with the physical assessment. During the assessment the nurse asks Jose if he has any questions. Jose asks her about a Buddhist ritual that he heard about from a friend. The nurse has not heard about that ritual before and states, "I'm not sure what you're asking about. After we're finished here, I'll try to get some information for you." In this interaction the nurse is exhibiting the attitude for critical thinking known as _____.

2. Jose's mother comes with Jose to a clinic visit. During the visit the nurse asks Jose's mother, "Which spiritual activities are part of your life?" Jose's mother responds that she goes to daily Mass, listens to religious music, and spends time praying while she sits in her garden. When asked if there is anything the nurse can do for Jose's mother, she responds that she would like to meet with a priest while she is visiting Jose. She then states, "My biggest concern is remaining strong for Jose. It is so hard to watch your child die." Which nursing diagnosis is appropriate for Jose's mother at this time?
3. Jose is too ill to come to the clinic. He now is being seen every other day by the hospice team. Jose's family and his partner, Will, are at his side. Describe two nursing interventions the hospice nurse could implement to enhance the family's connectedness.

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. An emergency department nurse is caring for a patient who was severely injured in a car accident. The patient's family is in the waiting room. They are crying softly. The nurse sits down next to the family, takes the mother's hand, and says, "I can only imagine how you're feeling. What can I do to help you feel more at peace right now?" In this example the nurse is demonstrating:
   1. Prayer.
   2. Presence.
   3. Coaching.
   4. Instilling hope.
2. A patient states that he does not believe in the existence of God. This patient most likely is an:
   1. Academic.
   2. Atheist.
   3. Agnostic.
   4. Anarchist.
3. As the nurse cares for a patient in an outpatient clinic, the patient states that he recently lost his position as a volunteer coordinator at a local community center. He expresses that he is angry with his former boss and with God. The nurse knows that the priority at this time is to assess the patient's spirituality in relation to his:
   1. Vocation.
   2. Life satisfaction.
   3. Fellowship and community.
   4. Connectedness with his family and co-workers.
4. A patient who is hospitalized with heart failure states that she sees her illness as an opportunity and a challenge. Despite her illness, she is still able to see that life is worth living. This is an example of:
   1. Hope.
   2. Faith.
   3. Values.
   4. Connectedness.
5. Which of the following statements made by an older adult whose husband recently died most indicates the need for follow-up by the nurse?
   1. "I planted a tree at church in my husband's honor."
   2. "I have been unable to talk with my children lately."
   3. "My friends think that I need to go to a grief support group."
   4. "I believe that someday I'll meet my husband in heaven."
6. Which of the following nursing interventions support(s) a healing relationship with a patient? (Select all that apply):
   1. Praying with the patient
   2. Giving pain medications before a painful procedure
   3. Telling a patient that it is time to take a bath before family arrive to visit
   4. Making the patient's bed following hospital protocol
   5. Helping a patient see positive aspects related to a chronic illness
7. A patient expresses the desire to learn how to meditate. What does the nurse need to do first?
   1. Answer the patient's questions
   2. Help the patient get into a comfortable position
   3. Select a teaching environment that is free from distractions
   4. Encourage the patient to meditate for 10 to 20 minutes 2 times a day
8. An older adult is receiving hospice care. Which nursing intervention(s) help the patient cope with feelings related to death and dying? (Select all that apply.)
   1. Teaching the patient how to use guided imagery
   2. Encouraging the family to visit the patient frequently
   3. Taking the patient's vital signs every time the nurse visits
   4. Teaching the patient how to manage pain and take pain medications
   5. Helping the patient put significant photographs in a scrapbook for the family
9. Which of the following questions would best assess a patient's level of connectedness?
   1. What gives your life meaning?
   2. Which aspects of your spirituality would you like to discuss right now?
   3. Who do you consider to be the most important person in your life at this time?
   4. How do you feel about the accomplishments you've made in your life so far?
10. A nurse is using the B-E-L-I-E-F tool to complete a spiritual assessment on a 12-year-old male who has recently been diagnosed with acute lymphocytic leukemia. Which of the following questions would the nurse use to assess the child's involvement in the spiritual community?
    1. Which church do you attend?
    2. Which sports do you like to play?
    3. Are there any foods you cannot eat?
    4. In which church activities do you participate?
11. A nurse is caring for a patient who refuses to eat until after the sun sets. Which religion does this patient most likely practice?
    1. Islam
    2. Sikhism
    3. Hinduism
    4. Catholicism

12. A Catholic patient with diabetes receives the following items on his meal tray on the Friday before Easter. For which of the foods does the nurse offer to substitute?
    1. Apple sauce
    2. Cheese and crackers
    3. Spaghetti with meat sauce
    4. Tossed salad with ranch dressing
13. A nurse is working in a health clinic on a Navajo reservation. He or she plans care for the patients knowing which of the following is true?
    1. The patients may not be on time for their appointments.
    2. The patients most likely do not trust the doctors and nurses.
    3. The patients probably are not comfortable if they have to remove their undergarments.
    4. Terminally ill patients probably want to receive the sacrament, the anointing of the sick.
14. A 62-year-old male patient has just been told he has a terminal illness. Which of the following statements supports a nursing diagnosis of *spiritual distress related to diagnosis of terminal illness?*
    1. "I have nothing to live for now."
    2. "What will happen to my wife when I die?"
    3. "How much longer do I have to live?"
    4. "I need to go to church and pray for a miracle."
15. Which of the following would be the most appropriate outcome for a patient who has a nursing diagnosis of *spiritual distress related to loneliness?*
    1. Encourage the patient to meditate 2 to 3 times a week.
    2. The patient will set up a time to speak to a close friend in 1 week.
    3. Encourage the patient to phone his brother and set up a time to go out for dinner.
    4. The patient will experience greater connections with family members in 2 months.

Answers: **1.** 2; **2.** 2; **3.** 1; **4.** 1; **5.** 2; **6.** 1, 5; **7.** 3; **8.** 1, 2, 5; **9.** 3; **10.** 4; **11.** 1; **12.** 3; **13.** 1; **14.** 1; **15.** 2.

CHAPTER

36

The Experience of Loss, Death, and Grief

OBJECTIVES

- Identify the nurse's role when caring for patients who are experiencing loss, grief, or death.
- Describe the types of loss experienced throughout life.
- Discuss grief theories.
- Identify types of grief.
- Describe characteristics of a person experiencing grief.
- Discuss variables that influence a person's response to grief.
- Develop a nursing care plan for a patient and family experiencing loss and grief.
- Identify ways to collaborate with family members and the interdisciplinary team to provide palliative care.
- Describe interventions for symptom management in patients at the end of life.
- Discuss the criteria for hospice care.
- Describe care of the body after death.
- Discuss the nurse's own grief experience when caring for dying patients.
- Identify methods for nurse self-care in grief and loss.

KEY TERMS

Actual loss, p. 709
Ambiguous loss, p. 710
Anticipatory grief, p. 710
Autopsy, p. 724
Bereavement, p. 709
Compassion fatigue, p. 726
Complicated grief, p. 710
Disenfranchised grief, p. 710
Disorganization and despair, p. 710
Grief, p. 709
Hope, p. 712
Hospice, p. 719
Maturational loss, p. 709
Mourning, p. 709
Necessary loss, p. 709
Normal (uncomplicated) grief, p. 709
Numbing, p. 710
Organ and tissue donation, p. 724
Palliative care, p. 719
Postmortem care, p. 724
Perceived loss, p. 709
Reminiscence, p. 711
Reorganization, p. 710
Situational loss, p. 709
Yearning and searching (separation anxiety), p. 710

Nurses have a primary duty to prevent illness and injury and help patients return to health. They also play a vital role in helping patients and families cope with things that cannot be changed and facilitate a peaceful death. Patients and families need expert nursing care through grief and death, perhaps more than at any other time. Caring for patients at the end of life requires knowledge and caring to bring comfort, even when the hope for cure or continued life is not possible. Although specialized roles and a sophisticated knowledge base for palliative and hospice care nurses have expanded greatly in the last two decades, nurses in all settings (i.e., residential facilities, hospitals, nursing homes, critical care units, and home health) provide most of the care for the seriously ill and dying.

Despite the pervasiveness of serious chronic illness and the high incidence of death in health care settings, many health care professionals feel apprehensive about providing end-of-life care (Weigel et al., 2007). Talking openly about death is discouraged in American society (i.e., in our everyday lives, our language, and even our thinking) (Matzo and Sherman, 2010). Terminal illness reminds friends and family members of their own mortality, which often causes them, sometimes unconsciously, to withdraw from the dying person. Nurses also grieve when witnessing the suffering of others.

You need to know that you are capable of providing the asset most valued by patients and family members at the end of life: a compassionate, attentive, and patient-centered approach to care. With each experience of caring for people at the end of life, you gain more confidence, courage, and compassion to accompany patients and family members through this intimate and meaningful phase of human transition. Your skills and knowledge base develop quickly if you have the desire and willingness to learn, be present, and seek the help needed to learn how to give excellent care at the end of life.

SCIENTIFIC KNOWLEDGE BASE

Loss

Throughout a lifetime people grieve the loss of multiple things: body parts or function, self-esteem, friendships, confidence, or income. Children develop independence from the adults who raise them, begin and leave school, change friends, begin careers, and form new relationships. From birth to death people form attachments and suffer losses. Illness also changes or threatens a person's identity, and at some point everyone dies. People experience loss when another person, possession, body part, familiar environment, or sense of self changes or is no longer present (Table 36-1). The values learned in one's family, religious community, society, and culture shape what a person regards as loss and how to grieve (Walter and McCoyd, 2009).

Life changes are natural and often positive. As people move forward in life, they learn that change always involves a **necessary loss,** which is a part of life. They learn to expect that most necessary losses are eventually replaced by something different or better. However, some losses cause them to undergo permanent changes in their lives and threaten their sense of belonging and security. The death of a loved one, divorce, or loss of independence changes life forever and often significantly disrupts a person's physical, psychological, and spiritual health. A **maturational loss** is a form of necessary loss and includes all normally expected life changes across the life span. A mother feels loss when her child leaves home for the first day of school. A grade school child does not want to lose her favorite teacher and classroom. Maturational losses associated with normal life transitions help people develop coping skills to use when they experience unplanned, unwanted, or unexpected loss. Some losses seem unnecessary and are not part of expected maturation experiences. Sudden, unpredictable external events bring about **situational loss.** For example, a person in an automobile accident sustains an injury with physical changes that make it impossible to return to work or school, leading to loss of function, income, life goals, and self-esteem.

TABLE 36-1 Types of Loss

DEFINITION	IMPLICATIONS OF LOSS
Loss of possessions or objects (e.g., theft, deterioration, misplacement, or destruction)	Extent of grieving depends on value of object, sentiment attached to it, or its usefulness.
Loss of known environment (e.g., leaving home, hospitalization, new job, moving out of a rehabilitation unit)	Loss occurs through maturational or situational events or by injury/illness. Loneliness in an unfamiliar setting threatens self-esteem, hopefulness, or belonging.
Loss of a significant other (e.g., divorce, loss of friend, trusted caregiver, or pet)	Close friends, family members, and pets fulfill psychological, safety, love, belonging, and self-esteem needs.
Loss of an aspect of self (e.g., body part, job, psychological or physiological function)	Illness, injury, or developmental changes result in loss of a valued aspect of self, altering personal identity and self-concept.
Loss of life (e.g., death of family member, friend, co-worker, or one's own death)	Loss of life grieves those left behind. Dying persons also feel sadness or fear pain, loss of control, and dependency on others.

Losses may be actual or perceived. An **actual loss** occurs when a person can no longer feel, hear, see, or know a person or object. Examples include the loss of a body part, death of a family member, or loss of a job. Lost valued objects include those that wear out or are misplaced, stolen, or ruined by disaster. A child grieves the loss of a favorite toy washed away in a flood. A **perceived loss** is uniquely defined by the person experiencing the loss and is less obvious to other people. For example, some people perceive rejection by a friend to be a loss, which creates a loss of confidence or changes their status in a group. How an individual interprets the meaning of the perceived loss affects the intensity of the grief response. Perceived losses are easy to overlook because they are experienced so internally and individually, but they are grieved in the same way as an actual loss.

Each person responds to loss differently. The type of loss and the person's perception of it influence the depth and duration of the grief response. For some individuals the loss of an object (e.g., home or treasured inherited gift) generates the same level of distress as the loss of a person, depending on the value the person places on the object. Chronic illnesses, disabilities, and hospitalization produce multiple losses. When entering an institution for care, patients lose access to familiar people and environments, privacy, and control over body functions and daily routines. A chronic illness or disability adds financial hardships for most people and often brings about changes in lifestyle and dependence on others. Even brief illnesses or hospitalizations cause temporary changes in family role functioning, daily activities, and relationships.

Death is the ultimate loss. Although it is a necessary part of the continuum of life and of being human, death represents the unknown and generates anxiety, fear, and uncertainty for many people. Death permanently separates people physically from important persons in their lives and causes fear, sadness, and regret for the dying person, family members, friends, and caregivers. A person's culture, spirituality, personal beliefs and values, previous experiences with death, and degree of social support influence the way he or she approaches death.

Grief

Grief is the emotional response to a loss, manifested in ways unique to an individual and based on personal experiences, cultural expectations, and spiritual beliefs (Walter and McCoyd, 2009) (see Chapters 9 and 35). Coping with grief involves a period of **mourning,** the outward, social expressions of grief and the behavior associated with loss. Most mourning rituals are culturally influenced, learned behaviors. For example, the Jewish mourning ritual of *Shivah* incorporates the helping behaviors of the community toward those experiencing death, sets expectations for survivor behavior, and sustains the community with tradition and rituals (Bauer-Wu et al., 2007). The term **bereavement** encompasses both grief and mourning and includes the emotional responses and outward behaviors of a person experiencing loss (AACN, 2008). Recognizing that there are different types of grief can help nurses plan and implement appropriate care.

Normal Grief. Normal (uncomplicated) grief is a common, universal reaction characterized by complex emotional, cognitive, social, physical, behavioral, and spiritual responses to loss and death. Feelings of acceptance, disbelief, yearning, anger, and depression are displayed in normal bereavement grief. Although manner of death (violent, unexpected, or traumatic) poses greater risk to survivors, it does not always determine how an individual will grieve. Helpful coping mechanisms for grieving people include

hardiness and resilience, a personal sense of control, and the ability to make sense of and identify positive possibilities after a loss.

Anticipatory Grief. A person experiences **anticipatory grief,** the unconscious process of disengaging or "letting go" before the actual loss or death occurs, especially in situations of prolonged or predicted loss (Simon, 2008). When grief extends over a long period of time, people absorb loss gradually and begin to prepare for its inevitability. They experience intense responses to grief (e.g., shock, denial, and tearfulness) before the actual death occurs and often feel relief when it finally happens. The idea that people actually grieve in anticipation (rather than following a loss) is debated by researchers. Another way to think about anticipatory grief is that it is a forewarning or cushion that gives people time to prepare or complete the tasks related to the impending death. However, this idea may not apply in every situation. Although forewarning is a buffer for some individuals, it increases stress for others, creating an emotional roller coaster of highs and lows.

Disenfranchised Grief. People experience **disenfranchised grief,** also known as *marginal* or *unsupported grief,* when their relationship to the deceased person is not socially sanctioned, cannot be openly shared, or seems of lesser significance. The person's loss and grief do not meet the norms of grief acknowledged by his or her culture, cutting the grieving person off from social support and the sympathy given to persons with "legitimate" losses. The grieving person often wonders if he or she should call the experience a loss. Examples include the death an ex-spouse, a gay partner, or a pet or death from a stigmatized illness such as alcoholism or during the commission of a crime (Hooyman and Kramer, 2008; Walter and McCoyd, 2009).

Ambiguous Loss. Sometimes people experience losses that are marked by uncertainty. **Ambiguous loss,** a type of disenfranchised grief, occurs when the lost person is physically present but not psychologically available, as in cases of severe dementia or severe brain injury. Other times the person is gone (e.g., after a kidnapping or as a prisoner of war); but the grieving person maintains an ongoing, intense psychological attachment, never sure of the reality of the situation. Ambiguous losses are particularly difficult to process because of the lack of finality and unknown outcomes (Walter and McCoyd, 2009).

Complicated Grief. Some people do not experience a normal grief process. In **complicated grief** a person has a prolonged or significantly difficult time moving forward after a loss. He or she experiences a chronic and disruptive yearning for the deceased; has trouble accepting the death and trusting others; and/or feels excessively bitter, emotionally numb, or anxious about the future. Complicated grief occurs more often when a person had a conflicted relationship with the deceased, prior or multiple losses or stressors, mental health issues, or lack of social support. Loss associated with homicide, suicide, sudden accidents, or the death of a child has the potential to become complicated. Specific types of complicated grief include exaggerated, delayed, and masked grief.

Exaggerated Grief. A person with an exaggerated grief response often exhibits self-destructive or maladaptive behavior, obsessions, or psychiatric disorders. Suicide is a risk for these people.

Delayed Grief. A person's grief response is unusually delayed or postponed, often because the loss is so overwhelming that the person must avoid the full realization of the loss. A delayed grief response is frequently triggered by a second loss, sometimes seemingly not as significant as the first loss.

Masked Grief. Sometimes a grieving person behaves in ways that interfere with normal functioning but is unaware that the disruptive behavior is a result of the loss and ineffective grief resolution (AACN, 2008).

Theories of Grief and Mourning

Knowledge of grief theories and normal responses to loss and bereavement will help you better understand these complex experiences and how to help a grieving person. Grief theorists describe the physical, psychological, and social reactions to loss. Remember that people who vary from expected norms of grief or theoretical descriptions are not abnormal. The variety of theories supports the complexity and individuality of grief responses. Although most grief theories describe how people cope with death, they also help to understand responses to other significant losses. A review of some classic grief theories follows.

Stages of Dying. Basing her research on interviews with dying people, Kübler-Ross (1969) describes five stages of dying in her classic behavioral theory: denial, anger, bargaining, depression, and acceptance. A person in the denial stage cannot accept the fact of the loss, which often provides psychological protection from a loss that the person cannot yet bear. When experiencing the anger stage of adjustment to loss, a person expresses resistance and sometimes feels intense anger at God, other people, or the situation. Bargaining cushions and postpones awareness of the loss by trying to prevent it from happening. Grieving or dying people make promises to self, God, or loved ones that they will live or believe differently if they can be spared death. When a person realizes the full impact of the loss, depression occurs. Some individuals feel overwhelmingly sad, hopeless, and lonely. In acceptance the person incorporates the loss into life; develops the capacity to have a breadth of emotions, even positive ones; and finds ways to move forward. The stages of dying are not linear. Patients will move back and forth through the stages.

Attachment Theory. Bowlby's (1980) attachment theory, also a stage theory, describes the experience of mourning based on his studies of children separated from their parents during World War II. Attachment, an instinctive behavior, leads to the development of bonds between children and their primary caregivers. Relational bonds are present and active throughout the life cycle, and individuals later generalize them to persons in other relationships. Attachment behavior ensures survival because it keeps people close to those who offer love, protection, and support.

Bowlby describes four stages of mourning: numbing, yearning and searching, disorganization and despair, and reorganization. **Numbing,** the shortest stage of mourning, may last from a few hours to a week or more. The grieving person describes this stage as feeling "stunned" or "unreal." Numbing protects the person from the full impact of the loss. Emotional outbursts of tearful sobbing and acute distress characterize the second bereavement stage, **yearning and searching (separation anxiety).** Common physical symptoms in this stage include tightness in the chest and throat, shortness of breath, a feeling of lethargy, insomnia, and loss of appetite. A person also experiences an inner, intense yearning for the lost person or object. This stage lasts for months or considerably longer. During the stage of **disorganization and despair,** a person endlessly examines how and why the loss occurred or expresses anger at anyone who seems responsible for the loss. The grieving person retells the loss story again and again and gradually realizes that the loss is permanent. With **reorganization,** which usually takes a year or more, the person begins to accept change, assume unfamiliar roles, acquire new skills, and build new relationships. Persons who are reorganizing begin to separate themselves from their lost relationship without feeling that they are lessening its importance.

Grief Tasks Model. Worden (1982) proposes a task-based grief theory. He describes how individuals actively engage in behaviors by responding to outside interventions to help themselves. Working through the grief tasks typically requires a minimum of a full year, although the time varies from person to person.

- *Task I: Accept the reality of the loss.* Even when a death is expected, survivors register some disbelief and surprise that it has really happened. Task I involves the process of accepting that the person or object is gone and will not return.
- *Task II: Experience the pain of grief.* Even though people respond to loss differently, it is impossible to experience a significant loss without some emotional pain. People react with sadness, loneliness, despair, or regret and work through painful feelings using the coping mechanisms most familiar and comfortable to them.
- *Task III: Adjust to a world in which the deceased is missing.* A person does not realize the full impact of a loss for at least 3 months. Family members or friends pay less attention to the bereaved person at about the same time, just as the finality of the loss becomes real. People completing this task begin to take on roles formerly filled by the deceased, including some jobs they do not want.
- *Task IV: Emotionally relocate the deceased and move on with life.* The deceased person is not forgotten but rather takes a different and less prominent place in the survivor's emotional life. People often fear that in making new attachments they will forget their loved one or seem disloyal, making this a potentially difficult task to complete. Realizing that it is possible to love other people without betraying the deceased, the person moves forward.

Rando's "R" Process Model. Rando (1993) describes grief as a series of processes instead of stages or tasks. However, her processes are similar to the stages and tasks already described. Rando's processes include recognizing the loss, reacting to the pain of separation, reminiscing, relinquishing old attachments, and readjusting to life after loss. **Reminiscence** is an important activity in grief and mourning. A person recollects and reexperiences the deceased and the relationship by mentally or verbally anecdotally reliving and remembering the person and past experiences.

Dual Process Model. Newer theories account for gender and cultural variations and address the limitations of theories focused mainly on internal, emotional responses to grief. The dual process model describes the everyday life experiences of grief as moving back and forth between loss-oriented and restoration-oriented activities (Wright and Hogan, 2008). Loss-oriented behaviors include grief work, dwelling on the loss, breaking connections with the deceased person, and resisting activities to move past the grief. Restoration-oriented activities such as attending to life changes, finding new roles or relationships, coping with finances, and participating in distractions provide balance to the loss-oriented state. The extent to which an individual engages in loss or restoration-oriented processes depends on factors such as personality, coping styles, or cultural practices.

Post Modern Grief Theories. Some experts believe the stage and task theories described previously lack empirical evidence, do not allow for cultural differences, and assume there is an end point in grieving (Walter and McCoyd, 2009). More recent grief theories take into consideration that human beings construct their own experiences and truths differently and make their own meanings when confronted with loss and death. Differences in social and historical context, family structure, and cognitive capacities shape an individual's truths and grief experiences. No one's grief follows a predetermined path.

NURSING KNOWLEDGE BASE

Nurses develop plans of care to help patients and family members who are undergoing loss, grief, or death experiences. Based on nursing research, practice evidence, nursing experience, and patient and family preferences, nurses implement plans of care in acute care, nursing home, hospice, home care, and community settings. Extensive nursing education programs support the improvement of end-of-life care at every level of practice. The End-of-Life Nursing Education Consortium (ELNEC) provides nurses with basic and advanced curricula to care for patients and families experiencing loss, grief, death, and bereavement (AACN, 2008); and nursing textbooks provide advanced discussions on multiple dimensions of palliative and end-of-life care (Ferrell and Coyle, 2010; Matzo and Sherman, 2010). In conjunction with the Hospice and Palliative Care Nurses Association, the American Nurses Association has developed the Scope and Standards of Hospice and Palliative Nursing Practice (2007). Professional nursing organizations such as the American Society of Pain Management Nurses and the American Association of Critical Care Nurses offer evidence-based practice guidelines for managing clinical and ethical issues at the end of life in many health care settings.

Factors Influencing Loss and Grief

Multiple factors influence the way a person perceives and responds to loss. They include developmental factors, personal relationships, the nature of the loss, coping strategies, socioeconomic status, and cultural and spiritual influences and beliefs.

Human Development. Patient age and stage of development affect the grief response. For example, toddlers cannot understand loss or death but often feel anxiety over the loss of objects and separation from parents. They sometimes express the sense of absence they feel with changes in eating and sleeping patterns, fussiness, or bowel and bladder disturbances. School-age children understand the concepts of permanence and irreversibility but do not always understand the causes of a loss. Some have intense periods of emotional expression. Young adults undergo many necessary developmental losses related to their evolving future. They leave home, begin school or a work life, or form significant relationships. Illness or death disrupts the young adult's future and establishment of an autonomous sense of self. Midlife adults also experience major life transitions such as caring for aging parents, dealing with changes in marital status, and adapting to new family roles (Walter and McCoyd, 2009). For older adults the aging process leads to necessary and developmental losses. Some older adults experience age discrimination, especially when they become dependent or are near death; but they show resilience after a loss as a result of their prior experiences and developed coping skills (Box 36-1).

Personal Relationships. When loss involves another person, the quality and meaning of the lost relationship influence the grief response. When a relationship between two people was very rewarding and well connected, the survivor often finds it difficult to move forward. Grief resolution is hampered by regret and a sense of unfinished business, especially when people are closely related but did not have a good relationship at the time of death. Social support and the ability to accept help from others are critical variables in recovery from loss and grief. When patients do not receive supportive understanding and compassion from

BOX 36-1 FOCUS ON OLDER ADULTS

Grief Considerations in Older Adults

- There is little evidence that grief experiences differ because of age alone. Responses to loss are more likely related to the nature of the specific loss experience and individual differences.
- Increased age increases the likelihood that older adults have faced multiple losses—loved ones, friends, valued objects, a child, or declining health. Older adults residing in communal living situations experience many losses as friends die.
- Many older adults exhibit resilience. Others around them can learn from their courage and ability to respond to life challenges graciously, accepting life with integrity and wholeness (Walter and McCoyd, 2009).
- Older adults are at risk for complicated grieving as a result of multiple losses, potential for cognitive impairment, or decreased physical resources. The risks include depression, loneliness, and accompanying functional decline.
- Physical decline caused by chronic illness sometimes leads to grief over lost health, function, and roles.
- Pain is often undertreated in older adults, particularly in people with dementia or cognitive impairments. Side effects of pain medications are usually more pronounced in older adults (Matzo and Sherman, 2010).
- Older adults benefit from the same therapeutic techniques as persons in other age-groups. Evidence indicates that positive reappraisal (cognitive restructuring) helps older adults adapt to significant losses. Older adults have opportunities for growth and development through their loss experiences (Hooyman and Kramer, 2008).
- Relieving depression and maintaining physical function are therapeutic goals for grieving older adults.

others, grief becomes complicated or prolonged (Hooyman and Kramer, 2008).

Nature of the Loss. Exploring the meaning a loss has for your patient helps you better understand the effect of the loss on the patient's behavior, health, and well-being. Highly visible losses generally stimulate a helping response from others. For example, the loss of one's home from a tornado often brings community and governmental support. A more private loss such as a miscarriage brings less support from others. A sudden and unexpected death poses different challenges than those in a debilitating chronic illness. When the death is sudden and unexpected, the survivors do not have time to let go. In chronic illness survivors have memories of prolonged suffering, pain, and loss of function. Death by violence or suicide or multiple losses by their very nature complicate the grieving process in unique ways (Walter and McCoyd, 2009).

Coping Strategies. Life experiences shape the coping strategies that a person uses to deal with the stress of loss. Patients rely first on familiar coping strategies. When the usual coping strategies do not work, they need new ones. Emotional disclosure (i.e., venting, talking about one's feelings, or expressing anger or other negative feelings) is one way to cope with loss. Negative themes that are present when people talk about grief sometimes predict more distressful reactions (Maciejewski, 2007). However, some individuals cope better in situations of loss when they instead focus on positive emotions and optimistic feelings. Emotional disclosure is often accomplished by having people write about their feelings in letters to lost loved ones or personal journals.

Socioeconomic Status. Socioeconomic status influences a person's ability to access support and resources for coping with loss and physical responses to stress (Cohen et al., 2006). When people lack financial, educational, or occupational resources, the burdens of loss multiply. For example, a patient with limited finances is not able to replace a car demolished in an accident and pay for the associated medical expenses.

Culture and Ethnicity. Culture and family or religious affiliation influences interpretations of loss and the ability to establish acceptable expressions of grief, which affects the ability to provide stability and structure in the midst of chaos and loss. Expressions of grief in one culture do not always make sense to people from a different culture (see Chapter 9). Try to understand and appreciate each patient's cultural values related to loss, death, and grieving. Grief theories commonly used to understand loss and death have cultural limitations. For example, some theorists describe grief as a process of "work" or "tasks" that occurs in stages or on projected timelines. North Americans may better understand work, tasks, and time expectations for grief compared to other cultural groups not as defined by work achievements or with a different sense of time. Some cultural groups experience grief as a timeless, communal expression or state of being. Many people in Western European and American cultures hold back their public displays of emotion. In other cultures behaviors such as public wailing and physical demonstrations of grief, including survivor body mutilation, show respect for the dead. Core American cultural values of individualism and self-determination stand in contrast with communal, family, or tribal ways of life. Americans value and expect honesty and truth telling in end-of-life situations, but some cultures have strict taboos surrounding what should be discussed regarding the diagnosis and prognosis in serious illness (Erichsen et al., 2010; Johnstone and Kanitsaki, 2009). Cultural differences influence processes such as obtaining informed consent or making life-support decisions. Research has shown that ethnicity is strongly related to attitudes toward life-sustaining treatments during terminal illness and the use of hospice services (Rosenfeld et al., 2007).

Spiritual and Religious Beliefs. The care of seriously ill patients usually involves medical interventions to restore or maintain health. A contrasting set of practices (i.e., transformative strategies) acknowledge life limits and help dying people find meaning in suffering so they are able to transcend (go beyond) their personal existence. Transformative practices are associated with healing and spiritual or religious beliefs. Spiritual resources include faith in a higher power, communities of support, friends, a sense of hope and meaning in life, and religious practices. Spirituality affects the patient's and family members' ability to cope with loss. Positive correlations show that spiritual well-being, peacefulness, comfort, and serenity are all important aspects of a peaceful death (Kruse et al., 2007). Findings in the literature verify that religious beliefs provide a sense of structure in end-of-life situations and are linked to more positive attitudes toward death (Ladd, 2007).

Hope, a multidimensional concept considered to be a component of spirituality, energizes and provides comfort to individuals experiencing personal challenges. Hopefulness gives a person the ability to see life as enduring or having meaning or purpose. As a future-shaping, motivating force, hope helps patients maintain anticipation of a continued good, an improvement in their circumstances, or a lessening of something unpleasant (Clayton et al., 2008). With hope a patient moves from feelings of weakness and vulnerability to living as fully as possible. Maintaining a sense of hope depends in part on a person having strong relationships and emotional connectedness to others. On the other hand, spiritual distress often arises from a patient's inability to feel hopeful or foresee any favorable outcomes. Spirituality and hope play a vital role in a patient's adjustment to loss and death (see Chapter 35).

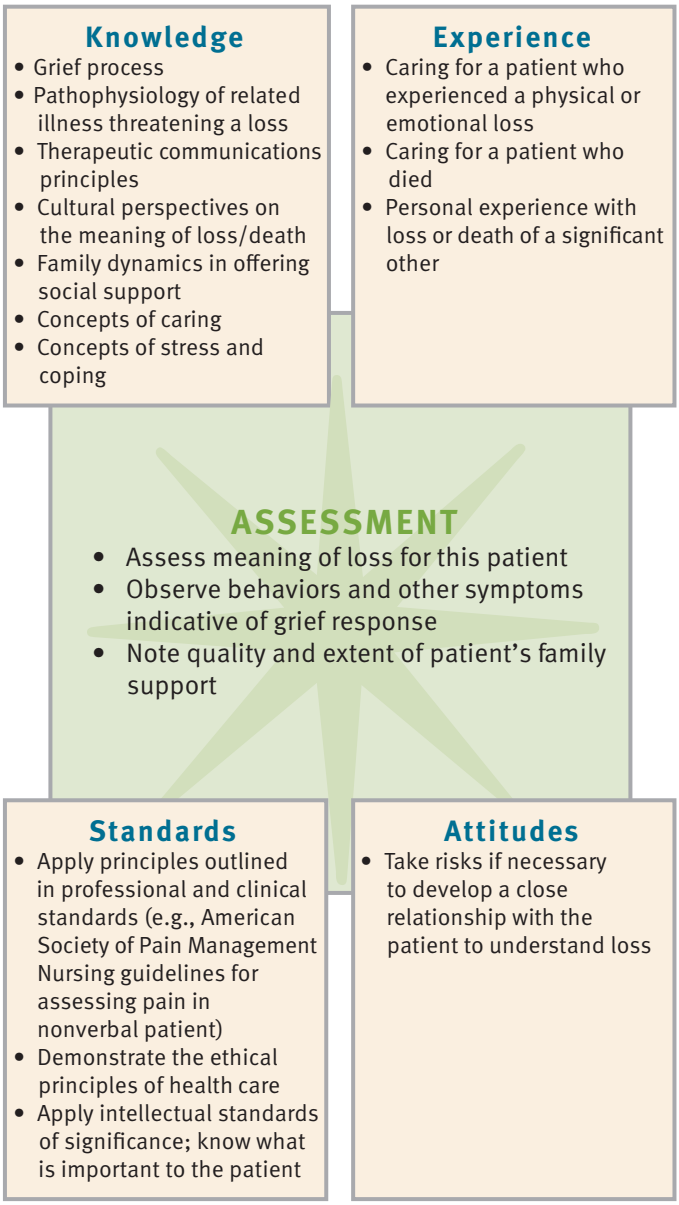

FIG. 36-1 Critical thinking model for loss, death, and grieving assessment.

CRITICAL THINKING

To provide appropriate and responsive care for the grieving patient and family, use critical thinking skills to synthesize scientific knowledge from nursing and nonnursing disciplines, professional standards, evidence-based practice, patient assessments, previous caregiving experiences, and self-knowledge. Critical thinking informs all steps of the nursing process (see Chapter 15).

During the assessment phase use critical thinking to gather and analyze the data that lead to the selection of appropriate nursing diagnoses (Fig. 36-1). To understand a patient's subjective experiences of loss, form assessment questions based on your theoretical and professional knowledge of grief and loss but then listen carefully to the patient's perceptions. A culturally competent nurse also uses culture-specific understanding of grief to explore the meaning of loss with a patient.

BOX 36-2 A DYING PERSON'S BILL OF RIGHTS

I have the right to be treated as a living human being until I die.
I have the right to be in control.
I have the right to maintain a sense of hopefulness, however changing its focus may be.
I have the right to be cared for by those who can maintain a sense of hopefulness, however changing this may be.
I have the right to have a sense of purpose.
I have the right to express my feelings and emotions about my approaching death in my own way.
I have the right to participate in decisions about my care.
I have the right to expect continuing medical and nursing attention even though "cure" goals must be changed to "comfort" goals.
I have the right not to die alone.
I have the right to be free of pain.
I have the right to have a respected spirituality.
I have the right to have my questions answered honestly.
I have the right not to be deceived.
I have the right to have help from and for my family in accepting my death.
I have the right to die in peace and dignity.
I have the right to retain my individuality and not be judged for my decisions that may be contrary to beliefs of others.
I have the right to discuss and enlarge my religious and/or spiritual experiences, whatever these may mean to others.
I have a right to expect that the sanctity of my human body will be respected after death.
I have the right to be cared for by caring, sensitive, knowledgeable people who will try to understand my needs and will be able to gain some satisfaction in helping me face my death.

Modified from Barbus AJ: The dying person's bill of rights, *Am J Nurs* 75:99, 1975; and Dying person's bill of rights, www.kingston.gov.uk/dyingbillofrightsp.pdf. Accessed November 10, 2011.

Being familiar with commonly experienced responses to loss enables you to better understand a patient's emotions and behaviors. Some patients ignore, lash out, plead with, or withdraw from other people as part of a normal response to loss. Instead of "taking things personally," a critically thinking nurse integrates theory, prior experience, appreciation of subjective experiences, and self-knowledge to respond to the patient's emotions with patience and understanding. In designing plans of care, use professional standards, including the Nursing Code of Ethics (see Chapter 22), the dying person's bill of rights (Box 36-2), the American Nurses Association Scope and Standards of Hospice and Palliative Nursing Practice (2007), and clinical standards such as the American Society of Pain Management Nurses' guidelines for pain assessment in the nonverbal patient (Herr et al., 2006).

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. A trusting, helping

relationship with grieving patients and family members is essential to the assessment process. A caring nurse encourages a patient to tell his or her story, which then becomes a primary source of assessment data (Betcher, 2010). Look for opportunities to invite patients to share their experiences, being aware that attitudes about self-disclosure; sharing emotions; or talking about illness, fears, and death are shaped by an individual's personality, coping style, and culture.

Through the Patient's Eyes. Explore with patients their unique responses to grief or their preferences for end-of-life care, which may include advance directives. Patient perceptions and expectations influence how you prioritize your nursing diagnoses. To assess patient perceptions, you ask, "What is the most important thing I can do for you right now?" You usually gather information from patients first, but with advanced illness and as death approaches, patients often rely on family members to communicate for them. Encourage family members to share their goals and perceptions with you. Whether or not they accurately represent a patient's viewpoints or wishes has been the topic of extensive research (Gardner and Kramer, 2010). Most often they provide valuable information about patient preferences and clarify misunderstandings or identify overlooked information. Assess patients' and family members' understanding of treatment options to implement a mutually developed care plan. Assessment of grief responses extends throughout the course of an illness into the bereavement period following a death. Patients with advanced chronic illness and their families eventually face end-of-life care decisions and should discuss the content of any advance directives together. Because most deaths are now "negotiated" among patients, family members, and the health care team, discuss end-of-life care preferences early in the assessment phase of the nursing process. If you feel uncomfortable in assessing a patient's wishes for end-of-life care by yourself, ask a health care provider experienced in discussing these issues to help you. Communicate what you have learned about patient preferences during any RN hand-off, at health care team conferences, in written care plans, and through ongoing consultation (see Chapter 26).

Speak to patients and family members using honest and open communication, remembering that cultural practices influence how much information the patient shares. Keep an open mind, listen carefully, and observe the patient's verbal and nonverbal responses. Facial expressions, voice tones, and avoided topics often disclose more than words. Anticipate common grief responses, but allow patients to describe their experiences in their own words. Open-ended questions such as "What do you understand about your diagnosis?" or "You seem sad today. Can you tell me more?" may open the door to a patient-centered discussion. Many people find it difficult to talk about loss, fear, death, or grief. The use of pauses, gentle questioning, and silence honors the patient's privacy and readiness to talk. Talk to patients and family members in a private, quiet setting. Many times a patient wants to have family members present so everyone hears the same thing and has an opportunity to add to the conversation. However, some people want their concerns and questions addressed privately. Ask patients and family members about their preferences. As you gather assessment data, summarize and validate your impressions with the patient or family member. Information from the medical record and other members of the health care team, physicians, social workers, and spiritual care providers contributes to your assessment data.

Because of the importance of symptom management and priority of comfort in end-of-life care, prioritize your initial assessment to encourage patients to identify any distressing symptoms. Completing a thorough assessment is difficult when patients are in pain, anxious, depressed, or short of breath.

Grief Variables. Conversations about the meaning of loss to a patient often leads to other important areas of assessment, including the patient's coping style, the nature of family relationships, social support systems, the nature of the loss, cultural and spiritual beliefs, life goals, family grief patterns, self-care, and sources of hope (Box 36-3). Use skills appropriate for assessing a patient's culture, family, self-concept, or spiritual beliefs (see Chapters 9, 10, 33, and 35) to acquire a deeper understanding of his or her loss.

Knowing the commonly experienced reactions to grief and loss and grief theories guides your critical thinking and assessment skills. A single behavior can occur in all types of grief. If a grieving patient describes loneliness and difficulty falling asleep, consider all factors surrounding the loss in context. What was the loss? When did it occur? What was the meaning of the loss to the patient? For example, when your patient exhibits signs of a normal grief reaction, but you learn that the loss occurred 2 years ago, the patient's response most likely indicates a complicated, chronic grief experience. Focus your assessment on how a patient is reacting to

BOX 36-3 NURSING ASSESSMENT QUESTIONS

Nature of Relationships
- How long have you known _____ (the deceased person)?
- What role did (name person) play in your life?
- Tell me about your relationship with (name person).

Social Support Systems
- Who is "there for you?" Absent? Who provides support?
- What do others do for you that is most meaningful or helpful?
- Are family/friends available when needed? Which friends or relatives do you wish were here?

Nature of the Loss
- What does this loss mean to you?
- What other losses have you experienced?

Cultural and Spiritual Beliefs
- What is your belief about death? Meaning of life?
- Which rituals are important to you at the end of life?
- How do members of your culture or religious group respond to this loss?

Life Goals
- What are your life goals at this time?
- How have your goals changed because of this experience?
- Are you able to envision what you will do in the future?

Family Grief Patterns
- How have you/your family dealt with loss in the past?
- What are your family's strengths?
- How have family relationships changed as a result of your loss?
- What role do you assume in your family during stressful situations?

Self-Care
- Tell me how you are feeling.
- What are you doing to take care of yourself now?
- What helps you when you feel this sad? What doesn't help?

Hope
- What do you hope for right now?
- What helps you to remain hopeful? What causes you to lose hope?

loss or grief and not on how *you* believe that patient should be reacting.

Grief Reactions. Use psychological and physical assessment skills to assess a patient's unique grief responses. Most grieving people show some common outward signs and symptoms (Box 36-4). Analyze assessment data and identify possible related causes for the signs and symptoms that you observe. For example, after a significant loss a person has a sad affect, withdrawn behaviors, headaches, upset stomach, and decreased ability to concentrate. You associate these symptoms with several potential causes, including anxiety, gastrointestinal disturbances, medication side effects, or impaired memory. Careful analysis of the symptoms in context leads you to an accurate nursing diagnosis. Ask: How are the symptoms related to one another when they occur? When did they begin? Were they present before the loss? To what does the person attribute them?

Loss takes place in a social context; thus family assessment is a vital part of your data gathering. If a father of a young family is dying, he will not be able to fulfill certain roles, causing a change in family structure. When a person develops a disability, the patient and family members realign their roles and responsibilities to meet new demands. Family members also experience a variety of physical and psychological symptoms. Assess the family's response to loss and recognize that sometimes they are dealing with their grief at a different pace.

BOX 36-4 SYMPTOMS OF NORMAL GRIEF

Feelings
- Sorrow
- Fear
- Anger
- Guilt or self-reproach
- Anxiety
- Loneliness
- Fatigue
- Helplessness/hopelessness
- Yearning
- Relief

Cognitions (Thought Patterns)
- Disbelief
- Confusion or memory problems
- Problems with decision making
- Inability to concentrate
- Feeling the presence of the deceased

Physical Sensations
- Headaches
- Nausea and appetite disturbances
- Tightness in the chest and throat
- Insomnia
- Oversensitivity to noise
- Sense of depersonalization ("Nothing seems real")
- Feeling short of breath, choking sensation
- Muscle weakness
- Lack of energy
- Dry mouth

Behaviors
- Crying and frequent sighing
- Distancing from people
- Absentmindedness
- Dreams of the deceased
- Keeping the deceased's room intact
- Loss of interest in regular life events
- Wearing objects that belonged to the deceased

NURSING DIAGNOSIS

Use critical thinking to cluster assessment data cues, identify defining characteristics, draw conclusions regarding the patient's actual or potential needs or resources, and identify nursing diagnoses applicable to the patient's situation (Box 36-5). In addition to numerous diagnoses related to physical symptoms at the end of life, additional nursing diagnoses relevant for patients experiencing grief, loss, or death include:

- Compromised family coping
- Death anxiety
- Fear
- Impaired comfort
- Ineffective denial
- Grieving
- Complicated grieving
- Risk for complicated grieving
- Hopelessness
- Pain (Acute or Chronic)
- Risk for loneliness
- Spiritual distress
- Readiness for enhanced spiritual well-being

You cannot make accurate nursing diagnoses on the basis of just one or two defining characteristics. Carefully review the data to consider if more than one diagnosis applies. For example, a dying patient who cries often, has angry outbursts, and reports nightmares gives evidence of several possible nursing diagnoses: *pain (acute or chronic), ineffective coping, grieving,* or *spiritual distress.* Examine the available data, validate assumptions with the patient, and look for other validating behaviors and symptoms before making a diagnosis.

BOX 36-5 NURSING DIAGNOSTIC PROCESS

Hopelessness Related to Deteriorating Physical Condition

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient to discuss her understanding of her health situation.	Patient sighs and offers a negative view of her future. She is ready to give up and join her deceased husband.
Observe patient's nonverbal behavior.	Patient keeps eyes closed and has sad facial and voice expressions.
Observe patient's responses to care options.	Patient does not want scheduled test. "There is nothing they can do."
Assess activity level.	Patient states that she has no energy and reports pain; wants to stay in bed.
Observe patient's interactions with others.	Patient shows lack of interest, communicates minimally, and does not want to contact daughter yet.

As part of the diagnostic process, identify the appropriate "related to" factor for each diagnosis. Clarification of the related factors ensures that you select appropriate interventions. For example, a nursing diagnosis of *complicated grieving related to the permanent loss of mobility* requires different interventions than a diagnosis of *complicated grieving related to infertility after an ectopic pregnancy.*

When identifying nursing diagnoses related to a patient's grief or loss, you sometimes identify other related diagnoses. Some patients experiencing grief or impending death have nursing diagnoses such as *disturbed body image* or *impaired physical mobility.* A patient entering the phase of active dying often has diagnoses related to physical changes, including *impaired urinary elimination, bowel incontinence, acute pain, nausea, disturbed sensory perception,* and *ineffective breathing pattern.*

PLANNING

Nurses provide holistic, physical, emotional, social, and spiritual care to patients experiencing grief, death, or loss. Fig. 36-2 illustrates the interrelatedness of critical thinking factors during the planning phase of the nursing process. The use of critical thinking ensures a well-designed care plan that supports a patient's self-esteem and autonomy by including him or her in the planning process. A care plan for the dying patient focuses on comfort; preserving dignity and quality of life; and providing family members with emotional, social, and spiritual support (see the Nursing Care Plan).

Goals and Outcomes. During planning establish realistic goals and expected outcomes based on the nursing diagnoses. Consider a patient's own resources such as physical energy and activity tolerance, family support, and coping style. A nursing diagnosis of *powerlessness related to experimental cancer therapy* with a goal of "Patient will be able to describe the expected course of disease" is realistic for a patient who frequently asks for clarification about the treatment plan and participates in educational discussions. In contrast, an expected outcome of "Patient will identify a minimum of three effective coping skills" is appropriate for a patient with the same nursing diagnosis who is experiencing depression from feeling powerless about having experimental cancer treatment.

The goals of care for a patient experiencing loss are either short or long term, depending on the nature of the loss and the patient's condition. Some nursing care goals for patients facing loss or death include accommodating grief, accepting the reality of a loss, or maintaining meaningful relationships. A possible goal for a young woman with advanced breast cancer is "Maintain a sense of control," with the following potential expected outcomes:

- Patient will participate in all treatment decisions.
- Patient will identify a minimum of three ways to maintain a parental role in the care of her young child.
- Patient will communicate a minimum of three treatment side effects or concerns to the health care team.

Setting Priorities. Encourage patients and family members to share their priorities for care at the end of life. Patients at the end of life or with advanced chronic illness are more likely to want their comfort, social, or spiritual needs met rather than pursuing medical cures. Give priority to a patient's most urgent physical or psychological needs while also considering his or her expectations and priorities. If a terminally ill patient's goals include pain control and promoting self-esteem, pain control takes priority when the patient experiences acute physical discomfort. When comfort needs have been met, then you address other issues important to the patient and family. When it is realistic for the patient to remain independent, strategies that foster his or her sense of autonomy and ability to function independently take priority. A patient's condition at the end of life often changes quickly; therefore maintain an ongoing assessment to revise the plan of care according to patient needs and preferences.

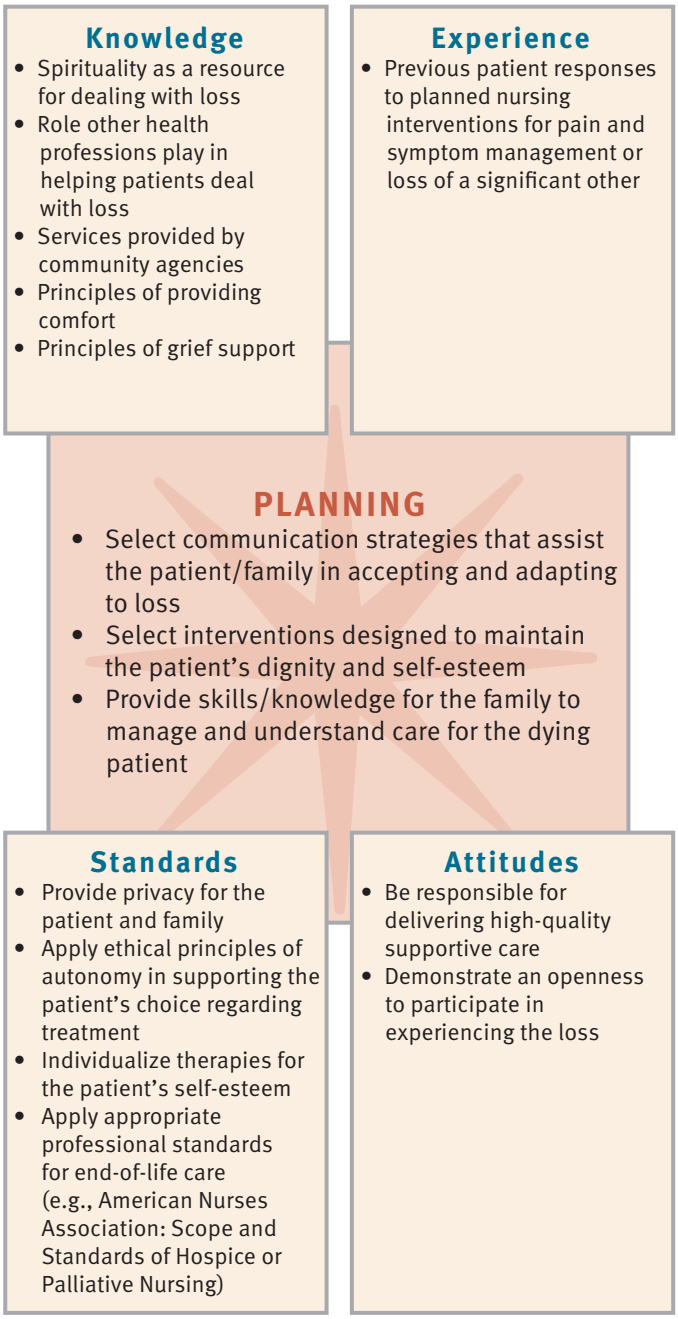

FIG. 36-2 Critical thinking model for loss, death, and grief planning.

When a patient has multiple nursing diagnoses, it is not possible to address them all simultaneously. Fig. 36-3 illustrates a concept map developed for Mrs. Allison, an elderly patient with a medical diagnosis of advanced cancer (leukemia). In conjunction with her recent medical diagnosis, she experiences associated health problems identified in the nursing diagnoses *chronic pain, imbalanced nutrition: less than body requirements, fatigue, and hopelessness.* In

NURSING CARE PLAN

Hopelessness

ASSESSMENT

Mrs. Allison, an 80-year-old woman, was brought to the hospital after a neighbor found her lying on the floor. She was unable to get up after falling down 4 hours earlier. She was admitted to the hospital with low blood pressure, dehydration, and weakness. She reports having severe pain in her back and toes, making it difficult for her to walk. She has also lost weight, has a poor appetite, and is too tired to cook or enjoy activities. Blood tests and physical examination reveal that she has a more serious health problem, likely a form of leukemia, for which she needs a bone marrow biopsy to make a medical diagnosis. Mrs. Allison lives alone since her husband's death 2 years earlier. She has the support of her neighbors and church community and one daughter who lives out of town. On entering the room the nurse notes that Mrs. Allison appears withdrawn and tearful. The nurse talks to her to gather more information.

Assessment Activities	*Findings/Defining Characteristics**
Ask open-ended questions. "It looks like you're having a difficult time. What do you understand about your situation right now?"	"The doctors say that **I might have cancer. Shrugging her shoulders** she states, **"There's nothing they can do. I don't want the test."**
Observe Mrs. Allison's behaviors and nonverbal communication.	Mrs. Allison **appears sad and keeps her eyes closed.** She **cries and sighs frequently.**
Assess Mrs. Allison's pain and energy level.	Mrs. Allison's **great toes are swollen and red.** Reports **constant back pain.** She has **"no energy for anything."**
Observe Mrs. Allison's interactions and interest in others.	Mrs. Allison **does not look at people and does not want to talk to her daughter yet.**
Assess meaning of recent events with Mrs. Allison and invite her to talk about her situation.	Mrs. Allison states that **"It's time to quit on life and be with my late husband."**

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Hopelessness related to declining physical condition.

PLANNING

Goals	*Expected Outcomes (NOC)*†
Mrs. Allison will discuss care priorities and preferences within 1 day.	Mrs. Allison identifies the concerns causing the greatest amount of suffering or distress.
Mrs. Allison will communicate with support persons within next 12 hours.	Daughter, church community, and neighbors provide supportive care.
Mrs. Allison will identify what help she needs to live at home by discharge from the hospital.	Mrs. Allison identifies ways she can live at home with the help of others.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Presence	
Develop an open and caring relationship through active listening and emotional support.	Active listening provides opportunity for patients to find new coping strategies (Benzein and Saveman, 2008).
Establish trust and positive regard for patient in her grief and suffering.	A trusting relationship decreases feelings of abandonment. Believing that others are present gives hope in suffering (Ferrell and Coyle, 2008).
Symptom Management	
Provide pharmacological and nonpharmacological relief for chronic back and foot pain.	When people feel relaxed and obtain relief from discomfort, they are able to communicate their spiritual needs and resources (Bephage, 2009).
Grief Work Facilitation	
Help Mrs. Allison identify her personal goals, desires, and priorities. Evaluate effectiveness and promote goal achievement as appropriate.	Having a future orientation and a degree of normalcy fosters hope and sense of control over circumstances (Innes and Payne, 2009).
Assist Mrs. Allison in identifying available resources. Initiate discussions with interdisciplinary team as appropriate.	Hope is strengthened when one finds realistic possibilities and can adapt to life challenges (McDonald and McCallin, 2010).
Discuss Mrs. Allison's spiritual beliefs, practices, needs, and resources.	Spiritual and religious practices provide structure, a sense of belonging, and a more positive outlook in negative events (Ladd, 2007).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

NURSING CARE PLAN

***Hopelessness*—cont'd**

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Validate Mrs. Allison's experience: "It must be difficult to face such a big life change."	Mrs. Allison responds, "My life has changed, but I have good friends and a good daughter."	Mrs. Allison shows beginning acceptance of her changed health condition.
Use open-ended question: "Tell me how you're feeling now."	Mrs. Allison explains, "I'm not sure what will happen. I may not be able to take care of myself much longer, but I'll try."	She is able to express normal grieving behaviors and feelings of uncertainty resulting from loss of her life as she knew it.
Observe Mrs. Allison's planning activities and behavior with her daughter and friends.	Mrs. Allison and daughter discuss what they can do so she can stay at home longer.	She indicates ability to make plans for a change of care location. Daughter supports revised plans.

CONCEPT MAP

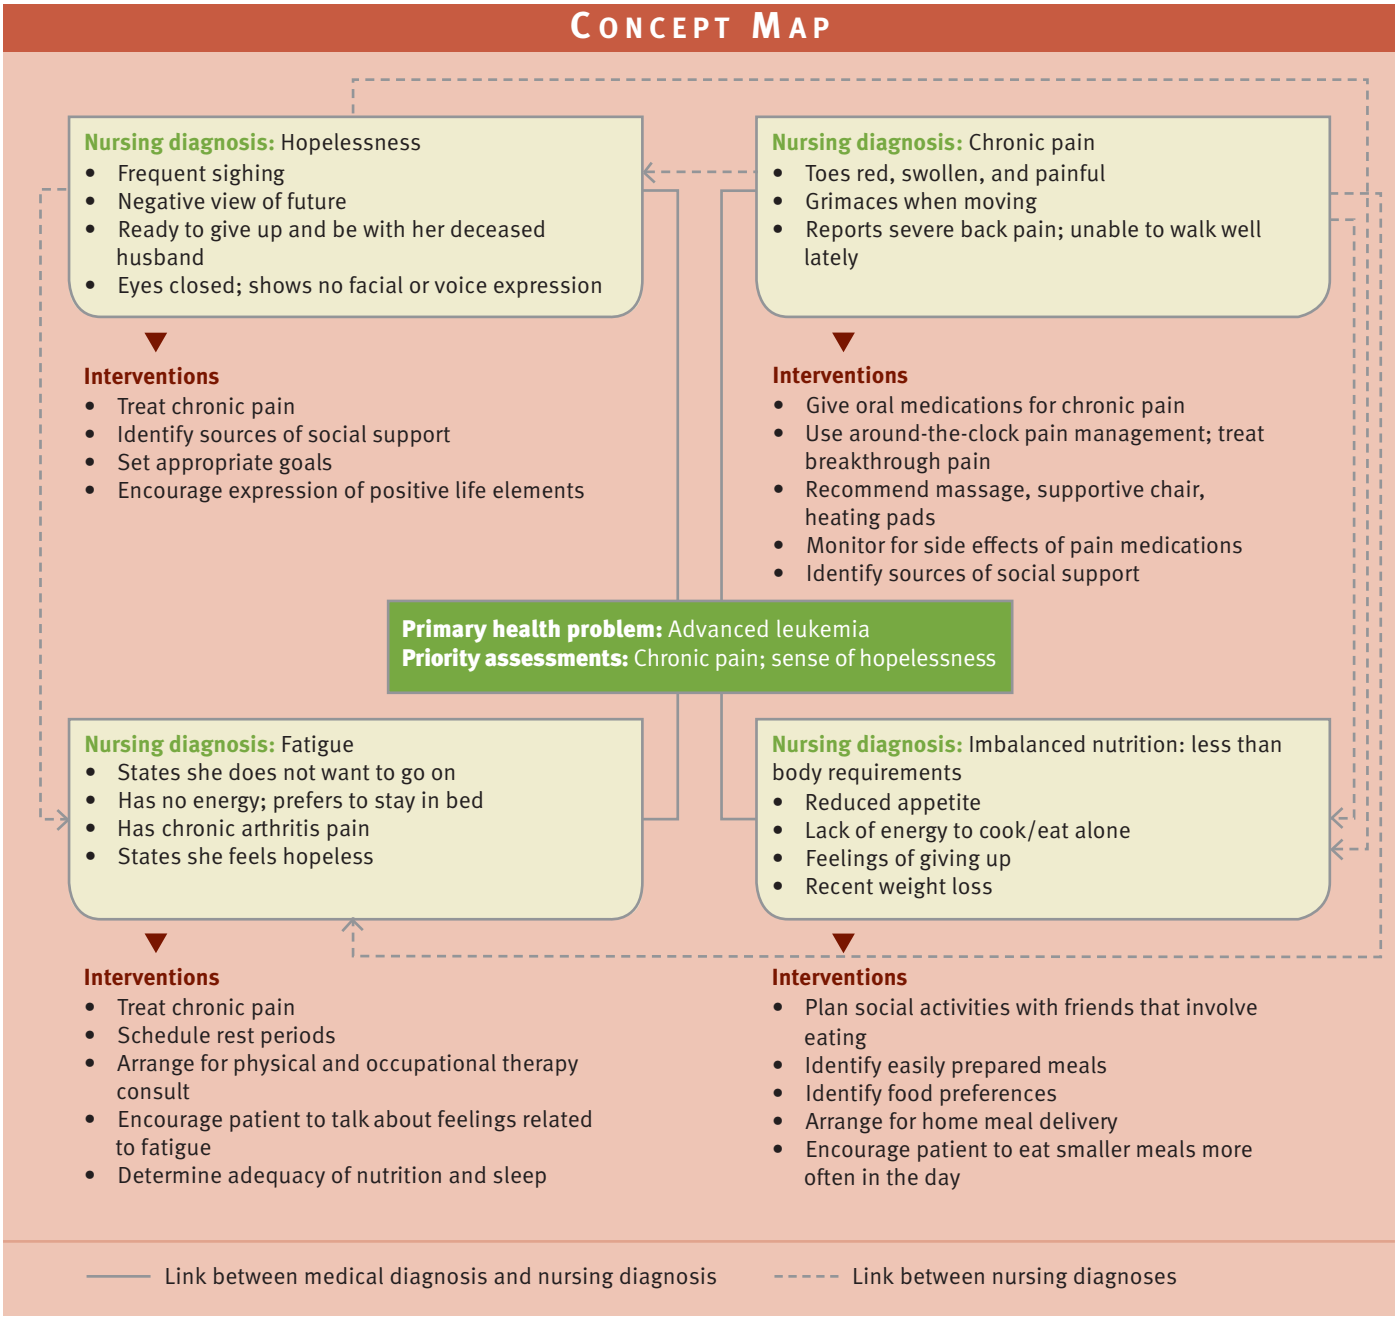

FIG. 36-3 Concept map for Mrs. Allison.

such a situation determine which of the four diagnoses should take priority. The chronic pain experienced by the patient is often the first focus. Until the patient's pain is under control, it will not be possible for her to feel more energized, eat well, or regain her sense of hopefulness.

Teamwork and Collaboration. As described previously, grief, loss, and death affect people physically, emotionally, spiritually, and culturally. No one is able to address all of these dimensions alone. A team of nurses, physicians, social workers, spiritual care providers, nutritionists, pharmacists, physical and occupational therapists, patients, and family members works together to provide palliative care, grief care, and care at the end of life. Massage or music/art therapists who provide alternative therapies are sometimes part of the team (see Chapter 32). As a patient's care needs change, team members take a more or less active role, depending on the patient's shifting priorities. Team members communicate with one another on a regular basis to ensure coordination and effectiveness of care.

Building Competency in Teamwork and Collaboration You are caring for Ms. Allison, an older patient who has recently been diagnosed with a terminal illness. She wants to go home again for as long as possible but lives alone. She has lost strength as a result of decreased activity, depression, and back pain. She has a decreased appetite and has had little desire or energy to prepare meals. How can you help Mrs. Allison achieve her goal of returning home by addressing her multiple health concerns through interdisciplinary collaboration?

Answers to questions can be found on the Evolve website.

BOX 36-6 PATIENT TEACHING

Maintaining Self-Care

Objective

- The patient will participate in activities to manage symptoms and prepare for death.

Teaching Strategies

- Encourage patient to set realistic goals and help him or her identify ways to achieve them.
- Identify ways patient can maintain usual daily routines that provide comfort and sense of normalcy.
- Demonstrate forms of complementary therapy that patient can use for symptom management.
- Discuss ways that patient can prepare for death to enhance his or her sense of control over end-of-life planning and maintain a realistic outlook (advance directives, funeral planning, and preferred location of death).
- Discuss patient's needs for presence of particular support people or for solitude.
- Identify methods to facilitate safety and ease in managing activities of daily living as patient's abilities change (assistive devices, in-home caregivers).
- Provide patient with information about who to call for questions or emergencies so he or she knows that constant support exists in difficult times.

Evaluation

- Ask patient to describe symptom management methods used and rate their effectiveness.
- Have patient describe wishes related to end-of-life planning.

IMPLEMENTATION

Health Promotion. Health promotion in serious chronic illness or death focuses on facilitating successful coping and optimizing physical, emotional, and spiritual health. Many people continue to look for and find meaning even in difficult life circumstances. They often find personal growth and spiritual insights they have not previously experienced and need family and nurse support as they strive to maintain a degree of normalcy; live with loss; make health care decisions; prepare for death; and adjust to disappointments, frustration, and anxieties along the way (Box 36-6).

Palliative Care in Acute and Restorative Settings. Interventions for people who face chronic life-threatening illnesses or who are at the end of life need palliative care. **Palliative care** focuses on the prevention, relief, reduction, or soothing of symptoms of disease or disorders throughout the entire course of an illness, including care of the dying and bereavement follow-up for the family. The primary goal of palliative care is to help patients and families achieve the best possible quality of life. Although it is especially important in advanced or chronic illness, it is appropriate for patients of any age, with any diagnosis, at any time, or in any setting.

Patients who have complex serious illnesses often benefit from palliative care throughout the course of their illness, even while seeking treatment for their disease. As the goals of care change and cure for illnesses becomes less likely, the focus shifts to more palliative care strategies. Palliative care interventions are not only appropriate at the end of life. Making this distinction is important because some patients, family members, or health care professionals refuse helpful palliative care interventions, believing that palliative care is only for the dying.

Hospice Care. **Hospice** care is a philosophy and a model for the care of terminally ill patients and their families. Hospice is not a place but rather a patient- and family-centered approach to care. It gives priority to managing a patient's pain and other symptoms; comfort; quality of life; and attention to physical, psychological, social, and spiritual needs and resources. Patients accepted into a hospice program usually have less than 6 to 12 months to live. Hospice services are available in home, hospital, extended care, or nursing home settings.

Many patients prefer to die at home in a familiar setting, whereas others fear burdening their families or prefer to die in a hospital or nursing home. It is important that the hospice team knows the patient's preference. When family issues complicate the options, hospice caregivers try to support the patient's wishes but also consider what is best for everyone. Sometimes the complexity and severity of patients' symptoms prevent them from being cared for at home, despite the willingness of family and friends to provide care. Patients receiving hospice care are active participants in all aspects of care, and caregivers prioritize care according to patient wishes. Patient care goals are mutually set, and all participants fully understand the patient's care preferences and try to honor them. Hospice services provide bereavement visits made by the staff after the death of the patient to help the family move through the grieving process.

To be eligible for home hospice services, a patient must have a family caregiver to provide care when the patient is no longer able to function alone. Home care aides offer help with hygienic needs, and a nurse is available to coordinate and manage symptom relief. Nurses providing hospice care use therapeutic communication, offer psychosocial care and expert symptom management, promote patient dignity and self-esteem, maintain a comfortable

and peaceful environment, provide spiritual comfort and hope, protect against abandonment or isolation, offer family support, assist with ethical decision making, and facilitate mourning. Hospice team members offer 24-hour accessibility and coordinate care between the home and inpatient setting. A patient receiving home hospice care may enter the hospital for stabilization of symptoms or for caregiver respite. As a patient's death comes closer, the hospice team provides intensive support to the patient and family (Hospice Foundation of America, 2010).

Use Therapeutic Communication. Establish a caring, trusting relationship with a patient and family by using an "open hearted," nonassuming communication style (Galvin and Todres, 2009; Wright et al., 2009). Open-ended questions invite patients to expand on their thoughts and tell their stories. Patients usually give short answers (yes or no) when you use closed-ended questions, which limits what you can learn about a patient's situation. Use active listening, learn to be comfortable with silence, and use prompts (e.g., "go on," "tell me more") to encourage continued conversation (Fig. 36-4). Empathize with the patient's grief; offer your caring, transformative presence and use intentional, meaningful touch (Newman, 2008).

Feelings of sadness, numbing, denial, or anger make talking about these situations especially difficult. For example, a grieving patient experiences anger and becomes hostile with family members or caregivers. Some patients become demanding and accusing. Remain supportive by letting patients and family members know that feelings such as anger are normal by saying, "You are understandably upset right now. I just want you to know I'm here to talk with you if you want." Invite patients to reveal the emotions and concerns of greatest importance to them and acknowledge their feelings and concerns in a nonjudgmental manner. If a patient chooses not to share feelings or concerns, express a willingness to be available at any time. Some patients do not discuss emotions for personal or cultural reasons, and other patients hesitate to express their emotions for fear that others will abandon them. If you are reassuring and respectful of a patient's privacy, a therapeutic relationship likely develops. Sometimes patients need to begin resolving their grief privately before they discuss their loss with others, especially strangers.

Avoid communication barriers such as denying a patient's grief, providing false reassurance, or avoiding discussion of sensitive issues (see Chapter 24). When you sense that a patient wants to talk about something, make time immediately if at all possible. This is very challenging if you have limited experience with dying patients or are in a busy acute care setting. Above all, remember that a patient's emotions are not something you can "fix." Instead view emotional expression as a necessary part of the patient's adjustment to significant life changes and development of effective coping skills. Help family members access other professional resources. For example, call on a spiritual care provider to help patients and family members discuss difficult issues related to personal meanings, faith beliefs, and values.

FIG. 36-4 A nurse's presence and active listening affirm the patient's dignity and worth.

Provide Psychosocial Care. Patients at the end of life experience a range of psychological symptoms, including anxiety, depression, altered body image, denial, powerlessness, uncertainty, and isolation (Taylor and Ashelford, 2008). Patients experience anguish from not knowing or being unaware of aspects of their health status or treatment. Worry or fear is common in many patients and often heightens their perception of discomfort and suffering. Providing information helps patients understand their condition, the course of their disease, and the benefits and burdens of treatment options. Suffering, a complex social and psychological response to illness, loss, and death, goes beyond psychological diagnoses. Nurses validate and support those who suffer (Ferrell and Coyle, 2008).

Manage Symptoms. Managing the multiple symptoms commonly experienced by chronically ill or dying patients remains a primary goal of palliative care nursing. Symptom distress, discomfort, and anguish often complicate a patient's dying experience. Despite the availability of effective treatment options for pain, many patients suffer with avoidable pain at the end of life. Maintain an ongoing assessment by reassessing pain and medication side effects, using pain management expertise, and advocating for change if the patient does not obtain relief from the prescribed regimen. Implement evidence-based pain management protocols (Paice, 2010) (see Chapter 43). It is essential for you to learn how to assess patients who are debilitated or dying because they often lose their ability to communicate or self-advocate (Herr et al., 2006). During the dying process, patients' renal and liver function decline, decreasing metabolism and rate of drug clearance and leading to a need for decreased medication dosages to avoid toxicities. Also be aware that advancing disease pathology, anxiety, or delirium sometimes requires the use of higher doses or different drug therapies.

Remain alert to the potential side effects of opioid administration: constipation, nausea, sedation, respiratory depression, or myoclonus. Family members often worry about potential addiction to opioid medications. Not only is the incidence of true addiction very low, but a patient's need for pain relief at the end of life takes priority. Table 36-2 provides a basic overview of nursing care for common symptoms experienced at the end of life.

Promote Dignity and Self-Esteem. A sense of dignity includes a person's positive self-regard, an ability to invest in and gain strength from one's own meaning in life, feeling valued by others, and how one is treated by caregivers. Nurses promote patients' self-esteem and dignity by respecting them as a whole (i.e., as people with feelings, accomplishments, and passions independent of the illness experience). Giving importance to the things that a patient cares about validates the person, at the same time strengthening communication among the patient, family members, and the nurse. Spending time with patients as they share their life stories helps you know him or her better and facilitates the development of individualized interventions. Show respect for older patients by calling them by surnames and titles and obtaining their permission to include others in private conversations.

Attending to the patient's physical appearance promotes dignity and self-esteem. Cleanliness, absence of body odors, and attractive clothing give patients a sense of worth. When caring for a patient's bodily functions, show patience and respect, especially after the patient becomes dependent. Allow patients to make decisions such as how and when to administer personal hygiene, diet preferences, and timing of nursing interventions. Keep the patient and family members informed about daily activities, tests, or therapies; their purposes; and anticipated effects. Provide privacy during nursing care procedures and be sensitive to when the patient and family need time alone together.

Maintain a Comfortable and Peaceful Environment. A comfortable, clean, pleasant environment helps patients relax, promotes good sleep patterns, and minimizes symptom severity. Keep a patient comfortable through frequent repositioning, making sure that bed linens are dry and controlling extraneous environmental noise and offensive odors. Pictures, cherished objects, and cards or letters from family members and friends create a familiar and

TABLE 36-2 Promoting Comfort in the Terminally Ill Patient

SYMPTOMS	CHARACTERISTICS OR CAUSES	NURSING IMPLICATIONS
Pain	Multiple causes, depending on patient diagnosis.	See Chapter 43 for a full discussion of pain management.
Skin and mucous membrane discomfort	Any source of skin irritation increases discomfort.	Provide skin care as needed based on patient comfort or preference. Apply lotion to skin; dry, clean bed linens to reduce irritants (see Chapter 39).
Mucous membrane discomfort	Mouth breathing or dehydration leads to dry mucous membranes; tongue and lips become dry or chapped.	Provide oral care, including tongue, every 2 to 4 hours with soft toothbrushes or foam swabs and using nonabrasive toothpaste or water. Apply a light film of lip balm for dryness. Apply topical analgesics to oral lesions (see Chapter 39).
Corneal irritation	Blinking reflexes diminish near death, causing drying of cornea.	Optical lubricants or artificial tears reduce corneal drying. Eye care with warm water removes crusts from eyelid margins.
Fatigue	Metabolic demands, stress, disease states, decreased oral intake, and heart function cause weakness and fatigue.	Balance activity and rest periods according to patient's priorities and preferred time of day. Conserve patient energy by modifying environment (Kehl, 2008).
Anxiety	Physical, social, or spiritual distress causes anxiety; causes may be situational or event specific.	Address underlying cause; provide calm, supportive environment, active listening; use benzodiazepines for acute anxiety (Pasacreta et al., 2010).
Nausea	Medications, pain, or decreased intestinal blood flow with impending death	Administer antiemetics or promotility agents; discontinue medications or foods that cause nausea; provide oral care at least every 2 to 4 hours; offer clear liquid diet and ice chips; avoid liquids that increase stomach acidity (Acreman, 2009).
Constipation	Opioids, medications, and immobility slow peristalsis. Lack of bulk in diet or reduced fluid.	Use a stimulant laxative with opioids. Make dietary alterations as preferred or tolerated; increase fluid intake if tolerated (Enck, 2009).
Diarrhea	Disease processes, treatment or medications, and gastrointestinal (GI) infections.	Assess for fecal impaction. Confer with health care provider to change medication if identified as the cause. Protect skin with moisture barrier (Kyle, 2010).
Urinary incontinence	Progressive disease and decreased level of consciousness.	Protect skin from irritation or breakdown by maintaining dry linens and clothing. Use indwelling urinary catheter or condom catheters for comfort or prevention of skin problems (Kyle, 2010).
Altered nutrition	Medications, depression, decreased activity, and decreased blood flow to the GI tract; nausea produces anorexia.	Offer smaller portions of patient-preferred foods. Treat underlying cause of anorexia if patient still wants to eat. Do not force food on patients (Acreman, 2009).
Dehydration	Patient is less willing or able to maintain oral fluid intake; has fever.	Reduce discomfort from dehydration; give mouth care at least every 2 to 4 hours; offer ice chips or moist cloth to lips. Keep lips and tongue moist.
Ineffective breathing patterns (e.g., dyspnea, shortness of breath)	Anxiety; fever; pain; increased oxygen demand; disease processes; and anemia, which reduces oxygen-carrying capacity.	Treat or control underlying cause. Position for comfort and maximal respiratory excursion, provide supplemental oxygen if comforting; reduce anxiety or fever; and provide effective pain management. Use fan for air movement, stimulating trigeminal nerve in cheek, which decreases dyspneic sensation. Administer anxiolytics, bronchodilators, inhaled steroids, or opioids to suppress cough and ease breathing and apprehension (Balkstra, 2010).
Noisy breathing ("death rattle")	Noisy breathing is the sound of secretions moving in the airway during inspiratory and expiratory phases caused by thick secretions, decreased muscle tone, swallow, and cough.	Elevate head to facilitate postural drainage. Turn from side to side to mobilize and drain secretions. Stop oral intake; avoid suctioning because of discomfort and ineffectiveness. Anticholinergic medications are sometimes helpful (Hipp and Letizia, 2009).

comforting environment for the patient dying in an institutional setting. Consider nonpharmacological interventions to increase patient comfort (Running et al., 2008). Family members are often able to provide these interventions, increasing their sense that they are making a positive contribution. Research supports the use of soft massage and brief hand massages for reducing stress (Osaka et al., 2009). Use patient-preferred music in the background, provide guided-imagery exercises, and dim the lights to provide a soothing environment for the patient and family. Patient-preferred forms of complementary therapies offer noninvasive methods to increase comfort and well-being at the end of life (Mariano, 2010) (see Chapter 32).

Promote Spiritual Comfort and Hope. Help patients make connections to their spiritual practice or cultural community. Patients are comforted when they have assurance that some aspect of their lives will transcend death. Draw on the resources of spiritual care providers in an institutional setting or collaborate with the patient's own spiritual or religious leaders and communities. Making an audiotape or videotape for the family, writing letters, or keeping a journal assures patients that something of their essence will survive past their death.

The spiritual concept of hope takes on special significance near the end of life. Nursing strategies that promote hope are often quite simple: be present and provide holistic care that affirms a patient's life and maintains dignity (Daaleman et al., 2008). Patients perceive the love of family and friends, faith, goal setting, positive relationships with professional caregivers, humor, and uplifting memories as hope promoting. Circumstances that hinder the preservation of hope include abandonment or isolation, uncontrolled symptoms, or being devalued as a person. Patients and their families hope for different things over the course of their experience with illness and death. Some hope to live for an anniversary, sit outdoors for a meal, see an important person one last time, gain pain relief, or have a peaceful death. Listen for shifts in patients' hopes and find ways to help them meet their desired goals.

Protect Against Abandonment and Isolation. Many patients with terminal illness fear dying alone. Patients feel more hopeful when others are near to help them. Nurses in institutional settings need to answer call lights promptly and check on patients often to reassure them that someone is close at hand. Consider carefully whether or not to place a patient who is actively dying in a private room. If family members plan to stay with the patient at all times or if you have assessed high privacy needs for the patient and family, a private room is best. On the other hand, many patients appreciate being able to stay involved and interact with others, which is possible when sharing a room.

Some family members who have a difficult time accepting a patient's impending death cope by making fewer visits. When family members do visit, inform them of the patient's status and share meaningful insights or encounters that you have had with the patient. Find simple and appropriate care activities for the family to perform such as offering food, cooling the patient's face, combing hair, or filling out a menu. Nighttime can be particularly lonely. Suggest that a family member stay through the night if possible. Make exceptions to visiting policies, allowing family members to remain with patients who are dying at any time. Family members appreciate having open access or closeness to their loved one through their experiences at the end of life. Record contact information for them so you can reach them at any time.

Support the Grieving Family. In palliative care patients and family members constitute the unit of care. When a patient becomes debilitated or approaches the end of life, family members also suffer. They describe caregiving at the end of life as unpredictable, frightening, and anguishing. On the other hand, they report being deeply moved by their experiences and describe their activities as affirming (Phillips, 2009). In these extremely intimate and emotionally challenging times, offer holistic, family-centered support, compassion, and education that incorporates the uniqueness of each patient. Often family members face challenging and complex situations long before their loved one is actively dying. Family members caring for people with serious life-limiting illness need attention and support early and consistently throughout the experience of illness and death (Box 36-7).

Families report that they especially value having access to the information they need to make important decisions (Spichiger, 2008). Educate family members in all settings about the symptoms that the patient will likely experience and the implications for care. For example, patients in the last days of life often develop anorexia or feel nauseated by food. Illness, decreased activity, treatments, and fatigue decrease a patient's caloric needs and appetite. Family members, distressed with the decline, often believe that they need to encourage the patient to eat. Forcing food or fluids stresses the patient's compromised gastrointestinal and cardiovascular systems, potentially creating increased discomfort (Acreman, 2009). Help families shift their focus to other helping activities during this time.

BOX 36-7 EVIDENCE-BASED PRACTICE

Patient and Family Member Satisfaction with End-of-Life Care

PICO Question: For patients who are dying and their family members, which nursing interventions are most successful in enhancing satisfaction with end-of-life care?

Evidence Summary

Above all nurses strive for positive patient-centered outcomes at the end of life. A growing body of research literature reveals what patients and family members perceive to be important at the end of life (i.e., helping caregivers focus on behaviors that bring about the highest degree of patient and family satisfaction). A systematic review of research literature included 21 qualitative studies that focused on caregiver interventions that patients and family members described as satisfying care. The dominant themes of satisfaction that surfaced in the research studies include accessibility, coordination of care, competence, communication and relationships, education, emotional support, personalization of care, and support for patient decision making (Dy et al., 2008). Other important nursing interventions include symptom management and providing comfort care and emotional support. Patients and family members are most satisfied when they receive attentive, compassionate care. Novice nurses who are grounded in authentic, open-hearted, holistic nursing care practices are capable of providing valuable care to patients at the end of life.

Application to Nursing Practice

- Individualize your plan of care. Discuss priorities and preferences for care with patients and family members frequently.
- Give as much time as needed to discuss a sensitive topic, maintain contact, and respond to requests promptly.
- Coordinate care by maintaining effective interdisciplinary communication.
- Support patient's decision making and provide assistance with end of life to maintain a sense of control.
- Provide information about what to expect at a level understandable to the patient.

BOX 36-8 PHYSICAL CHANGES HOURS OR DAYS BEFORE DEATH

- Increased periods of sleeping/unresponsiveness
- Coolness and color changes in extremities, nose, fingers
- Bowel or bladder incontinence
- Decreased urine output; dark-colored urine
- Restlessness or disorientation
- Decreased intake of food or fluids; inability to swallow
- Congestion/increased pulmonary secretions; noisy respirations (death rattle)
- Altered breathing (apnea, labored or irregular breathing, Cheyne-Stokes pattern)
- Decreased muscle tone, relaxed jaw muscles, sagging mouth
- Weakness and fatigue

Family members who have limited prior experience with death do not know what to expect. They may need personal time with the nurse to share their concerns, ask about treatment options, validate perceived changes in the patient's status, or explore the possible meaning of patient behaviors. Whenever possible, communicate news of a patient's declining condition or impending death when family members are together so they can support each other. Provide information privately and stay with the family as long as needed or desired. Reduce family member anxiety, stress, or fear by describing what to expect as death approaches. Become familiar with common manifestations of impending death (Box 36-8), remembering that patients usually experience some but not all of these changes. Do not try to predict the time of death; instead use your assessments to help family members anticipate what is happening. Share your observations and through your role modeling encourage a sense of patience, compassion, and comfort throughout the dying process.

After death assist the family with decision making such as notification of a funeral home, transportation of family members, and collection of the patient's belongings. Nurses are a primary source of family support. Remember that, because of differing responses to grief, some family members prefer to be alone at the time of a death, whereas others want to be surrounded by a support community. When uncertain about what a family member prefers for support, pose simple questions and offer suggestions for assistance.

With the death of a patient, family members benefit from the many resources of the health care team. When the patient chooses to die at home, family members provide direct care, which is often emotionally stressful and physically exhausting. In the home setting fatigued family caregivers benefit from respite care. During respite care, a patient temporarily receives care from others so family members are able to get away to rest and relax. Hospice program benefits include some days of respite care. Inform family members of home care, hospice, and community service options so they can access the best resources for their situation.

Assist with End-of-Life Decision Making. Patients and family members often face complex treatment decisions at the end of life. Decisions the family often need to make include: Which medical interventions would the patient want to use? Should life-extending treatments be stopped if there appears to be little chance of recovery? Should artificial nutrition and hydration be provided when a patient is near death and no longer able to eat? (Wainwright and Gallagher, 2007). They need time and careful explanations by nurses and other health care providers to make decisions (Mahon, 2010).

Difficult ethical decisions at the end of life complicate a survivor's grief, create family divisions, or increase family uncertainty at the time of death (see Chapter 22). When ethical decisions are handled well, survivors achieve a sense of control and experience a meaningful conclusion to their loved one's death. Suggest to patients that they clearly communicate their wishes for end-of-life care so family members are able to act as faithful surrogates when the patient can no longer speak for himself or herself. Advance directives often decrease the stress of family members when end-of-life decisions must be made (see Chapter 23) (Tilden et al., 2001). Some patients and family members rely on the nurse and other members of the health care team to initiate discussions regarding end-of-life care. Nurses often provide options that family members do not know are available and are advocates for patients and family members making decisions at the end of life.

Facilitate Mourning. Nurses who work with grieving family members often provide bereavement care after the patient's death. Helpful strategies for assisting grieving persons include the following:

- Help the survivor accept that the loss is real. Discuss how the loss or illness occurred or was discovered, when, under what circumstances, who told him or her about it, and other factual topics to reinforce the reality of the event and put it in perspective.
- Support efforts to adjust to the loss. Use a problem-solving approach. Have survivors make a list of their concerns or needs, help them prioritize, and lead them step-by-step through a discussion of how to proceed. Encourage survivors to ask for help.
- Encourage establishment of new relationships. Reassure people that new relationships do not mean that they are replacing the person who has died. Encourage involvement in nonthreatening group social activities (e.g., volunteer activities or church events).
- Allow time to grieve. "Anniversary reactions" (i.e., renewed grief around the time of the loss in subsequent years) are common. A return to sadness or the pain of grief is often worrisome. Openly acknowledge the loss, provide reassurance that the reaction is normal, and encourage the survivor to reminisce.
- Interpret "normal" behavior. Being distractible, having difficulty sleeping or eating, and thinking that they have heard the deceased's voice are common behaviors following loss. These symptoms do not mean that an individual has an emotional problem or is becoming ill. Reinforce that these behaviors are normal and will resolve over time.
- Provide continuing support. Survivors need the support of a nurse with whom they have bonded for a time following a loss, especially in home care or hospice nursing. The nurse has become an important "actor" in the drama of the deceased's life and death and has helped them through some very intimate and memorable times. Attachment for awhile after the death is appropriate and healing for both the survivor and the nurse.
- Be alert for signs of ineffective, potentially harmful coping mechanisms such as alcohol and substance abuse or excessive use of over-the-counter analgesics or sleep aids.

Care After Death. Federal and state laws require institutions to develop policies and procedures for certain events that occur after death: requesting organ or tissue donation, performing an autopsy, certifying and documenting the occurrence of a death, and providing safe and appropriate postmortem care. In accordance

with federal law, a specially trained professional (e.g., transplant coordinator or social worker) makes requests for **organ and tissue donation** at the time of every death. The person requesting organ or tissue donation provides information about who can legally give consent, which organs or tissues can be donated, associated costs, and how donation affects burial or cremation.

In extremely stressful circumstances created by the loss of a loved one, grieving survivors usually cannot remember all they were told. Nurses provide support and reinforce and clarify explanations given to them during the request process. In addition, understanding the physiology of organ donation is often difficult for family members. Even though a patient who is brain dead is legally declared dead, he or she remains on life support to provide the vital organs with blood and oxygen before transplant. The appearance of a live-looking body confuses the family, and they need help to understand that the life support is only preserving the vital organs. Nonvital tissues such as corneas, skin, long bones, and middle ear bones are taken at the time of death without artificially maintaining vital functions. If the deceased has not left behind instructions concerning organ and tissue donation, the family gives or denies consent at the time of death. Review your state organ retrieval laws and institutional policy and procedure regarding the formal consent process. Be aware that the laws governing who to approach for organ donation may not be acceptable in other cultures.

Family members give consent for an **autopsy** (i.e., the surgical dissection of a body after death) to determine the exact cause and circumstances of death or discover the pathway of a disease (see Chapter 23). In most cases a coroner or medical examiner determines the need to perform an autopsy. Law sometimes requires that an autopsy be performed when death is the result of foul play; homicide; suicide; or accidental causes such as motor vehicle crashes, falls, the ingestion of drugs, or deaths within 24 hours of hospital admission. Unattended deaths or those that occur in the workplace or during incarceration also usually require an autopsy (AMA, 2004).

Usually the physician or other designated health care provider asks for autopsy permission while the nurse answers questions and supports the family's choices. Inform family members that an autopsy does not deform the body and that all organs are replaced in the body. Family members are often comforted to know that others may be helped by either the gift of organ and tissue donation or through autopsy. Respect and honor family wishes and final decisions.

Documentation of a death provides a legal record of the event. Follow agency policies and procedures carefully to provide an accurate and reliable medical record of all assessments and activities surrounding a death. Physicians or coroners sign some medical forms such as a request for autopsy, but the registered nurse gathers and records much of the remaining information surrounding a death. Nurses also usually witness or delegate the signing of forms (e.g., release of body or personal belongings forms). Nursing documentation becomes relevant in risk management or legal investigations into a death, underscoring the importance of accurate, legal reporting. Documentation also validates success in meeting patient goals or provides justification for changes in treatment or expected outcomes. Box 36-9 lists important documentation elements for end-of-life care.

Family members deserve and expect a clear description of what happened to their loved one, especially in cases of sudden, unusual, or unexpected circumstances. Give only factual information in a nonjudgmental, objective manner and avoid sharing your opinions. State law and agency policy govern the sharing of the written medical record information, which usually involves a written request. Follow legal guidelines for documentation and sharing of medical records (see Chapter 23).

BOX 36-9 DOCUMENTATION OF END-OF-LIFE CARE

- Time and date of death and all actions taken to respond to the impending death
- Name of health care provider certifying the death
- Persons notified of the death (e.g., health care providers, family members, organ request team, morgue, funeral home, spiritual care providers) and person who comes to declare time of death
- Name of person making request for organ or tissue donation
- Special preparations of the body (e.g., desired or required religious/cultural rituals)
- Medical tubes, devices, or lines left in or on the body
- Personal articles left on and secured to the body
- Personal items given to the family with description, date, time, to whom given
- Location of body identification tags
- Time of body transfer and destination
- Any other relevant information or family requests that help clarify special circumstances

When a patient dies in an institutional or home care setting, nurses provide or delegate **postmortem care,** the care of a body after death. Above all, a human body deserves the same respect and dignity as a living person and needs to be prepared in a manner consistent with the patient's cultural and religious beliefs. Death produces physical changes in the body quite quickly; thus you need to perform postmortem care as soon as possible to prevent discoloration, tissue damage, or deformities.

Maintaining the integrity of cultural and religious rituals and mourning practices at the time of death gives survivors a sense of fulfilled obligations and promotes acceptance of the patient's death (Box 36-10). The ability of families to mourn in a manner consistent with cultural values helps survivors experience some predictability and control in an otherwise uncertain and confusing time. Some cultures consider "family" as more than a nuclear biological unit. Health care providers need to understand the makeup of a family network and know which individuals to involve in end-of-life decisions and care.

The nurse coordinates patient and family care during and after a death. Become familiar with applicable policies and procedures for postmortem care because they vary across settings or institutions. See the procedural guideline (Box 36-11) for standard activities for care of the body after death.

EVALUATION

Through the Patient's Eyes. The success of the evaluation process depends partially on the bond that you have formed with the patient. Patients are more likely to share personal expectations or their wishes if you form a trusting relationship with them. Refer back to the goals and expected outcomes established during the planning phase to determine the effectiveness of nursing interventions. A patient's responses and perceptions of the effectiveness of the interventions determine if the existing plan of care is effective or if different strategies are necessary. For example, if the goal

BOX 36-10 CULTURAL ASPECTS OF CARE

Care of the Body After Death

There are culturally specific rituals and mourning practices that loved ones use to achieve a sense of acceptance and inner peace and participate in socially accepted expressions of grief. One's culture greatly influences what behaviors and rituals are expected at the time of death. Institutional guidelines and end-of-life care procedures for patients from all cultures provide standards based on compassion, maintaining privacy and dignity, and respect for patients' and family members' cultural beliefs and practices. Expert end-of-life care allows time for patients and their families to make private and public preparations and complete unfinished communication. Understanding the uniqueness of cultural expectations at the end of life helps a nurse know what questions to ask. The cultural or religious practices described below are not necessarily exclusive to the culture named but are offered to give you an idea of some culturally specific concerns you may encounter in end-of-life care.

Implications for Practice

- **African American:** Care of the body after death depends on the African American's country of origin and degree of American acculturation. The presence of large extended family groups, including the church family, is common at time of death. The mourning period is relatively short, with a memorial service and a public viewing of the body or a wake before burial. Organ donation and autopsy are allowable.
- **Chinese:** Death is regarded as a negative life event, and there is no concept of an afterlife. The dead are treated with the same respect as the living and may be buried with food and other artifacts. Members of an extended family usually stay with the deceased for up to 8 hours after death. The oldest son or daughter bathes the body under direction from an older relative or a temple priest. They often believe the body should remain intact; thus organ donation and autopsy are uncommon (Xu Y, 2007).
- **Hispanic or Latino:** Honoring family values and roles is essential in providing care and making decisions at the end of life. People in Hispanic and Mexican-American cultures often use special objects such as amulets or rosary beads, alternative healing practices (folk medicine), and prayer. Grief is expressed openly. Religious and spiritual rituals (predominantly Catholic) are essential at the end of life. Death is often believed to be the will of God (Gonzales et al., 2008; Taxis et al., 2008).
- **Native American:** Native Americans encompass diverse tribal groups with differing practices, traditions, and ceremonies. Traditional Navajos do not touch the body after death. Care of the body in the large Navajo tribe includes cleansing the body, painting the deceased's face, dressing in clothing, and attaching an eagle feather to symbolize a return home. Mourners also have a ritual cleansing of their bodies. The dead are buried on the deceased's homeland (Hanley, 2008).
- **Islamic:** The deceased's body is ritualistically washed, wrapped, cried over, prayed for, and buried as soon as possible after death. The eyes and mouth are closed, and the face of the deceased is turned toward Mecca. Muslims of the same gender prepare the body for burial. Bodies are buried, not cremated. Autopsies interfere with a quick burial; make autopsy requests with sensitivity and only if necessary. The proximity of loved ones after death is important since it is believed that the soul stays with the body until it is buried. Organ donation is permissible by some Qur'an interpretations (Gatrad and Sheikh, 2008).
- **Buddhist:** Buddhists believe in an afterlife in which humans manifest in different forms. Death is preferred at home, and a person's state at the time of death is important. Individuals usually minimize emotional expressions and maintain a peaceful, compassionate atmosphere. Male family members prepare the body. Buddhists recommend not touching the body after death to give the deceased a smoother transition to the afterlife. People often say prayers while touching and standing at the head of the deceased. The body is not left alone after death. Family and friends pay respects after death and before cremation of the body (Bauer-Wu et al., 2007).
- **Hindu:** The body is placed on the floor with the head facing north. Persons of the same gender handle the body after death. There are no general prohibitions against autopsy. Bodies are cremated after death to purify by fire (Gatrad et al., 2008).
- **Jewish:** If the family practices Orthodox Judaism, determine if members from the Jewish Burial Society are coming to the facility before preparing the body. A family member often stays with the body until burial. Usually the burial occurs within 24 hours but not on the Sabbath. Some but not all types of Judaism avoid cremation, autopsy, and embalming (Bauer-Wu et al., 2007).

is to have the patient communicate a sense of hope to family members, evaluate verbal and nonverbal communication and behaviors for cues related to expressions of hope. Continue to evaluate the patient's progress, the effectiveness of the interventions, and patient and family interactions. Even when a patient is not seeking care specifically related to a loss, be alert for signs and symptoms of grief. They provide the criteria for evaluating whether a patient is coping with a loss and how he or she is moving through the grief process. Critical thinking ensures that the evaluation process accurately reflects the patient's situation and desired outcomes (Fig. 36-5).

Patient Outcomes. The following questions help you validate achievement of patient goals and expectations:

- What is the most important thing I can do for you at this time?
- Are your needs being addressed in a timely manner?
- Are you getting the care for which you hoped?
- Would you like me to help you in a different way?
- Do you have a specific request that I have not met?

Especially in home care settings, you include family members in the evaluation process. The short- and long-term outcomes that signal a family's recovery from a loss guide your evaluation. Short-term outcomes indicating effectiveness of grief interventions include talking about the loss without feeling overwhelmed, improved energy level, normalized sleep and dietary patterns, reorganization of life patterns, improved ability to make decisions, and finding it easier to be around other people. Long-term achievements include the return of a sense of humor and normal life patterns, renewed or new personal relationships, and decrease of inner pain.

Importance of Nurses' Self-Care

You cannot give fully engaged, compassionate care to others when you feel depleted or do not feel cared for yourself. Nurses experience grief and loss too. Many times, even before a nurse has a chance to recover from an emotionally draining situation, he or she encounters another difficult human story. Nurses in acute care settings often witness prolonged, concentrated suffering on a daily basis, leading to feelings of frustration, anger, guilt, sadness, or anxiety. Nursing students report initially feeling hesitant and uncomfortable with their first encounters with a dying patient and identify feelings of sadness, anxiety, and discomfort (Allchin, 2006).

BOX 36-11 PROCEDURAL GUIDELINES

Care of the Body After Death

Delegation Considerations

The skill of care of the body after death can be delegated to nursing assistive personnel (NAP). Nurses often find it meaningful to help care for a patient after death and assist the NAP whenever possible. Instruct the NAP to:

- Contact the nurse for all questions and procedures related to organ/tissue donation and autopsy requests.
- Alert nurse to family members' questions related to manner of death or after-death activities.

Equipment

Bath towels, washcloths, washbasin, scissors, shroud kit with name tags, bed linen, documentation forms.

1. Confirm the health care provider certified the death and documented the time of death and actions taken.
2. Determine if the health care provider requested an autopsy. An autopsy is required for deaths that occur under certain circumstances.
3. Validate the status of request for organ or tissue donation. Given the complex and sensitive nature of such requests, only specially trained personnel make the requests. Maintain sensitivity to personal, religious, and cultural beliefs in this process.
4. Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.
5. Provide sensitive and dignified nursing care to the patient and family.
   a. Elevate the head of the bed as soon as possible after death to prevent discoloration of the face.
   b. Collect ordered specimens.
   c. Ask if the family wishes to participate in preparation of the body. Offer to make arrangements for supportive company for the family (patient/family religious leader, spiritual care personnel, or bereavement specialist) during body preparation.
   d. Ask about family requests for body preparation such as wearing special clothing or religious artifacts. Be aware that personal, religious, or cultural practices determine whether or not to shave male facial hair. Get permission before shaving a beard.
   e. Remove all equipment, tubes, and indwelling lines. Note that autopsy or organ donation often poses exceptions to removal; thus consult agency policy in these situations.
   f. Cleanse the body thoroughly, maintaining safety standards for body fluids and contamination when indicated. Comb patient's hair or apply personal hairpieces.
   g. Cover body with a clean sheet, place head on a pillow, and leave arms outside covers if possible. Close eyes by gently holding them shut; leave dentures in the mouth to maintain facial shape; cover any signs of body trauma.
   h. Prepare and clean the environment, deodorize room if needed, and lower the lights.
   i. Offer family members the option to view the body and ask if they want you or other support persons to accompany them. Honor and respect individual choices.
   j. Encourage grievers to say good-bye in their own way: words, touch, singing, religious rituals, or prayers.
   k. Provide privacy and an unrushed atmosphere. Assess family members' need or desire for your presence at this time. If you leave, tell them how to reach you.
   l. Determine which personal belongings stay with the body (e.g., wedding ring or religious symbol) and give other personal items to family members. Document time, date, description of the items taken, and who received them. Save any items that are accidentally left behind and contact family for further instructions.
   m. Apply identifying name tags and shroud according to agency policy before transporting the body. Follow safety procedures for body fluid precautions or contamination concerns.
   n. Complete documentation in the narrative notes section (see Box 36-9).
   o. Maintain privacy and dignity when transporting the body to another location; cover the body or stretcher with a clean sheet.

Frequent, intense, or prolonged exposure to grief and loss places nurses at risk for developing **compassion fatigue.** Compassion fatigue, described as physical, emotional, and spiritual exhaustion resulting from seeing patients suffer, leads to a decreased capacity to show compassion or empathize with suffering people (Bush, 2009).

To avoid the extremes of either becoming overly involved in patients' suffering or detaching from them, nurses develop self-care strategies to maintain balance. Self-reflection, an element of critical thinking, serves as a useful tool when you feel overwhelmed. For example, ask yourself if your sadness is related to caring for a patient or to an unresolved, disruptive experience in your personal life. Talking with friends, a spiritual care provider, or a close colleague helps you recognize your own grief and reflect on the meaning of caring for dying patients. Creative strategies help you cope with the loss of a patient to whom you have become attached. You sometimes gain closure by attending a mortuary viewing or a funeral or writing a sympathy letter to the family. Stress management techniques (see Chapter 37) help restore your energy and enjoyment in caring for patients. In some instances nurses choose to work temporarily in less emotionally stressful settings.

Nurses who practice self-care are more likely to experience professional and personal growth and find meaning in their work. Care for your physical health by eating well, exercising, engaging in relaxing activities, laughing, and getting enough sleep. To promote emotional health, participate in calming activities such as meditation, daily gratitude reflections, deep breathing, walking, or listening to music (Showalter, 2010). Activities for self-transcendence (spiritual awareness) include journal writing, sharing stories, recognizing one's own positive contributions and unique gifts, and connecting with one's self (Hunnibell et al., 2008). Because of the ongoing demands of professional caregiving, set limits on the how much you do and spend time enjoying your favorite activities (Fig. 36-6). Pay attention to the people who nurture you.

Research indicates that nurses maintain hope and a positive outlook when they have adequate resources to care for patients, believe they are making a difference, and feel supported by team members (Duggleby and Wright, 2007). Receiving recognition for the many ways in which nurses make valuable contributions to the quality of patients' lives contributes greatly to job satisfaction (Perry, 2009). Nurture your work relationships and learn to ask for and accept help. Creative workplace strategies and educational offerings provide nurses with opportunities for healing, restoration of balance, and personal recognition (Parsons, 2009).

Remember that caring for seriously ill and dying people gives you opportunities to find meaning and importance in being a

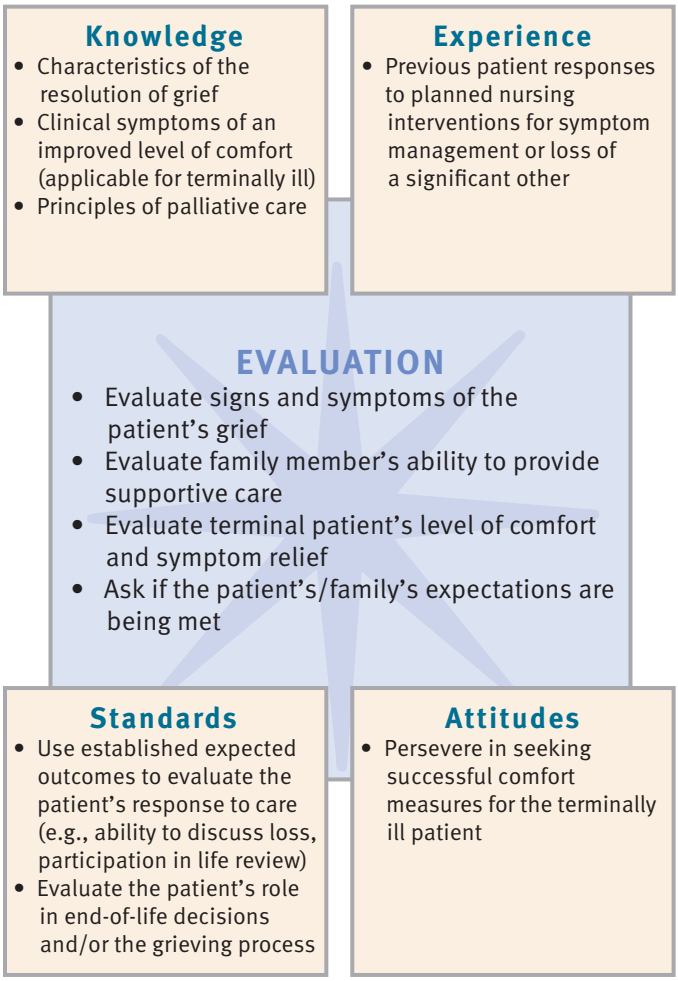

FIG. 36-5 Critical thinking model for loss, death, and grief evaluation.

nurse. You learn from the courage of your patients, find joy and beauty in life, and become more open to others. The same nursing students who experience discomfort in their first experiences with death also note that they reflect on those experiences well beyond their clinical time and are able to identify personal and professional benefits to their experience (Allchin, 2006).

KEY POINTS

- When caring for patients who have experienced a loss, facilitate the grief process by helping survivors feel the loss, express it, and move through their grief.
- Loss comes in many forms, based on the values and priorities learned within a person's sphere of influence (i.e., family, friends, religion, society, and culture).
- The type and perception of the loss influence how a person experiences grief.
- Death is difficult for the dying person and the person's family, friends, and caregivers.
- Theorists describe grief as stages, tasks, and processes undertaken by survivors to successfully complete their bereavement and adapt to life with a loss.
- Survivors move back and forth through a series of stages and/or tasks many times, possibly extending over a long period of time.
- Grieving people use their own unique history, context, and resources to make meaning out of their loss experiences. Listen as patients share the experience in their own way.
- Knowledge of the types of grief helps nurses identify appropriate interventions.
- A person's development, coping strategies, socioeconomic status, personal relationships, nature of loss, and cultural and spiritual beliefs influence the way he or she perceives and responds to grief.
- Nursing interventions involve reinforcing patients' successful coping mechanisms and introducing new coping approaches when needed.
- Assess the terminally ill patient and family wishes for end-of-life care, including the preferred place for death, desired level of intervention, and expectations for pain and symptom management.
- Establish a caring presence and use effective communication strategies to encourage patients to share to the degree they are comfortable.
- Palliative care allows patients to make more informed choices, achieve better alleviation of symptoms, and experience a higher quality of life through an illness or death experience.
- Hospice is not a place but rather a philosophy of family-centered, whole-person care at the end of life.
- Practice self-care, ask for and accept help, and reflect on the meaning of nursing experiences of caring for the dying patient and family.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Mrs. Allison feels hopeless and uncertain about her future. As noted in the concept map, her chronic pain and associated hopelessness contribute to other health problems. She has lost her desire to eat or see other people and has difficulty walking. As a result her activity and balance are also decreased. Describe how you plan to communicate with Mrs. Allison, who is having intense emotional reactions to loss and grief.
2. Mrs. Allison's family members express concern about how they can best offer support when she goes home. What do you include in a family teaching plan?
3. Mrs. Allison wants to go home to live independently as long as she is able. Her daughter arrives to help make decisions for her

mother's care. Mrs. Allison and her daughter do not understand hospice care and want you to tell them about it to see if it might be a good care option for them. What major points do you plan to include in a conversation with the patient and family related to hospice philosophy, services, and impact on the family?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Regarding the request for organ and tissue donation at the time of death, the nurse needs to be aware that:
   1. Specially educated personnel make requests.
   2. Requests are usually made by the nurse caring for the patient at the time of death.
   3. Only patients who have given prior instruction regarding donation become donors.
   4. Professionals need to be very selective in whom they ask for organ and tissue donation.
2. The nurse notes that a woman who recently began cancer treatment appears quiet and withdrawn, states that she does not believe the treatments will make any difference, does not ask about her progress, and missed two chemotherapy sessions. Based on the above assessment data, the nurse gathers more information to consider making which of the following nursing diagnoses?
   1. Anxiety
   2. Hopelessness
   3. Spiritual distress
   4. Complicated grieving
3. A family member asks a home care nurse what he should do if the patient's serious chronic illness worsens even with increased medical interventions. How does the nurse best begin a conversation about the goals of care at the end of life?
   1. Encourage the family member to think more positively about the patient's new therapy
   2. Avoid the discussion because it has to do with medical, not nursing, diagnoses
   3. Initiate a discussion about advance directives with the patient, family, and health care team
   4. Begin the discussion by asking the patient to identify his or her beliefs about the goals of care while the family member is present
4. Which of the following nursing actions best reflects sensitivity to cultural differences related to end-of-life care?
   1. Practice honesty with everyone, telling patients about their illness, even if the news is not good.
   2. Ask family members if they prefer to help with the care of the body after death.
   3. Provide postmortem care at the time of death to relieve family members of this difficult job.
   4. Value patient self-determination, understanding that each person makes his or her own decisions.
5. A young man is diagnosed with a serious, life-changing illness. His conversations during his first 2 days of hospitalization are abrupt, superficial, and unrelated to his illness. What understanding about communication enhances your therapeutic communication with this patient?
   1. Younger patients are usually less talkative about their diagnosis.
   2. All patients benefit by talking about their feelings with another person.
   3. Avoid discussing illness-related topics with quiet patients.
   4. Remain alert for signals that the patient wants to discuss his illness.
6. A woman experiences the loss of a very early–term pregnancy. Her friends do not mention the loss, and someone suggests to her that she can "always try again." The woman feels confusion over her sadness and stops talking about it with others. What type of grief response is she most likely experiencing?
   1. Delayed
   2. Anticipated
   3. Exaggerated
   4. Disenfranchised
7. A nurse has the responsibility of managing a deceased patient's post-mortem care. Arrange the steps for post-mortem care in the proper order.
   1. Bathe the body of the deceased.
   2. Collect any needed specimens.
   3. Remove all tubes and indwelling lines.
   4. Position the body for family visit/viewing.
   5. Speak to the family members about their possible participation.
   6. Confirm that request for organ/tissue donation and/or autopsy has been made.
   7. Notify a support person (e.g., spiritual care provider, bereavement specialist) for the family.
   8. Accurately tag the body, indicating the identity of the deceased and safety issues regarding infection control.
   9. Elevate the head of the bed.
8. A family member of a recently deceased patient talks casually with the nurse at the time of the patient's death and expresses relief that she will not have to visit at the hospital anymore. What theoretical description of grief best applies to this family member?
   1. Denial
   2. Anticipatory grief
   3. Dysfunctional grief
   4. Yearning and searching
9. A self-care goal you set when caring for dying and grieving patients includes:
   1. Learning not to take losses so seriously.
   2. Limiting involvement with patients who are grieving.
   3. Maintaining life balance and reflecting on the meaning of your work.
   4. Admitting that you are not well suited to care for people who are grieving and asking the charge nurse not to assign you to care for these patients.
10. A nurse is providing postmortem care. Which action is the priority?
    1. Locating the patient's clothing
    2. Providing culturally and religiously sensitive care in body preparation
    3. Transporting the body to the morgue as soon as possible to prevent body decomposition
    4. Providing all postmortem care to protect the family of the deceased from having to see the body
11. Which approach to helping grieving people is most consistent with postmodern grief theories?

1. Help the patient identify the tasks to be accomplished during his or her grief.
2. Encourage people to recognize stages of grieving in anticipation of what is to come.
3. Listen carefully to a person's story of how his or her grief experience is unfolding.
4. Offer general grief timelines to help the person know when a phase will pass.

12. A patient who has a serious, life-limiting chronic illness wants to continue to engage in self-care and live as normally as possible. Which of the following nursing responses reflect a helpful understanding of patient self-care at the end of life?
    1. "Learning to accept that you can't perform some activities anymore will bring you more acceptance and peace."
    2. "Which activities are most important to you, and how can you continue to do them?"
    3. "People in your life want to help you with things; allow them to do what they want for you."
    4. "Spending more of your time resting or reading will conserve your energy."
13. The nurse suggests that a patient receive a palliative care consultation for symptom management related to anxiety and increasing pain. A family member asks the nurse if this means that the patient is dying and is now "in hospice." What does the nurse tell the family member about palliative care? (Select all that apply.)
    1. Hospice and palliative care are the same thing.
    2. Palliative care is for any patient, any time, any disease, in any setting.
    3. Palliative care strategies are primarily designed to treat the patient's illness.
    4. Palliative care interventions relieve the symptoms of illness and treatment.
14. You have identified three nursing diagnoses for a patient who is having anxiety and hopelessness as a result of a loss. Which general approach do you take to prioritize the nursing diagnoses? (Select all that apply.)
    1. Use family members and physician orders as primary resources for prioritizing your actions.
    2. Address the nursing diagnosis that most affects the medical diagnosis.
    3. Ask the patient to identify the most distressing symptom and first address that diagnosis.
    4. Use nursing knowledge to address the problem that is the underlying cause of other diagnoses.
15. Regarding grief in older adults, which understanding helps guide your relationship with an elderly patient?
    1. Older adults have usually sustained many losses in life, which influence the current loss.
    2. Older adults with a poor memory experience grief less intensely.
    3. Older adults generally handle loss better because they have more experience with it.
    4. Social support is less important because an older adult's circle of friends has become smaller.

Answers: **1.** 1; **2.** 2; **3.** 4; **4.** 2; **5.** 4; **6.** 4; **7.** 6, 9, 2, 5, 7, 3, 1, 4, 8; **8.** 2; **9.** 3; **10.** 2; **11.** 3; **12.** 2; **13.** 2; 4; **14.** 3, 4; **15.** 1.

CHAPTER

37

Stress and Coping

OBJECTIVES

- Describe the three stages of the general adaptation syndrome.
- Describe characteristics of posttraumatic stress disorder.
- Discuss the integration of stress theory with nursing theories.
- Describe stress management techniques beneficial for coping with stress.
- Discuss the process of crisis intervention.
- Develop a care plan for patients who are experiencing stress.
- Discuss how stress in the workplace affects the nurse.

KEY TERMS

Health care professionals need to know about stress so they are able to recognize it in patients and families and intervene effectively. Caregiver stress frequently affects family members of patients and must be considered in patient care. Equally important, health care professionals also experience stressful events that occur in the course of clinical practice and in their own lives. Nurses need to recognize the signs and symptoms of stress and understand stress management techniques to aid personal coping and design stress management interventions for their patients and families.

People use the term **stress** in many ways. It is an experience to which a person is exposed through a stimulus or stressor. **Stressors** are tension-producing stimuli operating within or on any system (Neuman and Fawcett, 2011). It is also the appraisal, or perception, of a stressor. **Appraisal** is how people interpret the impact of the stressor on themselves or on what is happening and what they are able to do about it (Lazarus, 2007). Finally stress is a physical, emotional, or psychological demand that often leads to growth or overwhelms a person and leads to illness (Varcarolis and Halter, 2010). Stress refers to the consequences of the stressor and the person's appraisal of it.

People experience stress as a consequence of daily life events and experiences. It stimulates thinking processes and helps people stay alert to their environment. It results in personal growth and facilitates development. How people react to stress depends on how they view and evaluate the impact of the stressor, its effect on their situation and support at the time of the stress, and their usual coping mechanisms. When stress overwhelms existing coping mechanisms, patients lose emotional balance, and a **crisis** results. If symptoms of stress persist beyond the duration of the stressor, a person has experienced a **trauma.**

SCIENTIFIC KNOWLEDGE BASE

The **fight-or-flight response** to stress, which is arousal of the sympathetic nervous system, prepares a person for action (Fig. 37-1). Neurophysiological responses to stress function through negative feedback. The process of negative feedback senses an abnormal state such as lowered body temperature and makes an adaptive response such as initiating shivering to generate body heat. Three structures, the medulla oblongata, the reticular formation, and the pituitary gland, control the response of the body to a stressor.

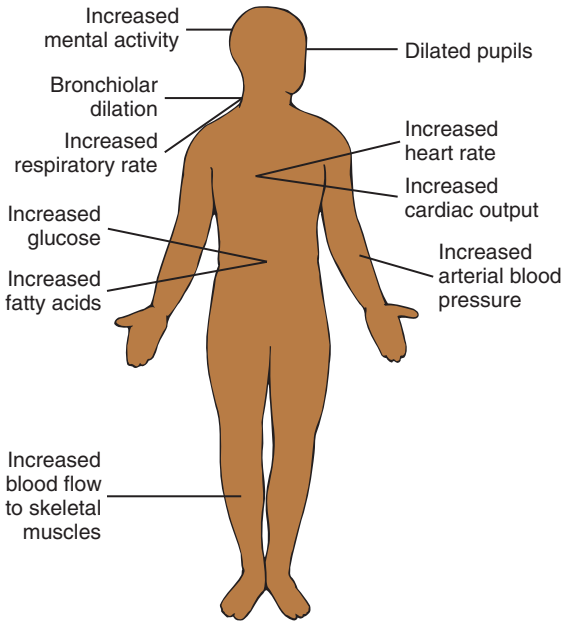

FIG. 37-1 Fight-or-flight response.

Medulla Oblongata

The medulla oblongata, located in the lower portion of the brainstem, controls heart rate, blood pressure, and respirations. Impulses traveling to and from the medulla oblongata increase or decrease these vital functions. For example, sympathetic or parasympathetic nervous system impulses traveling from the medulla oblongata to the heart control regulation of the heartbeat. The heart rate increases in response to impulses from sympathetic fibers and decreases with impulses from parasympathetic fibers.

Reticular Formation

The reticular formation, a small cluster of neurons in the brainstem and spinal cord, continuously monitors the physiological status of the body through connections with sensory and motor tracts. For example, certain cells within the reticular formation cause a sleeping person to regain consciousness or increase the level of consciousness when a need arises.

Pituitary Gland

The pituitary gland is a small gland immediately beneath the hypothalamus. It produces hormones necessary for adaptation to stress such as adrenocorticotropic hormone, which in turn produces cortisol. In addition, the pituitary gland regulates the secretion of thyroid, gonadal, and parathyroid hormones. A feedback mechanism continuously monitors hormone levels in the blood and regulates hormone secretion. When hormone levels drop, the pituitary gland receives a message to increase hormone secretion. When they rise, it decreases hormone production.

General Adaptation Syndrome

The **general adaptation syndrome (GAS),** a three-stage reaction to stress, describes how the body responds to stressors through the alarm reaction, the resistance stage, and the exhaustion stage. The GAS is triggered either directly by a physical event or indirectly by a psychological event. It involves several body systems, especially the autonomic nervous and endocrine systems, and responds immediately to stress (Fig. 37-2). When the body encounters a physical demand such as an injury, the pituitary gland initiates the GAS.

During the **alarm reaction** rising hormone levels result in increased blood volume, blood glucose levels, epinephrine and norepinephrine amounts, heart rate, blood flow to muscles, oxygen intake, and mental alertness. In addition, the pupils of the eyes dilate to produce a greater visual field. If the stressor poses an extreme threat to life or remains for a long time, the person progresses to the second stage, resistance.

During the **resistance stage** the body stabilizes and responds in a manner opposite to that of the alarm reaction. Hormone levels, heart rate, blood pressure, and cardiac output return to normal; and the body repairs any damage that has occurred. However, if the stress response is chronically activated, a state of allostasis occurs. This chronic arousal with the presence of powerful hormones causes excessive wear and tear on the person and is called **allostatic load.** An increased allostatic load leads to chronic illness (Diamond, 2009/2010). A persistent allopathic load can cause long-term physiological problems such as chronic hypertension, depression, sleep deprivation, chronic fatigue syndrome, and autoimmune disorders (McEwen, 2005).

The **exhaustion stage** occurs when the body is no longer able to resist the effects of the stressor and has depleted the energy necessary to maintain adaptation. The physiological response has intensified; but with a compromised energy level, the person's adaptation to the stressor diminishes.

Reaction to Psychological Stress. The GAS is activated indirectly for psychological threats, which are different for each person and produce differing reactions. The intensity and duration of the psychological threat and the number of other stressors that occur at the same time affect the person's response to the threat. In addition, whether or not the person anticipated the stressor influences its effect. It is often more difficult to cope with an unexpected stressor. Personal characteristics that influence the response to a stressor include the level of personal control, presence of a social support system, and feelings of competence.

A person experiences stress only if the event or circumstance is personally significant. Evaluating an event for its personal meaning is **primary appraisal.** Appraisal of an event or circumstance is an ongoing perceptual process. If primary appraisal results in the person identifying the event or circumstance as a harm, loss, threat, or challenge, the person experiences stress. If stress is present, **secondary appraisal** focuses on possible coping strategies. Balancing factors contribute to restoring equilibrium. According to crisis theory, feedback cues lead to reappraisals of the original perception. Therefore coping behaviors constantly change as individuals perceive new information.

Coping is the person's effort to manage psychological stress. Effectiveness of coping strategies depends on the individual's needs. A person's age and cultural background influence these needs. For this reason no single coping strategy works for everyone or for every stressor. The same person may cope differently from one time to another. In stressful situations most people use a combination of problem- and emotion-focused coping strategies. In other words, when under stress a person obtains information, takes action to change the situation, and regulates emotions tied to the stress. In some cases people avoid thinking about the situation or change the way they think about it without changing the actual situation itself. The type of stress, people's goals, their beliefs about themselves and the world, and personal resources determine how people cope with stress. Resources include intelligence, money, social skills, supportive family and friends, physical attractiveness,

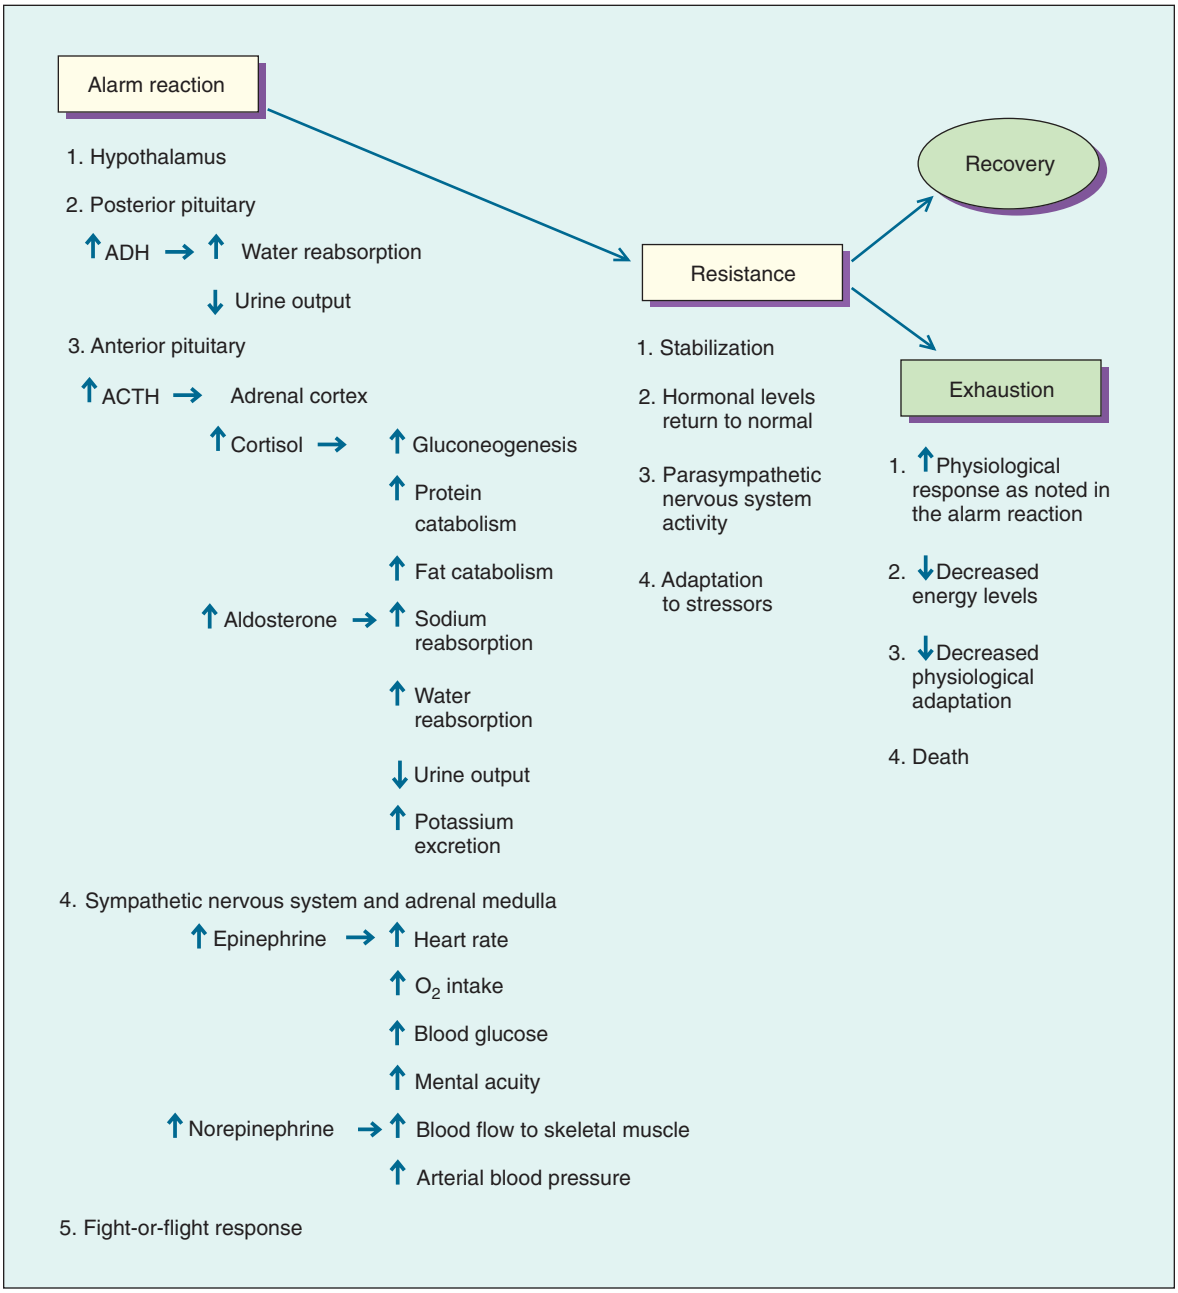

FIG. 37-2 General adaptation syndrome (GAS).

health and energy, and ways of thinking such as optimism (Lazarus, 2007).

Coping mechanisms include psychological adaptive behaviors. Such behaviors are often task oriented, involving the use of direct problem-solving techniques to cope with threats. **Ego-defense mechanisms** regulate emotional distress and thus give a person protection from anxiety and stress. Ego-defense mechanisms help a person cope with stress indirectly and offer psychological protection from a stressful event. Everyone uses them unconsciously to protect against feelings of worthlessness and anxiety. Occasionally a defense mechanism becomes distorted and no longer helps the person adapt to a stressor. However, people generally find them very helpful in coping and use them spontaneously (Box 37-1). Frequently short-term stressors activate ego-defense mechanisms. These usually do not result in psychiatric disorders.

Types of Stress

Stress includes work, family, chronic, and acute stress; daily hassles; trauma; and crisis. One person looks at a stimulus and sees it as a challenge, leading to mastery and growth. Another sees the same stimulus as a threat, leading to stagnation and loss. The individual with family responsibilities and a full-time job outside the home can experience chronic stress. It occurs in stable conditions and from stressful roles. Living with a long-term illness produces chronic stress. Conversely, time-limited events that threaten a person for a relatively brief period provoke acute stress. Recurrent daily hassles such as commuting to work, maintaining a house, dealing with difficult people, and managing money further complicate chronic or acute stress.

Posttraumatic stress disorder (PTSD) begins when a person experiences, witnesses, or is confronted with a traumatic event and

BOX 37-1 EXAMPLES OF EGO-DEFENSE MECHANISMS

- Compensation is making up for a deficiency in one aspect of self-image by strongly emphasizing a feature considered an asset. (Example: A person who is a poor communicator relies on organizational skills.)
- Conversion is unconsciously repressing an anxiety-producing emotional conflict and transforming it into nonorganic symptoms (e.g., difficulty sleeping, loss of appetite).
- Denial is avoiding emotional conflicts by refusing to consciously acknowledge anything that causes intolerable emotional pain. (Example: A person refuses to discuss or acknowledge a personal loss.)
- Displacement is transferring emotions, ideas, or wishes from a stressful situation to a less anxiety-producing substitute. (Example: A person transfers anger over an interpersonal conflict to a malfunctioning computer.)
- Identification is patterning behavior after that of another person and assuming that person's qualities, characteristics, and actions.
- Dissociation is experiencing a subjective sense of numbing and a reduced awareness of one's surroundings.
- Regression is coping with a stressor through actions and behaviors associated with an earlier developmental period.

responds with intense fear or helplessness. Some examples of traumatic events that lead to PTSD include motor vehicle crashes, natural disasters, violent personal assault, and military combat. Anxiety associated with PTSD is sometimes manifested by nightmares and emotional detachment. Some people with PTSD experience **flashbacks,** or recurrent and intrusive recollections of the event. Responses may also include self-destructive behaviors such as suicide attempts and substance abuse.

A crisis implies that a person is facing a turning point in life. This means that previous ways of coping are not effective and the person must change. There are three types of crises: (a) maturational or **developmental crises,** (b) **situational crises,** and (c) disasters or **adventitious crises** (Varcarolis and Halter, 2010). A new developmental stage such as marriage, birth of a child, or retirement requires new coping styles. Developmental crises occur as a person moves through the stages of life. External sources such as a job change, a motor vehicle crash, a death, or severe illness provoke situational crises. A major natural disaster, man-made disaster, or crime of violence often creates an adventitious crisis.

Patient-centered care provides an important context for crisis intervention. The view of the person experiencing a crisis is the frame of reference for the crisis. The vital questions for a person in crisis are, "What does this mean to you; how is it going to affect your life?" What causes extreme stress for one person is not always stressful to another. The perception of the event, situational supports, and coping mechanisms all influence return of equilibrium or homeostasis. A person either advances or regresses as a result of a crisis, depending on how he or she manages the crisis (Lazarus, 2007).

NURSING KNOWLEDGE BASE

Nurses have proposed theories related to stress and coping. Because stress plays a central role in vulnerability to disease, symptoms of stress often require nursing intervention.

Nursing Theory and the Role of Stress

The Neuman Systems Model is based on the concepts of stress and reaction to it. Nurses are responsible for developing interventions to prevent or reduce stressors on the patient or make them more bearable him or her (Neuman and Fawcett, 2011). This model views the person, family, or community as constantly changing in response to the environment and stressors and helps explain individual, family, and community responses to stressors. All systems experience multiple stressors, each of which potentially disturbs the person's, family's, or community's balance. Examples of stress include intrapersonal stressors such as an illness or injury, interpersonal stressors such as an argument or misunderstanding between two people, or extrapersonal stressors such as financial concerns. Every person develops a set of responses to stress that constitute the "normal line of defense" (Neuman and Fawcett, 2011). This line of defense helps to maintain health and wellness. However, when physiological, psychological, sociocultural, developmental, or spiritual resources are unable to buffer stress, the normal line of defense is broken, and disease often results.

The Neuman Systems Model emphasizes the importance of accuracy in assessment and interventions that promote optimal wellness using primary, secondary, and tertiary prevention strategies (Neuman and Fawcett, 2011). According to Neuman's theory, the goal of primary prevention is to promote patient wellness by stress prevention and reduction of risk factors. Secondary prevention occurs after symptoms appear. The nurse determines the meaning of the illness and stress to the patient and the patient's needs and resources for meeting them. Tertiary prevention begins when the patient's system becomes more stable and recovers. At the tertiary level of prevention the nurse supports rehabilitation processes involved in healing and moving the patient back to wellness and the primary level of disease prevention.

Factors Influencing Stress and Coping

Potential stressors and coping mechanisms vary across the life span. Adolescence, adulthood, and old age bring different stressors. The appraisal of stressors, the amount and type of social support, and coping strategies all balance when assessing stress and depend on previous life experiences. Furthermore, situational and social stressors place people who are vulnerable at higher risk for prolonged stress.

Situational Factors. Situational stress arises from personal or family job changes or relocation. Stressful job changes include promotions, transfers, downsizing, restructuring, changes in supervisors, and additional responsibilities. Adjusting to chronic illness leads to situational stress. Common diseases such as obesity, hypertension, diabetes, depression, asthma, and coronary artery disease provoke stress. Uncertainty associated with treatment and illness triggers stress in patients of all ages. Paying for treatment and limited access to providers also create stress. Although being a family caregiver for someone with a chronic illness such as Alzheimer's disease is associated with stress, the actions of competent health care providers often minimize the stress for caregivers (Box 37-2).

Maturational Factors. Stressors vary with life stage. Children identify stressors related to their physical appearance, their families, their friends, and school. Preadolescents experience stress related to self-esteem issues, changing family structure as a result of divorce or death of a parent, or hospitalizations. As adolescents search for their identity with peer groups and separate from their families, they experience stress. In addition, they face stressful questions about using mind-altering substances, sex, jobs, school, and career choices. Stress for adults centers around major changes in life circumstances. These include the many milestones of beginning a family and a career, losing parents, seeing children leave home, and accepting physical aging. In old age stressors include the loss of

BOX 37-2 EVIDENCE-BASED PRACTICE

Recognizing Sources of Caregiver Stress

PICO Question: How do family caregivers of patients with chronic illness perceive caregiving?

Evidence Summary

Research about effects of family caregiving on caregivers typically focuses on multiple stressors experienced by family caregivers and the personal benefits of caregiving. A common stressor for family caregivers is dealing with the patient's emotional well-being and mood. For example, when caring for a family member with heart failure, the most difficult tasks for family caregivers often include dealing with behavior problems (e.g., moodiness), providing emotional support, and managing dietary needs (Pressler et al., 2009). Similarly, when caring for a family member who has had a stroke, the most stressful caregiving tasks for family caregivers often include managing problems with mood (depression, loneliness, and anxiety), memory, and physical care (bowel control) (Haley et al., 2009).

Family caregivers also experience positive aspects of caregiving. For example, family members who care for patients who have had strokes often appreciate life more, feel needed, experience stronger relationships with others, and develop a more positive attitude toward life (Haley et al., 2009).

Attitude toward caregiving is sometimes a good predictor of stress in both Japanese American and American cultures (Anngela-Cole and Hilton, 2009). Caregivers who believe that their job is important and who want to provide care may experience lower levels of depression and greater life satisfaction than those who see caregiving as a burden.

Two psychosocial themes emerge from the findings of these studies: the urgent desire to deal with mood problems of the patient and the benefit of the caregiver having a positive attitude toward being a caregiver.

Application to Nursing Practice

- Focus education for family caregivers on behavior management strategies, communication skills (including therapeutic silence), and assessment tools that family caregivers can use to anticipate and reduce behavior problems.
- Engage family caregivers in discussions to help them identify benefits of caregiving (Haley et al., 2009).
- Develop supportive interventions to help family caregivers reframe their caregiving as loving and generous while recognizing the impact of stressors on them (Anngela-Cole and Hilton, 2009).

BOX 37-3 FOCUS ON OLDER ADULTS

Understanding Differences in Stress and Coping Among Older Adults

- Ordinary hassles of day-to-day living are a source of stress; older people have more hassles with home maintenance and health than do younger people (Folkman et al., 1987).
- Older adults use more passive, intrapersonal, emotion-focused forms of coping such as distancing, humor, accepting responsibility, and reappraising the stressor in a positive way (Folkman et al., 1987).
- Life experiences and perspectives of older adults make most problems seem insignificant, and many older adults have acquired appropriate stress-management techniques (Folkman et al., 1987).
- Older adults' coping improves based on earlier experience with coping with traumatic situations (Yancura and Aldwin, 2008).
- Coping affects health in older adults more than in younger adults (Yancura and Aldwin, 2008).
- Because of the high incidence of depression in older adults, you need to assess for suicidal thoughts and intent.
- Conditions such as hypoxia and thyroid dysfunction are common in older adults and initially present symptoms that mimic the consequences of stress and anxiety.
- Differentiate signs of stress and crisis in older adults from dementia and acute confusion.

BOX 37-4 CULTURAL ASPECTS OF CARE

Cultural Variations in Stress Appraisal and Coping Strategies

A patient's culture defines what is stressful to the person and ways of coping with stress (Aldwin, 2007). Cultural context shapes the types of environmental stimuli that produce stress. For example, diverse cultures address developmental transitions and turning points in life differently. Culture affects how a person leaves the parental home, experiences health crises or chronic illness, cares for the family, or becomes disabled or dependent. Furthermore, how a person appraises stress also depends on his or her culture. What is perceived as a major stressor in one culture might be viewed as a minor problem in another. A person's response to the stress of pain is an example of a culture-based response to stress. In some cultures patients maintain personal control, whereas others become emotionally expressive. Coping strategies are also influenced by one's cultural background. Cultures vary in their emotion- and problem-focused coping strategies. Some cultures stress that emotions should be controlled, whereas others believe in expressing emotions. Problem-focused coping refers to controlling or managing stress. Different cultures control stress in different ways. Cultures provide different resources for coping with stress. These include the legal system for conflict resolution, advice givers or support groups, and rituals.

Implications for Practice

- Realize that stressors and coping styles vary with different cultures.
- Reflect on your own perceptions of stress and coping in a cultural context.
- Assess the influence of culture on a patient's appraisal of stress.
- Determine resources in a patient's culture that facilitate coping.

autonomy and mastery resulting from general frailty or health problems that limit stamina, strength, and cognition (Box 37-3).

Sociocultural Factors. Environmental and social stressors often lead to developmental problems. Potential stressors that affect any age-group but are especially stressful for young people include prolonged poverty and physical handicap. Children become vulnerable when they lose parents and caregivers through divorce, imprisonment, or death or when parents have mental illness or substance abuse disorders. Living under conditions of continuing violence, disintegrated neighborhoods, or homelessness affects people of any age, especially young people (Pender et al., 2011). A person's culture also influences stress and coping (Box 37-4).

CRITICAL THINKING

When caring for a patient experiencing stress, use critical thinking skills to understand the patient's stressor and the stress response. Integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients to understand stress and its impact on the patient and family. Know the neurophysiological changes that occur in the patient experiencing the alarm reaction, resistance stage, and exhaustion stage of the general adaptation syndrome. In addition, know communication principles that contribute to assessing patient's behaviors. Give utmost attention to determining the patient's perception of the situation and his or her ability to cope with the stress. If the

patient's usual coping skills have not helped or his or her support systems have failed, use crisis intervention counseling.

Experience teaches you to understand the patient's unique perspective and view each person as an individual, recognizing that no two people are exactly alike. Experience with patients also helps you to recognize responses to stress. In addition, personal experiences with stress and coping increase your ability to empathize with a patient temporarily immobilized by stress.

Be confident in the belief that you and your patients can effectively manage stress. Patients who feel overwhelmed and perceive events as being beyond their capacity to cope rely on you as an expert. Patients respect your advice and counsel and gain confidence from your belief in their ability to move past the stressful event or illness. Patients overwhelmed by life events are often unable, at least initially, to act on their own behalf and require either direct intervention or guidance. Integrity is an essential attitude through which you respect the patient's perception of the stressor. Make the effort to have the patient explain his or her unique viewpoint and situation.

The practice standards for psychiatric mental health nursing (ANA, 2007) guide assessment of a patient's stress, coping mechanisms, and support system before intervening. Use linguistic and culturally effective communication skills to clearly and precisely understand a patient's perception of stress. Focus on factors relevant to his or her well-being. In addition, the patient expects you to exhibit confidence and integrity when he or she feels vulnerable. Be especially aware of the ethical responsibility in caring for someone who has diminished autonomy as a result of stress.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Assessment of a patient's stress level and coping resources requires that you first establish a trusting nurse-patient relationship because you are asking a patient to share personal and sensitive information. Learn from the patient both by asking questions and by making observations of nonverbal behavior and the patient's environment. Synthesize the information and adopt a critical thinking attitude while observing and analyzing patient behavior (Fig. 37-3). Often the patient has difficulty expressing exactly what is most bothersome about the situation until there is an opportunity to discuss it with someone who has time to listen.

Begin your assessment with an open-ended question such as, "What is happening in your life that caused you to come today?" or "What happened in your life that is *different?*" This requires some focusing by the patient. Next assess the patient's perception of the event, available situational supports, and what he or she usually does when there is a problem that he or she cannot solve. Determine if a person is suicidal or homicidal by asking directly. For example, ask, "Are you thinking of killing yourself or someone else?" If so, determine in a caring and concerned manner if the person has a plan and determine how lethal the means are.

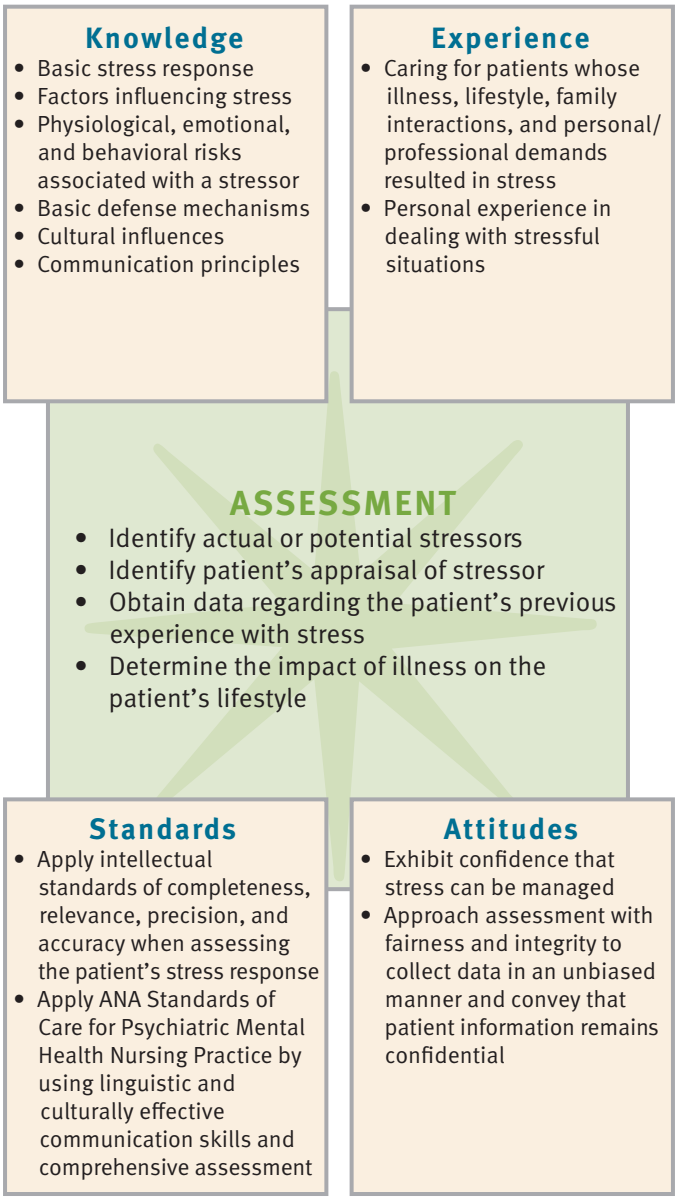

FIG. 37-3 Critical thinking model for stress and coping assessment. *ANA,* American Nurses Association.

Take time to understand a patient's meaning of the precipitating event and the ways in which stress is affecting his or her life. Allow time for him or her to express priorities for coping with stress. For example, in the case of a woman who has just been told that a breast mass was identified on a routine mammogram, it is important to know what the patient wants and needs most from the nurse. Although some women in this situation identify their need for information about biopsy or mastectomy as their personal priority, others need guidance and support in discussing how to share the news with family members. In some cases, when there is nothing that will change or improve the situation, allowing the patient to use denial as a coping mechanism is helpful. Gaining an understanding of patient expectations does not mean excluding certain types of care that are important simply because a patient does not identify them as needs. However, by inquiring about patient expectations and priorities, you are better able to ensure that you address *all* of the patient's needs in some way.

BOX 37-5 NURSING ASSESSMENT QUESTIONS

Perception of Stressor
- What is bothering you most right now?
- What do you think about when you're lying awake?

Maladaptive Coping Used
- Do you live alone or with others?
- Who helps you?
- Have you started drinking or smoking?
- Has your caffeine intake increased?

Adherence to Healthy Practices
- Do you have high blood pressure?
- Have you noticed an increase or decrease in weight?
- Are you taking your prescribed medications?
- Have you increased any medications?

Stress also occurs in a family or a community. Stress in a family is sometimes from a critically ill family member, the sudden loss of a job, a move, or becoming homeless. An example of stress in a community is a natural disaster such as a major flood or the sudden, unexpected death of a beloved teacher or teenager. To develop appropriate and safe nursing care when caring for families or communities, ensure that you understand the meaning that the stress has for that group.

Subjective Findings. When assessing a patient's level of stress and coping resources, create a nonthreatening physical environment for the interaction. Assume the same height as the patient, arranging the interview environment so you can maintain or avoid eye contact comfortably. You do this by placing chairs at a 90-degree angle or side by side to reduce the intensity of the interaction (Varcarolis and Halter, 2010). Gather information about the health status of the patient from his or her perspective and begin the process of developing a trusting relationship with him or her. Use the interview to determine the patient's view of the stress, coping resources, any possible maladaptive coping, and adherence to prescribed medical recommendations such as medication or diet (Box 37-5). If the patient is using denial as a coping mechanism, be alert to whether he or she is overlooking necessary information. As in all interactions with the patient, respect the confidentiality and sensitivity of the information shared.

Objective Findings. Obtain objective findings related to stress and coping through observation of the appearance and nonverbal behavior of a patient. Observe grooming and hygiene, gait, characteristics of the handshake, actions while sitting, quality of speech, eye contact, and the attitude of the patient during the interview. Before the interview begins or at the end of the interview, depending on the anxiety level of the patient, obtain basic vital signs to assess for physiological signs of stress such as elevated blood pressure, heart rate, or respiratory rate. Make certain to incorporate cultural components of interpreting the patient's nonverbal communication behaviors.

Building Competency in Safety You are caring for Lois, an 80-year-old woman who appears highly anxious and distressed about the health of her dog. Her concerns seem rather unspecific to you, yet Lois is having insomnia and anorexia. She's lost 5 pounds since you last visited her home. What conditions do you need to consider in addition to her apparent stress and anxiety?

Answers to questions can be found on the Evolve website.

BOX 37-6 NURSING DIAGNOSTIC PROCESS

Ineffective Coping

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient about change in sleeping patterns.	Sleep disturbance Difficulty falling asleep at nights Sighing
Ask patient to complete a sleep diary for 2 weeks.	Excessive sleeping
Observe patient's behavior and response to questions during assessment.	Fatigue Inability to concentrate Inaccurate response to questions Inappropriate laugh or crying
Observe patient's appearance.	Poor grooming Self-harm
Ask patient about changes in eating patterns.	Weight gain or loss Lack of interest in food

NURSING DIAGNOSIS

A review of assessment data leads the nurse to cluster data that indicate a potential or actual stressor and the patient's response. Clustering data, along with the application of the nurse's knowledge and experiences with patients in stress, leads to individualized nursing diagnoses (Box 37-6).

Nursing diagnoses for people experiencing stress generally focus on coping. Specifically major defining characteristics of *ineffective coping* include verbalization of an inability to cope and an inability to ask for help. To identify defining characteristics, ask the patient what is of most concern at the time of the interview. It is important to allow him or her sufficient time to answer. Observe for nonverbal signs of anxiety, fear, anger, irritability, and tension in a patient who is experiencing ineffective coping. Other defining characteristics include the presence of life stress, an inability to meet role expectations and basic needs, alteration in societal participation, self-destructive behavior, change in usual communication patterns, high rate of accidents, excessive food intake, drinking, smoking, and sleep disturbances. Stress often results in multiple nursing diagnoses. Examples of these diagnoses include but are not limited to the following:

- Anxiety
- Caregiver role strain
- Ineffective coping
- Fear
- Risk for post-trauma syndrome
- Insomnia
- Situational low self-esteem
- Stress overload

PLANNING

Goals and Outcomes. Desirable outcomes for persons experiencing stress frequently include effective coping, family coping, caregiver emotional health, and psychosocial adjustment: life change. The nurse often selects interventions for stress and improved coping such as coping enhancement and crisis intervention in addition to individualized interventions after considering

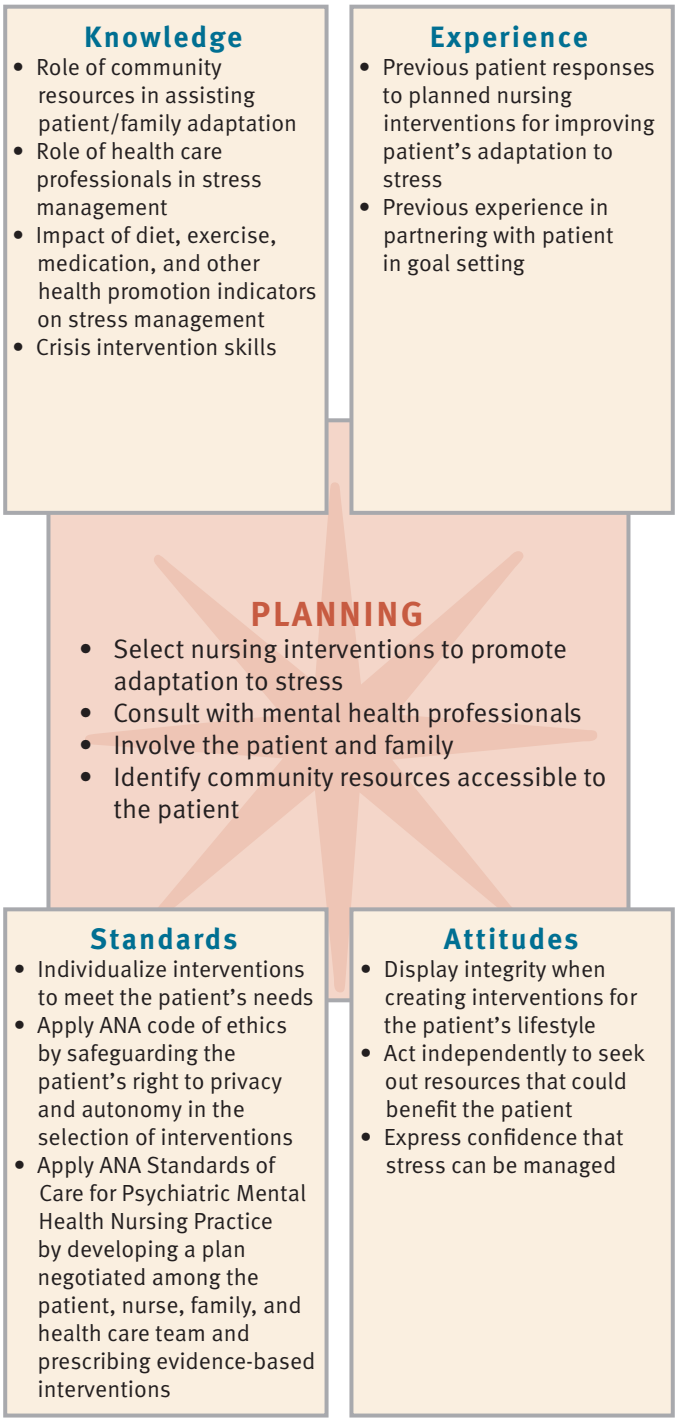

FIG. 37-4 Critical thinking model for stress and coping planning. *ANA,* American Nurses Association.

the nursing diagnosis, the resources available to the patient, and the goals identified by the patient and nurse (Fig. 37-4).

Nursing interventions are designed within the framework of primary, secondary, and tertiary prevention. At the primary level of prevention you direct nursing activities to identifying individuals and populations who are possibly at risk for stress. Nursing interventions at the secondary level include actions directed at symptoms such as protecting the patient from self-harm. Tertiary-level interventions assist the patient in readapting and can include relaxation training and time-management training. The nurse and the patient assess the level and source of the existing stress and determine the appropriate points for intervention to reduce it (Pender et al., 2011) (see the Nursing Care Plan).

Another method of planning care is through the use of a concept map (Fig. 37-5 on p. 740). Concept maps identify multiple nursing diagnoses from the assessment database and show how they are related. In this example the nursing diagnoses are linked to the patient's medical diagnosis of depression. In addition, the concept map shows the relationship among the nursing diagnoses *chronic low self-esteem, ineffective coping, anxiety, and caregiver role strain*. Use of a concept map requires critical thinking skills to organize patient data and assists in planning for patient-centered care.

Just as the nursing assessment of the patient's stress and coping depends on the patient's perception of the problem and coping resources, the interventions focus on a partnership with the patient and support system, usually the family. In the case of a family or community stressor and impaired family or community coping, the view of the situation and resources is broader.

Setting Priorities. Consider the patient's perspective and responses to assessment questions when setting priorities for care (see the Nursing Care Plan). The patient's clinical condition and perception of stress determine which nursing diagnosis has the greatest priority. As in all areas of nursing, safety of the patient and others in his or her environment is the first priority.

Building Competency in Safety You are interviewing Dave, a 60-year-old man who has recently lost his job and whose wife has terminal cancer. He says, "I don't see how I can go on." This raises a warning flag for you. How would you determine if Bob is suicidal?

Answers to questions can be found on the Evolve website.

If suicide or homicide is not an issue, examine other potential threats to the safety of vulnerable people who are under the care of the patient. Provide for their temporary care or supervision if necessary. Other potential threats to safety include nutritional deficits; insomnia; self-care deficits; and poor judgment and impulsiveness that possibly lead to unsafe decisions about sex, drugs, money, or damage to personal relationships that the person might later regret. Determine the degree of work, school, home, and family disruption in the person's life. When you have completed immediate assessment and ensured safety, begin the problem-solving process.

Teamwork and Collaboration. Collaborate with occupational therapists, dietitians, pastoral care professionals, and health care professionals from other clinical specialties, depending on the patient's situation. The scope of your nursing practice cannot meet all of the patient's needs. Patients experiencing stress from medical conditions or psychiatric disorders present needs that make it necessary for you to consult with advanced practice mental health nurses, psychiatrists, psychologists, or psychiatric social workers. A multidisciplinary approach addresses the holistic needs of the patient. Recognize the need for collaboration and consultation; inform the patient about potential resources; and make arrangements for interventions such as consultations, group sessions, or therapy as needed. A hospital social worker shares ideas for available resources both within the hospital and in the community. A home care nurse knows community services, groups, and appropriate contacts.

In addition to maximizing use of available resources for the patient, collaborative care also benefits the nurse. While working

NURSING CARE PLAN

Caregiver Role Strain

ASSESSMENT

Evelyn was recently diagnosed with Alzheimer's dementia. Carl, her husband, is her main caregiver. When the home health nurse first goes to Evelyn and Carl's house, she finds the home in slight disarray. The lawn is overgrown, there are dirty dishes in the sink, and an empty can of soup is sitting on the kitchen counter. Carl is standing in the living room folding clothes from a laundry basket, and Evelyn is watching television. Carl looks tired and states, "I'm just worn out." The home health nurse knows that a new diagnosis of dementia often creates stress, especially for the caregiver.

Assessment Activities	*Findings/Defining Characteristics**
Ask Carl about his recent stressors and coping strategies.	Carl states, **"There's so much to do that I don't even know where to begin."** He **awakens 3 to 4 times per night** to find Evelyn wandering about.
Observe Carl's grooming and hygiene.	Carl is **unshaven and appears disheveled.**
Ask Carl about his sleep and nutrition patterns.	Carl states that he has **lost 20 pounds in the past 6 months** and that his **appetite has been poor.**
Assess Carl's mood and affect by asking how he is feeling.	Carl states, **"I feel very tired. Everything feels overwhelming."**
Assess Carl's suicide potential.	Carl denies being suicidal.
Assess health status and health care status.	Carl **has not seen a health care provider for his own health in over a year.**

*Defining characteristics are shown in **bold type.**

NURSING DIAGNOSIS: Caregiver role strain related to recent diagnosis of wife's Alzheimer's dementia

PLANNING

Goals	*Expected Outcomes (NOC)*†
Carl will appear rested in 1 month.	**Caregiver Physical Health** Carl will verbalize approaches used to involve others in Evelyn's caregiving activities within 2 weeks.
Carl will state that he has resumed one outside activity within 1 month.	**Caregiver Lifestyle Disruption** Carl will report a balanced routine that incorporates time for own rest or relaxation within 1 week.

†Outcome classification labels from Moorhead S et al: Nursing outcomes classification (NOC), ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Caregiver Support	
Help Carl locate an Internet video support group.	An Internet video support group helps lower stress related to the care recipient's cognitive impairment and decline in function (Marziali and Garcia, 2011).
Identify sources of respite care in the form of adult day care programs.	Adult day programs reduce caregiver burden much more successfully than in-home services (Sussman and Regehr, 2009).
Explore community resources for a short-term education group for Carl that teaches self-care tools to reduce stress.	Education groups help caregivers develop self-care tools to reduce stress, change negative self-talk, communicate more effectively, and make difficult decisions (Oken et al., 2010).
Teach Carl mindfulness meditation strategies.	Mindfulness meditation, a form of cognitive therapy, reduces stress in caregivers (Oken et al, 2010).

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Carl if his fatigue and stress level have decreased.	Carl states that he feels more rested and less depressed.	Carl sleeps for 6 hours at night and takes a 30-minute nap in the afternoon.
Ask Carl to describe modifications that he has made in his daily routine.	Carl uses mindfulness meditation several times a week and states that he is feeling much more relaxed.	Meditation is reducing stress and allowing Carl to care for his own needs.

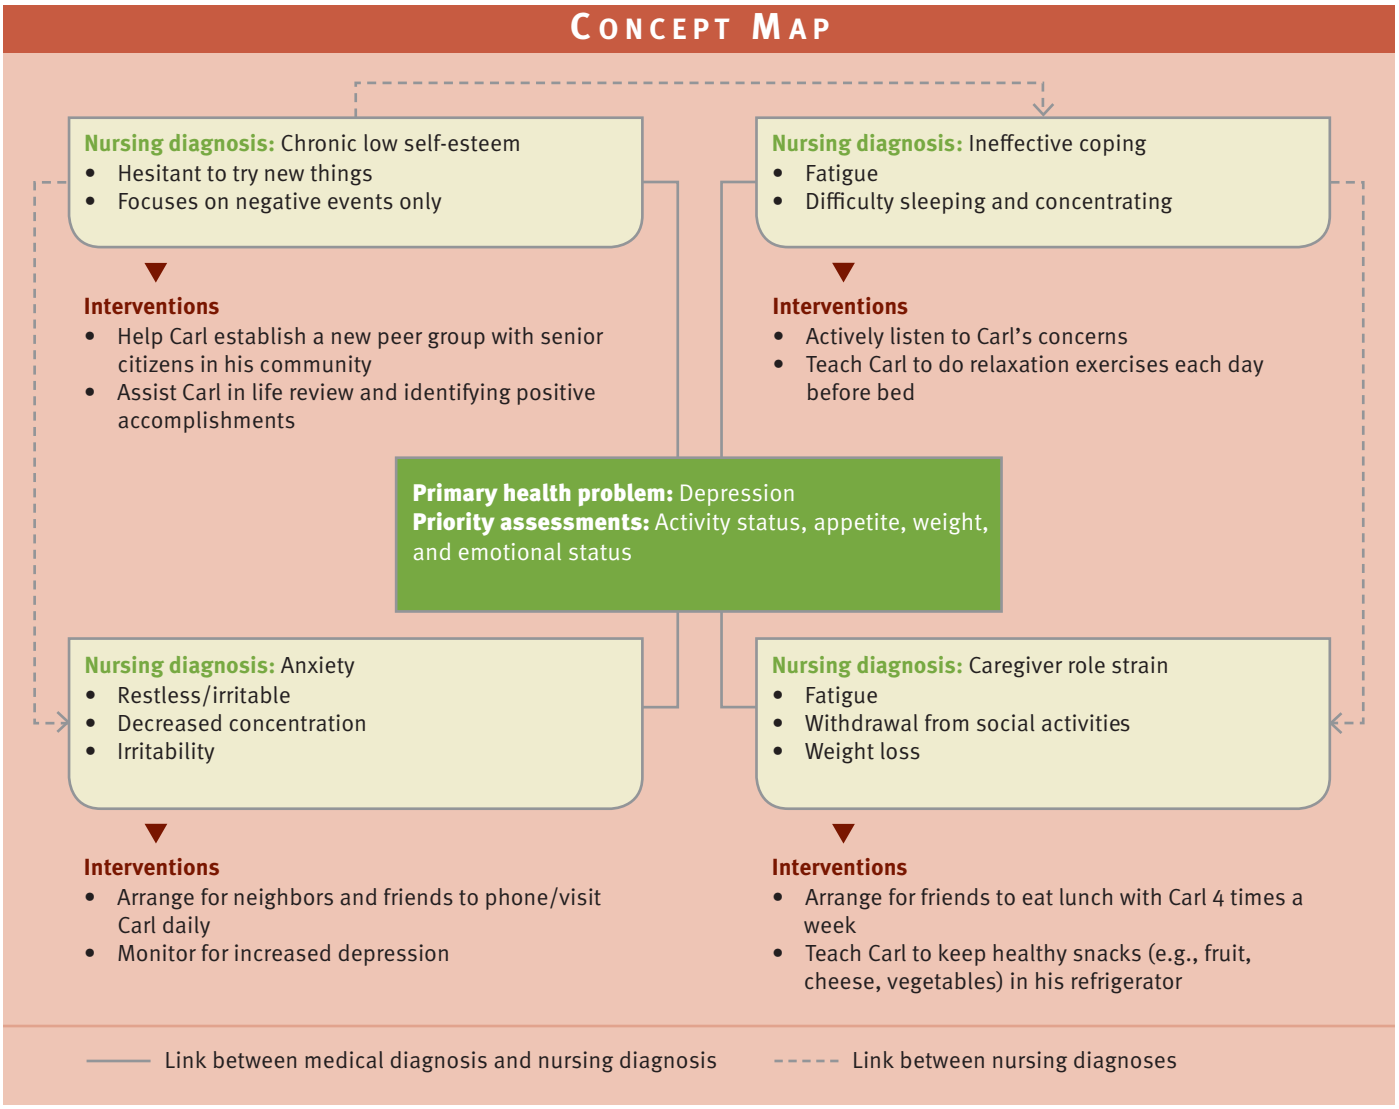

FIG. 37-5 Concept map for Carl.

with patients experiencing stress, you gain a broad understanding of the multitude of health care disciplines. Work becomes more satisfying. Contacts with other members of the multidisciplinary team and the community provide a feeling of contributing to the teamwork of providing holistic care.

IMPLEMENTATION

Health Promotion. Three primary modes of intervention for stress are to decrease stress-producing situations, increase resistance to stress, and learn skills that reduce physiological response to stress (Pender et al., 2011). Educate patients and families about the importance of health promotion (Box 37-7).

Regular Exercise. A regular exercise program improves muscle tone and posture, controls weight, reduces tension, and promotes relaxation. In addition, exercise reduces the risk of cardiovascular disease and improves cardiopulmonary functioning. Patients who have a history of a chronic illness, are at risk for developing an illness, or are older than 35 years of age should begin a physical exercise program only after discussing the plan with a health care provider (Fig. 37-6).

Building Competency in Evidence-Based Practice You are a nurse educator for a diabetes rehabilitation program. You recognize the value of exercise for these patients, yet you are not sure about the best way to persuade the patients to increase their exercise. You've located a current systematic review (which represents the highest quality of research evidence) that found three types of interventions to be most effective in promoting physical activity among chronically ill adults. These are to (1) target physical activity exclusively, (2) use behavioral (as opposed to cognitive) strategies, and (3) encourage self-monitoring (Ruppar and Conn, 2010). On the basis of the evidence, which of the following interventions is (are) most likely to be successful? (Select all that apply.)

1. Develop a program that focuses on multiple behaviors, including diet, exercise, and medication compliance.
2. Develop a program that teaches tai chi.
3. Ask patients to keep a written log of the amount of physical activity they have each day.
4. Ask patients to list the ways that exercise helps them.
5. Provide patients with pedometers to record their daily steps.
6. Ask patients to set goals for exercise every day.

Answers to questions can be found on the Evolve website.

FIG. 37-6 Regular exercise assists in coping with stress. (Courtesy Rudolph A. Furtado.)

BOX 37-7 PATIENT TEACHING

Stress Management

Objective

- Patient will report less anxiety, depression, and pain related to chronic health problems.

Teaching Strategies

- Familiarize patient with one or more of the following mind-body therapies, referring to a group or specialized practitioner when necessary (Bertisch et al., 2009):
  - Meditation
  - Deep breathing
  - Progressive muscle relaxation
  - Guided imagery
  - Hypnosis
  - Biofeedback
  - Yoga
  - Tai Chi
  - Qigong
- Teach patient to exercise for at least 15-30 minutes every day.
- Encourage patient to lower or stop caffeine intake (i.e., in coffee, tea, and soda).
- Instruct patient to do the following:
  - Listen to music that you enjoy.
  - Keep a journal of your thoughts and feelings.
  - Replace unnecessary time-consuming activities with activities that are pleasurable or interesting.
  - Look for humor in stressful situations.

Evaluation

- Ask the patient to report effects of the alternative therapy(ies) on pain, anxiety, and depression.
- Observe the patient for signs of stress.

Support Systems. A support system of family, friends, and colleagues who listen, offer advice, and provide emotional support benefits a patient experiencing stress. Many support groups are available to individuals (e.g., those sponsored by the American Heart Association and the American Cancer Society, local hospitals and churches, and mental health organizations).

Time Management. Time management techniques include developing lists of prioritized tasks. For example, help patients list tasks that require immediate attention, those that are important and can be delayed, and those that are routine and can be accomplished when time becomes available. In many cases setting priorities helps individuals identify tasks that are not necessary or can be delegated to someone else.

Guided Imagery and Visualization. Guided imagery is based on the belief that a person significantly reduces stress with imagination. It is a relaxed state in which a person actively uses imagination in a way that allows visualization of a soothing, peaceful setting. Typically the image created or suggested uses many sensory words to engage the mind and offer distraction and relaxation.

Progressive Muscle Relaxation. In the presence of anxiety-provoking thoughts and events, a common physiological symptom is muscle tension. Diminish physiological tension through a systematic approach to releasing tension in major muscle groups. Typically an individual achieves a relaxed state through deep chest breathing. Once the patient is breathing deeply, direct him or her to alternately tighten and relax muscles in specific groupings.

Assertiveness Training. Assertiveness includes skills for helping individuals communicate effectively regarding their needs and desires. The ability to resolve conflict with others through assertiveness training is important for reducing stress. Teaching assertiveness in a group setting increases the benefits of the experience.

Journal Writing. For many people keeping a private, personal journal provides a therapeutic outlet for stress. Suggest that patients keep journals, especially during difficult situations. In a private journal patients are able to express a full range of emotion and vent their honest feelings without hurting anyone else's feelings and without concern for how they appear to others.

Stress Management in the Workplace. Stressors such as rapid changes in health care technology, diversity in the workforce, organizational restructuring, and changing work systems place stress on employees. **Burnout** occurs as a result of chronic stress. In nursing burnout frequently results from intense caregiving and manifests as emotional exhaustion, loss of a sense of personal identity, and feelings of failure.

If you or your patients experience burnout, it helps to make changes in behavior to cope with workplace stress. An important step is identifying the limits and scope of responsibilities at work. Recognizing the areas over which you have control and can change and those for which you do not have responsibility is a vital insight. Making a clear separation between work and home life is also crucial. Strengthening friendships outside of the workplace, arranging for temporary social isolation for personal "recharging" of emotional energy, and spending off-duty hours in interesting activities all help reduce burnout.

Acute Care

Crisis Intervention. When stress overwhelms a person's usual coping mechanisms and demands mobilization of all available resources, it becomes a crisis. A crisis creates a turning point in a person's life because it changes the direction of his or her life in some way. The precipitating event usually occurs approximately 1 to 2 weeks before the individual seeks help, but sometimes it has occurred within the past 24 hours. Generally a person resolves the crisis in some way within approximately 6 weeks. Crisis intervention aims to return the person to a precrisis level of functioning and promote growth (Fig. 37-7).

Because an individual's or family's usual coping strategies are ineffective in managing the stress of the precipitating event, the use of new coping mechanisms is necessary. This experience forces the use of unfamiliar strategies and results in either a heightened awareness of previously unrecognized strengths and resources or deterioration in functioning. Thus a crisis is often referred to as a

situation of both danger and opportunity. Some individuals or families emerge from a crisis state functioning more effectively, whereas others find themselves weakened, and still others are completely dysfunctional.

Crisis intervention is a specific type of brief psychotherapy with prescribed steps. It is more directive than traditional psychotherapy or counseling, and any member of the health care team who has been trained in its techniques can use it. The basic approach is problem solving, and it focuses only on the problem presented by the crisis.

When using a crisis intervention approach, you help the patient make the mental connection between the stressful event and his or her reaction to it. This is crucial because he or she is sometimes unable to see the whole situation clearly. You also help the person become aware of present feelings such as anger, grief, or guilt to help him or her reduce feelings of tension. In addition, you help the patient explore coping mechanisms, perhaps identifying new methods of coping. Finally you help the person increase social contacts if he or she has been isolated and overly self-focused.

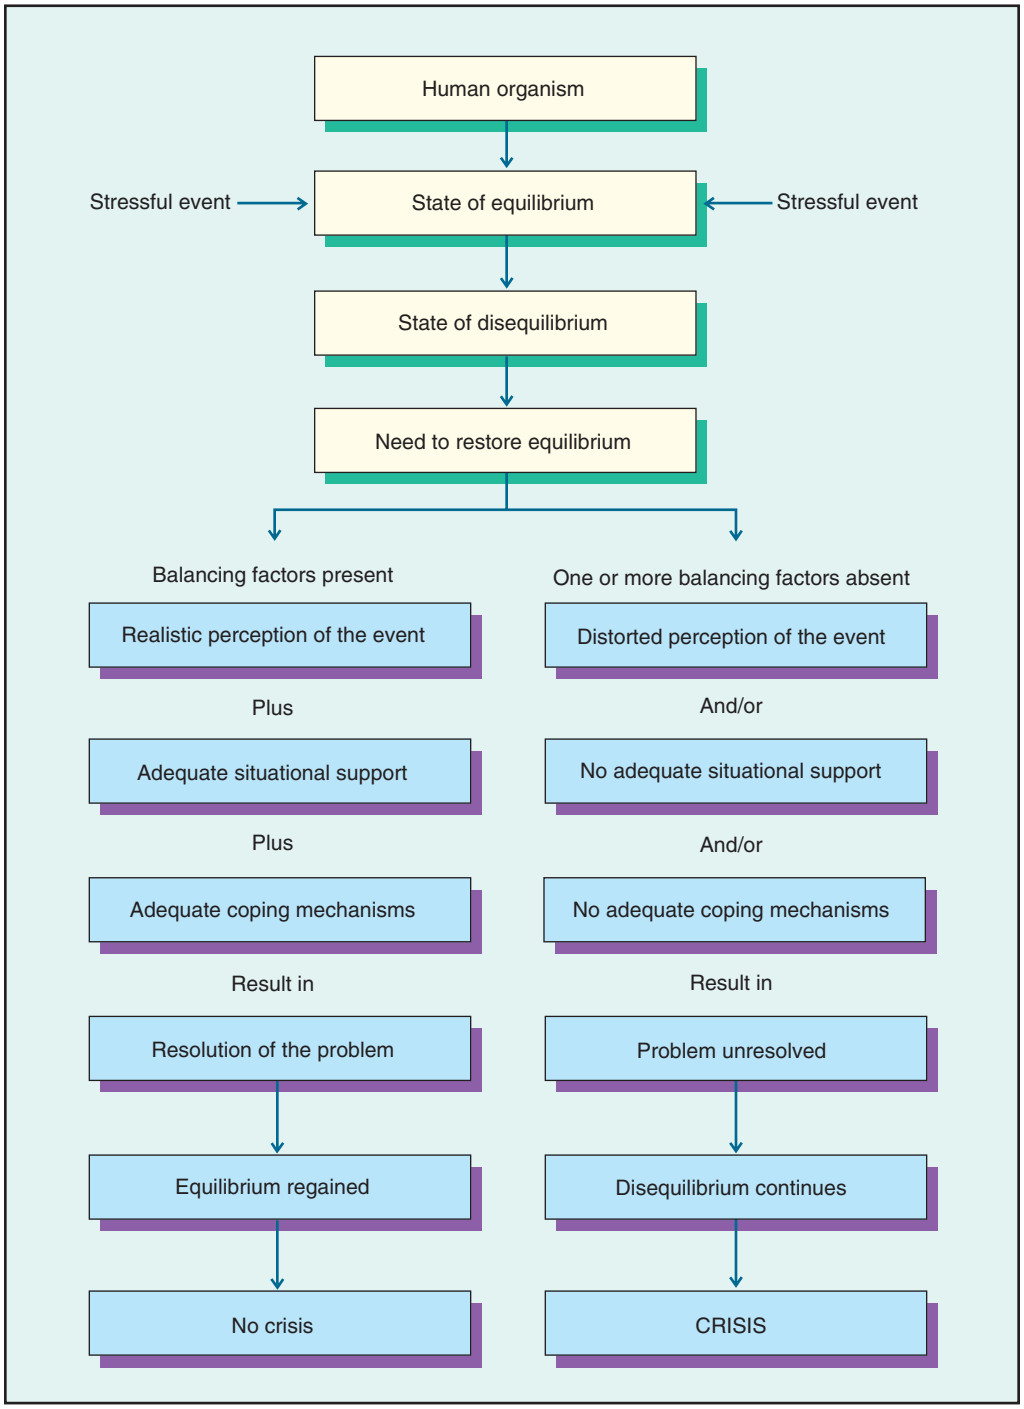

FIG. 37-7 Crisis intervention model. (Redrawn from Aguilera DC: *Crisis intervention: theory and methodology,* ed 8, St Louis, 1998, Mosby.)

Restorative and Continuing Care. A person under stress recovers when the stress is removed or coping strategies are successful; however, a person who has experienced a crisis has changed, and the effects often last for years or for the rest of the person's life. The final stage of adapting to a crisis is acknowledgment of the long-term implications of the crisis. If a person has successfully coped with a crisis and its consequences, he or she becomes more mature and healthy. When a person recovers from a stressful situation, the time is right for introducing stress management skills to reduce the number and intensity of stressful situations in the future.

EVALUATION

Through the Patient's Eyes. A patient recovering from acute stress often spontaneously reports feeling better when the stressor is gone. The recovery from chronic stress occurs more gradually as the patient emerges from the strain. In either situation reassess the patient for the presence of new or recurring stress-related symptoms (Fig. 37-8). Observe patient behaviors and talk with the patient and family if appropriate. Ask the patient about sleep patterns, appetite, and ability to concentrate. Ask about coping strategies that the patient uses and determine their effectiveness. Ask patients to compare current feelings and behaviors with feelings and behaviors 6 months ago. If desired outcomes have been met, the patient reports feeling better now than 6 months ago.

