND PRINCIPLES?

The educational process involves the concepts of teaching and learning. **Teaching** is an interactive process that involves planning and implementing instructional activities to meet intended learner outcomes or providing activities that allow the learner to learn (Bastable, 2008). Teachers must have effective communication skills to (1) adequately convey information, (2) assess verbal and nonverbal feedback, and (3) accommodate various learning styles. In patient education, nurses can use teaching, counseling, and behavioral modification together to achieve effective client learning.

Learning is a change in behavior, knowledge, skills, or attitudes. It occurs as a result of planned or spontaneously occurring situations, events, or exposures. *Conscious, goal-oriented learning* is intended and deliberate. It involves motivation to learn. Learning can occur in a rote manner, informally by circumstance, by formal instruction, or by a combination of approaches. It is not enough for the teacher to give the person written or verbal information; information alone will not change behaviors. Box 19-1 summarizes some basic principles of learning and provides a quick check for planning teaching sessions. For information about learning theories (social learning theory, behavioral learning theory, cognitive theory, and humanism),

Go to Chapter 19, **Supplemental Materials: Learning Theories,** on Davis*Plus*.

KnowledgeCheck 19-1

- Identify at least three reasons nurses have a responsibility to teach clients.
- Define *teaching*.
- Define *learning*.

BOX 19-1 ■ Five Rights of Teaching

When you are making a teaching plan, you can use this as a checklist to ensure that you consider each of the five "rights" of teaching in the plan.

Right Time

- Is the learner ready, free of pain and anxiety, and motivated?
- Have you and the learner developed a trusting relationship?
- Have you set aside sufficient time for the teaching session?

Right Context

- Is the environment quiet, free of distractions, and private?
- Is the environment soothing or stimulating, depending on the desired effect?

Right Goal

- Is the learner actively involved in planning the learning objectives?
- Are you and your client both committed to reaching mutually set goals of learning that achieve the desired behavioral changes?
- Are family or friends included in planning so that they can help follow through on behavioral changes?
- Are the learning objectives realistic and valued by the client; do they reflect the client's lifestyle?

Right Content

- Is the content appropriate for the client's needs?
- Is it new information or reinforcement of information that has already been provided?
- Is the content presented at the learner's level?
- Does the content relate to the learner's life experiences or is it otherwise relevant to the learner?

Right Method

- Do the teaching strategies fit the learning style of the learner?
- Do the strategies fit the client's learning ability?
- Are the teaching strategies varied?

Learning Occurs in Three Domains

People learn in three ways, or *domains*: cognitive, psychomotor, and affective (Bloom & Krathwohl, 1956). You should include each of these domains, involving thinking, doing, and feeling/caring, when writing objectives and planning teaching and evaluation strategies, which are discussed later in this chapter. Table 19-1 provides examples of client learning in each of the domains. For a more detailed version of this table, which identifies levels of behavior associated with each domain,

Go to Chapter 19, **Tables, Boxes, Figures: ESG Table 19-1,** on Davis*Plus*.

Table 19-1 ➤ Bloom's Domains of Learning

DOMAIN AND LEVELS OF BEHAVIOR	EXAMPLES
Cognitive (thinking)	
Includes memorization; recall; comprehension; and ability to analyze, synthesize, apply, and evaluate ideas.	A client is able to report the names and doses of the three medications he is taking. A client explains the expected effect of the medication she has been prescribed. A client designs a planned schedule for dressing changes for a wound on her leg. A client describes how to distinguish between normal inflammation and signs of infection in a wound. A client recognizes the need for behavioral changes to decrease the chance of recurrence of infection.
Psychomotor (skills)	
Includes sensory awareness of cues involved in learning, as well as imitation and performance of skills and creation of new skills.	A client identifies that he needs to read directions before starting a project. A client brings personal equipment to a teaching session. A new mother follows the instructor who is demonstrating diapering of her newborn, imitating her movements. A new father is observed diapering his newborn after observing a demonstration. A client independently changes her complex dressing. The wound heals with no signs of infection. A client with limited vision creates a new approach to giving his daily injections.
Affective (feelings)	
Includes receiving and responding to new ideas, demonstrating commitment to or preference for new ideas, and integrating new ideas into a value system.	An adolescent makes eye contact with the nurse as she explains the admission process. A client asks questions about what to expect during a procedure he is to undergo. A parent of a child who has just been admitted to the hospital expresses commitment to staying with her child after the nurse explains the impact of hospitalization. A client who has overcome drug addiction chooses to present his story to high school groups.

Adapted from Bloom B. S., & Krathwohl, D. R. (1956). Taxonomy of educational objectives: The classification of educational goals. *Handbook I: Cognitive domain.* New York: Longmans, Green; and Bloom, B. S., Mesia, B. B., & Krathwohl, D. R. (1964). Taxonomy of educational objectives (Vol. 1: *The affective domain* and Vol. 2: *The cognitive domain*). New York: David McKay.

Anderson and Krathwohl (2001) adapted Bloom's model describing learning using a more outcomes-based approach, including the following domains:

Remember
Understand
Apply
Analyze
Evaluate
Create

Cognitive Learning

Cognitive learning includes storing and recalling information in the brain. Ranging from simple to complex processes, it encompasses six levels of behavior: memorization, recall, comprehension and analysis, synthesis, application, and evaluation of ideas (see Table 19-1). Strategies and tools to support teaching cognitive-type content include lectures, reading materials, panel discussions, audiovisual materials, programmed instruction, computer-assisted instruction (CAI), and problem-based learning (e.g., case studies and care plans).

Psychomotor Learning

Psychomotor learning involves learning a skill that requires both mental and physical activity. It requires the learner to accept and value the skill (the affective domain) as well as know about the skill (the cognitive domain). Strategies and tools used to teach psychomotor skills include demonstration and return demonstration, simulation models, audiovisual materials (e.g., DVDs, streaming video), journaling and self-reflection, and printed materials, especially with photographs and illustrations.

Affective Learning

Affective learning involves changes in feelings, beliefs, attitudes, and values. It is considered the "feeling domain." Strategies and tools for promoting affective learning include role modeling, group work, panel discussion, role playing, mentoring, one-to-one counseling and discussion, audiovisual materials (e.g., DVDs, streaming video, interactive computer-based modules, movies), computer and printed materials. Levels of affective behavior are shown in ESG Table 19-1, on Davis*Plus*.

KnowledgeCheck 19-2

- What are the three domains of learning?
- What strategies and tools are used to promote learning within each of the three domains of learning?
- Give an example of each of the domains of learning.

ThinkLike a Nurse 19-1

By now, you have probably already learned how to assess a patient's blood pressure (BP).

- Think about how you were taught to perform that *skill*. What would have been the best way for *you* to learn to take a BP? To read a book and look at the photos closely? To watch a DVD? To have someone tell you how to do it? To have someone demonstrate the skill? Perform the blood pressure measurement yourself? Some other way?
- Now think about the *principles* involved with BP (e.g., normal ranges, the physiological regulation of the BP). What, for you, would have been the best way to learn the principles? Read a book? Listen to a lecture? Physically obtain a BP reading for a patient? Work a case involving BP? Some other way?
- From your answers to the two preceding questions, what (if anything) can you conclude about different domains of learning and the kinds of activities to use in teaching and learning in each domain?

Many Factors Affect Client Learning

Because learning is complex, many factors can either enhance or interfere with it. An understanding of the following factors will help you to design effective teaching interventions and promote client learning.

Motivation

Motivation is desire from within. It is created by an idea, a physical need, an emotion, or some other kind of force. Without motivation, little learning can occur. Motivation is greatest when clients recognize the need for learning, believe it is possible to improve their health, and are interested in the information they are being given. Think about classes you have taken. Have you studied harder in some than in others? What motivated you? Was it because you were intrigued by the information, wanted to earn a good grade or the approval of the instructor, or had other incentives?

Motivation may be based on physical and social needs, the need for task mastery or success, and health beliefs. In your teaching, try to apply the following principles for motivating learners:

- Conveying your interest in and respect for the learner and the learning process helps to motivate the learner.
- Creating a warm, friendly environment can enhance social needs motivation, as can your enthusiasm.
- You can sometimes motivate clients by helping them identify a physical need. For example, Heather (Meet Your Patient) may not be aware that her child is at risk for accidents and injury from home hazards. Helping her to understand the normal behavior of a 4-year-old may help her to see the need for childproofing her home.
- The need for achievement and competence is related to task mastery and self-efficacy. When a person succeeds at a task, he is usually motivated to continue learning. Rewards and incentives can provide this type of motivation.
- The client will be motivated to learn only if she believes that health is important. For example, Heather may understand that a 4-year-old likes to explore and may recognize there are safety hazards in the home; however, she will not be motivated to learn safety measures if her attitude is that "it is no big deal."

Many of the following factors also provide motivation as well as contributing in other ways to learning.

Readiness

Readiness is the demonstration of behaviors that indicate the learner is both *motivated* and *able* to learn *at a specific time*. For instance, a client may not be "ready" for teaching right before scheduled diagnostic tests or invasive treatments because anxiety makes it difficult to focus on the material. In addition, readiness for learning includes the physical and emotional capacity to take in, process, and recall information.

Physical Condition Physical and intact cognition contribute to a patient's readiness to learn. You must consider them in your planning. For example:

- Pain interferes with the ability to concentrate on the material the nurse presents.
- The client needs adequate strength, coordination, energy, and mobility to demonstrate psychomotor learning.
- You will need to adapt your teaching and evaluation strategies to accommodate clients with impaired cognition, hearing, or vision.

Emotions Emotions such as severe anxiety, stress, and emotional pain interfere with the ability to learn. In addition, the learning itself, and the idea that behaviors must be changed, can create anxiety. However, a mild level of anxiety can enhance learning by providing motivation. For example, a client newly diagnosed with diabetes may not be experiencing physical complications related to the disease, so he may not be interested in learning about diabetes. You may be able to motivate him (i.e., create some anxiety) by pointing out the potential and serious complications (e.g., blindness, kidney damage) of uncontrolled diabetes. Provoke mild anxiety carefully so the client does not interpret your words as a threat or excessive negativity.

Timing

You must present information at a time when the learner is open to learning. Timing is therefore related to readiness, and it is important in the following ways, as well:

- People retain information better when they have an opportunity to use it soon after it is presented. For example, a student reads about insulin in her textbook and takes a test on the content 2 weeks later. Another student reads the same information and during the 2 weeks also administers different types of insulin to several patients. The second student will have an advantage at test time.
- For some concepts, the learner might need more time to absorb and apply information, especially when more complex thinking is required.

Active Involvement

Learning is more meaningful when the client is actively engaged in the planning and the learning activities. Learners retain 10% of what they read, but they retain 90% of what they speak and do (London, 1999). Passive listening is not typically as effective for processing and retaining information as activities involving more than one style of learning. For instance, a demonstration with a return demonstration and a patient education brochure is often an effective way to teach patients how to perform a new skill. Demonstration is particularly effective for kinesthetic learners (which most adults are). Can you think of other examples of learning that involve multiple senses?

Feedback

Feedback is information about the learner's performance. For example, a test grade is feedback for students, conveying the message, "You need to work on that content some more," or "You have successfully mastered the lesson." Feedback in the clinical setting or skills lab might be, "You consistently maintained sterile technique."

Key Point: ***Positive feedback encourages learners and boosts morale when it comes to tackling difficult content or devoting the time and effort needed to get the most out of the educational process. This is especially critical when significant behavioral changes are required to be a successful learner.***

Patients, too, tend to respond well to positive interaction while learning. For example, the patient teaching experience reinforces the patient with a new ostomy who successfully changes her appliance or a patient with diabetes who learns to correctly draw up an insulin dose. Sometimes you may need to act like a coach, encouraging the learner with frequent feedback and praise or by suggesting alternatives. At other times, you may need to point out errors; but try to do so in a positive way. Be careful not to seem judgmental when clients are learning a new skill or are giving home care. Fear of failure or judgment can be a serious barrier to learning at what could be the patient's most teachable moment.

Repetition

The client is more likely to retain information and incorporate it into his life if the content is repeated. Each time the learner hears the information, the likelihood of retention increases. For example, often patients forget what medication is prescribed for certain conditions. Repeating the name of the drug can help patients better remember it. This is especially true for learning psychomotor skills. Do you remember the first time you counted a radial pulse? Even that simple skill may have been difficult at first. By now it is probably very easy for you.

ThinkLike a Nurse 19-2

Use examples from your own experience, if you can. Do not use examples you have read in the preceding sections.

- Give an example to illustrate the importance of relevance in learning.
- Give an example to illustrate the importance of repetition in learning.
- Give an example to illustrate the importance of timing in learning.

Learning Environment

Have you ever tried to concentrate on a lecture right after lunch when you were sitting in a warm, stuffy room? Or when someone is talking or texting you via cell phone? Keep in mind, though, that some learners are best motivated and engaged when teaching occurs in a group situation. Social learners can be distracted from the task when alone in a quiet space.

When you are planning a teaching session, provide lighting and comfortable seating that is conducive for conversations. Have your teaching materials ready at hand to avoid gaps in the teaching session. If you have an area that is set aside for teaching, try to use inspirational or motivational accessories (e.g., photographs, posters).

A quiet, private space, free of distractions, is ideal for teaching. If none is available, at least try to find a quiet corner, pull the bed curtain shut, close the door, or sit close to the client so that you can talk softly (Fig. 19-1). Make the best of what you have to work with.

Did you recognize how the concept of learning environment is related to the concepts of teaching and learning?

Scheduling the Session

Plan for uninterrupted time to allow you to adequately assess and understand the client. The teaching time doesn't always need to be long, just uninterrupted. Based on the client's condition (e.g., activity intolerance, attention span, fatigue, pain), shorter teaching sessions may be best for comprehension and retention. Finding suitable time to teach can be a challenge, but a moment can be a teaching session, as shown in Box 19-2.

Amount and Complexity of the Content

The more complex or detailed the content, the more difficult it is for most people to learn and retain, as you probably know from your own learning experiences. For example, imagine teaching parents about the need for isolation precautions for their newborn who has just been diagnosed with an immune disorder. In comparison, teaching parents how to diaper their healthy newborn would be far less challenging.

In addition, the greater the change, the greater will be the challenge for both teacher and client. For example, a client rehabilitating after a stroke who has to relearn using eating utensils, swallowing, and other basic tasks for daily hygiene and self-care will experience a more demanding learning challenge than one who has to learn only a daily schedule for taking medications.

FIGURE 19-1 To provide privacy, sit or stand close to the patient so that you can talk privately.

BOX 19-2 ■ Teachable Moments

This week in class a student nurse has been studying patient teaching. Her instructor has informed the students that she expects them to incorporate teaching into each clinical day. While caring for the patient, the student ponders, "I am way too busy to find time to teach. What am I going to do?" Later in the day, she asks the nurse who is co-assigned to her client for suggestions. The nurse questions the student: "Did you take the patient's blood pressure?" When the student answers that she did, the nurse says, "Did you explain why you were doing that and what the BP readings mean?" Again the student says, "Yes." The nurse asks, "When you gave your patient his medications, did you explain why you were giving each one and the common side effects?" The student begins to understand that almost every patient contact presents an opportunity for teaching and doesn't have to take a long time.

Communication

Communication is central to the teaching and learning process in which teachers and learners communicate information, perceptions, and feelings. Barriers to communication include pain, anxiety, fatigue, illness, hunger, dysfunctional relationships, language differences, vision and hearing impairment, cultural factors, and various environmental issues, such as noise and distraction. Attend carefully to verbal and nonverbal feedback that the client gives; it can tell you whether or not the learner is attentive and focusing on the learning activities. For more information about communication, see Chapter 21.

ThinkLike a Nurse 19-3

A client who has a brain injury needs to learn how to administer insulin. Another learner who must learn to change a wound dressing has attention deficit-hyperactivity disorder (ADHD).

- How do you think these clients' health status might affect:
  1. Their motivation to learn?
  2. Their ability to be actively involved in the learning?
- What approaches or changes might you need to make in:
  1. The learning environment?
  2. The timing of the teaching session?
  3. The use of repetition?
  4. Your communication?
  5. The amount and complexity of content presented in a session?
  6. Your use of feedback?
  7. The amount of teacher support?

Special Populations

For clients who have special needs (e.g., those with learning disabilities, ADHD, mental illness, affective or communication disorders, mental illness, or brain injury) you must plan carefully to ensure that you use appropriate strategies to maximize learning. Consider a variety of teaching approaches—one size does not fit all. For example, you may need to use brief, frequent learning sessions or pay special attention to minimizing distracting stimuli in the environment. Or you may need to present information slowly, use repetition, and be satisfied with slower progress. The adaptations you make will depend on the nature of the special need, so if you are not familiar with the patient's condition, you must acquire theoretical knowledge of it. Include a family member, caregiver, or other significant person in the teaching to reinforce the learning and act as a safety net for implementing the information.

Developmental Stage

An understanding of intellectual development will help you to gear your teaching strategies and content to the level of the learner. When teaching psychomotor skills, you will need to assess the person's fine and gross motor development. For example, a young child may not have adequate fine motor skills to complete a skill such as tying shoes without assistance (Fig. 19-2). If you would like to review an extensive discussion of intellectual development, including Piaget's theory (1966), see Chapter 9.

Stages of Cognitive Development

Piaget identified three stages of cognitive development that are especially important in client teaching in the cognitive domain:

- **The Preoperational Stage** (2 to 7 years old), in which the child begins to acquire language skills and find meaning through use of symbols and pictures.
- **The Stage of Concrete Operations** (7 to 11 years old), in which the child learns best by manipulating concrete, tangible objects and can classify objects in two or more ways (e.g., identify a shape as a triangle and also as green). Logical thinking begins, and the child can understand the relationship between numbers and the idea of reversibility. He also can begin to recognize and adapt to the perspective of others.
- **The Formal Operational Stage** (age 11 years or older), in which the person can use abstract thinking and deductive reasoning. The person can relate general concepts to specific situations, consider alternatives, begin to establish values, and try to find meaning in life. Not everyone reaches this stage, including some adults.

FIGURE 19-2 When teaching psychomotor skills, consider the person's gross and fine motor development.

Always assess cognitive development. For clients who have not achieved the stage of formal operations, use examples instead of definitions; use concrete rather than abstract terms.

Teaching Older Adults

When teaching older adults, consider the numerous factors that can adversely affect the teaching. Possible barriers include vision and hearing impairments, illness, pain, reduced social interaction, reduced mobility, dementia, medication effects, sensory deficit, sociocultural factors, and a noisy or chaotic environment. Allow extra time for teaching, and stop occasionally for rest periods. Assess for sensory deficits (e.g., hearing and vision) and adapt your style according to any restrictions. Use large print for the visual aids, and repeat information as necessary. Refer to Table 19-2 for some learning principles that apply to older adults, as well as tips for effectively teaching older adults.

Teaching Children

When you work with children, use strategies to gain trust, reduce their anxiety, promote cooperation, and enhance their emotional readiness to learn. For instance, for a child who needs surgery, schedule a tour of the hospital at least 1 week before the admission date, and introduce the child to staff members and other patients of the same age (if possible). Have the child practice breathing exercises or other aspects of tests or treatments that he will be involved in. With the parents' permission, provide the child with ice cream or other food, game, or material "reward," and give the child a coloring book or other item about the upcoming surgery to take home.

If you are teaching a child in the preoperational stage or an adult with limited intellectual development, you will need to simplify the content and use pictures and concrete examples. For example, there is little point in going into detail with a preschooler regarding the rationale for taking an antibiotic. Instead, tell the child that the medicine will keep her from getting sick; use pictures of a child drinking from a medicine cup, or provide a calendar that the child can mark each time she takes a dose. A reward system is often an effective way of improving compliance.

Cultural Factors

Awareness of norms, values, communication, social structure, time orientation, and cultural identification are important in planning teaching (see Chapter 15 to review these concepts). If English is not the client's primary language, you may need to use an interpreter.

Key Point: *Cultural sensitivity involves respect for clients' identity and needs, regardless of who they are, where they're from, how they speak, how old they are, what if any religion they practice, whether they are disabled, how much wealth or poverty they experience, how much they weigh, how socially popular they are, or any other aspect that can lead to unfair treatment.*

Table 19-2 ➤ Incorporating Principles of Adult Learning Into the Teaching of Older Adults

CHARACTERISTICS OF ADULT AND OLDER ADULT LEARNERS	TIPS FOR TEACHING ADULTS
Attitudes	
Adults are independent and self-directed learners.	Help them to identify their own learning needs.
Adults must recognize the need to learn before they become willing to learn.	Explain why the information or new skill is important. Be sure to include materials with practical tips and realistic goals for learning.
Some adults may be afraid of the learning process because of (1) fear of failure, (2) past unsatisfactory experiences with educational processes, (3) not having participated in formal education for many years, or (4) feeling that "being taught" is for children.	Present content in a nonthreatening environment, where there is no risk of judgment or embarrassment in front of peers. Offer feedback (evaluation) simply to improve important skills and not for the sake of a grade. Remember the intent of patient education is to improve clinical outcome. Privacy is often necessary.
Adults are more motivated to learn if they think they will be able to use the information or skills immediately.	Plan the teaching session at the time of greatest need. That is, hold the teaching session close to the time the patient will need the information or need to perform a new skill.
Adults prefer to be partners in the learning process—to have some control over what they learn and how they learn it.	Encourage learners to tell you first what they intend to gain from the educational session. You might spell out the goals of your session in advance and allow the learner to customize it.
Some adults may feel threatened by the need to learn new information. They may feel, "I've gotten along just fine all these years without needing to know that; why should I learn it now?" Or they may believe that they are "too old to learn." These attitudes may be defenses to avoid failure or to resist change.	Work with the learner to establish the "need to know" at the onset of the program. Involve the learner in defining what he or she intends to gain from the educational session. Reassure the learner about the importance of the information and encourage the learner to tackle a little at a time.
Older adults may be socially less active and might perceive bias, ageism, or isolation.	As for any group of people, it is essential to honor cultural backgrounds, local customs and practices, and personal preferences.
Experience	
Adults have previous life experiences that can enhance learning.	Relate new content to past experiences and knowledge and have learners use their experiences to solve problems. Encourage older adults to share life experiences.
Messages are best received when they are part of the real-life experience.	In the teacher role, model the message you are conveying to your audience. "Walk the walk" and not just "talk the talk."
Learning Environment	
Many adult learners do well when a hands-on approach is used. Older adults must practice a new skill, or rehearse new information, in order to learn it.	Offer active participation and opportunities for interaction with instructor and other learners. Demonstrations and practical tips are useful for adult learners, particularly older adults.
Many older adult learners need to review new information away from the initial learning environment in order to retain it. It might not be until later that information sinks in.	Use take-home materials, such as colorful posters, table tents, and tip sheets, and patient-friendly brochures to reinforce information.
Older adult learners can be distracted and annoyed by cell phones and other electronic devices.	Request phones, radios, or other electronic devices be turned off for the educational session. Turn off your own phone's ringer, as well.
Many older adults were raised in an era when learning occurred primarily through the reading, discussion, and retelling of stories. Technology was not as prevalent as it is today.	Use informal teaching sessions that include storytelling. Tie the patient's past experiences to what you are teaching. To elicit stories, you must be a patient and empathetic listener. Keep your stories short. Ask open-ended questions and be willing to wait for the answer. Convey your genuine interest in your learners before sharing personal stories. Allow more time for older adults, especially those with chronic illness, to tell their own stories.