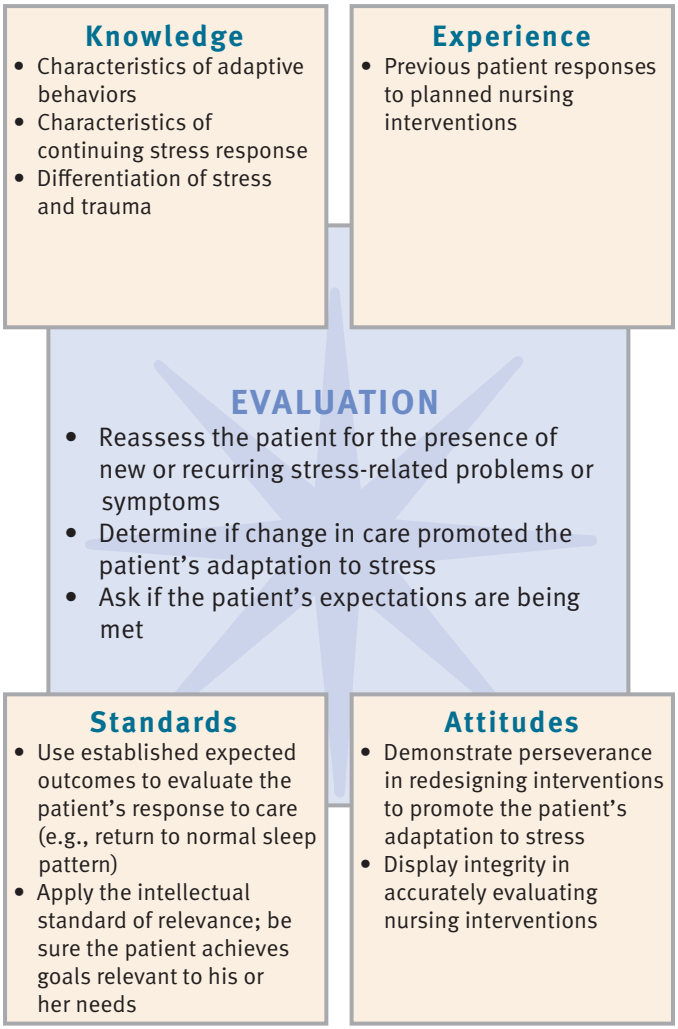

FIG. 37-8 Critical thinking model for stress and coping evaluation.

Patient Outcomes. Remember that coping with stress takes time. Maintain ongoing communication with patients regarding their coping. Patients under severe stress, or trauma, often experience feelings of powerlessness, vulnerability, and loss of control. The nurse addresses these feelings by actively involving patients and families in the processes of problem identification (assessment), prioritizing, goal setting, and evaluation. Involving patients in these processes gives them an opportunity to direct their energy in a positive way and moves them toward taking greater responsibility for health maintenance and promotion.

Engaging the patient as a partner in health care sets the stage for open communication. In such an environment the patient feels freer to give important feedback about interventions that are successful and helps the nurse better understand why some interventions fail to meet the established goals. If he or she reports continued acute stress, assess for safety by asking about whether or not there have been any recent accidents at home, in the car, or at work. Ask about coping strategies to determine if the patient is using unsafe, maladaptive strategies. If the patient reports continued chronic stress, ask about his or her perception of the stressor and coping behaviors used. Discuss the stressor with the patient to determine if it needs to be redefined. If contact with a patient ends before you have achieved the resolution of goals, it is important to refer him or her to appropriate resources so progress is not delayed or interrupted.

An essential part of the evaluation process is collaborating with patients to determine if their own expectations from nursing have been met. Any revision in the plan of care includes steps to address patient expectations.

KEY POINTS

- The general adaptation syndrome is an immediate physiological response of the whole body to stress and involves several body systems, especially the autonomic nervous and endocrine systems. Physiological responses to stress also include immunological changes.
- Stress can make people ill as a result of increased levels of powerful hormones that change bodily processes.
- A person is under psychological stress only if he or she evaluates the event or circumstance as personally significant. Such an evaluation of an event for its personal meaning is called *primary appraisal*.
- There are several types of stress, including work, family, chronic, and acute stress; daily hassles; trauma; and crisis.
- Nurses recognize and respond to caregiver stress of family members of patients.
- Rapid changes in health care technology, diversity in the workforce, organizational redesign, and changing work systems place stress on employees, including nurses.
- Potential stressors and coping mechanisms vary across the life span.
- Coping means making an effort to manage psychological stress.
- Coping is a process that constantly changes to manage demands on a person's resources.
- Three primary modes for stress intervention are to decrease stress-producing situations, increase resistance to stress, and learn skills that reduce physiological response to stress.
- A patient whose stress is so severe that he or she is unable to cope using any of the means that have worked before is experiencing a crisis.

- A crisis is a turning point in life and is developmental, situational, or adventitious.
- Generally a crisis is resolved in some way within approximately 6 weeks. Crisis intervention aims to return the person to a pre-crisis level of functioning and to promote growth.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. You are making a home visit to see 80-year-old Carl and 81-year-old Evelyn because Evelyn has Alzheimer's dementia and her health care provider is concerned about her nutrition. He also wants to know if she is taking her medications. Carl has been providing Evelyn's care, and he is also worried about his own health. Discuss the various stressors that need to be considered when assessing their situation.
2. Carl reports dizziness; however, based on your thorough assessment, you do not identify any physical findings that would account for this. As you talk with Carl, he tells you that his life is very stressful and he is barely coping. He is the sole caregiver for his wife, Evelyn, who has dementia. He is worried about what might happen to her if his health failed. He has not been able to play golf with his friends or go to church in months. His only social activity is a trip to the grocery store while his neighbor stays with Evelyn. He is worried that they will spend all their life savings if she needs to go to a nursing home, and he loses his patience with her. Develop nursing diagnoses related to this situation.
3. Carl is admitted to the hospital with a fractured hip sustained from a fall when he got up during the night to check on Evelyn who was wandering in the house. Before his injury he cared for Evelyn, who suffers from advancing Alzheimer's disease. While he is hospitalized, Evelyn stays with a niece who lives 100 miles away, but this cannot be a permanent situation because their niece is also in frail health. Carl and Evelyn's children live across the country and are very involved in their careers. He is concerned about who will care for Evelyn and how he will manage when he is discharged. What approach would be the best to take in planning Carl's care?

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. When teaching a patient about the negative feedback response to stress, the nurse includes which of the following to describe the benefits of this stress response?
   1. Results in neurophysiological response.
   2. Reduces body temperature
   3. Causes a person to be hypervigilant
   4. Reduces level of consciousness to conserve energy.
2. A nurse observes that a patient whose home life is chaotic with intermittent homelessness, a child with spina bifida, and an abusive spouse appears to be experiencing an allostatic load. As a result, the nurse expects to detect which of the following while assessing the patient?
   1. Posttraumatic stress disorder
   2. Rising hormone levels
   3. Chronic illness
   4. Return of vital signs to normal
3. A patient who is having difficulty managing his diabetes mellitus responds to the news that his hemoglobin A1C, a measure of blood sugar control over the past 90 days, has increased by saying, "The hemoglobin A1C is wrong. My blood sugar levels have been excellent for the last 6 months." The patient is using the defense mechanism:
   1. Denial.
   2. Conversion.
   3. Dissociation.
   4. Displacement.
4. When doing an assessment of a young woman who was in an automobile accident 6 months before, the nurse learns that the woman has vivid images of the crash whenever she hears a loud, sudden noise. The nurse recognizes this as _____.
5. A grandfather living in Japan worries about his two young grandsons who disappeared after a tsunami. This is an example of:
   1. A situational crisis.
   2. A maturational crisis.
   3. An adventitious crisis.
   4. A developmental crisis.
6. During the assessment interview of an older woman experiencing a developmental crisis, the nurse asks which of the following questions?
   1. How is this flood affecting your life?
   2. Since your husband has died, what have you been doing in the evening when you feel lonely?
   3. How is having diabetes affecting your life?
   4. I know this must be hard for you. Let me tell you what might help.
7. The nurse plans care for a 16-year-old male, taking into consideration that stressors experienced most commonly by adolescents include which of the following?
   1. Loss of autonomy caused by health problems
   2. Physical appearance, family, friends, and school
   3. Self-esteem issues, changing family structure
   4. Search for identity with peer groups and separating from family
8. A child who has been in a house fire comes to the emergency department with her parents. The child and parents are upset and tearful. During the nurse's first assessment for stress the nurse says:
   1. "Tell me who I can call to help you."
   2. "Tell me what bothers you the most about this experience."
   3. "I'll contact someone who can help get you temporary housing."
   4. "I'll sit with you until other family members can come help you get settled."
9. When assessing an older adult who is showing symptoms of anxiety, insomnia, anorexia, and mild confusion, one of the first assessments includes which of the following?
   1. The amount of family support
   2. A 3-day diet recall
   3. A thorough physical assessment
   4. Threats to safety in her home
10. After a health care provider has informed a patient that he has colon cancer, the nurse enters the room to find the patient gazing out the window in thought. The nurse's first response is which of the following?
    1. "Don't be sad. People live with cancer every day."
    2. "Have you thought about how you are going to tell your family?"

3. "Would you like for me to sit down with you for a few minutes so you can talk about this?"
4. "I know another patient whose colon cancer was cured by surgery."

11. A 34-year-old man who is anxious, tearful, and tired from caring for his three young children tells you that he feels depressed and doesn't see how he can go on much longer. Your best response would be which of the following?
    1. "Are you thinking of suicide?"
    2. "You've been doing a good job raising your children. You can do it!"
    3. "Is there someone who can help you?"
    4. "You have so much to live for."
12. The nurse is evaluating the coping success of a patient experiencing stress from being newly diagnosed with multiple sclerosis and psychomotor impairment. The nurse realizes that the patient is coping successfully when the patient says:
    1. "I'm going to learn to drive a car so I can be more independent."
    2. "My sister says she feels better when she goes shopping, so I'll go shopping."
    3. "I've always felt better when I go for a long walk. I'll do that when I get home."
    4. "I'm going to attend a support group to learn more about multiple sclerosis."
13. A patient newly diagnosed with type 2 diabetes says, "My blood sugar was just a little high. I don't have diabetes." The nurse responds:
    1. "Let's talk about something cheerful."
    2. "Do other members of your family have diabetes?"
    3. "I can tell that you feel stressed to learn that you have diabetes."
    4. With silence.
14. A staff nurse is talking with the nursing supervisor about the stress that she feels on the job. The supervising nurse recognizes that:
    1. Nurses who feel stress usually pass the stress along to their patients.
    2. A nurse who feels stress is ineffective as a nurse and should not be working.
    3. Nurses who talk about feeling stress are unprofessional and should calm down.
    4. Nurses frequently experience stress with the rapid changes in health care technology and organizational restructuring.
15. A crisis intervention nurse working with a mother whose Down syndrome child has been hospitalized with pneumonia and who has lost her entitlement check while the child is hospitalized can expect the mother to regain stability after how long?
    1. After 2 weeks when the child's pneumonia begins to improve
    2. After 6 weeks when she adjusts to the child's respiratory status and reestablishes the entitlement checks
    3. After 1 month when the child goes home and the mother gets help from a food pantry
    4. After 6 months when the child is back in school

CHAPTER

38

Activity and Exercise

OBJECTIVES

- Describe the role of the musculoskeletal and nervous systems in the regulation of movement.
- Discuss physiological and pathological influences on body alignment and joint mobility.
- Describe how to maintain and use proper body mechanics.
- Describe how exercise and activity benefit physiological and psychological functioning.
- Describe the benefits of implementing an exercise program for the purpose of health promotion.
- Describe important factors to consider when planning an exercise program for patients across the life span and for those with specific chronic illnesses.
- Assess patients for impaired mobility and activity intolerance.
- Formulate nursing diagnoses for patients experiencing problems with impaired mobility and activity intolerance.
- Write a nursing care plan for a patient with impaired mobility and activity intolerance.
- Describe interventions for maintaining activity tolerance and mobility.
- Evaluate the nursing care plan for maintaining activity and exercise for patients across the life span and with specific chronic illnesses.

KEY TERMS

Activities of daily living (ADLs), p. 746
Activity tolerance, p. 747
Antagonistic muscles, p. 748
Antigravity muscles, p. 748
Cartilage, p. 748

A program of regular physical activity and **exercise** has the potential to enhance all aspects of a patient's biopsychosocial and spiritual model of health. This chapter provides you with knowledge of exercise and activity as they relate to health promotion, the acute phase of illness, and the restorative and continuing care of patients, as well as nursing strategies to help plan an individualized exercise and activity program for a variety of patients with specific disease entities and needs.

SCIENTIFIC KNOWLEDGE BASE

Regular physical activity and exercise contribute to both physical and emotional well-being (Edelman and Mandle, 2010; Ferrand et al., 2008). Knowing the physiology and regulation of body mechanics, exercise, and activity helps provide individualized care.

Overview of Exercise and Activity

The coordinated efforts of the musculoskeletal and nervous systems maintain balance, **posture,** and body alignment during lifting, bending, moving, and performing **activities of daily living (ADLs).** Proper balance, posture, and body alignment reduce the risk of injury to the musculoskeletal system and facilitate body movements, allowing physical mobility without muscle strain and excessive use of muscle energy.

Body Alignment. Body alignment refers to the relationship of one body part to another along a horizontal or vertical line. Correct alignment involves positioning so no excessive strain is placed on a person's joints, tendons, ligaments, or muscles, thereby maintaining adequate **muscle tone** and contributing to balance.

Body Balance. Body balance occurs when a relatively low **center of gravity** is balanced over a wide, stable base of support and a vertical line falls from the center of gravity through the base of support. When the vertical line from the center of gravity does not fall through the base of support, the body loses balance. Proper posture or a body position that most favors function, requires the least muscular work to maintain, and places the least strain on muscles, ligaments, and bones enhances body balance (Patton and Thibodeau, 2010). Nurses use balance to maintain proper body alignment and posture through two simple techniques. First widen the base of support by separating the feet to a comfortable distance. Second, increase balance by bringing the center of gravity closer to the base of support. For example, you raise the height of the bed when performing a procedure such as changing a dressing to prevent bending too far at the waist and shifting the base of support.

Coordinated Body Movement. Coordinated body movement is a result of weight, center of gravity, and balance. Weight is the force exerted on a body by gravity. When an object is lifted, the lifter must overcome the weight of the object and be aware of the center of gravity of the object. In symmetrical objects the center of gravity is located at the exact center of the object. The force of weight is always directed downward. An unbalanced object has its center of gravity away from the midline and falls without support. Because people are not geometrically perfect, their centers of gravity are usually midline, at 55% to 57% of standing height. Like unbalanced objects, patients who are unsteady do not maintain a balance with their center of gravity, which places them at risk for falling. You need to be able to identify these patients and intervene to maintain their safety.

Friction. **Friction** is a force that occurs in a direction to oppose movement. Reduce friction by following some basic principles. When you move objects, those with a greater surface area create more friction. To reduce friction, you need to decrease the object's surface area. For example, when helping patients move up in bed, place their arms across the chest. This decreases surface area and reduces friction.

A patient who is passive or immobilized produces greater friction to movement (see Chapter 47). When possible, use some of your patients' strength and mobility when positioning and transferring them. Explain the procedure and tell your patients when to move. You decrease friction when your patients bend their knees as you help them move up in the bed.

You can also reduce friction by using an air-assisted device when performing lateral patient transfers (Baptiste et al., 2006). Air-assisted devices are commercially available transfer devices that are effective solutions to reducing injury to health care employees and patients.

Exercise and Activity. Exercise is physical activity used to condition the body, improve health, and maintain fitness. Sometimes exercise is also a therapeutic measure. A patient's individualized exercise program depends on the patient's **activity tolerance** or the type and amount of exercise or activity that the patient is able to perform. Physiological, emotional, and developmental factors influence the patient's activity tolerance.

An active lifestyle is important for maintaining and promoting health; it is also an essential treatment for chronic illnesses (Perez et al., 2009). Regular physical activity and exercise enhance functioning of all body systems, including cardiopulmonary functioning (endurance), musculoskeletal fitness (flexibility and bone integrity), weight control and maintenance (body image), and psychological well-being (ACSM, 2007; Edelman and Mandle, 2010).

The best program of physical activity includes a combination of exercises that produces different physiological and psychological benefits. Three categories of exercise are isotonic, isometric, and resistive isometric. The type of muscle contraction involved determines the classification of the exercise. Isotonic exercises cause muscle contraction and change in muscle length **(isotonic contraction).** Examples are walking, swimming, dance aerobics, jogging, bicycling, and moving arms and legs with light resistance. Isotonic exercises enhance circulatory and respiratory functioning; increase muscle mass, tone, and strength; and promote osteoblastic activity (activity by bone-forming cells), thus combating osteoporosis.

Isometric exercises involve tightening or tensing muscles without moving body parts **(isometric contraction).** Examples are quadriceps set exercises and contraction of the gluteal muscles. This form of exercise is ideal for patients who do not tolerate increased activity. A patient who is immobilized in bed can perform isometric exercises. The benefits are increased muscle mass, tone, and strength, thus decreasing the potential for muscle wasting; increased circulation to the involved body part; and increased osteoblastic activity.

Resistive isometric exercises are those in which the individual contracts the muscle while pushing against a stationary object or resisting the movement of an object (Hoeman, 2006). A gradual increase in the amount of resistance and length of time that the muscle contraction is held increases muscle strength and endurance. Examples of resistive isometric exercises are push-ups and hip lifting, in which a patient in a sitting position pushes with the hands against a surface such as a chair seat and raises the hips. In some long-term care settings, **footboards** are placed on the end of beds; patients push against them to move up in bed. Resistive isometric exercises help promote muscle strength and provide sufficient stress against bone to promote osteoblastic activity.

Regulation of Movement

Coordinated body movement involves the integrated functioning of the skeletal, muscular, and nervous systems. Because these three systems cooperate so closely in mechanical support of the body, they are often considered as a single functional unit.

Skeletal System. Bones perform five functions in the body: support, protection, movement, mineral storage, and hematopoiesis (blood cell formation). In the discussion of body mechanics, two of these functions (i.e., support and movement) are most important (see Chapter 47). Bones serve as support by providing the framework and contributing to the shape, alignment, and positioning of the body parts. Bones, together with their joints, constitute levers for muscle attachment to provide movement. As muscles contract and shorten, they pull on bones, producing joint movement (Patton and Thibodeau, 2010).

Joints. An articulation, or **joint,** is the connection between bones. Each joint is classified according to its structure and degree of mobility. On the basis of connective structures, joints are classified as fibrous, cartilaginous, or synovial (Huether and McCance, 2008). **Fibrous joints** fit closely together and are fixed, permitting little, if any, movement such as the syndesmosis between the tibia and fibula. **Cartilaginous joints** have little movement but are elastic and use cartilage to unite separate body surfaces such as the synchondrosis that attaches the ribs to the costal cartilage. **Synovial joints,** or true joints, such as the hinge type at the elbow, are freely movable and the most mobile, numerous, and anatomically complex body joints.

Ligaments, Tendons, and Cartilage. Ligaments, tendons, and cartilage support the skeletal system (see Chapter 47). **Ligaments** are

white, shiny, flexible bands of fibrous tissue that bind joints and connect bones and cartilage. They are elastic and aid joint flexibility and support. **Tendons** are white, glistening, fibrous bands of tissue that connect muscle to bone. **Cartilage** is nonvascular, supporting connective tissue with the flexibility of a firm, plastic material. Because of its gristle-like nature, cartilage sustains weight and serves as a shock absorber between articulating bones.

Skeletal Muscle. Contraction of skeletal muscles allows people to walk, talk, run, breathe, or participate in physical activity. There are more than 600 skeletal muscles in the body. In addition to facilitating movement, these muscles determine the form and contour of our bodies. Most of our muscles span at least one joint and attach to both articulating bones. When contraction occurs, one bone is fixed while the other moves. The origin is the point of attachment that remains still; the insertion is the point that moves when the muscle contracts (Patton and Thibodeau, 2010).

Muscles Concerned with Movement. The muscles of movement are located near the skeletal region, where a lever system causes movement (Patton and Thibodeau, 2010). The lever system makes the work of moving a weight or load easier. It occurs when specific bones such as the humerus, ulna, and radius and the associated joints such as the elbow act as a lever. Thus the force applied to one end of the bone to lift a weight at another point tends to rotate the bone in the direction opposite that of the applied force. Muscles that attach to bones of leverage provide the necessary strength to move the object.

Muscles Concerned with Posture. Gravity continually pulls on parts of the body; the only way the body is held in position is for muscles to pull on bones in the opposite direction. Muscles accomplish this counterforce by maintaining a low level of sustained contraction. Poor posture places more work on muscles to counteract the force of gravity. This leads to fatigue and eventually interferes with bodily functions and causes deformities.

Muscle Groups. The nervous system coordinates the antagonistic, synergistic, and antigravity muscle groups that are responsible for maintaining posture and initiating movement. **Antagonistic muscles** cause movement at the joint. During movement the active mover muscle contracts while its antagonist relaxes. For example, during flexion of the arm the active mover, the biceps brachii, contracts; and its antagonist, the triceps brachii, relaxes. During extension of the arm the active mover, now the triceps brachii, contracts; and the new antagonist, the biceps brachii, relaxes.

Synergistic muscles contract to accomplish the same movement. When the arm is flexed, the strength of the contraction of the biceps brachii is increased by contraction of the synergistic muscle, the brachialis. Thus with synergistic muscle activity there are now two active movers (i.e., the biceps brachii and the brachialis), which contract while the antagonistic muscle, the triceps brachii, relaxes.

Antigravity muscles stabilize joints. These muscles continuously oppose the effect of gravity on the body and permit a person to maintain an upright or sitting posture. In an adult the antigravity muscles are the extensors of the leg, the gluteus maximus, the quadriceps femoris, the soleus muscles, and the muscles of the back.

Skeletal muscles support posture and carry out voluntary movement. The muscles are attached to the skeleton by tendons, which provide strength and permit motion. The movement of the extremities is voluntary and requires coordination from the nervous system.

Nervous System. The nervous system regulates movement and posture. The major voluntary motor area, located in the cerebral cortex, is the precentral gyrus, or motor strip. A majority of motor fibers descend from the motor strip and cross at the level of the medulla. Thus the motor fibers from the right motor strip initiate voluntary movement for the left side of the body, and motor fibers from the left motor strip initiate voluntary movement for the right side of the body.

Transmission of the impulse from the nervous system to the musculoskeletal system is an electrochemical event and requires a neurotransmitter. Basically neurotransmitters are chemicals (e.g., acetylcholine) that transfer the electrical impulse from the nerve across the myoneural junction to stimulate the muscle, causing movement. Several disorders impair movement. For example, Parkinson's disease alters neurotransmitter production, myasthenia gravis disrupts transfer from the neurotransmitter to the muscle, and multiple sclerosis impairs muscle activity (Huether and McCance, 2008).

Proprioception. **Proprioception** is the awareness of the position of the body and its parts (Huether and McCance, 2008). Proprioceptors located on nerve endings in muscles, tendons, and joints monitor proprioception. The nervous system regulates posture, which requires coordination of proprioception and balance. As a person carries out ADLs, proprioceptors monitor muscle activity and body position. For example, the proprioceptors on the soles of the feet contribute to correct posture while standing or walking. In standing, pressure is continuous on the bottom of the feet. The proprioceptors monitor the pressure, communicating this information through the nervous system to the antigravity muscles. The standing person remains upright until deciding to change position. As a person walks, the proprioceptors on the bottom of the feet monitor pressure changes. Thus, when the bottom of the moving foot comes in contact with the walking surface, the individual automatically moves the stationary foot forward.

Balance. A person needs adequate balance to stand, run, lift, or perform ADLs. The nervous system controls balance specifically through the cerebellum and the inner ear. The cerebellum coordinates all voluntary movement, particularly highly skilled movements such as those required in skiing.

Within the inner ear are the semicircular canals, three fluid-filled structures that help maintain balance. Fluid within the canals has a certain inertia; when the head is suddenly rotated in one direction, the fluid remains stationary for a moment, but the canal turns with the head. This allows a person to change position suddenly without losing balance.

Principles of Transfer and Positioning Techniques

Using principles of safe patient transfer and positioning during routine activities decreases work effort (Box 38-1). Teach colleagues and patients' families how to transfer or position patients properly. Teaching a patient's family to transfer the patient from bed to chair increases and reinforces the family's knowledge about proper transfer and position techniques.

Whether you are moving a patient who is immobile, assisting a patient from the bed to the chair, or teaching a patient to carry out ADLs efficiently, knowledge of safe patient transfer and positioning is crucial. You also incorporate knowledge of physiological and pathological influences on body alignment and mobility.

Pathological Influences on Body Alignment and Mobility. Many pathological conditions affect body alignment and mobility. These conditions include congenital defects; disorders of bones, joints, and muscles; central nervous system damage; and musculoskeletal trauma.

BOX 38-1 PRINCIPLES OF SAFE PATIENT TRANSFER AND POSITIONING

- Mechanical lifts and lift teams are essential when the patient is unable to assist.
- When a patient is able to assist, remember the following principles:
  - The wider the base of support, the greater the stability of the nurse.
  - The lower the center of gravity, the greater the stability of the nurse.
  - The equilibrium of an object is maintained as long as the line of gravity passes through its base of support.
  - Facing the direction of movement prevents abnormal twisting of the spine.
  - Dividing balanced activity between arms and legs reduces the risk of back injury.
  - Leverage, rolling, turning, or pivoting requires less work than lifting.
  - When friction is reduced between the object to be moved and the surface on which it is moved, less force is required to move it.

Congenital Defects. Congenital abnormalities affect the efficiency of the musculoskeletal system in regard to alignment, balance, and appearance. Osteogenesis imperfecta is an inherited disorder that affects bone. Bones are porous, short, bowed, and deformed; as a result, children experience curvature of the spine and shortness of stature. Scoliosis is a structural curvature of the spine associated with vertebral rotation. Muscles, ligaments, and other soft tissues become shortened. Balance and mobility are affected in proportion to the severity of abnormal spinal curvatures (Hockenberry and Wilson, 2011).

Disorders of Bones, Joints, and Muscles. Osteoporosis, a well-known and well-publicized disorder of aging, results in the reduction of bone density or mass. The bone remains biochemically normal but has difficulty maintaining integrity and support. The cause is uncertain, and theories vary from hormonal imbalances to insufficient intake of nutrients (Huether and McCance, 2008).

Osteomalacia is an uncommon metabolic disease characterized by inadequate and delayed mineralization, resulting in compact and spongy bone (Lewis et al., 2011). Mineral calcification and deposition do not occur. Replaced bone consists of soft material rather than rigid bone.

Joint mobility is altered by inflammatory and noninflammatory joint diseases and articular disruption. Inflammatory joint disease (e.g., arthritis) is characterized by inflammation or destruction of the synovial membrane and articular cartilage and by systemic signs of inflammation. Noninflammatory diseases have none of these characteristics, and the synovial fluid is normal (Huether and McCance, 2008). Joint degeneration, which can occur with inflammatory and noninflammatory disease, is marked by changes in articular cartilage combined with overgrowth of bone at the articular ends. Degenerative changes commonly affect weight-bearing joints.

Articular disruption involves trauma to the articular capsules and ranges from mild, such as a tear resulting in a sprain, to severe, such as a separation leading to dislocation. Articular disruption usually results from trauma but sometimes is congenital, as with developmental dysplasia of the hip (Hockenberry and Wilson, 2011).

Central Nervous System Damage. Damage to any part of the central nervous system that regulates voluntary movement causes impaired body alignment and immobility. For example, a patient with a traumatic head injury experiences damage in the motor strip in the cerebrum. The amount of voluntary motor impairment is directly related to the amount of destruction of the motor strip. For example, a patient with a right-sided cerebral hemorrhage and permanent damage to the right motor strip has left-sided **hemiplegia,** whereas a patient with a right-sided head injury experiences cerebral edema around (but not destruction of) the motor strip. The patient with hemiplegia does not regain movement, whereas the second patient's voluntary movement gradually returns to the left side following extensive physical therapy.

Musculoskeletal Trauma. Musculoskeletal trauma often results in bruises, contusions, sprains, and fractures. A fracture is a disruption of bone tissue continuity. Fractures most commonly result from direct external trauma. They also occur because of some deformity of the bone (e.g., with pathological fractures of osteoporosis) (see Chapter 47).

NURSING KNOWLEDGE BASE

Application of nursing knowledge allows you to think critically about the holistic needs of patients. Nursing knowledge as it pertains to activity and exercise helps you assess, identify, and intervene when patients have decreased activity tolerance or physical limitation that affects their ability to exercise.

Factors Influencing Activity and Exercise

Factors influencing activity and exercise include developmental changes, behavioral aspects, family and social support, cultural and ethnic origin, and environmental issues. Consider these areas of knowledge and incorporate into the plan of care whether the patient is seeking health promotion, acute care, or restorative and continuing care.

Developmental Changes. Throughout the life span the appearance and functioning of the body undergo change. The greatest change and effect on the maturational process occurs in childhood and old age.

Infants Through School-Age Children. The newborn infant's spine is flexed and lacks the anteroposterior curves of the adult. The first spinal curve occurs when the infant extends the neck from the prone position. As growth and stability increase, the thoracic spine straightens, and the lumbar spinal curve appears, which allows sitting and standing.

The toddler's posture is awkward because of the slight swayback and protruding abdomen. As the child walks, the legs and feet are usually far apart, and the feet are slightly everted (turned outward). Toward the end of toddlerhood, posture appears less awkward, curves in the cervical and lumbar vertebrae are accentuated, and foot eversion disappears.

By the third year the body is slimmer, taller, and better balanced. Abdominal protrusion decreases, the feet are not as far apart, and the arms and legs have increased in length. The child appears more coordinated. From the third year through the beginning of adolescence, the musculoskeletal system continues to grow and develop (see Chapter 12).

Adolescence. The period of adolescence usually begins with a tremendous growth spurt. Growth is frequently uneven. As a result, the adolescent appears awkward and uncoordinated. Adolescent girls usually grow and develop earlier than boys. Hips widen; and fat deposits in the upper arms, thighs, and buttocks. The adolescent boy's changes in shape are usually a result of long-bone growth and increased muscle mass (see Chapter 12).

Young to Middle Adults. An adult with correct posture and body alignment feels good, looks good, and generally appears self-confident. The healthy adult also has the necessary musculoskeletal

development and coordination to carry out ADLs (see Chapter 13). Normal changes in posture and body alignment in adulthood occur mainly in pregnant women. These changes result from the adaptive response of the body to weight gain and the growing fetus. The center of gravity shifts toward the anterior. The pregnant woman leans back and is slightly swaybacked; as a result, pregnant women often complain of back pain.

Older Adults. A progressive loss of total bone mass occurs with the older adult. Some of the possible causes of this loss include physical inactivity, hormonal changes, and increased osteoclastic activity (i.e., activity by cells responsible for bone tissue absorption). The effect of bone loss is weaker bones, causing vertebrae to be softer and long shaft bones to be less resistant to bending.

In addition, older adults may walk more slowly and appear less coordinated. They often take smaller steps and keep their feet closer together, which decreases the base of support. Thus body balance is unstable, and they are at greater risk for falls and injuries (see Chapter 14).

Behavioral Aspects. Patients are more likely to incorporate an exercise program into their daily lives if supported by family, friends, nurses, health care providers, and other members of the health care team. The nurse takes into consideration the patient's knowledge of exercise and activity, barriers to a program of exercise and physical activity, and current exercise habits. Patients are more open to developing an exercise program when they are at a stage of readiness to change their behavior (Prochaska, Norcross, and DiClemente, 1994). Information about the benefits of regular exercise is often helpful to the patient who is not at the stage of readiness to act. Patients' decisions to change behavior and include a daily exercise routine in their lives sometimes occur gradually with repeated information individualized to patients' needs and lifestyle (Box 38-2). Once the patient is at the stage of readiness, collaborate with him or her to develop an exercise program that fits his or her needs and provide continued follow-up support and assistance until the exercise program becomes a daily routine.

Environmental Issues

Work Site. A common barrier for many patients is the lack of time needed to engage in a daily exercise program. Some work sites help their employees overcome the obstacle of time constraints by offering opportunities, reminders, and rewards for those committed to physical fitness (Kuoppala, Lamminpää, and Husman, 2008). Reminders such as signs that encourage employees to use the stairs instead of elevators are useful. Rewards such as free parking or discounted parking fees are also effective for employees who park in distant lots and walk.

Schools. Children today are less active, resulting in an increase in childhood obesity (Harper, 2006; Ward et al., 2010). Schools are excellent facilitators of physical fitness and exercise. Strategies for physical activity incorporated early into a child's daily routine often provide a foundation for lifetime commitment to exercise and physical fitness.

Community. Community support of physical fitness is instrumental in promoting the health of its members (e.g., providing walking trails and track facilities in parks and physical fitness classes). Success in implementing physical fitness programs depends on a collaborative effort from public health agencies, parks and recreational associations, state and local government agencies, health care agencies, and the members of the community (Bors et al., 2009; Harper, 2006).

Cultural and Ethnic Influences. Exercise and physical fitness are beneficial to all people. When developing a physical fitness program for culturally diverse populations, consider what motivates them and what they see as appropriate and enjoyable. It is also important to know which specific disease entities are associated with different cultural and ethnic origins (Box 38-3).

Family and Social Support. Social support is one motivational tool to encourage and promote exercise and physical fitness. For example, a patient engages a friend or significant other to participate in a "buddy system" where they walk together each day at a specified time. This companionship provides for socialization, increases the enjoyment, and develops a lifelong commitment to physical fitness. Parents support their children in sports and physical activity by providing encouragement, praise, and transportation (Davison and Jago, 2010; Dunton, 2010). Other parents support physical activity by including their children in family outings such as bicycling or a basketball game in the neighborhood schoolyard.

BOX 38-2 GENERAL GUIDELINES FOR INITIATING AN EXERCISE PROGRAM

Five steps to beginning an exercise program:

Step 1: Assess fitness level.
- Seek approval from a health care provider to begin. Are there any limitations to consider before determining the exercises in the fitness program?
- Record baseline fitness scores such as pulse rate, how long it takes to walk 1 mile, waist circumference, and body mass index.

Step 2: Design the fitness program.
- Consider fitness goals. Make goals attainable.
- Plan a logical progression of activities (e.g., walk a mile and gradually increase the pace).
- Build the program into a daily routine.
- Plan the fitness program with creativity and different activities.

Step 3: Assemble equipment.
- Choose athletic shoes designed for the chosen exercise.
- Try equipment at a fitness center before purchasing to make sure it fits into the fitness program.
- Buy used fitness equipment.
- Try homemade equipment (e.g., half-gallon milk jugs filled with sand for weights).

Step 4: Get started.
- Start slowly, including a warm-up and cool-down period.
- Divide exercise time throughout day if time or fatigue is a barrier. Ten minutes of exercise 3 times a day instead of a single 30-minute workout may be better for some patients' schedules and medical conditions.

Step 5: Monitor progress.
- Retake fitness assessment at 6 weeks and then every 3 to 6 months.
- If losing motivation: set new goals, exercise with a friend, or incorporate new activities

Modified from American College of Sports Medicine: *Position stand on fitness: the recommended quantity and quality of exercise for developing and maintaining cardiorespiratory and muscular fitness and flexibility in healthy adults,* 2007, accessed August 2010 from http://www.50plus.org/Libraryitems/1_5positionstandonfitness.htm; and Mayo Clinic Tools for Healthier Lives: *Fitness programs: 5 steps to getting started,* 2008, accessed August 2010 from http://www.mayoclinic.com/health/fitness/HQ00171/NSECTIONGROUP=2.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Patients' conditions are always changing. Clinical judgments require you to

BOX 38-3 CULTURAL ASPECTS OF CARE

Incidence and Challenges of Type 2 Diabetes Among Ethnic Groups in the United States

Studies of ethnic groups indicate that physical inactivity is one of the risk factors associated with type 2 diabetes. In the United States type 2 diabetes is more prevalent in blacks and Native Americans. Physical activity plays an important role in the prevention and treatment of type 2. However, the black and Native American populations have a disproportionate number of individuals who are poor, unemployed, and disadvantaged and who lack access to the health care system (Huang et al., 2009; Maskarinec et al., 2009).

Implications for Practice

- Physical inactivity is a modifiable risk factor for the development of type 2. Prevention and treatment programs need to focus on exercise and be tailored to the activity tolerance and interests of each patient.
- Support promotion of physical activity through formal programs in schools, churches, and government agencies within black and Native American communities.
- Incorporate motivational factors into the exercise program such as providing a healthy snack or meal for the participants and furnishing each patient with a log to monitor weight loss and blood glucose levels.
- Exercise and diabetes prevention programs need to remove potential barriers such as transportation and cost to facilitate commitment to the program.

anticipate the necessary information, analyze the data, and make decisions regarding patient care.

To understand activity tolerance, physical fitness, and the effect on the patient, you integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients. As you plan patient care, consider the relationship among a variety of concepts to provide the best outcome for the patient. For example, you lay the foundation for planning and decision making by understanding the relationship between the musculoskeletal system and health alterations that create problems with activity and exercise, positioning, and transferring. Professional standards such as those developed by the American College of Sports Medicine (ACSM) (2007) and the American Diabetes Association (ADA) (2007) provide valuable guidelines for exercise and physical fitness. In addition, using the recommendations from the American Nurses Association (ANA) (2008) reduces the risk for work-related musculoskeletal disorders.

Any acquired or congenital condition that affects the structure of the musculoskeletal or nervous system impairs activity, body alignment, or joint mobility to some degree. The impairment is sometimes temporary, such as casting of an extremity, or is permanent, such as a contracture. For patients with limited **range of motion (ROM)** or mobility, the nursing care plan needs to include interventions that maintain the present level of alignment and joint mobility and increase the level of motor function.

Your experiences and critical thinking attitude affect the problem-solving approach with patients and are evaluated with each new patient. Remember that some patients have the capacity for recovery in spite of the loss of some physical function. Restoration of function begins early in the care of patients whose ability to perform self-care is disrupted. Encouragement, support, commitment, and perseverance are important attitudes in critical thinking for these patients.

Perseverance is necessary when caring for patients who depend on you for assistance with positioning, turning, or ambulation. Hourly responsibility for turning often becomes repetitive, and some nurses lose sight of its importance. Perseverance is especially important in delegating these activities to other personnel. Making certain that the task is performed correctly is an essential nursing function. Problems with activity and mobility are often prolonged; creativity is necessary when designing interventions for improving activity tolerance and mobility skills.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, you thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Complete the assessment of body alignment and posture with the patient standing, sitting, or lying down. Use assessment to determine normal physiological changes in growth and development; deviations related to poor posture, trauma, muscle damage, or nerve dysfunction; and any learning needs of patients. In addition, provide opportunities for patients to observe their posture and obtain important information about other factors that contribute to poor alignment such as inactivity, fatigue, malnutrition, and psychological problems. Ask questions related to the patient's exercise and activity tolerance to gather important information (Box 38-4). During assessment (Fig. 38-1) consider all of the elements that help you make appropriate nursing diagnoses. The first step in assessing body alignment is to put the patient at ease so he or she does not assume unnatural or rigid positions. When assessing body alignment of a patient who is immobilized or unconscious, remove pillows from the bed if not contraindicated and place the patient in the supine position.

Through the Patient's Eyes. In patient-centered care, assessing the patient's expectations concerning activity and exercise and determining individual perceptions of what is normal or acceptable is of utmost importance in developing a plan of care. For example, one of the factors affecting physical activity is freedom from pain. When patients experience pain or fatigue following exercise, they often lack commitment to desired interventions. When patients are content with their present physical activity and fitness, they do not perceive a need for improvement.

Standing. Assessment of the standing patient includes the following: the head is erect and midline, body parts are symmetrical, the spine is straight with normal curvatures (cervical concave, thoracic convex, lumbar concave), the abdomen is comfortably tucked, the knees are in a straight line between the hips and ankles and slightly flexed, the feet are flat on the floor and pointed directly forward and slightly apart to maintain a wide base of support, and the arms hang comfortably at the sides (Fig. 38-2). The patient's center of gravity is in the midline, and the line of gravity is from the middle of the forehead to a midpoint between the feet. Laterally the line of gravity runs vertically from the middle of the skull to the posterior third of the foot (Wilson and Giddens, 2009).

Sitting. Assessment of the patient in the sitting position includes the following: the head is erect, and the neck and vertebral column are in straight alignment; the body weight is distributed on the buttocks and thighs; the thighs are parallel and in a

BOX 38-4 NURSING ASSESSMENT QUESTIONS

Nature of the Problem
- Which types of problems are you having with activities and exercise?
- What makes you think your exercise and activity are inadequate?
- Describe for me your typical daily exercise routine and activity.
- Which type of exercise do you prefer?
- How long do you exercise at any given time?

Signs and Symptoms
- Do you experience muscular or joint pain during or after exercise?
- Do you experience shortness of breath during activity?
- Do you experience chest discomfort or pain during exercise or activity?

Onset and Duration
- Which activities cause you to become short of breath?
- How long does it take to resume normal breathing after exercise or an activity?

Severity
- How far do you walk before the pain in your legs begins?
- On a scale of 0 to 10 (10 being the worse discomfort), rate your leg pain.
- Do you describe your shortness of breath as minimal, moderate, or severe after activities and/or exercise?

Barriers to Exercise and Activity
- Do you have any chronic illnesses that affect your ability to carry out activities of daily living or exercise?
- Do you have any physical limitations that prevent you from exercising on a daily basis?
- Do you have access to a community walking path and exercise equipment?
- What prevents you from exercising 30 minutes each day?

Effect on Patient
- How has the lack of an exercise routine affected your weight?
- Do you feel more fatigued since you have not been able to exercise routinely?
- Have you noticed any increase in shortness of breath when performing activities that require little exertion?

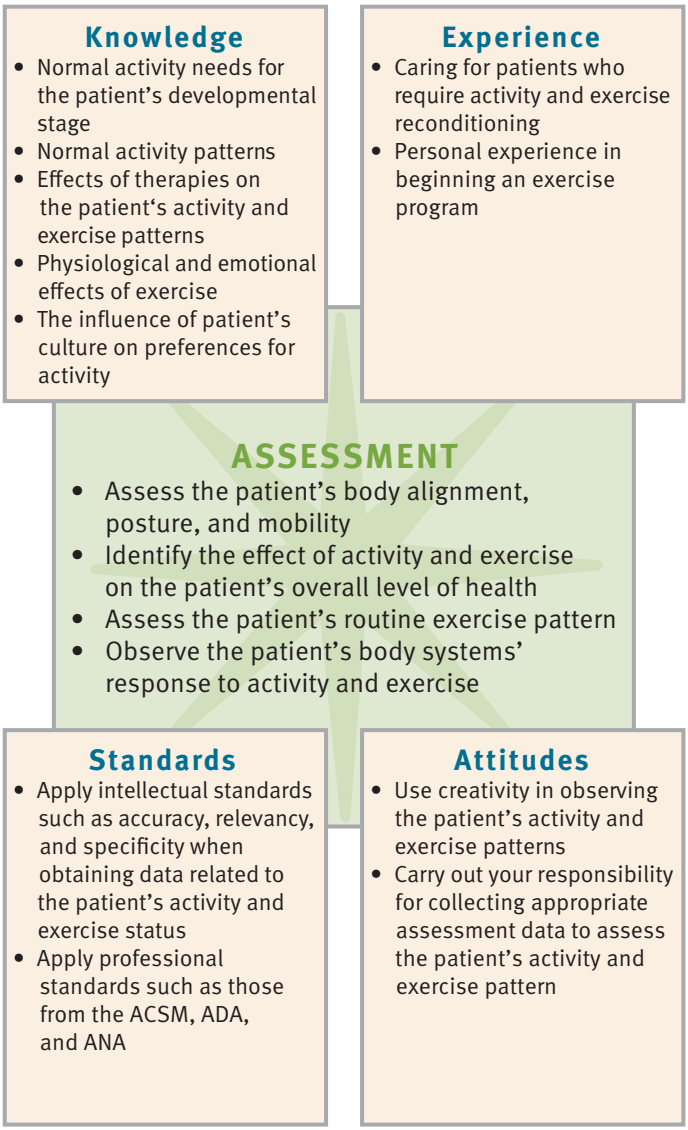

FIG. 38-1 Critical thinking model for activity and exercise assessment. *ACSM,* American College of Sports Medicine; *ADA,* American Diabetes Association; *ANA,* American Nurses Association.

horizontal plane (be careful to avoid pressure on the popliteal nerve and blood supply); the feet are supported on the floor; and the forearms are supported on the armrest, in the lap, or on a table in front of the chair.

Assessment of alignment in the sitting position is particularly important for the patient with muscle weakness, muscle paralysis, or nerve damage. A patient with these alterations has diminished sensation in affected areas and is unable to perceive pressure or decreased circulation. Proper sitting alignment reduces the risk of musculoskeletal system damage.

Recumbent Position. When assessing the patient in the recumbent position, you place the patient in the lateral position, removing all positioning supports and all but one pillow. The vertebrae are in straight alignment without observable curves. This assessment provides baseline data concerning the patient's body alignment.

Conditions that create a risk of damage to the musculoskeletal system when lying down include impaired mobility (e.g., traction), decreased sensation (e.g., **hemiparesis** from a stroke), impaired circulation (e.g., diabetes), and lack of voluntary muscle control (e.g., spinal cord injuries).

When a patient is unable to change position voluntarily, assess the position of body parts while the patient is lying down. Make sure that the vertebrae are in straight alignment without any observable curves. Also check that the extremities are in alignment and not crossed over one another. The head and neck need to be aligned without excessive flexion or extension.

Mobility. Assessment of mobility helps to determine the patient's coordination and balance while walking, the ability to carry out ADLs, and the ability to participate in an exercise program. The assessment of **mobility** has three components: ROM, gait, and exercise.

Range of Motion. Assessing ROM is one assessment technique used to determine the degree of damage or injury to a joint (see Chapter 47). By measuring the ROM of a joint you are able to answer questions about joint stiffness, swelling, pain, limited movement, and unequal movement. Limited ROM often indicates inflammation such as arthritis, fluid in the joint, altered nerve supply, or contractures. Increased mobility (beyond normal) of a

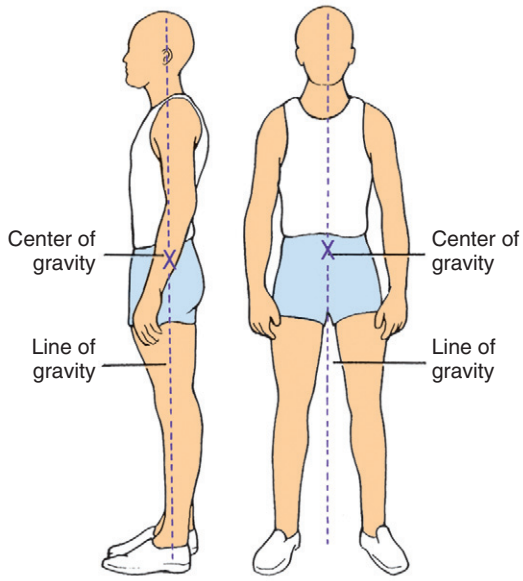

FIG. 38-2 Correct body alignment when standing.

joint sometimes indicates connective tissue disorders, ligament tears, or possible joint fractures.

Gait. Gait is the manner or style of walking, including rhythm, cadence, and speed. Assessing gait allows you to draw conclusions about balance, posture, and the ability to walk without assistance. Assessment findings in patients with normal gait include a regular, smooth rhythm; symmetry in the length of leg swing; smooth swaying related to the gait phase; and a smooth, symmetrical arm swing (Wilson and Giddens, 2009).

Exercise. Exercise conditions the body, improves health, maintains fitness, and provides therapy for correcting a deformity or restoring the overall body to a maximal state of health. When a person engages in physical activity, physiological changes occur in body systems (Box 38-5). Determine how much the patient exercises regularly.

Activity Tolerance. Activity tolerance is the kind and amount of exercise or activity that a person is able to perform. Assessment of activity tolerance is necessary when planning physical activity for health promotion and for patients with acute or chronic illness. This assessment provides baseline data about the patient's activity patterns and helps determine which factors (physical, psychological, or motivational) affect activity tolerance (Box 38-6).

NURSING DIAGNOSIS

Assessment of the patient's activity tolerance, physical fitness, body alignment, and joint mobility provides clusters of data or defining characteristics to support a nursing diagnosis. You need to be accurate when identifying diagnoses. For example, you consider nursing diagnoses of *activity intolerance* or *fatigue* in a patient who reports being tired and weak. Further review of assessed defining characteristics (e.g., abnormal heart rate and dyspnea) leads to the definitive diagnosis *(activity intolerance)*.

When patients have problems with activity and exercise, nursing diagnoses often focus on the ability to move. The diagnostic label and related factors direct nursing interventions. This requires the correct selection of the related factors. For example, *activity intolerance related to excess weight gain* requires very different interventions than if the related factor is prolonged bed rest. Box 38-7 provides an example of how the diagnostic process leads to accurate diagnosis selection. The following are examples of nursing diagnoses related to activity and exercise:

- Activity intolerance
- Ineffective coping
- Impaired gas exchange
- Risk for injury
- Impaired physical mobility
- Imbalanced nutrition: more than body requirements
- Acute or chronic pain

BOX 38-5 EFFECTS OF EXERCISE

Cardiovascular System
- Increased cardiac output
- Improved myocardial contraction, thereby strengthening cardiac muscle
- Decreased resting heart rate
- Improved venous return

Pulmonary System
- Increased respiratory rate and depth followed by a quicker return to resting state
- Improved alveolar ventilation
- Decreased work of breathing
- Improved diaphragmatic excursion

Metabolic System
- Increased basal metabolic rate
- Increased use of glucose and fatty acids
- Increased triglyceride breakdown
- Increased gastric motility
- Increased production of body heat

Musculoskeletal System
- Improved muscle tone
- Increased joint mobility
- Improved muscle tolerance to physical exercise
- Possible increase in muscle mass
- Reduced bone loss

Activity Tolerance
- Improved tolerance
- Decreased fatigue

Psychosocial Factors
- Improved tolerance to stress
- Reports of "feeling better"
- Reports of decrease in illness (e.g., colds, influenza)

Data from Huether SE, McCance KL: *Understanding pathophysiology,* ed 4, St Louis, 2008, Mosby.

PLANNING

During planning synthesize information from multiple resources (Fig. 38-3). Critical thinking ensures that the patient's plan of care integrates all patient information. Professional standards are especially important to consider when developing a plan of care. These standards often establish scientifically proven guidelines for selecting effective nursing interventions.

Concept maps are a tool to assist in the planning of care. Fig. 38-4 shows the relationship between a patient's medical diagnosis of heart failure and the identified nursing diagnosis.

Goals and Outcomes. Once you identify the nursing diagnoses, you and the patient set goals and expected outcomes to direct

BOX 38-6 FACTORS INFLUENCING ACTIVITY TOLERANCE

Physiological Factors
- Skeletal abnormalities
- Muscular impairments
- Endocrine or metabolic illnesses (e.g., diabetes mellitus, thyroid disease)
- Hypoxemia
- Decreased cardiac function
- Decreased endurance
- Impaired physical stability
- Pain
- Sleep pattern disturbance
- Prior exercise patterns
- Infectious processes and fever

Emotional Factors
- Anxiety
- Depression
- Chemical addictions
- Motivation

Developmental Factors
- Age
- Sex

Pregnancy
- Physical growth and development of muscle and skeletal support

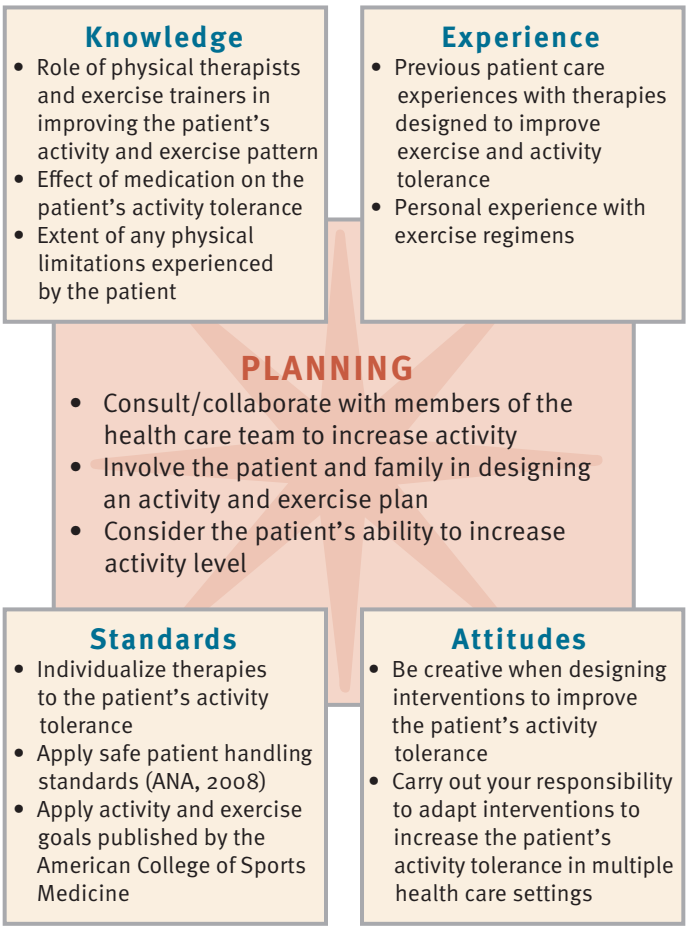

FIG. 38-3 Critical thinking model for activity and exercise planning.

BOX 38-7 NURSING DIAGNOSTIC PROCESS

Impaired Physical Mobility

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Observe patient's gait.	Shuffled gait Uncoordinated gait Patient reports slower walking speed
Observe patient performing tasks such as feeding, dressing, or recreational activities.	Uncoordinated movements Limited fine-motor coordination
Measure range of joint motion.	Reduced joint motion in lower and/or upper extremities Stiffness in joints

interventions. The plan includes consideration of any risks for injury to the patient and preexisting health concerns. It is especially important to have knowledge of the patient's home environment when planning therapies to maintain or improve activity, body alignment, and mobility. Include the patient's family in the care plan. For some patients with alterations in joint mobility, family members may be caregivers. The general goal related to exercise and activity is to improve or maintain the patient's motor function and independence. The following are examples of outcomes for patients with deficits in activity and exercise (Ackley and Ladwig, 2008):

- Participates in prescribed physical activity while maintaining appropriate heart rate, blood pressure, and breathing rate
- Verbalizes an understanding of the need to gradually increase activity based on tolerance and symptoms
- Expresses understanding of balancing rest and activity

Setting Priorities. Care planning is patient centered, taking into consideration the patient's most immediate needs. You determine the immediacy of any problem by the effect of the problem on the patient's mental and physical health. Because of the many skills associated with the care of patients with activity intolerance; improper body mechanics; and/or impaired mobility such as turning, transferring, and positioning, it is easy to overlook the complications associated with these health alterations. Therefore be vigilant in monitoring the patient and supervising assistive personnel in carrying out activities to prevent complications and potential injury.

Teamwork and Collaboration. Planning involves understanding the patient's need to maintain function and independence. For example, it is important to collaborate with physical and occupational therapists. Sometimes long-term rehabilitation is necessary. Discharge planning begins when a patient enters the health care system. In addition, always individualize a plan of care directed at meeting the actual or potential needs of the patient (see the Nursing Care Plan).

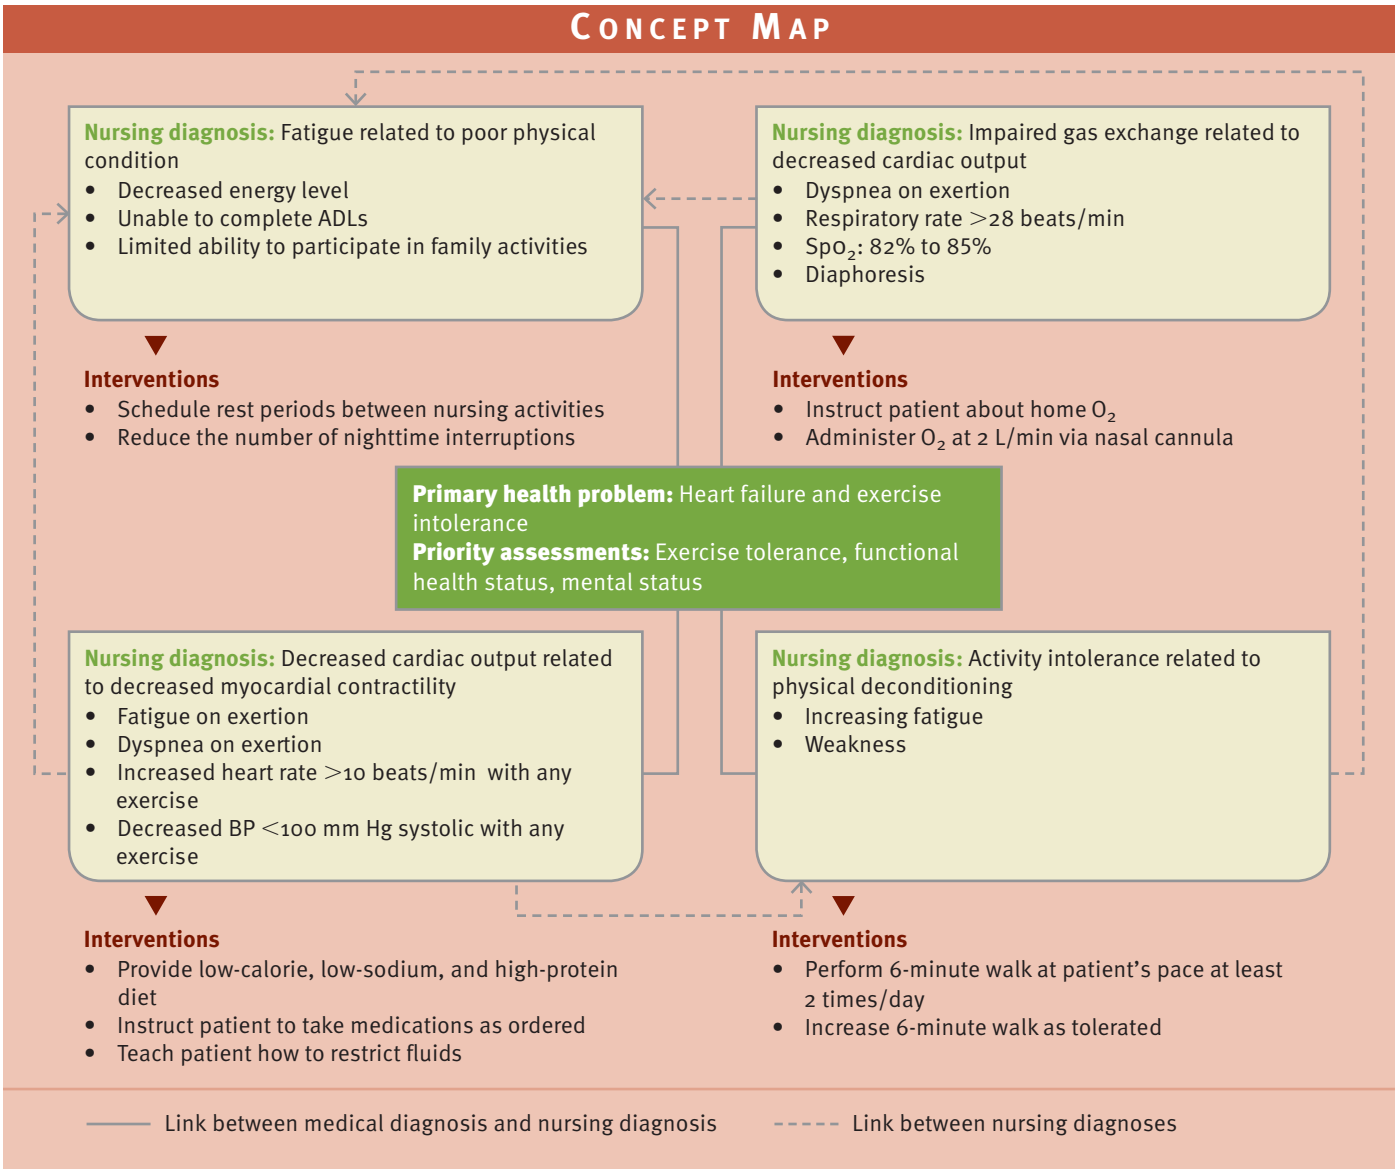

FIG. 38-4 Concept map for Mrs. Smith. *ADLs,* Activities of daily living.

NURSING CARE PLAN

Activity Intolerance

ASSESSMENT

Mrs. Smith is a 45-year-old housewife. She is in a cardiovascular rehabilitation program prescribed by her health care provider and conducted by Erich Sieple, a registered nurse. Mrs. Smith has a history of cardiovascular disease with mild heart failure. She expresses feelings of stress caused by excessive demands on her time. Erich's assessment includes a discussion of Mrs. Smith's current health problem and a pertinent physical examination.

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Smith what prompted her health care provider to recommend a cardiovascular rehabilitation program.	She responds, "I **gained 50 pounds** over the past year. I become easily **fatigued** and lack the energy to keep up with even simple household chores. I don't want to leave the house anymore. I don't have extra money to join one of those fancy gyms."
Ask Mrs. Smith about her exercise and eating habits.	She responds, "I want to exercise, but with the demands of child care and taking care of my aging parents, I just don't feel like it. I feel pulled in every direction; that increases my **stress**, and then I want to eat, eat, and eat!"

Continued

NURSING CARE PLAN

***Activity Intolerance*—cont'd**

Perform baseline assessment.	Height: 5 feet 3 inches Weight: **225 pounds** (102 kg) Blood pressure: **152/90 mm Hg (at rest)** Pulse: **96 beats/min (at rest)** Breathing rate: 20 breaths/min (at rest) Blood pressure: **164/96 mm Hg (climbing 10 steps)** Pulse: **120 beats/min (climbing 10 steps)** Breathing rate: **36 breaths/min (climbing 10 steps)**

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Activity intolerance related to inactivity and lack of cardiovascular fitness

PLANNING

Goals	*Expected Outcomes (NOC)*†
Mrs. Smith's activity tolerance will improve above baseline.	**Activity Tolerance** Mrs. Smith will perform and record exercise patterns 3 to 4 times over the next 2 weeks. Mrs. Smith's level of fatigue associated with exercise will remain the same or decrease.
Mrs. Smith's cardiopulmonary response to exercise will improve.	**Cardiovascular Pump Effectiveness** Mrs. Smith's resting diastolic blood pressure will remain below 80 mm Hg. Her systolic blood pressure will be below 140 mm Hg. Mrs. Smith's resting heart rate will range between 75 and 85 beats/min.

†Outcome classification labels from Moorhead S, et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Exercise Promotion	
Instruct Mrs. Smith about the physiological benefits of a regular exercise program.	Physical activity and exercise protect against the further development of cardiovascular disease (CVD) and decrease other risk factors associated with CVD such as obesity, hypertension, and hyperlipidemia (Donges et al., 2010; Hamer and Stamatakis, 2009; Mandic et al., 2009).
Develop a progressive plan of exercise with Mrs. Smith, such as 2 to 3 miles of brisk walking and quadriceps, bicep, and gluteal muscle isometric exercises 3 to 4 times per week.	Cross-training (combination of exercise activities) provides variety to combat boredom and increases potential for total-body conditioning (Edelman and Mandle, 2010).
Instruct Mrs. Smith to use an exercise log and record the day, time, duration, and responses (pulse, feelings, shortness of breath, daily weight).	Keeping a log may increase adherence to exercise prescription.
Schedule routine visits with Mrs. Smith for follow-up and review of exercise log, progress, and barriers.	Patients are more likely to increase physical activity and remain compliant with an exercise program if they are counseled by a health care professional (Edelman and Mandle, 2010).

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Record weight, blood pressure, and pulse.	Weight, 210 pounds. Resting heart rate remains between 80 and 85 beats/min. Blood pressure, 146/86 mm Hg.	Improved cardiovascular effects of exercise: • Heart rate is within normal range. • Blood pressure is lower but not at expected range. Monitor blood pressure as patient continues to lose weight.
Ask Mrs. Smith if exercise is helping to lower fatigue level.	"At first, finding time to exercise was hard, but once I started feeling less tired and even less stressed, it was easy to integrate exercise into my daily activities."	Activity tolerance improved with exercise.

BOX 38-8 PROCEDURAL GUIDELINES

Helping Patients to Exercise

Delegation Considerations

The skill of helping patients to exercise can be delegated to nursing assistive personnel (NAP). However, the nurse first must assess the patient's ability and tolerance to exercise. The nurse also teaches patients and their families how to implement exercise programs. NAP can prepare patients for exercise (e.g., putting on shoes and clothing, providing hygiene needs and obtaining preexercise and postexercise vital signs). Instruct NAP to do the following:

- Notify nurse if patient reports pain before, during, or after exercise.
- Notify nurse if patient complains of increased fatigue, dizziness, or lightheadedness when obtaining preexercise and/or postexercise vital signs.
- Notify nurse of vital sign values.

1. Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.
2. Assess for any medical limitations (e.g., weight-bearing status, untreated fracture, cardiovascular disease).
3. Know patient's mobility level before hospitalization.
4. Teach patient breathing skills to help reduce anxiety and fully oxygenate tissues and expand lungs.
5. Assess for patient's physiological and psychological limitations for learning and implementing an exercise program.
6. Assess for joint limitations and do not force a muscle or a joint during exercise.
7. Teach patient to wear comfortable shoes and clothing for exercise.
8. Let each patient move at his or her own pace.
9. Observe for proper posture, body alignment, and proper body mechanics during exercise.
10. Monitor vital signs before, during, and after exercise.
11. Assess for pain, shortness of breath, or a change in vital signs. If present, stop exercise.
12. Document patient's progress and provide feedback as patient exercises.

Data from Edelman CL, Mandle CL, editors: *Health promotion throughout the life span,* ed 7, St Louis, 2010, Mosby; and Monahan FD, et al: *Phipps' medical-surgical nursing: health and illness perspectives,* ed 8, St Louis, 2007, Mosby.

IMPLEMENTATION

Health Promotion. A sedentary lifestyle contributes to the development of health-related problems. You promote health by encouraging patients to engage in a regular exercise program (Box 38-8). Take a holistic approach to develop and implement a plan that enhances the patient's overall physical fitness. Discuss recommendations for physical activity and fitness and collaborate with the patient to design a program of exercise.

Before starting an exercise program, teach patients to calculate their maximum heart rate by subtracting their current age in years from 220 and then obtaining their target heart rate by taking 60% to 90% of the maximum, depending on their health care provider's recommendation. No matter which exercise prescription is implemented for the patient, a warm-up and cool-down period needs to be included in the program (Edelman and Mandle, 2010). The warm-up period usually lasts about 5 to 10 minutes and frequently includes stretching, calisthenics, and/or the aerobic activity performed at a lower intensity. It prepares the body and decreases the potential for injury. The cool-down period follows the exercise routine and usually lasts about 5 to 10 minutes. It allows the body to readjust gradually to baseline functioning and provides an opportunity to combine movement such as stretching with relaxation-enhancing mind-body awareness.

BOX 38-9 INCORPORATING ACTIVE EXERCISE INTO ACTIVITIES OF DAILY LIVING (ADLs)

Lower-Intensity ADLs

- Doing laundry
- Making the bed
- Ironing
- Washing dishes

Moderate-Intensity ADLs

- Sweeping the kitchen or sidewalk
- Washing windows
- Folding clothes
- Vacuuming

High-Intensity ADLs

- Moving furniture
- Carrying boxes or heavier items up and down stairs

Hints to a Good Workout While Doing Housework

- To make housework more aerobic, work faster, scrub harder
- Bend your legs rather than your back
- Start daily household chores with gentle stretches
- Alternate cleaning activities to prevent overworking the same muscle groups

From Collins A: *Getting fit: unstructured exercise,* http://www.suite101.com/lesson.cfm/18274/1552). Accessed August 2010.

Building Competency in Safety In order for patients to exercise safely, you need to be able to calculate their maximum heart rate. Determine the range of maximum heart rate for the patient in the nursing care plan, 45-year-old Mary Smith.

Answers to questions can be found on the Evolve website.

Many patients find it difficult to incorporate an exercise program into their daily lives because of time constraints. For these patients it is beneficial to reinforce that they can use ADLs to accumulate the recommended 30 minutes or more per day of moderate-intensity physical activity (Box 38-9).

Other patients benefit from a prescribed exercise and physical fitness program carefully designed to meet their needs and expectations. An exercise prescription usually includes a combination of aerobic exercises, stretching and flexibility exercises, and resistance training. Aerobic exercise includes walking, running, bicycling, aerobic dance, jumping rope, and cross-country skiing. Recommended frequency of aerobic exercise is 3 to 5 times per week or every other day for approximately 30 minutes. Cross-training is recommended for the patient who prefers to exercise every day. For example, the patient runs one day and does yoga the next day.

Stretching and flexibility exercises include active ROM and stretch all muscle groups and joints. This form of exercise is ideal for warm-up and cool-down periods. Benefits include increased flexibility, improved circulation and posture, and an opportunity for relaxation.

Resistance training increases muscle strength and endurance and is associated with improved performance of daily activities and avoidance of injuries and disability. Formal resistance training includes weight training; but patients can obtain the same benefits by performing ADLs such as pushing a vacuum cleaner, raking leaves, shoveling snow, and kneading bread. Some patients use

TABLE 38-1 PREVENTING LIFT INJURIES IN HEALTH CARE WORKERS

ACTION	RATIONALE
When planning to move a patient, arrange for adequate help. If your institution has a lift team, use it as a resource.	A lift team is properly educated in techniques to prevent musculoskeletal injuries.
Use patient-handling equipment and devices such as height-adjustable beds, ceiling-mounted lifts, friction-reducing slide sheets, and air-assisted devices (Nelson and Baptiste, 2004; Nelson and Hughes, 2009; Tullar et al., 2010).	These devices reduce the caregiver's muscular strain during patient handling.
Encourage patient to assist as much as possible.	This promotes patient's independence and strength while minimizing workload.
Keep back, neck, pelvis, and feet aligned. Avoid twisting.	Reduces risk of injury to lumbar vertebrae and muscle groups. Twisting increases risk of injury.
Flex knees; keep feet wide apart.	A broad base of support increases stability.
Position self close to patient (or object being lifted).	Reduces horizontal reach and stress on caregiver's back.
Use arms and legs (not back).	The leg muscles are stronger, larger muscles capable of greater work without injury.
Slide patient toward your body using a pull sheet or slide board. When transferring a patient onto a stretcher or bed, a slide board is more appropriate.	Sliding requires less effort than lifting. Pull sheet minimizes shearing forces, which can damage patient's skin.
Person with the heaviest load coordinates efforts of team involved by counting to three.	Simultaneous lifting minimizes the load for any one lifter.
Perform manual lifting as last resort and only if it does not involve lifting most or all of patient's weight (Nelson and Baptiste, 2004; Nelson and Hughes, 2009; Tullar, 2010).	Lifting is a high-risk activity that causes significant biochemical and postural stressors.

weight training to bulk up their muscles. However, the purpose of weight training from a health perspective is to develop tone and strength and stimulate and maintain healthy bone (O'Donovan et al., 2010).

Body Mechanics. The U.S. Occupational Safety and Health Administration released federal ergonomic guidelines to prevent musculoskeletal injuries in the workplace (OSHA, 2009). Half of all back pain is associated with manual lifting tasks (Box 38-10). Coordinated musculoskeletal activity is necessary when positioning and transferring patients. The most common back injury is strain on the lumbar muscle group, which includes the muscles around the lumbar vertebrae. Injury to these areas affects the ability to bend forward, backward, and from side to side. The ability to rotate the hips and lower back is also decreased (Nelson and Hughes, 2009). Body mechanics alone are not sufficient to prevent musculoskeletal injuries when positioning or transferring patients (Table 38-1).

Before lifting, assess the weight to be lifted, determine the assistance needed, and evaluate available resources. Use safe patient-handling equipment when the patient is unable to assist in transfer. Lift teams, consisting of two physically fit people competent in lifting techniques, reduce the risk of injury to the patient and members of the health care team (Baptiste et al., 2006; Pelczarski, 2007). Use manual lifting only as a last resort when you need to lift a small portion of the patient's weight (Nelson and Baptiste, 2004; Nelson et al., 2008; Tullar et al., 2010). Teaching health care workers about patient-handling equipment, proper body mechanics, and the use of lift teams is most effective in preventing injury (Nelson and Baptiste, 2004; Nelson et al., 2008).

Acute Care. Encourage patients who are hospitalized to do stretching and isometric exercises, active ROM exercises, and low-intensity walking, depending on their condition. When patients cannot participate in active ROM, maintain joint mobility and prevent contractures by implementing passive ROM into the plan of care. If needed, medicate patients for pain 30 minutes before exercise.

BOX 38-10 EVIDENCE-BASED PRACTICE

Promoting Safe Handling of Patients and Prevention of Injury to Nurses and Their Patients

PICO Question: What is the effect on patient and nurse safety in health care agencies that have safe patient handling policies when compared with agencies that do not have these policies?

Evidence Summary

Musculoskeletal disorders are the most prevalent and debilitating occupational health hazards for nurses. Preventive interventions are needed to avoid the hazards and economic burdens associated with patient-handling tasks. The American Nurses Association (ANA, 2008) position statements call for the use of assistive equipment and devices to promote a safe health care environment for nurses and their patients. The use of assistive equipment and continued use of proper body mechanics significantly reduces the risk of musculoskeletal injuries. In addition, the Occupational Safety and Health Administration (OSHA, 2009) recommends minimizing or eliminating manual lifting of patients. Current evidence supports the benefits of instituting safe patient handling (SPH) programs in health care organizations. The U.S. Bureau of Labor Statistics (2007) reported a reduction in workers' compensation claims and costs associated with absenteeism because of SPH programs. As a result, many facilities are moving toward limited lift policies to minimize patient handling by nurses and using lift devices. Research shows these policies effectively reduce on-the-job injuries (Nelson and Baptiste, 2004; Nelson and Hughes, 2009; Tullar et al., 2010).

Application to Nursing Practice

- Be familiar with health care facility safety information and training concerning the transfer, positioning, and lifting of patients.
- Use recommended back safety guidelines to prevent musculoskeletal injuries.
- Use current research, standards, and guidelines regarding safe positioning and transferring of patients.
- Use "lift teams" and patient-handling equipment such as mechanical lifts to prevent injury to yourself and the patient.

Musculoskeletal System. Help maintain the musculoskeletal system during acute care by encouraging the use of stretching and isometric exercises. Review the patient's chart and collaborate with the health care provider to identify possible contraindications before initiating isometric exercises. You design an isometric exercise program for the specific needs of a patient. For example, an exercise program includes isometric exercises of the biceps and triceps to prepare your patient for crutch walking. Instruct the patient to stop the activity if pain, fatigue, or discomfort is experienced.

Generally the muscle group is tightened (contracted) for 10 seconds and then completely relaxed for several seconds (Hoeman, 2006). Repetitions are gradually increased for each muscle group until the isometric exercise is repeated 8 to 10 times. Instruct patients to perform the exercises slowly and increase repetitions as their physical condition improves. Patients need to isometrically exercise muscle groups (quadriceps and gluteal) used for walking 4 times per day until they are ambulatory.

Joint Mobility. The easiest intervention to maintain or improve joint mobility for patients and one that can be coordinated with other activities is the use of ROM exercises (see Chapter 47). In active ROM exercises patients are able to move their joints independently. With passive ROM exercises you move each joint in patients who are unable to perform these exercises themselves. The use of ROM exercises provides data to systematically assess and improve the patient's joint mobility.

Joints that are not moved periodically are at risk for contractures, a permanent shortening of a muscle followed by the eventual shortening of associated ligaments and tendons. Over time the joint becomes fixed in one position, and the patient loses normal use of it. Passive ROM exercises are the exercises of choice for patients who do not have voluntary motor control.

Older adults experiencing a decline in physical activity and changes in joints often have limited mobility and joint flexibility. Use a variety of recommended approaches to help older adults use proper body mechanics and prevent injury (Box 38-11).

Mechanical devices place specific joints through continuous passive motion (CPM). You will use CPM machines most commonly after joint replacement surgery to place joints through a selective repetitive ROM. You set the machine to certain degrees of joint mobility, with increasing joint mobility or flexion as the goal. Unless contraindicated, the nursing care plan includes exercising each joint through as nearly a full ROM as possible. Initiate passive ROM exercises as soon as the patient loses the ability to move the extremity or joint. Chapter 47 details ROM exercises for each area and illustrates the motion of each joint.

Walking. Walking increases joint mobility. Measure distances walked in feet or yards instead of charting "ambulated to nurses' station and back." Illness or trauma usually reduces activity tolerance, resulting in the need for assistance with walking or the use of mechanical devices such as crutches, canes, or walkers.

Helping a Patient to Walk. Helping a patient to walk requires preparation. Assess the patient's activity tolerance, strength, coordination, baseline vital signs, and balance to determine the type of assistance needed. Also assess the patient's orientation and determine if there are any signs of distress. Postpone walking if you determine the patient cannot safely walk. Evaluate the environment for safety before ambulation; this includes the removal of obstacles, a clean and dry floor, and the identification of rest points in case the patient's activity tolerance becomes less than expected or if the patient becomes dizzy. Also have the patient wear supportive, nonskid shoes.

BOX 38-11 FOCUS ON OLDER ADULTS

Helping the Older Adult Initiate and Maintain an Exercise Program

- Encourage older adults to avoid prolonged sitting and get up and stretch. Frequent stretching decreases the risk of developing joint contractures.
- Be sure that the older patient maintains proper body alignment when sitting to minimize joint and muscle stress.
- Teach patients how to use stronger joints or larger muscle groups. Efficient distribution of the workload decreases joint stress and pain.
- Provide resources for planned exercise programs. Weight-bearing and resistance exercise slows bone loss and prevents fractures in older adults with osteoporosis (De Kam et al., 2009; Monahan et al., 2007).
- Recommend resistance- and agility-training programs. These forms of exercise reduce fear of falling and increase sense of well-being in older adults (De Kam et al., 2009; Sherrington et al., 2008).
- Teach older adults that it is never too late to begin an exercise program (Chodzko-Zajko et al., 2009; Edelman and Mandle, 2010). Consult a health care provider before beginning an exercise program, particularly in the presence of heart or lung disease and other chronic illnesses.
- Use assessment data to determine when you need to make adjustments to exercise programs for those in advanced age.
- When developing an exercise program for older adults, consider current activity level, range of motion, muscle strength and tone, response to physical activity, and personal interests, capacities, and limitations.
- Encourage older adults who are unable to participate in a formal exercise program to improve joint mobility and enhance circulation by simply stretching and exaggerating movements during the performance of routine activities of daily living.

Help the patient to a position of sitting at the side of the bed and dangling the legs over the side of the bed for 1 to 2 minutes before standing. Some patients experience orthostatic hypotension, a drop in blood pressure that occurs when they change from a horizontal to a vertical position (Capan and Lynch, 2007; Monahan et al., 2007). Those at higher risk are patients who are immobilized, patients who are on prolonged bed rest, older adults, and patients with chronic illnesses such as diabetes mellitus and cardiovascular disease (Capan and Lynch, 2007). Signs and symptoms of orthostatic hypotension include dizziness, light-headedness, nausea, tachycardia, pallor, and even fainting. Dangling a patient's legs before standing is an intermediate step that allows assessment of the patient before changing positions to maintain safety and prevent injury to the patient. In some instances you will need to obtain the patient's blood pressure while he or she is sitting on the side of the bed.

Several methods are used to assist a patient with ambulation. Provide support at the waist so the patient's center of gravity remains midline. This is achieved with the use of a gait belt. A gait belt encircles the patient's waist and may have handles attached for the nurse to hold while the patient ambulates.

If the patient has a fainting (syncope) episode or begins to fall, assume a wide base of support with one foot in front of the other, thus supporting the patient's body weight (Fig. 38-5, *A*). Extend one leg, let the patient slide against the leg, and gently lower the patient to the floor, protecting the head (Fig. 38-5, *B* and *C*). Practice this technique with a friend or classmate before attempting it in a clinical setting. When the patient attempts to ambulate again, proceed more slowly, monitoring for reports of dizziness, and take the patient's blood pressure before, during, and after ambulation.

FIG. 38-5 **A,** Stand with feet apart to provide a broad base of support. **B,** Extend one leg and let patient slide against it to the floor. **C,** Bend knees to lower body as patient slides to the floor.

Restorative and Continuing Care. Restorative and continuing care involves implementing activity and exercise strategies to assist the patient with ADLs after acute care is no longer needed. Restorative and continuing care also includes activities and exercises that restore and promote optimal functioning in patients with specific chronic illnesses such as coronary heart disease (CHD), hypertension, chronic obstructive pulmonary disease (COPD), and diabetes mellitus.

Assistive Devices for Walking. In collaboration with other health care professionals such as physical therapists, promote activity and exercise by teaching the proper use of canes, walkers, or crutches, depending on the assistive device most appropriate for the patient's condition.

Walkers. Walkers are extremely light, movable devices that are about waist high and made of metal tubing (Fig. 38-6). They have four widely placed, sturdy legs. The patient holds the handgrips on the upper bars, takes a step, moves the walker forward, and takes another step. A walker requires a patient to lift the device up and forward. In the home many patients prefer walkers with wheels or short runners on the legs that allow them to push the walker. Instruct patients on how to use walkers safely and avoid risk of falling.

FIG. 38-6 Patient using a walker.

Canes. Canes are lightweight, easily movable devices made of wood or metal. They provide less support than a walker and are less stable. A person's cane length is equal to the distance between the greater trochanter and the floor (Pierson and Fairchild, 2008). Two common types of canes are the single straight-legged cane and the quad cane. The single straight-legged cane is more common and is used to support and balance a patient with decreased leg strength. Have the patient keep the cane on the stronger side of the body. For maximum support when walking, the patient places the cane forward 15 to 25 cm (6 to 10 inches), keeping body weight on both legs. The weaker leg is moved forward to the cane so body weight is divided between the cane and the stronger leg. The stronger leg is then advanced past the cane so the weaker leg and the body weight are supported by the cane and weaker leg. During walking the patient continually repeats these three steps. The patient needs to learn that two points of support such as both feet or one foot and the cane are on the floor at all times.

The quad cane provides the most support and is used when there is partial or complete leg paralysis or some hemiplegia (Fig. 38-7). You teach the patient the same three steps that are used with the straight-legged cane.

Crutches. Crutches are often needed to increase mobility. Begin crutch instruction with guidelines for safe use (Box 38-12). The use of crutches is often temporary (e.g., after ligament damage to the knee). However, some patients with paralysis of the lower extremities need them permanently. A crutch is a wooden or metal staff. The two types of crutches are the double adjustable Lofstrand or forearm crutch and the axillary wooden or metal crutch. The

FIG. 38-7 Bottom of quad cane.

BOX 38-12 PATIENT TEACHING

Crutch Safety

Objective

- Patient will state and demonstrate safe crutch walking.

Teaching Strategies

- Teach patient not to lean on crutches to support body weight.
- Teach patient with axillary crutches about the dangers of pressure on the axillae, which occurs when leaning on the crutches to support body weight.
- Explain why patient needs to use crutches that were measured for him or her.
- Show patient how to routinely inspect crutch tips. Securely attach rubber tips to the crutches. Replace worn tips. Rubber crutch tips increase surface friction and help prevent slipping.
- Explain that the crutch tips need to remain dry. Water decreases surface friction and increases the risk of slipping. Show patient how to dry the crutch tips if they become wet; patient may use paper or cloth towels.
- Show patient how to inspect the structure of the crutches. Cracks in a wooden crutch decrease its ability to support weight. Bends in aluminum crutches alter body alignment.
- Provide patient with a list of medical supply companies in the community for obtaining repairs, new rubber tips, handgrips, and crutch pads.
- Instruct patient to have spare crutches and tips readily available.

Evaluation

- Patient states principles of crutch safety.
- Patient correctly demonstrates proper use of crutches.
- Axilla is free of pressure.

forearm crutch has a handgrip and a metal band that fits around the patient's forearm. The metal band and the handgrip are adjusted to fit the patient's height. The axillary crutch has a padded curved surface at the top, which fits under the axilla. A handgrip in the form of a crossbar is held at the level of the palms to support the body. It is important to measure crutches for the appropriate length and to teach patients how to use their crutches safely to achieve a stable gait, ascend and descend stairs, and rise from a sitting position.

Measuring for Crutches. The axillary crutch is the more common crutch used. Measurements include the patient's height, the angle of elbow flexion, and the distance between the crutch pad and the axilla. When crutches are fitted, ensure the length of the crutch is three to four finger widths from the axilla to a point 15 cm (6 inches) lateral to the patient's heel (Pierson and Fairchild, 2008) (Fig. 38-8).

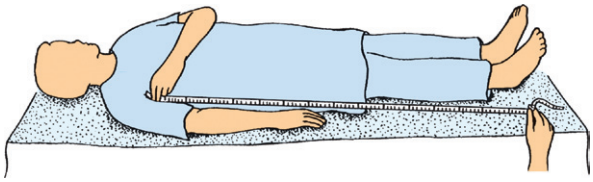

FIG. 38-8 Measuring crutch length.

FIG. 38-9 Using the goniometer to verify correct degree of elbow flexion for crutch use.

Position the handgrips so the axillae are not supporting the patient's body weight. Pressure on the axillae increases risk to underlying nerves, which sometimes results in partial paralysis of the arm. Determine correct position of the handgrips with the patient upright, supporting weight by the handgrips with the elbows slightly flexed at 30 degrees (Pierson and Fairchild, 2008). Elbow flexion may be verified with a goniometer (Fig. 38-9). When you determine the height and placement of the handgrips, verify that the distance between the crutch pad and the patient's axilla is three to four finger widths (Fig. 38-10).

Crutch Gait. Patients assume a **crutch gait** by alternately bearing weight on one or both legs and on the crutches. Determine the gait by assessing the patient's physical and functional abilities and the disease or injury that resulted in the need for crutches. This section summarizes the basic crutch stance and the four standard gaits: four-point alternating gait, three-point alternating gait, two-point gait, and swing-through gait.

The basic crutch stance is the tripod position, formed when the crutches are placed 15 cm (6 inches) in front of and 15 cm (6 inches) to the side of each foot (Fig. 38-11). This position improves the patient's balance by providing a wider base of support. The body alignment of the patient in the tripod position includes an erect head and neck, straight vertebrae, and extended hips and knees. The axillae should not bear any weight. The patient assumes the tripod position before crutch walking.

Four-point alternating, or four-point, gait gives stability to the patient but requires weight bearing on both legs. Each leg is moved alternately with each opposing crutch so three points of support are on the floor at all times (Fig. 38-12, *A*).

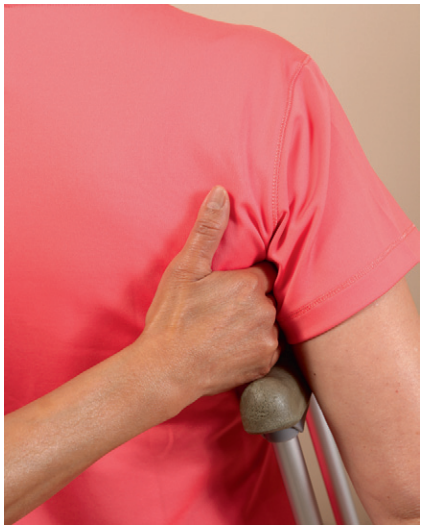

FIG. 38-10 Verifying correct distance between crutch pads and axilla.

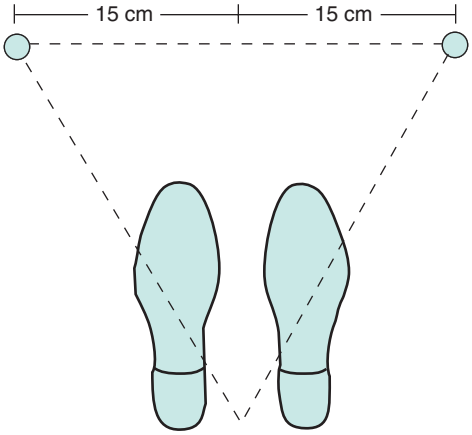

FIG. 38-11 Tripod position, basic crutch stance.

Three-point alternating, or three-point, gait requires the patient to bear all of the weight on one foot. In a three-point gait the patient bears weight on both crutches and then on the uninvolved leg, repeating the sequence (Fig. 38-12, *B*). The affected leg does not touch the ground during the early phase of the three-point gait. Gradually the patient progresses to touchdown and full weight bearing on the affected leg.

The two-point gait requires at least partial weight bearing on each foot (Fig. 38-12, *C*). The patient moves a crutch at the same time as the opposing leg so the crutch movements are similar to arm motion during normal walking.

Individuals with paraplegia who wear weight-supporting braces on their legs frequently use the swing-through gait. With weight placed on the supported legs, the patient places the crutches one stride in front and then swings to or through them while they support his or her weight.

Crutch Walking on Stairs. When ascending stairs on crutches, the patient usually uses a modified three-point gait (Fig. 38-13). He or she stands at the bottom of the stairs and transfers body weight to the crutches. The unaffected leg is advanced between the crutches to the stairs. The patient then shifts weight from the crutches to the unaffected leg. Finally he or she aligns both crutches

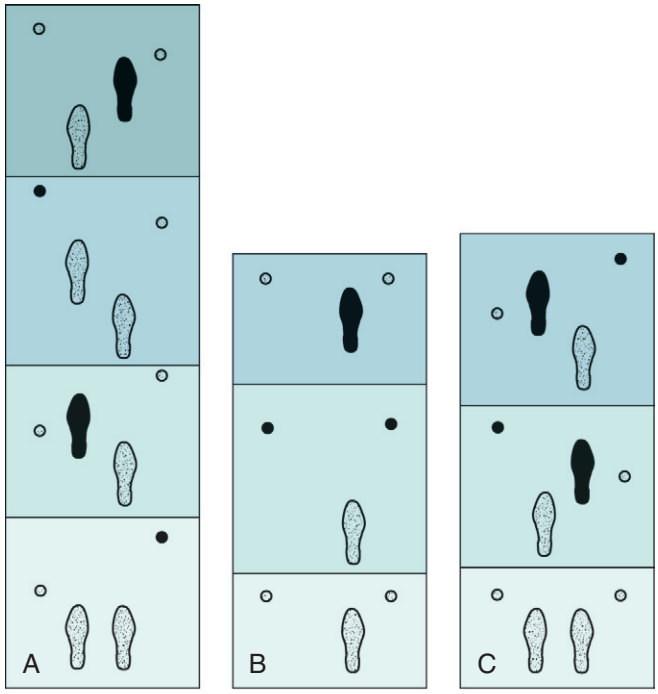

FIG. 38-12 **A,** Four-point alternating gait. Solid feet and crutch tips show the order of foot and crutch tip movement in each of the four phases. (Read from bottom to top.) **B,** Three-point gait with weight borne on unaffected leg. Solid foot and crutch tips show weight bearing in each phase. (Read from bottom to top.) **C,** Two-point gait with weight borne partially on each foot and each crutch advancing with opposing leg. Solid areas indicate leg and crutch tips bearing weight. (Read from bottom to top.)

on the stairs. The patient repeats this sequence until he or she reaches the top of the stairs.

A three-phase sequence is also used to descend the stairs (Fig. 38-14). The patient transfers body weight to the unaffected leg. The crutches are placed on the stairs, and the patient begins to transfer body weight to the crutches, moving the affected leg forward. Finally the unaffected leg is moved to the stairs with the crutches. The patient repeats the sequence until reaching the bottom of the stairs.

Because in most cases patients need to use crutches for some time, they need to be taught to use them on stairs before discharge. This instruction applies to all patients who are dependent on crutches, not only those who have stairs in their homes. You will frequently collaborate with physical therapists to provide instruction about crutch walking.

Building Competency in Patient-Centered Care You are caring for Mr. Slane, a 72-year-old patient who has undergone a left total knee replacement. His orders are that he is allowed no weight bearing on the left leg, and he has been fitted with crutches. As you prepare for his discharge he states, "I'm not sure how I'm going to get up and down the stairs to go to bed and down the basement stairs to do my laundry. I can't read these silly directions on how to use my crutches on the stairs; the print is so small." Which assessment questions and teaching strategies, approaches, and tools do you use to enhance Mr. Slane's learning and ability to safely use his crutches when ascending and descending stairs?

Answers to questions can be found on the Evolve website.

FIG. 38-13 Ascending stairs. **A,** Weight is placed on crutch. **B,** Weight is transferred from crutches to unaffected leg on stairs. **C,** Crutches are aligned with unaffected leg on stairs.

FIG. 38-14 Descending stairs. **A,** Body weight is on unaffected leg. **B,** Body weight is transferred to crutches. **C,** Unaffected leg is aligned on stairs with crutches.

Sitting in a Chair with Crutches. As with crutch walking and crutch walking up and down stairs, the procedure for sitting in a chair involves phases and requires the patient to transfer weight (Fig. 38-15). First the patient positions himself or herself at the center front of the chair with the posterior aspect of the legs touching the chair. Then the patient holds both crutches in the hand opposite the affected leg. If both legs are affected, as with a person with paraplegia who wears weight-supporting braces, the crutches are held in the hand on the patient's stronger side. With both crutches in one hand, the patient supports body weight on the unaffected leg and the crutches. While still holding the crutches, the patient grasps the arm of the chair with the remaining hand and lowers his or her body into it. To stand the procedure is reversed; and the patient, when fully erect, assumes the tripod position before beginning to walk.

Restoration of Activity and Chronic Illness. Nurses design care plans to increase activity and exercise in patients with specific disease conditions and chronic illnesses such as CHD, hypertension, COPD, and diabetes mellitus.

Coronary Heart Disease. Research shows activity and exercise play a role in secondary prevention or recurrence of CHD. Cardiac rehabilitation is an integral part of comprehensive care of patients

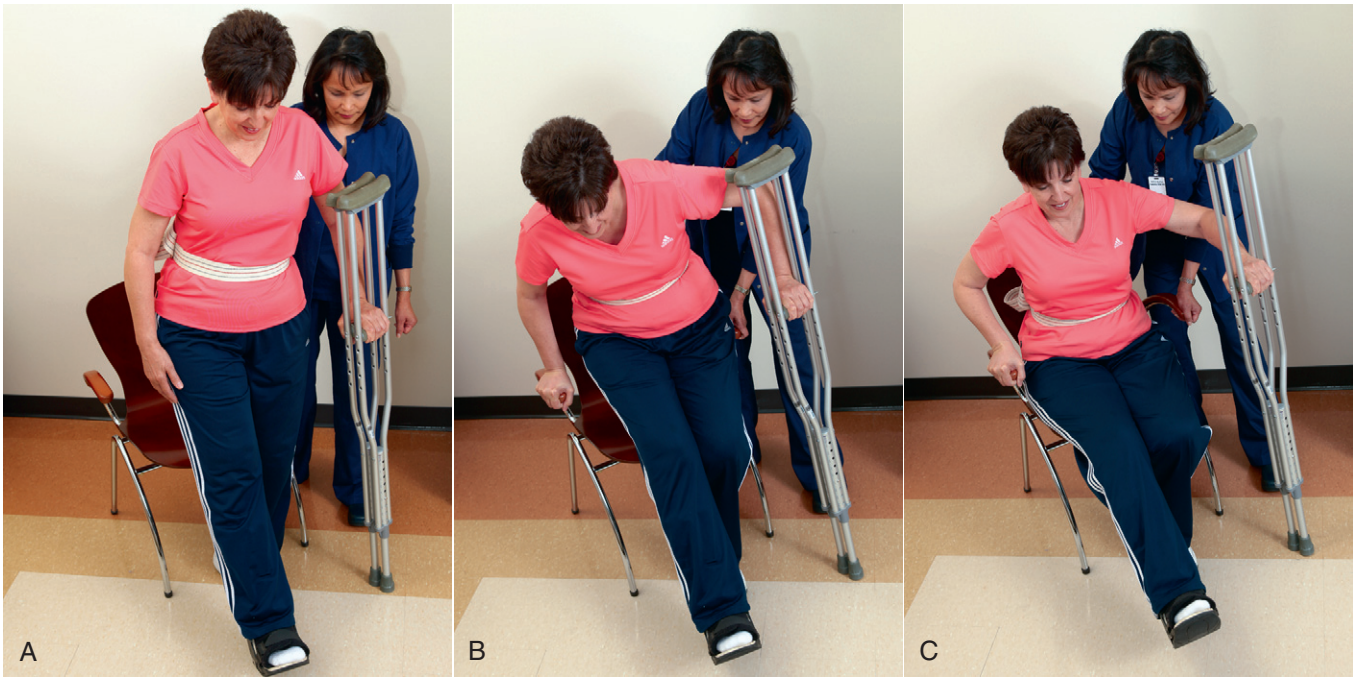

FIG. 38-15 Sitting in a chair. **A,** Both crutches are held in one hand. Patient transfers weight to crutches and unaffected leg. **B,** Patient grasps arm of chair with free hand and begins to lower herself into chair. **C,** Patient completely lowers herself into chair.

diagnosed with CHD. Nurses are involved in many aspects of cardiac rehabilitation and assist patients to develop a program of exercise that fits their needs and level of functioning. Increased physical activity benefits individuals with myocardial infarction (MI), angina pectoris, or heart failure and patients who have had a coronary artery bypass graft (CABG) or percutaneous transluminal coronary angioplasty (PTCA). Patients with CHD benefit from exercise and activity in terms of reduced mortality and morbidity, improved quality of life, improved left ventricular function, increased functional capacity, decreased blood lipids and apolipoproteins (protein components of lipoprotein complexes), and psychological well-being (Donges et al., 2010; Hamer and Stamatakis, 2009; Mandic et al., 2009).

Hypertension. Exercise reduces systolic and diastolic blood pressure readings. Low- to moderate-intensity aerobic exercise (brisk walking or bicycling) is the most effective in lowering blood pressure, whereas weight training and high-intensity aerobics have minimal benefits (Balady et al., 2010; Ciolac et al., 2009; Edelman and Mandle, 2010).

Chronic Obstructive Pulmonary Disease. Pulmonary rehabilitation helps patients reach an optimal level of functioning. Some patients are fearful of participating in exercise because of the potential of worsening dyspnea (difficulty breathing). This aversion to physical activity sets up a progressive deconditioning in which minimal physical exertion results in dyspnea. Pulmonary rehabilitation provides a safe environment for monitoring patients' progress. In addition, they receive encouragement and support to increase activity and exercise (Berry et al., 2010; Salhi et al., 2010).

Diabetes Mellitus. Along with diet, glucose monitoring, and medication, exercise is an important component in the care of patients with diabetes mellitus. Individuals with type 1 diabetes need to exercise because it leads to improved glucose control, cardiovascular fitness, and psychological well-being. Exercise lowers blood sugar levels, and the effects of exercise on blood sugar levels often last for at least 24 hours. Instruct the patient with type 1 diabetes about the risks and precautions regarding exercise. Instruction includes the need for a physical examination before beginning an exercise program and precautions to monitor blood glucose level immediately before and after exercise. Also instruct patients to perform low- to moderate-intensity exercises, carry a concentrated form of carbohydrates (sugar packets or hard candy), and wear a medical alert bracelet. The patient with type 2 diabetes who decides to participate in a regular program of exercise needs to include low-intensity warm-up and cool-down exercises, aerobic exercise at 50% to 75% of maximal oxygen uptake, and exercise for 20 to 45 minutes 3 days per week (ADA, 2007; Morrato et al., 2006).

EVALUATION

Through the Patient's Eyes. For activity and exercise you measure the effectiveness of nursing interventions by the success of meeting the patient's expected outcomes and goals of care. The patient is the only one who knows the effectiveness and benefits of activity and exercise (Fig. 38-16). Continuous evaluation helps to determine whether new or revised therapies are needed and if new nursing diagnoses have developed.

Patient Outcomes. To evaluate the effectiveness of nursing interventions to enhance activity and exercise, make comparisons with baseline measures that include pulse, blood pressure, strength, endurance, and psychological well-being. Compare actual outcomes with expected outcomes to determine the patient's health status and progression. The following is an example of questions you ask when your patients do not meet their expected outcomes:

- The last time we met, you planned to walk outside for 20 minutes three days a week. However, you report that you are only able to walk twice a week right now. What do you think is preventing you from meeting your goal?
- Your weight is the same this month as it was last month. We were hoping that increasing your activity would lead to a

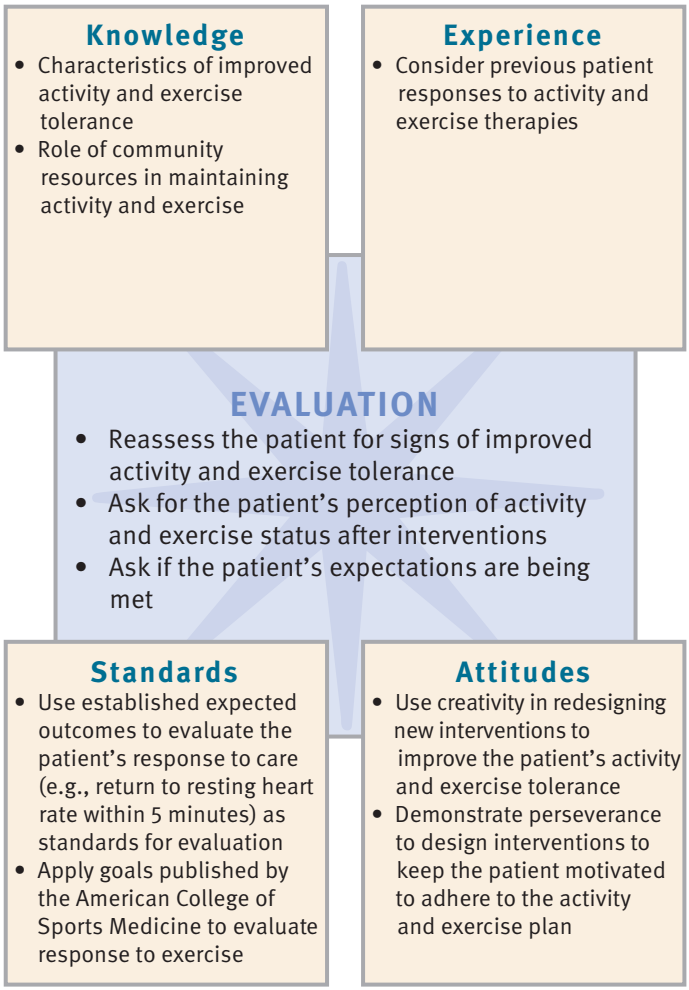

FIG. 38-16 Critical thinking model for activity and exercise evaluation.

decrease in your weight. Help me understand the factors you believe are preventing you from losing weight right now.

- You state that you experience leg pain after walking short distances. Describe your pain. What pain-relieving measures have you tried?

KEY POINTS

- Exercise is physical activity for the purpose of conditioning the body, improving health, and maintaining fitness; it also is a therapeutic measure.
- Activity tolerance is the kind and amount of exercise or work that a person is able to perform. Physiological, emotional, and developmental factors influence the patient's activity tolerance.
- The best program of physical activity includes a combination of exercises that produces different physiological and psychological benefits.
- Body mechanics are the coordinated efforts of the musculoskeletal and nervous systems as the person moves, lifts, bends, stands, sits, lies down, and completes daily activities.
- Coordinated body movement requires integrated functioning of the skeletal system, skeletal muscles, and nervous system.
- Muscles primarily associated with movement are located near the skeletal region, where movement results from leverage, which is characteristic of movements of the upper extremities.
- Coordination and regulation of muscle groups depend on muscle tone and activity of antagonistic, synergistic, and antigravity muscles.
- The nervous system controls balance through the functions of the cerebellum and inner ear.
- You achieve body balance when there is a wide base of support, the center of gravity falls within the base of support, and a vertical line falls from the center of gravity through the base of support.
- Developmental changes, behavioral aspects, environmental issues, cultural and ethnic origin, and family and social support influence the patient's perception and motivation to engage in physical activity and exercise.
- Ability to engage in normal physical activity and exercise depends on intact and functioning nervous and musculoskeletal systems.
- Use the nursing process to provide care for patients who are experiencing or are at risk for activity intolerance and impaired physical mobility.
- After identifying nursing diagnoses, plan and implement interventions to increase activity and exercise in collaboration with the patient when possible.
- Range-of-motion exercises incorporated into daily activities include one or all of the body joints.
- Mechanical devices to promote walking include canes, walkers, and crutches.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Smith has experienced some success in initiating an exercise program. However, maintaining her exercise plan is becoming challenging, and she is not seeing the improvements that she expects. She states, "I feel like I'm doing everything right, but I'm getting few results for my efforts."

1. Mrs. Smith states, "I don't want to leave the house anymore." She also expresses feelings of overwhelming stress and excessive demands on her time. What interventions do you suggest to Mrs. Smith to help overcome this barrier to exercise?
2. Mrs. Smith has several challenges to initiating and maintaining an exercise program. Develop a stepwise approach for Mrs. Smith that helps her initiate and maintain an exercise program, keeping in mind the challenges that she faces.
3. Develop an educational component to Mrs. Smith's care plan, emphasizing the benefits of exercise.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient on bed rest for several days attempts to walk with assistance. He becomes dizzy and nauseated. His pulse rate jumps from 85 to 110 beats/min. These are most likely symptoms of which of the following?
   1. Rebound hypertension
   2. Orthostatic hypotension
   3. Dysfunctional proprioception.
   4. Central nervous system rebound hypotension
2. Which action(s) are appropriate for the nurse to implement when a patient experiences orthostatic hypotension? (Select all that apply.)

1. Call for assistance.
2. Allow patient to sit down.
3. Take patient's blood pressure and pulse.
4. Continue to ambulate patient to build endurance.
5. If patient begins to faint, allow him to slide against the nurse's leg to the floor.

3. Which of the following *best* motivates a patient to participate in an exercise program?
   1. Giving a patient information on exercise
   2. Providing information to the patient when the patient is ready to change behavior
   3. Explaining the importance of exercise when a patient is diagnosed with a chronic disease such as diabetes
   4. Following up with instructions after the health care provider tells a patient to begin an exercise program
4. Which of the following is a principle of proper body mechanics when lifting or carrying objects?
   1. Keep the knees in a locked position.
   2. Bend at the waist to maintain a center of gravity.
   3. Maintain a wide base of support.
   4. Hold objects away from the body for improved leverage.
5. Which group of patients is at most risk for severe injuries related to falls?
   1. Adolescents
   2. Older adults
   3. Toddlers
   4. Young children
6. A nurse plans to provide education to the parents of school-aged children and includes which of the following result of children being less physically active outside of school?
   1. An increase in obesity
   2. An increase in heart disease
   3. Higher computer literacy
   4. Improved school attendance and grades
7. A nursing assistive personnel asks for help to transfer a patient who is 125 pounds (56.8 kg) from the bed to a wheelchair. The patient is unable to assist. What is the nurse's best response?
   1. "As long as we use proper body mechanics, no one will get hurt."
   2. "The patient only weighs 125 lb. You don't need my assistance."
   3. "Call the lift-team for additional assistance."
   4. "The two of us can easily lift the patient."
8. You are transferring a patient who weighs 320 lb (145.5 kg) from his bed to a chair. The patient has an order for partial weight bearing as a result of bilateral reconstructive knee surgery. Which of the following is the best technique for transfer?
   1. Use a transfer board.
   2. Obtain a stand assist device.
   3. Implement a three-person carry.
   4. Use the ceiling-mounted lift.
9. Which is the correct gait when a patient is ascending stairs on crutches?
   1. A modified two-point gait. The affected leg is advanced between the crutches to the stairs.
   2. A modified three-point gait. The unaffected leg is advanced between the crutches to the stairs.
   3. A swing-through gait.
   4. A modified four-point gait. Both legs advance between the crutches to the stairs.
10. A patient recovering from bilateral knee replacements is prescribed bilateral partial weight bearing. You reinforce crutch walking knowing that which of the following crutch gaits is most appropriate for this patient?
    1. Two-point gait
    2. Three-point gait
    3. Four-point gait
    4. Swing-through gait
11. A patient with a right knee replacement is prescribed no weight bearing on the right leg. You reinforce crutch walking knowing that which of the following crutch gaits is most appropriate for this patient?
    1. Two-point gait
    2. Three-point gait
    3. Four-point gait
    4. Swing-through gait
12. A patient on week-long bed rest is now performing isometric exercises. Which nursing diagnosis best addresses the safety of this patient?
    1. Disturbed thought processes
    2. Impaired skin integrity
    3. Disturbed body image
    4. Risk for activity intolerance
13. Which of the following activities does the nurse delegate to nursing assistive personnel in regard to crutch walking? (Select all that apply.)
    1. Notify nurse if patient reports pain before, during, or after exercise.
    2. Notify nurse of patient complaints of increased fatigue, dizziness, light-headedness when obtaining vital signs before and/or after exercise.
    3. Notify nurse of vital sign values.
    4. Evaluate the patient's ability to use crutches properly.
    5. Prepare the patient for exercise by assisting in dressing and putting on shoes.
14. Select statements that apply to the proper use of a cane. (Select all that apply.)
    1. For maximum support when walking, the patient places the cane forward 15 to 25 cm (6 to 10 inches), keeping body weight on both legs. The weaker leg is moved forward to the cane so body weight is divided between the cane and the stronger leg.
    2. A person's cane length is equal to the distance between the elbow and the floor.
    3. Canes provide less support than a walker and are less stable.
    4. The patient needs to learn that two points of support such as both feet or one foot and the cane need to be present at all times.
15. A patient is discharged after an exacerbation of chronic obstructive pulmonary disease (COPD). She states, "I'm afraid to go to pulmonary rehabilitation." What is your best response?
    1. Pulmonary rehabilitation provides a safe environment for monitoring your progress.
    2. You have to participate or you will be back in the hospital.
    3. Tell me more about your concerns with going to pulmonary rehabilitation.
    4. The staff at our pulmonary rehabilitation facility are professionals and will not cause you any harm.

Answers: **1.** 2; **2.** 1, 2, 3, 5; **3.** 2; **4.** 3; **5.** 2; **6.** 1; **7.** 3; **8.** 4; **9.** 2; **10.** 1; **11.** 2; **12.** 4; **13.** 1, 2, 3, 5; **14.** 1, 3, 4; **15.** 1.

CHAPTER

39

Hygiene

OBJECTIVES

- Describe factors that influence personal hygiene practices.
- Discuss the role that critical thinking plays in providing hygiene.
- Conduct a comprehensive assessment of a patient's total hygiene needs.
- Discuss conditions that place patients at risk for impaired skin integrity.
- Discuss factors that influence the condition of the nails and feet.
- Explain the importance of foot care for the patient with diabetes.
- Discuss conditions that place patients at risk for impaired oral mucous membranes.
- List common hair and scalp problems and their related interventions.
- Describe how hygiene care for the older adult differs from that for the younger patient.
- Discuss different approaches used in maintaining a patient's comfort and safety during hygiene care.
- Successfully perform hygiene procedures for the care of the skin, perineum, feet and nails, mouth, eyes, ears, and nose.
- Adapt hygiene care for a patient who is cognitively impaired.

Personal hygiene affects patients' comfort, safety, and well-being. Hygiene care includes cleaning and grooming activities that maintain personal body cleanliness and appearance. Personal hygiene activities such as taking a bath or shower, brushing and flossing the teeth, washing and grooming the hair, and performing nail care promote comfort and relaxation, foster a positive self-image, promote healthy skin, and help prevent infection and disease. Healthy people fulfill their own hygiene needs; but when ill or physically or emotionally challenged, people often require some degree of assistance with hygiene care. A variety of personal, social, and cultural factors influence hygiene practices.

In both agency and home care settings, determine a patient's ability to perform self-care and provide hygiene care according to individual needs and preferences. In addition, in the home setting help the patient and family adapt hygiene techniques and approaches. Use the close contact required for hygiene care to promote a caring therapeutic relationship and provide needed patient teaching and counseling. Integrate other nursing activities during hygiene care, including assessment and interventions such as range-of-motion (ROM) exercises, application of dressings, or inspection and care of intravenous (IV) sites. During hygiene care preserve as much of the patient's independence as possible, assess his or her ability to perform hygiene care, ensure privacy, convey respect, and foster his or her physical comfort.

SCIENTIFIC KNOWLEDGE BASE

Proper hygiene care requires an understanding of the anatomy and physiology of the skin, nails, oral cavity, eyes, ears, and nose. The skin and mucosal cells exchange oxygen, nutrients, and fluids with underlying blood vessels. The cells require adequate nutrition, hydration, and circulation to resist injury and disease. Good hygiene techniques promote the normal structure and function of these tissues.

Apply knowledge of pathophysiology to provide preventive hygiene care. Recognize disease states that create changes in the integument, oral cavity, and sensory organs. For example, diabetes mellitus often results in chronic vascular changes that impair healing of the skin and mucosa. In the early stages of acquired

TABLE 39-1 Function of the Skin and Implications for Care

FUNCTION/DESCRIPTION	IMPLICATIONS FOR CARE
Protection	
Epidermis is relatively impermeable layer that prevents entrance of microorganisms. Although microorganisms reside on skin surface and in hair follicles, relative dryness of surface of skin inhibits bacterial growth. Sebum removes bacteria from hair follicles. Acidic pH of skin further retards bacterial growth.	Weakening of epidermis occurs by scraping or stripping its surface (e.g., use of dry razors, tape removal, improper turning or positioning techniques). Excessive dryness causes cracks and breaks in skin and mucosa that allow bacteria to enter. Emollients soften skin and prevent moisture loss, soaking skin improves moisture retention, and hydrating mucosa prevents dryness. However, constant exposure of skin to moisture causes maceration or softening, interrupting dermal integrity and promoting ulcer formation and bacterial growth. Keep bed linen and clothing dry. Misuse of soap, detergents, cosmetics, deodorant, and depilatories cause chemical irritation. Alkaline soaps neutralize the protective acid condition of skin. Cleaning skin removes excess oil, sweat, dead skin cells, and dirt, which promote bacterial growth.
Sensation	
Skin contains sensory organs for touch, pain, heat, cold, and pressure.	Minimize friction to avoid loss of stratum corneum, which results in development of pressure ulcers. Smoothing linen removes sources of mechanical irritation. Remove rings from fingers to prevent accidentally injuring patient's skin. Make sure that bath water is not excessively hot or cold.
Temperature Regulation	
Radiation, evaporation, conduction, and convection control body temperature.	Factors that interfere with heat loss alter temperature control. Wet bed linen or gowns interfere with convection and conduction. Excess blankets or bed coverings interfere with heat loss through radiation and conduction. Coverings promote heat conservation.
Excretion and Secretion	
Sweat promotes heat loss by evaporation. Sebum lubricates skin and hair.	Perspiration and oil harbor microorganisms. Bathing removes excess body secretions; although, if excessive, it causes dry skin.

immunodeficiency syndrome (AIDS), fungal infections of the oral cavity are common. Paralysis of the trigeminal nerve (cranial nerve V) eliminates the blink reflex, causing risk of corneal drying. In the presence of conditions such as these, adapt hygiene practices to minimize injury. Use time spent providing hygiene care to identify abnormalities and initiate appropriate actions to prevent further injury to sensitive tissues.

The Skin

The skin serves several functions, including protection, secretion, excretion, body temperature regulation, and cutaneous sensation (Table 39-1). It consists of two primary layers: the epidermis and the dermis. Just beneath the skin lies the subcutaneous tissue (also known as the hypodermis), which shares some of the protective functions of the skin.

Several thin layers of epithelial cells comprise the outer layer, or **epidermis;** these cells shield underlying tissue against water loss and injury and prevent entry of disease-producing microorganisms. The innermost layer of the epidermis generates new cells to replace the dead cells that the outer surface of the skin continuously sheds. Bacteria commonly reside on the outer epidermis. These resident bacteria are normal flora (see Chapter 28) that do not cause disease but instead inhibit the multiplication of disease-causing microorganisms.

Bundles of collagen and elastic fibers form the thicker dermis that underlies and supports the epidermis. Nerve fibers, blood vessels, sweat glands, sebaceous glands, and hair follicles run through the dermal layers. Sebaceous glands secrete sebum, an oily, odorous fluid, into the hair follicles. Sebum softens and lubricates the skin and slows water loss from the skin when the humidity is low. More important, sebum has bactericidal action.

The subcutaneous tissue layer contains blood vessels, nerves, lymph, and loose connective tissue filled with fat cells. The fatty tissue functions as a heat insulator for the body. Subcutaneous tissue also supports upper skin layers to withstand stresses and pressure without injury and anchors the skin loosely to underlying structures such as muscle. Very little subcutaneous tissue underlies the oral mucosa.

The skin often reflects a change in physical condition by alterations in color, thickness, texture, turgor, temperature, and hydration (see Chapter 30). As long as the skin remains intact and healthy, its physiological function remains optimal. Hygiene practices frequently influence skin status and can have both beneficial and negative effects on the skin. For example, too-frequent bathing and use of hot water frequently leads to dry, flaky skin and loss of protective oils.

The Feet, Hands, and Nails

The feet, hands, and nails often require special attention to prevent infection, odor, and injury. The condition of a patient's hands and feet influences the ability to perform hygiene care. Without the ability to bear weight, ambulate, or manipulate the hands, the patient is at risk for losing self-care ability.

A wide range of dexterity exists in the hand because of the movement between the thumb and fingers. Any condition that interferes with movement of the hand (e.g., superficial or deep pain or joint inflammation) impairs a patient's self-care abilities. Foot pain often changes the patient's gait, causing strain on different joints and muscle groups. Discomfort while standing or walking limits self-care abilities.

The nails grow from the root of the nail bed, which is located in the skin at the nail groove, hidden by the fold of skin called the **cuticle.** A scalelike modification of the epidermis forms the visible part of the nail (nail body), which has a crescent-shaped white area known as the lunula. Under the nail lies a layer of epithelium called the nail bed. A normal healthy nail appears transparent, smooth, and convex, with a pink nail bed and translucent white tip. Disease causes changes in the shape, thickness, and curvature of the nail (see Chapter 30).

The Oral Cavity

The oral cavity consists of the lips surrounding the opening of the mouth, the cheeks running along the sidewalls of the cavity, the tongue and its muscles, and the hard and soft palate. The mucous membrane, continuous with the skin, lines the oral cavity. The floor of the mouth and the undersurface of the tongue are richly supplied with blood vessels. Normal oral mucosa glistens and is pink, soft, moist, smooth, and without lesions. Ulcerations or trauma frequently result in significant bleeding. Several glands within and outside the oral cavity secrete saliva. Saliva cleanses the mouth, dissolves food chemicals to promote taste, moistens food to facilitate bolus formation, and contains enzymes that start breakdown of starchy foods. The effects of medications, exposure to radiation, dehydration, and mouth breathing impair salivary secretion in the mouth. Strong sympathetic nervous system stimulation almost completely inhibits the release of saliva and results in **xerostomia** or dry mouth.

The teeth lie in sockets in the gum-covered mandible and maxilla; they tear and grind ingested food so it can be mixed with saliva and swallowed for digestion. A normal tooth consists of the crown, neck, and root. The enamel-covered crown extends above the gingiva or gum, which normally surrounds the tooth like a tight collar. A constricted portion of the tooth called the *neck* connects the crown and the root; the root is embedded in the jawbone. The periodontal membrane lies just below the gum margins, surrounds a tooth, and holds it firmly in place. Healthy teeth appear white, smooth, shiny, and properly aligned.

Difficulty in chewing develops when surrounding gum tissues become inflamed or infected or when teeth are lost or become loosened. Regular oral hygiene helps to prevent **gingivitis** (i.e., inflammation of the gums) and **dental caries** (i.e., tooth decay produced by interaction of food with bacteria).

The Hair

Hair growth, distribution, and pattern indicate a person's general health status. Hormonal changes, nutrition, emotional and physical stress, aging, infection, and some illnesses affect hair characteristics. The hair shaft itself is lifeless, and physiological factors do not directly affect it. However, hormonal and nutrient deficiencies of the hair follicle cause changes in hair color or condition.

The Eyes, Ears, and Nose

When providing hygiene care, the eyes, ears, and nose require careful attention. Chapter 30 describes the structure and function of these organs. Clean the sensitive sensory tissues in a way that prevents injury and discomfort for a patient, such as using care not to get soap in his or her eyes. In addition, the time you spend with your patient during hygiene provides an excellent opportunity to ask if there are any changes in vision, hearing, or sense of smell.

NURSING KNOWLEDGE BASE

A number of factors influence personal preferences for hygiene and the ability to maintain hygiene practices. Since no two individuals perform hygiene care in the same manner, you individualize patient care based on learning about his or her unique hygiene practices and preferences. Individualized hygiene care requires use of therapeutic communication skills to promote the therapeutic relationship. In addition, use the opportunity provided during hygiene care to assess a patient's health promotion practices, emotional status, and health care education needs. Be aware that developmental changes influence the need and preferences for type of hygiene care.

Factors Influencing Hygiene

Social Practices. Social groups influence hygiene preferences and practices, including the type of hygiene products used and the nature and frequency of personal care practices. Parents and caregivers perform hygiene care for infants and young children. Family customs play a major role during childhood in determining hygiene practices such as the frequency of bathing, the time of day bathing is performed, and even whether certain hygiene practices such as brushing of the teeth or flossing are performed. As children enter adolescence, peer groups and media often influence hygiene practices. For example, some young girls become more interested in their personal appearance and begin to wear makeup. During the adult years involvement with friends and work groups shape the expectations that people have about personal appearance. Some older adults' hygiene practices change because of changes in living conditions and available resources.

Personal Preferences. Patients have individual desires and preferences about when to perform hygiene and grooming care. Some patients prefer to shower, whereas others prefer to bathe. Patients select different hygiene and grooming products according to personal preferences. Knowing patients' personal preferences promotes individualized care. Help the patient develop new hygiene practices when indicated by an illness or condition. For example, you need to teach a patient with diabetes proper foot hygiene. Safe and effective patient-centered nursing care elicits individual preferences, allows patients to make personal choices whenever possible, and promotes patient involvement and independence (Cronenwett et al., 2007).

Body Image. Body image is a person's subjective concept of his or her body, including physical appearance, structure, or function (see Chapter 33). Body image affects the way in which individuals maintain personal hygiene. If a patient maintains a neatly groomed appearance, be sure to consider the details of grooming when planning care and consult with the patient before making decisions about how to provide hygiene care. Patients who appear unkempt or uninterested in hygiene sometimes need education about its importance or further assessment regarding their ability to participate with daily hygiene.

Surgery, illness, or a change in emotional or functional status often affects a patient's body image. Discomfort and pain, emotional stress, or fatigue diminish the ability or desire to perform hygiene self-care and require extra effort to promote hygiene and grooming.

Socioeconomic Status. A person's economic resources influence the type and extent of hygiene practices used. Be sensitive in considering that the patient's economic status influences the ability to regularly maintain hygiene. He or she may not be able to afford desired basic supplies such as deodorant, shampoo, and toothpaste. A patient may need to modify the home environment by adding safety devices such as nonskid surfaces and grab bars in the bath to perform hygiene self-care safely. When he or she lacks socioeconomic resources, it becomes difficult to participate and take a responsible role in health promotion activities such as basic hygiene.

Health Beliefs and Motivation. Knowledge about the importance of hygiene and its implications for well-being influences hygiene practices. However, knowledge alone is not enough. Motivation also plays a key role in a patient's hygiene practices. Patient teaching is often needed to foster hygiene self-care. Provide information that focuses on a patient's health-related issues relevant to the desired hygiene care behaviors. Patient perceptions of the benefits of hygiene care and the susceptibility to and

BOX 39-1 CULTURAL ASPECTS OF CARE

Hygiene Practices

Patients deserve a culturally congruent plan for hygiene care. For many patients culture influences hygiene practices, and hygiene care becomes a potential source of conflict and stress in the caregiving environment. Patient-centered care mandates that care be based on respect for the individual patient's cultural background (Cronenwett et al., 2007).

Implications for Practice

- Maintain privacy, especially for women from cultures that value female modesty (e.g., Muslim, Hispanic, Nigerian) (Galanti, 2008).
- Avoid uncovering the lower torso and exposing the arms of Middle Eastern and East Asian Women.
- Allow family members to participate in care if desired by adapting the schedule of hygiene activities.
- Provide gender-congruent caregivers as needed or requested.
- Recognize that some cultures prohibit or restrict touching. For some patients from Arab and Hispanic cultures touching between unrelated males and females is forbidden (Maier-Lorentz, 2008).
- Incorporate awareness that people from various cultures have differing preferences regarding personal space. Hispanics, Asians, and Middle Easterners often feel very comfortable in closer proximity than people of European and North American descent (Maier-Lorentz, 2008).
- Do not cut or shave hair without prior discussion with patient or family (Galanti, 2008).
- Be aware that toileting practices vary by culture (e.g., Asians may prefer squatting for toileting) (Galanti, 2008).
- Recognize that people from the Japanese culture often prefer to cleanse while sitting before getting into a bath tub. Immersion in a tub occurs after cleansing because the bath represents spiritual cleansing. Japanese people prefer that the water be deeper (submerged to the neck) and hotter than the typical western bath (McGraw and Drennan, 2009).

seriousness of developing a problem affect the motivation to change behavior (Pender, Murdaugh, and Parsons, 2011). For example, do patients perceive that they are at risk for dental disease, that dental disease is serious, and that brushing and flossing are effective in reducing risk? When they recognize that there is a risk and that they can take reasonable action without negative consequences, they are more likely to be receptive to nurses' counseling and teaching efforts.

Cultural Variables. Cultural beliefs and personal values influence hygiene care (Box 39-1). People from diverse cultural backgrounds frequently follow different self-care practices (see Chapter 9). Maintaining cleanliness does not hold the same importance for some ethnic or social groups as it does for others (Galanti, 2008). In North America it is common to bathe or shower daily and use deodorant to prevent body odors. However, people from some cultures are not sensitive to body odors, prefer to bathe less frequently, and do not use deodorant. Some homeless people believe that a layer of dirt helps protect them from becoming sick (Galanti, 2008). Do not express disapproval when caring for patients whose hygiene practices differ from yours. Avoid forcing changes in hygiene practices unless the practices affect the patient's health. In these situations use tact, provide information, and allow choices. Religious beliefs associated with culture sometimes influence hygiene practices. Facilitate a patient's religious practices whenever possible. For example, Muslim patients often remove their shoes and assume different positions for prayer. This increases the risk of developing foot pathology such as calluses on the toes and lateral ankles. When caring for Muslim patients who have diabetes mellitus, you need to be supportive of religious practices while also stressing the need to be diligent in inspecting the feet after prayer sessions for any blisters or calluses.

Developmental Stage. The normal process of aging influences the condition of body tissues and structures. A patient's developmental stage affects the ability of the patient to perform hygiene care and the type of care needed. Apply knowledge of developmental changes as you assess your patients and plan, implement, and evaluate hygiene care.

Skin. The neonate's skin is relatively immature at birth. The epidermis and dermis are loosely bound together, and the skin is very thin. Friction against the skin layers causes bruising. Handle the neonate carefully during bathing. Any break in the skin easily results in an infection.

A toddler's skin layers become more tightly bound together. Thus the child has a greater resistance to infection and skin irritation. However, because of his or her more active play and the absence of established hygiene habits, parents and caregivers need to provide thorough hygiene and teach good hygiene habits.

During adolescence the growth and maturation of the integument increases. In girls estrogen secretion causes the skin to become soft, smooth, and thicker with increased vascularity. In boys male hormones produce an increased thickness of the skin with some darkening in color. Sebaceous glands become more active, predisposing adolescents to **acne** (i.e., active inflammation of the sebaceous glands accompanied by pimples). Sweat glands become fully functional during puberty. Adolescents usually begin to use antiperspirants. More frequent bathing and shampooing also become necessary to reduce body odors and eliminate oily hair.

The condition of the adult's skin depends on hygiene practices and exposure to environmental irritants. Normally the skin is elastic, well hydrated, firm, and smooth. When an adult bathes frequently or is exposed to an environment with low humidity, it becomes dry and flaky. With aging the rate of epidermal cell replacement slows, and the skin thins and loses resiliency. Moisture leaves the skin, increasing the risk for bruising and other types of injury. As the production of lubricating substances from skin glands decreases, the skin becomes dry and itchy (Meiner, 2011). These changes warrant caution when turning and repositioning older adults and when bathing. Too-frequent bathing and bathing with hot water or harsh soap cause the skin to become excessively dry (American Academy of Dermatology, 2009).

Feet and Nails. With aging and continued exposure the patient is more likely to develop chronic foot problems as a result of poor foot care, improper fit of footwear, and systemic disease. Older adults do not always have the strength, flexibility, visual acuity, or manual dexterity to care for their feet and nails. Long or roughened nails lead to traumatic nail avulsions in which the nail plate is torn from the nail bed (Berridge, 2009).

Older adults often have dry feet because of a decrease in sebaceous gland secretion and dehydration of epidermal cells. Common problems of the feet affecting older adults include corns, calluses, bunions, hammertoe, and fungal infections (Wright, 2009). Older adults frequently complain of foot pain (Meiner, 2011). Painful feet result from a variety of congenital deformities, weak structure, injuries, and diseases such as diabetes and rheumatoid arthritis.

The Mouth. At approximately 6 to 8 months of age, infants begin teething. The first permanent (secondary) teeth erupt at about 6 years of age (Hockenberry and Wilson, 2011). From adolescence, when all of the permanent teeth are in place, through

middle adulthood, the teeth and gums remain healthy if a person follows healthy eating patterns and dental care. Avoiding fermentable carbohydrates and sticky sweets helps to keep the teeth free of **caries.** In addition, regular brushing and flossing help to prevent caries and periodontal disease.

As a person ages, numerous factors result in poor oral health. These include age-related changes of the mouth, chronic disease such as diabetes, physical disabilities involving hand grasp or strength affecting the ability to perform oral care, lack of attention to oral care, and prescribed medications that have oral side effects. Gums lose vascularity and tissue elasticity, which causes dentures to fit poorly. If the older adult becomes **edentulous** (i.e., without teeth) and wears complete or partial dentures, include assessment of underlying gums and palate.

Hair. Throughout life changes in the growth, distribution, and condition of the hair influence hair hygiene. As males reach adolescence, shaving becomes a part of routine grooming. Young girls who reach puberty often begin to shave their legs and axillae. With aging, as scalp hair becomes thinner and drier, shampooing is usually performed less frequently.

Eyes, Ears, and Nose. Chapter 49 addresses changes in hearing, vision, and olfaction across the life span as a result of growth and development. Alterations in sensory function often require modifications in hygiene care. Use your knowledge of developmental changes when planning hygienic care.

Physical Condition. Patients with certain types of physical limitations or disabilities associated with disease and injury lack the physical energy and dexterity to perform hygiene self-care safely. A patient whose arm is in a cast or who has an IV line needs help with hygiene care. A weakened grasp resulting from arthritis, stroke, or muscular disorders makes using a toothbrush, washcloth, or hairbrush difficult or ineffective. Sensory deficits not only alter a patient's ability to perform care but also place the patient at risk for injury. Safety is a priority for a patient with a sensory deficit. For example, the inability to feel that the water is too hot can lead to a burn injury during bathing.

Chronic illnesses such as cardiac disease, cancer, neurological disorders, and some mental health illnesses often exhaust or incapacitate patients. Patients who become fatigued frequently need to have complete hygiene care provided. Include periods of rest during care to allow patients who are fatigued the opportunity to participate in their care. Pain often accompanies illness and injury, limiting a patient's ability to tolerate hygiene and grooming activities or perform self-care. Pain frequently limits ROM, resulting in impaired use of the arms or hands or limited ability to move about in the environment, impairing the ability to perform hygiene self-care. Sedation and drowsiness associated with analgesics used for pain management also limit a patient's ability to safely participate in care.

Limited mobility caused by a variety of factors (e.g., physical injury, weakness, surgery, pain, prolonged inactivity, medication effect, and presence of indwelling catheter or IV line) decreases a patient's ability to perform hygiene self-care activities safely. Individualized care considers a patient's ability to perform care, the amount of assistance needed, and the need for assistive and safety devices to facilitate safe hygiene care.

Acute and chronic cognitive impairments such as stroke, brain injury, psychoses, and dementia often result in the inability to perform self-care independently. When people with cognitive impairments are unaware of their hygiene and grooming needs, they become fearful and agitated during hygiene care, resulting in aggressive behavior (Hoeffer et al., 2006). Safe, effective patient care takes the effect of cognitive impairment on hygiene care into consideration and allows for appropriate modifications.

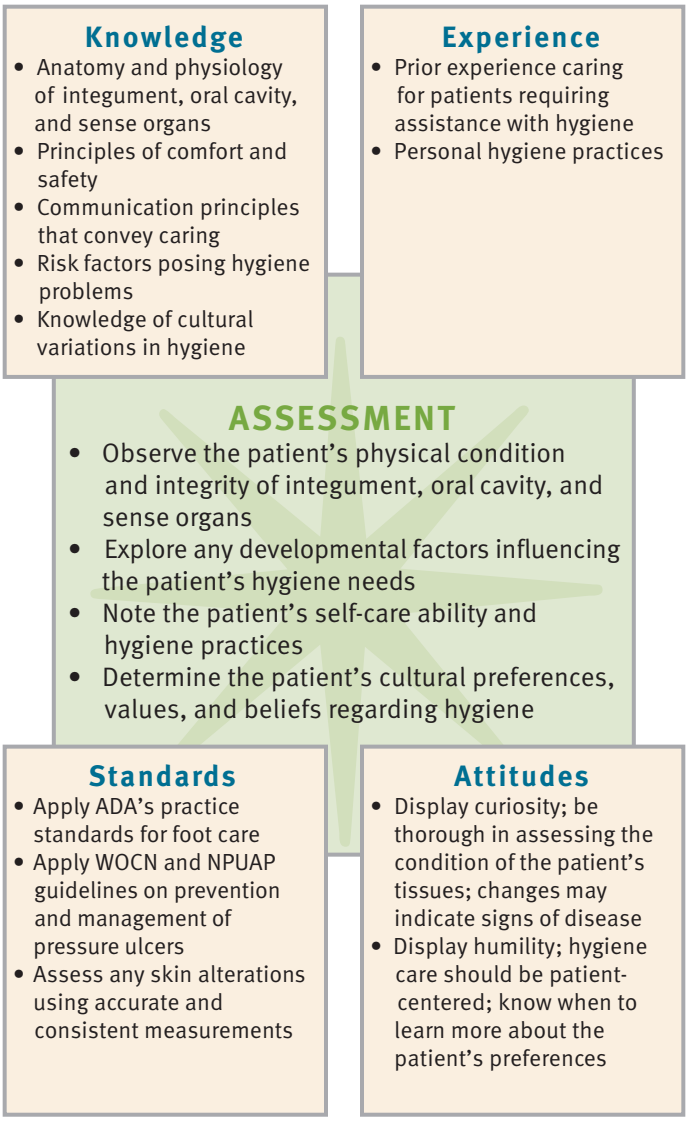

FIG. 39-1 Critical thinking model for hygiene assessment. *ADA,* American Diabetes Association; *NPUAP,* National Pressure Ulcer Advisory Panel; *WOCN,* Wound Ostomy Continence Nurses.

CRITICAL THINKING

Effective critical thinking requires synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information necessary to analyze data and make decisions regarding care. A patient's condition is always changing, requiring ongoing critical thinking. During assessment consider all elements that build toward making appropriate nursing diagnoses (Fig. 39-1). Apply the elements of critical thinking as you use the nursing process to meet patients' hygiene needs.

Integrate nursing knowledge with knowledge from other disciplines. For example, the patient with diabetes mellitus has special needs for nail and foot care. Knowledge about the pathophysiology of diabetes and its potential effects on his or her peripheral circulation and sensory status provides the scientific knowledge base

needed to implement safe and effective foot care. In addition, integrate knowledge about developmental and cultural influences as you identify and meet hygiene needs.

Be aware of the impact of critical thinking attitudes as you plan and implement care. For example, think creatively to help patients adapt existing hygiene practices or develop new hygiene practices when illness or loss of function impairs self-care abilities. Be nonjudgmental and confident when providing care. Because of variations in individual patients' physical status and hygiene practices, you need to approach care with an attitude of flexibility. For example, when caring for a patient who is fatigued, you pace activities and plan rest periods during hygiene care to prevent exhaustion.

Draw on your own experiences as you assist with your patients' hygiene care. Reflect on times when you helped family members or others close to you with their hygiene. Usually an early clinical experience involves providing or assisting with hygiene care for a patient. Finally rely on professional standards such as those for skin and foot care from the American Diabetes Association (ADA) and specialty nursing groups such as Wound Ostomy Continency Nurses (WOCN) when planning care to meet a patient's hygiene needs. As your experience and knowledge grow, your comfort and expertise in meeting the individualized hygiene needs of your patients increase.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Assessment of a patient's hygiene status and self-care abilities requires you to complete a nursing history and perform a physical assessment. You do not routinely assess all body regions before providing hygiene. However, you need to conduct a brief history to determine priority areas and help you plan individualized hygiene care. Assessment of a patient's ability to provide hygiene self-care helps you make decisions about the kind and amount of hygiene care to provide and how much the patient can be encouraged to participate in care.

Through the Patient's Eyes. Providing safe, quality hygiene care requires a complete awareness of the patient's perspective. Because patients have varying expectations, you need to avoid making personal hygiene care a simple routine. Complete a nursing history that not only elicits personal preferences but also addresses the patient's cultural or religious customs and beliefs.

Explore the patient's viewpoint regarding hygiene care by asking him or her about preferred personal hygiene and grooming practices. Ask about personal care products desired and preferences such as frequency, time of day, and amount of assistance needed. Also ask questions such as "To make you most comfortable and feel at home, how can I best perform your bath and personal care?" Determine the patient's awareness of any hygiene-related problems and his or her knowledge and ability to perform hygiene care measures (Box 39-2). Learning a patient's expectations and applying them in practice fosters a caring relationship. Fully individualizing hygiene care shows the nurse's respect for the patient's needs. As you learn what the patient expects, you incorporate this information into a plan of care.

BOX 39-2 NURSING ASSESSMENT QUESTIONS

Cultural and/or Religious Practices
- Do any cultural or religious practices affect your personal hygiene care?
- How can I include these in your care?

Tolerance of Hygiene Activities
- Do hygiene activities cause any symptoms such as shortness of breath, pain, or fatigue?
- What can I do to minimize these symptoms?
- Which aspects of hygiene care worsen your discomfort or make you fatigued?

Assistance with Hygiene
- Do you use any aids to help you with your bath such as grab bars in your tub or shower?
- Do you prefer someone of the same gender to assist in your hygiene care?
- Which parts of personal hygiene can you do for yourself? With which parts of hygiene care do you need help?

Skin Care
- Which type of bath do you prefer?
- How often and when do you usually bathe?
- What kind of soap and lotion do you use?
- Have you noticed any skin changes or irritation?
- Do you have any known allergies or reactions to soaps, cosmetics, or skin care products?

Mouth Care
- Do you have any mouth pain or toothaches, or have you noticed any sores in your mouth?
- Do you wear dentures or a partial plate?

Foot and Nail Care
- How do you usually care for your feet and nails? Do you soak your feet?
- Do you file or trim your own fingernails and toenails?

Hair and Scalp Care
- Have you recently experienced itching of the scalp or noticed flaking or dandruff?
- Have you noticed any changes in the texture or thickness of your hair?

Assessment of Self-Care Ability. Assess a patient's physical status as it relates to ability to perform or assist with hygiene care safely and efficiently; include assessment of the patient's muscle strength, flexibility, balance, visual acuity, and ability to detect thermal and tactile stimuli. Determine your patient's mental status, including orientation and cognitive function (see Chapter 30). The patient with impaired cognitive function may be unaware of hygiene care needs or less able to follow instructions and assist with care. Observe the patient performing hygiene care, noting complaints or physical manifestations that suggest activity intolerance. Assess respiratory rate and effort, skin color, and pulse rate. Ask questions to assess the patient for dizziness, weakness, or fatigue. To determine the amount of assistance the patient needs, observe him or her performing care activities such as brushing teeth or combing hair (Fig. 39-2). Patients who have limited upper-extremity mobility, reduced vision, fatigue, or inability to grasp small objects require assistance. For example, current evidence

FIG. 39-2 The nurse observes the patient brushing teeth. During such observations the nurse can determine how much assistance the patient may need.

shows that older adults who have poor hand function have more dental plaque when they perform their own oral care (Padilha et al., 2007). Also note the presence of equipment such as IV lines or urinary catheters. When patients have self-care limitations, family may assist with care. Determine how the family can help the patient, how often they can provide this assistance, and what their feelings are about being caregivers. In addition, assess the home environment and its influence on the patient's hygiene practices. Are there barriers in the home that affect his or her self-care abilities? Water faucets that are too tight to adjust easily, bathtubs with high sides, and a bathroom too small to fit a chair in front of a sink are a few examples.

Assessment of the Skin. Perform an assessment of the skin (see Chapter 30), noting color, texture, thickness, turgor, temperature, and hydration. In the healthy person the skin is smooth, warm, and supple with good turgor. Pay special attention to the presence and condition of any lesions. Note dryness of the skin indicated by flaking, redness, scaling, and cracking. Discovering manifestations of common skin problems influences how you administer hygiene care (Table 39-2).

TABLE 39-2 Common Skin Problems

CHARACTERISTICS	IMPLICATIONS	INTERVENTIONS
Dry Skin		
Flaky, rough texture on exposed areas such as hands, arms, legs, or face	Skin becomes infected if epidermal layer cracks.	Bathe less frequently and rinse body of all soap because residue left on skin can cause irritation and breakdown. Add moisture to air with use of humidifier. Increase fluid intake when skin is dry. Use moisturizing cream to aid healing. (Cream forms protective barrier and helps maintain fluid within skin.) Use creams to clean skin that is dry or allergic to soaps and detergents.
Acne		
Inflammatory, papulopustular skin eruption, usually involving bacterial breakdown of sebum; appears on face, neck, shoulders, and back	Infected material within pustule spreads if area is squeezed or picked. Permanent scarring can result.	Wash hair and skin thoroughly each day with warm water and soap to remove oil. Use cosmetics sparingly because oily cosmetics or creams accumulate in pores and tend to make condition worse. Implement dietary restrictions if necessary. (Eliminate foods that aggravate condition from diet.) Use prescribed topical antibiotics for severe forms of acne.
Skin Rashes		
Skin eruptions that result from overexposure to sun or moisture or from allergic reaction (flat or raised, localized or systemic, pruritic or nonpruritic)	If skin is continually scratched, inflammation and infection may occur. Rashes also cause discomfort.	Wash area thoroughly and apply antiseptic spray or lotion to prevent further itching and aid in healing process. Apply warm or cold soaks to relieve inflammation if indicated.
Contact Dermatitis		
Inflammation of skin characterized by abrupt onset with erythema; pruritus; pain; and appearance of scaly, oozing lesions (seen on face, neck, hands, forearms, and genitalia)	Dermatitis is often difficult to eliminate because person is usually in continual contact with substance causing skin reaction. Substance is often hard to identify.	Avoid causative agents (e.g., cleansers and soaps).
Abrasion		
Scraping or rubbing away of epidermis that results in localized bleeding and later weeping of serous fluid	Infection occurs easily because of loss of protective skin layer.	Be careful not to scratch patient with jewelry or fingernails. Wash abrasions with mild soap and water; dry thoroughly and gently. Observe dressing or bandage for retained moisture because it increases risk of infection.

Determine the degree of cleanliness by observing the appearance of the skin and detecting body odors that possibly indicate inadequate cleansing or excessive perspiration caused by fever or pain. Inspect less obvious or difficult-to-reach skin surfaces such as under the breasts or scrotum, around the female patient's perineum, or in the groin for redness, excessive moisture, and soiling or debris. Separate skinfolds for observation and palpation.

Be attentive to characteristics of skin problems most influenced by hygiene measures. Is the skin dry from too much bathing or from use of hot water or irritating soap? Does the patient have a rash caused by an allergic reaction to a skin care product? Certain conditions place patients at risk for impaired skin integrity (Box 39-3). Because of increased risk be particularly alert when assessing patients with reduced sensation, impaired circulation, nutrition or hydration alterations, body secretions, incontinence, altered cognition, external devices, and decreased mobility. Patients may be unaware of skin problems because they are unable to feel pain or pressure or see their skin in some places (e.g., the back or the feet). Carefully assess the skin under orthopedic devices (braces, splints, casts) and beneath items such as antiembolic stockings and tape. Assess the condition and cleanliness of the perineal and anal areas during hygiene care and when the patient requires toileting assistance. When prolonged contact of urine or feces occurs such as with diarrhea or incontinence, skin breakdown often results. Most people consider these areas to be private. Use sensitivity in your approach.

When caring for patients with dark skin pigmentation, be aware of assessment techniques and skin characteristics unique to highly pigmented skin (see Chapter 30). Carefully assess the skin in dark-skinned patients at risk for pressure ulcers (see Chapter 48).

Assessment of the Feet and Nails. A variety of common foot and nail problems can be caused by inadequate hygiene and are actually detected during hygiene care. Problems sometimes result from abuse or poor care of the feet and hands such as nail biting or trimming nails improperly, exposure to harsh chemicals, and wearing poorly fitting shoes. Question the patient to determine type of footwear and usual foot and nail care practices.

Examine all skin surfaces of the feet, including the areas between the toes and over the entire sole of the foot. Poorly fitting shoes often irritate the heels, soles, and sides of the feet. Inspection of the feet for lesions includes noting areas of dryness, inflammation, or cracking. Chronic foot problems are common in older adults who often experience dry feet because of a decrease in sebaceous gland secretion, dehydration, or poor condition of footwear.

People are often unaware of foot or nail problems until pain or discomfort occurs. Assess patients with diseases that affect peripheral circulation and sensation for the adequacy of circulation and sensation of the feet. Foot ulceration is the most common single precursor to lower-extremity amputations among people with diabetes (Frykberg et al., 2006). Daily inspection and preventive foot care help maintain ulcer-free feet. Palpate the dorsalis pedis and posterior tibial pulses and assess for intact sensation to light touch, pinprick, and temperature (see Chapter 30).

Observe the patient's gait. Painful foot disorders or decreased sensation cause limping or an unnatural gait. Ask whether the patient has foot discomfort and determine factors that aggravate the pain. Foot problems sometimes result from bone or muscular alterations or wearing poorly fitting footwear.

Inspect the condition of the fingernails and toenails, looking for lesions, dryness, inflammation, or cracking, which are often associated with a variety of common nail problems (Table 39-3). The cuticle that surrounds the nail can grow over it and become inflamed if nail care is not performed correctly and periodically. Ask women whether they frequently polish their nails and use polish remover because chemicals in these products cause excessive nail dryness. Disease changes the shape and curvature of the nails (see Chapter 30). Inflammatory lesions and fungus of the nail bed cause thickened, horny nails that separate from the nail bed.

Assessment of the Oral Cavity. The condition of the oral cavity reflects overall health and also indicates oral hygiene needs. Inspect all areas of the mouth carefully for color, hydration, texture, and lesions (see Chapter 30). Patients frequently develop common oral problems as a result of inadequate oral care or consequence of disease (e.g., oral malignancy) or as a side effect of treatments such as radiation and chemotherapy. These problems include receding gum tissue, inflamed gums (gingivitis), a coated tongue, **glossitis** (inflamed tongue), discolored teeth (particularly along gum margins), dental caries, missing teeth, and **halitosis** (foul-smelling breath). Localized pain and infection commonly accompany oral problems. Apply clean gloves to palpate any tender areas or lesions. Observe for cleanliness and use olfaction to detect halitosis. If you

BOX 39-3 RISK FACTORS FOR SKIN IMPAIRMENT

Immobilization
When restricted from moving freely, dependent body parts are exposed to pressure that reduces circulation to affected tissues. Know which patients require help to turn and change positions.

Reduced Sensation
Patients with paralysis, circulatory insufficiency, or local nerve damage are unable to sense an injury to the skin. During a bath assess the status of sensory nerve function by checking for pain, tactile sensation, and temperature sensation.

Nutrition and Hydration Alterations
Patients with limited caloric and protein intake develop thinner, less elastic skin with loss of subcutaneous tissue, which results in impaired or delayed wound healing.

Secretions and Excretions on the Skin
Moisture on the surface of the skin serves as a medium for bacterial growth and causes irritation, softens epidermal cells, and leads to skin maceration. Presence of perspiration, urine, watery fecal material, and wound drainage on the skin results in breakdown and infection.

Vascular Insufficiency
Inadequate arterial supply to tissues and impaired venous return decrease circulation to the extremities. Inadequate blood flow causes ischemia and breakdown. Risk of infection also exists because delivery of nutrients, oxygen, and white blood cells to injured tissues is inadequate.

External Devices
An external device applied to or around the skin exerts pressure or friction on the skin. Assess all surfaces exposed to casts, cloth restraints, bandages and dressings, tubing, or orthopedic braces.

Altered Cognition
Patients who have decreased level of awareness as a result of altered thought processes may be unaware of or unable to verbalize their skin care needs. They may not realize the effect of pressure or prolonged contact with secretions or excretions. Be extra vigilant for warning signs of skin breakdown and provide preventive hygiene care.

TABLE 39-3 Common Foot and Nail Problems

CHARACTERISTICS	IMPLICATIONS	INTERVENTIONS
Callus		
Thickened portion of epidermis consists of mass of horny, keratotic cells. Callus is usually flat, painless, and found on undersurface of foot or palm of hand.	Local friction or pressure causes callus formation, which causes discomfort when wearing tight shoes.	Soft-sole shoes with insoles are recommended. Advise patient to wear gloves when using tools or objects that create friction on palmar surfaces. Advise patients, especially with callus formation, not to self-treat but seek interventions from a podiatrist.
Corns		
Friction and pressure from ill-fitting or loose shoes causes keratosis. It is seen mainly on or between toes, over bony prominence. Corn is usually cone shaped, round, and raised. Soft corns are macerated.	Compresses the underlying dermis, making it thin and tender. Pain is aggravated when wearing tight shoes. Tissue becomes attached to bone if allowed to grow. Patient suffers alteration in gait resulting from pain.	Surgical removal is necessary, depending on severity of pain and size of corn. Avoid use of oval corn pads, which increase pressure on toes and reduce circulation. Warm water soaks soften corns before gentle rubbing with a callus file or pumice stone (consult with health care provider). Wider and softer shoes, especially shoes with a wider toe box, are helpful.
Plantar Warts		
Fungating lesion appears on sole of foot and is caused by the papilloma virus.	Some warts are contagious. They are painful and make walking difficult.	Treatment ordered by health care provider often includes applications of salicylic acid, electrodessication (burning with electrical spark), or freezing with solid carbon dioxide.
Athlete's Foot (Tinea Pedis)		
Athlete's foot is fungal infection of foot; scaling and cracking of skin occurs between toes and on soles of feet. Small blisters containing fluid appear.	Athlete's foot spreads to other body parts, especially hands. It is contagious and frequently recurs.	Make sure that feet are well ventilated. Drying feet well after bathing and applying powder help prevent infection. Wearing clean socks or stockings reduces incidence. Health care provider orders application of griseofulvin, miconazole, or tolnaftate.
Ingrown Nails		
Toenail or fingernail grows inward into soft tissue around nail. Ingrown nail often results from improper nail trimming.	Ingrown nails cause localized pain when pressure is applied.	Treatment is frequent hot soaks in antiseptic solution and removal of part of nail that has grown into skin. Instruct patient in proper nail-trimming techniques and refer to podiatrist.
Foot Odors		
Foot odors are result of excess perspiration, promoting microorganism growth.	Condition causes discomfort because of excess perspiration.	Frequent washing, use of foot deodorants and powders, and wearing clean footwear prevent or reduce problem.

identify any oral problems, notify the patient's health care provider. Early identification of poor oral hygiene practices and common oral problems reduces the risk for gum disease and dental caries.

Assessment of the Hair and Hair Care. Before performing hair care, assess the condition of the patient's hair and scalp. Findings help determine the frequency and type of care needed. Normally the hair is clean, shiny, and untangled; and the scalp is clear of lesions. Table 39-4 summarizes hair and scalp problems with implications and interventions.

Observe the patient's ability to perform hair care. A person's appearance and feeling of well-being often are related to the way the hair looks and feels. Illness, disability, and conditions such as arthritis, fatigue, and the presence of physical barriers (e.g., cast or IV access) alter a patient's ability to maintain daily hair care.

In community health and home care settings it is particularly important to inspect the hair for lice so you can provide appropriate hygienic treatment. If you suspect **pediculosis capitis** (head lice), guard against self-infestations by handwashing and using gloves or tongue blades to inspect the patient's hair.

The loss of hair **(alopecia)** results from the effects of chemotherapy medications, hormonal changes, or improper hair care practices. Alopecia often appears as brittle and broken hair in the hair line that progresses to bald patches. If noted, be sure to question the patient about specific hair care practices, especially the use of chemicals and heat application during hair care.

Assessment of the Eyes, Ears, and Nose. Examine the condition and function of the eyes, ears, and nose (see Chapter 30). The healthy eye is not inflamed and is without drainage. The presence of redness indicates allergic or infectious conjunctivitis, which can be highly contagious. The crusty drainage associated with conjunctivitis easily spreads from one eye to the other. Wear clean gloves to examine the eyes and perform proper hand hygiene before and after the examination. Determine if a patient wears contact lenses, especially when he or she enters the health care agency in an unresponsive or confused state. To determine if a contact lens is present, stand to the side of the patient's eyes and observe the corneas for the presence of a soft or rigid lens. Also observe the sclera because the lens may have shifted off the cornea. An undetected contact lens causes corneal injury when left in place too long.

Assessment of the external ear structures includes inspection of the auricle and external ear canal (see Chapter 30). Observe for the presence of accumulated **cerumen** (earwax) or drainage in the ear

TABLE 39-4 Hair and Scalp Problems

CHARACTERISTICS	IMPLICATIONS	INTERVENTIONS
Dandruff		
Scaling of scalp is accompanied by itching. In severe cases dandruff is on eyebrows.	Dandruff causes person embarrassment. If it enters eyes, conjunctivitis often develops.	Shampoo regularly with medicated shampoo. In severe cases obtain health care provider's advice.
Ticks		
Small, gray-brown parasites burrow into skin and suck blood.	Ticks transmit several diseases to people. Most common are Rocky Mountain spotted fever, tularemia, and Lyme disease.	Using blunt tweezers, grasp tick as close to the head as possible and pull upward with even, steady pressure. Hold until tick pulls out, usually for about 3-4 minutes. Save tick in plastic bag and put in freezer if it is necessary to identify type of tick.
Pediculosis (Lice)		
Pediculosis Capitis (Head Lice)		
Parasite resides on scalp attached to hair strands. Eggs look like oval particles, similar to dandruff. Bites or pustules may be observed behind ears and at hairline.	Head lice are difficult to remove and spread to furniture and other people if not treated. They do not carry disease, cannot fly or jump, and are carried by animals.	Wearing gloves, check entire scalp by using a tongue depressor or special lice comb. Use medicated shampoo for eliminating lice. *Caution against use of products containing lindane because the ingredient is toxic and known to cause adverse reactions* (CDC, 2008). Manual removal is best option when treatment has failed. Vacuum infested areas of home.
Pediculosis Corporis (Body Lice)		
Parasites tend to cling to clothing; thus they are not always easy to see. Body lice suck blood and lay eggs on clothing and furniture.	Patient itches constantly. Scratches seen on skin become infected. Hemorrhagic spots appear on skin where lice are sucking blood.	Bathe or shower thoroughly. After skin is dried, apply recommended pediculicide lotion. After 12 to 24 hours take another bath or shower. Bag infested clothing or linen until laundered in hot water. Vacuum rooms thoroughly and throw away bag after completion.
Pediculosis Pubis (Crab Lice)		
Parasites are in pubic hair. Crab lice are gray-white with red legs.	Lice spread through bed linen, clothing, or furniture or between people via sexual contact.	Shave hair off affected area. Clean as for body lice. If lice were sexually transmitted, notify partner.
Hair Loss (Alopecia)		
Alopecia occurs in all races. Balding patches are in periphery of hair line. Hair becomes brittle and broken.	Patches of uneven hair growth and loss alter patient's appearance.	Stop hair care practices that damage hair. The use of hair curlers, hair picks, tight braiding, and hot comb contributes to hair-loss condition.

canal and local inflammation. Question patients about tenderness on palpation or the presence of pain and ask how they usually clean their ears.

Inspect the nares for signs of inflammation, discharge, lesions, edema, and deformity (see Chapter 30). The nasal mucosa is normally pink and clear and has little or no discharge. Allergies cause a clear, watery discharge. If patients have any form of tubing exiting the nose (e.g., nasogastric), observe for tissue damage, localized tenderness, inflammation, drainage, and bleeding where the tubing comes in contact with the nares..

Use of Sensory Aids. For patients who wear eyeglasses, contact lenses, artificial eyes, or hearing aids, assess their knowledge and methods used for care and have them describe the typical approach used in routine care. When possible observe the patient performing care. Compare information gathered from him or her with the proper care technique for these devices. Any difference between patient and standard practice provides an opportunity for patient education.

Assessment of Hygiene Care Practices. Assessment of hygiene practices reveals the patient's preferences for grooming. For example, a patient chooses to groom the hair in a certain style or trim nails in a certain way. When a patient has a physical disability, special precautions may be necessary to perform grooming without injury. For example, teach patients with loss of sensation to file nails instead of clipping. By observing the patient perform hygiene care, you can detect any needed areas of teaching or assistance while maintaining the patient's maximal level of independence.

Assessment of Cultural Influences. A patient's cultural background influences hygiene needs. Culture plays a role not only in hygiene practices and preferences but also in sensitivity to personal space and gender sensitivity (see Box 39-1 and Chapter 9). Ask what makes the patient feel most comfortable during a bath. Perhaps he or she prefers a partial instead of a full bath from the nurse, with a family member completing the bathing of more private body parts. Some patients also defer part of hygiene. If you believe that hygiene is critical to prevent developing or worsening problems such as skin breakdown, take the time to understand the patient's concerns and then offer an explanation that helps him or her accept your intervention.

Patients at Risk for Hygiene Problems. Some patients present risks that require more attentive and rigorous hygiene care (Table 39-5). These risks result from side effects of medications or other medical therapy; a lack of knowledge; immobilization; an inability to perform hygiene; or a physical condition that potentially injures the skin, mouth, feet and nails, or hair. Anticipate whether a patient is predisposed to risks and follow through with a complete assessment. For example, if a patient is receiving cancer chemotherapy, there is a risk of the medication producing ulcerations of the mouth, which are painful and create a risk for infection and impaired nutrition because of reluctance to eat and drink.

TABLE 39-5 Risk Factors for Hygiene Problems

RISKS	HYGIENE IMPLICATIONS
Oral Problems	
Patients who are unable to use upper extremities because of paralysis, weakness, or restriction (e.g., cast, dressing)	Patient lacks upper-extremity strength or dexterity needed to brush teeth (Lewis et al., 2011).
Dehydration, inability to take fluids or food by mouth (NPO)	Dehydration causes excess drying and fragility of mucosa; increases accumulation of secretions on tongue and gums.
Presence of nasogastric or oxygen tubes; mouth breathers	Tubes cause drying of mucosa and lips.
Chemotherapeutic drugs	Drugs kill rapidly multiplying cells, including normal cells lining oral cavity. Ulcers and inflammation develop.
Lozenges, cough drops, antacids, and chewable over-the-counter vitamins	Medications contain large amounts of sugar. Repeated use increases sugar or acid content in mouth, causing dental caries.
Radiation therapy to head and neck	Radiation therapy reduces salivary flow and lowers pH of saliva; leads to stomatitis and tooth decay (Lewis et al., 2011).
Oral surgery, trauma to mouth, placement of oral airway	These cause trauma to oral cavity with swelling, ulcerations, inflammation, and bleeding.
Immunosuppression; altered blood clotting	These predispose to inflammation and bleeding gums.
Diabetes mellitus	Patients are prone to dryness of mouth, gingivitis, periodontal disease, and loss of teeth.
Endotracheal intubation with mechanical ventilation	Potential for ventilator-associated pneumonia (VAP) exists. Use of chlorhexidine reduces risk of VAP. Chlorhexidine is an inexpensive effective agent for reducing VAP, especially in patients who have heart surgery (Berry et al., 2007).
Dialysis	Oral problems commonly found in these patients include halitosis, xerostomia (dry mouth), gingivitis, stomatitis, tooth decay, tooth loss, and jaw problems. Causes include decreased saliva production, uremia, and inattention to care (Gonyea, 2009).
Skin Problems	
Immobilization	Dependent body parts are exposed to pressure from underlying surfaces. The inability to turn or change position increases risk for pressure ulcers.
Reduced sensation caused by stroke, spinal cord injury, diabetes, local nerve damage	Patient does not receive normal transmission of nerve impulses when applying excessive heat or cold, pressure, friction, or chemical irritants to skin.
Limited protein or caloric intake and reduced hydration (e.g., fever, burns, gastrointestinal alterations, poorly fitting dentures)	Limited caloric and protein intake predispose to impaired tissue synthesis. Skin becomes thinner, less elastic, and smoother with a loss of subcutaneous tissue. Poor wound healing results. Reduced hydration impairs skin turgor.
Excessive secretions or excretions on skin from perspiration, urine, watery fecal material, and wound drainage	Moisture is a medium for bacterial growth and causes local skin irritation, softening of epidermal cells, and skin maceration.
Presence of external devices (e.g., cast, restraint, bandage, dressing)	Device exerts pressure or friction against surface of skin.
Vascular insufficiency	Arterial blood supply to tissues is inadequate, or venous return is impaired, causing decreased circulation to extremities. Tissue ischemia and breakdown often occur. Risk for infection is high.
Foot Problems	
Patient unable to bend over or has reduced visual acuity	Patient is unable to fully visualize entire surface of each foot, impairing ability to adequately assess condition of skin and nails.
Eye Care Problems	
Reduced dexterity and hand coordination	Physical limitations create inability to safely insert or remove contact lenses.

A patient who receives broad-spectrum antibiotics develops an opportunistic infection when the normal flora of the mouth is disrupted by the antibiotic. These examples demonstrate the need to identify patients at risk and be thorough and detailed during the oral examination, checking all surfaces of the tongue and mucosa. For a patient who is diaphoretic, provide special attention to body areas such as beneath the woman's breasts and in the groin and perineal area, where moisture collects and irritates skin surfaces. Anticipate problems created by these risks to provide preventive care. Assessment includes a review of the patient's medical and surgical history, medications, and the specific risk factors that the patient presents.

NURSING DIAGNOSIS

Thorough assessment of a patient's hygiene status and self-care abilities identifies clusters of data or defining characteristics that support actual or at-risk hygiene-related diagnoses. Identification of the defining characteristics leads you to select the NANDA International diagnostic label that best communicates the individual

BOX 39-4 NURSING DIAGNOSTIC PROCESS

Bathing Self-Care Deficit

ASSESSMENT ACTIVITIES	FINDINGS/DEFINING CHARACTERISTICS
Observe patient attempt to bathe self.	Patient is unable to wash lower body, back, or perineal area.
Assess patient's upper-extremity strength and range of motion.	Patient has restricted upper-extremity range of motion and weakness and is unable to turn water faucets on and off.
Observe patient's ability to move from bed to bathroom and to maneuver in bathroom.	Patient cannot transfer from bed to chair without assistance, cannot ambulate, relies on wheelchair to move around, is unable to maneuver the wheelchair in the bathroom without help or transfer to shower seat unassisted.

patient's situation. For example, when caring for an older adult with degenerative arthritis you observe swollen joints, weakness, and limited ROM in the dominant hand along with a generally unkempt appearance. Closer review of data reveals defining characteristics of an inability to wash body parts and difficulty turning and regulating a water faucet. The nursing diagnosis of *bathing self-care deficit* becomes part of the plan of care. Accurate selection of nursing diagnoses requires critical thinking to identify actual or potential problems. Be thorough in assessment to reveal all appropriate defining characteristics so you can make an accurate diagnosis (Box 39-4).

Use a patient's actual alteration (e.g., *impaired tissue integrity)* or the alteration for which the patient is at risk (e.g., *risk for infection)* to determine the focus of nursing interventions. The patient with an actual alteration requires extensive hygiene care, often more thorough than routine hygiene. For example, if a patient has skin breakdown, initiate care more frequently to keep skin surfaces clean and dry and eliminate factors such as moisture or drainage that worsen skin condition. Also provide care to promote healing of injured skin surfaces (see Chapter 48). If the patient is at risk for a problem, take preventive measures. For example, if a patient is at risk for developing an infection in his or her mouth and has the nursing diagnosis *risk for infection,* keep the mucosa well hydrated, minimize foods irritating to tissues, and provide cleaning that soothes and reduces tissue inflammation.

Completing a nursing diagnosis requires identification of the related factor, which will guide your selection of nursing interventions. A diagnosis of *impaired oral mucous membrane related to malnutrition* and a diagnosis of *impaired oral mucous membrane related to chemical trauma* require different interventions. When poor nutrition is a causal factor, you need to consult with a dietitian for appropriate dietary supplements and incorporate patient education into the plan. When chemotherapy injures the oral mucosa, you follow cancer nursing guidelines regarding care for oral **mucositis** (i.e., painful inflammation of oral mucous membranes), including frequent gentle brushing with soft toothbrush, flossing, rinsing with bland rinse, limiting diet to soft foods, and applying water-based moisturizer to lips (Harris et al., 2008). Although many possible nursing diagnoses apply to patients in need of supportive hygiene care, the following list represents examples of diagnoses commonly associated with hygiene problems:

- Activity intolerance
- Bathing self-care deficit
- Dressing self-care deficit
- Impaired physical mobility
- Impaired oral mucous membrane
- Ineffective health maintenance
- Risk for infection

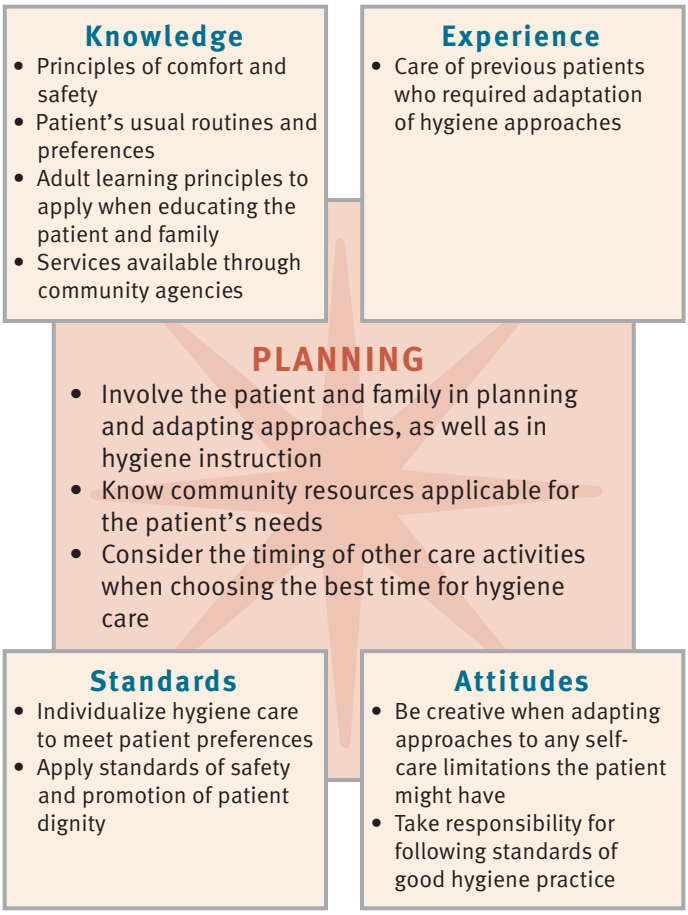

FIG. 39-3 Critical thinking model for hygiene planning.

PLANNING

During planning synthesize information from multiple resources (Fig. 39-3). Critical thinking ensures that a patient's plan of care integrates all that is known about the individual patient and key critical thinking elements. In many situations patients present with multiple nursing diagnoses. Use a concept map (Fig. 39-4) to visualize how nursing diagnoses interrelate. Rely on knowledge, experience, and established standards of care when developing the care plan. Remember critical thinking attitudes such as creativity when developing a patient-centered plan for hygiene care. Consciously include the patient in this important step of the nursing process. Identify patient goals and outcomes, set priorities for care, and select evidence-based interventions. Consider continuity of care and involve other health care team members (e.g., occupational or physical therapy) when developing the plan.

Previous experience with other patients is useful in knowing how to adapt hygiene techniques for special needs. Professional standards guide selection of the most effective nursing interventions. These standards often establish evidence-based guidelines for care.

Goals and Outcomes. Partner with the patient and family to identify goals and expected outcomes and develop an

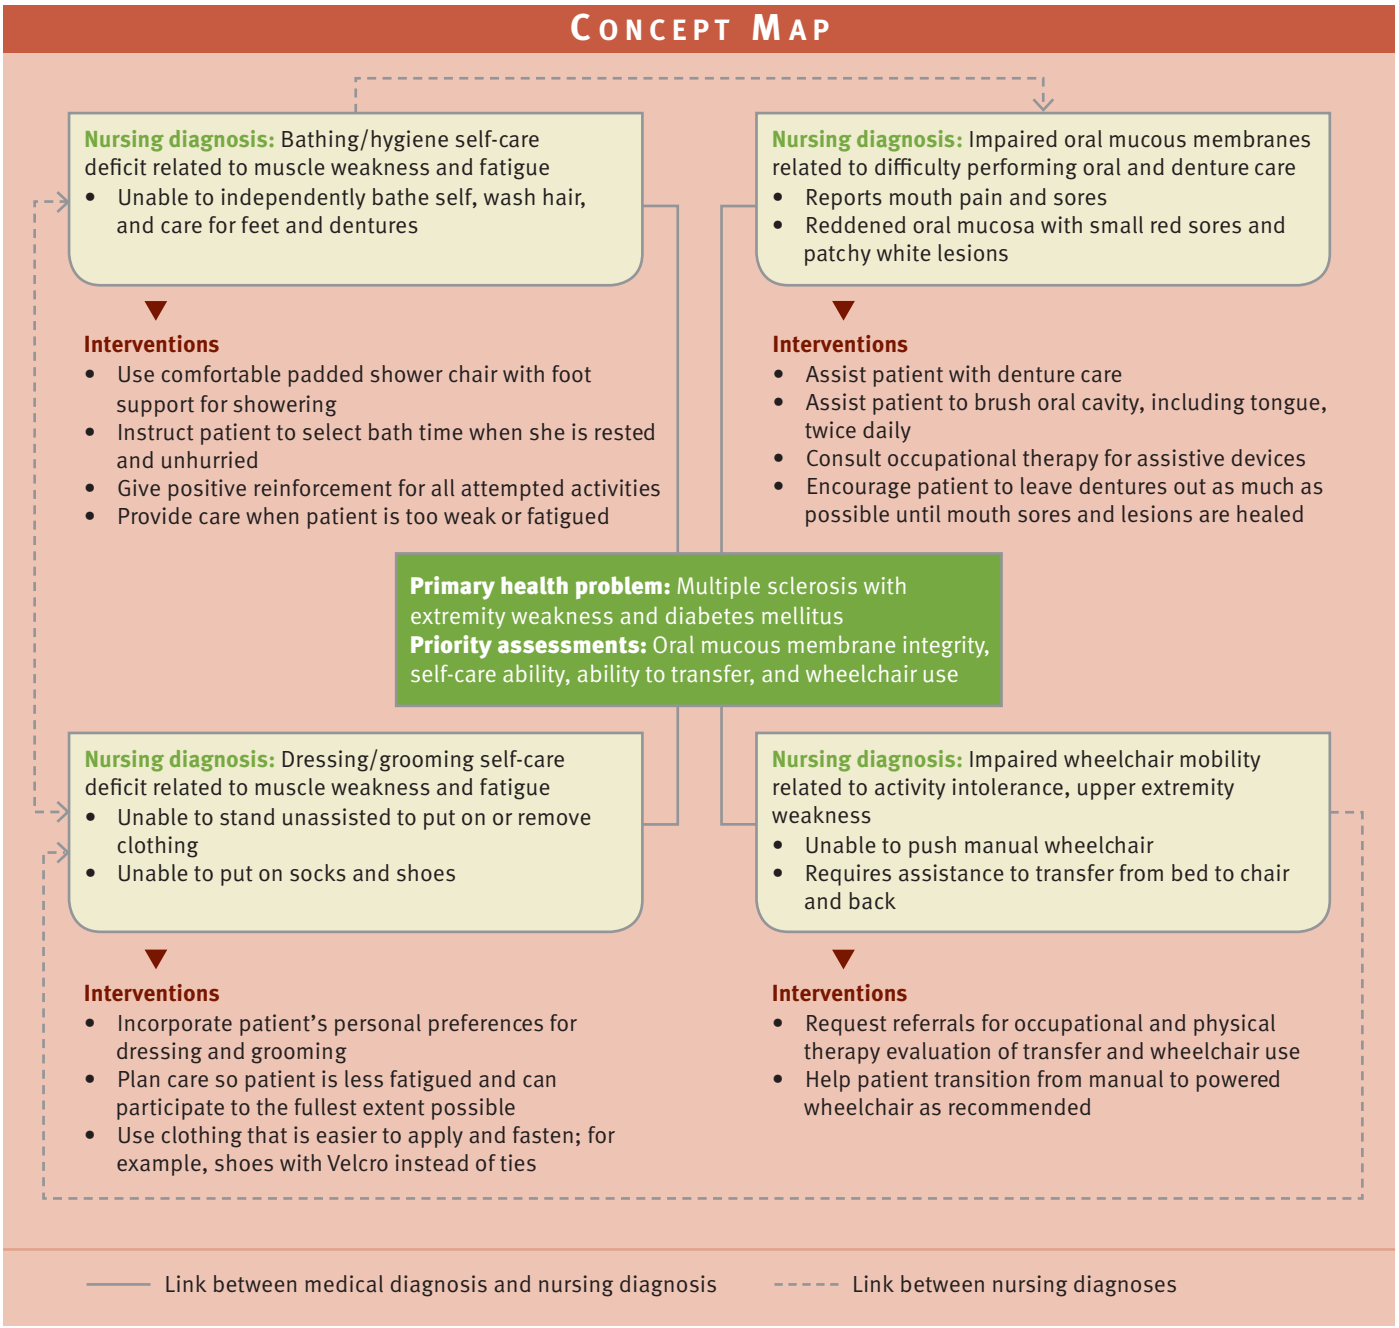

FIG. 39-4 Concept map for Mrs. Winkler.

individualized plan of care based on the patient's nursing diagnoses (see the Nursing Care Plan). For example, establish goals with the patient's self-care abilities and resources in mind and focus on maintaining or improving the condition of the skin and oral cavity. Make outcomes measurable and achievable within patient limitations. In addition, work with the patient to select individualized hygiene measures.

When providing for patient hygiene, you care for a variety of patients with different self-care abilities and needs. For example, the nurse and a patient who has one-sided paralysis following a cerebral vascular accident develop the following goal: "Patient's skin remains free of breakdown." Then the nurse establishes a series of realistic, individualized expected outcomes to measure the patient's progress toward meeting this goal. These outcomes may include the following:

- Patient's skin is clean, dry, and intact without signs of inflammation.
- Patients' skin remains elastic and well hydrated.
- Patient's skin is free from areas of pressure.

Setting Priorities. The patient's condition influences your priorities for hygiene care. Set priorities based on the necessary assistance required by the patient, the extent of the hygiene-related problems, and the nature of the patient's nursing diagnoses. For example, a seriously ill patient usually needs a daily bath because body secretions accumulate and the patient is unable to independently maintain cleanliness. Some older patients at home require

NURSING CARE PLAN

Impaired Oral Mucous Membrane

ASSESSMENT

Mrs. Winkler is a 58-year-old woman admitted recently to an extended care nursing facility with a medical history of multiple sclerosis and diabetes mellitus. She uses a wheelchair for mobility. She recently became weaker, is now unable to push the chair herself, and requires assistance with transferring to and from the chair. She has both upper- and lower-extremity weakness. She wears full dentures. Jamie Johnson is a nursing student assigned to care for Mrs. Winkler today. As Jamie is talking with Mrs. Winkler before breakfast is served, she learns that Mrs. Winkler likes to wash her face and hands and then put in her dentures. Mrs. Winkler states, "I want to stay in bed today because I'm tired and I don't feel well. I just get so weak when I do anything. Also, I think I have sores on the roof of my mouth. They really hurt."

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Winkler what care is important this morning.	Mrs. Winkler says, "I want to be able to wear my teeth and feel clean and look nice."
Assess the condition of Mrs. Winkler's oral cavity.	Mrs. Winkler **reports mouth pain and sores.** On visual inspection, Jamie observes generalized **reddened oral mucosa** with small **red sores** and **patchy white lesions** most notable on the roof of the mouth; thick secretions **coating** the gums, cheeks, and tongue; and some **bleeding** from the **inflamed, swollen tissues.** Jamie detects **halitosis.**
Assess Mrs. Winkler's ability to bathe and perform oral hygiene care, including an assessment of her range of motion and upper-extremity strength.	Mrs. Winkler states, "I have trouble holding my arms up above my waist, and I have trouble holding my brush or small things. My muscles are just so weak. I get so tired doing anything." Unable to raise arms over head with restricted shoulder range of motion to flexion of 90 degrees and upper extremity muscle strength 2/5.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Impaired oral mucous membrane related to difficulty performing oral and denture care associated with upper-extremity weakness

PLANNING

Goals	*Expected Outcomes (NOC)†*
Mrs. Winkler will verbalize preventive and routine oral and denture care by discharge.	**Knowledge: Illness Care** Mrs. Winkler will state importance of reporting signs and symptoms, including mouth tenderness and discomfort, sores, dry mouth, and presence of coating, within 2 days. Mrs. Winkler will describe correct preventive oral hygiene care practices within 1 week.
Mrs. Winkler will have return of intact oral mucosa within 1 week.	**Oral Hygiene** Mrs. Winkler's oral mucosa will be moist and free of thick coating and sores within 1 week. Mrs. Winkler's oral cavity will be odor free within 2 days. Mrs. Winkler will report mouth feels clean within 1 day.

†Outcome classification labels from Moorhead S, et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Oral Health Restoration	
Provide oral care at least twice a day, cleaning for a minimum of 90 seconds with a soft-bristled toothbrush or toothette. Explain importance of oral care and problems to report to health care provider during care.	Stimulates gums and cleans oral cavity. Recommended oral care protocol for mucositis (Harris et al., 2008). Provides patient education during routine care to enhance learning.
Assist Mrs. Winkler with rinsing mouth 4 times a day with a bland rinse (normal saline, sodium bicarbonate, or mixture of saline and sodium bicarbonate).	Rinses remove loose debris and aid in oral hydration. Sodium bicarbonate reduces acidity of oral fluids, dilutes accumulating mucus, and discourages yeast colonization (Harris et al., 2008).
Remove, clean, and do not replace dentures except for meals (if desired).	Promotes healing during cases of mild-to-moderate stomatitis (Sciubba, 2009).
Refer for dental appointment to check fit of dentures and possibility of denture-induced stomatitis.	Denture-induced stomatitis is related in part to dentures that fit poorly, especially if worn while sleeping (Sciubba, 2009).
Carefully observe oral mucosa at least twice daily, noting worsening of manifestations.	Monitor effectiveness of treatment and patient progress toward goal.

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

NURSING CARE PLAN

***Impaired Oral Mucous Membrane*—cont'd**

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mrs. Winkler about importance of reporting signs and symptoms.	Mrs. Winkler states that she now realizes that her oral discomfort and sores may be related to how she cares for her dentures and that she will report these if they recur.	Able to participate in prevention of oral problems by reporting signs and symptoms indicating a problem.
Ask Mrs. Winkler about preventive oral care.	Mrs. Winkler lists the steps that she needs to take to prevent the recurrence of oral problems. She states, "I will now always take my teeth out at night so they can soak and clean. Until my mouth sores are gone I will only wear my dentures when eating."	Although Mrs. Winkler does not currently have the ability to perform her own care, she is involved in care by requesting oral and denture care.
Assess Mrs. Winkler's oral cavity.	Mrs. Winkler's oral cavity mucosa is pink, moist, and not swollen; no lesions or sores are present. No odor is detected. No coating is observed.	Inflammation and infection in the mouth are resolved.

a visit from a home care aide to help with a tub bath or shower. Patients who are normally inactive during the day and have skin that tends to be dry may need to bathe only twice a week, whereas a patient with urinary and bowel incontinence needs perineal cleaning with each episode of soiling. Plan for necessary assistance for patients who are weakened or possess poor coordination. For example, a patient who is partially paralyzed and has difficulty getting out of a tub needs a tub chair, handrails, or extra personnel available for help.

Timing is also important in planning hygiene care. Being interrupted in the middle of a bath often frustrates and embarrasses the patient.

Teamwork and Collaboration. Plan for care throughout the stay in a hospital, including discharge to a rehabilitation facility or home. In hospital or extended care settings, work closely with nursing assistive personnel who often provide hygiene care. Provide them with the necessary information and equipment so they can provide safe, effective hygiene care. Collaborate with other health team members as indicated (e.g., work with physical therapy and occupational therapy to enhance the patient's independence with self-care activities).

When a patient needs assistance as a result of a self-care limitation, the family often becomes a valuable resource to the nurse and helps with hygiene measures. In these cases family members often need guidance in adapting techniques to fit patient limitations. Be aware of equipment and procedures used in the agency so the patient and family are knowledgeable about the care, have the skills needed to provide it, and have access to necessary equipment. Depending on the patient's limitations, some insurance plans provide staff to assist with basic hygiene needs. Explore this option with the patient and family members.

Collaborate with community agencies as needed. For example, the nurse involved in the care of a homeless patient needs to be aware of the location of clothing distribution centers for basic hygiene supplies, a shelter where bathing facilities are available, and any organization that offers free health care or reduced fees. Partner with social workers or staff in local area churches, not-for-profit organizations, and schools to be sure that patients have the resources they need to maintain hygiene.

IMPLEMENTATION

Hygiene is a part of basic patient care. Use caring practices when performing hygiene measures to reduce patient anxiety and promote comfort and relaxation. For example, while giving a patient a bath and changing a gown, use a gentle approach as you turn and reposition him or her. A soft, gentle voice while conversing with the patient helps to relieve fears or concerns. For patients suffering symptoms such as pain or nausea, administering medications to relieve the symptoms before providing hygiene interventions helps to maintain patient comfort during hygiene care. Consider the stress that hygiene care invokes and be alert for any cues of anxiety or fear. Some patients fear pain or are frightened about falling or sustaining injury associated with hygiene care.

Implementation also focuses on assisting and preparing patients to be able to perform as much of their hygiene care as they can independently. Teach patients proper hygiene techniques and signs and symptoms of hygiene problems. Inform patients about available resources in the community for dealing with these problems if they arise.

Health Promotion. In primary health care situations educate and counsel patients and caregivers on proper hygiene techniques. For example, a new mother needs to learn how to bathe her newborn, whereas an older adult needs information on the importance of regular ear care to avoid accumulated cerumen and hearing impairment. The hygiene skills described throughout this chapter provide standards for excellent physical care. When caring for patients in primary health care settings, maintain these standards and incorporate adaptations as needed to meet the patient's lifestyle, functional status, living arrangements, and preferences. Key points when teaching patients about hygiene include the following:

- Make any instruction relevant based on your assessment of the patient's knowledge, motivation, preferences, and health beliefs. For example, when teaching the patient with diabetes, include how circulation to the feet is impaired and how this causes poor healing and infection, especially when the skin is injured or broken.
- Adapt instruction to the patient's personal bathing facilities and resources. Not all patients have the ideal situation that exists in a health care setting (e.g., easily accessible shower or a bedside table to place over a bed). Adapt available resources so the patient can comfortably and safely reach and use needed items. For example, a young mother has more room and believes that bathing her infant is safer if she uses her kitchen sink and counter rather than her bathroom sink.

- Teach the patient ways to avoid injury. Almost any hygiene procedure poses risks (e.g., cutting a nail too close to the skin or failing to adjust the water temperature of the bath). Include safety risks and tips with all instructions.
- Reinforce infection control practices. Damage to the skin, mucosa, eyes, or other tissues creates an immediate risk for infection. Determine that the patient understands the relationship among healthy and intact skin and tissues, hand hygiene practices, and the prevention of infection.

Acute, Restorative, and Continuing Care. Nursing knowledge and skills needed for performing hygiene care are consistent across all health care settings where acute care, restorative care, and continuing care are provided. In addition, some of the skills in this section are applicable in areas of health promotion.

The variety and timing of hygiene measures vary across health care settings and according to individual patient needs. In the acute care setting factors such as more frequent diagnostic and treatment plans and the need for more extensive hygiene care resulting from acute illness or injury affect scheduling. In extended care facilities and nursing homes, bathing may be scheduled less frequently.

Bathing and Skin Care. Consider a patient's normal grooming routines, including type of hygiene products used and the time of day when hygiene is routinely performed. Individualize your care based on the patient's preferences. The extent, type, and timing or frequency of bathing and the methods used depend on a patient's physical abilities, health problems, and the degree of hygiene required (Boxes 39-5 and 39-6). In addition to cleansing baths, the health care provider may prescribe therapeutic baths, including sitz baths or medicated baths (e.g., oatmeal, cornstarch, or Aveeno). A sitz bath cleans and reduces pain and inflammation of perineal and anal areas. Medicated baths relieve skin irritation and create an antibacterial and drying effect.

If a patient is physically dependent or cognitively impaired, increase the frequency of skin assessment and provide skin care directed toward reducing the risk for skin breakdown. When bathing patients with cognitive impairments, consider special needs and challenges (Box 39-7). These patients easily become afraid and use physical and verbal aggressive behaviors to express their needs. Apply available evidence to your care of the patient who is cognitively impaired. When family members assist in bathing cognitively impaired patients, you need to provide them with coaching, practice, and support (Mahoney et al., 2006).

Building Competency in Patient-Centered Care You are a home health nurse and visit the home of your patient, Anna, a 74-year-old female with Alzheimer's disease. Anna lives with her daughter Rose. You notice that Anna appears unkempt and her gown is soiled with food and urine. Rose tearfully tells you, "I just don't know what we are going to do. It's such a battle to clean Mom. She yells and hits me when I try to wash her." Which assessments do you make and which teaching do you implement to help Rose provide the necessary hygiene care in a caring manner?

Answers to questions can be found on the Evolve website.

BOX 39-5 HYGIENE CARE SCHEDULE IN ACUTE AND LONG-TERM CARE SETTINGS

Early Morning Care
Nursing personnel on the night shift provide basic hygiene to patients getting ready for breakfast, scheduled tests, or early morning surgery. "AM care" includes offering a bedpan or urinal if the patient is not ambulatory, washing the patient's hands and face, and assisting with oral care.

Routine Morning Care
After breakfast assist by offering a bedpan or urinal to patients confined to bed; provide a bath or shower, including perineal care and oral, foot, nail, and hair care; give a back rub; change the patient's gown or pajamas; change the bed linens; and straighten the patient's bedside unit and room. This is often referred to as "complete AM care."

Afternoon Care
Hospitalized patients often undergo many exhausting diagnostic tests or procedures in the morning. In rehabilitation centers patients participate in physical therapy in the morning. Afternoon hygiene care includes washing the hands and face, assisting with oral care, offering a bedpan or urinal, and straightening bed linen.

Evening, or Hour-Before-Sleep, Care
Before bedtime offer personal hygiene care that helps patients relax and promotes sleep. "PM care" often includes changing soiled bed linens, gowns, or pajamas; helping patients wash the face and hands; providing oral hygiene; giving a back massage; and offering the bedpan or urinal to nonambulatory patients. Some patients enjoy a beverage such as juice; check diet to determine which beverages are allowed.

BOX 39-6 TYPES OF BATHS

Complete bed bath: Bath administered to totally dependent patient in bed (see Skill 39-1).

Partial bed bath: Bed bath that consists of bathing only body parts that would cause discomfort if left unbathed such as the hands, face, axillae, and perineal area. Partial bath may also include washing back and providing back rub. Provide a partial bath to dependent patients in need of partial hygiene or self-sufficient bedridden patients who are unable to reach all body parts.

Sponge bath at the sink: Involves bathing from a bath basin or sink with patient sitting in a chair. Patient is able to perform part of the bath independently. Assistance is needed for hard-to-reach areas.

Tub bath: Involves immersion in a tub of water that allows more thorough washing and rinsing than a bed bath. Patient may still require the nurse's assistance. Some institutions have tubs equipped with lifting devices that facilitate positioning dependent patients in the tub.

Shower: Patient sits or stands under a continuous stream of water. The shower provides more thorough cleaning than a bed bath but can cause fatigue.

Bag bath/travel bath: Contains several soft, nonwoven cotton cloths that are premoistened in a solution of no-rinse surfactant cleanser and emollient. The bag bath offers an alternative because of the ease of use, reduced time bathing, and patient comfort.

A **complete bed bath** (Skill 39-1 on pp. 797-805) often exhausts a patient. Turning during a complete bed bath and receiving back care increase oxygen consumption and demand. Anticipate and assess whether patients are physically able to tolerate a complete bath. Assessing heart rate before, during, and after the bath provides a measure of their physical tolerance. Provide a **partial bed bath** (see Skill 39-1) to patients who are aging, dependent, in need of only partial hygiene, or bedridden and unable to reach all body parts. Wear gloves when there is a risk of contacting body fluids. Control environmental factors that alter skin integrity,

BOX 39-7 EVIDENCE-BASED PRACTICE

Making Bathing Better for Patients with Cognitive Impairment

PICO Question: Do patients who are cognitively impaired have fewer negative behaviors when nurses and other caregivers use person-centered care techniques during bathing than patients who do not receive patient-centered care during bathing?

Evidence Summary

For patients with Alzheimer's disease and related dementia, bathing frequently creates high levels of discomfort. Confusion causes these patients to feel vulnerable or as if they are being attacked during bathing, resulting in screaming, crying, and even aggressively lashing out at caregivers. Bathing leaves both the patient and caregiver feeling unsatisfied. Research shows that using nontraditional bathing techniques and educating caregivers to provide person-centered care ease the conflict and reduce aggressive, negative behaviors associated with bathing activities (Hoeffer et al., 2006). Caregivers need to recognize and eliminate triggers that cause negative behaviors during bathing. Use of patient-centered showering techniques and the in-bed towel bath with no-rinse soap results in a reduction of discomfort and aggressive incidents compared with traditional methods (Rader et al., 2006). Evidence disputes the need to force people against their wishes to bathe at routine intervals and in traditional ways (Rader et al., 2006).

Application to Nursing Practice

- Use person-centered care techniques when bathing patients with cognitive impairments. Develop a therapeutic relationship with the patient. Include him or her in planning care as much as possible, especially in regard to comfort and personal preferences. For example, let the patient select whether to shower or take a towel bath. Show respect in all interactions and communication. Use a gentle approach and avoid rushing. Approach the situation focusing on the person instead of on the task (Rader et al., 2006).
- Address factors that contribute to bathing difficulties, including pain; fatigue and weakness; fear and misunderstanding; anxiety and apprehension associated with fear of falling, noisy bathing areas, and being naked in front of strangers; triggers specific to the patient; and discomfort associated with cold, drafty air or cold water spray (Rader et al., 2006). Provide privacy and promote comfort. Close the door and pull room curtains around the bathing area. Control drafts and keep the patient covered, exposing only the body part being washed. For showering, consider leaving a light gown on during the shower. Change the bathing environment to be more inviting and calming. Avoid common triggers such as starting the bath by washing the face or forcing the patient to bathe.
- Support caregivers by providing education and materials needed for person-centered care. Empower staff as caregivers to recognize that agitation and aggressive behaviors are used by patients to communicate their needs (Hoeffer et al., 2006).

including moisture, heat, and external sources of pressure such as wrinkled bed linen and improperly placed drainage tubing.

When administering either a complete or partial bath, assess the condition of the skin to determine if soap is necessary or if the patient requires daily bathing. Patients with excessively dry skin are predisposed to skin impairment. Use soaps that contain emollients to hydrate dry skin. Avoid overly hot water because it can dry the skin by removing natural oils. Lubricate the skin with emollient lotions to reduce dryness.

Use the tub bath or shower (see Skill 39-1) to give a more thorough bath than a bed bath. Implement safety measures to prevent fall injuries because the surface of the tub or shower stall is slippery. In some settings a health care provider's order for a shower or tub bath is necessary. Place a chair in the shower for patients with weakness or poor balance. Both tubs and showers need to have grab bars for patients to hold during entry and exit and maneuvering during the bath or shower. Patients vary in how much help they need.

Regardless of the type of bath the patient receives, use the following guidelines:

- *Provide privacy.* Close the door and/or pull room curtains around the bathing area. While bathing the patient, expose only the areas being bathed by using proper draping.
- *Maintain safety.* Keep side rails up when away from the patient's bedside when patients are dependent or unconscious. NOTE: When side rails serve as a restraint, you need a health care provider's order (see agency-specific policy for restraint usage) (see Chapter 27). Place the call light in the patient's reach if leaving the bedside even temporarily.
- *Maintain warmth.* Keep the room warm because the patient is partially uncovered and easily chilled. Wet skin causes an excess loss of heat through evaporation. Control drafts and keep windows closed. Keep patient covered, only exposing the body part being washed during the bath.
- *Promote independence.* Encourage the patient to participate in as much of the bathing activities as possible. Offer assistance when needed.
- *Anticipate needs.* Bring a new set of clothing and hygiene products to the bedside or bathroom.

Teach patients to follow a few general rules for skin health. Encourage them to routinely inspect their skin for changes in color or texture and report abnormalities to their health care provider. Instruct patients to handle the skin gently, avoiding excessive rubbing. Also encourage them to eat nutritious foods from all food groups, including those rich in vitamins and minerals, and to consume adequate fluids. Stress safety concerns such as failing to adjust or check the water temperature, cutting nails too close to the skin, and slipping on wet surfaces. Ensure that patients understand that healthy and intact skin and tissues protect them from infection. Reinforce infection control practice, including proper hand hygiene.

Bag Baths. This innovative approach to the traditional bed bath was developed because of nurses' concern for patients who are predisposed to dry skin and the risk for infection (see Skill 39-1). Not cleaning and drying washbasins completely after use provides a risk for contamination by disease-producing gram-negative organisms. Based on their study in intensive care units, Johnson, Lineweaver, and Maze (2009) concluded that bath basins provide a reservoir for bacteria and are a possible source of transmission of hospital-acquired infections. The bag bath contains a no-rinse surfactant, a humectant to trap moisture, and an emollient. Nurses in another study expressed a significant overall preference for the disposable bag bath versus the traditional basin bath, especially for patients who are unable to bathe themselves in critical and long-term care settings (Larson et al., 2004). Some facilities have switched from the traditional bath in favor of the bag bath because of concerns related to infection control.

Perineal Care. Cleansing patients' genital and anal areas is called **perineal care.** It usually occurs as part of a complete bed bath (see Skill 39-1). Patients most in need of perineal care include those at greatest risk for acquiring an infection (e.g., uncircumcised males, patients who have indwelling urinary catheters, or those who are recovering from rectal or genital surgery or childbirth). In

addition, women who are having a menstrual period require perineal care. Encourage patients to perform their own perineal care. Sometimes you are embarrassed about providing perineal care, particularly to patients of the opposite sex. Similarly the patient may feel embarrassed. Do not let embarrassment cause you to overlook the patient's hygiene needs. When staffing levels permit, use a gender-congruent caregiver. A professional, dignified, and sensitive approach reduces embarrassment and helps put the patient at ease.

If a patient performs self-care, various problems such as vaginal and urethral discharge, skin irritation, and unpleasant odors often go unnoticed. Stress the importance of perineal care in preventing skin breakdown and infection. Be alert for complaints of burning during urination or localized soreness, excoriation, or pain in the perineum. Inspect vaginal and perineal areas and the patient's bed linen for signs of discharge and use your sense of smell to detect abnormal odors. Risk factors for skin breakdown in the perineal area include urinary or fecal incontinence, rectal and perineal surgical dressings, indwelling urinary catheters, and morbid obesity.

Back Rub. A back rub or back massage usually follows the patient's bath. It promotes relaxation, relieves muscular tension, and decreases perception of pain. **Effleurage** (i.e., long, slow, gliding strokes of a massage) is associated with reduced measured anxiety, heart rate, and respiratory rate. Studies show that slow-stroke back massages of 3 minutes and hand massages of 10 minutes significantly improve both physiological and psychological indicators of relaxation in older people (Harris and Richards, 2010).

When providing a back rub, enhance relaxation by reducing noise and ensuring that the patient is comfortable. It is important to ask whether a patient would like a back rub or if he or she prefers gentle instead of deep massage, because some individuals dislike physical contact. Consult the medical record for any contraindications to a massage (e.g., fractured ribs, burns, and heart surgery).

Foot and Nail Care. Incorporate foot and nail care into a person's regular hygiene routine. Routine care involves soaking to soften cuticles and layers of horny cells, thorough cleaning, drying, and proper nail trimming. Patients with diabetes mellitus should not soak their nails because of the risk of overdrying the feet and developing breaks in the skin with resulting infection. When providing nail care, the patient remains in bed or sits in a chair (Skill 39-2 on pp. 805-808). In some settings or with specific patients such as a person with diabetes mellitus, you need a health care provider's order to trim toenails. Before implementing this procedure, check agency policy to determine if the order is necessary.

Take time during the procedure to teach the patient and family proper techniques for cleaning and nail trimming. You need to stress measures to prevent infection and promote good circulation. Patients learn to protect the feet from injury, keep them clean and dry, and wear footwear that fits properly. Instruct patients in the proper way to inspect all surfaces of the feet and hands for redness, lesions, dryness, or signs of infection. Teach foot care to family members or caregivers for patients who need regular foot care and have peripheral vascular disease, visual difficulties, physical constraints preventing movement, or cognitive problems.

Certain conditions place patients with diabetes at increased risk for amputation (American Diabetes Association, 2007). These factors include peripheral neuropathy, limited joint mobility, bony deformity, peripheral vascular disease, and a history of skin ulcers or previous amputation. Observe for changes that indicate peripheral neuropathy or vascular insufficiency (Box 39-8). Advise patients to use the following guidelines in a routine foot and nail care program (American Diabetes Association, 2010):

BOX 39-8 SIGNS OF PERIPHERAL NEUROPATHY OR VASCULAR INSUFFICIENCY

Peripheral Neuropathy
- Muscle wasting of lower extremities
- Absence of deep tendon reflexes
- Foot deformities
- Infections
- Abnormal gait
- Decreased or absent vibratory sensation

Vascular Insufficiency
- Decreased hair growth on legs and feet
- Absent or decreased pulses
- Infection in the foot
- Poor wound healing
- Thickened nails
- Shiny appearance of the skin
- Blanching of the skin on elevation

Data from American Diabetes Association: Position statement on standards of medical care in diabetes 2007, *Diabetes Care* 30:S4, 2007.

- Receive a thorough foot examination at least once a year. People with one or more high-risk foot conditions need an evaluation more frequently.
- Inspect the feet daily, including the bottoms and tops, heels, and areas between the toes. Use a mirror to help inspect the feet thoroughly or ask a family member to check daily.
- Wash feet daily in lukewarm water. Dry thoroughly, especially between the toes.
- Wear shoes and clean, dry socks at all times; never go barefoot. Check inside shoes before wearing them for rough areas or objects that may rub against the foot.
- Keep skin soft and smooth by applying an emollient lotion over all surfaces of the feet but not between the toes.
- If you can see and reach your toenails, trim them straight across and square file the edges smooth.
- Keep the blood flowing to your feet by putting them up when sitting and wiggling your toes and moving your ankles up and down for 5 minutes 2 or 3 times a day. Do not cross your legs for long periods and don't smoke.
- Protect the feet from hot and cold. Do not use heating pads or electric blankets and always wear shoes at the beach or on hot pavement.

Oral Hygiene. Regular oral hygiene, including brushing, flossing, and rinsing, prevents and controls plaque-associated oral diseases. Evidence relates poor oral health to risk of impaired nutrition, stroke, poor blood sugar control in diabetes, and nursing home–acquired pneumonia (Jablonski, 2009). Inadequate oral care and some medications diminish salivary production, which in turn reduces the ability of the oral environment to help fight effects of pathogens (Box 39-9).

Brushing cleans the teeth of food particles, plaque, and bacteria. It also massages the gums and relieves discomfort resulting from unpleasant odors and tastes. Flossing removes tartar that collects at the gum line. Rinsing removes dislodged food particles and excess toothpaste. Complete oral hygiene enhances well-being and comfort and stimulates the appetite.

When patients become ill, many factors influence their need for oral hygiene. Patients in hospitals or long-term care facilities do

BOX 39-9 FOCUS ON OLDER ADULTS

Oral Health

- Many older adults are edentulous (without teeth), and the teeth that are present are often diseased or decayed (Meiner, 2011).
- The periodontal membrane weakens with aging, making it more prone to infection. Periodontal disease predisposes the older adult to systemic infection.
- Dentures or partial plates do not always fit properly, causing pain and discomfort, which in turn affect digestive processes, enjoyment of food, and nutritional status.
- An age-related decline in saliva secretion and some medications (e.g., antihypertensives, diuretics, antiinflammatories, antidepressants) cause dry mouth (Meiner, 2011).
- Financial limitations and the belief that dentures eliminate the need for routine dental care are reasons why older adults do not seek dental care (Meiner, 2011).

not always receive the aggressive oral care they need. Base the frequency of care on the condition of the oral cavity and the patient's level of comfort. Some patients require oral care as often as every 1 to 2 hours.

Acidic fruits in the patient's diet reduce plaque formation. A well-balanced diet contributes to the integrity of oral tissues. To prevent tooth decay, patients sometimes need to change eating habits (e.g., reducing intake of carbohydrates, especially sweet snacks between meals). Advise patients of all ages to visit a dentist regularly for checkups. Education about common gum and tooth disorders and methods of prevention may motivate patients to follow good oral hygiene practices.

Brushing. The American Dental Association (2010) guidelines for effective oral hygiene include brushing the teeth at least twice a day with American Dental Association–approved fluoride toothpaste. Fluoride and antimicrobial mouth rinses also help prevent tooth decay. Do not use fluoride rinse in children ages 6 or under because of the risk of swallowing the rinse. Use antimicrobial toothpastes and 0.12% chlorhexidine oral rinses for patients at increased risk for poor oral hygiene (e.g., older adults and patients with cognitive impairments and who are immunocompromised) (Garcia and Caple, 2011). The toothbrush needs to have a straight handle and a brush small enough to reach all areas of the mouth. Rounded soft bristles stimulate the gums without causing abrasion and bleeding. Any patient who experiences decreased dexterity as a result of a medical condition or the aging process requires an enlarged handle with an easier grip.

Brush all tooth surfaces thoroughly (Skill 39-3 on pp. 808-811). Commercially made foam swabs are ineffective in removing plaque (Garcia and Caple, 2011). Electric or powered toothbrushes improve the quality of cleaning and may be easier to use than manual brushes when nurses provide care for dependent patients. Do not use lemon-glycerin sponges because they dry mucous membranes and erode tooth enamel.

To prevent cross-contamination, teach patients to avoid sharing toothbrushes with family members or drinking directly from a bottle of mouthwash. The use of disclosure tablets or drops to stain the plaque that collects at the gum line is useful for showing patients how effectively they brush. Instruct patients to obtain a new toothbrush every 3 months or following a cold or upper respiratory infection to minimize growth of microorganisms on the brush surfaces (American Dental Association, 2010).

Flossing. Dental flossing removes plaque and tartar between teeth. Flossing involves inserting waxed or unwaxed dental floss between all tooth surfaces, one at a time. The seesaw motion used to pull floss between teeth removes plaque and tartar from tooth enamel. Use unwaxed floss and avoid vigorous flossing near the gum line on patients who are receiving chemotherapy, radiation, or anticoagulant therapy to prevent bleeding. If toothpaste is applied to the teeth before flossing, fluoride comes in direct contact with tooth surfaces, aiding in cavity prevention. According to American Dental Association (2010) recommendations, flossing once a day is sufficient. Because it is important to clean all teeth surfaces thoroughly, do not rush to complete flossing. Placing a mirror in front of the patient helps you demonstrate the proper method for holding the floss and cleaning between the teeth. Flossing a patient's teeth is not realistic or appropriate in all care settings.

Patients with Special Needs. Some patients require special oral hygiene methods. For example, patients with diabetes mellitus frequently experience periodontal disease. Therefore they need to visit the dentist every 3 to 4 months, clean their teeth up to 4 times a day, and handle oral tissues gently with a minimum of trauma. Other patients depend on their caregivers for oral care. Being unconscious or having an artificial airway (e.g., endotracheal or tracheal tubes) increases the susceptibility for patients to have drying of salivary secretions because they are unable to eat or drink, frequently breathe through the mouth, and often receive oxygen therapy. Unconscious patients cannot swallow salivary secretions that accumulate in the mouth. These secretions often contain gram-negative bacteria that cause pneumonia if aspirated into the lungs. While providing hygiene, protect the patient from choking and aspiration and use topical chlorhexidine, especially in ventilated patients. Current evidence shows that use of chlorhexidine with oral hygiene reduces the risk for ventilator-associated pneumonia (Munro et al., 2009).

Patients with decreased levels of consciousness need special attention because they often do not have a gag reflex. Proper oral hygiene requires keeping the mucosa moist and removing secretions that contribute to infection. When providing oral hygiene to an unconscious patient, you need to protect him or her from choking and aspiration. Have two nurses provide the care; turn the patient's head toward you, and place the bed in semi-Fowler's position. You can delegate nursing assistive personnel to participate. One nurse does the actual cleaning, and the other caregiver removes secretions with suction equipment. Some agencies use equipment that combines a mouth swab with the suction device; you can use this equipment safely by yourself. While cleansing the oral cavity, use a small oral airway or a padded tongue blade to hold the mouth open. Never use your fingers to hold the patient's mouth open. A human bite contains multiple pathogenic microorganisms. Even though the patient is not awake or alert, explain the steps of mouth care and the sensations that he or she will feel. Also tell the patient when the procedure is completed (Skill 39-4 on pp. 811-813).

Some treatments such as chemotherapy, immunosuppressive agents, head and neck radiation, and nasogastric intubation place patients at higher risk of experiencing stomatitis or inflammation of the oral mucosa. **Stomatitis** causes burning, pain, and change in food and fluid tolerance. When caring for patients with stomatitis, brush with a soft toothbrush and floss gently to prevent bleeding of the gums. In some cases flossing needs to be temporarily omitted from oral care. Advise patients to avoid alcohol and commercial mouthwash and stop smoking. Normal saline rinses (approximately 30 mL) on awaking in the morning, after each

meal, and at bedtime help clean the oral cavity. Patients can increase the rinses to every 2 hours if necessary. Consult with the health care provider to obtain topical or oral analgesics for pain control.

Denture Care. Encourage patients to clean their dentures on a regular basis to avoid gingival infection and irritation. When patients become disabled, someone else assumes responsibility for denture care (Box 39-10). Dentures are the patient's personal property and must be handled with care because they break easily. They must be removed at night to rest the gums and prevent bacterial buildup. To prevent warping, keep dentures covered in water when they are not worn and always store them in an enclosed, labeled cup with the cup placed in the patient's bedside stand. Discourage patients from removing their dentures and placing them on a napkin or tissue because they could easily be thrown away.

Implement measures to prevent denture-induced stomatitis when caring for patients who wear dentures. Poorly fitting dentures, wearing dentures while sleeping, and poor dental hygiene habits contribute to denture-induced stomatitis (Sciubba, 2009). Signs and symptoms range from redness and swelling under the dentures to painful red sores on the roof of the mouth and infection with the yeast *Candida albicans*. Some patients deny pain, and others complain of pain worsened by wearing dentures. To prevent denture-induced stomatitis, rinse the mouth and dentures after meals, clean them carefully and regularly, remove and soak them overnight, brush and floss any remaining teeth, and visit a dentist regularly for examination (Sciubba, 2009).

Hair and Scalp Care. A person's appearance and feeling of well-being often depend on the way the hair looks and feels. Illness or disability often prevents a patient from maintaining daily hair care. When patients are immobilized, their hair soon becomes tangled. Some dressings or diagnostic procedures leave sticky residue on the hair. Basic hair and scalp care includes brushing, combing, and shampooing.

Brushing and Combing. Frequent brushing helps keep hair clean and distributes oil evenly along hair shafts. Combing prevents hair from tangling. Encourage patients to maintain routine hair care and provide help for patients with limited mobility or weakness and those who are confused or weakened by illness. Patients in a hospital or extended care facility appreciate the opportunity to have their hair brushed and combed before being seen by others.

When caring for patients from different cultures, learn as much as possible from them or their family about preferred hair care practices. For example, the hair of African Americans tends to be quite dry. Use special lanolin conditioners for conditioning. Cultural preferences also affect how hair is combed and styled and whether it can be cut.

Long hair easily becomes matted when a patient is confined to bed, even for a short period. When lacerations or incisions involve the scalp, blood and topical medications also cause tangling. Frequent brushing and combing keep long hair neatly groomed. Braiding helps to avoid repeated tangles; however, patients need to unbraid hair periodically and comb it to ensure good hygiene. Braids that are too tight lead to bald patches. Obtain permission from the patient before braiding the hair.

To brush hair part it into two sections and separate each section into two more sections. Brushing from the scalp toward the hair ends minimizes pulling. Moistening the hair with water or an alcohol-free detangle product makes it easier to comb. Never cut a patient's hair without consent.

Patients who develop head lice require special considerations in the way combing is performed. The lice are small, about the size of a sesame seed; thus you need bright light or natural sunlight to see

Care of Dentures

Delegation Considerations

The skill of denture care can be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Inform the nurse if there are cracks in dentures.
- Inform the nurse if the patient complains of oral discomfort.
- Inform the nurse of any lesions in the mouth.

Equipment

Soft-bristle toothbrush or denture toothbrush, denture-cleaning agent or toothpaste, denture adhesive *(optional),* glass of water, emesis basin or sink, washcloth, clean gloves, denture cup (if dentures are to be stored after cleaning)

1. Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.
2. Ask patient if dentures fit and if there is any gum or mucous membrane tenderness or irritation.
3. Ask patient about preferences for denture care and products used. If patient is unable to care for own dentures, provide this care. Clean dentures for patient during routine mouth care.
4. Fill emesis basin with tepid water; or, if using sink, place washcloth in bottom of sink and fill sink with an inch (2.5 cm) of water.
5. Remove dentures: If patient is unable to do this independently, perform hand hygiene and apply gloves, grasp upper plate at front with thumb and index finger wrapped in gauze, and pull downward. To remove lower denture, gently lift it from the jaw and rotate one side downward. Place dentures in emesis basin or sink.
6. Apply cleaning agent to brush and brush surfaces of dentures (see illustration). Hold dentures close to water. Hold brush horizontally and use back-and-forth motion to clean biting surfaces. Use short strokes from top of denture to biting surfaces to clean outer and inner teeth surfaces. Hold brush vertically and use short strokes to clean inner tooth surfaces. Hold brush horizontally and use back-and-forth motion to clean undersurface of dentures.

STEP 6 Brushing dentures.

7. Some patients use an adhesive to seal dentures in place. Apply a thin layer to undersurface before inserting.
8. If patient needs help inserting dentures, moisten upper denture and press firmly to seal it in place. Insert moistened lower denture. Ask if dentures feel comfortable.
9. Some patients prefer to have their dentures stored to rest the gums and reduce risk of infection. Keeping dentures moist prevents warping and facilitates easier insertion. Store in a secure place to prevent loss.
10. Remove and discard gloves and perform hand hygiene.

them. Thorough combing is more effective than use of pediculicidal shampoos, which are often toxic and ineffective against resistant lice. Follow these steps:

- Apply disposable gown and gloves.
- Use a grooming comb or hairbrush to remove tangles.
- Divide the patient's hair in sections and fasten off hair that is not being combed.
- Comb out from the scalp to the end of the hair (special combs are available in drug stores).
- Dip the comb in a cup of water or use a paper towel to remove lice between each passing.
- After combing look through the hair carefully for attached lice.
- You can catch live lice with a tweezers or comb.
- After combing thoroughly, move to next section.
- Instruct family to clean the comb with an old toothbrush and dental floss and boil the comb. The ideal is to discard the comb after each use, but some patient's financial situations prevent the purchase of multiple combs.
- Instruct family to comb and screen for lice daily.
- Instruct family to contain patient's clothes and wash them in hot water.
- Instruct family to vacuum the home and patient's room and immediately empty vacuum bag or bagless collection device.
- Instruct caregivers in how to prevent transmission of lice:
  - Do not share bed linens or hair care products.
  - Avoid placing bare hand on patient's head.
  - Immediately wash hands after providing hair care.

If a pediculicidal shampoo is ordered, instruct the patient and caregiver in its proper use. These shampoos have neurological side effects. The very young and very old have increased susceptibility to the toxic effects of seizure, dizziness, headache, paresthesia, and death. Never use organochloride lindane to treat people with seizure disorders, pregnant or breastfeeding women, people with irritated skin or sores where lindane will be applied, people who weigh less than 110 pounds, and older adults (CDC, 2008). As with any medication preparation, it is important to review and understand pertinent information. Most side effects associated with pediculicidal shampoos occur as a result of applying too much medicated shampoo, leaving the shampoo in place too long, or repeating a shampoo too soon. To avoid overtreatment, teach patients that itching is a common side effect (Grose, 2011).

Shampooing. Frequency of shampooing depends on a person's daily routines and the condition of the hair. Remind patients in hospitals or extended care facilities that staying in bed, excess perspiration, or treatments that leave blood or solutions in the hair require more frequent shampooing. In some agencies you need a health care provider's order to shampoo a patient who is dependent or has limited mobility because it is challenging to find ways to shampoo the hair without causing injury.

The patient who can shower or tub bathe usually shampoos the hair without difficulty. A shower or tub chair facilitates shampooing for patients who are ambulatory and weight bearing and become tired or faint. Handheld shower nozzles allow patients to easily wash the hair in the tub or shower. Some patients allowed to sit in a chair choose to be shampooed in front of a sink or over a washbasin; however, certain conditions (e.g., eye surgery or neck injury) limit bending. In these situations teach the patient and family the degree of bending allowed.

If a patient is unable to sit but can be moved, transfer him or her to a stretcher for transportation to a sink or shower equipped with a handheld nozzle. Use caution when positioning the patient's head and neck, particularly in patients with any form of head or neck injury.

FIG. 39-5 Shave in the direction of hair growth. Use longer strokes on the larger areas of the face. Use short strokes around the chin and lips. (From Sorrentino SA, Remmert LN: *Mosby's textbook for nursing assistants*, ed 8, St Louis, 2012, Mosby.)

If a patient is unable to sit in a chair or be transferred to a stretcher, shampoo the hair with the patient in bed (Box 39-11). Position a special shampoo trough under his or her head to catch water and suds. After shampooing, patients like having their hair styled and dried. Most health care centers have portable hair dryers. Dry shampoos that reduce the need to wet the patient's hair are also available but are not highly effective. Dry shampoo preparations vary; therefore follow the application procedures listed on the container.

Shaving. Shave facial hair after the bath or shampoo. Some women prefer to shave their legs or axillae while bathing. When assisting a patient, take care to avoid cutting him or her with the razor blade. Patients prone to bleeding (e.g., those receiving anticoagulants or high doses of aspirin or those with low platelet counts) need to use an electric razor. Before using an electric razor, check for frayed cords or other electrical hazards. Use razor blades and electric razors on only one patient because of infection control considerations.

When using a razor blade for shaving, the skin must be softened to prevent pulling, scraping, or cuts. Moisten the skin with lukewarm water and apply shaving cream. Avoid use of bar soap, which leaves a film on the blade, resulting in a poorer-quality shave (Draelos, 2010). You need to shave patients when they are unable to shave themselves independently. To avoid causing discomfort or razor cuts, gently pull the skin taut and use long, firm razor strokes in the direction the hair grows (Fig. 39-5). Short downward strokes work best to remove hair over the upper lip or chin. The patient usually explains the best way to move the razor across the skin. Facial hair of African Americans tends to be curly and becomes ingrown unless shaved close to the skin.

Mustache and Beard Care. Mustaches or beards require daily grooming. Grooming keeps food particles and mucus from collecting in the hair. If a patient is unable to carry out self-care, do so

BOX 39-11 PROCEDURAL GUIDELINES

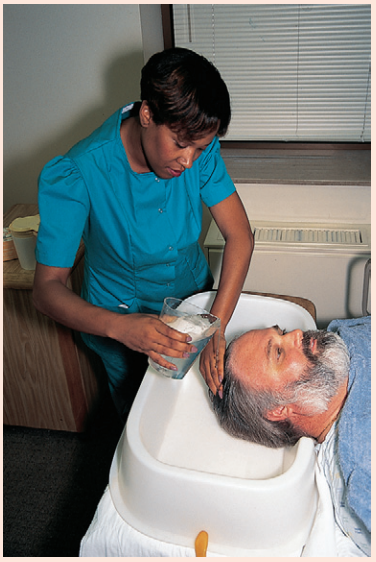
View Video!

Shampooing Hair of Patient Who Is Bed-Bound

Delegation Considerations

The skill of shampooing hair can be delegated to nursing assistive personnel (NAP). Instruct the NAP:

- About any precautions needed in positioning the patient.
- To inform the nurse if the patient reports neck pain.
- To inform the nurse of any new skin lesions.



Equipment

Brush, comb, shampoo board, shampoo, conditioner *(optional),* hydrogen peroxide *(optional),* towels (three or more), waterproof pad, hair dryer, basin of very warm water, clean gloves (if needed)

1. Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.
2. Before washing patient's hair, determine that there are no contraindications to procedure.
3. Perform hand hygiene and apply gloves if needed. Inspect the hair and scalp before initiating the procedure to determine the presence of any conditions that require the use of special shampoos or treatments (e.g., for dandruff or the removal of dried blood).
4. Place waterproof pad under patient's shoulders, neck, and head. Position patient supine, with head and shoulders at top edge of bed. Place plastic trough under patient's head and washbasin at end of trough. Be sure that trough spout extends beyond edge of mattress.
5. Place rolled towel under patient's neck and bath towel over patient's shoulders (see illustration).
6. Brush and comb patient's hair.
7. Obtain warm water.
8. Offer patient the option of holding face towel or washcloth over eyes.
9. Slowly pour water from water pitcher over hair until it is completely wet (see illustration). If hair contains matted blood, put on gloves, apply peroxide to dissolve clots, and rinse hair with saline. Apply small amount of shampoo.
10. Work up lather with both hands. Start at hairline and work toward back of neck. Lift head slightly with one hand to wash back of head. Shampoo sides of head. Massage scalp by applying pressure with fingertips.
11. Rinse hair with water. Make sure that water drains into basin. Repeat rinsing until hair is free of soap.
12. Apply conditioner or cream rinse if requested and rinse hair thoroughly.
13. Wrap patient's head in bath towel. Dry patient's face with cloth used to protect eyes. Dry off any moisture along neck or shoulders.
14. Dry patient's hair and scalp. Use second towel if first becomes saturated.
15. Comb hair to remove tangles and dry with dryer if desired.
16. Apply oil preparation or conditioning product to hair if desired by patient.
17. Assist patient to comfortable position and complete styling of hair.

STEP 5 Placing bath towel over patient's shoulders.

STEP 9 Pouring water over hair.

at his or her request. Comb out beards gently and obtain the patient's permission before trimming or shaving off a mustache or beard.

Care of the Eyes, Ears, and Nose. Give special attention to cleaning the eyes, ears, and nose during a routine bath and when drainage or discharge accumulates. This aspect of hygiene not only makes a patient more comfortable but also improves sensory reception (see Chapter 49). Care focuses on preventing infection and maintaining normal sensory function. In addition, care of the eyes, ears, and nose requires approaches that consider the patient's special needs.

Basic Eye Care. Cleaning the eyes involves simply washing with a clean washcloth moistened in water (see Skill 39-1). Soap causes burning and irritation. Never apply direct pressure over the eyeball because it causes serious injury. When cleaning a patient's eyes, obtain a clean washcloth and clean from inner to outer canthus. Use a different section of the washcloth for each eye.

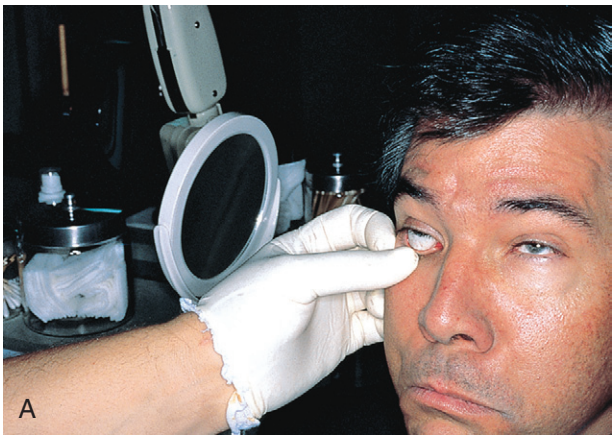
Unconscious patients often require more frequent eye care. Secretions collect along the lid margins and inner canthus when the blink reflex is absent or when the eye does not close completely. When an eye does not close completely, you may need to place an eye patch over the involved eye to prevent corneal drying and irritation. Apply lubricating eyedrops according to the health care provider's orders.

Eyeglasses. Glasses are made of hardened glass or plastic that is impact resistant to prevent shattering. Nevertheless, because of

BOX 39-12 PATIENT TEACHING

Contact Lens Care

Objective



- Patient verbalizes and/or demonstrates proper care for contact lenses and common warning signs of problems associated with contact lens wear.

Teaching Strategies

- Instruct patients on the following:
  - Do not use fingernail on lens to remove dirt or debris.
  - Do not use tap water to clean soft lenses.
  - Follow recommendations of lens manufacturer or eye care practitioner when inserting, cleaning, and disinfecting lenses.
  - Keep lenses moist or wet when not worn.
  - Use fresh solution daily when storing and disinfecting lenses.
  - Thoroughly wash and rinse lens storage case on a daily basis. Clean periodically with soap or liquid detergent, rinse thoroughly with warm water, and air dry.
  - If lens is dropped, moisten finger with cleaning or wetting solution and gently touch it to pick it up. Then clean, rinse, and disinfect lens.
- To avoid mix-up, always start with the same lens when removing or inserting lenses.
- Throw away disposable or planned replacement lenses after prescribed wearing period.
- Encourage patient to remember the acronym RSVP: *R*edness, *S*ensitivity, *V*ision problems, and *P*ain. If one of these problems occurs, remove contact lenses immediately. If problems continue, contact a vision care specialist (Lewis et al., 2011).

Evaluation

- Ask patient to state warning signs of corneal irritation and eye infection.
- Ask patient to describe methods of contact lens care that lead to infection.
- Ask patient to demonstrate cleaning and storing contact lenses.

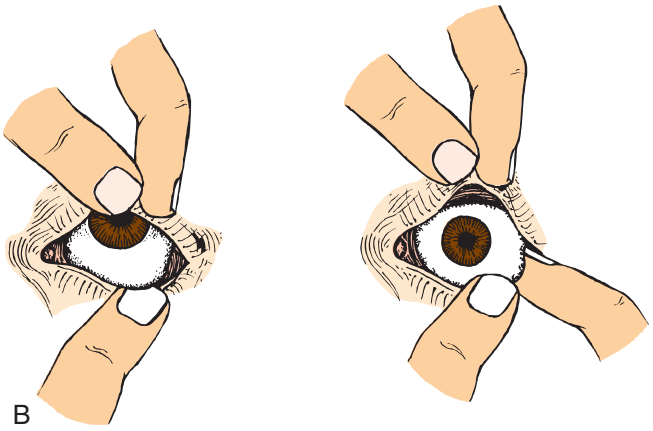


FIG. 39-6 Removal of prosthetic eye.

the cost, be careful when cleaning glasses and protect them from breakage or other damage when they are not worn. Put glasses in a case in a drawer of the bedside table when not in use.

Cool water sufficiently cleans glass lenses. Use a soft cloth for drying to prevent scratching the lens since paper towels can scratch it. Plastic lenses in particular scratch easily; special cleaning solutions and drying tissues are available.

Contact Lenses. A contact lens is a thin, transparent, circular disk that fits directly over the cornea of the eye. Contact lenses correct refractive errors of the eye or abnormalities in the shape of the cornea. Daily-wear lenses are removed nightly for cleansing and disinfection, whereas extended-wear lenses may be worn overnight and removed at least weekly for cleaning and disinfection. Remove disposable-wear lenses nightly and replace when indicated (e.g., daily, weekly, monthly). All contact lenses must be removed periodically to prevent ocular infection and corneal ulcers or abrasions. Common infectious agents are *Pseudomonas aeruginosa* and staphylococci. Patient education includes a discussion of proper lens care techniques (Box 39-12). Pain, tearing, discomfort, and redness of the conjunctivae indicate lens overwear. Report persistence of these symptoms even after lens removal to the patient's vision health care provider.

Care of contact lenses includes proper cleaning and disinfection, insertion and removal, and storage. When patients require help to clean their contact lenses, first perform hand hygiene and then clean and disinfect the lenses with appropriate contact lens solution. Before reinsertion rinse the lenses with an appropriate solution such as sterile saline. Caution patients to never use saliva or homemade saline when cleaning lenses because these solutions contain microorganisms that can cause serious infection. Instruct the patient to clean the contact lens case frequently with warm water and allow it to air dry.

When patients are admitted to the hospital or agency in an unresponsive or confused state, determine if they normally wear contact lenses and if the lenses are in place. If a patient wears contact lenses and no one detects this, severe corneal injury can result. If you find that your patient is wearing contact lenses and the patient cannot remove them, seek assistance. Once the lenses are removed, document the removal, the condition of the patient's eyes following removal, and the storage of the lenses.

Artificial Eyes. Patients with artificial eyes have had an **enucleation** (i.e., removal) of an entire eyeball as a result of tumor growth, severe infection, or eye trauma. Some artificial eyes are permanently implanted, whereas others must be removed for cleaning. Patients with artificial eyes usually prefer to care for their own eyes. Respect the patient's wishes and help by assembling needed equipment.

At times patients require assistance in prosthesis removal and cleaning. To remove an artificial eye, retract the lower eyelid and exert slight pressure just below the eye (Fig. 39-6). This action causes the artificial eye to rise from the socket because the suction

holding the eye in place has been broken. You can also use a small, rubber bulb syringe or medicine-dropper bulb to create a suction effect. Place the bulb tip directly over the eye and squeeze it to create suction needed to lift the eye from the socket.

The artificial eye is usually made of glass or plastic. Warm normal saline cleans the prosthesis effectively. Also clean the edges of the eye socket and surrounding tissues with soft gauze moistened in saline or clean tap water. Report signs of infection immediately because bacteria can spread to the neighboring eye, underlying sinuses, or even underlying brain tissue. To reinsert the eye, retract the upper and lower lids and gently slip the eye into the socket, fitting it neatly under the upper eyelid. Store an artificial eye in a labeled container filled with tap water or saline.

Ear Care. Routine ear care involves cleaning the ear with the end of a moistened washcloth, rotated gently into the ear canal. Gentle, downward retraction at the entrance of the ear canal usually causes visible cerumen to loosen and slip out. Instruct patients never to use objects such as bobby pins, toothpicks, paper clips, or cotton-tipped applicators to remove earwax. These objects can injure the ear canal and rupture the tympanic membrane. They may also cause cerumen to become impacted within the ear canal.

Children and older adults commonly have impacted cerumen. You can usually remove excessive or impacted cerumen by irrigation, which requires a health care provider's order. Review the order for type of solution and ear(s) to receive the irrigation. Before irrigation question the patient for history of perforated eardrum and inspect his or her tympanic membrane to be sure that it is intact; a perforated tympanic membrane contradicts performing irrigation. Visually inspect the pinna and external meatus for redness, swelling, drainage, and presence of foreign objects. Also determine the patient's ability to hear in the affected ear before irrigation.

To irrigate the ear, have the patient sit or lie on the side with the affected ear up. For adults and children over 3 years of age, gently pull the pinna up and back. In children 3 years of age or younger, the pinna should be pulled down and back. Using a bulb-irrigating syringe or a Water Pik set on No. 2 setting; gently wash the ear canal with warm solution (37° C or 98.6° F), being careful to not occlude the canal, which results in pressure on the tympanic membrane. Direct the fluid slowly and gently toward the superior aspect of the ear canal, maintaining the flow in a steady stream. Periodically during the irrigation ask if the patient is experiencing pain, nausea, or vertigo. These symptoms indicate that the solution is too hot or too cold or is being instilled with too much pressure. After the canal is clear, wipe off any moisture from the ear with cotton balls and inspect the canal for remaining earwax.

Hearing Aid Care. A hearing aid amplifies sounds in a controlled manner; the aid receives normal low-intensity sound inputs and delivers them to the patient's ear as louder output. Hearing aids come in a variety of types. The new class of hearing aids reduces background noise interference. Computer chips placed in the aids allow for fine adjustments to the specific patient's hearing needs. People who are hard of hearing (slight or moderate hearing loss) or deaf (severe or profound hearing loss) use hearing aids.

There are three popular types of hearing aids. An in-the-canal (ITC) aid (Fig. 39-7, *A*) is the newest, smallest, and least visible and fits entirely in the ear canal. It has cosmetic appeal, is easy to manipulate and place in the ear, and does not interfere with wearing eyeglasses or using the telephone; and the patient can wear it during most physical exercise. However, it requires adequate ear diameter and depth for proper fit. It does not accommodate progressive hearing loss; and it requires manual dexterity to operate, insert, remove, and change batteries. In addition, cerumen tends to plug this model more than the others.

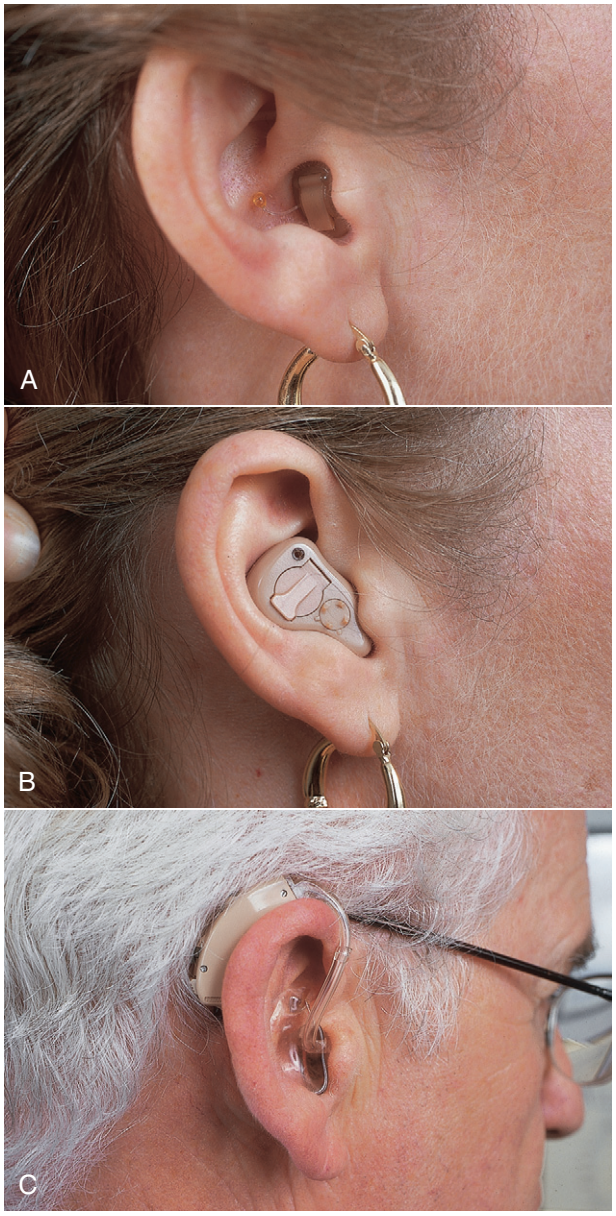

FIG. 39-7 Three common types of hearing aids. **A,** In the canal (ITC). **B,** In the ear (ITE). **C,** Behind the ear (BTE).

An in-the-ear (ITE, or intraaural) aid (Fig. 39-7, *B*) fits into the external auditory canal and allows for more fine tuning. It is more powerful and stronger and therefore is useful for a wider range of hearing loss than the ITC aid. It is easy to position and adjust and does not interfere with eyeglass wearing. However, it is more noticeable than the ITC aid and is not for people with moisture or skin problems in the ear canal.

A behind-the-ear (BTE, or postaural) aid (Fig. 39-7, *C*) hooks around and behind the ear and is connected by a short, clear, hollow plastic tube to an ear mold inserted into the external auditory canal. It allows for fine tuning. It is the largest of the three aids and is useful for patients with rapidly progressing hearing loss or manual dexterity difficulties or those who find partial ear occlusion

BOX 39-13 CARE AND USE OF HEARING AIDS

- Initially wear a hearing aid 15 to 20 minutes; gradually increase time to 10 to 12 hours.
- Once inserted, turn the aid slowly to one-third to one-half volume.
- A whistling sound indicates incorrect ear mold insertion, improper fit of aid, or buildup of earwax or fluid.
- Adjust volume to a comfortable level for talking at a distance of 1 yard.
- Do not wear aid under heat lamps or a hair dryer or in very wet, cold weather.
- Batteries last 1 week with daily wearing of 10 to 12 hours.
- Remove or disconnect battery when not in use.
- Replace ear molds every 2 or 3 years.
- Routinely check battery compartment: Is it clean? Are batteries inserted properly? Is compartment shut all the way?
- Make sure that dials on hearing aid are clean and easy to rotate, creating no static during adjusting.
- Keep aid clean. See manufacturer instructions. Aids are usually cleaned with a soft cloth.
- Avoid use of hairspray and perfume while wearing hearing aids, the residue from the spray causes aid to become oily and greasy.
- Do not submerse in water.
- Routinely check cord or tubing (depending on type of aid) for cracking, fraying, and poor connections.
- Routine follow-up with audiologist is recommended to evaluate effectiveness of current aid.

Data from Ebersole P, et al: *Toward healthy aging,* ed 7, St Louis, 2008, Mosby.

intolerable. The larger size of this type of aid can make use of eyeglasses and phones difficult; it is more difficult to keep in place during physical exercise. Box 39-13 reviews guidelines for the care and cleaning of hearing aids.

Nasal Care. The patient usually removes secretions from the nose by gently blowing into a soft tissue. Caution the patient against harsh blowing that creates pressure capable of injuring the eardrum, nasal mucosa, and even sensitive eye structures. Bleeding from the nares is a sign of harsh blowing.

If the patient is unable to remove nasal secretions, help by using a wet washcloth or a cotton-tipped applicator moistened in water or saline. Never insert the applicator beyond the length of the cotton tip. You can remove excessive nasal secretions by gentle suctioning.

When nasogastric, feeding, or endotracheal tubes are inserted through a patient's nose, change the tape anchoring the tube at least once a day. When tape becomes moist from nasal secretions, the skin and mucosa easily become macerated. Friction from a tube causes tissue sloughing. After carefully removing the tape, maintain hold of the tubing and thoroughly clean and dry the nasal surface.

Patient's Room Environment. Attempt to make a patient's room as comfortable as the home. It needs to be safe and large enough to allow the patient and visitors to move about freely. Control room temperature, ventilation, noise, and odors. Keeping the room neat and orderly also contributes to the patient's sense of well-being.

Maintaining Comfort. What makes a comfortable environment depends on a patient's age, severity of illness, and level of normal daily activity. Depending on age and physical condition, maintain the room temperature between 20° and 23° C (68° and 73.4° F). Infants, older adults, and the acutely ill often need a warmer room. However, certain ill patients benefit from cooler room temperatures to lower the metabolic demands of the body.

FIG. 39-8 Typical hospital room.

An effective ventilation system keeps stale air and odors from lingering in the room. Protect the acutely ill, infants, and older adults from drafts by ensuring that they are adequately dressed and covered with a lightweight blanket. Always empty and rinse commodes, bedpans, and urinals promptly. Room deodorizers help remove many unpleasant odors. Before using room deodorizers determine that the patient is not allergic or sensitive to the deodorizer itself. Thorough hygiene measures provide the best control of body or breath odors.

Ill patients seem to be more sensitive to noises and lighting commonly found in health care. Try to control the noise level, especially when the patient is trying to sleep. Explain the source of unfamiliar noises such as an IV pump or pulse oximeter alarm. Proper lighting provides for safety and comfort. A brightly lit room usually stimulates, whereas a darkened room promotes rest and sleep. Adjust room lighting by closing or opening drapes, regulating over-bed and floor lights, and closing or opening room doors. When entering a patient's room at night, refrain from abruptly turning on an overhead light unless necessary.

Room Equipment. Although there are variations across health care settings, a typical hospital room contains the following basic pieces of furniture: over-bed table, bedside stand, chairs, and bed (Fig. 39-8). Long-term care and rehabilitation facilities often have similar equipment. You can adjust the over-bed table, which rolls on wheels, to various heights over the bed or a chair. The table provides ideal working space for performing procedures. It also provides a surface on which to place meal trays, toiletry items, and objects frequently used by the patient. Clean the top of the over-bed table with an antiseptic cleaner before using it for meals. Do not place the bed pan or urinal on the over-bed table. The bedside stand is for storing the patient's personal possessions and hygiene equipment. The telephone, water pitcher, and drinking cup are usually on top of the bedside stand.

Most hospital rooms contain an armless straight-backed chair or an upholstered lounge chair with arms. Straight-backed chairs

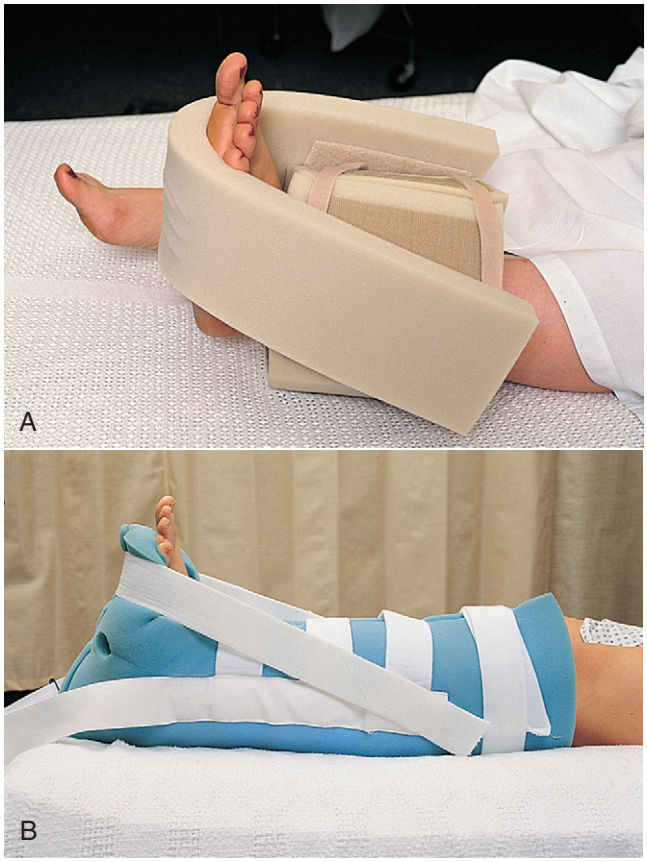

FIG. 39-9 **A,** Foot boot. **B,** Foot boot with lower leg extension.

FIG. 39-10 Nurse instructing patient in use of call light and bed controls.

are convenient when temporarily transferring the patient from the bed such as during bed making. Lounge chairs tend to be more comfortable when a patient is willing and able to sit for an extended period.

Each room usually has an over-bed light and floor level night lighting. Position movable lights that extend over the bed from the wall for easy reach, but move them aside when not in use. Additional portable lighting provides extra light during bedside procedures. Some facilities have permanent examination lights mounted in the ceiling or wall.

Other equipment usually found in a patient's room includes a call light, a television set, a wall-mounted blood pressure gauge, oxygen and vacuum wall outlets, and personal care items. Special equipment designed for comfort or positioning patients includes foot boots (Fig. 39-9), special mattresses (see Chapter 48), and bed boards. Whenever you use comfort and positioning equipment, check agency policy and manufacturer directions before application.

Beds. Seriously ill patients often remain in bed for a long time. Because a bed is the piece of equipment used most by a hospitalized patient, it is designed for comfort, safety, and adaptability for changing positions.

The typical hospital bed has a firm mattress on a metal frame that you can raise and lower horizontally. More and more hospitals are converting the standard hospital bed to one in which the mattress surface can be electronically adjusted for patient safety and comfort. Different bed positions promote patient comfort, minimize symptoms, promote lung expansion, and improve access during certain procedures (Table 39-6).

You change the position of a bed usually by using electrical controls incorporated into the patient's call light and in a panel on the side or foot of the bed (Fig. 39-10). Be familiar with use of the bed controls. Ease in raising and lowering a bed and changing position of the head and foot eliminates undue musculoskeletal strain on a nurse. Instruct patients in the proper use of controls and caution them against raising the bed to a position that causes harm. Maintain the bed height at the lowest horizontal position when the patient is unattended.

Beds contain safety features such as locks on the wheels or casters. Lock wheels when the bed is stationary to prevent accidental movement. Side rails allow patients to move more easily in bed and prevent accidents. Do not use side rails to restrict a patient from moving in bed. When using side rails as a restraint, you need a health care provider's order (see Chapter 27). You can remove the headboard and footboard from most beds. This is important when the medical team needs to have easy access to the patient such as during cardiopulmonary resuscitation.

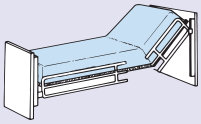
Bed Making. Keep a patient's bed clean and comfortable. This requires frequent inspection to be sure that linen is clean, dry, and free of wrinkles. When patients are diaphoretic, have draining wounds, or are incontinent, check more frequently for wet or soiled linen.

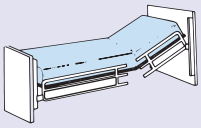
Usually you make the bed in the morning after the patient's bath or while he or she is bathing, in a shower, sitting in a chair eating, or out of the room for procedures or tests. Throughout the day straighten linen that is loose or wrinkled. Also check the bed linen for food particles after meals and for wetness or soiling. Change any linen that becomes soiled or wet.

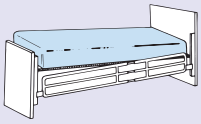
When changing bed linen, follow principles of medical asepsis by keeping soiled linen away from the uniform (Fig. 39-11). Place soiled linen in special linen bags before placing in a hamper. To avoid air currents that spread microorganisms, never shake the linen. To avoid transmitting infection, do not place soiled linen on the floor. If clean linen touches the floor or any unclean surface, immediately place it in the dirty linen container.

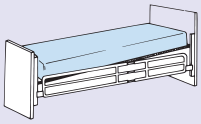
During bed making use safe patient handling procedures and proper body mechanics (see Chapter 47). Always raise the bed to the appropriate height before changing linen so you do not have

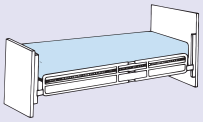
TABLE 39-6 Common Bed Positions











POSITION	DESCRIPTION	USES
Fowler's 	Head of bed raised to angle of 45 degrees or more; semi-sitting position; foot of bed may also be raised at knee	While patient is eating During nasogastric tube insertion and nasotracheal suction Promotes lung expansion Eases difficult breathing
Semi-Fowler's 	Head of bed raised approximately 30 degrees; inclination less than Fowler's position; foot of bed may also be raised at knee	Promotes lung expansion, especially with ventilator-assisted patients Used when patients receive gastric feedings to reduce regurgitation and risk of aspiration
Trendelenburg's 	Entire bed frame tilted with head of bed down	Used for postural drainage Facilitates venous return in patients with poor peripheral perfusion
Reverse Trendelenburg's 	Entire bed frame tilted with foot of bed down	Used infrequently Promotes gastric emptying Prevents esophageal reflux
Flat 	Entire bed frame horizontally parallel with floor	Used for patients with vertebral injuries and in cervical traction Used for patients who are hypotensive Patients usually prefer for sleeping

FIG. 39-11 Holding linen away from the uniform prevents contact with microorganisms.

to bend or stretch over the mattress. You move back and forth to opposite sides of the bed while applying new linen. Body mechanics and safe handling are important when turning or repositioning the patient in bed.

When patients are confined to bed, organize bed-making activities to conserve time and energy (Skill 39-5 on pp. 813-817). The patient's privacy, comfort, and safety are all important when making a bed. Using side rails to aid positioning and turning, keeping call lights within the patient's reach and maintaining the proper bed position help promote comfort and safety. After making a bed, return it to the lowest horizontal position and verify that the wheels are locked to prevent accidental falls when the patient gets in and out alone.

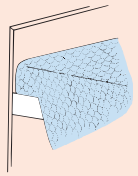
When possible, make the bed while it is unoccupied (Box 39-14). Use judgment to determine the best time for the patient to sit up in a chair so you can make the bed. When making an unoccupied bed, follow the same basic principles as for occupied bed making.

An unoccupied bed can be made as an open or closed bed. In an open bed the top covers are folded back so it is easy for a patient to get into bed. In a closed bed the top sheet, blanket, and bedspread are drawn up to the head of the mattress and under the pillows. A closed bed is prepared in a hospital room before a new patient is admitted to that room. A surgical, recovery, or postoperative bed is a modified version of the open bed. The top bed linen is arranged for easy transfer of the patient from a stretcher to the bed. The top sheets and spread are not tucked or mitered at the corners. Instead they are folded to one side or to the bottom third of the bed (Fig. 39-12). This makes patient transfer into the bed easier.

Linens. Many agencies have "nurse servers" either within or just outside a patient's room where a daily supply of linen is stored. Because of the importance of cost control in health care, avoid bringing excess linen into a patient's room. Once you bring the

BOX 39-14 PROCEDURAL GUIDELINES

Making an Unoccupied Bed



Delegation Considerations

The skill of making an unoccupied bed can be delegated to nursing assistive personnel (NAP).

Equipment

Linen bag, mattress pad (change only when soiled), bottom sheet (flat or fitted), drawsheet *(optional),* top sheet, blanket, bedspread, waterproof pads *(optional),* pillowcases, bedside chair or table, clean gloves (if linen is soiled), washcloth, and antiseptic cleanser

1. If patient has been incontinent or if excess drainage is on linen, gloves are necessary.
2. Assess activity orders or restrictions in mobility in planning if patient can get out of bed for procedure. Assist to bedside chair or recliner.
3. Lower side rails on both sides of bed and raise bed to comfortable working position.
4. Remove soiled linen and place in laundry bag. Avoid shaking or fanning linen.
5. Reposition mattress and wipe off any moisture using a washcloth moistened in antiseptic solution. Dry thoroughly.
6. Apply all bottom linen on one side of bed before moving to opposite side.
7. Be sure that fitted sheet is placed smoothly over mattress. To apply a flat unfitted sheet, allow about 25 cm (10 inches) to hang over mattress edge. Make sure that lower hem of sheet lies seam down, even with bottom edge of mattress. Pull remaining top portion of sheet over top edge of mattress.
8. While standing at head of bed, miter top corner of bottom sheet (see Skill 39-5, Step 14).
9. Tuck remaining portion of unfitted sheet under mattress from head to foot of bed.
10. *Optional:* Apply drawsheet, laying centerfold along middle of bed lengthwise. Smooth drawsheet over mattress and tuck excess edge under mattress, keeping palms down.
11. Move to opposite side of bed and spread bottom sheet smoothly over edge of mattress from head to foot of bed.
12. Apply fitted sheet smoothly over each mattress corner. For an unfitted sheet, miter top corner of bottom sheet (see Step 8), making sure that corner is taut.
13. Grasp remaining edge of unfitted bottom sheet and tuck tightly under mattress while moving from head to foot of bed. Smooth folded drawsheet over bottom sheet and tuck under mattress, first at middle, then at top, and then at bottom.
14. If needed, apply waterproof pad over bottom sheet or drawsheet.
15. Place top sheet over bed with vertical centerfold lengthwise down middle of bed. Open sheet out from head to foot, being sure that top edge of sheet is even with top edge of mattress.
16. Make horizontal toe pleat: stand at foot of bed and make fanfold in sheet 5 to 10 cm (2 to 4 inches) across bed. Pull sheet up from bottom to make fold approximately 15 cm (6 inches) from bottom edge of mattress (see illustration, Skill 39-5, Step 31).
17. Tuck in remaining portion of sheet under foot of mattress. Then place blanket over bed with top edge parallel to top edge of sheet and 15 to 20 cm (6 to 8 inches) down from edge of sheet. (*Optional:* Apply additional spread over bed.)
18. Make cuff by turning edge of top sheet down over top edge of blanket and spread.
19. Standing on one side at foot of bed, lift mattress corner slightly with one hand; with other hand tuck top sheet, blanket, and spread under mattress. Be sure that toe pleats are not pulled out.
20. Make modified mitered corner with top sheet, blanket, and spread. After making triangular fold, do not tuck tip of triangle (see illustration).

STEP 20 Modified mitered corner.

21. Go to other side of bed. Spread sheet, blanket, and spread out evenly. Make cuff with top sheet and blanket. Make modified corner at foot of bed.
22. Apply clean pillowcase.
23. Place call light within patient's reach on bed rail or pillow and return bed to height allowing for patient transfer. Assist patient to bed.
24. Arrange patient's room. Remove and discard supplies. Perform hand hygiene.

FIG. 39-12 Surgical or recovery bed.

linen into a patient's room, if unused, it must be laundered before being used. This increases agency costs. Excess linen lying around a patient's room creates clutter and obstacles for patient care activities.

Before making a bed collect necessary bed linens and the patient's personal items. In this way all equipment is accessible to prepare the bed and room. When fitted sheets are not available, flat sheets usually are pressed with a center crease to be placed down the center of the bed. The linens unfold easily to the sides, with creases often fitting over the mattress edge. Apply clean linens whenever there is soiling.

Handle linen properly to minimize the spread of infection (see Chapter 28). Agency policies provide guidelines for the proper way to bag and dispose of soiled linen. After a patient is discharged, all bed linen goes to the laundry, and housekeeping cleans the mattress and bed before clean linen is applied.

EVALUATION

Through the Patient's Eyes. Evaluate patient responses to nursing interventions to determine if goals and outcome criteria have been met. A critical thinking approach considers all factors when evaluating the patient's care (Fig. 39-13). Critical thinking ensures that the nurse considers the patient's perspectives and applies what is known about hygiene to the patient's unique situation.

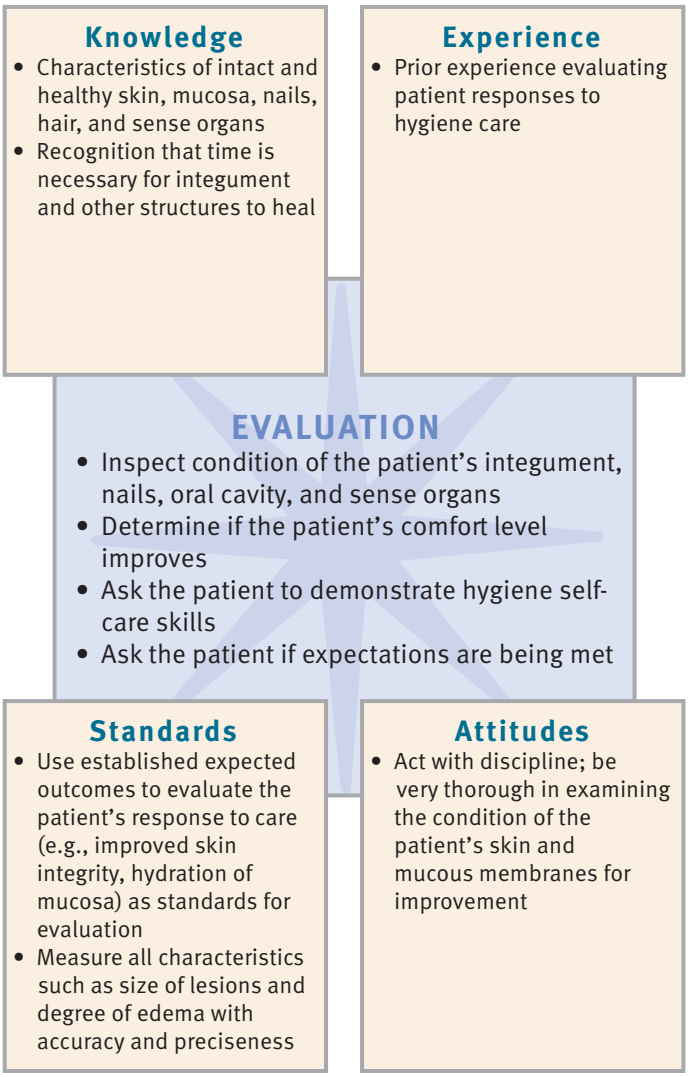


FIG. 39-13 Critical thinking model for hygiene evaluation.

The patient's expectations are important guidelines in determining patient satisfaction. You need to feel comfortable in addressing his or her concerns and expectations. A caring approach facilitates discussion of these issues. Evaluate patient responses to hygiene measures both during and after each particular hygiene intervention. For example, when the bath is completed, ask if the patient's comfort and relaxation have improved. When evaluating for the effectiveness of hygiene measures, observe for changes in his or her behavior. Does the patient assume a more relaxed position? Is he or she free of body odor? Is he or she able to fall asleep? Does his or her facial expression convey a sense of comfort?

Patient Outcomes. Frequently it takes time for hygiene care to result in an improvement in the patient's condition. The presence of oral lesions, a scalp infestation, or skin excoriation often requires repeated measures and a combination of nursing interventions. The nurse's knowledge base and experience provide important perspectives when analyzing assessment data about a patient. For example, frequent observation of the oral mucosa helps to determine the effectiveness of oral hygiene practices. Are previously inflamed mucosa improving? The standards for evaluation are the expected outcomes established in the planning stage of the patient's care. If outcomes are not met, you need to revise the care plan. Continue to apply critical thinking attitudes when considering all evaluation findings.

The final aspect of evaluation determines whether or not the patient's expectations for hygiene were met.

When outcomes are not met, ask questions to determine appropriate changes in interventions. Examples of questions include:

- Did your bath and back rub help make you comfortable?
- Are there ways we can do a better job with your foot care?
- What is preventing you from being able to perform your foot care at home?
- Which further measures do you think are necessary to keep your mouth clean and refreshed?
- What other questions do you have about helping your father with his bath?
- What do you think would help you be more independent with your hygiene care?

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Always perform hygiene measures moving from the cleanest to less clean or dirty areas. This often requires you to change gloves and perform hand hygiene during care activities.
- Use clean gloves when you anticipate contact with nonintact skin or mucous membranes or when there will likely be contact with drainage, secretions, excretions, or blood during hygiene care.
- When using water or solutions for hygiene care, be sure to test the temperature to prevent burn injury.
- To avoid injury when performing hygiene care, use principles of body mechanics and safe patient handling.
- When giving or assisting with hygiene care, be sensitive to the invasion of privacy and possible loss of self-esteem associated with these procedures. Foster acceptance and comfort by using therapeutic communication techniques, draping and providing privacy, and informing the patient before touching sensitive or private body parts.
- Remember that you are responsible and accountable for assessing the patient both before and after care to detect unexpected outcomes and give proper direction to nursing assistive personnel when delegating hygiene care.

SKILL 39-1 BATHING AND PERINEAL CARE

Delegation Considerations

The skill of bathing and perineal care can be delegated to nursing assistive personnel (NAP). Direct the NAP to:

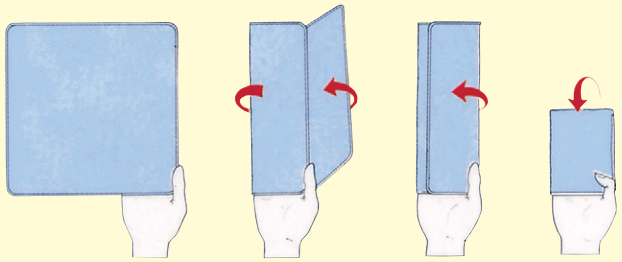
- Avoid massaging reddened skin areas.
- Report early signs of impaired skin integrity, including redness or pale skin, to the nurse.
- Properly position patients with musculoskeletal limitations and indwelling catheters or intravenous (IV) lines.
- Report patient fatigue, shortness of breath, or pain during hygiene care.
- Report changes in patient's skin to the nurse.

Equipment

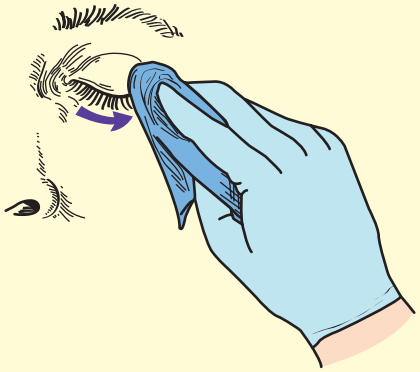
- Washcloths and bath towels (optional disposable cloths)
- Bath blanket
- Soap and soap dish or liquid soap (optional no rinse solution)
- Toiletry items (deodorant, powder, lotion, cologne)
- Toilet tissue or wipes
- Warm water
- Clean hospital gown or patient's own pajamas or gown
- Laundry bag
- Clean gloves (when risk for contacting body fluids)
- Washbasin

STEP	RATIONALE
ASSESSMENT	
1 Assess patient's tolerance for bathing: activity tolerance, comfort level during movement, cognitive ability, musculoskeletal function, and the presence of shortness of breath.	Determines patient's ability to perform or tolerate bathing and level of assistance required (e.g., tub bath, partial bed bath).
CLINICAL DECISION: *Patients with dementia may become agitated and aggressive during bathing activities. Consider using alternative bathing procedures with these patients (see Box 39-7).*	
2 Assess patient's visual status, ability to sit without support, hand grasp, range of motion (ROM) of extremities.	Determines degree of assistance patient needs for bathing.
3 Assess for presence of equipment (e.g., IV line, oxygen tubing, Foley catheter)	Affects how you plan bathing activities and positioning. Helps determine how to set up supplies.
4 Assess patient's bathing preferences: frequency and time of day preferred, type of hygiene products used, and other factors related to patient preferences.	Patient participates in plan of care. Promotes patient's comfort and willingness to cooperate. Includes cultural or personal hygiene preferences into care.
5 Ask if patient has noticed any problems related to condition of skin and genitalia: excess moisture, inflammation, drainage or excretions from lesions or body cavities, rashes or other skin lesions.	Provides you with information to direct physical assessment of skin and genitalia during bathing. Also influences selection of skin care products.
6 Before or during bath, assess condition of patient's skin. Note presence of dryness, indicated by flaking, redness, scaling, and cracking.	Provides a baseline for comparison over time in determining if bathing improves condition of skin.
7 Assess patient's knowledge of skin hygiene in terms of its importance, preventive measures to take, and common problems.	Determines patient's learning needs.
PLANNING	
1 Review orders for specific precautions concerning patient's movement or positioning.	Prevents injury to patient during bathing activities. Determines level of assistance required by patient.
2 Check for a health care provider's therapeutic bath order; if there is an order, note type of solution, length of time for bath, body part to be attended.	Therapeutic baths are ordered for specific physical effect, which usually includes promotion of healing or soothing effects.
3 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
4 Explain procedure and ask patient for suggestions on how to prepare supplies. If partial bath, ask how much of bath patient wishes to complete.	Promotes patient's cooperation and participation.
5 Prepare equipment and supplies. If it is necessary to leave room, be sure that call light is within patient's reach.	Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment.
IMPLEMENTATION	
1 Complete or partial bed bath	
a. Offer patient bedpan or urinal. Provide toilet tissue.	Patient feels more comfortable after voiding. Prevents interruption of bath.
b. Perform hand hygiene. If patient has nonintact skin or skin is soiled with drainage, excretions, or body secretions, apply clean gloves. Ensure that patient is not allergic to latex.	Reduces transmission of microorganisms. Prevents allergic reaction if latex gloves are used.
c. Verify that bed is in locked position and raise bed to a comfortable working height. Lower side rail closest to you and assist patient into comfortable supine position, maintaining body alignment. Bring patient toward side closest to you.	Prevents bed from moving. Helps you reach patient without stretching and reaching across bed, thus minimizing strain on back muscles.

SKILL 39-1 BATHING AND PERINEAL CARE—cont'd



STEP	RATIONALE
d. Place bath blanket over patient and loosen and remove top covers without exposing him or her. If possible, have patient hold top of bath blanket. Place soiled linen in laundry bag. Take care to not allow linen to touch your uniform. *Optional:* Use top sheet when bath blanket is not available or patient prefers.	Bath blanket provides warmth and privacy during bath.
e. Remove patient's gown or pajamas.	Provides full exposure of body parts during bathing.
(1) If available, use gown with ties or snaps on sleeves for patient with IV line, upper-extremity injury, or limited ROM.	
(2) If snap-on gown or gown with ties on arms is not used and patient has limited upper-extremity ROM or an IV access, remove gown from *unaffected side first.*	Undressing unaffected side first allows easier manipulation of gown over body part with reduced ROM.
(3) Remove gown from arm without IV line first. Then remove gown from arm with IV line (see illustrations). Remove IV tubing from pole and slide IV container and tubing through arm of patient's gown. Rehang IV container and check flow rate. Regulate if necessary.	Manipulation of IV tubing and container may disrupt flow rate. Do **not** delegate regulation of IV flow rate to NAP.



STEP 1e(3) **A,** Remove patient's gown. **B,** Remove IV tubing from pole. **C,** Slide IV tubing through arm of patient's gown. **D,** Rehang IV bag.

(4) If IV pump is in use, turn pump off, clamp tubing, remove tubing from pump, and proceed as in Step (3). Reinsert tubing into pump, unclamp tubing, and turn pump on at correct rate. Observe flow rate and regulate if necessary. *Do not disconnect tubing.*	Regulation is necessary to prevent improper infusion of fluids. Do **not** delegate regulation of IV pump to NAP. Disconnecting IV tubing places patient at risk of introduction of microorganisms into the IV line.
f. Pull side rail up. Lower bed temporarily to lowest position and raise to comfortable working height on return after filling washbasin two-thirds full with warm water. Place basin and supplies on over-bed table. Check water temperature and also have patient place fingers in water to test temperature tolerance. Place plastic container of bath lotion in bath water to warm if desired.	Raising side rail and lowering bed position maintain patient's safety while you leave bedside. Keeping bed at working height during bath prevents back strain. Warm water promotes comfort, relaxes muscles, and prevents unnecessary chilling. Testing temperature prevents accidental burns. Bath water warms lotion for application to patient's skin.

STEP	RATIONALE
g. Lower side rail, remove pillow if tolerated, and raise head of bed 30 to 45 degrees if allowed. Place bath towel under patient's head. Place second bath towel over patient's chest.	Aids your access to patient. You do not have to reach across bed, thus minimizing strain on back muscles. Removal of pillow makes it easier to wash patient's ears and neck. Placing towels prevents bed linen and bath blanket from getting soiled or wet.
h. Wash face.	
(1) Ask if patient is wearing contact lenses.	Prevents accidental injury to eyes.
(2) Fold washcloth around fingers of your hand to form a mitt (see illustration). Immerse mitt in water and wring thoroughly.	Mitt retains water and heat better than loosely held washcloth; keeps cold edges from brushing against patient and prevents splashing.
(3) Wash patient's eyes with plain warm water. Use different section of mitt for each eye. Move mitt from inner to outer canthus (see illustration). Soak any crusts on eyelid for 2 to 3 minutes with damp cloth before attempting removal. Dry eyes thoroughly but gently.	Soap irritates eyes. Use of separate sections of mitt reduces infection transmission. Bathing eye from inner to outer canthus prevents secretions from entering nasolacrimal duct. Pressure can cause internal injury.
(4) Ask if patient prefers to use soap on face. Otherwise wash, rinse, and dry forehead, cheeks, nose, neck, and ears without using soap. (Men may wish to shave at this point or wait until after bath.)	Soap tends to dry face, which is exposed to air more than other body parts.
i. Wash trunk and upper extremities.	
(1) Remove bath blanket from patient's arm that is closest to you. Place bath towel lengthwise under arm. Bathe arm with soap and water using long, firm strokes from distal to proximal areas (fingers to axilla).	Towel prevents soiling of bed. Soap lowers surface tension and facilitates removal of debris and bacteria when friction is applied during washing. Long, firm strokes stimulate circulation; moving distal to proximal promotes venous return.
(2) Raise and support arm above head (if possible) to wash, rinse, and dry axilla thoroughly (see illustration). Apply deodorant or powder to underarms if desired or needed.	Movement of arm exposes axilla and exercises normal ROM of joint. Alkaline residue from soap discourages growth of normal skin bacteria. Drying prevents excess moisture, which can cause skin maceration or softening. Respect patient's preference for use of hygiene products.

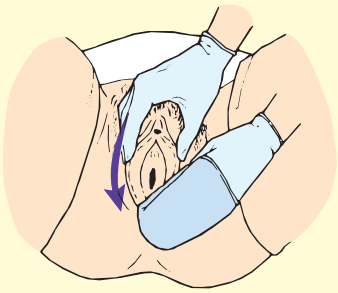
STEP 1h(2) Steps for folding washcloth to form a mitt.

STEP 1h(3) Wash eye from inner to outer canthus.

STEP 1i(2) Positioning arm to wash axilla.

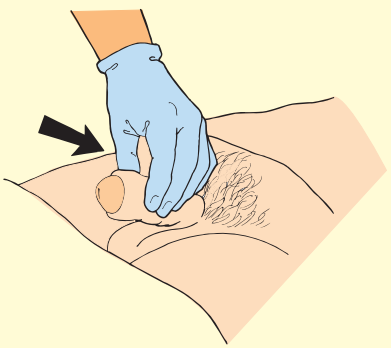
SKILL 39-1 BATHING AND PERINEAL CARE—cont'd

STEP	RATIONALE
(3) Move to other side of bed and repeat Steps (1) and (2) with other arm.	Provides for better access to patient and helps prevents back strain.
(4) Place bath towel across patient's chest so it covers chest and arms and fold bath blanket down to umbilicus. While lifting edge of towel away from chest with one hand, bathe chest with mitted washcloth on other hand using long, firm strokes. Take special care to wash skinfolds under female's breasts. It is often necessary to lift breast upward while bathing underneath it. Keep patient's chest covered between wash and rinse periods. Rinse and dry well.	Draping prevents unnecessary exposure of body parts. Towel maintains warmth and privacy. Secretions and dirt collect easily in areas of tight skinfolds. Skin under breasts is vulnerable to excoriation if not kept clean and dry.
j. Wash hands and nails.	
(1) Fold bath towel in half and lay it on bed beside patient. Place basin on towel. Immerse patient's hand in water. Allow hand to soak for 2 to 3 minutes before washing hand and fingernails. Remove basin and dry hand well. Repeat for other hand.	Soaking softens cuticles and calluses of hand, loosens debris beneath nails, and enhances feeling of cleanliness. Thorough drying removes moisture between fingers.
k. Check temperature of bath water and change water when cool or soapy.	Warm water maintains patient's comfort. Alkaline soap residue is irritating to skin and can decrease the normal protectiveness of acid ph.
CLINICAL DECISION: *If patient is at risk for falling, be sure that two side rails are up before obtaining fresh water. In addition, lower bed when it is necessary to leave bedside. NOTE: Having all side rails raised is considered a restraint. Check agency policy.*	
l. Wash the abdomen.	
(1) Place bath towel lengthwise over chest and abdomen. (Two towels may be needed.) Fold bath blanket down to just above pubic region. With one hand lift bath towel. With mitted hand bathe and rinse abdomen, giving special attention to umbilicus and skinfolds of abdomen and groin. Stroke from side to side. Keep abdomen covered between washing and rinsing. Rinse and dry well.	Draping prevents unnecessary exposure of body parts. Towel maintains warmth and privacy. Keeping skinfolds clean and dry helps prevent odor and skin irritation. Moisture and sediment that collect in skinfolds predispose skin to maceration.
(2) Apply clean gown or pajama top. If an extremity is injured or immobilized, dress affected side first. (This step may be omitted until completion of bath; gown should not become soiled during remainder of bath.)	Maintains patient's warmth and comfort. Dressing affected side first allows easier manipulation of gown over body part with reduced ROM.
m. Wash the lower extremities.	
(1) Cover chest and abdomen with top of bath blanket. Cover legs with bottom of blanket. Expose near leg by folding blanket toward midline. Be sure to keep other leg and perineum draped.	Prevents unnecessary exposure.
(2) Place bath towel under leg, supporting leg at knee and ankle. If appropriate, place patient's foot in bath basin to soak while washing and rinsing. (Bend patient's leg at knee; and, while grasping patient's heel, elevate leg from mattress slightly and place bath basin on towel.) If patient is unable to support leg, cleaning can be done by washing feet thoroughly with washcloth.	Towel prevents soiling of bed linen. Support of joint and extremity during lifting prevents strain on musculoskeletal structures. Sudden movement by patient could spill bath water. Soaking softens calluses and rough skin.
CLINICAL DECISION: *If patient has diabetes or peripheral vascular disease with impaired circulation and/or sensation, do not soak feet.*	
(3) Wash leg using long, firm strokes from ankle to knee and from knee to thigh (see illustration). Do not rub or massage the back of the calf. Rinse and dry well. Clean foot, making sure to bathe between toes. Rinse and dry toes and feet completely. Clean and clip nails as needed (see Skill 39-2). Remove and discard towel.	Promotes circulation and venous return. Excess massage of calf could loosen deep vein thrombus. Secretions and moisture may be present between toes, predisposing patient to maceration and breakdown.
(4) Raise side rail, move to opposite side of bed, lower side rail, and repeat Steps (2) and (3) for other leg and foot. If skin is dry, apply moisturizer. When finished, cover patient with bath blanket.	
CLINICAL DECISION: *Do not use long, firm strokes to wash the lower extremities of patients with history of deep vein thromboses or blood-clotting disorders. Use short, light strokes instead.*	
n. Cover patient with bath blanket, raise side rail for patient's safety, remove soiled gloves, and/or perform hand hygiene. Change bath water.	Decreased bath water temperature causes chilling. Clean water reduces microorganism transmission to perineal structures.

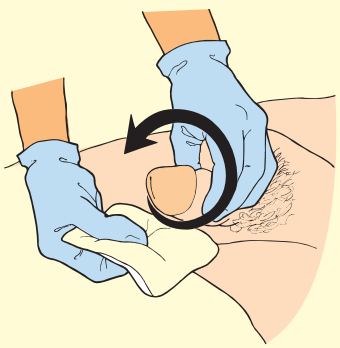


STEP	RATIONALE
o. Provide perineal hygiene.	
(1) If patient is able to maneuver and handle washcloth, allow him or her to clean perineum on own.	Maintains patient's dignity and self-care ability.
(2) Female patient	
(a) Apply pair of clean gloves. Lower side rail. Assist patient into dorsal recumbent position. Note restrictions or limitations in patient's positioning. Place waterproof pad under patient's buttocks. Drape patient with bath blanket placed in the shape of a diamond. Lift lower edge of bath blanket to expose perineum (see illustration).	Provides full exposure of female genitalia. If patient is totally dependent, provide assistance to support patient in side-lying position and raise leg as perineum is bathed. If position causes patient discomfort, reduce degree of abduction in female's hips.
(b) Fold lower corner of bath blanket up between patient's legs onto abdomen. Wash and dry patient's upper thighs.	Keeping patient draped until procedure begins minimizes anxiety. Buildup of perineal secretions soils surrounding skin surfaces.
(c) Wash labia majora. Use nondominant hand to gently retract labia from thigh: with dominant hand, wash carefully in skinfolds. Wipe in direction from perineum to rectum. Repeat on opposite side using separate section of washcloth. Rinse and dry area thoroughly.	Perineal care involves thorough cleaning of the patient's external genitalia and surrounding skin. Skinfolds may contain body secretions that harbor microorganisms. Wiping front to back reduces chance of transmitting fecal organisms to urinary meatus.
(d) Gently separate labia with nondominant hand to expose urethral meatus and vaginal orifice. With dominant hand, wash downward from pubic area toward rectum in one smooth stroke (see illustration). Wash middle and both sides of the perineum. Use separate section of cloth for each stroke. Clean thoroughly around labia minora, clitoris, and vaginal orifice. Avoid placing tension on indwelling catheter if present and clean area around it thoroughly.	Cleansing method reduces transfer of microorganisms to urinary meatus. (For menstruating women or patients with indwelling catheters, clean with cotton balls.)
(e) Provide catheter care as needed (see Chapter 45).	Cleaning along catheter from exit site reduces incidence of health care–associated urinary infection.
(f) Rinse area thoroughly. May use bedpan and pour warm water over perineal area. Dry thoroughly from front to back.	Rinsing removes soap and microorganisms more effectively than wiping. Retained moisture harbors microorganisms.

STEP 1m(3) Washing leg.

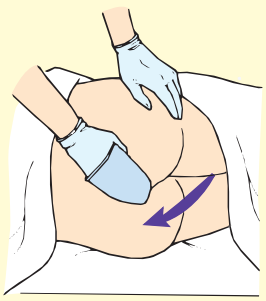


STEP 1o(2)(a) Drape patient for perineal care.



STEP 1o(2)(d) Cleanse from perineum to rectum.

SKILL 39-1 BATHING AND PERINEAL CARE—cont'd



STEP	RATIONALE
(g) Fold lower corner of bath blanket back between patient's legs and over perineum. Ask patient to lower legs and assume comfortable position.	
(3) Male patient	
(a) Apply pair of clean gloves. Lower side rail. Assist patient to supine position. Note any restriction in mobility.	Provides full exposure of male genitalia. Position patients who are unable to lie supine on their side.
(b) Fold lower half of bath blanket up to expose upper thighs. Wash and dry thighs.	Buildup of perineal secretions soils surrounding skin surfaces.
(c) Cover thighs with bath towels. Raise bath blanket up to expose genitalia. Gently raise penis and place bath towel underneath. Gently grasp shaft of penis. If patient is uncircumcised, retract foreskin (see illustration). If patient has an erection, defer procedure until later.	Draping minimizes patient anxiety. Towel prevents moisture from collecting in inguinal area. Gentle but firm handling of penis reduces chance of an erection. Secretions capable of harboring microorganisms collect underneath foreskin.
(d) Wash tip of penis at urethral meatus first. Using circular motion, clean from meatus outward (see illustration). Discard washcloth and repeat with a clean cloth until penis is clean. Rinse and dry gently.	Direction of cleaning moves from area of least contamination to area of most contamination, preventing microorganisms from entering urethra.
(e) Return foreskin to its natural position. This is extremely important in patients with decreased sensation in their lower extremities.	Tightening of foreskin around shaft of penis causes local edema and discomfort. Patients with reduced sensation do not feel tightening of foreskin.
(f) Gently clean shaft of penis and scrotum by having patient abduct legs. Pay special attention to underlying surface of penis. Lift scrotum carefully and wash underlying skinfolds. Rinse and dry thoroughly.	Vigorous massage of penis may cause an erection. Underlying surface of penis is an area where secretions accumulate. Abduction of legs provides easier access to scrotal tissues. Secretions easily collect between skinfolds.
(g) Avoid placing tension on indwelling catheter if present and clean area around it thoroughly. Provide catheter care (see Chapter 45).	Cleaning along catheter from exit site reduces incidence of nosocomial urinary infection.
p. Remove soiled gloves and discard in trash; raise side rail before leaving bedside to dispose of water and obtain fresh water.	Prevents transmission of infection. Protects patient from injury.
q. Wash back. (This follows both female and male perineal care.)	
(1) Perform hand hygiene and apply clean pair of gloves if indicated. Lower side rail. Assist patient into prone or side-lying position (as applicable). Place towel lengthwise along patient's side and keep him or her covered with bath blanket.	Exposes back and buttocks for bathing while limiting exposure.
(2) Keep patient draped by sliding bath blanket over shoulders and thighs during bathing. Wash, rinse, and dry back from neck to buttocks using long, firm strokes. Move from back to buttocks and anus. Pay special attention to folds of buttocks and anus.	Cleaning buttocks and anus after back prevents contamination of water.
(3) Perform hand hygiene and apply clean pair of gloves. Lower side rail. Assist patient into prone or side-lying position (as applicable). Place towel lengthwise along patient's side and keep him or her covered with bath blanket.	Exposes back and buttocks for bathing while limiting exposure.
(4) If fecal material is present, enclose in a fold of underpad or toilet tissue and remove with disposable wipes.	Skinfolds near buttocks and anus may contain fecal secretions that harbor microorganisms.
(5) Clean buttocks and anus, washing front to back (see illustration). Clean, rinse, and dry area thoroughly. If needed, place a clean absorbent pad under patient's buttocks. Remove contaminated gloves. Raise side rail and perform hand hygiene.	Cleaning motion prevents contaminating perineal area with fecal material or microorganisms.

STEP 1o(3)(c) Retract foreskin.

STEP 1o(3)(d) Use circular motion to cleanse tip of penis.

STEP 1q(5) Cleanse buttocks from front to back.

STEP	RATIONALE
(6) Return to bed and lower side rail; give a back rub.	Promotes patient relaxation. Make sure that a back rub is appropriate for your patient. Back rubs are contraindicated in some cardiac patients.
r. Apply additional body lotion or oil to patient's skin as needed.	Moisturizing lotion prevents dry, chapped skin.
s. Remove soiled linen and place in dirty-linen bag. Clean and replace bathing equipment. Wash hands.	Reduces transmission of microorganisms.
t. Assist patient in dressing. Comb patient's hair. Women may want to apply makeup. Help as needed.	Promotes patient's body image.
u. Make patient's bed (see Skill 39-5 and Box 39-14).	Provides clean, comfortable environment.
v. Check the function and position of external devices (e.g., indwelling urethral catheters, nasogastric tubes, IV lines).	Ensures that systems remain functional after bathing activities.
w. Place bed in lowest position.	Maintains patient's safety by decreasing height of bed frame from floor.
x. Replace call light and personal possessions. Leave room as clean and comfortable as possible.	Prevents transmission of infection. Clean environment promotes patient's comfort. Keeping call light and articles of care within reach promotes patient's safety.
y. Perform hand hygiene.	Reduces transmission of microorganisms.
2 Commercial bag bath or cleansing pack	
a. The cleansing pack contains 8 to 10 premoistened towels for cleaning (see illustrations). Warm package contents in microwave following package directions.	Provides warm soothing heat.

STEP 2a **A,** Patient uses individual towels to bathe. **B,** Commercial bath cleansing pack.

b. Use a single towel for each general body part cleaned. Follow the same order of cleaning as the total or partial bed bath.	Reduces transmission of microorganisms.
c. Allow the skin to air dry for 30 seconds. It is permissible to lightly cover patient with a bath towel to prevent chilling.	Drying the skin with a towel removes the emollient that is left behind after the water/cleaner solution evaporates.
d. NOTE: If there is excessive soiling (e.g., in the perineal region), use an extra bag bath or conventional washcloths, soap, water, and towels.	
3 Tub Bath or Shower	
a. Consider patient's condition and review orders for precautions concerning his or her movement or positioning.	Prevents accidental injury to patient during bathing.
b. Schedule use of shower or tub.	Prevents unnecessary waiting, which causes fatigue.
c. Check tub or shower for cleanliness. Use cleaning techniques outlined in agency policy. Place rubber mat on tub or shower bottom. Place disposable bath mat or towel on floor in front of tub or shower.	Cleaning prevents transmission of microorganisms. Mats prevent slipping and falling.
d. Collect all hygienic aids, toiletry items, and linens requested by patient. Place within easy reach of tub or shower.	Placing items close at hand prevents possible falls when patient reaches for equipment.
e. Assist patient to bathroom if necessary. Have him or her wear robe and slippers.	Assistance prevents accidental falls. Wearing robe and slippers prevents chilling.
f. Demonstrate how to use call signal for assistance.	Bathrooms are equipped with signaling devices in case patient feels faint or weak or needs immediate assistance. Patients prefer privacy during bath if safety is not jeopardized.

SKILL 39-1 BATHING AND PERINEAL CARE—cont'd

STEP	RATIONALE
g. Place "occupied" sign on bathroom door.	Maintains patient's privacy.
h. Fill bath tub halfway with warm water. Check temperature of bath water, have patient test water, and adjust temperature if water is too warm. Explain which faucet controls hot water. If patient is taking shower, turn shower on and adjust water temperature before patient enters shower stall. Use shower seat or tub chair if needed (see illustration).	Adjusting water temperature prevents accidental burns. Older adults and patients with neurological alterations (e.g., diabetes, spinal cord injury) are at high risk for burn as a result of reduced sensation. Use of assistive devices facilitates bathing and minimizes physical exertion.

STEP 3h Shower seat for patient safety.

i. Instruct patient to use safety bars when getting in and out of tub or shower. Also instruct to pull cord to summon assistance (if available). Caution patient against use of bath oil in tub water.	Prevents slipping and falling. Oil causes tub surfaces to become slippery.
j. Instruct patient not to remain in tub longer than 10 to 15 minutes. Check on him or her every 5 minutes.	Prolonged exposure to warm water causes vasodilation and pooling of blood in some patients, leading to light-headedness or dizziness.
k. Return to bathroom when patient signals and knock before entering.	Provides privacy.
l. For patient who is unsteady, drain tub of water before he or she attempts to get out. Place bath towel over patient's shoulders. Assist patient out of tub as needed and help with drying.	Prevents accidental falls. Patient may become chilled as water drains.

CLINICAL DECISION: *Weak or unstable patients need extra assistance in getting out of a tub. Planning for additional personnel is essential before attempting to help the patient.*

m. Help patient as needed with getting dressed in a clean gown or pajamas, slippers, and robe. (In home setting patient may put on regular clothing.)	Maintains warmth to prevent chilling.
n. Assist patient to room and comfortable position in bed or chair.	Maintains relaxation gained from bathing.
o. Clean tub or shower according to agency policy. Remove soiled linen and place in dirty-linen bag. Discard disposable equipment in proper receptacle. Place "unoccupied" sign on bathroom door. Return supplies to storage area.	Prevents transmission of infection through soiled linen and moisture.
p. Perform hand hygiene.	Reduces transfer of microorganisms.

EVALUATION

1 Observe skin, paying particular attention to areas previously soiled, reddened, dry, or showing early signs of breakdown.	Techniques used during bathing leave skin clean and clear. Over time dry skin diminishes. If patient shows areas of redness, use Braden scale to measure risk for pressure ulcers (see Chapter 48).
2 Observe ROM during bath.	Measures joint mobility.
3 Ask patient to rate level of comfort.	Determines patient's tolerance of bathing activities.
4 Ask patient to rate level of fatigue.	Determines patient's tolerance of bathing activities.

STEP	RATIONALE

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Areas of excessive dryness, rashes, or pressure ulcers appear on skin.
   - Complete pressure ulcer assessment (see Chapter 48).
   - Apply moisturizing lotions or topical skin applications per agency policy.
   - Limit frequency of complete baths.
   - Obtain special bed surface if patient is at risk for skin breakdown.
2. Patient becomes excessively fatigued or unable to cooperate or participate in bathing.
   - Reschedule bathing to a time when patient is more rested.
   - Provide pillow or elevate head of bed during bath for patient with breathing difficulties.
   - Notify health care provider if this is a change in patient's fatigue level.
   - Perform hygiene measures in stages between scheduled rest periods.
3. The rectum, perineum, or genital area is inflamed or swollen or has foul-smelling odor.
   - Bathe perineal area frequently enough to keep clean and dry.
   - Obtain an order for a sitz bath.
   - Apply protective barrier ointment or antiinflammatory cream.
   - Report findings to health care provider.

RECORDING AND REPORTING

- Report any breaks in skin or ulcerations to nurse in charge or health care provider. These are serious in patients with altered circulation to the lower extremities.
- Report intolerance of activity to patient's nurse.
- Record procedure, amount of assistance provided, patient's participation in care, condition of skin, and any significant findings (e.g., reddened areas, breaks in skin, inflammation, ulcerations).

HOME CARE CONSIDERATIONS

- Assess patient's tub and shower area for need for safety devices (e.g., grab bars).
- Assess patient for the need for assistive bathing devices (e.g., shower chair, handheld shower).

SKILL 39-2 PERFORMING NAIL AND FOOT CARE

Delegation Considerations

The skill of nail and foot care of patients *without* circulatory problems or diabetes can be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Not clip patient's toenails.
- Use warm, not hot, water for soaking nails.
- Not soak feet of patients who have diabetes or peripheral vascular disease.
- Report any changes that may indicate inflammation or injury to tissue.

Equipment

- Washbasin
- Emesis basin
- Washcloth
- Bath or face towel
- Nail clippers
- Soft cuticle or nail brush
- Orangewood stick
- Emery board or nail file
- Body lotion
- Disposable bath mat (optional)
- Paper towels
- Clean gloves (if drainage is present)
- Linen bag or hamper

STEP	RATIONALE

ASSESSMENT

1 Inspect all surfaces of fingers, toes, feet, and nails. Pay particular attention to areas of dryness, inflammation, or cracking. Also inspect areas between toes, heels, and soles of feet.	Integrity of feet and nails determines frequency and level of hygiene required. Heels, soles, and sides of feet are prone to irritation from ill-fitting shoes.

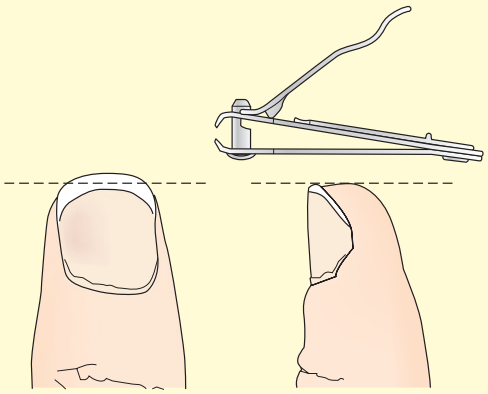
CLINICAL DECISION: *Patients with peripheral vascular diseases or diabetes mellitus, older adults, and patients whose immune system is suppressed often require nail care from a specialist to reduce the risk of tissue injury and infection. Defer care other than washing the feet in these cases until patient has been evaluated.*

2 Assess color and temperature of toes, feet, and fingers. Assess capillary refill of nails. Palpate radial and ulnar pulse of each hand and dorsalis pedis pulse of foot; note character of pulses (see Chapter 30).	Assesses adequacy of blood flow to extremities. Circulatory alterations often change integrity of nails and increase patient's chance of localized infection when break in skin integrity occurs.

SKILL 39-2 PERFORMING NAIL AND FOOT CARE—cont'd

STEP	RATIONALE
3 Ask female patients about whether they use nail polish and polish remover frequently.	Chemicals in these products cause excessive dryness.
4 Assess type of footwear worn by patient: Does patient wear socks? Are shoes tight or ill fitting? Does patient wear garters or knee-high nylons? Is footwear clean?	Types of shoes and footwear predispose patient to foot and nail problems (e.g., infection, areas of friction, ulcerations). These conditions decrease mobility and increase the risk for amputation in the patient with diabetes.
5 Identify patient's risk for foot or nail problems:	Certain conditions increase likelihood of foot or nail problems.
a. Older adult	Poor vision, lack of coordination, or inability to bend over contributes to difficulty in performing foot and nail care. Normal physiological changes of aging also result in nail and foot problems (Meiner, 2011).
b. Diabetes mellitus, peripheral vascular disease	Vascular changes associated with diabetes mellitus reduce blood flow to peripheral tissues. Break in skin integrity places patient with diabetes at high risk for skin infection.
c. Heart failure, renal disease	Both conditions increase tissue edema, particularly in dependent areas (e.g., feet). Edema reduces blood flow to neighboring tissues.
d. Cerebrovascular accident (stroke)	Presence of residual foot or leg weakness or paralysis results in altered walking patterns. Altered gait pattern causes increased friction and pressure on feet.
6 Assess type of home remedies that patient uses for existing foot problems:	Certain preparations or applications cause more injury to soft tissue than initial foot problem.
a. Over-the-counter liquid preparations to remove corns	Liquid preparations cause burns and ulcerations.
b. Cutting corns or calluses with razor blade or scissors	Cutting corns or calluses sometimes results in infection caused by break in skin integrity. The patient with diabetes or any patient with decreased peripheral circulation has an increased risk for infection secondary to a break in skin integrity.
c. Use of oval corn pads	Oval pads exert pressure on toes, thereby decreasing circulation to surrounding tissues.
d. Application of adhesive tape	Skin of older adult is thin and delicate and prone to tearing when adhesive tape is removed.
7 Assess patient's ability to care for nails or feet: visual alterations, fatigue, and musculoskeletal weakness.	Determines patient's ability to perform self-care and degree of assistance required from nurse.
8 Assess patient's knowledge of foot and nail care practices.	Determines patient's need for health teaching.
PLANNING	
1 Obtain health care provider's order for cutting nails if agency policy requires it.	Patients with reduced circulation are more at risk for infection. Accidental cutting of skin increases risk for infection for them.
2 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Patient needs to be able to place fingers and feet in basin for 10 to 20 minutes. Some patients may become fatigued.
3 Explain procedure. Include proper soaking; requires several minutes.	
4 Collect appropriate equipment.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
IMPLEMENTATION	
1 Perform hand hygiene. Apply gloves if lesions or drainage present or anticipated.	Reduces transmission of microorganisms.
2 Arrange equipment on over-bed table.	Easy access to equipment prevents delays.
3 Provide privacy by closing curtains around bed or closing door.	Maintaining privacy reduces embarrassment and anxiety.
4 Assist ambulatory patient to sit in bedside chair. Help bed-bound patient to supine position with head of bed elevated. Place disposable bath mat or towel on floor under patient's feet or place towel on bed.	Sitting in chair facilitates immersing feet in basin. Bath mat or towel protects feet from exposure to soil or microorganisms on floor; towel lessens chance of splashing water on floor or bed.
5 Fill wash basin with warm water. Test water temperature.	Warm water softens nails and thickened epidermal cells, reduces inflammation of skin, and promotes local circulation. Proper water temperature prevents burns.
6 Place basin on bath mat or towel and help patient place feet in basin. Place call light within patient's reach.	Patients with muscular weakness or tremors often have difficulty positioning feet. Maintains patient's safety.

CLINICAL DECISION: *Soaking the feet of patients with diabetes mellitus or peripheral vascular disease is not recommended. Soaking may lead to maceration (excessive softening of the skin) and drying of the skin (ADA, 2010) leading to tissue breakdown and infection.*



STEP	RATIONALE
7 Adjust over-bed table to low position and place it over patient's lap. (Patient sits in chair or lies in bed).	Easy access prevents accidental spills.
8 Fill emesis basin with warm water and place basin on paper towels on over-bed table.	Warm water softens nails and thickened epidermal cells.
9 Instruct patient to place fingers in emesis basin and arms in comfortable position.	Prolonged positioning causes discomfort unless normal anatomical alignment is maintained.
10 Allow patient's feet and fingernails to soak for 10 to 20 minutes. Rewarm water after 10 minutes.	Softening of corns, calluses, and cuticles ensures easy removal of dead cells and easy manipulation of cuticle.
11 Clean gently under fingernails with orangewood stick while fingers are immersed (see illustration). Remove emesis basin and dry fingers thoroughly.	Orangewood stick removes debris under nails that harbors microorganisms. Thorough drying impedes fungal growth and prevents maceration of tissues.
12 Using nail clippers, clip fingernails straight across and even with tops of fingers; check agency policy regarding clipping of nails (see illustration). Using a file, shape nails straight across. If patient has circulatory problems, do not cut nail; file the nail only.	Cutting straight across prevents splitting of nail margins and formation of sharp nail spikes that irritate lateral nail margins. Filing prevents cutting nail too close to nail bed.
13 Use a soft cuticle brush or nail brush around cuticles. Do not push cuticles back roughly or cut cuticles.	Reduces incidence of inflamed cuticles.
14 Move over-bed table away from patient.	Provides easier access to feet.
15 Put on clean gloves and scrub callused areas of feet with washcloth.	Gloves prevent transmission of fungal infection. Friction removes dead skin layers.
16 Clean gently under nails with orangewood stick. Remove feet from basin and dry thoroughly.	Nails harbor debris and dirt and are a source of potential infection (Berridge, 2009).
17 Clean and trim toenails using procedures in Steps 11 and 12. Do not file corners of toenails. Check agency policy for trimming patient's nails.	Shaping corners of toenails damages tissues.
18 Apply lotion to feet and hands and assist patient back to bed and into comfortable position.	Lotion lubricates dry skin by helping to retain moisture.
19 Remove clean gloves and place in receptacle. Clean and return equipment and supplies to proper place. Dispose of soiled linen in hamper. Perform hand hygiene.	Reduces transmission of infection.

EVALUATION

1 Inspect nails and surrounding skin surfaces after soaking and nail trimming.	Evaluates condition of skin and nails. Allows nurse to note any remaining rough nail edges.
2 Ask patient to explain or demonstrate nail care.	Evaluates patient's level of learning foot and nail care techniques.
3 Observe patient's walk after toenail care.	Evaluates level of comfort and mobility achieved.

STEP 11 Clean under fingernails.

STEP 12 Use nail clippers to clip nails straight across.

SKILL 39-2 PERFORMING NAIL AND FOOT CARE—cont'd

STEP	RATIONALE

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Cuticles and surrounding tissues are inflamed and tender to touch.
- Repeated soakings are necessary to relieve inflammation and loosen layers of cells from calluses or corns.
- Patients with peripheral vascular disease or diabetes often require referral to a podiatrist.
- Evaluate need for antifungal cream.

2 Localized areas of tenderness occur on feet with calluses or corns at point of friction.
- Change in footwear is necessary.
- Refer to a podiatrist or nurse in charge.

3 Ulcer appears between toes or other pressure areas in foot.
- Notify physician or nurse in charge.
- Refer to a podiatrist or nurse certified in foot care.
- Increase frequency of foot assessment and hygiene.

RECORDING AND REPORTING

- Record procedure and observations (e.g., breaks in skin, inflammation, ulcerations).
- Report any breaks in skin or ulcerations to nurse in charge or physician. These are serious in patients with peripheral vascular disease and illnesses in which the patient's circulation is impaired. Special foot care treatments are often necessary.
- Record procedure and observations (e.g., breaks in skin, inflammation, ulcerations).

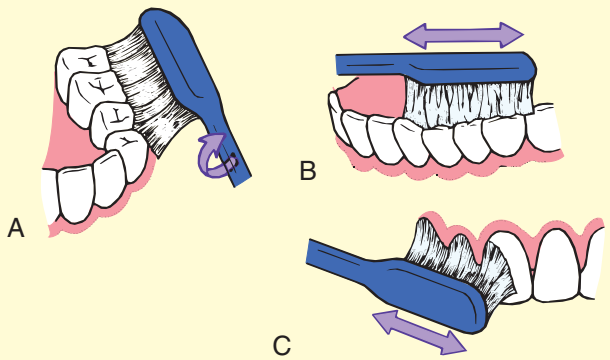
HOME CARE CONSIDERATIONS

- If the patient has diabetes or decreased peripheral circulation, perform procedure only after consulting with a health care provider.
- Alternative therapies: moleskin applied to areas of feet that are under friction is less likely to cause pressure than corn pads; spot adhesive bandages guard against friction, but they do not have padding to protect against pressure; wrapping small pieces of lamb's wool around toes reduces irritation of soft corns between toes.
- If patient is ambulatory, instruct to soak feet in bathtub. When patient's mobility is limited, use a large basin or pan.

SKILL 39-3 PROVIDING ORAL HYGIENE

View Video!

Delegation Considerations



The skill of performing oral hygiene can be delegated to nursing assistive personnel (NAP). However, the nurse is responsible for assessing the risk for aspiration. Direct the NAP to:
- Position the patient to avoid aspiration.
- Immediately report to the nurse excessive patient coughing or choking during or after oral hygiene.
- Report bleeding of oral mucosa or gums, patient report of pain, or lesions.

Equipment

- Soft-bristle toothbrush (hard toothbrushes damage enamel and gums)
- Nonabrasive fluoride toothpaste or dentifrice
- Dental floss
- Tongue depressor
- Water glass with cool water
- Normal saline or an essential-oil antiseptic mouthwash (optional; follow patient's preference)
- Emesis basin
- Face towel
- Paper towels
- Clean gloves

STEP	RATIONALE
ASSESSMENT	
1 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
2 Instruct patient to not bite down. Inspect integrity of lips, teeth, buccal mucosa, gums, palate, and tongue (see Chapter 30).	Determines status of patient's oral cavity and extent of need for oral hygiene.
3 Identify presence of common oral problems:	Helps determine type of hygiene patient requires and information that he or she needs for self-care.
a. Dental caries—Chalky white discoloration of tooth or presence of brown or black discoloration	
b. Gingivitis—Inflammation of gums	
c. Periodontitis—Receding gum lines, inflammation, gaps between teeth	Receding gums occur with aging; as a result older patients require meticulous oral hygiene.
d. Halitosis—Bad breath	
e. Cheilitis—Cracked lips	
f. Stomatitis—Inflammation of the mouth	Patients receiving immunosuppressive chemotherapy (e.g., cancer chemotherapy, antirejection medication after organ transplant) or patients with suppressed immune function are at risk for stomatitis.

STEP	RATIONALE
4 Assess patient's risk for aspiration: impaired swallowing, reduced gag reflex.	Accumulation of secretions and dentifrice increase patient's risk for aspiration because of reduced ability to control oral secretions.
5 Remove gloves and perform hand hygiene.	Prevents spread of microorganisms.
6 Assess risk for oral hygiene problems (see Table 39-5).	Certain conditions increase likelihood of impaired oral cavity integrity and need for preventive care.
7 Determine patient's oral hygiene practices; question him or her and observe patient performing care if possible.	Allows you to identify errors in technique, deficiencies in preventive oral hygiene, and patient's level of knowledge regarding dental care.
a. Frequency of toothbrushing and flossing	The American Dental Association (2010) recommends at least twice-a-day brushing and once-daily flossing as part of routine oral care.
b. Type of toothpaste or dentifrice used	The American Dental Association (2010) recommends the use of an ADA-approved fluoride toothpaste.
c. Last dental visit and frequency of dental visits	The American Dental Association (2010) recommends regular visits to the dentist for professional cleanings and oral examinations.
d. Type of mouthwash or moistening preparation	Lemon-glycerin preparations are harmful. Glycerin is an astringent that dries and shrinks mucous membranes and gums. Lemon exhausts salivary reflex and erodes tooth enamel. Mouthwash provides pleasant aftertaste but dries mucosa after extended use if it has an alcohol base. Mouthwashes are not a replacement for flossing (American Dental Association, 2010).
8 Assess patient's ability to grasp and manipulate toothbrush.	Toothbrush test assesses dexterity and strength. Determines level of assistance required. Older adults or people with musculoskeletal or nervous system alterations are sometimes unable to hold toothbrush with firm grip or manipulate brush.
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure to patient and discuss preferences regarding use of hygiene aids.	Some patients feel uncomfortable about having the nurse care for their basic needs. Patient involvement with procedure minimizes anxiety.
3 Place paper towels on over-bed table and arrange other equipment within easy reach.	Creates organized work space.
IMPLEMENTATION	
1 Raise bed to comfortable working position. Raise head of bed (if allowed) and lower side rail. Move patient or help patient move closer. Use side-lying position if needed.	Raising bed and positioning patient prevent nurse from straining muscles. Semi-Fowler's position helps prevent patient from choking or aspirating. Side-lying position facilitates drainage of secretions.
2 Place towel over patient's chest.	Prevents soiling of patient's gown.
3 Apply clean gloves.	Prevents contact with microorganisms or blood in saliva.
4 Apply toothpaste to brush. Holding brush over emesis basin, pour small amount of water over toothpaste.	Moisture aids in distribution of toothpaste over tooth surfaces.
5 Patient may assist with brushing. Hold toothbrush bristles at 45-degree angle to gum line. Be sure that tips of bristles rest against and penetrate under gum line. Brush inner and outer surfaces of upper and lower teeth by brushing from gum to crown of each tooth. Clean biting surfaces of teeth by holding top of bristles parallel with teeth and brushing gently back and forth. Brush sides of teeth by moving bristles back and forth (see illustration).	Angle allows brush to reach all tooth surfaces and clean under gum line where plaque and tartar accumulate. Back-and-forth motion dislodges food particles caught between teeth and along chewing surfaces.

STEP 5 Direction for toothbrush placement. **A,** A 45-degree angle brushes gum line. **B,** Parallel position brushes biting surfaces. **C,** Lateral position brushes sides of teeth.

SKILL 39-3 PROVIDING ORAL HYGIENE—cont'd

STEP	RATIONALE
6 Have patient hold brush at 45-degree angle and lightly brush over surface and sides of tongue (see illustration). Avoid initiating gag reflex.	Microorganisms collect and grow on surface of tongue and contribute to bad breath. Gagging can cause aspiration of toothpaste.

STEP 6 Assisting patient with brushing tongue.

7 Allow patient to rinse mouth thoroughly by taking several sips of water, swishing water across all tooth surfaces and spitting into emesis basin.	Irrigation removes food particles.
8 Allow patient to gargle to rinse mouth with mouthwash as desired.	Mouthwash leaves a pleasant taste in mouth but dries mucosa after extended use if it has an alcohol base.
9 Assist in wiping patient's mouth.	Promotes sense of comfort.
10 Allow patient to floss. Floss between all teeth. Hold floss against tooth while moving it up and down sides of teeth and under gum line.	Reduces tartar on tooth surfaces and prevents gum disease. The American Dental Association (2010) recommends flossing once daily.
11 Allow patient to rinse mouth thoroughly with cool water and spit into emesis basin. Help to wipe patient's mouth.	Irrigation removes plaque and tartar from oral cavity.
12 Remove one soiled glove before raising side rail and lowering bed to original position. Remove second soiled glove and perform hand hygiene.	Reduces transmission of microorganisms to environmental surfaces and provides for patient safety.
13 Assist patient to comfortable position, raising bed as needed to working height and lowering when finished.	Provides for patient comfort and safety; prevents straining for nurse when helping patient to move.
14 Apply clean gloves. Wipe off over-bed table, cleanse and dry emesis basin, discard paper towels in trash. Remove gloves and perform hand hygiene. Return equipment to proper place. Gather soiled linen bag and paper towels in appropriate containers.	Reduces transmission of microorganisms. Preventing areas of residual moisture decreases microorganism reservoir. Proper disposal of soiled equipment prevents spread of Infection.
15 Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Ask patient if any area of oral cavity feels uncomfortable or irritated.	Pain indicates an oral cavity problem.
2 Apply gloves and inspect condition of oral cavity.	Determines effectiveness of hygiene and rinsing.
3 Ask patient to describe proper hygiene techniques.	Evaluates patient's learning.
4 Observe patient brushing and flossing.	Evaluates patient's ability to use correct technique.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Oral mucosa is dry and inflamed.
- Increase frequency of oral hygiene.
- Increase patient's hydration.
- Apply protectant to patient's lips.

2 Gum margins are retracted from teeth, with localized areas of inflammation. Bleeding occurs around gum margins.
- Determine if patient has underlying bleeding tendency (e.g., anticoagulant therapy).
- Report findings to health care provider.
- Use soft-bristle toothbrush.
- Increase frequency of oral hygiene.

3 Teeth show signs of dental caries.
- Refer patient to dentist on order from health care provider.
- Review patient's hygiene routine.
- Teach patient oral hygiene.

STEP	RATIONALE
RECORDING AND REPORTING	
• Record procedure on flow sheet. Note condition of oral cavity in nurses' notes.	
• Report bleeding or presence of lesions to nurse in charge or health care provider.	
HOME CARE CONSIDERATIONS	
• Teach patient and caregiver to assess oral cavity daily to determine any effects of medications on it (e.g., reddened, inflamed gums) and to detect oral cavity problems.	

SKILL 39-4 PERFORMING MOUTH CARE FOR AN UNCONSCIOUS OR DEBILITATED PATIENT

Delegation Considerations

The skill of performing mouth care for an unconscious or debilitated patient can be delegated to nursing assistive personnel (NAP). However, the nurse assesses the patient's risk for aspiration before care, including determining presence of the gag reflex. Instruct the NAP about:

- Proper positioning of patient to lessen chance of aspiration.
- The safe use of an oral suction catheter for clearing oral secretions (see Skill 40-1),
- Signs of impaired integrity of oral mucosa to report to the nurse.
- Reporting any bleeding of mucosa or gums, painful reaction by patient, or excessive coughing or choking to the nurse.

Equipment

- Antibacterial solution (e.g., 0.12% chlorhexidine rinse and paste) (requires a health care provider's order) (IHI, 2011)
- Small pediatric soft-bristle toothbrush, sponge toothettes or swabs
- Tongue blade
- Face towel
- Small oral airway
- Paper towels
- Emesis basin
- Water glass with cool water
- Water-soluble lip lubricant
- Small-bulb syringe or suction machine equipment (required for patients with poor or absent gag reflex)
- Clean gloves

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Perform hand hygiene. Apply clean gloves.	Reduces transmission of microorganisms. Gloves prevent contact with microorganisms in blood or saliva.
3 Assess patient's risk for oral hygiene problems (see Table 39-5).	Impaired level of consciousness increases the likelihood of alterations in integrity of oral cavity structures and requires more frequent care. Proper oral care reduces the risk of pneumonia (Bassim et al., 2008).
4 Test for presence of gag reflex by placing tongue blade on back half of patient's tongue.	Reveals whether patient is at risk for aspiration. Helps determine need for and type of suction apparatus to have available.
5 Inspect condition of oral cavity (see Chapter 30).	Determines integrity of gums, teeth, mucosa, and tongue and need for hygiene.
6 Remove gloves. Perform hand hygiene.	Prevents spread of infection.
PLANNING	
1 Explain procedure to patient even if patient is unconscious.	Allows debilitated patient to anticipate procedure without anxiety. Unconscious patient may retain ability to hear.
2 Collect appropriate equipment.	Prevents interruptions during procedure.
3 Place paper towels on over-bed table and arrange equipment. If needed, turn on suction machine and connect tubing to suction catheter.	Prevents soiling of table top. Equipment prepared in advance ensures smooth, safe procedure.
IMPLEMENTATION	
1 Unless contraindicated (e.g., head injury, neck trauma), raise bed, lower side rail, and position patient close to side of bed with head of bed raised up to 30 degrees; turn patient's head toward mattress. Patient can also be placed on side (Sims' position). Raise side rail.	Turning patient's head to the side allows secretions to drain from mouth instead of collecting in back of pharynx. Prevents aspiration, which could cause lower respiratory tract infection (pneumonia). Moving patient close to side of bed and raising bed facilitate proper body mechanics during the skill and reduce risk for injury to the nurse. Proper use of side rail protects caregiver from straining and provides for patient safety.
2 Pull curtain around bed or close room door.	Provides privacy.
3 Lower side rail.	Prevents straining to reach.

SKILL 39-4 PERFORMING MOUTH CARE FOR AN UNCONSCIOUS OR DEBILITATED PATIENT—cont'd

STEP	RATIONALE
4 Apply clean gloves.	Reduces transfer of microorganisms.
5 Place towel under patient's head and emesis basin under chin.	Prevents soiling of bed linen.
6 Remove partial plate or dentures if present (see Box 39-10)	Allows for thorough cleaning of prosthetics later. Provides clearer access to oral cavity.
7 If patient is unconscious, uncooperative, or having difficulty keeping mouth open, insert an oral airway. Insert upside down and turn the airway sideways and then over tongue to keep teeth apart. Do not use force.	Prevents patient from biting down on nurse's fingers and provides access to oral cavity.
CLINICAL DECISION: *Never place fingers into the mouth of an unconscious or debilitated patient. The normal response of the patient is to bite down.*	
8 Clean mouth using brush moistened with water or a cleaning agent such as chlorhexidine paste if prescribed. Clean chewing and inner tooth surfaces first. Clean outer tooth surfaces. Moisten brush with chlorhexidine rinse to rinse. Use swab or toothette to clean roof of mouth, gums, and inside cheeks (see illustration). Gently swab or brush tongue but avoid stimulating gag reflex. Moisten clean swab or toothette with chlorhexidine to rinse. Use bulb syringe as needed to remove excess rinse.	Brushing action removes food particles between teeth and along chewing surfaces. Chlorhexidine 0.12% is an antimicrobial agent effective against dental plaque biofilms (IHI, 2011). Swabbing helps remove secretions and crusts from mucosa and moistens mucosa. Repeated rinsing removes peroxide, which is irritating to mucosa, and debris.
9 For patients without teeth, use a toothette moistened in chlorhexidine rinse to clean oral cavity.	This is less traumatic to mucosa of gums.
10 Suction oral secretions as they accumulate if needed.	Suction removes secretions and fluid that collect in posterior pharynx.
11 Apply thin layer of water-soluble jelly to lips (see illustration).	Water-soluble jelly lubricates lips to prevent drying and cracking.
12 Inform patient that procedure is completed.	Provides meaningful stimulation to patient.
13 Remove gloves and dispose in proper receptacle. Raise side rail. Perform hand hygiene.	Prevents transmission of microorganisms to environmental surfaces (e.g., side rails, patient's linens). Reduces risk for patient injury.
14 Reposition patient comfortably, raise side rail, and return bed to original position.	Maintains patient's comfort and safety.
15 Apply clean gloves to clean equipment. Return supplies to proper place. Place soiled linen in proper receptacle.	Proper disposal of soiled equipment and handling of soiled linens prevent spread of infection.
16 Remove and discard soiled gloves. Perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Apply clean gloves and inspect oral cavity.	Determines efficacy of cleaning. Once you have removed thick secretions, this reveals any underlying inflammation or lesions.
2 Remove gloves and dispose in proper receptacle. Perform hand hygiene.	Reduces transmission of microorganisms.
3 Ask patient if mouth feels clean.	Evaluates level of comfort.
4 Assess patient's respirations and auscultate lung sounds on an ongoing basis.	Ensures early recognition of aspiration.

STEP 8 Using moistened toothette to rinse teeth in patient with oral airway inserted.

STEP 11 Application of water-soluble moisturizer to lips.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Secretions or crusts remain on oral mucosa, tongue, or gums.
- Increase frequency of oral hygiene.
- Use a pediatric-size toothbrush to provide better hygiene.

2 Localized inflammation of gums or mucosa is present, or lips are cracked and inflamed.
- Increase frequency of oral hygiene with a soft-bristle toothbrush.
- Apply water-soluble moisturizing gel on oral mucosa and massage.
- Apply water-soluble moisturizing gel or lubricant to lips.

3 Patient aspirates secretions.
- Suction oral airway as secretions accumulate to maintain patent airway.
- Perform tracheal bronchial suctioning.
- Notify health care provider immediately.
- Elevate patient's head of bed to facilitate breathing.
- Be prepared to have chest x-ray film examination ordered by health care provider.

RECORDING AND REPORTING

- Record procedure, including pertinent observations (e.g., presence of bleeding gums, dry mucosa, ulcerations, crusts on tongue).
- Report any unusual findings to nurse in charge or health care provider.

HOME CARE CONSIDERATIONS

- Irrigate oral cavity with bulb syringe; patient can use a gravy baster to remove secretions.
- Give mouth care at least twice a day.
- Have caregivers demonstrate positioning patient to prevent aspiration.

SKILL 39-5 MAKING AN OCCUPIED BED

Delegation Considerations

The skill of making an occupied bed can be delegated to nursing assistive personnel (NAP). The nurse reviews any precautions or activity restrictions. Instruct the NAP about:
- Any activity or positioning restrictions for the patient.
- Looking for wound drainage, dressing materials, drainage tubes, or intravenous (IV) tubing that becomes dislodged or is found in the linens.
- What to do if patient becomes fatigued.

Equipment (Fig. 39-14)

- Linen bag(s)
- Mattress pad (optional depending on facility practice; needs to be changed only when soiled)
- Bottom sheet (flat or fitted)
- Drawsheet
- Top sheet
- Blanket (optional depending on patient preference)
- Bedspread
- Waterproof pads and/or bath blankets (optional)
- Pillowcases
- Bedside chair or table
- Clean gloves (optional)
- Towel
- Disinfectant

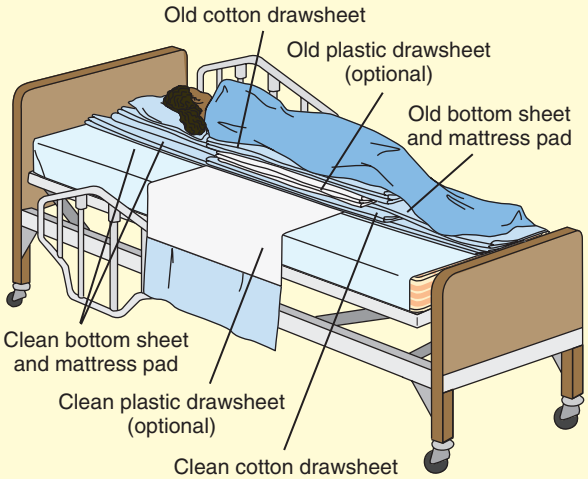


FIG. 39-14 Equipment for making occupied bed.

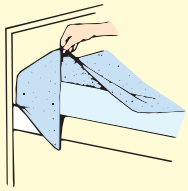
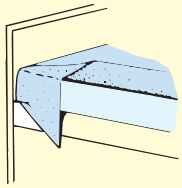
SKILL 39-5 MAKING AN OCCUPIED BED—cont'd

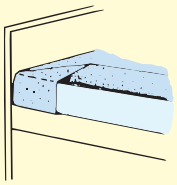
STEP	RATIONALE
ASSESSMENT	
1 Assess potential for patient incontinence or excess drainage on bed linen.	Determines need for protective waterproof pads or extra bath blankets on bed and whether gloves are likely needed for procedure.
2 Check chart for orders or specific precautions concerning movement and positioning.	Ensures patient safety and use of proper body mechanics.
PLANNING	
1 Explain procedure to patient, including that he or she will be asked to turn on side and roll over linen.	Minimizes anxiety and promotes cooperation.
2 Gather needed supplies, being sure to not let clean linen touch your uniform.	Securing needed supplies ensures that procedure can be implemented without interruption. Uniform is less clean than the clean linen.
IMPLEMENTATION	
1 Perform hand hygiene and apply clean gloves (wear gloves only if old linen is soiled or there is risk for contact with body secretions).	Reduces transmission of microorganisms.
2 Arrange equipment on bedside chair or over-bed table. Remove unnecessary equipment such as a dietary tray or items used for hygiene.	Organizing equipment provides for smooth procedure and assists in increasing patient's comfort. Placing linen on clean surface minimizes spread of infection.
3 Pull room curtain around bed and/or close door.	Maintains patient's privacy.
4 Adjust bed height to comfortable working position with bed flat if patient can tolerate. Lower raised side rail on one side of bed. Remove call light.	Minimizes strain on back. It is easier to remove and apply linen evenly to bed in flat position. Provides easy access to bed and linen. If patient has trouble breathing, leave head of bed elevated to comfort level.
5 Loosen top linen at foot of bed.	Makes linen easier to remove.
6 Remove bedspread and blanket separately. If spread and blanket are soiled, place them in linen bag. Keep soiled linen away from uniform.	Reduces transmission of microorganisms.
7 If blanket and spread are to be reused, fold them by bringing the top and bottom edges together. Fold farthest side over onto nearer bottom edge. Bring top and bottom edges together again. Place folded linen over back of chair.	Folding method facilitates replacement and minimizes wrinkles.
8 Cover patient with bath blanket in the following manner: unfold bath blanket over top sheet. Ask patient to hold top edge of bath blanket. If patient is unable to help, tuck top of bath blanket under shoulders. Grasp top sheet under bath blanket at patient's shoulders and bring sheet down to foot of bed. Remove sheet and discard in linen bag.	Bath blanket provides warmth and keeps body parts covered during linen removal.
9 With assistance from 1 or 2 other care providers, slide mattress toward head of bed if needed.	If mattress slides toward foot of bed when head of bed is raised, it is difficult to tuck in linen. In addition, it is uncomfortable for the patient because his or her feet may be pressed against or hang over the foot of the bed.
10 Position patient on far side of bed, turned onto side and facing away from you. Be sure that side rail in front of patient is up. Adjust pillow under patient's head.	Turning patient onto side provides space for placement of clean linen. Side rail ensures patient's safety from forward falls from bed surface and helps patient in moving.
11 Loosen bottom linens, moving from head to foot. With seam side down (facing the mattress), fanfold bottom sheet and drawsheet toward patient—first drawsheet, then bottom sheet. Tuck edges of linen just under buttocks, back, and shoulders. Do not fanfold mattress pad if it is to be reused (see illustration).	Prepares for removal of all bottom linen simultaneously. Provides maximum work space for placing clean linen. Later, when patient turns to other side, you can remove soiled linen easily.



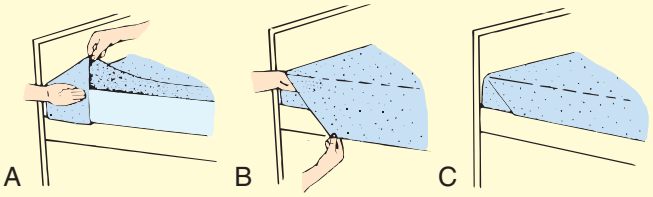
STEP 11 Old linen tucked under patient.



STEP	RATIONALE
12 Wipe off any moisture on exposed mattress with towel and appropriate disinfectant. Make sure that mattress surface is dry before applying linens.	Reduces transmission of microorganisms.
13 Apply clean linen to exposed half of bed:	
a. Place clean mattress pad on bed (if used) by folding it lengthwise with center crease in middle of bed. Fanfold top layer over mattress. (If pad is reused, simply smooth out any wrinkles.)	Applying linen over bed in successive layers minimizes energy and time used in bed making.
b. If using flat sheet for bottom sheet, unfold sheet lengthwise so center crease is situated lengthwise along center of bed. Fanfold top layer of sheet toward center of bed alongside the patient. Smooth bottom layer of sheet over mattress and bring edge over closest side of mattress. If using a fitted sheet, pull sheet smoothly over mattress ends. Allow edge of flat unfitted sheet to hang about 25 cm (10 inches) over mattress edge. Make sure that lower hem of bottom flat sheet lies seam down and even with bottom edge of mattress (see illustration).	Proper positioning of linen on one side ensures that adequate linen is available to cover opposite side of bed. Keeping seam edges down eliminates irritation to patient's skin.
14 If flat sheet is used for bottom sheet, miter bottom flat sheet at head of bed:	Ensures that secure flat sheet does not loosen easily.
a. Face head of bed diagonally. Place hand away from head of bed under top corner of mattress, near mattress edge, and lift.	
b. With other hand tuck top edge of bottom sheet smoothly under mattress so side edges of sheet above and below mattress meet when brought together.	
c. Face side of bed and pick up top edge of sheet at approximately 45 cm (18 inches) from top of mattress (see illustration).	
d. Lift sheet and lay it on top of mattress to form a neat triangular fold, with lower base of triangle even with mattress side edge (see illustration).	
e. Tuck lower edge of sheet, which is hanging free below the mattress, under mattress. Tuck with palms down without pulling triangular fold (see illustration).	
f. Hold portion of sheet covering side of mattress in place with one hand. With the other hand, pick up top of triangular linen fold and bring it down over side of mattress. Tuck this portion under mattress (see illustrations).	Mitered corner cannot be loosened easily even if patient frequently moves in bed.

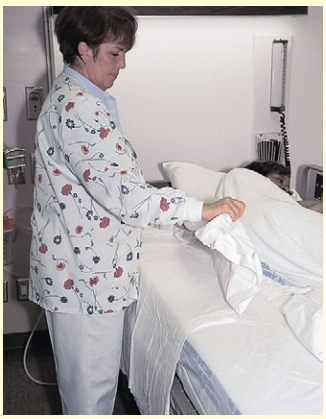


STEP 13b Clean linen applied to bed.



STEP 14c Top edge of sheet picked up.

STEP 14d Sheet on top of mattress in a triangular fold

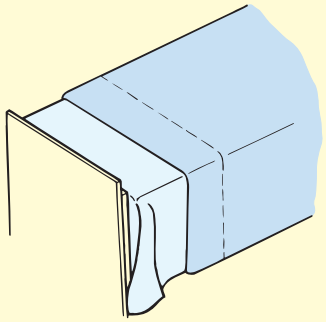


STEP 14e Lower edge of sheet tucked under mattress.

STEP 14f **A** and **B,** Triangular fold placed over side of mattress. **C,** Linen tucked under mattress.

SKILL 39-5 MAKING AN OCCUPIED BED—cont'd

STEP	RATIONALE
15 Tuck remaining portion of sheet under mattress, moving toward foot of bed. Keep linen smooth.	Folds of linen are source of irritation.
16 *(Optional)* Open clean drawsheet so it unfolds in half. Lay centerfold along middle of bed lengthwise and position sheet so it is under patient's buttocks and torso (see illustration). Fanfold top layer toward patient with edge along patient's back. Smooth bottom layer out over mattress and tuck excess edge under mattress (keep palms down).	Drawsheet is used to lift and reposition patient. Placement under patient's torso distributes most of patient's body weight over sheet.
17 Place waterproof pad over drawsheet, *(optional)* with centerfold against patient's side. Fanfold top layer toward patient.	Protects bed linen from being soiled.
18 Advise patient that rolling over thick layer of linens is necessary and that he or she will feel a lump. Have patient roll slowly toward you over the layers of linen. Raise side rail on working side before going to other side of bed.	Positions patient for removal and placement of linens. Maintains patient's safety.
19 Lower side rail. Assist patient in positioning on other side as needed. Loosen edges of soiled linen from under mattress (see illustration).	Ensures patient comfort. Exposes opposite side of bed for removal of soiled linen and placement of clean linen. Makes linen easier to remove.
20 Remove soiled linen by folding it into a bundle or square with soiled side turned in. Discard in linen bag. If necessary, wipe mattress with antiseptic solution and dry mattress surface before applying new linen.	Reduces transmission of microorganisms.
21 Pull clean, fanfolded linen smoothly over edge of mattress from head to foot of bed.	Smooth linen does not irritate patient's skin.
22 Help patient roll back into supine position. Reposition pillow.	Maintains patient's comfort.
23 Pull fitted sheet smoothly over mattress ends. Miter top corner of bottom sheet (see Step 14). When tucking corner, be sure that sheet is smooth and free of wrinkles.	Wrinkles and folds cause irritation to skin.
24 Facing side of bed, grasp remaining edge of bottom flat sheet. Lean back, keep back straight, and pull while tucking excess linen under mattress. Proceed from head to foot of bed. (Avoid lifting mattress during tucking to ensure fit.)	Proper use of body mechanics while tucking linen prevents injury.
25 Smooth fanfolded drawsheet out over bottom sheet. Grasp edge of sheet with palms down, lean back, and tuck sheet under mattress. Tuck from middle to top and then to bottom.	Tucking first at top or bottom pulls sheet sideways, causing poor fit.
26 Place top sheet over patient with centerfold lengthwise down middle of bed. Open sheet from head to foot and unfold over patient.	Correctly positioning centerfold ensures that sheet is equally distributed over bed.
27 Ask patient to hold clean top sheet or tuck sheet around his or her shoulders. Remove bath blanket and discard in linen bag.	Sheet prevents exposure of body parts. Having patient hold sheet encourages patient participation in care.
28 Place blanket on bed, unfolding it so crease runs lengthwise along middle of bed. Unfold blanket to cover patient. Make sure that top edge is parallel with edge of top sheet and 15 to 20 cm (6 to 8 inches) from edge of top sheet.	Blanket covers patient completely and provides adequate warmth.
29 Place spread over bed according to Step 28. Be sure that top edge of spread extends about 2.5 cm (1 inch) above edge of blanket. Tuck top edge of spread over and under top edge of blanket.	Gives bed neat appearance and provides extra warmth.
30 Make cuff by turning edge of top sheet down over top edge of blanket and spread.	Protects patient's face from rubbing against blanket or spread.



STEP 16 Optional drawsheet.

STEP 19 Assisting patient to position after rolling over folds of linen.

STEP	RATIONALE
31 Standing on one side at foot of bed, lift mattress corner slightly with one hand and tuck linens under mattress. Top sheet and blanket are tucked under together. Be sure that linens are loose enough to allow movement of patient's feet. Making a horizontal toe pleat is an option (see illustration).	Makes neat-appearing bed. Pressure ulcers develop on patient's toes and heels from feet rubbing against tight-fitting bed sheets.

STEP 31 Optional toe pleat.

32 Make modified mitered corner with top sheet, blanket, and spread (see illustration in Box 39-14, Step 20).	Ensures that top covers do not loosen easily.
a. Pick up side edge of top sheet, blanket, and spread approximately 45 cm (18 inches) from foot of mattress. Lift linen to form triangular fold and lay it on bed.	
b. Tuck lower edge of sheet, which is hanging free below mattress, under mattress. Do not pull triangular fold.	
c. Pick up triangular fold and bring it down over mattress while holding linen in place alongside of mattress. Do not tuck tip of triangle.	Secures top linen but keeps even edge of blanket and top sheet draped over mattress.
33 Raise side rail. Make other side of bed; spread sheet, blanket, and bedspread out evenly. Fold top edge of spread over blanket and make cuff with top sheet (see Step 30); make modified mitered corner at foot of bed (see Step 32).	Correct use of side rails aids patient's movement in bed.
34 Change pillowcase:	
a. Have patient raise head. While supporting neck with one hand, remove pillow. Allow patient to lower head.	Support of neck muscles prevents injury during flexion and extension of neck.
b. Remove soiled case by grasping pillow at open end with one hand and pulling case back over pillow with other hand. Discard case in linen bag.	Pillows slide out easily, thus minimizing contact with soiled linen.
c. Grasp clean pillowcase at center of closed end. Gather case, turning it inside out over the hand holding it. With same hand pick up middle of one end of pillow. Pull pillowcase down over pillow with other hand.	Eases sliding of pillowcase over pillow.
d. Be sure that pillow corners fit evenly into corners of pillowcase. Place pillow under patient's head.	Poorly fitting case constricts fluffing and expansion of pillow and interferes with patient comfort.
35 Place call light within patient's reach and return bed to comfortable position and height.	Ensures patient safety and comfort.
36 Open room curtains and rearrange furniture. Place personal items within easy reach on over-bed table or bedside stand.	Promotes sense of well-being.
37 Place dirty linen in hamper or chute. Remove gloves (if worn); dispose and perform hand hygiene.	Prevents transmission of microorganisms.

EVALUATION

1 Ask if patient feels comfortable.	Ensures that bed linens are smooth and patient is positioned comfortably.
2 Inspect skin for areas of irritation.	Folds or creases in linen cause pressure on skin.
3 Assess patient for signs and symptoms of fatigue, dyspnea, pain, or discomfort.	Provides you with data about patient's level of activity tolerance and ability to participate in other procedures.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient feels discomfort from linen fold.
- Tighten sheets.
- Change patient's position frequently.

2 Patient's skin shows signs of breakdown.
- Institute skin care measures to reduce risk of pressure ulcer (see Chapter 48).
- Change patient's position more frequently.

RECORDING AND REPORTING

- Making an occupied bed does not need to be recorded.

KEY POINTS

- Assess a patient's physical and cognitive ability to perform basic hygiene measures.
- Provide hygiene care according to a patient's needs and preference.
- During hygiene integrate other activities such as physical assessment, wound care, and ROM exercises.
- While providing daily hygiene needs, use teaching and communication skills to develop a caring relationship with the patient.
- Various personal, sociocultural, economic, and developmental factors influence patients' hygiene practices.
- Patients' health beliefs predict the likelihood of assuming health promotion behavior such as maintaining good hygiene.
- Reduced sensation, vascular insufficiency, and immobility place a patient at greater risk for impaired skin integrity.
- Administering symptom relief therapies before hygiene to patients suffering symptoms such as pain or nausea better prepares them for any procedure.
- When administering oral care to unconscious patients, take measures to prevent aspiration.
- A patient's room needs to be comfortable, safe, and large enough to allow the patient and visitors to move about freely.
- Evaluation of hygiene care is based on a patient's sense of comfort, relaxation, well-being, and understanding of hygiene techniques.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Winkler is an 87-year-old resident of an extended care facility who has diabetes mellitus. When Jamie, the nursing student, enters the room, she finds Mrs. Winkler's daughter, Carol, preparing a basin of hot water. Carol tells Jamie, "Mom needs a good pedicure. I'm going to soak her feet in hot sudsy water, clip her toenails, and then put on her favorite polish." Jamie notices that Mrs. Winkler's nails are thick, long, and curved.

1. Which response or action by Jamie is the appropriate initial response to the daughter's statement?
   a. Sits down and helps pick out a nail polish color
   b. "Oh my gosh! You shouldn't soak her feet."
   c. Explains why not to soak the feet.
   d. Checks with Mrs. Winkler's nurse to see if it is okay to soak her feet
2. Which assessment does Jamie need to complete before helping Mrs. Winkler and Carol continue with foot care?
   a. Measuring blood glucose at the bedside
   b. Observing condition of the feet and nails
   c. Asking Mrs. Winkler about her last bowel movement
   d. Observing condition of the skin
3. Jamie helps wash Mrs. Winkler's feet and applies a lanolin cream. Which approach should Jamie take regarding trimming Mrs. Winkler's toenails?
   a. Collaborate with Mrs. Winkler's nurse to obtain a podiatrist consult order
   b. Carefully cut the nails using nail scissors
   c. File the long curving nails
   d. Ask Carol to trim the nails

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is assisting a patient with rheumatoid arthritis to bathe at the sink. During the bath the patient states that she is tired. The nurse notices the patient is breathing rapidly and the pulse is rapid. What is the nurse's best response?
   1. Finish the bath quickly
   2. Help the patient return to bed
   3. Leave the patient alone to rest in the chair at the sink for a few minutes
   4. Instruct the patient to take deep breaths and try to relax
2. A patient who is cognitively impaired and has dementia requires hygiene care. The patient often displays aggressive behavior such as screaming and hitting during the bath. Which techniques make the bathing experience less stressful for both the nurse and the patient? (Select all that apply.)
   1. Allow the patient to perform as much of the care as possible.
   2. Start by washing the face.
   3. Try an alternative to traditional bathing such as the "bag bath."
   4. Use restraints to prevent the patient from injuring self or the nurse.
3. What is the priority concern when providing oral hygiene for a patient who is unconscious?
   1. Thoroughly brushing all tooth and oral surfaces
   2. Preventing aspiration
   3. Controlling mouth odor
   4. Applying local antiseptic such as chlorhexidine
4. A male nurse is caring for a 32-year-old female Muslim patient who has an indwelling Foley catheter. After introducing himself to the patient, the nurse learns that the patient does not want him to help her with personal hygiene care. Which of the following is(are) appropriate actions? (Select all that apply.)
   1. Finding a female nurse to help the patient
   2. Convincing the patient that he will work quickly and provide as much privacy as possible
   3. Skipping hygiene care for the day except for the parts that the patient can complete independently
   4. Asking the patient if she prefers a family member assist with the care
5. You are helping a female patient bathe. As you are about to perform perineal care, the patient says, "I can finish my bath." The patient has discomfort and burning in the perineal area. What action do you need to take initially?
   1. Explain to the patient that, because of her symptoms, you need to observe the perineal area.
   2. Insist that you are supposed to complete the care.
   3. Honor the patient's request to complete her own perineal care to avoid any embarrassment.
   4. Ask the patient if a family member can complete the care instead.
6. Your patient wears full dentures. His usual denture care includes taking the teeth out once a day to brush. He wears the dentures overnight. You are concerned that he might be at risk for developing denture-induced stomatitis. Which points do you include in a teaching plan for denture care? (Select all that apply.)
   1. Remove dentures overnight once a week while they soak in a cleansing bath.
   2. Do not wear damaged or poorly fitting dentures.

3. Observe mouth for reddened areas under the dentures and small red sores on the roof of the mouth.
4. See dentist regularly.
5. Rinse dentures after meals.
6. Clean dentures every night with cleanser, rinsing well before replacing in mouth at bedtime.

7. A patient who is receiving chemotherapy has inflamed gums and oral mucosa and painful sores in the mouth. Which of the following oral care actions are appropriate? (Select all that apply.)
   1. Decreasing frequency of oral hygiene
   2. Applying water-soluble moisturizing gel on the oral mucosa
   3. Encouraging intake of soft foods
   4. Using commercial mouthwash
8. While planning morning care, which of the following patients would receive the highest priority to receive his or her bath first?
   1. A patient who just returned to the nursing unit from surgery and is experiencing pain at a level of 7 on a scale of 0 to 10
   2. A patient who prefers a bath in the evening when his wife visits and can help him
   3. A patient who is experiencing frequent incontinent diarrheal stools
   4. A patient who has just returned from diagnostic testing and complains of being very fatigued
9. During bathing your patient experiences shortness of breath and labored breathing with a respiratory rate of 30. The bed is in a flat position. You change the bed position to:
   1. Trendelenburg's.
   2. Reverse Trendelenburg's.
   3. Fowler's.
   4. Semi-Fowler's.
10. A nurse caring for a male patient observes the nursing assistive personnel (NAP) performing perineal care. Which of the following observed actions indicates a need for further teaching for the NAP? The NAP:
    1. Used clean gloves.
    2. Did not retract the foreskin before cleansing.
    3. Used the clean portion of washcloth for each cleansing wipe.
    4. Used a circular motion to cleanse from urinary meatus outward.
11. A nurse teaching a family member caregiver how to bathe the patient explains the importance of using long strokes on the patient's extremities, moving from distal to proximal. Which explanation does the nurse include? Long strokes moving from distal to proximal are used to:
    1. Decrease the chance of infection.
    2. Help remove dry, flaky skin.
    3. Prevent skin trauma.
    4. Stimulate venous return.
12. Which of the following actions would best help prevent skin breakdown in a patient who is incontinent of stools and very weak and drowsy?
    1. Checking frequently for soiling
    2. Washing the perineal area with strong soap and water
    3. Placing the call light within easy reach
    4. Keeping a pad under the patient
13. The nurse is caring for a patient who has reduced sensation in both feet. Which of the following should the nurse do? (Select all that apply.)
    1. Avoid cleaning the feet until an order from the health care provider is received.
    2. Wash the feet with lukewarm water and then dry well.
    3. Apply moisturizing lotion to the feet, especially between the toes.
    4. File the toenails straight across.
14. The nurse recognizes that her older-adult patient needs additional teaching about skin care when the older adult says, "I should:
    1. Bathe twice a week.
    2. Rinse well after using soap.
    3. Use hot water for bathing.
    4. Drink plenty of fluids.
15. You ask the nursing assistive personnel (NAP) to clean a patient who has been incontinent of urine. Several minutes later you pass the open door of the room and see the NAP changing the patient's gown and linen. Which of the following requires your immediate attention?
    1. Room temperature is overly warm.
    2. Room door is open to the hallway.
    3. Television volume is too loud.
    4. Strong odor of urine is detected.

Answers: **1.** 2; **2.** 1, 3; **3.** 2; **4.** 1, 4; **5.** 1; **6.** 2, 3, 4, 5; **7.** 2, 3; **8.** 3; **9.** 3; **10.** 2; **11.** 4; **12.** 1; **13.** 2, 4; **14.** 3; **15.** 2.

CHAPTER

40

Oxygenation

OBJECTIVES

- Describe the structure and function of the cardiopulmonary system.
- Describe the physiological processes of ventilation, perfusion, and exchange of respiratory gases.
- State the process of the neural and chemical regulation of respiration.
- Differentiate among the physiological processes of cardiac output, myocardial blood flow, and coronary artery circulation.
- Describe the relationship of cardiac output, preload, afterload, contractility, and heart rate to the process of oxygenation.
- Identify the clinical outcomes occurring as a result of hyperventilation, hypoventilation, and hypoxemia.
- Identify the clinical outcomes occurring as a result of disturbances in conduction, altered cardiac output, impaired valvular function, myocardial ischemia, and impaired tissue perfusion.
- Discuss the effect of a patient's level of health, age, lifestyle, and environment on oxygenation.
- Assess for the risk factors affecting a patient's oxygenation.
- Assess for the physical manifestations that occur with alterations in oxygenation.
- Develop a plan of care for a patient with altered need for oxygenation.
- Describe nursing care interventions used to promote oxygenation in the primary care, acute care, and restorative and continuing care settings.

SCIENTIFIC KNOWLEDGE BASE

Oxygen is necessary to sustain life. The cardiac and respiratory systems supply the oxygen demands of the body. Blood is oxygenated through the mechanisms of ventilation, perfusion, and transport of respiratory gases. Neural and chemical regulators control the rate and depth of respiration in response to changing tissue oxygen demands. The cardiovascular system provides the transport mechanisms to distribute oxygen to cells and tissues of the body.

Respiratory Physiology

The exchange of respiratory gases occurs between the environment and the blood. Respiration is the exchange of oxygen and

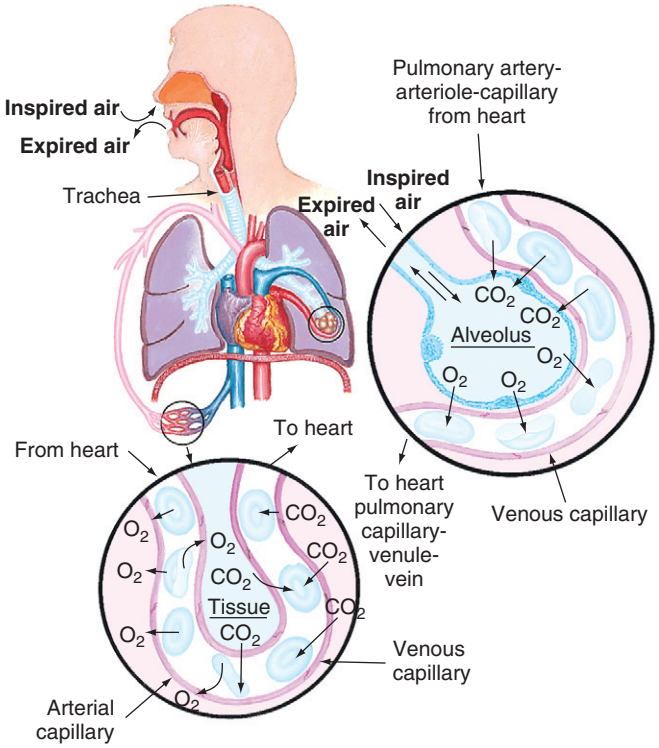

FIG. 40-1 Structures of pulmonary system. (From Thompson J et al: *Mosby's manual of clinical nursing,* ed 3, St Louis, 1993, Mosby.)

carbon dioxide during cellular metabolism. The airways of the lung transfer oxygen from the atmosphere to the alveoli, where the oxygen is exchanged for carbon dioxide. Through the alveolar capillary membrane, oxygen transfers to the blood, and carbon dioxide transfers from the blood to the alveoli. There are three steps in the process of oxygenation: ventilation, perfusion, and diffusion.

Structure and Function. Conditions or diseases that change the structure and function of the pulmonary system alter respiration. The respiratory muscles, pleural space, lungs, and alveoli (Fig. 40-1) are essential for ventilation, perfusion, and exchange of respiratory gases. Gases move into and out of the lungs through pressure changes. Intrapleural pressure is negative, or less than atmospheric pressure, which is 760 mm Hg at sea level. For air to flow into the lungs, intrapleural pressure becomes more negative, setting up a pressure gradient between the atmosphere and the alveoli. The diaphragm and external intercostal muscles contract to create a negative pleural pressure and increase the size of the thorax for inspiration. Relaxation of the diaphragm and contraction of the internal intercostal muscles allow air to escape from the lungs.

Ventilation is the process of moving gases into and out of the lungs. It requires coordination of the muscular and elastic properties of the lung and thorax. The major inspiratory muscle of respiration is the diaphragm. It is innervated by the phrenic nerve, which exits the spinal cord at the fourth cervical vertebra. **Perfusion** relates to the ability of the cardiovascular system to pump oxygenated blood to the tissues and return deoxygenated blood to the lungs. Finally, diffusion is responsible for moving the respiratory gases from one area to another by concentration gradients. For the exchange of respiratory gases to occur, the organs, nerves, and muscles of respiration need to be intact; and the central nervous system needs to be able to regulate the respiratory cycle.

Work of Breathing. Work of breathing (WOB) is the effort required to expand and contract the lungs. In the healthy individual breathing is quiet and accomplished with minimal effort. The amount of energy expended on breathing depends on the rate and depth of breathing, the ease in which the lungs can be expanded (compliance), and airway resistance.

Inspiration is an active process, stimulated by chemical receptors in the aorta. **Expiration** is a passive process that depends on the elastic recoil properties of the lungs, requiring little or no muscle work. **Surfactant** is a chemical produced in the lungs to maintain the surface tension of the alveoli and keep them from collapsing. Patients with advanced chronic obstructive pulmonary disease (COPD) lose the elastic recoil of the lungs and thorax. As a result, the patient's work of breathing increases. In addition, patients with certain pulmonary diseases have decreased surfactant production and sometimes develop atelectasis. **Atelectasis** is a collapse of the alveoli that prevents normal exchange of oxygen and carbon dioxide.

Accessory muscles of respiration can increase lung volume during inspiration. Patients with COPD, especially emphysema, frequently use these muscles to increase lung volume. Prolonged use of the accessory muscles does not promote effective ventilation and causes fatigue. During assessment observe for elevation of the patient's clavicles during inspiration, which can indicate ventilatory fatigue, air hunger, or decreased lung expansion.

Compliance is the ability of the lungs to distend or expand in response to increased intraalveolar pressure. Compliance decreases in diseases such as pulmonary edema, interstitial and pleural fibrosis, and congenital or traumatic structural abnormalities such as kyphosis or fractured ribs.

Airway resistance is the increase in pressure that occurs as the diameter of the airways decreases from mouth/nose to alveoli. Any further decrease in airway diameter by bronchoconstriction can increase airway resistance. Diseases causing airway obstruction such as asthma and tracheal edema increase airway resistance. When airway resistance increases, the amount of oxygen delivered to the alveoli decreases.

Decreased lung compliance, increased airway resistance, and the increased use of accessory muscles increase the WOB, resulting in increased energy expenditure. Therefore the body increases its metabolic rate and the need for more oxygen. The need for elimination of carbon dioxide also increases. This sequence is a vicious cycle for a patient with impaired ventilation, causing further deterioration of respiratory status and the ability to oxygenate adequately.

Lung Volumes. The normal lung values are determined by age, gender, and height. Tidal volume is the amount of air exhaled after normal inspiration. Residual volume is the amount of air left in the alveoli after a full expiration. Forced vital capacity is the maximum amount of air that can be removed from the lungs during forced expiration (McCance and Huether, 2010). Variations in tidal volume and other lung volumes are associated with alterations in patients' health status or activity, such as pregnancy, exercise, obesity, or obstructive and restrictive conditions of the lungs.

Pulmonary Circulation. The primary function of pulmonary circulation is to move blood to and from the alveolar capillary membrane for gas exchange. Pulmonary circulation begins at the pulmonary artery, which receives poorly oxygenated mixed venous blood from the right ventricle. Blood flow through this system depends on the pumping ability of the right ventricle. The flow continues from the pulmonary artery through the pulmonary

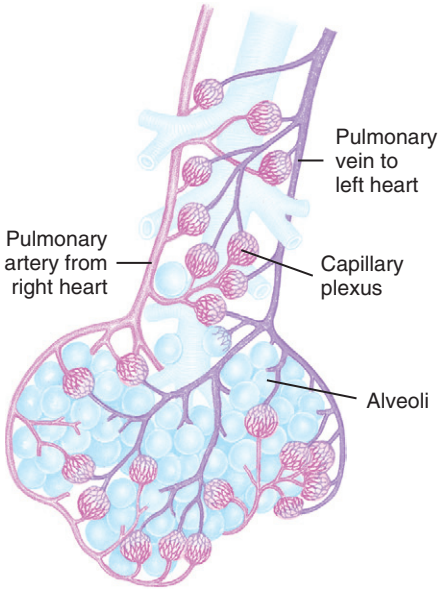

FIG. 40-2 Alveoli at terminal end of lower airway. (From Thompson J et al: *Mosby's manual of clinical nursing,* ed 3, St Louis, 1993, Mosby.)

arterioles to the pulmonary capillaries, where blood comes in contact with the alveolar capillary membrane and the exchange of respiratory gases occurs. The oxygen-rich blood then circulates through the pulmonary venules and pulmonary veins, returning to the left atrium.

Respiratory Gas Exchange. Diffusion is the process for the exchange of respiratory gases in the alveoli and the capillaries of the body tissues. Diffusion of respiratory gases occurs at the alveolar capillary membrane (Fig. 40-2). The thickness of the membrane affects the rate of diffusion. Increased thickness of the membrane impedes diffusion because gases take longer to transfer across the membrane. Patients with pulmonary edema, pulmonary infiltrates, or pulmonary effusion have a thickened membrane, resulting in slow diffusion, slow exchange of respiratory gases, and decreased delivery of oxygen to tissues. Chronic diseases (e.g., emphysema), acute diseases (e.g., pneumothorax), and surgical processes (e.g., lobectomy) often alter the amount of alveolar capillary membrane surface area.

Oxygen Transport. The oxygen-transport system consists of the lungs and cardiovascular system. Delivery depends on the amount of oxygen entering the lungs (ventilation), blood flow to the lungs and tissues (perfusion), rate of diffusion, and oxygen-carrying capacity. Three things influence the capacity of the blood to carry oxygen: the amount of dissolved oxygen in the plasma, the amount of hemoglobin, and the tendency of hemoglobin to bind with oxygen. Hemoglobin, which is a carrier for oxygen and carbon dioxide, transports most oxygen (approximately 97%). The hemoglobin molecule combines with oxygen to form oxyhemoglobin. The formation of oxyhemoglobin is easily reversible, allowing hemoglobin and oxygen to dissociate (deoxyhemoglobin), which frees oxygen to enter tissues.

Carbon Dioxide Transport. Carbon dioxide, a product of cellular metabolism, diffuses into red blood cells and is rapidly hydrated into carbonic acid (H_2CO_3). The carbonic acid then dissociates into hydrogen (H) and bicarbonate (HCO_3^-) ions. Hemoglobin buffers the hydrogen ion, and the (HCO_3^-) diffuses into the plasma (see Chapter 41). Reduced hemoglobin (deoxyhemoglobin) combines with carbon dioxide, and the venous blood transports the majority of carbon dioxide back to the lungs to be exhaled.

Regulation of Respiration. Regulation of respiration is necessary to ensure sufficient oxygen intake and carbon dioxide elimination to meet the demands of the body (e.g., during exercise, infection, or pregnancy). Neural and chemical regulators control the process of respiration. Neural regulation includes the central nervous system control of respiratory rate, depth, and rhythm. The cerebral cortex regulates the voluntary control of respiration by delivering impulses to the respiratory motor neurons by way of the spinal cord. Chemical regulation maintains the appropriate rate and depth of respirations based on changes in the carbon dioxide (CO_2), oxygen (O_2), and hydrogen ion (H^+) concentration (pH) in the blood. Changes in chemical content of O_2, CO_2, and H (pH) stimulate the chemoreceptors located in the medulla, aortic body, and carotid body, which in turn stimulate neural regulators to adjust the rate and depth of ventilation to maintain normal arterial blood gas levels.

Cardiovascular Physiology

Cardiopulmonary physiology involves delivery of deoxygenated blood (blood high in carbon dioxide and low in oxygen) to the right side of the heart and then to the lungs, where it is oxygenated. Oxygenated blood (blood high in oxygen and low in carbon dioxide) then travels from the lungs to the left side of the heart and the tissues. The cardiac system delivers oxygen, nutrients, and other substances to the tissues and facilitates the removal of cellular metabolism waste products by way of blood flow through other body systems such as respiratory, digestive, and renal (McCance and Huether, 2010).

Structure and Function. The right ventricle pumps deoxygenated blood through the pulmonary circulation (Fig. 40-3). The left ventricle pumps oxygenated blood through the systemic circulation. As blood passes through the circulatory system, there is an exchange of respiratory gases, nutrients, and waste products between the blood and the tissues.

Myocardial Pump. The pumping action of the heart is essential to oxygen delivery. There are four cardiac chambers, two atria and two ventricles. The ventricles fill with blood during diastole and empty during systole. The volume of blood ejected from the ventricles during systole is the **stroke volume.** Hemorrhage and dehydration cause a decrease in circulating blood volume and a decrease in stroke volume.

Myocardial fibers have contractile properties that allow them to stretch during filling. In a healthy heart this stretch is proportionally related to the strength of contraction. As the myocardium stretches, the strength of the subsequent contraction increases; this is known as the *Frank-Starling (Starling's) law of the heart*. In the diseased heart (cardiomyopathy or myocardial infarction [MI]) Starling's law does not apply because the increased stretch of the myocardium is beyond the physiological limits of the heart. The subsequent contractile response results in insufficient stroke volume, and blood begins to "back up" in the pulmonary (left heart failure) or systemic (right heart failure) circulation.