Table 19-2 ➤ Incorporating Principles of Adult Learning Into the Teaching of Older Adults—cont'd

CHARACTERISTICS OF ADULT AND OLDER ADULT LEARNERS	TIPS FOR TEACHING ADULTS
Older individuals may bring family members or other caregivers to the teaching session to help interpret or remember information presented. Sometimes the extra people in the room can be noisy and distracting to the patient's learning situation.	If they are distracting, it may be helpful to ask others in the room to minimize other conversations, or in some circumstances to leave the room for a time.
Some older adults learn better when they are not overwhelmed with multiple needs, topics, or skills at one time.	Introduce only a few topics at a time. Usually tackling one to three new topics or skills is enough. Identify what is the most important information for your learner to walk away with. Define those topics and cover them well. Remember, slow and steady wins the race, especially when it comes to learning information that is essential to the patient's health.
Sensory and Physical	
Changes in visual distance, depth, acuity, and light perception occur with aging, thus diminishing the ability to take in information. Older adults experience increased sensitivity to glare and reduced color perception with aging. Processing of sensory information is also slower in the latter decades of life.	(1) Avoid colors such as blue, green, and lavender, because they are difficult for older adults to differentiate. (2) Remove physical barriers that could compromise the field of vision, such as projector position, tables, and so on. (3) In teaching materials, choose fonts that are bold, black, and a minimum size of 18-points. Fancy lettering is harder to decipher. (4) A nonglare background without a stylized pattern is easier to see and process than complex designs. (5) For those who cannot read or who have severe visual impairment, consider recording instructional material.
Reduced hearing acuity is common in older adults. Auditory perception for various tones and filtration of extraneous noise also diminish with age.	(1) Speak slowly, using a normal tone of voice. If you must speak more loudly than normal, be careful not to sound demeaning as though speaking to a child. You don't want learners to perceive annoyance in your tone. (2) Many older adults do some lip reading, although they may be unaware of it. You can facilitate lip reading by not distorting your facial features by exaggerated pronunciation. (3) Provide a quiet setting and reduce background noise. Close the door or windows if outside noise interferes with the teaching/learning experience.
Because of some short-term memory loss that occurs with aging, some older adults learn better when they have a source of supplemental information or support.	Reinforce your teaching with follow-up opportunities and connections to the community for information and support in grasping new information or acquiring a new skill.
Older adult learners can be particularly affected by fatigue, illness, medication, pain, stress, and other personal factors.	Be sure to plan the teaching session when the patient is well rested, pain-free as possible, and comfortable.

Box 19-3 highlights key concepts of teaching with a culturally competent approach.

Health Literacy

Health literacy is the capacity to obtain, process, and understand basic health information and services needed to make appropriate healthcare decisions (Nielsen-Bohlman, Panzer, & Kindig, and the Institute of Medicine of the National Academies, 2004; Ratzan & Parker, 2000). It does not refer simply to a person's ability to read and write but rather the way a person can apply language skills to understanding instructions on a medication bottle, or fully understanding explanations regarding a medical procedure to provide informed consent, for instance. On the contrary, **health illiteracy** occurs when the language spoken is not the patient's preferred language (i.e., limited English proficiency). Or perhaps the format through which the information is communicated is not suited to the patient. For example, if the patient has a hearing impairment and discharge teaching is done verbally, then a communication gap can occur. A gap in health literacy results when a healthcare provider uses medical terminology that is unfamiliar or misunderstood by the patient, thus resulting in an unintended message or lack of meaningful information. Limited health literacy is more common among the medically underserved community, minority populations, and older adults.

Patients with low health literacy are not as likely to understand the connection between risky behavior and

BOX 19-3 ■ Culturally Competent Teaching

Assessments

- Inquire or observe interactions among family members to decide who is the decision maker and how decisions are made. Include the family in the planning and teaching.
- Assess for customs or taboos that may conflict with the information you plan to present.
- Observe verbal and nonverbal communication patterns.
- Assess whether the family is past, present, or future oriented.
- Determine if the patient and/or family prefers a same-sex nurse to teach a client about personal topics, such as birth control and sexually transmitted infections. Different cultures have different ideas about what is appropriate for discussion between men and women.
- Determine whether the client's values and wishes are in congruence or conflict with the family.

Self-Knowledge

- Admit unfamiliarity with the culture, but express willingness to learn.
- Find sources of information that can help you learn about the culture and its healthcare practices.

Caring

- Respect, accept, and validate the client's beliefs.
- Find ways to incorporate the client's current healthcare practices and beliefs into the plan of care unless there is potential for harm.

Interventions

- Allow the patient to include cultural practices in the plan of care.
- Speak slowly and clearly; avoid slurring syllables.
- Do not use slang expressions.
- Use short sentences and concrete rather than abstract words. Present only one idea in each sentence.
- Use pictures and other visual aids to help communicate your meaning.
- Provide teaching materials in the client's language. If you cannot read it, have it translated so that you can judge its appropriateness.
- Avoid using humor; jokes often do not translate well because of connotations, jargon, and culture-specific context.

Feedback

- Obtain feedback carefully. Do not assume that a client who smiles, nods, and says yes really understands what you are teaching. The client may be embarrassed to ask questions or may feel that it will embarrass you.
- Encourage the client to ask questions; stop often to evaluate client understanding.

health. The following are some of the problems they encounter:

- Difficulty taking medication as prescribed (Berkman, Sheridan, Donahue, et al., 2011)
- Difficulty managing complex or chronic health problems (Osborn, Paasche-Orlow, Bailey, et al., 2011).
- Higher rates of ED visits, hospitalization, rehospitalization, and death (Mitchell, Sadikova, Jack, et al., 2012; Murray, Wu, Tu, et al., 2009).

Older adults, especially, are less likely to recall information after a clinic visit (Kessels, 2003).

Inability to read or write English is a growing problem in the United States with regard to health literacy. One in five do not speak English at home (Sarkar, Karter, Liu, et al., 2010). Patients with limited reading proficiency in English might not be able to grasp information in health-related brochures or printed discharge instructions. To enhance understanding between you and your patients, refer to Box 19-4, which presents tips for promoting health literacy.

Barriers to Teaching and Learning

As you gain experience in teaching, you will learn to recognize the factors we have just discussed (e.g., timing, the environment) and to manipulate those that can be changed to enhance the teaching and learning experience. At the same time, take care to avoid factors that act as outright barriers to teaching/learning In a traditional, on-site classroom, for example, transportation, class schedule, time, childcare, didactic-style instruction are a few of the barriers. The most common barriers to effective teaching are identified in Box 24-5.

When learning outside the traditional classroom, one of the highest rated problems is the lack of social interactions. Poor learner motivation, diverse learning styles, time issues, and technical problems also contribute to

BOX 19-4 ■ Promoting Health Literacy With Patients

- Ask questions that involve "how" and "what" rather than "yes" and "no".
- Assist patients in completing forms and/or health histories as needed.
- Organize information so the most important material stands out and is repeated for emphasis and clarity.
- Present information in three to five "chunks" at a time.
- Write out instructions and appointments using plain language while avoiding medical jargon and technical terms.
- For those with low health literacy, printed materials should have words with three or fewer syllables and sentences with fewer than 15 words. However, paragraphs made of short, simple sentences can make information too basic and therefore, may not accurately communicate complex information (Badarudeen & Sabharwal, 2010).
- Speak using simple words, short sentences, and structuring sentences with active rather than passive voice. For example, instead of saying, "The pill should be taken every 8 hours," say "Take the pill every 8 hours."
- Use as many drawings and photographs as possible to illustrate your statements.
- For those with Limited English Proficiency (LEP), provide information in primary language, use online or software translation tools, or seek an interpreter to translate.

BOX 19-5 ■ Barriers to Effective Teaching and Learning in the Healthcare Environment

Barriers for the Teacher

- Competing demands on the nurse's time
- Limited opportunity to prepare for teaching
- Conflicting schedules between the nurse's available time for teaching and patient's available time to learn (e.g., sleep, procedures, physical therapy)
- Lack of space and privacy
- Teaching not seen as a priority (either by the nurse or the organization)
- No third-party reimbursement for teaching
- Frustration with the amount of documentation needed
- Lack of coordination by various healthcare providers

Barriers for the Learner

- Illness, fatigue, and personal stress
- Physical condition
- Anxiety
- Low literacy
- A negative environmental influence
- Lack of time to learn
- Overwhelming amount of behavioral change needed
- Lack of support and ongoing positive reinforcement
- Lack of willingness to take responsibility
- The complexity of the healthcare system, which can lead to discouragement or abandonment
- Communication gap resulting from language barrier
- Teaching not adapted to the learner's preferences and learning style
- Provider who uses excessive jargon and technical terminology
- Lack of perceived need for the information taught

dissatisfaction with the online learning environment. Access to the Internet can be problematic for some people (Muilenburg & Bergeb, 2005). When deciding whether online learning is best suited to your learners, consider learners' technical and health literacy (Sarkar, Karter, Liu, et al., 2010). For more information about barriers to online learning,

Go to Chapter Resources, Chapter 19, **ESG Box 19-1, Barriers to Technology-based Learning Environment,** on Davis*Plus*.

KnowledgeCheck 19-3

- List and define six factors that affect the learning process.
- What is one strategy you could use to motivate a client who seems uninterested in learning?
- What are some aspects of the environment that can enhance or interfere with learning?
- What two strategies might you use with a learner functioning with low cognitive ability?

ThinkLike a Nurse 19-4

- List some actions you can take to avoid each of the barriers for the teacher.
- Give an example of each of the barriers to the learner. Take the example of stress of illness: A patient is frightened after having a heart attack, fearing death or serious, long-term impairment; worried about the cost of the medical treatment; and concerned about not being able to go to work. Therefore, he cannot concentrate on the health information you are presenting to him.

Note: These questions may be difficult, depending on your knowledge base and experience. Work with others to answer the questions, as necessary.

PracticalKnowledge knowing how

The teaching process parallels the nursing process. You will assess learning needs and readiness, make educational diagnoses, write learning objectives, plan and implement teaching strategies, and evaluate client learning. Effective client teaching begins with assessment of learning needs.

ASSESSMENT

A learning assessment will help you to determine the right setting for the teaching, the necessary content to cover, learning goals, and teaching strategies. Your initial assessment consists of general information about the amount of time and resources available for your teaching. Also be clear about your intended audience. For example, with Heather (Meet Your Patient) assess the following:

Learning Needs To understand her child's behaviors, Heather needs to learn about normal growth and development and nutritional needs of 4-year-olds. She will need safety and health instructions for the next year because her child may not return for another checkup until age 5.

Client's Knowledge Level You need to identify Heather's current expectations of her preschooler as well as her understanding of how the child has developed up to this point. You should also find out what Heather knows about preschooler nutrition and language development.

Health Beliefs and Practices Determine Heather's (and her daughter's) current healthcare practices as well as trust and investment in the healthcare system. For example, what kinds of meals does she offer the preschooler?

Physical Readiness Is Heather able to sit and listen to the information presented? You may need to provide appropriate play materials for her preschooler so that she will require less attention from her. Some interruptions are likely, because 4-year-olds have short attention spans.

Emotional Readiness In the case of Heather, emotional maturity is a factor in her readiness to learn. Heather has expressed concern that her child is so small, which offers you an opportunity to begin the teaching based on her interest in her child's progress and health. However, she may have trouble focusing on her responses to the care provider during the healthcare visit if her child is restless or if she has limited time for her appointment.

Ability to Learn During the interview, you can begin to assess Heather's ability to learn, based on her responses to questions. You can also ask about her educational level.

Literacy Level You might ask Heather to read a short statement or paragraph related to the topic you're teaching. Then ask questions to determine if Heather understood the printed information.

Neurosensory Factors By observing Heather's interactions with her preschooler, you can assess her vision, hearing, and manual dexterity. Observe her response to visual and auditory clues that are given by her child or healthcare providers. Watching her manipulate a pen, pencil, or toy could help you determine manual dexterity.

Learning Styles Ask Heather how she learns best. Understanding that she probably doesn't have extensive blocks of time or focused attention to read or listen, you might give her single-page handouts, videos, or pamphlets instead of books or more detailed booklets.

For guidelines and questions to ask when conducting a learning assessment,

Go to Chapter 19, **Assessment Guidelines and Tools, Learning Assessment Guidelines,** in Volume 2.

ANALYSIS/NURSING DIAGNOSIS

Deficient Knowledge is the most frequently used (and perhaps misused) nursing diagnosis for a teaching plan. It may be either a problem or the etiology of a problem.

Deficient Knowledge as the Primary Problem

Key Point: ***You should use Deficient Knowledge only if you believe that the lack of knowledge is the*** **primary** ***problem. Use it to describe conditions in which the "patient needs new, additional, or extensive knowledge.***

Identify the specific knowledge deficit as the problem, and follow with the etiology and related signs and symptoms. For example:

Deficient Knowledge (diabetic foot care) related to lack of prior experience, as manifested by anxiety and many questions about foot care

Deficient Knowledge as the Etiology

Deficient Knowledge is probably most useful as the etiology of other nursing diagnoses, such as the following:

- Ineffective Health Maintenance related to (r/t) Deficient Knowledge of immunizations
- Risk for Impaired Parenting r/t Deficient Knowledge of child developmental stages and needs for stimulation
- Ineffective Self-Health Management r/t Deficient Knowledge of the procedure for drawing up and injecting insulin
- Risk for Imbalanced Nutrition: Less Than Body Requirements r/t the pregnant woman's Deficient Knowledge about additional calories and nutrients needed during pregnancy and her fear of "getting fat"

Wellness Diagnoses

Teaching is the primary intervention for wellness diagnoses, such as Readiness for Enhanced Breastfeeding, Readiness for Enhanced Communication, and the almost 30 other NANDA-I labels beginning with the phrase "Readiness for Enhanced."

Incorrect Uses of Deficient Knowledge

Beware of routine or premature diagnosing. It is easy to see that a patient lacks information, label it as a Deficient Knowledge problem, and try to solve the problem by giving information—which may not be what the patient needs at all. Always look beyond the knowledge deficit to see what problematic *responses* it produces.

Do not use Deficient Knowledge routinely as a problem label for all patients (Jarrell, Alpers, & Wotring, 2011). There are information needs associated with almost every medical and nursing diagnosis. However, you cannot assume a particular patient needs to be taught that information. For example, a person with a foot ulcer secondary to long-standing diabetes may already know more than you do about foot care. For most nursing diagnoses (e.g., Anxiety, Imbalanced Nutrition), you can merely write a nursing order to provide the informal teaching needed instead of writing a Deficient Knowledge diagnosis.

Do not use Deficient Knowledge for problems involving the client's *ability to learn*. To accurately describe such situations, use non-NANDA-I diagnoses such as:

- Impaired Ability to Learn r/t fear and anxiety
- Impaired Ability to Learn r/t delayed cognitive development
- Lack of Motivation to Learn r/t feelings of powerlessness

PLANNING OUTCOMES

Before making a teaching plan, educators contract with the learner for what they want to accomplish together. **Contractual agreements** are statements of understanding between teacher and learner about how to achieve mutually set goals. The contract usually describes the responsibilities of both teacher and learner, time frame for the teaching, content to be included, and expectations of all participants. Learning contracts increase commitment by the learner to reach the teaching and behavioral goals. They are usually informal.

Teaching goals are broad in scope and set down what is expected as the final outcome of the teaching and learning process. They should address all three domains of learning. In contrast, **learning objectives** are single, specific, one-dimensional behaviors that must be completed to accomplish the goal. They are short term and ideally are accomplished in one or two sessions. Similar to patient outcomes in the nursing process, learning objectives/goals should include an action verb, an activity that can be measured or observed, the circumstances of the learner's performance, and how learning will be measured. For example:

Goal: Client will demonstrate ability to perform newborn care in 3 days.

Learning Objectives: (1) Client changes infant's diaper, making sure that umbilical cord remains outside the diaper. (2) Client demonstrates bathing baby while maintaining newborn's axillary temperature of greater than 98.5°F (36.9°C).

See Table 19-3 for examples of active verbs for each domain of learning. See Chapter 5 for a review of goals and outcomes.

NOC standardized outcomes for Deficient Knowledge depend on the content that needs to be taught. *Nursing Outcomes Classification (NOC)* (Moorhead, Johnson, Maas, et al., 2013) has identified more than 60 Health Knowledge outcomes for specific topics, for example, Knowledge: Diabetes Management and Knowledge: Infant Care.

Go to Chapter 19, **Standardized Language, NOC Outcomes for Health Knowledge,** on Davis*Plus*.

If you use Deficient Knowledge as the etiology of another diagnosis (e.g., Imbalanced Nutrition) then you would use NOC outcomes linked to that diagnosis (e.g., Knowledge: Diet, or Nutritional Status).

Individualized goals/outcome statements you might write for a client with a diagnosis of Deficient Knowledge include examples such as the following:

- For Deficient Knowledge (Breastfeeding): After demonstration and teaching, mother will position infant correctly at breast.
- For Deficient Knowledge (Child Physical Safety): After demonstration and explanation, parents will fasten preschooler safely and securely in infant car seat.
- For Deficient Knowledge (Diabetes Management): After reading pamphlets, client will explain the relationship of carbohydrate intake and exercise to blood sugar.

As you can see, choice of outcome is directly related to the area in which the client lacks knowledge or information.

The outcomes you choose depend on whether you have used Deficient Knowledge in the problem clause or the etiology clause of the nursing diagnosis. For example, if your nursing diagnosis for Heather (Meet Your Patient) was Deficient Knowledge (Preschooler Nutrition) related to lack of experience and family support, then one outcome might be, "Heather will plan nutritious meals for her child, based on the MyPlate recommendations." If, however, your diagnosis for the child was Risk for Impaired Nutrition: Less Than Body Requirements related to the mother's Deficient Knowledge about nutrition, then one outcome might be, "Preschooler will gain weight so that she is in at least the 10th percentile for weight by September of this year."

Table 19-3 ➤ Active Verbs for Domains of Learning

COGNITIVE DOMAIN	AFFECTIVE DOMAIN	PSYCHOMOTOR DOMAIN
Compare	Cry	Adapt
Define	Choose	Apply
Describe	Defend	Arrange
Design	Discuss	Assemble
Differentiate	Display	Begin
Explain	Form (e.g., an opinion)	Change
Give examples	Express	Construct
Identify	Give	Create
List	Help	Demonstrate
Name	Initiate	Draw up (e.g., medication)
Plan	Justify	Inject (e.g., medication)
State	Relate	Manipulate
Summarize	Revise	Move
	Select	Organize
	Share	Show
	Smile	Start
	State a feeling	Take
	Use	Work
	Value	

Think**Like a Nurse** 19-5

A client has just been diagnosed with diabetes mellitus. He must monitor and record his blood glucose three times a day. The two of you establish a goal that he will be able to perform glucose testing independently within 1 week. What objectives would you need to write to achieve this goal?

PLANNING INTERVENTIONS/IMPLEMENTATION

In Chapters 5 and 6, you learned about creating a nursing care plan. For clients and families with learning needs, you will create individualized teaching plans. The teaching plan is often one part of the client's complete nursing care plan. For an example, see the teaching plan at end of this chapter.

Creating Teaching Plans

The process of creating a teaching plan differs from that of creating a nursing care plan in two key ways. First, in a teaching plan, the interventions are actually teaching strategies. Second, when planning teaching, you will plan content, sequencing, and the types of instructional materials to be used.

Let's apply these aspects of a teaching plan, using the Heather (Meet Your Patient) scenario. You have assessed the need for anticipatory guidance regarding safety for her 4-year-old. Your nursing diagnosis is Deficient Knowledge (safety for a 4-year-old) related to the mother's inexperience.

Teaching Strategies are the method used to present content. For Heather, they might include one-to-one instruction and printed information. You must use plain language always. The Joint Commission (2007) recommends "teach back" and "show back" techniques to assess and ensure patient understanding. You may use drawings, models, or devices to demonstrate your teaching message. Build feedback points into the plan where you will encourage your patients to ask questions to avoid misunderstanding.

Content includes the information the learner must understand to reach the desired goal. It can include facts, skills, or emotions. For Heather, the content of your informal teaching might include the following:

- Poison control and prevention—Curiosity and lack of ability to understand danger puts the preschooler at greater risk.
- Accident prevention—This would include the need for car seats, increased supervision when exploring, and the use of a helmet when the child rides a tricycle.
- Risk of choking—Foods that are hard to swallow or chunky (e.g., hot dogs) are a concern for a 4-year-old.
- Need for immunizations and physical checkup during the next year.

Scheduling and Sequencing refer to how you organize the information, that is, in what order to present the topics. As a general rule, you should present simple before complex topics and nonthreatening topics before more controversial ones. You must also determine when the teaching session(s) should be scheduled based on the client's and teacher's needs. When extensive content is involved, it is best to schedule a teaching session in advance; the teacher and learner are then committed and prepared for the session. Using small amounts of time can be effective if teaching is brief and organized.

For example, you could teach Heather (Meet Your Patient) about poison control and accident prevention in the lobby while she and her preschooler are waiting for the child to be examined. During the child's examination, you could review immunizations and the need for an annual checkup. At the end of the examination, when discussing the child's nutrition, you might include a discussion of foods that are a choking hazard, such as a hot dog.

Instructional Materials are used to introduce information and reinforce learning. You might give Heather printed handouts about poison control (including the Poison Control Center [PCC] telephone number) and about accident prevention (e.g., how to properly install a child car seat). The child's immunization record would list current immunizations and the schedule for further immunizations may be printed on it. To involve the child, you might include a coloring book and stickers about one of the topics.

Patient Teaching

General Tips for Effective Patient Teaching

Create a conducive learning environment.

- **Provide private space to talk** with your patient and other designated family members. Be sure the setting allows for privacy and is free of distractions and interruptions.
- **Time the session when the patient is in the best state of mind to concentrate** on what you are saying. For example, you will want to be sure the patient has pain under control but is not drowsy from pain relievers. Anxiety, depression, and fatigue also interfere with learning.
- **Help your patient decide who should be involved in the teaching session.** Caregivers assisting in the care after discharge would benefit from the learning process. On the other hand, some patients may not want others to be present because of modesty or cultural practices.

Plan and communicate information according to your patient's needs.

- **Be considerate of cultural, religious, or other issues** that might influence the way your patient receives information.
- **Developmental delays or cognitive impairment can also hamper learning.** Adjust learning style and level of complexity accordingly. Likewise, modify teaching approach for those with visual or hearing deficits. Also, consider limited English proficiency when communicating with patients.
- **Find out what your patient needs to know before making a teaching plan.** Involve him in the learning process. This not only improves your patient's motivation to learn, but also helps your patient to get more out of the education.
- **Be sure you provide the vital information needed for home care.** As time, staffing, and resources are limited in the healthcare setting, decide what is most important and set that as priority teaching (Alsbaugh, n.d.).

Teaching Plan

Client Data

Emily O'Connor is the advanced practice nurse (APN) in charge of the student health center on campus at State University. A research project by one of her nursing students last semester revealed that 60% of students surveyed on campus reported they spent 300 minutes per week of moderate intensity exercise, which was consistent with a study examining compliance with the *Physical Activity Guidelines for Americans* (Tucker, Welk, & Beyler, 2011). However, researchers found 62% adherence by self-report but only 10% when measured via accelerometer. Thus, Emily decides to teach students and interested campus staff members about the importance of physical activity for physical and emotional well-being. To reinforce the content, Ms. O'Connor develops colorful brochures with photos and charts to make the information more visually appealing, and an interactive teaching session to capture learners' attention. She also provides food, so people will have additional motivation to attend.

Nursing Diagnosis

Possible Deficient Knowledge (health behaviors) about physical activity as evidenced by campus-wide survey results showing that less than two-thirds of students comply with the U.S. Department of Health and Human Services recommendation for physical activity.

NOC Outcome	NIC Intervention
Knowledge: Health Behavior (1805)	Teaching: Group (5604)

Teaching Environment

1. Provide an environment conducive to learning. Promote comfort by making personal introductions and offering refreshments during break time.

   Rationale: When adult learners are in an environment in which they feel comfortable, they are less distracted and more able to learn. Physical and emotional comfort of the participants is important for creating a positive atmosphere for adult learning. The environment influences a learner's interest level and actual motivation to acquire new knowledge (Edutopia, 2011).

Overall Strategy / Approach

1. Focus on real-world problems.
2. Emphasize application of content to everyday life.
3. Relate content to life experience.
4. Explain how the education will solve a problem.
5. Involve learners in the educational process.
6. Use a variety of methodologies.

   Rationale: Utilizes principles of adult learning. Using a variety of methodologies is important because different people learn in different ways.

Instructional Materials

1. Printed materials (brochures, fact sheets)

   Rationale: Print materials at an appropriate reading level (usually 6th to 7th grade) for the target audience allow participants to review information when it is convenient for them (U.S. Department of Health and Human Services, 2013). In a study looking at the effectiveness of five different types of media (print materials, online PDF, audio files, audio with text Web page, and streaming video demonstration) for improving patient's learning, findings show that although participants preferred multimedia presentations, patients retained information using supplementary materials regardless of form the content was presented in (Wilson, Makoul, Bojarski, et al., 2012).

2. Video (DVD) demonstrating types of exercises

   Rationale: In a study investigating the effectiveness of video for patient education, findings indicate patients using streaming video reported video as better than text for presenting health information (Hoffman, Salzman, Garbaccio, et al., 2011).

(continued)

Teaching Plan (continued)

3. Flash, streaming video, or other interactive multimedia (animation, narration, and text) on computer, to accompany PowerPoint slides

Rationale: In a study examining the effectiveness of streaming video on medical student learning, researchers found a positive effect on learning when it was used to complement other in-class methods and multimedia sources (Bridge, Jackson, & Robinson, 2009).

Learning Objective	Schedule / Sequence	Content	Teaching Strategy
By the end of the first educational session, participants will be able to explain why physical activity is important.	April 1–8	1. Determine date, time, and content of class to be held.	Advertise the educational session by using posters on campus, the campus newspaper, newsletter, social networking sites, school's web-calendar, and text and e-mail blasts.
	April 9 6:30–7:00 p.m.	2. Social hour. Healthy snacks and beverages. Get acquainted.	
	7:00–7:30 p.m.	3. Identify barriers to engaging in at least 300 minutes of moderate intensity or 150 minutes of vigorous intensity physical activity per week.	Lecture with PowerPoint slides, including photos
	7:30–7:50 p.m.	4. Describe how physical activity helps to promote health, prevent illness, control weight, and enhance overall quality of life.	Projected information (e.g., PowerPoint, YouTube)
	7:50–8:00 p.m.	5. Provide thorough instruction for proper technique for exercises to build strength, improve balance, and increase flexibility.	Live or videotaped demonstration of different types of exercises, with participant demonstration of techniques
	8:00–9:00 p.m.	6. Promote awareness and track activity recorded in fitness logs in follow-up contact with participants.	Questions and answers
		7. Provide access to group fitness classes at the local community center.	Handout printed passes or URL for downloading them from the community center's Web site, if available.

Rationale: Content is based on the Health Belief Model, designed by the U.S. Public Health Service. It identifies four key factors that promote health-seeking behavior (adapted for this setting): (1) Person perceives she is at risk for disease (low activity level). (2) Person perceives poor fitness is harmful and has serious consequences. (3) Person believes the suggested intervention (300 min/week of physical activity) will improve health and. (4) Person believes treatment (physical activity) effectiveness is worth overcoming barriers (Boston University School of Public Health, 2013).

Teaching Plan (continued)

Evaluation

Eighteen women and twenty men attended the session. When Emily O'Connor began the educational session, the participants were seated in chairs facing the front of the room, where the screen was set up for a YouTube video presentation. She distributed the printed handout materials and provided a short introduction. Before she began teaching, two women began talking about their battle with obesity and difficulty getting out to exercise. Three women shared stories about friends and family members who had suffered poor health and immobility. One had a question about sports-related injuries. During this discussion, the participants turned their chairs to face each other and talked among themselves.

Ms. O'Connor realized that learning takes place when participants share stories with facilitation by the group leader. Teaching does not have to be led exclusively by the facilitator. Even though she had a teaching plan, she was flexible enough to modify the plan to meet participants' needs. She turned off the PowerPoint, turned on the lights, and, instead of lecturing or showing videos from the CDC Web site, she shared information by answering questions and guiding the discussion.

During this process, Ms. O'Connor realized she had made assumptions about the participants' goals for this educational program and their educational needs. She learned that the women who attended came to the program with an understanding of the benefits of exercise and consequences of low levels of physical activity; they knew that exercise is important for health and fitness. They wanted to talk about their obstacles, concerns, and questions; they wanted to separate myths from facts; and they wanted to learn proper technique and how they could maintain motivation to perform at least 300 min/week of moderate intensity physical activity

After the session, Ms. O'Connor realized that she needed to revise her plan and offer a second session in a week or two. Her assumption that a lack of knowledge was responsible for the low number of people adhering to the Physical Activity Guidelines for Americans was not confirmed by discussion with the participants. She developed new goals for the second session:

1. By the end of the educational intervention, participants will:
   a. State that questions pertaining to weekly physical fitness have been addressed.
   b. Identify the factors that act as a barrier to engaging in physical activity.
   c. Share strategies for overcoming barriers to engaging in physical activity.
   d. Suggest at least five ways to perform at least 300 minutes of moderate intensity physical activity per week.
   e. List steps to follow if an injury occurs while engaging in physical activity
2. At the 1-year follow-up visit, participants will report that they increased physical activity by 60 minutes per week during the last 12 months.

References

Boston University School of Public Health. (2013); Edutopia (2011); Tucker, Welk, & Beyler (2011; U.S. Department of Health and Human Services (2013); Wilson, Makoul, Bojarski, et al. (2012).

Selecting NIC Interventions

NIC standardized interventions related to patient learning depend on the nursing diagnoses you have identified. The *Nursing Interventions Classification (NIC)* (Bulechek, Butcher, Dochterman, et al., 2013) lists 30 patient education interventions from which to choose, depending on the content being taught. An example is Health Education and Teaching: Disease Process. To see the entire list,

Go to Chapter 19, **Standardized Language, NIC Interventions for Patient Education,** on Davis*Plus*.

Selecting Specific Teaching Strategies

Several different types of teaching strategies are currently available. Before selecting one, consider the learner's differences, needs, learning style, and advantages and disadvantages of each method. For a comparison of advantages and disadvantages of each of the teaching formats discussed following, see Table 19-4. For more information about other teaching strategies, such as audiovisual materials, simulation, role-playing, self-instruction, distance learning, computer assisted instruction, online coursework, gaming, case method, and concept mapping,

Go to Chapter 19, **Supplemental Materials, General Teaching Strategies,** on Davis*Plus*.

The nurse may reinforce material taught by various methods by asking, "What questions do you have?" However, when asking "Do you understand?" some patients are likely to answer "yes" out of embarrassment or a need to cooperate.

Key Point: ***A patient's lack of questions does not necessarily mean that she understands what's been taught; it could in fact mean the opposite (Dickens & Piano, 2013).***

Demonstration and Return Demonstration

In this method, the teacher explains and demonstrates a skill or task. The learner then demonstrates comprehension by returning the demonstration. Return demonstrations should be scheduled close to the initial teaching of the skill. This format allows for targeted questions and answers and practical matters, rather than theory. This method requires the demonstrator to have specialized expertise if highly technical tasks are involved. Mannequins are being used more and more in clinical teaching (Fig. 19-3).

One-to-One Instruction and Mentoring

In one-to-one instruction, generally one teacher presents information to an individual learner. They mutually formulate objectives at the beginning of the session. Often the learner receives printed or audiovisual materials to reinforce the information presented. As a nurse, you will often use this method for patient teaching. Mentoring involves a more personal interaction between teacher and learner, involving not only the exchange of information but also role modeling and problem-solving. It offers an opportunity to directly observe and offer feedback on the learner's performance. Mentoring often involves learners in a clinical practice.

FIGURE 19-3 Simulation mannequins can offer realism and relevance to the educational experience.

Printed Materials

Printed materials may be available in the form of fact sheets, discharge instructions, printed pamphlets, or detailed booklets. When teaching children, you might use age-appropriate printed books, coloring books, and activity books with mazes and other games. To be sure the clients understand the information, you must provide an opportunity for them to ask questions after they have read the materials. You will usually use printed materials to supplement other teaching strategies.

When you are creating your own teaching materials, remember the tips for ensuring readability in the Health Literacy section of this chapter (see Box 19-4). Many standard word processing programs allow you to check the reading level of materials you create. However, keep in mind that health-related information often contains medical terminology, which tends to have more syllables. Reading levels computed based on the syllable count can falsely indicate a higher-grade for reading level than what is reflected predominantly in the document. Figure 19-4 is an example of a patient teaching fact sheet written at the level of grade 6.8.

Include specific step-by-step actions you want them to take. Avoid abstract words in the instructions. Be sure the materials do not contain jargon, abbreviations, or acronyms, as readers might not be familiar with these. Create printed materials in an easy-to-read font (e.g., Arial, Helvetica, Times Roman). Active voice and action verbs are clearer than the passive form. To reinforce what you want patients to remember, phrase directions positively (e.g., say "do" rather than "don't" or "never").

Provide your clients with a take-home summary of the main points you want them most to remember after the teaching session. Having something clients can put their hands on to refer to at a later time can be invaluable for reinforcing important information.

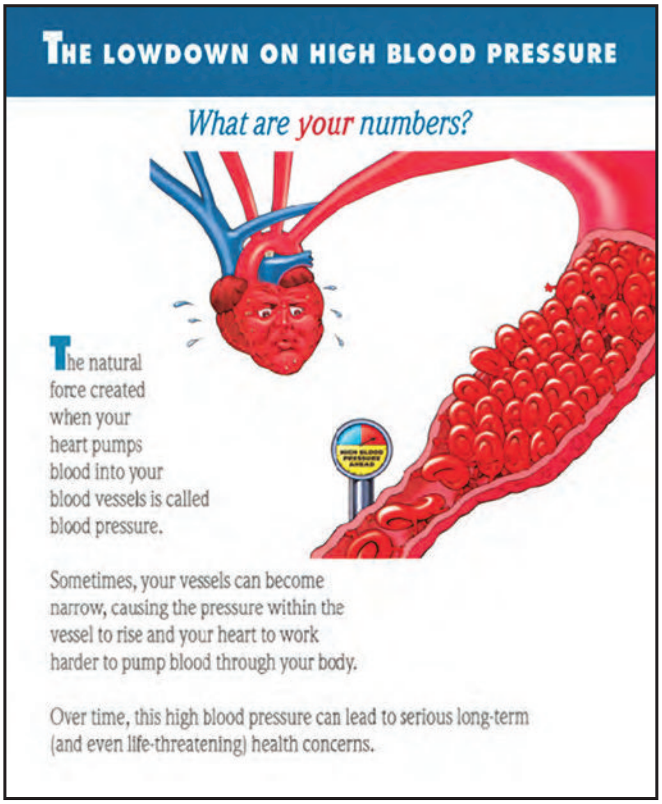

FIGURE 19-4 Reading level of this patient teaching aid is grade 6.8.

Role Modeling

In role modeling, the instructor teaches by example, demonstrating the behaviors and/or attitudes that learners should adopt. Role modeling is even more effective when the teaching point corresponds with the role model's action. Role modeling is integral to mentoring relationships in which students or patients learn by seeing, hearing, and doing. Be aware that learning occurs unconsciously as well as intentionally. Therefore, you must consider what you are communicating. Role models must connect the learning to the objectives. Role modeling is more successful when the teaching point is made apparent to learners during the learning experience.

Many experienced pediatric nurses find that role modeling using a puppet or a child's own doll or stuffed animal can be helpful in reducing the child's anxiety and enhancing the child's learning. For instance, you can suggest that the child be "the nurse" and "feel Miss Bunny's pulse," or have a puppet "suggest" to a child, "When I get a shot, I say, 'Ouch!' real loud, and then it's all over!"

Digital Sources of Information

Learners can obtain extensive information and support geared toward the lay public as well as healthcare professionals via the Internet through electronic mailing lists and credible Web sites (e.g., Centers for Disease Control and Prevention [CDC], the Joanna Briggs Institute [Best Practice], Hartford Geriatric Nursing Initiative). Electronic learning platforms offer education through multimedia, search engines, electronic libraries, content portals, and social networking sites and blogs. Learners can connect with others in similar situations through electronic mailing lists, which are online communities sharing a common focus or interest. Through blogs, electronic mailing lists, and other threaded discussions, participants exchange information; express opinions; offer support; inquire about topics of interest to the greater community; promote special interests; and network with others for personal or professional intent.

Mobile technology with applications (apps) for smartphones, tablet computers, and electronic book readers offers learners convenient access to a variety of engaging learning tools and gaming opportunities. For example, smartphone and tablet apps are designed with customizable medication reminders, rewards systems for healthy behaviors, and educational components.

Quality and Safety Education for Nurses

Teaching Clients Through Collaborative Partnership

Chapter Key Concepts: *Teaching, Learning*

Competency: *Patient-Centered Care; Teamwork and Collaboration (Knowledge, skills, attitudes)**

Background Often patients with chronic illnesses or multiple comorbidities have learning needs related to their medical conditions. Successfully attending to the learning needs of patients requires the nurse to actively engage and empower the patient. Collaboration with the patient as a full partner in care empowers the patient and potentially improves health outcomes (Hain & Sandy, 2013). Effective patient teaching should increase patient knowledge and should facilitate health decision-making by the patient. In order to effectively teach patients, one must utilize a patient-centered, collaborative approach. Collaboration requires the nurse to engage the patient in the entire teaching/learning process, establish a partnership with the patient as the core member of the healthcare team, and empower the patient to make informed health decisions.

Think about it: Using a patient-centered, collaborative approach, what should be your first step in order to teach effectively?

- Discuss how you would engage the patient in the teaching/learning process.
- Discuss how patient partnership and empowerment has the potential to change health behaviors.
- Describe how you would arrive at the desired outcomes for a teaching/learning session?

Reference: Hain, D., & Sandy, D. (2013).
*For specific Knowledge, Skills, and Attitudes,

Go to the QSEN Web site at **http://qsen.org/competencies/pre-licensure-ksas/**

Audiovisual materials (e.g., streaming video or Flash format, computer animations, audio clips online or per CD/DVD, film, slides, or computer-generated material) can be effective supplements to other methods, especially if the teaching session is followed by a question-and-answer session, a discussion of the content, a test, or printed materials to expand understanding.

Lecture

Lecture is a traditional method in which one or more presenters orally share information while learners listen. It can be enhanced by including discussion and question-and-answer periods for clarifying content and by use of computer-projected slide presentation, streaming video, flip charts, transparencies, posters, brochures, models, and other audiovisual formats. Teachers can engage learners with an attention-getting opening and by supporting teaching points with stories, quotes, images, analogies or metaphors, and humor.

Group Discussion

In a group discussion, several participants discuss topics, exchanging information and presenting their points of view. The teacher acts as a facilitator to achieve objectives shared with the group at the beginning of the session. Effective group discussion requires an atmosphere of trust that encourages everyone to participate. Openness to new ideas and confidentiality of the content expressed are essential for participation. One type of group discussion is *brainstorming*, which is a process for generating multiple ideas for solving a problem. Participants suggest a maximum number of ideas and consider a wide array of creative ideas; then they analyze options, identify a best solution, and develop a plan of action.

KnowledgeCheck 19-4

- True or false: When a patient has a learning disability, you should use a non-NANDA-I diagnosis (e.g., Impaired Ability to Learn) to describe the problem.
- True or false: Learning objectives are short term and ideally should be accomplished in one or two teaching sessions.
- List and state the advantages and disadvantages of at least six teaching strategies.

EVALUATION OF LEARNING

As with all nursing interventions, evaluation is central to the educational process—that is, patient learning is an outcome that is achieved or not. Evaluation of the effectiveness of the teaching plan is essential to improving the quality of instruction. You should evaluate the entire nursing

Toward Evidence-Based Practice

Free, C., Phillips, G., Galli, L., et al. (2013). The effectiveness of mobile-health technology-based health behavior change or disease management interventions for health care consumers: A systematic review. *PLoS, 10*, e1001363. Retrieved August 14, 2013, from http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3548655/

A rigorous scientific review of 75 controlled trials examined the effectiveness of mobile technology for healthcare consumers.

- Text messaging improved education adherence for low-income patients receiving antiretroviral therapy as well as for a smoking cessation group in a high-income setting. Text messaging also showed short-term benefit in glucose management as well as physical activity and psychological support for patients with diabetes. Attendance for vaccination was increased with text reminders and information.
- PDA-based education also increased scores for confidence in self-care for patients with lung transplantation.

Deniard-Thompson, N. R., Steven, S. S., & Wofford, J. L. (2012). iPod technology for teaching patients about anticoagulation: A pilot study of mobile computer-assisted patient education. *Primary Health Care Research and Development, 13*(1), 42–47. doi: 10.1017/S146342361100034X

Researchers interested in knowing whether education modules using a handheld, multimedia computer (iPod) are beneficial for office-based patient education found the mobile devices to be a practical and sustainable strategy. Ninety percent of subjects reported the content, audio, and visual display as high in quality. More patients preferred the educational experience using the mobile technology as compared with print materials. The iPod method also standardized the educational content, improved clinic efficiency, and contributed to higher numbers of patients receiving patient education. None of the equipment was lost, stolen, or broken during the study period.

1. In the first article discussing mobile technology for patient education and compliance, why do you think text messaging for conveying health information and reminders was more effective for patient teaching than traditional methods?

2. Based on the results of the second study, why do you think mobile devices might be an effective method of instruction for office- or clinic-based healthcare or even inpatient care?

3. Have you experienced use of tablet computer from your healthcare provider as part of your own patient education? Was it beneficial to you for learning new information or reinforcing information you received prior to your visit? Why or why not?

Go to Chapter 19, **Toward Evidence-Based Practice Suggested Responses,** on Davis*Plus*.

process (as you may recall from Chapter 7). Was your assessment adequate, or did you fail to notice that the patient was physically uncomfortable and therefore not ready to learn? Was your nursing diagnosis accurate? Were your learning objectives realistic? When evaluating the teaching, consider the type of strategy you used, the timing of the teaching, the content, the amount of information, and the teaching materials. The client is your best source for feedback. He can tell you whether the materials and methods were helpful, or uninteresting, and so on.

Table 19-4 ➤ Formats for Patient Teaching: Advantages and Disadvantages

Advantages	Limitations
Lecture	
Advantages. An efficient and cost-effective way to impart information, especially to large groups. Is useful for conveying basic concepts and information that serve as the foundation for higher-level, critical thinking later. The presenter can use media-rich formats within the lecture in order to reach learners with auditory and visual learning styles. Lectures may be recorded for future use.	***Limitations*** ■ Does not allow for individualization of teaching. ■ Passive-learning technique that for most learners is not suited for optimal retention of information. ■ May not be geared to the level of the learner. ■ Not effective for teaching in the psychomotor or affective domains. ■ Can lead to oversaturation if too much information is presented in too short a time frame. ■ Boredom is common. ■ Not a good strategy for promoting critical thinking. ■ Little opportunity for assessment of learner comprehension.
Group Discussion	
Advantages. A learner-centered and effective method for teaching in the affective and cognitive domains. Many students enjoy a learning environment with opportunities for interaction with peers. Social involvement can enhance content.	***Limitations*** ■ Less effective with large groups. ■ The teacher must be comfortable with less structure and with unpredictable learner responses. ■ Managing group discussion requires good leadership skills of the instructor. ■ Group discussion is not well suited for teaching in the psychomotor domain. ■ The quality of group work can be negatively affected by "group think"—a force that stifles creativity by succumbing to the subtle pressure of agreeing with the group even though affirmation doesn't reflect the learner's individual opinion. ■ Brainstorming fails when participants are distracted or fail to contribute ideas because of fears of rejection or ridicule by peers. Some might even hold back with brainstorming when anticipating the ideas to be unpopular with the instructor. Individuals who dominate can be equally problematic when crowding out less confident participants. Those who are disruptive or intentionally sabotage the activity can interfere in successful group discussion.
Demonstration and Return Demonstration	
Advantages. Is most effective in teaching psychomotor skills (e.g., use of equipment, self-injection, dressing changes). It can be used in small groups if enough equipment is available. When the task or skill is performed correctly, return demonstration can increase self-confidence.	***Limitation.*** ■ Does not work well with large groups or for those who do not learn best by observing others. ■ May not be well suited for participants who learn at different rates; some might need repeated demonstration or slow enactment of steps, while others do not. ■ Time consuming and labor intensive. ■ Involves preparation time to set up equipment. ■ Space must be suitable for the demonstration format.