Myocardial Blood Flow. To maintain adequate blood flow to the pulmonary and systemic circulation, myocardial blood flow must supply sufficient oxygen and nutrients to the myocardium itself. Blood flow through the heart is unidirectional. The four heart valves ensure this forward blood flow (see Fig. 40-3). During ventricular diastole the atrioventricular (mitral and tricuspid) valves open, and blood flows from the higher-pressure atria into the relaxed ventricles. As systole begins, ventricular pressure rises and

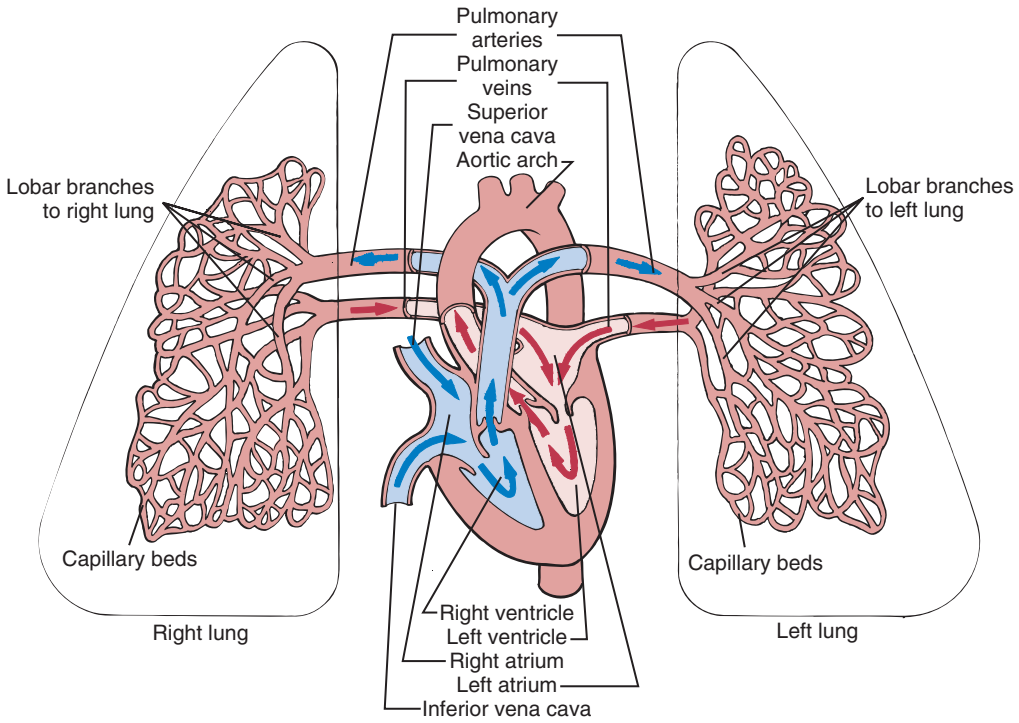

FIG. 40-3 Schematic representation of blood flow through the heart. *Arrows* indicate direction of flow and pulmonary circulation. (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.)

closes the mitral and tricuspid valves. Valve closure causes the first heart sound (S_1).

During the systolic phase the semilunar (aortic and pulmonic) valves open, and blood flows from the ventricles into the aorta and pulmonary artery. The mitral and tricuspid valves stay closed during systole so all of the blood is moved forward into the pulmonary artery and aorta. As the ventricles empty, the ventricular pressures decrease, allowing closure of the aortic and pulmonic valves, which causes the second heart sound (S2). Some patients with valvular disease have backflow or regurgitation of blood through the incompetent valve, causing a murmur that you can hear on auscultation (see Chapter 30).

Coronary Artery Circulation. The coronary circulation is the branch of the systemic circulation that supplies the myocardium with oxygen and nutrients and removes waste. The coronary arteries fill during ventricular diastole (McCance and Huether, 2010). The left coronary artery has the most abundant blood supply and feeds the more muscular left ventricular myocardium, which does most of the work of the heart.

Systemic Circulation. The arteries of the systemic circulation deliver nutrients and oxygen to tissues, and the veins remove waste from tissues. Oxygenated blood flows from the left ventricle through the aorta and into large systemic arteries. These arteries branch into smaller arteries; then arterioles; and finally the smallest vessels, the capillaries. The exchange of respiratory gases occurs at the capillary level, where the tissues are oxygenated. The waste products exit the capillary network through venules that join to form veins. These veins become larger and form the vena cava, which carry deoxygenated blood to the right side of the heart, where it then returns to the pulmonary circulation.

Blood Flow Regulation. The amount of blood ejected from the left ventricle each minute is the **cardiac output.** The normal cardiac output is 4 to 6 L/min in the healthy adult at rest. The circulating volume of blood changes according to the oxygen and metabolic needs of the body. For example, cardiac output increases during exercise, pregnancy, and fever but decreases during sleep. The following formula represents cardiac output:

$$\text{Cardiac output (CO)} = \text{Stroke volume (SV)} \times \text{Heart rate (HR)}$$

The amount of blood in the left ventricle at the end of diastole (preload), the resistance to left ventricular ejection (afterload), and myocardial contractility all affect stroke volume.

Preload is the end-diastolic volume. The ventricles stretch when filling with blood. The more stretch on the ventricular muscle, the greater the contraction and the greater the stroke volume (Starling's law). In clinical situations, medical treatment can alter the preload and subsequent stroke volumes by changing the amount of circulating blood volume. For example, during treatment of a patient who is hemorrhaging, increased fluid therapy and replacement of blood increase circulating volume, thus increasing the preload and stroke volume, which increases cardiac output. If volume is not replaced, preload, stroke volume and the subsequent cardiac output decreases.

Afterload is the resistance to left ventricular ejection. The heart works harder to overcome the resistance so blood can be fully ejected from the left ventricle. The diastolic aortic pressure is a good clinical measure of afterload. In hypertension the afterload increases, making cardiac workload also increase.

Myocardial contractility also affects stroke volume and cardiac output. Poor ventricular contraction decreases the amount of blood ejected. Injury to the myocardial muscle such as an acute MI causes a decrease in myocardial contractility. The myocardium of the older adult is stiffer with a slower ventricular filling rate and prolonged contraction time (Linton and Lach, 2007).

Heart rate affects blood flow because of the relationship between rate and diastolic filling time. With a sustained heart rate greater

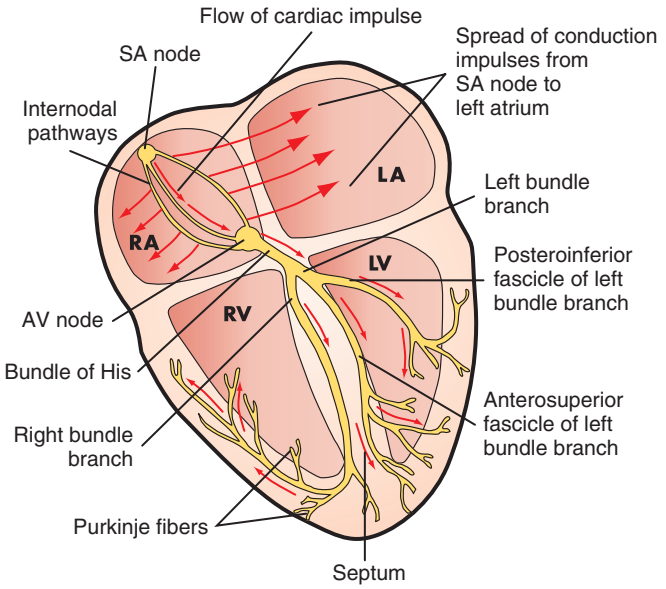

FIG. 40-4 Conduction system of the heart. *AV,* Atrioventricular; *LA,* Left atrium; *LV,* left ventricle; *RA,* right atrium; *RV,* right ventricle; *SA,* sinoatrial. (From Lewis SM et al: *Medical-surgical nursing: assessment and management of clinical problems,* ed 7, St Louis, 2007, Mosby.)

than 160 beats/min, diastolic filling time decreases, decreasing stroke volume and cardiac output. The heart rate of the older adult is slow to increase under stress, but studies have found that this may be caused more by lack of conditioning than age. Exercise is beneficial in maintaining function at any age (Linton and Lach, 2007).

Conduction System. The rhythmic relaxation and contraction of the atria and ventricles depend on continuous, organized transmission of electrical impulses. The cardiac conduction system generates and transmits these impulses (Fig. 40-4).

The conduction system of the heart generates the impulses needed to initiate the electrical chain of events for a normal heartbeat. The autonomic nervous system influences the rate of impulse generation and the speed of transmission through the conductive pathway and the strength of atrial and ventricular contractions. Sympathetic and parasympathetic nerve fibers innervate all parts of the atria and ventricles and the sinoatrial (SA) and atrioventricular (AV) nodes. Sympathetic fibers increase the rate of impulse generation and speed of transmission. The parasympathetic fibers originating from the vagus nerve decrease the rate.

The conduction system originates with the SA node, the "pacemaker" of the heart. The SA node is in the right atrium next to the entrance of the superior vena cava. Impulses are initiated at the SA node at an intrinsic rate of 75 cardiac action potentials per minute in an adult at rest (McCance and Huether, 2010).

The electrical impulses are transmitted through the atria along intraatrial pathways to the AV node. The AV node mediates impulses between the atria and the ventricles. It assists atrial emptying by delaying the impulse before transmitting it through the bundle of His and the ventricular Purkinje network.

An **electrocardiogram (ECG)** reflects the electrical activity of the conduction system. An ECG monitors the regularity and path of the electrical impulse through the conduction system; however, it does not reflect the muscular work of the heart. The normal sequence on the ECG is called the **normal sinus rhythm (NSR)** (Fig. 40-5).

NSR implies that the impulse originates at the SA node and follows the normal sequence through the conduction system. The P wave represents the electrical conduction through both atria. Atrial contraction follows the P wave. The PR interval represents the impulse travel time from the SA node through the AV node, through the bundle of His, and to the Purkinje fibers. The normal length for the PR interval is 0.12 to 0.2 second. An increase in the time greater than 0.2 second indicates a block in the impulse transmission through the AV node; whereas a decrease, less than 0.12 second, indicates the initiation of the electrical impulse from a source other than the SA node.

The QRS complex indicates that the electrical impulse traveled through the ventricles. Normal QRS duration is 0.06 to 0.1 second. An increase in QRS duration indicates a delay in conduction time through the ventricles. Ventricular contraction usually follows the QRS complex.

The QT interval represents the time needed for ventricular depolarization and repolarization. The normal QT interval is 0.12 to 0.42 second. This interval varies inversely with changes in heart rate (McCance and Huether, 2010). Changes in electrolyte values such as hypocalcemia or therapy with drugs such as disopyramide (Norpace) or amiodarone (Cordarone) increase the QT interval. Shortening of the QT interval occurs with digitalis therapy, hyperkalemia, and hypercalcemia.

Factors Affecting Oxygenation

Four factors influence adequacy of circulation, ventilation, perfusion, and transport of respiratory gases to the tissues: (1) physiological, (2) developmental, (3) lifestyle, and (4) environmental. The physiological factors are discussed here, and the others are discussed in the Nursing Knowledge Base section that follows.

Physiological Factors. Any condition affecting cardiopulmonary functioning directly affects the ability of the body to meet oxygen demands. Respiratory disorders include hyperventilation, hypoventilation, and hypoxia. Cardiac disorders include disturbances in conduction, impaired valvular function, myocardial hypoxia, cardiomyopathic conditions, and peripheral tissue hypoxia. Other physiological processes affecting a patient's oxygenation include alterations affecting the oxygen-carrying capacity of blood, decreased inspired oxygen concentration, increases in the metabolic demand of the body, and alterations affecting chest wall movement caused by musculoskeletal abnormalities or neuromuscular alterations.

Decreased Oxygen-Carrying Capacity. Hemoglobin carries the majority of oxygen to tissues. Anemia and inhalation of toxic substances decrease the oxygen-carrying capacity of blood by reducing the amount of available hemoglobin to transport oxygen. Anemia (i.e., a lower-than-normal hemoglobin level) is a result of decreased hemoglobin production, increased red blood cell destruction, and/or blood loss. Patients have fatigue, decreased activity tolerance, increased breathlessness, increased heart rate, and pallor (especially seen in the conjunctiva of the eye). Oxygenation decreases as a secondary effect with anemia. The physiological response to chronic hypoxemia is the development of increased red blood cells (polycythemia). This is the adaptive response of the body to increase the amount of hemoglobin and the available oxygen-binding sites.

Carbon monoxide (CO) is the most common toxic inhalant decreasing the oxygen-carrying capacity of blood. In CO toxicity hemoglobin strongly binds with CO, creating a functional anemia. Because of the strength of the bond, CO does not easily dissociate from hemoglobin, making hemoglobin unavailable for oxygen transport.

Hypovolemia. Conditions such as shock and severe dehydration cause extracellular fluid loss and reduced circulating blood volume, or **hypovolemia.** Decreased circulating blood volume results in hypoxia to body tissues. With significant fluid loss, the body tries to adapt by peripheral vasoconstriction and increasing the heart rate to increase the volume of blood returned to the heart, thus increasing the cardiac output.

Decreased Inspired Oxygen Concentration. With the decline of the concentration of inspired oxygen, the oxygen-carrying capacity of the blood decreases. Decreases in the fraction of inspired oxygen concentration (FiO_2) are caused by upper or lower airway obstruction, which limits delivery of inspired oxygen to alveoli; decreased environmental oxygen (at high altitudes); or hypoventilation (occurs in drug overdoses).

Increased Metabolic Rate. Increased metabolic activity increases oxygen demand. The level of oxygenation declines when body systems are unable to meet this demand. An increased metabolic rate is normal in pregnancy, wound healing, and exercise because the body is using energy or building tissue. Most people are able to meet the increased oxygen demand and do not display signs of oxygen deprivation. Fever increases the need of tissues for oxygen; as a result carbon dioxide production increases. When fever persists, the metabolic rate remains high, and the body begins to break down protein stores. This causes muscle wasting and decreased muscle mass, including respiratory muscles such as the diaphragm and intercostal muscles.

The body attempts to adapt to the increased carbon dioxide levels by increasing the rate and depth of respiration. The patient's WOB increases, and the patient eventually displays signs and symptoms of hypoxemia. Patients with pulmonary diseases are at greater risk for hypoxemia.

Conditions Affecting Chest Wall Movement. Any condition reducing chest wall movement results in decreased ventilation. If the diaphragm does not fully descend with breathing, the volume of inspired air decreases, delivering less oxygen to the alveoli and tissues.

Pregnancy. As the fetus grows during pregnancy, the enlarging uterus pushes abdominal contents upward against the diaphragm. In the last trimester of pregnancy, the inspiratory capacity declines, resulting in dyspnea on exertion and increased fatigue.

Obesity. Patients who are morbidly obese have reduced lung volumes from the heavy lower thorax and abdomen, particularly when in the recumbent and supine positions. Many morbidly obese patients suffer from obstructive sleep apnea. Morbidly obese patients have a reduction in lung and chest wall compliance as a result of encroachment of the abdomen into the chest, increased WOB, and decreased lung volumes. In some patients an obesity-hypoventilation syndrome develops in which oxygenation is decreased and carbon dioxide is retained. The obese patient is also susceptible to atelectasis or pneumonia after surgery because the lungs do not expand fully and the lower lobes retain pulmonary secretions.

Musculoskeletal Abnormalities. Musculoskeletal impairments in the thoracic region reduce oxygenation. Such impairments result from abnormal structural configurations, trauma, muscular diseases, and diseases of the central nervous system. Abnormal structural configurations impairing oxygenation include those affecting the rib cage such as pectus excavatum and the vertebral column such as kyphosis, lordosis, or scoliosis.

Trauma. Flail chest is a condition in which multiple rib fractures cause instability in part of the chest wall. The unstable chest wall allows the lung underlying the injured area to contract on inspiration and bulge on expiration, resulting in hypoxia. Patients with thoracic or upper abdominal surgical incisions use shallow respirations to avoid pain, which also decreases chest wall movement. Opioids used to treat pain depress the respiratory center, further decreasing respiratory rate and chest wall expansion.

Neuromuscular Diseases. Neuromuscular diseases affect tissue oxygenation by decreasing the patient's ability to expand and contract the chest wall. Ventilation is impaired, resulting in atelectasis, hypercapnia, and hypoxemia. Examples of conditions causing hypoventilation include myasthenia gravis, Guillain-Barré syndrome, and poliomyelitis.

Central Nervous System Alterations. Diseases or trauma of the medulla oblongata and/or spinal cord result in impaired respiration. When the medulla oblongata is affected, neural regulation of respiration is impaired, and abnormal breathing patterns develop. Cervical trauma at C3 to C5 usually results in paralysis of the phrenic nerve. When the phrenic nerve is damaged, the diaphragm does not descend properly, thus reducing inspiratory lung volumes and causing hypoxemia. Spinal cord trauma below the C5 vertebra usually leaves the phrenic nerve intact but damages nerves that innervate the intercostal muscles, preventing anteroposterior chest expansion.

Influences of Chronic Disease. Oxygenation decreases as a direct consequence of chronic lung disease. Changes in the anteroposterior diameter of the chest wall (barrel chest) occur because of overuse of accessory muscles and air trapping in emphysema. The diaphragm is flattened, and the lung fields are overdistended, resulting in varying degrees of hypoxemia and/or hypercapnia (McCance and Huether, 2010).

Alterations in Respiratory Functioning

Illnesses and conditions affecting ventilation or oxygen transport cause alterations in respiratory functioning. The three primary alterations are hypoventilation, hyperventilation, and hypoxia.

The goal of ventilation is to produce a normal arterial carbon dioxide tension ($PaCO_2$) between 35 and 45 mm Hg and a normal arterial oxygen tension (PaO_2) between 80 and 100 mm Hg. Hypoventilation and hyperventilation are often determined by arterial blood gas analysis (McCance and Huether, 2010). Hypoxemia refers to a decrease in the amount of arterial oxygen. Nurses monitor arterial oxygen saturation (SpO_2) using a noninvasive oxygen saturation monitor pulse oximeter. Normally SpO_2 is greater than or equal to 95% (see Chapter 41).

Hypoventilation. **Hypoventilation** occurs when alveolar ventilation is inadequate to meet the oxygen demand of the body or eliminate sufficient carbon dioxide. As alveolar ventilation decreases, the body retains carbon dioxide. For example, atelectasis, a collapse of the alveoli, prevents normal exchange of oxygen and carbon dioxide. As more alveoli collapse, less of the lung is ventilated, and hypoventilation occurs.

In patients with COPD, the administration of excessive oxygen results in hypoventilation. These patients have adapted to a high carbon dioxide level so their carbon dioxide–sensitive chemoreceptors are essentially not functioning. Their peripheral chemoreceptors of the aortic arch and carotid bodies are primarily sensitive to lower oxygen levels, causing increased ventilation. Because the stimulus to breathe is a decreased arterial oxygen (PaO_2) level, administration of oxygen greater than 24% to 28% (1 to 3 L/min) prevents the PaO_2 from falling to a level (60 mm Hg) that stimulates the peripheral receptors, thus destroying the stimulus to breathe (McCance and Huether, 2010). The resulting hypoventilation causes excessive retention of carbon dioxide, which can lead to respiratory acidosis and respiratory arrest.

Signs and symptoms of hypoventilation include mental status changes, dysrhythmias, and potential cardiac arrest. If untreated, the patient's status rapidly declines, leading to convulsions, unconsciousness, and death.

Hyperventilation. **Hyperventilation** is a state of ventilation in which the lungs remove carbon dioxide faster than it is produced by cellular metabolism. Severe anxiety, infection, drugs, or an acid-base imbalance induces hyperventilation. Acute anxiety leads to hyperventilation and exhalation of excessive amounts of carbon dioxide. Increased body temperature (fever) increases the metabolic rate, thereby increasing carbon dioxide production. The increased carbon dioxide level stimulates an increase in the patient's rate and depth of respiration, causing hyperventilation.

Hyperventilation is sometimes chemically induced. Salicylate (aspirin) poisoning and amphetamine use result in excess carbon dioxide production, stimulating the respiratory center to compensate by increasing the rate and depth of respiration. It also occurs as the body tries to compensate for metabolic acidosis. For example, the patient with diabetes in ketoacidosis produces large amounts of metabolic acids. The respiratory system tries to correct the acid-base balance by overbreathing. Ventilation increases to reduce the amount of carbon dioxide available to form carbonic acid (see Chapter 41). This can also result in the patient developing respiratory alkalosis. Signs and symptoms of hyperventilation include rapid respirations, sighing breaths, numbness and tingling of hands/feet, light-headedness, and loss of consciousness (Ackley and Ladwig, 2011).

Hypoxia. **Hypoxia** is inadequate tissue oxygenation at the cellular level. It results from a deficiency in oxygen delivery or oxygen use at the cellular level. It is a life-threatening condition. Untreated it produces possibly fatal cardiac dysrhythmias.

Causes of hypoxia include (1) a decreased hemoglobin level and lowered oxygen-carrying capacity of the blood; (2) a diminished concentration of inspired oxygen, which occurs at high altitudes; (3) the inability of the tissues to extract oxygen from the blood, as with cyanide poisoning; (4) decreased diffusion of oxygen from the alveoli to the blood, as in pneumonia; (5) poor tissue perfusion with oxygenated blood, as with shock; and (6) impaired ventilation, as with multiple rib fractures or chest trauma.

The clinical signs and symptoms of hypoxia include apprehension, restlessness, inability to concentrate, decreased level of consciousness, dizziness, and behavioral changes. The patient with hypoxia is unable to lie flat and appears both fatigued and agitated. Vital sign changes include an increased pulse rate and rate and depth of respiration. During early stages of hypoxia the blood pressure is elevated unless the condition is caused by shock. As the hypoxia worsens, the respiratory rate declines as a result of respiratory muscle fatigue.

Cyanosis, blue discoloration of the skin and mucous membranes caused by the presence of desaturated hemoglobin in capillaries, is a late sign of hypoxia. The presence or absence of cyanosis is not a reliable measure of oxygen status. Central cyanosis, observed in the tongue, soft palate, and conjunctiva of the eye where blood flow is high, indicates hypoxemia. Peripheral cyanosis, seen in the extremities, nail beds, and earlobes, is often a result of vasoconstriction and stagnant blood flow.

Alterations in Cardiac Functioning

Illnesses and conditions affecting cardiac rhythm, strength of contraction, blood flow through the heart or to the heart muscle, and decreased peripheral circulation cause alterations in cardiac functioning. Older adults experience alterations in cardiac function as a result of calcification of the conduction pathways, thicker and stiffer heart valves caused by lipid accumulation and fibrosis, and a decrease in the number of pacemaker cells in the SA node (Linton and Lach, 2007; Meiner, 2011).

Disturbances in Conduction. Electrical impulses that do not originate from the SA node cause conduction disturbances. These rhythm disturbances are called **dysrhythmias,** meaning a deviation from the normal sinus heart rhythm. Dysrhythmias occur as a primary conduction disturbance such as in response to ischemia; valvular abnormality; anxiety; drug toxicity; caffeine, alcohol, or tobacco use; or as a complication of acid-base or electrolyte imbalance (see Chapter 41).

Dysrhythmias are classified by cardiac response and site of impulse origin. Cardiac response is tachycardia (greater than 100 beats/min), bradycardia (less than 60 beats/min), a premature (early) beat, or a blocked (delayed or absent) beat. Tachydysrhythmias and bradydysrhythmias lower cardiac output and blood pressure. Tachydysrhythmias reduce cardiac output by decreasing diastolic filling time. Bradydysrhythmias lower cardiac output because of the decreased heart rate.

Atrial fibrillation is a common dysrhythmia frequently seen in older adults. The electrical impulse in the atria is chaotic and originates from multiple sites. The rhythm is irregular because of the multiple pacemaker sites and the unpredictable conduction to the ventricles. The QRS complex is normal; however, it occurs at irregular intervals. Atrial fibrillation is often described as an irregularly irregular rhythm.

Abnormal impulses originating above the ventricles are supraventricular dysrhythmias. The abnormality on the waveform is the configuration and placement of the P wave. Ventricular conduction usually remains normal, and there is a normal QRS complex.

Paroxysmal supraventricular tachycardia is a sudden, rapid onset of tachycardia originating above the AV node. It often begins and ends spontaneously. Sometimes excitement, fatigue, caffeine, smoking, or alcohol use precipitates paroxysmal supraventricular tachycardia.

Ventricular dysrhythmias represent an ectopic site of impulse formation within the ventricles. It is ectopic in that the impulse originates in the ventricle, not the SA node. The configuration of the QRS complex is usually widened and bizarre. P waves are not always present; often they are buried in the QRS complex. **Ventricular tachycardia** and **ventricular fibrillation** are

life-threatening rhythms that require immediate intervention. Ventricular tachycardia is a life-threatening dysrhythmia because of the decreased cardiac output and the potential to deteriorate into ventricular fibrillation or sudden cardiac death (AHA, 2010b).

Altered Cardiac Output. Failure of the myocardium to eject sufficient volume to the systemic and pulmonary circulations occurs in heart failure. Primary coronary artery disease, cardiomyopathy, valvular disorders, and pulmonary disease lead to myocardial pump failure.

Left-Sided Heart Failure. Left-sided heart failure is an abnormal condition characterized by decreased functioning of the left ventricle. If left ventricular failure is significant, the amount of blood ejected from the left ventricle drops greatly, resulting in decreased cardiac output. Signs and symptoms include fatigue, breathlessness, dizziness, and confusion as a result of tissue hypoxia from the diminished cardiac output. As the left ventricle continues to fail, blood begins to pool in the pulmonary circulation, causing pulmonary congestion. Clinical findings include crackles in the bases of the lungs on auscultation, hypoxia, shortness of breath on exertion, cough, and paroxysmal nocturnal dyspnea.

Right-Sided Heart Failure. Right-sided heart failure results from impaired functioning of the right ventricle. It more commonly results from pulmonary disease or as a result of long-term left-sided failure. The primary pathological factor in right-sided failure is elevated pulmonary vascular resistance (PVR). As the PVR continues to rise, the right ventricle works harder, and the oxygen demand of the heart increases. As the failure continues, the amount of blood ejected from the right ventricle declines, and blood begins to "back up" in the systemic circulation. Clinically the patient has weight gain, distended neck veins, hepatomegaly and splenomegaly, and dependent peripheral edema.

Impaired Valvular Function. Valvular heart disease is an acquired or congenital disorder of a cardiac valve that causes either hardening (stenosis) or impaired closure (regurgitation) of the valves. When stenosis occurs, the flow of blood through the valves is obstructed. For example, when stenosis occurs in the semilunar valves (aortic and pulmonic valves), the adjacent ventricles have to work harder to move the ventricular blood volume beyond the stenotic valve. Over time the stenosis causes the ventricle to hypertrophy (enlarge); and, if the condition is untreated, left- or right-sided heart failure occurs. When regurgitation occurs, there is a backflow of blood into an adjacent chamber. For example, in mitral regurgitation the mitral leaflets do not close completely. When the ventricles contract, blood escapes back into the atria, causing a murmur, or "whooshing" sound (see Chapter 30).

Myocardial Ischemia. **Myocardial ischemia** results when the supply of blood to the myocardium from the coronary arteries is insufficient to meet myocardial oxygen demands. Two common outcomes of this ischemia are angina pectoris and MI.

Angina. **Angina pectoris** is a transient imbalance between myocardial oxygen supply and demand. The condition results in chest pain that is aching, sharp, tingling, or burning or that feels like pressure. Typically chest pain is left sided or substernal and often radiates to the left or both arms, the jaw, neck, and back. In some patients angina pain does not radiate. It usually lasts from 3 to 5 minutes (McCance and Huether, 2010). Patients report that it is often precipitated by activities that increase myocardial oxygen demand (e.g., eating heavy meals, exercise, or stress). It is usually relieved with rest and coronary vasodilators, the most common being a nitroglycerin preparation.

Myocardial Infarction. **Myocardial infarction (MI)** or **acute coronary syndrome (ACS)** results from sudden decreases in coronary blood flow or an increase in myocardial oxygen demand without adequate coronary perfusion. Infarction occurs because ischemia is not reversed. Cellular death occurs after 20 minutes of myocardial ischemia (McCance and Huether, 2010).

Chest pain associated with MI in men is usually described as crushing, squeezing, or stabbing. The pain is often in the left chest and sternal area; may be felt in the back; and radiates down the left arm to the neck, jaws, teeth, epigastric area, and back. It occurs at rest or exertion and lasts more than 20 minutes. Rest, position change, or sublingual nitroglycerin administration does not relieve the pain.

There is a significant difference between men and women in relation to coronary artery disease. As women get older, their risk of heart disease begins to rise (AHA, 2010a). Women on average have greater blood cholesterol and triglyceride levels than men. Obesity in women is more prevalent, which also increases risk for diabetes and cardiac disease (Shaw et al., 2009). Women's symptoms differ from those of men. The most common initial symptom in women is angina, but they also present with atypical symptoms such as fatigue, indigestion, shortness of breath, and back or jaw pain. Women have twice the risk of dying within the first year after a heart attack than men.

NURSING KNOWLEDGE BASE

Factors Influencing Oxygenation

In addition to physiological factors, multiple developmental, lifestyle, and environmental factors affect patients' oxygenation status. It is important to recognize these as possible risks or factors that impact their health care goals.

Developmental Factors. The developmental stage of a patient and the normal aging process affect tissue oxygenation.

Infants and Toddlers. Infants and toddlers are at risk for upper respiratory tract infections as a result of frequent exposure to other children, an immature immune system, and exposure to secondhand smoke. In addition, during the teething process some infants develop nasal congestion, which encourages bacterial growth and increases the potential for respiratory tract infection. Upper respiratory tract infections are usually not dangerous, and infants or toddlers recover with little difficulty.

School-Age Children and Adolescents. School-age children and adolescents are exposed to respiratory infections and respiratory risk factors such as cigarette smoking or secondhand smoke. A healthy child usually does not have adverse pulmonary effects from respiratory infections. The American Lung Association (2008) reported a study showing that cigarette smoking in college students (19.2%) had declined in 2006 compared to those smoking in 1999 (30.6%). Although this is still higher than the national goal set by the U.S. Department of Health and Human Services (12%), there is hope that the decline will continue. The biggest risk factor for those still smoking in college was if they started smoking in high school (American Lung Association, 2008). A person who starts smoking in adolescence and continues to smoke into middle age has an increased risk for cardiopulmonary disease and lung cancer.

Young and Middle-Age Adults. Young and middle-age adults are exposed to multiple cardiopulmonary risk factors: an unhealthy diet, lack of exercise, stress, over-the-counter and prescription drugs not used as intended, illegal substances, and smoking. Reducing these modifiable factors decreases a patient's risk for cardiac or pulmonary diseases. This is also the time when individuals

BOX 40-1 FOCUS ON OLDER ADULTS

Oxygenation Changes in Older Adults

- The tuberculin skin test is an unreliable indicator of tuberculosis in older patients. They frequently display false-positive or false-negative skin test reactions.
  - Older patients are at an increased risk for reactivation of dormant organisms that were present for decades as a result of age-related changes in the immune system.
  - The standard 5-TU Mantoux test is given and repeated or repeated with the 250-TU strength to create a booster effect.
  - If the older patient has a positive reaction, a complete history is necessary to determine any risk factors.
- Older adults have more atypical signs and symptoms of coronary artery disease (Meiner, 2011).
- The incidence of atrial fibrillation increases with age and is the leading contributing factor for stroke in the older adult (Meiner, 2011).
- Mental status changes are often the first signs of respiratory problems and often include forgetfulness and irritability.
- Older adults do not always complain of dyspnea until it affects the activities of daily living that are important to them.
- Changes in the older adult's cough mechanism lead to retention of pulmonary secretions, airway plugging, and atelectasis if patients do not use cough suppressants with caution.
- Age-related changes in the immune system lead to a decline of both cell-mediated and humoral immunity, resulting in an increased risk of respiratory infections (McCance and Huether, 2010).
- Changes in the thorax that occur from ossification of costal cartilage, decreased space between vertebrae, and diminished respiratory muscle strength lead to problems with chest expansion and oxygenation (Linton and Lach, 2007).

establish lifelong habits and lifestyles. In 2007 20.6% of adults were smokers (LungUSA, 2010). It is important to help your patients make good choices and informed decisions about their health care practices. The increased cost of cigarettes plus the state smoke-free air policies and laws that reduce smoking in public places have proven to be helpful in smoking cessation (American Lung Association, 2008).

Older Adults. The cardiac and respiratory systems undergo changes throughout the aging process (Box 40-1). The changes are associated with calcification of the heart valves, SA node, and costal cartilages. The arterial system develops atherosclerotic plaques.

Osteoporosis leads to changes in the size and shape of the thorax. The trachea and large bronchi become enlarged from calcification of the airways. The alveoli enlarge, decreasing the surface area available for gas exchange. The number of functional cilia is reduced, causing a decrease in the effectiveness of the cough mechanism, putting the older adult at increased risk for respiratory infections (Meiner, 2011).

Lifestyle Factors. Lifestyle modifications are difficult for patients because they often have to change an enjoyable habit such as cigarette smoking or eating certain foods. Risk-factor modification is important and includes smoking cessation, weight reduction, a low-cholesterol and low-sodium diet, management of hypertension, and moderate exercise (see Chapter 6). Although it is difficult to change long-term behavior, helping patients acquire healthy behaviors reduces the risk for or slows or halts the progression of cardiopulmonary diseases (Meiner, 2011).

Nutrition. Nutrition affects cardiopulmonary function in several ways. Severe obesity decreases lung expansion, and increased body weight increases tissue oxygen demands. The malnourished patient experiences respiratory muscle wasting, resulting in decreased muscle strength and respiratory excursion. Cough efficiency is reduced secondary to respiratory muscle weakness, putting the patient at risk for retention of pulmonary secretions.

Patients who are morbidly obese and/or malnourished are at risk for anemia. Diets high in carbohydrates play a role in increasing the carbon dioxide load for patients with carbon dioxide retention. As carbohydrates are metabolized, an increased load of carbon dioxide is created and excreted via the lungs.

Dietary practices also influence the prevalence of cardiovascular diseases. Cardioprotective nutrition includes diets rich in fiber; whole grains; fresh fruits and vegetables; nuts; antioxidants; lean meats, fish, and chicken; and omega-3 fatty acids. The latest update by the Joint National Committee (JNC, 2003) recommended that dietary restriction of sodium is beneficial in reducing antihypertensive medication requirements; in some cases it causes left ventricular hypertrophy to regress. Diets high in potassium prevent hypertension and help improve control in patients with hypertension. A 2000-calorie diet of fruits; vegetables; and low-fat dairy foods that are high in fiber, potassium, calcium, and magnesium and low in saturated and total fat helps prevent and reduce the effects of hypertension.

Exercise. Exercise increases the metabolic activity and oxygen demand of the body. The rate and depth of respiration increase, enabling the person to inhale more oxygen and exhale excess carbon dioxide. A physical exercise program has many benefits (see Chapter 38). People who exercise for 30 to 60 minutes daily have a lower pulse rate and blood pressure, decreased cholesterol level, increased blood flow, and greater oxygen extraction by working muscles. Fully conditioned people increase oxygen consumption by 10% to 20% because of increased cardiac output and increased efficiency of the myocardial muscle (JNC, 2003).

Smoking. Cigarette smoking and secondhand smoke are associated with a number of diseases, including heart disease, COPD, and lung cancer. Cigarette smoking worsens peripheral vascular and coronary artery diseases (McCance and Huether, 2010). Inhaled nicotine causes vasoconstriction of peripheral and coronary blood vessels, increasing blood pressure and decreasing blood flow to peripheral vessels.

Women who take birth control pills and smoke cigarettes have an increased risk for thrombophlebitis and pulmonary emboli. Smoking during pregnancy can result in low-birth-weight babies, preterm delivery, and babies with reduced lung function (LungUSA, 2010). Even exposure to secondhand smoke can be a risk for low-birth-weight babies, preterm delivery, and miscarriages (ACS, 2010).

The risk of lung cancer is 10 times greater for a person who smokes than for a nonsmoker. In the United States the use of tobacco accounts for 30% of all cancer deaths. This includes 87% of the deaths from lung cancer and cancer of the larynx, mouth, pharynx, esophagus, and bladder. Smoking has been linked to the development of other cancers, including kidney, cervix, and leukemia (ACS, 2010). Nicotine patches, gum, and lozenges are available over the counter, and nicotine nasal spray and inhalers can be obtained by prescription. Prescription drugs such as bupropion (Zyban) and varenicline (Chantix) are also available to help people quit smoking (LungUSA, 2010).

Exposure to environmental tobacco smoke (secondhand smoke) increases the risk of lung cancer and cardiovascular disease in the

nonsmoker. Children with parents who smoke have a higher incidence of asthma, pneumonia, and ear infections. Babies exposed to secondhand smoke are at higher risk for sudden infant death syndrome (ACS, 2010).

Substance Abuse. Excessive use of alcohol and other drugs impairs tissue oxygenation in two ways. First, the person who chronically abuses substances often has a poor nutritional intake. With the resultant decrease in intake of iron-rich foods, hemoglobin production declines. Second, excessive use of alcohol and certain other drugs depresses the respiratory center, reducing the rate and depth of respiration and the amount of inhaled oxygen. Substance abuse by either smoking or inhaling substances such as crack cocaine or fumes from paint or glue cans causes direct injury to lung tissue that leads to permanent lung damage. The report on inhalant abuse (huffing) by teenagers to get a euphoric effect includes use of a wide variety of substances such as paint thinner, nail polish remover, glue, spray paint, nitrous oxide, and other common household products. Sudden death can occur from cardiac arrhythmias; or chronic abuse can cause damage to heart, lungs, and kidneys (Stoppler, 2005).

Stress. A continuous state of stress or severe anxiety increases the metabolic rate and oxygen demand of the body. The body responds to anxiety and other stresses with an increased rate and depth of respiration. Most people adapt; but some, particularly those with chronic illnesses or acute life-threatening illnesses such as an MI, cannot tolerate the oxygen demands associated with anxiety (see Chapter 37).

Environmental Factors. The environment also influences oxygenation. The incidence of pulmonary disease is higher in smoggy, urban areas than in rural areas. In addition, a patient's workplace sometimes increases the risk for pulmonary disease. Occupational pollutants include asbestos, talcum powder, dust, and airborne fibers. For example, farm workers in dry regions of the southwestern United States are at risk for coccidioidomycosis, a fungal disease caused by inhalation of spores of the airborne bacterium *Coccidioides immitis.* Asbestosis is an occupational lung disease that develops after exposure to asbestos. The lung with asbestosis often has diffuse interstitial fibrosis, creating a restrictive lung disease. Patients exposed to asbestos are at risk for developing lung cancer, and this risk increases with exposure to tobacco smoke.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate information, analyze the data, and make decisions regarding your patient's care. During assessment consider all elements that build toward making an appropriate nursing diagnosis (Fig. 40-6).

To understand how alterations in oxygenation affect patients and the interventions necessary, you need to integrate knowledge from nursing and other disciplines and information gathered from patients. Critical thinking attitudes ensure that you approach patient care in a methodical and logical way. The use of professional standards such as those developed by the Agency for Healthcare Research and Quality (AHRQ), the American Cancer Society (ACS), the American Heart Association (AHA), the American Lung Association (ALA), the American Thoracic Society (ATS), and the American Nurses Association (ANA) provide valuable guidelines for care and management of patients.

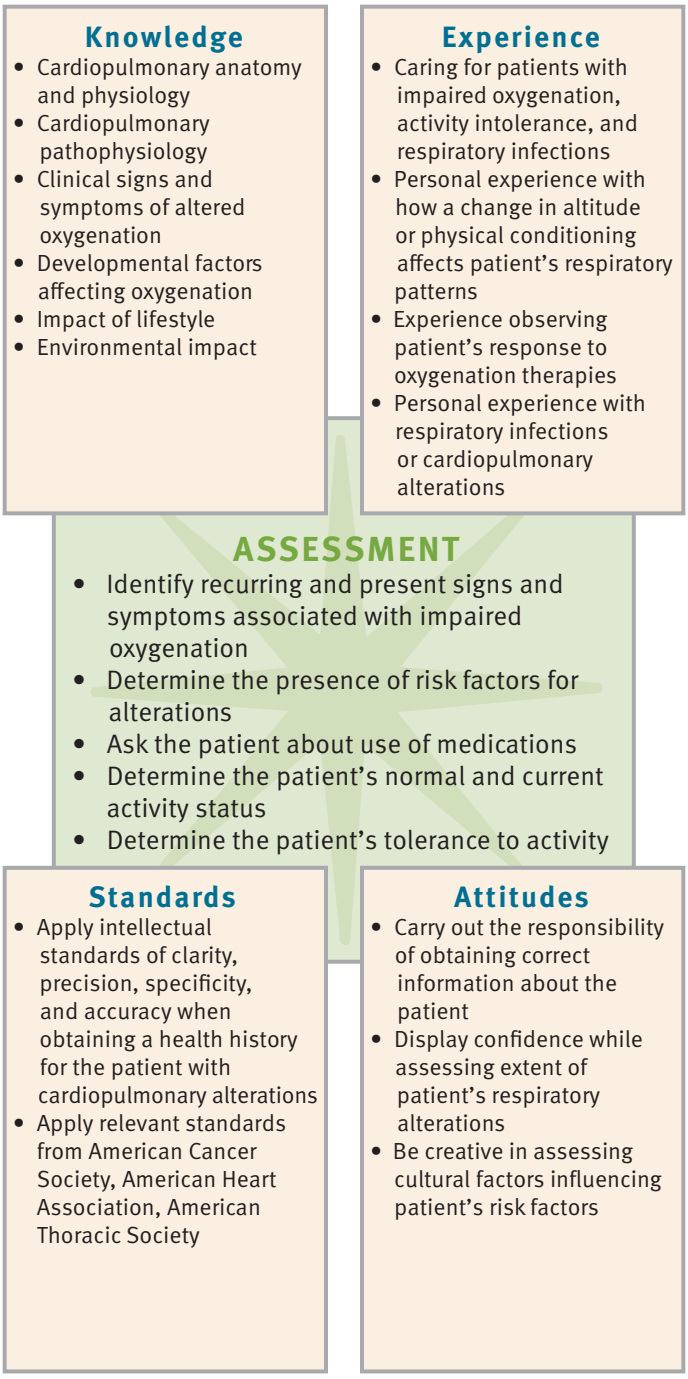

FIG. 40-6 Critical thinking model for oxygenation assessment.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Nursing

assessment of cardiopulmonary functioning includes an in-depth history of a patient's normal and present cardiopulmonary function, past impairments in circulatory or respiratory functioning, and methods that a patient uses to optimize oxygenation. The nursing history includes a review of drug, food, and other allergies. Physical examination of a patient's cardiopulmonary status reveals the extent of existing signs and symptoms. Finally, a review of laboratory and diagnostic test results provides valuable assessment data.

Through the Patient's Eyes. Ask patients about their priorities and what they expect from their health care visit. Identifying their expectations involves patients in the decision-making process and helps them participate in their care. For example, planning a smoking cessation program for a patient who is not ready for the change is frustrating for both the patient and the nurse. Establish realistic, short-term outcomes that build to a larger goal. For example, tobacco cessation treatments are effective, but the patient needs to be willing to participate in the program and may need to use several strategies to be successful. Educating the patient on the opportunities for individual, group, or telephone counseling and identifying a social support system give more individual choices when developing the cessation plan. After this is determined, the various nicotine and nonnicotine medications for treatment of tobacco dependence can be discussed to find one that may fit the patient's lifestyle. A combination of counseling and medication is more effective than either one alone (CDC, 2008).

Remember that your goals and expectations do not always coincide with those of your patient. By addressing a patient's concerns and expectations, you establish a relationship that addresses other health care goals and expected outcomes. Knowing your patients' mindsets and respecting their wishes goes a long way in helping them make significant beneficial lifestyle changes.

Nursing History. The nursing history focuses on the patient's ability to meet oxygen needs. The nursing history for respiratory function includes the presence of a cough, shortness of breath, dyspnea, wheezing, pain, environmental exposures, frequency of respiratory tract infections, pulmonary risk factors, past respiratory problems, current medication use, and smoking history or secondhand smoke exposure. The nursing history for cardiac function includes pain and characteristics of pain, fatigue, peripheral circulation, cardiac risk factors, and the presence of past or concurrent cardiac conditions. Ask specific questions related to cardiopulmonary disease (Box 40-2).

Pain. The presence of chest pain requires an immediate thorough evaluation, including location, duration, radiation, and frequency. Cardiac pain does not occur with respiratory variations. Chest pain in men is most often on the left side of the chest and radiates to the left arm. Chest pain in women is much less definitive and is often a sensation of breathlessness, jaw or back pain, nausea, and fatigue (AHA, 2006a). Pericardial pain results from inflammation of the pericardial sac, occurs on inspiration, and does not usually radiate.

Pleuritic chest pain is peripheral and radiates to the scapular regions. Inspiratory maneuvers such as coughing, yawning, and sighing worsen pleuritic chest pain. An inflammation or infection in the pleural space often causes this; and patients usually describe it as knifelike, lasting from a minute to hours and always in association with inspiration.

Musculoskeletal pain is often present following exercise, rib trauma, and prolonged coughing episodes. Inspiration worsens this pain, and patients often confuse it with pleuritic chest pain.

BOX 40-2 NURSING ASSESSMENT QUESTIONS

Nature of the Cardiopulmonary Problem
- What types of breathing problems are you having?
- Describe the problem that you're having with your heart.
- Does the problem (e.g., chest pain, rapid heart rate) occur at a specific time of the day, during or after exercise, or all the time?

Signs and Symptoms
- How has your breathing pattern changed?
- Do you have sputum with coughing? Is this different?
- Is your sputum a different color?
- Are you having any chest pain? Does the pain occur with breathing?

Onset and Duration
- If you are having chest pain, what causes the pain and how long does it last? Is this a different type of pain?
- When did you notice your sputum change in color and amount?
- When did your coughing increase? How does this differ from your usual pattern of coughing?

Severity
- On a scale of 0 to 10, with 10 being the most severe, rate your shortness of breath.
- What helps relieve your shortness of breath?
- On a scale of 0 to 10, with 0 being no pain and 10 the most severe pain, rate your chest pain. Is the severity of your pain different today?
- What do you do for this pain?

Predisposing Factors
- Have you been exposed to a cold or flu?
- Are you taking your prescribed medications?
- Do you smoke? Have you been exposed to secondhand smoke?
- Have you been doing any unusual exercises?

Effect of Symptoms on Patient
- Do these symptoms affect your daily activities? If so how?
- What impact do these symptoms have on your appetite, sleeping habits, activity status?

Fatigue. Fatigue is a subjective sensation in which the patient reports a loss of endurance. Fatigue in the patient with cardiopulmonary alterations is often an early sign of a worsening of the chronic underlying process. To provide an objective measure of fatigue, ask the patient to rate it on a scale of 0 to 10, with 10 being the worst level and 0 representing no fatigue.

Dyspnea. **Dyspnea** is a clinical sign of hypoxia. It is the subjective sensation of difficult or uncomfortable breathing. Dyspnea is shortness of breath usually associated with exercise or excitement, but in some patients it is present without any relation to activity or exercise. It is associated with many conditions such as pulmonary diseases, cardiovascular diseases, neuromuscular conditions, and anemia. In addition, it occurs in the pregnant woman in the final months of pregnancy. Finally, environmental factors such as pollution, cold air, and smoking also cause or worsen dyspnea.

Dyspnea is associated with exaggerated respiratory effort, use of the accessory muscles of respiration, nasal flaring, and marked increases in the rate and depth of respirations. The use of a Visual Analogue Scale (VAS) helps patients objectively assess their dyspnea. The VAS is a 100-mm vertical line. Have patients rate their dyspnea on a scale of 0 to 10, with 0 equated with no dyspnea and

10 equated with the worst breathlessness a patient has experienced. The use of the VAS to assess the level of a patient's dyspnea is helpful in later evaluating nursing interventions designed to reduce dyspnea (Meek and Lareau, 2003).

When conducting a nursing history on a patient with dyspnea, ask when it occurs (such as with exertion, stress, or respiratory tract infection). Determine whether the patient's dyspnea affects the ability to lie flat. **Orthopnea** is an abnormal condition in which a patient uses multiple pillows when reclining to breathe easier or sits leaning forward with arms elevated. The number of pillows used usually helps to quantify the orthopnea (e.g., two or three-pillow orthopnea). Also ask if the patient must sleep in a recliner chair to breathe easier.

Cough. Cough is a sudden, audible expulsion of air from the lungs. The person breathes in, the glottis is partially closed, and the accessory muscles of expiration contract to expel the air forcibly. Coughing is a protective reflex to clear the trachea, bronchi, and lungs of irritants and secretions. A cough is difficult to evaluate, and almost everyone has periods of coughing. Patients with a chronic cough tend to deny, underestimate, or minimize their coughing, often because they are so accustomed to it that they are unaware of how frequently it occurs.

Patients with chronic sinusitis usually cough only in the early morning or immediately after rising from sleep. This clears the airway of mucus resulting from sinus drainage. Patients with chronic bronchitis generally cough and produce sputum all day, although greater amounts are produced after rising from a semirecumbent or flat position. This is a result of the dependent accumulation of sputum in the airways and is associated with reduced mobility (see Chapter 38).

If the patient has a cough, determine how frequently it occurs and whether it is productive or nonproductive. A productive cough results in sputum production (i.e., material coughed up from the lungs that a patient swallows or expectorates). Sputum contains mucus, cellular debris, microorganisms, and sometimes pus or blood. Collect data about the type and quantity of sputum. Instruct the patient to try to cough up some sputum and not to simply clear the throat, which produces only saliva. Inspect the sputum for color such as green or blood tinged, consistency such as thin or thick, odor such as none or foul, and amount such as increased or decreased.

If **hemoptysis** (bloody sputum) is present, determine if it is associated with coughing and bleeding from the upper respiratory tract, sinus drainage, or the gastrointestinal tract **(hematemesis).** Hemoptysis has an alkaline pH, and hematemesis has an acidic pH; thus pH testing of the specimen may help to determine the source (McCance and Huether, 2010). Describe hemoptysis according to amount and color and whether it is mixed with sputum. When there is bloody or blood-tinged sputum, health care providers frequently perform diagnostic tests such as examination of sputum specimens, chest x-ray examinations, **bronchoscopy,** and other x-ray film studies.

Wheezing. **Wheezing** is a high-pitched musical sound caused by high-velocity movement of air through a narrowed airway. It is associated with asthma, acute bronchitis, or pneumonia. It occurs during inspiration, expiration, or both. Determine if there are any precipitating factors such as respiratory infection, allergens, exercise, or stress.

Environmental or Geographical Exposures. Environmental exposure to inhaled substances is closely linked with respiratory disease. Investigate exposures in the patient's home and workplace. The most common environmental exposures in the home are cigarette smoke, CO, and radon. In addition, determine whether a patient who is a nonsmoker is exposed to secondhand smoke.

CO poisoning often results from a blocked furnace flue or fireplace. The patient will have vague complaints of general malaise, flulike symptoms, and excessive sleepiness. Patients are particularly at risk in the late fall when they turn the furnace on or begin to use the fireplace again. Radon gas is a radioactive substance from the breakdown of uranium in soil, rock, and water that enters homes through the ground or well water. When homes are poorly ventilated, this gas is unable to escape and becomes trapped. If a patient who smokes also lives in a home with a high radon level, the risk for lung cancer is very high (EPA, 2010). Ask if there are any CO or radon detectors in the home.

Smoking. It is important to determine patients' direct and secondary exposure to tobacco. Ask about any history of smoking; include the number of years smoked and the number of packages smoked per day. This is recorded as pack-year history. For example, if a patient smoked two packs a day for 20 years, the patient has a 40 pack-year history (packages per day × years smoked). Determine exposure to secondhand smoke because any form of tobacco exposure increases a patient's risk for cardiopulmonary diseases.

Respiratory Infections. Obtain information about the patient's frequency and duration of respiratory tract infections. Although everyone occasionally has a cold, for some people it results in bronchitis or pneumonia. On average patients have four colds per year. Determine if and when the patient has had a pneumococcal or influenza (flu) vaccine. This is especially important when assessing older adults because of their increased risk for respiratory disease (Linton and Lach, 2007). Ask about any known exposure to tuberculosis (TB) and the date and results of the last tuberculin skin test.

Determine the patient's risk for human immunodeficiency virus (HIV) infection. Patients with a history of intravenous (IV) drug use and multiple unprotected sexual partners are at risk of developing HIV infection. Patients do not always display symptoms of HIV infection until they present with *Pneumocystis carinii* pneumonia (PCP) or *Mycoplasma* pneumonia. Presentation with PCP or *Mycoplasma* pneumonia indicates a significant depression of a patient's immune system and progression to acquired immunodeficiency syndrome (AIDS).

Allergies. Inquire about your patient's exposure to airborne allergens (e.g., pet dander or mold). The allergic response is often watery eyes, sneezing, runny nose, or respiratory symptoms such as cough or wheezing. When obtaining information, ask specific questions about the type of allergens, response to these allergens, and successful and unsuccessful relief measures. In addition, determine the effect of environmental air quality and secondhand smoke exposure on the patient's allergy and symptoms.

Safe nursing practice also includes obtaining information about food, drug, or insect sting allergies on the initial history and physical. However, always double-check this information with the patient on any subsequent assessment, especially concerning respiratory allergens.

Health Risks. Determine familial risk factors such as a family history of lung cancer or cardiovascular disease. Documentation includes blood relatives who had the disease and their present level of health or age at time of death. Other family risk factors include the presence of infectious diseases, particularly TB.

Medications. Another component of the nursing history describes medications that a patient is using. These include prescribed medications, over-the-counter medications, folk medicine, herbal medicines, alternative therapies, and illicit drugs and

TABLE 40-1 Assessment Findings in the Aging Cardiopulmonary System

FUNCTION	PATHOPHYSIOLOGICAL CHANGE	KEY CLINICAL FINDINGS
Heart		
Muscle contraction	Thickening of the ventricular wall, increased collagen and decreased elastin in the heart muscle	Decreased cardiac output Diminished cardiac reserve
Blood flow	Heart valves become thicker and stiffer, more often in the mitral and aortic valves	Systolic ejection murmur
Conduction system	SA node becomes fibrotic from calcification; decrease of number of pacemaker cells in SA node	Increased PR, QRS, and Q-T intervals, decreased amplitude of QRS complex Irregular heart rhythm
Arterial vessel compliance	Calcified vessels, loss of arterial distensibility, decreased elastin in vessel walls, more tortuous vessels	Hypertension with an increase in systolic blood pressure.
Lungs		
Breathing mechanics	Decreased chest wall compliance, loss of elastic recoil Decreased respiratory muscle mass/strength	Prolonged exhalation phase Decreased vital capacity
Oxygenation	Increased ventilation/perfusion mismatch Decreased alveolar surface area Decreased carbon dioxide diffusion capacity	Decreased PaO_2 Decreased cardiac output Slightly increased $PaCO_2$
Breathing control/breathing pattern	Decreased responsiveness of central and peripheral chemoreceptors to hypoxemia and hypercapnia	Increased respiratory rate Decreased tidal volume
Lung defense mechanisms	Decreased number of cilia Decreased IgA production and humoral and cellular immunity	Decreased airway clearance Diminished cough reflex Increased risk for infection
Sleep and breathing	Decreased respiratory drive Decreased tone of upper airway muscles	Increased risk of aspiration and respiratory infection Decreased PaO_2 Snoring, obstructive sleep apnea

IgA, Immunoglobulin A; *$PaCO_2$,* arterial carbon dioxide tension; *PaO_2,* arterial oxygen tension; *SA,* sinoatrial.

substances. Some of these preparations have adverse effects by themselves or because of interactions with other drugs. For example, a person using a prescribed bronchodilator drug decides to use an over-the-counter inhalant as well. Many of these contain ephedrine or *ma huang,* a natural ephedrine, which acts like epinephrine. This product reacts with the prescribed medication by potentiating or decreasing the effect of the prescribed medication. Patients taking warfarin (Coumadin) for blood thinning prolong the prothrombin time (PT)/international normalized ratio (INR) results if they are taking gingko biloba, garlic, or ginseng with the anticoagulant. The drug interaction can precipitate a life-threatening bleed.

It is important to determine if a patient uses illicit drugs. Illicit drugs, particularly inhaled opioids, which are often diluted with talcum powder, cause pulmonary disorders resulting from the irritant effect of the powder on lung tissues. Marijuana is usually smoked in the form of a joint or pipe. Marijuana smoke contains carcinogens and is an irritant to the lungs, putting users at higher risk for lung cancer and respiratory illnesses (NIDA, 2009). Cocaine is snorted through the nose, smoked, or injected. Cocaine abusers can have acute changes such as constricted blood vessels and increased heart rate and blood pressure, which result in heart attack or stroke. Cocaine deaths are caused by cardiac arrest and respiratory failure (NIDA, 2010).

As with all medications, assess the patient's knowledge and ability to self-administer medications correctly (see Chapter 31). Of particular importance is the assessment that the patient understands the potential side effects of medications. Patients need to recognize adverse reactions and be aware of the dangers in combining prescribed medications with over-the-counter drugs.

Building Competency in Safety You are caring for Mary, an 87-year-old patient with diabetes, hypertension, and heart failure. She has recently developed an increase in shortness of breath, weakness, and fatigue. Her daughter brings in a paper bag containing all the medications found in Mary's medicine cabinet. Which of the following medications would put Mary at increased risk of further cardiopulmonary or other problems caused by drug interactions?

- Glucotrol 5 mg 30 minutes before breakfast for diabetes
- Enalapril (Vasotec) 10 mg morning and evening for heart failure and elevated blood pressure
- Furosemide (Lasix) 20 mg every morning as a diuretic for heart failure and to lower blood pressure
- Warfarin (Coumadin) 5 mg every afternoon as a blood thinner to prevent clot formation
- Melatonin 50 mg at bedtime for sleep
- Ginseng 200 mg at bedtime to reduce cholesterol and blood sugar

Answers to questions can be found on the Evolve website.

Physical Examination. The physical examination includes assessment of the cardiopulmonary system (see Chapter 30). Give special consideration when assessing an older adult patient of changes that occur with the aging process (Table 40-1). These changes affect the patient's activity tolerance and level of fatigue or

cause transient changes in vital signs and are not always associated with a specific cardiopulmonary disease.

Inspection. Using inspection techniques, perform a head-to-toe observation of the patient for skin and mucous membrane color, general appearance, level of consciousness, adequacy of systemic circulation, breathing patterns, and chest wall movement (Table 40-2). Investigate any abnormalities further during palpation, percussion, and auscultation.

Inspection includes observations of the nails for clubbing (see Chapter 29). Clubbed nails often occur in patients with prolonged oxygen deficiency, endocarditis, and congenital heart defects.

Observe chest wall movement for retraction (i.e., sinking in of soft tissues of the chest between the intercostal spaces) and use of accessory muscles. Also observe the patient's breathing pattern and assess for paradoxical breathing (the chest wall contracts during inspiration and expands during exhalation) or asynchronous breathing. At rest the normal adult rate is 12 to 20 regular breaths/min. Bradypnea is less than 12 breaths/min, and tachypnea is greater than 20 breaths/min (see Chapter 29). In some conditions, such as metabolic acidosis, the acidic pH stimulates an increase in both rate and depth of respirations **(Kussmaul respiration)** to compensate by decreasing carbon dioxide levels. **Apnea** is the absence of respirations for a period of time. **Cheyne-Stokes respiration** occurs when there is decreased blood flow or injury to the brainstem. This respiratory pattern has periods of apnea followed by periods of deep breathing and then shallow breathing followed by more apnea. The apnea periods can last 15 to 60 seconds (McCance and Huether, 2010). Also note the shape of the chest wall. Conditions such as emphysema, advancing age, and COPD cause the chest to assume a rounded "barrel" shape.

TABLE 40-2 Inspection of Cardiopulmonary Status

ABNORMALITY	CAUSE
Eyes	
Xanthelasma (yellow lipid lesions on eyelids)	Hyperlipidemia
Corneal arcus (whitish opaque ring around junction of cornea and sclera)	Abnormal finding in young to middle-age adults with hyperlipidemia (normal finding in older adults with arcus senilis)
Pale conjunctivae	Anemia
Cyanotic conjunctivae	Hypoxemia
Petechiae on conjunctivae	Fat embolus or bacterial endocarditis
Mouth and Lips	
Cyanotic mucous membranes	Decreased oxygenation (hypoxia)
Pursed-lip breathing	Associated with chronic lung disease
Neck Veins	
Distention	Associated with right-sided heart failure
Nose	
Flaring nares	Air hunger, dyspnea
Chest	
Retractions	Increased work of breathing, dyspnea
Asymmetry	Chest wall injury
Skin	
Peripheral cyanosis	Vasoconstriction and diminished blood flow
Central cyanosis	Hypoxemia
Decreased skin turgor	Dehydration (normal finding in older adults as a result of decreased skin elasticity)
Dependent edema	Associated with right- and left-sided heart failure
Periorbital edema	Associated with kidney disease
Fingertips and Nail Beds	
Cyanosis	Decreased cardiac output or hypoxia
Splinter hemorrhages	Bacterial endocarditis
Clubbing	Chronic hypoxemia

From Potter PA, Weilitz PB: *Health assessment, pocket guide series,* ed 6, St Louis, 2007, Mosby.

Palpation. Palpation of the chest provides assessment data in several areas. It documents the type and amount of thoracic excursion; elicits any areas of tenderness; and helps to identify tactile fremitus, thrills, heaves, and the cardiac point of maximal impulse (PMI). Palpation of the extremities provides data about the peripheral circulation (i.e., the presence and quality of peripheral pulses, skin temperature, color, and capillary refill) (see Chapter 30).

Palpation of the feet and legs determines the presence or absence of peripheral edema. Patients with alterations in cardiac function such as those with heart failure or hypertension often have pedal or lower-extremity edema. Edema is graded from +1 to +4 depending on the depth of visible indentation after firm finger pressure (see Chapter 30).

Palpate the pulses in the neck and extremities to assess arterial blood flow (see Chapter 30). Use a scale of 0 (absent pulse) to +4 (full, bounding pulse) to describe what you feel. The normal pulse is +2; and a weak, thready pulse is +1.

Percussion. Percussion detects the presence of abnormal fluid or air in the lungs. It also determines diaphragmatic excursion (see Chapter 30).

Auscultation. Auscultation helps identify normal and abnormal heart and lung sounds (see Chapter 30). Auscultation of the cardiovascular system includes assessment for normal S_1 and S_2 sounds and the presence of abnormal S_3 and S_4 sounds (gallops), murmurs, or rubs. Identify the location, radiation, intensity, pitch, and quality of a murmur. Auscultation also identifies any bruit over the carotid, abdominal aorta, and femoral arteries.

Auscultation of lung sounds involves listening for movement of air throughout all lung fields: anterior, posterior, and lateral. Adventitious, or abnormal, breath sounds occur with collapse of a lung segment, fluid in a lung segment, or narrowing or obstruction of an airway.

Diagnostic Tests. A variety of diagnostic tests monitor cardiopulmonary functioning. Some of these screening tests involve simple blood specimens, x-rays, or other noninvasive means. One screening mechanism is TB skin testing (Box 40-3). This is a simple test and is required for health care workers; restaurant employees; students on entry to school, teachers, and other school employees; prisoners and correctional facility employees; and residents of long-term care facilities (CDC, 2010a, 2010b).

Diagnostic testing used in the assessment and evaluation of the patient with cardiopulmonary alterations are summarized in Tables 40-3 through 40-5. When reviewing results of pulmonary function studies, be aware of expected variations in patients from different cultures. These changes are caused by structural variations in chest wall size (Box 40-4).

Invasive diagnostic tests such as a thoracentesis are painful. How painful a diagnostic procedure is depends on the patient's tolerance for pain (see Chapter 43). Reduce the patient's anxiety by explaining the thoracentesis procedure and telling him or her what to

expect. Be sure that he or she understands the importance of following instructions such as taking a deep breath and holding it when requested and not coughing during the procedure. Provide appropriate pain management before the procedure to reduce the perception of pain. After any procedure monitor the patient for signs of changes in cardiopulmonary functioning such as sudden shortness of breath, pain, oxygen desaturation, and anxiety.

NURSING DIAGNOSIS

Based upon your assessment, you develop nursing diagnoses for patients with oxygenation alterations by clustering specific defining characteristics and identifying the related etiology (Box 40-5). The defining characteristics for diagnoses related to oxygenation can be similar. For example, both *impaired gas exchange* and *ineffective*

BOX 40-3 TUBERCULOSIS SKIN TESTING

- Skin testing determines whether a person is infected with *Mycobacterium tuberculosis*.
- Tuberculosis (TB) skin testing (TST) is performed by an intradermal injection of 0.1 mL of tuberculin purified protein derivative (PPD) on the inner surface of the forearm (see Chapter 31). The injection produces a pale elevation of the skin (a wheal) 6 to 10 mm in diameter. Afterward the injection site is circled, and the patient is instructed not to wash the circle off.
- Read tuberculin skin tests between 48 to 72 hours after the test. If the site is not read within 72 hours, a patient must have another skin test.
- *Positive results:* A palpable, elevated, hardened area around the injection site, caused by edema and inflammation from the antigen-antibody reaction, measured in millimeters. (See Chapter 31 for evaluation of positive results by millimeters.) People born outside the United States may have had bacille Calmette Guérin (BCG) vaccine for TB disease, which results in a positive reaction to the TST and may complicate the treatment plan. The positive skin reaction does not indicate that the BCG vaccine provided protection against the disease (CDC, 2010b).
- Reddened flat areas are *not* positive reactions and are not measured.
- TST is less reliable in older adults (see Box 40-1) and those with an altered immune function such as a human immunodeficiency virus (HIV)–positive patient or someone receiving chemotherapy.

BOX 40-5 NURSING DIAGNOSTIC PROCESS

Impaired Gas Exchange Related to Decreased Lung Expansion

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient or family about patient's mood, attentiveness, memory, and activity level.	Confusion Decreased activity Fatigue Irritability Restlessness Sleepiness
Observe patient's respirations for rate, rhythm, depth.	Dyspnea Nasal flaring Tachypnea Use of accessory muscles
Inspect skin and mucous membranes.	Diaphoresis Pallor Cyanosis
Auscultate chest.	Decreased respiratory excursion Abnormal, distant lung sounds

BOX 40-4 CULTURAL ASPECTS OF CARE

Cultural Impact on Pulmonary Diseases

The impact of pulmonary diseases on the patient and family varies among cultures. It is important to understand these variations in terms of assessing for and providing care in patients with lung diseases.

- Differences occur as a result of the variation in chest size. Caucasians have the largest chest volumes, followed by African Americans, Asian Americans, and Native Americans. The variations in the chest size affect the forced expiratory volume (FEV_1), forced vital capacity (FVC), and the FEV_1/FVC ratio (Meiner, 2011).
- In 2008 Asian Americans had the highest incidence rate of tuberculosis (TB), followed by native Hawaiians and Pacific Islanders. Asian Americans had 23.3 times the incidence rate of Caucasians. United States–born Asian Americans only make up 3% of TB cases compared to 43% of foreign-born Asian Americans. Major countries of origin for foreign-born TB cases are the Philippines, Vietnam, India, and China (American Lung Association, 2010b). Ask if they have had the bacille Calmette-Guérin (BCG) vaccine, which can cause a positive reaction to the TB skin test.
- The cigarette smoking prevalence rate in America's youth is highest in Alaskan Natives (23.1%), followed by Caucasians (14.9%), Hispanics (9.3%), African Americans (6.5%), and Asian Americans (4.3%). This puts them at risk for lung cancer, chronic obstructive pulmonary disease (COPD), and heart disease (American Lung Association, 2010a).
- African Americans have higher mortality rates from lung cancer despite the lower smoking prevalence. African American men are 37% more likely to get lung cancer, and 22.5% are more likely to die of the disease compared to Caucasian men (American Lung Association, 2010a).
- Air pollution has also been linked to cancer, asthma, and heart disease, which puts both African Americans and Hispanics at increased risk since they are more likely to live in areas with high levels of air toxins and heavy vehicle traffic (American Lung Association, 2010b). Female African Americans have the highest mortality rates from asthma among all ethnic/gender groups (Lewis et al., 2007).
- Caucasians have the highest incidences of COPD and cystic fibrosis, which is uncommon among African Americans, Hispanics, and Asian Americans (Lewis et al., 2007). They are more likely to die from COPD than any other racial group (American Lung Association, 2010b).
- African Americans and Hispanics are less likely to get flu or pneumonia vaccines than Caucasians. A recent report on health care disparities found that Asian Americans over the age of 65 had the highest rates of never having received a pneumococcal vaccine, which explains why influenza and pneumonia are the fourth leading cause of death in this group (American Lung Association, 2010b). Community Health Departments need to target these groups during education programs for their flu and pneumonia vaccine clinics.

Implications for Practice

- Public health programs for those at highest risk for pulmonary diseases should focus on pollution prevention and smoking cessation programs.
- Immunization clinics should concentrate on the underserved urban communities, especially those with large numbers of older adults.

TABLE 40-3 Cardiopulmonary Diagnostic Blood Studies

TEST AND NORMAL VALUES	INTERPRETATION
Complete Blood Count	
Normal values for a complete blood count (CBC) vary with age and gender	A CBC determines the number and type of red and white blood cells per cubic millimeter of blood.
Cardiac Enzymes	
Creatine kinase (CK): A serial CK with 50% increase between two samples 3-6 hours apart, peaking 12-24 hours after chest pain or a single CK elevation twofold is diagnostic for an acute myocardial infarction. Male normal: 55-170 units/L; female normal: 30-135 units/L	Providers use cardiac enzymes to diagnose acute myocardial infarcts.
Cardiac Troponins	
Plasma cardiac troponin I <0.03 ng/mL	Value elevates as early as 3 hours after myocardial injury. Value often remains elevated for 7-10 days.
Plasma cardiac troponin T <0.1 ng/mL	Value often remains elevated for 10-14 days.
Myoglobin	
<90 mcg/L	Early index of damage to myocardium in myocardial infarction or reinfarction. Increases within 3 hours.
Serum Electrolytes	
Potassium (K+) 3.5-5 mEq/L or 3.5-5 mmol/L	Patients on diuretic therapy are at risk for hypokalemia (low potassium). Patients receiving angiotensin-converting enzyme (ACE) inhibitors are at risk for hyperkalemia (elevated potassium).
Cholesterol	
Fasting cholesterol less than 200 mg/dL or less than 5.2 mmol/L (SI units)	Contributing factors include sedentary lifestyle with intake of saturated fatty acids, familial hypercholesterolemia.
Low-density lipoproteins (LDLs) (bad cholesterol) <130 mg/dL Very low–density lipoproteins (VLDLs) 7-32 mg/dl	High LDL cholesterol (hypercholesterolemia) is caused by excessive intake of saturated fatty acids, dietary cholesterol intake, and obesity. Familial hypercholesterolemia and hyperlipidemia, hypothyroidism, nephrotic syndrome, and diabetes mellitus are also contributing factors. VLDLs are predominant carriers of triglycerides and can be converted to LDL by lipoprotein lipase. Levels in excess of 25%-50% indicate increased risk of cardiac disease.
High-density lipoproteins (HDLs) (good cholesterol) Male: >45 mg/dL; female: >55 mg/dL	Factors such as cigarette smoking, obesity, lack of regular exercise, beta-adrenergic blocking agents, genetic disorders of HDL metabolism, hypertriglyceridemia, and type 2 diabetes cause low HDL cholesterol.
Triglycerides Male: 40-160 mg/dL; female: 35-135 mg/dL	Obesity, excessive alcohol intake, diabetes mellitus, beta-adrenergic blocking agents, and familial hypertriglyceridemia cause hypertriglyceridemia.

Data from Pagana KD, Pagana TJ: *Mosby's diagnostic and laboratory test reference,* ed 10, St Louis, 2011, Mosby.

TABLE 40-4 Cardiac Function Diagnostic Tests

TEST	SIGNIFICANCE
Holter monitor	Portable ECG worn by a patient. The test produces a continuous ECG tracing over a period of time. Patients keep a diary of activity, noting when they experience rapid heartbeats or dizziness. Evaluation of the ECG recording along with the diary provides information about the electrical activity of the heart during activities of daily living.
ECG exercise stress test	ECG is monitored while a patient walks on a treadmill at a specified speed and duration of time. Test evaluates the cardiac response to physical stress. It is not a valuable tool for evaluation of cardiac response in women because of an increased false-positive finding.
Thallium stress test	ECG stress test with the addition of thallium-201 injected intravenously. It determines coronary blood flow changes with increased activity.
Electrophysiological study (EPS)	EPS is an invasive measure of intracardiac electrical pathways. It provides more specific information about difficult-to-treat dysrhythmias and assesses adequacy of antidysrhythmic medication.
Echocardiography	This is a noninvasive measure of heart structure and heart wall motion. It graphically demonstrates overall cardiac performance.
Scintigraphy	Scintigraphy is radionuclide angiography; used to evaluate cardiac structure, myocardial perfusion, and contractility.
Cardiac catheterization and angiography	These are used to visualize cardiac chambers, valves, the great vessels, and coronary arteries. Pressures and volumes within the four chambers of the heart are also measured.

ECG, Electrocardiogram.

TABLE 40-5 Ventilation and Oxygenation Diagnostic Studies

MEASUREMENT AND NORMAL VALUES	INTERPRETATION
Arterial Blood Gases	
pH 7.35-7.45 PCO_2 35-45 mm Hg HCO_3 21-28 mEq/L PO_2 80-100 mm Hg SaO_2 saturation >95% Base excess 0 ± 2 mEq/L	Provide important information for assessment of patient's respiratory and metabolic acid/base balance and adequacy of oxygenation (see Chapter 41)
Pulmonary Function Tests	
Basic ventilation studies (Pulmonary functions vary by ethnic group.)	Determines ability of the lungs to efficiently exchange oxygen and carbon dioxide Used to differentiate pulmonary obstructive from restrictive disease
Peak Expiratory Flow Rate (PEFR)	
The point of highest flow during maximal expiration (Normal is based on age and body weight.)	Reflects changes in large airway sizes; an excellent predictor of overall airway resistance in a patient with asthma Daily measurement for early detection of asthma exacerbations
Bronchoscopy	
Normal airways without masses, pus, or foreign bodies	Visual examination of the tracheobronchial tree through a narrow, flexible fiberoptic bronchoscope Performed to obtain fluid, sputum, or biopsy samples; remove mucus plugs or foreign bodies
Lung Scan	
Normal lung structure without masses	Nuclear scanning test used to identify abnormal masses by size and location Identification of masses used in planning therapy and treatments Also used to find a blood clot preventing normal perfusion or ventilation ($\dot{V}/\dot{Q}$ scan)
Thoracentesis	
Surgical perforation of chest wall and pleural space with a needle to aspirate fluid for diagnostic or therapeutic purposes or to remove a specimen for biopsy; performed using aseptic technique and local anesthetic (Patient usually sits upright with the anterior thorax supported by pillows or an over-bed table.)	Specimen of plural fluid obtained for cytological examination Results may indicate an infection or neoplastic disease Identification of infection or a type of cancer important in determining a plan of care
Sputum Specimens	
Normal: negative	
Sputum culture and sensitivity	Obtained to identify a specific microorganism or organism growing in sputum Identifies drug resistance and sensitivities to determine appropriate antibiotic therapy
Sputum for acid-fast bacillus (AFB)	Screens for presence of AFB for detection of tuberculosis by early-morning specimens on 3 consecutive days
Sputum for cytology	Obtained to identify lung cancer Differentiates type of cancer cells (small cell, oat cell, large cell)

breathing pattern have the defining characteristics of dyspnea and nasal flaring. A closer review of assessment findings as well as an analysis of the patient's history will help you clarify and select the correct diagnosis. For example, a patient who is a victim of trauma and has rib pain and is showing an increased respiratory rate is more likely to be suffering *ineffective breathing pattern*. The clustered defining characteristics and related factor must support the nursing diagnosis.

These nursing diagnosis examples are appropriate for the patient with alterations in oxygenation (Ackley and Ladwig, 2011):

- Activity intolerance
- Decreased cardiac output
- Fatigue
- Impaired gas exchange
- Impaired spontaneous ventilation
- Impaired verbal communication
- Ineffective airway clearance
- Ineffective breathing pattern
- Ineffective health maintenance
- Risk for aspiration
- Risk for imbalanced fluid volume
- Risk for infection
- Risk for suffocation

PLANNING

During planning, use critical thinking skills to synthesize information from multiple sources (Fig. 40-7). Critical thinking ensures that your plan of care integrates individualized patient needs. Professional standards are especially important to consider

when developing a plan of care. These standards often establish scientifically proven guidelines for selecting effective nursing interventions.

Goals and Outcomes. Develop an individualized plan of care for each nursing diagnosis (see the Nursing Care Plan). Together with your patient set realistic expectations, goals, and measurable outcomes of care.

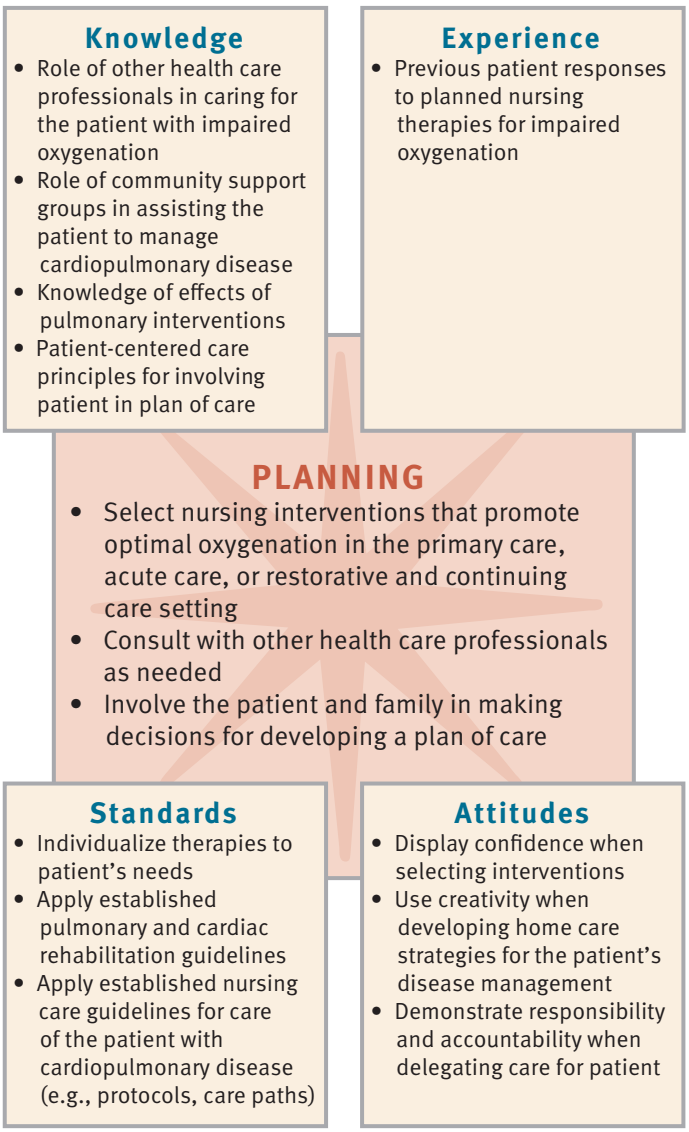

FIG. 40-7 Critical thinking model for oxygenation planning.

Patients with impaired oxygenation require a nursing care plan directed toward meeting actual or potential oxygenation needs. Allow patients to collaborate in setting relevant goals of care. Develop individual outcomes based on patient-centered goals. For example, for the goal of maintaining a patent airway, select specific expected outcomes for the patient, such as the following:

- Patient's lungs are clear to auscultation.
- Patient achieves bilateral lung expansion.
- Patient coughs productively.
- Pulse oximetry (SpO_2) is maintained or improved.

Often a patient with cardiopulmonary disease has multiple nursing diagnoses (Fig. 40-8). In this case identify when goals or outcomes apply to more than one diagnosis. The presence of multiple diagnoses also makes priority setting a critical activity.

Setting Priorities. A patient's level of health, age, lifestyle, and environmental risks affect the level of tissue oxygenation. Patients with severe impairments in oxygenation frequently require nursing interventions in multiple areas. Consider which goal is the most important to achieve while the patient is in the hospital or primary care setting. For example, in an acute care setting maintaining a patent airway has a higher priority than improving the patient's exercise tolerance. The need for a patent airway is immediate; and, as the patient's level of oxygen improves, activity tolerance increases. In a second example, when caring for a patient who has an abdominal incision, pain control is a priority. In this situation controlling the patient's pain facilitates coughing and deep breathing.

However, in a community-based or primary care setting, priorities often focus on smoking cessation, exercise, and/or diet modifications. Both you and the patient need to focus on the same goal and expected outcomes. In addition to individualizing each goal, be sure that the goals are realistic, have a reasonable time frame, and are attainable for the patient. In addition, be sure to respect the patient's preferences for his or her degree of active engagement in the care process. Some will choose to be very active and desire to make day-to-day decisions. Others may choose to assume a more passive role, preferring you to choose a course of action while keeping them informed.

Teamwork and Collaboration. The time spent with a patient in any setting is limited. Therefore collaborate with family members, colleagues, and other specialists to achieve the established goals and expected outcomes. Some patients need to improve their exercise and activity tolerance; for other patients continuing care involves participating in a community-based cardiopulmonary rehabilitation program. Finally, some patients need home physical therapy.

Collaboration with physical therapists, nutritionists, and community-based nurses is valuable for patients with heart failure or chronic lung conditions. These professionals work with patients and use resources in the community to assist them

NURSING CARE PLAN

Ineffective Airway Clearance

ASSESSMENT

Mr. Edwards is a 75-year-old Caucasian male who is currently lying in a semi-Fowler's position in bed talking with his wife. Kathy Allen is a nursing student completing a respiratory assessment. Mr. Edwards has a history of chronic obstructive pulmonary disease for 2 years. He continues to smoke ½ pack of cigarettes a day and does not participate in any exercise. He does not "see any reason" to increase his fluid intake. His SpO_2 ranges from 78% to 84%. He must do his self-care activities slowly because of fatigue. Presently he is admitted for right upper lobe pneumonia. He reports having an intermittent productive cough that occasionally produces thick, yellow sputum. He has more episodes of coughing when lying flat. His vital signs are temperature, 101.4° F (38.5° C); pulse, 102 beats/min; respirations, 30 breaths/min; blood pressure, 130/90 mm Hg; and SpO_2, 84%. He has episodes of chilling and diaphoresis. His health care provider has told him that, if he gradually increases his exercise, drinks more fluids, and stops smoking, his respiratory status will improve.

NURSING CARE PLAN

***Ineffective Airway Clearance*—cont'd**

Assessment Activities	*Findings/Defining Characteristics**
Ask Mr. Edwards how long he has had this cough.	He replies, "I have a morning **cough** every day, but this cough is different. It started about a week ago. It is worse when I lie flat."
Ask Mr. Edwards what is different about this cough.	He replies, "My ribs are getting sore. It is difficult to cough up anything, my **mouth** is **dry**, and I have become more **fatigued**."
Observe Mr. Edwards' skin and mucous membranes.	**Skin and mucous membranes** are **dry.**
Auscultate lung fields.	**Abnormal lung sounds** (crackles) are heard in lower lobes bilaterally.
Ask Mr. Edwards to produce a sputum sample.	Sputum is **thick** and **discolored** yellow to yellow-green.

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Ineffective airway clearance related to retained thick pulmonary secretions

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Respiratory Status: Airway Patency
Mr. Edwards will be able to effectively clear secretions by discharge.	Lung sounds will be clear in 48 hours. Mr. Edwards will notice increased ease in coughing within 48 hours. Sputum will be thin and white within 3 days. Respiratory rate will be within 12 to 20 breaths/min in 48 hours.
Mr. Edwards will increase oral hydration within 48 hours.	Mr. Edwards will drink 2500 mL of water or preferred liquids every 24 hours starting today. Mr. Edwards will verbalize that his mouth is not dry in 48 hours.

†Outcome classification labels from Moorhead S et al.: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Airway Management	
Position Mr. Edwards with head elevated 30-45 degrees.	An upright angle allows for thoracic expansion; lying flat allows abdominal organs to push up against the diaphragm, compromising inspiration. This allows for a more normal respiratory rate (Lawrence et al., 2006).
Ambulate in room or hall as tolerated at least 2 times a day. If unable to ambulate, reposition from side to side every 2 hours or more.	Body movement helps mobilize secretions (Perme and Chandrashekar, 2009).
Have Mr. Edwards deep breathe and cough every 2 hours. Teach him to take a deep breath, hold it for several seconds, open his mouth, tighten his abdominal muscles, and cough 2 to 3 times with his mouth open.	Retained secretions predispose patient to atelectasis and pneumonia. Controlled coughing that uses the diaphragmatic muscles make the cough more effective in removing mucus (AARC, 1993).
Administer 2 L/min of oxygen as ordered per nasal cannula if SpO_2 less than 90%.	This dependent nursing intervention will relieve hypoxia.
Increase fluids to 2500 mL in 24 hours if not contraindicated by cardiac or renal status. Offer fluids Mr. Edwards prefers.	Fluids help to liquefy secretions and promote ease of removal. Fluids relieve oral mucosa and skin dryness.

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Auscultate the chest.	Mr. Edwards reports that he has not heard any rattling in his chest.	Lung sounds are normal.
Ask Mr. Edwards if he can deep breathe and cough and measure SpO_2.	Mr. Edwards reports that it is easier to cough up his secretions. SpO_2 is 95%.	Airway clears with coughing. SpO_2 is within normal levels.
Observe sputum.	Mr. Edwards states, "My sputum is thinner and white now."	Sputum is thin and white.
Monitor respiratory rate.	Mr. Edwards says that it is easier to breathe.	Rate is between 12 and 20 breaths/min.
Assess Mr. Edwards' level of hydration (skin turgor, condition of mucosa).	Mucous membranes are moist. Fluid intake in previous 24 hours was 2600 mL.	Oral membranes are pink and moist. Minimum fluid intake of 2500 mL was achieved.

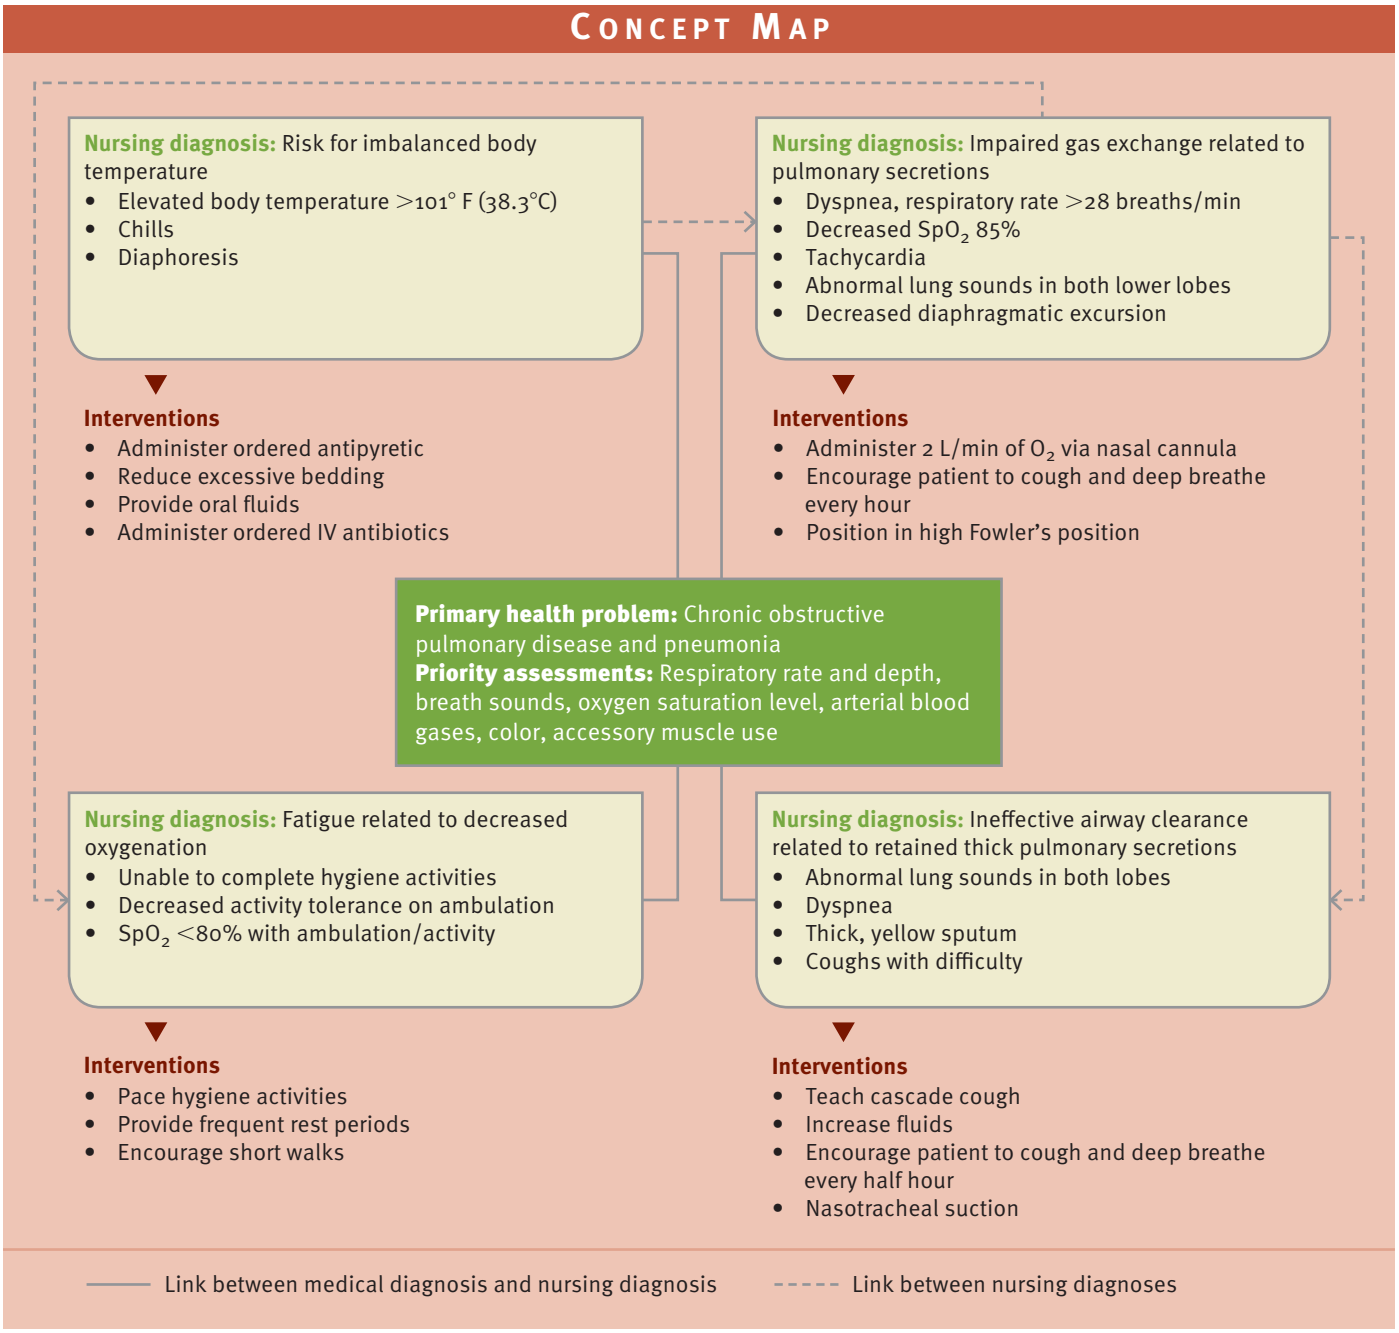

FIG. 40-8 Concept map for Mr. Edwards. *IV,* Intravenous.

in attaining and maintaining the highest possible level of wellness. In addition, professionals identify community resources and support systems for both the patient and family in preventing and managing symptoms related to cardiopulmonary diseases. Communicating among everyone on the patient's health care team and recognizing everyone's contributions in achieving the health care goals for the patient are imperative.

IMPLEMENTATION

There are interventions for promoting and maintaining adequate oxygenation across the continuum of care. As a nurse, you will be responsible for independent interventions such as positioning, coughing techniques, and health education for disease prevention. In addition, you will provide physician-initiated interventions such as oxygen therapy, lung inflation techniques, and chest physiotherapy.

Health Promotion. Maintaining the patient's optimal level of health is important in reducing the number and/or severity of respiratory symptoms. Prevention of respiratory infections is foremost in maintaining optimal health. Providing cardiopulmonary-related health information (Box 40-6) is an important nursing responsibility.

Vaccinations. Annual flu vaccines are recommended for all people 6 months and older. Patients with chronic illnesses (heart, lung, kidney, or immunocompromised), infants, older adults, and pregnant women can get very sick; thus they should be immunized. Close contacts of infants under 6 months should also be

BOX 40-6 PATIENT TEACHING

Prevention of Respiratory Infections

Objective

- The patient will be able to verbalize the methods to reduce the risk factors for respiratory infection and the steps needed to adopt health promotion behaviors.

Teaching Strategies

- Establish rapport with the patient and maintain eye contact as long as it is culturally acceptable.
- Teach the importance of not smoking. Refer to smoking cessation programs and discuss appropriate medication to support smoking cessation from the primary health provider.
- If a patient does not smoke, teach the importance of avoiding secondhand smoke and areas of high air pollution.
- Inform patient about other risk factors for pulmonary disease such as diabetes, obesity, and lack of physical inactivity.
- Teach how to implement a balanced diet low in fat, sodium, and carbohydrates. Provide sample menus.
- Discuss the benefits of exercising 30 to 60 minutes a day and help patient develop an exercise program suited to lifestyle.
- Teach patient about the importance of getting annual influenza vaccines and the pneumovax vaccine. If younger than 65 at the time of the primary vaccination, a one-time revaccination is recommended within 5 years (CDC, 2011).
- Teach the importance of handwashing during flu and cold season.
- Inform patient of signs of respiratory infection that should be reported to health care provider such as increased coughing, shortness of breath, change of color of sputum, fever, and fatigue.

Evaluation

- Ask patient to verbalize what they learned about smoking cessation, secondhand smoke, diet and exercise.
- Ask patient to describe in simple terms the symptoms of respiratory infection and when to call the health care provider.
- Have patient tell you how he or she plans to prevent exposure to respiratory infections.
- Ask if patient has any other questions or need for additional information or referrals.

immunized. Anyone who had the 2009 H1N1 (pandemic) vaccine or who actually had the pandemic flu in 2009 should get the 2010-2011 vaccine because it provides protection against A/H1N1 and two other flu viruses. The vaccine is also recommended for people in close or frequent contact with anyone in the high-risk groups. It is effective in reducing the severity of illness and the risk of serious complications and death (CDC, 2010c).

Researchers do not fully understand the value of vaccination in immune-compromised patients. HIV-positive patients receive the flu vaccine; however, they often require a second vaccine to gain protection. People with a known hypersensitivity to eggs or other components of the vaccine should not be vaccinated. Adults with an acute febrile illness should schedule the vaccination after they have recovered. The vaccines are formulated annually based on worldwide surveillance data. The live, attenuated nasal spray vaccine is given to people from 2 through 49 years of age if they are not pregnant or do not have certain long-term health problems such as asthma; heart, lung or kidney disease; diabetes; or anemia. The inactivated flu shot should be given to these individuals and those 50 and older (CDC, 2010c).

Pneumococcal vaccine (PCV13) is routinely given to infants in a series of four doses and is recommended for patients at increased risk of developing pneumonia. This includes all adults over 65 years of age, those with chronic illnesses or who are immunocompromised (such as HIV/AIDS), any adult who smokes or has asthma, and those living in special environments such as nursing homes or long-term care facilities (CDC, 2010d, 2011).

Healthy Lifestyle. Identification and elimination of risk factors for cardiopulmonary disease are important parts of primary care. Encourage patients to eat a healthy low-fat, high-fiber diet; monitor their cholesterol, triglyceride, high-density lipoprotein (HDL), and low-density lipoprotein (LDL) levels; reduce stress; exercise; and maintain a body weight in proportion to their height. Eliminating cigarettes and other tobacco, reducing pollutants, monitoring air quality, and adequately hydrating are additional healthy behaviors. Encourage patients to examine their habits and make appropriate changes.

Exercise is a key factor in promoting and maintaining a healthy heart and lungs. Encourage patients to exercise at least 3 to 4 times a week for 30 to 60 minutes. Aerobic exercise is necessary to improve lung and heart function and strengthen muscles. Walking is an efficient way to achieve a good aerobic workout. Many shopping malls have programs allowing people to walk in the enclosed mall before the shops open. During the hot summer months teach patients to limit activities to early in the day or late in the evening, when temperatures are lower. Teach patients how to maintain adequate hydration and sodium intake, especially if they are taking diuretics.

Patients with cardiopulmonary alterations need to minimize their risk for infection, especially during the winter months. Teach them to avoid large, crowded places; keep their mouth and nose covered; and be sure to dress warmly, including a scarf, hat, and gloves. This is especially important during the peak of the flu season.

Patients with known cardiac disease and those with multiple risk factors are cautioned to avoid exertion in cold weather. Shoveling snow is especially risky and often precipitates a cardiac event. Other activities such as hanging holiday lights and decorations in the extreme cold can precipitate chest pain and bronchospasm.

Environmental Pollutants. Avoiding exposure to secondhand smoke is essential to maintaining optimal cardiopulmonary function. Most businesses and restaurants now ban smoking or have separate areas designated as smoking areas. If patients are exposed to secondhand smoke in their home environments, counseling and support for all family members are necessary to assist the smoker in successful smoking cessation or alterations in behavior patterns such as smoking outside.

Consider if a patient is exposed to chemicals and pollutants in the work environment. Farmers, painters, carpenters, and others benefit from the use of particulate filter masks to reduce the inhalation of particles.

Acute Care. Patients with acute pulmonary illnesses require nursing interventions directed toward halting the pathological process (e.g., respiratory tract infection); shortening the duration and severity of the illness (e.g., hospitalization with pneumonia); and preventing complications from the illness or treatments (e.g., hospital-acquired infection resulting from invasive procedures).

Dyspnea Management. Dyspnea is difficult to measure and treat. Health care providers will individualize treatments for each patient and usually implement more than one therapy. Treatment of the underlying process causing dyspnea is then followed with

other therapies (e.g., pharmacological measures, oxygen therapy, physical techniques, and psychosocial techniques). Pharmacological agents include bronchodilators, inhaled steroids, mucolytics, and low-dose antianxiety medications. Oxygen therapy reduces dyspnea associated with exercise and hypoxemia. Physical techniques such as cardiopulmonary reconditioning (e.g., exercise, breathing techniques, and cough control), relaxation techniques, biofeedback, and meditation are also beneficial.

Airway Maintenance. The airway is patent when the trachea, bronchi, and large airways are free from obstructions. Airway maintenance requires adequate hydration to prevent thick, tenacious secretions. Proper coughing techniques remove secretions and keep the airway open. A variety of interventions such as suctioning, chest physiotherapy, and nebulizer therapy assist patients in managing alterations in airway clearance.

Mobilization of Pulmonary Secretions. The ability of a patient to mobilize pulmonary secretions makes the difference between a short-term illness and a long recovery involving complications. Nursing interventions promoting removal of pulmonary secretions assist in achieving and maintaining a clear airway and help to promote lung expansion and gas exchange.

Hydration. Maintenance of adequate systemic hydration keeps mucociliary clearance normal. In patients with adequate hydration, pulmonary secretions are thin, white, watery, and easily removable with minimal coughing. Excessive coughing to clear thick, tenacious secretions is fatiguing and energy depleting. The best way to maintain thin secretions is to provide a fluid intake of 1500 to 2500 mL/day unless contraindicated by cardiac or renal status. The color, consistency, and ease of mucus expectoration determine adequacy of hydration.

Humidification. **Humidification** is the process of adding water to gas. Temperature is the most important factor affecting the amount of water vapor a gas can hold. Relative humidity is the percentage of water in the gas. Air or oxygen with a high relative humidity keeps the airways moist and loosens and mobilizes pulmonary secretions. Humidification is necessary for patients receiving oxygen therapy at greater than 4 L/min (check agency protocol). It might be necessary to add humidification at lower oxygen concentrations if the environment is dry and arid. Bubbling oxygen through water adds humidity to the oxygen delivered to the upper airways (see Skill 40-4).

An oxygen hood is used for infants, and a humidity tent is used for children with illnesses such as croup and tracheitis to liquefy secretions and help reduce fever (Hockenberry and Wilson, 2011). The nebulizer at the top of the humidity tent remains filled with water to prevent nonhumidified air or oxygen from entering the tent. Air in the humidity tent sometimes becomes cool and falls below 20° C (68° F), causing the child to become chilled. Children in humidity tents require frequent changes of clothing and bed linen to remain warm and dry.

Nebulization. **Nebulization** adds moisture or medications to inspired air by mixing particles of varying sizes with the air. Aerosolization suspends the maximum number of water drops or particles of the desired size in inspired air. The moisture added through nebulization improves clearance of pulmonary secretions. Nebulization is used for administration of bronchodilators and mucolytic agents.

When the thin layer of fluid supporting the mucous layer over the cilia dries, the cilia are damaged and unable to adequately clear the airway. Humidification through nebulization enhances mucociliary clearance, the natural mechanism of the body for removing mucus and cellular debris from the respiratory tract.

Coughing and Deep-Breathing Techniques. Coughing is effective for maintaining a patent airway. Directed coughing is a deliberate maneuver that is effective when spontaneous coughing is not adequate (AARC, 1993). Directed coughing permits a patient to remove secretions from both the upper and lower airways. The normal series of events in the cough mechanism are deep inhalation, closure of the glottis, active contraction of the expiratory muscles, and glottis opening. Deep inhalation increases the lung volume and airway diameter, allowing the air to pass through partially obstructing mucus plugs or other foreign matter. Contraction of the expiratory muscles against the closed glottis causes a high intrathoracic pressure to develop. When the glottis opens, a large flow of air is expelled at a high speed, providing momentum for mucus to move to the upper airways where the patient can expectorate or swallow it.

Diaphragmatic breathing/belly breathing is a technique that encourages deep breathing to increase air to the lower lungs. The belly moves out when breathing in and sinks in when breathing out (CFF, 2005). Deep breathing also opens the pores of Kohn between alveoli to allow sharing of oxygen between alveoli. This is especially important if the airway of the alveoli is plugged with mucus. The neighboring alveoli can share the air distribution through the pores of Kohn (McCance and Huether, 2010).

Evaluate the effectiveness of coughing by sputum expectoration, the patient's report of swallowed sputum, or clearing of adventitious sounds by auscultation. Encourage patients with chronic pulmonary diseases, upper respiratory tract infections, and lower respiratory tract infections to deep breathe and cough at least every 2 hours while awake. Encourage patients with a large amount of sputum to cough every hour while awake and then awaken them at night in order to cough every 2 to 3 hours. This is necessary until the acute phase of mucus production has ended. After surgery it is recommended that directed cough be performed every 2 to 4 hours while awake to prevent accumulation of secretions. Offer postoperative patients support devices (folded blanket, pillow, or palmed hands) to splint an abdominal or thoracic incision to minimize pain during directed coughing. Cough is a source of droplet transmission of pulmonary pathogens; thus the health care provider should follow Standard Precautions. Coughing techniques include deep breathing and coughing for the postoperative patient, cascade, huff, and quad coughing (AARC, 1993).

With the *cascade cough* the patient takes a slow, deep breath and holds it for 2 seconds while contracting expiratory muscles. Then he or she opens the mouth and performs a series of coughs throughout exhalation, thereby coughing at progressively lowered lung volumes. This technique promotes airway clearance and a patent airway in patients with large volumes of sputum.

The *huff cough* stimulates a natural cough reflex and is generally effective only for clearing central airways. While exhaling, the patient opens the glottis by saying the word *huff*. With practice he or she inhales more air and is able to progress to the cascade cough.

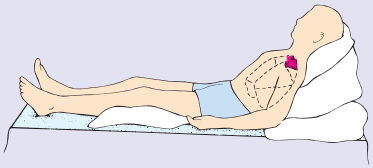
The *quad cough* technique is for patients without abdominal muscle control such as those with spinal cord injuries. While the patient breathes out with a maximal expiratory effort, the patient or nurse pushes inward and upward on the abdominal muscles toward the diaphragm, causing the cough.

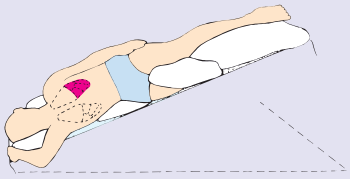
Chest Physiotherapy. **Chest physiotherapy (CPT)** is a group of therapies for mobilizing pulmonary secretions. These therapies include postural drainage, chest percussion, and vibration. CPT is followed by productive coughing or suctioning of a patient who has a decreased ability to cough. It is recommended for patients who produce greater than 30 mL of sputum per day or have

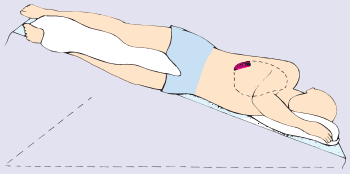
evidence of atelectasis on chest x-ray examination. The procedure is safe for infants and young children; however, at times conditions and diseases unique to children contraindicate it. CPT is for a select group of patients. Box 40-7 describes the guidelines to determine if CPT is indicated.

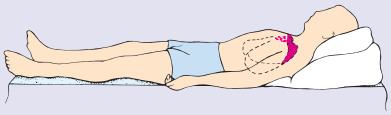
Postural drainage is a component of pulmonary hygiene; it consists of drainage, positioning, and turning and is sometimes accompanied by chest percussion and vibration (CFF, 2005). It improves secretion clearance and oxygenation. Positioning includes most lung segments (Table 40-6) and helps to drain secretions from specific segments of the lungs and bronchi into the trachea. Some patients do not require postural drainage of all lung segments, and clinical assessment is crucial in identifying specific lung segments requiring it. For example, patients with left lower lobe atelectasis require postural drainage of only the affected region, whereas a child with cystic fibrosis often requires postural drainage of all lung segments.

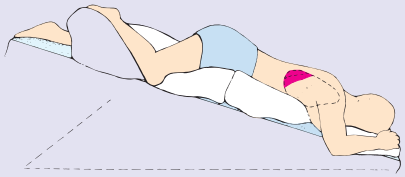
Chest percussion involves rhythmically clapping on the chest wall over the area being drained to force secretions into larger airways for expectoration. Position the hand so the fingers and thumb touch and the hands are cupped. The cupping makes the hand conform to the chest wall while trapping a cushion of air to soften the intensity of the clapping. The procedure should produce a hollow sound and should not be painful (CFF, 2005). Perform chest percussion by vigorously striking the chest wall alternately with cupped hands (Fig. 40-9). Perform percussion over a single layer of clothing, not over buttons, snaps, or zippers. The single layer of clothing prevents slapping the patient's skin. Thicker or multiple layers of material dampen the vibrations.







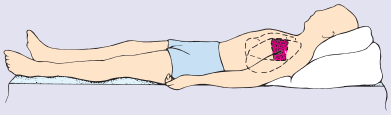


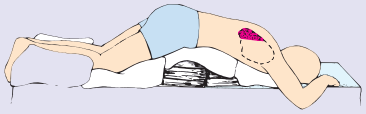


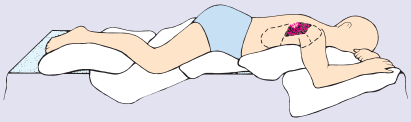
Percussion is contraindicated in patients with bleeding disorders, osteoporosis, or fractured ribs. Avoid percussion over burns,

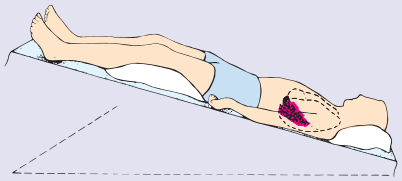
BOX 40-7 GUIDELINES FOR CHEST PHYSIOTHERAPY

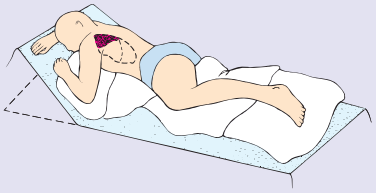
Nursing and respiratory therapy collaborate with the health care provider to determine if chest physiotherapy (CPT) is best for the patient. The following guidelines help in physical assessment and subsequent decision making:

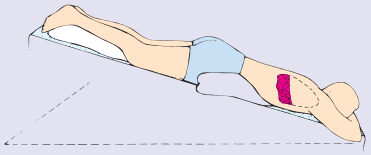


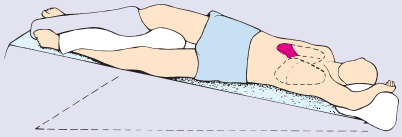


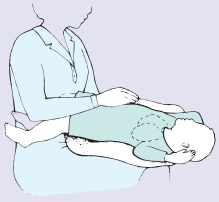


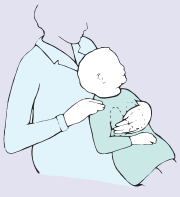












- Know a patient's normal range of vital signs. Conditions requiring CPT such as atelectasis and pneumonia affect vital signs. The degree of change is related to the level of hypoxia, overall cardiopulmonary status, and tolerance to activity.
- Conduct a respiratory assessment to confirm need for CPT, including sputum production, effectiveness of cough, history of pulmonary problems successfully relieved with CPT, abnormal lung sounds, documented conditions such as atelectasis, pneumonia, and changes in oxygenation status.
- Know the patient's medications. Certain medications, particularly diuretics and antihypertensives, cause fluid and hemodynamic changes. These decrease a patient's tolerance to positional changes and postural drainage. Long-term steroid use increases a patient's risk of pathological rib fractures and often contraindicates vibration.
- Know the patient's medical history. Certain conditions such as increased intracranial pressure, spinal cord injuries, and abdominal aneurysm resection contraindicate the positional changes of postural drainage. Thoracic trauma or surgery contraindicates percussion and vibration.
- Know the patient's level of cognitive function. Participation in controlled coughing techniques requires him or her to follow instructions. Congenital or acquired cognitive limitations alter a patient's ability to learn and participate in these techniques.
- Be aware of the patient's exercise tolerance. CPT maneuvers are fatiguing. When a patient is not used to physical activity, initial tolerance to the maneuvers is often decreased. However, with gradual increases in activity and planned CPT, patient tolerance for the procedure improves.

open wounds, or skin infections of the thorax. Take caution to percuss the lung fields under the ribs and not the over the spine, breastbone, stomach or lower back or trauma can occur to the spleen, liver, or kidneys (CFF, 2005).

Vibration is a gentle, shaking pressure applied to the chest wall to shake secretions into larger airways. Place a flattened hand or two hands (pressing top and bottom hand into each other to vibrate) firmly on the chest wall over the appropriate segment and tense the muscles of the arm to provide a shaking motion. Have the patient exhale as slowly as possible during the vibration. This technique increases the velocity and turbulence of exhaled air, facilitating secretion removal. Vibration increases the exhalation of trapped air, shakes mucus loose, and induces a cough (CFF, 2005).

Suctioning Techniques. Suctioning is necessary when patients are unable to clear respiratory secretions from the airways by coughing or other less invasive procedures. Suctioning techniques include oropharyngeal and nasopharyngeal suctioning, orotracheal and nasotracheal suctioning, and suctioning an artificial airway.

In most cases use sterile technique for suctioning because the oropharynx and trachea are considered sterile. The mouth is

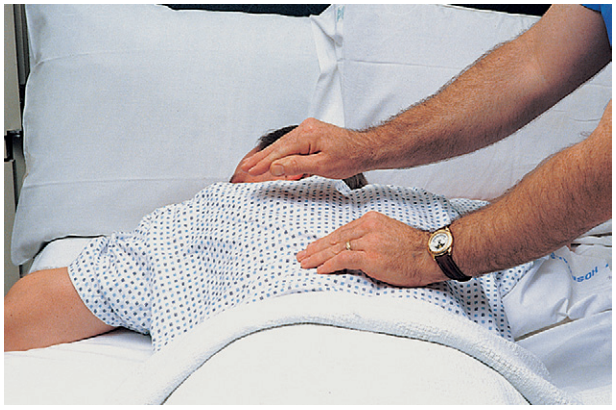

FIG. 40-9 Chest wall percussion, alternating hand clapping against patient's chest wall.

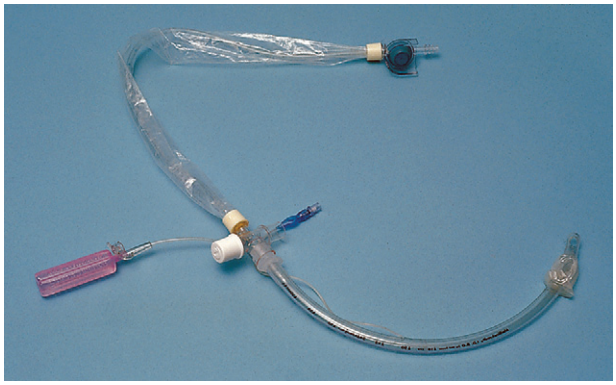

FIG. 40-10 Ballard tracheal care, closed suction catheter.

considered clean; therefore you suction oral secretions after suctioning the oropharynx and trachea. In the home setting a "clean" versus "sterile" technique is used because the patient is not exposed to pathogens common to health care settings; however, appropriate measures for disinfecting equipment should be taught (AARC, 2004).

Each type of suctioning requires the use of a round-tipped, flexible catheter with holes on the sides and end of the catheter. When suctioning, you apply negative pressures (not greater than 150 mm Hg) during withdrawal of the catheter, never on insertion. Patient assessment determines the frequency of suctioning. It is indicated when audible on auscultation (rhonchi, gurgling breath sounds, diminished breath sounds) or visible secretions are present after other methods to remove airway secretions have failed. You may also use suctioning to obtain a sputum specimen for culture or cytology if the patient is not able to cough productively. Too-frequent suctioning puts patients at risk for development of hypoxemia, hypotension, arrhythmias, and possible trauma to the mucosa of the lungs (AARC, 2004).

Oropharyngeal and Nasopharyngeal Suctioning. Oropharyngeal or nasopharyngeal suctioning is used when the patient is able to cough effectively but unable to clear secretions by expectorating. Apply suction after a patient has coughed (Skill 40-1 on pp. 855-861). Once the pulmonary secretions decrease and a patient is less fatigued, he or she is then able to expectorate or swallow the mucus, and suctioning is no longer necessary.

Orotracheal and Nasotracheal Suctioning. Orotracheal or nasotracheal suctioning is necessary when a patient with pulmonary secretions is unable to manage secretions by coughing and does not have an artificial airway present (see Skill 40-1). You pass a sterile catheter through the mouth or nose into the trachea. The nose is the preferred route because stimulation of the gag reflex is minimal. The procedure is similar to nasopharyngeal suctioning, but you advance the catheter tip farther into the patient's trachea. The entire procedure from catheter passage to its removal is done quickly, lasting no longer than 15 seconds (AARC, 2004). Unless in respiratory distress, allow the patient to rest between passes of the catheter. If the patient is using supplemental oxygen, replace the oxygen cannula or mask during rest periods.

Tracheal Suctioning. You perform tracheal suctioning through an artificial airway such as an endotracheal (ET) or tracheostomy tube. The size of a catheter should be as small as possible but large enough to remove secretions. Recommendation is about half the internal diameter of the ET tube (Pedersen et al., 2009). Never apply suction pressure while inserting the catheter to avoid traumatizing the lung mucosa. Once you insert a catheter the necessary distance, maintain suction pressure between 120 and 150 mm Hg (AARC, 2004) as you withdraw. Apply suction intermittently ***only*** while withdrawing the catheter. Rotating the catheter enhances removal of secretions that have adhered to the sides of the ET tube.

The practice of normal saline instillation (NSI) into artificial airways to improve secretion removal is inconclusive. Clinical studies comparing the results of suctioning following NSI with standard suctioning have not shown any clinical or significant results (Box 40-8). There are anecdotal results supporting the theory that NSI stimulates patients to cough and as a result the airway secretions are loosened and dislodged. However, the practice of NSI has the potential of causing detrimental effects such as increased heart rate and blood pressure and an increased risk of respiratory infection (Kuriakose, 2008).

The two current methods of suctioning are the open and closed methods. Open suctioning involves using a new sterile catheter for each suction session (Pedersen et al., 2009). Wear sterile gloves and follow Standard Precautions during the suction procedure. Closed suctioning involves using a reusable sterile suction catheter that is encased in a plastic sheath to protect it between suction sessions (Fig. 40-10). Closed suctioning is most often used on patients who require mechanical ventilation to support their respiratory efforts because it permits continuous delivery of oxygen while suction is performed and reduces the risk of oxygen desaturation. Although sterile gloves are not used in this procedure, nonsterile gloves are recommended to prevent contact with splashes from body fluids (Box 40-9).

Artificial Airways. An artificial airway is for a patient with a decreased level of consciousness or airway obstruction and aids in removal of tracheobronchial secretions. The presence of an artificial airway places a patient at high risk for infection and airway injury. Use clean technique for oral airways, but use sterile technique in caring for and maintaining endotracheal and tracheal airways to prevent health care–associated infections (HAIs). Artificial airways need to stay in the correct position to prevent airway damage (Skill 40-2 on pp. 861-869).

Oral Airway. The oral airway, the simplest type of artificial airway, prevents obstruction of the trachea by displacement of the tongue into the oropharynx (Fig. 40-11). The oral airway extends from the teeth to the oropharynx, maintaining the tongue in the normal position. Use the correct-size airway. Determine the proper oral airway size by measuring the distance from the corner of the mouth to the angle of the jaw just below the ear. The length is equal

BOX 40-8 EVIDENCE-BASED PRACTICE

The Effectiveness of Instilling Normal Saline into Artificial Airways Before Suctioning

PICO Question: In patients with artificial airways, does instilling normal saline into artificial airways before suctioning increase the output of mucus?

Evidence Summary

The practice of instilling normal saline before suctioning artificial airways to dilute and loosen secretions has been questioned by researchers. Several meta-analysis studies report more harmful effects from normal saline instillation than benefits. One of the complications found was significant decreased oxygenation saturation in patients receiving normal saline instillation compared to patients who did not. The saline group actually took 5 minutes to return to baseline SaO_2 after suctioning (Halm and Krisko-Hagel, 2008; Kuriakose, 2008; Rauen et al., 2008).

Another complication reported was increased dyspnea in people over 60 years if they had saline instilled (Kuriakose, 2008; Pedersen et al., 2009). Along with dyspnea, patients reported anxiety, dread, and increased pain when saline was used (Halm and Krisko-Hagel, 2008).

Increased colonization of the lower respiratory tract after 48 hours was found to be five times higher in patients receiving saline. It was thought that the saline actually dislodged colonies and dispersed them to the lower airways (Halm and Krisko-Hagel, 2008; Kuriakose, 2008).

Studies looking at the amount of sputum yield after suctioning following saline instillation showed that the amount obtained was not clinically important. It was even found that the saline was rapidly absorbed and did not really mix with the secretions (Halm and Krisko-Hagel, 2008). The problem with the yield studies was how to quantify the amount removed (Rauen et al., 2008).

The evidence of adverse effects of instilling saline both physically and psychologically supports not using saline instillation before suctioning. However, change in practice is a challenge since surveys have found that 2 to 3 times as many respiratory therapists report that they continue to use saline before suctioning compared to nurses (Halm and Krisko-Hagel, 2008; Rauen et al., 2008). However, surveys of nursing practice report that 24% to 33% of nurses still use saline (Rauen et al., 2008). What may help change practice is the American Association of Respiratory Care guideline for endotracheal suctioning of mechanically ventilated patients with artificial airways (2010a), which states that normal saline should not be used before suctioning on a routine basis.

Application to Nursing Practice

- Normal saline and mucus do not appear to mix so it does not thin or mobilize secretions. It would be better to increase humidification by improving systemic hydration either orally or by intravenous infusion.
- Use humidification with oxygen and refer to respiratory therapy for appropriate nebulizer treatments to disperse the humidification more uniformly.
- Increase ambulation and mobility even in intensive care units to help mobilize secretions.
- Use chest physiotherapy to help mobilize secretions.
- Use positioning such as "good lung down" to facilitate oxygenation and elevation of head of bed to at least 45 degrees. Turn critically ill patients more frequently than every 2 hours.

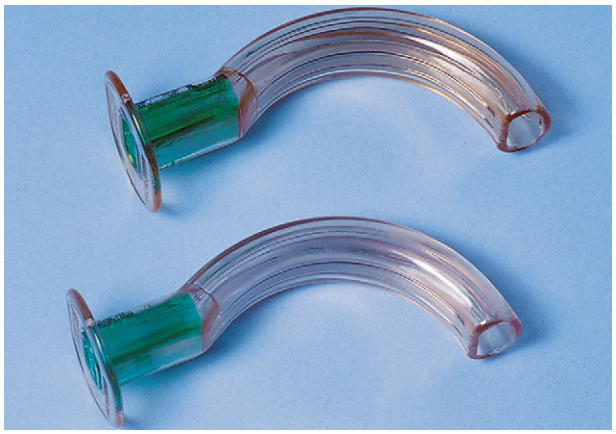

FIG. 40-11 Artificial oral airways.

to the distance from the flange of the airway to the tip. If the airway is too small, the tongue does not stay in the anterior portion of the mouth; if the airway is too large, it forces the tongue toward the epiglottis and obstructs the airway.

Insert the airway by turning the curve of the airway toward the cheek and placing it over the tongue. When the airway is in the oropharynx, turn it so the opening points downward. Correctly placed, the airway moves the tongue forward away from the oropharynx, and the flange (i.e., the flat portion of the airway) rests against the patient's teeth. Incorrect insertion merely forces the tongue back into the oropharynx.

Endotracheal and Tracheal Airway. An **endotracheal (ET) tube** is a short-term artificial airway to administer mechanical ventilation, relieve upper airway obstruction, protect against aspiration,

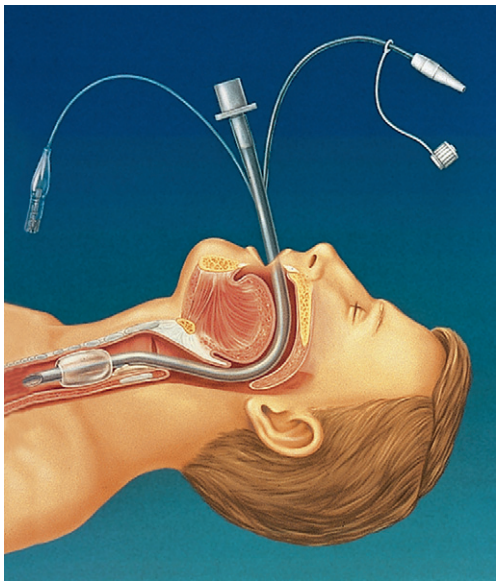

FIG. 40-12 Endotracheal tube inserted into trachea. Cuff inflated to maintain position. (From Nellcor Puritan Bennett: *Hi-Lo Evac endotracheal tube with evacuation lumen*, http://www.nellcor.com/_Catalog/PDF/Product/Hi-LoEvac.pdf. Accessed August 2, 2011).

or clear secretions. A physician or specially trained clinician inserts the ET tube. The tube is passed through the patient's mouth, past the pharynx, and into the trachea (Fig. 40-12). It is generally removed within 14 days; however, it is sometimes used for a longer period of time if the patient is still showing progress toward weaning from mechanical ventilation and extubation.

BOX 40-9 PROCEDURAL GUIDELINES

Closed (In-Line) Suction Catheter

Delegation Considerations

Airway suctioning with a closed (in-line) suction catheter cannot be routinely delegated to nursing assistive personnel (NAP). This procedure may be delegated when suctioning a patient with a permanent tracheostomy is necessary (follow agency policy). The nurse is responsible for the patient's cardiopulmonary assessment and evaluation. The nurse informs the NAP about:

- Any individualized aspects of patient care that pertain to suctioning (e.g., position, duration of suction, pressure settings).
- The expected quality, quantity, and color of secretions and to immediately report any changes to the nurse.
- Patient's anticipated response to suction and to immediately report to the nurse changes in vital signs, complaints of pain, changes in respiratory status, mental status, or increased restlessness

Equipment

Closed system or in-line suction catheter; suction machine, 6 feet of connecting tubing, clean gloves (optional), face shield, goggles (optional) or mask (optional), saline vial or syringe (for rinsing tubing), clean towel, pulse oximeter and stethoscope

1. Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.
2. Perform assessment as in Skill 40-1.
3. Explain the procedure to patient and the importance of coughing during the suctioning procedure.
4. Assist patient with assuming a position of comfort usually semi-or high-Fowler's position. Place towel across patient's chest.
5. Perform hand hygiene, apply face shield and clean gloves, and attach suction. NOTE: If risk for splash is present or patient is on respiratory precautions, mask and goggles may be needed.
   a. In some settings a respiratory therapist attaches the catheter to the closed ventilator circuit. If catheter is not already in place, open closed-suction catheter package using aseptic technique, attach catheter to ventilator circuit by removing swivel adapter, and place catheter apparatus on endotracheal or tracheostomy tube. Connect Y on mechanical ventilator circuit to closed-suction catheter with flex tubing (see Fig. 40-10).
   b. Connect one end of connecting tubing to suction machine and the other to the end of a closed system or in-line suction catheter, if not already done. Turn suction device on and set vacuum regulator to appropriate negative pressure (see manufacturer directions). Many closed-system suction catheters require slightly higher suction; consult manufacturer guidelines.
6. Hyperinflate and/or hyperoxygenate patient with bag-valve mask or manual breathing mechanism on mechanical ventilator according to institution protocol and clinical status (usually 100% oxygen).
7. Unlock suction-control mechanism if required by manufacturer. Open saline port and attach saline syringe or vial.
8. Pick up suction catheter enclosed in plastic sleeve with dominant hand.

CLINICAL DECISION: The instillation of normal saline into the airway before closed in-line suctioning may not be appropriate for all patients and needs further investigation. Normal saline instillation in conjunction with artificial airway suctioning may lead to the dispersion of microorganisms into the lower respiratory tract (Kuriakose, 2008).

9. Insert catheter; use a repeating maneuver of pushing catheter and sliding (or pulling) plastic sleeve back between thumb and forefinger until you feel resistance or patient coughs.
10. Encourage patient to cough and apply suction by squeezing on suction-control mechanism while withdrawing catheter. It is difficult to apply intermittent pulses of suction and nearly impossible to rotate the catheter compared with a standard catheter. Be sure to withdraw catheter completely into plastic sheath so it does not obstruct airflow (AARC, 2004).
11. Reassess cardiopulmonary status, including pulse oximetry, to determine need for subsequent suctioning or complications. Repeat Steps 5 through 9 one to two more times to clear secretions. Allow adequate time (at least 1 full minute) between suction passes for ventilation and reoxygenation (AARC, 2004).
12. When airway is clear, withdraw catheter completely into sheath. Be sure that colored indicator line on catheter is visible in the sheath. Squeeze vial or push syringe while applying suction to rinse the inner lumen of catheter. Use at least 5 to 10 mL of saline to rinse the catheter until it is clear of retained secretions, which cause bacterial growth and increase the risk of infection (AARC, 2004). Lock suction mechanism, if applicable, and turn off suction.
13. If patient requires oral or nasal suctioning, perform Skill 40-1 with separate standard suction catheter.
14. Reposition patient.
15. Remove gloves and face shield, discard into appropriate receptacle, and perform hand hygiene.
16. Compare patient's respiratory assessment with evaluation findings after suctioning and observe airway secretions.

If a patient requires long-term assistance from an artificial airway, a **tracheostomy** is considered. A surgical incision is made into the trachea, and a short artificial airway (a tracheostomy tube) is inserted. Most tracheostomies have a small plastic inner tube that fits inside a larger one (the inner cannula). The most common complication of a tracheostomy tube is partial or total airway obstruction caused by buildup of respiratory secretions. If this occurs, the inner tube can be removed and cleaned or replaced with a temporary spare inner tube that should be kept at the patient's bedside. Keep tracheal dilators at the bedside to have available for emergency tube replacement or reinsertion. Humidification from air humidifiers or humidified oxygen tracheostomy collars can help prevent drying of secretions that cause occlusion. Tracheostomy suctioning should be done as often as necessary to clear secretions. The majority of patients with a tracheostomy tube cannot speak because the tube is inserted below the vocal cords. It is important to use written or nonverbal communication (lip reading) strategies to help patients communicate. Be sure to assess patients for anxiety caused by the inability to speak (Higgins, 2009). Care and cleaning of the tracheostomy tube is discussed in Skill 40-2.

Maintenance and Promotion of Lung Expansion. Nursing interventions to maintain or promote lung expansion include noninvasive techniques such as ambulation, positioning, incentive spirometry, and noninvasive ventilation. Invasive medical interventions such as chest tube insertion and management assist in restoring lung expansion.

Ambulation. Immobility is a major factor in developing atelectasis, ventilator-associated pneumonia (VAP), and functional limitations. The research has shown that, after 1 week of bed rest, muscle strength declines by as much as 20%, which results in an

increased oxygen demand, weakened respiratory muscles, and a decline of functional status. Early ambulation studies indicate that the therapeutic benefits of activity include an increase in general strength and lung expansion. Even the patient who requires mechanical ventilation benefits by an early mobility program. Such mobility programs should include input from both respiratory and physical therapists in the treatment plan (Perme and Chandrashekar, 2009). Progressive mobilization from dangling the legs to standing and then walking is safe for intubated patients (Rauen et al., 2008).

Positioning. The healthy, completely mobile person maintains adequate ventilation and oxygenation by frequent position changes during daily activities. However, when a person's illness or injury restricts mobility, the risk for respiratory impairment is increased. Frequent changes of position are simple and cost-effective methods for reducing stasis of pulmonary secretions and decreased chest wall expansion, both of which increase the risk of pneumonia. Research has shown that turning critically ill patients every 2 hours is not often enough to prevent pneumonia (Rauen et al., 2008).

The 45-degree semi-Fowler's is the most effective position to promote lung expansion and reduce pressure from the abdomen on the diaphragm. When a patient is in this position, be sure that he or she does not slide down in bed, which can reduce lung expansion. A patient with unilateral lung disease such as pneumothorax, atelectasis, pneumonia, thoracotomy, and trauma of one lung should be positioned in a manner to promote perfusion of the healthy lung and improve oxygenation. In most cases, position the patient with the good lung down (Rauen et al., 2008). In the presence of pulmonary abscess or hemorrhage, position the patient with the affected lung down to prevent drainage toward the healthy lung. For bilateral lung disease the best position depends on the severity of the disease.

Incentive Spirometry. **Incentive spirometry** encourages voluntary deep breathing by providing visual feedback to patients about inspiratory volume. It promotes deep breathing and prevents or treats atelectasis in the postoperative patient. There is solid evidence to support the use of lung expansion with incentive spirometry in preventing postoperative pulmonary complications following abdominal surgery (Lawrence et al., 2006).

Flow-oriented incentive spirometers consist of one or more plastic chambers that contain freely moving colored balls. A patient inhales slowly and with an even flow to elevate the balls and keep them floating as long as possible to ensure a maximally sustained inhalation.

Volume-oriented incentive spirometry devices have a bellows that is raised to a predetermined volume by an inhaled breath (Fig. 40-13). An achievement light or counter is used to provide feedback. Some devices are constructed so the light does not turn on unless the bellows is held at a minimum desired volume for a specified period to enhance lung expansion (see Chapter 50).

Incentive spirometry encourages patients to use visual feedback to maximally inflate their lungs and sustain that inflation (Basoglu et al., 2005). A postoperative inspiratory capacity one half to three fourths of the preoperative volume is acceptable because of postoperative pain. The AARC guidelines (2011) recommend 5 to 10 breaths per session every hour while awake. Administration of pain medications before incentive spirometry helps a patient achieve deep breathing by reducing pain and splinting.

Noninvasive Ventilation. **Noninvasive positive-pressure ventilation (NPPV)** is used to prevent using invasive artificial airways (ET tube or tracheostomy) in patients with acute respiratory failure, cardiogenic pulmonary edema, or exacerbation of COPD. It has also been used following extubation of an ET tube (Agarwal et al., 2007). The purpose of NPPV is to maintain a positive airway pressure and improve alveolar ventilation. This prevents or treats atelectasis by inflating the alveoli, reducing pulmonary edema by forcing fluid out of the lungs back into circulation, and improving oxygenation in those with sleep apnea. Ventilatory support is achieved using a variety of modes, including **continuous positive airway pressure (CPAP)** and **bilevel positive airway pressure (BiPAP).**

CPAP treats patients with obstructive sleep apnea, patients with heart failure, and preterm infants with underdeveloped lungs. In obstructive sleep apnea, airways collapse, causing shallow or absent breathing. Any air moving past the obstruction results in loud snoring. An overnight sleep study may be needed to determine the correct settings for a CPAP machine (see Chapter 42). Equipment includes a mask (Fig. 40-14) that fits over the nose or both nose and mouth and a CPAP machine that delivers air to the mask (National Heart Lung and Blood Institute, 2010). The

FIG. 40-13 Volume-oriented incentive spirometer.

FIG. 40-14 CPAP mask.

smallest mask with the proper fit is the most effective. Because straps hold the mask in place, it is important to assess for excess pressure on the patient's face or nose that could cause skin breakdown or necrosis. The mask should have enough slack to allow one to two fingers between the straps and the face (Soo Hoo, 2010). However, it must also be tight enough to form a tight seal on the face so the air does not escape. With higher pressures escape of some air may be avoidable.

The most common mode of support is BiPAP that provides both inspiratory positive airway pressure (IPAP) and expiratory airway pressure (EPAP), also known as *positive end-expiratory pressure (PEEP)*. The difference between these two pressures indicates the amount of pressure support a patient needs (Soo Hoo, 2010). During inhalation the positive pressure increases the patient's tidal volume and alveolar ventilation. The pressure support decreases when the patient exhales, allowing for easier exhalation.

Complications of noninvasive ventilation include facial and nasal injury and skin breakdown, dry mucous membranes and thick secretions, and aspiration of gastric contents if vomiting occurs during ventilation. Complications avoided by noninvasive ventilation are VAP, sinusitis, and effects of large-dose sedative agents. Use of noninvasive ventilation results in shorter intensive care unit (ICU) and hospital stays (Soo Hoo, 2010). Perform good oral hygiene every few hours while a patient is on BiPAP to relieve dryness.

Chest Tubes. A **chest tube** (Fig. 40-15) is a catheter inserted through the thorax to remove air and fluids from the pleural space, to prevent air or fluid from reentering the pleural space, or to reestablish normal intrapleural and intrapulmonic pressures (Roman and Mercado, 2006). Chest tubes are common after chest surgery and chest trauma and are used for treatment of pneumothorax or hemothorax to promote lung reexpansion (Skill 40-3 on pp. 869-873).

A **pneumothorax** is a collection of air in the pleural space. The loss of negative intrapleural pressure causes the lung to collapse. There are a variety of causes for a pneumothorax. A secondary pneumothorax can occur as a result of chest trauma (e.g., stabbing, gunshot wound, or rib fracture from striking the chest against the steering wheel in an automobile accident). Other causes of secondary pneumothorax are the rupture of an emphysematous bleb on the surface of the lung (the destruction caused by emphysema), tearing of the pleura from an invasive procedure such as surgery, insertion of a subclavian IV line, and mechanical ventilation, including PEEP. Spontaneous (primary) pneumothorax is a genetic condition that occurs unexpectedly in healthy individuals who develop blisterlike formations (blebs) on the visceral pleura, usually on the apex of the lungs. The blebs can rupture during sleep or exercise (McCance and Huether, 2010). A patient with a pneumothorax usually feels pain as atmospheric air irritates the parietal pleura. The pain is sharp and pleuritic and worsens on inspiration. Dyspnea is common and worsens as the size of the pneumothorax increases.

A **hemothorax** is an accumulation of blood and fluid in the pleural cavity between the parietal and visceral pleura, usually as a result of trauma. It produces a counter pressure and prevents the lung from full expansion. A rupture of small blood vessels from inflammatory processes such as pneumonia or TB can cause a hemothorax. In addition to pain and dyspnea, signs and symptoms of shock develop if blood loss is severe.

A variety of chest tubes are available to drain air or excess fluid from the pleural space to relieve respiratory distress. A small-bore chest tube (12 to 20 Fr) is used to remove a small amount of air, and a larger-bore chest tube is used to remove large amounts of fluid or blood and large amounts of air (Coughlin and Parchinsky, 2006).

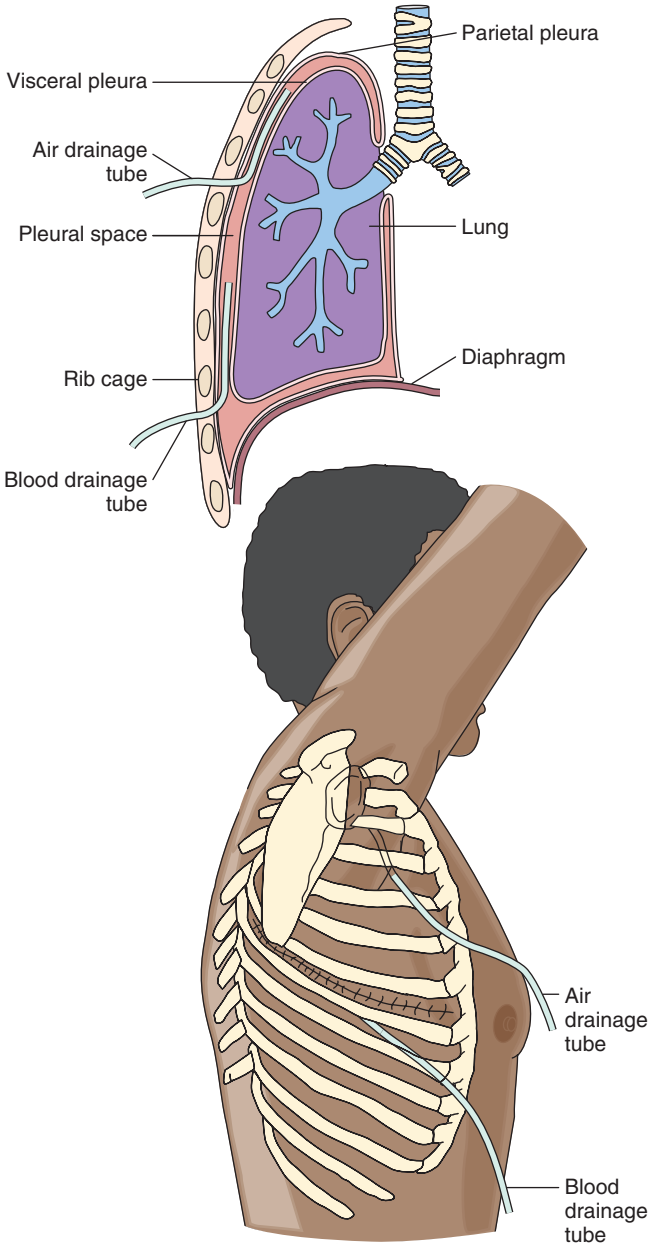

FIG. 40-15 Chest tube placement.

After a chest tube is inserted, it is attached to a drainage system. A traditional chest drainage unit (CDU) has three chambers for collection, water seal, and suction control. This unit can drain a large amount of both fluid and air (Coughlin and Parchinsky, 2006). Mobile systems rely on gravity, not suction, for drainage. In selected patients these mobile drains reduce the length of time needed for the chest tube, improve ambulation, and decrease the length of time in the hospital (Carroll, 2005). Nonventilated patients and patients who had thoracoscopic lung surgery or minimally invasive cardiac surgery do well with these mobile chest drains. They are lighter and smaller; thus patients are able to move more easily. As a result this reduces the risks of deep vein thrombosis and pulmonary embolism.

The simplest closed drainage system is the single chamber unit. The chamber serves as a fluid collector and a water seal. During normal respiration the fluid in the chamber ascends with inspiration and descends with expiration. A single chamber is used for smaller amounts of drainage such as an empyema (i.e., a collection of infected fluid or pus in the pleural space).

The use of two chambers permits any fluid to flow into the collection chamber as air flows into the water-seal chamber. Fluctuations in the water-seal tube are still anticipated. Two chambers allow for more accurate measurement of chest drainage and are used when larger amounts of drainage are expected.

When a volume of air or fluid needs to be evacuated with controlled suction, all three chambers are used. Mark the suction control with centimeter readings to adjust the amount of suction. Usually 15 to 20 cm of water is used for adults (Roman and Mercado, 2006). This means that the chamber is filled with sterile water to the 15- or 20-cm water level.

There is a new dry chest drainage system that does not use water in the suction chamber. An automatic control valve (ACV) is located inside the regulator and continuously balances the force of the suction with the atmospheres. As a result, the ACV responds and adjusts to changes in patient air leaks and fluctuations in suction source vacuum to deliver accurate suction. Set the pressure between −10 cm H_2O and −40 cm H_2O (Roman and Mercado, 2006). Regardless of the system used, the principles of patient management are the same.

Special Considerations. Keep a chest tube system closed and below the chest (see Skill 40-3). The tube should be secured to the chest wall. Watch for slow, steady bubbling in the suction-control chamber and keep it filled with sterile water at the prescribed level. Make sure that the water-seal chamber is filled to the manufacturer-specified level and watch for fluctuation (tidaling) of the fluid level to ensure that the chest tube and system are working. A constant or intermittent bubbling in the water-seal chamber indicates a leak in the drainage system, and the health care provider must be notified immediately. Mark the level on the outside of the collection chambers every shift. Report any unexpected cloudy or bloody drainage. Do not let the tubing kink or loop, and ideally it should lie horizontally across the bed or chair before dropping vertically into the drainage device. Encourage your patient to cough, deep breath, and use the incentive spirometer. Make sure that he or she is frequently repositioned and ambulated if not contraindicated. Routinely assess respiratory rate, breath sounds, SpO_2 levels, and the insertion site for subcutaneous emphysema (Rushing, 2007).

Clamping a chest tube is contraindicated when ambulating or transporting a patient. Clamping can result in a tension pneumothorax. Air pressure builds in the pleural space, collapsing the lung and creating a life-threatening event. A chest tube is only clamped when replacing the chest drainage system, assessing for an air leak, or during removal (Rushing, 2007).

Chest tubes are not routinely stripped or milked to move clots or increase chest tube drainage (Rushing, 2007). Stripping or milking chest tubes is based on nursing assessment (see Skill 40-3). Stripping is when the thumb and forefinger are used to compress the chest tube and the other hand is used to pull the tube away from the chest wall. Milking is squeezing, twisting, or kneading the tube to create a burst of suction to move clots. The excessive pressure caused by milking can lead to damaged tissue being trapped in the eyelets of the chest tube, resulting in increased bleeding (Halm, 2007).

Handle the chest drainage unit carefully and maintain the drainage device below the patient's chest. If the tubing disconnects from the drainage unit, instruct the patient to exhale as much as possible and to cough. This maneuver rids the pleural space of as much air as possible. Temporarily reestablish a water seal by immersing the open end of the chest tube into a container of sterile water (Roman and Mercado, 2006).

Removal of chest tubes requires patient preparation. The most frequent sensations reported by patients during chest tube removal include burning, pain, and a pulling sensation. Make sure that the patient is given pain medication at least 30 minutes before removal. The nurse assists the health care provider in removing the chest tube and monitors the dressing placed over the insertion site and the patient's respiratory status after tube removal.

Maintenance and Promotion of Oxygenation. Promotion of lung expansion, mobilization of secretions, and maintenance of a patent airway assist patients in meeting their oxygenation needs. However, some patients also require oxygen therapy to keep a healthy level of tissue oxygenation.

Oxygen Therapy. Oxygen therapy is widely available and used in a variety of settings to relieve or prevent tissue hypoxia. The goal of oxygen therapy (AARC, 2007) is to prevent or relieve hypoxia by delivering oxygen at concentrations greater than ambient air (21%). Oxygen is a medical gas and should be used in accordance with federal, state, and local regulations. It has dangerous side effects such as oxygen toxicity. The dosage or concentration of oxygen is monitored continuously. Routinely check the health care provider's orders to verify that the patient is receiving the prescribed oxygen concentration. The six rights of medication administration also pertain to oxygen administration (see Chapter 31).

Safety Precautions. Oxygen is a highly combustible gas. Although it does not burn spontaneously or cause an explosion, it can easily cause a fire in a patient's room if it contacts a spark from an open flame or electrical equipment. With increasing use of home oxygen therapy, patients and health care professionals need to be aware of the dangers of combustion. Chapter 27 describes steps to take in case of fire.

Promote oxygen safety by the following measures:

- Oxygen is a therapeutic gas and must be prescribed and adjusted only with a health care provider's order. Distribution must be in accordance with federal, state, and local regulations (AARC, 2007).
- Place an "Oxygen in Use" sign on the patient's door and in the patient's room. If using oxygen at home, place a sign on the door of the house. No smoking should be allowed on the premises.
- Keep oxygen-delivery systems 10 feet from any open flames.
- Determine that all electrical equipment in the room is functioning correctly and properly grounded (see Chapter 27). An electrical spark in the presence of oxygen can result in a serious fire.
- When using oxygen cylinders, secure them so they do not fall over. Store them upright and either chained or secured in appropriate holders.
- Check the oxygen level of portable tanks before transporting a patient to ensure that there is enough oxygen in the tank.

Supply of Oxygen. Oxygen is supplied to a patient's bedside either by oxygen tanks or through a permanent wall-piped system. Oxygen tanks are transported on wide-based carriers that allow the tank to be placed upright at the bedside. Regulators control the amount of oxygen delivered. One common type is an upright flowmeter with a flow adjustment valve at the top. A second type is a cylinder indicator with a flow adjustment handle. In the home setting oxygen therapy is also supplied in a variety of

TABLE 40-7 Approximate FIO_2 with Different Oxygen-Delivery Devices

OXYGEN-DELIVERY DEVICE	FIO_2 DELIVERED	ADVANTAGES	DISADVANTAGES
Nasal cannula	1 L/min: 24% 2 L/min: 28% 3 L/min: 32% 4 L/min: 36% 5 L/min: 40% 6 L/min: 44%	Safe and simple Easily tolerated Delivers low concentrations while allowing patients to eat, speak, and drink Does not impede eating or talking Disposable	Unable to use with nasal obstruction Drying to mucous membranes, so flow greater than 4 L/min needs to be humidified Can dislodge from nares easily Causes skin irritation or breakdown over ears or at nares Not good for mouth breathers Patient's breathing pattern affects exact FIO_2
Transtracheal oxygen cannula	Flow rates range from ¼ to 4 L/min and range from 22%-45% (AARC, 2007).	Small intravenous-size catheter inserted directly into trachea that provides individualized delivery for patients with chronic lung disease More comfortable and cosmetic than nasal cannula Provides adequate oxygen at lower flow rates; thus less expensive	Requires more monitoring and has more complications Patient needs to be educated on cleaning of catheter to prevent infection
Simple face mask	5-6 L/min: 40% 6-7 L/min: 50% 7-8 L/min: 60% >8 L/min: 60%	Assists in providing humidified oxygen	Exact FIO_2 level is difficult to estimate Requires high FIO_2 levels at 5 L/min or more to prevent rebreathing of carbon dioxide Patient inhales room air through the side holes in the mask Possible pressure areas and skin irritation with long-term use More difficult to eat, speak, or drink when in place
Partial nonrebreather mask with a reservoir bag	Delivers high concentrations of oxygen at 6-10 L/min to provide 40%-70% FIO_2.	Oxygen flow supplied to maintain the reservoir bag at least ⅓ to ½ full on inspiration (AARC, 2002).	Possible pressure areas and skin irritation with long-term use More difficult to eat, speak, or drink when in place Need to check frequently to make sure that bag is inflated
Nonrebreather mask with reservoir bag	Minimum flow of 10 L/min and delivers FIO_2 of 60%-80%	Similar to partial nonrebreather with reservoir bag but has valve between bag and mask to prevent exhaled air from returning to bag	Possible pressure areas and skin irritation with long-term use More difficult to eat, speak, or drink when in place
Venturi mask	4 L/min: 24%-28% 8 L/min: 35%-40% 12 L/min: 50%-60%	Controls amount of specified oxygen concentration; delivers percentage of FIO_2 from 24% to 60% Does not dry mucous membranes Delivers humidity with oxygen concentration	Hot and confining, increased levels of humidification irritate skin Specific flow rate necessary to deliver a specific FIO_2; possible decrease in FIO_2 if mask does not fit properly Interferes with eating and talking

FIO_2, Fraction of inspired oxygen concentration.

methods, including oxygen concentrators and refillable cylinders (AARC, 2007).

In the hospital or home oxygen tanks are delivered with the regulator in place. In the hospital the respiratory care department usually connects the regulator to the oxygen source. Home care vendors are usually responsible for connecting the oxygen tank to the regulator for home use.

Methods of Oxygen Delivery. The nasal cannula and oxygen masks are the most common devices to deliver oxygen to patients.

Nasal Cannula. A **nasal cannula** is a simple, comfortable device used for precise oxygen delivery (Skill 40-4 on pp. 873-875). The two nasal prongs are slightly curved and inserted in a patient's nostrils. To keep the nasal prongs in place, fit the attached tubing over the patient's ears and secure it under the chin using the sliding connector. Be alert for skin breakdown over the ears and in the nostrils from too tight an application. Attach the nasal cannula to a humidified oxygen source with a flow rate up to 6 L/min (24% to 40% oxygen). Flow rates equal to or greater than 4 L/min have a drying effect on the mucosa and thus need to be humidified (AARC, 2007). Know which flow rate produces a given percentage of inspired oxygen concentration (FIO_2) (Table 40-7).

Oxygen Masks. An oxygen mask is a plastic device that fits snugly over the mouth and nose and is secured in place with a strap. It delivers oxygen as the patient breathes through either the mouth or nose by way of a plastic tubing at the base of the mask that is attached to an oxygen source. An adjustable elastic band is attached to either side of the mask that slides over the head to above the ears to hold the mask in place. There are two primary types of oxygen masks: those delivering low concentrations of oxygen and those delivering high concentrations.

The simple face mask (Fig. 40-16) is used for short-term oxygen therapy. It fits loosely and delivers oxygen concentrations from

FIG. 40-16 Simple face mask.

FIG. 40-17 Plastic face mask with reservoir bag.

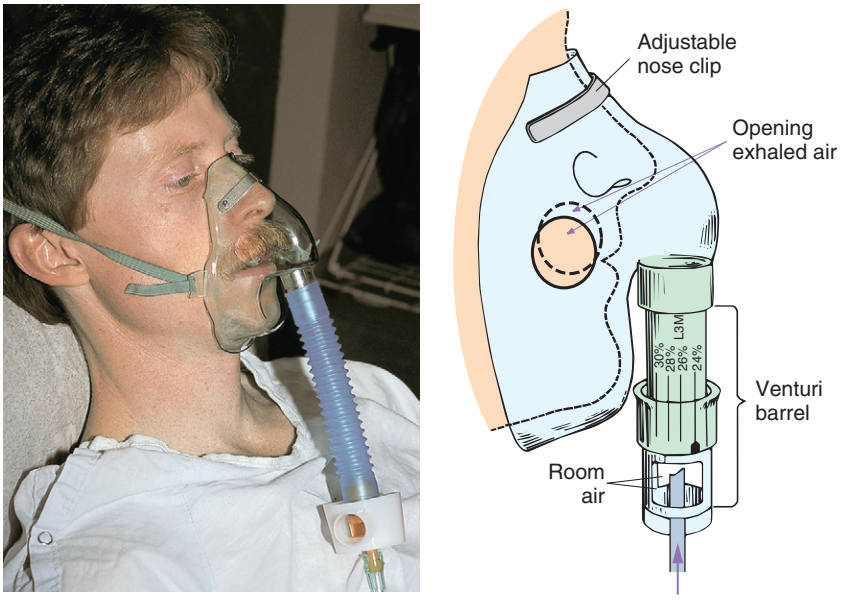

FIG. 40-18 Venturi mask.

35% to 50% FIO_2. The mask is contraindicated for patients with carbon dioxide retention because retention can be worsened. Flow rates should be 5 L or more to avoid rebreathing exhaled carbon dioxide retained in the mask. Be alert to skin breakdown under the mask with long-term use (AARC, 2002).

A plastic face mask with a reservoir bag (Fig. 40-17) is capable of delivering higher concentrations of oxygen. A partial rebreather mask is a simple mask with a reservoir bag that should be at least one third to one half full on inspiration and delivers from 40% to 70% FIO_2 with a flow rate of 6 to 10 L/min. When used as a nonrebreather mask, a similar face mask has one-way valves that prevent exhaled air from returning to the reservoir bag. The flow rate should be a minimum of 10 L/min and deliver FIO_2 of 60% to 80% (AARC, 2002). Frequently inspect the reservoir bag to make sure that it is inflated. If it is deflated, the patient is breathing large amounts of exhaled carbon dioxide. High-flow oxygen systems should be humidified (AARC, 2007).

The Venturi mask (Fig. 40-18) delivers higher oxygen concentrations of 24% to 60% with oxygen flow rates of 4 to 12 L/min, depending on the flow-control meter selected.

Home Oxygen Therapy. Indications for home oxygen therapy include an arterial partial pressure (PaO_2) of 55 mm Hg or less or an arterial oxygen saturation (SaO_2) of 88% or less on room air at rest, on exertion, or with exercise. Home oxygen therapy is administered via nasal cannula or face mask. Patients with permanent tracheostomies use either a T tube or tracheostomy collar (AARC, 2007). Home oxygen therapy has beneficial effects for patients with chronic cardiopulmonary diseases. This therapy improves patients' exercise tolerance and fatigue levels and in some situations assists in the management of dyspnea.

There are three types of oxygen delivery systems: compressed gas cylinders, liquid oxygen, and oxygen concentrators. Before placing a certain delivery system in a home, assess the advantages and disadvantages (Table 40-8) of each type, along with the

TABLE 40-8 Home Oxygen Systems

PRIMARY USE	ADVANTAGES	DISADVANTAGES
Compressed Gas Cylinders		
Intermittent therapy such as for exercise or sleep only	100% oxygen stored in steel or aluminum cylinders; relatively inexpensive, no loss of gas during storage, relatively portable, delivery of up to 15 L/min; does not require electrical source; smaller tanks available	Bulky and heavy; frequent refilling necessary with continuous use; patient must know how to read regulator and understand when to call supplier; portable cylinders weigh 15 lbs
Liquid Oxygen Systems		
System of choice for high-volume users and active patients	100% oxygen; more oxygen occupies a smaller space; patient carries convenient ambulatory units refilled at home as shoulder bag, backpack, or wheeled luggage cart; delivery of up to 6 L/min; patient can safely refill ambulatory units from larger reservoir; quiet and easy operation; does not require electricity for operation; requires relatively fewer deliveries of oxygen	Evaporates, especially in warmer temperatures and when not in use; potential for connections to freeze together or form frost at connections if tight connection not maintained during filling; costly setup and delivery fees
Oxygen Concentrators		
Cost-effective for patients requiring low-flow continuous oxygen and patients with limited mobility inside or outside the home	Inexpensive, fixed monthly costs; most units with delivery of 1 to 5 L/min; good choice for people who do not leave their homes frequently; no cylinders or tanks to refill; delivery up to 10 L/min with specific makes and models	Oxygen concentration decreases as liter flow increases (usually 85% or greater 90%); power supply needed; increased electric costs; is not an ambulatory unit, therefore requires second system for portability; requires regular maintenance and backup system

Data from AARC: *Clinical practice guideline—2007 revision and update,* Cleveland Clinic Foundation: *Home oxygen therapy,* 2010b, from http://www.cchs.net/health/health-info/docs/2400/2412.asp?index=8707. Accessed September 14, 2010.

patient's needs and community resources. In the home the major consideration is the oxygen-delivery source.

Patients and their family caregivers need extensive teaching to be able to manage oxygen therapy efficiently and safely (Skill 40-5 on pp. 875-878). Teach the patient and family about home oxygen delivery (i.e., oxygen safety, regulation of the amount of oxygen, and how to use the prescribed home oxygen-delivery system) to ensure their ability to maintain the oxygen-delivery system. The home health nurse coordinates the efforts of the patient and family, home respiratory therapist, and home oxygen equipment vendor. The social worker usually assists initially with arranging for the home care nurse and oxygen vendor.

Restoration of Cardiopulmonary Functioning. If a patient's hypoxia is severe and prolonged, cardiac arrest results. A cardiac arrest is a sudden cessation of cardiac output and circulation. When this occurs, oxygen is not delivered to tissues, carbon dioxide is not transported from tissues, tissue metabolism becomes anaerobic, and metabolic and respiratory acidosis occurs. Permanent heart, brain, and other tissue damage occur within 4 to 6 minutes.

Cardiopulmonary Resuscitation. During cardiac arrest there is an absence of pulse and respiration. The American Heart Association continues to research cardiac arrest treatment and outcomes. The 2010 Consensus Conference reviewed the most current and comprehensive resuscitation literature/research to develop the *2010 AHA Guidelines for Cardiopulmonary Resuscitation (CPR) and Emergency Cardiac Care (ECC),* thus simplifying the basic life support (BLS) steps (AHA, 2010b).

The previous ABC (establish an ***A***irway, initiate ***B***reathing, and maintain ***C***irculation) of **cardiopulmonary resuscitation (CPR)** is changed to CAB (***C***hest compression, ***A***irway, ***B***reathing) for adults and pediatric patients (excluding newborns). In adults (the majority of cardiac arrests) the critical initial elements found to be essential for survival were chest compressions and early defibrillation. In the previous ABC sequence, establishing an airway first delays chest compressions. Now ventilation is done after the first cycle of 30 chest compressions. Another issue is that bystander CPR may increase if those not comfortable with doing ventilations would at least perform chest compression. For most adults with out-of-the-hospital arrest, hands-only CPR by bystanders has had similar outcomes to conventional CPR. A lone health care provider who sees an adult in cardiac arrest should activate the emergency response system, get and use an automatic external defibrillator (AED) if available, and give CPR. Defibrillation by AED (Box 40-10) is needed to stop an abnormal heart rhythm, and AEDs are now available in public places such as schools, airports, and workplaces (AHA, 2006a, 2010b).

BOX 40-10 AUTOMATED EXTERNAL DEFIBRILLATOR

- An automated external defibrillator (AED) is a device used to administer an electrical shock through the chest wall to the heart to stop the abnormal rhythm and restore a normal heart rhythm.
- Built-in computers assess patient's heart rhythm and determine if defibrillation is necessary. New technology has made them user friendly with audio and visual cues telling users what to do when using them (AHA, 2010b).
- The AED analyzes the patient's heart rhythm and determines if a shock is needed. It delivers a shock to the patient after announcing, "Everyone stand clear of patient." A shock is only delivered if the patient needs it.
- Lay rescuer AED programs train lay personnel (security guards, police, and firefighters) on the use of the AED (AHA, 2006b, 2010b).
- The AED is used to strengthen the chain of survival. Every minute of a sudden cardiac arrest without defibrillation decreases the survival rate by 7% to 10% (AHA, 2010b).
- For witnessed ventricular fibrillation, early cardiopulmonary resuscitation with defibrillation within the first 3 to 5 minutes can result in greater than 50% long-term survival (AHA, 2010a).

Restorative and Continuing Care. Restorative and continuing care emphasizes cardiopulmonary reconditioning as a structured rehabilitation program. **Cardiopulmonary rehabilitation** helps patients achieve and maintain an optimal level of health through controlled physical exercise, nutrition counseling, relaxation and stress-management techniques, and prescribed medications and oxygen. As physical reconditioning occurs, a patient's complaints of dyspnea, chest pain, fatigue, and activity intolerance decrease. In addition, the patient's anxiety, depression, or somatic concerns often decrease. The patient and the rehabilitation team define the goals of rehabilitation.

Respiratory Muscle Training. Respiratory muscle training improves muscle strength and endurance, resulting in improved activity tolerance. Respiratory muscle training prevents respiratory failure in patients with COPD. One method for respiratory muscle training is the incentive spirometer resistive breathing device (ISRBD). Patients achieve resistive breathing by placing a resistive breathing device into a volume-dependent incentive spirometer. Patients achieve muscle training when they use the ISRBD on a scheduled routine (e.g., twice a day for 15 minutes or 4 times a day for 15 minutes).

Breathing Exercises. Breathing exercises include techniques to improve ventilation and oxygenation. The three basic techniques are deep-breathing and coughing exercises, pursed-lip breathing, and diaphragmatic breathing. Deep-breathing and coughing exercises, previously discussed, are routine interventions used by postoperative patients (see Chapter 50).

Pursed-Lip Breathing. **Pursed-lip breathing** involves deep inspiration and prolonged expiration through pursed lips to prevent alveolar collapse. While sitting up, instruct the patient to take a deep breath and exhale slowly through pursed lips as if blowing through a straw. Have him or her blow through a straw into a glass of water to learn the technique. Patients need to gain control of the exhalation phase so it is longer than inhalation. The patient is usually able to perfect this technique by counting the inhalation time and gradually increasing the count during exhalation. In studies using pulse oximetry as a feedback tool, patients are able to demonstrate an increase in their arterial oxygen saturation during pursed-lip breathing (AARC, 1993).

Diaphragmatic Breathing. **Diaphragmatic breathing** is useful for patients with pulmonary disease, postoperative patients, and women in labor to promote relaxation and provide pain control. The exercise improves efficiency of breathing by decreasing air trapping and reducing the WOB.

Diaphragmatic breathing is more difficult than other breathing methods because it requires a patient to relax intercostal and accessory respiratory muscles while taking deep inspirations, which takes practice. The patient places one hand flat below the breastbone (upper hand) and the other hand (lower hand) flat on the abdomen. Ask him or her to inhale slowly, making the abdomen push out (as the diaphragm flattens, the abdomen should extend out) and moving the lower hand outward. When the patient exhales, the abdomen goes in (the diaphragm ascends and pushes on lungs to help expel trapped air). The patient practices these exercises initially in the supine position and then while sitting and standing. The exercise is often used with the pursed-lip breathing technique.

EVALUATION

Evaluate nursing interventions and therapies by comparing the patient's progress with the goals and expected outcomes of the nursing care plan (Fig. 40-19). Patient expectations evaluate the care from the patient's perspective.

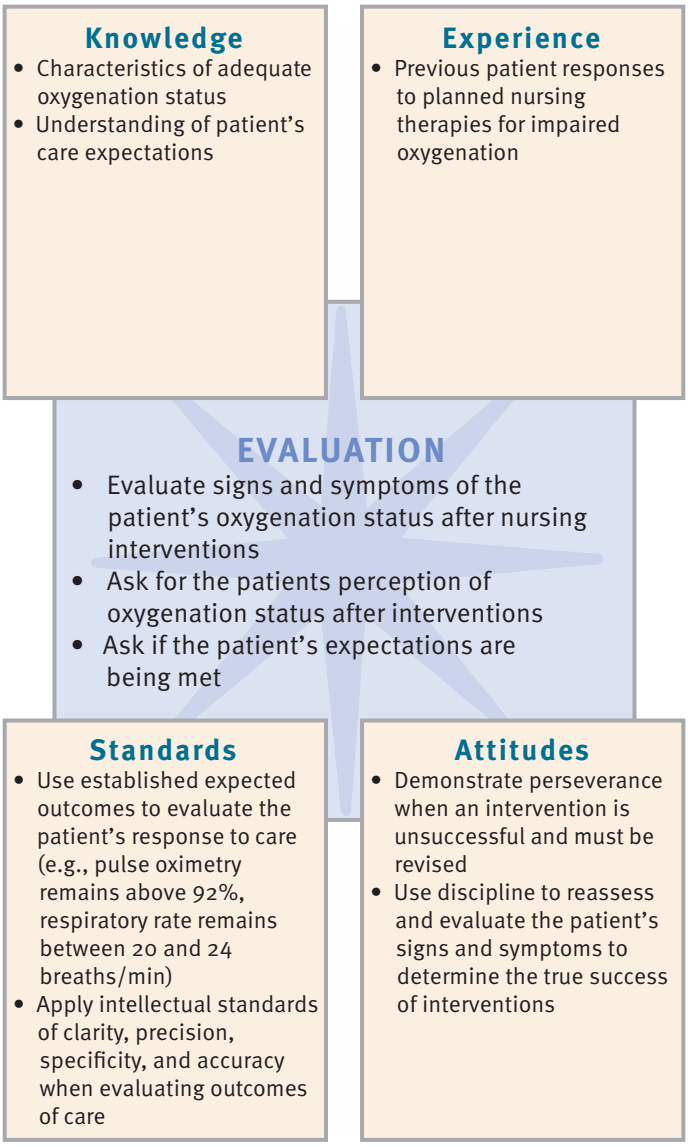

FIG. 40-19 Critical thinking model for oxygenation evaluation.

Through the Patient's Eyes. It is important to determine a patient's perceptions of how the disease affecting his or her need for oxygenation is also affecting his or her lifestyle. Focus on evaluating how the disease is affecting day-to-day activities and how the patient believes he or she is responding to treatment. Patients who have chronic lung problems often must be motivated to participate in necessary therapies. Evaluate the patient's motivation and emotional readiness to adhere to treatments provided. Be aware of the need to change a treatment plan to be culturally sensitive to improve adherence to it. Determine if the patient or family/caregiver feels more in control of the health situation after you have provided instruction. Consider the use of survey tools such as COPD Self Efficacy Scale, Chronic Respiratory Disease Questionnaire, and Pulmonary-Specific Quality of Life for COPD Scale (AARC, 2010b) to evaluate a patient's perception of his or her quality of life.

Patient Outcomes. Compare the patient's actual progress to the goals and expected outcomes of the nursing care plan to determine his or her health status. If the nursing measures used are not successful in improving oxygenation, modify the care plan and reevaluate. Continuous evaluation helps to determine whether new

or revised therapies are required and if new nursing diagnoses have developed and require a new plan of care. Do not hesitate to notify the health care provider about a patient's deteriorating oxygenation status. Prompt notification helps avoid an emergency situation or even the need for CPR.

- Ask the patient about his or her degree of breathlessness. Observe respiratory rate before, during, and after any activity or procedure.
- Ask the patient if the distance ambulated without fatigue has increased.
- Ask the patient to rate breathlessness on a scale of 0 to 10, with 0 being no shortness of breath and 10 being severe shortness of breath.
- Ask the patient which interventions help reduce dyspnea.
- Ask the patient about frequency of cough and sputum production and assess any sputum produced.
- Auscultate lung sounds for improvement in adventitious sounds.
- Evaluate pulse oximetry changes to decreases in oxygen delivery.
- Monitor arterial blood gas levels, pulmonary function tests, chest x-ray films, ECG tracings, and physical assessment data to provide objective measurement of the success of therapies and treatments.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Patients with sudden changes in their vital signs, level of consciousness, or behavior are possibly experiencing profound hypoxia (McCance and Huether, 2010).
- Perform tracheal suctioning before pharyngeal suctioning whenever possible. The mouth and pharynx contain more bacteria than the trachea. If a large amount of oral secretions is present before beginning the procedure, suction mouth with separate oral suction device.
- Use caution when suctioning patients with a head injury. The suction procedure causes elevations in intracranial pressure (ICP). Reduce this risk by presuctioning hyperventilation, which results in hypocarbia, which in turn induces vasoconstriction, thereby reducing the risk of increased ICP. It is recommended that you limit the introduction of the catheter to 2 times with each suctioning procedure (Gholamzadeh and Javadi, 2009).
- The routine use of NSI into the airway before ET and tracheostomy suctioning is not recommended. Normal saline is not effective in thinning secretions or improving removal. Use of NSI is associated with the adverse effects of excessive coughing, bronchospasm, spread of organisms to the lower respiratory tract, and decreased oxygen saturation (AARC, 2010b).
- Check your institutional policy before stripping or milking chest tubes. Nursing assessment determines if these procedures are necessary. These procedures can cause excessive pressure that has the potential to damage tissue trapped in the eyelets of the chest tube and cause increased bleeding.
- The most serious tracheostomy complication is airway obstruction, which can result in cardiac arrest. Most tracheostomy tubes are designed with a small plastic inner tube that sits inside the larger one. If the airway becomes occluded, the smaller one can be removed and replaced with a temporary spare. It is important to always have a spare at the bedside for emergency replacement (Higgins, 2009).
- Patients with COPD who are breathing spontaneously should never receive high levels of oxygen therapy because it results in a decreased stimulus to breathe. Do not administer oxygen more than 2 L/min unless a health care provider's order is obtained (AARC, 2007).

SKILL 40-1 SUCTIONING

View Video!

Delegation Considerations

The skill of nasotracheal suctioning and suctioning a new artificial airway cannot be delegated to nursing assistive personnel (NAP). However, when a patient has been assessed by the nurse to be stable, oropharyngeal and permanent tracheostomy tube suctioning can be delegated to NAP. Instruct NAP about:

- Unique modifications of the skill such as the need to reapply any supplemental oxygen equipment following the procedure.
- Reporting to the nurse any change in patient's respiratory status, level of consciousness, secretion color or volume, or unresolved coughing or gagging.
- Reporting to the nurse any change in patient's color, vital signs, or complaints of pain.

Equipment

- Appropriate-size suction catheter (smallest diameter that removes secretions effectively) or Yankauer catheter (oral suction). Outer diameter of catheter should not exceed half of internal diameter of an artificial airway (AARC, 2010a)
- Nasal or oral airway (if indicated)
- Two sterile gloves (open suction) or clean gloves (closed or oropharyngeal suction)
- Clean towel or paper drape
- Portable or wall suction as vacuum source
- Mask, goggles, or face shield
- Connecting tube (6 feet) and collection bottle
- Oxygen source and/or manual resuscitation bag equipped with oxygen-enrichment device
- Pulse oximeter
- Stethoscope

If not using closed-suction catheter

- Water-soluble lubricant
- Small Y adapter if catheter does not have a suction port
- Sterile basin
- Sterile normal saline solution or water (about 100 mL)

SKILL 40-1 SUCTIONING—cont'd

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Assess for signs and symptoms of upper and lower airway obstruction requiring suctioning: abnormal respiratory rate, adventitious sounds on inspiration or expiration, nasal secretions, gurgling, drooling, restlessness, gastric secretions or vomitus in mouth, and coughing without clearing secretions from airway.	Physical signs and symptoms result from decreased oxygen to tissues and pooling of secretions in upper and lower airways. Complete assessment measures before and after suction procedure (AARC, 2004).
3 Assess signs and symptoms associated with hypoxia and hypercapnia: decreased SpO_2, increased pulse and blood pressure, increased respiratory rate, apprehension, anxiety, decreased ability to concentrate, lethargy, decreased level of consciousness (especially acute), increased fatigue, dizziness, behavioral changes (especially irritability), dysrhythmias, pallor, and cyanosis.	Physical signs and symptoms resulting from decreased oxygen to tissues indicate need for suctioning (AARC, 2004).
4 Assess for risk factors for upper or lower airway obstruction, including chronic obstructive pulmonary disease, pulmonary infection, fluid imbalance, lack of humidity, impaired mobility, decreased level of consciousness, decreased gag or cough reflex, dysphagia, presence of feeding tube.	The presence of these risk factors impairs a patient's ability to clear secretions from the airway, thickens secretions, or increases risk for retaining secretions and thus requires suctioning.
5 Assess for anatomic factors that influence upper or lower airway function, such as recent surgery; head, chest, or neck trauma; tumors; neuromuscular disease.	Abnormal anatomy or head and neck trauma impairs normal drainage of secretions. Tumors in or around the lower airway impair secretion removal by occluding or externally compressing lumen of airway.
6 Identify **contraindications to nasotracheal suctioning** (AARC, 2004): occluded nasal passages; nasal bleeding, epiglottitis, or croup; acute head, facial, or neck injury or surgery, coagulopathy or bleeding disorder; irritable airway; laryngospasm or bronchospasm; gastric surgery with high anastomosis; myocardial infarction.	These conditions are **contraindicated because the passage of a catheter through the nasal route** causes trauma to existing facial trauma or surgery, increases nasal bleeding, or causes severe bleeding in the presence of bleeding disorders. In the presence of epiglottitis, croup, laryngospasm, or irritable airway, the entrance of a suction catheter via the nasal route causes intractable coughing, hypoxemia, and severe bronchospasm, necessitating emergency intubation or tracheostomy. Hypoxemia could worsen cardiac damage in myocardial infarction (AARC, 2004).
7 Review sputum microbiology data.	Certain bacteria are easier to transmit or require isolation because of virulence or antibiotic resistance.
8 Assess patient's understanding of procedure.	Reveals need for patient instruction and encourages cooperation.
PLANNING	
1 Explain to patient how procedure will help clear airway and relieve breathing problems and that temporary coughing, sneezing, gagging, or shortness of breath is normal. Encourage patient to cough out secretions.	Encourages cooperation and minimizes risks, anxiety, and pain.
2 Explain importance of and encourage coughing during procedure. Practice coughing if able. Splint surgical incisions if necessary.	Facilitates secretion removal and reduces frequency and duration of future suctioning.
3 Assist patient with assuming comfortable position (usually semi-Fowler's or sitting upright with head hyperextended, unless contraindicated). Nurse should stand on patient's right if nurse is right-handed or on patient's left if nurse is left-handed.	Reduces stimulation of gag reflex, promotes patient comfort and secretion drainage, and prevents aspiration. Hyperextension facilitates insertion of catheter into trachea.
4 Place pulse oximeter on patient's finger. Take reading and leave pulse oximeter in place.	Provides baseline SpO_2 to determine patient's response to suctioning.
5 Place towel across patient's chest.	Reduces transmission of microorganisms by protecting gown from secretions.
IMPLEMENTATION	
1 Perform hand hygiene. Apply mask, goggles, or face shield if splashing is likely.	Reduces transmission of microorganisms.
2 Connect one end of connecting tubing to suction machine and place other end in convenient location near patient. Turn suction device on and set vacuum regulator to appropriate negative pressure (120 to 150 mm Hg) (AARC, 2004).	Excessive negative pressure damages nasal, pharyngeal, and tracheal mucosa and induces greater hypoxia. Negative pressures should not exceed 150 mm Hg because higher pressure increases risk for airway trauma, hypoxemia, and atelectasis (AARC, 2004).
3 If indicated, increase supplemental oxygen therapy to 100% or as ordered by health care provider. Encourage patient to deep breathe.	Hyperoxygenation provides some protection from suction-induced decline in oxygenation. It is most effective in the presence of hyperinflation such as encouraging the patient to deep breathe or increase ventilator tidal volume settings (Bourgault et al., 2006; Pedersen et al., 2009).