(continued)

Table 19-4 ➤ Formats for Patient Teaching: Advantages and Disadvantages—cont'd

One-to-One Instruction and Mentoring	
Advantages. Gives the teacher the opportunity to establish a relationship with a learner; convey interest in his learning needs; and tailor the teaching to the learner's needs as the session proceeds. Mentoring allows reluctant learners to more readily ask questions. It enables the teacher to obtain frequent feedback so that material can be repeated and clarified as needed. The method is useful for teaching in all three domains: affective, psychomotor, and cognitive. It provides an opportunity for learners to build skills and problem-solve in situations with expert supervision, guidance, and feedback.	***Limitations*** ▪ Can be labor intensive and reaches the fewest numbers of learners. ▪ May be overwhelming to learners because of the large quantity of information given in a short period of time, and therefore may not promote retention. ▪ One-on-one instruction tends to isolate the learner from others who may share the same learning needs and who could provide support. ▪ Can be hampered by personality conflicts. ▪ Relies heavily on the instructor, preceptor, or nurse being a good role model and having effective teaching skills.
Printed Materials	
Advantages. Allows for standardized information to be presented to each client, but with some room for individualization. Hard-copy documents are an excellent way to reinforce material taught in lecture, demonstration and return demonstration, or one-to-one instruction. Handouts allow the teacher to cover just the main ideas while using the time more efficiently for face-to-face instruction. Printed materials are portable, so people can read the information when it most convenient.	***Limitations*** ▪ Assumes literacy, motivation to read the content, organization to keep track of materials, and visual acuity to decipher the print. ▪ Materials must be written at a 5th grade reading level with words that most people understand.
Role Modeling	
Advantages. Allows the learner to identify with the teacher. It can be a subtle but powerful method to increase motivation and ability to perform a desired behavior. It tends to generate high learner interest, and doesn't usually require additional preparation on the part of the role model.	***Limitations*** ▪ Learners need to be aware and receptive to this type of teaching. ▪ A role model who does not effectively represent desired behaviors can send the wrong message.
Online Sources of Information	
Advantages. The Internet makes a vast amount of information readily available. The easily available health-related information makes it possible for consumers to participate in self-care and make informed decisions. Patients feel empowered when they have access to relevant and understandable information. They often cope better and experience less uncertainty when health information is available. Using audiovisual materials is a stimulating method because it engages both sight and hearing, and can accommodate large groups.	***Limitations*** ▪ The teacher has little control over the quality of information learners access via the Internet. Before recommending particular Web sites to a patient, you need to read it yourself to be sure the information is accurate and the format and reading level are best suited to your patient. See Chapter 41 for information about evaluating materials you obtain from a Web site. ▪ Audiovisual hardware and software can be expensive and must be replaced when they become outdated.

The following methods are commonly used for outcomes evaluation (client learning):

- *Oral questions/interviews/questionnaires/checklists* allow clients to evaluate their own progress and determine future learning needs. You may obtain more information by talking with the client; however, you may obtain more honest responses by using written questions and providing for anonymous completion of the evaluations.
- *Direct observations of client performance* are anecdotal, descriptive notes that you make of the learner's performance. They will help you in providing feedback to the client either to reinforce accurate learning or to

correct misinformation. Provide feedback as soon as possible after you observe performance.

- *Reports and client records.* Clients and/or families can keep records of performance and results. You can then evaluate the data and give feedback accordingly. Documentation of performance is best when following criteria or other clear expectations. You can make plans for further teaching when you analyze the data and determine the learners' knowledge deficits.
- *Tests, checklists, and written exercises* can be used to measure retention and progress toward meeting cognitive objectives. This method requires the learner to be actively involved and have adequate literacy skills.

Clients will not remember everything you teach them. That is normal. If you start to question your effectiveness as a teacher, think about one of the courses you took last semester. Did you score 100% on every test? How much of the material presented in that course do you remember now? Repetition, reinforcement, and practice are necessary for retention; and so is information made memorable.

Documentation of Teaching and Learning

As is true for all nursing interventions (as you learned in Chapter 18), it is important to record the responses of the client and family to teaching interventions. Documentation also provides legal evidence that teaching was done and communicates the information to other health professionals. Write objective statements about what was taught and the client skills and behaviors that demonstrate learning. For informal teaching that occurs during other care activities, you may simply record in the nursing notes. For planned teaching that is provided frequently for a particular population of clients, many agencies provide special documentation forms. For an example of a patient education record,

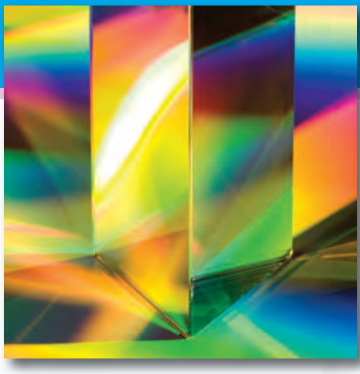
CHAPTER 20



Measuring Vital Signs

Learning Outcomes

After completing this chapter, you should be able to:

- Describe the physiological processes involved in regulating body temperature, pulse, respirations, and blood pressure.
- Convert between the Fahrenheit and centigrade temperature scales.
- For different patient situations, choose the best procedure for measuring temperature, pulse, respiration, and blood pressure, including site and equipment.
- Discuss the concept of a "normal" temperature.
- Describe nursing interventions for the patient with temperature alterations.
- Given a client's age, differentiate between normal vital signs findings and those that should be referred to the primary healthcare provider.
- State at least one nursing diagnosis that might be used to describe a problem for each of the vital signs: temperature, pulse, respirations, and blood pressure.
- Define *arterial oxygen saturation*, *hypoxia*, *hyperventilation*, and *hypoventilation*.
- Discuss nursing interventions for the client with impaired respiratory status.
- State the normal temperature, pulse, respiration, and blood pressure ranges for the average adult.
- Explain why it is important to interpret a client's blood pressure pattern rather than relying on a single reading.
- Discuss the importance of cuff size when obtaining a blood pressure reading.
- Define *hypotension*, *hypertension*, *essential hypertension*, and *secondary hypertension*.
- Identify nursing interventions for the client with hypertension.
- Demonstrate correct technique for measuring temperature, pulse, respiration, and blood pressure.

Key Concepts

Vital signs
Thermoregulation
Perfusion (pulse, blood pressure)
Oxygenation (respirations)

Related Concepts

Hypothermia
Hypertension
Hypotension

Meet Your Patients

Your instructor has scheduled a clinical day at a local community health fair for students to answer health-related questions, administer flu vaccines, check blood sugar levels, and take vital signs: temperature, pulse, respirations, and blood pressure. You have been asked to check vital signs.

Jason. The first person who arrives at the booth is Rosemary, a young mother, with Jason, her 2-year-old son. She tells you he has been eating poorly and is very irritable. The child's skin is warm and dry and he is flushed. Rosemary explains that she does not have a thermometer, and she would like you to take her son's temperature. Jason's axillary temperature is 101.8°F (38.8°C).

Now it is time to think like a nurse! What could this temperature reading mean? What, if any, additional data should you collect? How will you explain your findings to Rosemary? What action would you advise Rosemary to take? You may not yet have all the theoretical knowledge you need to answer these questions, but try to do so anyway, based on your present knowledge base and your life experiences.

Ms. Sharma. The next person to arrive at the booth is Ms. Sharma, an active 80-year-old woman who works part-time in a local literacy program and walks 3 miles four times per week. Ms. Sharma notes that she has "lost a little pep. I don't feel sick, but I'm tired lately." Her pulse is difficult to feel. The rhythm is irregular, and the strength of the pulse is uneven—some beats are strong, while others are weak. What might this finding mean? What questions do you have for Ms. Sharma? What, if any, additional data should you collect? How will you explain your findings to Ms. Sharma? What action would you advise her to take?

Mr. Jackson. As Mr. Jackson sits down next to you, you notice he is short of breath. His respiratory rate is 28 breaths/min, and he appears to be struggling to breathe. What do you think this respiratory rate means? What should be your next action? What would you say to Mr. Jackson?

Lucas. The next client to arrive is Lucas, a 35-year-old accountant who works for a firm in a nearby office building. Lucas tells you he has been under a lot of stress and is worried about his blood pressure. You measure his blood pressure as 150/98 mm Hg. Is this an acceptable blood pressure? What does this reading mean? What should you discuss with Lucas? What advice should you offer?

You will gain the theoretical knowledge you need to answer the preceding questions as you work through this chapter and learn more about vital signs.

ABOUT THE KEY CONCEPTS

All of the content in this chapter pertains to the concept of **vital signs**. The key concepts of **thermoregulation, perfusion,** and **oxygenation** pertain to specific vital signs you will learn about (temperature, pulse, respirations, and blood pressure). A grasp of these underlying concepts will help you understand and remember the rationale for what you do when measuring vital signs.

WHAT ARE VITAL SIGNS?

The term **vital signs (VS)** suggests assessment of vital or critical physiological functions. Variations in temperature (T), pulse (P), respirations (P), or blood pressure (BP) are indicators of a person's state of health and function of the body systems. Therefore, these four measurements are among the most frequent assessments you will make as a nurse. Because of their importance, your accurate measurements and documentation of each vital sign is a top priority.

Do not become complacent when a client's vital signs are within normal limits. Although stable vital signs *indicate* physiological well-being, they do not *guarantee* it. Vital signs alone are limited in detecting some important physiological changes; for example, vital signs may sometimes remain stable even when there is moderately large blood loss. Evaluate the vital signs in the context of your overall assessment of the client.

Other Vital Signs Some experts have recommended that other factors that affect patient care and outcomes be added to the four traditional measures of physiological status, for example:

- *Pain* is widely regarded as the fifth vital sign. See Chapter 31.
- *Oxygen saturation* obtained by pulse oximetry provides important information on arterial blood oxygen concentration.
- *Smoking status* has been assessed by some providers as a VS during the initial patient encounter (Lockwood & Conroy-Hiller, 2004; Rothemich, Woolf, Johnson,

et al., 2008), although it does not fit with the traditional concept.

- *Emotional distress* is recommended by some as a vital sign.

Rather than being overly concerned about whether or not these parameters should be referred to as vital signs, we recommend that nurses include them in all of their ongoing assessments of patients: temperature, pulse, and respirations (TPR); blood pressure (BP); pain; pulse oximetry; emotional status; and (on initial encounter) smoking status.

The rest of this chapter explains the meaning of each of the traditional vital signs and how to assess them.

When Should I Measure a Patient's Vital Signs?

In the Meet Your Patients scenario, clients asked you to take their vital signs. However, in many clinical settings you and other care providers will determine how often to measure and document VS. The following are common occasions for assessing vital signs:

- On admission to the hospital
- For inpatients, at the beginning of a shift
- At a visit to the healthcare provider's office or clinic
- Before, during, and after surgery or certain procedures
- To monitor the effects of certain medications or activities
- Whenever the patient's condition changes

The optimal frequency for assessing vital signs depends on the patient's condition and the events taking place (Schulman & Staul, 2010). Also, agency policies usually require that nurses monitor and record vital signs regularly. The frequency varies by setting. Below are commonly used frequencies. However, one recent study suggests that low-risk patients might be allowed to rest instead of waking them up for routine vital signs during the night (Jordan, Yoder, Yuen, et al., 2013).

- In the hospital: once every 4 to 8 hours
- In the home health setting: at each visit
- In the clinic: at each visit
- In skilled nursing facilities, also known as convalescent hospitals: weekly to monthly

It is up to the nurse to decide whether vital signs need to be monitored more frequently than the primary care provider has prescribed. Initially, you will measure VS to establish the patient's baseline.

Key Point: ***A baseline is important because (1) a change in vital signs may be caused by a disease state, the effect of therapies, or merely by changes in activity and environment; and (2) there are normal variations in vital signs among individuals.***

Table 20-1 shows average or normal findings for adults, but it is important to remember that each person has his or her own baseline for "normal." If a patient's vital signs vary from established norms, compare the finding to that person's baseline to determine the degree and severity of the variation. When a client's VS vary from their baseline, you should assess and document them more frequently, perhaps every 5 to 15 minutes. As a beginning practitioner, you should validate your clinical assessments with a more experienced nurse.

Table 20-1 ➤ Vital Signs: Average Normal Findings for Adults

Mean Adult Temperature	
Oral	98°F (36.7°C)*
Rectal	98.6°F (37°C)*
Pulse	
Normal range	60–100 beats/min
Average	80 beats/min
Respirations	
Normal range	12–20 breaths/min
Blood Pressure	
Normal range	100–119 systolic and 60–80 diastolic
Prehypertensive	120–139 systolic and 80–89 diastolic
Average	110/70 (the middle of the "normal" range) (Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure, 2004)

*This is revised downward from the traditional norms to reflect more recent research (Mackowiak, Wasserman, & Levine, 1998) and a systematic review of the literature (Sund-Levander, Forsberg, & Wahren, 2002). The systematic review reported the following mean normal temperatures: Oral 97.3°F (36.3°C), Rectal 98.3°F (36.9°C). The traditional Wunderlich (1871) average normal temperature is 98.6°F (37.0°C) to 99.5°F (37.5°C), depending on measurement site.

How Do I Document Vital Signs?

Most agencies have special flowsheets for documenting vital signs. If the VS are not within normal limits, you will also record them in the nurses' notes, along with any associated symptoms (e.g., cyanosis [blue-gray skin] with abnormal respirations). Nurses are required to take appropriate actions based on their assessment finding. Therefore, you must document your interventions as well (e.g., elevating the head of the bed when the patient has shortness of breath). For an example of a graphic flowsheet for documenting vital signs,

Go to Chapter 20, **Forms,** in Volume 2.

BODY TEMPERATURE

Body temperature is the degree of heat maintained by the body. It is the difference between heat produced by the body and heat lost to the environment.

Theoretical Knowledge knowing why

Although the focus in this chapter is on body temperature, you must understand the concept of "thermoregulation" to assess and support regulation of body temperature at a professional level. You will learn the normal temperature range, how heat is produced by and lost from the body, and factors that influence body temperature.

What Is a Normal Temperature?

No single number can be considered "normal," because body temperature varies among individuals as a result of differences in metabolism. Furthermore, each person's temperature fluctuates with age, exercise, and environmental conditions. However, the body does function optimally within a narrow temperature range.

There is little definitive evidence about what, exactly, is a normal temperature. You may see different values in the many sources you read. We can at least conclude that the traditional belief of 98.6°F (37°C) for an average normal reading is too high, based on available research. A systematic review of the literature found a mean normal oral temperature of 97.3°F (36.3°C) (Sund-Levander, Forsberg, & Wahren, 2002). See Table 20-1. Research findings are inconsistent as to whether older adults have lower body temperatures (Lu & Dai, 2009) and recommend that body temperature be evaluated based on individual variability (Sund-Levander, Grodzinsky, Loyd, et al., 2004).

Pregnant women run higher baseline body temperatures. For age-related variations for all vital signs, including temperature,

Chapter Resources: Chapter 20, **Tables, Boxes, Figures: ESG Table 20-1, Comparison of Normal Vital Signs for Various Ages,** on Davis*Plus*.

An adult's normal internal temperature, called the **core temperature**, ranges from about 97°F to 100.8°F (36.1°C to 38.2°C). Most research and clinical practice situations do not report core body temperature because it is not convenient to measure. The core temperature is typically 1°F to 2°F (0.6°C to 1.2°C) higher than surface (skin) temperature. Rectal and tympanic membrane measurements are used to represent core temperatures; oral and axillary measurements reflect surface temperatures.

Temporary, slight variations of temperature above or below normal usually are not significant. Greater variations indicate a disturbance of function in some system or region of the body (Fig. 20-1). However, the degree of temperature elevation does not always indicate the seriousness of the underlying disease or condition. For example, some acute, even fatal, infections may cause only a mild temperature elevation. However, a continuous elevation, even if slight, is cause for concern and indicates a need for further evaluation.

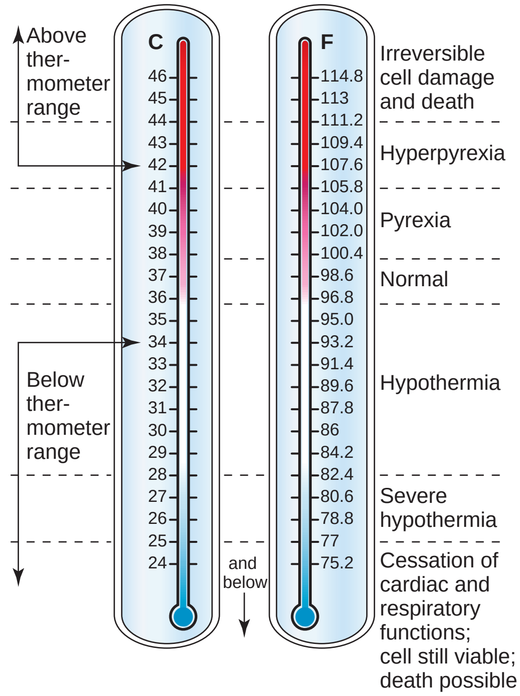

FIGURE 20-1 Ranges of normal and altered body temperatures.

What Is Thermoregulation?

Thermoregulation is the process of maintaining a stable temperature. To keep the body temperature constant, the body must balance heat production and heat loss. This balance is controlled by the hypothalamus, located between the cerebral hemispheres of the brain. Similar to a thermostat, the hypothalamus recognizes even small changes in body temperature that are sent to it by sensory receptors in the skin.

Decreasing the Body Temperature When heat sensors in the hypothalamus are stimulated, they send out impulses to reduce the body temperature. This activates compensatory mechanisms, such as peripheral vasodilation, sweating, and inhibition of heat production. **Vasodilation** (increase in the diameter of the blood vessels) diverts core-warmed blood to the body surface, where heat can be transferred to the surrounding environment.

Increasing the Body Temperature When the sensors in the hypothalamus detect cold, they send out impulses to increase heat production and reduce heat loss. To produce heat, the body responds with shivering and the release of epinephrine, which increases metabolism. To reduce heat loss, the blood vessels constrict. **Vasoconstriction** (narrowing of the blood vessels) conserves heat by shunting blood away from the periphery (where heat is lost) to the core of the body, where the blood is warmed. **Piloerection** (hairs standing on end) also occurs, but it is not an important heat-conserving mechanism in humans.

Behavioral Control of Temperature In addition, body temperature is under our behavioral control. When people feel cool, they can turn up the thermostat, put on more clothing, or move to a warmer place. When they feel too warm, they can turn on an air conditioner, remove some clothing, or take a cool shower.

How Is Heat Produced in the Body?

The body produces heat through the interaction of three factors: metabolism, the movement of skeletal muscles, and nonshivering thermogenesis.

Metabolism

Metabolism is the sum of all physical and chemical processes and changes that take place in the body. Metabolism uses energy and generates heat. The **basal metabolic rate (BMR)** is the amount of energy required to maintain the body at rest. Body size, lean muscle mass, and numerous hormones influence BMR. For example, hyperthyroidism (an increase in the thyroid hormone **thyroxine**) increases the BMR. Clients with hyperthyroidism often complain of feeling warm even when in a cool environment. By contrast, when the thyroxine level is low (hypothyroidism), less heat is produced, and clients commonly report feeling cold. Epinephrine and norepinephrine, produced from stimulation of the sympathetic nervous system, also increase BMR and heat production.

Skeletal Muscle Movement

Skeletal muscles are used in all body movements. Muscles need fuel to function. The breakdown (**catabolism**) of fats and carbohydrates in muscle produces energy and heat. It requires very little muscle activity to sit and read this text. However, if you were to go for a run, you would use more skeletal muscles. After your run, your body temperature would be higher, perhaps as high as 101°F to 104°F (38.3°C to 40°C). In contrast, if you were to go outside without a coat when the temperature was 35°F (1.6°C), you would begin to feel cold. Your hypothalamus would sense a drop in body temperature and you would begin shivering. This mechanism is so efficient that body heat production can rise to about four times the normal rate in just a few minutes.

Nonshivering Thermogenesis

Nonshivering thermogenesis is the metabolism of brown fat to produce heat. It is used by infants because they cannot produce heat through shivering, as do adults and children. This mechanism disappears in the first few months after birth.

How Is Heat Exchanged Between the Body and the Environment?

Heat moves from an area of higher to an area of lower temperature; that is, cool air and objects "pick up" heat from warmer ones. The mechanisms that affect the exchange of heat between the body and the environment are radiation, convection, evaporation, and conduction (Fig. 20-2).

Radiation is the loss of heat through electromagnetic waves emitting from surfaces that are warmer than the surrounding air. If the uncovered skin is warmer than the air, the body loses heat through the skin. This is why a cool room warms by radiation when it is filled with many people. In contrast, a person can acquire heat by turning on a heat lamp or being in the sunlight. Radiation accounts for almost 50% of body heat loss.

Convection is the transfer of heat through currents of air or water. Nurses use this principle to intentionally effect changes in a patient's body temperature. Immersion in a warm bath may raise body temperature for a hypothermic client. In contrast, the currents of cool air produced by a fan can help reduce a fever. Together, the processes of convection and conduction account for approximately 15% to 20% of all heat loss to the environment.

Evaporation occurs when water is converted to vapor and lost from the skin (as perspiration) or the mucous membranes (through the breath). Evaporation causes cooling. Water loss by evaporation is called **insensible loss.** Evaporation is affected by the relative **humidity** (moisture in the environment). If the air already contains much humidity, then less moisture evaporates from the skin and less cooling occurs.

Conduction is the process whereby heat is transferred from a warm to a cool surface by direct contact. Suppose that a patient's temperature is 98.6°F (37°C) while he is fully dressed in the examination room. If he dresses in a thin, hospital gown and lies on a cool metal radiology table, his temperature will drop, perhaps as much as a full degree Fahrenheit in the first hour.