STEP	RATIONALE
4 Preparation for all types of suctioning	
a. Open appropriate suction kit or catheter, using aseptic technique. If sterile drape is available, place it across patient's chest or on the over-bed table. Do not allow the suction catheter to touch any nonsterile surfaces.	Prepares catheter and prevents transmission of microorganisms. Provides sterile surface on which to lay suction catheter between passes, if needed.
b. Unwrap or open sterile basin and place on bedside table. Fill basin or cup with approximately 100 mL of sterile normal saline solution or water (see illustration).	Solution is used to flush catheter after each suction pass.
c. Open lubricant. Squeeze small amount onto open sterile catheter package without touching package. NOTE: Lubricant is not necessary for oropharyngeal or artificial airway suctioning.	Prepares lubricant while maintaining sterility. Use water-soluble lubricant to avoid lipoid aspiration pneumonia. Excessive lubricant application can occlude the catheter.
5 Apply gloves:	
a. Apply clean glove to each hand or dominant hand for oropharyngeal suctioning.	Suction of oral cavity does not require sterile glove use.
b. Apply sterile glove to each hand or nonsterile glove to nondominant hand and sterile glove to dominant hand for nasopharyngeal, nasotracheal, and artificial airway suctioning.	Reduces transmission of microorganisms and allows nurse to maintain sterility of suction catheter.
c. For artificial airway, see Step 8c.	Personal protective equipment is applied before gloving.
6 Pick up suction catheter with dominant hand without touching nonsterile surface. Pick up connecting tubing with nondominant hand. Secure catheter to tubing (see illustration)	
7 Place tip of catheter into sterile basin and suction a small amount of normal saline by occluding suction vent.	Ensures suction is functioning. Lubricates internal catheter and tubing.
8 Suction airway.	
a. Oropharyngeal suctioning	
(1) Remove oxygen mask if present. Keep oxygen mask near patient's face. If patient has a nasal cannula, it may remain in place.	Allows access to patient's mouth while having access to oxygen-delivery system.
CLINICAL DECISION: *Be prepared to quickly reapply oxygen mask if SpO_2 falls or respiratory distress develops during or at the end of suctioning.*	
(2) Insert Yankauer catheter into patient's mouth. With suction applied intermittently, move catheter around mouth, including pharynx and gum line, until secretions are cleared.	If catheter does not have a suction control to apply intermittent suction, take care not to allow suction tip to irritate oral mucosal surfaces with continuous suction.
(3) Encourage patient to cough and repeat suctioning if needed. Replace oxygen mask if used.	Coughing moves secretions from lower to upper airways into mouth.
(4) Rinse catheter with saline or water from basin with suction on continuously until catheter is cleared of secretions.	Clearing secretions before they dry reduces probability of transmission of microorganisms and enhances delivery of preset suction pressures.
b. Nasopharyngeal and nasotracheal suctioning	
(1) Lightly coat distal 6-8 cm (2-3 inches) of catheter tip with water-soluble lubricant.	Lubricates catheter for easier insertion.
(2) Remove oxygen-delivery device, if applicable, with nondominant hand. Without applying suction and using dominant thumb and forefinger, gently insert catheter into naris during inhalation.	Application of suction pressure while introducing catheter into nasopharyngeal tissues increases risk of damage to mucosa. When advanced into trachea, suction could damage mucosa and increase risk of hypoxia.

STEP 4b Pouring saline into basin.

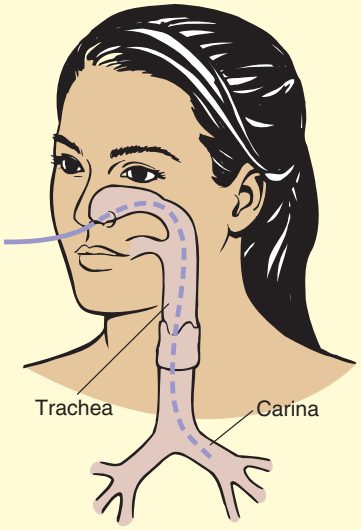
STEP 6 Attaching catheter to suction.

SKILL 40-1 SUCTIONING—cont'd

STEP	RATIONALE

CLINICAL DECISION: *Be sure to insert catheter during patient inhalation, especially if inserting into trachea because epiglottis is open. Do not insert during swallowing, or catheter will most likely enter the esophagus. If patient gags or becomes nauseated, the catheter is most likely in the esophagus and must be removed.* ***Never apply suction during insertion.***

(3) *Nasopharyngeal:* Have patient take a deep breath and insert catheter, following natural course of naris; slightly slant catheter downward and advance to back of pharynx. Do not force through naris. In adults insert catheter about 16 cm (6 inches); in older children, 8 to 12 cm (3 to 5 inches); in infants and young children, 4 to 8 cm (2 to 3 inches). Rule of thumb is to insert catheter distance from tip of nose (or mouth) to angle of mandible.



Proper placement ensures removal of pharyngeal secretions.

(a) Apply intermittent suction for no more than 15 seconds by placing and releasing nondominant thumb over catheter vent. Slowly withdraw catheter while rotating it back and forth between thumb and forefinger.

Intermittent suction up to 15 seconds safely removes pharyngeal secretions. Suction time greater than 15 seconds increases risk for suction-induced hypoxemia (AARC, 2004).

(4) *Nasotracheal:* Follow natural course of naris and advance catheter slightly slanted and downward to just above entrance into trachea. While patient takes a deep breath, quickly insert catheter about 15 to 20 cm (6 to 8 inches in adult) into trachea (see illustration). Patient will begin to cough. **NOTE:** In older children advance the catheter 16 to 20 cm (6 to 8 inches), and in young children and infants, 8 to 14 cm (3 to 5½ inches).

Ensures that catheter is inserted into trachea with minimum stress to patient. In young children and infants, shallow suctioning is recommended instead of deep tracheal suctioning, which increases the risk of tracheal edema and inflammation (AARC, 2010a). Premeasured suction catheters are used in some pediatric settings to avoid deep suctioning (Hockenberry and Wilson, 2011).

STEP 8b(4) Distance of insertion of nasotracheal catheter.

CLINICAL DECISION: *When there is difficulty passing the catheter, ask patient to cough or say "ahh" or try to advance during inspiration. Both these measures assist in opening the glottis to permit passage of the catheter into the trachea.*

(a) *Positioning option:* In some instances turning patient's head to right helps suction the left mainstem bronchus; turning head to left helps suction the right mainstem bronchus. If you feel resistance after insertion of catheter to maximum recommended distance, catheter has probably hit carina. Pull it back 1 to 2 cm (½ inch) before applying suction.

Turning patient's head to the side elevates the bronchial passage on the opposite side and facilitates passage of the catheter.

CLINICAL DECISION: *Use nasotracheal suctioning before pharyngeal suctioning whenever possible. The mouth and pharynx contain more bacteria than the trachea. If copious oral secretions are present before beginning the procedure, suction mouth with oral suction device.*

STEP	RATIONALE
(b) Apply intermittent suction for no more than 15 seconds by placing and releasing nondominant thumb over vent of catheter. Slowly withdraw catheter while rotating it back and forth between the dominant thumb and forefinger. Encourage patient to cough. Replace oxygen device if applicable.	Intermittent suction and rotation of catheter prevent injury to mucosa. If catheter "grabs" mucosa, remove thumb to release suction. Suctioning longer than 15 seconds causes cardiopulmonary compromise, usually from hypoxemia or vagal overload.

CLINICAL DECISION: *Monitor patient's vital signs and oxygen saturation during procedure; note whether there is a change of 20 beats/min (either increase or decrease) or if pulse oximetry falls below 90% or 5% from baseline. If this occurs, stop suctioning.*

(5) Rinse catheter and connecting tubing with normal saline or water until cleared.	Removes secretions from catheter. Secretions that remain in suction catheter or connecting tubing decrease suctioning efficiency.
(6) Assess for need to repeat suctioning procedure. Do not perform more than two passes with catheter. Allow at least 1 minute between passes for ventilation and oxygenation (AARC, 2004). Ask patient to deep breathe and cough.	Observe for alterations in cardiopulmonary status. Suctioning induces hypoxemia, dysrhythmias, laryngospasm, and bronchospasm (AARC, 2004). Deep breathing hyperventilates and reoxygenates alveoli and reduces the risk for suction-induced hypoxemia (Bourgault et al., 2006). Repeated passes clear the airway of excessive secretions but also remove oxygen and can induce laryngospasm.
c. Artificial airway (tracheostomy or endotracheal [ET] tube) suctioning	
(1) Apply mask, goggles, or face shield.	Reduces transmission of microorganisms.
(2) Apply one sterile glove to each hand or nonsterile glove to nondominant hand and sterile glove to dominant hand.	Reduces transmission of microorganisms and allows nurse to maintain sterility of suction catheter.
(3) Pick up suction catheter with dominant hand without touching nonsterile surfaces. Pick up connecting tubing with nondominant hand. Secure catheter to tubing.	Maintains catheter sterility. Establishes suction.
(4) Check that equipment is functioning properly by placing tip of catheter into basin and suctioning small amount of saline.	Ensures equipment function; lubricates catheter and tubing.
(5) Hyperinflate and/or hyperoxygenate patient before suctioning, using manual resuscitation AMBU-bag connected to oxygen source or sigh mechanism on mechanical ventilator. Some mechanical ventilators have a button that, when pushed, delivers 100% oxygen for a few minutes and then resets to the previous value.	Hyperinflation along with hyperoxygenation decreases the risk for a decrease in oxygenation saturation. Routine use of hyperinflation is not recommended because of the possibility of trauma resulting from large volumes and high peak pressures (Pedersen et al., 2009).
(6) If patient is receiving mechanical ventilation, open swivel adapter or, if necessary, remove oxygen- or humidity-delivery device with nondominant hand.	Exposes artificial airway.
(7) Without applying suction gently but quickly insert catheter using dominant thumb and forefinger into artificial airway (see illustration) (best to time catheter insertion with inspiration) until you meet resistance or patient coughs; then pull back 1 cm (½ inch).	Application of suction pressure while introducing catheter into trachea increases risk of damage to tracheal mucosa and increased hypoxia related to removal of entrained oxygen present in airways. Pulling back stimulates cough and removes catheter from mucosal wall so catheter is not resting against tracheal mucosa during suctioning.

STEP 8c(7) Suctioning tracheostomy.

CLINICAL DECISION: *If unable to insert catheter past the end of the ET tube, it is probably caught in the Murphy eye (i.e., side hole at the distal end of the ET tube that allows for collateral airflow in the event of mainstem intubation). If this happens, rotate the catheter to reposition it away from the Murphy eye or withdraw it slightly and reinsert with the next inhalation. Usually the catheter meets resistance at the carina. One indication that the catheter is at the carina is acute onset of coughing because the carina contains many cough receptors. Pull the catheter back 1 cm (½ inch).*

SKILL 40-1 SUCTIONING—cont'd

STEP	RATIONALE
(8) Apply intermittent suction by placing and releasing nondominant thumb over vent of catheter; slowly withdraw catheter while rotating it back and forth between dominant thumb and forefinger. Encourage patient to cough. Watch for respiratory distress.	Intermittent suction and rotation of catheter prevent injury to tracheal mucosal lining. If catheter "grabs" mucosa, remove thumb to release suction.
CLINICAL DECISION: *If patient develops respiratory distress, immediately withdraw catheter and supply additional oxygen and breaths as needed. In an emergency administer oxygen directly through the catheter. Disconnect suction and give 100% oxygen through the catheter.*	
(9) If patient is receiving mechanical ventilation, close swivel adapter or replace oxygen-delivery device.	Reestablishes the artificial airway.
(10) Encourage patient to deep breathe if able. Some patients respond well to several manual breaths from the mechanical ventilator or bag-valve mask.	Reoxygenates and expands alveoli. Suctioning sometimes causes hypoxemia and atelectasis.
(11) Rinse catheter and connecting tubing with normal saline until clear. Use continuous suction.	Removes catheter secretions. Secretions left in tubing decrease suction and provide environment for microorganism growth. Secretions left in connecting tube decrease suctioning efficiency.
(12) Assess patient's cardiopulmonary status for secretion clearance and complications. Repeat Steps (5) through (8) once or twice more to clear secretions. Allow adequate time (at least 1 full minute) between suction passes for ventilation and hyperoxygenation. Do not perform more than two passes with the catheter (AARC, 2010a).	Suctioning sometimes induces dysrhythmias, hypoxia, and bronchospasm and impairs cerebral circulation or adversely affects hemodynamics (AARC, 2010a). Repeated passes with suction catheter clear airway of excessive secretions and promote improved oxygenation.
(13) Perform nasopharyngeal and oropharyngeal suctioning if necessary. After performing nasopharyngeal and oropharyngeal suctioning, catheter is contaminated; do not reinsert into ET or tracheostomy tube.	Upper airway is "clean," and lower airway is "sterile." Therefore you can use the same catheter to suction from sterile to clean areas but not from clean to sterile areas.
9 Complete procedure.	
a. Place Yankauer catheter in a clean, dry area for reuse with suction turned off or within patient's reach with suction on if patient is capable of suctioning self.	Facilitates prompt removal of airway secretions when suctioning is necessary in the future.
b. Disconnect nasal and artifical airway catheters from connecting tubing. Turn off suction. Roll catheter around fingers of dominant hand. Pull glove off inside out so catheter remains in glove. Pull off other glove over first glove in same way to contain contaminants. Discard into appropriate receptacle. Turn off suction device.	Reduces transmission of microorganisms. Do not touch clean equipment with contaminated gloves.
c. Remove towel and place in laundry or remove drape and discard in appropriate receptacle.	Reduces transmission of organisms.
d. Reposition patient as indicated by condition. Reapply clean gloves for patient's personal care (e.g., oral hygiene).	Proper positioning based on patient's condition promotes comfort, encourages secretion drainage, and reduces risk of aspiration.
e. If indicated, readjust oxygen to original level.	Helps patient's blood oxygen level return to baseline.
CLINICAL DECISION: *If patient develops respiratory distress during the suctioning procedure, immediately withdraw catheter and supply additional oxygen and breaths as needed. In an emergency administer oxygen directly through the catheter. Disconnect suction and attach oxygen at prescribed flow rate through the catheter.*	
f. Discard remainder of normal saline into appropriate receptacle. If basin is disposable, discard into appropriate receptacle. If basin is reusable, rinse and place in soiled utility room.	Solution is contaminated; this reduces transmission of microorganisms.
g. Remove and discard goggles, mask, or face shield and perform hand hygiene.	Reduces transmission of microorganisms.
h. Place unopened suction kit on suction machine table or at head of bed according to institution preference.	Provides for immediate access of suction catheter and equipment in event of an emergency or for next suctioning procedure.
EVALUATION	
1 Compare patient's vital signs and SpO_2 saturation before and after suctioning.	Provides objective data about any physiological effects of suctioning.
2 Ask patient if breathing is easier and congestion is decreased.	Provides subjective confirmation that airway obstruction is relieved with suctioning procedure.
3 Auscultate lungs for change in adventitious lung sounds.	Provides objective information about any improvement in lung sounds.
4 Observe airway secretions.	Provides data to document presence or absence of respiratory tract infection.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Worsening cardiopulmonary status
- Limit length of suctioning.
- Determine need for presuctioning hyperoxygenation and hyperinflation.
- Determine need for more frequent suctioning, possibly shorter duration.
- Notify health care provider of changes.

2 Return of bloody secretions
- Determine amount of suction pressure used and adjust accordingly.
- Evaluate suctioning frequency and reduce if appropriate.
- Determine other factors that lead to bloody secretions (e.g., prolonged bleeding time).
- Provide more frequent oral hygiene.

3 Unable to pass suction catheter through first naris attempted
- Try other naris or oral route.
- Insert nasal airway, especially if suctioning through patient naris frequently.
- Guide catheter along naris floor to avoid turbinates.
- If obstruction is mucus, apply suction to relieve obstruction but do not apply suction to mucosa. If you think obstruction is a blood clot, consult health care provider.
- Increase lubrication of catheter.

RECORDING AND REPORTING

- Record amount, consistency, color, and odor of secretions.
- Record patient's response to procedure.
- Record and report patient's presuctioning and postsuctioning cardiopulmonary status.

HOME CARE CONSIDERATIONS

- Adhere to best practices for infection control while weighing cost-effectiveness in the presence of a chronic situation. If a patient has an established tracheostomy or requires long-term nasotracheal suctioning and infection is not present, clean suction technique is appropriate.
- Although most patients with airway clearance problems at home have a tracheostomy, some also require nasal pharyngeal suctioning. Catheters are often used for a 24-hour period and then cleaned and disinfected; or they are cleaned with soapy water after each use and discarded after 24 hours.
- Stress to family caregivers the importance of brief intervals of applying suction pressure. Instruct those performing suction to hold their breath during the application of negative suction pressure to help them remember to not suction too long.
- Instruct patient to clean and disinfect or change the secretion collection container every 24 hours according to home care or institutional protocol.
- Teach patient and family how to practice infection-control measures when emptying the suction container jar. These secretions are emptied in the toilet but have a splash risk. Instruct caregiver to apply mask (shield if available) and gloves and bring the jar as close to the toilet bowel as possible to decrease the risk of splash.

SKILL 40-2 CARE OF AN ARTIFICIAL AIRWAY

View Video!

Delegation Considerations

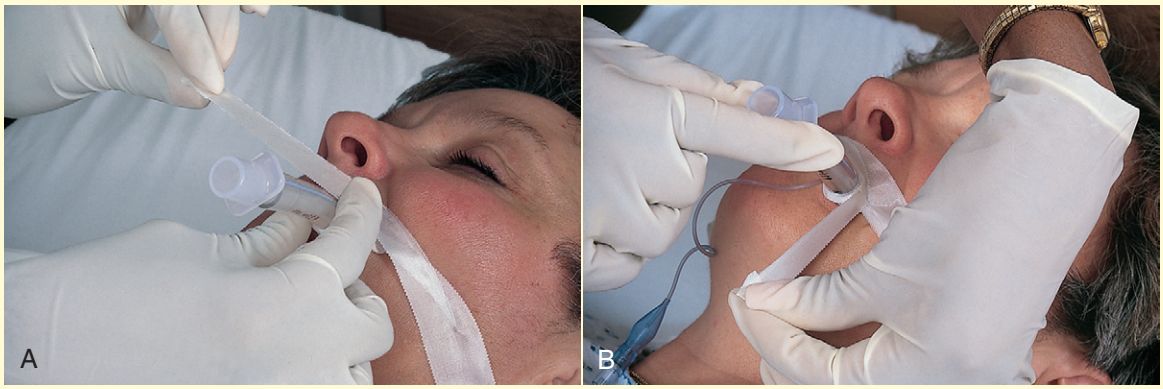
The skill of performing artificial airway care cannot be delegated to nursing assistive personnel (NAP). In some settings patients who have well-established tracheostomy tubes may have their care delegated to the NAP. Instruct the NAP to:
- Immediately report to the nurse changes in patient's respiratory status, change in level of consciousness, confusion, restlessness or irritability, change in vital signs (range to report), decreased pulse oximetry level (values to report), or change in level of comfort.
- Immediately report to the nurse if the endotracheal (ET) tube or tracheostomy tube appears to have becomes dislodged, obstructed, or moved.
- Immediately report to the nurse any unexpected drainage or secretions from tracheostomy or change in color of stoma.

Equipment

- Stethoscope
- ET tube care
  - Towel
  - ET and oropharyngeal suction equipment
  - 1- to 1½-inch (2.5- to 4-cm) adhesive or waterproof tape (not paper or silk tape) or commercial ET holder and mouth guard (follow manufacturer instructions for securing)
  - Clean gloves (two pairs)
  - Adhesive remover swab
  - Mouth care supplies
  - Powdered toothbrush or brush with non-foaming paste (sodium monofluorophosphate 0.7% [Sona et al., 2009])
  - 0.12% to 0.20% Chlorhexidine mouthwash, rinse, or gel
  - Tap water
  - Clean toothette
  - Face cleaner (e.g., wet washcloth, towel, soap, shaving supplies)
  - Clean 2 × 2 gauze
  - Tincture of benzoin, liquid adhesive, or skin preparation pad

SKILL 40-2 CARE OF AN ARTIFICIAL AIRWAY—cont'd

Equipment—cont'd



- Face shield, mask, goggles (if indicated)
- Tongue blade (optional)
- Oral airway
- Tracheostomy care
  - Towel
  - Tracheostomy suction supplies
  - Sterile tracheostomy care kit, if available, or two sterile 4 × 4 gauze pads
  - Sterile cotton-tipped applicators
  - Sterile tracheostomy dressing (precut and sewn surgical dressing)
  - Sterile basin
  - Small sterile brush (or disposable inner cannula)
  - Tracheostomy ties (e.g., twill tape, manufactured tracheostomy ties, Velcro tracheostomy ties)
  - Normal saline (NS)
  - Scissors
  - Clean gloves (two)
  - Face shield, mask, or goggle if indicated

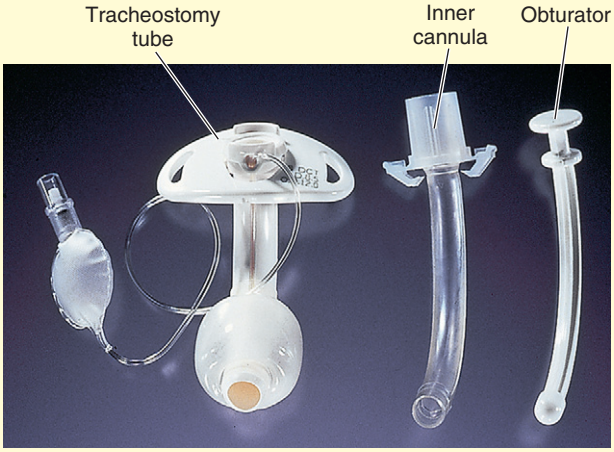
STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Auscultate lung sounds and observe respiratory rate and depth.	Provides baseline measure of ventilation and ease of breathing.
3 Assess condition of surrounding tissues (soiled or loose tape, ties, or dressing; pressure sores on nares, lips, or corner of mouth; excess nasal, oral, or peristomal secretions; patient moving endotracheal tube with tongue; biting tube or tongue; or foul-smelling mouth).	Determines need for airway care and identifies potential pressure sites from airway devices.
4 Observe patency of airway. Excess intratracheal or endotracheal secretions, diminished airflow through airway, signs and symptoms of airway obstruction.	Buildup of secretions in airways impair oxygenation.
5 Observe for factors that increase risk for complications from ET tube: type and size of tube, movement of tube up and down trachea, cuff size and overinflation or underinflation, duration of tube placement, facial trauma, malnutrition, and neck or thoracic radiation.	Movement of tube predisposes patient to tracheal trauma or tube dislodgment and indicates the need for another size airway. Cuff size indicates the amount of air needed to properly inflate cuff. An underinflated cuff increases patient's risk for aspiration. Cuff overly inflated may cause ischemia or necrosis of tracheal tissue. Longer duration of intubation increases risk for lower airway complications (Hess, 2005). Tissue is prone to breakdown in the presence of malnutrition and radiation.
6 Determine proper ET tube depth, noted by centimeters at lip or gum line. Line is marked on tube and recorded in medical record at time of intubation.	
7 Assess patient's knowledge of procedure and ability to perform trach care at home, and answer any questions of family.	Reinforces information given to patient and family and provides opportunity to ask additional questions. Encourages cooperation and minimizes anxiety.
PLANNING	
1 Obtain assistance from available staff for this procedure.	Reduces risk for accidental extubation of artificial airway.
2 Assist patient with assuming comfortable position for both patient and nurse (usually supine or semi-Fowlers).	Provides access to site and facilitates completion of procedure without causing the nurse muscle strain or patient discomfort.
3 Place towel across patient's chest.	Reduces transmission of microorganisms to linens and bedclothes.
4 Explain importance of patient's participation, including importance of not biting or moving ET tube with tongue, trying not to cough when tape is temporarily removed from the airway, not pulling on tube with hand.	Reduces anxiety, encourages cooperation, and reduces risks. Removal of tape can be uncomfortable.
IMPLEMENTATION	
1 Perform hand hygiene. Apply mask, goggles, or face shield if indicated.	Reduces transmission of microorganisms.
2 Perform tracheal (tracheostomy), endotracheal (endotracheal tube), nasopharyngeal, or oropharyngeal suction (see Skill 40-1). (When suctioning tracheostomy, remove soiled dressing and discard in glove with coiled catheter.)	Removes secretions and diminishes patient's need to cough during procedure.
3 Connect Yankauer suction catheter to suction source.	Prepares for oropharyngeal suctioning.

STEP	RATIONALE
4 Care of artificial airways	
a. Endotracheal (ET) tube care	
(1) Prepare method to secure ET tube (check agency policy).	
(a) **Tape method:** Cut piece of tape long enough to go completely around patient's head from naris to naris plus 15 cm (6 inches): adult, about 30 to 60 cm (1 to 2 feet). Lay adhesive side up on bedside table. Cut and lay 8 to 15 cm (3 to 6 inches) of tape, adhesive sides together, in center of long strip to prevent tape from sticking to hair. Smaller strip of tape covers area between ears around back of head.	Preparing tape ahead will allow you to have one hand positioned on ET tube throughout the procedure. Adhesive tape needs to be placed around head from cheek to cheek below ears. Avoid over ears because this results in a pressure sore.
(b) **Commercially available ET tube holder:** Open package per manufacturer instructions. Set device aside with head guard in place and Velcro strips open.	Commercial devices are latex free, fast, and convenient. These devices avoid need for tape and resultant skin breakdown and are easily applied in presence of facial hair.
(2) Apply clean gloves and instruct NAP or another RN to apply gloves and hold ET tube firmly at patients' lips or naris throughout the procedure. Note the number marking on ET tube at gum line or lips.	Reduces transmission of microorganisms. Maintains proper tube position and prevents accidental extubation.
(3) Remove old tape or device.	Provides access to underlying skin for assessment and hygiene. Reduces transmission of microorganisms.
(a) **Tape:** Carefully remove tape from ET tube and patient's face. If tape is difficult to remove, moisten with soapy water or adhesive tape remover. Discard tape in appropriate receptacle if nearby.	Limits tape burns around face and neck.
(b) **Commercially available device:** Remove Velcro strips from ET tube and remove ET tube holder from patient.	Velcro strips secure ET tube in place and provide a marker to measure distance to patient's lips or gums. These devices all permit access to patient's mouth and lips for ease in oropharyngeal suctioning and oral hygiene.
CLINICAL DECISION: *Do not allow helper to hold the tube away from the lips or naris. Doing so allows too much "play" in the tube and increases the risk for tube movement and accidental extubation. Never let go of the ET tube because it could become dislodged.*	
(4) Remove excess secretions or adhesive left on patient's face. Use adhesive remover swab to remove excess adhesive left on face after tape removal. Wash adhesive remover from face.	Promotes hygiene. Retained adhesive causes damage to skin and makes it difficult for new tape to adhere.
(5) Remove oral airway or bite block if present and place on towel.	Provides access and complete observation of patient's oral cavity.
CLINICAL DECISION: *Do not remove oral airway if patient is actively biting. Wait until tape or device is partially or completely secured to ET tube.*	
(6) Provide oral care. (Have Yankauer suction catheter on and at hand.) Brush oral mucosa, gums, and teeth with powdered toothbrush, or brush with nonfoaming antiseptic paste for 2 minutes (Sona et al., 2009; Needleman et al., 2011). Rinse carefully using tap water. Suction orally as needed during brushing and rinsing. Moisten brush with water to rinse, then use brush or a clean toothette to apply chlorhexidine rinse or gel (Sona et al., 2009; Morris et al., 2011; Labeau et al., 2011). Perform oral care twice daily at 12-hour intervals (Sona et al., 2009).	The use of an oral antiseptic for oral care of intubated patients has a beneficial effect in preventing ventilator-associated pneumonia (Labeau et al., 2011; Sona et al., 2009; Morris et al., 2011).
(7) Oral ET tube only: Note "cm" ET tube marking at lips or gums. With help of assistant, move ET tube to opposite side or center of mouth. Do not change tube depth.	Prevents pressure sore formation at sides of patient's mouth. Ensures correct position of tube and allows for quick visual of displaced tube. Measuring tube at lip line can be distorted because of edema, trauma, or disease process (Vollman, 2006).
(8) Repeat oral cleaning as in Step (6) on opposite side of mouth.	Cleanses oral cavity and removes secretions from mouth and oropharynx.
(9) Clean face and neck with soapy washcloth; rinse and dry. Shave male patient as necessary.	Moisture and beard growth prevent adhesive tape adherence.
(10) Use small amount of skin protectant or liquid adhesive on clean 2×2 gauze and dot on upper lip (oral ET tube) or across nose (nasal ET tube) and cheeks to ear. Allow tincture to dry completely.	Protects and makes skin more receptive to tape.
(11) Secure ET tube.	
(a) Tape method	
[1] Slip tape under patient's head and neck, adhesive side up. Take care not to twist tape or catch hair. Do not allow tape to stick to itself. It helps to stick tape gently to a tongue blade, which serves as a guide as tape is passed behind patient's head. Center tape so double-faced tape extends around back of neck from ear to ear.	Positions tape to secure ET tube in proper position.

SKILL 40-2 CARE OF AN ARTIFICIAL AIRWAY—cont'd

STEP	RATIONALE
[2] On one side of face, secure tape from ear to naris (nasal ET tube) or over lip to edge of mouth (oral ET tube). Tear remaining tape in half lengthwise, forming two pieces that are ½- to ¾-inch (1 to 1.5 cm) wide. Secure bottom half of tape across upper lip (oral ET tube) or across top of nose (nasal ET tube) to opposite ear (see illustration, *A*). Wrap top half of tape around tube (see illustration, *B*). Tape should encircle main part of tube at least 2 times for security.	Secures tape to face. Using top tape to wrap prevents downward drag on ET tube.
[3] Gently pull other side of tape firmly to pick up slack and secure to remaining side of face (see illustration). Have assistant release hold when tube is secure.	Secures tape to face and tube. ET tube should be at same depth as the lips. Check earlier assessment for verification of tube depth in centimeters.
(b) Commercially available device	
[1] Thread ET tube through opening designed to secure it. Be sure that pilot balloon to ET tube is accessible.	Commercially available holders have a slit in front of holder designed to secure the ET tube.
[2] Place Velcro strips of ET holder under patient at occipital region of the head.	
[3] Verify that ET tube is at established depth, using lip or gum line marker as guide.	Ensures that ET tube remains at correct depth as determined during assessment.
[4] Secure Velcro strips at base of patient's head. Leave 1 cm (½ inch) slack in strips.	
[5] Verify that tube is secure, it does not move forward from patient's mouth or backward down into patient's throat, and there are no pressure areas on the oral mucosa or the occipital region of the head (see illustration).	The tube needs to be secure so its position remains at correct depth. It can be secured without being tight and causing pressure.

STEP 4a(11)(a)[2] **A,** Securing bottom half of tape across patient's upper lip. **B,** Securing top half of tape around tube.



STEP 4a(11)(a)[3] Tape securing ET tube.

STEP 4a(11)(b)[5] ET holder in place. (Courtesy Dale Medical Products, Plainesville, Mass.)

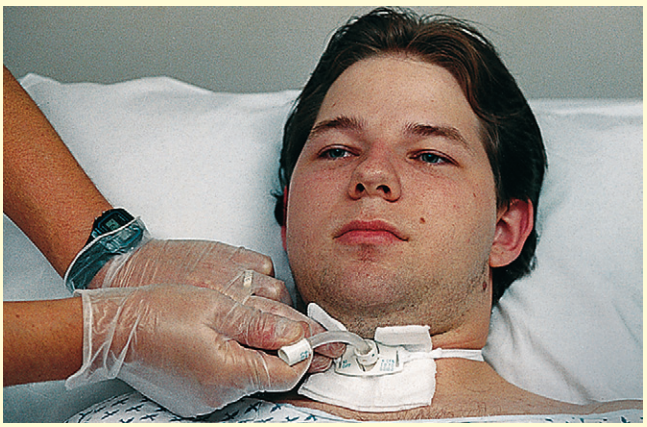
STEP	RATIONALE
(12) Remove and clean oral airway in warm soapy water and rinse well. Then rinse in chlorhexidine rinse. Shake excess solution from oral airway. **Option:** Insert new oral airway if secretions are difficult to remove.	Promotes hygiene. Reduces transmission of microorganisms.
(13) For unconscious patient reinsert oral airway without pushing tongue into oropharynx and secure with tape.	Prevents patient from biting ET tube and allows access for oropharyngeal suctioning. An oral airway in a conscious, cooperative patient causes excessive gagging and pressure ulcers to mouth and tongue.
b. Tracheostomy care	
(1) While patient is replenishing oxygen stores following suctioning, prepare equipment on bedside table.	Preparation and organization of equipment allows completion of tracheostomy care procedure efficiently and reconnection of patient to oxygen source in timely manner.
(a) Open two packages of cotton-tipped swabs. Keeping contents sterile, pour NS onto one of the packages.	
(b) Open tracheostomy kit. Open two 4 × 4 gauze packages using aseptic technique and pour saline on one package. Leave second package dry. Do not recap NS.	A tracheostomy tube has multiple components (see illustration). Some of these components might be used during tracheostomy care.

STEP 4b(1)(b) Tracheostomy tube. (Courtesy Mallinckrodt Inc. Shiley Tracheostomy Products, St Louis, Mo.)

(c) Unwrap sterile basin and pour about 2 cm (1 inch) of NS into it.	
(d) Open small sterile brush package and place aseptically into sterile basin.	
(e) Open sterile tracheostomy dressing package.	
(f) Prepare length of twill tape long enough to go around patient's neck two times, about 60 to 75 cm (25 to 30 inches) for an adult. Cut ends on the diagonal. Lay aside in dry area.	Cutting ends of tie on a diagonal aids in inserting tie through eyelet.
(g) If using commercial tracheostomy tube holder, open package according to manufacturer's directions.	
(2) Apply sterile gloves. Keep dominant hand sterile throughout procedure.	Reduces transmission of microorganisms.
(3) Hyperoxygenate patient if oxygen saturation levels are below 92% (Demir and Dramali, 2005). Apply oxygen source loosely over tracheostomy if patient desaturates during procedure.	Helps reduce amount of desaturation.

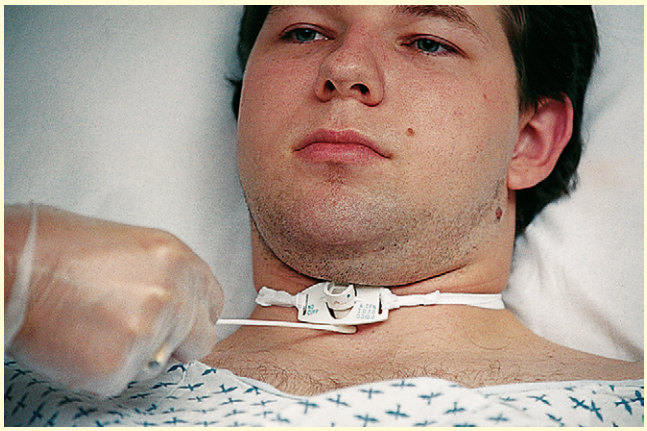
CLINICAL DECISION: *It is important to stabilize the tracheostomy tube at all times during tracheostomy care to prevent injury and unnecessary discomfort. Have another nurse or NAP assist during procedure if necessary.*

CLINICAL DECISION: *For tracheostomy tube with no inner cannula or Kistner button, continue with Step (6).*



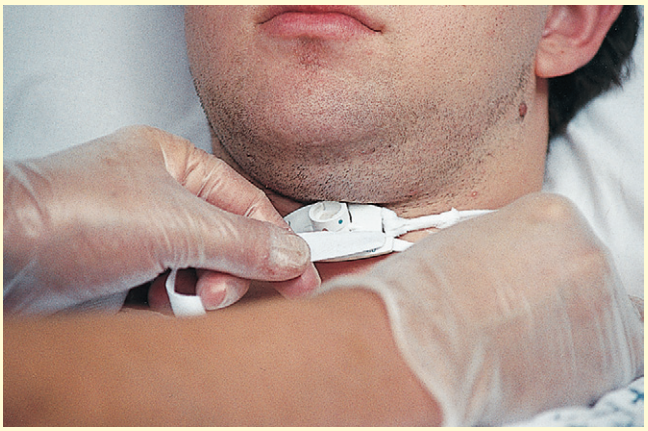
(4) Tracheostomy with **inner cannula** care.	
(a) While touching only the outer aspect of tube, unlock and remove inner cannula with nondominant hand. Drop inner cannula into NS basin.	Removes inner cannula for cleaning. Hydrogen peroxide loosens secretions from inner cannula; but, if it is too irritating, use NS only (Johns Hopkins, 2010).

SKILL 40-2 CARE OF AN ARTIFICIAL AIRWAY—cont'd

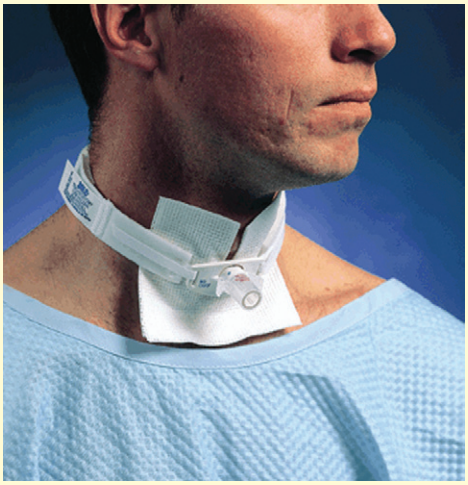


STEP	RATIONALE
(b) Place tracheostomy collar or T tube and ventilator oxygen source over or near outer cannula. (NOTE: T tube and ventilator oxygen devices cannot be attached to all outer cannulas when inner cannula is removed.)	Maintains supply of oxygen to patient.
(c) To prevent oxygen desaturation in affected patients, quickly pick up inner cannula and use small brush to remove secretions inside and outside cannula (see illustration).	Tracheostomy brush provides mechanical force to remove thick or dried secretions.
(d) Hold inner cannula over basin and rinse with NS, using nondominant hand to pour.	Removes secretions from inner cannula (Cleveland Clinic, 2010a).
(e) Replace inner cannula (see illustration) and secure "locking" mechanism. Hyperventilate patient if needed. Reapply ventilator or oxygen sources.	Secures inner cannula and reestablishes oxygen supply.
(5) Disposable inner cannula care	
(a) Remove cannula from manufacturer packaging.	
(b) While touching only the outer aspect of tube, withdraw inner cannula and replace with new cannula. Lock into position.	Reestablishes airway quickly.
(c) Dispose of contaminated cannula in appropriate receptacle and apply oxygen source or ventilator.	Prevents unnecessary oxygen desaturation.
(6) Using NS-saturated cotton-tipped sterile swabs and 4 × 4 gauze, clean exposed outer cannula surfaces and stoma under faceplate, extending 5 to 10 cm (2 to 4 inches) in all directions from stoma (see illustration). Clean in circular motion from stoma site outward using dominant hand to handle sterile supplies.	Aseptically removes secretions from stoma site. Moving in outward circle pulls mucus and other contaminants from stoma to periphery.

STEP 4b(4)(c) Cleaning tracheostomy inner cannula.



STEP 4b(4)(e) Reinserting inner cannula.



STEP 4b(6) Cleaning around stoma.

STEP	RATIONALE
(7) Using NS-prepared cotton-tipped swabs and 4 × 4 gauze, clean outer tracheostomy tube flange and skin surfaces.	Removes secretions that can be source of infection.
(8) Using dry 4 × 4 gauze, pat lightly at skin and exposed outer cannula surfaces.	Dry surfaces prohibit formation of moist environment for microorganism growth and skin excoriation.
(9) Securing tracheostomy	
(a) Tracheostomy tie method	
[1] Instruct assistant, if available, to apply clean gloves and securely hold tracheostomy tube securely in place, then cut old ties.	Promotes hygiene, reduces transmission of microorganisms. Secures tracheostomy tube to prevent incidental extubation.
CLINICAL DECISION: *Assistant must not release hold on tracheostomy tube until new ties are firmly tied to reduce risk of accidental extubation. If no assistant is present, do not cut old ties until new ties are in place and securely tied.*	
[2] Take prepared twill tape, insert one end of tie through faceplate eyelet, and pull ends even (see illustration).	
[3] Slide both ends of ties behind head and around neck to other eyelet and insert one tie through second eyelet.	
[4] Pull snugly.	Secures tracheostomy tube in place.
[5] Tie ends securely in double square knot, allowing space for only one loose or two snug finger widths in tie.	One-finger slack prevents ties from being too tight when tracheostomy dressing is in place and also prevents movement of tracheostomy into lower airway.
(b) Tracheostomy tube holder method (see illustration)	
[1] While wearing gloves, maintain secure hold on tracheostomy tube. This can be done with an assistant or, when an assistant is not available, leave old tracheostomy tube holder in place until new device is secure.	Prevents incidental displacement of tube.
[2] Align strap under patient's neck. Be sure that Velcro attachments are positioned on either side of tracheostomy tube.	
[3] Place narrow end of ties under and through faceplate eyelets. Pull ends even and secure with Velcro closures.	
[4] Verify that there is space for only one loose or two snug finger width(s) under neck strap.	Prevents skin necrosis.

STEP 4b(9)(a)[2] Replacing tracheostomy ties when an assistant is not available. Do not remove old tracheostomy ties until new ones are secure.

STEP 4b(9)(b) Tracheostomy tube holder in place. (Courtesy Dale Medical Products, Plainesville, Mass.)

SKILL 40-2 CARE OF AN ARTIFICIAL AIRWAY—cont'd

STEP	RATIONALE
(10) Insert fresh tracheostomy dressing under clean ties/holder and faceplate (see illustration).	Absorbs drainage. Dressing prevents pressure on clavicle heads.

STEP 4b(10) Applying tracheostomy dressing.

5 Position patient comfortably and evaluate respiratory status.	Promotes comfort. Some patients require posttracheostomy care suctioning.
6 Replace any oxygen-delivery devices.	Maintains oxygen therapy.
7 Remove and discard gloves. Perform hand hygiene.	Prevents transmission of microorganisms.

CLINICAL DECISION: *Keep tracheostomy obturator at bedside with a fresh tracheostomy to facilitate reinsertion of the outer cannula if dislodged. Keep an additional tracheostomy tube of the same size and shape on hand for emergency replacement (Higgins, 2009).*

EVALUATON

1 Compare respiratory assessments before and after procedure.	Identifies any changes in presence and quality of breath sounds after procedure. Determines effectiveness of artificial airway care.
2 Observe depth and position of ET tubes according to health care provider's recommendation.	Verifies that position of tube is correct and not altered.
3 Assess security of tape/holder securing ET tube by gently tugging at tube.	Artificial airway (ET tube) should not move. Patient may cough.
4 Assess fit of new tracheostomy ties and ask patient if tube feels comfortable.	If tracheostomy ties are uncomfortable, ties that are too loose or tight place patient at risk for injury.
5 Assess skin around mouth, oral mucosa (ET tube), and tracheostomy stoma for drainage, pressure, irritation, or signs of infection.	Skin breakdown and/or irritation should not be present. Broken skin places patient at risk for infection.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Unexpected extubation of ET tube
- Call for assistance while remaining with patient.
- Assist respirations with bag-valve mask as needed.
- Assess patient for airway patency, spontaneous breathing, and vital signs.
- Prepare for reintubation.

2 Accidental decannulation of tracheostomy tube
- Call for assistance while remaining with patient.
- Replace old tracheostomy tube with new spare tube of same size and kind kept at the bedside. Some experienced nurses or respiratory therapists may be able to quickly reinsert tracheostomy tube (Higgins, 2009).
- Same-size ET tube can be inserted in stoma in an emergency.
- Be prepared to manually ventilate patient who develops respiratory distress.

3 Movement of ET tube
- Repeat taping or securing procedure.
- In very active patients without facial injury who are at risk for self-extubation, consider applying a second piece of tape around back of head.

4 Pressure area around tracheostomy tube
- Increase frequency of tracheostomy care. Keep dressing under faceplate at all times.
- Consider using double dressing or applying hydrocolloid or stoma adhesive dressing around stoma.

RECORDING AND REPORTING

- Record respiratory assessment measures before and after care.
- Record ET tube care: depth of ET tube, frequency and extent of care, patient tolerance of procedure, and special care of any unexpected outcomes related to presence of the tube.
- Record tracheostomy care: type and size of tracheostomy tube, frequency and extent of care, patient tolerance of procedure, and special care of any unexpected outcomes related to presence of the tube.

HOME CARE CONSIDERATIONS TRACHEOSTOMY ONLY (CLEVELAND CLINIC, 2010A).

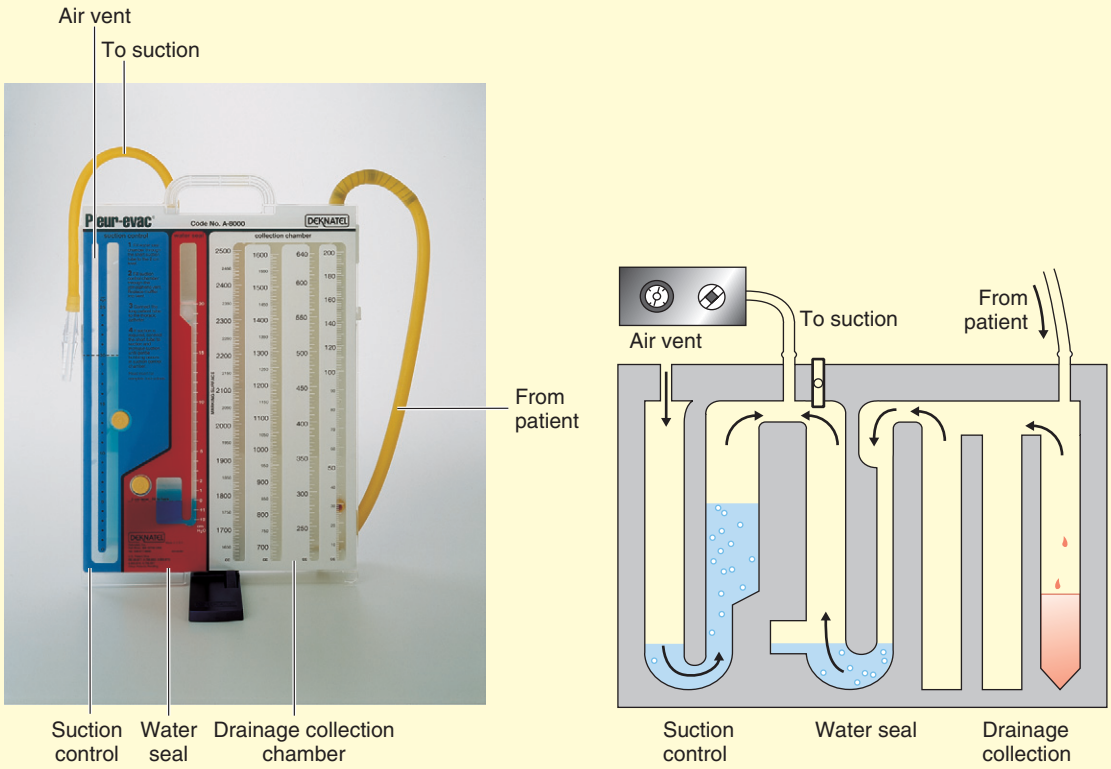
- Instruct family caregivers in how to obtain supplies. Routine tracheostomy care should be done at least once a day after discharge from hospital. At home clean technique is used with nonsterile gloves.
- Immediately after tracheostomy insertion, patients must communicate with others by writing or use of computer.
- Instruct caregivers in signs and symptoms of respiratory distress, tube dysfunction, and respiratory and stoma infections. Call health care provider if patient feels pain or discomfort longer than a week after insertion, if breathing does not improve after usual method of clearing secretions, or if secretions become thick or mucus plugs are present.
- When outside, use tracheostomy covers to protect from dust or cold air.
- Never remove the outer cannula unless instructed by health care provider to do so.

SKILL 40-3 CARE OF PATIENTS WITH CHEST TUBES

Delegation Considerations

The skill of care of patients with chest tubes cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:

- Proper positioning of patient with chest tubes to facilitate chest tube drainage and optimal function of the system.
- How to safely ambulate and transfer patient with chest drainage.
- The appropriate setup of drainage equipment for the type of system to be used.
- Reporting to the nurse any changes in vital signs or SpO_2, chest pain, sudden shortness of breath, or excessive bubbling in water-seal chamber.
- Immediately notifying the nurse if there is disconnection of system, change in type and amount of drainage, sudden bleeding, or sudden cessation of bubbling in water-seal chamber.



Equipment

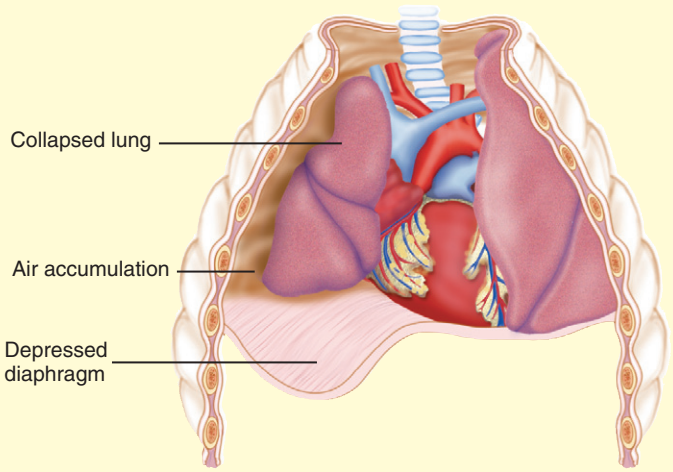
- Stethoscope
- Pulse oximeter
- Clean gloves
- Two rubber-tipped (also called *shodded*) hemostats for each tube
- 2-inch (5-cm) adhesive tape for taping connections
- Sterile gauze sponges
- Suction source and setup (wall canister or portable) if physician is inserting chest tube
- Water suction system: Add sterile water or normal saline (NS) solution to cover the lower 2.5 cm (1 inch) of water-seal U tube, sterile water or NS solution to put into the suction-control chamber if suction is to be used (see manufacturer directions)
- Waterless system: Add vial of 30 mL injectable sodium chloride or water, 20-mL syringe, 21-gauge needle, and antiseptic swab

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birthday or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Assess pulmonary status,	
a. Signs and symptoms of increased respiratory distress (displaced trachea, decreased breath sounds over affected and nonaffected lungs, marked cyanosis, asymmetrical chest movements).	Baseline measures allow you to determine if signs and symptoms of respiratory distress improve after insertion of chest tube. If respiratory distress is not relieved or worsens or if there is sharp stabbing chest pain with or without decreased blood pressure and increased heart rate, notify health care provider immediately. These symptoms indicate a pneumothorax.
b. Assess for sharp, stabbing chest pain or chest pain on inspiration; hypotension; and tachycardia. Ask patient to rate level of comfort on a scale of 0 to 10.	Symptoms may indicate a tension pneumothorax. Presence of a pneumothorax or hemothorax is painful, often causing sharp inspiratory pain.
3 Obtain baseline and serial vital signs, level of cognition, and SpO_2.	Changes in pulse, SpO_2, and blood pressure often indicate infection, respiratory distress, or pain. Cognitive changes indicate hypoxia.
4 Assess patient's current hemoglobin and hematocrit levels	Provides measure reflecting blood loss and subsequent levels of oxygenation.
5 Observe chest tube status:	
a. Chest tube dressing and site surrounding tube insertion. Apply clean gloves if drainage is present.	Ensures that dressing is intact, without air or fluid leaks, and that area surrounding insertion site is free of drainage or skin irritation.

SKILL 40-3 CARE OF PATIENTS WITH CHEST TUBES—cont'd

STEP	RATIONALE
b. Tubing for kinks, dependent loops, or clots.	Maintains patent, freely draining system, preventing fluid accumulation in chest cavity. Presence of kinks, dependent loops, or clotted drainage increases patient's risk for infection, atelectasis, and tension pneumothorax (Centre for Reviews and Dissemination, 2008).
c. Check existing drainage system to ensure that it is upright and below level of tube insertion. Note amount of drainage in system (see illustration).	Facilitates drainage. Ensures that system is in this position to function properly.

STEP 5c *Left,* Pleur-Evac drainage system, a commercial three-bottle chest drainage device. *Right,* Schematic of drainage device.



PLANNING

1 Provide two rubber-tipped hemostats or approved clamps for each chest tube, attached to top of patient's bed with adhesive tape. Chest tubes are only clamped under specific circumstances per health care provider's order or nursing policy and procedure: **a.** To assess air leak. **b.** To quickly empty or change disposable systems; performed by a nurse who has received education in the procedure. **c.** To assess if patient is ready to have chest tube removed (which is done by health care provider's order); monitor patient for recurrent pneumothorax (see illustration).	Hemostat has a covering to prevent it from penetrating chest tube. Use of these rubber-tipped hemostats or other clamps prevents air from reentering pleural space in emergencies (Rushing, 2007).
2 Position patient.	Permits optimal drainage of fluid and/or air.
a. Semi-Fowler's position to evacuate air (pneumothorax)	Air rises to highest point in chest. Pneumothorax tubes are usually placed on anterior aspect at midclavicular line, second or third intercostal space.
b. High-Fowler's position to drain fluid (hemothorax, effusion)	Permits optimal drainage of fluid. Posterior tubes are placed on midaxillary line, eighth or ninth intercostal space.

IMPLEMENTATION

1 Be sure that tube connection between chest and drainage tube is intact and taped.	Secures chest tube to drainage system and reduces risk of air leak causing breaks in airtight system.
a. Make sure that water-seal vent on drainage system is not occluded.	Permits displaced air to pass into atmosphere.
b. Make sure that suction-control chamber vent is not occluded when using suction. Waterless systems have relief valves without caps.	Provides safety factor of releasing excess negative pressure into atmosphere.

STEP	RATIONALE

STEP 1c Pneumothorax. (From Seidel HM et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2011, Mosby.)

2 Coil excess drainage tubing on mattress next to patient. Secure with rubber band, safety pin, or plastic clamp. Allow enough room for patient to reposition.	Prevents excess tubing from hanging over edge of mattress in dependent loop. It is possible for drainage to collect in loop and occlude drainage system (Centre for Reviews and Dissemination, 2008).
3 Adjust tubing to hang in straight line from top of mattress to drainage chamber.	Promotes drainage and prevents fluid or blood from accumulating in pleural cavity (Halm, 2007).
4 If chest tube is draining fluid, indicate time (e.g., 0900) that you began measuring drainage on adhesive tape on drainage bottle or on write-on surface of disposable commercial system.	Provides a baseline for continuous assessment of type and quality of drainage.
5 Strip or milk chest tube only if indicated (this means compressing along tube to encourage clots to pass through the tube) (See agency policy.) Stripping is compression along length of tubing beginning at patient and continuing until reaching drainage unit. Milking is compressing and releasing tube sequentially.	Stripping may cause complications because it can create excessive negative intrapleural pressure (over 100 cm H_2O). Milking causes less of a pressure change and is recommended (Halm, 2007).
a. Manipulate postoperative mediastinal chest tubes if assessment indicates an obstruction or decreased drainage from clots or debris in tubing.	Stripping is performed only if hospital policy permits and there is a health care provider's order. There is no evidence that stripping or milking increases output or causes significant complications (Centre for Reviews and Dissemination, 2008).
6 Perform hand hygiene.	Reduces transmission of infection.
EVALUATION	
1 Monitor vital signs and pulse oximetry as ordered or if patient's condition changes.	Provides ongoing data about patient's level of oxygenation.
Evaluate patient for decreased respiratory distress and chest pain, auscultate lung sounds over affected lung area, and monitor SpO_2.	Increasing respiratory distress, decreased breath sounds, marked cyanosis, asymmetrical chest wall movements, presence of subcutaneous emphysema around insertion site or neck, hypotension, tachycardia, and/or mediastinal shift are critical and indicate a severe change in patient status such as excessive blood loss or tension pneumothorax. Notify health care provider immediately.
2 Observe:	
a. Appearance of chest tube dressing.	Drainage is often caused by tube occlusion, causing drainage to exit around tube.
CLINICAL DECISION: *Check the dressing carefully because it needs to remain occlusive. It can come loose from the skin, although this is not readily apparent. Assess for drainage and reinforce to maintain seal. Follow hospital policy as needed.*	
b. Make sure that tubing is free of kinks and dependent loops.	Straight and coiled drainage tube positions are optimal for pleural drainage. However, when a dependent loop is unavoidable, periodic lifting and draining the tube promote pleural drainage.
c. Make sure that chest drainage system is upright and below level of tube insertion. Note presence of clots or debris in tubing. Monitor position of system relative to chest tube carefully, especially during patient transport.	System must be in the upright position to function and facilitate proper drainage.

SKILL 40-3 CARE OF PATIENTS WITH CHEST TUBES—cont'd

STEP	RATIONALE
d. Observe water seal for fluctuations with patient's inspiration and expiration.	Indicates appropriate function of negative pressure system.
(1) *Waterless system:* Diagnostic indicator for fluctuations with patient's inspirations and expirations	In nonmechanically ventilated patient, fluid rises in water seal or diagnostic indicator with inspiration and falls with expiration. Opposite occurs in patient who is mechanically ventilated. This indicates that system is functioning properly (Lewis et al., 2007).
(2) *Water-seal system:* Bubbling in water-seal chamber	When system is initially connected to patient, expect bubbles from the chamber. These are from air present in system and from patient's intrapleural space. After a short time bubbling stops. Fluid continues to fluctuate in water seal on inspiration and expiration until lung reexpands or system is occluded.
(3) *Water-seal system:* Bubbling in suction-control chamber (when using suction)	Suction-control chamber has constant gentle bubbling. Tubing remains free of obstruction, and suction source is turned to appropriate setting.
e. Observe type and amount of fluid drainage: note color of drainage and skin color. Look at fluid in drainage tubing and not just in collection chamber. What is the normal amount of drainage? Is it bright red, dark red, or pink? Is it opaque, or can you see through it?	Character of drainage indicated if it is as expected or if infection or hemorrhage is developing.
(1) *In adult:* less than 50 to 200 mL/hr immediately after surgery in a mediastinal chest tube; approximately 500 mL in first 24 hours.	Dark-red drainage is normal only in postoperative period, turning serous with time.
(2) Between 100 and 300 mL of fluid drains in a pleural chest tube in an adult during first 3 hours after insertion. Rate decreases after 2 hours; expect 500 to 1000 mL in first 24 hours. Drainage is grossly bloody during first several hours after surgery and then changes to serous. Sudden gush of drainage is often retained blood and not active bleeding and is usually the result of patient repositioning (Lewis et al., 2007).	Reexpansion of lungs forces drainage into tube. Coughing also causes large gushes of drainage or air. Report excessive amounts and/or continued presence of frank, bloody drainage the first several hours after surgery to health care provider, along with patient's vital signs and respiratory status.

CLINICAL DECISION: *If drainage increases suddenly or is bright red or if there is more than 100 mL/hr of bloody drainage (except for the first 3 hours after surgery), notify the health care provider, remain with the patient, and assess vital signs and cardiopulmonary status. This may indicate hemorrhage or perforation of the lung.*

f. *Waterless system:* The suction control (float ball) indicates the amount of suction that patient's intrapleural space is receiving.	Suction float ball dictates amount of suction in system. Float ball allows no more suction than dictated by its setting. If suction source is set too low, suction float ball cannot reach prescribed setting. In this case increase suction for float ball to reach the prescribed setting.
g. Ask patient to rate level of comfort on a scale of 0 to 10.	Indicates need for analgesia. Patient with chest tube discomfort hesitates to take deep breaths and as a result is at risk for pneumonia and atelectasis.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Air leak unrelated to patient respirations
- Assess all connections between patient and drainage system to find source and tighten any loose connections (Coughlin and Parchinsky, 2006).
- If air leak persists, notify health care provider to change drainage system.

2 Tension pneumothorax present
- Determine that chest tubes are not clamped, kinked, or occluded. Obstructed chest tubes trap air in intrapleural space when air leak originates within patient and can cause a tension pneumothorax.
- Notify patient's health care provider immediately.
- Prepare immediately for another chest tube insertion; obtain a flutter (Heimlich) valve or large-gauge needle for short-term emergency release of air in intrapleural space; have emergency equipment (e.g., oxygen, code cart) near patient.

3 Continuous bubbling in water-seal chamber, indicating that leak is between patient and water seal
- Tighten loose connections between patient and water-seal system.
- Check agency policy and, if instructed, cross-clamp chest tube closer to patient's chest using hemostat clamps. If bubbling stops, the air leak is inside patient's thorax or at chest tube insertion site.
- Unclamp chest tube.
- Reinforce dressing.
- Notify health care provider.

RECORDING AND REPORTING

- Record and report patency of chest tube; presence, type, and amount of drainage; presence of fluctuations; patient's vital signs; chest dressing status; amount of suction and/or water seal; and patient's level of comfort.

HOME CARE CONSIDERATIONS

- Patients with chronic conditions (e.g., uncomplicated pneumothorax, effusions, empyema) that require long-term chest tube may be discharged with smaller mobile drains. These systems do not have a suction-control chamber and use a mechanical one-way valve instead of a water-seal chamber.
- Instruct patient in how to ambulate and remain active with a mobile chest tube drainage system.
- Provide patient with information as to when to contact health care professionals regarding changes in health status or drainage system (e.g., chest pain, breathlessness, change in drainage).

SKILL 40-4 APPLYING A NASAL CANNULA OR OXYGEN MASK

View Video!

Delegation Considerations

The skill of applying (not adjusting oxygen flow) a nasal cannula or oxygen mask can be delegated to nursing assistive personnel (NAP). The nurse is responsible for assessing patient's respiratory system; response to oxygen therapy; and setup of oxygen therapy, including adjustment of oxygen flow rate. Direct the NAP by:

- Informing how to safely position and adjust the device (e.g., loosening the strap on oxygen mask) and clarifying its correct placement and positioning.
- Instructing to inform the nurse immediately about any vital sign changes; skin irritation from the cannula, mask, or straps; if patient reports pain or breathlessness; or if patient presents with decreased level of consciousness or increased confusion.
- Having personnel provide skin care around patient's ears and nose.

Equipment

- Oxygen-delivery device as ordered by patient's health care provider
- Oxygen tubing (consider extension tubing)
- Humidifier if indicated
- Sterile water for humidifier
- Oxygen source
- Oxygen flowmeter
- Stethoscope, pulse oximeter
- Appropriate room signs

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Assess patient's respiratory status, including symmetry of chest wall expansion, chest wall abnormalities (e.g., kyphosis), temporary conditions (e.g., pregnancy, trauma) affecting ventilation, respiratory rate and depth, sputum production, and lung sounds.	Decreased chest wall movement, crackles or decreased lung sounds, increased respiratory rate, increased sputum production, and/or hypoxia indicate need for noninvasive ventilation to improve oxygenation.
3 Observe for patent airway and remove secretions by having patient cough and expectorate mucus or by suctioning.	Presence of airway secretions decreases effectiveness of oxygen delivery by plugging airway.
CLINICAL DECISION: *Patients with sudden changes in their vital signs, level of consciousness, or behavior are often experiencing profound hypoxia. Patients who demonstrate subtle changes over time have worsening of a chronic or existing condition or a new medical condition (Jarvis, 2006).*	
4 Obtain patient's most recent SpO_2 or arterial blood gas (ABG) values if available.	Provides objective baseline data to use to compare outcome of oxygen therapy.
5 Review patient's medical record for medical order for oxygen, noting delivery method, flow rate, and duration of oxygen therapy.	Ensures safe and accurate oxygen administration. Safe oxygen delivery includes the six rights of medication administration.
PLANNING	
1 Explain to patient and family what happens during procedure and the purpose of oxygen therapy.	Decreases patient's anxiety, which reduces oxygen consumption and increases patient/family adherence and cooperation.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of infection.
2 Attach oxygen-delivery device (e.g., nasal cannula or mask) to oxygen tubing and attach to humidified oxygen source adjusted to prescribed flow rate (see illustration).	Humidity prevents drying of nasal and oral mucous membranes and airway secretions. Ensures correct oxygen delivery.
3 Position tips of nasal cannula properly in patient's nares and adjust elastic headband or plastic slide on cannula so it is snug and comfortable (see illustration). Position face mask so it is snug and comfortable. If using an oxygen mask, adjust elastic headband until mask fits comfortably over patient's face and mouth.	Directs flow of oxygen into patient's upper respiratory tract. Patient is more likely to keep cannula or face mask in place if it fits comfortably.

SKILL 40-4 APPLYING A NASAL CANNULA OR OXYGEN MASK—cont'd

STEP	RATIONALE

STEP 2 Adjusting flowmeter to prescribed oxygen flow rate.

STEP 3 Applying nasal cannula and adjusting fit to patient comfort.

4 Maintain sufficient slack on oxygen tubing and secure to patient's clothes.
Allows patient to turn head without removing oxygen mask or dislodging cannula and reduces pressure on tips of nares.

5 Observe for proper functioning of oxygen-delivery device:
Ensures patency of delivery device and proper oxygen flow.

- **a.** *Nasal cannula:* Cannula is positioned properly in nares with humidification functioning.
  Oxygen therapy causes drying of nasal mucosa. Oxygen delivered at flow rates greater than 4 L/min must be humidified (AARC, 2002).
- **b.** *Reservoir nasal cannula Oxymizer:* Fit as for nasal cannula. Reservoir is positioned under patient's nose or worn as a pendant.
  Delivers higher flow of oxygen than cannula without changing to a mask, which is claustrophobic for some patients. Delivers a 2:1 ratio (e.g., 6 L/min nasal cannula is approximately equivalent to 3.5 L/min with Oxymizer device).
- **c.** *Nonrebreathing mask*: Apply mask over patient's mouth and nose to form tight seal. Valves on mask close so exhaled air does not enter reservoir bag.
  Does not allow exhaled air to be rebreathed. Valves on mask side ports permit exhalation but close during inhalation to prevent inhaling room air.
- **d.** *Partial rebreathing mask:* Apply mask over patient's mouth and nose to form tight seal. Ensure that bag remains partially inflated.
  Allow exhaled air to mix with inhaled air. Port on side of mask permits most of expired air to escape; however, the bag remains partially inflated.
- **e.** *Venturi mask:* Apply mask over patient's mouth and nose to form a tight seal. Select appropriate flow rate.
  Reduces carbon dioxide buildup.
- **f.** *Face tent:* Apply tent under patient's chin and over mouth and nose. It will be loose, and a mist is always present.
  Excellent source of humidification; however, you cannot control oxygen concentrations.

6 Verify setting on flowmeter and oxygen source for proper setup and prescribed flow rate.
Ensures delivery of prescribed oxygen therapy in conjunction with the specific cannula/mask.

7 Check cannula/mask every 8 hours. Keep humidification container filled at all times.
Ensures patency of cannula and oxygen flow. Oxygen is a dry gas: when it is administered via any route, you must add humidification so the patient inhales humidified oxygen (Woodrow, 2007).

8 Perform hand hygiene.
Reduces transmission of microorganisms.

EVALUATION

1 Monitor patient's response to changes in oxygen flow rate with pulse oximetry. NOTE: Monitor ABGs when ordered; however, obtaining ABG measurement is an invasive procedure, and ABGs are not measured frequently.
Continual monitoring with pulse oximetry is required for patients on oxygen therapy. Base changes in supplemental oxygen on individual patient's oxygen saturation levels.

2 Observe for decreased anxiety, improved level of consciousness and cognitive abilities, decreased fatigue, absence of dizziness, decreased respiratory rate, improved color, improved oxygen saturation, and return to patient's baseline vital signs.
Evaluates patient's response to supplemental oxygen. As patient's oxygen level improves, physical signs and symptoms improve.

3 Check adequacy of oxygen flow each shift.
Ensures patency of oxygen-delivery device.

4 Observe patient's external ears, bridge of nose, nares, and nasal mucous membranes for evidence of skin breakdown.
Oxygen therapy sometimes causes drying of nasal mucosa. The delivery device can cause skin breakdown where it comes in contact with face, neck, and ears.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient experiences continued hypoxia.
- Check that oxygen-delivery device is patent, not kinked, and attached to oxygen flowmeter.
- Check oxygen level set on flowmeter; determine if delivered amount is consistent with health care provider's order.
- Obtain orders for follow-up pulse oximetry monitoring or ABG assessment.
- Consider measures to improve airway patency, coughing techniques, and oropharyngeal suctioning.
- Notify health care provider.

2 Dry nasal and upper airway mucosa or epistaxis.
- If oxygen flow rate is greater than 4 L/min, determine need for humidification.
- Assess patient's fluid status and increase fluids if appropriate.
- Provide frequent oral care.
- Obtain health care provider's order for use of sterile nasal saline intermittently.

3 Skin irritation or breakdown (e.g., at ears, bridge of nose, nares, other pressure areas).
- Adjust tightness of elastic strap to looser level.
- Provide good hygiene and skin care around the ears.
- Use soft, woven 4 × 4s as nonabrasive pad between elastic and ears.
- Reposition elastic strap frequently.

RECORDING AND REPORTING

- Record and report type of oxygen-delivery device and liter flow in medical record; document patient and family education.
- Record respiratory assessment findings; patient response to oxygen therapy, and any adverse reactions or side effects.
- Report any unexpected outcomes to health care provider or nurse in charge.

SKILL 40-5 USING HOME OXYGEN EQUIPMENT

Delegation Considerations

The skill of administering home oxygen equipment cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP about:
- The unique needs of patient (e.g., amount of assistance in applying nasal cannula or mask) and any assistance needed in filling liquid canisters.
- The type of equipment patient should have in the home and the oxygen flow rate.
- Immediately reporting to the nurse increased rate of breathing, decreased level of consciousness, increased confusion, and pain.

Equipment

- Nasal cannula equipment (see Skill 40-4)
- Humidification device if oxygen delivery greater than 4 L/min
- Oxygen tubing available in lengths of 50 feet
- Home low-flow oxygen-delivery system with appropriate equipment

STEP	RATIONALE
ASSESSMENT	
1 While patient is still in the hospital, determine patient's or family caregiver's ability to use oxygen equipment correctly. In home setting reassess for appropriate use of equipment.	Physical or cognitive impairments necessitate instructing family member or significant other how to operate home oxygen equipment. Ongoing assessment enables nurse to determine specific components of skill that patient or family can complete easily.
2 Assess home environment for adequate electrical service if oxygen concentrator is ordered.	Oxygen concentrators require electricity to work. Continuous oxygen therapy must not be interrupted.
3 Assess patient's and family's ability to observe for signs and symptoms of hypoxia: apprehension, anxiety, decreased ability to concentrate, decreased level of consciousness, increased fatigue, dizziness, behavioral changes, increased pulse, increased respiratory rate, pallor, or cyanosis of the mucous membranes.	Hypoxia occurs at home despite use of oxygen therapy. Worsening of patient's physical condition or another underlying condition such as change in the respiratory status can cause hypoxia.
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Determine appropriate resources in community for equipment and assistance, including maintenance and repair services and medical equipment supplier.	Ensures readily available assistance for patients with home oxygen systems. Delivery and setup with basic instruction on how to use and maintain the home oxygen equipment must be in accordance with federal, state, and local laws (AARC, 2007).

SKILL 40-5 USING HOME OXYGEN EQUIPMENT—cont'd

STEP	RATIONALE
3 In case of power failure, determine appropriate backup systems when using compressor. Have spare oxygen tank available.	Many municipalities require that patients with home oxygen equipment notify emergency medical service (EMS) before bringing the equipment home. When there is a power outage, EMS calls the home, and in some cases the home is on a priority list for power restoration.
4 Obtain appropriate referrals to determine if patient meets standards for third-party reimbursement.	Indications include (1) a PaO_2 less than or equal to 55 mm Hg or SaO_2 less than or equal to 88% breathing room air; (2) PaO_2 less than or equal to 56-59 mm Hg or SaO_2 less than or equal to 89% with conditions such as cor pulmonale, heart failure, or hematocrit greater than 56%; (3) oxygen therapy is needed during activities that cause hypoxia such as ambulation, sleep, or exercise causing an SaO_2 of less than or equal to 88% (AARC, 2007).
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of infection.
2 Place oxygen-delivery system in clutter-free environment that is well ventilated; away from walls, drapes, bedding, and combustible materials; and at least 8 feet from heat source.	Prevents injury from improper placement of oxygen equipment.
3 Demonstrate each step for preparation and completion of oxygen therapy.	Teaches psychomotor skills and enables patient to ask questions.
a. Compressed oxygen system—available in large cylinders as stationary units or smaller, lightweight cylinders in carrying bags and/or wheel carts.	Smaller units are used for ambulation and as a backup of stationary unit if there is power failure or equipment malfunction (AARC, 2007).
(1) Turn cylinder valve counterclockwise two or three turns with wrench. Store wrench with oxygen tank.	Turns on oxygen. Keeps wrench available.
(2) Check cylinders by reading amount on pressure gauge (see illustration).	Verifies adequate oxygen supply for patient use.

STEP 3a(2) Verify oxygen level by reading gauge on top of canister.

b. Oxygen concentrator system—available as stationary unit or portable device.	Extracts oxygen from other gases in atmospheric air (AARC, 2007).
(1) Plug concentrator into appropriate outlet.	Provides power source. Make sure that it is in an open area and never in a closet or other closed space (Cleveland Clinic, 2010b).
(2) Turn on power switch.	Starts concentrator motor.
(3) Alarm sounds for a few seconds.	Alarm turns off when desired pressure inside concentrator is reached.
c. Liquid oxygen systems—available in large-reservoir canisters that can be used to refill a smaller portable unit (AARC, 2007). Portable unit weighs 5 to 13 lbs and can be carried with a shoulder strap or pulled on a cart.	When liquid oxygen is warmed, it goes from liquid to gas. More oxygen can be stored as a liquid than gas.
d. Refill oxygen tank	
(1) Check for amount of oxygen in tank	If not in use, evaporation empties portable canister; thus always check it before use (Cleveland Clinic, 2001b).
(2) Wipe both filling connectors with clean, dry, lint-free cloth.	Removes dust and moisture from system.
(3) Turn off flow selector of ambulatory unit.	
(4) Attach ambulatory unit to stationary reservoir by inserting adapter from ambulatory tank into adapter of stationary reservoir.	

STEP	RATIONALE
(5) Open fill valve on ambulatory tank and apply firm pressure to top of stationary reservoir (see illustration). Stay with unit while it is filling. You will hear a loud hissing noise. Tank fills in about 2 minutes.	Prevents leaking of oxygen during filling process. If oxygen leaks during filling process, connection between ambulatory tank and reservoir ices up and valves stick together.

STEP 3d(5) Open fill valve on ambulatory tank while applying firm pressure to top of ambulatory unit.

(6) Disengage ambulatory unit from stationary reservoir when hissing noise changes and vapor cloud begins to form from stationary unit.	Overfilling causes ambulatory unit to malfunction caused by high pressure in tank.
(7) Wipe both filling connectors with clean, dry, lint-free cloth.	Ice sometimes forms during filling. Removes moisture from oxygen system.

CLINICAL DECISION: *If ambulatory unit does not separate easily, valves from reservoir and ambulatory unit may be frozen together. Wait until valves warm to disengage (about 5 to 10 minutes). Do not touch any frosted areas because contact with skin causes skin damage from frostbite.*

4 Connect oxygen-delivery device to oxygen system.	Connects oxygen source to delivery system.
5 Adjust to prescribed flow rate (L/min).	Ensures appropriate oxygen prescription.
6 Place oxygen-delivery device on patient.	Delivers oxygen to patient.
7 Perform hand hygiene.	Reduces transmission of microorganisms.
8 Instruct patient and family not to change oxygen flow rate.	
9 Guide patient and family caregiver as they perform each step. Provide written material for reinforcement and review.	Allows nurse to correct for errors in technique and discuss their implications.
10 Instruct patient and family caregiver to notify health care provider if signs or symptoms of hypoxia or respiratory tract infection (e.g., fever, increased sputum, change in color of sputum, or odor) occur.	Respiratory tract infections increase oxygen demand and affect oxygen transfer from lungs to blood. Can create severe exacerbation of patient's pulmonary disease.
11 Discuss emergency plan for power loss, natural disaster, and acute respiratory distress. Have patient or family/caregiver call 911 and notify health care provider and home care agency.	Ensures appropriate response and prevents worsening of patient's condition.
12 Instruct patient and family caregiver in safe home oxygen practices, including not allowing smoking in the house, keeping oxygen tanks away from open flame, and storing tanks upright.	Ensures safe use of oxygen in the home and prevents injury to patient and family.
13 Monitor oxygen-delivery rate. All oxygen-delivery equipment should be checked at least daily by patient or caregiver.	Determines if patient is using oxygen at prescribed rate.
14 Oxygen-delivery equipment must be maintained and serviced routinely according to manufacturer's guidelines (AARC, 2007).	Routine maintenance ensures proper function of equipment.

SKILL 40-5 USING HOME OXYGEN EQUIPMENT—cont'd

STEP	RATIONALE
EVALUATION	
1 Ask patient and family caregiver about ease of administering or problems associated with home oxygen.	Determines ability of patient and family to deal with stressors associated with home oxygen use.
2 Ask patient and family caregiver to state safety guidelines, emergency precautions, and emergency plan.	Determines patient's knowledge of what to do if power fails, there is a failure in equipment, or patient's status worsens.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient reports no oxygen flow.
- Check tank pressure gauge. If level of oxygen is low, refill tank if portable or provide alternate source of oxygen such as concentrator.
- Notify home oxygen supplier of need for refill.
- Reassure patient and family.

2 Patient or family caregiver is unable to fill portable liquid oxygen from main source.
- Check to see that portable tank is connected correctly.
- Determine if valve is frozen.
- Contact home oxygen supplier for service visit.
- Provide alternate oxygen source if necessary.

RECORDING AND REPORTING

- Record teaching plan and patient's and family caregiver's ability to safely use home oxygen equipment; report type of home oxygen equipment to be used, patient's and family's understanding of how to use equipment, knowledge of safety guidelines and unexpected outcomes, and ability to return demonstrate proper use of oxygen-delivery device.

KEY POINTS

- The primary function of the lungs is to transfer oxygen from the atmosphere into the alveoli and carbon dioxide out of the body as a waste product.
- Changes in intrapleural and intraalveolar pressures and lung volumes cause the process of inspiration (active process) and expiration (passive process).
- Decreased hemoglobin levels alter the patient's ability to transport oxygen.
- Impaired chest wall movement reduces the level of tissue oxygenation.
- Hyperventilation is a respiratory rate greater than that required to maintain normal levels of carbon dioxide.
- Hypoventilation causes carbon dioxide retention.
- Hypoxia occurs if the amount of oxygen delivered to tissues is too low.
- The primary functions of the heart are to deliver deoxygenated blood to the lungs for oxygenation and oxygen and nutrients to the tissues.
- The nursing history includes information about the patient's cough, dyspnea, fatigue, wheezing, chest pain, environmental exposures, respiratory infection, cardiopulmonary risk factors, and use of medications.
- Nursing assessment includes respiratory pattern, thoracic inspection, palpation, and auscultation for deviations from normal.
- Diagnostic and laboratory tests complete the database for a patient with decreased oxygenation.
- Health promotion includes vaccinations against flu and pneumonia, exercise programs, nutrition support, smoking cessation, and environmental assessment for pollutants and air quality.
- Airway maintenance requires mobilization of secretions by increased fluid intake, humidification, or nebulization.
- Breathing exercises improve ventilation, oxygenation, and sensations of dyspnea.
- Chest physiotherapy includes postural drainage, percussion, and vibration to mobilize pulmonary secretions.
- Airway maintenance may require use of artificial airways and suctioning.
- Promotion of lung expansion can be achieved by mobility, positioning, incentive spirometry, and chest tube insertion.
- Nasal cannulas and oxygen masks deliver oxygen therapy, which improves the levels of tissue oxygenation.
- Learning breathing exercises, including pursed-lip breathing and diaphragmatic breathing, benefits patients with chronic pulmonary diseases.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Forty-eight hours after admission to the hospital, Mr. Edwards had abnormal lung sounds (crackles) in the left base and both upper lobes. His vital signs were as follows: temperature, 102.4° F (39.1° C); blood pressure, 140/92 mm Hg; pulse, 110 beats/min; respirations, 32 breaths/min; and SpO_2, 82%. He could not lie flat, and it was difficult for him to speak because of dyspnea. He was placed on a nonrebreather mask at an oxygen concentration of 60%. He was also unable to cough up any sputum.

Mr. Edwards's health care provider determined his pneumonia had worsened. A chest x-ray film and arterial blood gas levels were obtained. His chest x-ray film indicated that both upper lobes and the left lower lobe had infiltrates. The arterial blood gas levels indicated respiratory acidosis (see Chapter 41). His PaO_2 was 55 mm Hg, $PaCO_2$ was 65 mm Hg, pH was 7.30, and SpO_2 was

80%. He spent 5 days in an intensive care unit (ICU) and 2 weeks in a transitional care unit. He is being discharged on home oxygen therapy. His discharge plan includes an outpatient rehabilitation program to begin 1 month after discharge.

1. When Mr. Edwards was hypoxic (PaO_2 55 mm Hg, SpO_2 80%), which additional assessment findings would you expect to find?
2. Based on the case scenario and information in Question 1, determine the two priority nursing diagnoses for Mr. Edwards and list the appropriate interventions or nursing activities that you must implement.
3. What do you need to do to prepare Mr. and Mrs. Edwards for home oxygen therapy?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient who started smoking in adolescence and continues to smoke 40 years later comes to the clinic. The nurse understands that this patient has an increased risk for being diagnosed with which disorder:
   1. Alcoholism and hypertension
   2. Obesity and diabetes
   3. Stress-related illnesses
   4. Cardiopulmonary disease and lung cancer
2. A patient has been diagnosed with severe iron deficiency anemia. During physical assessment for which of the following symptoms would the nurse assess to determine the patient's oxygen status?
   1. Increased breathlessness but increased activity tolerance
   2. Decreased breathlessness and decreased activity tolerance
   3. Increased activity tolerance and decreased breathlessness
   4. Decreased activity tolerance and increased breathlessness
3. A patient is admitted to the emergency department with suspected carbon monoxide poisoning. Even though the patient's color is ruddy, not cyanotic, the nurse understands that the patient is at a risk for decreased oxygen-carrying capacity of blood because carbon monoxide does which of the following:
   1. Stimulates hyperventilation, causing respiratory alkalosis
   2. Forms a strong bond with hemoglobin, creating a functional anemia.
   3. Stimulates hypoventilation, causing respiratory acidosis
   4. Causes alveoli to overinflate, leading to atelectasis
4. A 6-year-old boy is admitted to the pediatric unit with chills and a fever of 104° F (40° C). What physiological process explains why the child is at risk for developing dyspnea?
   1. Fever increases metabolic demands, requiring increased oxygen need.
   2. Blood glucose stores are depleted, and the cells do not have energy to use oxygen.
   3. Carbon dioxide production increases as result of hyperventilation.
   4. Carbon dioxide production decreases as a result of hypoventilation.
5. A patient is admitted with the diagnosis of severe left-sided heart failure. The nurse expects to auscultate which adventitious lung sounds?
   1. Sonorous wheezes in the left lower lung
   2. Rhonchi midsternum
   3. Crackles only in apex of lungs
   4. Inspiratory crackles in lung bases
6. The nurse is caring for a patient who has decreased mobility. Which intervention is a simple and cost-effective method for reducing the risks of stasis of pulmonary secretions and decreased chest wall expansion?
   1. Antibiotics
   2. Frequent change of position
   3. Oxygen humidification
   4. Chest physiotherapy
7. A patient is admitted with severe lobar pneumonia. Which of the following assessment findings would indicate that the patient needs airway suctioning?
   1. Coughing up thick sputum only occasionally
   2. Coughing up thin, watery sputum easily after nebulization
   3. Decreased independent ability to cough
   4. Lung sounds clear only after coughing
8. A patient was admitted after a motor vehicle accident with multiple fractured ribs. Respiratory assessment includes signs/symptoms of secondary pneumothorax, which includes which of the following?
   1. Sharp pleuritic pain that worsens on inspiration
   2. Crackles over lung bases of affected lung
   3. Tracheal deviation toward the affected lung
   4. Increased diaphragmatic excursion on side of rib fractures
9. A patient has been newly diagnosed with emphysema. In discussing his condition with the nurse, which of his statements would indicate a need for further education?
   1. "I'll make sure that I rest between activities so I don't get so short of breath."
   2. "I'll rest for 30 minutes before I eat my meal."
   3. "If I have trouble breathing at night, I'll use two to three pillows to prop up."
   4. "If I get short of breath, I'll turn up my oxygen level to 6 L/min."
10. The nurse goes to assess a new patient and finds him lying supine in bed. The patient tells the nurse that he feels short of breath. Which nursing action should the nurse perform first?
    1. Raise the head of the bed to 45 degrees.
    2. Take his oxygen saturation with a pulse oximeter.
    3. Take his blood pressure and respiratory rate.
    4. Notify the health care provider of his shortness of breath.
11. The nurse is caring for a patient who exhibits labored breathing and uses accessory muscles. The patient has crackles in both lung bases and diminished breath sounds. Which would be priority assessments for the nurse to perform? (Select all that apply.)
    1. SpO_2 levels
    2. Amount of sputum production
    3. Change in respiratory rate and pattern
    4. Pain in lower calf area
12. Which of the following statements made by a student nurse indicates the need for further teaching about suctioning a patient with an endotracheal tube?
    1. "Suctioning the patient requires sterile technique."
    2. "I'll apply suction while rotating and withdrawing the suction catheter."
    3. "I'll suction the mouth after I suction the endotracheal tube."
    4. "I'll instill 5 mL of normal saline into the tube before hyperoxygenating the patient."
13. Two hours after surgery the nurse assesses a patient who had a chest tube inserted during surgery. There is 200 mL of

dark-red drainage in the chest tube at this time. What is the appropriate action for the nurse to perform?
1. Record the amount and continue to monitor drainage
2. Notify the health care provider
3. Strip the chest tube starting at the chest
4. Increase the suction by 10 mm Hg

14. Which nursing intervention is appropriate for preventing atelectasis in the postoperative patient?
1. Postural drainage
2. Chest percussion
3. Incentive spirometer
4. Suctioning

15. The nurse needs to apply oxygen to a patient who has a precise oxygen level prescribed. Which of the following oxygen-delivery systems should the nurse select to administer the oxygen to the patient?
1. Nasal cannula
2. Venturi mask
3. Simple face mask without inflated reservoir bag
4. Plastic face mask with inflated reservoir bag

CHAPTER

41

Fluid, Electrolyte, and Acid-Base Balance

OBJECTIVES

- Describe the processes involved in regulating extracellular fluid volume, body fluid osmolality, and fluid distribution.
- Describe the processes involved in regulating plasma concentrations of potassium, calcium, magnesium, and phosphate ions.
- Describe the processes involved in regulating acid-base balance.
- Describe common fluid, electrolyte, and acid-base imbalances.
- Identify risk factors for fluid, electrolyte, and acid-base imbalances.
- Choose appropriate clinical assessments for specific fluid, electrolyte, and acid-base imbalances.
- Interpret basic fluid, electrolyte, and acid-base laboratory values.
- Apply the nursing process when caring for patients with fluid, electrolyte, and acid-base imbalances.
- Discuss purpose and procedure for initiation and maintenance of intravenous therapy.
- Calculate an intravenous flow rate.
- Describe how to measure and record fluid intake and output.
- Explain how to change intravenous solutions and tubing and discontinue an infusion.
- Describe potential complications of intravenous therapy and what to do if they occur.
- Discuss the procedure for initiating a blood transfusion and interventions to manage a transfusion reaction.

Fluid surrounds all the cells in the body and is also inside cells. Body fluids contain electrolytes such as sodium and potassium; they also have a certain degree of acidity. Fluid, electrolyte, and acid-base balances within the body maintain the health and function of all body systems. The characteristics of body fluids influence body system function because of their effects on cell function. These characteristics include the fluid amount (volume), concentration (osmolality), composition (electrolyte concentration), and degree of acidity (pH). All of these characteristics have regulatory mechanisms, which keeps them in balance for normal function. In this chapter you learn how the body normally maintains fluid, electrolyte, and acid-base balance. You also learn how

imbalances develop; how various fluid, electrolyte, and acid-base imbalances affect patients; and ways to help patients maintain or restore balance safely.

SCIENTIFIC KNOWLEDGE BASE

This section provides the foundation for your critical thinking regarding patients who have or are at risk of having, fluid, electrolyte, or acid-base imbalances.

Location and Movement of Water and Electrolytes

Water makes up a substantial proportion of body weight. In fact, about 60% of the body weight of an adult man is water. This proportion decreases with age; approximately 50% of an older man's weight is water. Women typically have less water content than men. Obese people have less water in their bodies than lean people because fat contains less water than muscle. The term **fluid** means water that contains dissolved or suspended substances such as glucose, mineral salts, and proteins.

Fluid Compartments. Body fluids are located in two distinct compartments: **extracellular fluid (ECF)** outside the cells, and **intracellular fluid (ICF)** inside the cells (Fig. 41-1). In adults ICF is approximately two thirds of total body water. ECF is approximately one third of total body water. ECF has two major divisions **(intravascular fluid** and **interstitial fluid)** and a minor division **(transcellular fluids).** Intravascular fluid is the liquid portion of the blood (i.e., the plasma). Interstitial fluid is located between the cells and outside the blood vessels. Transcellular fluids such as cerebrospinal, pleural, peritoneal, and synovial fluids are secreted by epithelial cells (Hall, 2011).

Fluid in the body compartments contains mineral salts known technically as **electrolytes.** An electrolyte is a compound that separates into **ions** (charged particles) when it dissolves in water. Ions that are positively charged are called **cations;** ions that are negatively charged are called **anions.** Cations in body fluids are sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium ions (Mg^{2+}). Anions in body fluids are chloride (Cl^-) and bicarbonate (HCO_3^-). Anions and cations combine to make salts. If you put table salt (NaCl) in water, it separates into Na^+ and Cl^-. Other combinations of anions and cations do the same. Clinical laboratories usually report electrolyte measurements in milliequivalents per liter (mEq/L) or millimoles per liter (mmol/L), two different units of concentration (Table 41-1). Millimoles per liter represent the number of milligrams of the electrolyte divided by its molecular weight that are contained in a liter of the fluid being measured (usually blood plasma or serum). Milliequivalents per liter is the millimoles per liter multiplied by the electrolyte charge (e.g., 1 for Na^+, 2 for Ca^{2+}). A milliequivalent of one electrolyte can combine with a milliequivalent of another electrolyte, which is why this measurement unit is used (Rose, 2011).

Fluid that contains a large number of dissolved particles is more concentrated than the same amount of fluid that contains only a few particles. **Osmolality** of a fluid is a measure of the number of particles per kilogram of water. Some particles (e.g., urea) pass easily through cell membranes; others such as Na^+ cannot cross easily. The particles that cannot cross cell membranes easily (nonpermeant particles) determine tonicity of a fluid (Caon, 2008). A fluid with the same concentration of nonpermeant particles as

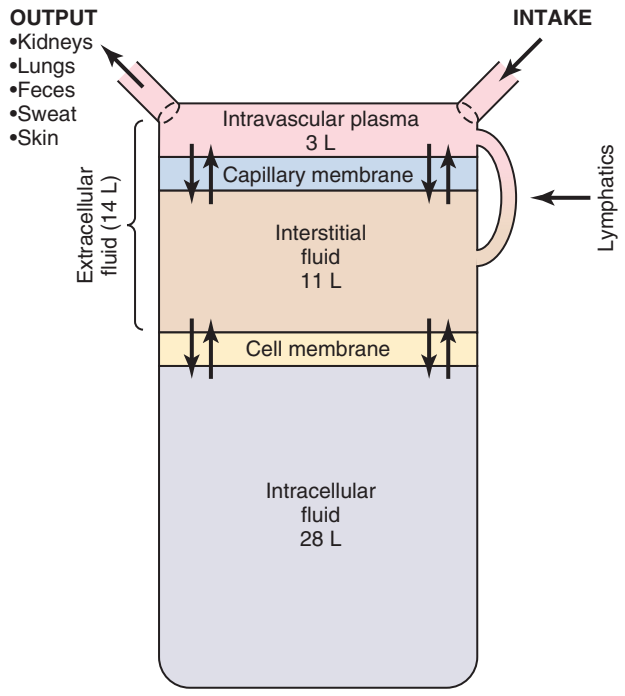

FIG. 41-1 Body fluid compartments. (From Hall JE: *Guyton and Hall textbook of medical physiology*, ed 12, Philadelphia, 2011, Saunders.)

TABLE 41-1 Laboratory Normal Values for Adults

ITEM MEASURED	NORMAL VALUE IN SERUM OR BLOOD
Osmolality	280-300 mOsm/kg H_2O (280-300 mmol/kg H_2O)
Electrolytes	
Sodium (Na^+)	136-145 mEq/L (136-145 mmol/L)
Potassium (K^+)	3.5-5.0 mEq/L (3.5-5 mmol/L)
Chloride (Cl^-)	98-106 mEq/L (98-106 mmol/L)
Total CO_2 (CO_2 total content)	22-30 mEq/L (22-30 mmol/L)
Bicarbonate (HCO_3^-)	Arterial 22-26 mEq/L (22-26 mmol/L) Venous 24-30 mEq/L (24-30 mmol/L)
Total calcium (Ca^{2+})	8.4-10.5 mg/dL (2.1-2.6 mmol/L)
Ionized calcium (Ca^{2+})	4.5-5.3 mg/dL (1.1-1.3 mmol/L)
Magnesium (Mg^{2+})	1.5-2.5 mEq/L (0.75-1.25 mmol/L)
Phosphate (PO_4^{3-})	2.7-4.5 mg/dL (0.87-1.45 mmol/L)
Anion gap	5-11 mEq/L (5-11 mmol/L)
Arterial Blood Gases	
pH	7.35-7.45
$PaCO_2$	35-45 mm Hg (4.7-6 kPa)
PaO_2	80-100 mm Hg (10.7-13.3 kPa)
O_2 saturation	95%-100% (0.95-1.00)
Base excess	–2 to +2 mmol/L

normal blood is called **isotonic.** A **hypotonic** solution is more dilute than the blood, and a **hypertonic** solution is more concentrated than normal blood (Fig. 41-2).

Movement of Water and Electrolytes. Active transport, diffusion, osmosis, and filtration are processes that move water and electrolytes between body compartments. These processes maintain equal osmolality in all compartments while allowing for different electrolyte concentrations.

Active Transport. Fluids in different body compartments have different concentrations of electrolytes that are necessary for normal function. For example, concentrations of Na^+, Cl^-, and HCO_3^- are higher in the ECF than in the ICF, whereas the concentrations of K^+, Mg^{2+}, and PO_4^{3-} are higher in the ICF than in the ECF. Cells maintain their high intracellular electrolyte concentration by **active transport.** Active transport requires energy in the form of adenosine triphosphate (ATP) to move electrolytes across cell membranes against the concentration gradient (from areas of lower concentration to areas of higher concentration). One example of active transport is the sodium-potassium pump, which moves Na^+ out of a cell and K^+ into it, keeping ICF lower in Na^+ and higher in K^+ than the ECF.

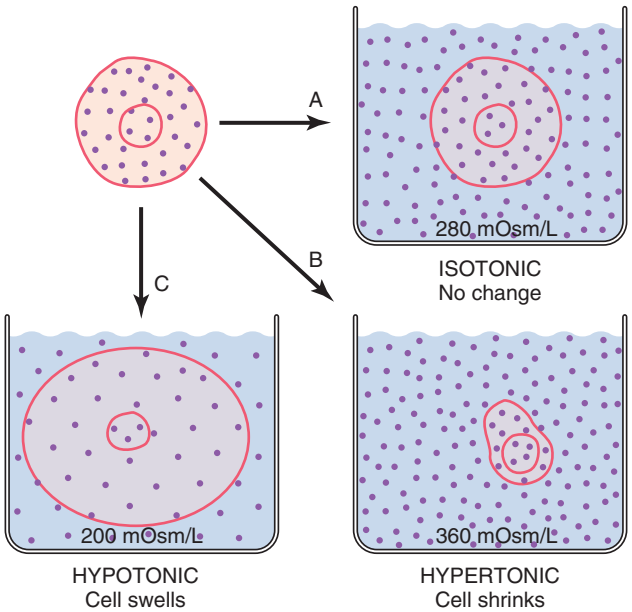

FIG. 41-2 Effects of isotonic, hypotonic, and hypertonic solutions. (From Hall JE: *Guyton and Hall textbook of medical physiology*, ed 12, Philadelphia, 2011, Saunders.)

Diffusion. Diffusion is passive movement of electrolytes or other particles down the concentration gradient (from areas of higher concentration to areas of lower concentration). Within a body compartment electrolytes diffuse easily by random movements until the concentration is the same in all areas. However, diffusion of electrolytes across cell membranes requires proteins that serve as ion channels. For example, when a sodium channel in a cell membrane is open, Na^+ diffuses passively across the cell membrane into the ICF because concentration is lower in the ICF. Opening of ion channels is tightly controlled and plays an important part in muscle and nerve function.

Osmosis. Water moves across cell membranes by **osmosis,** a process by which water moves through a membrane that separates fluids with different particle concentrations (Fig. 41-3). Cell membranes are semipermeable, which means that water crosses them easily but they are not freely permeable to many types of particles, including electrolytes such as sodium and potassium. These semipermeable cell membranes separate interstitial fluid from ICF. The fluid in each of these compartments exerts **osmotic pressure,** an inward-pulling force caused by particles in the fluid. The particles already inside the cell exert ICF osmotic pressure, which tends to pull water into the cell. The particles in the interstitial fluid exert interstitial fluid osmotic pressure, which tends to pull water out of the cell. Water moves into the compartment that has a higher osmotic pressure (inward-pulling force) until the particle concentration is equal in the two compartments.

If the particle concentration in the interstitial compartment changes, osmosis occurs rapidly and moves water into or out of cells to equalize the osmotic pressures. For example, when a hypotonic solution (more dilute than normal body fluids) is administered intravenously, it dilutes the interstitial fluid, decreasing its osmotic pressure below intracellular osmotic pressure. Water moves rapidly into cells until the two osmotic pressures are equal again. On the other hand, infusion of a hypertonic intravenous (IV) solution (more concentrated than normal body fluids) causes water to leave cells by osmosis to equalize the osmolality between interstitial and intracellular compartments.

Filtration. Fluid moves into and out of capillaries (between the vascular and interstitial compartments) by the process of **filtration** (Fig. 41-4). Filtration is the net effect of four forces, two that tend to move fluid out of capillaries and small venules and two that tend

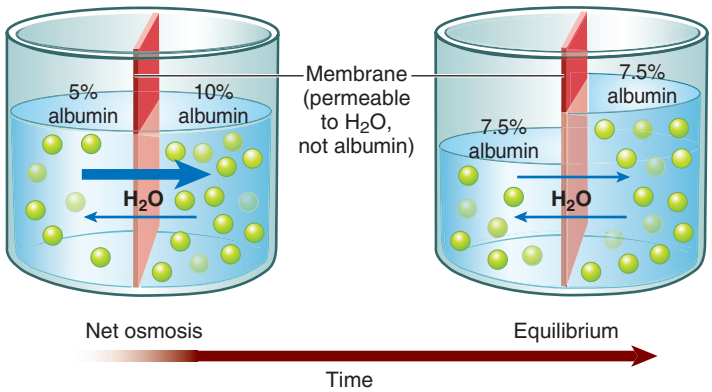

FIG. 41-3 Osmosis moves water through semipermeable membrane. (From Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 7, St Louis, 2010, Mosby.)

to move fluid back into them (Rose, 2011). **Hydrostatic pressure** is the force of the fluid pressing outward against a surface. Similarly, capillary hydrostatic pressure is a relatively strong outward-pushing force that helps move fluid from capillaries into the interstitial area. Interstitial fluid hydrostatic pressure is a weaker opposing force that tends to push fluid back into capillaries.

Blood contains albumin and other proteins known as **colloids.** These proteins are much larger than electrolytes, glucose, and other molecules that dissolve easily. Most colloids are too large to leave capillaries in the fluid that is filtered, so they remain in the blood. Because they are particles, colloids exert osmotic pressure. Blood **colloid osmotic pressure,** also called **oncotic pressure,** is an inward-pulling force caused by blood proteins that helps move fluid from the interstitial area back into capillaries. Interstitial fluid colloid osmotic pressure normally is a very small opposing force.

At the arterial end of a normal capillary, capillary hydrostatic pressure is strongest, and fluid moves from the capillary into the interstitial area, bringing nutrients to cells. At the venous end capillary hydrostatic pressure is weaker, and the colloid osmotic pressure of the blood is stronger. Thus fluid moves into the capillary at the venous end, removing waste products from cellular metabolism. Lymph vessels remove any extra fluid and proteins that have leaked into the interstitial fluid.

Disease processes and other factors that alter these forces may cause accumulation of excess fluid in the interstitial space, known as *edema*. For example, people with heart failure develop edema. In this situation, venous congestion from a weakened heart, which no longer pumps effectively, increases capillary hydrostatic pressure, causing edema by moving excessive fluid into the interstitial space. Inflammation is another cause of edema. It increases capillary blood flow and allows capillaries to leak colloids into the interstitial space. The resulting increased capillary hydrostatic pressure and increased interstitial colloid osmotic pressure produce localized edema in the inflamed tissues.

Fluid Balance

Fluid homeostasis is the dynamic interplay of three processes: fluid intake and absorption, fluid distribution, and fluid output (Felver, 2010b). Human total daily fluid output consists of hypotonic sodium-containing fluid. People must have intake of an equivalent amount of hypotonic sodium-containing fluid (or water plus foods with some salt) to maintain fluid balance.

Fluid Intake. Fluid intake occurs orally through drinking but also through eating because most foods contain some water. Food metabolism creates additional water. Average fluid intake from these routes for healthy adults is about 2300 mL, although it varies widely (Table 41-2). Other routes of fluid intake include IV, rectal (e.g., enemas), and irrigation of body cavities that can absorb fluid.

Although you might think that the major regulator of oral fluid intake is thirst, habit and social reasons actually account for most fluid intake (Johnson, 2007). Thirst, the conscious desire for water, is an important regulator of fluid intake when plasma osmolality increases (osmoreceptor-mediated thirst) or the blood volume decreases (baroreceptor-mediated thirst and angiotensin II– and III–mediated thirst). The thirst-control mechanism is located within the hypothalamus in the brain (Fig. 41-5). Osmoreceptors continually monitor plasma osmolality; when it increases, they cause thirst by stimulating neurons in the hypothalamus. Dry oral mucous membranes also cause thirst. People who are alert can obtain fluid or communicate their thirst to others, and fluid intake restores fluid balance. Infants, patients with neurological or psychological problems, and some older adults who are unable to perceive or communicate their thirst are at risk for dehydration.

Fluid Distribution. The term *fluid distribution* means the movement of fluid among its various compartments. Fluid

TABLE 41-2 Healthy Adult Average Daily Fluid Intake and Output

FLUID INTAKE	NORMAL	PROLONGED HEAVY EXERCISE
Fluids ingested:		
Oral	1100-1400 mL	?
Foods	800-1000 mL	?
Metabolism	300 mL	200 mL
TOTAL	**2200-2700 mL**	**?**
FLUID OUTPUT		
Skin (insensible and sweat)	500-600 mL	5350 mL
Insensible-lungs	400 mL	650 mL
GI	100-200 mL	100 mL
Urine	1200-1500 mL	500 mL
TOTAL	**2200-2700 mL**	**6600 mL**

Data from Heitz UE, Horne MM: *Mosby's pocket guide series: Fluid, electrolyte and acid base balance,* ed 5, St Louis, 2005, Mosby; Hall JE: *Guyton and Hall textbook of medical physiology,* ed 12, Philadelphia, 2011, Saunders.

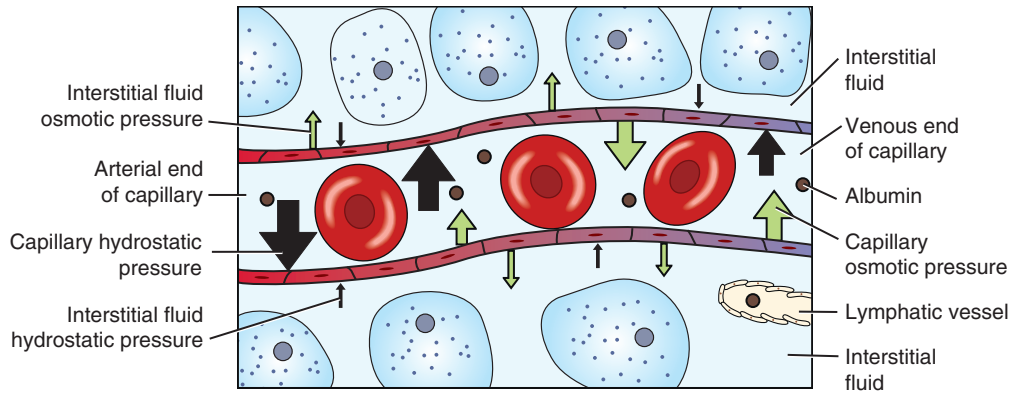

FIG. 41-4 Capillary filtration moves fluid between vascular and interstitial compartments. (From Copstead LC, Banasik JL: *Pathophysiology,* ed 4, St Louis, 2010, Saunders.)

distribution between the extracellular and intracellular compartments occurs by osmosis. Fluid distribution between the vascular and interstitial portions of the ECF occurs by filtration.

Fluid Output. Fluid output normally occurs through four organs: the skin, lungs, gastrointestinal (GI) tract, and kidneys. Examples of abnormal fluid output include vomiting, wound drainage, or hemorrhage (Felver, 2010b). Table 41-2 shows average amounts of fluid excretion for healthy adults, although urine output varies greatly, depending on fluid intake. Insensible (not visible) water loss through the skin and lungs is continuous. It increases when a person has a fever or a recent burn to the skin (Metheny, 2010). Sweat, which is visible and contains sodium, occurs intermittently and increases fluid output substantially. The GI tract plays a vital role in fluid balance. Approximately 3 to 6 L of fluid moves into the GI tract daily and then returns again to the ECF. The average adult normally excretes only 100 mL of fluid each day through feces. However, diarrhea causes a large fluid output from the GI tract.

The kidneys are the major regulator of fluid output because they respond to hormones that influence urine production. When healthy adults drink more water, they increase urine production to maintain fluid balance. If they drink less water, sweat a lot, or lose fluid by vomiting, their urine volume decreases to maintain fluid balance. These adjustments primarily are caused by the actions of antidiuretic hormone (ADH), the renin-angiotensin-aldosterone system (RAAS), and atrial natriuretic peptides (ANPs) (Goldstein et al., 2010) (Fig. 41-6).

Antidiuretic Hormone. ADH regulates the osmolality of the body fluids by influencing how much water is excreted in urine. It is synthesized by neurons in the hypothalamus that release it from the posterior pituitary gland. ADH circulates in the blood to the kidneys, where it acts on the collecting ducts (Koeppen and Stanton, 2008). Its name—antidiuretic hormone—tells you what it does. It causes renal cells to resorb water, taking water from the renal tubular fluid and putting it back in the blood. This action decreases urine volume, concentrating the urine while diluting the blood by adding water to it (see Fig. 41-6, *A*).

People normally have some ADH release to maintain fluid balance. More ADH is released if body fluids become more concentrated. Factors that increase ADH levels include severely decreased blood volume (e.g., dehydration, hemorrhage), pain, stressors, and some medications.

ADH levels decrease if body fluids become too dilute. This allows more water to be excreted in urine, creating a larger volume of dilute urine and concentrating the body fluids back to normal osmolality. For example, ethyl alcohol decreases ADH release,

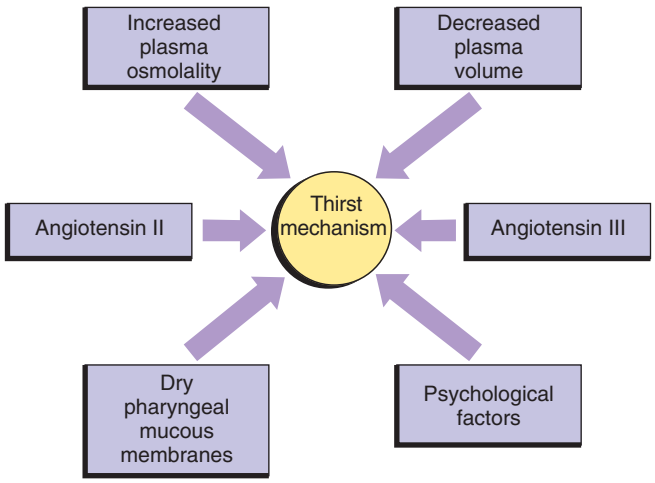

FIG. 41-5 Stimuli affecting thirst mechanism.

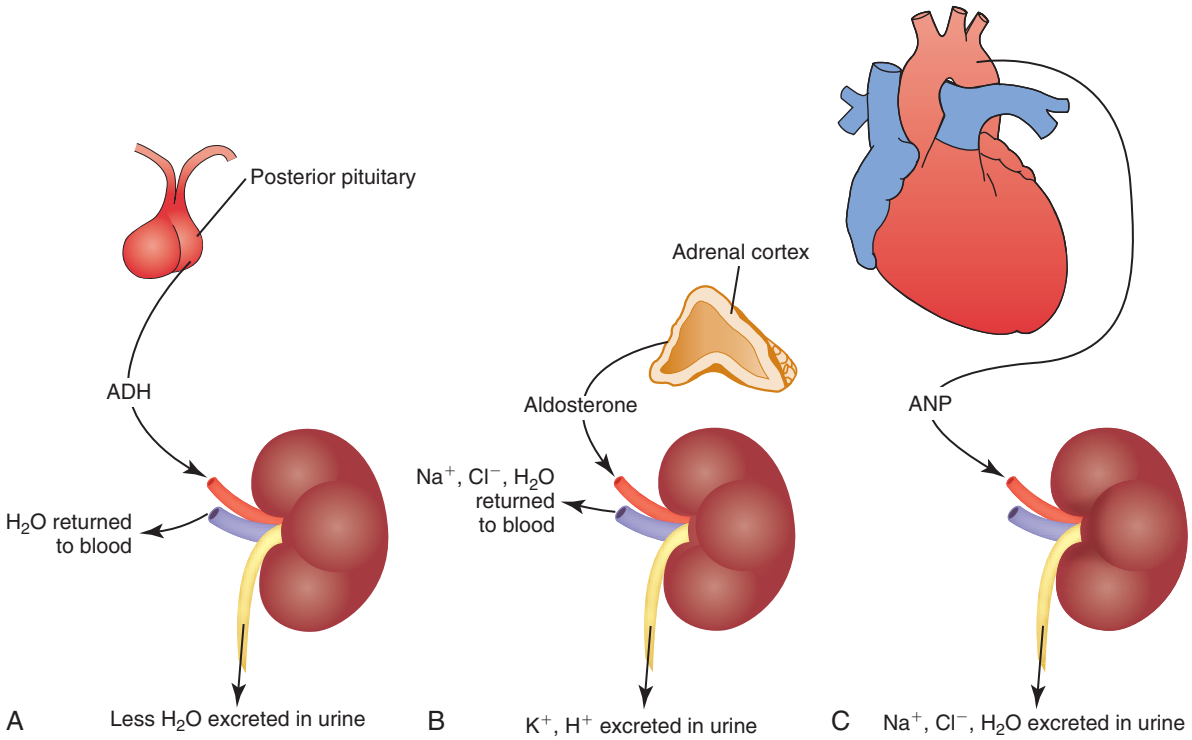

FIG. 41-6 Major hormones that influence renal fluid excretion. **A,** Antidiuretic hormone (ADH). **B,** Aldosterone. **C,** Atrial natriuretic peptide (ANP).

which causes people to urinate frequently when they drink alcoholic beverages.

Renin-Angiotensin-Aldosterone System. The renin-angiotensin-aldosterone system (RAAS) regulates ECF volume by influencing how much sodium and water are excreted in urine. It also contributes to regulation of blood pressure. Specialized cells in the kidneys release the enzyme renin, which acts on angiotensinogen, an inactive protein secreted by the liver that circulates in the blood. Renin converts angiotensinogen to angiotensin I, which other enzymes in the lung capillaries convert to angiotensin II (Koeppen and Stanton, 2008). Angiotensin II has several functions, one of which is vasoconstriction in some vascular beds. The important fluid homeostasis functions of angiotensin II include stimulation of aldosterone release from the adrenal cortex.

Aldosterone circulates to the kidneys, where it causes resorption of sodium and water in isotonic proportion in the distal renal tubules. Removing sodium and water from the renal tubules and returning it to the blood increases the volume of the ECF (see Fig. 41-6, *B*). Aldosterone also contributes to electrolyte and acid-base balance by increasing urinary excretion of potassium and hydrogen ions.

To maintain fluid balance, normally some action of the RAAS occurs. Certain stimuli increase or decrease the activity of this system to restore fluid balance. For example, if hemorrhage or vomiting decreases the extracellular fluid volume (ECV), blood flow decreases through the renal arteries, and more renin is released. This increased RAAS activity causes more sodium and water retention, helping to restore ECV.

Atrial Natriuretic Peptide. Atrial natriuretic peptide (ANP) also regulates ECV by influencing how much sodium and water are excreted in urine. Cells in the atria of the heart release ANP when they are stretched (e.g., by an increased ECV). ANP is a weak hormone that inhibits ADH by increasing the loss of sodium and water in the urine (see Fig. 41-6, *C*). Thus ANP opposes the effect of aldosterone (Koeppen and Stanton, 2008).

Fluid Imbalances

If disease processes, medications, or other factors disrupt fluid intake or output, imbalances sometimes occur (Felver, 2010b). For example, with diarrhea there is an increase in fluid output, and a fluid imbalance (dehydration) occurs if fluid intake does not increase appropriately. There are two major types of fluid imbalances: volume imbalances and osmolality imbalances (Fig. 41-7). Volume imbalances are disturbances of the *amount of fluid in the extracellular compartment*. Osmolality imbalances are disturbances of the *concentration of body fluids*. Volume and osmolality imbalances occur separately or in combination.

Extracellular Fluid Volume Imbalances. In an ECV imbalance there is either too little (ECV deficit) or too much (ECV excess) isotonic fluid. **ECV deficit** is present when there is insufficient isotonic fluid in the extracellular compartment. Remember that there is a lot of sodium in normal ECF. With ECV deficit, output of isotonic fluid exceeds intake of sodium-containing fluid. Because ECF is both vascular and interstitial, signs and symptoms arise from lack of volume in both of these compartments. Table 41-3 lists specific causes and signs and symptoms of ECV deficit. The term **hypovolemia** means decreased vascular volume and often is used when discussing ECV deficit (Metheny, 2010).

ECV excess occurs when there is too much isotonic fluid in the extracellular compartment. Intake of sodium-containing isotonic fluid has exceeded fluid output. For example, when you eat more salty foods than usual and drink water, you may notice that your ankles swell or rings on your fingers feel tight and you gain 2 lbs (1 kg) or more overnight. These are manifestations of mild ECV excess. See Table 41-3 for other specific causes and signs and symptoms.

Osmolality Imbalances. In an osmolality imbalance body fluids become hypertonic or hypotonic, which causes osmotic shifts of water across cell membranes. The osmolality imbalances are called *hypernatremia* and *hyponatremia*.

Hypernatremia, also called *water deficit,* is a hypertonic condition. Two general causes make body fluids too concentrated: loss of relatively more water than salt or gain of relatively more salt than water (Felver, 2010b). Table 41-3 lists specific causes under these categories. When the interstitial fluid becomes hypertonic, water leaves cells by osmosis, and they shrivel. Signs and symptoms of hypernatremia are those of cerebral dysfunction, which arise when brain cells shrivel. Hypernatremia may occur in combination with ECV deficit; this combined disorder is called clinical **dehydration.**

Hyponatremia, also called *water excess* or *water intoxication,* is a hypotonic condition. It arises from gain of relatively more water than salt or loss of relatively more salt than water (Felver, 2010b) (see Table 41-3). The excessively dilute condition of interstitial fluid causes water to enter cells by osmosis, causing the cells to swell. Signs and symptoms of cerebral dysfunction occur when brain cells swell.

Clinical Dehydration. ECV deficit and hypernatremia often occur at the same time; this combination is called *clinical dehydration* (Bryant, 2007). The ECV is too low, and the body fluids are too concentrated. Clinical dehydration is common with gastroenteritis or other causes of severe vomiting and diarrhea when people are not able to replace their fluid output with enough intake of dilute sodium-containing fluids. Signs and symptoms of clinical dehydration are those of both ECV deficit and hypernatremia (see Table 41-3).

Electrolyte Balance

You can best understand electrolyte balance by considering the three processes involved in electrolyte homeostasis: electrolyte intake and absorption, electrolyte distribution, and electrolyte

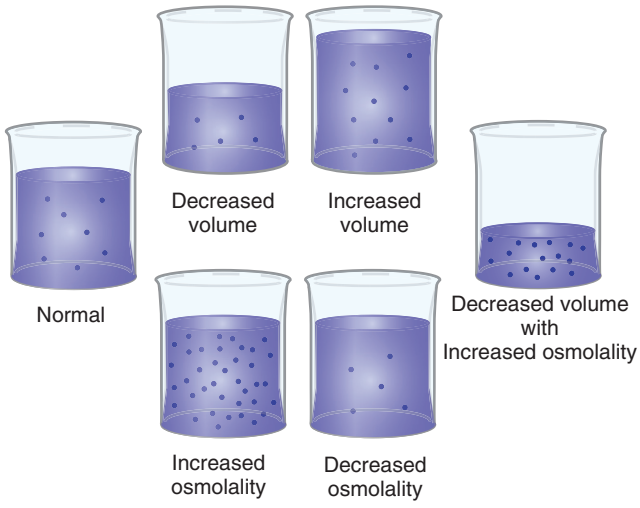

FIG. 41-7 Fluid volume and osmolality imbalances. (From Copstead LC, Banasik JL: *Pathophysiology online for pathophysiology*, ed 4, St Louis, 2010, Mosby.)

TABLE 41-3 Fluid Imbalances

IMBALANCE AND RELATED CAUSES	SIGNS AND SYMPTOMS
Volume Imbalances	
Extracellular Fluid Volume Deficit—Body Fluids Have Decreased Volume but Normal Tonicity	
Sodium and water intake less than output, causing isotonic loss: Severely decreased oral intake of water and salt *Increased GI output:* Diarrhea, vomiting, laxative overuse, or drainage from fistulas or tubes *Increased renal output:* Use of diuretics, adrenal insufficiency, salt-wasting renal disorders *Loss of blood or plasma:* Hemorrhage, burns Massive sweating without water and salt replacement	*Physical examination:* Sudden weight loss (e.g., overnight), postural hypotension, tachycardia, thready pulse, neck veins flat or collapsing with inhalation when supine, slow vein filling, oliguria (<30 mL/hr), dark yellow urine, dry mucous membranes, inelastic skin turgor, absence of tears and sweat, longitudinal furrows in tongue, thirst, restlessness, confusion, cold clammy skin, hypotension, ***hypovolemic shock.*** *Laboratory findings:* Increased hematocrit; BUN greater than 25 mg/dL (8.9 mmol/L) caused by hemoconcentration; urine specific gravity greater than 1.030
Extracellular Fluid Volume Excess—Body Fluids Have Increased Volume but Normal Tonicity	
Sodium and water intake greater than output, causing isotonic gain: Excessive administration of sodium-containing isotonic parenteral fluids Excessive oral intake of salty foods and water *Decreased renal output caused by elevated aldosterone:* Chronic heart failure, cirrhosis, aldosterone-secreting tumor *Decreased renal output from other causes:* Oliguric acute kidney disease, end-stage chronic renal disease, glucocorticoid excess	*Physical examination:* Sudden weight gain (e.g., overnight), edema (especially in dependent areas), neck veins full when upright or semi-upright, crackles in dependent portion of lungs, ***pulmonary edema*** *Laboratory findings:* Decreased hematocrit; BUN less than 10 mg/dL (3.6 mmol/L) caused by hemodilution
Osmolality Imbalances	
Hypernatremia (Water Deficit; Hyperosmolar Imbalance)—Hypertonic Body Fluids	
Loss of relatively more water than salt: Diabetes insipidus (ADH deficiency) Osmotic diuresis Greatly increased insensible perspiration and respiratory water output without increased water intake Gain of relatively more salt than water: Overuse of salt tablets Administration of tube feedings or hypertonic parenteral fluids Difficulty swallowing fluids, as in Parkinson's disease Lack of access to water or deliberate water deprivation Inability to respond to thirst (immobility, aphasia) Dysfunction of osmoreceptor-driven thirst drive	*Physical examination:* Extreme thirst, dry and flushed skin, postural hypotension, fever, restlessness, confusion, agitation, ***coma***, ***seizures*** if develops rapidly or is very severe *Laboratory findings:* Serum Na^+ level greater than 145 mEq/L (145 mmol/L) and serum osmolality greater than 295 mOsm/kg (295 mmol/kg), urine specific gravity 1.030
Hyponatremia (Water Excess; Water Intoxication; Hypoosmolar Imbalance)—Hypotonic Body Fluids	
Gain of relatively more water than salt: Excessive ADH (SIADH) Psychogenic polydipsia or forced excessive water drinking Excessive IV administration of 5% dextrose in water (D_5W) Use of hypotonic irrigating solutions Tap-water enemas Loss of relatively more salt than water: Renal salt-wasting disease Replacement of large body fluid output (diarrhea, vomiting, gastric suction) with water but not salt	*Physical examination:* Apprehension, nausea and vomiting, headaches, decreased level of consciousness (confusion, lethargy, muscle weakness, ***coma***); ***seizures*** if develops rapidly or is very severe *Laboratory findings:* Serum Na^+ level less than 135 mEq/L (135 mmol/L) and serum osmolality 280 mOsm/kg (280 mmol/kg) or less, urine specific gravity below 1.010 (if not SIADH)
Combined Volume and Osmolality Imbalance	
Clinical Dehydration (Extracellular Fluid Volume Deficit plus Hypernatremia)—Body Fluids Have Decreased Volume and Are Hypertonic	
Sodium and water intake less than output, with loss of relatively more water than salt: Most of the causes of ECV deficit (see previous causes) with no water intake, often with increased insensible water output through skin with fever	*Physical examination and laboratory findings:* Combination of those for ECV deficit plus those for hypernatremia (see previous signs)

ADH, Antidiuretic hormone; *BUN*, blood urea nitrogen; *ECV*, extracellular fluid volume; *GI*, gastrointestinal; *IV*, intravenous; *SIADH*, syndrome of inappropriate secretion of antidiuretic hormone.

Text in bold italics denotes potentially life-threatening manifestations.

TABLE 41-4 Electrolyte Intake and Absorption, Distribution, and Output

ELECTROLYTE	INTAKE AND ABSORPTION	DISTRIBUTION	OUTPUT/LOSS	IMPORTANT FUNCTION
Potassium (K^+)	Fruits Potatoes Instant coffee Molasses Brazil nuts Absorbs easily	Low in ECF, high in ICF. Insulin, epinephrine, and alkalosis shift K^+ into cells. Some types of acidosis shift K^+ out of cells.	Aldosterone, black licorice, hypomagnesemia, and polyuria increase renal excretion; oliguria decreases renal excretion. Acute or chronic diarrhea increases fecal excretion.	Maintains resting membrane potential of skeletal, smooth, and cardiac muscle, allowing for normal muscle function
Calcium (Ca^{2+})	Dairy products Canned fish with bones Broccoli Oranges Requires vitamin D for best absorption Undigested fat prevents absorption	Ca^{2+} is low in ECF, mostly in bones and intracellular. Some Ca^{2+} in blood is bound and inactive; only ionized Ca^{2+} is active. Parathyroid hormone shifts Ca^{2+} out of bone; calcitonin shifts Ca^{2+} into bone. Ca^{2+} decreases in blood if phosphate rises and vice versa.	Thiazide diuretics decrease renal excretion. Chronic diarrhea and undigested fat increase fecal excretion.	Influences excitability of nerve and muscle cells; necessary for muscle contraction
Magnesium (Mg^{2+})	Dark green leafy vegetables Whole grains Mg^{2+}-containing laxatives and antacids Undigested fat prevents absorption	Mg^{2+} is low in ECF, mostly in bones and intracellular. Some Mg^{2+} in blood is bound and not active; only free Mg^{2+} is active.	Rising blood ethanol increases renal excretion; oliguria decreases renal excretion. Chronic diarrhea and undigested fat increase fecal excretion.	Influences function of neuromuscular junctions and is a cofactor for numerous enzymes
Phosphate (PO_4)	Milk Processed foods Aluminum antacids prevent absorption	PO_4 is low in ECF; it is higher in ICF and in bones. Insulin and epinephrine shift phosphate into cells. Decreases in blood if calcium rises and vice versa.	Oliguria decreases renal excretion.	Necessary for production of ATP, the energy source for cellular metabolism

ATP, Adenosine triphosphate; *ECF,* extracellular fluid; *ICF,* intracellular fluid.

output (Table 41-4) (Felver, 2010b). Although sodium is an electrolyte, it is not included here because serum sodium imbalances are the osmolality imbalances discussed previously.

Electrolyte distribution is an important issue. Plasma concentrations of K^+, Ca^{2+}, Mg^{2+}, and phosphate are very low compared with their concentrations in cells and bone (Metheny, 2010). These concentration differences are necessary for normal muscle and nerve function. The electrolyte values that you review from laboratory reports are measured in blood serum and do not measure intracellular levels.

Electrolyte output occurs through normal excretion in urine, feces, and sweat. Output also occurs through vomiting, drainage tubes or fistulas. When electrolyte output increases, electrolyte intake must increase to maintain electrolyte balance. Similarly, if electrolyte output decreases such as with oliguria, electrolyte intake must also decrease to maintain balance (Felver, 2010b).

Electrolyte Imbalances

Factors such as diarrhea, endocrine disorders, and medications that disrupt electrolyte homeostasis cause electrolyte imbalances. Electrolyte intake greater than electrolyte output or a shift of electrolytes from cells or bone into the ECF causes plasma electrolyte excess. Electrolyte intake less than electrolyte output or shift of electrolyte from the ECF into cells or bone causes plasma electrolyte deficit (Felver, 2010b).

Potassium Imbalances. **Hypokalemia** is abnormally low potassium concentration in the blood. Hypokalemia results from decreased potassium intake and absorption, a shift of potassium from the ECF into cells, and an increased potassium output (Table 41-5). Common causes of hypokalemia from increased potassium output include diarrhea, repeated vomiting, and use of potassium-wasting diuretics. People who have these conditions need to increase their potassium intake to reduce their risk of hypokalemia. Hypokalemia causes muscle weakness, which becomes life threatening if it includes respiratory muscles and potentially life-threatening cardiac dysrhythmias.

Hyperkalemia is abnormally high potassium ion concentration in the blood. Its general causes are increased potassium intake and absorption, shift of potassium from cells into the ECF, and decreased potassium output (see Table 41-5). People who have oliguria (decreased urine output) are at high risk of hyperkalemia from the resultant decreased potassium output unless their potassium intake also decreases substantially. Understanding this principle helps you remember to check urine output before you administer IV solutions containing potassium. Hyperkalemia can cause muscle weakness, potentially life-threatening cardiac dysrhythmias, and cardiac arrest.

Calcium Imbalances. **Hypocalcemia** is abnormally low calcium concentration in the blood. The physiologically active form of calcium in the blood is ionized calcium. Total blood

TABLE 41-5 Electrolyte Imbalances

IMBALANCE AND RELATED CAUSES	SIGNS AND SYMPTOMS
Hypokalemia—Low Serum Potassium (K^+) Level	
Decreased K^+ intake and absorption: Excessive use of potassium-free IV solutions Shift of K^+ from ECF into cells: Alkalosis Treatment of diabetic ketoacidosis with insulin Increased K^+ output: Aldosterone excess Polyuria Use of potassium-wasting diuretics Glucocorticoid therapy Acute or chronic diarrhea, vomiting, or other GI losses	*Physical examination:* Bilateral muscle weakness that begins in quadriceps and may ascend to respiratory muscles, abdominal distention, decreased bowel sounds, constipation, ***cardiac dysrhythmias;*** signs of digoxin toxicity at normal digoxin levels *Laboratory findings:* Serum K^+ level less than 3.5 mEq/L (3.5 mmol/L); possible ECG abnormalities
Hyperkalemia—High Serum Potassium (K^+) Level	
Increased K^+ intake and absorption: Iatrogenic administration of large amounts of IV potassium Rapid infusion of stored blood Excessive ingestion of K^+ salt substitutes Shift of K^+ from cells into ECF: Massive cellular damage such as from crushing trauma or cytotoxic chemotherapy Insufficient insulin (e.g., diabetic ketoacidosis) Some types of acidosis Decreased K^+ output: Acute or chronic oliguria (e.g., severe ECV deficit, end-stage renal disease) Adrenal insufficiency Use of potassium-sparing diuretics	*Physical examination:* Bilateral muscle weakness in quadriceps, transient abdominal cramps and diarrhea, ***cardiac dysrhythmias, cardiac arrest*** *Laboratory findings:* serum K^+ level greater than 5 mEq/L (5 mmol/L); possible ECG abnormalities
Hypocalcemia—Low Serum Calcium (Ca^{2+}) Level	
Decreased Ca^{2+} intake and absorption: Calcium-deficient diet Vitamin D deficiency (includes end-stage renal disease) Chronic diarrhea, laxative misuse Steatorrhea (e.g., pancreatitis) Shift of Ca^{2+} from ECF into bone or inactive form: Hypoparathyroidism Rapid administration of citrated blood Hypoalbuminemia Alkalosis Hyperphosphatemia (includes end-stage renal disease) Increased Ca^{2+} output: Steatorrhea Chronic diarrhea	*Physical examination:* Positive Chvostek's sign (contraction of facial muscles when facial nerve is tapped), positive Trousseau's sign (carpal spasm with hypoxia), numbness and tingling of fingers and circumoral (around mouth) region, hyperactive reflexes, muscle twitching and cramping, tetany, seizures, ***laryngospasm, cardiac dysrhythmias*** *Laboratory findings:* Total serum Ca^{2+} less than 8.4 mg/dL (2.1 mmol/L) or serum ionized Ca^{2+} level less than 4.5 mg/dL (1.1 mmol/L); ECG abnormalities possible

calcium also contains inactive forms that are bound to plasma proteins and small anions such as citrate. Factors that cause too much ionized calcium to shift to the bound forms cause symptomatic *ionized hypocalcemia*. Table 41-5 summarizes general causes. People who have acute pancreatitis frequently develop hypocalcemia because calcium binds to undigested fat in their feces and is excreted. This process decreases absorption of dietary calcium and also increases calcium output by preventing resorption of calcium contained in GI fluids. Hypocalcemia increases neuromuscular excitability, the basis for its signs and symptoms.

Hypercalcemia is abnormally high calcium concentration in the blood. Hypercalcemia results from increased calcium intake and absorption, shift of calcium from bones into the ECF, and decreased calcium output (see Table 41-5). Patients with cancer often develop hypercalcemia because some cancer cells secrete chemicals into the blood that are related to parathyroid hormone. When these chemicals reach the bones, they cause shift of calcium from bones into the ECF. This weakens bones, and the person sometimes develops pathological fractures (i.e., bone breakage caused by forces that would not break a healthy bone). Hypercalcemia decreases neuromuscular excitability, the basis for its other signs and symptoms, the most common of which is lethargy.

Magnesium Imbalances. **Hypomagnesemia** is abnormally low magnesium concentration in the blood. Its general causes are decreased magnesium intake and absorption, shift of plasma magnesium to its inactive bound form, and increased magnesium output (see Table 41-5). Signs and symptoms are similar to those of hypocalcemia because hypomagnesemia also increases neuromuscular excitability.

TABLE 41-5 Electrolyte Imbalances—cont'd

IMBALANCE AND RELATED CAUSES	SIGNS AND SYMPTOMS
Hypercalcemia—High Serum Calcium (Ca^{2+}) Level	
Increased Ca^{2+} intake and absorption: Milk-alkali syndrome Shift of Ca^{2+} from bone into ECF: Prolonged immobilization Hyperparathyroidism Bone tumors Nonosseous cancers that secrete bone-resorbing factors Decreased Ca^{2+} output: Use of thiazide diuretics	*Physical examination:* Anorexia, nausea and vomiting, constipation, fatigue, diminished reflexes, lethargy, decreased level of consciousness, confusion, personality change, ***cardiac dysrhythmias;*** possible flank pain from renal calculi; with hypercalcemia caused by shift of calcium from bone: pathological fractures; signs of digoxin toxicity at normal digoxin levels *Laboratory findings:* Total serum Ca^{2+} greater than 10.5 mg/dL (2.6 mmol/L) or serum ionized Ca^{2+} greater than 5.3 mg/dL (1.3 mmol/L); possible ECG abnormalities
Hypomagnesemia—Low Serum Magnesium (Mg^{2+}) Level	
Decreased Mg^{2+} intake and absorption: Malnutrition Chronic alcoholism Chronic diarrhea, laxative misuse Steatorrhea (e.g., pancreatitis) Shift of Mg^{2+} into inactive form: Rapid administration of citrated blood Increased Mg^{2+} output: Aldosterone excess Use of thiazide or loop diuretics Steatorrhea, chronic diarrhea or other GI losses	*Physical examination:* Positive Chvostek's and Trousseau's signs, hyperactive deep tendon reflexes, insomnia, muscle cramps and twitching, grimacing, dysphagia, tachycardia, hypertension, tetany, seizures, ***cardiac dysrhythmias;*** signs of digoxin toxicity at normal digoxin levels *Laboratory findings:* Serum Mg^{2+} level less than 1.5 mEq/L (0.75 mmol/L)
Hypermagnesemia—High Serum Magnesium (Mg^{2+}) Level	
Increased Mg^{2+} intake and absorption: Excessive use of Mg^{2+}-containing laxatives and antacids Parenteral overload of magnesium Decreased Mg^{2+} output: End-stage renal disease Adrenal insufficiency	*Physical examination:* Lethargy, hypoactive deep tendon reflexes, bradycardia, hypotension; acute elevation in magnesium levels: flushing, sensation of warmth; severe hypermagnesemia: flaccid muscle paralysis, ***decreased rate and depth of respirations, cardiac dysrhythmias, cardiac arrest*** *Laboratory findings:* Serum Mg^{2+} level greater than 2.5 mEq/L (1.25 mmol/L); possible ECG abnormalities

ECF, Extracellular fluid, *ECG*, electrocardiogram, *ECV*, extracellular fluid volume, *GI*, gastrointestinal, *IV*, intravenous. ***Text in bold italics denotes potentially life-threatening manifestations.***

Hypermagnesemia is abnormally high magnesium concentration in the blood (see Table 41-5). End-stage renal disease causes hypermagnesemia unless the person decreases magnesium intake to match the decreased output. Signs and symptoms are caused by decreased neuromuscular excitability, with lethargy and decreased deep tendon reflexes being most common.

Acid-Base Balance

For optimal cell function the body maintains a balance between acids and bases. Acid-base homeostasis is the dynamic interplay of three processes: acid production, acid buffering, and acid excretion (Felver, 2010a). Normal acid-base balance is maintained with acid excretion equal to acid production. Acids release hydrogen (H^+) ions; bases (alkaline substances) take up H^+ ions. The more H^+ ions that are present, the more acidic is the solution.

The degree of acidity in blood and other body fluids is reported from the clinical laboratory as pH. The pH scale goes from 1.0 (very acid) to 14.0 (very alkaline; basic). A pH of 7.0 is considered neutral. The normal pH range of adult arterial blood is 7.35 to 7.45. Maintaining pH within this normal range is very important for optimal cell function. If the pH goes outside the normal range, enzymes within cells do not function properly; hemoglobin does not manage oxygen properly; and serious physiological problems occur, including death. Laboratory tests of a sample of arterial blood called **arterial blood gases (ABGs)** are used to monitor a patient's acid-base balance (Kramer and Raymond, 2009) (Table 41-6).

Acid Production. Cellular metabolism constantly creates two types of acids: carbonic acid and metabolic acids (Fig. 41-8). Cells produce carbon dioxide (CO_2), which acts like an acid in the body by converting to carbonic acid (H_2CO_3):

$$CO_2 + H_2O \leftrightarrow H_2CO_3 \leftrightarrow H^+ + HCO_3^-$$

Carbon dioxide + Water ↔ Carbonic acid ↔ Hydrogen ion + Bicarbonate

Metabolic acids are any acids that are not carbonic acid. They include citric acid, lactic acid, and many others.

Acid Buffering. Buffers are pairs of chemicals that work together to maintain normal pH of body fluids. If there are too many free H^+ ions, a buffer takes them up so they no longer are free. If there are too few, a buffer can release H^+ ions to prevent an acid-base imbalance. Buffers work rapidly, within seconds.

TABLE 41-6 Arterial Blood Gas Measures

LABORATORY MEASURE	NORMAL RANGE IN ADULT ARTERIAL BLOOD	DEFINITION AND INTERPRETATION
pH	7.35-7.45	pH is a negative logarithm of the free H^+ concentration, a measure of how acid or alkaline the blood is. Values below 7.35 indicate abnormally acid, and above 7.45 indicate abnormally alkaline. Small changes in pH denote large changes in H^+ concentration and are clinically important.
$PaCO_2$	35-45 mm Hg (4.7-6 kPa)	$PaCO_2$ is partial pressure of carbon dioxide (CO_2), a measure of how well the lungs are excreting CO_2 produced by cells. Increased $PaCO_2$ indicates CO_2 accumulation in blood (more carbonic acid) caused by hypoventilation; decreased $PaCO_2$ indicates excessive CO_2 excretion (less carbonic acid) through hyperventilation.
HCO_3^-	22-26 mEq/L (22-26 mmol/L)	HCO_3^- is concentration of the base (alkaline substance) bicarbonate, a measure of how well the kidneys are excreting metabolic acids. Increased HCO_3^- indicates that the blood has too few metabolic acids; decreased HCO_3^- indicates that the blood has too many metabolic acids.
PaO_2	80-100 mm Hg (10.7-13.3 kPa)	PaO_2 is partial pressure of oxygen (O_2), a measure of how well gas exchange is occurring in the alveoli of the lungs. Values below normal indicate poor oxygenation of the blood.
SaO_2	95%-100%	SaO_2 is oxygen saturation, the percentage of hemoglobin that is carrying as much O_2 as possible. It is influenced by pH, $PaCO_2$, and body temperature. It drops rapidly when PaO_2 falls below 60 mm Hg (8 kPa).
Base excess	–2 to +2 mmol/L	Base excess is observed buffering capacity minus the normal buffering capacity, a measure of how well the blood buffers are managing metabolic acids. Values below –2 (negative base excess) indicate excessive metabolic acids; values above +2 indicate excessive amounts of bicarbonate.

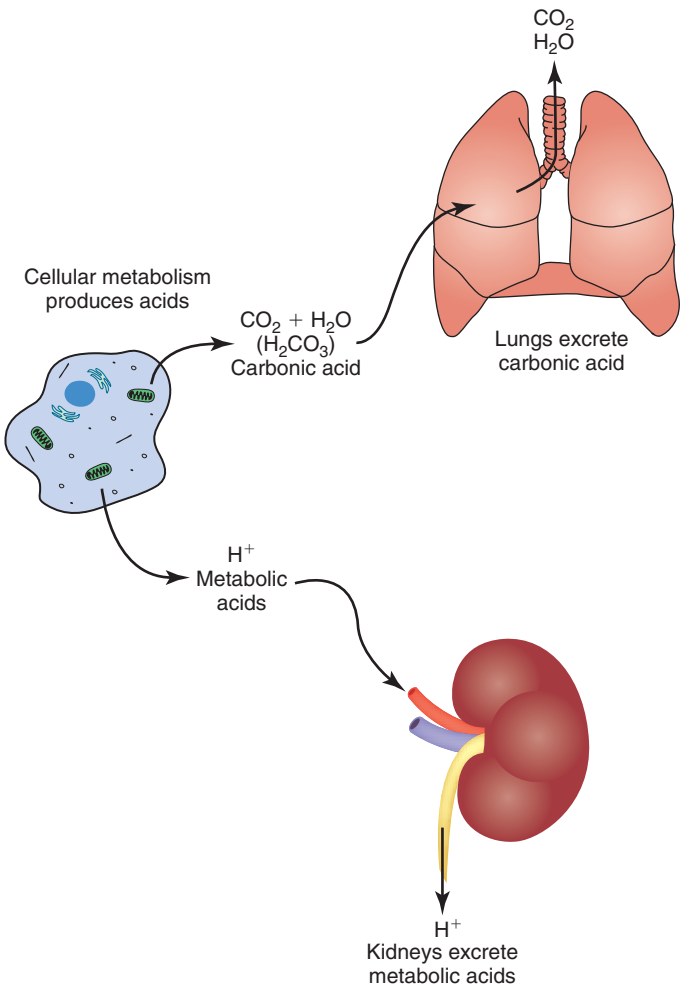

FIG. 41-8 Acid production and excretion.

All body fluids contain buffers. The major buffer in the ECF is the bicarbonate (HCO_3^-) buffer system, which buffers metabolic acids. It consists of a lot of bicarbonate and a small amount of carbonic acid (normally a 20 to 1 ratio). Addition of H^+ released by a metabolic acid to a bicarbonate ion makes more carbonic acid. Now the H^+ is no longer free and will not decrease the blood pH:

$$HCO_3^- + H^+ \leftrightarrow H_2CO_3$$

$$\text{Bicarbonate ion} + \text{Hydrogen ion} \leftrightarrow \text{Carbonic acid}$$

If there are too few H^+ ions, the carbonic acid portion of the buffer pair will release some, increasing the bicarbonate, again returning pH to normal.

$$H_2CO_3 \leftrightarrow HCO_3^- + H^+$$

$$\text{Carbonic acid} \leftrightarrow \text{Bicarbonate ion} + \text{Hydrogen ion}$$

Other buffers include hemoglobin, protein buffers, and phosphate buffers. Cellular and bone buffers also contribute. Buffers normally keep the blood from becoming too acid when acids that are produced by cells circulate to the lungs and kidneys for excretion.

Acid Excretion. The body has two acid-excretion systems: lungs and kidneys. The lungs excrete carbonic acid; the kidneys excrete metabolic acids (see Fig. 41-8).

Excretion of Carbonic Acid. When you exhale, you excrete carbonic acid in the form of CO_2 and water. If the $PaCO_2$ (i.e., level of CO_2 in the blood) rises, the chemoreceptors trigger faster and deeper respirations to excrete the excess. If the $PaCO_2$ falls, the chemoreceptors trigger slower and shallower respirations so more of the CO_2 produced by cells remains in the blood and makes up the deficit. These alterations in respiratory rate and depth maintain the carbonic acid portion of acid-base balance (Coggon, 2008a). Sometimes people who have lung disease have difficulty with normal excretion of carbonic acid, which causes it to accumulate and make the blood more acid.

Excretion of Metabolic Acids. The kidneys excrete all acids except carbonic acid. They secrete H^+ into the renal tubular fluid, putting HCO_3^- back into the blood at the same time. If there are too many H^+ ions in the blood, renal cells move more H^+ ions into the renal tubules for excretion, retaining more HCO_3^- in the process. If there are too few H^+ ions in the blood, renal cells secrete fewer H^+ ions.

Phosphate buffers in the renal tubular fluid keep the urine from becoming too acidic when the kidneys excrete H^+ ions. If the kidneys need to excrete a lot of H^+, renal tubular cells secrete ammonia, which combines with the H^+ ions in the tubules to make NH_4^+, ammonium ions. Buffering by phosphate and the creation of NH_4^+ turn free H^+ ions into other molecules in the renal tubular fluid (Rose, 2011). This process enables metabolic acid excretion in urine without making urine too acidic. People who have kidney disease often have difficulty with normal excretion of metabolic acids.

Acid-Base Imbalances

People develop acid-base imbalances when their normal homeostatic mechanisms are dysfunctional or overwhelmed. The term **acidosis** describes a condition that tends to make the blood relatively too acidic. Because our cells produce two types of acid, there are two different types of acidosis: respiratory acidosis and metabolic acidosis. The term **alkalosis** describes a condition that tends to make the blood relatively too basic (alkaline). There are two types of alkalosis: respiratory alkalosis and metabolic alkalosis.

The body has compensatory mechanisms that limit the extent of pH change with acid-base imbalances (Coggon, 2008b; Rose, 2011). It is important to remember that the kidney or lung cannot compensate for itself. Therefore the kidneys compensate for respiratory acid-base imbalances; the respiratory system compensates for metabolic acid-base imbalances. These compensatory mechanisms do not correct the problem, but they assist the body to adapt. However, if the underlying condition is not corrected, these compensatory mechanisms will fail.

Respiratory Acidosis. **Respiratory acidosis** arises from alveolar hypoventilation; the lungs are unable to excrete enough CO_2. The $PaCO_2$ rises, creating an excess of carbonic acid in the blood, which decreases pH (Table 41-7). The kidneys compensate by increasing excretion of metabolic acids in the urine, which increases blood bicarbonate. This compensatory process is slow, often taking 24 hours to show clinical effect and 3 to 5 days to reach steady state. Decreased cerebrospinal fluid (CSF) pH and intracellular pH of brain cells cause decreased level of consciousness.

Respiratory Alkalosis. **Respiratory alkalosis** arises from alveolar hyperventilation; the lungs excrete too much carbonic acid (CO_2 and water). The $PaCO_2$ falls, creating a deficit of carbonic acid in the blood, which increases pH (see Table 41-7). Respiratory alkalosis usually is short lived; thus the kidneys do not have time to compensate. When the pH of blood, CSF, and ICF increases acutely, cell membrane excitability also increases, giving rise to neurological symptoms such as excitement, confusion, and paresthesias. If the pH rises high enough, central nervous system (CNS) depression can occur.

Metabolic Acidosis. **Metabolic acidosis** occurs from an increase of metabolic acid or a decrease of base (bicarbonate). The kidneys are unable to excrete enough metabolic acids, which accumulate in the blood, or bicarbonate is removed from the body directly as with diarrhea (see Table 41-7). In either case the blood HCO_3^- decreases, and the pH falls. With an increase of metabolic acids, blood HCO_3^- decreases because it is used to buffer metabolic acids. Similarly, when patients have conditions that cause the removal of HCO_3^-, the amount of HCO_3^- in the blood decreases. To help identify the specific cause, health care providers and the laboratory calculate the **anion gap,** a reflection of unmeasured anions in plasma. You calculate anion gap by subtracting the sum of plasma concentrations of the anions Cl^- and HCO_3^- from the plasma concentration of the cation Na^+ (Rose, 2011). When reviewing laboratory reports, check the reference values from the laboratory that measured the electrolyte concentrations (Table 41-8).

The abnormally low pH in metabolic acidosis stimulates the chemoreceptors so the respiratory system compensates for the acidosis by hyperventilation. Compensatory hyperventilation begins in a few minutes and removes carbonic acid from the body. This process does not correct the problem, but it helps limit the pH decrease. Metabolic acidosis decreases one's level of consciousness (see Table 41-7).

Metabolic Alkalosis. **Metabolic alkalosis** occurs from a direct increase of base (HCO_3^-) or a decrease of metabolic acid, which increases blood HCO_3^- by releasing it from its buffering function. Common causes include vomiting and gastric suction (see Table 41-7). The respiratory compensation for metabolic alkalosis is hypoventilation. The decreased rate and depth of respiration allow carbonic acid to increase in the blood, as seen by an increased $PaCO_2$. The need for oxygen may limit the degree of respiratory compensation for metabolic alkalosis. Because HCO_3^- crosses the blood-brain barrier with difficulty, neurological signs and symptoms are less severe or even absent with metabolic alkalosis (Rose, 2011).

NURSING KNOWLEDGE BASE

You will apply knowledge about fluid, electrolyte, and acid-base imbalance in many clinical settings. Use the scientific knowledge base in clinical decision making to provide safe, optimal fluid therapy. For example, apply knowledge of risk factors for fluid imbalances and physiology of normal aging when assessing older adults, knowing that this age-group has high risk of fluid imbalances (Bryant, 2007). Nursing knowledge includes questions to ask to elicit risk factors for fluid, electrolyte, and acid-base imbalance; specific clinical assessments for signs and symptoms of these imbalances; and nursing and collaborative interventions to maintain or restore fluid and electrolyte balance (Metheny, 2010). Skills and techniques for safe IV therapy, are a vital area of the nursing knowledge base and the focus of much nursing research to support evidence-based practice.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information necessary to analyze the data and make decisions regarding patient care. Patients' conditions are always changing. During assessment, consider all critical thinking elements and data about the specific patient to develop appropriate nursing diagnoses.

In the case of fluid, electrolyte, and acid-base balance, you integrate knowledge of physiology, pathophysiology, and pharmacology and previous experiences and information gathered from patients. Critical analysis of data enables an understanding of how fluid, electrolyte, and acid-base imbalances affect a specific patient and his or her family. In addition, critical thinking attitudes such

TABLE 41-7 Acid-Base Imbalances

IMBALANCE AND RELATED CAUSES	SIGNS AND SYMPTOMS
Respiratory Acidosis—Excessive Carbonic Acid Caused by Alveolar Hypoventilation	
Impaired gas exchange: Type B COPD (chronic bronchitis) or end-stage type A COPD (emphysema) Pneumonia Severe acute asthma episode Airway obstruction Extensive atelectasis Obstructive sleep apnea Impaired neuromuscular function: Respiratory muscle weakness or paralysis from hypokalemia or neurological dysfunction Respiratory muscle fatigue, respiratory failure Chest injury or surgery causing pain with respiration Dysfunction of brainstem respiratory control: Drug overdose with a respiratory depressant Central sleep apnea	*Physical examination:* Headache, light-headedness, decreased level of consciousness (confusion, lethargy, ***coma***), ***cardiac dysrhythmia***, warm and flushed skin, muscular twitching Laboratory findings in blood: pH less than 7.35 $PaCO_2$ greater than 45 mm Hg (6 kPa) HCO_3^- level normal if uncompensated or greater than 26 mEq/L (26 mmol/L) if compensated
Respiratory Alkalosis—Deficient Carbonic Acid Caused by Alveolar Hyperventilation	
Hypoxemia Acute pain Anxiety, psychological distress, prolonged sobbing Inappropriate mechanical ventilator settings Stimulation of brainstem respiratory control: head injuries, meningitis, gram-negative sepsis, salicylate overdose	*Physical examination:* Increased rate and depth of respirations (hyperventilation), light-headedness, numbness and tingling of extremities and circumoral region (paresthesias), excitement and confusion possibly followed by decreased level of consciousness, ***cardiac dysrhythmias*** Laboratory findings in blood: pH greater than 7.45 $PaCO_2$ less than 35 mm Hg (4.7 kPa) HCO_3^- level normal if short lived or uncompensated or less than 22 mEq/L (22 mmol/L) if compensated K^+ level may be decreased (less than 3.5 mEq/L) Ionized Ca^{2+} level may be decreased (below 4.5 mg/dL)
Metabolic Acidosis—Excessive Metabolic Acids	
Increase of metabolic acid: Ketoacidosis (diabetes, starvation, alcoholism) Hypermetabolic state (severe hyperthyroidism, burns, severe infection) Oliguric renal disease (acute kidney injury, end-stage renal disease) Circulatory shock (lactic acidosis) Ingestion of acid or acid precursors (e.g., methanol, ethylene glycol, boric acid, salicylate overdose) Decrease of base (bicarbonate): Diarrhea Pancreatic fistula or intestinal decompression Renal tubular acidosis	*Physical examination:* Decreased level of consciousness (lethargy, confusion, ***coma***), abdominal pain, ***cardiac dysrhythmias,*** increased rate and depth of respirations (compensatory hyperventilation) Laboratory findings in blood: pH less than 7.35 $PaCO_2$ normal if uncompensated or less than 35 mm Hg (4.7 kPa) if compensated HCO_3^- level less than 22 mEq/L (22 mmol/L) Anion gap normal or high, depending on cause K^+ level may be elevated (greater than 5 mEq/L), depending on cause
Metabolic Alkalosis—Deficient Metabolic Acids	
Increase of base (bicarbonate): Excessive administration of $NaHCO_3$ Massive blood transfusion (liver converts citrate to HCO_3^-) Mild or moderate ECV deficit (contraction alkalosis) Decrease of metabolic acid: Excessive or prolonged vomiting Prolonged gastric suctioning Hypokalemia Excess aldosterone	*Physical examination:* Light-headedness, numbness and tingling of fingers, toes, and circumoral region (paresthesias); possible excitement and confusion followed by decreased level of consciousness, ***cardiac dysrhythmias*** (may be caused by hypokalemia) Laboratory findings in blood: pH greater than 7.45 $PaCO_2$ normal if uncompensated or greater than 45 mm Hg (6.0 kPa) if compensated HCO_3^- greater than 26 mEq/L (26 mmol/L) K^+ level often decreased (less than 3.5 mEq/L) Ionized Ca^{2+} level may be decreased (less than 4.5 mg/dL)

COPD, Chronic obstructive pulmonary disease, *ECV*, extracellular fluid volume. ***Text in bold italics denotes potentially life-threatening manifestations.***

TABLE 41-8 Anion Gap in Metabolic Acidosis

ANION GAP TYPE	VALUES (WITHOUT K^+)	CAUSES
Normal anion gap	5-11 mEq/L (5-11 mmol/L) Varies, depending on laboratory	*Excess output of bicarbonate:* Diarrhea, pancreatic fistula, intestinal decompression, renal tubular acidosis Increase of chloride-containing acid: Parenteral HCl therapy
High anion gap	Greater than 11 mEq/L (11 mmol/L) Varies, depending on laboratory	*Increase of any acid except HCl:* Ketoacids (DKA, starvation, alcoholism), lactic acid (circulatory shock, extreme exercise), excessive normal metabolic acids (oliguric acute kidney injury, end-stage renal disease, severe hyperthyroidism, burns, severe infection), unusual organic acids (salicylate overdose, acids metabolized from methanol, ethylene glycol, paraldehyde)

Data from Rose BD: *Clinical physiology of acid-base disorders*, ed 6, New York, 2011, McGraw-Hill.
DKA, Diabetic ketoacidosis.

as accountability, discipline, and integrity assist you in identifying appropriate nursing diagnoses and planning successful interventions. Professional standards such as the Infusion Nurses Society (INS) standards of practice (INS, 2011) provide valuable guidance for appropriate assessment.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. For patients at high risk for fluid, electrolyte, and/or acid-base imbalances or those who already have these imbalances, an individualized approach is the foundation for safe and effective patient-centered nursing care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure you make patient-centered clinical decisions required for safe nursing care. Using a systematic approach in assessment enables you to help patients maintain or restore fluid, electrolyte, and acid-base balances safely (Fig. 41-9).

Through the Patient's Eyes. A patient's fluid, electrolyte, or acid-base imbalance is sometimes so severe that it prevents initial discussion of his or her expressed needs, values, and preferences. However, when a patient is alert enough to discuss care, you need to elicit this information. Focus on the patient's experience with fluid, electrolyte, or acid-base alterations and his or her perceptions of the illness. For example, for a patient who is hospitalized for clinical dehydration from diarrhea, ask if he or she has experienced dehydration previously, and assess his or her interpretation of the signs and symptoms experienced and possible causes. For example, ask how the person manages diarrhea at home to assess

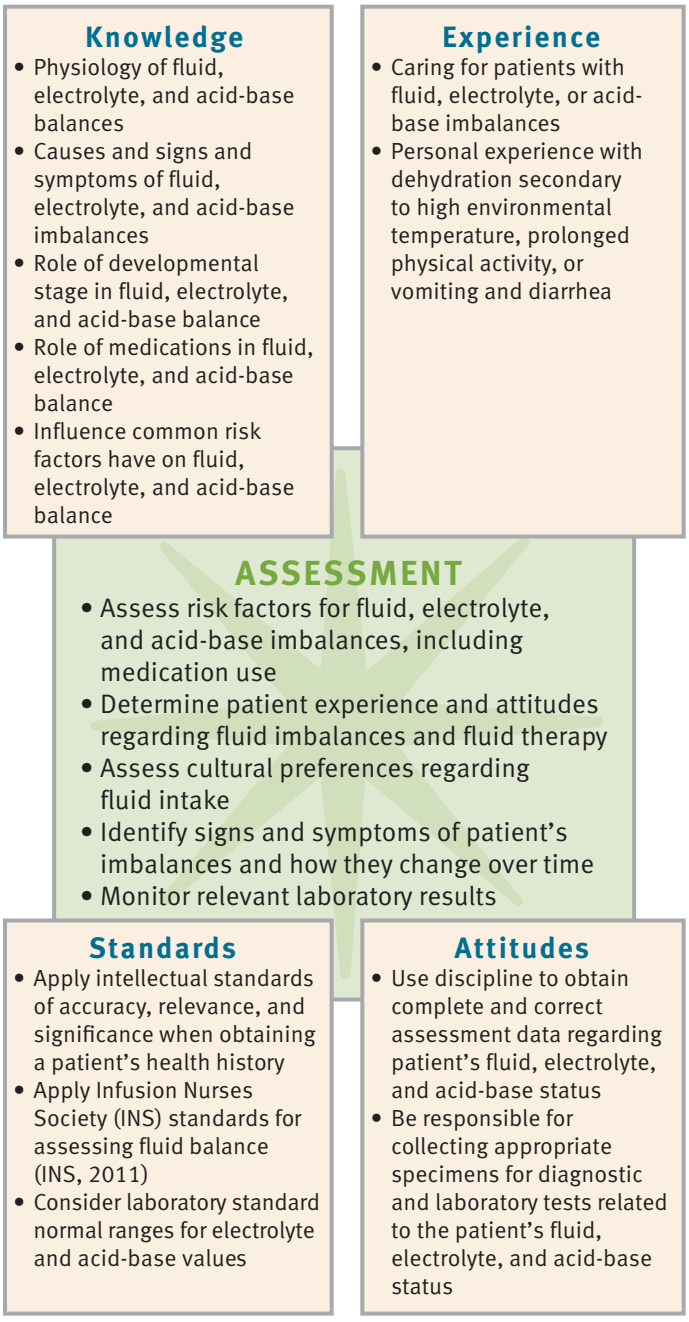

FIG. 41-9 Critical thinking model for fluid, electrolyte, and acid-base balances assessment.

the patient's understanding of how to prevent the imbalances from occurring in the future. Assess potential barriers to rehydration, such as concerns regarding IV therapy or lack of availability of favorite fluids at the preferred fluid temperature. Ask about the patient's greatest concerns regarding fluid status to build the basis for active partnership in planning, implementing, and evaluating patient-centered care.

Nursing History

Clinical assessment begins with a patient history designed to reveal risk factors that cause or contribute to fluid, electrolyte, and acid-base imbalances (Table 41-9). Ask specific, focused questions to

TABLE 41-9 Risk Factors for Fluid, Electrolyte, and Acid-Base Imbalances

Age	*Very young:* ECV deficit, osmolality imbalances, clinical dehydration *Very old:* ECV excess or deficit, osmolality imbalances
Environment	Sodium-rich diet: ECV excess Electrolyte-poor diet: Electrolyte deficits *Hot weather:* Clinical dehydration
Gastrointestinal output	*Diarrhea:* ECV deficit, clinical dehydration, hypokalemia, hypocalcemia (if chronic), hypomagnesemia (if chronic), metabolic acidosis *Drainage (e.g., nasogastric suctioning, fistulas):* ECV deficit, hypokalemia; metabolic acidosis if intestinal or pancreatic drainage *Vomiting:* ECV deficit, clinical dehydration, hypokalemia, hypomagnesemia, metabolic alkalosis
Chronic diseases	*Cancer:* Hypercalcemia; with tumor lysis syndrome: hyperkalemia, hypocalcemia, hyperphosphatemia; other imbalances, depending on side effects of therapy Chronic obstructive pulmonary disease: Respiratory acidosis *Cirrhosis:* ECV excess, hypokalemia *Heart failure:* ECV excess; other imbalances, depending on therapy *Oliguric renal disease:* ECV excess, hyperkalemia, hypermagnesemia, hyperphosphatemia, metabolic acidosis
Trauma	*Burns:* ECV deficit, metabolic acidosis Crush injuries: Hyperkalemia *Head injuries:* Hyponatremia or hypernatremia, depending on ADH response *Hemorrhage:* ECV deficit; hyperkalemia if circulatory shock
Therapies	Diuretics and other medications (see Box 41-3) *IV therapy:* ECV excess, osmolality imbalances, electrolyte excesses *PN:* Any fluid or electrolyte imbalance, depending on components of solution

ADH, Antidiuretic hormone; *ECV,* extracellular fluid volume; *IV,* intravenous; *PN,* parenteral nutrition.

BOX 41-1 NURSING ASSESSMENT QUESTIONS

Environment
- Do you work or exercise in a hot environment?
- If so, which type of fluid do you drink during that time?

Dietary Intake
- How much do you usually drink every day? Which type of fluids do you drink?
- Tell me what you eat in a typical day.
- Which snacks do you usually eat?
- Are you on a special diet because of a medical problem? How does that work for you?
- Are you following any weight loss program?
- Do you use a salt substitute?
- Do you take calcium, magnesium, or potassium supplements? If so, how often?
- Do you have any difficulties chewing or swallowing?

Lifestyle
- How much alcohol do you drink in a typical week?

Gastrointestinal Output
- Have you had recent vomiting or diarrhea? If so, for how long? How many times per day?

Medications and Other Therapies
- Which medications/herbal remedies do you use regularly? Occasionally?
- Do you take diuretics? Drugs for high blood pressure?
- Do you use antacids? If so, which ones? How often? Do you ever use baking soda as an antacid? Do you use fizzy (effervescent) medications for colds?
- Do you use laxatives? If so, how often? Which type of stool do you get when you use them?
- What do you use for an upset stomach?

Signs and Symptoms
- If you weigh yourself every day, how has your weight changed over the past few days?
- Do you get light-headed when you stand up?
- Do you feel thirsty, have a dry mouth, or notice a lack of tears?
- Have you noticed a change in your urine output: decreased volume, dark color, or concentrated appearance?
- Are you experiencing swelling of your fingers, feet, or ankles?
- Do you have difficulty breathing when you lie down at night?
- Are you having difficulty concentrating, or do you feel confused? What is normal for you?
- Are you having more difficulty than usual standing up from a sofa or soft chair? Do your legs feel unusually heavy when you climb stairs? Do you have muscle weakness that is unusual for you?
- Have you noticed any muscle cramps or unusual sensations such as numbness or tingling fingers?

identify factors that contribute to a patient's potential imbalances (Box 41-1).

Age. First assess a patient's age. An infant's proportion of total body water (70% to 80% total body weight) is greater than that of children or adults. Infants and young children have greater water needs and immature kidneys (Hockenberry and Wilson, 2011). They are at greater risk for ECV deficit and hypernatremia because body water loss is proportionately greater per kilogram of weight.

Children who are between the ages of 2 and 12 frequently respond to illnesses with fevers of higher temperatures and longer duration than those of adults (Hockenberry and Wilson, 2011). At any age fever increases the rate of insensible water loss. Adolescents have increased metabolism and increased water production because of their rapid growth changes. Fluctuations in fluid balance are greater in adolescent girls because of hormonal changes associated with the menstrual cycle.

Older adults experience a number of age-related changes that potentially affect fluid, electrolyte, and acid-base balances (Box 41-2). They often have more difficulty recovering from imbalances resulting from the combined effect of normal aging, various disease conditions, and multiple medications.

Environment. Hot environments increase fluid output through sweating. Sweat is a hypotonic sodium-containing fluid.

BOX 41-2 FOCUS ON OLDER ADULTS

Factors Affecting Fluid, Electrolyte, and Acid-Base Balance

- Body composition changes, causing a decreased percentage of body weight as water (50%), which increases risk of extracellular fluid volume (ECV) deficit and dehydration (Felver, 2010b).
- Some older adults restrict fluid intake because of impaired mobility or concerns about bladder control; this increases their risk of hypernatremia and ECV deficit.
- Decreased elasticity of skin alters skin turgor even with normal fluid balance; do not rely on skin turgor to assess ECV deficit or dehydration in older adults.
- Decreased thirst sensation increases risk of hypernatremia and dehydration; do not rely on thirst to assess hypernatremia, ECV deficit, or dehydration in older adults (Wotton, Crannitch, and Munt, 2008).
- Baroreceptors become sluggish with age, often causing brief postural hypotension; have older adults arise slowly when you take orthostatic blood pressure measurements.
- Cardiovascular changes with aging often decrease the ability to adapt to a sudden increase in vascular volume, increasing risk of pulmonary edema with rapid infusion of isotonic intravenous fluids.
- Older-adult kidneys are less able to concentrate urine, making them less able to conserve fluid when needed; this increases the risk of hypernatremia, ECV deficit, and dehydration (Meiner, 2010).
- Kidney changes of normal aging make it more difficult to excrete a large acid load, increasing the risk of metabolic acidosis.
- Increased sensitivity to anticholinergic effects of medications causes dry mouth; use several different assessments for ECV deficit and dehydration rather than relying solely on dry mouth (Lehne, 2010).
- The combined effects of normal aging, chronic diseases, and multiple medications often pose challenges to maintaining fluid and electrolyte balance.

Excessive sweating without adequate replacement of salt and water can lead to ECV deficit, hypernatremia, or clinical dehydration. Ask patients about their normal level of physical work and whether they engage in vigorous exercise in hot environments. Do the patients have fluid replacements containing salt available during exercise and activity?

Dietary Intake. Assess dietary intake of fluids; salt; and foods rich in potassium, calcium, and magnesium (see Table 41-4). Ask patients if they follow weight-loss diets. Starvation diets or those with high fat and no carbohydrate content often lead to metabolic acidosis (see Table 41-7). In addition, assess the patient's ability to chew and swallow, which, if altered, interferes with adequate intake of electrolyte-rich foods and fluids.

Lifestyle. Take an alcohol intake history. Chronic alcohol abuse commonly causes hypomagnesemia, in part because it increases renal magnesium excretion.

Medications. Obtain a complete list of your patient's current medications, including over-the-counter (OTC) and herbal preparations, to assess the risk for fluid, electrolyte, and acid-base imbalances (Box 41-3). Use a drug reference book or reputable online database to check the potential effects of other medications. Ask specifically about the use of baking soda as an antacid, which can cause ECV excess because of its high sodium content that holds water in the extracellular compartments. For an individual who uses laxatives, ask about the consistency and frequency of stools. Multiple loose stools remove fluid and electrolytes from the body, thus causing numerous imbalances.

BOX 41-3 COMMONLY USED MEDICATIONS THAT CAUSE FLUID, ELECTROLYTE, AND ACID-BASE IMBALANCES

- *ACE inhibitors (e.g., captopril [Capoten]) and angiotensin II receptor blockers (e.g., Losartan [Cozaar]):* Hyperkalemia
- *Antidepressants, SSRI (e.g., fluoxetine [Prozac]):* Hyponatremia
- *Calcium carbonate antacids:* Hypercalcemia, mild metabolic alkalosis
- *Corticosteroids (e.g., prednisone):* Hypokalemia, metabolic alkalosis
- *Diuretics, potassium-wasting (e.g., furosemide [Lasix], thiazides):* ECV deficit, hyponatremia (thiazides), hypokalemia, hypomagnesemia, mild metabolic alkalosis
- *Diuretics, potassium-sparing (e.g., spironolactone [Aldactone]):* Hyperkalemia, mild metabolic acidosis
- *Effervescent (fizzy) antacids and cold medications (high Na^+ content):* ECV excess
- *Laxatives:* ECV deficit, hypokalemia, hypocalcemia, hypomagnesemia, metabolic acidosis
- *Magnesium hydroxide (e.g., Milk of Magnesia):* Hypermagnesemia
- *Nonsteroidal antiinflammatory drugs (e.g., ibuprofen [Advil]):* Mild ECV excess, hyponatremia
- *Penicillins, high-dose (e.g., carbenicillin):* Hypokalemia, metabolic alkalosis; hyperkalemia with penicillin G (contains K^+)

Data from Haskal R: Current issues for nurse practitioners: hyponatremia, *J Am Acad Nurs Practitioners* 19(11):563, 2007; Lehne, RA: *Pharmacology for nursing care*, ed 7, Philadelphia, 2010, Saunders; Metheny NM: *Fluids and electrolytes balance: nursing applications,* ed 5, Sudbury, Mass, 2010, Jones & Bartlett Learning.

ACE, Angiotensin-converting enzyme; *ECV,* extracellular fluid volume; *SSRI,* selective serotonin reuptake inhibitor.

Medical History

Recent Surgery. Surgery causes a physiological stress response, which increases with extensive surgery and blood loss. In the second to fifth postoperative day, increased secretion of aldosterone, glucocorticoids, and ADH cause increased ECV, decreased osmolality, and increased potassium excretion (Monahan et al., 2007). In otherwise healthy patients these imbalances resolve without difficulty, but patients who have preexisting illnesses or additional risk factors often need treatment during this time period.

Gastrointestinal Output. Increased output of fluid through the GI tract is a common and important cause of fluid, electrolyte, and acid-base imbalances that requires careful assessment. Vomiting and diarrhea, either acute or chronic, can cause ECV deficit, hypernatremia, clinical dehydration, and hypokalemia by increasing the output of fluid, Na^+, and K^+. In addition, chronic diarrhea can cause hypocalcemia and hypomagnesemia by decreasing electrolyte absorption. Removal of gastric acid from the body through vomiting or nasogastric suction can cause metabolic alkalosis. In contrast, removal of the bicarbonate-rich intestinal or pancreatic fluids through diarrhea, intestinal suction, or fistula can cause metabolic acidosis.

Acute Illness or Trauma. Acute conditions that place patients at high risk for fluid, electrolyte, and acid-base alterations include respiratory diseases, burns, trauma, GI alterations, and acute oliguric renal disease.

Respiratory Disorders. Many acute respiratory disorders predispose patients to respiratory acidosis. For example, bacterial pneumonia causes alveoli to fill with exudate that impairs gas exchange, causing the patient to retain carbon dioxide, which leads to increased $PaCO_2$ and respiratory acidosis.

Burns. Burns place patients at high risk for ECV deficit from numerous mechanisms, including plasma-to-interstitial fluid shift and increased evaporative and exudate output. The greater the body surface burned, the greater is the fluid loss (Copstead and Banasik, 2010). Patients with burns often develop metabolic acidosis because of greatly increased cellular metabolism, which produces more metabolic acids than their kidneys are able to excrete.

Trauma. Hemorrhage from any type of trauma causes ECV deficit from blood loss. Some types of trauma create additional risks. For example, crush injuries cause hyperkalemia. The trauma from the crush injury destroys the cellular structure, resulting in a massive release of intracellular K^+ into the blood.

Head injury typically alters ADH secretion. It may cause diabetes insipidus (secretion of too little ADH), in which patients excrete large volumes of very dilute urine and develop hypernatremia. In contrast, head injury may cause the syndrome of inappropriate antidiuretic hormone (SIADH), in which excess secretion of ADH causes hyponatremia by retaining too much water and concentrating the urine (Copstead and Banasik, 2010).

Chronic Illness. Many chronic diseases create ongoing risk of fluid, electrolyte, and acid-base imbalances. In addition, the treatment regimens for chronic disease often cause imbalances. Assess patients for the presence of these conditions.

Cancer. The types of fluid and electrolyte imbalances that occur with cancer depend on the type and progression of the cancer and treatment regimen. Many patients with cancer develop hypercalcemia when their cancer cells secrete chemicals that circulate into bones and cause calcium to enter the blood. Other fluid and electrolyte imbalances occur in cancer because some types of tumors cause metabolic and endocrine abnormalities. In addition, patients with cancer are at risk for fluid and electrolyte imbalances as a result of the side effects (e.g., anorexia, diarrhea) of chemotherapy, biological response modifiers, or radiation (Copstead and Banasik, 2010).

Heart Failure. Patients who have chronic heart failure have diminished cardiac output, which reduces kidney perfusion and activates the RAAS. The action of aldosterone on the kidneys causes ECV excess and risk of hypokalemia. Most diuretics used to treat heart failure increase the risk of hypokalemia while reducing the ECV excess. Dietary sodium restriction is important with heart failure because Na^+ holds water in the ECF, making the ECV excess worse. In severe heart failure restriction of both fluid and sodium is prescribed to decrease the workload of the heart by reducing excess circulating fluid volume (Copstead and Banasik, 2010).

Oliguric Renal Disease. Oliguria occurs when the kidneys have a reduced capacity to make urine. Some conditions, such as acute rephritis, cause a sudden onset of oliguria, whereas other problems, such as chronic kidney disease, lead to chronic oliguria. Oliguric renal disease prevents normal excretion of fluid, electrolytes, and metabolic acids, resulting in ECV excess, hyperkalemia, hypermagnesemia, hyperphosphatemia, and metabolic acidosis. The severity of these imbalances is proportional to the degree of renal failure. Although chronic kidney disease is progressive, successful management of imbalances is possible with dietary restriction of sodium and other electrolytes, fluid restriction in severe cases, and eventually dialysis or renal transplant (Copstead and Banasik, 2010).

Physical Assessment

Data gathered through a focused physical assessment validates and extends the information collected in the patient history. Table 41-10 summarizes focused assessments for patients with fluid, electrolyte, and acid-base imbalances. Focus your assessment on the areas pertinent to each patient situation. For example, for patients at risk of fluid imbalances, focus your assessment on body weight changes, clinical markers of vascular and interstitial volume, thirst, behavior changes, and level of consciousness. Additional focused assessments for patients at high risk of electrolyte and acid-base imbalances include specific cardiac, respiratory, neuromuscular, and GI markers. Grouping your assessments under these categories helps you know which assessments to prioritize and enables you to assess effectively.

Daily Weights and Fluid Intake and Output Measurement. Daily weights are an important indicator of fluid status (Metheny, 2010). Each kilogram (2.2 lbs) of weight gained or lost overnight is equal to 1 L of fluid retained or lost. These fluid gains or losses indicate changes in the amount of total body fluid, usually ECF, but do not indicate shift between body compartments. Weigh patients with heart failure and those who are at high risk for or actually have ECV excess daily. Daily weights are also useful for patients with clinical dehydration or other causes or risks for ECV deficit. Weigh the patient at the same time each day with the same scale after a patient voids. Calibrate the scale each day or routinely. The patient needs to wear the same clothes or clothes that weigh the same; if using a bed scale, use the same number of sheets on the scale with each weighing. Compare the weight of each day with that of the previous day to determine fluid gains or losses. Look at the weights over several days to recognize trends. Interpretation of daily weights guides medical therapy and nursing care. Teach patients with heart failure to take and record their daily weights at home and to contact their health care provider if their weight increases suddenly by a set amount (obtain parameters from their health care providers). Recognizing trends in daily weights taken at home is important. Research shows that patients who are hospitalized for decompensated heart failure often experience steady increases in daily weights during the week before hospitalization. A weight gain of more than 2.2 lbs (1 kg) was associated with increased risk of hospitalization because of heart failure (Chaudry et al., 2007).

Measuring and recording all liquid intake and output (I&O) during a 24-hour period is an important aspect of fluid balance assessment. Compare a patient's 24-hour intake with his or her 24-hour output. The two measures should be approximately equal if the person has normal fluid balance. To interpret situations in which I&O are substantially different, consider the individual patient. For example, if intake is substantially greater than output, there are two possibilities: the patient may be gaining excessive fluid or may be returning to normal fluid status by replacing fluid lost previously from the body. Similarly, if intake is substantially smaller than output, there are also two possibilities: The patient may be losing needed fluid from the body and developing ECV deficit and/or hypernatremia or may be returning to normal fluid status by excreting excessive fluid gained previously.

In most health care settings I&O measurement is a nursing assessment. Some agencies require a health care provider's order for I&O. If you want to measure I&O for a patient with compromised fluid status, check your agency policies to determine whether you can institute it or if you need a health care provider's order.

Fluid intake includes all liquids that a person eats (e.g., gelatin, ice cream, soup), drinks, (e.g., water, coffee, juice), or receives through nasogastric or jejunostomy feeding tubes (see Chapter 44). IV fluids (continuous infusions and intermittent IV piggybacks) and blood components are also sources of intake. Water swallowed while taking pills and liquid medications also counts as intake. A patient receiving tube feedings often receives numerous liquid medications, and water is used to flush the tube before and/or after medications. Over a 24-hour period these liquids amount to significant intake and always are recorded on the I&O record.

TABLE 41-10 Focused Nursing Assessments for Patients with Fluid, Electrolyte, and Acid-Base Imbalances

ASSESSMENT	IMBALANCES
Body Weight Changes from Previous Day	
Loss of 2.2 lbs (1 kg) or more in 24 hours for adults	ECV deficit
Gain of 2.2 lbs (1 kg) or more in 24 hours for adults	ECV excess
Clinical Markers of Vascular Volume	
Blood pressure:	
Hypotension or orthostatic hypotension	ECV deficit
Light-headedness on sitting upright or standing	ECV deficit
Pulse rate and character:	
Rapid, thready	ECV deficit
Bounding	ECV excess
Fullness of neck veins:	
Flat or collapsing with inhalation when supine	ECV deficit
Full or distended when upright or semi-upright	ECV excess
Capillary refill: Sluggish	ECV deficit
Lung auscultation, dependent portions: Crackles or rhonchi with progressive dyspnea	ECV excess
Urine output: Small volume of dark yellow urine	ECV deficit
Clinical Markers of Interstitial Volume	
Presence of edema: Present in dependent areas (ankles or sacrum) and possibly fingers or around eyes	ECV excess
Mucous membranes: Dry between cheek and gum, decreased or absent tearing	ECV deficit
Skin turgor: Pinched skin fails to return to normal position within 3 seconds	ECV deficit
Presence of thirst: Thirst present	Hypernatremia, severe ECV deficit
Behavior and Level of Consciousness	
Restlessness and mild confusion	Severe ECV deficit
Decreased level of consciousness (lethargy, confusion, coma)	Hyponatremia, hypernatremia, hypercalcemia, acid-base imbalances
Cardiac and Respiratory Signs of Electrolyte or Acid-Base Imbalances	
Pulse rhythm and ECG: Irregular pulse and ECG changes	K^+, Ca^{2+}, Mg^{2+}, and/or acid-base imbalances
Rate and depth of respirations:	
Increased rate and depth	Metabolic acidosis (compensatory mechanism); respiratory alkalosis (cause)
Decreased rate and depth	Metabolic alkalosis (compensatory mechanism); respiratory acidosis (cause)
Neuromuscular Markers of Electrolyte or Acid-Base Imbalances	
Muscle strength bilaterally, especially quadriceps muscles:	
Muscle weakness	Hypokalemia, hyperkalemia
Reflexes and sensations:	
Decreased deep tendon reflexes	Hypercalcemia, hypermagnesemia
Hyperactive reflexes, muscle twitching and cramps, tetany	Hypocalcemia, hypomagnesemia
Numbness, tingling in fingertips, around mouth	Hypocalcemia, hypomagnesemia, respiratory alkalosis
Muscle cramps, tetany	Hypocalcemia, hypomagnesemia, respiratory alkalosis
Tremors	Hypomagnesemia
Gastrointestinal Signs of Electrolyte Imbalances	
Inspection and auscultation:	
Abdominal distention	Hypokalemia, third-spacing of fluid
Decreased bowel sounds	Hypokalemia
Motility: Constipation	Hypokalemia, hypercalcemia

ECG, Electrocardiogram; *ECV,* extracellular fluid volume.

Ask patients who are alert and oriented to assist with measuring their oral intake and explain to families why they should not drink or eat from the patient's meal trays or water pitcher.

Fluid output includes urine, diarrhea, vomitus, gastric suction, and drainage from postsurgical wounds or other tubes (see Chapter 50). Record a patient's urinary output after each voiding. Instruct patients who are alert, oriented, and ambulatory to save their urine in a calibrated insert, which attaches to the rim of the toilet bowl (Fig. 41-10). Teach patients and families the purpose of I&O measurements. Teach them to notify the nurse or nursing assistive personnel (NAP) to empty any container with voided fluid or how to measure and empty the container themselves and report the result appropriately. Patients need to have good vision and motor skills to perform these measurements. Active involvement of patient and family is an aspect of patient-centered care that is essential to maintaining accurate I&O measurements. When a patient has an indwelling urinary catheter, drainage tube, or suction, record output (e.g., at the end of each nursing shift or every hour) as the patient's condition requires.

You can delegate portions of I&O measurement and recording to NAP with competent skills in measurement. Research shows that visual estimates of fluid volumes often are unreliable; actual measurement is preferable (McConnell et al., 2007). In many institutions NAP record oral intake but not intake through feeding or IV tubes, which are nursing responsibilities. Similarly NAP often record urine, diarrhea, and vomitus output but not drainage through tubes. The responsible registered nurse (RN) or licensed practical nurse/licensed vocational nurse (LPN/LVN) and the NAP work as a team to record measurements in the designated location in the electronic health record (EHR), often on a flow sheet with other information. The EHR program usually calculates the 24-hour totals. If an EHR is not used, record I&O on paper forms attached to the bedside chart or room door. You or the NAP calculate the 24-hour totals (see agency policy). Accurate I&O facilitates ongoing evaluation of a patient's hydration status.

Laboratory Values

Review the patient's laboratory test results and compare them with the normal ranges to obtain further objective data about fluid, electrolyte, and acid-base balances. Normal and abnormal test results are summarized in Tables 41-1, 41-3, 41-5, 41-6, and 41-7. The frequency of electrolyte level measurements depends on the severity of the patient's illness. Analysis of laboratory results requires a good medical clinician, especially if a person develops an acute imbalance while also having a chronic disease. Serum electrolyte tests usually are performed routinely on any patient entering a hospital to screen for imbalances and serve as a baseline for future comparisons.

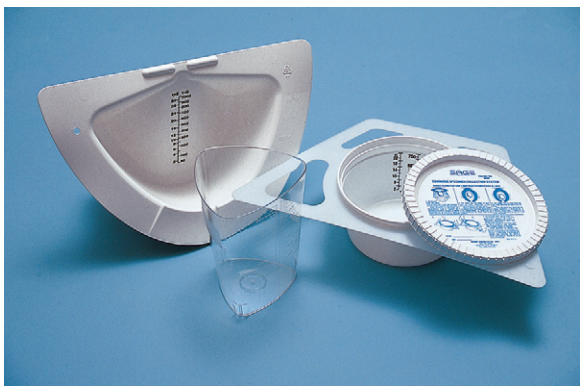

FIG. 41-10 Containers for measuring urine output.

NURSING DIAGNOSIS

When caring for patients with suspected fluid, electrolyte, and acid-base imbalances, it is particularly important to use critical thinking to formulate nursing diagnoses. The assessment data that establish the risk for or the actual presence of a nursing diagnosis in these areas are often subtle, and patterns and trends emerge only when there has been astute assessment. Multiple body systems are often involved; careful clustering of defining characteristics leads to selection of the appropriate diagnoses (Box 41-4).

In addition to the accurate clustering of assessment data, an important part of formulating nursing diagnoses is identifying the relevant causative or related factor. You choose interventions that treat or modify the related factor for the diagnosis to be resolved. For example, *deficient fluid volume related to loss of GI fluids from vomiting* requires therapies that manage the patients' emesis and restore fluid volume with IV therapy. In contrast, the diagnosis of *deficient fluid volume related to elevated body temperature* requires therapies to lower the patient's body temperature and replace lost body fluids through oral fluid replacement or possibly IV therapy. Possible nursing diagnoses for patients with fluid, electrolyte, and acid-base alterations include the following:

- Decreased cardiac output
- Acute confusion
- Risk for electrolyte imbalance
- Deficient fluid volume
- Excess fluid volume
- Impaired gas exchange
- Risk for injury
- Deficient knowledge regarding disease management
- Impaired oral mucous membrane
- Impaired skin integrity
- Ineffective tissue perfusion

PLANNING

During the planning process use critical thinking to synthesize information from multiple resources (Fig. 41-11). Ensure that

BOX 41-4 NURSING DIAGNOSTIC PROCESS

Deficient Fluid Volume Related to Loss of Gastrointestinal Fluids via Vomiting

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Assess postural blood pressure and pulse.	Patient has postural hypotension with increased heart rate; pulse is weak.
Inspect oral mucous membranes for degree of moisture.	Oral mucous membranes between cheek and gum are dry.
Obtain daily weight measurements.	Adult patient loses 2.2 lbs (1 kg) or more in 24 hours.
Measure urine output and observe color; if available, measure specific gravity of urine.	Patient produces small volume of dark yellow urine; urine specific gravity is increased.
Test skin turgor (not reliable for older adults).	Decreased skin turgor noted.

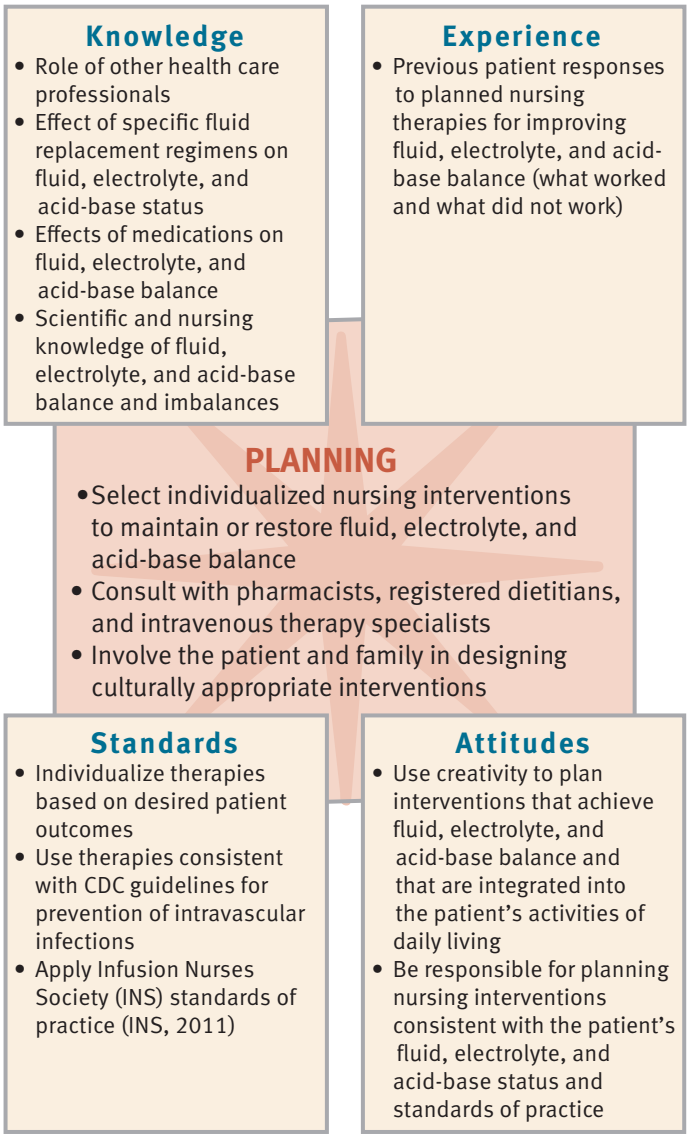

FIG. 41-11 Critical thinking model for fluid, electrolyte, and acid-base balances planning. *CDC,* Centers for Disease Control and Prevention.

the patient's plan of care integrates both scientific and nursing knowledge and all of the information that you collected about the individual patient.

Goals and Outcomes. Establish an individual patient plan of care for each nursing diagnosis (see the Nursing Care Plan) that includes mutually established patient goals for each diagnosis. Goals need to be individualized and realistic with measurable outcomes. For example, with a nursing diagnosis of *deficient fluid volume,* the following related outcomes may be established for the goal, "The patient will achieve normal hydration status at discharge":

- The patient will be free of complications associated with the IV device throughout the duration of IV therapy.
- The patient will demonstrate balanced I&O measurements within 48 hours.
- The patient will have serum electrolytes within the normal range within 48 hours.

Setting Priorities. The patient's clinical condition determines which of the nursing diagnoses takes the greatest priority. Many nursing diagnoses in the area of fluid, electrolyte, and acid-base balances are of highest priority because the consequences for the patient can be serious or even life threatening. For example, in the concept map (Fig. 41-12 on p. 903) for Mrs. Beck, the occurrence of vomiting and diarrhea created a high-priority nursing diagnosis of *fluid volume deficit*. In this situation intervention is necessary to help resolve her vomiting and diarrhea and replace her deficient fluid volume. If these priorities are unmet, Mrs. Beck's fluid imbalance likely will worsen.

Teamwork and Collaboration. Consultation with a patient's health care provider helps to set realistic time frames for the goals of care, particularly when the patient's physiological status is unstable. Ongoing communication and consultation are important because the patient's condition can change quickly. Collaboration with the patient and family and other members of the interdisciplinary health care team such as IV therapy and pharmacy assists in achieving patient outcomes. Patient and family are very helpful in identifying approaches for successful therapies, such as ways to increase fluid intake. Incorporate patient preferences and resources into the plan of care. Do **not** delegate administration of IV fluid and hemodynamic assessment to NAP. When the patient is stable, you can delegate daily weights, I&O, and direct physical care to NAP.

NURSING CARE PLAN

Deficient Fluid Volume

ASSESSMENT

Mrs. Hilda Beck is a 72-year-old seen by her health care provider this morning after falling at home and telephoning a neighbor for assistance. She lives alone in an apartment and has no chronic disease except for osteoarthritis of her hands. She has had diarrhea and vomiting for over 24 hours and has not eaten anything. Despite feeling slightly nauseated, she tried to drink a little water, because she knew she needed it. Mrs. Beck is admitted for intravenous (IV) fluid therapy. X-ray films indicate that she has no broken bones. Mrs. Beck voids a small amount of dark yellow urine. Review of laboratory findings: hematocrit 55% (hemoconcentration caused by hypovolemia); sodium 148 mEq/L, and potassium 3 mEq/L. (NOTE: Mrs. Beck has hypokalemia in addition to extracellular fluid volume [ECV] deficit and hypernatremia [clinical dehydration].)

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Beck to describe when her vomiting and diarrhea began and any accompanying signs and symptoms.	She states that her gastrointestinal (GI) problems began suddenly yesterday and that she **gets weak and light-headed when she stands or sits upright,** which is why she fell. She feels **weak** and has a **dry mouth.**
Ask her about current status of vomiting and diarrhea.	Says she still was vomiting earlier this morning. Has not done so for the past 3 hours. Feels slightly nauseated. Had three episodes of watery diarrhea this morning and more than six yesterday.

NURSING CARE PLAN

***Deficient Fluid Volume*—cont'd**

Assess Mrs. Beck's vital signs.	**Heart rate 102** beats/min with regular rhythm and a **weak pulse; supine blood pressure (BP) is 90/58.** Temperature and respirations within normal limits. Postural BP measurement not taken since patient says that she **gets light-headed when she sits upright.**
Evaluate physical signs of ECV.	Neck veins flat when she is supine; **100 mL of dark yellow urine** in past 4 hours; dry mucous membranes between cheek and gum; prolonged capillary refill time of 5 seconds.
Weigh Mrs. Beck using a bed scale.	Weight 120 lb (54.5 kg). States usual weight at home is 127 lb (46.27 kg) **(7 lb [3.17 kg] weight loss).**

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Deficient fluid volume related to increased output of GI fluids from vomiting and diarrhea

PLANNING

Goals	*Expected Outcomes (NOC)*†
Mrs. Beck's fluid volume will return to normal by hospital discharge.	**Fluid Balance** Heart rate and BP will return to normal within 24 hours. Mrs. Beck will not report light-headedness when sitting or standing within 24 hours. Urine color will become light yellow within 24 hours. Daily urine output will equal intake of at least 1500 mL by discharge.
Mrs. Beck will describe how to manage fluid balance at home before hospital discharge.	Mrs. Beck will describe how to replace GI fluid loss with fluids that contain sodium. She will describe signs and symptoms indicating need to increase fluid and sodium intake.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 4, St Louis, 2008, Mosby.

INTERVENTIONS‡ (NIC) *Fluid/Electrolyte Management*	RATIONALE
Provide Mrs. Beck her favorite noncaffeinated fluids at her preferred temperature.	Patient-centered care takes individual preferences into account (Cronenwett et al., 2007). Cultural preferences regarding temperature of oral fluid influence fluid intake (Giger and Davidhizar, 2008). Avoid caffeinated beverages because of their diuretic effect.
Provide a pitcher and glass of water at Mrs. Beck's preferred temperature at her bedside; ensure that she can access and pour from it easily; provide a straw if she wishes.	Weakness or chronic disease such as osteoarthritis of hands may make it difficult to manipulate a full water pitcher. Make fluid available in a form that is easy for a patient to access.
Administer IV therapy as prescribed, monitoring closely for early side effects of complications.	IV fluid replacement augments oral replacement when ECV deficit exists. Age-appropriate care is needed because of older adult's anatomical and physiological changes that effect volume delivery (INS, 2011).
Discuss different ways to prevent and treat dehydration at home. Provide written handout of information.	Patient education is enhanced in older adults when you use multiple senses during teaching sessions (Meiner, 2011).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC)*, ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Monitor vital signs, intake and output (I&O), daily weight, and postural BP when no longer light-headed.	T 37° C (98.6° F), RR 10, HR 72 bpm, BP 120/78 sitting, 122/78 standing, denies light-headedness Intake 2000 mL, output 2000 mL of light yellow urine Today's weight 129 lb (58.5 kg)	Vital signs returned to normal range. No postural hypotension. I&O measurements are balanced, urine is light yellow. Daily weight returned to Mrs. Beck's normal.
Assess neck vein fullness when supine, mucous membranes.	Neck veins full when supine; mucous membranes moist	Additional markers of ECV are normal.
Evaluate effectiveness of teaching regarding maintaining fluid balance at home.	Mrs. Beck identified salty broth and commercial electrolyte replacement fluids for replacing GI fluid loss and indicated need to increase her intake if her urine becomes dark yellow or she becomes light-headed when sitting upright.	Mrs. Beck describes effective home management of fluid balance.

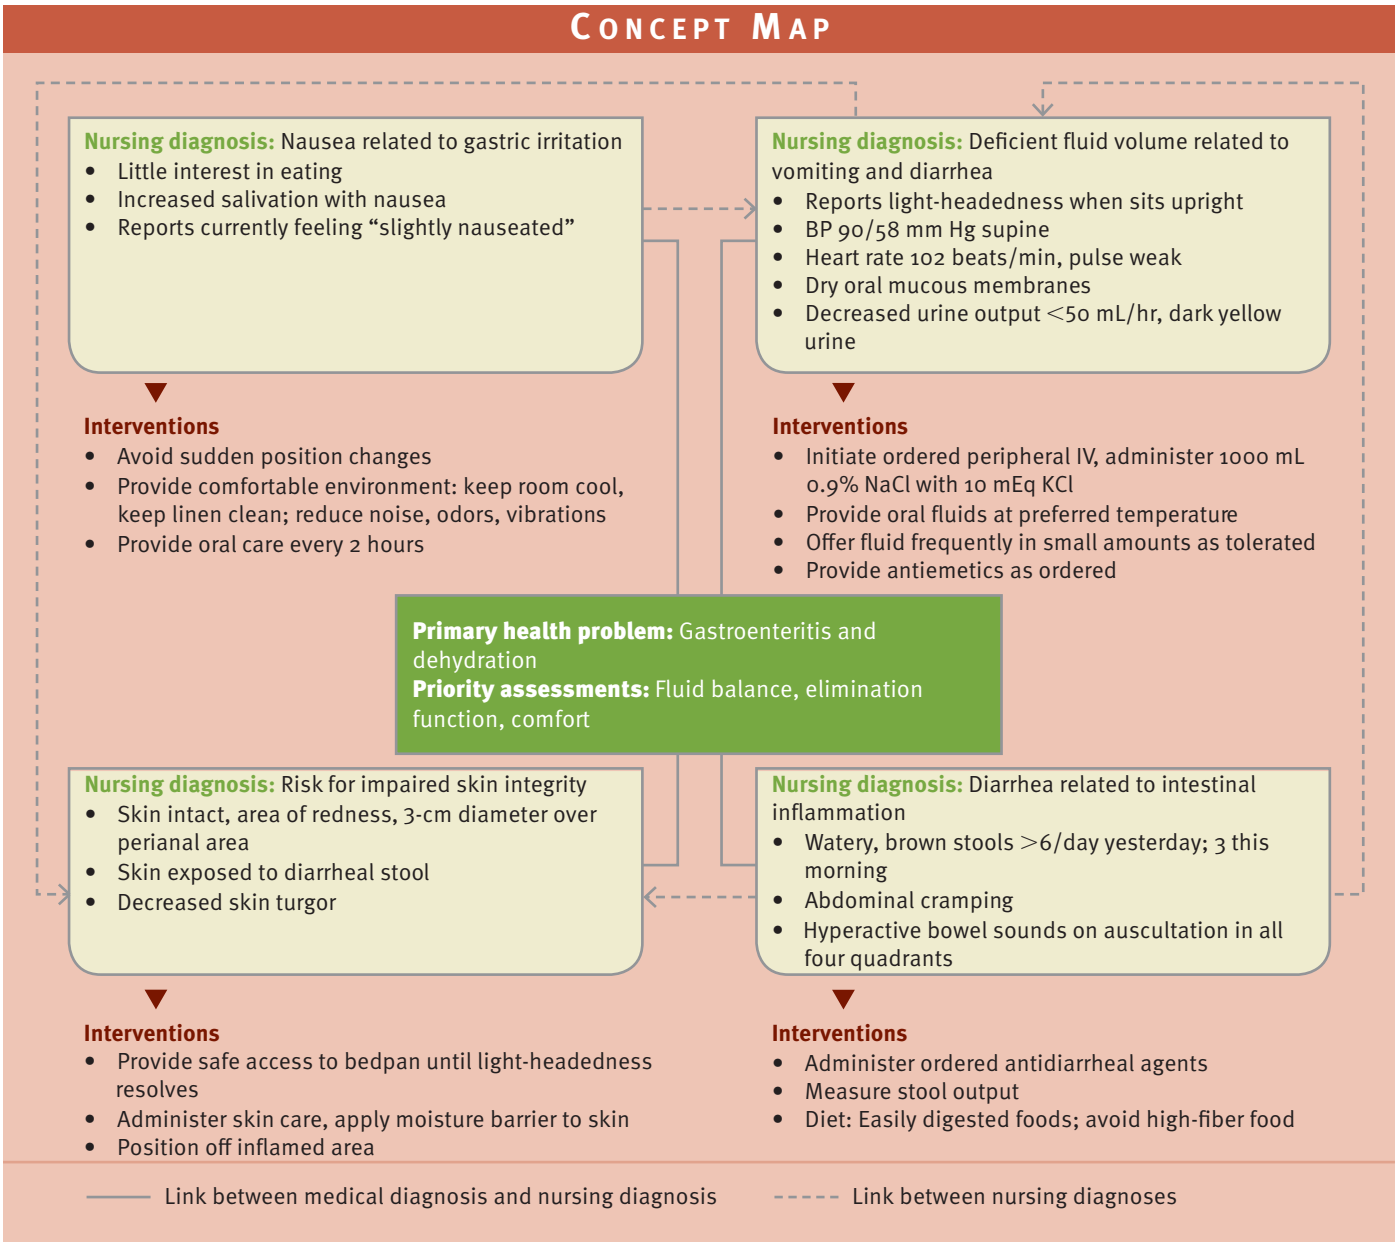

FIG. 41-12 Concept map for Mrs. Beck.

Begin discharge planning early for patients with acute or chronic fluid and electrolyte disturbances by anticipating the needs of the patient and family as they transition to another setting. In the hospital, collaboration with other members of the health care team ensures that care will continue in the home or long-term care setting with few disruptions. You ensure that therapeutic regimens established in one setting continue through completion at the next setting. For example, for a patient who is discharged on IV therapy, you assess the knowledge and skills of the family member or friend who is to assume caregiving responsibilities and initiate a referral to home IV therapy as soon as possible. Close collaboration with members of the health care team such as the patient's health care provider, dietitian, and pharmacist is essential to ensure positive patient outcomes. A dietitian is a valuable resource in recommending food sources to increase or reduce intake of specific electrolytes (see Chapter 44). A pharmacist helps identify medications or combinations of medications likely to cause electrolyte or acid-base disturbances and offer information regarding patient education about side effects to anticipate for prescribed drugs. The patient's health care provider directs the treatment of fluid, electrolyte, or acid-base imbalances.

IMPLEMENTATION

Health Promotion. Health promotion activities focus primarily on patient education. Teach patients and caregivers to recognize risk factors for developing imbalances and implement appropriate preventive measures. For example, parents of infants need to understand that GI losses lead quickly to serious imbalances; therefore, when vomiting or diarrhea occurs in an infant, they need to promptly rehydrate with sodium-containing fluid or seek health care to restore normal balance. People of any age need to

learn to replace body fluid losses with sodium-containing fluid and water.

Patients with chronic health alterations often are at risk for developing fluid, electrolyte, and acid-base imbalances. They need to understand their own risk factors and the measures to be taken to avoid imbalances. For example, patients with end-stage renal disease often need to restrict intake of fluid, sodium, potassium, magnesium, and phosphate. Through diet education these patients learn the types of foods to avoid and the suitable volume of fluid that they are permitted daily (see Chapter 44). Teach patients with chronic diseases and their family caregivers the early signs and symptoms of the fluid, electrolyte, and acid-base imbalances for which they are at risk and what to do if these occur.

Acute Care. Although fluid, electrolyte, and/or acid-base imbalances occur in all settings, they are common in acute care. Acute care nurses administer medications and oral and IV fluids to replace fluid and electrolyte deficits or maintain normal homeostasis; they also assist with restricting intake as part of therapy for excesses.

Enteral Replacement of Fluids. Oral replacement of fluids and electrolytes is appropriate as long as the patient is not so physiologically unstable that oral fluids cannot be replaced rapidly. Oral replacement of fluids is contraindicated when the patient has a mechanical obstruction of the GI tract, is at high risk for aspiration, or has impaired swallowing. Some patients unable to tolerate solid foods are still able to ingest fluids. Strategies to encourage fluid intake include offering small sips of fluid frequently, popsicles, and ice chips. Record one half the volume of the ice chips in I&O measurement. For example, if a patient ingests 240 mL of ice chips, you record 120 mL of intake. Encourage patients to keep their own record of intake to involve them actively. Family members who are properly instructed can also assist. Pay attention to each patient's preferred temperature of oral fluids. Cultural beliefs regarding appropriate fluid temperature may interfere with fluid intake unless the fluid with the preferred temperature is available (Box 41-5).

When replacing fluids by mouth in a patient with ECV deficit, choose fluids that contain sodium (e.g., Pedialyte and Gastrolyte). Liquids containing lactose, caffeine, or low-sodium content are not appropriate when a patient has diarrhea.

A feeding tube is appropriate when the patient's GI tract is healthy but the patient cannot ingest fluids (e.g., after oral surgery or with impaired swallowing). Options for administering fluids include gastrostomy or jejunostomy instillations or infusions through small-bore nasogastric feeding tubes (see Chapter 44).

Restriction of Fluids. Patients who have hyponatremia usually require restricted water intake. Patients who have very severe ECV excess sometimes have both sodium and fluid restrictions. Fluid restriction often is difficult for patients, particularly if they take medications that dry the oral mucous membranes or if they are mouth breathers. Explain the reason that fluids are restricted and ensure that the patient and family visitors know the amount of fluid permitted orally and understand that ice chips, gelatin, and ice cream are fluids. Help the patient decide the amount of fluid to drink with each meal, between meals, before bed, and with medications. It is important to allow patients to choose preferred fluids unless contraindicated. Frequently patients on fluid restriction can swallow a number of pills with as little as 1 oz (30 mL) of liquid.

In acute care settings fluid restrictions usually allot half the total oral fluids between 7 AM and 3 PM, the period when patients are more active, receive two meals, and take most of their oral medications. Offer the remainder of the fluids during the evening and night shifts. Patients on fluid restriction need frequent mouth care to moisten mucous membranes, decrease the chance of mucosal drying and cracking, and maintain comfort (see Chapter 39).

BOX 41-5 CULTURAL ASPECTS OF CARE

Fluid Therapy

Cultural and religious beliefs influence how you manage fluid therapy and how patients communicate their needs. For example, the family elder may be the person who receives explanations and makes health care decisions rather than the patient. A person's cultural and religious beliefs may cause refusal of therapies. For example, hot-cold beliefs often cause patients to refuse cold oral fluids when they have certain illnesses because they believe that hot fluids are needed to restore balance (Giger and Davidhizar, 2008). Religious practices may require modifications of intravenous (IV) tubing length (e.g., patients need to kneel on the floor and pray several times daily).

Implications for Practice

- Establish communication. If appropriate, determine who the family elder is and explain fluid restriction or IV therapy procedures.
- Elicit patient/family values and preferences in your clinical interview. Ask specifically about preferred temperature of oral fluids and provide (if oral intake is allowed).
- Determine needed length of IV tubing and incorporate one or more segments of long extension tubing into the IV setup if patient kneels on the floor to pray.
- Determine acceptance of or abstinence from therapeutic regimens and respect patients/family choices regarding therapy.
- Although some patients refuse whole blood or packed red blood cells because of religious or personal beliefs, they may accept other blood products or alternatives.
- When the natural skin color is dark, assess carefully for subtle color changes at vascular access device site that might indicate phlebitis, which may be more difficult to recognize.
- Communicate patient/family values and choices to other members of the health care team.

Parenteral Replacement of Fluids and Electrolytes. Fluid and electrolytes may be replaced through infusion of fluids directly into veins (intravenously) rather than via the digestive system. Parenteral replacement includes parenteral nutrition (PN), IV fluid and electrolyte therapy (crystalloids), and blood and blood component (colloids) administration. IV devices are called *peripheral IVs* when the catheter tip lies in a vein in one of the extremities; they are called *central venous IVs* when the catheter tip lies in the central circulatory system (e.g., in the vena cava close to the right atrium of the heart) (Fig. 41-13).

Practice standard body fluid precautions when administering parenteral fluids (see Chapter 28) to minimize your own risk for exposure to bloodborne pathogens. Read and understand the policy and procedures for parenteral infusions at the institution for which you work.

Parenteral Nutrition. PN, also called *total parenteral nutrition (TPN),* is IV administration of a complex, highly concentrated solution containing nutrients and electrolytes that is formulated to meet a patient's needs. Depending on their osmolality, PN solutions are administered through a central IV catheter (high osmolality) or peripherally (lower osmolality). Chapter 44 reviews principles and guidelines for PN administration, which is used when patients are unable to receive enough nutrition orally or through enteral feeding.

TABLE 41-11 Intravenous Solutions

SOLUTION	CONCENTRATION	COMMENTS
Dextrose in Water Solutions		Dextrose is another name for glucose.
Dextrose 5% in water (D_5W)	Isotonic	Isotonic when first enters vein. Dextrose enters cells rapidly, leaving free water, which dilutes ECF; most of the water then enters cells by osmosis.
Dextrose 10% in water ($D_{10}W$)	Hypertonic	Dextrose enters cells rapidly, leaving free water, which dilutes ECF; most of the water then enters cells by osmosis.
Saline Solutions		Saline is sodium chloride in water.
0.225% sodium chloride (quarter normal saline; ¼ NS; 0.225% NaCl)	Hypotonic	Expands ECV (vascular and interstitial) and rehydrates cells
0.45% sodium chloride (half normal saline; ½ NS; 0.45% NaCl)	Hypotonic	Expands ECV (vascular and interstitial) and rehydrates cells
0.9% sodium chloride (normal saline; NS; 0.9% NaCl)	Isotonic	Expands ECV (vascular and interstitial); does not enter cells
3% or 5% sodium chloride (hypertonic saline; 3% or 5% NaCl)	Hypertonic	Draws water from cells into ECF by osmosis
Dextrose in Saline Solutions		
Dextrose 5% in 0.45% NaCl sodium chloride ($D_5½NS$; $D_50.45\%$ NaCl)	Hypertonic	Dextrose enters cells rapidly, leaving 0.45% sodium chloride.
Dextrose 5% in 0.9% sodium chloride (D_5NS; $D_50.9\%$ NaCl)	Hypertonic	Dextrose enters cells rapidly, leaving 0.9% sodium chloride.
Balanced Electrolyte Solutions		
Lactated Ringer's (LR)	Isotonic	Contains Na^+, K^+, Ca^{2+}, Cl^-, and lactate, which the liver metabolizes to HCO_3^-. Expands ECV (vascular and interstitial); does not enter cells.
Dextrose 5% in lactated Ringer's (D_5LR)	Hypertonic	Dextrose enters cells rapidly, leaving lactated Ringer's.

ECF, Extracellular fluid; *ECV,* extracellular fluid volume.

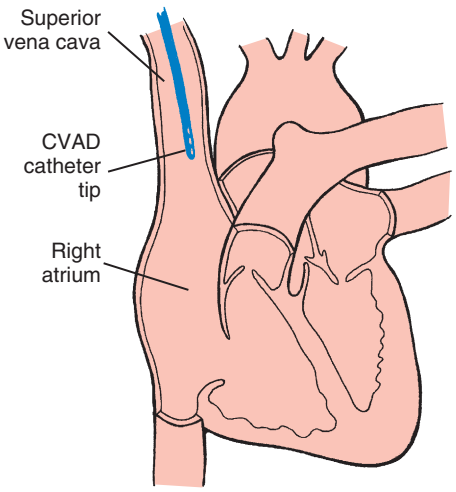

FIG. 41-13 Central venous lines deliver intravenous fluid into superior vena cava near heart. *CVAD,* Central venous access device.

Intravenous Therapy (Crystalloids). The goal of IV fluid administration is to correct or prevent fluid and electrolyte disturbances. It allows for direct access to the vascular system, permitting the continuous infusion of fluids over a period of time. You regulate IV fluid therapy continuously because of ongoing changes in a patient's fluid and electrolyte balance. To provide safe and appropriate therapy to patients who require IV fluids, you need knowledge of the correct ordered solution, the reason the solution was ordered, the equipment needed, the procedures required to initiate an infusion, how to regulate the infusion rate and maintain the system, how to identify and correct problems, and how to discontinue the infusion.

Types of Solutions. Many prepared IV solutions are available for use (Table 41-11). An IV solution is isotonic, hypotonic, or hypertonic. Isotonic solutions have the same effective osmolality as body fluids. Sodium-containing isotonic solutions such as normal saline are indicated for ECV replacement to prevent or treat ECV deficit. Hypotonic solutions have an effective osmolality less than body fluids, thus decreasing osmolality by diluting body fluids and moving water into cells. Hypertonic solutions have an effective osmolality greater than body fluids. If they are hypertonic sodium-containing solutions, they increase osmolality rapidly and pull water out of cells, causing them to shrivel (David, 2007). The decision to use a hypotonic or hypertonic solution is based on the patient's specific fluid and electrolyte imbalance. For example, a patient with hypernatremia that cannot be treated with oral water generally receives a hypotonic IV solution to dilute the ECF and rehydrate cells. Too rapid or excessive infusion of any IV fluid has the potential to cause serious patient problems.

Additives such as potassium chloride (KCl) are common in IV solutions. A health care provider's order is necessary if an IV is to have additives added (e.g., 1000 mL $D_5½NS$ with 20 mEq KCl at 125 mL/hr). Administer KCl carefully because hyperkalemia can cause fatal cardiac dysrhythmias. Under no circumstances should it be administered by IV push (directly through a port in IV tubing). Verify that a patient has adequate kidney function and urine output before administering an IV solution containing potassium. Patients with normal renal function who are receiving nothing by mouth should have potassium added to IV solutions. The body cannot conserve potassium, and the kidneys continue to

excrete potassium even when the plasma level falls. Without potassium intake, hypokalemia develops quickly.

Vascular Access Devices. **Vascular access devices (VADs)** are catheters or infusion ports designed for repeated access to the vascular system. Peripheral catheters are for short-term use (e.g., fluid restoration after surgery and short-term antibiotic administration). Devices for long-term use include central catheters and implanted ports, which empty into a central vein. Remember that the term *central* applies to the location of the catheter tip, not to the insertion site. Peripherally inserted central catheters (PICC lines) enter a peripheral arm vein and extend through the venous system to the superior vena cava where they terminate. Other central lines enter a central vein such as the subclavian or jugular vein or are tunneled through subcutaneous tissue before entering a central vein. Central lines are more effective than peripheral catheters for administering large volumes of fluid, PN, and medications or fluids that irritate veins. Proper care of central line insertion sites is critical for the prevention of catheter-related bloodstream infections (CRBSI). The National Quality Forum (NQF) (2010) identified CRBSIs as one of their endorsed patient safety measures that health care institutions are encouraged to report. *Beginning in October of 2008, the Centers for Medicare and Medicaid Services (CMS) no longer reimburses* over and above the typical inpatient prospective payment system rate for care required to manage and correct a CRBSI. This means that a hospital is not paid for the added costs and hospital days needed to treat it. Nurses require specialized education regarding care of central venous catheters and implanted infusion ports. Nursing responsibilities for central lines include careful monitoring, flushing to keep the line patent, and site care and dressing changes to prevent CRBSIs.

Equipment. Correct selection and preparation of IV equipment assists in safe and quick placement of an IV line. Because fluids infuse directly into the bloodstream, sterile technique is necessary. Organize all equipment at the bedside for an efficient insertion. IV equipment includes VADs, tourniquet, clean gloves, dressings, IV fluid containers, various types of tubing, and electronic infusion devices (EIDs), also called *infusion pumps*. VADs that are short, peripheral IV catheters are available in a variety of gauges such as the commonly used 20 and 22 gauges. A larger gauge indicates a smaller-diameter catheter. A peripheral VAD is called an over-the-needle catheter; it consists of a small plastic tube or catheter threaded over a sharp stylet (needle). Once you insert the stylet and advance the catheter into the vein, you withdraw the stylet, leaving the catheter in place. These devices have a safety mechanism that covers the sharp stylet when withdrawing it to reduce the risk of needlestick injury (Fig. 41-14). Needleless systems allow you to make connections without using needles, which reduces needlestick injuries (Hadaway and Richardson, 2010).

The main IV fluid used in a continuous infusion flows through tubing called the *primary line*. The primary line connects to the IV catheter. Injectable medications such as antibiotics are usually added to a small IV solution bag and "piggybacked" as a secondary set into the primary line or as a primary intermittent infusion to be administered over a 30- to 60-minute period (see Chapter 31). The type and amount of solution are prescribed by the patient's health care provider and depend on the medication added and the patient's physiological status. If an IV infusion is connected to an EID, use the tubing designated for that EID. For gravity-flow IVs (not using an EID), select tubing as described in the equipment list of Skill 41-1 on pp. 916-925. Add IV extension tubing to increase the length of the primary line, which reduces pulling of the tubing and increases a patient's mobility in changing position.

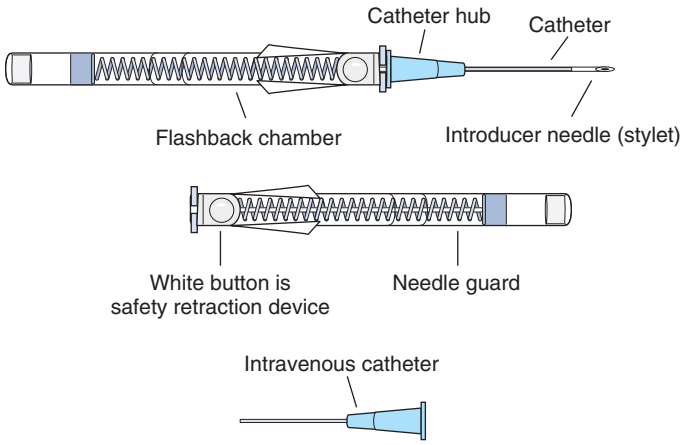

FIG. 41-14 Over-the-needle catheter for venipuncture.

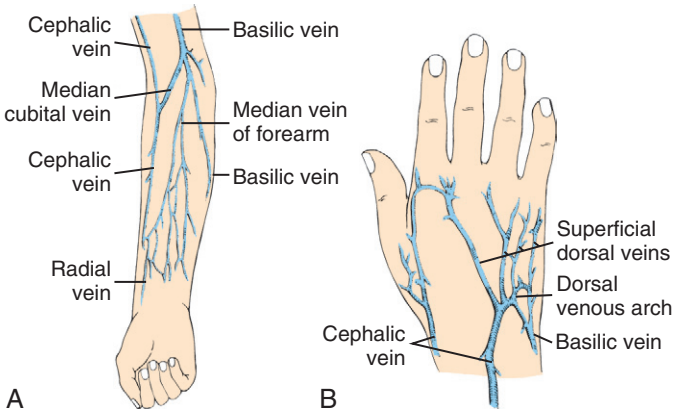

FIG. 41-15 Common IV sites. **A,** Inner arm. **B,** Dorsal surface of hand.

Initiating the Intravenous Line. After you collect the equipment at the patient's bedside, prepare to insert the IV line by assessing the patient for a venipuncture site (see Skill 41-1). The most common IV sites are on the inner arm (Fig. 41-15). Do not use hand veins on older adults or ambulatory patients. IV insertion in a foot vein is common with children, but avoid these sites in adults because of the increased risk of thrombophlebitis (INS, 2011).

As you assess a patient for potential venipuncture sites, consider conditions that exclude certain sites. Venipuncture is contraindicated in a site that has signs of infection, infiltration, or thrombosis. An infected site is red, tender, swollen, and possibly warm to the touch. Exudate may be present. Do not use an infected site because of the danger of introducing bacteria from the skin surface into the bloodstream. Avoid using an extremity with a vascular (dialysis) graft/fistula or on the same side as a mastectomy. Avoid areas of flexion if possible (INS, 2011). Choose the most distal appropriate site (INS, 2011). Using a distal site first allows for the use of proximal sites later if the patient needs a venipuncture site change.

Venipuncture is a technique in which a vein is punctured through the skin by a sharp rigid stylet (e.g., metal needle). The stylet is partially covered either with a plastic catheter or a needle attached to a syringe. General purposes of venipuncture are to collect a blood specimen, start an IV infusion, provide vascular access for later use, instill a medication, or inject a radiopaque or other tracer for special diagnostic examinations. Skill 41-1 describes

BOX 41-6 FOCUS ON OLDER ADULTS

Protection of Skin and Veins During Intravenous Therapy

- Use the smallest-gauge catheter or needle possible (e.g., 22 to 24 gauge). Veins are very fragile, and a smaller gauge allows better blood flow to provide increased hemodilution of the intravenous (IV) fluids or medications (Fabian, 2010).
- Avoid the back of the hand, which may compromise the patient's need for independence and mobility (O'Halloran, El-Masri, and Fox-Wasylyshyn, 2008).
- Avoid placement of IV line in veins that are easily bumped because older adults have less subcutaneous support tissue.
- Avoid vigorous friction while cleaning the site to prevent tearing fragile skin.
- If the patient has fragile skin and veins, use minimal or no tourniquet pressure.
- If using a tourniquet, place it over the patient's sleeve or use a blood pressure cuff.
- With loss of supportive tissue, veins tend to lie more superficially; lower the insertion angle for venipuncture to 10 to 15 degrees after penetrating the skin (Fabian, 2010).
- Veins roll away from the needle easily because of loss of subcutaneous tissue. To stabilize the vein, apply traction to the skin below the projected insertion site (Fabian, 2010).
- Secure IV site with a catheter stabilization device and perhaps a mesh dressing for protection, avoiding excessive use of tape on fragile skin (Fabian, 2010).
- Numerous medications and supplements (e.g., anticoagulants, antibiotics, glucocorticoids, and garlic) increase the likelihood of bruising and bleeding.

venipuncture for peripheral IV fluid infusion, incorporating INS (2011) standards of practice. It takes practice to become proficient in venipuncture. Only experienced practitioners perform it for patients whose veins are fragile or collapse easily, such as older adults. Box 41-6 describes principles to follow for venipuncture in older adults.

Nurses require specialized knowledge and education to place PICCs. Some central lines and implanted ports require insertion by physicians or advanced practice nurses. Both types of central catheters require close monitoring and maintenance. This chapter focuses on peripheral catheters.

Regulating the Infusion Flow Rate. After initiating a peripheral IV infusion and checking it for patency, regulate the rate of infusion according to the health care provider's orders (Skill 41-2 on pp. 925-929). For patient safety avoid uncontrolled flow of IV fluid into a patient. You are responsible for calculating the flow rate per hour that delivers the IV fluid in the prescribed time frame. The correct IV infusion rate ensures patient safety by preventing too-slow or too-rapid administration of IV fluids. An infusion rate that is too slow often leads to further physiological compromise in a patient who is dehydrated, in circulatory shock, or critically ill. An infusion rate that is too rapid overloads the patient with IV fluid, causing fluid and electrolyte imbalances and cardiac complications in vulnerable patients (e.g., older adults or patients with preexisting heart disease).

Electronic infusion devices (EIDs), also called *IV pumps* or *infusion pumps,* deliver an accurate hourly IV infusion rate. EIDs use positive pressure to deliver a measured amount of fluid during a specified unit of time (e.g., 125 mL/hr). Familiarize yourself with the brand of EID in use at your agency so you are able to accurately set the flow rate. Many EIDs have capabilities that allow for single- and multiple-solution infusions at different rates. A variety of electronic detectors and alarms respond to air in IV lines, occlusion, completion of infusion, high and low pressure, and low battery power.

When you open a roller clamp or other type of clamp on an infusion tubing that is not yet properly inserted in an EID or on a gravity-flow IV system, the IV fluid infuses very rapidly. Nonelectronic volume control devices are used occasionally with an IV solution infused by gravity to prevent accidental infusion of a large fluid volume. These devices hang between the IV bag and the patient and hold only a small volume of fluid that can infuse into the patient. Regardless of the device in use, monitor the patient regularly to verify correct infusion of IV fluids. Patency of an IV catheter means that IV fluid flows easily through it. For patency there must be no clots at the tip of the catheter, and the catheter tip must not be against the vein wall. A blocked catheter slows or stops the rate of infusion of the IV fluids. IV flow rate also can be slowed by infiltration, vasospasm, a knot or kink in the tubing, external pressure on the tubing, and position changes of the patient's extremity. If the flow decreases or stops and the EID is working correctly, inspect the tubing. Sometimes the patient is lying or sitting on it. Also inspect the area around the insertion site for anything that obstructs the flow of IV fluids. For gravity flow, the height of the container influences flow rate. Raising the container usually increases the rate because of increased driving pressure.

Flexion of an extremity, particularly at the wrist or elbow, can decrease IV flow rate by compressing the vein. Although VAD placement in areas of flexion is discouraged, occasionally it becomes necessary. In that case INS standards specify use of an arm board or other joint stabilization device to protect the IV site by keeping the joint extended (INS, 2011). Use padding with arm boards because they may cause skin or nerve damage from pressure. Starting an infusion in a new location rather than relying on a site that causes problems may be more comfortable for a patient. Before discontinuing the current infusion, choose another site and start the infusion to verify that the patient has other accessible veins.

Maintaining the System. After placing an IV line and regulating the flow rate, maintain the IV system. Line maintenance involves (1) keeping the system sterile and intact; (2) changing IV fluid containers, tubing, and contaminated site dressings; (3) assisting a patient with self-care activities so as not to disrupt the system; and (4) monitoring for complications of IV therapy. The frequency and options for maintaining the system are identified in agency policies.

An important component of patient care is maintaining the integrity of an IV line to prevent infection. Potential sites for contamination of a VAD are shown in Fig. 41-16. Inserting an IV line under appropriate aseptic technique reduces the chances of contamination from the patient's skin microflora. After insertion the conscientious use of infection control principles, including thorough hand hygiene before and after handling any part of the IV system and maintaining sterility of the system during tubing and fluid container changes, prevents infection.

Always maintain the integrity of an IV system. Never disconnect tubing because it becomes tangled or it might seem more convenient for positioning or moving a patient or applying a gown. If a patient needs more room to maneuver, use aseptic technique to add extension tubing to an IV line. However, keep the use of extension tubing to a minimum, because each connection of tubing

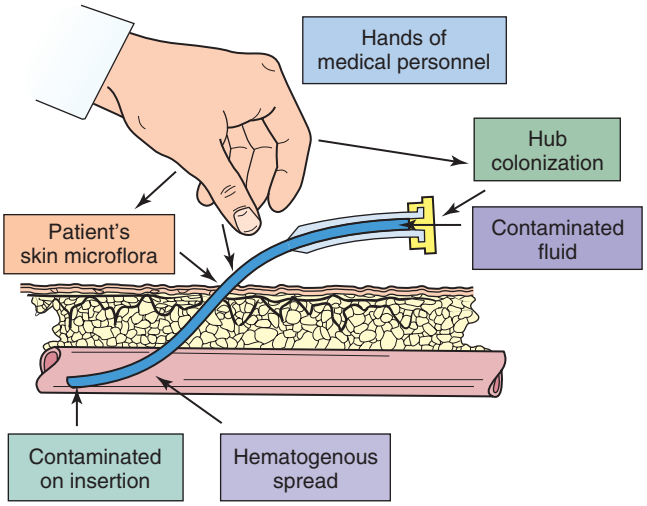

FIG. 41-16 Potential sites for contamination of vascular access device.

FIG. 41-17 Catheter stabilization device. (Copyright © C.R. Bard, Inc. Used with permission.)

provides opportunity for contamination. *Never let IV tubing touch the floor.* You do not use stopcocks for connecting more than one solution to a single IV site because they are sources of contamination (CDC, 2002; INS, 2011). IV tubing contains needleless injection ports through which syringes or other adaptors can be inserted for medication administration. Clean an injection port thoroughly with 2% chlorhexidine (preferred), 70% alcohol, or povidone-iodine solution and let it dry before accessing the system (INS, 2011).

Protective devices designed to prevent movement or accidental dislodgment of a VAD are called *catheter stabilization devices* (Fig. 41-17). These devices are available in many hospitals, and nurses decide whether or not to use them when starting an IV line (Box 41-7). This is a patient safety issue. INS standards indicate that use of these devices is preferable over taping when feasible (INS, 2011).

Changing Intravenous Fluid Containers, Tubing, and Dressings. Patients receiving IV therapy over several days require periodic changes of IV fluid containers (Skill 41-3 on pp. 929-934). It is important to organize tasks so you can change containers rapidly before a thrombus forms in the catheter.

BOX 41-7 EVIDENCE-BASED PRACTICE

Preventing Complications at Peripheral Intravenous Sites

PICO Question: Does use of standard taping compared with a catheter stabilization device prevent phlebitis and other complications of peripheral intravenous (IV) catheters in adult patients?

Evidence Summary

Phlebitis and infiltration are the most frequent complications of peripheral IV therapy. To prevent these and other complications such as catheter dislodgement, nurses traditionally stabilized the catheter by taping the hub to the skin, often with a chevron taping method. Commercially manufactured catheter stabilization devices are now available. Research shows that catheter stabilization devices extend the time that a catheter remains in a vein without complications. One study used a protocol requiring routine IV catheter removal and reinsertion every 96 hours unless complications occurred. The study found that only 8% of taped peripheral IV sites survived 96 hours compared to 52% of sites that used a specific brand of catheter stabilization device (Smith, 2006). Pooled data from over 10,000 patients in 83 hospitals showed a 67% reduction in total complications and a 76% reduction in unscheduled peripheral IV starts with the use of manufactured catheter stabilization devices (Schears, 2006). Substantial cost savings were achieved as well. Infusion Nurses Society standards of practice indicate that a catheter stabilization device is preferred over tape (INS, 2011).

Application to Nursing Practice

- If available, use a manufactured catheter stabilization device when you initiate IV therapy or change a peripheral IV site to reduce the incidence of phlebitis, infiltration, and infection.
- Work with an IV therapy team or other knowledgeable nurses to develop your skills in applying manufactured catheter stabilization devices if you are not familiar with them.
- If manufactured catheter stabilization devices are available at your agency but not widely used, consider educational offerings and other techniques to increase their use.
- If manufactured catheter stabilization devices are not available at your agency, review the research on these devices in a nursing practice committee or with your IV therapy team to influence policy and procedures and request their purchase.

Recommended frequency of IV tubing change depends on whether it is used for continuous or intermittent infusion. INS (2011) standards specify that continuous infusion tubing changes occur *no more frequently* than every 96 hours unless the tubing has been compromised or has become contaminated, which requires immediate tubing change. In contrast, change tubing for *intermittent* infusion every 24 hours because of the increased risk of contamination from opening the IV system (INS, 2011). Blood, blood components, and lipids are likely to promote bacterial growth in tubing. INS standards (2011) specify tubing changes every 4 hours for blood and blood components and every 24 hours for continuous IV lipids. For lipids use tubing that is free of diethylhexylphthalate (DEHP), a toxin that leaches into lipid solutions (INS, 2011). Whenever possible, schedule tubing changes when it is time to hang a new IV container to decrease risk of infection (INS, 2011). To prevent entry of bacteria into the bloodstream, maintain sterility during tubing and IV fluid container changes (INS, 2011).

A sterile dressing over an IV site reduces the entrance of bacteria into the insertion site. Transparent dressings, the most common type, help secure the VAD, allow continuous visual inspection of

the IV site, and become less easily soiled or moistened than gauze dressings. You leave transparent dressings in place until the IV tubing is replaced (INS, 2011). If a gauze dressing is used, change it every 48 hours (INS, 2011). Both types of dressings must be changed when the IV device is removed or replaced or when the dressing becomes damp, loosened, or soiled (INS, 2011) (Skill 41-4 on pp. 934-936).

Assisting Patients to Protect Intravenous Integrity. To prevent the accidental disruption of an IV system, a patient often needs assistance with hygiene, comfort measures, meals, and ambulation. Changing gowns is difficult for a patient with an IV in the arm. Teach nursing assistive personnel (NAP) and patients that they must not break the integrity of an IV line to change a gown because it leads to contamination. It helps to use a gown with snaps along the top sleeve seam to facilitate changing the gown without disturbing the venipuncture site. Change regular gowns by following these steps for maximum speed and arm mobility:

1. *To remove a gown,* remove the sleeve of the gown from the arm without the IV line, maintaining the patient's privacy.
2. Remove the sleeve of the gown from the arm with the IV line.
3. Remove the IV solution container from its stand and pass it and the tubing through the sleeve. (If this involves removing the tubing from an EID, use the roller clamp to slow the infusion to prevent the accidental infusion of a large volume of solution or medication).
4. *To apply a gown,* place the IV solution container and tubing through the sleeve of the clean gown and hang it on its stand. (If the IV line is controlled by an EID, reassemble, turn on the pump, and open the roller clamp.)
5. Place the arm with the IV line through the gown sleeve.
6. Place the arm without the IV line through the gown sleeve.

A patient with an arm or a hand infusion is able to walk unless contraindicated. Offer a rolling IV pole on wheels. Help the patient to get out of bed and place the IV pole next to the involved arm. Teach the patient to hold on to the pole with the involved hand and to push it while walking. Check that the IV container is at the proper height, there is no tension on the tubing, and the flow rate is correct. Instruct the patient to report any blood in the tubing, a stoppage in the flow, or increased discomfort.

Complications of Intravenous Therapy. Table 41-12 presents complications of IV therapy, with assessments and nursing interventions. A potentially dangerous complication of IV therapy is circulatory overload with IV solution, which occurs when a patient receives too-rapid administration or an excessive amount of fluids. Assessment findings depend on the type of IV solution that infuses in excess (see Table 41-12). The signs and symptoms often arise rapidly, which highlights the importance of frequent assessment of patients receiving IV therapy.

Building Competency in Safety You have an order to change an IV fluid container for Mrs. Jamison, age 48, who has no oral intake. The new IV fluid is 1000 mL NS with 20 mEq KCl; the previous IV fluid was 1000 mL NS and did not contain KCl. Which nursing assessments related to fluid and electrolyte imbalances do you need to make before you hang the new IV fluid container? Why?

Answers to questions can be found on the Evolve website.

Infiltration occurs when an IV catheter becomes dislodged or a vein ruptures and IV fluids inadvertently enter subcutaneous tissue around the venipuncture site. When the IV fluid contains additives that damage tissue, **extravasation** occurs (Hadaway, 2007). Infiltration or extravasation causes coolness, paleness, and swelling of the area. When infiltration occurs, immediately assess for any additives in the infiltrated fluid to determine what type of action is necessary to prevent local tissue damage and sloughing. Vasoconstrictors, high-dose potassium, and other IV additives in subcutaneous tissue need different treatments from those needed for an infiltrated additive-free IV (Doellman et al., 2009) (see Table 41-12). Although the INS removed their previous infiltration scale from their 2011 standards because of insufficient research validation, the society does recommend use of an infiltration scale to provide objectivity in infiltration measurement (Table 41-13).

Phlebitis (i.e., inflammation of a vein) results from chemical, mechanical, or bacterial causes. Risk factors for phlebitis include acidic or hypertonic IV solutions; rapid IV rate; IV drugs such as KCl, vancomycin, and penicillin; VAD inserted in area of flexion, poorly secured catheter; poor hand hygiene; and lack of aseptic technique (Roszell and Jones, 2010). The typical signs of inflammation (i.e., heat, erythema [redness], tenderness) occur along the course of the vein (Table 41-14). Phlebitis can be dangerous because blood clots (thrombophlebitis) form along the vein and in some cases cause emboli. This may cause permanent damage to veins. Although some agencies require routine removal of VADs and site rotation to help prevent phlebitis and other complications, the INS Standards of Practice (2011) recommend replacement of a peripheral IV catheter only if clinically indicated in adults (Webster et al., 2010). Avoid routine replacement of peripheral IV catheters in infants and children (INS, 2011).

In the absence of phlebitis, local infection at the venipuncture site is usually caused by poor aseptic technique during catheter insertion, daily monitoring, or catheter removal. Early recognition of local infection and treatment are important to prevent bacteria from entering the bloodstream (see Table 41-12).

Bleeding can occur around the venipuncture site during the infusion or through the catheter or tubing if these become disconnected inadvertently (see Table 41-12). Bleeding is more common in patients who receive heparin or other anticoagulants or who have a bleeding disorder (e.g., hemophilia or thrombocytopenia).

Discontinuing Peripheral Intravenous Access. Discontinue IV access after infusion of the prescribed amount of fluid; when infiltration, phlebitis, or local infection occurs; or if the IV catheter develops a thrombus at its tip. Skill 41-3 presents the steps for discontinuing peripheral IV access. You help patients and families understand that moving from IV infusion to oral fluid intake is a sign of progress toward recovery.

Blood Transfusion. Blood transfusion, or blood component therapy, is the IV administration of whole blood or a blood component such as packed red blood cells (RBCs), platelets, or plasma. Objectives for administering blood transfusions include (1) increasing circulating blood volume after surgery, trauma, or hemorrhage; (2) increasing the number of RBCs and maintaining hemoglobin levels in patients with severe anemia; and (3) providing selected cellular components as replacement therapy (e.g., clotting factors, platelets, albumin).

Blood Groups and Types. Blood transfusions must be matched to each patient to avoid incompatibility. RBCs have antigens in their membranes; the plasma contains antibodies against specific RBC antigens. If incompatible blood is transfused (i.e., a patient's RBC antigens differ from those transfused), the patient's antibodies trigger RBC destruction in a potentially dangerous **transfusion reaction** (i.e., an immune response to the transfused blood components).

TABLE 41-12 Complications of Intravenous Therapy with Nursing Interventions

COMPLICATION	DESCRIPTION	ASSESSMENT FINDINGS	NURSING INTERVENTIONS
Circulatory overload of IV solution	IV solution infused too rapidly or in too great an amount	Depends on type of solution ECV excess with Na^+ containing isotonic fluid (crackles in dependent portions of lungs, shortness of breath, dependent edema) Hyponatremia with hypotonic fluid (confusion, seizures) Hypernatremia with Na^+ containing hypertonic fluid (confusion, seizures) Hyperkalemia from K^+ containing fluid (cardiac dysrhythmias, muscle weakness, abdominal distention)	If symptoms appear, reduce IV flow rate and notify patient's health care provider. With ECV excess raise head of bed; administer oxygen and diuretics if ordered. Monitor vital signs and laboratory reports of serum levels. Health care provider may adjust additives in IV solution or type of IV fluid; watch for and implement order.
Infiltration or extravasation	IV fluid entering subcutaneous tissue around venipuncture site Extravasation: technical term used when a vesicant (tissue-damaging) drug enters tissues	Skin around catheter site taut, blanched, cool to touch, edematous; may be painful as infiltration or extravasation increases; infusion may slow or stop	Stop infusion. Discontinue IV infusion if no vesicant drug (see Skill 41-3). If vesicant drug, disconnect IV tubing and aspirate drug from catheter (Doellman et al., 2009). Agency policy and procedures may require delivery of antidote through catheter before removal. Elevate extremity. Contact health care provider if solution contained KCl, a vasoconstrictor, or other potential vesicant. Apply warm moist or cold compress according to procedure for type of solution infiltrated. Start new IV line in other extremity.
Phlebitis	Inflammation of inner layer of a vein	Redness, tenderness, pain, warmth along course of vein starting at access site; possible red streak and/or palpable cord along vein	Stop infusion and discontinue IV line (see Skill 41-3). Start new IV line in other extremity or proximal to previous insertion site if continued IV therapy is necessary. Apply warm moist compress or contact IV therapy team or health care provider if area needs additional treatment.
Local infection	Infection at catheter-skin entry point, during infusion or after removal of IV catheter	Redness, heat, swelling at catheter-skin entry point; possible purulent drainage	Culture any drainage (if ordered). Clean skin with alcohol; remove catheter and save for culture; apply sterile dressing. Notify health care provider. Start new IV line in other extremity. Initiate appropriate wound care (see Chapter 48) if needed.
Bleeding at venipuncture site	Oozing or slow, continuous seepage of blood from venipuncture site	Fresh blood evident at venipuncture site, sometimes pooling under extremity	Assess if IV system is intact. If catheter is within vein, apply pressure dressing over site or change dressing. Start new IV line in other extremity or proximal to previous insertion site if VAD is dislodged, IV is disconnected, or bleeding from site does not stop.

ECV, Extracellular volume; *IV,* intravenous; *VAD,* vascular access device.

The most important grouping for transfusion purposes is the ABO system, which identifies A, B, O, and AB blood types. Determination of blood type is based on the presence or absence of A and B red blood cell (RBC) antigens. Individuals with type A blood have A antigens on their RBCs and anti-B antibodies in their plasma. Individuals with type B blood have B antigens on their RBCs and anti-A antibodies in their plasma. A person who has type AB blood has both A and B antigens on the RBCs and no antibodies against either antigen in the plasma. A type O individual has neither A nor B antigens on RBCs but has both anti-A and anti-B antibodies in the plasma (Trick, 2010). Table 41-15 shows the compatibilities between blood types of donors and recipients. People with type O blood are considered universal blood donors because they can donate packed RBCs and platelets to people with any ABO blood type. People with type AB blood are called *universal blood recipients* because they can receive packed RBCs and platelets of any ABO type.

Another consideration when matching blood components for transfusions is the Rh factor, which refers to another antigen in RBC membranes. Most people have this antigen and are Rh

TABLE 41-13 Infiltration Scale

GRADE	CLINICAL CRITERIA
0	No symptoms
1	Skin blanched Edema <2.54 cm (1 inch) in any direction Cool to touch With or without pain
2	Skin blanched Edema 2.54-15.2 cm (1-6 inches) in any direction Cool to touch With or without pain
3	Skin blanched, translucent Gross edema >15.2 cm (6 inches) in any direction Cool to touch Mild-moderate pain Possible numbness
4	Skin blanched, translucent Skin tight, leaking Skin discolored, bruised, swollen Gross edema >15.2 cm (6 inches) in any direction Deep pitting tissue edema Circulatory impairment Moderate-to-severe pain Infiltration of any amount of blood product, irritant, or vesicant

ABO, Blood group consisting of groups A, AB, B, and O.

positive; a person without it is Rh negative. People who are Rh negative receive only Rh-negative blood components.

Autologous Transfusion. **Autologous transfusion** (autotransfusion) is the collection and reinfusion of a patient's own blood. Blood for an autologous transfusion most commonly is obtained by preoperative donation up to 6 weeks before a scheduled surgery (e.g., heart, orthopedic, plastic, or gynecological). A patient can donate several units of blood, depending on the type of surgery and his or her ability to maintain an acceptable hematocrit. Blood for autologous transfusion is also obtained at the time of surgery by normovolemic hemodilution or through blood salvage (e.g., during surgery for liver transplantation, trauma, or vascular and orthopedic conditions). After surgery blood is salvaged from drainage from chest tubes or joint cavities. Autologous transfusions are safer for patients because they decrease the risk of mismatched blood and exposure to bloodborne infectious agents (Trick, 2010).

Transfusing Blood. Transfusion of blood or blood components is a nursing procedure that requires an order from a health care provider. A blood transfusion reaction is one of the National Quality Forum's patient safety measures that should be included in a health care institution's public reporting of safety events (NQF, 2010). Patient safety is a nursing priority, and patient assessment, verification of health care provider's order, and verification of correct blood products for the correct patient are imperative.

Perform a thorough patient assessment before initiating a transfusion and monitor carefully during and after the transfusion. Assessment is critical because of the risk of transfusion reactions. Pretransfusion assessment includes establishing whether the patient knows the reason for the blood transfusion and whether he or she has ever had a previous transfusion or transfusion reaction. A patient who has had a transfusion reaction is usually at no greater risk for a reaction with a subsequent transfusion. However, he or she may be anxious about the transfusion, requiring nursing intervention. Before beginning a transfusion, explain the procedure and instruct the patient to report any side effects (e.g., chills, dizziness, or fever) once the transfusion begins. Ensure that he or she has signed an informed consent. Patients with certain cultural backgrounds may refuse blood transfusions (see Box 41-5).

Because of the danger of transfusion reactions, your pretransfusion assessment always includes the patient's baseline vital signs. These data allow you to identify when vital sign changes occur as a result of a transfusion reaction.

For patient safety always verify three things: that blood components delivered are the ones that were ordered; that blood delivered to the patient is compatible with the blood type listed in the medical record; and that the right patient receives the blood.

FIG. 41-18 Filling tubing for blood administration.

Together two RNs or one RN and an LPN (check agency policy and procedures) must check the label on the blood product against the medical record and against the patient's identification number, blood group, and complete name. If even a minor discrepancy exists, **do not** give the blood; notify the blood bank immediately to prevent infusion errors.

When administering a transfusion you need an appropriate-size IV catheter and blood administration tubing that has a special in-line filter (Fig. 41-18). Adults require a large catheter (e.g., 18- or 20-gauge) because blood is more viscous than crystalloid IV fluids. Children with small veins use a smaller catheter. Prime the tubing with 0.9% sodium chloride (normal saline) to prevent hemolysis or breakdown of RBCs. Initiate a transfusion slowly to allow for the early detection of a transfusion reaction. Maintain the ordered infusion rate, monitor for side effects, assess vital signs, and promptly record all findings. It is important to stay with the patient during the first 15 minutes, the time when a reaction is most likely to occur. After the initial time period, continue to monitor the patient and obtain vital signs periodically during the transfusion as directed by agency policy. If a transfusion reaction is anticipated or suspected, obtain vital signs more frequently (Table 41-16).

The transfusion rate usually is specified in the health care provider's orders. Ideally a unit of whole blood or packed RBCs is transfused in 2 hours. This time can be lengthened to 4 hours if the patient is at risk for ECV excess. Beyond 4 hours there is a risk for bacterial contamination of the blood.

When patients have a severe blood loss such as with hemorrhage, they often receive rapid transfusions through a central venous catheter. A blood-warming device often is necessary because the tip of the central venous catheter lies in the superior vena cava, above the right atrium. Rapid administration of cold blood can cause cardiac dysrhythmias. Patients who receive large-volume transfusion of citrated blood have high risk of hyperkalemia, hypocalcemia, hypomagnesemia, and metabolic alkalosis.

Transfusion Reactions and Other Adverse Effects. A transfusion reaction is an immune system reaction to the transfusion that ranges from a mild response to severe anaphylactic shock or acute intravascular hemolysis, both of which are life threatening. Table 41-16 presents the causes, manifestations, management, and prevention of transfusion reactions. Prompt intervention when a transfusion reaction occurs maintains or restores the patient's physiological stability. When you suspect acute intravascular hemolysis, do the following (Trick, 2010):

- Stop the transfusion immediately.
- Keep the IV line open by replacing the IV tubing down to the catheter hub with new tubing and running 0.9% sodium chloride (normal saline).
- *Do not* turn off the blood and simply turn on the 0.9% sodium chloride (normal saline) that is connected to the Y-tubing infusion set. This would cause blood remaining in the IV tubing to infuse into the patient. Even a small amount of mismatched blood can cause a major reaction.
- Immediately notify the health care provider or emergency response team.
- Remain with the patient, observing signs and symptoms and monitoring vital signs as often as every 5 minutes.
- Prepare to administer emergency drugs such as antihistamines, vasopressors, fluids, and corticosteroids per health care provider order or protocol.
- Prepare to perform cardiopulmonary resuscitation.
- Save the blood container, tubing, attached labels, and transfusion record for return to the blood bank.
- Obtain blood and urine specimens per health care provider order or protocol.

Acute adverse effects that do not involve an immune response to the blood components also can occur during a transfusion (see Table 41-16). Circulatory overload is a risk when a patient receives massive whole blood or packed RBC transfusions for massive hemorrhagic shock or when a patient with normal blood volume receives blood. Patients particularly at risk for circulatory overload are older adults and those with cardiopulmonary diseases. Transfusion of blood components that are contaminated with bacteria, especially gram-negative bacteria, can cause sepsis.

Another category of adverse transfusion effects is diseases transmitted by blood from infected donors who are asymptomatic. Symptoms of these conditions may arise long after the transfusion. Diseases transmitted through transfusions include hepatitis B and C, human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS), and cytomegalovirus infection (CDC, 2010). In the United States all units of blood for blood banks undergo screening for HIV, hepatitis B virus (HBV), hepatitis C virus (HCV), and syphilis, which reduces the risk of acquiring these bloodborne infections.

Interventions for Electrolyte Imbalances. In addition to the administration of prescribed medical therapies, there are nursing interventions for preserving or restoring electrolyte imbalance. For example, people who have hypokalemia or hypercalcemia often need bowel management for constipation. Patient safety interventions to prevent falls (see Chapter 27) are vital for patients who become lethargic from hypercalcemia and those with muscle weakness. Patients who have hypercalcemia need an increased fluid intake to prevent renal damage; nurses can help them meet the oral fluid intake goals. Teach patients the reasons for their therapies and the importance of balancing electrolyte I&O to prevent imbalances in the future.

TABLE 41-16 Acute Adverse Effects of Transfusions

ADVERSE EFFECT	CAUSE	CLINICAL MANIFESTATIONS	MANAGEMENT	PREVENTION
Transfusion Reactions—Caused by Immune Response to Blood Components				
Acute intravascular hemolytic	Infusion of ABO-incompatible whole blood, RBCs, or components containing 10 mL or more of RBCs Antibodies in recipient's plasma attach to antigens on transfused RBCs, causing RBC destruction	Chills, fever, low back pain, flushing, tachycardia, tachypnea, hypotension, hemoglobinuria, hemoglobinemia, sudden oliguria (acute kidney injury), circulatory shock, cardiac arrest, death	Stop transfusion and save blood bag and administration set for follow-up. Keep IV site open with normal saline infused through new tubing. Maintain BP and treat shock as ordered, if present. Obtain blood samples slowly to avoid hemolysis; then send for serological testing. Send urine specimen to laboratory. Give diuretics as prescribed to maintain urine flow. Insert indwelling urinary catheter or measure each voiding to monitor hourly urine output. Dialysis may be required if acute kidney injury occurs. ***Patient safety alert:*** Do not transfuse additional RBC-containing components until transfusion service provides newly cross-matched units.	Meticulously verify and document patient identification from sample collection to component infusion.
Febrile nonhemolytic (most common)	Antibodies against donor white blood cells	Sudden shaking chills (rigors), fever (rise in temperature 1° F [0.5° C] or more from start), headache, flushing, anxiety, muscle pain	Stop transfusion. Give antipyretics as prescribed; avoid aspirin in thrombocytopenic patients. ***Patient safety alert:*** Do not restart transfusion.	Consider leukocyte-poor blood products (filtered, washed, or frozen). Pretreat with antipyretics if prior history.
Mild allergic	Antibodies against donor plasma proteins	Flushing, itching, urticaria (hives)	Stop transfusion temporarily. Give antihistamine as directed. If symptoms are mild and transient, restart transfusion slowly. ***Patient safety alert:*** Do not restart transfusion if fever, pulmonary symptoms, or hypotension develop.	Treat prophylactically with antihistamines.
Anaphylactic	Antibodies to donor plasma, especially anti-IgA	Anxiety, urticaria, dyspnea, wheezing, progressing to cyanosis, severe hypotension, circulatory shock, possible cardiac arrest	Stop transfusion. Have epinephrine ready for injection (0.4 mL of 1:1000 solution subcutaneously or 0.1 mL of 1:1000 solution diluted to 10 mL with saline for IV use). Provide blood pressure support as ordered. Initiate CPR if indicated. ***Patient safety alert:*** Do not restart transfusion.	Transfuse extensively washed RBC products from which all plasma has been removed. Alternately use blood from IgA-deficient donor.
Other Acute Adverse Effects				
Circulatory overload	Blood administered faster than circulation can accommodate	Dyspnea, cough, crackles, or rales in dependent portions of lungs; distended neck veins when upright	Turn down transfusion rate or stop transfusion. Place patient upright with feet in dependent position. Administer prescribed diuretics, oxygen, morphine. Phlebotomy may be indicated.	Adjust transfusion volume and flow rate based on patient size and clinical status. Have transfusion service divide unit into smaller aliquots for better spacing of fluid input.
Sepsis	Bacterial contamination of transfused blood components	Rapid onset of chills, high fever, severe hypotension, and circulatory shock *May occur:* Vomiting, diarrhea, sudden oliguria (acute kidney injury), DIC	Stop transfusion. Obtain culture of patient's blood and send bag with remaining blood to transfusion service for further study. Treatment as ordered: antibiotics, IV fluids, vasopressors, glucocorticoids.	Collect, process, store, and transfuse blood products according to blood-banking standards and infuse within 4 hours of starting time.

Interventions for Acid-Base Imbalances. Nursing interventions to promote acid-base balance support prescribed medical therapies and aim at reversing the existing acid-base imbalance while providing for patient safety. When imbalances are life threatening, they require rapid treatment. Maintain a functional IV line and check the health care provider's orders frequently for new medications or fluids. Give fluid and electrolyte replacement and prescribed drugs such as insulin promptly. In addition, monitor patients closely for changes in their status. Use protective measures such as side rails for patients with decreased level of consciousness. Support compensatory hyperventilation for patients with metabolic acidosis by keeping their oral mucous membranes moist and positioning them to facilitate chest expansion. Chapter 40 reviews appropriate therapies for patients with respiratory acidosis. Patients with acid-base imbalances often require repeated ABG analysis.

Arterial Blood Gases. Determination of a patient's acid-base status requires obtaining a sample of arterial blood for laboratory testing. An ABG reveals acid-base status and the adequacy of ventilation and oxygenation. A qualified RN or other health care provider draws arterial blood from a peripheral artery (usually the radial) or from an existing arterial line (see agency policy and procedures). Before an arterial blood draw ensure that the patient has an ulnar pulse to prevent loss of blood flow to the hand if the radial artery is damaged. After the ABG puncture apply pressure to the puncture site for at least 5 minutes to reduce the risk of hematoma formation. A longer time is necessary if the patient takes anticoagulant medications. Reassess the radial pulse after removing the pressure. After obtaining the specimen, take care to prevent air from entering the syringe because this alters the blood gas values. To reduce oxygen usage by blood cells, submerge the syringe in crushed ice and transport it immediately to the laboratory.

Restorative Care. After experiencing acute alterations in fluid, electrolyte, or acid-base balance, patients often require ongoing maintenance to prevent a recurrence of health alterations. Older adults require special considerations to prevent complications from developing (see Box 41-2).

Home Intravenous Therapy. IV therapy often continues in the home setting for patients requiring long-term hydration, PN, or long-term medication administration. A home IV therapy nurse works closely with the patient to ensure that a sterile IV system is maintained and complications can be avoided or recognized promptly. Box 41-8 summarizes patient education guidelines for home IV therapy.

Nutritional Support. Most patients who have had electrolyte disorders or metabolic acid-base imbalances require ongoing nutritional support. Depending on the type of disorder, fluid or food intake may be encouraged or restricted (see Chapter 44). Patients or family members who are responsible for meal preparation need to learn to understand nutritional content of foods and read the labels of commercially prepared foods.

Medication Safety. Numerous medications, OTC drugs, and herbal preparations contain components or create potential side effects that can alter fluid and electrolyte balance. Patients with chronic disease who are receiving multiple medications and those with renal disorders are at significant risk for alterations. Once patients return to a restorative care setting, whether in the home, long-term care, or other setting, drug safety is very important. Patient and family education regarding potential side effects and drug interactions that can alter fluid, electrolyte, or acid-base balance is essential. Review all medications with patients, and encourage them to consult with their local pharmacist, especially if they wish to try a new OTC drug or herbal preparation.

BOX 41-8 PATIENT TEACHING

Home Intravenous Therapy

Objective

- The patient and/or family caregiver will demonstrate competence with administering intravenous (IV) therapy safely in the home.

Teaching Strategies

- Explain the importance of IV therapy in maintaining hydration and access for the delivery of medications.
- Emphasize the risks involved when the IV system is not kept sterile.
- Be sure that the patient and/or caregiver is able to manipulate the required equipment.
- Instruct in aseptic technique and hand hygiene in the handling of all IV equipment.
- Instruct in how to change IV solutions, tubing, and dressing when they become soiled or dislodged. (NOTE: The home care nurse may be able to visit frequently enough to perform scheduled tubing changes.)
- Instruct in procedures for safe disposal in appropriate containers of all sharps and IV materials exposed to blood. Keep sharps containers away from children.
- Instruct to apply pressure with sterile gauze if catheter falls out and, if patient is on anticoagulants, to tape pieces of sterile gauze in place for at least 20 minutes with pressure or until bleeding stops.
- Instruct about signs and symptoms of infiltration, phlebitis, and infection and reporting symptoms immediately.
- Instruct patient and/or caregiver to report if the infusion slows or stops or if blood is seen in the tubing.
- Teach patient with family caregiver's assistance how to ambulate, perform hygiene, and participate in other activities of daily living without dislodging or disconnecting catheter and tubing:
  - For showering, protect the IV site and dressing from getting wet by covering it completely with plastic. If using an EID, unplug around water.
  - Wear clothes that avoid pressure on the IV site and avoid trauma to the site when changing clothes.
  - Have patient avoid strenuous exercise of the arm with the IV line.

Evaluation

- Ask patient and family caregiver why it is necessary to maintain hydration and IV access for the delivery of medications.
- Ask what to do if the IV infusion stops.
- Ask patient and caregiver to describe signs and symptoms of complications and the action they should take.
- Observe the patient or caregiver changing the IV container, tubing, and dressing.
- Observe the patient ambulating and participating in activities of daily living to see how he or she protects and manipulates the IV catheter and apparatus.

EVALUATION

Through the Patient's Eyes. Review with patients how well their major concerns regarding fluid, electrolyte, or acid-base situations were alleviated or addressed. For example, ask a person admitted with dehydration who was concerned about falling due to light-headedness, "How confident are you in your ability to stand without getting light-headed now?" If the patient's concern was feeling uncomfortable with very dry mouth, ask, "How does your mouth feel now?" If the patient's concerns involved having a better understanding of a chronic problem, focus the evaluation

on the patient's view of the patient education provided. A patient's perspectives regarding care often depend in part on involvement of family and friends. If patients have concerns about returning home or to a different care setting, it is important to evaluate how well prepared they feel for the transition from acute care.

Patient Outcomes. Evaluate the effectiveness of interventions using the goals and outcomes established for the patient's nursing diagnoses. Evaluation of a patient's clinical status is especially important if acute fluid, electrolyte, and/or acid-base imbalances exist. A patient's condition can change very quickly, and it is important to recognize impending problems by integrating information about his or her presenting risk factors, clinical status, effects of the present treatment regimen, and potential causative agent. Knowledge of how various pathophysiological conditions affect fluid, electrolyte, and acid-base balance; the effects of medications and fluids; and the patient's presenting clinical status aid in evaluation (Fig. 41-19).

Compare your current assessment findings with the previous patient assessment. For example, a patient's hypokalemia demonstrates improvement when the serum potassium is increasing toward normal and the physical signs and symptoms of hypokalemia begin to disappear or lessen in intensity. Specifically the patient's heart rhythm becomes more regular, and normal bowel function returns.

For patients with less acute alterations, evaluation likely occurs over a longer period of time. In this situation evaluation may be more focused on behavioral changes (e.g., the patient's adherence to dietary restrictions and medication schedules). Another important element of evaluation is the family's ability to anticipate alterations and prevent problems from recurring.

The patient's level of progress determines whether the plan of care needs to continue or be revised. If goals are not met, you may need to consult a health care provider to discuss additional methods such as increasing the frequency of an intervention (e.g., providing more fluids to a dehydrated patient), introducing a new therapy (e.g., initiating insertion of an IV line), or discontinuing a particular therapy. Once outcomes are met, the nursing diagnosis is resolved, and you are able to focus on other priorities, including maintaining normal fluid, electrolyte, and acid-base balance. If established outcomes are not achieved, explore factors that contributed to why the planned outcomes were not met. Modification of the care plan occurs after this evaluation. Questions asked if outcomes are not achieved may include the following:

- "What difficulties are you having with measuring your I&O daily and keeping a record?"
- "What barriers are you experiencing to obtaining the potassium-rich foods you need?"
- "Are you continuing to have frequent loose stools or diarrhea?"
- "Have you purchased an antacid, or are you still using baking soda as an antacid?"

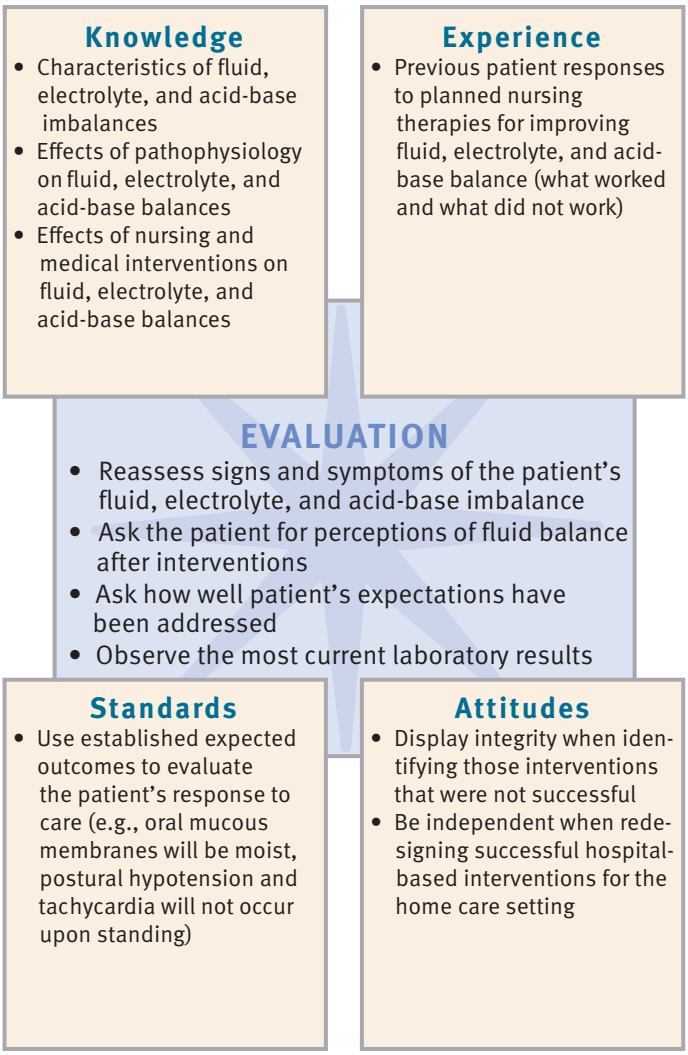

FIG. 41-19 Critical thinking model for fluid, electrolyte, and acid-base balances evaluation.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care:

- Check that you have the necessary information, a health care provider's order if required, and equipment available for the procedure before beginning.
- Before initiation of therapy, check patient identification using two patient identifiers, and assess the appropriate route and rate of infusion and potential incompatabilities between infusing fluids and medications (INS, 2011).
- Determine if the patient has a latex allergy and use nonlatex items if allergy is present (INS, 2011).
- Use special designated tubing for the brand of EID and for blood transfusions and some medications.
- Review the steps of the procedure mentally before entering a patient's room (i.e., consider modifications that you may need to make for this specific patient and verify that the type of IV solution is appropriate for this patient).

- Maintain strict aseptic and sterile techniques when required and sterility and integrity of the IV system to prevent bloodstream infections (INS, 2011).
- If you contaminate a sterile object during the procedure, do not use it. Use a new sterile one.
- Use standard body fluid precautions during procedures and place all disposable blood-contaminated items and sharp items in designated puncture-resistant biohazard containers (INS, 2011).

SKILL 41-1 INITIATING INTRAVENOUS THERAPY

View Video!

Delegation Considerations

The skill of initiating peripheral intravenous (IV) therapy cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. Instruct the NAP to inform you if:

- Patient indicates burning, bleeding, swelling, or coolness at the catheter insertion site.
- An IV dressing becomes wet or loose.
- Electronic infusion device (EID) alarm signals.
- Fluid container is almost empty.

Equipment

- Proper vascular access device (VAD) for venipuncture such as an over-the-needle catheter of appropriate gauge, depending on vein size; for continuous fluid infusions: peripheral 20-gauge catheter for an adult, 22-gauge for older adults and children (Perucca, 2010)
- IV start kit (available in some agencies)—contains a sterile drape to place under patient's arm, tourniquet, cleaning and antiseptic preparations, dressings, and a small roll of sterile tape
- If IV kit not available:
  - Disposable drape or towel
  - Tourniquet (Determine type of tourniquet based on patient assessment [e.g., blood pressure [BP] cuff—older adult, rubber band—infants]. Use single-use tourniquets to prevent transfer of microorganisms between patients.) (Perucca, 2010)
  - Antiseptic swabs (2% chlorhexidine preferred) (INS, 2011)]
  - Transparent dressing or, less commonly, 2 × 2 or 4 × 4 gauze sponge
  - Nonallergenic tape and sterile tape
- Local anesthetic (e.g., intradermal lidocaine, topical transdermal anesthetic, vapocoolant) (optional)
- Short extension tubing with fused or separate needleless connector (also called *saline lock, heparin lock, IV plug, injection cap, PRN adapter, buff cap,* or *buffalo cap)*
- Syringe containing 1 to 3 mL of preservative-free sterile 0.9% sodium chloride (normal saline) for adults, children, and neonates (INS, 2011; Mok, Kwong, and Chan, 2007); less frequently for neonates, heparin lock solution (10 units/mL or per agency protocol)
- Manufactured catheter stabilization device (e.g., STATLOCK), if available (see Fig. 41-17).
- Clean gloves
- Protective equipment: goggles, mask (optional, check agency policy)
- Patient gown with snaps at shoulder seams if available
- Needle disposal container (sharps container)
- For continuous IV fluid infusion, in addition to the above:
  - Correct type and amount of IV fluid
  - IV tubing administration set with tubing specific for the type of EID (If using gravity-flow, use microdrip tubing for small or very precise volumes and macrodrip tubing to infuse fluid more rapidly.)
  - In-line filter if particulate matter is likely, long-term or high-volume IV therapy is expected, or required by agency policy; size appropriate to type of solution (e.g., 0.22 micron for nonlipid solution, 1.2 microns for lipid solution)
  - Long extension tubing if desired for patient mobility
  - EID
  - IV pole, rolling, ceiling mounted, or attached to bed
  - Handheld bar code scanner, if using bar code system

STEP	RATIONALE
ASSESSMENT	
1 Review accuracy and completeness of health care provider's order for patient name, type and amount of IV fluid, medication additives, infusion time, and purpose of infusion. Follow six rights of medication administration (see Chapter 31).	Ensures that correct IV fluid is administered.
CLINICAL DECISION: *In most institutions health care providers do not write orders to "initiate peripheral access" or "perform venipuncture." The statement "Start IV" usually is written followed by the exact IV therapy order. The order to perform the venipuncture is implied. If the order is confusing or in question, clarify with the health care provider before proceeding.*	
2 Assess for clinical variables that respond to or are affected by IV fluid administration:	Provides baseline to determine effect that IV fluids have on patient's fluid and electrolyte balance.
a. Body weight	Daily weights reflect fluid retention or loss. One liter of fluid weighs 2.2 lb (1 kg). Compare with previous day's weight if available. Gain or loss of 2 lbs (1 kg) in 24 hours indicates gain or loss of 1 L of fluid. Body fat gain or loss takes longer.
b. Clinical markers of vascular volume:	Assess signs and symptoms as a group to interpret them accurately. Infusion of Na^+-containing IV fluid expands extracellular fluid volume (ECV) (vascular and interstitial).
(1) BP	Decreased BP or orthostatic hypotension may indicate ECV deficit caused by decreased stroke volume. Increased BP may indicate ECV excess.
(2) Pulse	Baroreceptor response causes rapid, thready pulse with ECV deficit; bounding, full pulse with ECV excess.
(3) Fullness of neck veins (normally neck veins are full when person is supine and flat when person is upright or semi-upright)	Indicator of fluid volume status: flat or collapsing with inhalation when supine with ECV deficit; full or distended when upright or semi-upright with ECV excess.

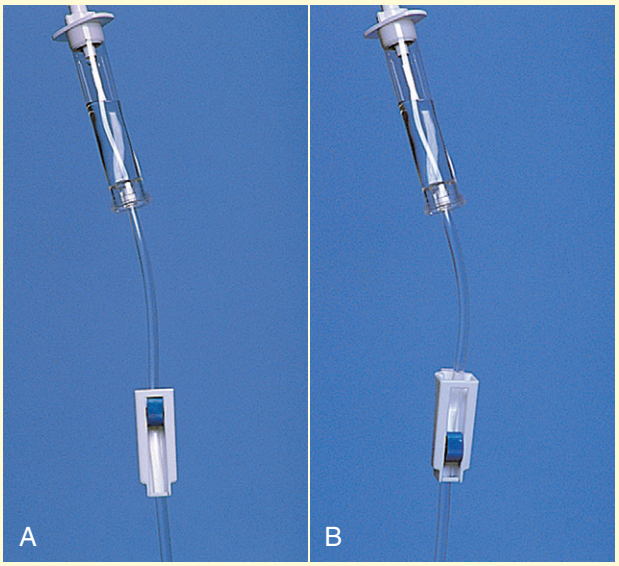
STEP	RATIONALE
(4) Capillary refill	Provides an indirect measure of tissue perfusion. Can indicate poor tissue perfusion (sluggish with ECV deficit).
(5) Auscultation of lungs	Crackles or rhonchi in dependent portions of lung may signal fluid buildup in lungs caused by ECV excess.
(6) Urine output (decreased; dark yellow with ECV deficit)	Kidneys respond to ECV deficit by reducing urine production and concentrating the urine. Average daily adult urine output is 1500 mL; oliguria is urine output of less than 400 mL/24 hr. Kidney disease and SIADH also can cause oliguria. Dark yellow indicates concentrated urine (Scales and Pilsworth, 2008)
c. Clinical markers of interstitial volume:	Assess signs and symptoms as a group to interpret them accurately. Infusion of Na^+-containing IV fluid expands ECV (vascular and interstitial).
(1) Dependent edema (rate severity by assessing pitting over bony prominences; 1+ indicates barely detectable edema to 4+ indicates deep persistent pitting (see Chapter 30)	Edema, indicating expanded interstitial fluid volume, is most evident in dependent areas bilaterally (i.e., feet and ankles if sitting) or sacrum if bedfast.
(2) Oral mucous membranes between cheek and gum.	More reliable indicator than dry lips or skin. Dry between cheek and gums indicates ECV deficit.
(3) Skin turgor (pinch skin over sternum or inside of forearm). Failure of skin to return to normal position within 3 seconds indicates ECV deficit.	Pinched skin that stays elevated for several seconds is called *poor skin turgor* or *"tenting."* May occur from ECV deficit, rapid weight loss, or normal aging.
d. Thirst	Occurs with hypernatremia and severe ECV deficit. Not a reliable indicator for older adults because thirst sensation decreases with age (Meiner, 2010).
e. Behavior and level of consciousness	
(1) Restlessness and mild confusion	Occurs with severe ECV deficit caused by lack of blood flow to brain.
(2) Decreased level of consciousness (lethargy, confusion, coma)	May occur with osmolality imbalances (hyponatremia and hypernatremia) and acid-base imbalances.
f. Cardiac signs of electrolyte or acid-base imbalances (e.g., irregular pulse and electrocardiogram [ECG] changes)	Rhythm and ECG changes may occur with K^+, Ca^{2+}, Mg^{2+}, and/or acid-base imbalances. Should improve as IV fluid replaces deficient electrolytes or occur if electrolyte infusion is excessive.
3 Assess patient's previous experience with and perceptions of IV therapy, understanding of purpose of IV therapy, and arm placement preference.	Provides patient-centered care by determining level of emotional support and instruction necessary. If patient is apprehensive about venipuncture, use a local anesthetic.
4 Obtain information from approved online database, drug reference book, or pharmacist about composition of IV fluids, purposes of administration, potential incompatibilities, side effects, monitoring guidelines, and need for special catheter or tubing for administration.	Allows detection of an inadvisable IV fluid order and helps to determine priority assessments.
5 Determine if patient is to undergo any planned surgeries or procedures.	Allows anticipation and placement of appropriate VAD and gauge for fluid infusion and avoids placement in an area that will interfere with medical procedures.
6 Assess for following risk factors: child or older adult; presence of heart failure or oliguric renal disease; skin lesions or infection near potential venipuncture sites; low platelet count or patient receiving anticoagulants	Older adults have proportionately less body water; persons with heart failure cannot adapt to sudden increases in vascular volume; and persons with oliguria cannot eliminate excess extracellular fluid, K^+, or Mg^{2+}. Skin lesions or infection influence choice of access site. Low platelet count or anticoagulant use increases patient's risk for bleeding from VAD site and seepage of blood from puncture site during venipuncture.
7 Assess laboratory data.	Helps determine priority assessments, establishes baseline for determining if therapy is effective, and may allow detection of an inadvisable fluid order.
CLINICAL DECISION: *If the current K^+, Ca^{2+}, or Mg^{2+} serum values are high, clarify order with health care provider before administering an IV solution containing the elevated electrolyte to avoid worsening the electrolyte excess.*	
8 Assess patient's history of allergies, especially to iodine, adhesive, or latex.	Equipment used during insertion of VAD may contain substances to which patient is allergic. Use alternatives if patient has allergy.
PLANNING	
1 Collect appropriate equipment. Be sure that you have the correct infusion set for the EID that will be used. If the IV container is rigid rather than collapsible, you need a vented spike on the IV tubing.	Provides patient safety.
2 Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medication administration record (MAR) or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).

SKILL 41-1 INITIATING INTRAVENOUS THERAPY—cont'd

STEP	RATIONALE
3 Explain to patient and family the rationale for IV fluids and medications, procedure for initiating an IV infusion, signs and symptoms of complications, what is expected of patient, and which sensations patient should expect.	Cognitive and sensory information decreases anxiety and helps promote cooperation.
4 Assist patient to comfortable sitting or supine position. Position a chair so you are level with patient. Provide adequate lighting.	Promotes comfort and relaxation for patient. Provides proper body mechanics for nurse. Aids in successful vein location.

IMPLEMENTATION

1 Perform hand hygiene. Organize equipment on clean, clutter-free bedside stand or over-bed table.	Reduces transmission of infection and risk of accidents.
2 Change patient's gown to more easily removable gown with snaps at shoulder if available.	Use of a special IV gown makes gown removal easier and protects VAD site from trauma during gown changes.
3 Open sterile packages using sterile aseptic technique (see Chapter 28).	Maintains sterility of equipment and reduces spread of microorganisms.
4 Prepare short extension tubing with needleless connector or stand-alone saline lock (check agency policy and procedures) to attach to VAD catheter hub.	Short extension tubing prevents traction on VAD. Many facilities use short extension tubing for continuous infusions and stand-alone saline locks (capped catheters). Continuous infusion attaches to needleless connector on short extension tubing. Saline locks provide IV access when continuous IV infusions are not needed.
a. Remove protective cap from needleless connector and attach syringe with 1 to 3 mL 0.9% sodium chloride (normal saline), maintaining sterility. Slowly inject enough saline to prime (fill) short extension tubing and connector, removing all air. Leave syringe attached to tubing (see illustration).	Replaces air with normal saline, preventing air from entering patient's vein during VAD insertion.



STEP 4a Prime short extension tubing, leaving syringe attached.

b. Maintain sterility of end of connector and set aside for attaching to catheter hub after successful venipuncture.	Prevents touch contamination, which allows microorganisms to enter infusion equipment and bloodstream.
5 ***For continuous infusion:*** Prepare IV tubing and solution	
a. Check IV solution, using six rights of medication administration (see Chapter 31). If using bar-code system, scan bar code on patient's wristband and then on IV fluid container. Be sure prescribed additives such as potassium or vitamins are included and noted on bag label. Check solution for color, clarity, and expiration date. Check bag for leaks.	IV solutions are medications and need to be checked carefully to reduce risk of error. Bar-code systems reduce medication errors by verifying right patient, medication, dose, route, and time with EHR (Poon et al., 2010). Do not use solutions that are discolored, contain particles, or are expired. Do not use leaky bags because they present an opportunity for infection.
b. Open infusion set, maintaining sterility of both ends of tubing.	Prevents touch contamination, which allows microorganisms to enter infusion equipment and bloodstream.
c. Removing appropriate end caps, attach extension tubing with injection port to distal end of infusion set, maintaining sterility of the connection. Do not touch point of entry of connection. Leave end cap on distal end of extension tubing.	Distal end of extension tubing with injection port attaches to IV catheter hub after venipuncture, providing greater ease of access and ability to change easily between continuous and intermittent IV infusion. Prevents touch contamination, which allows microorganisms to enter infusion equipment and bloodstream.

STEP	RATIONALE
d. Place roller clamp of IV tubing approximately 2 to 5 cm (1 to 2 inches) below drip chamber and move it to closed position (see illustrations).	Close proximity of roller clamp to drip chamber allows more accurate regulation of flow rate. Closing clamp prevents accidental spillage of IV fluid on patient, nurse, bed, or floor.
e. Remove protective sheath from IV tubing port on plastic IV solution bag or top of bottle while maintaining sterility (see illustration).	Provides access for insertion of infusion tubing into solution while preventing touch contamination.
f. *Insert infusion set into fluid bag or bottle:* Remove protective cap from tubing insertion spike, not touching spike, and insert it into port of IV container, using a twisting motion (see illustration). Clean rubber stopper on glass-bottled solution with single-use antiseptic and insert spike into rubber stopper of IV bottle.	Prevents contamination of IV solution during insertion of spike. Flat surface on top of bottled solution may contain contaminants, whereas opening to plastic bag is recessed.

CLINICAL DECISION: *Do not touch spike (it is sterile). If contamination occurs (e.g., you accidentally touch outside of bag with the spike or drop spike), discard that IV tubing and obtain a new one.*

g. Compress drip chamber and release, allowing it to fill one-half full with infusion fluid (see illustration).	Creates suction effect; fluid enters drip chamber, which prevents air from entering tubing.
h. Prime tubing by filling with IV solution: Remove protector cap on end of tubing if necessary (you can prime some tubing without removing cap) and slowly open roller clamp to allow fluid to travel from drip chamber through tubing to distal end. Maintain sterility of the end. Return roller clamp to closed position after tubing is filled with IV fluid. Replace protective cap on end of tubing if you removed it.	Priming replaces air in tubing with IV solution so air does not enter patient's vein. Slow fill of tubing decreases turbulence and chance of bubble formation. Closing clamp prevents continued flow of IV fluid. Cap on end of tubing maintains system sterility.

STEP 5d **A,** Roller clamp in open position. **B,** Roller clamp in off or closed position.

STEP 5e Remove protective covering from IV solution tubing port.

SKILL 41-1 INITIATING INTRAVENOUS THERAPY—cont'd

STEP	RATIONALE

STEP 5f Insert tubing spike into IV container.

STEP 5g Squeeze drip chamber to fill with fluid.

STEP 5i Removing air bubbles from tubing.

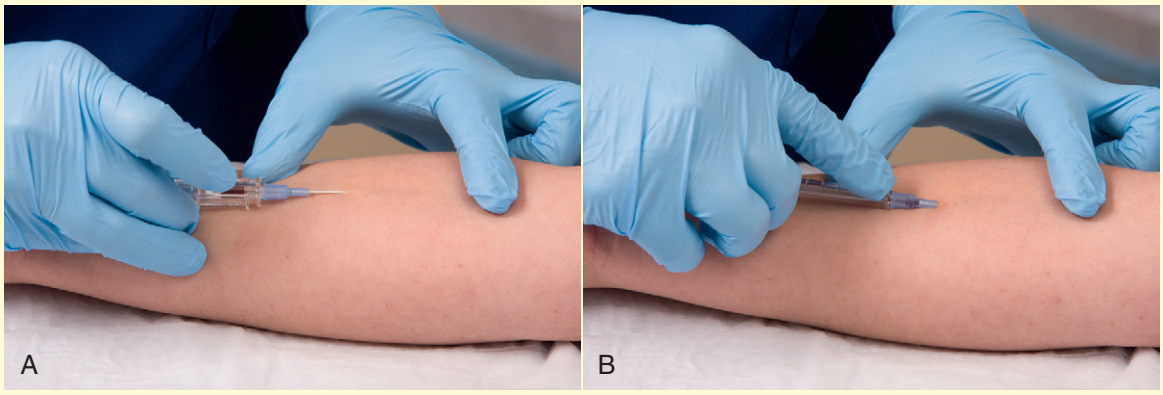
i. Be certain that tubing is clear of air and air bubbles. To remove small air bubbles, firmly tap tubing where they are located (see illustration). Check entire length of tubing to ensure that all air bubbles are removed. If using multiple-port tubing, turn ports upside down and tap to fill and remove air.	Tapping causes air bubbles to rise up to drip chamber. Large air bubbles may act as emboli.
CLINICAL DECISION: *Add a long extension tubing to IV tubing to provide more length, which enables patient to move much more freely while still keeping IV line stable.*	
j. If using optional long extension tubing (not short extension tubing in Step 4), remove protective cap and attach it to distal end of IV tubing, maintaining sterility. Then prime the long extension tubing.	Priming replaces air in tubing with IV solution so air does not enter patient's vascular system.
k. Insert primed tubing into EID, with power off.	Facilitates starting infusion as soon as IV site is ready.
6 Apply clean gloves. Wear eye protection and mask (check agency policy) if splash or spray of blood is possible.	Reduces transmission of microorganisms. Prevents spraying of blood on nurse's mucous membranes.
CLINICAL DECISION: *You can apply gloves before or after assessing veins. You must apply them before VAD insertion.*	
7 Apply tourniquet to begin vein selection around arm above antecubital fossa or 10 to 15 cm (4 to 6 inches) above proposed insertion site. Do not apply tourniquet too tightly to avoid injury, bruising the skin, or occluding arterial flow. Check for presence of radial pulse. *Option a:* You may apply tourniquet on top of a thin layer of clothing such as a gown sleeve to protect fragile or hairy skin. *Option b:* Use BP cuff instead of tourniquet. Inflate it to a level just below patient's normal diastolic pressure (less than 50 mm Hg).	Tourniquet slows venous return but should not occlude arterial flow. If you cannot find a vein in hand or lower arm, move up to antecubital fossa. Use antecubital fossa primarily for blood draws because a VAD there limits mobility. Use of BP cuff reduces trauma to skin and underlying tissues.
8 Select vein for VAD insertion. Veins on dorsal and ventral surfaces of upper extremities (e.g., cephalic, basilic, and median veins) are preferred in adults (see Fig. 41-15).	Ensures adequate vein that is easy to puncture and less likely to rupture.
a. Use most distal site in nondominant arm, if possible.	Patients with VAD placement in their dominant hand have decreased ability to perform activities of daily living (O'Halloran, El-Masri, and Fox-Wasylyshyn, 2008). Performing venipuncture distal to proximal increases availability of other sites for future IV therapy (INS, 2011).

STEP	RATIONALE
b. Select a well-dilated vein. Methods to foster venous distention include:	Increased volume of blood in vein at venipuncture site makes vein more visible.
(1) Stroking extremity from distal to proximal below proposed venipuncture site.	Promotes venous filling.
(2) Applying warmth to extremity for several minutes (e.g., with a warm washcloth).	Increases blood in vein by causing dilation.
(3) If possible, placing extremity in dependent position.	Gravity promotes venous dilation.
CLINICAL DECISION: *Vigorous friction and multiple tapping of a vein, especially in older adults, causes hematoma and/or venous constriction. Choose appropriate dilation method.*	
c. Select vein large enough for a VAD.	Prevents interruption of venous flow while allowing adequate blood flow around catheter.
d. With your index finger, palpate vein by pressing downward. Note resilient, soft, bouncy feeling while releasing pressure (see illustration).	Fingertip is more sensitive and better for assessing vein location and condition.
e. Avoid vein selection in:	
(1) Area with tenderness, pain, infection, or wound.	May indicate inflamed vein or increase risk of infection.
(2) Extremity affected by previous stroke (cerebrovascular accident [CVA]), paralysis, mastectomy, or dialysis graft.	Increases risk of complications such as lymphedema or vessel damage.
(3) Site distal to previous venipuncture site, sclerosed or hardened veins, infiltrate site or phlebotic vessels, bruised areas, or areas of venous valves.	Such sites cause infiltration around newly placed VAD site and excessive vessel damage.
(4) Fragile dorsal veins in older adult patients and vessels in an extremity with compromised circulation.	Small, fragile veins have increased risk of infiltration, hematoma from vessel rupture, and phlebitis from vessel damage.
f. Choose a site that does not interfere with patient's activities of daily living (ADLs), use of mobility aids such as a cane, or planned procedures. Clip arm hair with scissors if necessary (explain to patient).	Keeps patient as mobile and independent as possible. Hair impedes venipuncture or adherence of dressing.
CLINICAL DECISION: *If hair removal is needed, do not shave area with a razor. Shaving may cause microabrasions that increase risk of infection (**INS, 2011**).*	
9 Release tourniquet temporarily and carefully. *Option:* At this point in procedure you may apply a local anesthetic to site; wait several minutes for it to take effect (see product directions). Monitor for allergic reaction.	Restores blood flow and prevents venospasm while preparing for venipuncture. Local anesthetic reduces insertion pain (Anderson et al., 2010).
10 Apply clean gloves, if not done in Step 6.	Reduces transmission of microorganisms.
11 Place distal end of short infusion tubing (prepared in Step 4) or adaptor end of saline lock nearby on sterile gauze, avoiding touch contamination.	Permits smooth, quick connection to VAD after accessing vein. Prevents microorganisms from entering infusion equipment and bloodstream.
12 If area of insertion appears to need cleaning, use soap and water first and dry. Use antiseptic swab or applicator to clean insertion site, using friction in a horizontal plane with first swab, in a vertical plane with second swab, and in a circular motion moving outward with third swab (see illustration). Allow to dry completely. Refrain from touching clean site unless using sterile technique.	Mechanical friction penetrates antiseptic solution into cracks and fissures of the skin. Allowing antiseptic solution to air-dry completely reduces microbial counts and risk of phlebitis. Chlorhexidine 2% preparation is preferred (CDC, 2002; INS, 2011). If your fingers touch clean area, you have introduced microorganisms from your gloves and you must clean it again.
13 Reapply tourniquet or BP cuff 10 to 12 cm (4 to 6 inches) above anticipated insertion site or keep BP cuff inflated <50 mm Hg until venipuncture completed. Check presence of distal pulse.	Diminished arterial flow prevents venous filling. The pressure of the tourniquet cause vein to fill and dilate.

STEP 8d Palpate vein for resilience.

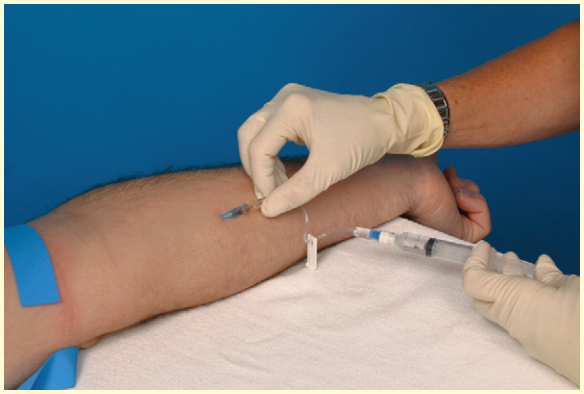
STEP 12 Clean site with chlorhexidine.

SKILL 41-1 INITIATING INTRAVENOUS THERAPY—cont'd



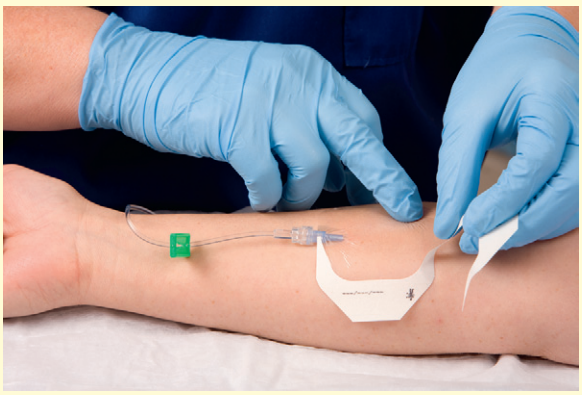
STEP	RATIONALE
14 Perform venipuncture. Anchor vein by placing thumb over it and stretching skin against direction of insertion 4 to 5 cm (1½ to 2 inches) distal to the site (see illustration).	Stabilizes vein for needle insertion. Places VAD parallel to vein.
a. Warn patient of sharp, quick stick.	Prepares patient to avoid movement of extremity during venipuncture.
b. Insert VAD with bevel up at 10- to 30-degree angle slightly distal to actual site of venipuncture in direction of vein (see illustration).	Places needle at optimal angle to vein to reduce risk of puncturing posterior vein wall when entering vein. Superficial veins require smaller insertion angle. Deeper veins require greater angle.
CLINICAL DECISION: *Use each VAD only once for each insertion attempt. If you need to try again, use a new VAD for patient safety and protection from infection.*	
15 Observe for blood return in flashback chamber of catheter, indicating that needle has entered vein (see illustration). Lower catheter until almost flush with skin. Advance catheter approximately ¼ inch into vein and loosen stylet. Continue to hold skin taut and advance catheter into vein until hub is near venipuncture site (see illustration). *Do not reinsert stylet once it is loosened.* Advance catheter while safety device automatically retracts stylet. (Techniques for retracting stylet vary with different VADs.) Follow manufacturer guidelines for specific safety catheter use. Place stylet directly into sharps container.	Increased venous pressure caused by tourniquet increases backflow of blood into catheter or tubing. Allows for full penetration of vein wall, placement of catheter in vein lumen, and advancement of catheter off stylet. Reduces risk of introduction of infectious microorganisms along catheter. Advancing entire stylet into vein may penetrate posterior vein wall, causing a hematoma. Reinsertion of stylet can cause catheter shearing and potential catheter embolization. Proper sharps disposal prevents needlestick injury (OSHA, 2011).
CLINICAL DECISION: *Each nurse should make no more than two attempts at initiating IV access (INS, 2011). If you are not successful with two attempts, have another nurse attempt the insertion.*	

STEP 14 Stabilize vein below insertion site.



STEP 14b Puncture vein with catheter at a 10- to 30-degree angle. Catheter enters vein.

STEP 15 **A,** Look for blood return in flashback chamber. **B,** Advance catheter into vein until hub is near insertion site.



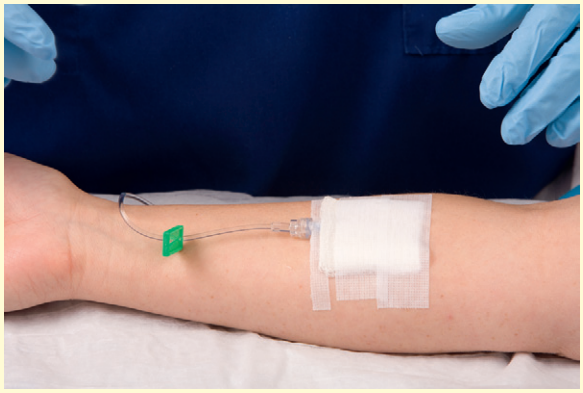
STEP	RATIONALE
16 Stabilize catheter with nondominant hand and release tourniquet or BP cuff with other. Apply gentle but firm pressure with middle finger of nondominant hand 3 cm (1¼ inches) above insertion site. Keep catheter stable with index finger.	Tourniquet release permits venous flow. Pressure with finger on vein reduces backflow of blood and allows connection with short extension tubing or saline lock with minimal blood loss.
17 Quickly connect distal end of primed short extension tubing from Step 11 or end of a prepared saline lock to catheter. Do not touch point of entry of connection. Secure connection.	Prompt connection of infusion set maintains patency of vein and prevents risk for exposure to blood. Maintains sterility.
18 Gently flush catheter using attached saline syringe to ensure that site is patent (see illustration). Observe for swelling at site while flushing.	Provides patient safety by not beginning infusion if site is not patent. Swelling during flush indicates infiltration, and site must be discontinued.
19 Remove syringe. For continuous infusion, attach distal end of IV tubing to needleless connector on short extension tubing that is attached to catheter (see illustration). Turn on EID, program it, and begin infusion at correct rate (see Skill 41-2). If using gravity flow instead of EID, begin infusion by slowly opening roller clamp to regulate rate.	Initiates flow of fluid through IV catheter, preventing clotting of device.
CLINICAL DECISION: *Be sure to calculate rate (see Skill 41-2) and set EID correctly to infuse IV solution at prescribed rate.*	
20 Observe insertion site for swelling.	Swelling indicates infiltration, which requires catheter removal.
21 Secure catheter and apply sterile dressing over site (procedures differ; follow agency policy).	Prevents accidental dislodgement of catheter and protects site from infection.
a. *Manufactured catheter stabilization device:* Wipe selected area with single-use skin protectant and allow to dry completely (10-15 seconds). Apply sterile adhesive strip over catheter hub. Place retainer over tubing end just behind spin nut. Peel off half of liner; press to adhere to skin. Repeat on other side (see Fig. 41-17). Then apply dressing.	A manufactured catheter stabilization device holds the catheter in place, improving patient outcomes by reducing risk of catheter dislodgement, phlebitis, and other complications (Harnage, 2007; INS, 2011).
b. *Transparent dressing:* Continue to secure catheter with nondominant hand.	Prevents accidental dislodgement of catheter.
(1) Remove adherent backing. Apply one edge of dressing and gently smooth remaining dressing over IV site, leaving connection between IV tubing and catheter hub uncovered. Remove outer covering and smooth dressing gently over site (see illustration).	Occlusive dressing protects site from bacterial contamination. Connection between administration set and hub needs to be uncovered to facilitate changing tubing if necessary.

STEP 18 Flush catheter gently to ensure patency.

STEP 19 Connect IV tubing to the short extension set that is attached to catheter.

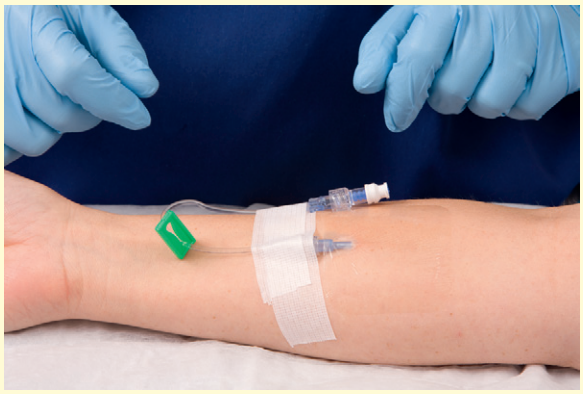
STEP 21b(1) Apply transparent dressing.

SKILL 41-1 INITIATING INTRAVENOUS THERAPY—cont'd



STEP	RATIONALE
(2) If manufactured catheter stabilization device is not used, secure catheter by placing a 2.5-cm (1-inch) piece of transparent tape over extension tubing or administration set. Do not apply tape on top of transparent dressing.	Removal of tape from transparent dressing might cause accidental dislodgement of catheter.
	Tape on top of a transparent dressing prevents moisture from being carried away from skin.
c. *Sterile gauze dressing:* If manufactured catheter stabilization device is not used, secure catheter by placing a narrow piece (½ inch) of sterile tape over catheter hub (see illustration). Place sterile tape only on hub, *never* over insertion site. Secure site for easy visualization. Avoid applying tape or gauze around arm.	Less frequently used than transparent dressing.
	Prevents accidental removal of catheter from vein. Prevents back-and-forth motion, which can irritate vein and introduce microorganisms on skin into vein. Sterile tape prevents site contamination.
	Wrapping anything around arm compresses veins or prevents visualization of insertion site.
(1) Place 2 × 2 gauze pad over insertion site and catheter hub. Secure all edges with tape (see illustration). Do not cover connection between IV tubing and catheter hub.	Secure dressing is less likely to allow entrance of microorganisms.
(2) *Option:* Fold 2 × 2 gauze pad in half and cover with a 2.5 cm (1 inch)–wide tape extending about an inch from each side. Place under tubing/catheter hub junction.	Tape on top of gauze makes it easier to access hub/tubing junction. Gauze pad elevates hub off skin to prevent pressure area.

CLINICAL DECISION: *Think carefully about where you place tape. Do not apply it over the catheter insertion site, over the connection between the tubing or port and the IV catheter hub, or on top of the transparent dressing.*



22 Curl loop of tubing alongside arm and place second piece of tape directly over tubing to secure it (see illustration).	Securing loop of tubing reduces risk of dislodging catheter if IV tubing is pulled (i.e., loop comes apart before catheter dislodges).
23 For gravity-flow IV fluid administration, recheck flow rate to correct drops per minute (see Skill 41-2).	Manipulation of catheter during dressing application may alter flow rate. Check flow rate to maintain accurate administration of IV fluids. Flow can fluctuate; thus it must be checked at intervals for accuracy.
24 Label dressing per agency policy. Include date and time of IV insertion, VAD gauge and length, and your initials (see illustration).	Provides immediate access to data regarding when IV was inserted and when to rotate site.

STEP 21c Apply tape over catheter hub.

STEP 21c(1) Place 2 × 2 inch gauze over insertion site and catheter hub.

STEP 22 Curl a loop of the short or long intravenous tubing alongside the arm. Secure tubing.

STEP 24 Label IV dressing.

STEP	RATIONALE
25 Dispose of used stylet or other sharps in appropriate sharps container if not done previously. Discard supplies. Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms, prevents accidental needlestick injuries, and follows guidelines for disposal of sharps (OSHA, 2011).
26 Teach patient how to move or turn without dislodging VAD.	Prevents accidental dislodgement of catheter.
EVALUATION	
1 Observe patient every 1 to 2 hours.	
a. Check that correct amount of IV fluid has infused by observing fluid level in IV container.	Administration of prescribed amount of fluid maintains or restores fluid balance.
b. Check rate on EID or count drip rate (if gravity drip).	Accurate monitoring of rate further ensures administration of correct amount of fluid.
c. Check patency of VAD.	Flow rate slows or stops if catheter becomes partially occluded or obstructed.
CLINICAL DECISION: *If IV line is positional, fluid runs quickly, slowly, or stops, depending on position of patient's arm. Instruct patient to position arm to maintain flow; if this continues, consider restarting IV in another site.*	
d. Observe patient during palpation of vessel for signs of discomfort.	Tenderness is an early sign of phlebitis.
e. Inspect insertion site, note skin color (e.g., redness, pallor). Inspect for presence of swelling, infiltration (see Table 41-13), and phlebitis (see Table 41-14). Palpate temperature of skin above dressing.	Redness, tenderness, and warmth indicate vein inflammation or phlebitis. Swelling above insertion site and cool temperature often indicate infiltration of fluid into tissues.
2 Change peripheral IV access per agency policy, per health care provider's orders, or immediately on suspected contamination or complication.	INS standards recommend VAD replacement and site rotation when clinically indicated rather than at set intervals (INS, 2011). A retrospective review showed that it was possible to have long catheter indwell times without complications in some patients (Powell et al., 2008).
3 Observe patient to determine response to therapy (e.g., measure intake and output [I&O], daily weights, vital signs).	IV fluids and additives are administered to maintain or restore fluid and electrolyte balance. Early recognition of complications leads to prompt treatment.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Overload of IV solution, infiltration, phlebitis, local infection, and bleeding at venipuncture site
- See Table 41-12.

2. Lack of effectiveness of IV therapy for ECV
- Notify patient's health care provider, providing baseline and current heart rate and BP and length of time IV has been infusing; adjust infusion rate or type of IV solution as ordered.
- Be prepared to draw blood for laboratory testing.

RECORDING AND REPORTING

- Document in nurses' notes or other designated location in an electronic health record (EHR) date and time of insertion; number and sites of attempts, precise description of insertion site (e.g., cephalic vein on dorsal surface of right lower arm, 2.5 cm above wrist); catheter gauge, type, length, and brand; type of dressing and catheter stabilization; flow rate; type of infusion, EID use, and your identity (INS, 2011). If using bar-code system, fluid type and time record automatically.
- Record patient's status, IV fluid, amount infused, and integrity and patency of system according to agency policy.
- Report to oncoming nursing staff: type of fluid, flow rate, status of VAD, amount of fluid remaining in present container, expected time to hang subsequent IV container, and patient condition.
- Report to health care provider: any adverse reactions.

HOME CARE CONSIDERATIONS

- Ensure that patient is able and willing to self-administer IV therapy or that a reliable family caregiver will provide IV therapy at home.
- Teach patient and caregiver information needed to administer IV therapy safely (see Box 41-8).

SKILL 41-2 REGULATING INTRAVENOUS FLOW RATE

View Video!

Delegation Considerations

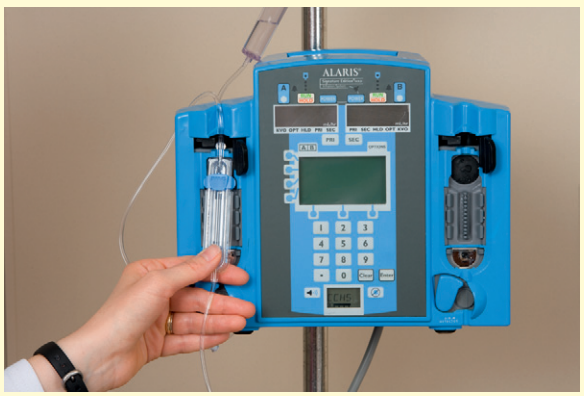
The skill of regulating intravenous (IV) flow rate cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. Instruct the NAP to inform you if:
- Patient indicates burning, bleeding, swelling, or coolness at catheter insertion site.
- Electronic infusion device (EID) alarm signals.
- Fluid container is almost empty.

Equipment

- Electronic infusion device (EID, IV pump) or for gravity infusion: volume control device and watch with second hand
- Calculator or paper and pen/pencil
- Tape
- Label

SKILL 41-2 REGULATING INTRAVENOUS FLOW RATE—cont'd

STEP	RATIONALE
ASSESSMENT	
1 Review accuracy and completeness of health care provider's order for patient name, type, and amount of IV fluid, medication additives, infusion time, and purpose of infusion. Follow six rights of medication administration (see Chapter 31).	Ensures administration of correct IV fluid at proper rate. IV fluids are medications. The six rights prevent medication administration error.
2 Perform hand hygiene.	Prevents transmission of microorganisms.
3 Observe for patency of IV tubing and vascular access device (VAD).	For fluid to infuse at proper rate, IV line and VAD must be free of kinks, knots, and clots.
4 Inspect IV site and verify with patient how existing IV site feels (e.g., determine if any tenderness, pain, or burning).	Tenderness, pain, or burning may be early indication of phlebitis. Includes patient in own care.
5 Assess patient's knowledge of how positioning of IV site affects flow rate.	Fosters patient participation in maintaining most effective position of arm with IV equipment.
6 Assess patient risk for fluid and electrolyte imbalance, given type of IV fluid (e.g., neonate, cardiac or kidney disease)	Helps prioritize nursing assessments.
PLANNING	
1 Gather paper and pencil or calculator to calculate flow rate.	Use accurate mathematical calculations to obtain correct rate for patient safety.
2 Check order to see how long each liter of fluid should infuse. If hourly rate (mL/hr) is not provided in order, calculate it by dividing volume by hours. For example:	Provides even infusion of fluid over prescribed hourly rate. A volume of 1 L = 1000 mL.



$$\text{mL/hr} = \frac{\text{Total infusion volume (mL)}}{\text{Hours of infusion}}$$

1000 mL/8 hr = 125 mL/hr
or if 3 L is ordered for 24 hours,
3000 mL/24 hr = 125 mL/hr

CLINICAL DECISION: *It is common for health care providers to write an abbreviated IV order such as "D_5W with 20 mEq KCl 125 mL/hr continuous." This order implies that IV infusion should be maintained at this rate until an order has been written for IV infusion to be discontinued. Occasionally an IV order calls for 1 L "TKO" or "KVO," either of which means at a slow rate to keep vein open. Clarify with the provider if any part of the order is unclear.*

3 If KVO (or TKO) rate is ordered, check agency policy regarding flow rate. KVO often falls in the range of 10 to 25 mL/hr.	KVO rate prevents catheter clotting, thus preserving venous access while infusing a minimal amount of fluid.
4 Use hourly rate to program EID (see Implementation) or, if gravity-flow infusion, use to calculate minute flow rate (gtt/min).	EID automatically delivers correct minute flow rate. Gravity infusion requires nurse calculation.
5 Calculate minute flow rate for gravity-flow infusion:	Use microdrip tubing when infusing small or very precise volumes. Use macrodrip tubing to infuse fluid more rapidly.
a. Determine drop factor (calibration) in drops per milliliter (gtt/mL) of infusion set currently in use: *Microdrip:* 60 gtt/mL *Macrodrip:* 10 or 15 gtt/mL; see label on administration set packaging.	Drop factor for macrodrip tubing varies with manufacturer.
b. Select one of the following formulas to calculate minute flow rate (drops/min) based on drop factor of infusion set:	Formulas compute correct flow rate over a minute.
(1) mL/hr/60 min = mL/min Drop factor × mL/min = gtt/min	
Or	
(2) mL/hr × drop factor/60 min = gtt/min Using formula (2) above, calculate minute flow rate for an IV solution that should infuse at 125 mL/hr:	
Microdrip: 125 mL/hr × 60 gtt/mL = 7500 gtt/hr 7500 gtt ÷ 60 minutes = 125 gtt/min	When using microdrip, mL/hr always equals gtt/min.
Macrodrip: 125 mL/hr × 15 gtt/mL = 1875 gtt/hr 1875 gtt ÷ 60 minutes = 31-32 gtt/min	Multiple hourly rate (mL/hr) by drop factor and divide product by 60 to convert hours to minutes.
(3) Option—use dimensional analysis (see Chapter 31)	

STEP	RATIONALE
IMPLEMENTATION	
1 Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medication administration record (MAR) or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Using an EID (infusion pump or smart pump):	
a. Consult manufacturer directions for setup of infusion. Use tubing compatible with EID.	Smart pumps with medication safety software are designed for administration of IV fluid that contains medications.
b. Close roller clamp on primed IV tubing and insert tubing into chamber of EID control mechanism or pump module per manufacturer directions (see illustration). Roller clamp on IV tubing goes between EID and patient.	Special infusion tubing is required for most EIDs. It is designed to prevent free flow of fluid when tubing is removed from device. Check agency equipment and associated policies and procedures. Most electronic infusion pumps use positive pressure to infuse. They move fluid through IV tubing by compressing and milking tubing.
c. Turn on EID power; test alarm; select required volume per hour, volume to be infused (VTBI), and any other information required. Close control chamber door if not already done and press run/start button. If smart pump alarms immediately and shuts down, your settings were outside unit parameters. Recalculate infusion rate and set EID again.	Program EID per manufacturer instructions for patient safety. Smart pumps require additional information such as patient unit and medication. They contain a computer that matches pump setting against a drug dose database (Hertzel and Sousa, 2009). If your setting does not match the database, the pump alarms and automatically shuts down for patient safety.
d. Open roller clamp completely while EID is in use.	Ensures that EID regulates infusion rate.
e. Check intermittently to see that correct amount of IV fluid has infused by observing fluid level in IV container.	EIDs do not replace frequent, accurate nursing evaluation. They may continue to infuse IV fluids even after an infiltration or other complication.
f. Assess patency of system if EID alarm signals.	Alarm indicates problem in system. Empty solution container, kinked tubing, air in tubing, closed clamp, infiltration, clotted catheter, and/or low battery all trigger EID alarm.
3 Using gravity flow:	
a. Ensure that IV container is 36 inches above IV site for adults.	Pressure caused by gravity is necessary to overcome venous pressure and resistance from tubing and catheter.
b. Slowly open roller clamp on tubing until you can see drops in drip chamber. Hold a watch with second hand at same level as drip chamber and count drip rate for 1 minute (see illustration). Adjust roller clamp to increase or decrease drip rate until you obtain desired number of drops per minute.	Regulate to prescribed rate of fluid infusion.
c. Monitor drip rate at least hourly.	Many factors influence drip rate; frequent monitoring ensures IV fluid administration as prescribed.
4 Using a volume-control device with gravity flow:	
a. Insert volume-control device spike into IV container and insert spike of infusion set into bottom end of volume controller tubing using aseptic technique.	Device is a graduated chamber with tubing inserted in an IV line just below IV container. It is used in pediatric units if an EID is not used. Delivers small volume of fluid to prevent bolus administration in case of equipment malfunction; especially important in pediatric units. You refill it as it becomes low.

STEP 2b Insert IV tubing into chamber of control mechanism of EID.

STEP 3b Nurse counting drip rate on gravity-flow infusion.

SKILL 41-2 REGULATING INTRAVENOUS FLOW RATE—cont'd

STEP	RATIONALE
b. Place no more than 2 hours' allotment of fluid into device by opening clamp between IV fluid container and device (see illustration).	Allows for continuous fluid infusion if you do not return in exactly 60 minutes to refill volume controller. If infusion rate accidentally increases, patient receives only a 2-hour allotment of fluid.

STEP 4b Open regulator clamp to fill volume control device.

c. Regulate flow rate manually with roller clamp by counting drops in drip chamber for 1 minute by watch and adjusting roller clamp to increase or decrease rate of infusion.	Regulate to prescribed rate of fluid infusion.
d. Assess system at least hourly; add fluid to volume-control device. Regulate flow rate.	Maintains patency of system and patient monitoring.
5 Attach piece of tape or label to IV fluid container with date and time of container change (check agency policy). If using polyvinylchloride (PVC) container, mark only on label and not container.	Provides reference to determine next time for container change, especially with KVO rate. Ink may leak into IV fluid through PVC container.
6 Instruct patient to avoid raising arm with IV line because it can affect flow rate; to avoid touching control clamp or other equipment; and about purpose of EID alarms.	Provides information so patient does not alter infusion rate. Ask patient to instruct family if appropriate.

EVALUATION

1 Monitor IV infusion at least every hour, noting volume of IV fluid infused and rate.	Ensures that correct volume infuses over prescribed time period.
2 Observe patient for signs of overhydration or dehydration to determine response to therapy and restoration of fluid balance.	Signs and symptoms of new overhydration or continued dehydration warrant changing rate of fluid infused. Contact health care provider for new infusion rate order.
3 Evaluate for signs of infiltration, inflammation at site, kink or knot in infusion tubing, or occluded VAD.	Prevents or identifies conditions that decrease or stop flow rate.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Circulatory overload of IV solution occurs.
- See Table 41-12.

2. IV fluid container empties with subsequent loss of VAD patency.
- Discontinue present IV infusion and start new IV line in other extremity or proximal to previous insertion site.

3. IV fluid infuses more slowly than ordered.
- Check for positional change that might affect rate, EID malfunction (or insufficient height of IV fluid container with gravity flow), kinking or obstruction of tubing, infiltration or other complications at VAD site.
- Consult health care provider for new order to provide necessary fluid volume.

RECORDING AND REPORTING

- Record rate of infusion in milliliters per hour (or drops per minute with gravity flow) in designated location in the patient's medical record.
- Document use of EID or volume-control device.
- Immediately record any new IV fluid rate.
- At change of shift or when leaving on break, report rate and volume left of infusion to nurse in charge or next nurse assigned to care for patient.

HOME CARE CONSIDERATIONS

- Ensure that patient is able and willing to operate infusion pump and administer IV therapy. If he or she is unable to provide self-care, be sure that a reliable family caregiver is available in the home.
- Ensure that EID functions properly before use and that patient's electrical outlets are properly grounded.
- Teach patient and caregiver what EID alarms mean, methods to troubleshoot them, and how to disconnect the tubing from the EID pump in case of pump failure. Provide a 24-hour access telephone number for patient to call for assistance.
- If using gravity administration, teach patient and family caregiver how to time drops per minute using watch with second hand.

SKILL 41-3 MAINTENANCE OF INTRAVENOUS SYSTEM

Delegation Considerations

The skills of changing an intravenous (IV) fluid container and tubing cannot be delegated to nursing assistive personnel (NAP). Some states allow NAP to discontinue peripheral IV access. Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. Instruct the NAP to inform you if:

- The IV fluid container is nearly empty.
- Any bleeding occurs after you remove the vascular access device (VAD).

Equipment

- Changing an IV fluid container and tubing (continuous infusion)
  - Correct type and volume of IV solution
  - Infusion tubing
  - Tape or tubing label
  - Filter (size appropriate to solution) and extension tubing (if necessary)
  - Handheld bar-code scanner if using bar-code system
- Changing an IV fluid container and tubing (intermittent infusion or saline lock)
  - Syringe containing 1 to 3 mL of preservative-free sterile 0.9% sodium chloride (normal saline) for adults, children, and neonates (INS, 2011; Mok, Kwong, and Chan 2007) (less frequently for neonates), heparin lock solution (10 units/mL or per agency protocol)
  - 2 × 2 gauze pads (optional)
  - Tape or label
  - Clean gloves
  - Antiseptic swab (chlorhexidine 2% preferred [INS, 2011])
- Discontinuing peripheral IV access
  - Clean gloves
  - Sterile 2 × 2 or 4 × 4 gauze sponge
  - Antiseptic swab
  - Tape

STEP	RATIONALE
ASSESSMENT	
1 Changing IV fluid container:	
a. Review accuracy and completeness of health care provider's order for patient name, type and amount of IV fluid, medication additives, infusion time, and purpose of infusion. Follow six rights of medication administration (see Chapter 31). If order is written for KVO (keep vein open) or TKO (to keep open), note date and time of last fluid container change and refer to agency policy to determine need for IV fluid container change.	Provides patient safety by preventing medication errors. Agency policy determines how often IV fluid container change is required for KVO infusion rate.
b. Determine compatibility of all IV fluids and additives by consulting approved online database, drug reference book, or pharmacist.	Incompatibilities cause physical and chemical changes with adverse patient outcomes.
2 Changing IV tubing:	
a. Assess current tubing for puncture, contamination, or occlusion, which requires immediate tubing change.	Compromised tubing allows fluid leakage, bacterial contamination, and entry of pathogens into patient's bloodstream. Whole blood, blood component products, or incompatible mixtures can occlude or partially occlude tubing because viscous solutions adhere to walls of tubing, decreasing size of lumen.
b. Note date and time of last IV tubing change. Agency policy indicates frequency of routine change for IV administration sets and saline/heparin locks.	INS (2011) recommends changing continuous IV tubing no more often than 96-hour intervals unless tubing becomes compromised. Change primary intermittent tubing set every 24 hours (INS, 2011).
3 Discontinuing peripheral IV access: Review accuracy and completeness of health care provider's order for discontinuing IV therapy.	Order required for discontinuing IV therapy.
4 Determine patient's/family member's understanding of need for IV therapy or reason for discontinuing it.	Reveals need for patient teaching.

SKILL 41-3 MAINTENANCE OF INTRAVENOUS SYSTEM—cont'd

STEP	RATIONALE
PLANNING	
1 Collect appropriate equipment at patient's bedside. *For changing IV fluid container:* Have next solution prepared at least 1 hour before needed. If prepared in pharmacy, ensure that it has been delivered to patient care unit. Check that solution is correct and properly labeled. Allow solution to warm to room temperature if refrigerated. Check solution expiration date. Observe for precipitate, discoloration, and leakage.	Keeps procedure organized and provides patient safety. Adequate planning for changing solution reduces risk of clot formation at catheter tip caused by lack of flow from an empty IV container. Checking that solution is correct prevents medication error.
2 Coordinate tubing changes with IV fluid container changes if possible.	Promotes patient safety by reducing number of times IV system is open.
3 Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medication administration record (MAR) or medical record. If using bar-code system, scan bar code on patient's wristband and then on IV fluid container.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011). Bar-code systems reduce medication errors by verifying right patient, medication, dose, and time with EHR (Poon et al., 2010).
4 Explain to patient/family member procedure, its purpose, and what is expected of patient. *For discontinuing peripheral IV access:* Explain that patient must hold extremity still, that he or she may feel burning sensation when you remove catheter, and that procedure will take about 5 minutes.	Promotes patient cooperation and decreases anxiety.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Changing IV fluid container:	
a. Determine patency of current VAD site: Look for swelling, coolness to touch, or tenderness around VAD site. With EID use VAD should be patent if site is not infiltrated and EID functions without alarm signals. If not using EID, carefully adjust roller clamp to see an increase in flow rate and then regulate back to prescribed rate.	New IV access site is necessary if infiltration or phlebitis is present, IV tubing is compromised, or VAD site is not patent. EID alarm signals when system is occluded. In absence of EID, adjusting roller clamp increases flow rate if there is no obstruction.
CLINICAL DECISION: *Lowering IV container below level of IV site for presence of blood return (retrograde) is an unreliable indicator of patency.*	
b. Prepare to change solution when about 50 mL of fluid remains in container. Be sure that drip chamber is at least half full.	Prevents air from entering tubing and vein from clotting from lack of flow.
c. Prepare new IV fluid container for changing. If using plastic bag, hang on IV pole and remove protective cover from IV tubing port. If using glass bottle, remove metal cap and disks.	Permits quick, smooth, and organized change from old to new IV fluid container.
d. Close roller clamp to stop flow of existing infusion. Remove tubing from EID. Then remove old IV fluid container from IV pole and hold it with tubing port pointing upward.	Prevents solution remaining in drip chamber from emptying while changing IV fluid container. Port held upward prevents IV fluid from spilling.
e. Quickly remove spike from old solution container (see illustration) and, without touching tip, insert it into new container (see illustration).	Reduces risk of solution in drip chamber running dry and maintains sterility.

STEP 2e A, Quickly remove spike from old solution container. **B,** Without touching tip, insert spike into new container.

STEP	RATIONALE
CLINICAL DECISION: *If you contaminate the spike, discard that IV tubing and use a new one.*	
f. Hang new fluid container on IV pole.	Gravity assists delivery of fluid into drip chamber.
g. Check for air in tubing. If bubbles form, remove them by closing roller clamp below them, stretching tubing downward, and tapping tubing with finger (bubbles rise in fluid to drip chamber) (see illustration). For larger amount of air, swab port below air with alcohol and allow to dry; insert needleless syringe into port and aspirate air into the syringe.	Reduces risk of air descending the tubing. Use of air-eliminating filter also reduces this risk.
h. Make sure that drip chamber is one-third to one-half full. If it is too full, pinch off tubing below it, invert container, squeeze drip chamber (see illustration) to push fluid into container, release tubing, and hang container.	Reduces risk of air entering tubing. If chamber is completely filled, you cannot observe drips.
i. Insert tubing into EID and restart pump. If no EID, regulate flow to prescribed rate with roller clamp.	Delivers IV fluid as ordered.
j. Attach piece of tape or label to IV fluid container with date and time of container change (check agency policy). If using polyvinylchloride (PVC) container, mark only on label and not container.	Provides reference to determine next time for container change, especially with KVO rate. Ink may leak into IV fluid through PVC container.
3 Changing IV tubing:	
a. Open new infusion set and connect add-on pieces (e.g., filter, extension tubing). Keep protective coverings over infusion spike and distal connector for VAD. Secure all connections.	Protective covers maintain sterility of IV system. Securing connections reduces risk of contamination, infection, and hemorrhage.
b. Apply clean gloves.	Reduces transmission of microorganisms (OSHA, 2011).
c. If catheter hub is not accessible, remove IV dressing as directed in Skill 41-4. Do not remove tape or catheter securement device that secures catheter to skin.	Catheter hub must be accessible to provide smooth transition when removing old and inserting new tubing.
d. *Prepare tubing, using existing continuous IV infusion:*	
(1) Close roller clamp on new IV tubing.	Prevents spillage of fluid after spiking container.
(2) Slow rate of infusion through old tubing to KVO rate, using EID or roller clamp if no EID.	Prevents complete infusion of fluid remaining in tubing, thus decreasing risk of VAD clotting.
(3) Compress and fill drip chamber of old tubing.	Ensures that drip chamber contains enough fluid to maintain IV patency while changing tubing.

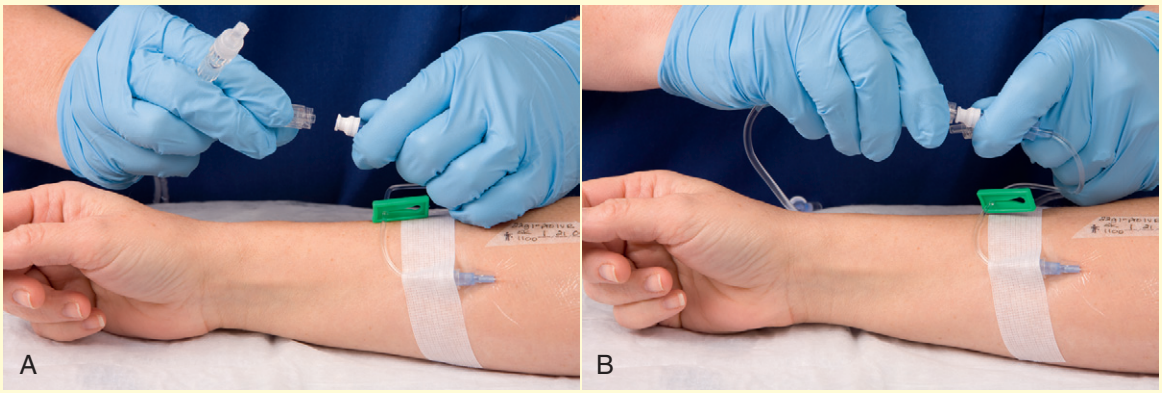
STEP 2g Nurse taps tubing to cause air bubbles to rise up to drip chamber.

STEP 2h Remove excess fluid from drip chamber.

SKILL 41-3 MAINTENANCE OF INTRAVENOUS SYSTEM—cont'd

STEP	RATIONALE
(4) Invert IV fluid container and remove old tubing. Keep spike sterile and upright. *Optional:* Tape old drip chamber to IV pole without contaminating spike.	Allows fluid to continue to flow through IV catheter while new tubing is prepared.
(5) Place insertion spike of new tubing into IV fluid container. Hang container on IV pole, compress and release drip chamber on new tubing, and fill drip chamber one-third to one-half full.	Permits flow of fluid from solution into new infusion tubing.

CLINICAL DECISION: *If you contaminate the spike, discard that IV tubing and use a new one.*



(6) Slowly open roller clamp, remove protective cap from adapter (if necessary), and flush new tubing with solution. Close roller clamp when full. Replace cap. Place capped end of adapter near patient's IV site.	Priming slowly instead of allowing a wide-open flow reduces formation of air in tubing. Removes air from tubing and replaces it with fluid.
(7) Stop EID if used and close roller clamp on old tubing.	Positions equipment for quick smooth connection of new tubing. Prevents spillage of fluid as tubing is removed from catheter.
e. *Prepare tubing, using existing saline lock:*	
(1) If loop or short extension tubing is needed, use sterile technique to connect new injection cap to new loop or tubing.	Sterile technique prevents transmission of infection.
(2) Swab injection cap with antiseptic swab and let dry. Insert syringe with 1 to 3 mL saline solution and inject through injection cap into loop of extension tubing (see illustration). Place capped end of tubing near patient's IV site.	Maintains patency of VAD.

STEP 3e(2) Flush injection port slowly.

f. *Reestablish infusion:*	
(1) Remove manufactured catheter stabilization device or tape from tubing. Gently disconnect old tubing from catheter hub (see illustration A) and quickly insert adapter of new tubing into catheter hub, being sure that it is secure, thus maintaining sterility of point of entry of connection (see illustration B).	Allows smooth transition from old to new tubing, minimizing time that system is open to infection. Careful technique prevents VAD dislodgement or vein trauma during tubing change and transmission of microorganisms.
(2) *For continuous infusion:* Open roller clamp on new tubing, allowing solution to run rapidly for 30 to 60 seconds, and then regulate drip rate using EID or roller clamp if gravity drip.	Brief rapid flow ensures catheter patency and prevents occlusion. Regulation restores infusion rate to deliver IV fluid as prescribed.

STEP	RATIONALE

STEP 3f(1) **A,** Disconnect old intravenous tubing. **B,** Connect Luer-Lok adapter of new intravenous tubing.

STEP 4e IV catheter is removed slowly, keeping catheter parallel to vein.

(3) Attach piece of tape or label with date and time of tubing change onto tubing below drip chamber.	Provides reference to determine next time for tubing change.
(4) Apply new manufactured catheter stabilization device or tape if used. Form loop of tubing and secure it to patient's arm with strip of tape.	Avoids accidental pulling against site and stabilizes catheter.
g. Remove and discard old IV tubing. If necessary, apply new dressing (see Skill 41-4). Remove and dispose of gloves. Perform hand hygiene.	Reduces transmission of microorganisms.
4 Discontinuing peripheral IV access	
a. Perform hand hygiene. Apply clean gloves.	Reduces transmission of microorganisms.
b. Turn off EID and close roller clamp or, if no EID, close roller clamp that controls rate.	Prevents spillage of IV fluid.
c. Remove IV site dressing and manufactured catheter stabilization device (see Skill 41-4). Remove any tape that secures catheter. Do not use scissors.	Exposes catheter with minimal discomfort. Scissors might accidentally damage catheter or injure patient (INS, 2011).
d. Hold catheter hub and clean site with antiseptic swab. Allow to dry completely.	Removes secretions around skin puncture site.
e. Place sterile gauze over venipuncture site and apply light pressure while withdrawing catheter, using slow, steady motion. Keep hub parallel to skin (see illustration). Do not raise or lift catheter before it is completely out of vein. Inspect end of catheter for intactness after removal.	Dry pad causes less irritation to puncture site. Removal technique avoids trauma to vein or hematoma formation. Inspection determines if catheter tip is intact. Tip of catheter can break off and embolize, an emergency situation.
f. Keep gauze in place and apply continuous pressure to site for 2 to 3 minutes and assess bleeding.	Controls bleeding and hematoma formation. Pressure should be applied until hemostasis occurs (INS, 2011).

CLINICAL DECISION: *If patient receives anticoagulants or platelet inhibitors (e.g., low-dose aspirin, warfarin sodium [Coumadin], heparin) or has a low platelet count, apply steady pressure longer (for 5 to 10 minutes) and assess bleeding.*

g. Apply sterile folded gauze dressing over insertion site and secure with tape.	Maintains pressure to prevent bleeding and reduces bacterial entry into puncture site.
h. Discard used supplies, remove gloves, and perform hand hygiene.	Reduces transmission of microorganisms.

SKILL 41-3 MAINTENANCE OF INTRAVENOUS SYSTEM—cont'd

STEP	RATIONALE
EVALUATION	
1 *For changing IV fluid container and/or tubing:*	
a. Evaluate IV flow rate hourly; observe connections for leaking and patency of system.	Ensures proper fluid administration.
b. Observe patient for signs of overhydration or dehydration to determine response to therapy and restoration of fluid balance.	Signs and symptoms of overhydration or continued dehydration warrant changing rate of fluid infused. Contact health care provider for new infusion rate order.
2 *For discontinuing peripheral IV access:* Observe site for bleeding soon after procedure and redness, tenderness, drainage, or swelling during a later evaluation.	Detects bleeding after catheter removal. Detects local infection or postinfusion phlebitis (INS, 2011). Postinfusion phlebitis may occur 48 to 96 hours after catheter removal.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Flow rate is incorrect; patient receives too little or too much fluid.
- Readjust infusion rate to ordered rate.
- Evaluate patient for adverse effects; notify health care provider if apparent.
- Determine and correct cause of incorrect flow rate (e.g., positional change that might affect rate, EID malfunction (or poor height of IV container with gravity flow), kinking or obstruction of tubing, infiltration or other complications of VAD site).
- Notify health care provider if patient's anticipated infusion is 100 to 200 mL less than or greater than expected (check agency policy).

2 Catheter tip is missing after withdrawal.
- Apply tourniquet high on extremity to restrict mobility of catheter embolus.
- Immediately notify health care provider.

3 See Table 41-12 for infiltration, phlebitis, and local infection.

RECORDING AND REPORTING

- Record amount and type of fluid infused, amount and type of fluid started, and tubing change on patient's medical record according to agency policy. If using bar-code system, fluid type and time record automatically in an EHR.
- Record time that peripheral IV access was discontinued on patient's record according to agency policy. Include site assessment information and status of catheter, including gauge, length, and catheter tip integrity.

HOME CARE CONSIDERATIONS

- Ensure that patient is able and willing to self-manage IV therapy (including changing IV containers) or that reliable family caregiver is at home to provide IV care.
- Instruct patient or caregiver in procedure for performing an IV solution and tubing change.
- Instruct patient or caregiver to notify health care provider if bleeding or drainage is noted at insertion site or if pain or tenderness occurs up to 4 days after catheter removal.

SKILL 41-4 CHANGING A PERIPHERAL INTRAVENOUS DRESSING

Delegation Considerations

The skill of changing a peripheral intravenous (IV) dressing cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. Instruct the NAP to inform you if:
- Patient indicates moistness or loosening of an IV dressing.

Equipment

- Antiseptic swabs (chlorhexidine 2% preferred [INS, 2011])
- Adhesive remover *(optional)*
- Skin protectant swab
- Clean gloves
- Strips of nonallergenic tape
- Manufactured catheter stabilization device, if available
- Dressing: Sterile transparent dressing (preferred) or sterile 2 × 2 or 4 × 4 inch gauze pad

STEP	RATIONALE
ASSESSMENT	
1 Determine agency policy regarding peripheral IV dressing changes. Transparent dressings usually remain in place until IV site is changed unless dressing becomes wet, soiled, or loose.	Dressing change increases risk of catheter displacement and is performed only if dressing is compromised.
2 Perform hand hygiene. Observe present dressing for moisture and intactness. Determine whether moisture is from site leakage or external source.	Moisture is a medium for bacterial growth and renders dressing contaminated. Loose dressing increases risk for bacterial contamination of venipuncture site or displacement of vascular access device (VAD).

STEP	RATIONALE
3 Observe IV system for proper functioning or complications. Apply clean gloves if dressing is moist. Palpate VAD site through intact dressing, assessing for pain or burning.	Unexplained decrease in flow rate requires investigating VAD placement and patency. Pain is associated with both phlebitis and infiltration.
4 Assess patient's understanding of need for continued IV infusion.	Determines need for patient teaching.
PLANNING	
1 Identify the patient using two identifiers (e.g., name and birthday or name and account number) according to facility policy. Compare identifiers with information on patient's medication administration record (MAR) or medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure and purpose to patient and family. Explain that patient must hold affected extremity still and how long procedure will take.	Decreases anxiety, promotes cooperation, and gives patient time frame around which to plan personal activities.
IMPLEMENTATION	
1 Perform hand hygiene. Collect equipment. Apply clean gloves.	Reduces transmission of microorganisms.
2 Remove transparent dressing by pulling up one corner and pulling dressing laterally while holding catheter hub and tubing with nondominant hand (see illustration). Leave tape or catheter stabilization device that secures IV catheter in place. *For gauze dressing:* Stabilize catheter hub while removing old dressing one layer at a time. Be cautious if catheter tubing becomes tangled between two layers of dressing.	Prevents accidental displacement of VAD.
3 Observe insertion site for signs and symptoms of infiltration, phlebitis (see Tables 41-12 to 41-14), and local infection (inflammation and exudate). Discontinue infusion if complication exists (see Skill 41-3).	Presence of infiltration, phlebitis, or local infection requires removal of VAD and new IV start in other extremity or proximal to previous insertion site if continued therapy is necessary.
4 If IV is infusing properly, gently remove any tape or stabilization device that secures catheter. Stabilize catheter with one hand. Use adhesive remover to clean skin and remove adhesive residue if needed.	Exposes venipuncture site. Stabilization prevents accidental displacement of catheter. Adhesive residue decreases ability of new tape to adhere securely to skin.
CLINICAL DECISION: *Keep one finger stabilizing VAD at all times until dressing is applied. This requires careful advance planning regarding placing and opening supplies and how to work with one hand. If patient is restless or uncooperative, ask another nurse to assist with dressing change.*	
5 While stabilizing VAD, clean insertion site with antiseptic swab using friction in a horizontal plane and then a vertical plane, followed by a circular motion moving from insertion site outward (see illustration). Allow antiseptic to dry completely.	Mechanical friction in this pattern allows penetration of antiseptic solution into cracks and fissures of epidermal layer of skin.
6 *Optional:* Apply skin protectant solution (e.g., Skin Prep, No Sting Barrier Film) to area where you will apply tape or dressing. Allow to dry.	Coats skin with protective solution to maintain skin integrity, prevents irritation from adhesive, and promotes adherence of dressing.
7 Secure catheter with stabilization device or tape (see Skill 41-1) and apply sterile dressing over site (procedures differ; follow agency policy).	Prevents accidental dislodgement of catheter and protects site from infection.
a. *Transparent dressing:* Apply as directed in Skill 41-1, Step 21b.	Occlusive dressing protects site from bacterial contamination.
b. *Gauze dressing:* Apply as directed in Skill 41-1, Step 21c.	Less frequently used than transparent dressing.
CLINICAL DECISION: *Think carefully about where you place tape. Do not apply it over catheter insertion site, over connection between tubing or port and IV catheter hub, or on top of transparent dressing.*	

STEP 2 Remove transparent dressing while pulling it laterally.

STEP 5 Cleanse peripheral insertion site with antiseptic swab.

SKILL 41-4 CHANGING A PERIPHERAL INTRAVENOUS DRESSING—cont'd

STEP	RATIONALE
8 Remove and discard gloves.	Reduces transmission of microorganisms.
9 *Optional:* Apply protective device over area if patient may pick at or bump dressing (see illustration).	Site protection devices include vented plastic or stretch netting coverings and mitts for hands. Designed to reduce risk of phlebitis, infiltration, or catheter displacement from mechanical motion.

STEP 9 IV House protective device. (Courtesy IV House, St Louis, Mo.)

10 Anchor IV tubing with additional pieces of tape if necessary.	Prevents accidental displacement of IV catheter.
11 Label dressing per agency policy. Label information should include date and time of original IV insertion and VAD gauge and length.	Labeling with IV insertion date and VAD length facilitates appropriate site rotation and safe discontinuation of IV access.
12 Discard equipment and perform hand hygiene.	Reduces transmission of microorganisms.
13 Ensure that flow rate is accurate.	Validates that IV line is patent and functioning correctly. Manipulation of catheter and tubing may affect rate of infusion.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 VAD is accidentally dislodged or removed.
- Start new IV line in other extremity or proximal to previous insertion site if continued therapy is necessary.

2 IV site develops infiltration, phlebitis, and local infection.
- See Table 41-12.

RECORDING AND REPORTING

- Record time that peripheral dressing was changed, reason for change, type of dressing material used, patency of system, and description of venipuncture site.
- Report to charge nurse or oncoming nursing shift that dressing was changed and any significant information about integrity of system.
- Report any complications to health care provider and document them.

KEY POINTS

- Body fluids containing water, Na^+, and other electrolytes are distributed between ECF and ICF compartments.
- A dynamic interplay of fluid intake and absorption, fluid distribution, and fluid output determines fluid balance.
- Fluid moves between blood vessels and interstitial fluid by filtration; water moves between ECF and ICF by osmosis.
- ECV deficit and excess are abnormal volumes of isotonic fluid, manifested as sudden changes in body weight and changes in markers of vascular and interstitial volume.
- Osmolality imbalances are abnormal concentrations of body fluids, manifested as altered serum Na^+ levels and decreased level of consciousness.
- Interplay of electrolyte intake and absorption, electrolyte distribution, and electrolyte output determines balance of K^+, Ca^{2+}, Mg^{2+}, and phosphate.
- Interplay of acid production, acid buffering, and acid excretion determines acid-base balance.
- Acid-base imbalances are caused by excesses or deficits of carbonic or metabolic acids, manifested as changes in level of consciousness and abnormalities of $PaCO_2$, HCO_3^-, and pH.
- Patients who are very young or very old, whose I&O of fluid and/or electrolytes are not equal, or who have various chronic diseases or trauma are at high risk for fluid, electrolyte, and acid-base imbalances.
- Treatment for ECV excess is Na^+ restriction and fluid restriction if severe; treatment for hyponatremia usually is water restriction.

- Prevention and treatment of ECV deficit, hypernatremia, and electrolyte deficits are accomplished with enteral or parenteral administration of appropriate fluid.
- Initiation and maintenance of IV therapy require clinical decision making, skill, and organized procedures to maintain sterility and patency of the system.
- Good IV practice requires periodic updating of procedures based on current research evidence.
- Nurses monitor vigilantly for complications of IV therapy, which include fluid overload, infiltration, phlebitis, local infection, and bleeding at the infusion site.
- Administration of blood or blood products requires a specific procedure for correctly identifying patient and blood product and responding to transfusion reactions quickly.
- Patient and family teaching is important for preventing fluid, electrolyte, and acid-base imbalances and effective restorative care.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Hilda Beck is a 72-year-old seen by her health care provider this morning after falling at home because she became light-headed after vomiting and having diarrhea that has lasted over 24 hours. She was admitted for oral and intravenous (IV) fluid therapy.

1. Why is Mrs. Beck likely becoming light-headed? When should you expect this to resolve?
2. Mrs. Beck's IV fluid order is 1000 mL 0.9% sodium chloride to run over 8 hours. Calculate the milliliters per hour that you should program into her infusion pump.
3. You auscultate crackles in Mrs. Beck's lung bases while her IV is infusing. What is your next action?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A patient who is comatose is admitted to the hospital with an unknown history. Respirations are deep and rapid. Arterial blood gas levels on admission are pH, 7.20; $PaCO_2$, 21 mm Hg; PaO_2, 92 mm Hg; and HCO_3^-, 8. You interpret these laboratory values to indicate:
   1. Metabolic acidosis
   2. Metabolic alkalosis
   3. Respiratory acidosis
   4. Respiratory alkalosis
2. A patient with a cardiac history is taking the diuretic furosemide (Lasix) and is seen in the emergency department for muscle weakness. Which laboratory value do you assess first?
   1. Serum albumin
   2. Serum sodium
   3. Hematocrit
   4. Serum potassium
3. Which of these patients do you expect will need teaching regarding dietary sodium restriction?
   1. An 88-year-old with a fractured femur scheduled for surgery
   2. A 65-year-old recently diagnosed with heart failure
   3. A 50-year-old recently diagnosed with asthma and diabetes
   4. A 20-year-old with vomiting and diarrhea from gastroenteritis
4. You teach patients to replace sweat, vomiting, or diarrhea fluid losses with which type of fluid?
   1. Tap water or bottled water
   2. Fluid that has sodium (salt) in it
   3. Fluid that has K^+ and HCO_3^- in it
   4. Coffee or tea, whichever they prefer
5. You assess four patients. Which patient is at greatest risk for the development of hypocalcemia?
   1. 56-year-old with acute kidney renal failure
   2. 40-year-old with appendicitis
   3. 28-year-old who has acute pancreatitis
   4. 65-year-old with hypertension and asthma
6. Which of the following activities can you delegate to nursing assistive personnel (NAP)? (Select all that apply.)
   1. Measuring oral intake and urine output
   2. Preparing intravenous (IV) tubing for routine change
   3. Reporting an IV container that is low in fluid
   4. Changing an IV fluid container
7. Place the following steps for intravenous (IV) catheter insertion in the correct order:
   1. Perform hand hygiene.
   2. Open and prepare infusion set.
   3. Select appropriate vein and insert catheter.
   4. Use two identifiers to ensure correct patient.
   5. Assess for risk factors such as age or platelet count.
   6. Carefully check the health care provider's order for the IV therapy.
8. Assessment findings consistent with intravenous (IV) fluid infiltration include: (Select all that apply.)
   1. Edema and pain
   2. Streak formation
   3. Pain and erythema
   4. Pallor and coolness
   5. Numbness and pain
9. Which of the following defining characteristics is consistent with *fluid volume deficit?*
   1. A 1-lb (0.5 kg) weight loss, pale yellow urine
   2. Engorged neck veins when upright, bradycardia
   3. Dry mucous membranes, thready pulse, tachycardia
   4. Bounding radial pulse, flat neck veins when supine
10. Which of the following assessments do you perform routinely when an older adult patient is receiving intravenous 0.9% NaCl?
    1. Auscultate dependent portions of lungs
    2. Check color of urine
    3. Assess muscle strength
    4. Check skin turgor over sternum or shin
11. While receiving a blood transfusion, your patient develops chills, tachycardia, and flushing. What is your priority action?
    1. Notify a health care provider
    2. Insert an indwelling catheter
    3. Alert the blood bank
    4. Stop the transfusion
12. The health care provider's order is 1000 mL 0.9% NaCl with 20 mEq K^+ intravenously over 8 hours. Which assessment finding causes you to clarify the order with the health care provider before hanging this fluid?
    1. Flat neck veins
    2. Tachycardia
    3. Hypotension
    4. Oliguria
13. Your patient who has diabetic ketoacidosis is breathing rapidly and deeply. Intravenous (IV) fluids and other treatments have

just been started. What should you do about this patient's breathing?
1. Notify her health care provider that she is hyperventilating
2. Provide frequent oral care to keep her mucous membranes moist
3. Ask her to breathe slower and help her to calm down and relax
4. Assess her for pain and request an order for a sedative

14. Your patient had 200 mL of ice chips and 900 mL intravenous (IV) fluid during your shift. Which total intake should you record?
1. 700 mL
2. 900 mL
3. 1000 mL
4. 1100 mL

15. The health care provider's order is 1000 mL 0.9% NaCl IV over 6 hours. Which rate do you program into the infusion pump?
1. 125 mL/hr
2. 167 mL/hr
3. 200 mL/hr
4. 1000 mL/hr

CHAPTER

42

Sleep

OBJECTIVES

- Explain the effect that the 24-hour sleep-wake cycle has on biological function.
- Discuss mechanisms that regulate sleep.
- Describe the stages of a normal sleep cycle.
- Explain the functions of sleep.
- Compare and contrast the sleep requirements of different age-groups.
- Identify factors that normally promote and disrupt sleep.
- Discuss characteristics of common sleep disorders.
- Conduct a sleep history for a patient.
- Identify nursing diagnoses appropriate for patients with sleep alterations.
- Identify nursing interventions designed to promote normal sleep cycles for patients of all ages.
- Describe ways to evaluate sleep therapies.

Proper rest and sleep are as important to health as good nutrition and adequate exercise. Physical and emotional health depends on the ability to fulfill these basic human needs. Individuals need different amounts of sleep and rest. Without proper amounts, the ability to concentrate, make judgments, and participate in daily activities decreases; and irritability increases.

Identifying and treating patients' sleep pattern disturbances are important goals. To help patients you need to understand the nature of sleep, the factors influencing it, and patients' sleep habits. Patients require individualized approaches based on their personal habits, patterns of sleep, and the particular problem influencing sleep. Nursing interventions are often effective in resolving short- and long-term sleep disturbances.

Sleep provides healing and restoration (McCance et al., 2010). Achieving the best possible sleep quality is important for the promotion of good health and recovery from illness. Ill patients often require more sleep and rest than healthy patients. However, the nature of illness often prevents some patients from getting adequate rest and sleep. The environment of a hospital or long-term care facility and the activities of health care personnel make sleep difficult. Some patients have preexisting sleep disturbances; other patients develop sleep problems as a result of illness or hospitalization.

SCIENTIFIC KNOWLEDGE BASE

Physiology of Sleep

Sleep is a cyclical physiological process that alternates with longer periods of wakefulness. The sleep-wake cycle influences and regulates physiological function and behavioral responses.

Circadian Rhythms. People experience cyclical rhythms as part of their everyday lives. The most familiar rhythm is the 24-hour, day-night cycle known as the diurnal or **circadian rhythm** (derived from Latin: *circa,* "about," and *dies,* "day"). The suprachiasmatic nucleus (SCN) nerve cells in the hypothalamus control the rhythm of the sleep-wake cycle and coordinate this cycle with other circadian rhythms (McCance et al., 2010). Circadian rhythms influence the pattern of major biological and behavioral functions. The predictable changing of body temperature, heart rate, blood pressure, hormone secretion, sensory acuity, and mood depend on the maintenance of the 24-hour circadian cycle (Van der Zee et al., 2009).

Factors such as light, temperature, social activities, and work routines affect circadian rhythms and daily sleep-wake cycles. All

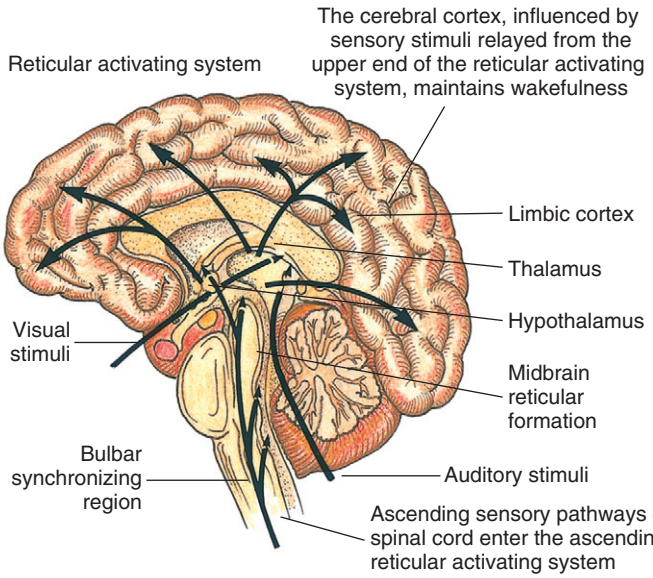

FIG. 42-1 Reticular activating system (RAS) and bulbar synchronizing region (BSR) control sensory input, intermittently activating and suppressing the higher centers of the brain to control sleep and wakefulness.

persons have **biological clocks** that synchronize their sleep cycles. This explains why some people fall asleep at 8 PM, whereas others go to bed at midnight or early in the morning. Different people also function best at different times of the day.

Hospitals or extended care facilities usually do not adapt care to an individual's sleep-wake cycle preferences. Typical hospital routines interrupt sleep or prevent patients from falling asleep at their usual time. Poor quality of sleep results when a person's sleep-wake cycle changes. Reversals in the sleep-wake cycle, such as when a person who is normally awake during the day falls asleep during the day, often indicate a serious illness.

The biological rhythm of sleep frequently becomes synchronized with other body functions. For example, changes in body temperature correlate with sleep patterns. Normally body temperature peaks in the afternoon, decreases gradually, and then drops sharply after a person falls asleep. When the sleep-wake cycle becomes disrupted (e.g., by working rotating shifts), other physiological functions usually change as well. For example, a new nurse who starts working the night shift experiences a decreased appetite and loses weight. Anxiety, restlessness, irritability, and impaired judgment are other common symptoms of sleep cycle disturbances. Failure to maintain an individual's usual sleep-wake cycle negatively influences the patient's overall health.

Sleep Regulation. Sleep involves a sequence of physiological states maintained by highly integrated central nervous system (CNS) activity. It is associated with changes in the peripheral nervous, endocrine, cardiovascular, respiratory, and muscular systems (McCance et al., 2010). Specific physiological responses and patterns of brain activity identify each sequence. Instruments such as the electroencephalogram (EEG), which measures electrical activity in the cerebral cortex; the electromyogram (EMG), which measures muscle tone; and the electrooculogram (EOG), which measures eye movements provide information about some structural physiological aspects of sleep.

The major sleep center in the body is the hypothalamus. It secretes hypocreatins (orexins) that promote wakefulness and rapid eye movement sleep. Prostaglandin D_2, L-tryptophan, and growth factors control sleep (McCance et al., 2010).

Researchers believe that the ascending reticular activating system (RAS) located in the upper brainstem contains special cells that maintain alertness and wakefulness. The RAS receives visual, auditory, pain, and tactile sensory stimuli. Activity from the cerebral cortex (e.g., emotions or thought processes) also stimulates the RAS. Arousal, wakefulness, and maintenance of consciousness result from neurons in the RAS releasing catecholamines such as norepinephrine (Izac, 2006).

Researchers hypothesize that the release of serotonin from specialized cells in the raphe nuclei sleep system of the pons and medulla produces sleep. This area of the brain is also called the *bulbar synchronizing region (BSR)*. Whether a person remains awake or falls asleep depends on a balance of impulses received from higher centers (e.g., thoughts), peripheral sensory receptors (e.g., sound or light stimuli), and the limbic system (emotions) (Fig. 42-1). As people try to fall asleep, they close their eyes and assume relaxed positions. Stimuli to the RAS decline. If the room is dark and quiet, activation of the RAS further declines. At some point the BSR takes over, causing sleep.

Stages of Sleep. Current theory suggests that sleep is an active multiphase process. Different brain-wave, muscle, and eye activity is associated with different stages of sleep (Izac, 2006). Normal sleep involves two phases: **nonrapid eye movement (NREM) sleep** and **rapid eye movement (REM) sleep** (Box 42-1). During NREM a sleeper progresses through four stages during a typical 90-minute sleep cycle. The quality of sleep from stage 1 through stage 4 becomes increasingly deep. Lighter sleep is characteristic of stages 1 and 2, during which a person is more easily aroused. Stages 3 and 4 involve a deeper sleep, called *slow-wave sleep*. REM sleep is the phase at the end of each sleep cycle. Different factors promote or interfere with various stages of the sleep cycle.

Sleep Cycle. The normal sleep pattern for an adult begins with a presleep period during which the person is aware only of a gradually developing sleepiness. This period normally lasts 10 to 30 minutes; however, if a person has difficulty falling asleep, it lasts an hour or more.

Once asleep, the person usually passes through four or five complete sleep cycles per night, each consisting of four stages of

BOX 42-1 STAGES OF THE SLEEP CYCLE

Stage 1: NREM
- Stage lasts a few minutes.
- It includes lightest level of sleep.
- Decreased physiological activity begins with gradual fall in vital signs and metabolism.
- Sensory stimuli such as noise easily arouses person.
- Awakened, person feels as though daydreaming has occurred.

Stage 2: NREM
- Stage lasts 10 to 20 minutes.
- It is a period of sound sleep.
- Relaxation progresses.
- Body functions continue to slow.
- Arousal remains relatively easy.

Stage 3: NREM
- Stage lasts 15 to 30 minutes.
- It involves initial stages of deep sleep.
- Muscles are completely relaxed.
- Vital signs decline but remain regular.
- Sleeper is difficult to arouse and rarely moves.

Stage 4: NREM
- Stage lasts approximately 15 to 30 minutes.
- It is the deepest stage of sleep.
- If sleep loss has occurred, sleeper spends considerable portion of night in this stage.
- Vital signs are significantly lower than during waking hours.
- Sleepwalking and enuresis (bed-wetting) sometimes occur.
- It is very difficult to arouse sleeper.

REM Sleep
- Stage usually begins about 90 minutes after sleep has begun.
- Duration increases with each sleep cycle and averages 20 minutes.
- Vivid, full-color dreaming occurs; less vivid dreaming occurs in other stages.
- Stage is typified by rapidly moving eyes, fluctuating heart and respiratory rates, increased or fluctuating blood pressure, loss of skeletal muscle tone, and increase of gastric secretions.
- It is very difficult to arouse sleeper.

NREM, Nonrapid eye movement; *REM,* rapid eye movement.

NREM sleep and a period of REM sleep (McCance et al., 2010). Each cycle lasts approximately 90 to 100 minutes. The cyclical pattern usually progresses from stage 1 through stage 4 of NREM, followed by a reversal from stages 4 to 3 to 2, ending with a period of REM sleep (Fig. 42-2). A person usually reaches REM sleep about 90 minutes into the sleep cycle. Seventy-five to eighty percent of sleep time is spent in NREM sleep.

With each successive cycle stages 3 and 4 shorten, and the period of REM lengthens. REM sleep lasts up to 60 minutes during the last sleep cycle. Not all people progress consistently through the stages of sleep. For example, a sleeper moves back and forth for short intervals between NREM stages 2, 3, and 4 before entering REM stage. The amount of time spent in each stage varies over the life span. Newborns and children spend more time in deep sleep. Sleep becomes more fragmented with aging, and a person spends more time in lighter stages (National Sleep Foundation, 2009). Shifts from stage to stage of sleep tend to accompany body movements. Shifts to light sleep or wakefulness tend to occur suddenly,

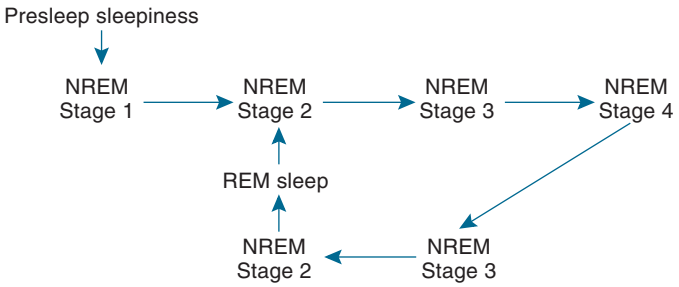

FIG. 42-2 Stages of adult sleep cycle.

whereas shifts to deep sleep tend to be gradual (Izac, 2006). The number of sleep cycles depends on the total amount of time that the person spends sleeping.