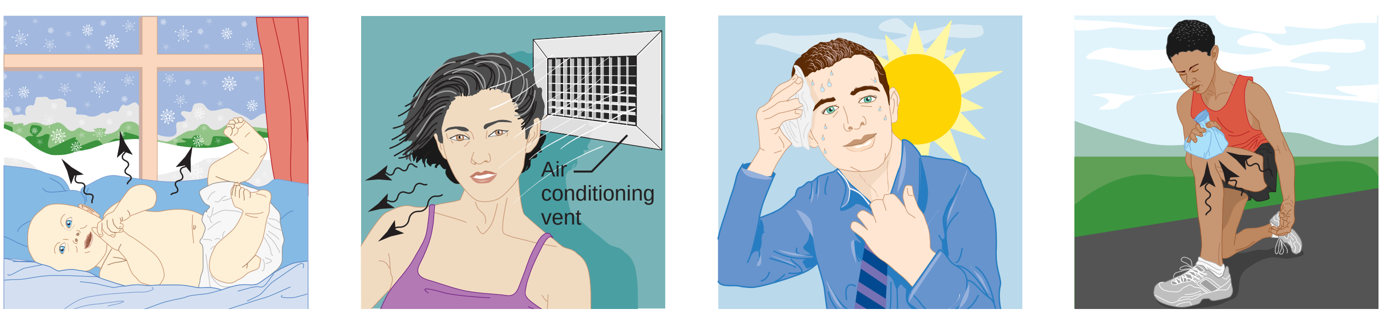

FIGURE 20-2 Mechanisms of heat exchange with the environment: Radiation, convection, evaporation, and conduction.

What Factors Influence Body Temperature?

The following are some examples of internal and external factors involved in the delicate balance of body temperature:

Developmental Level Infants and older adults are most susceptible to the effects of environmental temperature extremes. Infants lose approximately 30% of their body heat through the head, which is proportionally larger than the rest of the body compared to adults. This places them at increased risk for decreased body temperature. Body temperature begins to stabilize during early childhood and remains relatively stable until older adulthood.

Older adults have difficulty maintaining body heat because of slower metabolism, decreased vasomotor control, and loss of subcutaneous tissue. In a recent study, older adults (age 85 years and older) had mean body temperatures lower than 98.6°F (37°C) (Lu & Dai, 2009). Temperatures ranged from 94°F (34.4°C) to 99.6°F (37.6°C), but few ever reached 98.6°F (Gomolin, Aung, Wolf-Klein, et al., 2005). You can think of the average normal temperature for older adults as about 95°F to 96.8°F (35°C to 36°C).

For a comparison of normal VS for various ages,

Go to Chapter Resources: Chapter 20, **Tables, Boxes, Figures: ESG Table 20-1,** on Davis*Plus*.

Environment The environment strongly influences body temperature. For example, warm room temperatures, high humidity, or hot baths can increase body temperature. Very high external temperatures can significantly increase internal temperatures, causing heat stroke. In contrast, cold environments, especially with strong air currents, can lower body temperatures and, in severe cases, lead to hypothermia.

Gender A woman's body temperature varies (as much as 1°F, or 0.6°C) with her menstrual cycle and pregnancy. Body temperature is lower when progesterone levels are low and increases as progesterone levels increase. Hormonal fluctuations during menopause, when menses stop, often cause temperature fluctuations commonly known as *hot flashes,* which can produce episodes of intense body heat and sweating. Research studies have found differences in the range of normal body temperatures for women and men (Lu & Dai, 2009; Sund-Levander, Forsberg, & Wahren, 2002).

Exercise Because it increases metabolism, hard work or strenuous exercise can increase body core temperature to 101°F to 104°F (38.3°C to 40°C). The sweat that is produced during exercise evaporates and helps to cool the body.

Emotions and Stress Emotional stress, excitement, anxiety, and nervousness stimulate the sympathetic nervous system, causing production of epinephrine and norepinephrine. These biochemical agents trigger an increase in the metabolic rate, which in turn increases body temperature.

Circadian Rhythm **Circadian rhythm** is a cyclical repetition of certain physiological processes (e.g., changes in temperature and blood pressure) that occurs every 24 hours. Temperature fluctuates 1°F to 2°F (0.6°C to 1.2°C) over the course of 24 hours. It is usually lowest in the early morning hours and highest in late afternoon or early evening.

ThinkLike a Nurse 20-1

- You notice the following temperature readings in your client's medical records:
  0400: 97.4°F
  0800: 97.9°F
  1200: 98.4°F
  1600: 99.6°F
  2000: 100.9°F

When you assess the client's temperature at midnight, it is 101.2°F. What do you notice about the pattern of the temperature readings?

- What is important in this scenario?
- As a nursing student, what should you do?

KnowledgeCheck 20-1

- Which age groups are most susceptible to thermoregulation problems, and why?
- List five factors that affect body temperature.
- What are the compensatory mechanisms for decreasing body temperature?
- What are the compensatory mechanisms for increasing body temperature?

Example Problem: Fever (Pyrexia)

Fever, or **pyrexia**, is a temperature above the person's usual range of normal. Traditionally we have thought of fever as an oral temperature higher than 100°F (37.8°C), or a rectal temperature of 101°F (38.3°C) in an adult. But remember that many people, especially older adults, have lower normal body temperatures and that a person's normal body temperature changes by as much as 1°F (0.6°C) throughout the day. So it follows that many people, especially older adults, experience fever at a temperature lower than our traditional definition. A person with a fever is said to be **febrile**; one without fever is **afebrile**. A single high reading may not indicate fever. You need several readings at different times of the day, as well as the person's usual normal reading.

A moderate fever (up to 103°F, or 39.5°C) may be uncomfortable, and it may signal an underlying problem (e.g., influenza or other infection). However, the fever itself does not pose a threat to most clients and is the body's natural defense against infection. Higher fevers can damage body cells and cause delirium and seizures. **Hyperpyrexia** is fever above 105.8°F (41.0°C). Hyperpyrexia is dangerous and requires intervention.

Fever occurs in response to **pyrogens** (fever-producing substances). When bacteria or other foreign substances invade the body, they stimulate **phagocytes** (specialized white blood cells), which ingest the invaders and secrete pyrogens (e.g., interleukin-1). Pyrogens induce secretion of **prostaglandins** (substances that reset the hypothalamic thermostat at a higher temperature). The reset value is called the **set point**. The body's heat-regulating mechanisms then act to bring the core temperature up to this new setting. When the stressor is removed, the set point resets at normal.

Fever occurs in three phases:

1. ***The initial phase (febrile episode or onset):*** The period during which body temperature is rising but has not yet reached the new set point. The onset of fever may be sudden or gradual, depending on the condition causing it. The person usually feels chilly and generally uncomfortable and may shiver.
2. ***The second phase (course):*** The period during which body temperature reaches its maximum (set point) and remains fairly constant at the new higher level. The person is flushed and feels warm and dry during this phase, which may last from a few days to a few weeks.
3. ***The third phase (defervescence or crisis):*** The period during which the temperature returns to normal. The person feels warm and appears flushed in response to vasodilation. Diaphoresis occurs, which assists with heat loss by evaporation. This phase is commonly referred to as the fever's "breaking."

The following are four important ways to describe a fever:

- **Intermittent fever:** Temperature alternates regularly between periods of fever and periods of normal or below-normal temperature without pharmacological intervention; or the temperature returns to normal at least once every 24 hours.
- **Remittent fever:** Fluctuations in temperature (greater than 3.6°F, or 2°C), all above normal, during a 24-hour period.
- **Constant (sustained) fever:** Temperature may fluctuate slightly (less than 1°F, or 0.55°C) but is always above normal.
- **Relapsing (or recurrent) fever:** Short periods of fever alternating with periods of normal temperatures, each lasting 1 to 2 days.

At some time in your life, you most likely have taken acetaminophen (Tylenol) or ibuprofen (Advil, Motrin) for a fever. Can you think of a reason it may or may not always be a good idea to do that at the first signs of a fever? Why should you think carefully before administering **antipyretic** (fever-reducing) medications to a client?

The answer is that fever, up to a point, is beneficial (for most people). High temperatures (up to 102.2°F, or 39°C) enhance the immune response because they (1) kill or inhibit the growth of many microorganisms, (2) enhance phagocytosis, (3) cause the breakdown of lysosomes and self-destruction of virally infected cells, and (4) cause the release of interferon, a substance that protects cells from viral infection.

This does not mean that you should *never* administer, or take, antipyretic medications. They may be needed to promote comfort and keep the temperature from becoming dangerously high. Temperatures of 105.8°F (41.0°C) and above can damage cells throughout the body, especially in the brain, causing agitation, confusion, stupor, or coma. Vascular collapse may follow, producing cerebral edema, shock, and death. Death usually results if body temperature becomes higher than 109°F to 112°F (43°C to 44°C) (McCance & Huether, 2010). Note that certain patients (e.g., those with epilepsy) are especially sensitive to even slight temperature elevations, so antipyretics might be used at the first sign of temperature elevation.

Example Problem: Hyperthermia (Heat Exhaustion, Heat Stroke)

Hyperthermia, like hyperpyrexia (fever), is a body temperature above normal. However, in hyperthermia, the elevated body temperature is higher than the set point. The hypothalamic regulation of body temperature is overwhelmed and does not reset the set point as it does in fever. Hyperthermia occurs because the body cannot promote heat loss fast enough to balance heat production or high environmental temperatures. **Heat exhaustion** and **heat stroke** are common examples. With overexposure to high temperatures and inadequate fluid replacement, the body loses its ability to sweat and is unable to cool down.

Heat Exhaustion may occur with a core temperature of 98.6°F (37°C) to 103°F (39.4°C). Warning signs of heat exhaustion vary, but may include weakness, nausea, vomiting, syncope, tachycardia, tachypnea, muscle aches, headache, diaphoresis (heavy sweating), and flushed skin.

Heat Stroke occurs when the body's temperature regulation fails, usually when the hyperthermia progresses to a temperature above 103°F (39.4°C). Symptoms include rapid, strong pulse; throbbing headache; delirium; confusion; impaired judgment; lethargy; red, hot, dry skin; dizziness; seizures; and coma. The body is unable to sweat. Temperatures of 106°F (41.1°C) and higher may be reached. If emergency treatment is not given, heat stroke can result in permanent disability and death (Centers for Disease Control and Prevention [CDC], 2010b).

Example Problem: Hypothermia

The CDC (2010a) defines **hypothermia** as an abnormally low core temperature, less than 95°F (less than 35°C). You must know the person's usual normal range of temperature because some people, especially older adults, have a normal temperature of less than 95°F. As the body temperature drops, metabolic processes slow. Prolonged exposure to the cold is no longer correctable by shivering and may prove fatal (CDC, 2010a).

Hypothermia may be associated with surgery, extreme weather conditions, immersion in cold water, or lack of shelter and clothing. Hypothermia is sometimes deliberately induced under close monitoring to decrease the need for oxygen in body tissues (e.g., during cardiac or neurological surgery).

- **Early signs of hypothermia** include shivering, cyanosis of lips and fingers, and poor coordination. The person first feels cold, then may feel some pain in the extremities. As body temperature continues to fall, the person experiences mental impairment, confusion, disorientation, slowing of the heart rate and respirations, and inability to take precautions from the cold.
- **Severe hypothermia** occurs when the body temperature drops below 82.4°F (28°C). The person becomes unconscious and stops shivering. The pulse and respirations are irregular and difficult to detect. Although survival has been known to occur at a core temperature of 60.8°F (16°C), death usually results when body temperature falls below 70°F to 75°F (21°C to 24°C).

PracticalKnowledge knowing how

Now that you understand the concept of thermoregulation, you are ready to gain the practical knowledge of how to assess and support a patient's body temperature.

ASSESSMENT

In our daily routines, we commonly assess temperature by touch. For example, when you remove a blanket from a warming unit, you can feel that it is warm; however, you probably could not pinpoint the exact temperature of the blanket. The same is true of body temperature. Although some research has shown that people can use simple touch to detect fever, they cannot differentiate *degrees* of fever. Because vital signs are used as indicators of a client's health status, it is essential to have an accurate measure. To see the sequence of steps to take when measuring a patient's temperature,

Go to **Procedure 20-1: Assessing Body Temperature,** in Volume 2.

The Home Care section of Procedure 20-1, in Volume 2, will assist you in teaching clients how to check their temperature at home.

Temperature Measurement Scales: Fahrenheit and Centigrade

Two scales are used for recording temperature: Fahrenheit and centigrade (or Celsius), a metric scale. Most people in the United States are familiar with the Fahrenheit scale; however, some healthcare agencies use centigrade. Electronic and tympanic membrane thermometers can usually measure temperature in either scale; often all you need to do is to flip a switch. Some types of thermometers may read only one scale (Fig. 20-3 shows both scales, for comparison), so you may need to convert a reading from one scale to the other. For example, you may have obtained a centigrade reading for a child and plan to explain its significance to the mother, who is familiar only with Fahrenheit. For a chart to use to convert between Fahrenheit and centigrade readings,

Go to Chapter 20, **Centigrade–Fahrenheit Conversion Chart,** in Volume 2.

You will probably have access to a conversion chart in clinical settings, but if not you may need to convert mathematically. To convert from Fahrenheit to centigrade, subtract 32 from the Fahrenheit temperature and multiply by $\frac{5}{9}$. For example:

A client has a temperature of 102°F. What is his temperature as measured in centigrade?

$$(102 - 32) \times \tfrac{5}{9} = (70 \times 5) \div 9 = 39°C$$

To convert a centigrade reading to Fahrenheit, multiply the centigrade temperature by $\frac{9}{5}$, and add 32. As a cross-check we can verify the preceding example:

Client temperature = 39°C

$$(39 \times \tfrac{9}{5}) + 32 = (351 \div 5) + 32 = 102°F$$

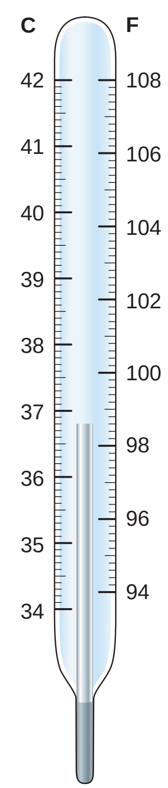

FIGURE 20-3 Thermometers are available with degree markings in Fahrenheit or centigrade. *Left,* Centigrade scale. *Right,* Fahrenheit scale.

Highlights of Procedures 20-1 through 20-6

For steps to follow in *all* procedures, refer to the Universal Steps for All Procedures found on the inside back cover of Volume 2. Go to the full procedures in Volume 2 to practice and learn the procedure steps. Use these procedure highlights later to help you review key points.

Procedure 20-1: Assessing Body Temperature

- Clean thermometer before and after using if it is not disposable.
- Select the appropriate site and thermometer type.
- Turn on or otherwise ready the thermometer.
- Insert the thermometer in its sheath, or use a thermometer designated only for the patient.
- Insert and leave an electronic thermometer in place until it beeps; for other thermometers use the recommended times.
- Cleanse and store in recharging base (store glass thermometers safely to prevent breakage).
- For an oral temperature, obtain a reading 20 to 30 minutes after the patient consumes hot or cold food or fluids or smokes.
- Hold a rectal thermometer securely in place, and never leave it unattended.

Procedure 20-2: Assessing Peripheral Pulses

- Make sure the client is resting while you assess the pulse.
- Count for 15 or 30 seconds if the pulse is regular; count for 60 seconds if it is irregular.
- Note pulse rate, rhythm, and quality.
- Compare pulses bilaterally.

Procedure 20-3: Assessing the Apical Pulse

- Position the patient supine or sitting.
- Palpate and place the stethoscope at the 5th intercostal space at the midclavicular line.
- Count for 60 seconds.
- Note pulse rate, rhythm, and quality and the S_1 and S_2 heart sounds.

Procedure 20-4: Assessing for an Apical-Radial Pulse Deficit

- Palpate and place stethoscope over apex of the heart.
- Palpate the radial pulse.
- Have two nurses carry out the procedure, if possible.
- Count for 60 seconds, simultaneously.
- Compare the pulse rate at both sites; calculate the difference.

Procedure 20-5: Assessing Respirations

- Count unobtrusively (e.g., while palpating the radial pulse).
- Count for 30 seconds if respirations are regular; count for 60 seconds if they are irregular.
- Observe the rate, rhythm, and depth of respirations.

Procedure 20-6: Measuring Blood Pressure

- If possible, place the patient in a sitting position, with the feet on the floor and the legs uncrossed.
- Measure BP after the patient has been inactive for 5 minutes.
- Support the patient's arm at the level of the heart.
- Use a cuff of the appropriate size.
- Wrap the cuff snugly.
- Inflate the cuff while palpating the artery. Inflate to 30 mm Hg above the point at which you can no longer feel the artery pulsating.
- Place the stethoscope on the artery, and release pressure at 2 to 3 mm Hg per second.
- Record systolic/diastolic pressures (first and last sounds heard—e.g., 110/80).
- Wait at least 2 minutes before remeasuring.

What Equipment Do I Need?

Nurses measure temperature with various kinds of thermometers. Each type has advantages and disadvantages, shown in Table 20-2, so you need to think critically about the type of thermometer best suited for each patient situation.

Glass Thermometers

Historically, the thermometer was a glass mercury-filled tube marked in degrees Fahrenheit or centigrade and read visually. Researchers at Children's Hospital Boston found that children under 4 years suffered broken glass to the mouth or rectum, exposure to mercury, and/or required imaging to detect foreign objects in the body associated with the use of glass thermometers (Aprahamian, Lee, Shannon, et al., 2009). Because of such dangers, the U.S. Environmental Protection Agency and the American Hospital Association now advise against use of equipment containing mercury (U.S. Environmental Protection Agency [EPA], 2012).

Many healthcare facilities have replaced glass thermometers with electronic digital thermometers or with glass or plastic thermometers containing other liquids, such as alcohol or gallium–indium–tin (galinstan). However, you may find some patients still using them at home.

Electronic Thermometers are rechargeable units consisting of an electronic probe attached to a portable unit by a thin wire. A beep sounds when the peak temperature is reached. Disposable plastic sheaths are used to cover the probe. To prevent transmission of infection, you discard the sheath after each use. Most units have a separate probe for rectal and oral temperatures, color-coded red and blue, respectively, to be certain the correct probe is used.

Electronic Infrared Thermometers are rechargeable units that contain a sensor that detects heat in the form of infrared energy given off by the body, for example, at the tympanic membrane or at the temporal artery. The thermometer does not actually touch the tympanic membrane. A beep sounds when the peak temperature is reached.

Disposable Chemical Thermometers are a thin plastic strip, patch, or tape containing a matrix of chemicals that produce color changes at a designated body temperature. Most are used once for an oral or axillary reading, and then discarded. Another form consists of temperature-sensitive tape containing liquid crystals that change color in response to temperature. The tape is

Table 20-2 ➤ Advantages and Disadvantages of Various Thermometers

ADVANTAGES	DISADVANTAGES
Glass Thermometer	
 ▪ Flexibility of use: Can be used for measuring oral, rectal, or axillary temperature. ▪ Inexpensive initial cost ▪ Accuracy, as indicated by several studies ▪ Easily disinfected	Do not use glass thermometers containing mercury. If you find one, recommend that it be replaced immediately. Avoid using glass thermometers when possible; some patients do still use them at home. ▪ Easily broken, so there is ongoing cost of replacement and risk for injury ▪ Slow: It takes 3–8 min to obtain an accurate reading, depending on the site. ▪ Difficult for some people to read accurately
Electronic Thermometer	
 ▪ Flexibility of use: Can be used for measuring oral, rectal, or axillary temperature. ▪ Ease of use ▪ Rapid measurement: It takes 2–60 sec to obtain reading, depending on the unit.	▪ Expensive initial cost ▪ Requires regular inspection and maintenance to ensure accuracy. ▪ Data are conflicting regarding their accuracy compared to other types of thermometer. ▪ Need to be kept charged.

(continued)

Table 20-2 ➤ Advantages and Disadvantages of Various Thermometers—cont'd

ADVANTAGES	DISADVANTAGES
Electronic With Infrared Sensor	
 A, Temporal scanner ■ Ease of use ■ Rapid measurement: It takes 2–5 sec to measure the temperature. ■ May be the most cost-effective method because of time and labor savings from their rapid reading capabilities. ■ Low rate of operator error	 B, Otic thermometer ■ Expensive initial cost. ■ Less accurate than electronic or glass/plastic thermometers when used for tympanic membrane temperatures, as some studies indicate. ■ Requires regular inspection and maintenance to ensure accuracy. ■ Batteries require recharging.
Disposable Chemical Thermometer	
 ■ Ease of use; requires no special training. ■ Equally as accurate as the electronic thermometer. ■ Less expensive than purchasing supplies for and maintaining an electronic thermometer. ■ Because it is disposable, it may prevent spread of infection among patients. ■ Recommended for measuring axillary temperature among pediatric patients over the age of 2 years (Cincinnati Children's Hospital Medical Center, 2011).	 ■ Less reliable than glass or plastic thermometers. ■ The skin must be dry. ■ Indicates only body surface temperature; does not reflect core. ■ Guidelines presently recommend only for pediatric patients.

applied to the skin of the forehead or abdomen and left for a time specified by the manufacturer (e.g., 15 seconds). Recent guidelines conclude that measurements done on children are as accurate as those done with electronic thermometers (Cincinnati Children's Hospital Medical Center, 2011). However, there is conflicting research regarding the accuracy of the temperature readings with disposal chemical thermometers (Barnason, Williams, & Proehl, 2012; Farnell, Maxwell, Tan, et al., 2005; Washington & Matney, 2008). Disposable thermometers are useful in the home and for patients in protective isolation.

Other Types of Thermometers For special uses, devices have been created to take measurements from the nasopharynx, the pulmonary artery, the bladder, and the skin. A wireless intestinal temperature monitoring system in the form of a pill and an external receiver is sometimes used, for example, during cardiac surgery. Infrared devices have also been used to take thermal measurements of skin surface temperature.

What Sites Should I Use?

Temperatures in the pulmonary artery, esophagus, and bladder accurately measure core temperature. These sites are used in surgery and intensive care, but they are invasive, expensive, and impractical for most clinical settings. Pulmonary artery temperature is considered the "gold standard" to which other sites are compared. A device is placed in the pulmonary artery, and readings are continuously displayed on a monitor.

The usual sites for intermittent measurements are the mouth, rectum, axillae, tympanic membrane, and skin over the temporal artery. These sites allow the thermometer to contact body tissues that are well supplied with blood vessels. This is essential for accurate measurement. Each site has advantages and disadvantages, so you must choose the safest, most accurate, and most reliable site for each client (Table 20-3).