Functions of Sleep

The purpose of sleep remains unclear. It contributes to physiological and psychological restoration. NREM sleep contributes to body tissue restoration (McCance et al., 2010). During NREM sleep biological functions slow. A healthy adult's normal heart rate throughout the day averages 70 to 80 beats/min or less if the individual is in excellent physical condition. However, during sleep the heart rate falls to 60 beats/min or less, which benefits cardiac function. Other biological functions decreased during sleep are respirations, blood pressure, and muscle tone (McCance et al., 2010).

The body needs sleep to routinely restore biological processes. During deep slow-wave (NREM stage 4) sleep, the body releases human growth hormone for the repair and renewal of epithelial and specialized cells such as brain cells (McCance et al., 2010). Protein synthesis and cell division for renewal of tissues such as the skin, bone marrow, gastric mucosa, or brain occur during rest and sleep. NREM sleep is especially important in children, who experience more stage 4 sleep.

Another theory about the purpose of sleep is that the body conserves energy during sleep. The skeletal muscles relax progressively, and the absence of muscular contraction preserves chemical energy for cellular processes. Lowering of the basal metabolic rate further conserves body energy supply (Izac, 2006).

REM sleep is necessary for brain tissue restoration and appears to be important for cognitive restoration. It is associated with changes in cerebral blood flow, increased cortical activity, increased oxygen consumption, and epinephrine release. This association assists with memory storage and learning (McCance et al., 2010).

The benefits of sleep on behavior often go unnoticed until a person develops a problem resulting from sleep deprivation. A loss of REM sleep leads to feelings of confusion and suspicion. Various body functions (e.g., mood, motor performance, memory, and equilibrium) are altered when prolonged sleep loss occurs (National Sleep Foundation, 2010a). Changes in the natural and cellular immune function also occur with moderate-to-severe sleep deprivation. Traffic, home, and work-related accidents caused by falling asleep cost billions of dollars a year in the United States because of lost productivity, health care costs, and accidents (Irwin et al., 2006).

Dreams. Although dreams occur during both NREM and REM sleep, the dreams of REM sleep are more vivid and elaborate; and some believe that they are functionally important to learning, memory processing, and adaptation to stress (Kryger et al., 2011). REM dreams progress in content throughout the night from dreams about current events to emotional dreams of childhood or

the past. Personality influences the quality of dreams (e.g., a creative person has elaborate and complex dreams, whereas a depressed person dreams of helplessness).

Most people dream about immediate concerns such as an argument with a spouse or worries over work. Sometimes a person is unaware of fears represented in bizarre dreams. Clinical psychologists try to analyze the symbolic nature of dreams as part of a patient's psychotherapy. The ability to describe a dream and interpret its significance sometimes helps resolve personal concerns or fears.

Another theory suggests that dreams erase certain fantasies or nonsensical memories. Because most people forget their dreams, few have dream recall or do not believe they dream at all. To remember a dream, a person has to consciously think about it on awakening. People who recall dreams vividly usually awake just after a period of REM sleep.

Physical Illness

Any illness that causes pain, physical discomfort, or mood problems such as anxiety or depression often results in sleep problems. People with such alterations frequently have trouble falling or staying asleep. Illnesses also force patients to sleep in unfamiliar positions. For example, it is difficult for a patient with an arm or leg in traction to rest comfortably.

Respiratory disease often interferes with sleep. Patients with chronic lung disease such as emphysema are short of breath and frequently cannot sleep without two or three pillows to raise their heads. Asthma, bronchitis, and allergic rhinitis alter the rhythm of breathing and disturb sleep. A person with a common cold has nasal congestion, sinus drainage, and a sore throat, which impair breathing and the ability to relax.

Connections between heart disease, sleep, and sleep disorders exist (Redeker, 2008). Sleep-related breathing disorders are linked to increased incidence of nocturnal angina (chest pain), increased heart rate, electrocardiogram changes, high blood pressure, and risk of heart diseases and stroke (McCance et al., 2010). Hypertension often causes early-morning awakening and fatigue. Hypothyroidism decreases stage 4 sleep, whereas hyperthyroidism causes persons to take more time to fall asleep. Research also identifies an increased risk of sudden cardiac death in the first hours after awakening.

Nocturia, or urination during the night, disrupts sleep and the sleep cycle. After repeated awakenings to urinate, returning to sleep is difficult, and the sleep cycle is not complete. This condition is most common in older people with reduced bladder tone or people with cardiac disease, diabetes, urethritis, or prostatic disease.

Many people experience restless legs syndrome (RLS), which occurs before sleep onset. More common in women, older people, and those with iron deficiency anemia, RLS symptoms include recurrent, rhythmical movements of the feet and legs. Patients feel an itching sensation deep in the muscles. Relief comes only from moving the legs, which prevents relaxation and subsequent sleep. RLS is sometimes a relatively benign condition, depending on how severely sleep is disrupted. Primary RLS is a CNS disorder. Researchers associate secondary RLS with lower levels of iron, pregnancy, and renal failure (Natarajan, 2010).

People with peptic ulcer disease often awaken in the middle of the night. Studies showing a relationship between gastric acid secretion and stages of sleep are conflicting. One consistent finding is that people with duodenal ulcers fail to suppress acid secretion in the first 2 hours of sleep (Kryger et al., 2011).

Sleep Disorders

Sleep disorders are conditions that, if untreated, generally cause disturbed nighttime sleep that results in one of three problems: insomnia, abnormal movements or sensation during sleep or when awakening at night, or excessive daytime sleepiness (Kryger et al., 2011). Many adults in the United States have significant sleep problems from inadequacies in either the quantity or quality of their nighttime sleep and experience **hypersomnolence** on a daily basis (National Sleep Foundation, 2010a). The American Academy of Sleep Medicine developed the International Classification of Sleep Disorders version 2 (ICSD-2), which classifies sleep disorders into eight major categories (Box 42-2).

The insomnias are disorders related to difficulty falling asleep. Individuals with sleep-related breathing disorders have disordered respirations during sleep. Hypersomnia not caused by sleep-related breathing disorders is a group of disorders that is not caused by disturbed circadian rhythms or nocturnal sleep. The circadian rhythm sleep disorders are caused by a misalignment between the timing of sleep and individual desires or the societal norm. The parasomnias are undesirable behaviors that occur usually during sleep. Sleep and wake disturbances are associated with many medical and psychiatric sleep disorders, including psychiatric, neurological, or other medical disorders. In sleep-related movement disorders the person experiences simple stereotyped movements that disturb sleep. The category of isolated symptoms, apparently normal variants, and unresolved issues includes sleep-related symptoms that fall between normal and abnormal sleep. The other sleep disorders category contains sleep problems that do not fit into other categories.

Sleep laboratory studies diagnose a sleep disorder. A **polysomnogram** involves the use of EEG, EMG, and EOG to monitor stages of sleep and wakefulness during nighttime sleep. The Multiple Sleep Latency Test (MSLT) provides objective information about sleepiness and selected aspects of sleep structure by measuring eye movements, muscle-tone changes, and brain electrical activity during at least four napping opportunities spread throughout the day. The MSLT takes 8 to 10 hours to complete. Patients wear an Actigraph device on the wrist to measure sleep-wake patterns over an extended period of time. Actigraphy data provide information about sleep time, sleep efficiency, number and duration of awakenings, and levels of activity and rest (Natale et al., 2009).

Insomnia. Insomnia is a symptom that patients experience when they have chronic difficulty falling asleep, frequent awakenings from sleep, and/or a short sleep or nonrestorative sleep (Kryger et al., 2011). It is the most common sleep-related complaint. People with insomnia experience excessive daytime sleepiness and insufficient sleep quantity and quality. However, frequently a patient gets more sleep than he or she realizes. Insomnia often signals an underlying physical or psychological disorder. It occurs more frequently in and is the most common sleep problem for women.

People experience transient insomnia as a result of situational stresses such as family, work, or school problems; jet lag; illness; or loss of a loved one. Insomnia sometimes recurs, but between episodes a patient is able to sleep well. However, a temporary case of insomnia caused by a stressful situation can lead to chronic difficulty in getting enough sleep, perhaps because of the worry and anxiety that develop about getting it.

Insomnia is often associated with poor **sleep hygiene,** or practices that a patient associates with sleep. If the condition continues, the fear of not being able to sleep is enough to cause wakefulness. During the day people with chronic insomnia feel sleepy, fatigued, depressed, and anxious. Treatment is symptomatic, including

BOX 42-2 CLASSIFICATION OF SELECT SLEEP DISORDERS

Insomnias
- Adjustment sleep disorder (acute insomnia)
- Inadequate sleep hygiene
- Behavioral insomnia of childhood
- Insomnia caused by medical condition

Sleep-Related Breathing Disorder
Central Sleep Apnea Syndromes
- Primary central sleep apnea
- Central sleep apnea caused by medical condition
- Obstructive sleep apnea syndromes

Hypersomnias Not Caused by a Sleep-Related Breathing Disorder
- Narcolepsy (four specified types)
- Menstrual-related hypersomnia
- Hypersomnia caused by a medical condition

Parasomnias
Disorders of Arousal
- Sleepwalking
- Sleep terrors

Parasomnias Usually Associated with REM Sleep
- Nightmare disorder
- REM sleep behavior disorder

Other Parasomnias
- Sleep-related hallucinations
- Sleep-related eating disorder
- Sleep-related enuresis (bed-wetting)

Circadian Rhythm Sleep Disorders
Primary Circadian Rhythm Sleep Disorders
- Delayed sleep phase type
- Advanced sleep phase type

Behaviorally Induced Circadian Rhythm Sleep Disorders
- Jet lag type
- Shift work type
- Drug or substance use

Sleep-Related Movement Disorders
- Restless legs syndrome
- Periodic limb movements
- Sleep-related bruxism (teeth grinding)

Isolated Symptoms, Apparently Normal Variants, and Unresolved Issues
- Long sleeper
- Short sleeper
- Sleep talking

Other Sleep Disorders
- Physiological (organic) sleep disorders
- Environmental sleep disorder

Data from American Academy of Sleep Medicine: International classes of diseases and international classification of sleep disorders. In Kryger HM et al: *Principles and practice of sleep medicine,* ed 5, St Louis, 2011, Saunders.
REM, Rapid eye movement.

improved sleep hygiene measures, biofeedback, cognitive techniques, and relaxation techniques. Behavioral and cognitive therapies have few adverse effects and show evidence of sustained improvement in sleep over time (Babson et al., 2010).

Sleep Apnea. **Sleep apnea** is a disorder characterized by the lack of airflow through the nose and mouth for periods of 10 seconds or longer during sleep. There are three types of sleep apnea: central, obstructive, and mixed apnea. The most common form is obstructive sleep apnea (OSA). Research estimates that 2% to 4% of the adults in the United States meet the diagnostic criteria for OSA (Adult Obstructive Sleep Apnea Task Force, 2009). The two major risk factors for OSA are obesity and hypertension (Sheldon et al., 2009). Smoking, heart failure, type II diabetes, alcohol, and a positive family history of OSA also greatly increase the risk of developing the problem (Adult Obstructive Sleep Apnea Task Force, 2009). It occurs in up to 2% of middle-age women and up to 4% of middle-age men, with occurrence higher in the older-adult population and African Americans (Malhotra and Desai, 2010).

OSA occurs when muscles or structures of the oral cavity or throat relax during sleep. The upper airway becomes partially or completely blocked, diminishing nasal airflow (hypopnea) or stopping it (apnea) for as long as 30 seconds (Kryger et al., 2011). The person still attempts to breathe because chest and abdominal movement continue, which often results in loud snoring and snorting sounds. When breathing is partially or completely diminished, each successive diaphragmatic movement becomes stronger until the obstruction is relieved. Structural abnormalities such as a deviated septum, nasal polyps, certain jaw configurations, larger neck circumference, or enlarged tonsils predispose a patient to OSA (Pinto and Caple, 2010). The effort to breathe during sleep results in arousals from deep sleep often to the stage 2 cycle. In severe cases hundreds of hypopnea/apnea episodes occur every hour, resulting in severe interference with deep sleep.

Excessive daytime sleepiness (EDS) and fatigue are the most common complaints of people with OSA. Persons with severe OSA often report taking daytime naps and experience a disruption in their daily activities because of sleepiness (Adult Obstructive Sleep Apnea Task Force, 2009). Feelings of sleepiness are usually most intense on awakening, right before going to sleep, and about 12 hours after the midsleep period. EDS often results in impaired waking function, poor work or school performance, accidents while driving or using equipment, and behavioral or emotional problems.

Obstructive apnea causes a serious decline in arterial oxygen saturation level. Patients are at risk for cardiac dysrhythmias, right heart failure, pulmonary hypertension, angina attacks, stroke, and hypertension. Sleep apnea contributes to high blood pressure and increased risk for heart attack and stroke (National Sleep Foundation, 2010b).

Central sleep apnea (CSA) involves dysfunction in the respiratory control center of the brain. The impulse to breathe fails temporarily, and nasal airflow and chest wall movement cease. The oxygen saturation of the blood falls. The condition is common in patients with brainstem injury, muscular dystrophy, and encephalitis. Less than 10% of sleep apnea is predominantly central in origin. People with CSA tend to awaken during sleep and therefore complain of insomnia and EDS. Mild and intermittent snoring is also present.

Patients with sleep apnea rarely achieve deep sleep. In addition to complaints of EDS, sleep attacks, fatigue, morning headaches, irritability, depression, difficulty concentrating, and decreased sex drive are common (Kryger et al., 2011). OSA affects quality of life

issues such as marital relationships and interactions within and outside the family and often is an embarrassment to a patient (Adult Obstructive Sleep Apnea Task Force, 2009). Treatment includes therapy for underlying cardiac or respiratory complications and emotional problems that occur as a result of the symptoms of this disorder.

Narcolepsy. Narcolepsy is a dysfunction of mechanisms that regulate sleep and wake states. Excessive daytime sleepiness is the most common complaint associated with this disorder. During the day a person suddenly feels an overwhelming wave of sleepiness and falls asleep; REM sleep occurs within 15 minutes of falling asleep. Cataplexy, or sudden muscle weakness during intense emotions such as anger, sadness, or laughter, occurs at any time during the day. If the cataplectic attack is severe, a patient loses voluntary muscle control and falls to the floor. A person with narcolepsy often has vivid dreams that occur as he or she is falling asleep. These dreams are difficult to distinguish from reality. Sleep paralysis, or the feeling of being unable to move or talk just before waking or falling asleep, is another symptom. Some studies show a genetic link for narcolepsy (Ahmed and Thorpy, 2010).

A person with narcolepsy falls asleep uncontrollably at inappropriate times. When individuals do not understand this disorder, a sleep attack is easily mistaken for laziness, lack of interest in activities, or drunkenness. Typically the symptoms first begin to appear in adolescence and are often confused with the EDS that commonly occurs in teens. Narcoleptic patients are treated with stimulants or wakefulness-promoting agents such as sodium oxybate, modafinil (Provigil) or armodafinil (Nuvigil) that only partially increase wakefulness and reduce sleep attacks. Patients also receive antidepressant medications that suppress cataplexy and the other REM-related symptoms. Brief daytime naps no longer than 20 minutes help reduce subjective feelings of sleepiness. Other management methods that help are following a regular exercise program, practicing good sleep habits, avoiding shifts in sleep, strategically timed daytime naps if possible, eating light meals high in protein, practicing deep breathing, chewing gum, and taking vitamins (Kryger et al., 2011). Patients with narcolepsy need to avoid factors that increase drowsiness (e.g., alcohol; heavy meals; exhausting activities; long-distance driving; and long periods of sitting in hot, stuffy rooms).

Sleep Deprivation. Sleep deprivation is a problem many patients experience as a result of dyssomnia. Causes include symptoms (e.g., fever, difficulty breathing, or pain) caused by illnesses, emotional stress, medications, environmental disturbances (e.g., frequent nursing care), and variability in the timing of sleep because of shift work. Physicians and nurses are particularly prone to sleep deprivation as a result of long work schedules and rotating shifts. Chronic sleep deprivation is associated with development of cardiovascular disease, weight gain, type II diabetes, poor memory, depression, and digestive problems (Ohlmann and O'Sullivan, 2009).

Hospitalization, especially in intensive care units (ICUs), makes patients particularly vulnerable to the extrinsic and circadian sleep disorders that cause the "ICU syndrome of sleep deprivation" (Fontana and Pittiglio, 2010). Constant environmental stimuli within the ICU such as strange noises from equipment, the frequent monitoring and care given by nurses, and ever-present lights confuse patients. Repeated environmental stimuli and the patient's poor physical status lead to sleep deprivation (Fontana and Pittiglio, 2010).

A person's response to sleep deprivation is highly variable. Patients experience a variety of physiological and psychological symptoms (Box 42-3). The severity of symptoms is often related to the duration of sleep deprivation.

BOX 42-3 SLEEP DEPRIVATION SYMPTOMS

Physiological Symptoms	Psychological Symptoms
• Ptosis, blurred vision	• Confused and disoriented
• Fine-motor clumsiness	• Increased sensitivity to pain
• Decreased reflexes	• Irritable, withdrawn, apathetic
• Slowed response time	• Agitated
• Decreased reasoning and judgment	• Hyperactive
• Decreased auditory and visual alertness	• Decreased motivation
• Cardiac arrhythmias	• Excessive sleepiness

Parasomnias. The parasomnias are sleep problems that are more common in children than adults. Some have hypothesized that sudden infant death syndrome (SIDS) is thought to be related to apnea, hypoxia, and cardiac arrhythmias caused by abnormalities in the autonomic nervous system that are manifested during sleep (Kryger et al., 2011). Because of an association between the prone position and the occurrence of SIDS, the American Academy of Pediatrics recommends that parents place apparently healthy infants in the supine position during sleep (Koren et al., 2010).

Parasomnias that occur among older children include somnambulism (sleepwalking), night terrors, nightmares, nocturnal enuresis (bed-wetting), body rocking, and bruxism (teeth grinding). When adults have these problems, it often indicates more serious disorders. Specific treatment varies. However, in all cases it is important to support patients and maintain their safety.

NURSING KNOWLEDGE BASE

Sleep and Rest

When people are at rest, they usually feel mentally relaxed, free from anxiety, and physically calm. Rest does not imply inactivity, although everyone often thinks of it as settling down in a comfortable chair or lying in bed. When people are at rest, they are in a state of mental, physical, and spiritual activity that leaves them feeling refreshed, rejuvenated, and ready to resume the activities of the day. People have their own habits for obtaining rest and can find ways to adjust to new environments or conditions that affect the ability to rest. They rest by reading a book, practicing a relaxation exercise, listening to music, taking a long walk, or sitting quietly.

Illness and unfamiliar health care routines easily affect the usual rest and sleep patterns of people entering a hospital or other health care facility. Nurses frequently care for patients who are on bed rest to reduce physical and psychological demands on the body in a variety of health care settings. However, these people do not necessarily feel rested. Some still have emotional worries that prevent complete relaxation. For example, concern over physical limitations or a fear of being unable to return to their usual lifestyle causes such patients to feel stressed and unable to relax. You must always be aware of a patient's need for rest. A lack of rest for long periods causes illness or worsening of existing illness.

Normal Sleep Requirements and Patterns

Sleep duration and quality vary among people of all age-groups. For example, one person feels adequately rested with 4 hours of sleep, whereas another requires 10 hours. Nurses play an important role in identifying treatable sleep-deprivation problems.

Neonates. The neonate up to the age of 3 months averages about 16 hours of sleep a day, sleeping almost constantly during the first week. The sleep cycle is generally 40 to 50 minutes with wakening occurring after one to two sleep cycles. Approximately 50% of this sleep is REM sleep, which stimulates the higher brain centers. This is essential for development because the neonate is not awake long enough for significant external stimulation.

Infants. Infants usually develop a nighttime pattern of sleep by 3 months of age. The infant normally takes several naps during the day but usually sleeps an average of 8 to 10 hours during the night for a total daily sleep time of 15 hours. About 30% of sleep time is in the REM cycle. Awakening commonly occurs early in the morning, although it is not unusual for an infant to awaken during the night.

Toddlers. By the age of 2 children usually sleep through the night and take daily naps. Total sleep averages 12 hours a day. After 3 years of age children often give up daytime naps (Hockenberry and Wilson, 2011). It is common for toddlers to awaken during the night. The percentage of REM sleep continues to fall. During this period toddlers may be unwilling to go to bed at night because they need autonomy or fear separation from their parents.

Preschoolers. On average a preschooler sleeps about 12 hours a night (about 20% is REM). By the age of 5 he or she rarely takes daytime naps except in cultures in which a siesta is the custom (Hockenberry and Wilson, 2011). The preschooler usually has difficulty relaxing or quieting down after long, active days and has bedtime fears, awakens during the night, or has nightmares. Partial awakening followed by normal return to sleep is frequent (Hockenberry and Wilson, 2011). In the awake period the child exhibits brief crying, walking around, unintelligible speech, sleepwalking, or bed-wetting.

School-Age Children. The amount of sleep needed varies during the school years. A 6-year-old averages 11 to 12 hours of sleep nightly, whereas an 11-year-old sleeps about 9 to 10 hours (Hockenberry and Wilson, 2011). The 6- or 7-year-old usually goes to bed with some encouragement or by doing quiet activities. The older child often resists sleeping because he or she is unaware of fatigue or has a need to be independent.

Adolescents. On average teenagers get about 7½ hours of sleep per night. The typical adolescent is subject to a number of changes such as school demands, after-school social activities, and part-time jobs, which reduce the time spent sleeping (Noland et al., 2009). Shortened sleep time often results in EDS, which frequently leads to reduced performance in school, vulnerability to accidents, behavior and mood problems, and increased use of alcohol (Noland et al., 2009; Vallido et al., 2009).

Young Adults. Most young adults average 6 to 8½ hours of sleep a night. Approximately 20% of sleep time is REM sleep, which remains consistent throughout life. It is common for the stresses of jobs, family relationships, and social activities to frequently lead to insomnia and the use of sleep medication. Daytime sleepiness contributes to an increased number of accidents, decreased productivity, and interpersonal problems in this age-group. Pregnancy increases the need for sleep and rest. Insomnia, periodic limb movements, RLS, and sleep-disordered breathing are common problems during the third trimester of pregnancy (Kryger et al., 2011).

Middle Adults. During middle adulthood the total time spent sleeping at night begins to decline. The amount of stage 4 sleep begins to fall, a decline that continues with advancing age. Insomnia is particularly common, probably because of the changes and stresses of middle age. Anxiety, depression, or certain physical illnesses cause sleep disturbances. Women experiencing menopausal symptoms often experience insomnia.

Older Adults. Complaints of sleeping difficulties increase with age. More than 50% of older adults report sleep problems (Neikrug and Ancoli-Israel, 2010). Older adults experience weakening, desynchronized circadian rhythms that alter the sleep-wake cycle (Neikrug and Ancoli-Israel, 2010). Episodes of REM sleep tend to shorten. There is a progressive decrease in stages 3 and 4 NREM sleep; some older adults have almost no stage 4, or deep sleep. An older adult awakens more often during the night, and it takes more time for him or her to fall asleep. The tendency to nap seems to increase progressively with age because of the frequent awakenings experienced at night.

The presence of chronic illness often results in sleep disturbances for the older adult. For example, an older adult with arthritis frequently has difficulty sleeping because of painful joints. Changes in sleep pattern are often caused by changes in the CNS that affect the regulation of sleep. Sensory impairment reduces an older person's sensitivity to time cues that maintain circadian rhythms.

Factors Influencing Sleep

A number of factors affect the quantity and quality of sleep. Often a single factor is not the only cause for a sleep problem. Physiological, psychological, and environmental factors frequently alter the quality and quantity of sleep.

Drugs and Substances. Sleepiness, insomnia, and fatigue often result as a direct effect of commonly prescribed medications (Box 42-4). These medications alter sleep and weaken daytime alertness, which is problematic (Kryger et al., 2011). Medications prescribed for sleep often cause more problems than benefits. Older adults take a variety of drugs to control or treat chronic illness, and the combined effects of their drugs often seriously disrupt sleep. Some substances such as L-tryptophan, a natural protein found in foods such as milk, cheese, and meats, promote sleep.

Lifestyle. A person's daily routine influences sleep patterns. An individual working a rotating shift (e.g., 2 weeks of days followed by a week of nights) often has difficulty adjusting to the altered sleep schedule. For example, the body's internal clock is set at 11 PM, but the work schedule forces sleep at 9 AM instead. The individual is able to sleep only 3 or 4 hours because his or her body clock perceives that it is time to be awake and active. Difficulties maintaining alertness during work time result in decreased and even hazardous performance. After several weeks of working a night shift, a person's biological clock usually does adjust. Other alterations in routines that disrupt sleep patterns include performing unaccustomed heavy work, engaging in late-night social activities, and changing evening mealtime.

Usual Sleep Patterns. In the past century the amount of sleep obtained nightly by U.S. citizens has decreased to about 6.7 hours per night, causing many Americans to be sleep deprived and experience excessive sleepiness during the day (Ohlmann and O'Sullivan, 2009). Sleepiness becomes pathological when it occurs at times when individuals need or want to be awake. People who experience temporary sleep deprivation as a result of an active social evening or lengthened work schedule usually feel sleepy the next day. However, they are able to overcome these feelings even though they have difficulty performing tasks and remaining attentive. Chronic lack of sleep is much more serious and causes serious alterations in the ability to perform daily functions. Sleepiness

BOX 42-4 DRUGS AND THEIR EFFECTS ON SLEEP

Hypnotics
- Interfere with reaching deeper sleep stages
- Provide only temporary (1 week) increase in quantity of sleep
- Eventually cause "hangover" during day; excess drowsiness, confusion, decreased energy
- Sometimes worsen sleep apnea in older adults

Antidepressants and Stimulants
- Suppress REM sleep
- Decrease total sleep time

Alcohol
- Speeds onset of sleep
- Reduces REM sleep
- Awakens person during night and causes difficulty returning to sleep

Caffeine
- Prevents person from falling asleep
- Causes person to awaken during night
- Interferes with REM sleep

Diuretics
- Nighttime awakenings caused by nocturia

Beta-Adrenergic Blockers
- Cause nightmares
- Cause insomnia
- Cause awakening from sleep

Benzodiazepines
- Alter REM sleep
- Increase sleep time
- Increase daytime sleepiness

Nicotine
- Decreases total sleep time
- Decreases REM sleep time
- Causes awakening from sleep
- Causes difficulty staying asleep

Narcotics
- Suppress REM sleep
- Cause increased daytime drowsiness

Anticonvulsants
- Decrease REM sleep time
- Cause daytime drowsiness

REM, Rapid eye movement.

tends to be most difficult to overcome during sedentary (inactive) tasks such as driving. There is an increased risk of motor vehicle accidents if an individual drives after less than 7 hours of sleep (Heaton et al., 2009).

Emotional Stress. Worry over personal problems or a situation frequently disrupts sleep. Emotional stress causes a person to be tense and often leads to frustration when sleep does not occur. Stress also causes a person to try too hard to fall asleep, to awaken frequently during the sleep cycle, or to oversleep. Continued stress causes poor sleep habits.

Older patients frequently experience losses that lead to emotional stress such as retirement, physical impairment, or the death of a loved one. Older adults and other individuals who experience depressive mood problems experience delays in falling asleep, earlier appearance of REM sleep, frequent or early awakening, feelings of sleeping poorly, and daytime sleepiness (National Sleep Foundation, 2010c).

Environment. The physical environment in which a person sleeps significantly influences the ability to fall and remain sleep. Good ventilation is essential for restful sleep. The size, firmness, and position of the bed affect the quality of sleep. If a person usually sleeps with another individual, sleeping alone often causes wakefulness. On the other hand, sleeping with a restless or snoring bed partner disrupts sleep.

In hospitals and other inpatient facilities noise creates a problem for patients. Noise in hospitals is usually new or strange and often loud. Thus patients wake easily. This problem is greatest the first night of hospitalization, when patients often experience increased total wake time, increased awakenings, and decreased REM sleep and total sleep time. People-induced noises (e.g., nursing activities) are sources of increased sound levels. ICUs are sources of high noise levels because of staff, monitor alarms, and equipment. Close proximity of patients, noise from confused and ill patients, ringing alarm systems and telephones, and disturbances caused by emergencies make the environment unpleasant. Noise causes increased agitation; delayed healing; impaired immune function; and increased blood pressure, heart rate, and stress (Dennis et al., 2010).

Light levels affect the ability to fall asleep. Some patients prefer a dark room, whereas others such as children or older adults prefer keeping a soft light on during sleep. Patients also have trouble sleeping because of the room temperature. A room that is too warm or too cold often causes a patient to become restless.

Exercise and Fatigue. A person who is moderately fatigued usually achieves restful sleep, especially if the fatigue is the result of enjoyable work or exercise. Exercising 2 hours or more before bedtime allows the body to cool down and maintain a state of fatigue that promotes relaxation. However, excess fatigue resulting from exhausting or stressful work makes falling asleep difficult. This is often seen in grade-school children and adolescents who keep stressful, long schedules because of school, social activities, and work.

Food and Caloric Intake. Following good eating habits is important for proper sleep. Eating a large, heavy, and/or spicy meal at night often results in indigestion that interferes with sleep. Caffeine, alcohol, and nicotine consumed in the evening produce insomnia. Coffee, tea, cola, and chocolate contain caffeine and xanthines that cause sleeplessness. Thus drastically reducing or avoiding these substances can improve sleep. Some food allergies cause insomnia. A milk allergy sometimes causes nighttime waking and crying or colic in infants.

Weight loss or gain influences sleep patterns. Weight gain contributes to OSA because of increased size of the soft tissue structures in the upper airway (Kryger et al., 2011). Weight loss causes insomnia and decreased amounts of sleep (Benca and Schneck, 2005). Certain sleep disorders are the result of the semi-starvation diets popular in a weight-conscious society.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, including information gathered from patients, experience, critical thinking attitudes, and intellectual and professional standards.

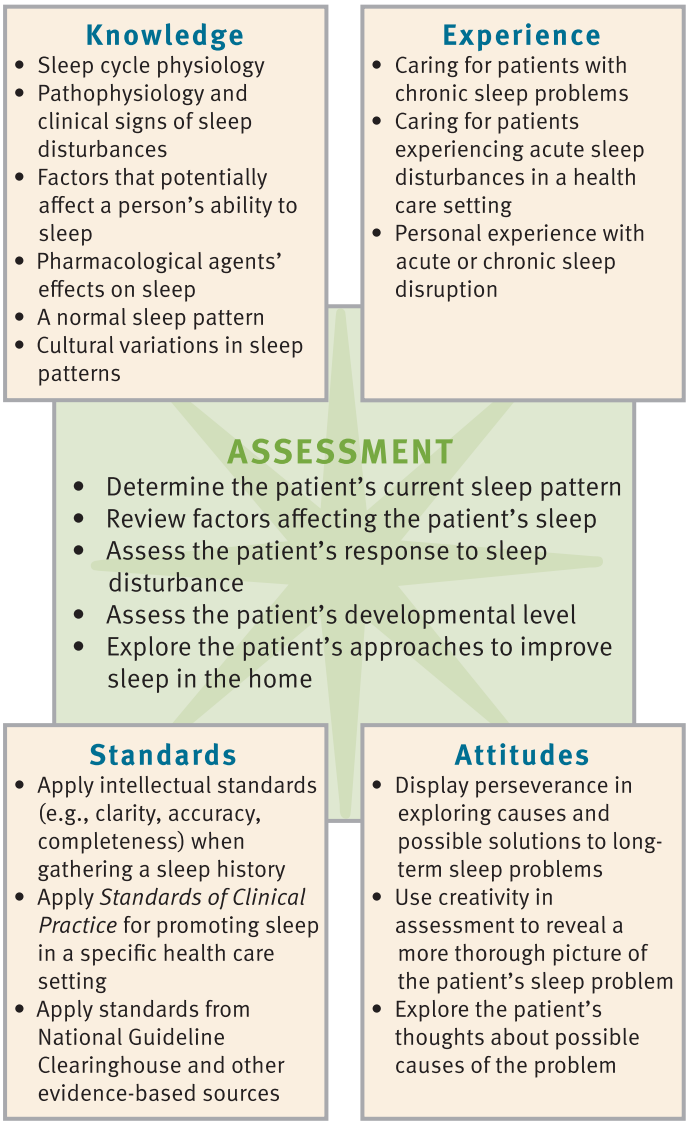

FIG. 42-3 Critical thinking model for sleep assessment.

Clinical judgments require you to anticipate the information necessary, analyze the data, and make decisions regarding patient care. You adapt critical thinking to the changing needs of the patient. During assessment (Fig. 42-3) consider all elements to make appropriate nursing diagnoses.

In the case of sleep, integrate knowledge from nursing and disciplines such as pharmacology and psychology. Personal experience with a sleep problem and experience with patients prepares you to know effective forms of sleep therapies. You use critical thinking attitudes such as perseverance, confidence, and discipline to complete a comprehensive assessment and develop a plan of care to provide successful management of the sleep problem. Professional standards such as the *Nursing Scope and Standards of Practice* (American Nurses Association, 2010), *Clinical Guidelines for the Evaluation and Management of Chronic Insomnia* (National Guideline Clearinghouse, 2008) and "Excessive Sleepiness" in *Evidence-based Geriatrics Nursing Protocols for Best Practice* (Chasens et al., 2008) provide valuable guidelines to assess and address the needs of patients with sleep disorders.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in the care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Assess patients' sleep patterns by using a nursing history to gather information about factors that usually influence sleep. Sleep is a subjective experience. Only the patient is able to report whether or not it is sufficient and restful. If the patient is satisfied with the quantity and quality of sleep received, you consider it normal, and the nursing history is brief. If a patient admits to or suspects a sleep problem, you need a detailed history and assessment. If a patient has an obvious sleep problem, consider asking if his or her sleep partner can be approached for further assessment data.

A poor night's sleep for a patient often starts a vicious cycle of anticipatory anxiety. The patient fears that sleep will again be disturbed while trying harder and harder to sleep. Use a skilled and caring approach to assess the patient's sleep needs. A caring nurse individualizes care for each patient. Always ask patients what they expect regarding sleep. This includes asking about the interventions that they currently use and how successful they are. It is important to understand patients' expectations regarding their sleep pattern. When patients ask for assistance because of sleep disturbances, they typically expect a nurse to respond promptly to help them improve the quantity and quality of their sleep.

Sleep Assessment. Most persons are able to provide a reasonably accurate estimate of their sleep patterns, particularly if any changes have occurred. Aim your assessment at understanding the characteristics of the patient's sleep problem and usual sleep habits so you incorporate ways for promoting sleep into nursing care. For example, if the nursing history reveals that a patient always reads before falling asleep, it makes sense to offer reading material at bedtime.

Sources for Sleep Assessment. Usually patients are the best resource for describing sleep problems and how they are a change from their usual sleep and waking patterns. Often the patient knows the cause for sleep problems such as a noisy environment or worry over a relationship.

In addition, bed partners are able to provide information about patients' sleep patterns that help reveal the nature of certain sleep disorders. For example, partners of patients with sleep apnea often complain that the patient's snoring disturbs their sleep. Often the partners must sleep in different beds or rooms to obtain adequate sleep. Ask bed partners (if the patient agrees) whether patients have breathing pauses during sleep and how frequently the apneic attacks occur. Some partners mention becoming fearful when patients apparently stop breathing for periods.

When caring for children, seek information about sleep patterns from parents or guardians because they are usually a reliable source of information. Hunger, excessive warmth, and separation anxiety often contribute to an infant's difficulty going to sleep or frequent awakenings during the night. Parents of infants need to keep a 24-hour log of their infant's waking and sleeping behavior for several days to determine the cause of the problem. They also need

to describe the infant's eating pattern and sleeping environment because these influence sleeping behavior. Older children often are able to relate fears or worries that inhibit their ability to fall asleep. If children frequently awaken in the middle of bad dreams, parents are able to identify the problem but perhaps do not understand the meaning of the dreams. Ask parents to describe the typical behavior patterns that foster or impair sleep. For example, excessive stimulation from active play or visiting friends predictably impairs sleep. With chronic sleep problems, parents need to relate the duration of the problem, its progression, and children's responses.

Tools for Sleep Assessment. Two effective subjective measures of sleep are the Epworth Sleepiness Scale and the Pittsburgh Sleep Quality Index. The Epworth Sleepiness Scale evaluates the severity of EDS (Chasens et al., 2008). The Pittsburgh Sleep Quality Index assesses sleep quality and sleep patterns (Smyth, 2008). Another effective, brief method for assessing sleep quality is the use of a visual analogue scale (Lashley, 2004). Draw a straight horizontal line 100 mm (4 inches) long. Opposing statements such as "best night's sleep" and "worst night's sleep" are at opposite ends of the line. Ask patients to place a mark on the horizontal line at the point corresponding to their perceptions of the previous night's sleep. Measuring the distances of the mark along the line in millimeters offers a numerical value for satisfaction with sleep. Use the scale repeatedly to show change over time. Such a scale is useful to assess an individual patient, not to compare patients.

Another brief subjective method to assess sleep is a numeric scale with a 0-to-10 sleep rating (Lashley, 2004). Ask individuals to separately rate the quantity and quality of their sleep on the scale. Instruct them to indicate with a number between 0 and 10 their sleep quantity and then their quality of sleep, with 0 being the worst sleep and 10 being the best.

Sleep History. When a patient reports having adequate sleep, a sleep history is usually brief. A determination of usual bedtime, normal bedtime rituals, preferred environment for sleeping, and what time the patient usually rises gives you information for planning care conducive to sleep. When suspecting a sleep problem, assess the quality and characteristics of sleep in greater depth by asking the patient to describe the problem. This includes recent changes in sleep pattern, sleep symptoms experienced during waking hours, use of sleep and other prescribed or over-the-counter medications, diet and intake of substances such as caffeine or alcohol that influence sleep, and recent life events that have affected the patient's mental and emotional status.

Description of Sleeping Problems. Conduct a more detailed history when a patient has a sleep problem. This ensures that you provide appropriate therapeutic care. Open-ended questions help a patient describe a problem more fully. A general description of the problem followed by more focused questions usually reveals specific characteristics that are useful in planning therapies. To begin, you need to understand the nature of the sleep problem, its signs and symptoms, its onset and duration, its severity, any predisposing factors or causes, and the overall effect on the patient. Ask specific questions related to the sleep problem (Box 42-5).

Proper questioning helps to determine the type of sleep disturbance and the nature of the problem. Box 42-6 gives examples of additional questions for you to ask a patient when you suspect specific sleep disorders. The questions assist in selecting specific sleep therapies and the best time for implementation.

As an adjunct to the sleep history, have the patient and bed partner keep a sleep-wake log for 1 to 4 weeks (Cuellar et al., 2007). The patient completes the sleep-wake log daily to provide information on day-to-day variations in sleep-wake patterns over extended periods. Entries in the log often include 24-hour information about various waking and sleeping health behaviors such as physical activities, mealtimes, type and amount of intake (alcohol and caffeine), time and length of daytime naps, evening and bedtime routines, the time the patient tries to fall asleep, nighttime awakenings, and the time of morning awakening. A partner helps record the estimated times the patient falls asleep or awakens. Although the log is helpful, the patient needs to be motivated to participate in its completion.

Usual Sleep Pattern. Normal sleep is difficult to define because individuals vary in their perception of adequate quantity and quality of sleep. However, it is important to have patients describe their usual sleep pattern to determine the significance of the changes caused by a sleep disorder. Knowing a patient's usual, preferred sleep pattern allows you to try to match sleeping conditions in a health care setting with those in the home. Ask the following questions to determine a patient's sleep pattern:

BOX 42-5 NURSING ASSESSMENT QUESTIONS

Nature of the Problem
- Describe for me the type of sleep problem you are having.
- Why do you think you are not getting enough sleep?
- Describe a recent night's sleep. How is this sleep different from your usual sleep?

Signs and Symptoms
- Do you have difficulty falling asleep, staying asleep, or waking up?
- Have you been told that you snore loudly?
- Do you have headaches when awakening?

Onset and Duration of Signs and Symptoms
- When did you notice the problem?
- What do you do to relieve the symptom?
- How long has this problem lasted?

Severity
- How long does it take you to fall asleep?
- How often during the week do you have trouble falling asleep?
- How many hours of sleep a night did you get this week?
- How does this compare to your usual amount of sleep?
- What do you do when you awaken during the night or too early in the morning?

Predisposing Factors
- What do you do just before you go to bed?
- Have you recently had any changes at work or at home?
- How is your mood? Have you noticed any changes recently?
- Which medications or recreational drugs do you take on a regular basis
- Are you taking any new prescriptions or over-the-counter medications?
- Do you eat food (spicy or greasy foods) or drink substances (alcohol or caffeinated beverages) that affect your sleep?
- Do you have a physical illness that affects your sleep?
- Does anyone in your family have a history of sleep problems?

Effect on Patient
- How has the loss of sleep affected you?
- Do you feel excessively sleepy or irritable or have trouble concentrating during waking hours?
- Do you have trouble staying awake? Have you fallen asleep at the wrong times (e.g., while driving, sitting quietly in a meeting)?

BOX 42-6 QUESTIONS TO ASK TO ASSESS FOR SPECIFIC SLEEP DISORDERS

Insomnia
- How easily do you fall asleep?
- Do you fall asleep and have difficulty staying asleep? How many times do you awaken?
- What time do you awaken in the morning? What causes you to awaken early?
- What do you do to prepare for sleep? To improve your sleep?
- What do you think about as you try to fall asleep?
- How often do you have trouble sleeping?

Sleep Apnea
- Do you snore loudly? Does anyone else in your family snore loudly?
- Has anyone ever told you that you often stop breathing for short periods during sleep? (Spouse or bed partner/roommate may report this.)
- Do you experience headaches after awakening?
- Do you have difficulty staying awake during the day?

Narcolepsy
- Do you fall asleep at the wrong times? (Friends or relatives may report this.)
- Do you have episodes of losing muscle control or falling to the floor?
- Have you ever had the feeling of being unable to move or talk just before waking or falling asleep?
- Do you have vivid, lifelike dreams when going to sleep or awakening?

1. What time do you usually get in bed each night?
2. How much time does it usually take to fall asleep? Do you do anything special to help you fall asleep?
3. How many times do you awaken during the night? Why?
4. What time do you typically wake up in the morning?
5. On average, how many hours do you sleep each night?

Compare patient data with their pattern before the sleep problem or with the predominant pattern usually found for other patients of the same age. On the basis of this comparison, you begin to assess for identifiable patterns such as insomnia.

Patients with sleep problems frequently show patterns drastically different from their usual one, or sometimes the change is relatively minor. Hospitalized patients usually need or want more sleep as a result of illness. However, some require less sleep because they are less active. Some patients who are ill think that it is important to try to sleep more than usual, eventually making sleeping difficult.

Physical and Psychological Illness. Determine whether the patient has any preexisting health problems that interfere with sleep. A history of psychiatric problems also makes a difference. For example, a patient who is living with bipolar disorder sleeps more when depressed than when manic. A patient who is depressed often experiences an inadequate amount of fragmented sleep. Chronic diseases such as chronic obstructive pulmonary disease and painful disorders such as arthritis interfere with sleep. Also assess the patient's medication history, including a description of over-the-counter and prescribed drugs. If a patient takes medications to aid sleep, gather information about the type and amount of medication and frequency used. Also assess the patient's daily caffeine intake.

If the patient has recently had surgery, expect him or her to experience some sleep disturbance. Patients usually awaken frequently during the first night after surgery and receive little deep or REM sleep. Depending on the type of surgery, it takes several days to months for a normal sleep cycle to return.

Current Life Events. In your assessment learn if the patient is experiencing any changes in lifestyle that disrupt sleep. A person's occupation often offers a clue to the nature of the sleep problem. Changes in job responsibilities, rotating shifts, or long hours contribute to a sleep disturbance. Questions about social activities, recent travel, or mealtime schedules help clarify the assessment.

Emotional and Mental Status. A patient's emotions and mental status affect the ability to sleep. For example, if a patient is experiencing anxiety, emotional stress related to illness, or situational crises such as loss of job or a loved one, he or she often experiences insomnia. When a sleep disturbance is related to an emotional problem, the key is to treat the primary problem; its resolution often improves sleep (Ramakrishnan and Scheid, 2007). Patients with mental illnesses may need mild sedation for adequate rest. Assess the effectiveness of any medication and its effect on daytime function.

Bedtime Routines. Ask patients what they do to prepare for sleep. For example, some patients drink a glass of milk, take a sleeping pill, eat a snack, or watch television. Assess habits that are beneficial compared with those that disturb sleep. For example, watching television promotes sleep for one person, whereas it stimulates another to stay awake. Sometimes pointing out that a particular habit is interfering with sleep helps patients find ways to change or eliminate habits that are disrupting sleep.

Pay special attention to a child's bedtime rituals. For example, the parents need to report whether it is necessary to read a bedtime story, rock the child to sleep, or engage in quiet play. Some young children need a special blanket or stuffed animal when going to sleep.

Bedtime Environment. During assessment ask the patient to describe preferred bedroom conditions, including preferences for lighting in the room, music or television in the background, or needing to have the door open versus closed. In addition, some children need the company of a parent to fall asleep. In a health care environment environmental distractions such as a roommate's television, an electronic monitor in the hallway, a noisy nurses' station, or another patient who cries out at night often interfere with sleep. Identify factors to reduce or control the environment.

Behaviors of Sleep Deprivation. Some patients are unaware of how their sleep problems are affecting their behavior. Observe for behaviors such as irritability, disorientation (similar to a drunken state), frequent yawning, and slurred speech. If sleep deprivation has lasted a long time, psychotic behavior such as delusions and paranoia sometimes develop. For example, a patient reports seeing strange objects or colors in the room, or he or she acts afraid when the nurse enters the room.

NURSING DIAGNOSIS

Review your assessment data, looking for clusters of data that include defining characteristics for a sleep pattern disturbance or other health problem. If you identify a sleep problem, specify the condition, such as insomnia or sleep deprivation. By specifying the sleep disturbance diagnosis, you are able to design more effective interventions. For example, you choose different therapies for patients with insomnia who are unable to fall asleep than for those with sleep deprivation. Box 42-7 demonstrates how to use nursing assessment activities to identify and cluster defining characteristics to make an accurate nursing diagnosis.

Assessment also identifies the related factor or probable cause of a sleep disturbance such as a noisy environment or a high intake of caffeinated beverages in the evening. These causes become the

BOX 42-7 NURSING DIAGNOSTIC PROCESS

Insomnia

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient to explain nature of sleep problem.	Patient reports difficulty falling asleep, taking up to 1 hour. Patient reports awakening two to three times nightly with difficulty returning to sleep.
Observe patient's behavior and ask spouse if patient is experiencing behavior changes.	Patient admits to not feeling well rested. Spouse describes times when patient was lethargic and irritable.
Determine if patient has had recent lifestyle changes.	Spouse reports that patient recently lost job and is concerned about finding new position.

focus of interventions for minimizing or eliminating the problem. For example, if a patient is experiencing insomnia as a result of a noisy health care environment, offer some basic recommendations for helping sleep such as controlling the noise of hospital equipment, reducing interruptions, or keeping doors closed. If the insomnia is related to worry over a threatened marital separation, introduce coping strategies and create an environment for sleep. If you incorrectly define the probable cause or related factors, the patient does not benefit from care.

Sleep problems affect patients in other ways. For example, you find that a patient with sleep apnea has problems with a spouse who is tired and frustrated over the patient's snoring. In addition, the spouse is concerned that the patient is breathing improperly and thus is in danger. The nursing diagnosis of *compromised family coping* indicates that you need to provide support to the patient and spouse so they understand sleep apnea and obtain the medical treatment needed. Examples of nursing diagnoses for patients with sleep problems include the following:

- Anxiety
- Ineffective breathing pattern
- Acute confusion
- Compromised family coping
- Ineffective coping
- Insomnia
- Fatigue
- Sleep deprivation
- Readiness for enhanced sleep

PLANNING

Goals and Outcomes. During planning you again synthesize information from multiple resources to develop an individualized plan of care (Fig. 42-4) (see the Nursing Care Plan). Professional standards are especially important to consider in developing a care plan. These standards often offer evidence-based guidelines for effective nursing interventions. For example, *the Evidence-based Geriatrics Protocol for Best Practice* (Chasens et al., 2008) titled "Excessive Sleepiness" recommends individualized nursing interventions that maintain and support an older adult's normal sleep pattern and bedtime ritual. It is important for a plan of care for sleep promotion to include strategies appropriate to the patient's sleep routines, living environment, and lifestyle.

As you plan care for a patient with sleep disturbances, creation of a concept map is another method for developing holistic

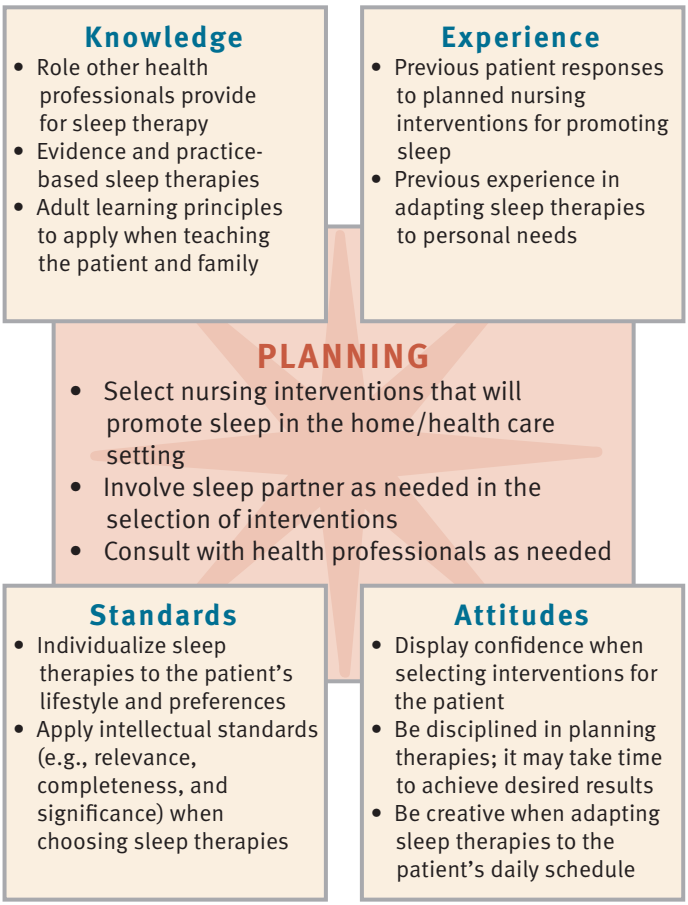

FIG. 42-4 Critical thinking model for sleep planning.

patient-centered care (Fig. 42-5 on p. 953). Create the map after identifying relevant nursing diagnoses from the assessment database. In this example the nursing diagnoses are linked to the patient's medical diagnosis of depression and situational stress. The concept map shows the relationships among the nursing diagnoses *insomnia, stress overload, sedentary lifestyle,* and *readiness for enhanced sleep.* This approach to planning care helps the nurse recognize relationships among planned interventions. For this patient, interventions and successful outcomes for one nursing diagnosis affect the resolution of another nursing diagnosis.

When developing goals and outcomes, it is important for a nurse and patient to collaborate. As a result, you are more likely to set realistic goals and measurable outcomes with your patients. An effective plan includes outcomes established over a realistic time frame that focus on the goal of improving the quantity and quality of sleep in the home. Often family members are very helpful in contributing to the plan. A sleep-promotion plan frequently requires many weeks to accomplish. The following is an example of a goal with patient outcomes:

Goal: The patient will control environmental sources disrupting sleep within 1 month.

Outcomes:

- Patient will identify factors in the immediate home environment that disrupt sleep in 2 weeks.
- Patient will report having a discussion with family members about environmental barriers to sleep in 2 weeks.
- Patient will report changes made in the bedroom to promote sleep within 4 weeks.

NURSING CARE PLAN

Insomnia

ASSESSMENT

Julie Arnold, a 42-year-old attorney, is the first patient of the morning at the neighborhood health clinic where you work. When you ask her how she is doing, she tells you that she is having difficulty sleeping. Her physician has diagnosed that she is suffering from depression. Julie is married and has two school-age children. She also tells you that she is caring for her mother, who is currently staying with them after she was discharged from the hospital following an exacerbation of her heart failure. Julie's assessment includes a thorough sleep history and a discussion of how the sleep problem has affected her life. You also conduct a physical examination.

Assessment Activities	*Findings/Defining Characteristics**
Ask Julie to explain the nature of her sleep problem.	Julie explains that she wakes up once or twice a night. She states, "I feel tired when I wake up, and I have trouble concentrating at work in the afternoon." She also reports that she has less patience with her children at home and no energy in the evenings.
Ask Julie if there have been any recent changes in her life.	Julie says that she is feeling pressured at work to complete an important case that she started on 2 weeks ago and because of this she is working longer hours. She also reports that, because of her heavy work schedule, she has **stopped** her **routine of walking 1 to 2 miles daily.** She reports that she **has no time for any exercise** when she gets home because **she needs to take care of her mother and the children.**
Ask Julie to describe her bedtime routine.	Julie responds that she is going to bed between 12 AM and 1 AM, which is 2 hours later than her usual bedtime. **It takes her an hour to fall asleep.** She says that she used to get 7 to 8 hours of sleep a night and now **it is more like 5 to 6 hours.** She drinks two to three cups of coffee after dinner while she is working on her case before bedtime. Julie reports drinking a glass of wine just before bedtime to help relax because she has been having trouble falling asleep.
Assess Julie for physical signs of sleep problems.	During the examination you note that Julie has dark circles under her eyes; she shifts her position in the chair multiple times and yawns frequently.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Insomnia related to psychological stress from job pressures.

PLANNING

Goals	*Expected Outcomes (NOC)*†
	Sleep
Patient will achieve an improved sense of adequate sleep within 4 weeks.	Patient will report waking up less frequently during the night and feeling rested within 4 weeks. Patient will verbalize adherence to a regular bedtime routine within 4 weeks.
Patient will achieve a more normal sleep pattern within 4 weeks.	Patient will fall asleep within 30 minutes of going to bed within 4 weeks. Patient will report sleeping 7 hours nightly within 4 weeks.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Sleep Enhancement	
Encourage patient to establish a bedtime routine and a regular sleep pattern.	Maintaining a consistent schedule helps induce sleep (National Guideline Clearinghouse, 2008).
Instruct patient to avoid caffeine, nicotine, and alcohol before bedtime.	Caffeine and nicotine are stimulants and cause difficulty in falling asleep. Alcohol lightens and fragments sleep (Reeve and Bailes, 2010).
Help patient identify ways to eliminate stressful concerns about work before bedtime (e.g., taking time before actual sleep time to read a light novel).	Excess worry and intense activities before bedtime stimulate patient and prevent sleep (Reeve and Bailes, 2010).
Adjust environment; have patient control noise, temperature, and light in the bedroom.	Develop an environment conducive to sleep (Wickwire and Collop, 2010).
Exercise Promotion	
Encourage patient to begin walking routinely during the day but not 2 to 3 hours before bedtime.	Regular exercise increases activity levels and improves sleep quality. Exercise just before bedtime is a stimulant that prevents sleep (Reeve and Bailes, 2010).

Continued

NURSING CARE PLAN

***Insomnia*—cont'd**

Relaxation Therapy

Instruct patient in how to perform muscle relaxation before bedtime; include demonstration.	Relaxation therapy helps reduce anxiety, which interferes with sleep (National Guideline Clearinghouse, 2008).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Julie if she is able to fall asleep and stay asleep.	Julie responds, "It usually takes 15 to 20 minutes to fall asleep, and I woke up once for only two nights last week."	Julie reports that she falls asleep within 30 minutes and wakes up less frequently during the night.
Ask Julie to describe her waking behaviors at work and home during the day.	Julie responds that she has completed her case at work and feels less pressure. She has restarted her walking routine and is better able to cope with her children. She is able to concentrate at work more.	Julie reports feeling more rested.
Observe Julie's waking nonverbal expressions and behavior.	Julie sits in the chair without shifting position. She does not yawn during the conversation. The dark circles under her eyes are almost gone.	Julie reports that she is sleeping an average of 7 hours a night.

- Patient will report having fewer than two awakenings per night within 4 weeks.

Setting Priorities. Work with patients to establish priority outcomes and interventions. Frequently sleep disturbances are the result of other health problems. For example, when physical symptoms are interfering with sleep, managing the symptoms is your first priority. After symptoms are relieved, focus on sleep therapies. Patients are a helpful resource in determining which interventions hold priority. For example, once patients understand the factors that disrupt sleep, they make choices about the types of changes they would like to make in their lifestyle or sleeping environment.

Teamwork and Collaboration. Partner closely with the patient and sleep partner to ensure that any therapies such as a change in the sleep schedule or changes to the bedroom environment are realistic and achievable. In a health care setting plan treatments or routines so the patient is able to rest. For example, in the ICU use available electronic monitors to track trends in vital signs without awakening a patient each hour. Other staff members need to be aware of the care plan so they can cluster activities at certain times to reduce awakenings. In a nursing home the focus of the plan involves better planning of rest periods around the activities of the other residents. Roommates often have very different schedules.

When patients have chronic sleep problems, the initial referral for a patient is often to a comprehensive sleep center for assessment of the problem. The nature of the sleep disturbance then determines whether referrals to additional health care providers are necessary. For example, if a sleep problem is related to a situational crisis or emotional problem, refer the patient to a mental health clinical nurse specialist or clinical psychologist for counseling. If the nurse works in an inpatient setting and the patient needs a referral for continued care after discharge, offering information about the sleep problem is useful to the home care nurse. The success of sleep therapy depends on an approach that fits the patient's lifestyle and the nature of the sleep disorder.

IMPLEMENTATION

Nursing interventions designed to improve the quality of a person's rest and sleep are largely focused on health promotion. Patients need adequate sleep and rest to maintain active and productive lifestyles. During times of illness, rest and sleep promotion are important for recovery. Nursing care in an acute, restorative, or continuing care setting differs from that provided in a patient's home. The primary differences are in the environment and the nurse's ability to support normal rest and sleep habits. A patient's age also influences the types of therapies that are most effective. Box 42-8 provides principles for promoting sleep in older patients.

Health Promotion. In community health and home settings help patients develop behaviors conducive to rest and relaxation. To develop good sleep habits at home, patients and their bed partners need to learn techniques that promote sleep and conditions that interfere with it (Kryger et al., 2011) (Box 42-9 on p. 954). Parents also learn how to promote good sleep habits for their children. Patients benefit most from instructions based on information about their homes and lifestyles such as which type of activities promotes sleep in a night-shift worker or how to make the home environment more conducive to sleep. They will more likely apply information that is useful and valued.

Environmental Controls. All patients require a sleeping environment with a comfortable room temperature and proper ventilation, minimal sources of noise, a comfortable bed, and proper lighting (National Heart, Lung, and Blood Institute, 2009). Children and adults vary more in regard to comfortable room temperature. Instruct parents to position cribs away from open windows or drafts and to cover the infant with a light, warm blanket. Older adults often require extra blankets or covers.

Eliminate distracting noise so the bedroom is as quiet as possible. In the home the television, telephone, or the intermittent chiming of a clock often disrupts a patient's sleep. Involve the family in identifying approaches for reducing noise in the home, especially if there are several family members, all with different sleep schedules. It is also important to remember that some patients sleep with familiar inside noises such as the hum of a fan. Commercial products that produce a soothing noise such as ocean waves or rainfall create a soothing environment for sleep.

A bed and mattress need to provide support and comfortable firmness. Bed boards placed under mattresses add support.

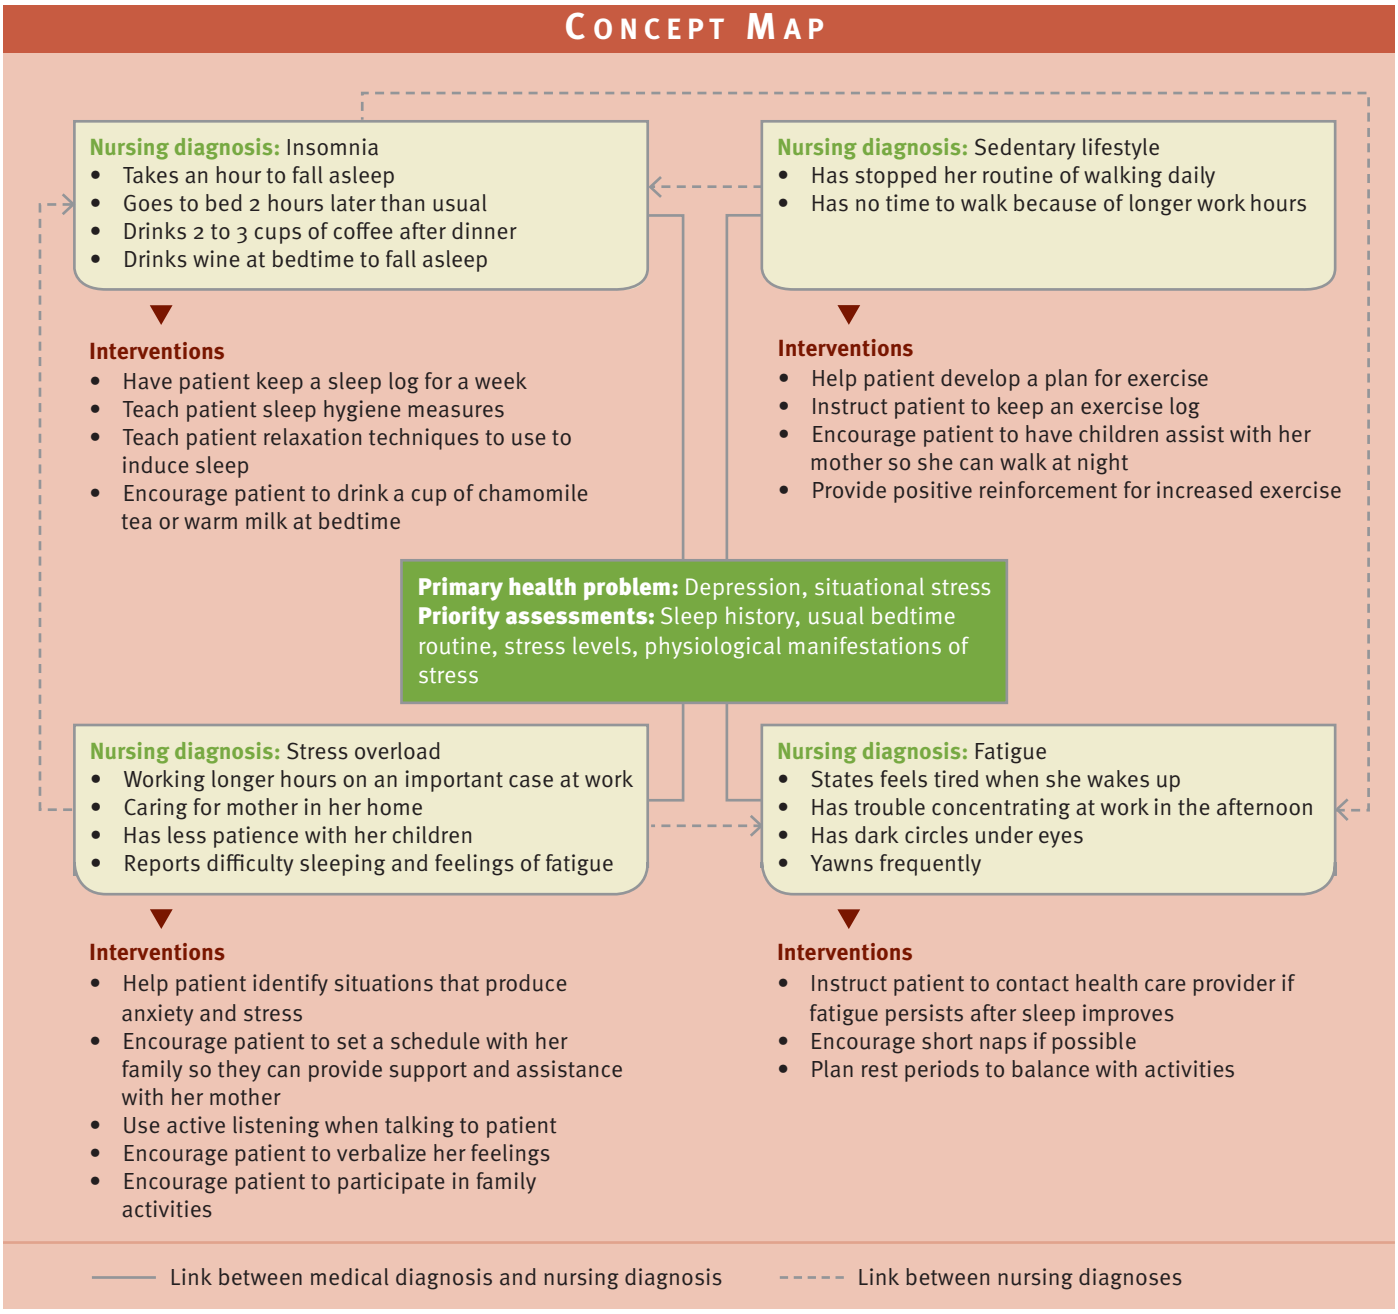

FIG. 42-5 Concept map for Julie Arnold.

Sometimes extra pillows are important to help a person position comfortably in bed. The position of the bed in the room also makes a difference for some patients.

Patients vary in regard to the amount of light that they prefer at night. Infants and older adults sleep best in softly lit rooms. Light should not shine directly on their eyes. Small table lamps prevent total darkness. For older adults light reduces the chance of confusion and prevents falls when walking to the bathroom. If streetlights shine through windows or when patients nap during the day, heavy shades, drapes, or slatted blinds are helpful.

Promoting Bedtime Routines. Bedtime routines relax patients in preparation for sleep (Bulechek, Butcher, and Dochterman, 2008). It is always important for persons to go to sleep when they feel fatigued or sleepy. Going to bed while fully awake and thinking about other things often causes insomnia and interferes with the bed as a stimulus for sleep. Newborns and infants sleep through so much of the day that a specific routine is hardly necessary. However, quiet activities such as holding them snugly in blankets, singing or talking softly, and gentle rocking help infants fall asleep.

A bedtime routine (e.g., same hour for bedtime, snack, or quiet activity) used consistently helps young children avoid delaying sleep. Parents need to reinforce patterns of preparing for bedtime. Quiet activities such as reading stories, coloring, allowing children to sit in a parent's lap while listening to music or listening to a prayer are routines that are often associated with preparing for bed.

Adults need to avoid excessive mental stimulation just before bedtime. Reading a light novel, watching an enjoyable television

BOX 42-8 FOCUS ON OLDER ADULTS

Promoting Sleep

Sleep-Wake Pattern

- Maintain a regular bedtime and wake-up schedule (Townsend-Roccichelli et al., 2010).
- Eliminate naps unless they are a routine part of the schedule.
- If naps are taken, limit to 20 minutes or less twice a day (Touhy and Jett, 2010).
- Go to bed when sleepy.
- Use warm bath and relaxation techniques (Ebersole et al., 2008).
- If unable to sleep in 15 to 30 minutes, get out of bed.
- Avoid stimulating activities before bedtime such as exercise or watching television (Townsend-Roccichelli et al., 2010).

Environment

- Sleep where you sleep best.
- Keep noise to minimum; use soft music to mask it if necessary.
- Use night-light and keep path to bathroom free of obstacles.
- Set room temperature to preference; use socks to promote warmth.
- Listen to relaxing music (Touhy and Jett, 2010).
- Increase exposure to bright light during the day (Neubauer, 2009).

Medications

- Use sedatives and hypnotics with caution as last resort and then only short term if absolutely necessary (Neubauer, 2009).
- Adjust medications being taken for other conditions and assess for drug interactions that may cause insomnia or excessive daytime sleepiness.

Diet

- Limit alcohol, caffeine, and nicotine in late afternoon and evening (Touhy and Jett, 2010).
- Consume carbohydrates or milk as a light snack before bedtime (Ebersole et al., 2008).
- Decrease fluids 2 to 4 hours before sleep (Ebersole et al., 2008).

Physiological/Illness Factors

- Elevate head of bed and provide extra pillows as preferred (Townsend-Roccichelli et al., 2010).
- Use analgesics 30 minutes before bed to ease aches and pains.
- Use therapeutics to control symptoms of chronic conditions as prescribed (Chasens et al., 2008).

BOX 42-9 PATIENT TEACHING

Sleep Hygiene Habits

Objective

- Patient will follow proper sleep hygiene habits at home.

Teaching Strategies

- Instruct patient to try to exercise daily, preferably in the morning or afternoon, and to avoid vigorous exercise in the evening within 2 hours of bedtime.
- Caution patient against sleeping long hours during weekends or holidays to prevent disturbance of normal sleep-wake cycle.
- Explain that, if possible, patients should not use the bedroom for intensive studying, snacking, television watching, or other nonsleep activity besides sex.
- Encourage patients to try to avoid worrisome thinking when going to bed and to use relaxation exercises.
- If patient does not fall asleep within 30 minutes of going to bed, advise him or her to get out of bed and do some quiet activity until feeling sleepy enough to go back to bed.
- Recommend that patient limit caffeine to morning coffee and limit alcohol intake (more than 1 to 2 drinks a day interrupts sleep cycle).
- Ask patient to examine environment. Instruct that use of earplugs and eyeshades may be helpful.
- Instruct patient to avoid heavy meals for 3 hours before bedtime; a light snack may help.

Evaluation

- Have patient complete sleep-wake log for 1 week and compare it with previous sleep-wake log.
- Ask patient to periodically complete visual analogue or sleep-rating scale for perceptions of quality of sleep.

program, or listening to music helps a person relax. Relaxation exercises such as slow, deep breathing for 1 or 2 minutes relieve tension and prepare the body for rest (see Chapter 43). Guided imagery and praying also promote sleep for some patients.

At home discourage patients from trying to finish office work or resolve family problems before bedtime. The bedroom is not a place to work, and patients need to always associate it with sleep. Working toward a consistent time for sleep and awakening helps most patients gain a healthy sleep pattern and strengthens the rhythm of the sleep-wake cycle.

Promoting Safety. For any patient prone to confusion or falls, safety is critical. A small night-light helps a patient orient to the room environment before going to the bathroom. Beds set lower to the floor lessen the chance of a person falling when first standing. Instruct patients to remove clutter and throw rugs from the path used to walk from the bed to the bathroom. If a patient needs assistance in ambulating from a bed to the bathroom, place a small bell at the bedside to call family members. Sleepwalkers are unaware of their surroundings and are slow to react, increasing the risk of falls. Do not startle sleepwalkers but instead gently awaken them and lead them back to bed.

Infants' beds need to be safe. To reduce the chance of suffocation, do not place pillows, stuffed toys, or the ends of loose blankets in cribs. Loose-fitting plastic mattress covers are dangerous because infants pull them over their faces and suffocate. Parents need to place an infant on his or her back to prevent suffocation.

Promoting Comfort. People fall asleep only after feeling comfortable and relaxed (Bulechek, Butcher, and Dochterman, 2008). Minor irritants often keep patients awake. Soft cotton nightclothes keep infants or small children warm and comfortable. Instruct patients to wear loose-fitting nightwear. An extra blanket is sometimes all that is necessary to prevent a person from feeling chilled and being unable to fall asleep. Patients need to void before retiring so they are not kept awake by a full bladder.

Establishing Periods of Rest and Sleep. In the home it helps to encourage patients to stay physically active during the day so they are more likely to sleep at night. Increasing daytime activity lessens problems with falling asleep. In a home setting you will frequently care for patients with chronic debilitating disease. The nursing care plan includes having patients set aside afternoons for rest to promote optimal health. Help adjust medication schedules, instruct patients to regularly void before rest periods, and suggest silencing the telephone ringer so rest periods are uninterrupted.

Stress Reduction. The inability to sleep because of emotional stress also makes a person feel irritable and tense. When patients are emotionally upset, encourage them to try not to force sleep.

Otherwise insomnia frequently develops, and soon bedtime is associated with the inability to relax. Encourage a patient who has difficulty falling asleep to get up and pursue a relaxing activity such as sewing or reading rather than staying in bed and thinking about sleep.

Preschoolers have bedtime fears (fear of the dark or strange noises), awaken during the night, or have nightmares. After nightmares the parent enters the child's room immediately and talks to him or her briefly about fears to provide a cooling-down period. One approach is to comfort children and leave them in their own beds so their fears are not used as excuses to delay bedtime. Keeping a light on in the room also helps some children. Cultural tradition causes families to approach sleep practices differently (Box 42-10). Always respect those that differ from traditional recommendations.

Bedtime Snacks. Some people enjoy bedtime snacks, whereas others cannot sleep after eating. A dairy product such as warm milk or cocoa that contains L-tryptophan is often helpful in promoting sleep. A full meal before bedtime often causes gastrointestinal upset and interferes with the ability to fall asleep.

Warn patients against drinking or eating foods with caffeine before bedtime. Coffee, tea, colas, and chocolate act as stimulants, causing a person to stay awake or to awaken throughout the night. Caffeinated foods and liquids and alcohol act as diuretics and cause a person to awaken in the night to void (National Heart, Lung, & Blood Institute, 2009).

Infants require special measures to minimize nighttime awakenings for feeding. It is common for children to need middle-of-the-night bottle-feeding or breastfeeding. Hockenberry and Wilson (2011) recommend offering the last feeding as late as possible. Tell parents not to give infants bottles in bed.

Pharmacological Approaches. Melatonin is a neurohormone produced in the brain that helps control circadian rhythms and promote sleep (Kryger et al., 2011). It is a popular nutritional supplement that is found to be helpful in improving sleep efficiency and decreasing nighttime awakenings (Pandi-Perumal et al., 2007). The recommended dose is 0.3 to 1 mg taken 2 hours before bedtime. Older adults who have decreased levels of melatonin find it beneficial as a sleep aid (Kryger et al., 2011). Short-term use of melatonin has been found to be safe, with mild side effects of nausea, headache, and dizziness being infrequent (Larzelere et al., 2010). Ramelton (Rozerem), a melatonin receptor agonist, is well tolerated and appears to be effective in improving sleep (Morin et al., 2007).

Several other herbal products assist in sleep. Valerian is effective in mild insomnia and RLS. It effects release of neurotransmitters and produces very mild sedation (Cuellar and Ratcliffe, 2009). Kava helps promote sleep in patients with anxiety. It needs to be used cautiously because of its potential toxic effects on the liver (Larzelere et al., 2010). Chamomile, an herbal tea, has a mild sedative effect that may be beneficial in promoting sleep (Moquin et al., 2009). Caution patients about the dosage and use of herbal compounds because the U.S. Food and Drug Administration (FDA) does not regulate them. Herbal compounds may interact with prescribed medication, and patients need to avoid using these together (Meiner, 2011).

Building Competency in Evidence-Based Practice Julie Arnold tells you that her mother used melatonin to help her sleep before her fall at home. She asks you if she should start taking melatonin to help her sleep. Based on the evidence, what is your best response to Julie?

Answers to questions can be found on the Evolve website.

BOX 42-10 CULTURAL ASPECTS OF CARE

Co-sleeping

Practices and patterns of sleep and rest vary among cultures. Culture and biology influence the development of sleep problems in children. Sleep patterns, bedtime routines, sleep aids, and sleep arrangements are components of cultural practices related to the use of space and interaction distances (Giger and Davidhizer, 2008). Traditionally experts recommend having infants and children sleep in their own beds. Co-sleeping, in which infants and children sleep with their parents, is a culturally preferred habit; and the practice of co-sleeping varies between cultures (AABMPC, 2008). It is more common in nonindustrialized countries. In some parts of the world co-sleeping practices are seen as part of the bonding process and warmth and protection for an infant (i.e., against the cold) (Sobralske and Gruber, 2009). This practice is also common in the United States with Asian, Hispanic, and African American families (AABMPC, 2008; Lahr et al., 2007). Health care providers in the United States discourage this practice because of safety issues, even though research does not show that the practice is unsafe. American culture promotes independence in childhood. One belief is that co-sleeping does not promote this independence; thus health care providers discourage it (Getter and McKenna, 2010). Research results related to co-sleeping and the incidence of sudden infant death syndrome (SIDS) are mixed (Getter and McKenna, 2010). As a nurse, be culturally sensitive when discussing co-sleeping practices with parents and developing sleeping plans for children. The type of bed for a child also varies. Some Native American tribes use a cradle board for infants, whereas American Samoan infants sleep on a pandanus mat covered with a blanket. These approaches lessen the child's anxiety and create a strong sense of security (Andrews and Boyle, 2008).

Implications for Practice

- Complete a thorough sleep assessment of the child and family.
- Discuss the risks of co-sleeping with parents. During the discussion remain culturally sensitive and respectful of the parents' views (Sobralske and Gruber, 2009).
- Co-sleeping has been linked to increased risk of SIDS under certain conditions such as parental smoking and alcohol or drug use (Getter and McKenna, 2010).
- Instruct parents that practice co-sleeping to avoid using alcohol or drugs that impair arousal. Decreased arousal prevents the parents from awakening if the child is having problems (Sobralske and Gruber, 2009).
- Co-sleeping should occur only with parents and not another adult or child (AABMPC, 2008).
- Co-sleeping should occur on a firm mattress (never on a water bed, sofa or couch) (AABMPC, 2008; Sobralske and Gruber, 2009).
- Encourage parents to use light sleeping clothes, keep room temperature comfortable, and not bundle the child tightly or in too many clothes.
- Avoid using heavy quilts, comforters, pillows, and stuffed animals in the bed (AABMPC, 2008).

The use of nonprescription sleeping medications is not advisable. Patients need to learn the risks of such drugs. Over the long term these drugs lead to further sleep disruption, even when they initially seemed to be effective. Caution older adults about using over-the-counter antihistamines because of their long duration of action, which can cause confusion, constipation, urinary retention, and increased risk of falls (Passarella and Duong, 2008). Help patients use behavioral and proper sleep hygiene measures to establish sleep patterns that do not require the use of drugs.

Acute Care. Patients in acute care settings have their normal rest and sleep routine disrupted, which generally leads to sleep

BOX 42-11 EVIDENCE-BASED PRACTICE

Creating a Sleep Environment in the Hospital

PICO Question: What are best practices for a sleep hygiene protocol to create an environment conducive to sleep for adult patients in a hospital?

Evidence Summary

Hospitalization causes a disruption in normal sleep habits for patients. Sleep in hospitalized patients is disrupted by noise, lighting, and patient-care activities. Sleep is needed for healing and recovery (Richardson et al., 2009). Implementing a specific sleep protocol that includes sleep hygiene measures is an effective strategy to improve sleep quality and ability to stay asleep in hospitalized patients (LaReau et al., 2008). A specified daytime quiet-time intervention that includes limiting treatment activities, use of positioning and pain-relief methods, and reduction of environmental stressors such as lighting and noise significantly improves patient sleep. There is a direct relationship between noise levels and number of patients sleeping (Gardner et al., 2009; Richardson et al., 2009). Raising staff awareness of noise levels and harmful effects of noise and providing education about strategies to reduce noise are effective in removing barriers to patient sleep (Richardson et al., 2009).

Application to Nursing Practice

- Cluster nursing activities to provide uninterrupted periods of sleep (LaReau et al., 2008).
- Provide programs for staff on the effects of noise and noise-reduction strategies (Richardson et al., 2009).
- Develop a designated quiet time period during the day that incorporates rest and reduction of noise on the unit (Gardner et al., 2009).
- Reduce lighting, telephone volumes, and staff conversations in the halls during quiet time and nighttime (Gardner et al., 2009)
- Use sleep hygiene measures with patients such as personal hygiene, adjusting room temperature, and relaxation methods (LaReau et al., 2008).

problems. In this setting nursing interventions focus on controlling factors in the environment that disrupt sleep, relieving physiological or psychological disruptions to sleep, and providing for uninterrupted rest and sleep periods for the patient. "Excessive Sleepiness" in the *Evidence-based Geriatric Nursing Protocols for Best Practice* is based on the principle that nurses need to individualize an effective strategy based on patient needs and that sleep medications are a last-resort intervention (Chasens et al., 2008).

Environmental Controls. In a hospital the nurse controls the environment in several ways (Box 42-11). Close the curtains between patients in semiprivate rooms. Dim lights on a hospital nursing unit at night. One of the biggest problems for patients in the hospital is noise. Important ways to reduce noise are to conduct conversations and reports in a private area away from patient rooms and keep necessary conversations to a minimum, especially at night (Gardner et al., 2009). Additional ways to control noise in the hospital are listed in Box 42-12.

Promoting Comfort. Compared with beds at home, hospital beds are often harder and of a different height, length, or width. Keeping them clean and dry and in a comfortable position helps patients relax. Some patients suffer painful illnesses requiring special comfort measures such as application of dry or moist heat, use of supportive dressings or splints, and proper positioning before retiring (Fig. 42-6).

Establishing Periods of Rest and Sleep. In a hospital or extended care setting it is difficult to provide patients with the time needed to rest and sleep. The most effective treatment for sleep

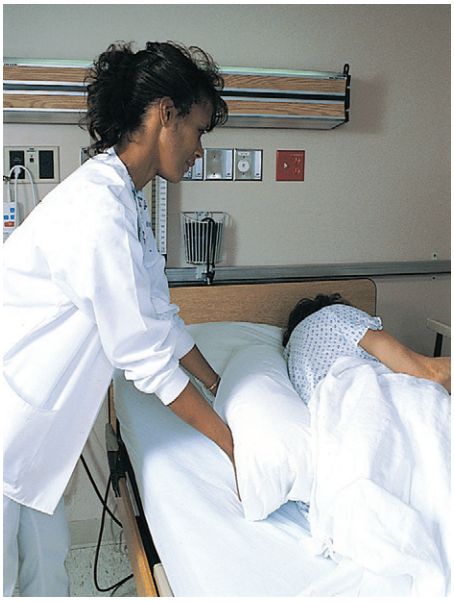

FIG. 42-6 Positioning patient for sleep.

BOX 42-12 CONTROL OF NOISE IN THE HOSPITAL

- Close doors to patients' room when possible.
- Keep doors to work areas on unit closed when in use.
- Reduce volume of nearby telephone and paging equipment.
- Wear rubber-soled shoes. Avoid clogs.
- Turn off bedside oxygen and other equipment that is not in use.
- Turn down alarms and beeps on bedside monitoring equipment.
- Turn off room television and radio unless patient prefers soft music.
- Avoid abrupt loud noise such as flushing a toilet or moving a bed.
- Keep necessary conversations at low levels, particularly at night.
- Conduct conversations and reports in a private area away from patient rooms.

disturbances is elimination or correction of factors that disrupt the sleep pattern. You need to plan care to avoid awakening patients for nonessential tasks. Do this by scheduling assessments, treatments, procedures, and routines for times when patients are awake. For example, if a patient's physical condition has been stable, avoid awakening him or her to check vital signs. Allowing patients to determine the timing and methods of delivery of basic care measures promotes rest. Do not give baths and routine hygiene measures during the night for nursing convenience. Draw blood samples at a time when the patient is awake. Unless maintaining the therapeutic blood level of a drug is essential, give medications during waking hours. Work with the radiology department and other support services to schedule diagnostic studies and therapies at intervals that allow patients time for rest. Always try to provide the patient with 2 to 3 hours of uninterrupted sleep during the night.

When the patient's condition demands more frequent monitoring, plan activities to allow extended rest periods. A nurse instructs assistive personnel in the coordination of patient care to reduce patient disturbances. This means planning activities so the patient has as long as an hour or more to rest quietly rather than having a nurse or other personnel return to the room every few minutes.

FIG. 42-7 Mask suitable for continuous positive airway pressure (CPAP).

For example, if a patient needs frequent dressing changes, is receiving intravenous therapy, and has drainage tubes from several sites, do not make a separate trip into the room to check each problem. Instead use a single visit to perform all three tasks. Become the patient's advocate for promoting optimal sleep. This means becoming a gatekeeper by postponing or rescheduling visits by family, asking consultants to reschedule visits, or questioning the frequency of certain procedures.

Promoting Safety. Patients with OSA are at risk for complications while in the hospital. Surgery and anesthesia disrupt normal sleep patterns. After surgery patients reach deep levels of REM sleep. This deep sleep causes muscle relaxation that leads to OSA (Hwang et al., 2008). Patients with OSA who are given opioid analgesics after surgery have an increased risk of developing airway obstruction because the medications suppress normal arousal mechanisms (Hwang et al., 2008). These patients often need ventilator support in the postoperative period because of the increased risk of respiratory complications. Monitor the patient's airway, respiratory rate, depth, and breath sounds frequently after surgery.

Recommend lifestyle changes to patients with OSA that include sleep hygiene, alcohol moderation, smoking cessation, and a weight-loss program (Freedman, 2010). Teach the patient to elevate the head of the bed and use a side or prone position for sleep. Use pillows to prevent a supine position (Lamm et al., 2008; Pinto and Caple, 2010).

One of the most effective therapies is use of a nasal continuous positive airway pressure (CPAP) device at night, which requires a patient to wear a mask over the nose. A mask delivers room air at a high pressure (Fig. 42-7). The air pressure prevents airway collapse. The CPAP device is portable and effective particularly for obstructive apnea. Another treatment option is the use of an oral appliance. These appliances advance the mandible or tongue to relieve pharyngeal obstruction (Wickwire and Collop, 2010). In cases of severe sleep apnea the tonsils, uvula, or portions of the soft palate are surgically removed. The success of surgical procedures to correct OSA varies.

Stress Reduction. Patients who are hospitalized for extensive diagnostic testing often have difficulty resting or sleeping because of uncertainty about the state of their health. Giving patients control over their health care minimizes uncertainty and anxiety. Providing information about the purpose of procedures and routines and answering questions give patients the peace of mind needed to rest or fall asleep. A nurse on the night shift needs to take time to sit and talk with patients unable to sleep. This helps to determine the factors keeping patients awake. Back rubs also help patients relax more thoroughly. If a sedative is indicated, confer with the patient's health care provider to be sure that the lowest dose is used initially. Discontinuing a sedative as soon as possible prevents a dependence that seriously disrupts the normal sleep cycle. Older adults' metabolism of drugs is slow, making them more vulnerable to the side effects of sedatives, hypnotics, antianxiety drugs, or analgesics.

Restorative or Continuing Care. The nursing interventions implemented in the acute care setting are also used in the restorative or continuing care environment. Controlling the environment, especially noise; establishing periods of rest and sleep; and promoting comfort are important considerations. Nursing interventions related to stress reduction and controlling physiological disturbances are also implemented in these settings. Helping a patient achieve restful sleep in this environment sometimes takes time.

Promoting Comfort. Providing for personal hygiene improves a patient's sense of comfort. A warm bath or shower before bedtime is relaxing. Offer patients restricted to bed the opportunity to void and wash their face and hands. Toothbrushing and care of dentures also help to prepare patients for sleep. Position patients to support their dependent body parts and protect pressure points. Offer a back or hand massage to aid in muscle relaxation just before a patient goes to sleep (Harris and Richards, 2010) (see Chapter 43).

Controlling Physiological Disturbances. As a nurse you will learn to control symptoms of physical illness that disrupt sleep. For example, a patient with respiratory abnormalities sleeps with two pillows or in a semi-sitting position to ease the effort to breathe. He or she benefits from taking prescribed bronchodilators before sleep to prevent airway obstruction. A patient with a hiatal hernia also needs special care. After meals he or she often experiences a burning sensation as a result of gastric reflux. To prevent sleep disturbances have the patient eat a small meal several hours before bedtime and sleep in a semi-sitting position. Patients with pain, nausea, or other recurrent symptoms receive any symptom-relieving medication timed so the drug takes effect at bedtime. Remove or change any irritants against the patient's skin such as moist dressings or drainage tubes.

Pharmacological Approaches. The liberal use of drugs to manage insomnia is quite common in American culture. CNS stimulants such as amphetamines, caffeine, nicotine, terbutaline, theophylline, and modafinil need to be used sparingly and under medical management (Lehne, 2010). In addition, withdrawal from CNS depressants such as alcohol, barbiturates, tricyclic antidepressants (amitriptyline, imipramine, and doxepin), and triazolam causes insomnia. You need to manage these carefully.

Medications that induce sleep are called **hypnotics. Sedatives** are medications that produce a calming or soothing effect (Lehne, 2010). A patient who takes sleep medications needs to know about their proper use and their risks and possible side effects. Long-term use of antianxiety, sedative, or hypnotic agents disrupts sleep and leads to more serious problems. The FDA requires that the product labels of all sleep medications contain safety information related to the potential adverse effects of severe allergic reactions; severe facial swelling; and complex sleep behaviors such as sleep-driving,

making phone calls, and preparing and eating food while asleep (USFDA, 2010).

Benzodiazepines and nonbenzodiazepines are common classifications of drugs used to treat sleep problems. The nonbenzodiazepines have become the treatment of choice for insomnia because of improved efficacy and safety of use (Neubauer, 2009). Experts recommend a low dose of a short-acting medication such as zolpidem (Ambien) for short-term use (no longer than 2 to 3 weeks) (Cramwell-Bruce, 2007). These drugs cause fewer problems with dependence and abuse and fewer rebound insomnia and hangover effects than benzodiazepines (Passarella and Duong, 2008).

The benzodiazepines cause relaxation, antianxiety, and hypnotic effects by facilitating the action of neurons in the CNS that suppress responsiveness to stimulation, thereby decreasing levels of arousal (Lehne, 2010). Short-acting benzodiazepines (e.g. oxazepam, lorazepam, or temazepam) at the lowest possible dose are recommended. Initial doses are small; and increments are added gradually, based on patient response, for a limited time. Warn patients not to take more than the prescribed dose, especially if the medication seems to become less effective after initial use. The use of benzodiazepines in older adults is potentially dangerous because of the tendency of the drugs to remain active in the body for a longer time. As a result, they also cause respiratory depression; next-day sedation; amnesia; rebound insomnia; and impaired motor functioning and coordination, which leads to increased risk of falls (Cramwell-Bruce, 2007; Neubauer, 2009). If older patients who were recently continent, ambulatory, and alert become incontinent or confused and/or demonstrate impaired mobility, the use of benzodiazepines needs to be considered as a possible cause.

Use benzodiazepines cautiously with children under 12 years of age. These medications are contraindicated in infants less than 6 months. Pregnant patients need to avoid them because their use is associated with risk of congenital anomalies. Nursing mothers do not receive the drugs because they are excreted in breast milk.

Regular use of any sleep medication often leads to tolerance and withdrawal. Rebound insomnia is a problem after stopping the medication. Immediately administering a sleeping medication when a hospitalized patient complains of being unable to sleep does the patient more harm than good. Consider alternative approaches to promote sleep. Routine monitoring of patient response to sleeping medications is important.

EVALUATION

Through the Patient's Eyes. With regard to problems with sleep, the patient is the source for evaluating outcomes. Each patient has a unique need for sleep and rest. The patient is the only one who knows if sleep problems are improved and which interventions or therapies are most successful in promoting sleep (Fig. 42-8). To evaluate the effectiveness of nursing interventions, make comparisons with baseline assessment data to evaluate if sleep has improved. It is important to ask the patient if his or her sleep needs have been met. For example, ask the patient, "Are you feeling more rested?"; "Can you tell me if you feel we have done all we can to help improve your sleep?"; or "What interventions have been most effective in helping you sleep?" If expectations have not been met, you need to spend more time trying to understand the patient's needs and preferences. Working closely with the patient and bed partner enables you to redefine expectations that can be met realistically within the limits of the patient's condition and treatment.

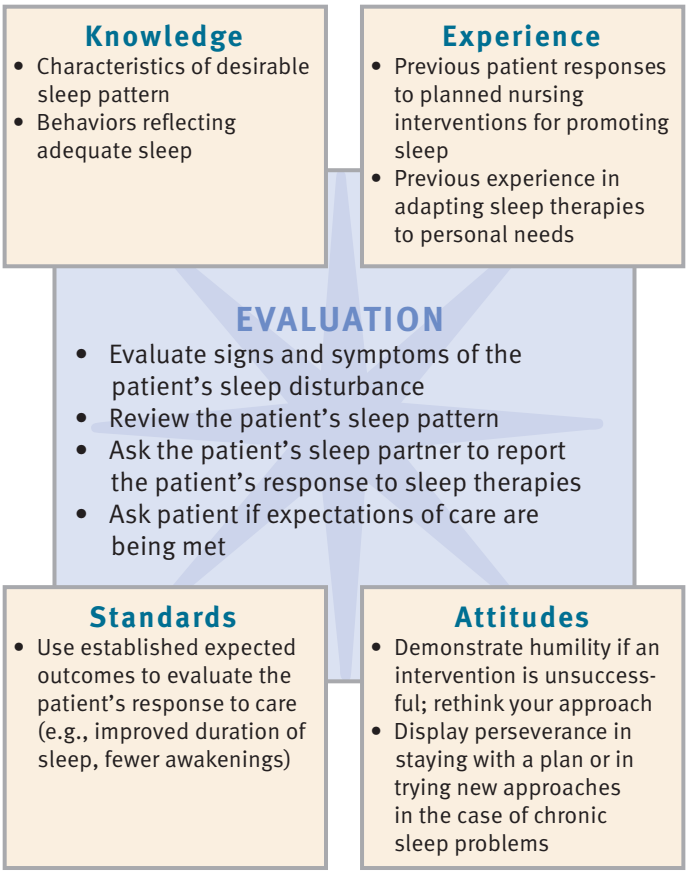

FIG. 42-8 Critical thinking model for sleep evaluation.

Patient Outcomes. Determine whether expected outcomes have been met. Use evaluative measures shortly after a therapy has been tried (e.g., observing whether a patient falls asleep after reducing noise and darkening a room). Use other evaluative measures after a patient awakens from sleep (e.g., asking a patient to describe the number of awakenings during the previous night). The patient and bed partner usually provide accurate evaluative information. Over longer periods use assessment tools such as the visual analogue or sleep-rating scale to determine whether sleep has progressively improved or changed.

Also evaluate the level of understanding that patients or family members gain after receiving instruction in sleep habits. You measure compliance with these practices during a home visit, when you are able to observe the environment. When expected outcomes are not met, revise the nursing measures or expected outcomes based on the patient's needs or preferences. When outcomes are not met, ask questions such as:

- Are you able to fall asleep within 20 minutes of getting in bed?
- Describe how well you sleep when you exercise.
- Does the use of quiet music at bedtime help you to relax?
- Do you feel rested when you wake up?

If a nurse has successfully developed a good relationship with a patient and a therapeutic plan of care, subtle behaviors often indicate the level of the patient's satisfaction. Note the absence of signs of sleep problems such as lethargy or frequent yawning or position changes in the patient. You are effective in promoting rest and sleep if the patient's goals and expectations are met.

KEY POINTS

- Sleep provides physiological and psychological restoration.
- The 24-hour sleep-wake cycle is a circadian rhythm that influences physiological function and behavior.
- The control and regulation of sleep depends on a balance among regulators within the CNS.
- During a typical night's sleep a person passes through four to five complete sleep cycles. Each sleep cycle contains three NREM stages of sleep and a period of REM sleep.
- The most common type of sleep disorder is insomnia.
- The hectic pace of a person's lifestyle, emotional and psychological stress, and alcohol ingestion frequently disrupt the sleep pattern.
- If a patient's sleep is adequate, assess his or her usual bedtime, normal bedtime ritual, preferred environment for sleeping, and usual preferred rising time.
- When a patient has a sleep problem, conduct a complete sleep history. Diagnosing sleep problems depends on identifying factors that impair sleep.
- When planning interventions to promote sleep, considers the usual characteristics of the patient's home environment and normal lifestyle.
- A regular bedtime routine of relaxing activities prepares a person physically and mentally for sleep.
- An environment with a darkened room, reduced noise, comfortable bed, and good ventilation promotes sleep.
- Important nursing interventions for promoting sleep in the hospitalized patient are establishing periods for uninterrupted sleep and rest and controlling noise levels.
- Pain or other disease symptom control is essential to promoting the ability to sleep.
- Long-term use of sleeping pills often leads to difficulty initiating and maintaining sleep.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Julie returns to the neighborhood health clinic with her husband, David, for a follow-up visit. She tells you that since she started her sleep hygiene plan she feels more rested but is still having some problems sleeping because of her husband's loud snoring. Besides Julie's report of David's snoring, you note that he is overweight.

1. Based on Julie's report of David's snoring, which additional assessment data should you gather from David?
2. Based on David's reported symptoms, what problem do you suspect he might have? What recommendations do you give David to improve his sleeping?
3. Julie and David tell you that they are concerned about their 6-year-old daughter. She just started school and is having sleep problems. List at least four interventions for Julie and David to use to improve their daughter's sleep patterns.

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is gathering a sleep history from a patient who is being evaluated for obstructive sleep apnea. Which common symptoms does the patient most likely report? (Select all that apply.)
   1. Headache
   2. Early wakening
   3. Excessive daytime sleepiness
   4. Difficulty falling asleep
   5. Snoring
2. The nurse incorporates which priority nursing intervention into a plan of care to promote sleep for a hospitalized patient?
   1. Have patient follow hospital routines
   2. Avoid awakening patient for nonessential tasks
   3. Give prescribed sleeping medications at dinner
   4. Turn television on low to late-night programming.
3. Older adults are cautioned about the long-term use of sedatives and hypnotics because these medications can:
   1. Cause headaches and nausea.
   2. Be expensive and difficult to obtain.
   3. Cause severe depression and anxiety.
   4. Lead to sleep disruption.
4. The nurse is providing health teaching for a patient using herbal compounds such as melatonin for sleep. Which points need to be included? (Select all that apply.)
   1. Can cause urinary retention
   2. Should not be used indefinitely
   3. May cause diarrhea and anxiety
   4. May interfere with prescribed medications
   5. Can lead to further sleep problems over time
   6. Are not regulated by the U.S. Food and Drug Administration (FDA)
5. The patient reports vivid dreaming to the nurse. Through understanding of the sleep cycle, the nurse recognizes that vivid dreaming occurs during which sleep phase?
   1. REM sleep
   2. Stage 1 NREM sleep
   3. Stage 4 NREM sleep
   4. Transition period from NREM to REM sleep
6. The nurse teaches a patient taking a benzodiazepine that this group of medications causes which symptom of a sleep problem?
   1. Nocturia
   2. Hyperactivity
   3. Grogginess and feeling hung over
   4. Increased sleep time
7. Which intervention is appropriate to include on a care plan for improving sleep in the older adult?
   1. Decrease fluids 2 to 4 hours before sleep
   2. Exercise in the evening to increase fatigue
   3. Allow the patient to sleep as late as possible
   4. Take a nap during the day to make up for lost sleep
8. Which statement made by a mother being discharged to home with her newborn infant indicates a need for further teaching?
   1. "I won't put the baby to bed with a bottle."
   2. "For the first few weeks we're putting the cradle in our room."
   3. "My grandmother told me that babies sleep better on their stomachs."
   4. "I know I'll have to get up during the night to feed the baby when he wakes up."
9. The nurse is developing a plan of care for a patient experiencing narcolepsy. Which intervention is appropriate to include on the plan?

1. Instruct the patient to increase carbohydrates in the diet
2. Have patient limit fluid intake 2 hours before bedtime
3. Preserve energy by limiting exercise to morning hours
4. Encourage patient to take one or two 20-minute naps during the day

10. Which nursing measure best promotes sleep in a school-age child?
    1. Encourage evening exercise
    2. Offer a glass of hot chocolate before bedtime
    3. Make sure that the room is dark and quiet
    4. Use quiet activities consistently before bedtime
11. Which action by the nursing assistant at bedtime requires the nurse to intervene?
    1. Giving the patient a back rub
    2. Turning on quiet music
    3. Dimming the lights in the patient's room
    4. Giving a patient a cup of coffee
12. Which statement made by the patient indicates a need for further teaching on sleep hygiene?
    1. "I'm going to do my exercises before I eat dinner."
    2. "I'll have a glass of wine at bedtime to relax."
    3. "I set my alarm to get up at the same time every morning."
    4. "I moved my computer to the den to do my work."
13. Which statement made by an older adult best demonstrates understanding of taking a sleep medication?
    1. "I'll take the sleep medicine for 4 or 5 weeks until my sleep problems disappear."
    2. "Sleep medicines won't cause any sleep problems once I stop taking them."
    3. "I'll talk to my health care provider before I use an over-the-counter sleep medication."
    4. "I'll contact my health care provider if I feel extreme sleepy in the mornings."
14. The school nurse is teaching health-promoting behaviors that improve sleep to a group of high school students. Which points should be included in the education? (Select all that apply.)
    1. Do not study in your bed.
    2. Go to sleep each night whenever you feel tired.
    3. Turn off your cell phone at bedtime.
    4. Avoid drinking coffee or soda before bedtime.
    5. Turn on the television to help you fall asleep.
15. The nurse is taking a sleep history from a patient. Which statement made by the patient needs further follow-up?
    1. I always feel tired when I wake up in the morning.
    2. I go to bed at the same time each night.
    3. It takes me about 15 minutes to fall asleep.
    4. Sometimes I have to get up during the night to urinate.

CHAPTER

43

Pain Management

OBJECTIVES

- Discuss common misconceptions about pain.
- Describe the physiology of pain.
- Identify components of the pain experience.
- Explain how the physiology of pain relates to selecting interventions for pain relief.
- Describe the components of pain assessment.
- Be able to perform an assessment of a patient experiencing pain.
- Explain how cultural factors influence the pain experience.
- Describe guidelines for selecting and individualizing pain interventions.
- Explain various pharmacological approaches to treating pain.
- Describe applications for use of nonpharmacological pain interventions.
- Discuss nursing implications for administering analgesics.
- Identify barriers to effective pain management.
- Evaluate a patient's response to pain interventions.

Everyone eventually experiences some type or degree of pain. Although it is the most common reason that people seek health care, pain is not well understood. A person in pain feels distress or suffering and seeks relief. As the nurse you cannot see or feel the patient's pain. It is purely subjective. No two people experience pain in the same way, and no two painful events create identical responses or feelings in a person. The International Association for the Study of Pain (IASP) defines pain as "an unpleasant, subjective sensory *and* emotional experience associated with actual or potential tissue damage, or described in terms of such damage" (IASP, 2010).

Congress declared 2000 to 2010 the Decade of Pain Control and Research, yet pain continues to be a leading public health problem in the United States. Providing pain relief is a basic human right and is in the Pain Care Bill of Rights (APF, 2007). According to the American Bar Association (2009), pain management is a basic right of people who are seriously ill. Nurses are legally and ethically responsible for managing pain and relieving suffering.

When caring for patients in pain, consider the nurse-patient relationship, patient advocacy, patient empowerment, compassion, and respect (Vaartio et al., 2009). Caring for patients in pain requires recognition that pain can and should be relieved. Effective communication among the patient, family, and professional caregivers is essential to achieve adequate pain management. You show respect for a patient in pain when you accept McCaffery's classic definition: "Pain is whatever the experiencing person says it is, existing whenever he says it does" (Pasero and McCaffery, 2011). Effective pain management improves quality of life; reduces physical discomfort; promotes earlier mobilization and return to previous activity levels; results in fewer hospital and clinic visits; and decreases hospital lengths of stay, resulting in lower health care costs.

SCIENTIFIC KNOWLEDGE BASE

Nature of Pain

The pain experience is complex, involving physical, emotional, and cognitive components. Pain is subjective and highly individualized. Its stimulus is physical and/or mental in nature. Pain uses a person's energy. It interferes with personal relationships and influences the meaning of life. You cannot measure it objectively. Only the patient knows whether pain is present and how the experience feels. It is not the responsibility of patients to prove that they are in pain; it is a nurse's responsibility to accept their report (APS, 2003).

Physiology of Pain

There are four physiological processes of nociceptive (normal) pain: transduction, transmission, perception, and modulation (Pasero and McCaffery, 2011). A patient in pain cannot discriminate among the processes. Understanding each process helps you recognize factors that cause pain, symptoms that accompany it, and the rationale for selected therapies.

Thermal, chemical, or mechanical stimuli usually cause pain. **Transduction** converts energy produced by these stimuli into electrical energy Transduction begins in the periphery when a pain-producing stimulus sends an impulse across a sensory peripheral pain nerve fiber **(nociceptor),** initiating an action potential. Once transduction is complete, **transmission** of the pain impulse begins.

Cellular damage caused by thermal, mechanical, or chemical stimuli results in the release of excitatory **neurotransmitters** such as **prostaglandins,** bradykinin, substance P, and histamine (Box 43-1). These pain-sensitizing substances surround the pain fibers in the extracellular fluid, creating an "inflammatory soup," spreading the pain message and causing an inflammatory response (Pasero and McCaffery, 2011). The pain stimulus enters the spinal cord via the dorsal horn and travels one of several routes until ending within the gray matter of the spinal cord. At the dorsal horn substance P is released, causing a synaptic transmission from the afferent (sensory) peripheral nerve to spinothalamic tract nerves, which cross to the opposite side (Pasero and McCaffery, 2011) (Fig. 43-1).

Nerve impulses resulting from the painful stimulus travel along afferent (sensory) peripheral nerve fibers. Two types of peripheral nerve fibers conduct painful stimuli: the fast, myelinated A-delta fibers and the very small, slow, unmyelinated C fibers. The A fibers send sharp, localized, and distinct sensations that specify the source of the pain and detect its intensity. The C fibers relay impulses that are poorly localized, burning, and persistent. For example, after stepping on a nail, a person initially feels a sharp, localized pain, which is a result of A-fiber transmission. Within a few seconds the pain becomes more diffuse and widespread, until the whole foot hurts because of C-fiber innervations (Pasero and McCaffery, 2011).

Along the spinothalamic tract, pain impulses travel up the spinal cord (Fig. 43-2). After the pain impulse ascends the spinal cord, the thalamus transmits information to higher centers in the brain, including the reticular formation, limbic system, somatosensory cortex, and association cortex. Once a pain stimulus reaches the cerebral cortex, the brain interprets the quality of the pain and processes information from past experience, knowledge, and cultural associations in the perception of the pain (Pasero and McCaffery, 2011). **Perception** is the point at which a person is aware of pain. The somatosensory cortex identifies the location and intensity of pain, whereas the association cortex, primarily

BOX 43-1 NEUROPHYSIOLOGY OF PAIN: NEUROREGULATORS

Neurotransmitters (Excitatory)

Prostaglandins

- Generated from the breakdown of phospholipids in cell membranes
- Thought to increase sensitivity to pain

Bradykinin

- Released from plasma that leaks from surrounding blood vessels at the site of tissue injury
- Binds to receptors on peripheral nerves, increasing pain stimuli
- Binds to cells that cause the chain reaction producing prostaglandins

Substance P

- Found in the pain neurons of the dorsal horn (excitatory peptide)
- Needed to transmit pain impulses from the periphery to higher brain centers
- Causes vasodilation and edema

Histamine

- Produced by mast cells causing capillary dilation and increases capillary permeability

Serotonin

- Released from the brainstem and dorsal horn to inhibit pain transmission

Neuromodulators (Inhibitory)

- Are natural supply of morphine-like substances in the body
- Activated by stress and pain
- Located within the brain, spinal cord, and gastrointestinal tract
- Cause analgesia when they attach to opiate receptors in the brain
- Present in higher levels in people who have less pain than others with a similar injury

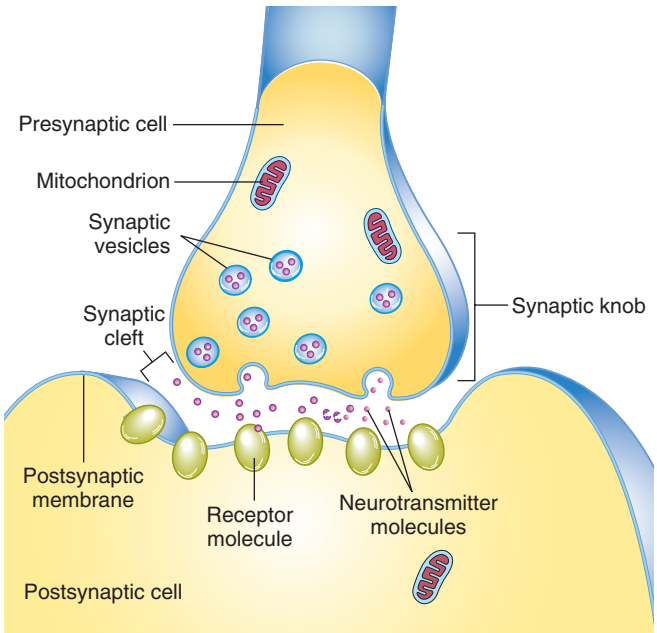

FIG. 43-1 Chemical synapses involve transmitter chemicals (neurotransmitters) that signal postsynaptic cells. (From Patton KT, Thibodeau GA: *Anatomy & physiology*, ed 7, St Louis, 2010, Mosby.)

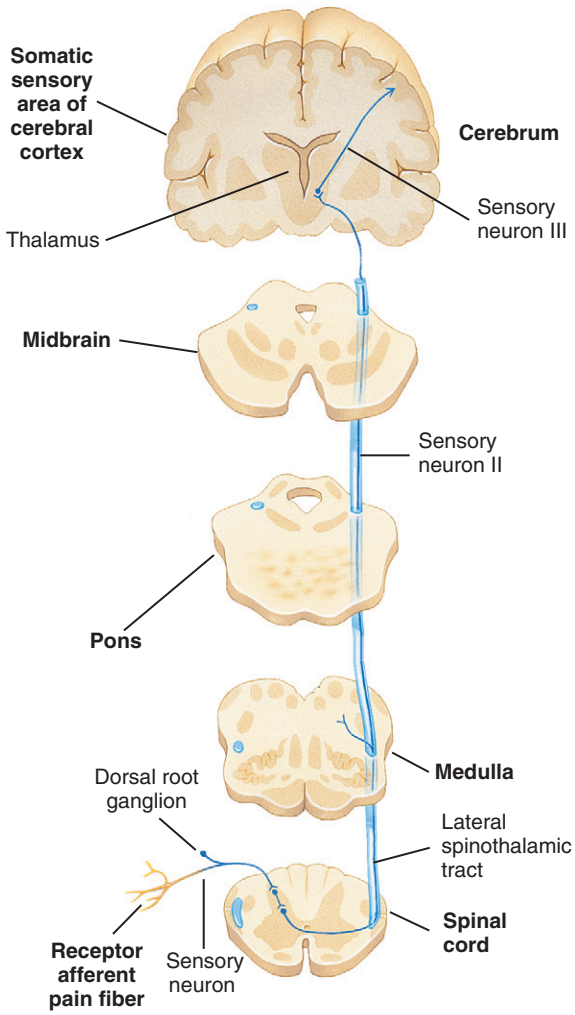

FIG. 43-2 Spinothalamic pathway that conducts pain stimuli to the brain.

the limbic system, determines how a person feels about it. There is no single pain center.

As a person becomes aware of pain, a complex reaction occurs. Psychological and cognitive factors interact with neurophysiological ones in the perception of pain. Perception gives awareness and meaning to pain, resulting in a reaction. The reaction to pain includes the physiological and behavioral responses that occur after an individual perceives pain (Pasero and McCaffery, 2011).

Once the brain perceives pain, there is a release of inhibitory neurotransmitters (see Box 43-1) such as endogenous opioids, serotonin, norepinephrine, and gamma aminobutyric acid (GABA), which work to hinder the transmission of pain and help produce an analgesic effect (Pasero and McCaffery, 2011). This inhibition of the pain impulse is the fourth and last phase of the nociceptive process known as **modulation** (Pasero and McCaffery, 2011).

A protective reflex response also occurs with pain reception (Fig. 43-3). A-delta fibers send sensory impulses to the spinal cord, where they synapse with spinal motor neurons. The motor impulses travel via a reflex arc along efferent (motor) nerve fibers back to a peripheral muscle near the site of stimulation, thus bypassing the brain. Contraction of the muscle leads to a protective withdrawal from the source of pain. For example, when you accidentally touch a hot iron, you feel a burning sensation, but your hand also reflexively withdraws from the surface of the iron.

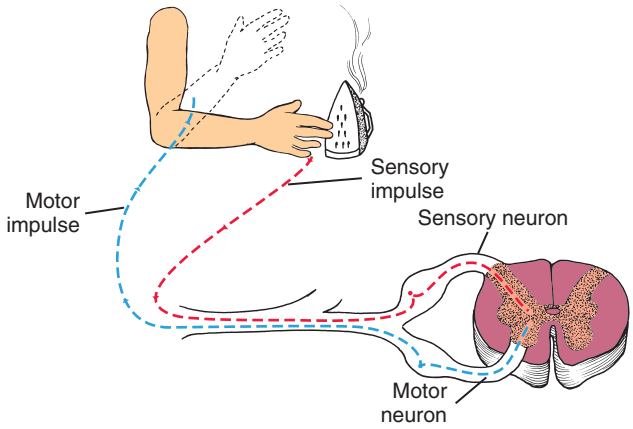

FIG. 43-3 Protective reflex to pain stimulus.

Gate-Control Theory of Pain. Melzack and Wall's gate-control theory (1965) first suggested that pain has emotional and cognitive components in addition to a physical sensation. According to this theory, gating mechanisms located along the central nervous system regulate or even block pain impulses. Pain impulses pass through when a gate is open and are blocked when a gate is closed. Closing the gate is the basis for nonpharmacological pain-relief interventions. You gain a useful conceptual framework for pain management by understanding the physiological, emotional, and cognitive influences on the gates. For example, factors such as stress and exercise increase the release of endorphins, often raising an individual's **pain threshold** (the point at which a person feels pain). Because the amount of circulating substances varies with every individual, the response to pain varies.

Physiological Responses. As pain impulses ascend the spinal cord toward the brainstem and thalamus, the stress response stimulates the autonomic nervous system. Pain of low to moderate intensity and superficial pain elicit the fight-or-flight reaction of the general adaptation syndrome (see Chapter 37). Stimulation of the sympathetic branch of the autonomic nervous system results in physiological responses (Table 43-1). Continuous, severe, or deep pain typically involving the visceral organs (e.g., with a myocardial infarction or colic from gallbladder or renal stones) activates the parasympathetic nervous system. Sustained physiological responses to pain sometimes seriously harm individuals. Except in cases of severe traumatic pain, which causes a person to go into shock, most people adapt to their pain, and their physical signs return to normal. Thus patients in pain do *not* always have changes in their vital signs. Changes in vital signs more often indicate problems other than pain.

Behavioral Responses. If left untreated or unrelieved, pain significantly alters quality of life. It usually interferes with every aspect of a person's life, which supports why effective pain management is essential. It threatens physical and psychological well-being. Some patients choose not to report pain if they believe that it inconveniences others or if it signals loss of self-control, and some endure severe pain without assistance. Encourage your patients to accept pain-relieving measures so they remain active and continue to maintain daily activities. In contrast, other patients seek relief before pain occurs, having learned that prevention is easier than treatment. A patient's ability to tolerate pain significantly influences your perceptions of the degree of the patient's discomfort. Patients who have a low **pain tolerance** (level of pain a person is willing to accept) are sometimes inaccurately perceived

TABLE 43-1 Physiological Reactions to Pain

RESPONSE	CAUSE OR EFFECT
Sympathetic Stimulation*	
Dilation of bronchial tubes and increased respiratory rate	Provides increased oxygen intake
Increased heart rate	Provides increased oxygen transport
Peripheral vasoconstriction (pallor, elevation in blood pressure)	Elevates blood pressure with shift of blood supply from periphery and viscera to skeletal muscles and brain
Increased blood glucose level	Provides additional energy
Diaphoresis	Controls body temperature during stress
Increased muscle tension	Prepares muscles for action
Dilation of pupils	Affords better vision
Decreased gastrointestinal motility	Frees energy for more immediate activity
Parasympathetic Stimulation†	
Pallor	Causes blood supply to shift away from periphery
Muscle tension	Results from fatigue
Decreased heart rate and blood pressure	Results from vagal stimulation
Rapid, irregular breathing	Causes body defenses to fail under prolonged stress of pain

*Pain of low-to-moderate intensity and superficial pain.
†Severe or deep pain.

as complainers. Teach patients the importance of reporting their pain sooner rather than later.

Body movements and facial expressions indicating pain include clenched teeth, holding the painful area, bent posture, and grimacing. Some patients cry or moan, are restless, or make frequent requests of a nurse. You soon learn to recognize patterns of behavior that reflect pain. This becomes especially important in patients who are unable to report their pain such as the cognitively impaired. However, lack of pain expression does not indicate that the patient is not experiencing pain (Pasero and McCaffery, 2011).

Types of Pain

Pain is categorized by duration (acute or chronic) or pathological condition (e.g., cancer or neuropathic).

Acute/Transient Pain. **Acute pain** is protective, has an identifiable cause, is of short duration, and has limited tissue damage and emotional response. It eventually resolves, with or without treatment, after an injured area heals. Because acute pain has a predictable ending (healing) and an identifiable cause, health team members are usually willing to treat it aggressively. Unrelieved acute pain can progress to chronic pain (Kehlet et al., 2006).

Acute pain seriously threatens a patient's recovery by resulting in prolonged hospitalization, increased risks of complications from immobility (see Chapter 47), and delayed rehabilitation. Physical and psychological progress is delayed as long as acute pain persists because a patient focuses all energy on pain relief. Efforts aimed at teaching and motivating the patient toward self-care are often hampered until the pain is successfully managed. Complete pain relief is not always achievable, but reducing pain to a tolerable level is realistic. Thus a primary nursing goal is to provide pain relief that allows patients to participate in their recovery.

Chronic/Persistent Noncancer Pain. Unlike acute pain, chronic pain is not protective and thus serves no purpose. **Chronic pain** lasts longer than 6 months and is constant or recurring with a mild-to-severe intensity (Ackley and Ladwig, 2011). It does *not* always have an identifiable cause and leads to great personal suffering. Examples of chronic noncancer pain include arthritis, low back pain, myofascial pain, headache, and peripheral neuropathy. Chronic pain is usually non–life threatening. Sometimes an injured area healed long ago, yet the pain is ongoing and does not respond to treatment.

The possible unknown cause of chronic pain, combined with the unrelenting nature and uncertainty of its duration, frustrates a patient, frequently leading to psychological depression and even suicide. Chronic pain is a major cause of psychological and physical disability, leading to problems such as job loss, inability to perform simple daily activities, sexual dysfunction, and social isolation.

The person with chronic noncancer pain often does not show obvious symptoms and does not adapt to the pain. Rather, he or she seems to suffer more with time because of physical and mental exhaustion. Associated symptoms of chronic pain include fatigue, insomnia, anorexia, weight loss, apathy, hopelessness, and anger. Chronic pain creates the uncertainty of how one will feel from day to day. If there is no objective evidence to confirm the existence of pain, the "burden of proof" lies with the patient (Shaw, 2006). Health care workers are usually less willing to treat chronic noncancer pain with opioids, although a policy statement supports the use of opioids for it (Chou et al., 2009). In addition, the American Society of Anesthesiologists (2010) developed "Practice Guidelines for Chronic Pain Management," which includes the use of opioids. Often a person with chronic pain who consults with numerous health care providers is labeled a drug seeker, when he or she is actually seeking adequate pain relief. This situation is called **pseudoaddiction.** Nurses need to discourage patients from having multiple health care providers for treating pain and refer them to pain specialists. Pain centers offer a holistic approach to chronic pain using both nonpharmacological and pharmacological strategies for pain management (Pasero and McCaffery, 2011).

Chronic Episodic Pain. Pain that occurs sporadically over an extended period of time is episodic pain. Pain episodes last for hours, days, or weeks. Examples are migraine headaches and pain related to sickle cell disease (Gruener and Lande, 2006).

Cancer Pain. Not all patients with cancer experience pain. For those who do, as many as 90% are able to have their pain managed with relatively simple means (Lehne, 2010). Some patients with cancer experience acute and/or chronic pain. The pain is nociceptive and/or neuropathic. Cancer pain is usually caused by tumor progression and related pathological processes, invasive procedures, toxicities of treatment, infection, and physical limitations. A patient senses pain at the actual site of the tumor or distant to the site, called *referred pain*. Assess reports of new pain by a patient with existing pain. Although the treatment of cancer pain has improved, undertreatment of cancer pain continues. Approximately 70% to 90% of patients with advanced cancer experience pain. Sixty percent of them report moderate-to-severe pain (Maxwell et al., 2005).

Pain by Inferred Pathological Process. Identifying the cause of pain is the first step in successful treatment. Nociceptive pain includes somatic (musculoskeletal) and visceral (internal organ) pain. Neuropathic pain arises from abnormal or damaged

TABLE 43-2 Classification of Pain by Inferred Pathology

NOCICEPTIVE PAIN	NEUROPATHIC PAIN
I. *Nociceptive pain:* Normal processing of stimuli that damages normal tissues or has the potential to do so if prolonged; usually responsive to nonopioids and/or opioids A. *Somatic pain:* Comes from bone, joint, muscle, skin, or connective tissue; is usually aching or throbbing in quality and well localized B. *Visceral pain:* Arises from visceral organs such as the gastrointestinal tract and pancreas; is sometimes subdivided: 1. Tumor involvement of organ capsule that causes aching and fairly well–localized pain 2. Obstruction of hollow viscus, which causes intermittent cramping and poorly localized pain	II. *Neuropathic pain:* Abnormal processing of sensory input by the peripheral or central nervous system; treatment usually includes adjuvant analgesics A. Centrally generated pain 1. *Deafferentation pain:* Injury to either the peripheral or central nervous system *Examples:* Phantom pain indicates injury to the peripheral nervous system; burning pain below the level of a spinal cord lesion reflects injury to the central nervous system. 2. *Sympathetically maintained pain:* Associated with impaired regulation of the autonomic nervous system *Examples:* Pain associated with complex regional pain syndrome, type I, type II B. Peripherally generated pain 1. *Painful polyneuropathies:* Pain felt along the distribution of many peripheral nerves. *Examples:* Diabetic neuropathy, alcohol-nutritional neuropathy, and Guillain-Barré syndrome. 2. *Painful mononeuropathies:* Usually associated with a known peripheral nerve injury; pain felt at least partly along the distribution of the damaged nerve *Examples:* Nerve root compression, nerve entrapment, trigeminal neuralgia

From Pasero C, McCaffery M: *Pain assessment and pharmacologic management,* St Louis, 2011, Mosby.

pain nerves (Table 43-2). Each of these pathological processes has distinct pain characteristics. The pain assessment section discusses these further.

Idiopathic Pain. **Idiopathic pain** is chronic pain in the absence of an identifiable physical or psychological cause or pain perceived as excessive for the extent of an organic pathological condition. An example of idiopathic pain is complex regional pain syndrome (CRPS). Research is needed to better identify the causes of idiopathic pain, thus leading to a more effective treatment (Pasero and McCaffery, 2011).

NURSING KNOWLEDGE BASE

Nursing knowledge of pain mechanisms and interventions continues to grow through nursing research. This section explores factors that influence the pain experience.

Knowledge, Attitudes, and Beliefs

Attitudes of nurses and other health care providers affect pain management. The traditional medical model of illness generates attitudes about pain. This model suggests that physical problems result from physical causes. Thus pain is a physical response to organic dysfunction. When there is no obvious source of pain (e.g., the patient with chronic low back pain or neuropathies), health care providers sometimes stereotype pain sufferers as malingerers, complainers, or difficult patients.

Studies of nurses' attitudes regarding pain management show that a nurse's personal opinion about a patient's report of pain affects pain assessment and titration of opioid doses. The amount of analgesia administered varies based on whether a patient is grimacing or smiling during the nurse's assessment (Pasero and McCaffery, 2011). Nurses with more than 6 years of work experience, higher job motivation, and perceived higher levels of pain-care skills in themselves often use more patient advocacy skills in providing pain management for patients (Vaartio et al., 2009).

Nurses' assumptions about patients in pain seriously limit their ability to offer pain relief. Biases based on culture, education, and experience influence everyone. Too often nurses allow misconceptions about pain (Box 43-2) to affect their willingness to intervene. Some nurses avoid acknowledging a patient's pain because of their own fear and denial. They do not believe a patient's report of pain if he or she does not look in pain. You are entitled to your personal beliefs; however, you must *accept* a patient's report of pain and act according to professional guidelines, standards, position statements, policies and procedures, and evidence-based research findings (Pasero and McCaffery, 2011).

BOX 43-2 COMMON BIASES AND MISCONCEPTIONS ABOUT PAIN

The following statements are *false:*

- Patients who abuse substances (e.g., use drugs or alcohol) overreact to discomforts.
- Patients with minor illnesses have less pain than those with severe physical alteration.
- Administering analgesics regularly leads to drug addiction.
- The amount of tissue damage in an injury accurately indicates pain intensity.
- Health care personnel are the best authorities on the nature of a patient's pain.
- Psychogenic pain is not real.
- Chronic pain is psychological.
- Patients who are hospitalized will experience pain.
- Patients who cannot speak do not feel pain.

To help a patient gain pain relief, view the experience through the patient's eyes. Acknowledging personal prejudices or misconceptions helps you address patient problems more professionally. When you become an active, knowledgeable observer of a patient in pain, you more objectively analyze the pain experience. The patient makes the diagnosis that pain is present, and you apply interventions that ultimately give relief.

Factors Influencing Pain

Pain is a complex process, involving physiological, social, spiritual, psychological, and cultural influences. Thus each individual's pain experience is different. Consider all factors that affect the patient in pain to ensure a holistic approach to the assessment and care of the patient.

BOX 43-3 FOCUS ON OLDER ADULTS

Factors Influencing Pain in Older Adults

- With aging, muscle mass decreases, body fat increases, and percentage of body water decreases. This increases concentration of water-soluble drugs such as morphine, and the volume of distribution for fat-soluble drugs such as fentanyl increases (Lehne, 2010).
- Older adults frequently eat poorly, resulting in low serum albumin levels. Many drugs are highly protein bound. In the presence of low serum albumin, more free drug (active form) is available, thus increasing the risk for side and/or toxic effects (Lehne, 2010).
- A decline of liver and renal function naturally occurs with aging. This results in reduced metabolism and excretion of drugs. Thus older adults often experience a greater peak effect and longer duration of analgesics (Arnstein, 2010).
- Age-related changes in the skin such as thinning and loss of elasticity affect the absorption rate of topical analgesics.

TABLE 43-3 Pain in Infants

MISCONCEPTION	CORRECTION
Infants cannot feel pain.	Infants have the anatomical and functional requirements for pain processing by mid-to-late gestation.
Infants are less sensitive to pain than older children and adults.	Term neonates have the same sensitivity to pain as older infants and children. Preterm neonates have a greater sensitivity to pain than term neonates or older children.
Infants cannot express pain.	Although infants cannot verbalize pain, they respond with behavioral cues and physiological indicators that are observable.
Infants must learn about pain from previous painful experiences.	Pain requires no prior experience; infants do not need to learn it from earlier painful experience. It occurs with the first insult.
You cannot accurately assess pain in infants.	You use behavioral cues (e.g., facial expressions, cry, body movements) and physiological indicators of pain (e.g., changes in vital signs) to reliably and validly assess pain in infants.
You cannot safely give analgesics and anesthetics to infants and neonates because of their immature capacity to metabolize and eliminate drugs and their sensitivity to opioid-induced respiratory depression.	Infants are very sensitive to drugs. Response to drugs is often intense and prolonged. Absorption is faster than expected. Dosages of drugs excreted by the kidneys need to be reduced (Lehne, 2010). Prescribers carefully select the medication, dosage, administration route, and time. Nurses monitor frequently for desired and undesired effects. Nurses also follow medication orders to titrate and wean medications to minimize adverse effects.

Physiological Factors

Age. Age influences pain, particularly in infants and older adults. Developmental differences found between these age-groups influence how children and older adults react to pain. Young children have trouble understanding pain and the procedures that cause it. If they have not developed full vocabularies, they have difficulty verbally describing and expressing pain to parents or caregivers. Toddlers and preschoolers are unable to recall explanations about pain or associate it with experiences that occur in various situations. With these developmental considerations in mind, you need to adapt approaches for assessing a child's pain, including what to ask and the behaviors to observe, and how to prepare a child for a painful medical procedure.

Pain is not an inevitable part of aging. However, older adults have a greater likelihood of developing pathological conditions, which are accompanied by pain. Serious impairment of functional status often accompanies pain in older patients. Pain potentially reduces mobility, activities of daily living (ADLs), social activities, and activity tolerance. The presence of pain in an older adult requires aggressive assessment, diagnosis, and management (Box 43-3).

The ability of older patients to interpret pain is complicated. They often suffer from multiple diseases with vague symptoms that affect similar parts of the body. You need to make detailed assessments when there is more than one source of pain. Different diseases sometimes cause similar symptoms. For example, chest pain does not always indicate a heart attack; it also is a symptom of arthritis of the spine or an abdominal disorder. When older adults experience cognitive impairment and confusion, they have difficulty recalling pain experiences and providing detailed explanations of their pain (Pasero and McCaffery, 2011). You need to address misconceptions about pain management in the very young and in older adults before intervening for a patient (Tables 43-3 and 43-4).

Fatigue. Fatigue heightens the perception of pain and decreases coping abilities. If it occurs along with sleeplessness, the perception of pain is even greater. Pain is often experienced less after a restful sleep than at the end of a long day.

Genes. Research on healthy human subjects suggests that genetic information passed on by parents possibly increases or decreases the person's sensitivity to pain and determines pain threshold or pain tolerance. A study of twins by Kato et al. (2006) suggested modest genetic influence in the development of chronic widespread pain without significant differences experienced between men and women.

Neurological Function. A patient's neurological function influences the pain experience. Any factor that interrupts or influences normal pain reception or perception (e.g., spinal cord injury, peripheral neuropathy, or neurological disease) affects the patient's awareness of and response to pain. Some pharmacological agents (analgesics, sedatives, and anesthetics) influence pain perception and response and thus require close monitoring.

Social Factors

Attention. The degree to which a patient focuses attention on pain influences pain perception. Increased attention is associated with increased pain, whereas distraction is associated with a diminished pain response. This concept is one that nurses apply in various pain-relief interventions such as relaxation, guided imagery, and massage. By focusing patients' attention and concentration on other stimuli, their perception of pain declines (see Chapter 32).

Previous Experience. Each person learns from painful experiences. Prior experience does not mean that a person accepts pain more easily in the future. Previous frequent episodes of pain without relief or bouts of severe pain cause anxiety or fear. In contrast, if a person repeatedly experiences the same type of pain that was relieved successfully in the past, the patient finds it easier to interpret the pain sensation. As a result, the patient is better prepared to take necessary actions to relieve the pain.

TABLE 43-4 Misconceptions About Pain in Older Adults

MISCONCEPTION	CORRECTION
Pain is a natural outcome of growing old.	Older adults are at greater risk (as much as twofold) than younger adults for many painful conditions; however, pain is not an inevitable result of aging.
Pain perception, or sensitivity, decreases with age.	This assumption is unsafe. Although there is evidence that emotional suffering specifically related to pain is possibly less in older than in younger patients, no scientific basis exists for the claim that a decrease in perception of pain occurs with age or that age dulls sensitivity to pain.
If the older patient does not report pain, he or she does not have pain.	Older patients commonly underreport pain. Reasons include expecting to have pain with increasing age; not wanting to alarm loved ones; being fearful of losing their independence; not wanting to distract, anger, or bother caregivers; and believing that caregivers know they have pain and are doing all they can to relieve it. The absence of a report of pain does not mean the absence of pain.
If an older patient appears to be occupied, asleep, or otherwise distracted from pain, he or she does not have pain.	Older patients often believe that it is unacceptable to show pain and have learned to use a variety of ways to cope with it (e.g., many patients use distraction successfully for short periods of time). Sleeping is sometimes a coping strategy; alternately, it indicates exhaustion, not pain relief. Do not make assumptions about the presence or absence of pain solely on the basis of a patient's behavior.
The potential side effects of opioids make them too dangerous to use to relieve pain in older adults.	Opioids are safe to use in older adults with moderate-to-severe pain (Arnstein, 2010). Although the opioid-naive older adult is usually more sensitive to opioids, this does not justify withholding their use in pain management. Slow titration prevents potentially dangerous opioid-induced side effects. Regular, frequent monitoring and assessment of a patient's response are necessary. Adjust dose and interval between doses when you detect side effects. If necessary, administer an opioid antagonist drug to reverse clinically significant respiratory depression.
Patients with Alzheimer's disease and other cognitive impairments do not feel pain, and their reports of pain are most likely invalid.	No evidence exists that cognitively impaired older adults experience less pain or that their reports of pain are less valid than those of individuals with intact cognitive function (Herr, 2010). Patients with dementia or other deficits of cognition most likely suffer significant unrelieved pain and discomfort. Assessment of pain in these patients is challenging but possible. The best approach is to accept a patient's report of pain and treat it as you would treat it in an individual with intact cognitive function.
Older patients report more pain as they age.	Even though older patients experience a higher incidence of painful conditions such as arthritis, osteoporosis, peripheral vascular disease, and cancer than younger patients, studies show that they underreport pain. Many older adults grew up valuing the ability to "grin and bear it" (Pasero and McCaffery, 2011).

When a patient has no experience with a painful condition, the first perception of it often impairs the ability to cope. For example, after abdominal surgery it is common for patients to experience severe incisional pain for several days. Unless a patient knows this is a common occurrence following surgery, the onset of pain seems like a serious complication. Rather than participate actively in postoperative breathing exercises (see Chapter 50), the patient lies immobile in bed and breathes shallowly because of fear that something is not right. In the anticipatory phase of the pain experience, you need to prepare a patient with a clear explanation of the type of pain to expect and methods to reduce it. This usually results in a reduced perception of pain.

Family and Social Support. People in pain often depend on family members or close friends for support, assistance, or protection. Although pain still exists, the presence of family or friends can often make the pain experience less stressful. The presence of parents is especially important for children experiencing pain.

Spiritual Factors. Spirituality stretches beyond religion and includes an active searching for meaning to situations in which one finds oneself. Spiritual questions include "Why has this happened to me?" "Why am I suffering?" Spiritual pain goes beyond what we can see. "Why has God done this to me?" "Is this suffering teaching me something?" Other spiritual concerns include loss of independence and becoming a burden to family (Otis-Green et al., 2002). Consider making a referral to pastoral care for patients in pain. Recall that pain is an experience that has physical *and* emotional components. Thus providing interventions designed to treat both aspects is essential for the best possible pain management (see Chapter 35).

Psychological Factors

Anxiety. A person perceives pain differently if it suggests a threat, loss, punishment, or challenge. For example, a woman in labor perceives pain differently than a woman with a history of cancer who is experiencing a new pain and fearing recurrence. In addition, the degree and quality of pain perceived by a patient influences the meaning of pain. The relationship between pain and anxiety is complex. Anxiety often increases the perception of pain, and pain causes feelings of anxiety. It is difficult to separate the two sensations.

Critically ill or injured patients who perceive a lack of control over their environment and care have high anxiety levels. This anxiety leads to serious pain-management problems. Pharmacological and nonpharmacological approaches to the management of anxiety are appropriate; however, anxiolytic medications are not a substitute for analgesia (Pasero and McCaffery, 2011).

Coping Style. Coping style influences the ability to deal with pain. Persons with internal loci of control perceive themselves as having control over events in their life and the outcomes such as pain. In contrast, persons with external loci of control perceive that other factors in their life such as nurses are responsible for the outcome of events. Patient-controlled analgesia (PCA) uses this concept. Patients who self-administer small doses of intravenous (IV) pain medication using PCA during an acute episode successfully achieve pain control more quickly than those who rely on nurses to administer intermittent doses of pain medications.

BOX 43-4 CULTURAL ASPECTS OF CARE

Assessing Pain in Culturally Diverse Patients

Pain is a biopsychosocial phenomenon. Culture shapes the experience of pain, its expression, its behaviors, or coping responses. Culture also affects lay remedies, help-seeking activities, and receptivity to medical treatment. Some health care providers undertreat pain because they do not understand the cultural effects on the perception of pain intensity. Differences exist both within cultural and ethnic groups and among them. Nurses care for patients with pain from a variety of cultures; thus you need to develop strategies to assess and manage pain in culturally diverse patients.

Implications for Practice

- Use culturally appropriate assessment tools to assess pain such as tools written in the patient's native language (Pasero and McCaffery, 2011).
- Recognize variations in subjective responses to pain. Some patients are stoic and less expressive, whereas others are emotive and more likely to verbalize pain.
- Be sensitive to variations in communication styles. Some cultures believe that nonverbal expression of pain is sufficient to describe the pain experience; whereas others assume that, if pain medication is appropriate, the nurse will bring it; thus asking is inappropriate.
- Understand that expression of pain is unacceptable within certain cultures. Some patients believe asking for help indicates a lack of respect, whereas others believe acknowledging pain is a sign of weakness.
- The meaning of pain varies among cultures. Pain is personal and related to religious beliefs. Some cultures consider suffering a part of life to be endured to enter heaven.
- Use knowledge of biological variations of pain. Significant differences in drug metabolism, dosing requirements, therapeutic response, and adverse effects occur in racial and ethnic groups. A wide range of responses is also possible within a cultural group. Therefore assess each patient's response to pain medication carefully.
- Develop a personal awareness of your own values and beliefs that affect your responses to patients' reports of pain.

You need to understand patients' coping resources during painful experiences. Use resources such as communicating with a supportive family, being active, or praying, in your plan of care to support patients and offer a degree of pain relief (see Chapter 37).

Cultural Factors. The meaning that a person associates with pain affects the experience of pain and how one adapts to it. This is often closely associated with a person's cultural background. Cultural beliefs and values affect how individuals cope with pain. Individuals learn what is expected and accepted by their culture, including how to react to pain. Health care providers often mistakenly assume that everyone responds to pain in the same way. Different meanings and attitudes are associated with pain across various cultural groups. An understanding of the cultural meaning of pain helps you design culturally sensitive care for people with pain (Pasero and McCaffery, 2011).

Culture affects pain expression. Some cultures believe that it is natural to be demonstrative about pain. Others tend to be more introverted. In addition, it is also important to know to what extent a member of a particular culture has assimilated into American society. For example, if several generations of a Hispanic patient's family have lived in the United States, the influence of the Spanish culture may be limited, whereas newly immigrated patients still embrace their cultural norms.

As a nurse, explore the impact of cultural differences on a patient's pain experience and make adjustments to the plan of care (Box 43-4). Work with the patient and family to facilitate communication about the assessment and management of pain. Find a culturally appropriate assessment tool and communicate use of that tool to other health care providers.

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. To make clinical judgments, you anticipate the information you need, analyze the data, and make decisions regarding patient care. A patient's condition or situation is always changing. During assessment consider all critical thinking elements that lead to appropriate nursing diagnoses.

Knowledge of pain physiology and the many factors that influence pain help you manage a patient's pain. Previous experience in caring for patients with pain sharpens your assessment skills and ability to choose effective therapies. Critical thinking attitudes and intellectual standards ensure the aggressive assessment, creative planning, and thorough evaluation needed to obtain an acceptable level of patient pain relief. Successful pain management does not necessarily mean pain elimination but rather attainment of a mutually agreed-on pain-relief goal that allows patients to control their pain instead of the pain controlling them.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

Nurses approach pain management systematically to understand and treat a patient's pain. Successful management of pain depends on establishing a relationship of trust among health care providers, patient, and family. Pain management extends beyond pain relief, encompassing the patient's quality of life and ability to work productively, enjoy recreation, and function normally in the family and society.

The American Nurses Association (ANA) (2005) upholds that pain assessment and management is within the scope of every nurse's practice. Thus the ANA offers a certification examination in pain management to staff nurses (http://www.aspmn.org/certification). Several clinical guidelines are available for managing pain in specific disorders. Guidelines are available through the American Pain Society (APS) on the management of pain in the primary care setting; sickle cell pain; cancer pain in adults and children; and pain in osteoarthritis, rheumatoid arthritis, and juvenile chronic arthritis. Sigma Theta Tau International offers guidelines for the older adult on their website (www.geriatricpain.org). In addition, the National Guidelines Clearinghouse (www.guideline.gov) posts a variety of pain-management guidelines, including ones on acute, chronic, spinal, chest, low back, cancer, and pancreatic pain.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Many people view pain as a part of life. Some patients experience it for hours or days before seeking health care assistance. They often expect and even accept a

BOX 43-5 NURSING ASSESSMENT QUESTIONS

Current Pain

- *P*alliative or *P*rovocative factors: What makes your pain worse? What makes it better?
- *Q*uality: How do you describe your pain?
- *R*egion or *R*adiation: Show me where you hurt. Does it stay there or does it spread somewhere else?
- *S*everity: On a scale of 0 to 10, how bad is your pain now?
- What is the worst pain you have had in the past 24 hours?
- What is the average pain you have had in the past 24 hours?
- *T*iming: Is your pain constant, intermittent, or both?
- *U:* Effect of pain: What does your pain prevent you from doing that you would like to do?

Allergies

- Do you have any allergies to medications?
- What type of problems have these allergies caused?
- How are these allergies treated?

Current Medications

- What medications are you taking now?
- Are you taking any herbs?
- Are these medications and herbs effective in relieving the pain?
- Which nonpharmacological treatments have you tried to relieve the pain?
- Which medications have you tried in the past that worked to stop your pain?
- Have you ever used recreational drugs or alcohol to alleviate pain?
- Have you ever been diagnosed with a gastrointestinal bleed or a kidney or liver disorder?
- Are you being treated for any other medical conditions?
- With whom do you live, and how do they help you when you have pain?

BOX 43-6 ROUTINE CLINICAL APPROACH TO PAIN ASSESSMENT AND MANAGEMENT: ABCDE

A: ***Ask*** about pain regularly. Assess pain systematically.
B: ***Believe*** the patient and family in their report of pain and what relieves it.
C: ***Choose*** pain control options appropriate for the patient, family, and setting.
D: ***Deliver*** interventions in a timely, logical, and coordinated fashion.
E: ***Empower*** patients and their families. Enable them to control their course to the greatest extent possible.

From Jacox A et al.: *Management of cancer pain,* Clinical Practice Guideline No. 9, AHCPR Publication No. 94-0592, Rockville, Md, 1994, Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services.

BOX 43-7 POSSIBLE SOURCES FOR ERROR IN PAIN ASSESSMENT

- Bias, which causes nurses to consistently overestimate or underestimate the pain that patients experience
- Vague or unclear assessment questions, which lead to unreliable assessment data
- Use of pain assessment tools that are not evidence based
- Patients who do not always provide complete, relevant, and accurate pain information
- Patients who are cognitively impaired and unable to use pain scales

certain amount of pain while being hospitalized. Asking patients about their tolerable pain level is the first step in helping them regain control. Assessing previous pain experiences and effective home interventions provides a foundation on which you can build. Patients expect nurses to accept their reports of pain and be prompt in meeting their pain needs.

When assessing pain, be sensitive to the level of discomfort and determine what level will allow your patient to function. For example, when caring for a patient with pain, you ask, "What level of pain will allow you to walk down the hall?" The patient answers that walking is possible when pain is at a level of 2 on a scale of 0 to 10, with 0 being no pain and 10 being worst pain imaginable. You then focus efforts on decreasing the pain to that level. If pain is acute or severe, it is unlikely that the patient is able to provide a detailed description of the entire experience. During an episode of acute pain you primarily assess its location, severity, and quality. Collect a more detailed acute pain assessment when the patient is more comfortable (Box 43-5). For patients with chronic pain, a thorough pain assessment includes affective, cognitive, behavioral, spiritual, and social dimensions. In the home care setting family members assess pain. Using the ABCs of pain management is an effective way to manage pain (Box 43-6).

Because pain is not static but dynamic, you monitor it on a regular basis along with other vital signs. Some institutions treat pain as the fifth vital sign. Pain assessment is *not* simply a number. Relying solely on a number is unsafe (Vila et al., 2005). Although pain assessment is a nursing function, nursing assistive personnel (NAP) also screen for pain (Schulman-Green et al., 2005). NAP have the responsibility to inform the nurse immediately when a patient is having pain so the nurse is able to confirm the assessment and begin appropriate treatment.

The ability to establish a nursing diagnosis, decide on appropriate interventions, and evaluate the patient's response (outcomes) to interventions depends on the fundamental activity of a factual, timely, accurate pain assessment (Fig. 43-4). The core of this complex activity is the exploration of the pain experience through the eyes of the patient. Nurses use a variety of tools to assess nociceptive pain and neuropathic pain (Jensen et al., 2006). The goal in using these tools is to identify how much pain exists without interfering with patient function, not to identify how much pain the patient tolerates.

The Agency for Healthcare Research and Quality (AHRQ) established specific guidelines for assessing patients with acute and cancer pain. The focus is on planning successful pain-management interventions before a patient has pain. Because it involves a collaborative approach, the AHRQ pain treatment flow chart (Fig. 43-5) offers a useful conceptual approach to the control of acute pain. Patients need to understand that informed reporting of pain is valuable and necessary if the health care team is to manage it effectively.

Always be aware of possible errors in pain assessment (Box 43-7). Using the right tools and methods helps you avoid errors and ensures that you choose the right pain interventions. Failure of clinicians to assess a patient's pain, accept the findings, and treat the report of pain is a common cause of unrelieved pain and suffering (Hughes, 2008).

Patient's Expression of Pain. A patient's self-report of pain is the single most reliable indicator of its existence and intensity (APS, 2003; Pasero and McCaffery, 2011). Pain is individualistic. Many patients fail to report or discuss discomfort. At the same time

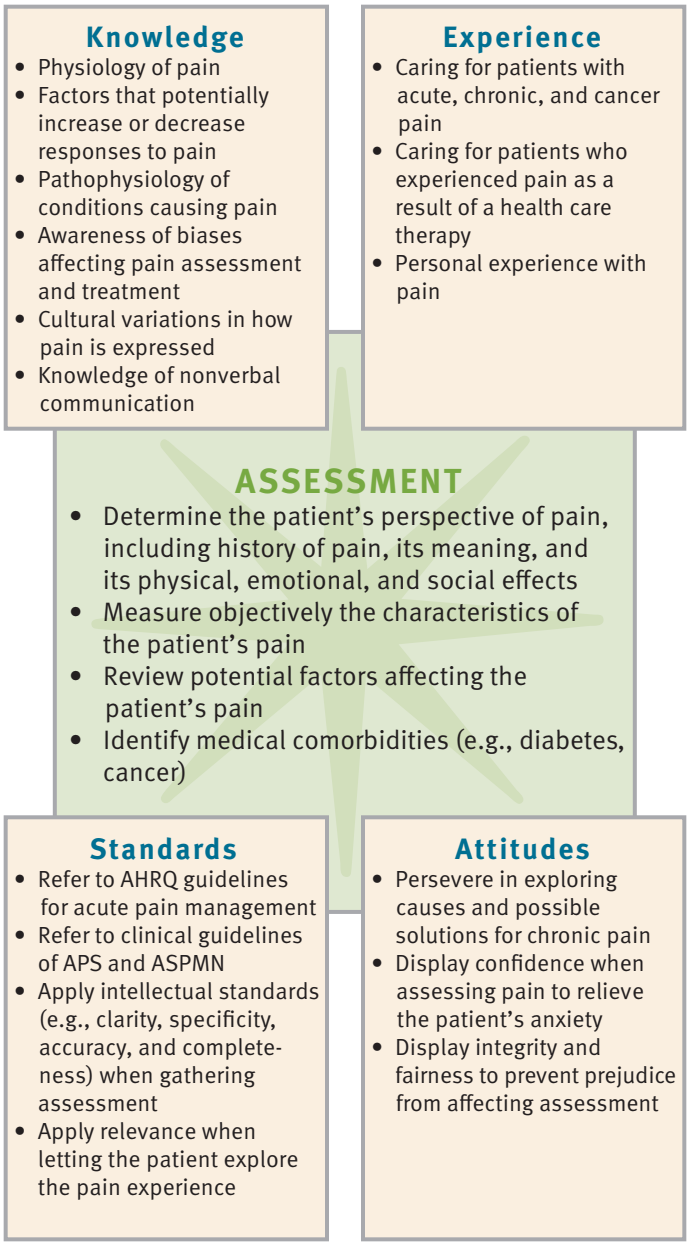

FIG. 43-4 Critical thinking model for pain assessment. *AHRQ,* Agency for Healthcare Research and Quality; *ANA,* American Nurses Association; *ASPMN,* American Society for Pain Management Nursing.

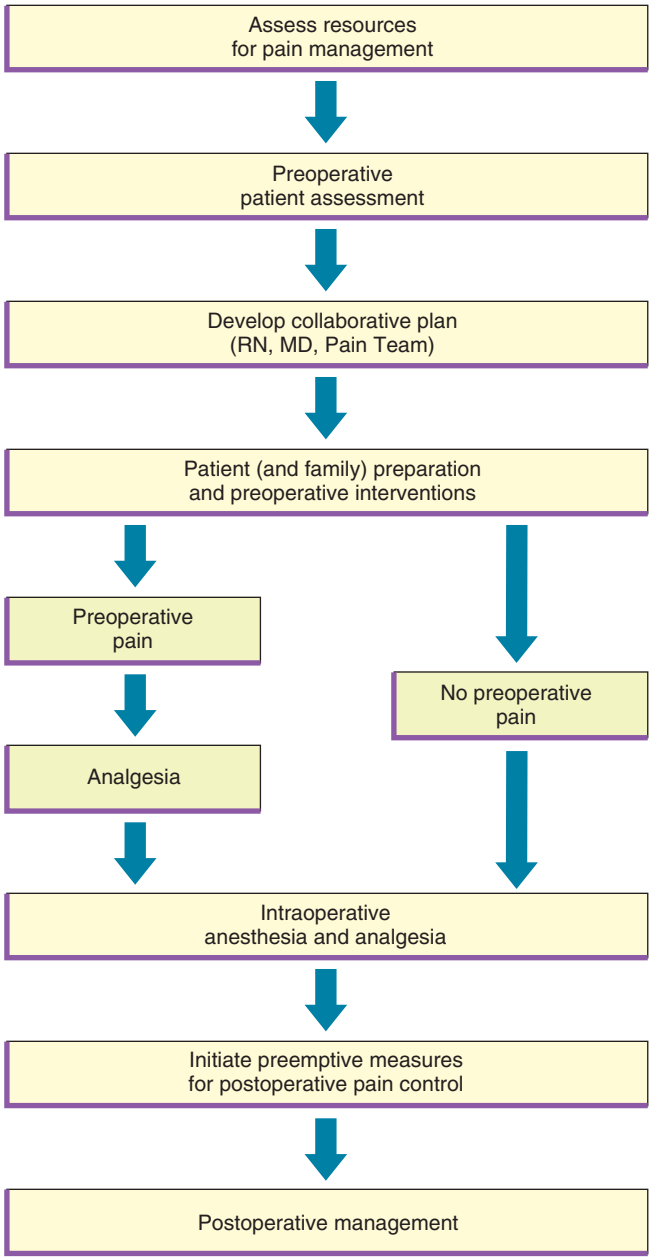

FIG. 43-5 Pain treatment flow chart: preoperative and intraoperative phases. *MD,* Medical doctor; *RN,* registered nurse. (From Agency for Health Care Policy and Research, Acute Pain Management Guideline Panel: *Acute pain management: operative or medical procedures and trauma,* Clinical Practice Guideline, AHCPR Pub No. 92-0032, Rockville, Md, 1992, Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services; and Jacox A et al: *Management of cancer pain,* Clinical Practice Guideline No. 9, AHCPR Pub No. 94-0592, Rockville, Md, 1994, Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services.)

many nurses believe that patients report pain if they have it. If patients sense that you doubt that pain exists, they share little information about their pain experience or minimize their report. You need to establish a caring therapeutic relationship that allows for open communication. Simple measures such as sitting when talking to patients about pain lets them know that you are sincerely concerned about their pain.

Patients unable to communicate effectively often require special attention during assessment. Children, people who are developmentally delayed, patients who are psychotic, the critically ill, patients with dementia, and patients who do not speak English all require different approaches. Herr et al. (2006a, 2006b) examined various pain behavior assessment tools used with patients who were cognitively impaired. Although no one tool had sufficient reliability and validity, there are clinical practice recommendations (Box 43-8). However, you need to understand that "the number obtained when using a pain-behavior scale is a pain-behavior score, not a pain-intensity rating" (Pasero and McCaffery, 2005). These tools identify the presence of pain but do not determine its intensity.

BOX 43-8 EVIDENCE-BASED PRACTICE

Pain Assessment in the Nonverbal Patient

PICO Question: In patients who are nonverbal, which method of pain assessment is the most effective?

Evidence Summary

A common misconception is that individuals who are nonverbal as a result of dementia or cognitive impairments do not experience pain (Herr, 2010). Patients who are nonverbal often present with atypical manifestations of pain caused by pathophysiological changes in the brain. Manifestations often include hitting, fearful expressions, combativeness, and resistance to care (Herr, 2010). An appointed task force of the American Society for Pain Management Nursing developed an evidence-based position statement and clinical practice recommendations for pain assessment in the nonverbal patient (Herr et al., 2006a). No single assessment strategy such as interpretation of behaviors, pathology, or estimates of pain by others is sufficient by itself in determining the presence of pain in a nonverbal patient.

Application to Nursing Practice

- Recommended assessment considerations:
  - Attempt a self-report of pain using simple yes/no responses or vocalizations or a numerical rating scale (Herr and Titler, 2009).
  - Search for potential causes of pain (Herr, 2010).
  - Assume that pain is present (APP) after ruling out other problems (infection, constipation) that cause pain.
  - Identify pathological conditions or procedures that cause pain.
  - Observe patient behaviors and list behaviors (e.g., facial expressions, vocalizations, body movements, changes in interactions or mental status) that indicate pain. These vary, depending on patient's developmental level (Herr, 2010).
  - Ask family members, parents, or caregivers for a surrogate report.
- Use behavioral pain assessment tools.
  - Use evidence-based tools to ensure appropriate pain assessment (Herr, 2010).
  - Evidence supports use of the Behavioral Pain Scale and the Nonverbal Pain Scale for patients who are mechanically ventilated (Juarez et al., 2010).
- Determine the appropriate scale based on individual patient needs; no one scale measures pain accurately for all groups of patients.
- Vital signs are not sensitive indicators for the presence of pain.
- For severe pain, consider starting the analgesic trial with an opioid. (Herr et al., 2006a).
- Choose analgesic, dose, and titration based on estimated intensity of pain.
- For mild-to-moderate pain, give nonopioid analgesics around the clock.
- After 24 hours reassess. If behaviors improve, assume that pain was the cause.
- If behaviors persist, consider giving a single, low-dose short-acting opioid (e.g., morphine). Observe effect.
- If behaviors continue, titrate dose upward by 25% to 50% and observe effect.
- Continue to titrate up until a therapeutic effect or bothersome adverse effects occur or if there is no benefit.
- If behaviors continue after a reasonable analgesic trial, explore other potential causes.

Patients with cognitive impairments often require simple assessment approaches involving close observation of behavior changes, especially with movement. Patients who are critically ill and have a clouded sensorium or the presence of nasogastric tubes or artificial airways require you to ask specific questions that they can answer with a nod of the head or by writing out a response. If the patient speaks a different language, pain assessment is difficult. An interpreter is often necessary (Pasero and McCaffery, 2011).

Characteristics of Pain. Assessment of common characteristics of pain helps you form an understanding of the type of pain, its pattern, and the types of interventions that bring relief. Use of instruments to quantify the extent and degree of pain depends on a patient being cognitively alert enough to be able to understand your instructions.

Onset and Duration. Ask questions to determine the onset, duration, and sequence of pain. When did it begin? How long has it lasted? Does it occur at the same time each day? How often does it recur?

Location. To assess pain location, ask the patient to describe or point to all areas of discomfort. Do not assume that your patient's pain always occurs in the same location. When describing pain location, use anatomical landmarks and descriptive terminology. The statement "Pain is localized in the upper right abdominal quadrant" is more specific than "The patient states the pain is in the abdomen." Pain classified by location is superficial or cutaneous, deep or visceral, referred, or radiating (Table 43-5).

Intensity. One of the most subjective and therefore most useful characteristics for reporting pain is its severity or intensity. Nurses use a variety of pain scales to help patients communicate their pain intensity. Examples of pain intensity scales include the verbal descriptor scale (VDS), the numerical rating scale (NRS), and the visual analogue scale (VAS) (Fig. 43-6). When using the NRS, a report of 0 to 3 indicates mild pain; 4 to 6, moderate pain; and 7 to 10, severe pain, considered a pain emergency (Miaskowski, 2005). These scales work best when assessing pain intensity before and after therapeutic interventions. Many of them are available in several languages to aid nurses when an interpreter is not present (Pasero and McCaffery, 2011). In addition to the current pain level, also ask patients to rate their average pain and the worst pain they have had over the past 24 hours.

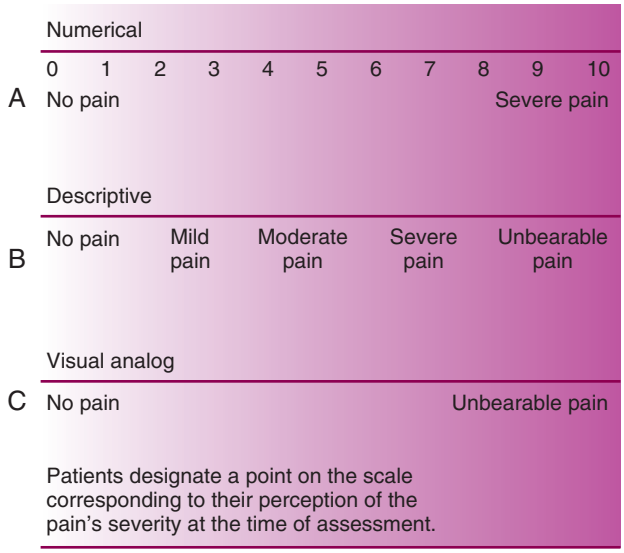
Although different patients prefer different pain scales, it is important for you to select and consistently use the same scale with a specific patient. Do not use a pain scale to compare the pain of one patient to that of another.

Assessing pain intensity in children requires special techniques. Children's verbal statements are most important (Hockenberry and Wilson, 2011). Young children do not always know what the word *pain* means; therefore assessment requires you to use words such as *owie, boo-boo,* or *hurt.* Some unique tools are available to measure pain intensity in children. The "Oucher" (Beyer et al., 1992) uses photographs of the face of a child (in increasing levels of discomfort) to cue children into understanding pain and its severity. A child points to a face on the tool, thus simplifying the task of describing the pain. There are ethnic versions of the tool (Fig. 43-7). The FACES scale (Wong and Baker, 1988) assesses pain in verbal children (Fig. 43-8). The scale consists of six cartoon faces ranging from a smiling face ("no hurt") to increasingly less happy faces; to a final sad, tearful face ("hurts worst"). Children as young as 3 years of age use the scale. Nurses use a variety of other tools to assess pain in neonates, infants, nonverbal toddlers, and children with cognitive impairments.

Quality. Because there is no common or specific pain vocabulary in general use, the words patients choose to describe pain vary. Patients of American descent often use *hurt* and *ache* to describe their pain, reserving the word *pain* for severe discomfort. Always use words other than *pain* to obtain an accurate report. For example, you say, "Tell me what your discomfort feels like." The

TABLE 43-5 Classification of Pain by Location

LOCATION	CHARACTERISTICS	EXAMPLES OF CAUSES
Superficial or Cutaneous Pain resulting from stimulation of skin	Pain is of short duration and localized. It usually is a sharp sensation.	Needlestick; small cut or laceration
Deep or Visceral Pain resulting from stimulation of internal organs	Pain is diffuse and radiates in several directions. Duration varies, but it usually lasts longer than superficial pain. Pain is sharp, dull, or unique to organ involved.	Crushing sensation (e.g., angina pectoris); burning sensation (e.g., gastric ulcer)
Referred Common phenomenon in visceral pain because many organs themselves have no pain receptors; entrance of sensory neurons from affected organ into same spinal cord segment as neurons from areas where individual feels pain; perception of pain in unaffected areas	Pain is in part of body separate from source of pain and assumes any characteristic.	Myocardial infarction, which causes referred pain to the jaw, left arm, and left shoulder; kidney stones, which refer pain to groin
Radiating Sensation of pain extending from initial site of injury to another body part	Pain feels as though it travels down or along body part. It is intermittent or constant.	Low back pain from ruptured intravertebral disk accompanied by pain radiating down leg from sciatic nerve irritation



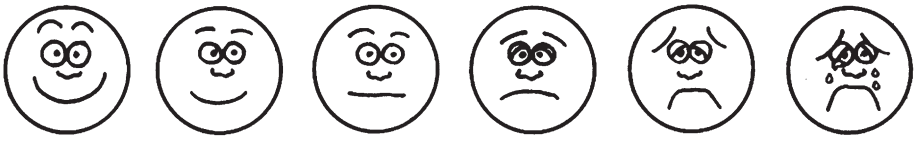


FIG. 43-6 Sample pain scales. **A,** Numerical. **B,** Verbal descriptive. **C,** Visual analogue.

patient likely describes the pain as crushing, throbbing, sharp, or dull. Although a list of descriptive terms is available, it is more accurate to have patients describe the pain in their own words whenever possible.

There is some consistency in the way people describe certain types of pain. The pain associated with a myocardial infarction is often described as crushing or viselike; whereas the pain of a surgical incision is often described as dull, aching, and throbbing, indicating nociceptive pain. Neuropathic pain is usually burning, shooting, or electric-like (Williams, 2006). When a patient's descriptions fit the pattern forming in the assessment, you then make a clearer analysis of the nature and type of pain. This leads to more appropriate pain management because you treat nociceptive and neuropathic pain differently.

FIG. 43-7 Asian girl version of the Oucher pain scale. (The Asian versions of the Oucher [male and female] were developed and copyrighted in 2003 by CH Yeh [University of Pittsburgh] and CH Wang, Taiwan.)

Brief word instructions: Point to each face using the words to describe the pain intensity. Ask the child to choose face that best describes own pain and record the appropriate number.

FIG. 43-8 Wong-Baker FACES pain-rating scale. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.)

Pain Pattern. Various factors affect the pattern of pain. It helps to assess specific events or conditions that precipitate or aggravate pain. Ask the patient to describe activities that cause pain such as physical movement or food. Also ask him or her to demonstrate actions that cause a painful response such as coughing or turning a certain way. For example, with a ruptured intravertebral disk the low back pain usually radiates down the leg to the foot, and bending over or lifting objects aggravates it. Asking the patient if there is a particular time of day that the pain is worse or if the pain is intermittent, constant, or a combination helps you plan interventions to prevent it from occurring or worsening.

Relief Measures. It is useful to know whether a patient has an effective way of relieving pain such as changing position, using ritualistic behavior (pacing, rocking, or rubbing), eating, meditating, praying, or applying heat or cold to the painful site. The patient's methods are ones you can use for treatment. Patients gain trust when they know you are willing to try their relief measures. They also gain a sense of control over the pain instead of the pain controlling them. Assessment of relieving factors includes identification of all the patient's health care providers (e.g., internist, orthopedist, acupuncturist, chiropractor, or dentist).

Contributing Symptoms. Some symptoms (depression, anxiety, fatigue, sedation, anorexia, sleep disruption, spiritual distress, and guilt) cause worsening of pain. You need to assess for these associated symptoms and evaluate their effects on the patient's pain perception. Reporting and treating associated symptoms contributes to successful pain management.

Effects of Pain on the Patient. Pain alters a person's lifestyle and affects psychological well-being. Chronic/persistent pain causes suffering, loss of control, loneliness, disabilities, exhaustion, and impaired quality of life. By recognizing the effects that pain has on patients, you better understand the patient's experience and provide the best pain management. When a patient is in pain, you need to conduct a focused physical and neurological examination and observe for nonverbal responses to pain (e.g., "grimacing, rigid body posture, limping, frowning, or crying") (Pasero and McCaffery, 2011). Examine the painful area to see if palpation or manipulation of the site increases pain.

Behavioral Effects. When a patient has pain, assess verbalization, vocal response, facial and body movements, and social interaction. A verbal report of pain is a vital part of assessment. You need to be willing to listen and understand. Many patients are unable to communicate their pain. An infant or a patient who is unconscious, disoriented or confused, aphasic or who speaks a foreign language is unable to explain the pain experience. In these cases it is especially important for you to be alert for behaviors that indicate pain (Box 43-9).

BOX 43-9 BEHAVIORAL INDICATORS OF EFFECTS OF PAIN

Vocalizations
- Moaning
- Crying
- Gasping
- Grunting

Facial Expressions
- Grimace
- Clenched teeth
- Wrinkled forehead
- Tightly closed or widely opened eyes or mouth
- Lip biting

Body Movement
- Restlessness
- Immobilization
- Muscle tension
- Increased hand and finger movements
- Pacing activities
- Rhythmic or rubbing motions
- Protective movement of body parts
- Grabbing or holding a body part

Social Interaction
- Avoidance of conversation
- Focus only on activities for pain relief
- Avoidance of social contacts
- Reduced attention span
- Reduced interaction with environment

The nonverbal expression of pain either supports or contradicts other information about it. If a woman in labor reports that her labor pains are occurring more frequently and if she begins to massage her abdomen more often, this confirms her report. If a patient reports severe abdominal pain but continues to grasp the chest, a more detailed assessment is necessary.

Influence on Activities of Daily Living. Patients who live with daily pain are less able to participate in routine activities, which results in physical deconditioning. Assessment of these changes reveals the extent of the patient's disability and adjustments necessary to help patients participate in self-care. Your primary goal as a nurse is to improve patient function.

Ask the patient whether pain interferes with sleep. Some patients experience difficulty in falling asleep and/or staying asleep. The pain awakens the patient during the night and makes it hard to fall back to sleep. Consider giving medications or trying nonpharmacological interventions to promote sleep (see Chapter 42). Do not use medications that promote sleep as a substitute for pain relief.

Depending on the location of the pain, some patients have difficulty independently performing ADLs. For example, some pain restricts mobility to the point at which the patient is no longer able to bathe in a bathtub. Patients with severe arthritis find it painful to grasp eating utensils or lower themselves to a toilet seat. Assess the patient's need for assistance with self-care activities and collaborate with members of the health care team (e.g., physical and

BOX 43-10 NURSING DIAGNOSTIC PROCESS

Chronic Pain

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Have patient describe pain intensity.	Pain constant; patient verbally reports 5 on a scale of 0 to 10
Assess onset and location of pain.	Present for 7 months in lower lumbar area
Observe patient behaviors.	Grimaces and grunts with movement, rubs flanks frequently; reduced movement
Assess effect of pain on activities of daily living (ADLs).	Appetite poor; gets little sleep; difficulty dressing
Review medical history.	Previous trauma; effectiveness of past pain control measures

occupational therapy). Also consider the need for family members or friends to assist patients with basic hygiene.

Pain sometimes impairs the ability to maintain normal sexual relations. Include in your assessment the extent to which pain affects the patient's sexual activity. It also helps to learn whether a patient is physically unable to participate or if pain reduces the desire for sexual intercourse.

Pain threatens a person's ability to work. The more physical activity required in a job, the greater the risk of discomfort when the pain is associated with movement. Pain related to emotional stress increases in individuals whose jobs involve stressful decision making. Assess the work that patients do and their abilities to function in their jobs. Assess the daily chores of homemakers in the same manner as the duties involved in jobs outside the home. Also assess whether it is necessary for patients to stop activity occasionally because of pain, and then help them select ways to minimize or control it so they are able to remain productive.

Include an assessment of the effect of pain on social activities. Some pain is so debilitating that the patient becomes too exhausted to socialize. Identify the patient's normal social activities, the extent to which activities have been disrupted, and the desire to participate in these activities.

NURSING DIAGNOSIS

You make an accurate diagnosis only after you have performed a complete assessment. The development of an accurate nursing diagnosis for a patient in pain results from thorough data collection and analysis (Box 43-10). Careful assessment reveals the presence or potential for pain. In addition, examine the patient's history for recent procedures or preexisting painful conditions.

The nursing diagnosis focuses on the specific nature of the pain to identify the most useful types of interventions for alleviating it and improving the patient's function. *Acute pain related to physical trauma* and *acute pain related to natural childbirth processes* require very different nursing interventions. Accurate identification of related factors is necessary in choosing appropriate nursing interventions. For example, interventions for *acute pain related to physical trauma* require pharmacological intervention, whereas *acute pain related to natural childbirth processes* is sometimes managed more appropriately with nonpharmacological interventions such as controlled breathing techniques.

Your assessment often directs you to diagnoses other than that of *acute* or *chronic pain.* The extent to which pain affects a patient's function and general state of health determines whether other nursing diagnoses are relevant. For example, your assessment reveals that a patient has pain of the hands and shoulders as a result of crippling arthritis for over 3 years. As a result the patient is unable to remove or fasten necessary items of clothing. The nursing diagnoses for this patient are *dressing/grooming self-care deficit* and *chronic pain.* The diagnosis of *self-care deficit* requires involvement by members of the interdisciplinary health care team to provide the patient with assistive devices for performing self-care. Examples of other diagnoses that are applicable to patients experiencing pain include the following:

- Activity intolerance
- Anxiety
- Ineffective coping
- Fatigue
- Fear
- Hopelessness
- Impaired physical mobility
- Imbalanced nutrition: less than body requirements
- Insomnia
- Powerlessness
- Chronic low self-esteem
- Impaired social interaction
- Spiritual distress

PLANNING

During the planning step of the nursing process, you synthesize information from multiple resources. Critical thinking ensures that the patient's plan of care (see the Nursing Care Plan) integrates all that you know about the individual patient and key critical thinking elements (Fig. 43-9, p. 978). Professional standards are especially important to consider when you develop a plan of care. These standards establish evidence-based guidelines for selecting effective nursing interventions. Professional standards of care regarding pain management are available as agency policies or through professional organizations such as the American Society for Pain Management Nursing (ASPMN).

Another effective method for planning care is a concept map. Patients who are in pain frequently have interrelated problems. As one problem gets worse, other aspects of a patient's level of health also change. The concept map helps you determine how the nursing diagnoses are interrelated with one another and linked to the patient's medical diagnosis. Using the example here, as you plan care for the patient with rheumatoid arthritis, note the relationships among *acute pain, impaired physical mobility, dressing and feeding self-care deficit,* and *fatigue* (Fig. 43-10). Identifying these relationships helps you develop a holistic and patient-centered plan of care.

Goals and Outcomes. When managing pain, goals of care promote a patient's optimal function. Determine, along with the patient, what the pain has prevented the patient from doing. Then decide on a mutually acceptable level of pain that allows return of function. An indication of the success of the plan is determined through attainment of goals and outcomes. For example, for the goal "the patient will achieve a satisfactory level of pain relief within 24 hours," the following are possible outcomes:

- Reports that pain is a 3 or less on a scale of 0 to 10
- Identifies factors that intensify pain
- Uses pain-relief measures safely
- Level of discomfort does not interfere with ADLs

NURSING CARE PLAN

Acute Pain

ASSESSMENT

Mrs. Mays, 75 years old, was diagnosed with a cancerous tumor in her left lung 2 months ago. She also has a history of osteoarthritis. After chemotherapy and radiation therapy, she took ibuprofen (Advil) 200 mg on an as-needed (prn) basis. Until today she was able to clean her home and climb the stairs to her bedroom without difficulty. She also maintained her body weight and slept well through the night. However, she is now admitted to the hospital with uncontrollable chest pain and possible pneumonia. Her husband is with her. The nurse begins a patient-controlled analgesia (PCA) of morphine 0.5 mg demand dose with a 10-minute lockout.

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Mays what she did at home to control her pain.	Her **pain escalated** from a 3 to a 10 on a scale of 0 to 10, so she doubled her medication and went to bed; but this did not help.
Ask Mrs. Mays what her pain intensity is now.	On a scale of 0 to 10, **she reports a 9.**
Ask Mrs. Mays what her pain has prevented her from doing.	She responds that she is **unable to complete her own hygiene activities, sleep, or eat well.**
Observe Mrs. Mays's nonverbal behavior.	She is **restless,** is **unable to stay focused,** her **muscles tense, and** she is **frowning** during the history taking.
Ask Mrs. Mays her pain-intensity goal (on a scale of 0 to 10).	She says that a pain intensity of 5 on a scale of 10 helps her function better right now. A goal of 3 is preferable.

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Acute pain related to abrupt onset of inflammation

PLANNING

Goals	*Expected Outcomes (NOC)†*
Mrs. Mays will reach a tolerable level of pain before discharge.	**Pain Control** Mrs. Mays will report pain at target goal of 3 or below. Mrs. Mays uses PCA device appropriately.
Mrs. Mays will actively participate in activities of daily living (ADLs).	**Pain: Disruptive Effects** Mrs. Mays will report sleeping for 5 to 6 hours without interruption from pain. Mrs. Mays will complete her own hygiene with minimal assistance. Mrs. Mays will walk the hallway with her husband every 4 hours for 15 minutes.
Mrs. Mays will not experience unmanageable opioid side effects.	**Medication Response** Mrs. Mays will report having a normal bowel movement every other day.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡ *Pain Management*	RATIONALE
Begin PCA at ordered dose. Explain to patient and spouse how to use the PCA. Emphasize the importance of only the patient pushing the button, not the husband.	Acute cancer pain rated a 7 (or more) on a scale of 0 to 10 requires immediate-release opioid. Discouraging the husband from pushing the button prevents unnecessary doses and reduces potential toxic effects of the opioid. Patient needs to be awake to perceive the pain and push the button (Pasero and McCaffery, 2011).
Monitor IV PCA morphine use. Explain to patient and spouse the action of the medication, potential side effects, and the importance of reporting unrelieved pain.	Pain is easier to prevent than to treat. Side effects are usually transient, except for constipation. Calculating 24-hour dosage of opioid helps determine appropriate oral dose (Pasero and McCaffery, 2011).
Have patients select nonpharmacological interventions that have relieved pain in the past (e.g., distraction, music, simple relaxation therapy) or that are acceptable to them.	Nonpharmacological approaches augment pharmacological therapy and help patients improve quality of life and decrease anxiety and depression (Chen and Francis, 2010).
Teach spouse how to perform slow-stroke back massage.	Slow-stroke back massage is easy to do, takes a brief time, and induces relaxation (Walters, 2010).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

NURSING CARE PLAN

***Acute Pain*—cont'd**

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Ask Mrs. Mays if she attained her pain relief goal most of the time.	She responds, "My pain usually runs around a 3, except when I start walking."	Mrs. Mays reports an acceptable level of pain. Instruct her to push her button before ambulating.
Observe Mrs. Mays performing ADLs, walking, and during sleep.	Mrs. Mays is dressed for breakfast, walking the hallway every 4 hours with her husband. The night nurse's notes indicate that she slept through the night.	Ability to perform ADLs and sleep has improved. Continue to monitor.
Observe Mrs. Mays as she ambulates in the hallway.	Mrs. Mays successfully ambulated in the hallway with her husband twice during the shift with minimal increase in pain intensity.	Improved pain control increased her activity, a nonverbal indicator of pain. Continue to monitor.
Ask Mr. Mays if he was able to give his wife a back rub.	Mr. Mays reported that she did not want a back rub but preferred to have her feet rubbed, which he was happy to do. "She said it made her feel more relaxed."	Nonpharmacological intervention was successful but needs to be changed from back rub to foot rub in the nursing care plan.
Ask Mrs. Mays when she last had a bowel movement and its consistency.	She has not had a bowel movement in 3 days (since starting the morphine PCA).	Assess her abdomen for bowel sounds and distention and return of flatus. Consult with health care provider about starting a stimulant laxative once intestinal obstruction is ruled out (Pasero and McCaffery, 2011).
Observe Mrs. Mays for excessive drowsiness.	Mrs. Mays is awake and alert during conversations and interacts frequently with her husband.	Sedation, an indicator of too much opioid, is not identified. Continue to monitor.