Temperature readings vary depending on the site used. Be aware that research on site differences is conflicting, for example:

- Temporal artery temperature is usually about the same as rectal temperature (Hebbar, Fortenberry, Rogers, et al., 2005).
- Some researchers report tympanic membrane temperatures to be higher than oral measurements (Fadzil, Choon, & Arumugam, 2010); however, others have found them to be similar.

From lowest to highest readings, the sites are generally thought to be as follows: axillary, oral, tympanic membrane, rectal, and temporal artery. For oral, axillary, and rectal temperatures, there is an approximately 0.8°F or 0.4°C difference between each site and the next higher one. For convenience, nurses tend to round the fraction up to a full 1°F (0.5°C). For example, an axillary temperature of 98.1°F is similar to an oral reading of 99.1°F or a rectal reading of 100.1°F. Use this *only* to help you understand your patient's data. You cannot reliably convert temperatures mathematically between sites. When you measure a temperature, record the value you obtain and the site used.

ThinkLike a Nurse 20-2

- Convert the following temperatures and analyze the readings. What might they mean?
  a. 38.5°C ________ °F
  b. 96.5°F ________ °C
  c. 37.0°C ________ °F
- Rank the expected early evening temperatures of the following individuals from lowest to highest.
  a. A 22-year-old college athlete
  b. A 5-year-old kindergarten student
  c. An 88-year-old nursing home resident

ANALYSIS/NURSING DIAGNOSIS

Fever and hypothermia may be medical diagnoses, nursing diagnoses, or symptoms of other problems. The following nursing diagnoses may be used when they describe a *client problem* and not just a symptom of an illness or other problem (e.g., fever may be a symptom of problems such as Deficient Fluid Volume, or dehydration). Notice that the nursing diagnosis of Hyperthermia can be used both for temperature elevation from fever (hyperpyrexia) and from heat exhaustion (hyperthermia).

- *Hyperthermia* is diagnosed when a person's body temperature is above normal. Defining characteristics are convulsions, flushed skin, tachycardia, tachypnea, and warmth to touch.
- *Hypothermia* is diagnosed when a person's body temperature is below normal range. Defining characteristics include cool skin, cyanotic nailbeds, elevated blood pressure, pallor, piloerection, shivering, slow capillary refill, and tachycardia.
- *Ineffective Thermoregulation* applies when a person's temperature fluctuates above and below the normal range.
- *Risk for Imbalanced Body Temperature* is used when the temperature is normal but the client is at risk for failure to maintain body temperature within the normal range (e.g., newborns and the frail elderly). As you can see, this diagnosis can also apply to risk for either hypothermia or fever.

PLANNING OUTCOMES/EVALUATION

Associated NOC standardized outcomes for NANDA-I diagnoses pertaining to body temperature include the following: Thermoregulation, Thermoregulation: Newborn, and Vital Signs. For other NOC outcomes you might use for alterations in temperature regulation,

Go to Chapter Resources: Chapter 20, **Standardized Language,** on Davis*Plus.*

Individualized goals/outcome statements you might write for a client with Hyperthermia include the following:

- Oral temperature of less than 97.6°F (less than 36.4°C) (client's usual normal temperature)
- No clinical signs of fever present (e.g., no chills or flushing)
- Pulse and respiratory rates within normal range for patient

For a client with Hypothermia, the following are examples of goal statements:

- Oral temperature greater than 97.6°F (greater than 36.4°C) (client's usual normal temperature)
- No clinical signs of Hypothermia present (e.g., no disorientation, no decrease in urine output)
- Pulse and respiratory rates within normal range

Use the goals set in the planning outcomes stage to evaluate client responses to interventions.

PLANNING INTERVENTIONS/IMPLEMENTATION

Overall care of the patient depends on the cause of the fever or hypothermia, and on specific orders from the primary provider. Nevertheless, there are nursing interventions and activities that address fever and hypothermia, regardless of the cause.

Interventions for Example Problem: Hyperthermia

NIC standardized interventions for Hyperthermia and Ineffective Thermoregulation include Fever Treatment, Malignant Hyperthermia Precautions, Newborn Care,

Table 20-3 ➤ Disadvantages and Contraindications of Various Sites for Measuring Temperature

ADVANTAGES	DISADVANTAGES	CONTRAINDICATIONS
Temporal Artery		
▪ Most accurate representation of core temperature. ▪ Fast. Most scanners provide a reading in about 3 sec. ▪ No discomfort is associated with the procedure. ▪ Safe. Can be used even for those who cannot follow instructions (e.g., infants). ▪ Less prone to error than tympanic thermometer.	▪ Requires special scanning thermometer. ▪ Any covering, hat, hair, etc., prevents heat from dissipating and causes the reading to be falsely high. This is also true for the side of the head lying on a pillow.	
Rectal		
▪ Accurately represents core (internal) body temperature. ▪ Use for clients who are unable to follow directions for oral temperature monitoring, or in situations where accuracy is crucial.	▪ Most clients find this method objectionable or embarrassing. ▪ Not recommended as the first choice of site because of the risk for injury to the rectal mucosa, especially infants. ▪ Requires special positioning of the client. ▪ Does not reflect changes in core temperature as rapidly as the oral method. ▪ Presence of stool may cause inaccurate reading.	▪ Clients who may be injured by this method (e.g., clients who have a rectal disease, severe diarrhea, or rectal surgery; newborns, whose rectal mucosa is fragile). ▪ Because it can slow the heart rate by stimulating the vagus nerve, this method is sometimes contraindicated for clients with cardiac surgery and some heart conditions. ▪ Clients with hemorrhoids. ▪ Immunosuppressed clients or those with clotting disorders.
Oral		
▪ Simple, convenient. ▪ Comfortable for most patients. ▪ Safe for adults and children who are old enough to follow simple directions .	▪ Glass thermometers can break if bitten. ▪ Slow; requires up to 8 min to ensure an accurate reading (if glass or plastic thermometer used). ▪ Patient must keep her mouth closed for several minutes (glass or plastic thermometers). ▪ Eating, drinking (e.g., ice water, hot tea), and smoking in the 30 minutes before measurement affect the accuracy of the reading. ▪ Bradypnea may create false temperature elevations.	▪ Clients who cannot cooperate with the instructions or who might be injured (e.g., infants and small children; patients who have had oral surgery, breathe through the mouth, have chills, or are confused or unconscious). When possible, avoid using a glass thermometer for all patients.
Axillary		
▪ Safe ▪ Easy to use ▪ Can be used for children and for uncooperative or unconscious clients.	▪ Not reflective of core temperature ▪ Considered one of the least accurate sites. ▪ Diaphoresis (sweating) can affect the reading.	▪ Clients who are perspiring heavily ▪ Does not accurately diagnose fever. If fever is suspected, confirm with measurement from another route.

Table 20-3 ➤ Disadvantages and Contraindications of Various Sites for Measuring Temperature—cont'd

ADVANTAGES	DISADVANTAGES	CONTRAINDICATIONS
▪ Recommended over rectal site for routine measurements.	▪ Thermometer may need to be left in place for a long time (8 minutes if glass or plastic is used).	
Tympanic Membrane		
▪ Fast (2–5 sec). ▪ Can be used for children and for uncooperative or unconscious clients.	▪ Requires a special thermometer, a relatively expensive initial purchase. ▪ More variable than oral and rectal sites. ▪ Must be carefully positioned to ensure accuracy; prone to caregiver measurement errors. ▪ Presence of cerumen (earwax) may affect accuracy. ▪ Significant differences have been found between readings in left and right ear of same patient. ▪ Risk of injury to tympanic membrane if not positioned carefully to avoid touching it. ▪ May be uncomfortable for the client. ▪ Chemical thermometers (skin temperatures) have been found to be more accurate and reliable than tympanic membrane instruments. ▪ Hearing aids must be removed.	▪ Clients who have had recent ear surgery. ▪ Contraindicated in the presence of ear infection.
Skin (e.g., forehead)		
▪ Safe, convenient. ▪ Easy to use for nonprofessionals. ▪ Can be used when other sites are contraindicated. ▪ Inexpensive (chemical paper or tape is used).	▪ Forehead skin temperature is generally 2–4°F (1–2°C) less than core temperature; if marked deviations in skin temperatures are detected, the readings must be confirmed via a more reliable route.	▪ Should not be used when accurate, reliable readings are required (e.g., in the presence of hypothermia or heatstroke). ▪ However, at least one study has shown skin temperatures to be accurate and reliable when obtained with an infrared skin thermometer (DeCurtis, Calzolari, Marciano, et al., 2008).

Temperature Regulation, Temperature Regulation: Intraoperative, and Vital Signs Monitoring. For other NIC labels you might use,

Go to Chapter Resources: Chapter 20, **Standardized Language, NOC Outcomes and NIC Interventions Associated With Abnormal Vital Signs,** on Davis*Plus*.

Specific nursing activities for clients with fever and/or nursing diagnoses of Hyperthermia or Ineffective Thermoregulation include the following:

Provide Focused Assessments such as the following:

- *Help determine the cause of the fever.* For example, you may collect specimens from various body sites for culture.
- *Monitor the temperature and other VS at least every 2 hours,* and more often if the temperature is rising rapidly or if the clinical symptoms are changing. Recall that the increased metabolism accompanying a fever also increases the pulse and respirations. When you suspect fever, it is wise to verify the reading obtained from the infrared tympanic thermometer or disposable thermometer by taking a rectal reading with a different type of thermometer for comparison. Obtain an oral reading if the rectal site is contraindicated.
- *Observe for the clinical signs that accompany a fever.* Symptoms vary, depending on the phase of the fever. The characteristic symptoms include flushed face; dry,

hot skin; eyes that appear bright and somewhat apprehensive; rapid, shallow respirations; increased heart rate; unusual thirst; loss of appetite; headache; and complaints of nausea. If the fever is extreme, urine may be concentrated and decreased in volume. Seizures, confusion, or delirium can also be associated with very high fevers.

Provide Collaborative Care to Treat the Underlying Cause of the Fever For example, you may administer antibiotics that a provider prescribes to treat a bacterial infection.

Use Nonpharmacological Measures to Reduce Fever

- Some measures are likely to produce shivering, which produces heat; therefore, they can actually raise instead of lower the patient's temperature. When using the following interventions, be careful not to cause your patient to shiver.
  - Cooling blankets that circulate water
  - Cloth-covered ice packs or cool washcloths to the groin, neck, or axillae
  - Circulating fan in the room
  - Instruct the client to use minimal bed covers
  - Alcohol or tepid baths

Although alcohol baths may be effective to reduce temperature, the topical application of large amounts of isopropyl alcohol can cause alcohol poisoning and toxicity in children and older adults (Smitherman, Janise, & Mathur, 2005; Thompson & Kagan, 2011).

- **Provide emergency treatment, if necessary.** Heat stroke is a medical emergency because death can occur rapidly. Cooling blankets or cool water baths can be used successfully if the surface temperature is not lowered too quickly. Rapid lowering of the surface temperature causes vasoconstriction, which delays core cooling.

Provide Supportive Measures for Associated Symptoms

- **Provide oral or intravenous fluids.** This replaces fluids lost through diaphoresis. They help prevent dehydration or hypovolemia (fluid deficiency) secondary to the fever.
- **Provide nutritional support.** Food is essential to meet the increased energy needs created by the high metabolic rate accompanying fever. However, lack of appetite often accompanies fever, so food must be made appealing to the patient.
  - **Provide special mouth care.** Apply a water-soluble lip lubricant. Lips may become dry and **cracked, the tongue may be s**wollen, and sores may be present.
- **Keep clothing and bed linens dry.** This promotes comfort and helps prevent chilling. Recall that diaphoresis occurs during defervescence.

Provide teaching for self-care such as the following.

- **Teach emergency treatment for hyperthermia and hyperpyrexia at home.** Immediately move the person to a shady area if he is outdoors. Cool the victim by placing him in a tub of cool water or a cool shower, or sponging with cool water.
  - **Advise older adults to stay in air-conditioned buildings** when the outside temperature is extremely high; to take cool baths and showers; to limit physical activity; and to drink plenty of nonalcoholic and noncaffeinated fluids.
- **Advise family to check on elderly neighbors and family members** at least twice a day, and make sure they have an electric fan.

Interventions for Example Problem: Hypothermia

NIC standardized interventions recommended for Hypothermia and Ineffective Thermoregulation include Hypothermia Treatment, Newborn Care, Temperature Regulation, Temperature Regulation: Intraoperative, and Vital Signs Monitoring. For other NIC labels,

Go to Chapter Resources: Chapter 20, **Standardized Language, NOC Outcomes and NIC Interventions Associated With Abnormal Vital Signs,** on Davis*Plus*.

Specific nursing activities include the following:

Provide Focused Assessments for Hypothermic Patients

- Monitor the temperature and other VS frequently. Hypothermia causes vasoconstriction, coagulation in the microcirculation, and tissue ischemia (lack of oxygen). In the heart, this can lead to dysrhythmias.
- Observe for the following symptoms of hypothermia:
  - Body temperature less than 95°F (less than 35°C)
  - Decreased or irregular pulse, respirations, and blood pressure
  - A subjective feeling of being cold
  - Severe shivering (only initially)
  - Pale, cool, shiny skin
  - Decreased urine output
  - Disorientation and/or drowsiness

Institute Warming Measures

- Provide warm, dry clothing, warm drinks, warm blankets, and a warm environment. For mild cases of Hypothermia, this may be enough to restore normal temperature.
- For patients with a temperature below 86°F (30°C), also use warmed intravenous fluids, heating pads or heating blankets, and/or warm baths.
- Give warm, sweet drinks if the person is conscious. Avoid alcoholic and caffeinated drinks.

- Rewarm a patient who is severely hypothermic gradually to prevent complications, such as shock or dysrhythmias (abnormal heartbeats) and to ensure core, as well as surface, warming.

Don't use electric blankets. Vasoconstricted skin burns easily.
Don't apply pulse oximetry probes to a vasoconstricted finger.

Teach Older Adults Ways to Prevent Hypothermia

Examples include the following tips (National Institutes for Health, n.d., last reviewed 2014):

- Keep your home warm enough, at least 68 to 70 degrees. Even mildly cool indoor temperatures of 60 to 65 degrees can lead to hypothermia in older adults.
- Wear socks and slippers, long underwear under your clothes. Wear a hat or cap indoors.
- Cover your legs and shoulders with a blanket or afghan to keep warm.
- Wear a hat, scarf, and gloves or mittens when going outdoors in the cold. This helps prevent loss heat through your head and hands. A large portion of body heat can be lost through the head, so the cap is important. Dress in several layers of warm loose clothing. This traps warm air between the layers and keeps body head in.

ThinkLike a Nurse 20-3

Recall the clients in the Meet Your Patients scenario. Two-year-old Jason's axillary temperature was 101.8°F (38.8°C) and his skin was warm, dry, and flushed. His mother told you that he had been eating poorly and was very irritable.

- What changes in behavior alert you that something is wrong?
- Do you have enough theoretical knowledge or patient information to know what is going on?
- What, if any, additional information about the patient situation do you need?

Toward Evidence-Based Practice

Paes, B., Vermeulen, K., Brohet, R., et al. (2010). Accuracy of tympanic and infrared skin thermometer in children. *Archives of Disease in Childhood*, *95*(12), 974–978.

Researchers evaluated the accuracy of the tympanic and infrared skin thermometer as alternatives to rectal temperature readings. In 100 hospitalized pediatric patients, the tympanic thermometer was less accurate than the rectal thermometer, but more accurate than the infrared skin thermometer.

Frommelt, T., Ott, C., & Hays, V. (2008). Accuracy of different devices to measure temperature. *MedSurg Nursing*, *17*(3), 171–182.

Using 86 postoperative adult patients, researchers measured oral, tympanic, and temporal artery temperature using different devices. The researchers found significant differences from the referenced oral thermometer and the oral disposable, tympanic, and temporal artery thermometers. The tympanic thermometry had the greatest variation (least accurate) from the oral thermometry.

Lawson, L., Bridges, E. J., Ballou, I., et al. (2007). Accuracy and precision of noninvasive temperature measurement in adult intensive care patients. *American Journal of Critical Care*, *16*(5), 485–496.

Over a period of 6 months, researchers took repeated measurements at various sites, including the gold standard pulmonary artery catheter, from 60 adults with cardiopulmonary disease in intensive care. They found oral and temporal artery measurements to be the most accurate and precise. Axillary measurements were less accurate, and ear measurements were the least accurate and precise.

Heusch, A. I., & McCarthy, P. W. (2005). The patient: A novel source of error in clinical temperature measurement using infrared aural thermometry. *Journal of Alternative & Complementary Medicine*, *11*(3), 473–476.

Researchers used an infrared tympanic thermometer to measure the temperatures of 132 subjects, ages 18 to 48 years, who were asymptomatic with no known pathological problems. Temperatures were measured in both ears. There was a significant difference in the temperature in the left compared with the right ear. Also, at temperatures below 36.7°C, the left ear registered a lower temperature than the right. At temperatures above 36.7°C, the left ear registered a higher temperature than the right ear. Researchers suggested that averaging the temperature in both ears might increase the reliability of infrared tympanic thermometers.

Farnell, S., Maxwell, L., Tan, S., et al. (2005). Temperature measurement: Comparison of non-invasive methods used in adult critical care. *Journal of Clinical Nursing*, *14*(5), 632–639.

Researchers took 160 sets of temperature measurements from 25 adult intensive care patients, using a chemical (Tempa·DOT) and a tympanic thermometer. Patients' temperatures were also being measuring with the gold standard pulmonary artery catheter. They found the chemical thermometer to be more accurate and reliable

(continued)

Toward Evidence-Based Practice—cont'd

than the tympanic thermometer. However, compared with the pulmonary artery catheter, both methods were associated with erroneous readings.

1. Make a table containing the following:
   a. The name of the first researcher (e.g., Paes)
   b. The number and type of subjects in the study
   c. What each study found about *tympanic* temperature measurements

2. Imagine that you are managing a residential long-term care facility that has recently purchased new tympanic thermometers to replace the old mercury-in-glass thermometers. In this facility, VS are routinely taken by nursing assistive personnel (NAPs). What implications do these five studies have for actions you might need to take? What, in general terms, do you plan to do, and why?

CarePlanning & MappingPractice

For Care Planning/Care Mapping practice,

Go to Chapter Resources, **Care Planning & Care Mapping Practice,** on Davis*Plus*.

PULSE

The concept of **perfusion** refers to the continuous supply of oxygenated blood through the blood vessels to the vital organs. The **pulse** is the rhythmic expansion of an artery produced when a bolus of oxygenated blood is forced into it by contraction of the heart. How do you think the pulse affects perfusion; how might perfusion affect the pulse?

TheoreticalKnowledge knowing why

To assess and support regulation of a client's pulse, you will need to understand the concept of perfusion, know the normal pulse range, how the pulse is produced and regulated, and factors that influence pulse rate. An important reason to assess the pulse is to identify when more advanced monitoring is required.

What Is a Normal Pulse Rate?

Pulse rate is measured in beats per minute. The normal range for healthy young and middle-aged adults is 60 to 100 beats/min, with an average rate of 70 to 80 beats/min. Table 20-1 identifies average pulse rates for adults. For average pulse rates for other age groups,

Go to Chapter 20, **Tables, Boxes, Figures: ESG Table 20-1,** on Davis*Plus*.

When the heart rate is of concern, you will most likely use a cardiac monitor to determine not only the rate, but also the rhythm and intensity of the pulse.

How Does the Body Produce and Regulate the Pulse?

The pulse wave begins when the left heart ventricle contracts and ends when it relaxes. Each contraction forces blood into the already filled aorta, increasing pressure within the arterial system. The intermittent pressure and expansion of the arteries causes the blood to move along in a wavelike motion toward the capillaries. You can palpate a light tap at the peak of the wave, when the artery expands. The trough (low point) of a pulse wave occurs when the artery contracts to push the blood along its way. The peak of the wave corresponds to **systole**, or the contraction of the heart; the trough corresponds to **diastole**, or the resting phase of the heart.

Stroke volume is the quantity of blood forced out by each contraction of the left ventricle. You will not usually know your patient's actual stroke volume, though it averages 70 mL in most healthy adults. If stroke volume decreases (as in a large blood loss, or *hemorrhage*), the body tries to maintain the same cardiac output by increasing the pulse rate. The **cardiac output** is the total quantity of blood pumped per minute. It is expressed in liters per minute and calculated as follows:

$$\text{Cardiac output} = \text{stroke volume} \times \text{pulse (heart) rate}$$

For a person with a pulse of 80 beats/min and an average stroke volume (70 mL), the cardiac output would be about 5,600 mL (or 5.6 liters) per minute.

The autonomic nervous system regulates the heart rate. Sympathetic stimulation increases the heart rate (and thus the cardiac output); parasympathetic stimulation decreases it. We discuss this in more detail in Chapter 37.

What Factors Influence the Pulse Rate?

In a healthy adult, the peripheral pulse rate is the same as the heart rate. Therefore, taking the pulse is a quick and simple way to assess the condition of the heart, blood vessels, and circulation. The pulse changes in response to changes in the volume of blood pumped through the heart, variations in heart rate, changes in the elasticity of the arterial walls, or any condition that interferes with heart function. Because the heart and blood vessels are regulated by the nervous system, conditions that interfere with normal functioning of the nervous system also affect the pulse. Other factors that may cause variations in pulse rate, rhythm, or quality include the following:

- *Developmental level.* Newborns have a rapid pulse rate. The rate stabilizes in childhood and gradually slows through old age. Although resting heart rate increases with age, variability decreases (Chester & Rudolph, 2011). Thus, you should not rely solely on changes in the pulse rate of older adults to detect their response to external stressors.
- *Gender.* Adult women have a slightly more rapid pulse rate than do adult men.
- *Exercise.* Muscle activity normally increases the pulse rate. After exercise, a well-conditioned heart returns to normal more quickly than does a nonconditioned heart. Also, people who are well conditioned have lower heart rates, both before and during exercise, than do those who are not.
- *Food.* Ingestion of food causes a slight increase in pulse rate for several hours.
- *Stress.* Stress triggers the fight-or-flight sympathetic nervous system response, which increases both pulse rate and strength of the heart contractions (stroke volume).
- *Fever.* The pulse rate tends to increase about 10 beats/min for each degree Fahrenheit of temperature elevation. The reasons are that (1) the metabolic rate increases and (2) the body attempts to compensate for the decrease in blood pressure produced by the peripheral vasodilation that occurs with fever.
- *Disease.* Diseases, such as heart disease, hyperthyroidism, respiratory diseases, and infections, are generally associated with increased pulse rates. Hypothyroidism is associated with decreased pulse rates.
- *Blood loss.* Small blood loss is generally well tolerated and produces only a temporary increase in pulse rate. Theoretically, a large blood loss stimulates the sympathetic nervous system, bringing about an increase in pulse rate to compensate for the decreased blood volume. However, some studies suggest that VS are limited in their ability to detect large blood losses and that a stable pulse and blood pressure alone do not ensure that there has been no blood loss. Research to detect early blood loss using sensors and smartphone technologies is being conducted (Worcester Polytechnic Institute, 2012).
- *Position changes.* Standing and sitting positions generally cause a temporary increase in pulse rate and decrease in blood pressure as a result of blood pooling in the veins of the feet and legs. This decreases blood return to the heart, decreasing blood pressure and subsequently increasing heart rate.
- *Medications.* Stimulant drugs (e.g., epinephrine) increase pulse rate. Cardiotonics (e.g., digitalis) and opioids (e.g., narcotic analgesics) or sedative drugs decrease pulse rate.

PracticalKnowledge knowing **how**

Now that you understand some of the concepts and factors that produce and affect the pulse, you are ready to learn the practical knowledge of how to assess and support this aspect of physical functioning.

ASSESSMENT

Assess the pulse by **palpation** (feeling) or **auscultation** (listening with a stethoscope). To palpate the pulse, select the pulse site and lightly compress the client's artery against the underlying bone with the index and middle finger of one of your hands. When a client's pulse is difficult to palpate, you may need to use a Doppler device, which has an ultrasound transducer that transmits the pulse sounds to an audio unit. For a summary of the steps for assessing a client's peripheral pulse, see the Highlights of Procedures box. For the full procedure,

Go to **Procedure 20-2: Assessing Peripheral Pulses,** in Volume 2.

What Equipment Do I Need?

To count the pulse, you need a watch or clock with a second hand or digital display. To auscultate the pulse, you will use a stethoscope. The stethoscope does not magnify sounds, but rather blocks out noise so that you can hear blood pressure and other faint sounds. A **stethoscope** consists of a sound-transmitting device (bell and diaphragm) that is attached to earpieces by rubber tubing and hollow metal tubes (Fig. 20-4). With the earpieces in place, you can use the bell to hear low-frequency sounds (e.g., certain heart sounds). Use the diaphragm to assess high-frequency sounds (e.g., lung sounds).

Stethoscopes can be either single lumen or double lumen. A single-lumen stethoscope has one tube connected to the chestpiece; a double-lumen stethoscope has two tubes attached to the chestpiece. Double-lumen stethoscopes are more sensitive than single-lumen instruments.

Most stethoscopes come with soft earpieces that help seal your ear canal to block room noise from interfering with the sound. Stethoscopes have varying lengths of tubing. Short tubing requires you to be close to the patient and to bend more, but the sound may be a bit better than with longer tubing, which is more likely to rub against the body or clothing. Some stethoscopes are made to work effectively through clothing; however, unless you know you are using that type you should place the instrument directly on the skin. Digital stethoscopes are also available, to provide sound clarity in noisy environments, with obese patients, and for care providers who have impaired hearing.

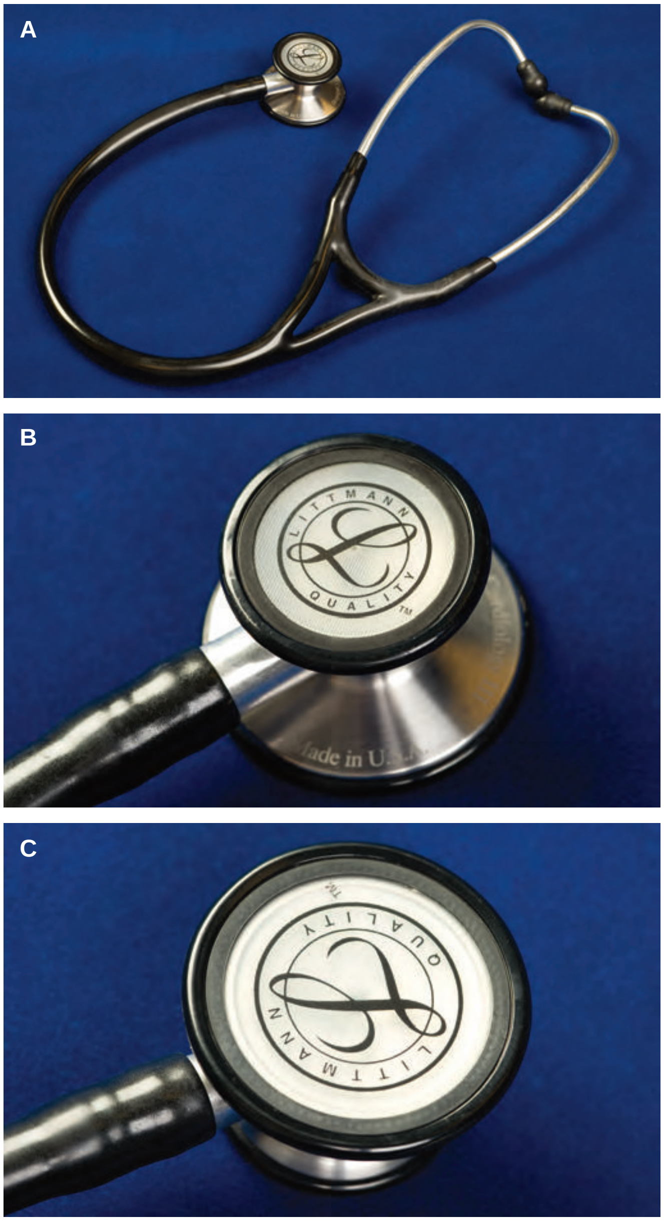

FIGURE 20-4 *A,* A stethoscope. *B,* The bell, for low-frequency sounds. *C,* The diaphragm, for high-frequency sounds.

To prevent cross-contamination, always clean your stethoscope before and after using it to examine a patient. Use a 70% alcohol or benzalkonium chloride wipe. Bacteria colonize on most stethoscopes, although only a small percentage are pathogenic. Cleaning can reduce the bacterial count by 94% to 100% (CDC, 2008; Kennedy, Dreimanis, Beckingham, et al., 2003; Rutala & Weber, 2004). Researchers found that the mean skin flora colony forming on stethoscopes decreased from 27 prior to cleaning to 1 after cleaning (Mitchell, DeAlwis, Collins, et al., 2010). Similarly subjects in the precleaning group had bacterial growth on their stethoscopes compared with no bacterial growth in the postcleaning group (Russell, Secrest, & Schreeder, 2012). Antimicrobial stethoscope covers have been developed to prevent surface contamination; however, research has associated them with higher colony counts (Wood, Lund, & Stevenson, 2007). A few agencies have wall-mounted "single-swipe" sterilizers for sterilizing stethoscopes.

To prevent injury, do not wear a stethoscope around your neck.

What Sites Should I Use?

Nurses assess the pulse at the apex of the heart **(apical pulse)** or at a place where an artery can be pressed by the fingers against a bone **(peripheral pulses).** Peripheral sites are shown in Figure 20-5.

The choice of pulse site depends on the reason for assessing the pulse and/or the accessibility of a site. To measure a peripheral pulse, you would, for example, use the:

- *Radial artery* for routine assessment of vital signs. This is the most commonly used site because it is easily found and readily accessible.
- *Brachial artery* when performing cardiopulmonary resuscitation of infants.
- *Carotid artery* when performing CPR of inpatient adults and for assessing circulation to the brain.

Palpate only one side of the neck at a time to avoid interrupting circulation to the head. Palpate lightly so that you don't occlude the artery; and don't massage the area because that can decrease the heart rate and blood pressure. Lay persons should not check the carotid pulse.

- *Temporal artery*—when assessing circulation to the head or when other sites are not easily accessible.
- *Dorsalis pedis* (also called *pedal pulse*) and *posterior tibial arteries* for assessing peripheral circulation.
- *Femoral artery* to determine circulation to the legs, in cases of cardiac arrest, and for children.
- *Popliteal artery* for assessing circulation to the lower leg.

ThinkLike a Nurse 20-4

- If you obtain a very slow radial pulse, how might you check to be sure your count is accurate?
- What kind of nursing knowledge does this require (i.e., theoretical, practical, self, or ethical knowledge)?

When Should I Take an Apical Pulse?

The apical pulse reading is the most accurate of the pulses. In a healthy person, the apical and peripheral pulses should be about the same. However, in some cardiovascular diseases, they can differ. If the heartbeat is weak, for example, some beats may be too weak to feel in a peripheral site. In this case, you would obtain a lower count for the radial than for the apical pulse. The apical pulse would accurately reflect the heartbeat. Use the apical site when:

- The radial pulse is weak or irregular.
- The rate is less than 60 beats/min or greater than 100 beats/min.

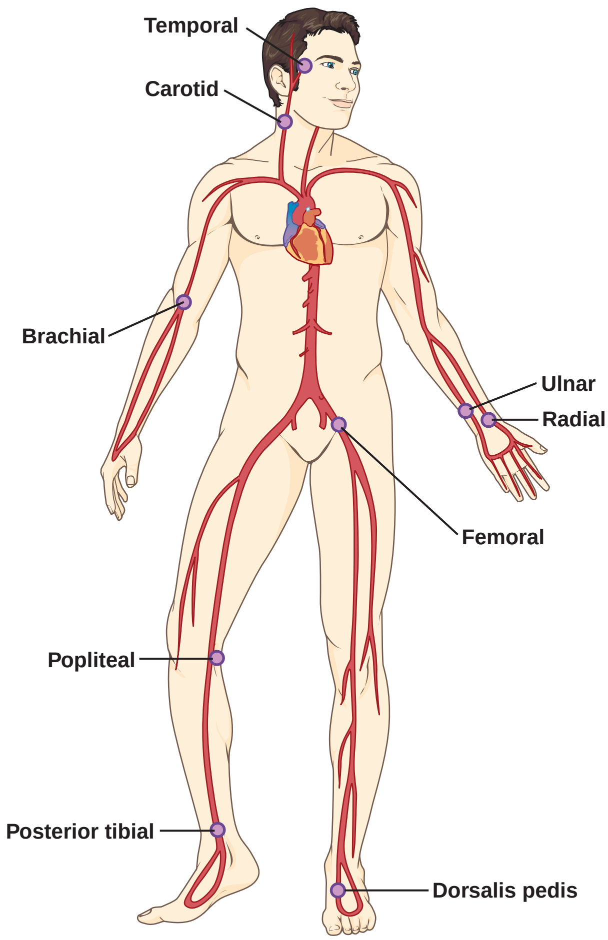

FIGURE 20-5 Sites commonly used for assessing a pulse.

- The patient is taking cardiac medications (e.g., digitalis).
- The patient is an infant or a child up to age 3 (because peripheral pulses may be difficult to palpate).

To assess the apical pulse, auscultate and count the number of heartbeats at the apex of the heart. For an adult, this site is on the anterior chest at 3 inches (8 cm) or less to the left of the sternum, at the 4th, 5th, or 6th intercostal space at the midclavicular line. For children, the location is different, depending on age (Fig. 20-6). You will hear two sounds, "lub" and "dub," as the heart valves close. Count each pair of sounds ("lub-dub") as one heartbeat. For step-by-step instructions, see the summary in the Highlights of Procedure box and

Go **Procedure 20-3: Assessing the Apical Pulse,** in Volume 2.

When Should I Take an Apical-Radial Pulse?

You will sometimes need to obtain a radial and apical pulse reading at the same time to assess for heart function or the presence of heart irregularities. A difference between the two counts **(pulse deficit)** indicates that not all apex beats are being transmitted or felt at the radial artery. As you are listening at the apical site, you will hear a beat without feeling a pulse at the radial artery.

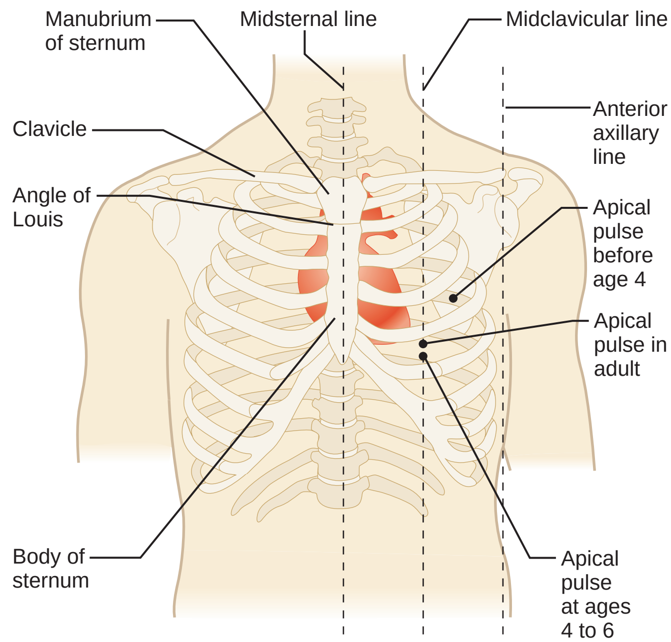

FIGURE 20-6 Location of apical pulse for adults and children.

You may detect a pulse deficit in conditions that interfere with peripheral perfusion, such as atrial fibrillation. You should report pulse deficits promptly to the primary care provider. See the Highlights of Procedures box for a summary, and

Go to **Procedure 20-4: Assessing for an Apical-Radial Pulse Deficit,** in Volume 2.

KnowledgeCheck 20-2

For each of the following, would you expect the pulse rate to be greater or less than the normal adult rate of 80 beats/min?

- A healthy professional tennis player
- A newborn infant
- An adolescent who has just finished running track
- A client who has just undergone a painful procedure
- A client with a fever
- An accident victim who is hemorrhaging
- A 90-year-old man

What Data Should I Collect?

A nurse has documented the following data for five patients:

Patient A: Radial pulse 80 beats/min, strong, regular, and equal bilaterally (the same in both arms)
Patient B: Pedal pulse 96 beats/min, regular, moderate volume, but stronger in the left ankle than the right
Patient C: Brachial pulse 86 beats/min in both arms, slightly irregular; skips about every fifth beat; weak but stronger in left arm
Patient D: Apical pulse 60 beats/min, slightly irregular; heart sounds clearly auscultated
Patient E: Radial pulse 92 beats/min, irregular—beats in triplets—weak, equal bilaterally

What types of information has the nurse gathered about these patients' pulses? (At least three different characteristics of the pulse are represented in the nurse's charting; look for patterns.)

Did you see that for each patient the nurse recorded the rate, rhythm (or pattern), and quality (or volume) of the pulse? If so, well done. Notice also that the nurse compared each patient's left side to the right side.

Pulse Rate

To assess the pulse **rate**, count the number of beats per minute while palpating or auscultating. Begin the count with one, rather than zero (Hwu, Coates, & Lin, 2000). For normal, healthy adults, you can determine the rate of a regular heart rhythm by counting the pulse for 15 seconds and multiplying the result by 4. Research is conflicting, but some studies indicate that a 30-second count is more accurate. If the pulse is irregular or slow, always count for 1 full minute. Table 20-1 identifies average pulse rates for adults. For average pulse rates for other age groups,

Go to Chapter 20, Tables, Boxes, Figures: **ESG Table 20-1, Comparison of Normal Vital Signs for Various Ages,** on Davis*Plus.*

Rates below 60 beats/min are known as **bradycardia** (*brady* = slow, *cardia* = heart). Rates over 100 beats/min are known as **tachycardia** (*tachy* = rapid, *cardia* = heart).

Pulse Rhythm

The intervals between heartbeats establish a pulse pattern known as the **rhythm**. Normally, the heart beats at regular intervals, much like a metronome. When the intervals between beats vary enough to be noticeable, the rhythm is abnormal **(dysrhythmia).** Abnormal rhythms may be single beats that occur too early or too late, or a group of irregular beats that form a pattern. When assessing an irregular pulse, it is important to determine whether the beat is *regularly irregular* (an irregular rhythm that forms a pattern) or *irregularly irregular* (an unpredictable rhythm). To make this distinction, you must count the rate for one full minute. An irregular heart rhythm can be very serious and may require additional assessment by **electrocardiogram (ECG),** a procedure that traces the electrical pattern of the heart.

Pulse Quality

The **quality** of the pulse is assessed by determining the pulse volume and bilateral (both sides) equality of pulses. **Pulse volume** refers to the amount of force produced by the blood pulsing through the arteries. Normally, the pulse volume for each beat is the same. The following terminology refers to the characteristics of the pulse volume; the numbers are assigned on a scale of 0 to 3.

0—Absent: Pulse cannot be felt.
1—Weak or thready: Pulse is barely felt and can be easily obliterated by pressing with the fingers.
2—Normal quality: Pulse is easily palpated, not weak or bounding.
3—Bounding or full: Pulse is easily felt with little pressure; not easily obliterated.

Bilateral equality is useful in determining whether the blood flow to a body part is adequate. Assess bilateral equality by comparing the pulses on both sides of the body for equal volume. For example, if you are concerned about the circulation to the left hand, assess both the right and left radial arteries to determine whether the volume is the same. If the pulses feel the same, they are said to be *equal in strength bilaterally*. If one pulse is stronger than the other, then the pulses are *unequal bilaterally*. You would record, "Radial pulses unequal in strength bilaterally; weaker in left arm." You may also document the equality by using a pulse volume scale. For example, you might record, "Radial pulses unequal in strength bilaterally; Right 2, Left 1."

If a peripheral pulse is absent or weak, it may be because the circulation is compromised in that extremity. If this is the case, then pallor or cyanosis may be present. **Pallor** refers to the paleness of skin in one area when compared to another part of the body. **Cyanosis** is a bluish or grayish discoloration of the skin resulting from deficient oxygen in the blood. For example, when circulation to the lower extremities is compromised, the feet often appear pale in comparison to the trunk or arms, the dorsalis pedis and/or posterior tibial pulses may be weak or absent, and the feet may feel cool to the touch.

ANALYSIS/NURSING DIAGNOSIS

An abnormal pulse may present as weak, thready, bounding, irregular, or absent. Pulse changes are symptoms, not problems. Therefore, nursing diagnoses are useful for describing the condition that is *causing* the pulse changes. By itself, a change in pulse (e.g., weak and thready) is not adequate to support the following diagnoses. Other symptoms must also be present.

- **Ineffective Tissue Perfusion (Peripheral)** can be used when a pulse is absent or weak and cool, pale skin is present.
- **Risk for Impaired Skin Integrity** and **Risk for Impaired Tissue Integrity** may be used as secondary diagnoses when Ineffective Tissue Perfusion is present. If tissue is not adequately perfused, tissue ischemia and *necrosis* (death of tissue) may occur.
- **Deficient Fluid Volume** may cause the pulse to be weak and thready.
- **Excess Fluid Volume** may cause the pulse to be bounding and full.
- **Decreased Cardiac Output** may cause tachycardia, bradycardia, or changes in pulse volume.

PLANNING OUTCOMES/EVALUATION

NOC standardized outcomes include the following:

- Vital Signs Status is the only outcome that directly pertains to assessing the pulse.

- Other outcomes depend on the nursing diagnosis causing the pulse changes. For example, Ineffective Peripheral Tissue Perfusion can be monitored with the NOC label of Circulation Status.

Some *individualized goal/outcome statements* you might write for pulse status follow:

- Apical pulse will be 60 to 80 beats/min when at rest.
- Pedal pulses will be 80 to 100 beats/min, 2 (on a scale of 0 to 3), and equal bilaterally.

ThinkLike a Nurse 20-5

Did you notice that the pulse rates in the preceding two goals are not the same as the full normal range shown in Table 20-1? What do you think might be a reason for this?

PLANNING INTERVENTIONS/IMPLEMENTATION

NIC standardized interventions include the following:

- Dysrhythmia Management, which applies to monitoring an abnormal pulse.
- Vital Signs Monitoring, which may be used for general evaluation of clients who do not have an identified problem with the pulse,

Go to Chapter 20, **Standardized Language, NOC Outcomes and NIC Interventions Associated With Abnormal Vital Signs,** on Davis*Plus*.

Specific nursing activities and focused assessments for a patient with a dysrhythmia depend on the cause of the problem and on specific orders from the physician. For example, a client with a pulse rate of 50 beats/min is usually considered to have bradycardia. However, such a slow resting heart rate would be perfectly normal for a well-trained athlete. Some dysrhythmias are *benign*; that is, they are not dangerous to the client, and they require no interventions. Nursing strategies that address dysrhythmias, regardless of cause, include the following:

- ***Closely monitor the patient's VS.*** A reduced heart rate may alter blood pressure and tissue perfusion. The extent of intervention depends on the effect of the dysrhythmia on the client's other vital signs.
- ***Monitor the patient's activity tolerance.*** The degree of activity, orientation, and level of fatigue while the dysrhythmia is present are indicators of the patient's ability to tolerate the dysrhythmia.
- ***Collect and assess laboratory data as prescribed.*** Cardiac function depends on normal electrolyte balance, particularly potassium, calcium, and magnesium levels. If a client is receiving medications that affect cardiac rhythm, serum levels of these medications must be checked periodically.
- ***Help determine the cause of the dysrhythmia.*** Determine when the client experiences the dysrhythmia. Are there precipitating or alleviating factors?
- ***Administer antidysrhythmic medications.*** These are prescribed to control the heart rhythm.
- ***Provide emotional support.*** The client experiencing a dysrhythmia may be frightened by the experience. Explain all procedures to the client and family members, and maintain a calm presence.

ThinkLike a Nurse 20-6

- Which of the following findings should be referred to the primary healthcare provider so that an electrocardiogram (ECG) can be ordered? Why?
  Patient A, who has a radial pulse of 100 beats/min, regular, and equal bilaterally
  Patient B, who has a regular apical pulse of 100 beats/min
  Patient C, who has a very irregular apical pulse of 78 beats/min
- Recall the clients in the Meet Your Patients scenario.
  Ms. Sharma is an active 80-year-old woman who works part-time and exercises four times per week. She is complaining of feeling tired. You find that her pulse is irregular and uneven.
  What other patient data do you need to know? How would you go about getting this additional information?
  What actions should you consider taking while meeting with Ms. Sharma?
  What theoretical knowledge (rationale) supports your beliefs and actions?

RESPIRATION

Respiration is the exchange of oxygen and carbon dioxide in the body. The process of respiration consists of two aspects: mechanical and chemical.