Setting Priorities. When setting priorities in pain management, consider the type of pain the patient is experiencing and the effect that it has on various body functions. Work with the patient to select interventions that are appropriate. For example, if an analgesic relieves acute pain, center your attention on how the pain is affecting your patient's activity, appetite, and sleep. In contrast, when a patient's pain continues to be severe, preventing you from implementing other interventions, immediate pain relief is the obvious priority. Your priorities change as a patient's pain experience changes.

Teamwork and Collaboration. A comprehensive plan includes a variety of resources for pain control. Resources available include advanced practice nurses, doctors of pharmacology (PharmDs), physical therapists, occupational therapists, and clergy. An oncology or pain clinical nurse specialist is very familiar with pharmacological and nonpharmacological interventions that are most effective for chronic/persistent pain. PharmDs are knowledgeable about pharmacological treatments of pain. Physical therapists plan exercises that strengthen muscle groups and lessen pain in affected areas. Occupational therapists devise splints to support painful body parts. Clergy members help patients focus on spiritual health. It is important to involve the family in the plan of care because they often administer care in the home after discharge. If the pain-management plan is not successful in achieving the identified pain relief goal, talk with the patient's health care provider about revising it. Consultation with a pain expert is sometimes necessary.

IMPLEMENTATION

Pain therapy requires an individualized approach, perhaps more so than any other patient problem. The nurse, patient, and frequently the family are partners in pain management. Nurses administer and monitor interventions ordered by health care providers for pain relief in addition to complementary pain-relief measures. Usually you try the least invasive or safest therapy first along with previously used successful patient remedies. If there is a question about a medical therapy, consult with the health care provider.

Health Promotion. Patients are better prepared to handle almost any situation when they understand it. The experience of pain is no exception. However, patients with moderate-to-severe pain are not always able to participate in the decision-making process until the pain is controlled at an acceptable level. Once you accomplish this, you are able to begin teaching.

Because pain affects physical and mental functioning, holistic health approaches are important interventions for maintaining wellness. Holistic health is an ongoing state of wellness that involves taking care of the physical self, expressing emotions appropriately and effectively, using the mind constructively, being creatively involved with others, and becoming aware of higher levels of consciousness (American Holistic Health Association, 2007). The concept of holistic health parallels the values of nursing in maintaining the integrity of the whole person.

Patients actively participate in their own well-being whenever possible. Common holistic health approaches include wellness education, regular exercise, rest, attention to good hygiene practices and nutrition, and management of interpersonal relationships. When a person develops pain, you can offer nonpharmacological and pharmacological strategies. Several of the nonpharmacological interventions are nurse initiated.

Nonpharmacological Pain-Relief Interventions. A number of nonpharmacological interventions lessen pain; however, they are to be used *with,* and not in place of, pharmacological measures (Gruener and Lande, 2006; Hughes, 2008). Nonpharmacological interventions include cognitive-behavioral and physical approaches. Cognitive-behavioral interventions change patients' perceptions of

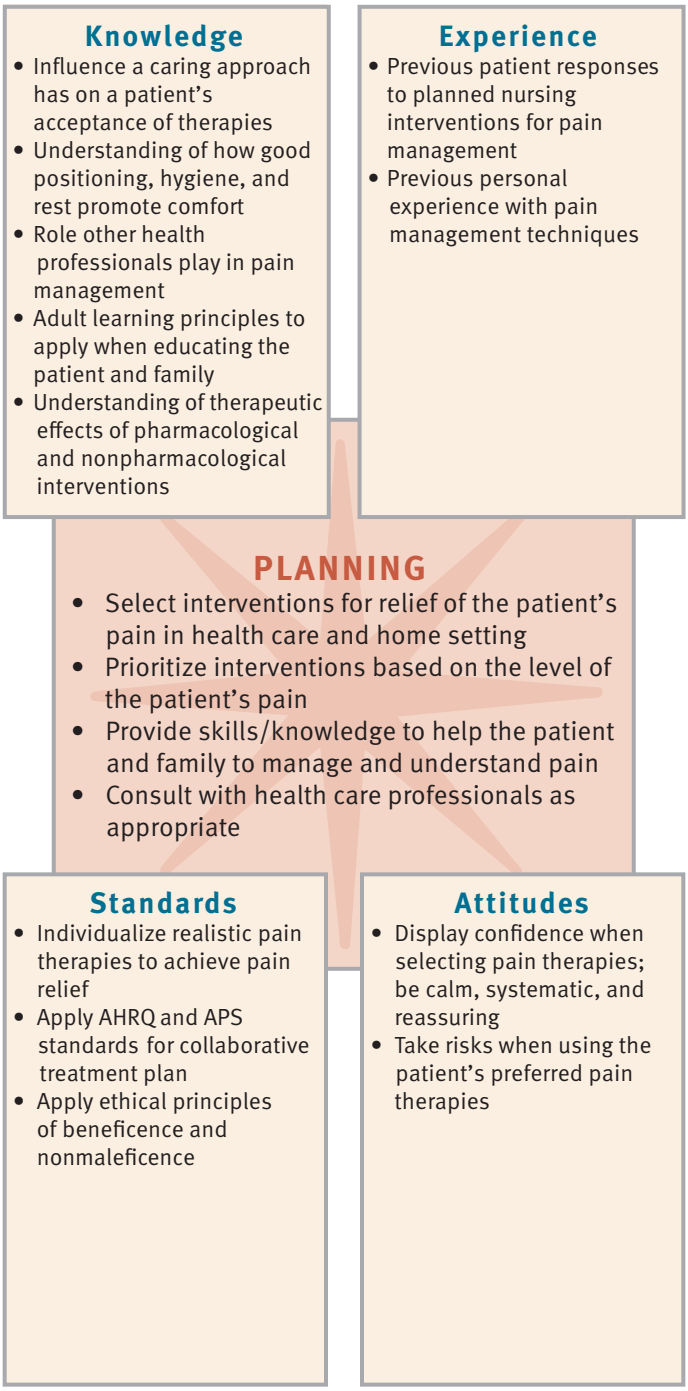

FIG. 43-9 Critical thinking model for pain management planning. *AHRQ,* Agency for Healthcare Research and Quality; *APS,* American Pain Society.

pain, alter pain behavior, and provide patients with a greater sense of control. Distraction, prayer, relaxation, guided imagery, music, and **biofeedback** are examples. Physical approaches aim to provide pain relief, correct physical dysfunction, alter physiological responses, and reduce fears associated with pain-related immobility. Chiropractic therapy and acupuncture/acupressure therapy are examples (see Chapter 32). Complementary and alternative medicine (CAM) therapies such as therapeutic touch also help to alleviate pain in some patients. The Agency for Health Care Policy and Research guidelines for acute pain management (AHCPR, 1992) cite nonpharmacological interventions to be appropriate for patients who meet the following criteria:

- Find such interventions appealing
- Express anxiety or fear
- Possibly benefit from avoiding or reducing drug therapy
- Are likely to experience and need to cope with a prolonged interval of postoperative pain
- Have incomplete pain relief after use of pharmacological interventions

Relaxation and Guided Imagery. Relaxation and **guided imagery** allow patients to alter affective-motivational and cognitive pain perception. **Relaxation** is mental and physical freedom from tension or stress that provides individuals a sense of self-control. You use relaxation techniques at any phase of health or illness. Physiological and behavioral changes associated with relaxation include the following: decreased pulse, blood pressure, and respirations; heightened awareness; decreased oxygen consumption; a sense of peace; and decreased muscle tension and metabolic rate. Relaxation techniques include meditation, yoga, Zen, guided imagery, and progressive relaxation exercises (see Chapter 32). For effective relaxation, teach techniques only when a patient is not distracted by acute discomfort. Sometimes you need to use a combination of these techniques to achieve optimal pain relief. With practice the patient performs relaxation exercises independently.

Distraction. The reticular activating system inhibits painful stimuli if a person receives sufficient or excessive sensory input. With sufficient sensory stimuli, a person ignores or becomes unaware of pain. Persons who are bored or in isolation have only their pain to think about and thus perceive it more acutely. Distraction directs a patient's attention to something other than pain and thus reduces awareness of it. One disadvantage of distraction is that, if it works, health care providers or family members question the existence or severity of the pain. Distraction works best for short, intense pain lasting a few minutes such as during an invasive procedure or while waiting for an analgesic to work. Use activities enjoyed by the patient as distractions (e.g., singing, praying, listening to music, humor or laughter therapy, playing games).

Music. Music treats acute or chronic pain, stress, anxiety, and depression (Allred et al., 2010). It diverts a person's attention away from the pain and creates a relaxation response. Music therapy uses all kinds of music. It is important to let patients select the type of music they prefer. Music produces an altered state of consciousness through sound, silence, space, and time. Therapeutic sessions usually last 20 to 30 minutes (Hughes, 2008). Patients use earphones to enhance their concentration on the music. This allows patients to adjust the volume of the music without interrupting other patients or staff. Evidence shows that music decreases the use of analgesics in some postoperative patients (Engwall and Duppils, 2009).

Cutaneous Stimulation. Stimulation of the skin helps relieve pain. A massage, warm bath, ice bag, and transcutaneous electrical nerve stimulation (TENS) stimulate the skin to reduce pain perception (Pain Management Center Staff, 2002). How **cutaneous stimulation** works is unclear. One suggestion is that it causes release of endorphins, thus blocking the transmission of painful stimuli. The gate-control theory suggests that cutaneous stimulation activates larger, faster-transmitting A-beta sensory nerve fibers. This closes the gate, thus decreasing pain transmission through small-diameter C fibers (Melzack and Wall, 1965).

Cutaneous stimulation gives patients and families some control over pain symptoms and treatment in the home. Using it properly helps to reduce muscle tension, resulting in less pain. When using

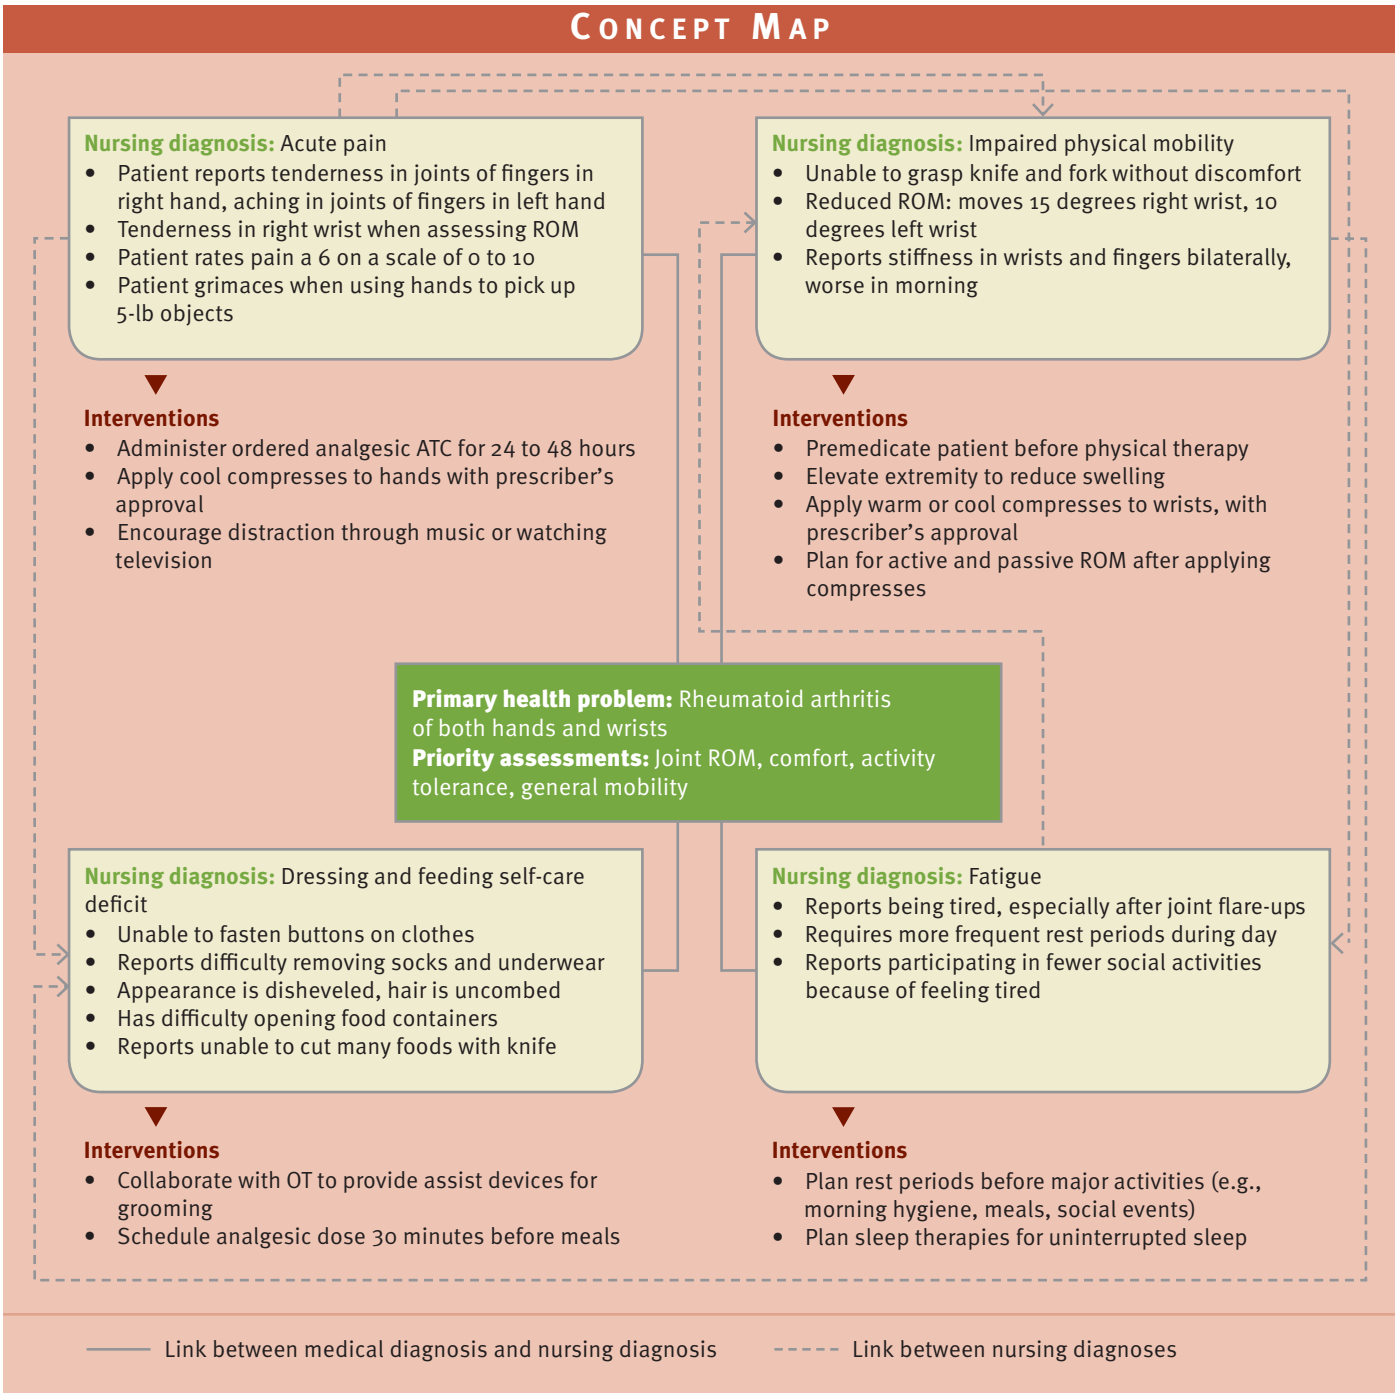

FIG. 43-10 Concept map for Mrs. Mays. *ATC,* Around the clock; *OT,* occupational therapist; *ROM,* range of motion.

cutaneous stimulation, eliminate sources of environmental noise, help the patient to assume a comfortable position, and explain the purpose of the therapy. Do not use it directly on sensitive skin areas (e.g., burns, bruises, skin rashes, inflammation, and underlying bone fractures).

Massage is effective for producing physical and mental relaxation, reducing pain, and enhancing the effectiveness of pain medication. Massaging the back, shoulders, hands, and/or feet for 3 to 5 minutes relaxes muscles and promotes sleep and comfort. Cutshall et al. (2010) reported a significant decrease in pain, anxiety, and tension in patients with cardiac problems who received a 20-minute massage. In older adults slow back massage and a 20-minute hand massage improved pain, anxiety, tension, and insomnia (Harris and Richards, 2010). Massages communicate caring and are easy for family members or other health care personnel to learn (Box 43-11).

Cold and heat applications (see Chapter 48) relieve pain and promote healing. The selection of heat versus cold interventions varies with patients' conditions (McCarberg and O'Connor, 2004). For example, moist heat helps to relieve the pain from a tension headache, and cold applications reduce the acute pain from inflamed joints. When using any form of heat or cold application,

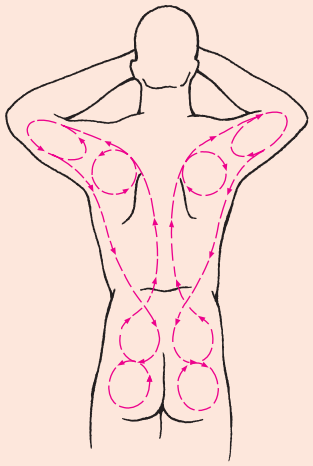
BOX 43-11 PROCEDURAL GUIDELINES

Massage

Delegation Considerations

The skill of administering a massage may be delegated to nursing assistive personnel (NAP). However, the nurse must first assess for any possible contraindication and evaluate the patient's response to massage. Direct the NAP to:

- Use massage techniques that are effective with the patient.
- Massage specific body parts.
- Avoid massaging reddened skin areas.
- Notify the nurse of early signs of impaired skin integrity.
- Report changes in the skin appearance.
- Report a worsening in the patient's pain.



Equipment

Bath towel, lotion, bath towel or blanket.

1. Based on patient assessment, decide on performing massage on one or more body parts.
2. Assess skin areas for reddened areas or impaired skin integrity.
3. Collect appropriate equipment.
4. Explain procedure to the patient.
5. Verify patient's identity by using at least two patient identifiers. Compare patient's name and one other identifier such as hospital identification number, according to facility policy.
6. Perform hand hygiene.
7. Help patient assume a comfortable lying or sitting position.
8. Dim room lights and/or turn on soft music according to patient preference.
9. Use warm body lotion as lubricant.

CLINICAL DECISION: *Do not give back or neck massages to patients who have had neck or spinal trauma and/or surgery without an order from their health care provider.*

10. Massage each body part at least 10 minutes.
    a. *Back:* Begin at the sacral area and massage in a circular motion (see illustration) while moving upward from buttocks to shoulders. Use a firm smooth stroke over the scapula. Continue in one smooth stroke to upper arms and laterally along sides of back down to iliac crests. Use long, gliding strokes along muscles of spine. Knead any muscles that feel tense or tight. Knead skin by gently grasping tissue between thumb and fingers. Knead upward along one side of spine from buttocks to shoulders around nape of neck. Knead or stroke downward toward sacrum. Repeat along other side of the back.
    b. *Neck:* Support neck at the hairline with one hand and massage up with a gliding stroke. Knead muscles on one side. Switch hands to support neck and knead other side. Stretch neck slightly, with one hand at top and the other at bottom.
    c. *Arms:* Use gliding stroke to massage from patient's wrist or forearm. With thumb and forefinger of both hands, knead muscles from forearm to shoulder. Continue kneading biceps, deltoid, and triceps muscles. Finish with gliding strokes from wrists to shoulder.
    d. *Hands:* Using both hands, slowly open patient's palm; glide fingers over palmar surface. While supporting the patient's hand, use both thumbs to apply friction to palm and move thumbs in a circular motion to stretch palm outward. Massage each finger using a corkscrew-like motion from base of finger to tip. With thumb and forefinger gently knead each muscle in the patient's fingers. Glide hands smoothly from fingertips to wrists. Repeat for other hand.
    e. *Feet:* Gently massage top and bottom of each foot. Using gliding motion, massage from heel to toe. Gently massage dorsal surface of foot and each toe. Repeat for other foot.

STEP 10a Back massage pattern.

CLINICAL DECISION: *Do not massage patient's legs or calf muscles because there is a risk of dislodging a vascular clot.*

11. At end of massage have patient relax, taking slow, deep breaths.
12. Ask patient to rate level of pain.
13. Note any areas of muscle pain or tension.
14. Note any areas of redness or impairment.

instruct the patient to avoid injury to the skin by checking the temperature and not applying cold or heat directly to the skin. Especially at risk are patients with spinal cord or other neurological disorders, older adults, and patients who are confused.

Cold therapies are particularly effective for pain relief. Ice massage involves the use of a large ice cube or a small paper cup filled with water and frozen (water rises out of the cup as it freezes to create a smooth surface of ice for massage). A nurse or the patient applies the ice with firm pressure to the skin, which is covered with a lightweight cloth. Then you use a slow, steady, circular massage over the area. You apply cold near the pain site, on the opposite side of the body corresponding to the pain site, or on a site located between the brain and the pain site. Each patient responds differently to the site of application. Application near the actual site of pain tends to work best. A patient feels cold, burning, and aching sensations and numbness. When numbness occurs, remove the ice for usually 5 to 10 minutes. Cold is effective for tooth or mouth pain when you place the ice on the web of the hand between the thumb and index finger. This point on the hand is an **acupressure** point that influences nerve pathways to the face and head. Cold applications are also effective before invasive needle punctures.

Heat application is more effective for some patients. You use heating pads, warm compresses, or commercial pillows that are warmed in the microwave. Teach patients to check the temperature of the compress and not to lie on the heating element, because burning can occur.

BOX 43-12 CONTROLLING PAINFUL STIMULI IN THE PATIENT'S ENVIRONMENT

- Tighten and smooth wrinkled bed linen.
- Reposition patient to avoid lying on tubing (e.g., IV tubing, chest tubes).
- Loosen constricting bandages (unless specifically applied as a pressure dressing).
- Change wet dressings and linens.
- Position patient in anatomical alignment according to individual preference or requirements.
- Check temperature of hot or cold applications, including bath water.
- Lift patient in bed—do not pull.
- Position patient correctly on bedpan.
- Avoid exposing skin or mucous membranes to irritants (e.g., urine, stool, wound drainage).
- Keep patients clean, dry, and turned if needed. Use urinary incontinence pads if indicated.
- Prevent urinary retention by keeping Foley catheters patent and free flowing while also monitoring urinary output.
- Prevent constipation with fluids, diet, exercise, and stimulant laxatives if needed.

Another form of cutaneous stimulation is **transcutaneous electrical nerve stimulation (TENS),** involving stimulation of the skin with a mild electrical current passed through external electrodes (Melzack and Wall, 2003). The therapy requires an order from a health care provider. The TENS unit consists of a battery-powered transmitter, lead wires, and electrodes. Place the electrodes directly over or near the site of pain. Remove any hair or skin preparations before attaching the electrodes. The patient turns the transmitter on when feeling pain. This creates a buzzing or tingling sensation. The patient adjusts the intensity and quality of skin stimulation and applies the tingling sensation until pain relief occurs. TENS is effective for postsurgical and procedural pain control.

Herbals. Many patients use herbals such as echinacea, ginseng, ginkgo biloba, and garlic supplements despite a lack of evidence supporting their use in pain relief (Wirth et al., 2005). Herbals often interact with prescribed analgesics; thus ask patients to report all substances they take to relieve pain (Yoon and Schaffer, 2006) (see Chapter 32).

Reducing Pain Perception. One simple way to promote comfort is to remove or prevent painful stimuli (Box 43-12). This is especially important for patients who are immobilized or have difficulty expressing themselves. For example, your patient becomes constipated and has abdominal distention and cramping. As the nurse you intervene to ensure that the normal elimination process continues: increasing fluids, ambulating the patient, and/or requesting stool softeners or laxatives. Another example involves reducing pain perception in the way you perform procedures. Always consider the patient's condition, aspects of the procedure that are uncomfortable, and techniques to avoid causing pain. In a patient with severe arthritic knee pain who has severe discomfort during any extreme flexion of the knee, take precautions before walking the patient to the bathroom. Use an elevated toilet seat to allow the patient to sit and rise with minimal discomfort.

Acute Care

Acute Pain Management. Nurses often care for patients who have acute pain resulting from invasive procedures (e.g., surgery) or trauma. The AHCPR established a pain treatment flow chart in 1992 that is still used today (Fig. 43-11) for treatment of postoperative pain and pain from medical procedures and trauma. This systematic approach ensures quick caregiver response to patient discomfort. The key to success is ongoing evaluation of interventions: Does the patient feel relief? Are there any unacceptable side effects from the medications? It is the responsibility of the health care team to collaborate to find the combination of therapy that works best for a patient.

Pharmacological Pain-Relief Interventions. Many pharmacological agents are available to provide pain relief. A nurse's judgment in the use and management of analgesics helps ensure the best pain relief possible. Unfortunately the ideal analgesic has yet to be developed.

Analgesics. **Analgesics** are the most common and effective method of pain relief. However, health care providers and nurses still tend to undertreat patients because of incorrect drug information, concerns about addiction, anxiety over errors in using opioid analgesics, and administration of excessive medication. You need to understand the drugs available for pain relief and their pharmacological effects.

There are three types of analgesics: (1) nonopioids, including acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs); (2) **opioids** (traditionally called *narcotics);* and (3) **adjuvants,** a variety of medications that enhance analgesics or have analgesic properties that were originally unknown (Pasero and McCaffery, 2011).

Acetaminophen (Tylenol) is considered one of the most tolerated and safest analgesics available. It has no antiinflammatory effects, and its action is unknown. Its major adverse effect is hepatotoxicity. It is in a variety of over-the-counter (OTC) cold, flu, and allergy remedies. The maximum 24-hour dose is 4 g (the same dose limitation for aspirin). It is often combined with opioids (e.g., Percocet [oxycodone], Vicodin [hydrocodone], Lortab [hydrocodone], and Ultracet [tramadol]) because it reduces the dose of opioid needed to achieve successful pain control. You treat overdoses of acetaminophen with acetylcysteine (Mucomyst) (Pasero and McCaffery, 2011).

Nonselective NSAIDs such as aspirin and ibuprofen provide relief for mild-to-moderate acute intermittent pain such as the pain associated with a headache or muscle strain. Treatment of mild-to-moderate postoperative pain begins with an NSAID unless contraindicated (Pasero and McCaffery, 2011). NSAIDs most likely inhibit the synthesis of prostaglandins (Lehne, 2010) and thus inhibit cellular responses to inflammation. Most NSAIDs act on peripheral nerve receptors to reduce transmission of pain stimuli and inflammation. Unlike opioids, NSAIDs do not depress the central nervous system, nor do they interfere with bowel or bladder function (Pasero and McCaffery, 2011). However, chronic NSAID use in the older patient is not recommended because it is associated with more frequent adverse effects (gastrointestinal bleeding and renal insufficiency). Mild-to-moderate musculoskeletal pain in older adults is effectively managed with the acetaminophen (AGS, 2002; Pasero and McCaffery, 2011). Some patients with asthma or an allergy to aspirin are also allergic to other NSAIDs (Kaufman, 2010). Some NSAIDs are available over-the-counter (OTC); thus advise patients to discuss the use of OTC NSAIDs to manage pain with their health care provider (D'Arcy, 2006).

Current evidence shows nonselective NSAIDs are safe when taken for short periods. Some patients who took selective COX-2 inhibitors for longer periods experienced heart attacks and strokes; thus Celebrex is the only selective COX-2 inhibitor currently available. The rest are no longer available on the market. Celebrex is not to be used in patients with a sulfa allergy.

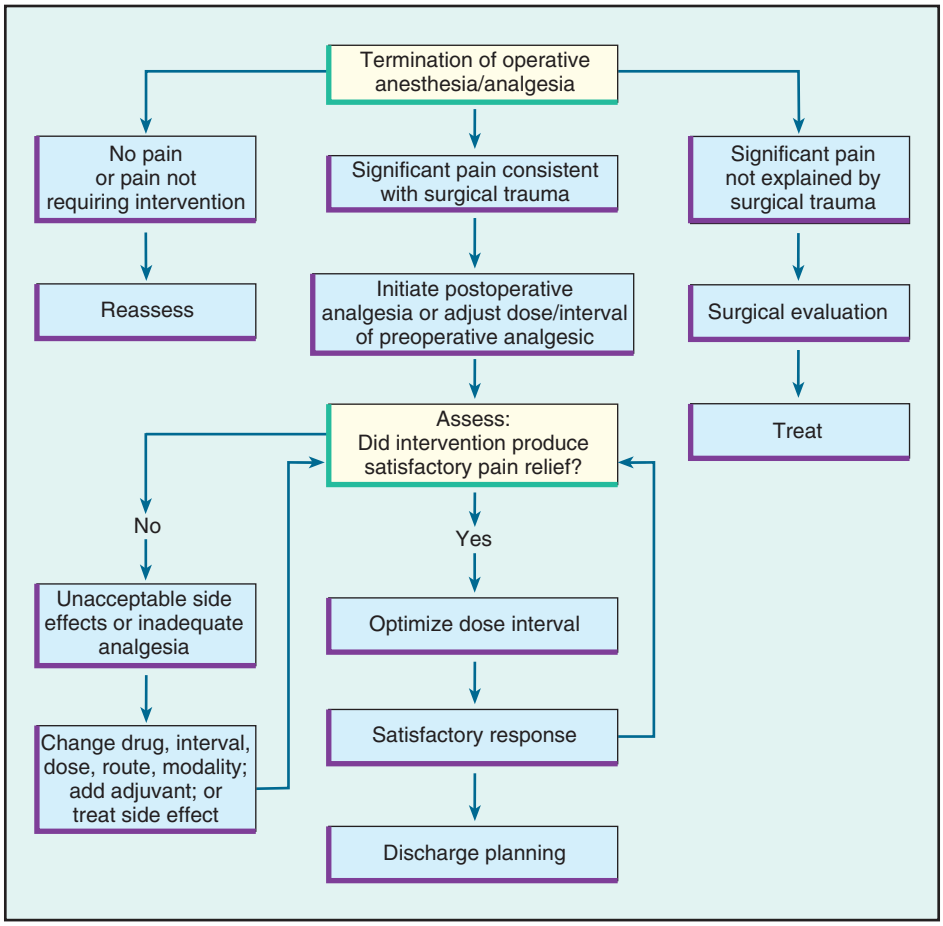


FIG. 43-11 Pain treatment flow chart: postoperative phase. (From Agency for Health Care Policy and Research, Acute Pain Management Guideline Panel: *Acute pain management: operative or medical procedures and trauma,* Clinical Practice Guideline, AHCPR Pub No. 92-0032, Rockville, Md, 1992, Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services.)

Opioid or opioid-like analgesics are generally prescribed for moderate-to-severe pain. These analgesics act on higher centers of the brain and spinal cord by binding with opiate receptors to modify perceptions of pain. A rare adverse effect of opioids in opioid-naive patients is respiratory depression. Respiratory depression is only clinically significant if there is a decrease in the rate *and* depth of respirations from the patient's baseline assessment (Pasero and McCaffery, 2011). Patients who are breathing deeply rarely have clinical respiratory depression. Sedation, another adverse effect of opioids, *always* occurs before respiratory depression. Thus closely monitor for sedation in opioid-naive patients (Pasero and McCaffery, 2011).

If a patient experiences respiratory depression, administer naloxone (Narcan) (0.4 mg diluted with 9 mL saline) intravenous push (IVP) at a rate of 0.5 mL every 2 minutes until the respiratory rate is greater than 8 breaths/min with good depth. Administering naloxone faster than recommended possibly causes severe pain and serious complications (Pasero and McCaffery, 2011). Reassess patients who receive naloxone every 15 minutes for 2 hours following drug administration because its duration is less than that of the opioid and respiratory depression sometimes returns.

Additional adverse effects of opioids include nausea, vomiting, constipation, itching, urinary retention, myoclonus, and altered mental processes (Ersek et al., 2004). Except for constipation, these side effects usually stop once a patient receives an opioid around the clock (ATC) for 4 to 10 days. Consider patients to be opioid naive until this point and opioid tolerant after about a week of ATC opioid dosing.

One way to maximize pain relief while potentially decreasing drug use is to administer analgesics on an ATC rather than a prn basis. The American Pain Society (APS, 2003) supports ATC administration if pain is anticipated for the majority of the day.

According to the American Geriatrics Society (AGS, 2002), opioids are probably not used enough with older persons. The AGS suggests a "start-low" (dose) and "go-slow" (upward dose titration) philosophy. Furthermore, do not use meperidine in older adults (AGS, 2002; Pasero and McCaffery, 2011). Meperidine (Demerol) is not recommended as an analgesic at any age because of its toxic metabolite, normeperidine, which causes seizures (APS, 2003; Pasero and McCaffery, 2011).

The proper use of analgesics requires careful assessment and critical thinking in the application of pharmacological principles and logic (Box 43-13). A person's response to an analgesic is highly individualized. If the pain is caused by inflammation, an NSAID is sometimes as effective as, or more effective than, an opioid. An orally administered analgesic usually has a longer onset

BOX 43-13 NURSING PRINCIPLES FOR ADMINISTERING ANALGESICS

Know Patient's Previous Response to Analgesics

- Determine whether patient has allergies.
- Know whether patient is at risk for using NSAIDs (e.g., history of GI bleeding or renal insufficiency) or opioids (e.g., history of obstructive or central sleep apnea).
- Identify previous doses and routes of analgesic administration to avoid undertreatment.
- Determine whether patient obtained relief.
- Ask whether a nonopioid was as effective as an opioid.

Select Proper Medications When More Than One Is Ordered

- Use nonopioid analgesics or opioid combination drugs for mild-to-moderate pain.
- You can give opioids with nonopioids.
- In older adults avoid combinations of opioids.
- Fentanyl patches, morphine, or hydromorphone are opioids of choice for long-term management of severe pain.
- Intravenous medications act more quickly and usually relieve severe, acute pain within 1 hour; whereas oral medications take as long as 2 hours to relieve pain.
- Avoid intramuscular analgesics, especially in older adults.
- Use an opioid with a nonopioid analgesic for severe pain because such combinations treat pain peripherally and centrally.
- For chronic pain give sustained-release oral formulations ATC.

Know Accurate Dosage

- Recall that 4 g is considered the maximum 24-hour dosage for acetaminophen and acetylsalicylic acid (ASA); 3200 mg for ibuprofen.
- Adjust doses as appropriate for children and older patients.
- Large doses of opioids are acceptable in opioid-tolerant patients, but not opioid-naive patients.
- When titrating opioids it is important to titrate to effect or to uncontrollable side effects.

Assess Right Time and Interval for Administration

- Administer analgesics as soon as pain occurs and before it increases in severity.
- An ATC administration schedule is usually best.
- Give analgesics before pain-producing procedures or activities.
- Know the average duration of action for a drug and the time of administration so the peak effect occurs when the pain is most intense.
- Use extended-release opioid formulations to treat chronic pain.
- Avoid abruptly stopping opioids in patients who are opioid tolerant.

Modified from Pasero, C. McCaffery M: *Pain assessment and pharmacological management,* St Louis, 2011, Mosby.
ATC, Around the clock; *GI,* gastrointestinal; *NSAIDs,* nonsteroidal antiinflammatory drugs.

and duration of action than an injectable form. In addition, controlled- or extended-release opioid formulations (morphine [MS Contin, Kadian, Avinza], oxycodone [OxyContin], and methadone) are available for administration every 8 to 12 hours ATC; they are not ordered prn.

You need to know the comparative potencies of analgesics in oral and injectable form. In addition, know the route of administration most effective for a patient so controlled, sustained pain relief is achieved. If nurses on succeeding shifts choose different routes for the same dose, the patient does not receive the same level of analgesia; and pain control will be poor. Equianalgesic charts (i.e., charts converting one opioid to another or parenteral forms of opioids [e.g., morphine to hydromorphone] to oral forms ([or vice versa]) are available on most nursing units or by contacting pharmacy staff.

Before administering opioids, it is important to consider a patient's situation, including current treatments, diseases/conditions, and/or organ (kidneys/liver) function. Opioid doses often need to be adjusted up or down according to patient circumstances. Situations requiring special considerations include breastfeeding mothers, patients on dialysis, those with neurological or respiratory conditions, and patients with recent abdominal surgery.

The Joint Commission requires health care agencies to have range-order policies in place to guide nurses in selecting the most appropriate dose of a medication. "Range orders are medication orders in which the dose varies over a prescribed range depending on the situation or the patient's status" (Manworren, 2006). An example is "Administer 5 to 10 mg morphine sulfate IVP for acute pain." Such an order is dangerous when there are no clinical guidelines to use for selecting the exact dose. Range orders give nurses the flexibility needed to treat patients' pain in a timely way while allowing for differences in patient response to pain and analgesia. Safe and effective range orders consider the patient's age, pain intensity, and co-morbidities; avoid frequency ranges; and prescribe a maximum dose that is at least two times but not more than four times the minimum dose in the range (Pasero et al., 2007; ASPMN, 2004).

Adjuvants are drugs originally developed to treat conditions other than pain but also have analgesic properties. For example, tricyclic antidepressants (e.g., nortriptyline [Pamelor]), anticonvulsants (e.g., gabapentin [Neurontin]), and infusional lidocaine successfully treat neuropathic pain. Corticosteroids relieve pain associated with inflammation and bone metastasis. Other examples of adjuvants are bisphosphonates and calcitonin given for bone pain (Pasero and McCaffery, 2011).

Sedatives, antianxiety agents, and muscle relaxants have *no* analgesic effect; however, they often cause drowsiness and impaired coordination, judgment, and mental alertness and contribute to respiratory depression. It is important to avoid attributing these adverse effects solely to opioids.

Patient-Controlled Analgesia. When patients depend on nurses for prn analgesia, an erratic cycle of alternating pain and analgesia often occurs. The patient feels pain and asks for medication, but you must first assess the patient and then prepare the medication. Under this circumstance analgesia finally occurs in about an hour, but pain relief may last only 30 minutes. Gradually the patient again feels discomfort, and the cycle begins again. The patient is constantly going in and out of analgesic therapeutic range.

A drug delivery system called **patient-controlled analgesia (PCA)** is a safe method for pain management that many patients prefer (Skill 43-1 on pp. 990-992). It is a drug delivery system that allows patients to self-administer opioids (morphine, hydromorphone, and fentanyl) with minimal risk of overdose. The goal is to maintain a constant plasma level of analgesic to avoid the problems of prn dosing. Systemic PCA traditionally involves IV or subcutaneous drug administration; however, a controlled analgesia device for oral medications, Medication on Demand (MOD), is now available. This device allows patients access to their own oral prn mediations, including opioids and other analgesics, antiemetics, and anxiolytics, at the bedside (Avancen, 2006).

FIG. 43-12 Patient-controlled analgesia pump with cassette. (Courtesy of Smiths Medical ASD, Inc, St Paul, Minn.)

PCA infusion pumps are portable and computerized and contain a chamber for a syringe or bag that delivers a small, preset dose of opioid (Fig. 43-12). To receive a demand dose, the patient pushes a button attached to the PCA device. Systems are designed to deliver a specified number of doses every 1 to 4 hours (depending on the pump settings) given every 5 to 15 minutes (programmable) to avoid overdoses (APS, 2003). Most pumps have locked safety systems that prevent tampering by patients or family members and are generally safe to be managed in the home. For patients with cancer pain, a low-dose continuous infusion (basal rate) of 0.5 to 1 mg/hr is sometimes programmed to deliver a steady dose of continuous medication (Pasero and McCaffery, 2011).

There are many benefits to PCA use. The patient gains control over pain, and pain relief does not depend on nurse availability. Patients also have access to medication when they need it. This decreases anxiety and leads to decreased medication use. Small doses of medications are delivered at short intervals, stabilizing serum drug concentrations for sustained pain relief.

Patient preparation and teaching is critical to the safe and effective use of PCA devices (Box 43-14). Patients need to understand PCA and be physically able to locate and press the button to deliver the dose. Be sure to instruct family members not to "push the button" for the patient. Use Authorized Agent Controlled Analgesia (AACA) guidelines to *authorize* a family member or nurse to administer the analgesic, when appropriate (Wuhrman et al., 2006).

Check the IV line and PCA device per institutional policy to ensure proper functioning. Even though patients control administration of analgesics, diligence of the nurse is needed to prevent errors related to programmable PCA devices. In opioid-naive patients, do not increase demand or basal dose *and* shorten the interval time simultaneously because this increases the risk for oversedation and respiratory depression. Document drug dosages and track medication wastes according to agency policy (Pasero and McCaffery, 2011). PCA basal doses are *not* recommended for opioid-naive patients following surgery because of the possibility for respiratory depression.

BOX 43-14 PATIENT TEACHING

Patient-Controlled Analgesia

Objective

- Patient achieves pain control with proper use of the patient-controlled analgesia (PCA) device.

Teaching Strategies

- Teach the use of PCA before procedures so patient understands how to use it after awakening from anesthesia or sedation. Reinforce as needed.
- Instruct patient in the purpose of PCA, emphasizing that patient controls medication delivery.
- Explain that the pump prevents the risk of overdose.
- Tell family members or friends not to operate the PCA device for patient.

Evaluation

- Ask patient to tell you the purpose of the PCA device.
- Observe patient administering a dose.
- Evaluate the severity of patient's pain while using the PCA device.

Building Competency in Patient-Centered Care You are caring for Mrs. Gonzales, a 62-year-old patient who had surgery earlier today for a total knee replacement. Her husband is at her side and very concerned about her condition. Mrs. Gonzales had preoperative instruction on use of PCA, and you are reinforcing that education with her and her husband. She states she does not want to become addicted to the pain medication and is hesitant to push the button to administer it. Mr. Gonzales tells her that he will push the button for her when she needs pain medication. What knowledge, skills and attitudes will best help you provide patient-centered care to Mrs. Gonzales?

Answers to questions can be found on the Evolve website.

Perineural Local Anesthetic Infusion. You are able to manage pain for a variety of inpatient and outpatient adult and pediatric surgical procedures with **perineural infusion** pumps (e.g., Breg and On-Q). An unsutured catheter from a surgical wound placed near a nerve or groups of nerves connects to a pump containing a local anesthetic (bupivacaine or ropivacaine). You set the pump on demand or continuous mode, and it is usually left in place for 48 hours. Patients learn how to discontinue the pump at home and bring the catheter to their next health care provider visit. Some patients still need oral analgesics, but perineural infusions often reduce the total dosage (Pasero, 2004).

Topical Analgesics. Topical analgesics such as ELA-Max/LMX and eutectic mixture of local anesthetics (EMLA) are available for children. Apply EMLA via a disk or thick cream to the skin 30 to 60 minutes before minor procedures (e.g., IV start, IM injection) or anesthetic infiltration of soft tissue. Do not place EMLA around the eyes, the tympanic membrane, or over large skin surfaces.

The Lidoderm patch is a topical analgesic effective for cutaneous neuropathic pain in adults. You place three patches, cut to size, on and around the pain site using a 12-hour on, 12-hour

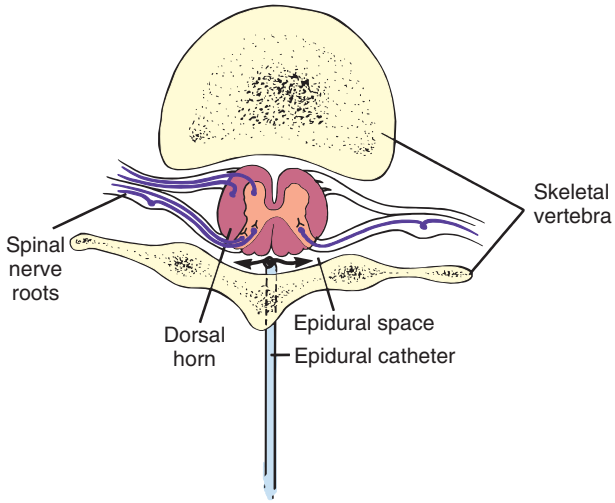

FIG. 43-13 Anatomical drawing of epidural space.

off schedule to avoid lidocaine toxicity. Other topical analgesics include ketoprofen patch and capsaicin lotion (Pasero and McCaffery, 2011).

Local and Regional Anesthetics. **Local anesthesia** is the local infiltration of an anesthetic medication to induce loss of sensation to a body part. Health care providers often use local anesthesia during brief surgical procedures such as removal of a skin lesion or suturing a wound by applying local anesthetics topically on skin and mucous membranes or by injecting them subcutaneously or intradermally to anesthetize a body part. The drugs produce temporary loss of sensation by inhibiting nerve conduction. Local anesthetics also block motor and autonomic functions, depending on the amount used and the location and depth of an injection. Smaller sensory nerve fibers are more sensitive to local anesthetics than are large motor fibers. As a result, the patient loses sensation before losing motor function, and conversely, motor activity returns before sensation.

Local anesthetics cause side effects, depending on their absorption into the circulation. Itching or burning of the skin or a localized rash is common after topical applications. Application to vascular mucous membranes increases the chance of systemic effects such as a change in heart rate.

Regional anesthesia is the injection of a local anesthetic to block a group of sensory nerve fibers. Tissues are anesthetized layer by layer as the surgeon or anesthesia provider introduces the agent into deeper structures of the body. Kinds of regional anesthesia include epidural anesthesia, pudendal blocks, and spinal anesthesia. **Epidural analgesia** is common for the treatment of acute postoperative pain, labor and delivery pain, and chronic cancer pain (Chumbley and Thomas, 2010). It permits control or reduction of severe pain and reduces the patient's overall opioid requirement, thus minimizing adverse effects. Epidural analgesia is short or long term, depending on a patient's condition and life expectancy.

The health care provider administers epidural analgesia into the spinal epidural space (Fig. 43-13) by inserting a blunt-tip needle into the level of the vertebral interspace nearest to the area requiring analgesia. The health care provider advances the catheter into the epidural space, removes the needle, and secures the remainder of the catheter with a dressing. Ensure the catheter is taped securely along the back of the patient. If the catheter is temporary, it is connected to tubing positioned along the spine and over the patient's shoulder. The end of the catheter is then placed on the patient's chest for the nurse's access. Nurse anesthetists, anesthesiologists, and nurses control epidural analgesia, depending on agency policy. Some patients control their demand dose, known as *patient-controlled epidural analgesia (PCEA)* (Pasero and McCaffery, 2011).

Nursing Implications. You maintain responsibility for providing emotional support to patients receiving local or regional anesthesia by explaining the insertion technique and warning patients that they will temporarily lose sensory function within minutes of injection. In the case of regional anesthesia, motor and autonomic (bowel and bladder control) function are also quickly lost. It is common for patients to fear paralysis because epidural and spinal injections come close to the spinal cord. To reassure the patient, explain that numbness, tingling, and coldness are common. Catheter insertion is painful unless the health care provider numbs the injection site. Prepare patients for such discomfort. Before a patient receives an analgesic, check for allergies. Also check to be sure that the drugs (morphine [Duramorph] and fentanyl [Sublimaze]) administered via the epidural catheter are free of potentially neurotoxic substances such as preservatives and additives. Assess vital signs to monitor systemic effects.

After administration of a local anesthetic, protect the patient from injury until full sensory and motor function return. Patients are at risk for injuring the anesthetized body part without knowing it. For example, after an injection into a joint, warn the patient to avoid using the joint until function returns. For patients with topical anesthesia, avoid applying heat or cold to numb areas. After spinal anesthesia the patient stays in bed until sensory and motor function return. Assist the patient the first time he or she tries to get out of bed.

When managing epidural infusions, connect the catheter to an infusion pump, a port, or reservoir or cap it off for bolus injections. To reduce the risk of accidental epidural injection of drugs intended for IV use, clearly label the catheter *epidural catheter*. Always administer continuous infusions through electronic infusion devices for proper control. Because of the catheter location, use surgical asepsis to prevent a serious and potentially fatal infection. Notify a patient's health care provider immediately of any signs or symptoms of infection or pain at the insertion site. Thorough hygiene is necessary during nursing procedures to keep the catheter system clean and dry.

Nursing implications for managing epidural analgesia are numerous (Table 43-6). Do not administer supplemental doses of opioids or sedative/hypnotics because of possible additive central nervous system adverse effects. Monitoring for effects of medications differs, depending on whether infusions are intermittent or continuous. Complications of epidural opioid use include nausea and vomiting, urinary retention, constipation, respiratory depression, and pruritus (Lehne, 2010). When patients receive epidural analgesia, you monitor them as often as every 15 minutes, including assessment of vital signs, respiratory effort, and skin color. Once stabilized, monitoring occurs every hour (refer to agency policy).

The patient needs to receive thorough education about epidural analgesia in terms of the action of the medication and its advantages and disadvantages. Instruct patients about the potential for side effects and to notify you or their health care provider if side effects develop. If the patient requires long-term epidural use, the health care provider tunnels a permanent catheter through the skin. The catheter exits at the patient's side. Teach a patient on long-term therapy how to safely administer home infusions with minimal ongoing nursing intervention.

TABLE 43-6 Nursing Care for Patients with Epidural Infusions

GOAL	ACTIONS
Prevent catheter displacement.	Secure catheter (if not connected to implanted reservoir) carefully to outside skin.
Maintain catheter function.	Check external dressing around catheter site for dampness or discharge. (Leak of cerebrospinal fluid may develop.) Use transparent dressing to secure catheter and aid inspection. Inspect catheter for breaks.
Prevent infection.	Use strict aseptic technique when caring for catheter (see Chapter 28). Do not routinely change dressing over site. Change infusion tubing every 24 hours.
Monitor for respiratory depression.	Monitor vital signs, especially respirations, per policy. Use pulse oximetry and apnea monitoring.
Prevent undesirable complications.	Assess for pruritus (itching) and nausea and vomiting. Administer antiemetics as ordered.
Maintain urinary and bowel function.	Monitor intake and output. Assess for bladder and bowel distention. Assess for discomfort, frequency, and urgency.

Invasive Interventions for Pain Relief. When severe pain persists despite medical treatment, invasive interventions available for consideration include intrathecal implantable pumps or injections, spinal cord stimulators, deep brain stimulation, neuroablative procedures (cordotomy, rhizotomy, thalamotomy), trigger point injections, radiofrequency ablation, cryoablation, intradiscal electrothermal (IDET) annuloplasty, vertebroplasty, and intraspinal medications (opioids, steroids, local anesthetics, alpha agonists). It is not acceptable to tell a patient with severe unrelieved pain that there is "nothing more we can do for you." Refer patients with pain unresponsive to medications to a pain expert.

Procedure Pain Management. The Thunder Project II (Puntillo et al., 2001) identified several procedures causing pain in critical care patients: turning, wound drain removal, tracheal suctioning, femoral catheter removal, placement of a central line, and changing of nonburn wound dressings.

Premedicating patients before painful procedures allows patients to cooperate more fully and reduces the experience of pain. The American Society of Anesthesiologists practice guidelines (2004) recommend premedicating patients before surgery as part of a multimodal analgesic pain management program.

Chronic Noncancer and Cancer Pain Management. Cancer pain is either chronic or acute. The AHCPR published clinical practice guidelines for cancer pain management in 1994 that continue to be a reference today (Lehne, 2010). The guidelines support comprehensive and aggressive treatment of cancer pain, including many options for pain relief (Fig. 43-14). The best choice of treatment often changes as the patient's condition and the characteristics of pain change. You can use nonpharmacological interventions with pharmacological interventions.

Various medications and routes of administration provide relief for patients with cancer pain. Long-acting or controlled-release medications are very successful in managing all types of chronic pain. These controlled-released medications (e.g., morphine [MS Contin, Roxanol SR], and oxycodone [OxyContin]) relieve pain for 8 to 12 hours. A 72-hour fentanyl patch is also available. You can manage most chronic pain by using oral or patch medications. Do not use the intramuscular route for controlling pain because the injection is painful and there is inconsistent, erratic drug absorption (Pasero and McCaffery, 2011).

BOX 43-15 TYPES OF BREAKTHROUGH PAIN

Incident pain: Pain that is predictable and elicited by specific behaviors such as physical therapy or wound dressing changes

End-of-dose failure pain: Pain that occurs toward the end of the usual dosing interval of a regularly scheduled analgesic

Spontaneous pain: Pain that is unpredictable and not associated with any activity or event

Data from Gruener D, Lande S: *Pain control in the primary care setting*, Glenview, Ill, 2006, American Pain Society.

Estimates of addiction in patients with persistent pain range from 6% to 10% (Pasero and McCaffery, 2011). Patients with persistent pain requiring prolonged opioid administration sometimes develop an opioid tolerance. As a result, patients require higher doses of opioids to attain pain relief. The higher opioid dose is not lethal because patients also develop a tolerance to respiratory depression.

It is necessary to give patients with chronic pain required analgesics on a regular basis. Prescribing analgesics on a prn basis for chronic pain is ineffective and causes more suffering. The patient with chronic pain needs to take an analgesic ATC, even when the pain subsides. Regular administration maintains therapeutic drug blood levels for ongoing pain control.

Administering analgesics to treat chronic pain requires applying principles different from those used to treat acute pain. The World Health Organization (Pasero and McCaffery, 2011) recommends a three-step approach to managing cancer pain (Fig. 43-15). Therapy begins with using NSAIDs and/or adjuvants and progresses to strong opioids if pain persists. Side effects of opioids such as nausea and constipation are treated aggressively so patients are able to continue using them. Patients usually become tolerant to their side effects, with the exception of constipation. Routinely administer stimulant laxatives, not simple stool softeners, to prevent and treat constipation.

Transdermal fentanyl, which is 100 times more potent than morphine, is available at predetermined doses that provide analgesia for 48 to 72 hours. The transdermal route is useful when patients are unable to take drugs orally. Fentanyl patches are only used with patients who are opioid tolerant. Patients find this system easy to use because it allows for continuous opioid administration without needles or pumps. Self-adhesive patches release the medication slowly over time, achieving effective analgesia. Transdermal fentanyl is not for adult patients who weigh less than 100 pounds (too little subcutaneous tissue for absorption) or who are hyperthermic (increases drug absorption). Do not place heating pads over the patch and never cut it. To dispose of the patch, fold in half, adhesive side onto itself, and flush down the toilet (Pasero and McCaffery, 2011).

A transmucosal fentanyl "unit" now exists to treat **breakthrough pain** (Box 43-15) in opioid-tolerant patients. Breakthrough pain is a transient flare of moderate-to-severe pain superimposed on continuous or persistent pain. Swab the fentanyl unit in the mouth over the buccal mucosa and gums. The unit remains intact to

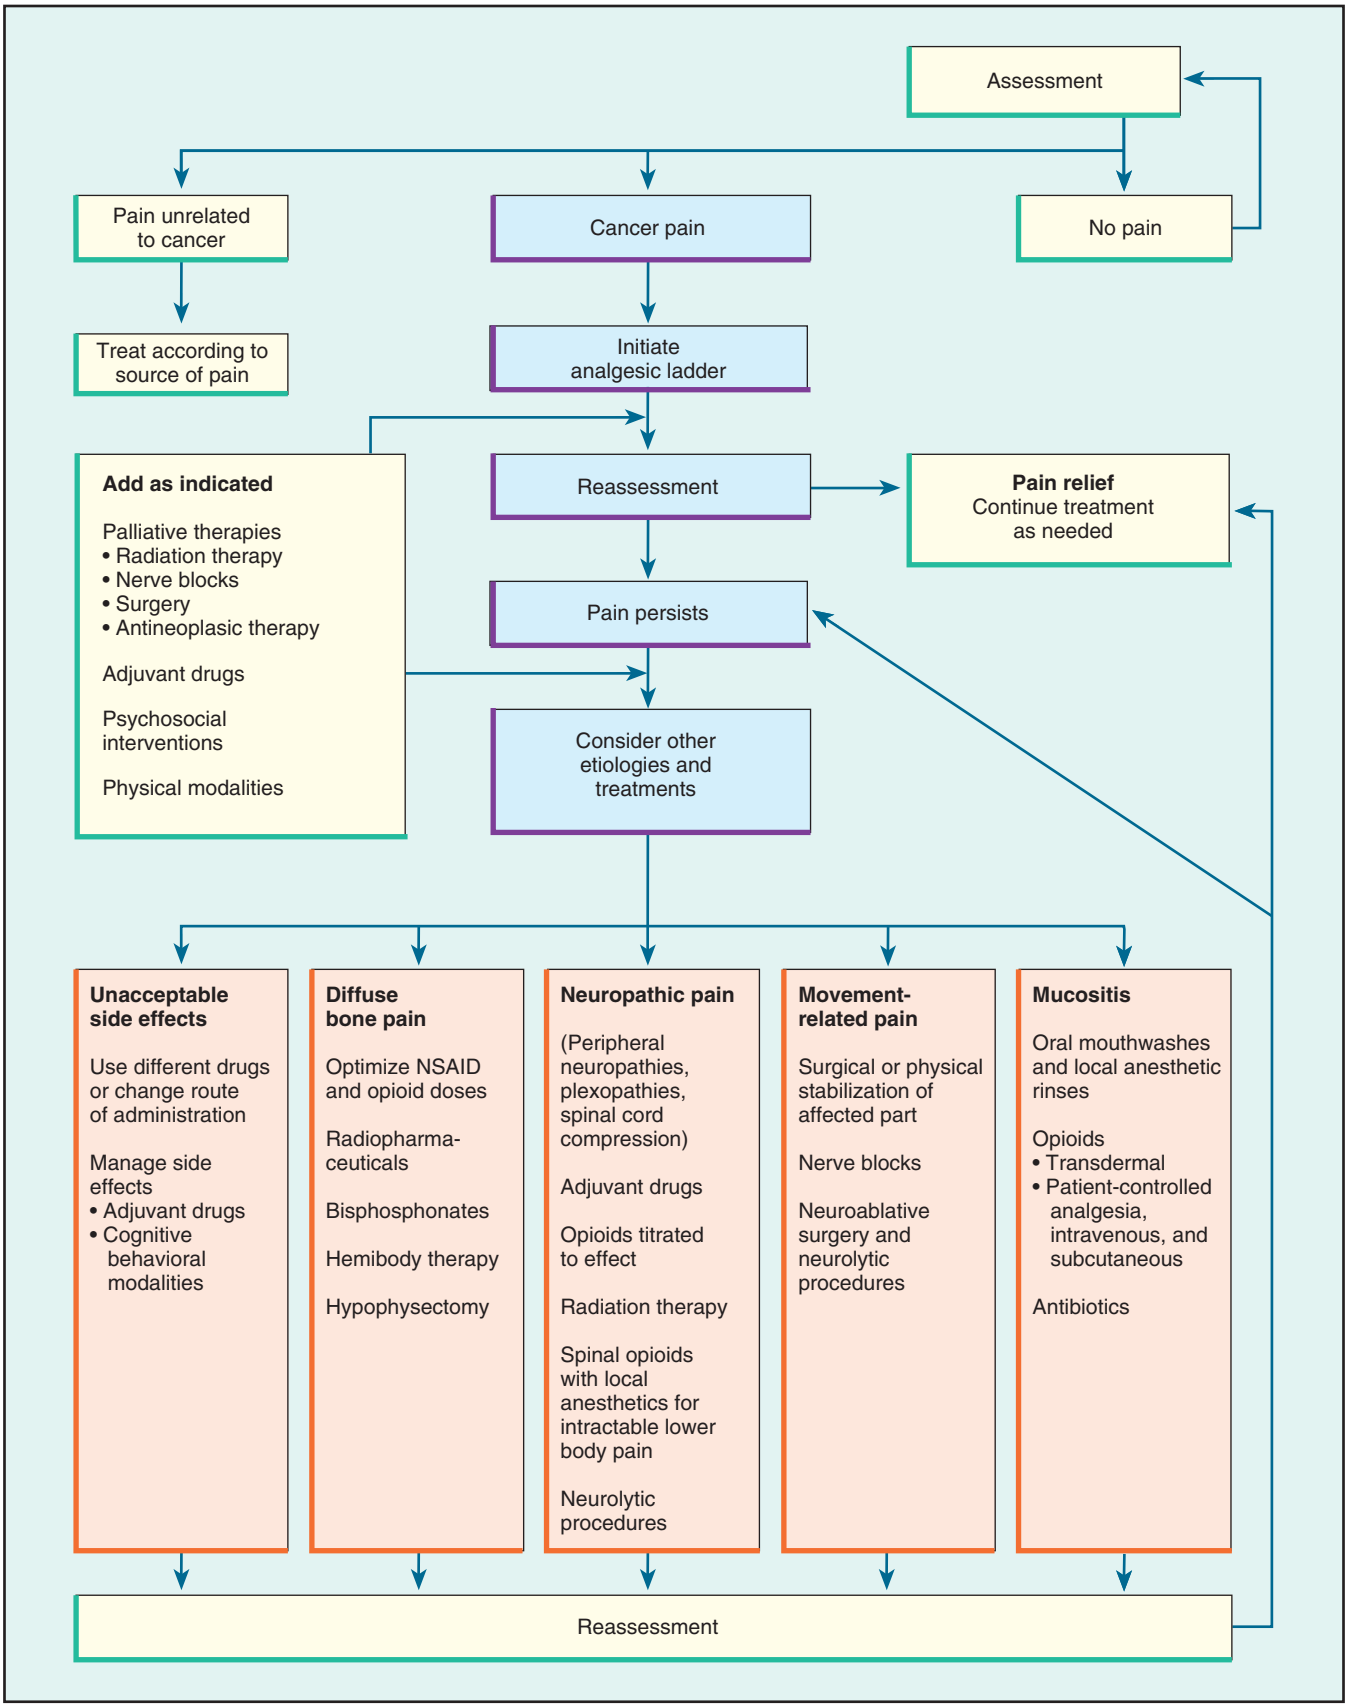

FIG. 43-14 Flow chart: continuing pain management in patients with cancer. *NSAID,* Nonsteroidal antiinflammatory drug. (From Jacox A et al: *Management of cancer pain,* Clinical Practice Guideline No. 9, AHCPR Pub No. 94-0592, Rockville, Md, 1994, Agency for Health Care Policy and Research, Public Health Service, US Department of Health and Human Services.)

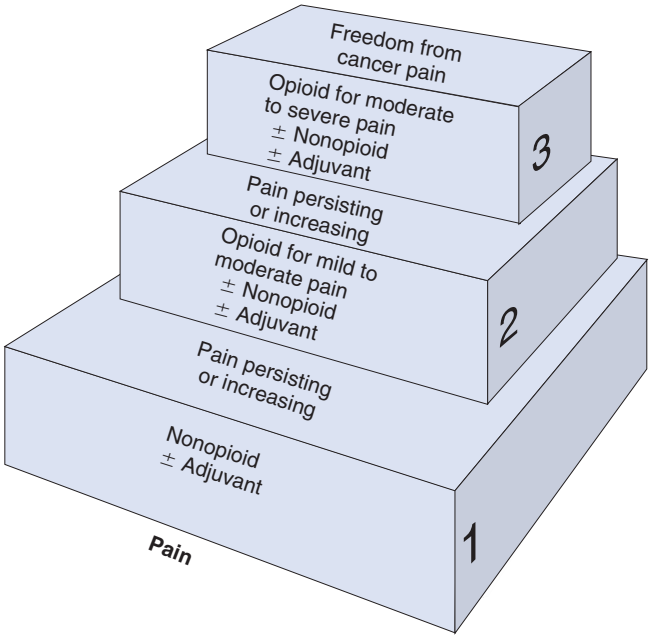

FIG. 43-15 WHO analgesic ladder is a three-step approach in treating cancer pain, accessed 9/27/10 from http://www.who.int/cancer/palliative/painladder/en/.

dissolve in the mouth, not chewed. Allow to absorb over a 15-minute period, delaying swallowing as long as possible. Use no more than two units per breakthrough pain episode. If the patient's pain is not relieved after two units, notify the patient's health care provider (Pasero and McCaffery, 2011).

Administer analgesics rectally when patients are unable to swallow, have nausea or vomiting, or are near death. This route is contraindicated for patients with diarrhea or cancerous lesions involving the anus or rectum. Morphine, hydromorphone, and oxymorphone are available in suppositories (Pasero and McCaffery, 2011).

Some patients use PCA devices to treat severe cancer pain in the home or acute care setting. PCA devices provide improved, uniform pain control with fewer peaks and valleys in plasma concentration, more effective drug action, and lower drug dosages overall. Patients who usually benefit from continuous infusions include those with severe pain for whom oral and injectable medications provide minimal relief, those with severe nausea and vomiting, and those unable to swallow oral medications.

When a patient first receives continuous-drip opioids, the IV access needs to be patent and without complications (see Chapter 41). A central-line catheter such as a Groshong or Hickman catheter, an implanted venous access port, or a peripherally inserted central catheter is usually best for long-term IV infusion. When IV access is poor, the subcutaneous route with a concentrated dose is possible. When infusions begin, monitor the patient very closely for the first hour and then according to agency policy. Patients who are placed on continuous analgesic infusions are opioid tolerant; thus respiratory depression is rare.

Barriers to Effective Pain Management. Barriers to effective pain management are complex, involving the patient, health care provider, and health care system (Box 43-16). Some health care providers require opioid agreements and random urine testing from patients who need long-term opioid therapy. However, evidence of the effectiveness of agreements is lacking, and there are ethical concerns about using them for all patients who require long-term opioid therapy (Arnold et al., 2006). This raises the question as to whether agreements protect patients or health care providers.

Patients and health care providers often do not understand the differences between **physical dependence, addiction,** and **drug tolerance** (Box 43-17). Experiencing a physical dependency does not imply addiction, and drug tolerance in and of itself is not the same as addiction. That is not to say that addiction does not occur

BOX 43-16 BARRIERS TO EFFECTIVE PAIN MANAGEMENT

Patient Barriers
- Fear of addiction
- Worry about side effects
- Fear of tolerance (won't be there when I need it)
- Takes too many pills already
- Fear of injections
- Concern about not being a "good" patient
- Doesn't want to worry family and friends
- May need more tests
- Needs to suffer to be cured
- Pain necessary for past indiscretions
- Inadequate education
- Reluctance to discuss pain
- Pain inevitable
- Pain part of aging
- Fear of disease progression
- Believes health care providers and nurses are doing all they can
- Just forgets to take analgesics
- Fear of distracting health care providers from treating illness
- Believes health care providers have more important or sicker patients to see
- Suffering in silence noble and expected

Health Care Provider Barriers
- Inadequate pain assessment skills
- Concern with addiction
- Opiophobia, fear of opioids
- Fear of legal repercussions
- No visible cause of pain
- Belief that patients need to learn to live with pain
- Reluctance to deal with side effects of analgesics
- Not believing patient's report of pain
- Fear that giving a dose will kill the patient
- Health care provider time constraints
- Inadequate reimbursement
- Belief that opioids "mask" symptoms
- Belief that pain is part of aging
- Overestimation of rates of respiratory depression

Health Care System Barriers
- Concern with creating "addicts"
- Difficulty in filling prescriptions
- Absolute dollar restriction on amount reimbursed for prescriptions
- Mail-order pharmacy restrictions
- Advanced practice nurses not used efficiently
- Extensive documentation requirements
- Poor pain policies and procedures regarding pain management
- Lack of money
- Inadequate access to pain clinics
- Poor understanding of economic impact of unrelieved pain

BOX 43-17 DEFINITIONS RELATED TO THE USE OF OPIOIDS IN PAIN TREATMENT*

Physical Dependence
A state of adaptation that is manifested by a drug class specific withdrawal syndrome produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist.

Addiction
A primary, chronic, neurobiological disease with genetic, psychosocial, and environmental factors influencing its development and manifestations. Addictive behaviors include one or more of the following: impaired control over drug use, compulsive use, continued use despite harm, and craving.

Drug Tolerance
A state of adaptation in which exposure to a drug induces changes that result in a diminution of one or more effects of the drug over time.

*Approved by the Boards of Directors of the American Academy of Pain Medicine, the American Pain Society, and the American Society of Addiction Medicine, February 2001 (American Pain Society, 2011).

or that true addicts should not be treated for pain. "Patients with addictive disease and pain have the right to be treated with dignity, respect, and the same quality of pain assessment and management as all other patients" (ASPMN Position Statement, 2002). Nurses and health care providers need to avoid labeling patients as *drug seeking* because this term is poorly defined and can cause bias and prejudice. If you are concerned that a patient is abusing opioids, voice your concerns to the patient and notify the patient's health care provider, explaining the reasons for your concern.

Follow recommendations for the management of acute pain in patients dependent on opioids who are not necessarily addicted (Mehta and Langford, 2006). A study of patients who had addictions and pain revealed that they did not feel respected by nurses who cared for them (Morgan, 2006). These patients used presentation (try to be nice and thank the nurse) and self-management strategies (do not get angry or make waves) to obtain pain relief.

Placebos. **Placebos** are medications or procedures that produce positive or negative effects in patients. These effects are not related to the specific physical or chemical properties of the placebo. Professional organizations discourage their use to treat pain. It is considered unethical and deceitful to administer them. Placebo use jeopardizes the trust between patients and their caregivers. If a placebo is ordered, you must question the order. Many health care agencies have policies that limit the use of placebos to research only (Pasero and McCaffery, 2011).

Restorative and Continuing Care

Pain Clinics, Palliative Care, and Hospices. Health professionals recognize pain as a significant health problem. Growth of pain centers, palliative care departments, and hospices designed to manage pain and suffering has increased. The Commission on Accreditation of Rehabilitation Facilities (CARF) accredits chronic pain treatment programs and sets standards for chronic pain management. A comprehensive pain center treats persons on an inpatient or outpatient basis. Staff members representing all health care disciplines (e.g., nursing, medicine, physical therapy, pastoral care, and dietetics) work with patients to find the most effective pain-relief measures. A comprehensive clinic provides not only diverse therapy but also research into new treatments and training for professionals.

Many hospitals have palliative-care departments to help patients and their family members successfully manage their diseases (Morrison et al., 2005). The goal of palliative care is to learn to live life fully with an incurable condition (see Chapter 36). Patients and their family members need ongoing assistance in managing their pain at home. A National Patient Safety Goal (TJC, 2011) recommends standardizing communication when a patient transfers into, out of, and within the medical system. Teaching pain management during discharge and ensuring continuation of pain management after discharge is essential.

Hospices are programs that care for patients at the end of life (see Chapter 36). The emphasis is on quality of life over quantity (Douglass et al., 2004). Hospice helps terminally ill patients continue to live at home or in a health care setting in comfort and privacy. Pain control is a priority for hospices. Under the guidance of hospice nurses, families learn to monitor patients' symptoms and become the primary caregivers. Some hospice patients become hospitalized, such as in the event of a brief acute care crisis or family problem.

Hospice programs help nurses overcome their fears of contributing to a patient's death when administering large doses of opioids. The American Nurses Association supports aggressive treatment of pain and suffering even if it hastens a patient's death (Fowler, 2010). Recent research suggests that moderate opioid dose increases in patients who are terminally ill do not hasten death (Bengoechea et al., 2010). The disease, not the opioid, is killing the patient.

EVALUATION

Through the Patient's Eyes. Evaluate patients' perceptions of the effectiveness of interventions used to relieve pain. Patients help decide the best times to attempt pain treatments. Essentially they are the best judge of whether a pain-relief intervention works. Often the family is another valuable resource, particularly in the case of a patient with pain who is not able to express discomfort. Also ask patients about tolerance to therapy and the overall amount of relief obtained. If patients state that an intervention is not helpful or even aggravates the discomfort, stop it immediately and seek an alternative. Time and patience are necessary to maximize the effectiveness of pain management. Educate the patient about what to expect. Reassure the patient that you will check back frequently to assess for changes in pain level. Continually assess whether the character of the patient's pain changes and whether individual interventions are effective.

Patient Outcomes. Evaluation of pain is one of many nursing responsibilities that require effective critical thinking (Fig. 43-16). A patient's behavioral responses to pain-relief interventions are not always obvious. Evaluating the effectiveness of a pain intervention requires you to evaluate the patient's pain after an appropriate period of time. For instance, oral medications usually peak in about 1 hour; whereas IVP medications peak in 15 to 30 minutes. Ask the patient if the medication alleviated the pain when it was peaking. Do not expect the patient to volunteer the information. Evaluate psychological and physiological responses to pain (e.g., "Does your pain ever cause you to get depressed or angry?").

If you evaluate that a patient continues to have discomfort after an intervention, try a different approach. For example, if an analgesic provides only partial relief, add relaxation exercises or guided-imagery exercises. You also consult with the patient's health care provider about increasing the dose, decreasing the interval between doses, or trying different analgesics. If patient outcomes are not met, ask the patient:

- What is your current pain level?
- How far away is your pain level from your goal?

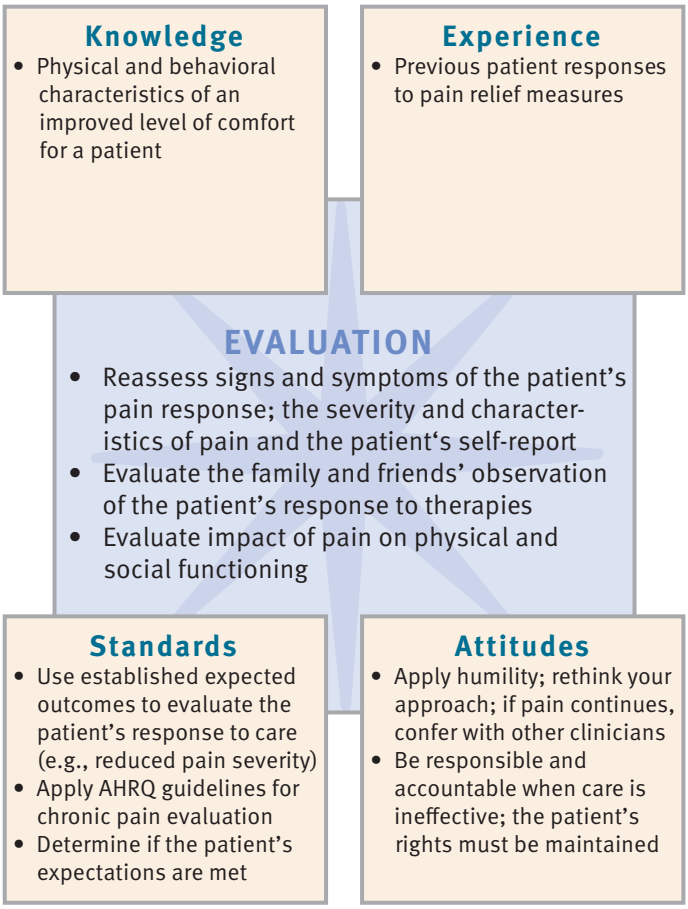

FIG. 43-16 Critical thinking model for pain-management evaluation. *AHRQ,* Agency for Healthcare Research and Quality.

BOX 43-18 CHECKLIST FOR COMMUNICATING PATIENTS' UNRELIEVED PAIN TO COLLEAGUES

- What is the pain rating now? Over the past period of time?
- Which pain rating is acceptable to the patient?
- How do you recommend that the patient's treatment be changed to reduce the pain rating?
- Which professional reference can be used, if needed, to support this recommendation?

From Pasero C, McCaffery M: *Pain assessment and pharmacologic management,* St Louis, 2011, Mosby.

- What side effects are you experiencing from your pain medication?
- Describe limitations in function you are experiencing related to uncontrolled pain.
- How is your pain limiting or altering your rest and sleep?

Effective communication of your assessment of a patient's pain and the response to intervention is facilitated by accurate and thorough documentation. This communication needs to happen from nurse to nurse, shift to shift, and nurse to other health care providers. It is your professional responsibility as the nurse caring for the patient to report the effectiveness of interventions for managing the patient's pain and evaluation of patient care goals and outcomes. A variety of tools such as a pain flow sheet or diary help centralize information about pain management. The patient expects you to be sensitive to his or her pain and to be attentive in attempts to manage that pain. Effectively communicating with colleagues (Box 43-18) helps you achieve optimal pain relief for patients.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- The patient is the only person who should press the button to administer the pain medication when using PCA.
- Monitor the patient for signs and symptoms of oversedation and respiratory depression.

SKILL 43-1 PATIENT-CONTROLLED ANALGESIA

View Video!

Delegation Considerations

The skill of administration of patient-controlled analgesia (PCA) cannot be delegated to nursing assistive personnel (NAP). Instruct the NAP to:

- Notify the nurse if the patient complains of pain or has signs of becoming oversedated.
- Notify the nurse if the patient has questions about the PCA process or equipment.
- Never administer a PCA dose for the patient.

Equipment

- PCA system
- Identification label and time tape (may already be attached and completed by pharmacy)
- Alcohol swab
- Adhesive tape
- Clean gloves, when applicable
- Equipment for vital signs and pulse oximeter

STEP	RATIONALE
ASSESSMENT	
1 Assess patient's cognitive ability.	Determines if patient is able to use PCA for pain management.
2 Assess for physical, behavioral, and emotional signs and symptoms of pain or discomfort.	Combination of signs and symptoms reveals source and nature of pain.
3 Assess characteristics of patient's pain.	Reveals source and nature of pain and factors that may increase pain.
4 Assess patency of intravenous (IV) access and surrounding tissue for inflammation or swelling.	IV line needs to be patent for safe administration of pain medication. Confirmation of placement of IV catheter and integrity of surrounding tissues ensures that medication is administered safely.
5 Check accuracy and completeness of each MAR or computer printout with health care provider's order for patient's name, name of medication, dose, frequency of medication (continuous or demand or both), and lockout period.	Health care provider order required for administration of opioid medication. Ensures patient receives right medications.
6 Have a second registered nurse (RN) confirm health care provider's order and correct setup of PCA. The second RN **independently checks** health care provider's order and the machine, not simply look at the first RN's setup.	Prevents medication errors.
7 Check patient's history for drug allergies. Be aware that nausea is not an allergic reaction and it can be treated; itching alone is not an allergic reaction and is common to opioid use. Itching is also treatable and does not rule out the use of PCA.	Avoids placing patient at risk for allergic reaction.
PLANNING	
1 Collect appropriate equipment.	
2 Review medication information in drug reference manual or consult with pharmacist if uncertain about any medications to be administered.	Understanding medications before administering them prevents medication errors (Brady, Malone, and Fleming, 2009).
3 Explain purpose and demonstrate function of PCA to patient and family (see Box 43-14).	Allows patient participation in care and independence in pain control. Preoperative education about PCA therapy improves postoperative pain relief (ASPMN, 2006).
4 Check infuser and patient-controlled module for accurate labeling or evidence of leaking.	Avoids medication error. Damage to system can occur in shipping and handling; inspect to avoid injury or harm to patient, self, or others.
5 Program computerized PCA pump to deliver prescribed medication dose and lockout interval.	Ensures safe, therapeutic drug administration.
6 Draw curtains around patient's bed or close door to room.	Maintains patient's privacy.
7 Position patient comfortably for procedure. Maintain any position restrictions. Venipuncture or central line site needs to be accessible.	Comfortable position enhances effectiveness of analgesia.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of infection.
2 Follow the six rights to be sure of correct medication. Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medication administration record (MAR) or medical record (see Chapter 31).	Minimizes risk for medication error and harm to patient. Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
3 Attach drug reservoir to infusion device and prime tubing.	Locks system and prevents air from infusing into IV tubing.
4 Apply clean gloves.	Reduces potential contact with blood when working with IV line.
5 Attach needleless adapter to tubing adapter of patient-controlled module.	Needed to connect with IV line.
6 Wipe injection port of maintenance IV line with alcohol if using a closed port.	Alcohol is a topical antiseptic that minimizes entry of surface microorganisms during needle insertion.
7 Insert and secure needleless adapter into injection port nearest patient.	Establishes route for medication to enter main IV line. Prevents delay of medication delivery to patient. Needleless systems prevent needlestick injuries.
8 Administer loading dose of analgesia as prescribed.	Give one-time doses manually or program into PCA pump.
9 Discard gloves and supplies in appropriate containers.	Reduces transmission of microorganisms.
10 If experiencing pain, have patient demonstrate use of PCA system; if not, have patient repeat instructions given earlier by nurse.	Repeating instructions reinforces learning. Checking patient's understanding through return demonstration helps nurse determine patient's level of understanding and ability to manipulate device.
11 Dispose of empty cassette or syringe in compliance with institutional policy.	The federal Controlled Substances Act regulates the control and dispensation of opioids for all institutions.
12 If PCA is discontinued before device is completely empty, record drug wastage on PCA medication administration record (MAR) per institutional policy. Note date, time, amount of drug wasted, and reason for wastage.	Two RNs must witness wastage of opioids (narcotics) and sign the record to meet requirements of the Controlled Substances Act for scheduled drugs.
13 Most PCA systems need a secondary IV infusion running at TKO (to keep open rate). Be sure that infusion is running properly (see Chapter 41).	To maintain patency of vein between PCA intermittent (bolus) doses.

SKILL 43-1 PATIENT-CONTROLLED ANALGESIA—cont'd

STEP	RATIONALE
EVALUATION	
1 Use pain-rating scale to evaluate patient's pain intensity according to agency policy.	Determines response to PCA dosing. Documenting "PCA in use" or "PCA effective" is not an adequate record of the patient's pain level.
2 Observe patient for nausea or itching.	Common side effects of opioid.
3 Observe for signs of adverse reactions, especially excessive sedation. Monitor level of sedation, vital signs, and pulse oximetry every 2 hours for the first 12 hours (APS, 2003).	Patient is at highest risk the first 12 hours of use. Excess sedation precedes respiratory depression.
4 Have patient demonstrate dose delivery.	Evaluates skill in use of PCA.
5 According to agency policy, evaluate number of attempts (number of times patient pushed the button), delivery of demand doses (number of times drug actually given), and basal dose if ordered.	Assists in evaluating effectiveness of PCA dose and frequency in relieving pain. Maintains compliance with Controlled Substances Act.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient verbalizes continued or worsening discomfort or displays nonverbal behaviors indicative of pain, suggesting that underlying condition has changed or patient is undermedicated.
- Perform complete pain assessment.
- Inspect IV site for possible catheter occlusion or infiltration.
- Consult with health care provider.

2 Patient is not readily arousable.
- Stop PCA, elevate head of bed unless contraindicated, and assess vital signs. **Do not** leave the patient's bedside.
- Notify health care provider and/or call for help.
- Prepare to administer an opioid-reversing agent.

3 Patient unable to manipulate PCA device to maintain pain control.
- Consult with health care provider regarding alternative medication route.
- Discuss with health care provider possible basal (continuous) dose.
- Assess patient support system for significant other who can responsibly manipulate PCA device (ASPMN, 2006).

RECORDING AND REPORTING

- Record drug, dose, and time begun on MAR. Note lockout time, demand, and basal dose.
- Record regular assessments of patient pain, vital signs, and oxygen saturation.
- Record amount of drug delivered and amount wasted.

KEY POINTS

- Pain is a purely subjective physical and psychosocial experience.
- Misconceptions about pain often result in doubt about the degree of the patient's suffering and unwillingness to provide relief.
- Knowledge of the nociceptive pain processes of the pain experience—transmission, transduction, perception, and modulation—provides guidelines for selecting pain-relief measures.
- An interaction of psychological and cognitive factors affects pain perception.
- A person's cultural background influences the meaning of pain and how it is expressed.
- It is common for older patients not to report pain.
- Patients who are in chronic pain are unlikely to show behavioral changes.
- The difference between acute and chronic pain involves the concept of harm. Acute pain is protective, thus preventing harm; chronic pain is no longer protective.
- Do not collect an in-depth pain history when the patient is experiencing severe discomfort.
- Pain causes physical signs and symptoms similar to those of other diseases.
- Individualize pain interventions by collaborating closely with the patient, using assessment findings, and trying a variety of interventions.
- Eliminating sources of painful stimuli is a basic nursing measure for promoting comfort.
- Using a regular schedule around-the-clock (ATC) for analgesic administration is more effective than an as-needed schedule in pain control.
- Sedation is an adverse effect of opioids that always precedes respiratory depression (which is rare).
- A PCA device gives patients pain control with low risk of overdose.
- While caring for a patient who receives local anesthesia, protect him or her from injury.
- Nursing implications for administering epidural analgesia include preventing infection and monitoring closely for respiratory depression.
- Addiction rarely occurs in patients who take opioids to relieve pain.
- The goal of pain management is to anticipate and prevent pain rather than treat it.

- Pain evaluation includes measuring the changing character of pain, the patient's response to interventions, and the patient's perceptions of the effectiveness of a therapy.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

After three doses (0.5 mg each) of morphine from the patient-controlled analgesia (PCA) device, Mrs. Mays started vomiting and stated that she was feeling "out of her head." She rated her chest pain as 3 on a scale of 0 to 10. She is breathing comfortably on 2 L of nasal cannula oxygen, and her lung sounds are clear to auscultation. Her husband is very concerned and anxious about his wife and wants the morphine stopped so she will not become "addicted."

1. Do you think Mrs. Mays is allergic to morphine? Support your answer.
2. What do you need to tell Mr. and Mrs. Mays about the adverse effects of morphine?
3. Which interventions do you need to complete before consulting the health care provider?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Which of the following signs or symptoms in an opioid-naive patient is of greatest concern to the nurse when assessing the patient 1 hour after administering an opioid?
   1. Oxygen saturation of 95%
   2. Difficulty arousing the patient
   3. Respiratory rate of 10 breaths/min
   4. Pain intensity rating of 5 on a scale of 0 to 10
2. A health care provider writes the following order for an opioid-naive patient who returned from the operating room following a total hip replacement. "Fentanyl patch 100 mcg, change every 3 days." Based on this order, the nurse takes the following action:
   1. Calls the health care provider, and questions the order
   2. Applies the patch the third postoperative day
   3. Applies the patch as soon as the patient reports pain
   4. Places the patch as close to the hip dressing as possible
3. A patient is being discharged home on an around-the-clock (ATC) opioid for chronic back pain. Because of this order, the nurse anticipates an order for which class of medication?
   1. Stool softener
   2. Stimulant laxative
   3. H_2 receptor blocker
   4. Proton pump inhibitor
4. A new medical resident writes an order for OxyContin SR 10 mg PO q12 hours prn. Which part of the order does the nurse question?
   1. The drug
   2. The time interval
   3. The dose
   4. The route
5. The nurse notices that a patient has received oxycodone/acetaminophen (Percocet) (5/325), two tablets PO every 3 hours for the past 3 days. What concerns the nurse the most?
   1. The patient's level of pain
   2. The potential for addiction
   3. The amount of daily acetaminophen
   4. The risk for gastrointestinal bleeding
6. A patient with chronic low back pain who took an opioid around-the-clock (ATC) for the past year decided to abruptly stop the medication for fear of addiction. He is now experiencing shaking chills, abdominal cramps, and joint pain. The nurse recognizes that this patient is experiencing symptoms of:
   1. Addiction.
   2. Tolerance.
   3. Pseudoaddiction.
   4. Physical dependence.
7. After having received 0.2 mg of naloxone (Narcan) intravenous push (IVP), a patient's respiratory rate and depth are within normal limits. The nurse now plans to implement the following action:
   1. Discontinue all ordered opioids
   2. Close the room door to allow the patient to recover
   3. Administer the remaining naloxone over 4 minutes
   4. Assess patient's vital signs every 15 minutes for 2 hours
8. Which one of the following instructions is crucial for the nurse to give to both family members and the patient who is about to be started on a patient-controlled analgesia (PCA) of morphine?
   1. Only the patient should push the button.
   2. Do not use the PCA until the pain is severe.
   3. The PCA prevents overdoses from occurring.
   4. Notify the nurse when the button is pushed.
9. A patient with a history of a stroke that left her confused and unable to communicate returns from interventional radiology following placement of a gastrostomy tube. The health care provider's order reads as follows: "Vicodin 1 tab, per tube, q4 hours, prn." Which action by the nurse is most appropriate?
   1. No action is required by the nurse because the order is appropriate.
   2. Request to have the ordered changed to ATC for the first 48 hours.
   3. Ask for a change of medication to meperidine (Demerol) 50 mg IVP, q3 hours, prn.
   4. Begin the Vicodin when the patient shows nonverbal symptoms of pain.
10. A patient returning to the nursing unit after knee surgery is verbalizing pain at the surgical site. The nurse's first action is to:
    1. Call the patient's health care provider.
    2. Administer pain medication as ordered.
    3. Check the patient's vital signs.
    4. Assess the characteristics of the pain.
11. The patient rates his pain as a 6 on a scale of 0 to 10, with 0 being no pain and 10 being the worst pain. The patient's wife says that he can't be in that much pain since he has been sleeping for 30 minutes. Which is the most accurate resource for assessing the pain?
    1. The patient's wife is the best resource for determining the level of pain since she has been with him continually for the entire day.
    2. The patient's report of pain is the best method for assessing the pain.
    3. The patient's health care provider has the best knowledge of the level of pain that the patient that should be experiencing.
    4. The nurse is the most experienced at assessing pain.

12. When using ice massage for pain relief, which of the following are correct? (Select all that apply.)
    1. Apply ice using firm pressure over skin.
    2. Apply ice until numbness occurs and remove the ice for 5 to 10 minutes.
    3. Apply ice until numbness occurs and discontinue application.
    4. Apply ice for no longer than 10 minutes.
13. When teaching a patient about transcutaneous electrical nerve stimulation (TENS), which information do you include?
    1. TENS works by causing distraction.
    2. TENS therapy does not require a health care provider's order.
    3. TENS requires an electrical source for use.
    4. TENS electrodes are applied near or directly on the site of pain.
14. While caring for a patient with cancer pain, the nurse knows that the World Health Organization (WHO) analgesic ladder recommends:
    1. Transitioning use of adjuvants with nonsteroidal antiinflammatory drugs (NSAIDs) to opioids.
    2. Using acetaminophen for refractory pain.
    3. Limiting the use of opioids because of the likelihood of side effects.
    4. Avoiding total sedation, regardless of how severe the pain is.
15. A postoperative patient is currently asleep. Therefore the nurse knows that:
    1. The sedative administered may have helped him sleep, but assessment of pain is still needed.
    2. The intravenous (IV) pain medication is effectively relieving his pain.
    3. Pain assessment is not necessary.
    4. The patient can be switched to the same amount of medication by the oral route.

Answers: **1.** 2; **2.** 1; **3.** 2; **4.** 2; **5.** 3; **6.** 4; **7.** 4; **8.** 1; **9.** 2; **10.** 4; **11.** 2; **12.** 1, 2; **13.** 4; **14.** 1; **15.** 1.

CHAPTER

44

Nutrition

OBJECTIVES

- Explain the importance of a balance between energy intake and energy requirements.
- List the end products of carbohydrate, protein, and fat metabolism.
- Explain the significance of saturated, unsaturated, and polyunsaturated fats.
- Describe food guidelines and discuss their value in planning meals for good nutrition.
- List the current dietary guidelines for the general population.
- Explain the variance in nutritional requirements throughout growth and development.
- Discuss the major methods of nutritional assessment.
- Identify three major nutritional problems and describe patients at risk.
- Establish a plan of care to meet the nutritional needs of a patient.
- Describe the procedure for initiating and maintaining enteral feedings.
- Describe the methods to avoid complications of enteral feedings.
- Describe the methods for avoiding complications of parenteral nutrition.
- Discuss medical nutrition therapy in relation to three medical conditions.
- Discuss diet counseling and patient teaching in relation to patient expectations.

Nutrition is a basic component of health and is essential for normal growth and development, tissue maintenance and repair, cellular metabolism, and organ function. The human body needs an adequate supply of nutrients for essential functions of cells. **Food security** is critical for all members of a household. This means that all household members have access to sufficient, safe, and nutritious food to maintain a healthy lifestyle; sufficient food is available on a consistent basis; and the household has resources to obtain appropriate food for a nutritious diet. Food also holds symbolic meaning. Giving or taking food is part of ceremonies, social gatherings, holiday traditions, religious events, the celebration of birth, and the mourning of death. The difficulty of the decision to withdraw food in a terminal illness, even in the form of intravenous (IV) nutrients, is a testament to the symbolic power of food and feeding.

Florence Nightingale understood the importance of nutrition, stressing a nurse's role in the science and art of feeding during the mid-1800s (Dossey, 1999). Since then the nurse's role in nutrition and diet therapy has changed. Medical nutrition therapy

BOX 44-1 EXAMPLES OF NUTRITION OBJECTIVES FOR *HEALTHY PEOPLE 2020*

Weight and Growth
- Increase proportion of adults who are at a healthy weight (body mass index [BMI] 18.5 to 24.9).
- Reduce the proportion of adults who are obese.
- Reduce the proportion of children (2 to 11 years) who are overweight or obese.

Food and Nutrient Consumption
- Decrease saturated fat intake in population 2 years and older.
- Increase the variety of vegetables and fruit intake in the population 2 years and older.
- Increase grain product intake and consumption of calcium in the population 2 years and older.
- Reduce sodium daily intake in the population 2 years and older.

Iron Deficiency and Anemia
- Reduce prevalence of iron deficiency in children and childbearing women.
- Reduce prevalence of anemia in pregnant women in third trimester to 20%.

Schools, Work Sites, and Nutrition Counseling
- Increase work-site nutrition-education and weight-management program offerings.
- Offer nutrition assessment and individualized planning at primary care sites.
- Increase the percentage of schools that offer nutritious foods and beverages outside of school meals.
- Increase the number of states with nutrition standards for food and beverages provided to preschool-age children in child care.

Food Security
- Increase food security to 94% of households.

Data from U.S. Department of Health and Human Services: *Healthy people 2020,* 2010, http://www.healthypeople.gov/hp2020/objectives.

(MNT) uses nutrition therapy and counseling to manage diseases (American Dietetic Association, 2010b). In some illnesses such as type 1 diabetes mellitus (DM) or mild hypertension, diet therapy is often the major treatment for disease control (ADA, 2008; American Heart Association, 2010). Other conditions such as severe inflammatory bowel disease require specialized nutrition support such as enteral nutrition (EN) or parenteral nutrition (PN). Current standards of care promote optimal nutrition in all patients (American Heart Association, 2010; ACS, 2011).

The U.S. Department of Health and Human Services (USDHHS) and the Public Health Service established nutritional goals and objectives for *Healthy People 2020* (USDHHS, 2010). *Healthy People 2020* is the United States' contribution to the "Health for All" strategy of the World Health Organization (WHO, 2010). *Healthy People 2020* (Box 44-1) continues the objectives initiated in *Healthy People 2000* and *Healthy People 2010,* with overall goals of promoting health and reducing chronic disease. All nutrition-related objectives include baseline data from which progress is measured. The challenge remains to motivate consumers to put these dietary recommendations into practice.

SCIENTIFIC KNOWLEDGE BASE

Nutrients: The Biochemical Units of Nutrition

The body requires fuel to provide energy for cellular metabolism and repair, organ function, growth, and body movement. The **basal metabolic rate (BMR)** is the energy needed to maintain life-sustaining activities (breathing, circulation, heart rate, and temperature) for a specific period of time at rest. Factors such as age, body mass, gender, fever, starvation, menstruation, illness, injury, infection, activity level, or thyroid function affect energy requirements. The **resting energy expenditure (REE),** or resting metabolic rate, is the amount of energy that an individual needs to consume over a 24-hour period for the body to maintain all of its internal working activities while at rest. Factors that affect metabolism include illness, pregnancy, lactation, and activity level.

In general, when energy requirements are completely met by **kilocalorie (kcal)** intake in food, weight does not change. When the kilocalories ingested exceed a person's energy demands, the individual gains weight. If the kilocalories ingested fail to meet a person's energy requirements, the individual loses weight.

Nutrients are the elements necessary for the normal function of numerous body processes. Energy needs are met from a variety of nutrients: carbohydrates, proteins, fats, water, vitamins, and minerals. Food is sometimes described according to its **nutrient density** (i.e., the proportion of essential nutrients to the number of kilocalories). High–nutrient dense foods such as fruits and vegetables provide a large number of nutrients in relationship to kilocalories. Low–nutrient dense foods such as alcohol or sugar are high in kilocalories but nutrient poor.

Carbohydrates. **Carbohydrates,** composed of carbon, hydrogen, and oxygen, are the main source of energy in the diet. Each gram of carbohydrate produces 4 kcal/g and serves as the main source of fuel (glucose) for the brain, skeletal muscles during exercise, erythrocyte and leukocyte production, and cell function of the renal medulla. People obtain carbohydrates primarily from plant foods, except for lactose (milk sugar). They are classified according to their carbohydrate units, or **saccharides.**

Monosaccharides such as glucose (dextrose) or fructose cannot be broken down into a more basic carbohydrate unit. Disaccharides such as sucrose, lactose, and maltose are composed of two monosaccharides and water. Both monosaccharides and disaccharides are classified as **simple carbohydrates** and are found primarily in sugars. Polysaccharides such as glycogen are made up of many carbohydrate units (i.e., complex carbohydrates). They are insoluble in water and digested to varying degrees. Starches are polysaccharides.

The body is unable to digest some polysaccharides because humans do not have enzymes capable of breaking them down. **Fiber** is a polysaccharide that is the structural part of plants that is not broken down by the human digestive enzymes. Because fiber is not broken down, it does not contribute calories to the diet. Insoluble fibers are not digestible and include cellulose, hemicellulose, and lignin. Soluble fibers dissolve in water and include barley, cereal grains, cornmeal, and oats.

Proteins. Proteins provide a source of energy (4 kcal/g), and they are essential for synthesis (building) of body tissue in growth, maintenance, and repair. Collagen, hormones, enzymes, immune cells, deoxyribonucleic acid (DNA), and ribonucleic acid (RNA) are all made of protein. In addition, blood clotting, fluid regulation, and acid-base balance require proteins. These proteins transport nutrients and many drugs in the blood. Ingestion of proteins maintains nitrogen balance.

The simplest form of protein is the **amino acid,** which is made up of hydrogen, oxygen, carbon, and nitrogen. The body does not synthesize **indispensable amino acids;** thus these need to be provided in the diet. Examples of indispensable amino acids are histidine, lysine, and phenylalanine. The body synthesizes **dispensable amino acids.** Examples of amino acids synthesized in the body are

alanine, asparagine, and glutamic acid. Amino acids can link together. Albumin and insulin are simple proteins because they contain only amino acids or their derivatives. The combination of a simple protein with a nonprotein substance produces a complex protein such as lipoprotein, formed by a combination of a lipid and a simple protein.

A complete protein, also called a *high-quality protein,* contains all essential amino acids in sufficient quantity to support growth and maintain nitrogen balance. Examples of foods that contain complete proteins are fish, chicken, soybeans, turkey, and cheese. Incomplete proteins are missing one or more of the nine indispensable amino acids and include cereals, legumes (beans, peas), and vegetables. Complementary proteins are pairs of incomplete proteins that, when combined, supply the total amount of protein provided by complete protein sources.

Nitrogen balance is achieved when the intake and output of nitrogen are equal. When the intake of nitrogen is greater than the output, the body is in positive nitrogen balance. Positive nitrogen balance is required for growth, normal pregnancy, maintenance of lean muscle mass and vital organs, and wound healing. The body uses nitrogen to build, repair, and replace body tissues. Negative nitrogen balance occurs when the body loses more nitrogen than it gains (e.g., with infection, burns, fever, starvation, head injury, and trauma). The increased nitrogen loss is the result of body tissue destruction or loss of nitrogen-containing body fluids. Nutrition during this period needs to provide nutrients to put patients into positive balance for healing.

Protein provides energy; however, because of the essential role of protein in growth, maintenance, and repair, a diet needs to provide adequate kilocalories from nonprotein sources. When there is sufficient carbohydrate in the diet to meet the energy needs of the body, protein is spared as an energy source.

Fats. Fats **(lipids)** are the most calorie-dense nutrient, providing 9 kcal/g. Fats are composed of triglycerides and fatty acids. **Triglycerides** circulate in the blood and are composed of three fatty acids attached to a glycerol. **Fatty acids** are composed of chains of carbon and hydrogen atoms with an acid group on one end of the chain and a methyl group at the other. Fatty acids can be **saturated,** in which each carbon in the chain has two attached hydrogen atoms; or **unsaturated,** in which an unequal number of hydrogen atoms are attached and the carbon atoms attach to each other with a double bond. **Monounsaturated** fatty acids have one double bond, whereas **polyunsaturated** fatty acids have two or more double carbon bonds. The various types of fatty acids have significance for health and the incidence of disease and are referred to in dietary guidelines.

Fatty acids are also classified as essential or nonessential. Linoleic acid, an unsaturated fatty acid, is the only essential fatty acid in humans. Linolenic acid and arachidonic acid (also unsaturated fatty acids) are important for metabolic processes but are manufactured by the body when linoleic acid is available. Deficiency occurs when fat intake falls below 10% of daily nutrition. Most animal fats have high proportions of saturated fatty acids, whereas vegetable fats have higher amounts of unsaturated and polyunsaturated fatty acids.

Water. Water is critical because cell function depends on a fluid environment. Water makes up 60% to 70% of total body weight. The percent of total body water is greater for lean people than obese people because muscle contains more water than any other tissue except blood. Infants have the greatest percentage of total body water, and older people have the least. When deprived of water, a person cannot survive for more than a few days.

An individual meets fluid needs by drinking liquids and eating solid foods high in water content such as fresh fruits and vegetables. Water is also produced during digestion when food is oxidized. In a healthy individual fluid intake from all sources equals fluid output through elimination, respiration, and sweating (see Chapters 41 and 45). An ill person has an increased need for fluid (e.g., with fever or gastrointestinal [GI] losses). By contrast, he or she also has a decreased ability to excrete fluid (e.g., with cardiopulmonary or renal disease), which often leads to the need for fluid restriction.

Vitamins. **Vitamins** are organic substances present in small amounts in foods that are essential to normal metabolism. They are chemicals that act as catalysts in biochemical reactions. When there is enough of any specific vitamin to meet the body's catalytic demands, the rest of the vitamin supply acts as a free chemical and is often toxic to the body. Certain vitamins are currently of interest in their role as antioxidants. These vitamins neutralize substances called *free radicals,* which produce oxidative damage to body cells and tissues. Researchers think that oxidative damage increases a person's risk for various cancers. These vitamins include betacarotene and vitamins A, C, and E (Nix, 2009).

The body is unable to synthesize vitamins in the required amounts and depends on dietary intake. Vitamin content is usually highest in fresh foods that are used quickly after minimal exposure to heat, air, or water. Vitamins are classified as fat soluble and water soluble.

Fat-Soluble Vitamins. The **fat-soluble vitamins** (A, D, E, and K) are stored in the fatty compartments of the body. With the exception of vitamin D, people acquire vitamins through dietary intake. **Hypervitaminosis** of fat-soluble vitamins results from megadoses (intentional or unintentional) of supplemental vitamins, excessive amounts in fortified food, and large intake of fish oils.

Water-Soluble Vitamins. The **water-soluble vitamins** are vitamin C and the B complex (which is eight vitamins). The body does not store water-soluble vitamins; thus they need to be provided in daily food intake. Water-soluble vitamins absorb easily from the GI tract. Although they are not stored, toxicity can still occur.

Minerals. **Minerals** are inorganic elements essential to the body as catalysts in biochemical reactions. They are classified as **macrominerals** when the daily requirement is 100 mg or more and microminerals or **trace elements** when less than 100 mg is needed daily. Macrominerals help to balance the pH of the body, and specific amounts are necessary in the blood and cells to promote acid-base balance. Interactions occur among trace minerals. For example, excess of one trace mineral sometimes causes deficiency of another. Selenium is a trace element that also has antioxidant properties. Silicon, vanadium, nickel, tin, cadmium, arsenic, aluminum, and boron play an unidentified role in nutrition. Arsenic, aluminum, and cadmium have toxic effects.

Anatomy and Physiology of the Digestive System

Digestion. Digestion of food is the mechanical breakdown that results from chewing, churning, and mixing with fluid and chemical reactions in which food is reduced to its simplest form. Each part of the GI system has an important digestive or absorptive function (Fig. 44-1). **Enzymes** are the proteinlike substances that act as catalysts to speed up chemical reactions. They are an essential part of the chemistry of digestion.

Most enzymes have one specific function. Each enzyme works best at a specific pH. For example, the enzyme amylase in the saliva breaks down starches into sugars. The secretions of the GI tract have very different pH levels. For example, saliva is relatively

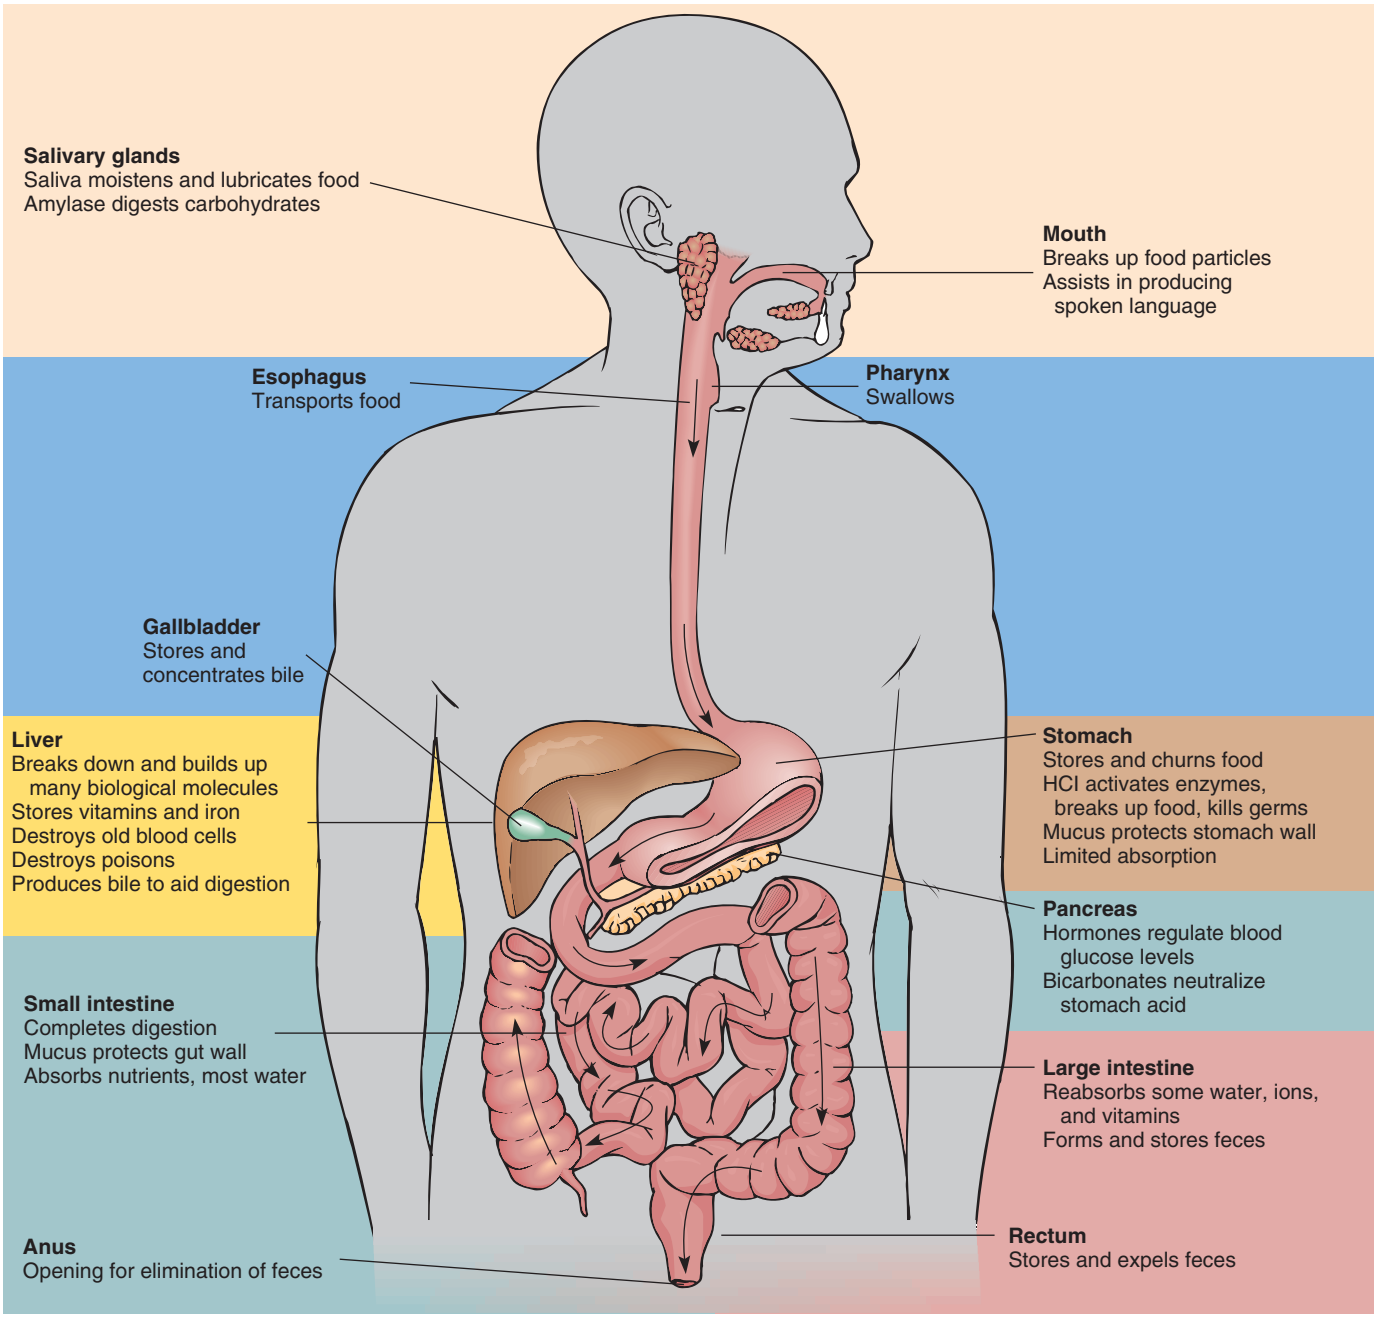

FIG. 44-1 Summary of digestive system anatomy/organ function. *HCl,* Hydrochloric acid. (From Rolin Graphics.)

neutral, gastric juice is highly acidic, and the secretions of the small intestine are alkaline.

The mechanical, chemical, and hormonal activities of digestion are interdependent. Enzyme activity depends on the mechanical breakdown of food to increase its surface area for chemical action. Hormones regulate the flow of digestive secretions needed for enzyme supply. Physical, chemical, and hormonal factors regulate the secretion of digestive juices and the motility of the GI tract. Nerve stimulation from the parasympathetic nervous system (e.g., the vagus nerve) increases GI tract action.

Digestion begins in the mouth, where chewing mechanically breaks down food. The food mixes with saliva, which contains ptyalin (salivary amylase), an enzyme that acts on cooked starch to begin its conversion to maltose. The longer an individual chews food, the more starch digestion occurs in the mouth. Proteins and fats are broken down physically but remain unchanged chemically because enzymes in the mouth do not react with these nutrients. Chewing reduces food particles to a size suitable for swallowing, and saliva provides lubrication to further ease swallowing of the food. The epiglottis is a flap of skin that closes over the trachea as a person swallows to prevent aspiration. Swallowed food enters the esophagus, and wavelike muscular contractions **(peristalsis)** move the food to the base of the esophagus, above the cardiac sphincter. Pressure from a bolus of food at the cardiac sphincter causes it to relax, allowing the food to enter the fundus, or uppermost portion, of the stomach.

The chief cells in the stomach secrete pepsinogen; and the pyloric glands secrete gastrin, a hormone that triggers parietal cells to secrete hydrochloric acid (HCl). The parietal cells also secrete HCl and intrinsic factor (IF), which is necessary for absorption of vitamin B_{12} in the ileum. HCl turns pepsinogen into pepsin, a protein-splitting enzyme. The body produces gastric lipase and amylase to begin fat and starch digestion, respectively. A thick layer of mucus protects the lining of the stomach from autodigestion. Alcohol and aspirin are two substances directly absorbed through the lining of the stomach. The stomach acts as a reservoir where food remains for approximately 3 hours, with a range of 1 to 7 hours.

Food leaves the antrum, or distal stomach, through the pyloric sphincter and enters the duodenum. Food is now an acidic, liquefied mass called **chyme.** Chyme flows into the duodenum and quickly mixes with bile, intestinal juices, and pancreatic secretions. The small intestine secretes the hormones secretin and cholecystokinin (CCK). Secretin activates release of bicarbonate from the pancreas, raising the pH of chyme. CCK inhibits further gastrin secretion and initiates release of additional digestive enzymes from the pancreas and gallbladder.

Bile is manufactured in the liver and concentrated and stored in the gallbladder. It acts as a detergent because it emulsifies fat to permit enzyme action while suspending fatty acids in solution. Pancreatic secretions contain six enzymes: amylase to digest starch; lipase to break down emulsified fats; and trypsin, elastase, chymotrypsin, and carboxypeptidase to break down proteins.

Peristalsis continues in the small intestine, mixing the secretions with chyme. The mixture becomes increasingly alkaline, inhibiting the action of the gastric enzymes and promoting the action of the duodenal secretions. Epithelial cells in the small intestinal villi secrete enzymes (e.g., sucrase, lactase, maltase, lipase, and peptidase) to facilitate digestion. The major portion of digestion occurs in the small intestine, producing glucose, fructose, and galactose from carbohydrates; amino acids and dipeptides from proteins; and fatty acids, glycerides, and glycerol from lipids. Peristalsis usually takes approximately 5 hours to pass food through the small intestine.

Absorption. The small intestine is the primary absorption site for nutrients. It is lined with fingerlike projections called *villi*. Villi increase the surface area available for absorption. The body absorbs nutrients by means of passive diffusion, osmosis, active transport, and pinocytosis (Table 44-1).

Carbohydrates, protein, minerals, and water-soluble vitamins are absorbed by the small intestine, processed in the liver, and released into the portal vein circulation. Fatty acids are absorbed in the lymphatic circulatory systems through lacteal ducts at the center of each microvilli in the small intestine.

Approximately 85% to 90% of water is absorbed in the small intestine (Huether et al., 2008). Approximately 8.5 L of GI secretions and 1.5 L of oral intake are managed daily within the GI tract. The small intestine resorbs 9.5 L, and the colon absorbs approximately 0.4 L. The remaining 0.1 L is eliminated in feces. In addition, electrolytes and minerals are absorbed in the colon, and bacteria synthesize vitamin K and some B-complex vitamins. Finally, feces are formed for elimination.

Metabolism and Storage of Nutrients. **Metabolism** refers to all of the biochemical reactions within the cells of the body. Metabolic processes are anabolic (building) or catabolic (breaking down). **Anabolism** is the building of more complex biochemical substances by synthesis of nutrients. Anabolism occurs when an individual adds lean muscle through diet and exercise. Amino acids are anabolized into tissues, hormones, and enzymes. Normal metabolism and anabolism are physiologically possible when the body is in positive nitrogen balance. **Catabolism** is the breakdown of biochemical substances into simpler substances and occurs during physiological states of negative nitrogen balance. Starvation is an example of catabolism when wasting of body tissues occurs.

Nutrients absorbed in the intestines, including water, are transported through the circulatory system to the body tissues. Through the chemical changes of metabolism, the body converts nutrients into a number of required substances. Carbohydrates, protein, and fat are metabolized to produce chemical energy and maintain a balance between anabolism and catabolism. To carry out the work of the body, the chemical energy produced by metabolism converts to other types of energy by different tissues. Muscle contraction involves mechanical energy, nervous system function involves electrical energy, and the mechanisms of heat production involve thermal energy.

Some of the nutrients required by the body are stored in tissues. The major form of body reserve energy is fat, stored as adipose tissue. Protein is stored in muscle mass. When the energy requirements of the body exceed the energy supplied by ingested nutrients, stored energy is used. Monoglycerides from the digested portion of fats are converted to glucose by gluconeogenesis. Amino acids are also converted to fat and stored or catabolized into energy through gluconeogenesis. All body cells except red blood cells and neurons oxidize fatty acids into **ketones** for energy when dietary carbohydrates (glucose) are not adequate. Glycogen, synthesized from glucose, provides energy during brief periods of fasting (e.g., during sleep). It is stored in small reserves in liver and muscle tissue. Nutrient metabolism consists of three main processes:

1. Catabolism of glycogen into glucose, carbon dioxide, and water **(glycogenolysis)**
2. Anabolism of glucose into glycogen for storage **(glycogenesis)**
3. Catabolism of amino acids and glycerol into glucose for energy **(gluconeogenesis)**

TABLE 44-1 Mechanisms for Intestinal Absorption of Nutrients

MECHANISM	DEFINITION
Active transport	An energy-dependent process whereby particles move from an area of greater concentration to an area of lesser concentration. A special "carrier" moves the particle across the cell membrane.
Passive diffusion	The force by which particles move outward from an area of greater concentration to lesser concentration. The particles do not need a special "carrier" to move outward in all directions.
Osmosis	Movement of water through a membrane that separates solutions of different concentrations. Water moves to equalize the concentration pressures on both sides of the membrane.
Pinocytosis	Engulfing of large molecules of nutrients by the absorbing cell when the molecule attaches to the absorbing cell membrane.

Data from Nix S: *Williams' basic nutrition and diet therapy*, ed 13, St Louis, 2009, Mosby.

Elimination. Chyme moves by peristaltic action through the ileocecal valve into the large intestine, where it becomes feces (see Chapter 46). Water absorbs in the mucosa as feces move toward the rectum. The longer the material stays in the large intestine, the more water is absorbed, causing the feces to become firmer. Exercise and fiber stimulate peristalsis, and water maintains consistency. Feces contain cellulose and similar indigestible substances, sloughed epithelial cells from the GI tract, digestive secretions, water, and microbes.

Dietary Guidelines

Dietary Reference Intakes. **Dietary reference intakes (DRIs)** present evidence-based criteria for an acceptable range of amounts of vitamins and nutrients for each gender and age-group (Institute of Medicine, 2006). There are four components to the DRIs. The estimated average requirement (EAR) is the recommended amount of a nutrient that appears sufficient to maintain a specific body function for 50% of the population based on age and gender. The recommended dietary allowance (RDA) is the average needs of 98% of the population, not the exact needs of the individual. The adequate intake (AI) is the suggested intake for individuals based on observed or experimentally determined estimates of nutrient intakes and is used when there is not enough evidence to set the RDA. The tolerable upper intake level (UL) is the highest level that likely poses no risk of adverse health events. It is not a recommended level of intake (Tolerable upper level intake, 2010).

Food Guidelines. The U.S. Department of Agriculture (USDA) and the U.S. Department of Health and Human Services (USDHHS) published the *Dietary Guidelines for Americans 2010* and provide average daily consumption guidelines for the five food groups: grains, vegetables, fruits, dairy products, and meats (Box 44-2). These guidelines are for Americans over the age of 2 years. As a nurse, consider the food preferences of patients from different racial and ethnic groups, vegetarians, and others when planning diets. The *ChooseMyPlate* program was developed by the U.S. Department of Agriculture to replace the *My Food Pyramid* program. *ChooseMyPlate* provides a basic guide for making food choices for a healthy lifestyle (Fig. 44-2). The *ChooseMyPlate* program includes guidelines for balancing calories; decreasing portion size; increasing healthy foods; increasing water consumption; and decreasing fats, sodium, and sugars (USDA, 2011a).

Daily Values. The Food and Drug Administration (FDA) created **daily values** for food labels in response to the 1990 Nutrition Labeling and Education Act (NLEA). The FDA first established two sets of reference values. The referenced daily intakes (RDIs) are the first set, comprising protein, vitamins, and minerals based on the RDA. The daily reference values (DRVs) make up the second set and consist of nutrients such as total fat, saturated fat, cholesterol, carbohydrates, fiber, sodium, and potassium. Combined, both sets make up the daily values used on food labels (USFDA, 2008). Daily values did not replace RDAs but provided a separate, more understandable format for the public. Daily values are based on percentages of a diet consisting of 2000 kcal/day for adults and children 4 years or older.

NURSING KNOWLEDGE BASE

Sociological, cultural, psychological, and emotional factors are associated with eating and drinking in all societies. Holidays and events are celebrated with food, food is brought to those who are grieving, and food is used for medicinal purposes. It is incorporated into family traditions and rituals and is often associated with eating behaviors. You need to understand patients' values, beliefs, and attitudes about food and how these values affect food purchase, preparation, and intake to affect eating patterns.

Nutritional requirements depend on many factors. Individual caloric and nutrient requirements vary by stage of development, body composition, activity levels, pregnancy and lactation, and the presence of disease. Registered dietitians (RDs) use predictive equations that take into account some of these factors to estimate patients' nutritional requirements.

BOX 44-2 2010 DIETARY GUIDELINES FOR AMERICANS: KEY RECOMMENDATIONS FOR THE GENERAL POPULATION

- Adopt a balanced eating pattern with a variety of nutrient-dense food and beverages among the basic food groups.
- Maintain body weight in a healthy range.
- Encourage physical activity and decrease sedentary activities.
- Encourage fruits, vegetables, whole-grain products, seafood, and fat-free or low-fat milk.
- Reduce amount of foods containing sugars.
- Eat moderate amount of lean meats, poultry, and eggs.
- Keep total fat intake between 20% and 35% of total calories, with most fats coming from polyunsaturated or monounsaturated fatty acids.
- Choose and prepare foods and beverages with little added sugar or sweeteners.
- Choose and prepare foods with little salt and eat potassium-rich foods.
- Limit intake of alcohol to moderate use (i.e., one drink daily for women and two drinks daily for men).
- Practice food safety to prevent bacterial foodborne illness. Use food safety principles of Clean, Separate, Cook, and Chill.

Data from US Department of Agriculture and US Department of Health and Human Services: Dietary Guidelines for Americans, 2010. *Report of Dietary Guidelines Advisory Committee on the dietary guidelines for Americans 2010,* http://www.cnpp.usda.gov/dietaryguidelines.htm. Accessed October 29, 2011.

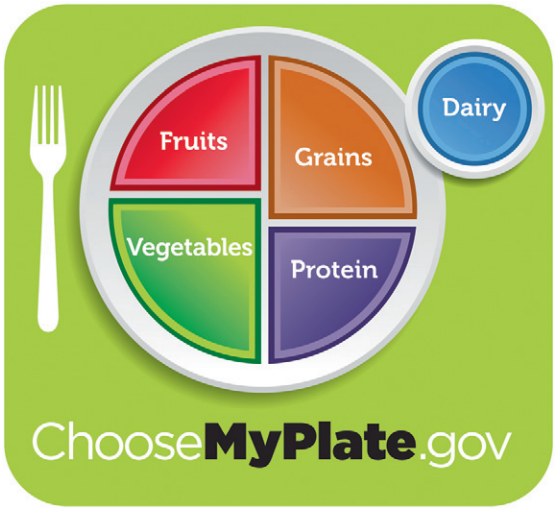

FIG. 44-2 ChooseMyPlate. (From US Department of Agriculture: ChooseMyPlate, 2011, http://www.choosemyplate.gov).

Factors Influencing Nutrition

Environmental Factors. Environmental factors beyond the control of individuals contribute to the development of obesity. Obesity is an epidemic in the United States. The prevalence of

obesity in adults has doubled since 1980, with 33% of adults in the United States overweight, 34% obese, and 6 % extremely obese (body mass index [BMI] ≥40) (Khan et al., 2009). Proposed contributing factors are sedentary lifestyle, work schedules, and poor meal choices often related to the increasing frequency of eating away from home and eating fast food (Kruskall, 2006). The likelihood of healthy eating and participation in exercise or other activities of healthy living is limited by environmental factors. Lack of access to full-service grocery stores, high cost of healthy food, widespread availability of less healthy foods in fast-food restaurants, widespread advertising of less healthy food, and lack of access to safe places to play and exercise are environmental factors that contribute to obesity (Khan et al., 2009).

Developmental Needs

Infants Through School-Age. Rapid growth and high protein, vitamin, mineral, and energy requirements mark the developmental stage of infancy. The average birth weight of an American baby is 3.2 to 3.4 kg (7 to 7½ pounds). An infant usually doubles birth weight at 4 to 5 months and triples it at 1 year. Infants need an energy intake of approximately 90 to 110 kcal/kg of body weight, with premature infants needing 105 to 130 kcal/kg per day (Nix, 2009). Commercial formulas and human breast milk both provide approximately 20 kcal/oz. A full-term newborn is able to digest and absorb simple carbohydrates, proteins, and a moderate amount of emulsified fat. Infants need about 100 to 120 mL/kg/day of fluid because a large portion of total body weight is water.

Breastfeeding. The American Dietetic Association strongly supports exclusive breastfeeding for the first 6 months of life and breastfeeding with complementary foods from 6 to 12 months (American Dietetic Association, 2009). Breastfeeding has multiple benefits for both infant and mother, including fewer food allergies and intolerances; fewer infant infections; easier digestion; convenience, availability, and freshness; temperature always correct; economical because it is less expensive than formula; and increased time for mother and infant interaction.

Formula. Infant formulas contain the approximate nutrient composition of human milk. Protein in the formula is typically whey, soy, cow's milk base, casein hydrolysate, or elemental amino acids. The American Academy of Pediatrics sets standards for the level of nutrients in infant formulas. Soy protein–based formulas are used for infants allergic or intolerant to cow's milk (Nix, 2009).

Infants should not have regular cow's milk during the first year of life. It is too concentrated for an infant's kidneys to manage, increases the risk of milk product allergies, and is a poor source of iron and vitamins C and E (Nix, 2009). Honey and corn syrup are potential sources of botulism toxin and should not be used in an infant's diet. This toxin is potentially fatal in children under 1 year of age (Nix, 2009).

Introduction to Solid Food. Breast milk or formula provides sufficient nutrition for the first 4 to 6 months of life. The development of fine-motor skills of the hand and fingers parallels an infant's interest in food and self-feeding. Iron-fortified cereals are typically the first semisolid food to be introduced. For infants 4 to 11 months, cereals are the most important nonmilk source of protein (Fox et al., 2006).

The addition of foods to an infant's diet is governed by an infant's nutrient needs, physical readiness to handle different forms of foods, and the need to detect and control allergic reactions. Foods such as wheat, egg white, nuts, citrus juice, and chocolate have a high incidence of allergies and should be added late (Nix, 2009). Caregivers should introduce new foods one at a time, approximately 4 to 7 days apart to identify allergies. It is best to introduce new foods before milk or other foods to avoid satiety (Hockenberry and Wilson, 2011).

The growth rate slows during toddler years (1 to 3 years). A toddler needs fewer kilocalories but an increased amount of protein in relation to body weight; consequently appetite often decreases at 18 months of age. Toddlers exhibit strong food preferences and become picky eaters. Small frequent meals consisting of breakfast, lunch, and dinner with three interspersed high nutrient–dense snacks help improve nutritional intake (Hockenberry and Wilson, 2011). Calcium and phosphorus are important for healthy bone growth.

Toddlers who consume more than 24 ounces of milk daily in place of other foods sometimes develop milk anemia because milk is a poor source of iron. Toddlers need to drink whole milk until the age of 2 years to make sure that there is adequate intake of fatty acids necessary for brain and neurological development. Certain foods such as hot dogs, candy, nuts, grapes, raw vegetables, and popcorn have been implicated in choking deaths and need to be avoided. Dietary requirements for preschoolers (3 to 5 years) are similar to those for toddlers. They consume slightly more than toddlers, and nutrient density is more important than quantity.

School-age children, 6 to 12 years old, grow at a slower and steadier rate, with a gradual decline in energy requirements per unit of body weight. Despite better appetites and more varied food intake, you need to assess school-age children's diets carefully for adequate protein and vitamins A and C. They often fail to eat a proper breakfast and have unsupervised intake at school. High fat, sugar, and salt result from too-liberal intake of snack foods. Physical activity level decreases consistently, and high-calorie, readily available food increases in consumption, leading to an increase in childhood obesity (Budd and Hayman, 2008).

In the last 20 years the prevalence of overweight children has risen. The percent of obesity in children ages 6 to 11 years has doubled to 17%, and the percent of overweight adolescents has more than tripled to 17.6% (Li and Hooker, 2010). A combination of factors contributes to the problem, including a diet rich in high-calorie foods, food advertising targeting children, inactivity, genetic predisposition, use of food as a coping mechanism for stress or boredom or as a reward or celebration, and family and social factors (Budd and Hayman, 2008). Childhood obesity contributes to medical problems related to the cardiovascular system, endocrine system, and mental health (Budd and Hayman, 2008). As a result of the obesity, the incidence of type II diabetes in children is also increasing. Prevention of childhood obesity is critical because of the long-term effects. Family education is an important component in decreasing the prevalence of this problem. Promote healthy food choices and eating in moderation along with increased physical activity.

Adolescents. During adolescence physiological age is a better guide to nutritional needs than chronological age. Energy needs increase to meet greater metabolic demands of growth. Daily requirement of protein also increases. Calcium is essential for the rapid bone growth of adolescence, and girls need a continuous source of iron to replace menstrual losses. Boys also need adequate iron for muscle development. Iodine supports increased thyroid activity, and use of iodized table salt ensures availability. B-complex vitamins are necessary to support heightened metabolic activity.

Many factors other than nutritional needs influence the adolescent's diet, including concern about body image and appearance, desire for independence, eating at fast-food restaurants, peer pressure, and fad diets. Nutritional deficiencies often occur in adolescent girls as a result of dieting and use of oral contraceptives. An

adolescent boy's diet is often inadequate in total kilocalories, protein, iron, folic acid, B vitamins, and iodine. Snacks provide approximately 25% of a teenager's total dietary intake. Fast food, particularly value-size or super-size meals, is common and adds extra salt, fat, and kilocalories (Budd and Hayman, 2008). Skipping meals or eating meals with unhealthy choices of snacks contributes to nutrient deficiency and obesity (Hockenberry and Wilson, 2011).

Fortified foods (nutrients added) are important sources of vitamins and minerals. Snack food from the dairy and fruit and vegetable groups are good choices. To counter obesity, increasing physical activity is often more important than curbing intake. The onset of eating disorders such as **anorexia nervosa** or **bulimia nervosa** often occurs during adolescence. Recognition of eating disorders is essential for early intervention (Box 44-3).

Sports and regular moderate-to-intense exercise necessitate dietary modification to meet increased energy needs for adolescents. Carbohydrates, both simple and complex, are the main source of energy, providing 55% to 60% of total daily kilocalories. Protein needs increase to 1 to 1.5 g/kg/day. Fat needs do not increase. Adequate hydration is very important. Adolescents need to ingest water before and after exercise to prevent dehydration, especially in hot, humid environments. Vitamin and mineral supplements are not required, but intake of iron-rich foods is required to prevent anemia.

Parents have more influence on adolescents' diets than they believe. Effective strategies include limiting the amount of unhealthy food choices kept at home, encouraging smart snacks such as fruit vegetables or string cheese, and enhancing the appearance and taste of healthy foods (Mayo Clinic Staff, 2009). Making healthy food choices more convenient at home and at fast-food restaurants and discouraging adolescents from eating while watching television are ways to promote healthy eating (Befort et al., 2006).

Pregnancy occurring within 4 years of menarche places a mother and fetus at risk because of anatomical and physiological immaturity. Malnutrition at the time of conception increases risk to the adolescent and her fetus. Most teenage girls do not want to gain weight. Counseling related to nutritional needs of pregnancy is often difficult, and teens tolerate suggestions better than rigid directions. The diet of pregnant adolescents is often deficient in calcium, iron, and vitamins A and C. Prenatal vitamin and mineral supplements are recommended.

Young and Middle Adults. There is a reduction in nutrient demands as the growth period ends. Mature adults need nutrients for energy, maintenance, and repair. Energy needs usually decline over the years. Obesity becomes a problem because of decreased physical exercise, dining out more often, and increased ability to afford more luxury foods. Adult women who use oral contraceptives often need extra vitamins. Iron and calcium intake continues to be important.

Pregnancy. Poor nutrition during pregnancy causes low birth weight in infants and decreases chances of survival. Generally the needs of a fetus are met at the expense of the mother. However, if nutrient sources are not available, both suffer. The nutritional status of the mother at the time of conception is important. Significant aspects of fetal growth and development often occur before the mother suspects the pregnancy. The energy requirements of pregnancy are related to the mother's body weight and activity. The quality of nutrition during pregnancy is important, and food intake in the first trimester includes balanced portions of essential nutrients with emphasis on quality. Protein intake throughout pregnancy needs to increase to 60 g daily. Calcium intake is especially critical in the third trimester, when fetal bones are mineralized. Iron needs to be supplemented to provide for increased maternal blood volume, fetal blood storage, and blood loss during delivery.

Folic acid intake is particularly important for deoxyribonucleic acid (DNA) synthesis and the growth of red blood cells. Inadequate intake can lead to fetal neural tube defects, anencephaly, or maternal megaloblastic anemia (Nix, 2009). Women of childbearing age need to consume 400 mcg of folic acid daily, increasing to 600 mcg daily during pregnancy. Prenatal care usually includes vitamin and mineral supplementation to ensure daily intakes; however, pregnant women should not take additional supplements beyond prescribed amounts.

Lactation. The lactating woman needs 500 kcal/day above the usual allowance because the production of milk increases energy requirements. Protein requirements during lactation are greater than those required during pregnancy. The need for calcium remains the same as during pregnancy. There is an increased need for vitamins A and C. Daily intake of water-soluble vitamins (B and C) is necessary to ensure adequate levels in breast milk. Fluid intake needs to be adequate but not excessive. Caffeine, alcohol, and drugs are excreted in breast milk and should be avoided.

Older Adults. Adults 65 years and older have a decreased need for energy because their metabolic rate slows with age. However, vitamin and mineral requirements remain unchanged from middle adulthood. Numerous factors influence the nutritional status of the older adult (Box 44-4). Age-related changes in appetite, taste, smell, and the digestive system affect nutrition (Touhy and Jett, 2010). For example, older adults often experience a decrease in taste cells that alters food flavor and may decrease intake. Multiple factors

BOX 44-3 POTENTIAL ASSESSMENT FOR EATING DISORDERS

Anorexia Nervosa

- Refusal to maintain body weight over a minimal normal weight for age and height (e.g., weight loss leading to maintenance of body weight less than 85% of ideal body weight) or failure to make expected weight gain during period of growth, leading to body weight less than 85% of that expected
- Intense fear of gaining weight or becoming fat, although underweight
- Disturbance in the way in which one's body weight, size, or shape is experienced (e.g., the person claims to "feel fat" even when emaciated; believes that one area of the body is "too fat" even when obviously underweight)
- In females absence of at least three consecutive menstrual cycles when otherwise expected to occur (primary or secondary amenorrhea). (A woman is considered to have amenorrhea if her periods occur only following hormone [e.g., estrogen] administration.)

Bulimia Nervosa

- Recurrent episodes of binge eating (rapid consumption of a large amount of food in a discrete period of time)
- A feeling of lack of control over eating behavior during eating binges
- Regularly engages in self-induced vomiting, use of laxatives or diuretics, strict dieting or fasting, or vigorous exercise to prevent weight gain
- Minimum average of two binge-eating episodes a week for at least 3 months

TABLE 44-2 Sample of Drug-Nutrient Interactions*

DRUG	EFFECT
Analgesic	
Acetaminophen	Decreased drug absorption with food; overdose associated with liver failure
Aspirin	Absorbed directly through stomach; decreased drug absorption with food; decreased folic acid, vitamins C and K, and iron absorption
Antacid	
Aluminum hydroxide	Decreased phosphate absorption
Sodium bicarbonate	Decreased folic acid absorption
Antiarrhythmic	
Amiodarone (Codarone)	Taste alteration
Digitalis	Anorexia, decreased renal clearance in older people
Antibiotic	
Penicillin	Decreased drug absorption with food, taste alteration
Cephalosporin	Decreased vitamin K
Rifampin (Rifadin)	Decreased vitamin B_6, niacin, vitamin D
Tetracycline	Decreased drug absorption with milk and antacids; decreased nutrient absorption of calcium, riboflavin, vitamin C caused by binding
Trimethoprim/sulfamethoxazole	Decreased folic acid

BOX 44-4 FOCUS ON OLDER ADULTS

Factors Affecting Nutritional Status

- Age-related gastrointestinal changes that affect digestion of food and maintenance of nutrition include changes in the teeth and gums, reduced saliva production, atrophy of oral mucosal epithelial cells, increased taste threshold, decreased thirst sensation, reduced gag reflex, and decreased esophageal and colonic peristalsis (Touhy and Jett, 2010).
- The presence of chronic illnesses (e.g., diabetes mellitus, end-stage renal disease, cancer) often affects nutrition intake (Ebersole et al., 2008).
- Adequate nutrition in older adults is affected by multiple causes such as lifelong eating habits, ethnicity, socialization, income, educational level, physical functional level to meet activities of daily living (ADLs), loss, dentition, and transportation (Touhy and Jett, 2010).
- Adverse effects of medications cause problems such as anorexia, gastrointestinal bleeding, xerostomia, early satiety, and impaired smell and taste perception (Lehne, 2010).
- Cognitive impairments such as delirium, dementia, and depression affect ability to obtain, prepare, and eat healthy foods (Chang and Roberts, 2008; Ebersole et al., 2008).

contribute to the risk of food insecurity in the older adult. Income is significant because living on a fixed income often reduces the amount of money available to buy food. Health is another important influence that affects a person's desire and ability to eat. Lack of transportation or ability to get to the grocery store because of mobility problems contributes to inability to purchase adequate and nutritious food. Often availability of nutritionally adequate and safe foods is limited or uncertain.

Maintaining good oral health is significant throughout adulthood, particularly as an individual ages. Difficulty chewing, missing teeth, having teeth in poor condition, and oral pain result from poor oral health. These often contribute to malnutrition and dehydration in older adults (Touhy and Jett, 2010). Poor oral hygiene and periodontal disease are potential risk factors for systemic diseases such as joint infections, ischemic stroke, cardiovascular disease, DM, and aspiration pneumonia (O'Connor, 2008).

The older adult is often on a therapeutic diet or has difficulty eating because of physical symptoms, lack of teeth, or dentures or is at risk for drug-nutrient interactions (Table 44-2). Caution older adults to avoid grapefruit and grapefruit juice because they alter absorption of many drugs. Thirst sensation diminishes, leading to inadequate fluid intake or dehydration (see Chapter 41). Symptoms of dehydration in older adults include confusion; weakness; hot, dry skin; furrowed tongue; rapid pulse; and high urinary sodium. Some older adults avoid meats because of cost or because they are difficult to chew. Cream soups and meat-based vegetable soups are nutrient-dense sources of protein. Cheese, eggs, and peanut butter are also useful high-protein alternatives. Milk continues to be an important food for older women and men who need adequate calcium to protect against osteoporosis (a decrease of bone mass density). Screening and treatment are necessary for both older men and women. Vitamin D supplements are important for improving strength and balance, strengthening bone health, and preventing bone fractures and falls (Park et al., 2008). The diet of older adults needs to contain choices from all food groups and often requires a vitamin and mineral supplement. MyPlate for Older Adults addresses the specific nutritional needs for older adults and encourages physical activity (Tufts University, 2011).

The USDHHS Administration on Aging (AOA) requires states to provide nutrition screening services to older adults who benefit from home-delivered or congregate meal services. This program requires meals to provide at least one third of the DRI for an older adult and meet the Dietary Guidelines for Americans (American Dietetic Association, 2010a). Homebound older adults with chronic illnesses have additional nutritional risks. They frequently live alone with little or no social or financial resources to assist in obtaining or preparing nutritionally sound meals, contributing to

TABLE 44-2 **Sample of Drug-Nutrient Interactions*—cont'd**

DRUG	EFFECT
Anticoagulant	
Warfarin (Coumadin)	Acts as antagonist to vitamin K
Anticonvulsant	
Carbamazepine (Tegretol)	Increased drug absorption with food
Phenytoin (Dilantin)	Decreased calcium absorption; decreased vitamins D and K and folic acid; taste alteration; decreased drug absorption with food
Antidepressant	
Amitriptyline	Appetite stimulant
Clomipramine (Anafranil)	Taste alteration, appetite stimulant
Fluoxetine (Prozac) (selective serotonin reuptake inhibitors [SSRIs])	Taste alteration, anorexia
Antihypertensive	
Captopril (Capoten)	Taste alteration, anorexia
Hydralazine	Enhanced drug absorption with food, decreased vitamin B_6
Labetalol (Normodyne)	Taste alteration (weight gain for all beta-blockers)
Methyldopa	Decreased vitamin B_{12}, folic acid, iron
Antiinflammatory	
All steroids	Increased appetite and weight, increased folic acid, decreased calcium (osteoporosis with long-term use), promotes gluconeogenesis of protein
Antiparkinson	
Levodopa (Dopar)	Taste alteration, decreased vitamin B_6 and drug absorption with food
Antipsychotic	
Chlorpromazine	Increased appetite
Thiothixene	Decreased riboflavin, increased need
Bronchodilator	
Albuterol sulfate	Appetite stimulant
Theophylline	Anorexia
Cholesterol Lowering	
Cholestyramine (Prevalite)	Decreased fat-soluble vitamins (A, D, E, K); vitamin B_{12}; iron
Diuretic	
Furosemide (Lasix)	Decreased drug absorption with food
Spironolactone (Aldactone)	Increased drug absorption with food
Thiazides	Decreased magnesium, zinc, and potassium
Laxative	
Mineral oil	Decreased absorption of fat-soluble vitamins (A, D, E, K), carotene
Platelet Aggregate Inhibitor	
Dipyridamole (Persantine)	Decreased drug absorption with food
Potassium Replacement	
Potassium chloride	Decreased vitamin B_{12}
Tranquilizer	
Benzodiazepines	Increased appetite

the risk for food insecurity. Approximately 19% of older adults experience some degree of food insecurity as a result of low income or poverty (American Dietetic Association, 2010a). Increased nutrition screening by the nurse results in early recognition and treatment of nutritional deficiencies. Undernourishment of older adults often results in health problems that lead to admission to acute care hospitals or long-term care facilities.

Alternative Food Patterns

Long before the FDA issued recommended allowances and guidelines, many people followed special patterns of food intake based on religion (Table 44-3), cultural background (Box 44-5), ethics, health beliefs, personal preference, or concern for the efficient use of land to produce food. Such special diets are not necessarily more or less nutritious than diets based on the MyPlate or other

TABLE 44-3 Religious Dietary Restrictions

MUSLIM	CHRISTIANITY	HINDUISM	JUDAISM	CHURCH OF JESUS CHRIST OF LATTER-DAY SAINTS (MORMONS)	SEVENTH-DAY ADVENTISTS CHURCH
Pork Alcohol Caffeine Ramadan fasting sunrise to sunset for month Ritualized methods of animal slaughter required for meat ingestion	Some faiths, such as Baptists, have minimal or no alcohol Some meatless days may be observed during the calendar year, commonly during Lent	All meats Fish, shellfish with some restrictions Alcohol	Pork Predatory fowl Shellfish (eat only fish with scales) Rare meats Blood (e.g., blood sausage) Mixing of milk or dairy products with meat dishes Must adhere to kosher food preparation methods 24 hr of fasting on Yom Kippur, a day of atonement No leavened bread eaten during Passover (8 days) No cooking on the Sabbath from sundown Friday to sundown Saturday	Alcohol Tobacco Caffeine, such as teas, coffees, and sodas	Pork Shellfish Fish Alcohol Caffeine Vegetarian or ovolactovegetarian diets encouraged

BOX 44-5 CULTURAL ASPECTS OF CARE

Nutrition

Food patterns developed as a child, habits, and culture interact to influence food intake. Culture also influences the meaning of food not related to nutrition. Eating is associated with sentiments and feelings such as "good" and "bad." For example, children are often rewarded for "being good" with a treat such as candy. They then associate candy with "being good." Food frequently enhances interpersonal relationships and demonstrates love and caring (Andrews and Boyle, 2008).

The incidence of lactose intolerance around the world occurs in the following ethnic or racial groups: Asian-Pacific, African and African American, Native American, Mexican American, Middle Eastern, and Caucasians. The incidence is highest in Asian-Pacific populations and lowest in Caucasians. It affects nutrient absorption. Calcium deficiency often results, causing decreased bone mass density.

The theory of hot and cold foods predominates in many cultures. The origin appears to be from Hippocratic beliefs concerning health and the four humors. Arabs were keepers of this knowledge during the Dark Ages and later influenced the Spanish to adopt this belief system in the later Middle Ages. The foundation of the theory is keeping harmony with nature by balancing "cold," "hot," "wet," and "dry." Some cultures believe that hot is warmth, strength, and reassurance; whereas cold is menacing and weak. Classification has nothing to do with spiciness but is a symbolic representation of temperature (Giger and Davidhizar, 2008). Different cultures also have beliefs about food and special dishes that should be eaten when sick (e.g., chicken soup during illness).

Implications for Practice

- Identify the meaning that types of food have for each patient.
- Lactose and other food intolerances unique to specific cultures require diet adaptation to meet nutrient, mineral, and vitamin daily intake requirements.
- When patients use hot and cold foods as part of their cultural health practices, dietary modifications are necessary. Hot foods include rice, grain cereals, alcohol, beef, lamb, chili peppers, chocolate, cheese, temperate zone fruits, eggs, peas, goat's milk, cornhusks, oils, onions, pork, radishes, and tamales. By contrast, cold foods are beans, citrus fruits, tropical fruits, dairy products, most vegetables, honey, raisins, chicken, fish, and goat.
- In some cultures specific conditions require hot foods. Menstruation, cancer, pneumonia, earache, colds, paralysis, headache, and rheumatism are cold illnesses requiring hot foods.
- Other conditions such as pregnancy, fever, infections, diarrhea, rashes, ulcers, liver problems, constipation, kidney problems, and sore throats are hot conditions requiring cold foods.

nutritional guidelines because good nutrition depends on a balanced intake of all required nutrients.

Vegetarian Diet. A common alternative dietary pattern is the vegetarian diet. **Vegetarianism** is the consumption of a diet consisting predominantly of plant foods. Some vegetarians are ovolactovegetarian (avoid meat, fish, and poultry but eat eggs and milk), lactovegetarians (drink milk but avoid eggs), or vegans (consume only plant foods). Through careful selection of foods, individuals following a vegetarian diet can meet recommendations for proteins and essential nutrients (Nix, 2009). Zen macrobiotic (primarily brown rice, other grains, and herb teas) and fruitarian (only fruit, nuts, honey, and olive oil) diets are nutrient poor and frequently result in malnutrition. Knowledge related to complementary use of high and low biological value proteins is necessary. Children who follow a vegetarian diet are especially at risk for protein and vitamin deficiencies such as vitamin B_{12}. Careful planning helps to ensure a balanced, healthy diet.

CRITICAL THINKING

Effective critical thinking requires a synthesis of knowledge, experience, information collected from patients, critical thinking

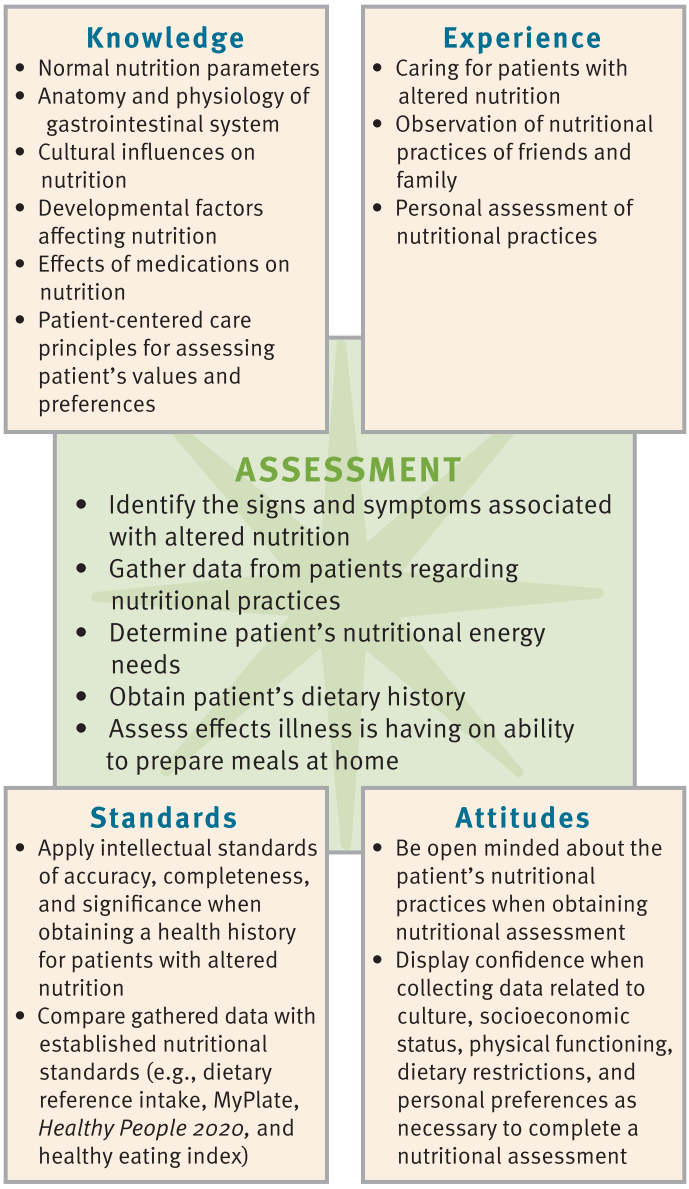

FIG. 44-3 Critical thinking model for nutrition assessment.

attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the required information, analyze the data, and make decisions regarding patient care. Critical thinking is a dynamic process. During assessment (Fig. 44-3) consider all elements that build toward making appropriate nursing diagnoses.

Integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients and families regarding customary food preferences and recent diet history. Use of professional standards such as the DRIs, the USDA MyPlate dietary guidelines, and *Healthy People 2020* objectives provide guidelines to assess and maintain patients' nutritional status. Other professional standards by the American Heart Association (AHA, 2010), the American Diabetes Association (ADA, 2008), The American Cancer Society (ACS, 2011), and the American Society for Parenteral and Enteral Nutrition (ASPEN) (Bankhead et al., 2009) are available. These standards are evidence based and regularly updated for optimal patient care.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. Early recognition of malnourished or at-risk patients has a strong positive influence on both short- and long-term health outcomes. Studies indicate that 40% to 55% of adult hospitalized patients are either malnourished or at risk for malnutrition (Mason, 2006). Patients who are malnourished on admission are at greater risk of life-threatening complications such as arrhythmia, sepsis, or hemorrhage during hospitalization.

Through the Patient's Eyes. Assess patients' nutritional status by using the nursing history to gather information about factors that usually influence nutrition. As the nurse you are in an excellent position to recognize signs of poor nutrition and take steps to initiate change. Close contact with patients and their families enables you to make observations about physical status, food intake, food preferences, weight changes, and response to therapy. Always ask patients about their food preferences, their values regarding nutrition, and what they expect from nutritional therapy. In attempting to affect eating patterns, you need to understand patient's values, beliefs, and attitudes about food. Also assess family traditions and rituals related to food, cultural values and beliefs, and nutritional needs. Determine how these factors affect food purchase, preparation, and intake.

Screening. Nutrition screening is an essential part of an initial assessment. Screening a patient is a quick method of identifying **malnutrition** or risk of malnutrition using sample tools (Charney, 2008). Nutrition screening tools need to gather data on the current condition, stability of the condition, assessment of whether it will worsen, and if the disease process accelerates. These tools typically include objective measures such as height, weight, weight change, primary diagnosis, and the presence of other co-morbidities (Charney, 2008). Combine multiple objective measures with subjective measures related to nutrition to adequately screen for nutritional problems. Identification of risk factors such as unintentional weight loss, presence of a modified diet, or the presence of altered nutritional symptoms (i.e., nausea, vomiting, diarrhea, and constipation) requires nutritional consultation.

Several standardized nutrition screening tools are available for use in the outpatient setting. The Subjective Global Assessment (SGA) uses the patient history, weight, and physical assessment data to evaluate nutritional status (Charney, 2008). SGA is a simple, inexpensive technique that is able to predict nutrition-related complications. The Mini Nutritional Assessment (MNA) (Fig. 44-4) was developed to use for screening older adults in home care programs, nursing homes, and hospitals. The tool has 18 items that are divided into screening and assessment. If a patient scores 11 or less on the screening portion, the health care provider completes the assessment portion (Kondrup et al., 2003). A total score of less than 17 indicates protein-energy malnutrition (Guigoz et al., 1996; Guigoz and Vellas, 1999). The Malnutrition Screening Tool (MST) is an effective measure of nutritional problems for patients in a variety of health care settings (Charney, 2008).

Mini Nutritional Assessment
MNA®

Last name: First name:

Sex: Age: Weight, kg: Height, cm: Date:

Complete the screen by filling in the boxes with the appropriate numbers. Total the numbers for the final screening score.

Screening

A Has food intake declined over the past 3 months due to loss of appetite, digestive problems, chewing or swallowing difficulties?
0 = severe decrease in food intake
1 = moderate decrease in food intake
2 = no decrease in food intake ☐

B Weight loss during the last 3 months
0 = weight loss greater than 3 kg (6.6 lbs)
1 = does not know
2 = weight loss between 1 and 3 kg (2.2 and 6.6 lbs)
3 = no weight loss ☐

C Mobility
0 = bed or chair bound
1 = able to get out of bed / chair but does not go out
2 = goes out ☐

D Has suffered psychological stress or acute disease in the past 3 months?
0 = yes 2 = no ☐

E Neuropsychological problems
0 = severe dementia or depression
1 = mild dementia
2 = no psychological problems ☐

F1 Body Mass Index (BMI) (weight in kg) / (height in m^2)
0 = BMI less than 19
1 = BMI 19 to less than 21
2 = BMI 21 to less than 23
3 = BMI 23 or greater ☐

IF BMI IS NOT AVAILABLE, REPLACE QUESTION F1 WITH QUESTION F2.
DO NOT ANSWER QUESTION F2 IF QUESTION F1 IS ALREADY COMPLETED.

F2 Calf circumference (CC) in cm
0 = CC less than 31
3 = CC 31 or greater ☐

Screening score ☐☐
(max. 14 points)

12-14 points: Normal nutritional status
8-11 points: At risk of malnutrition
0-7 points: Malnourished

FIG. 44-4 Mini Nutritional Assessment (MNA). (Copyright © Nestlé, 1994, Revision 2009. N67200 12/99 10M.)

Assess patients for malnutrition when they have conditions that interfere with their ability to ingest, digest, or absorb adequate nutrients. Use standardized tools to assess nutrition risks when possible. Congenital anomalies and surgical revisions of the GI tract interfere with normal function. Patients fed only by IV infusion of 5% or 10% dextrose are at risk for nutritional deficiencies. Chronic diseases or increased metabolic requirements are risk factors for development of nutritional problems. Infants and older adults are at greatest risk.

Anthropometry. **Anthropometry** is a measurement system of the size and makeup of the body. Nurses obtain height and weight for each patient on hospital admission or entry into any health care setting. If you are not able to measure height with the patient standing, position him or her lying flat in bed as straight as possible with arms folded on the chest and measure him or her lengthwise. Serial measures of weight over time provide more useful information than one measurement. The patient needs to be weighed at the same time each day, on the same scale, and with the same clothing or linen. Document his or her weight and compare height and weight to standards for height-weight relationships. An **ideal body weight (IBW)** provides an estimate of what a person should weigh. Rapid weight gain or loss is important to note because it usually reflects fluid shifts. One pint or 500 mL of fluid equals 1 lb (0.45 kg). For example, for a patient with renal failure, a weight increase of 2 lbs (0.90 kg) in 24 hours is significant because it usually indicates that the patient has retained a liter (1000 mL) of fluid.

Other anthropometric measurements often obtained by dietitians help identify nutritional problems. These include the ratio of height-to-wrist circumference, midupper arm circumference (MAC), triceps skinfold (TSF), and midupper arm muscle circumference (MAMC). A dietitian will compare values for MAC, TSF, and MAMC to standards and calculate them as a percentage of the standard. Changes in values for an individual over time are of greater significance than isolated measurements (Nix, 2009).

Body mass index (BMI) measures weight corrected for height and serves as an alternative to traditional height-weight relationships. Calculate BMI by dividing the patient's weight in kilograms by height in meters squared: Weight (kg) divided by height^2 (m^2). For example, a patient who weighs 165 lbs (75 kg) and is 1.8 m (5 feet 9 inches) tall has a BMI of 23.15 ($75 \div 1.8^2 = 23.15$). The website for the National Heart Lung and Blood Institute (http://www.nhlbisupport.com/bmi/) provides an easy way to calculate BMI. A patient is overweight if his or her BMI is 25 to 30. A BMI of greater than 30 is defined as obesity and places a patient at higher medical risk of coronary heart disease, some cancers, DM, and hypertension.

Laboratory and Biochemical Tests. No single laboratory or biochemical test is diagnostic for malnutrition. Factors that frequently alter test results include fluid balance, liver function, kidney function, and the presence of disease. Common laboratory tests used to study nutritional status include measures of plasma proteins such as albumin, transferrin, prealbumin, retinol binding protein, total iron-binding capacity, and hemoglobin. After feeding, the response time for changes in these proteins ranges from hours to weeks. The metabolic half-life of albumin is 21 days, transferrin is 8 days, prealbumin is 2 days, and retinol binding protein is 12 hours. Use this information to determine the most effective measure of plasma proteins for your patients. Factors that affect serum albumin levels include hydration; hemorrhage; renal or hepatic disease; large amounts of drainage from wounds, drains, burns, or the GI tract; steroid administration; exogenous albumin infusions; age; and trauma, burns, stress, or surgery. Albumin level is a better indicator for chronic illnesses, whereas prealbumin level is preferred for acute conditions (Pagana and Pagana, 2009).

Nitrogen balance is important to determining serum protein status (see discussion of protein in this chapter). Calculate nitrogen balance by dividing 6.25 into the total grams of protein ingested in a day (24 hours). Use laboratory analysis of a 24-hour urinary urea nitrogen (UUN) to determine nitrogen output. For patients with diarrhea or fistula drainage, estimate a further addition of 2 to 4 g of nitrogen output. Calculate nitrogen balance by subtracting the nitrogen output from the nitrogen intake. A positive 2- to 3-g nitrogen balance is necessary for anabolism. By contrast, negative nitrogen balance is present when catabolic states exist.

Diet History and Health History. In addition to the general nursing history, use data from a more specific diet history to assess a patient's actual or potential needs. Box 44-6 lists some specific assessment questions to ask in the diet history. The diet history focuses on a patient's habitual intake of foods and liquids and includes information about preferences, allergies, and other relevant areas such as the patient's ability to obtain food. Gather information about the patient's illness/activity level to determine

BOX 44-6 NURSING ASSESSMENT QUESTIONS

Dietary Intake and Food Preferences
- What type of food do you like?
- How many meals a day do you eat?
- What times do you normally eat meals and snacks?
- What portion sizes do you eat at each meal?
- Are you on a special diet because of a medical problem?
- Do you have any diet preferences because of your religion or culture?
- Who prepares the food at home?
- Who purchases the food?
- How do you cook your food (e.g., fried, broiled, baked, grilled)?

Unpleasant Symptoms
- Which foods cause indigestion, gas, or heartburn?
- Does this occur each time you have the food?
- What relieves the symptoms?

Allergies
- Are you allergic to any foods?
- Which types of problems do you have with these foods?
- How are these food allergies treated (e.g., EpiPen, oral antihistamines)?

Taste, Chewing, and Swallowing
- Have you noticed any changes in taste?
- Did these changes occur with medications or following an illness?
- Do you wear dentures? Are the dentures comfortable?
- Do you have any mouth pain or sores (e.g., cold sore, canker sores)?
- Do you have difficulty swallowing?
- Do you cough or gag when you swallow?

Appetite and Weight
- Have you had a change in appetite?
- Have you noticed a change in your weight?
- Was this change anticipated (e.g., were you on a weight-reduction diet)?

Use of Medications
- Which medications do you take?
- Do you take any over-the-counter medications that your doctor does not prescribe?
- Do you take any nutritional or herbal supplements?

BOX 44-7 CAUSES OF DYSPHAGIA

Myogenic
- Myasthenia gravis
- Aging
- Muscular dystrophy
- Polymyositis

Neurogenic
- Stroke
- Cerebral palsy
- Guillain-Barré syndrome
- Multiple sclerosis
- Amyotrophic lateral sclerosis (Lou Gehrig disease)
- Diabetic neuropathy
- Parkinson's disease

Obstructive
- Benign peptic stricture
- Lower esophageal ring
- Candidiasis
- Head and neck cancer
- Inflammatory masses
- Trauma/surgical resection
- Anterior mediastinal masses
- Cervical spondylosis

Other
- Gastrointestinal or esophageal resection
- Rheumatological disorders
- Connective tissue disorders
- Vagotomy

energy needs and compare food intake. Your nursing assessment of nutrition includes health status; age; cultural background (see Box 44-5); religious food patterns (see Table 44-3); socioeconomic status; personal food preferences; psychological factors; use of alcohol or illegal drugs; use of vitamin, mineral, or herbal supplements; prescription or over-the-counter (OTC) drugs (see Table 44-2); and the patient's general nutrition knowledge.

In outpatient settings the patient keeps a 3- to 7-day food diary. This allows you to calculate nutritional intake and to compare it with DRI to see if the patient's dietary habits are adequate. Use food questionnaires to establish patterns over time (Bankhead et al., 2009). In health care settings nurses collaborate with RDs to complete calorie counts for patients.

Physical Examination. The physical examination is one of the most important aspects of a nutritional assessment. Because improper nutrition affects all body systems, observe for malnutrition during physical assessment (see Chapter 30). Complete the general physical assessment of body systems and recheck relevant areas to evaluate a patient's nutritional status. The clinical signs of nutritional status (Table 44-4) serve as guidelines for observation during physical assessment.

Dysphagia. **Dysphagia** refers to difficulty swallowing. The causes (Box 44-7) and complications of dysphagia vary. Complications include aspiration pneumonia, dehydration, decreased nutritional status, and weight loss. Dysphagia leads to disability or decreased functional status, increased length of stay and cost of care, increased likelihood of discharge to institutionalized care, and increased mortality (Ashley et al., 2006).

Be aware of warning signs for dysphagia. They include cough during eating; change in voice tone or quality after swallowing; abnormal movements of the mouth, tongue, or lips; and slow, weak, imprecise, or uncoordinated speech. Abnormal gag, delayed swallowing, incomplete oral clearance or pocketing, regurgitation, pharyngeal pooling, delayed or absent trigger of swallow, and inability to speak consistently are other signs of dysphagia. Patients with dysphagia often do not show overt signs such as coughing when food enters the airway. *Silent aspiration* is aspiration that occurs in patients with neurological problems that lead to decreased sensation. It often occurs without a cough, and symptoms usually do not appear for 24 hours (Palmer and Metheny, 2008). Silent aspiration accounts for most of the 40% to 70% of aspiration in patients with dysphagia following stroke (Kwon et al., 2006).

BOX 44-8 NURSING DIAGNOSTIC PROCESS

Imbalanced Nutrition: Less Than Body Requirements

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Body mass index (BMI)	BMI = 17
Obtain weight	68-year-old woman 24-lb (10.8-kg) weight loss Weight is 20% below her ideal body weight
Obtain 24-hour food and fluid history	Lack of satiety Lack of interest in food Fluid intake is juice and coffee Eats sandwich in afternoon
Physical assessment	Poor muscle tone Fatigue Hair loss Dry scaly skin Pale conjunctiva and mucous membranes
Medication	Takes sertraline for depression
Social	Husband died 6 months ago Has quit attending monthly quilting club Started counseling 3 months ago

Dysphagia often leads to an inadequate amount of food intake, which often results in malnutrition. Frequently patients with dysphagia become frustrated with eating and show changes in skinfold thickness and albumin. Adjustment to new dietary restrictions during the rehabilitation period affects intake for long periods of time. Malnutrition significantly slows swallowing recovery and may increase mortality (Robbins et al., 2007).

Dysphagia screening quickly identifies problems with swallowing and helps nurses initiate referrals for more in-depth assessment by a speech pathologist (Skill 44-1 on pp. 1026-1027). Early and ongoing assessment of patients with swallowing difficulties and use of a valid dysphagia screening tool increase quality of care and decrease incidence of aspiration pneumonia (AY Cichero et al., 2009). Dysphagia screening includes medical record review; observation of a patient at a meal for change in voice quality, posture, and head control; percentage of meal consumed; eating time; drooling or leakage of liquids and solids; cough during/after a swallow; facial or tongue weakness; palatal movement; difficulty with secretions; pocketing; choking; and presence of voluntary and dry cough. A number of validated screening tools are available, such as the Bedside Swallowing Assessment, Burke Dysphagia Screening Test, Acute Stroke Dysphagia Screen, and Standardized Swallowing Assessment (Edmiaston et al., 2010). The Acute Stroke Dysphagia screen is an easily administered and reliable tool for health care professionals who are not speech-language pathologists. Screening for and treatment of dysphagia requires a multidisciplinary team approach of nurses, RDs, health care providers, and speech language pathologists (SLPs) (Robbins et al., 2007).

NURSING DIAGNOSIS

Cluster all assessment data to identify actual or at-risk nursing diagnoses (Box 44-8). A nutritional problem often occurs when overall intake is significantly decreased or increased or when one or more nutrients are not ingested, completely digested, or completely absorbed. Nursing diagnoses are related to either the actual

TABLE 44-4 Physical Signs of Nutritional Status

BODY AREA	SIGNS OF GOOD NUTRITION	SIGNS OF POOR NUTRITION
General appearance	Alert: responsive	Listless, apathetic, cachectic
Weight	Weight normal for height, age, body build	Obesity (usually 10% above ideal body weight [IBW]) or underweight (special concern for underweight)
Posture	Erect posture; straight arms and legs	Sagging shoulders; sunken chest; humped back
Muscles	Well-developed, firm; good tone; some fat under skin	Flaccid, poor tone, underdeveloped tone; "wasted" appearance; impaired ability to walk properly
Nervous system control	Good attention span; not irritable or restless; normal reflexes; psychological stability	Inattention; irritability; confusion; burning and tingling of hands and feet (paresthesia); loss of position and vibratory sense; weakness and tenderness of muscles (may result in inability to walk); decrease or loss of ankle and knee reflexes; absent vibratory sense
Gastrointestinal function	Good appetite and digestion; normal regular elimination; no palpable organs or masses	Anorexia; indigestion; constipation or diarrhea; liver or spleen enlargement
Cardiovascular function	Normal heart rate and rhythm; lack of murmurs; normal blood pressure for age	Rapid heart rate (above 100 beats/min), enlarged heart; abnormal rhythm; elevated blood pressure
General vitality	Endurance; energy; sleeps well; vigorous	Easily fatigued; no energy; falls asleep easily; tired and apathetic
Hair	Shiny, lustrous; firm; not easily plucked; healthy scalp	Stringy, dull, brittle, dry, thin, and sparse, depigmented; easily plucked
Skin (general)	Smooth and slightly moist skin with good color	Rough, dry, scaly, pale, pigmented, irritated; bruises; petechiae; subcutaneous fat loss
Face and neck	Uniform color; smooth, pink, healthy appearance; not swollen	Greasy, discolored, scaly, swollen; dark skin over cheeks and under eyes; lumpiness or flakiness of skin around nose and mouth
Lips	Smooth; good color; moist; not chapped or swollen	Dry, scaly, swollen; redness and swelling (cheilosis); angular lesions at corners of mouth; fissures or scars (stomatitis)
Mouth, oral membranes	Reddish-pink mucous membranes in oral cavity	Swollen, boggy oral mucous membranes
Gums	Good pink color; healthy and red; no swelling or bleeding	Spongy gums that bleed easily; marginal redness, inflammation; receding
Tongue	Good pink or deep reddish color; no swelling; smooth, presence of surface papillae; lack of lesions	Swelling, scarlet and raw; magenta, beefiness (glossitis); hyperemic and hypertrophic papillae; atrophic papillae
Teeth	No cavities; no pain; bright, straight; no crowding; well-shaped jaw; clean with no discoloration	Unfilled caries; missing teeth; worn surfaces; mottled (fluorosis), malpositioned
Eyes	Bright, clear, shiny; no sores at corner of eyelids; moist and healthy pink conjunctivae; prominent blood vessels; no fatigue circles beneath eyes	Eye membranes pale (pale conjunctivas); redness of membrane (conjunctival injection); dryness; signs of infection; Bitot's spots; redness and fissuring of eyelid corners (angular palpebritis); dryness of eye membrane (conjunctival xerosis); dull appearance of cornea (corneal xerosis); soft cornea (keratomalacia)
Neck (glands)	No enlargement	Thyroid or lymph node enlargement
Nails	Firm, pink	Spoon shape (koilonychia); brittleness; ridges
Legs, feet	No tenderness, weakness, or swelling; good color	Edema; tender calf; tingling; weakness
Skeleton	No malformations	Bowlegs; knock-knees; chest deformity at diaphragm; prominent scapulae and ribs

From Nix S: *Williams' basic nutrition and diet therapy,* ed 13, St Louis, 2009, Mosby.

nutrition problems (e.g., inadequate intake) or problems that place the patient at risk for nutritional deficiencies such as oral trauma, severe burns, or infections.

Select a nursing diagnostic statement based on defining characteristics in the assessment database. Make sure the nursing diagnosis is as precise as possible. The following are examples of nursing diagnoses that apply to nutritional problems:

- Risk for aspiration
- Diarrhea
- Deficient knowledge
- Imbalanced nutrition: less than body requirements
- Imbalanced nutrition: more than body requirements
- Risk for imbalanced nutrition: more than body requirements
- Readiness for enhanced nutrition
- Feeding self-care deficit
- Impaired swallowing

Be sure to select the appropriate related factor for a nursing diagnosis. Related factors need to be accurate so you select the appropriate interventions. In addition, there are also clinical situations in which patients have multiple related problems. The concept map in Fig. 44-5 shows the relationship of nursing diagnoses for Mrs. Cooper.

FIG. 44-5 Concept map for Mrs. Cooper.

PLANNING

Planning to maintain patients' optimal nutritional status requires a higher level of care than simply correcting nutritional problems. Often there is a need for patients to make long-term changes for nutrition to improve. Synthesis of patient information from multiple sources is necessary to create an individualized approach of care that is relevant to a patient's needs and situation (Fig. 44-6). Apply critical thinking to ensure that you consider all data sources in developing a patient's plan of care. The accurate identification of nursing diagnoses related to patients' nutritional problems results in a care plan that is relevant and appropriate (see the Nursing Care Plan). Referring to professional standards for nutrition is especially important during this step, because published standards are based on scientific findings.

Goals and Outcomes. Goals and outcomes of care reflect a patient's physiological, therapeutic, and individualized needs. Nutrition education and counseling are important to prevent disease and promote health. Patients on therapeutic diets need to understand the implications of their diets and how prescribed diets

NURSING CARE PLAN

Imbalanced Nutrition: Less Than Body Requirements

ASSESSMENT

Maria Steiner, a nurse practitioner in a senior citizens' center, is seeing Mrs. Cooper, who is 68 years old and has a history of heart failure. Recently Mrs. Cooper experienced an unexpected 15% weight loss. Three months have passed since she started taking sertraline (Zoloft) for depression related to the loss of her husband 6 months ago. She no longer participates in her monthly quilting club. She was also referred for counseling 3 months ago for help with grief and depression through a local senior service agency. When Maria inquired about her financial situation, Mrs. Cooper responded that it was tight living on a small pension and Social Security but she was able to manage.

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Cooper about her food intake during the last 2 days.	She responds that she drinks some juice in the morning and two or three cups of coffee. In addition, she often has a sandwich in the late afternoon. **"I'm just not interested in food. It has no taste."**
Ask Mrs. Cooper about social interaction.	Mrs. Cooper complains of loneliness and says that she does not get out much, although her psychologist recommended more socializing. Her friends at church call her to come back to meetings, but she is just not ready. She says that she tires easily and no longer attends the monthly meetings of her quilt club.
Weigh patient and assess posture.	Her **weight is 20% below her IBW** and her **BMI is 17.** This weight loss has happened over the past 6 months, and she has **lost 24 pounds.** **Stooped posture**
Observe Mrs. Cooper for signs of poor nutrition.	**Hair loss** **Sore oral mucous membranes** **Pale conjunctivae** and mucous membranes
Palpate muscles	**Generalized poor muscle tone**

*__Defining characteristics__ are shown in bold type.
BMI, Body mass index; *IBW,* ideal body weight.

NURSING DIAGNOSIS: Imbalanced nutrition: less than body requirements related to a decreased ability to ingest food as a result of depression

PLANNING

Goals	*Expected Outcomes (NOC)*†
Mrs. Cooper will progressively gain weight.	**Weight Gain Behavior** Mrs. Cooper will gain 1 to 2 pounds per month until goal of 130 pounds is reached.
Mrs. Cooper will consume adequate nourishment each day.	**Nutritional Status** Mrs. Cooper will ingest 1900 kcal/day, including 50 g of protein per day.
Mrs. Cooper will exhibit no signs of malnutrition.	**Nutritional Status: Biochemical Measures** Physical assessment findings will be within normal limits. Laboratory values will be within normal limits.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