- **Mechanical.** The mechanical aspects of respiration involve the active movement of air into and out of the respiratory system. This is known as **pulmonary ventilation** or, more commonly, breathing.
- **Chemical.** The chemical aspects of respiration include the following:
  ***External respiration*—**The exchange of oxygen and carbon dioxide between the alveoli and the pulmonary blood supply
  Gas transport—The transport of these gases throughout the body
  ***Internal respiration*—**The exchange of these gases between the capillaries and body tissue cells

This chapter focuses on the mechanical aspects of respiration. Chapters 36 and 37 explore gas exchange and transport throughout the body. For an animated visual explanation of respiration,

Go to Student Resources, **Animations: Cardiovascular/Pulmonary Animations, Carbon Dioxide/Oxygen Transport,** on Davis*Plus*.

Theoretical Knowledge knowing why

To assess and support clients' respirations, you will need to know the normal range of respiratory rates, how respiration is regulated, the mechanics of breathing, and factors that affect respiration.

What Is a Normal Respiratory Rate?

Respiratory rate normally varies with age, exertion, emotions, and other factors. Normal adult respirations are identified in Table 20-1. For normal respiratory rates at other developmental stages,

Go to Chapter 20, **Tables, Boxes, Figures: ESG Table 20-1,** on Davis*Plus*.

How Does the Body Regulate Respiration?

Special respiratory centers in the medulla oblongata and pons of the brain, along with nerve fibers of the autonomic nervous system, regulate breathing in response to minute changes in the concentrations of oxygen (O_2) and carbon dioxide (CO_2) in the arterial blood. The primary stimulus for breathing is the level of CO_2 tension in the blood.

- **Central chemoreceptors**, located in the respiratory centers, are sensitive to CO_2 and hydrogen ion (pH) concentrations. Minor increases in either stimulate respirations.
- **Peripheral chemoreceptors** are located in the carotid and aortic bodies. The partial pressure of oxygen in arterial blood (PaO_2) is normally between 80 and 100. When the PaO_2 falls below normal, peripheral chemoreceptors stimulate respirations.

Usually breathing is an involuntary action that requires little effort. However, it is possible to exert conscious control over respiration (e.g., a young child holding his breath during a temper tantrum; a person holding her breath when swimming).

What Are the Mechanics of Breathing?

Pulmonary ventilation depends on changes in the capacity of the chest cavity (Fig. 20-7).

Inspiration In response to impulses sent from the respiratory center along the phrenic nerve, the thoracic muscles and the diaphragm contract. The ribs move upward from midline ½ to 1 inch (1.2 to 2.5 cm), the diaphragm moves downward and out about 0.4 inch (1 cm), and the abdominal organs move downward and forward, expanding the thorax in all directions. As expansion causes airway pressure to decrease below atmospheric pressure, air moves into and expands the lungs. This stage of respiration (drawing air into the lungs) is termed **inspiration**.

Expiration When the diaphragm and thoracic muscles relax, the chest cavity decreases in size, and the lungs recoil, forcing air from the lungs until the pressure within the lungs again reaches atmospheric pressure. This stage, which involves the expulsion of air from the lungs, is called **expiration**. Expiration is passive and normally takes 2 to 3 seconds, compared to 1 to 1.5 seconds for inspiration. During normal breathing, the chest wall and abdomen gently rise and fall.

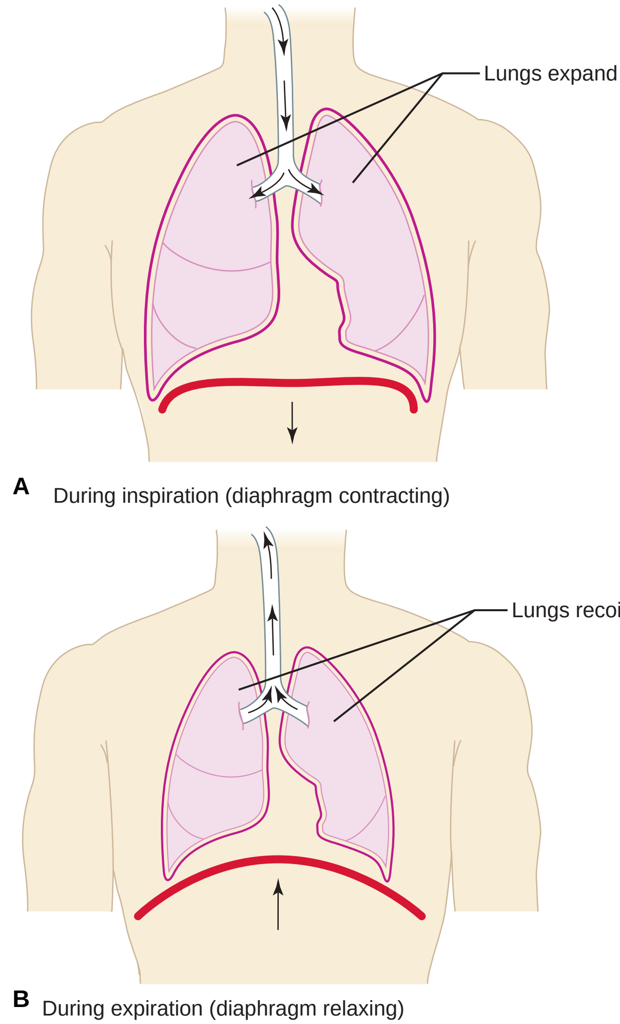

FIGURE 20-7 Changes in thoracic cavity during inspiration and expiration. *A*, During inspiration. *B*, During expiration.

KnowledgeCheck 20-3

- Which two gases are exchanged through respiration?
- Which respiratory process involves the movement of air into and out of the lungs?
- What is external respiration?
- What is the primary stimulus for breathing?
- What mechanical forces allow the lungs to expand?

What Factors Influence Respiration?

To interpret the meaning of your client's respiratory data, you need to be aware of factors that influence breathing.

- *Developmental level.* A newborn's respiratory rate usually ranges from 40 to 60 breaths per minute. However, some references give an upper limit of 90 breaths/min so long as it is for a short period of time (transient tachypnea). The rate gradually decreases until it reaches the normal adult rate of 12 to 20 breaths per minute. The respiratory rate decreases slightly in older adults.

- *Exercise.* Muscular activity causes a temporary increase in respiratory rate and depth so as to increase oxygen availability to the tissues and to rid the body of excess carbon dioxide.
- *Pain.* Acute pain causes an increase in respiratory rate, but a decrease in depth.
- *Stress.* Psychological stress, such as anxiety or fear, may markedly influence respiration as a result of sympathetic stimulation. The most common change is an increase in rate.
- *Smoking.* Chronic smoking increases resting respiratory rate as a result of changes in airway compliance (elasticity).
- *Fever.* When heart rate increases because of fever, respiratory rate also increases. For every 1°F (0.6°C) the temperature rises, the respiratory rate may increase up to 4 breaths/min.
- *Hemoglobin.* Respiratory rate and depth increase as a result of anemia (reduced hemoglobin), sickle cell anemia (abnormally shaped red blood cells), and high altitudes. When hemoglobin is decreased or abnormal, the rate and depth of respirations, as well as the heart rate, may increase to maintain adequate tissue oxygenation. High altitudes inhibit the binding of oxygen to hemoglobin and trigger similar compensation efforts.
- *Disease.* The rate of breathing may be increased or decreased by various diseases. For example, brainstem injuries and increased intracranial pressure may interfere with the respiratory center, inhibiting respirations or altering respiratory rhythm.
- *Medications.* Central nervous system depressants, such as morphine or general anesthetics, cause slower, deeper respirations. Caffeine and atropine can cause shallow, fast breathing.
- *Position.* Standing up maximizes respiratory depth; lying flat reduces respiratory depth. Slumping (sitting with shoulders forward, and the back curved in a C) prevents chest expansion, which impedes breathing.

Respiration is often thought of as the forgotten vital sign (Parkes, 2011). However, research has shown that respiratory rates greater than 27 beats/min are highly predictive of adverse events in older adults (Chester & Rudolph, 2011). You must remember that an accurate measurement of respiratory rate is an essential component of the assessment of older adults.

ThinkLike a Nurse 20-7

Consider the following client situations. What effect would each have on respirations?

- A client with four fractured ribs
- A woman who is 9 months pregnant
- A young child excited at her birthday party
- An adult who has consumed alcoholic beverages

PracticalKnowledge knowing how

Although you may assess the adequacy of external and internal respiration in various ways, it is pulmonary ventilation (breathing) that you assess as a vital sign. Accurate assessment of respirations depends on your ability to recognize normal breathing, abnormal breathing, and factors that affect breathing. This chapter discusses only assessment of respirations. For nursing diagnoses, outcomes, and interventions for respiratory problems, see Chapter 36.

ASSESSMENT

Because people can control their breathing rate, it is best to count respirations when the client is unaware of what you are doing. One way to do this is to palpate and count the radial pulse, and then count the respirations before removing your fingers from the client's wrist. For a summary of this procedure, see the Highlights of Procedures box. For the entire sequence of steps,

Go to **Procedure 20-5: Assessing Respirations,** in Volume 2.

What Equipment Do I Need?

The only equipment you need for measuring respiratory rate is a watch with a second hand or digital display. You will need a stethoscope if you auscultate respirations. Many electronic thermometers have counter displays and signals that indicate 15-, 30-, and 60-second time intervals for counting respirations.

What Data Should I Obtain?

In addition to measuring the respiratory rate, you will also observe indicators of overall respiratory function, including depth, rhythm, effort, and others. For additional information on respiratory assessment, see Chapter 22 and

Go to Chapter 22, **Procedure 22–12: Assessing the Chest and Lungs,** in Volume 2.

Respiratory Rate

The **respiratory rate** is the number of times a person breathes (or completes a cycle of inhalation and exhalation) within one full minute. You can easily count and observe respirations by:

- Placing your hand on the client's chest (palpation) or observing (inspection) the number of times the client's chest or abdomen rises (inspiration) and falls (expiration)
- Placing your stethoscope on the client's chest (auscultation) and counting the number of inhalation and exhalation cycles

For a new patient or when you need to ensure accuracy, you must count for 60 seconds (Morton & Rempher, 2009; Vital Signs, 1999). In some situations, for example, for a patient you know well and for whom respiratory rate is not directly relevant to the assessment, you may count for only 30 seconds and multiply by 2. If respirations vary from normal ranges, you should count for a full minute by auscultation. Normal adult respiratory rates are identified in Table 20-1.

Respiratory rate is a measure of the client's general condition, but rate alone is not a good indicator of the adequacy of respiration. You must also assess other characteristics of the respirations. If oxygenation must be carefully monitored, use a pulse oximeter (see Chapter 36). A person can tolerate **apnea**, cessation of breathing, for only a few minutes. If apnea continues for more than 4 to 6 minutes, brain damage and even death can occur. See Table 20-4 for terminology to describe respiratory rhythms.

Respiratory Depth

Tidal volume is the amount of air taken in on inspiration—about 300 to 500 mL for a healthy adult. Specialized equipment is required to measure tidal volume. However, you can estimate the adequacy of tidal volume by observing the depth of a client's respirations. This is a subjective evaluation of how much or how little the chest or abdomen rises during breathing. Respiratory depth is described as *deep* (taking in a very large volume of air and fully expanding one's chest or abdomen), *shallow* (when the chest barely rises and is difficult to observe), or *normal* (falling between shallow and deep).

Respiratory Rhythm

Rhythm is assessed simply as *regular* or *irregular.* Generally, the period between each respiratory cycle is the same, and there is a regular breathing pattern (see Eupnea, in Table 20-4). Infant breathing rhythms are more likely to be irregular than adult rhythms. An abnormal breathing pattern may indicate other healthcare problems and deserves further assessment. Two abnormal breathing patterns, Cheyne-Stokes and Biot's breathing, are discussed in Chapter 36.

Respiratory Effort

Respiratory effort refers to the degree of work required to breathe. Normal breathing is effortless. When diseases such as asthma or pneumonia are present, the person must work harder to breathe. Increased effort with breathing is called **dyspnea** or labored breathing. It is uncomfortable for the client and frequently produces fatigue and fear. **Orthopnea** is difficulty or inability to breathe when in a horizontal position. You will observe this in some clients with respiratory or cardiac conditions.

Table 20-4 ➤ Respiratory Rates and Rhythms

TYPE	DESCRIPTION	ILLUSTRATION
Eupnea	Normal respirations, with equal rate and depth, 12–20 breaths/min	Bradypnea	Slow respirations, < 10 breaths/min	
Tachypnea	Fast respirations, > 24 breaths/min, usually shallow	
Kussmaul's Respirations	Respirations that are regular but abnormally deep and increased in rate	Biot's Respirations	Irregular respirations of variable depth (usually shallow), alternating with periods of apnea (absence of breathing)	Cheyne-Stokes Respirations	Gradual increase in depth of respirations, followed by gradual decrease and then a period of apnea	Apnea	Absence of breathing	

Breath Sounds

You will use a stethoscope to listen for breath sounds. Normal respirations are quiet. Abnormal (adventitious) sounds include the following:

- **Wheezes** are high-pitched, continuous musical sounds, usually heard on expiration. Wheezes are caused by narrowing of the airways. Wheezes can often be heard without a stethoscope.
- **Rhonchi** are low-pitched, continuous gurgling sounds caused by secretions in the large airways. They often clear with coughing.
- **Crackles** are caused by fluid in the alveoli. They are discontinuous sounds usually heard on inspiration, but they may be heard throughout the respiratory cycle. They may be high-pitched, popping sounds or low-pitched, bubbling sounds, and have been described as similar to the sound made by rubbing strands of hair together with the fingertips.
- **Stridor** is a piercing, high-pitched sound that is heard without a stethoscope, primarily during inspiration, in infants who are experiencing respiratory distress or in someone with an obstructed airway.
- **Stertor** refers to labored breathing that produces a snoring sound. It is common with mouth breathing due to nasal congestion. The "death rattle" is a type of stertorous breathing.

See Chapter 22 for further discussion of abnormal breath sounds. To listen to the sounds,

Go to **Sound File, Breath Sounds,** on Davis*Plus.*

Chest and Abdomen Movement

The chest or abdomen normally rises with inspiration and falls with expiration in a gentle and rhythmic pattern. When a person is having difficulty moving air into or out of the lungs, respiratory patterns change. **Intercostal retraction** refers to the visible sinking of tissues around and between the ribs that occurs when the person must use additional effort to breathe. **Substernal retraction** exists when tissues are drawn in beneath the sternum (breastbone), and **suprasternal retraction** exists when tissues are drawn in above the clavicle (shoulder girdle).

Associated Clinical Signs

When you assess respiration, it is important to assess for clinical signs of oxygenation. Signs of **hypoxia** (inadequate cellular oxygenation) include pallor or cyanosis, restlessness, apprehension, confusion, dizziness, fatigue, decreased level of consciousness, tachycardia, tachypnea, and changes in blood pressure. When evaluating cyanosis, the tongue and oral mucosa are the best indicators of hypoxia. Cyanosis of the nails, lips, and skin may be caused by hypoxia, but may also be related to cold or reduced circulation in that area. Chronic hypoxia causes **clubbing** (loss of the nail angle) of the fingers.

A **cough** is a forceful or violent expulsion of air during expiration. Coughs may be *constant* (occurring frequently and consistently) or *intermittent* (occurring occasionally). If secretions are expectorated (coughed up), the cough is *productive.* If no secretions are produced, the cough is *nonproductive* or *dry.* A *hacking cough* is a series of dry coughs that occur together, whereas a *whooping cough* is a sudden, periodic cough that ends with a whooping sound on inspiration. Coughs may be symptoms of allergic reactions, lung disease, respiratory infection, or heart conditions.

KnowledgeCheck 20-4

- How can you estimate a client's tidal volume?
- What is the range of normal for an adult's respiratory rate?
- Besides the rate, what other characteristics of a client's respirations should you observe?
- What are some common clinical signs associated with poor oxygenation?

Arterial Oxygen Saturation

The rate, quality, and depth of the respirations are indicators of the general health of the respiratory system. However, they do not measure the amounts of oxygen and carbon dioxide present in the blood—information that is essential for evaluating the effectiveness of respiratory effort. Two methods exist to measure O_2 and CO_2 blood levels. One method is invasive; the other is not.

- **Arterial blood gas (ABG) sampling** directly measures the partial pressures of oxygen and carbon dioxide and blood pH, in other words, the gases in the arterial blood. This method requires the puncture of an artery followed by laboratory testing of the sample. It provides comprehensive data, but is invasive, painful, time consuming, and relatively expensive. If you need more information about this diagnostic test, consult a medical-surgical nursing or laboratory tests text.
- **Pulse oximetry** is a noninvasive method of monitoring respiratory status with a device that measures **oxygen saturation** (an indication of the oxygen being carried by hemoglobin in the arterial blood). The oximeter emits light, and a photosensor placed on the client's finger or earlobe measures the light passing through the site and calculates a pulse saturation (SpO_2) that is a good estimate of arterial oxygen saturation. The only risk in pulse oximetry is that clinicians may become too dependent on it or trust erroneous readings. Do not neglect the other aspects of holistic respiratory assessment. In many situations, oxygen saturation is monitored routinely along with the other vital signs. To learn how to apply a pulse oximeter,

Go to **Procedure 36–2: Monitoring Pulse Oximetry,** in Volume 2.

ThinkLike a Nurse 20-8

- Mrs. Dowell has smoked two packs of cigarettes per day for 45 years. She has recently been diagnosed with pneumonia—an infection of the lungs. What VS assessments would be important for Mrs. Dowell, and why?
- Recall the clients in the Meet Your Patients scenario. Mr. Jackson is short of breath and struggling to breathe. His respiratory rate is 28 breaths/min. What else do you need to know about the patient situation? What is important and what is not important in this scenario? What is probably least important?

ANALYSIS/NURSING DIAGNOSIS

As noted earlier, *hypoxia* refers to inadequate cellular oxygenation. It results from decreased oxygen intake, decreased ability of tissues to remove oxygen from blood, impaired ventilation or perfusion, impaired gas exchange between the blood and alveoli, or inadequate levels of hemoglobin. The following are two common alterations in respiration:

- **Hyperventilation** occurs when rapid and deep breathing result in excess loss of CO_2 (*hypocapnia*). A client who is hyperventilating may complain of feeling lightheaded and tingly. Causes of hyperventilation include anxiety, infection, shock, hypoxia, drugs (e.g., aspirin, amphetamines), diabetes mellitus, or acid–base imbalance.
- **Hypoventilation** occurs when the rate and depth of respirations are decreased and CO_2 is retained or alveolar ventilation is compromised. Hypoventilation may be related to chronic obstructive pulmonary disease (COPD), general anesthesia, impending respiratory failure, or other conditions that result in decreased respirations.

Two nursing diagnoses commonly used to describe various respiratory problems are Impaired Gas Exchange and Ineffective Breathing patterns. For a more complete list, see Chapter 36.

BLOOD PRESSURE

Blood pressure (BP), an important indicator of overall cardiovascular health, is the pressure of the blood as it is forced against arterial walls during cardiac contraction. **Systolic pressure** is the peak pressure exerted against arterial walls as the ventricles contract and eject blood. **Diastolic pressure** is the minimum pressure exerted against arterial walls, between cardiac contractions when the heart is at rest.

Blood pressure is measured in millimeters of mercury (mm Hg) and is recorded as systolic pressure over diastolic pressure (e.g., 110/74 mm Hg). The pulse that can be palpated to determine heart rate is due to the difference between the systolic and diastolic pressures. This difference is known as the **pulse pressure**. The pulse pressure for a BP of 120/80 mm Hg is 40 mm Hg. The pulse pressure is an indication of the volume output of the left ventricle. Generally, the pulse pressure should be no greater than one-third of the systolic pressure, as in the example of a BP of 120/80, with a pulse pressure of 40 ($\frac{1}{3} \times 120 = 40$).

KnowledgeCheck 20-5

- For a client whose BP is 150/80, what is the pulse pressure?
- Is that normal? If so, explain. If not, what should the pulse pressure be?

TheoreticalKnowledge knowing why

To assess and support clients' blood pressure, you will need to understand how it contributes to the concept of **perfusion**. An adequate BP is necessary to ensure that tissue perfusion is maintained. Contraction of the heart (systolic pressure) forces a bolus of oxygenated blood into the arterial circulation to provide a continuous supply of oxygen to all body cells. The heart then rests and refills with blood (diastolic pressure), which is pumped out to the tissues. Any factor that interferes with this cycle can cause impaired tissue perfusion.

You will also need to know, and will learn in this section, what constitutes a normal reading for a client, how the body regulates blood pressure, and what factors affect the blood pressure.

What Is a Normal Blood Pressure Reading?

For many years, a BP of less than 120 to 129 systolic and less than 80 to 84 diastolic was considered "optimal" for adults; and up to 130 systolic and 85 diastolic was considered "normal" for adults. More recently, an expert panel has classified "normal" as systolic BP below 120 and diastolic BP below 80 (Table 20-5) (Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure, 2004).

How Does the Body Regulate Blood Pressure?

Blood pressure regulation is a highly complex process. It is influenced by three factors: cardiac function, peripheral vascular resistance, and blood volume. The body constantly regulates and adjusts arterial pressure to supply blood to body tissues via perfusion of the capillary beds. For in-depth discussion, see Chapter 37.

Cardiac Function

Recall that *cardiac output* is the volume of blood pumped by the heart per minute, and that it reflects the functioning of the heart. An increase in cardiac output causes an increase in BP; a decrease in cardiac output causes a decrease in BP (if all other factors remain the same). A

Table 20-5 ➤ Classification of Adult Blood Pressure*

CATEGORY	SYSTOLIC (MM HG)		DIASTOLIC (MM HG)	FOLLOW-UP
Normal	< 120	and	< 80	Encourage lifestyle modification if there are risk factors. Recheck in 1–2 yr or sooner if there are risk factors.
Prehypertension	120–139	or	80–89	Encourage lifestyle changes; recheck in 1 yr or sooner if indicated. Antihypertensives are prescribed only with compelling indications, such as renal disease.
Stage I Hypertension	140–159	or	90–99	Encourage lifestyle modification. Follow up with primary care provider in 1–2 mo. (Most patients will be started on thiazide-type diuretics.) Newer (JNC 8) guidelines recommend treating older adults only when the B/P is 150/90.
Stage II Hypertension	≥ 160	or	≥ 100	Encourage lifestyle modification. Refer for care within 1 wk, or immediately if warranted. (Most patients will be given a two-drug combination therapy, e.g., thiazide-type diuretics with angiotensin-converting enzyme [ACE] inhibitors.)
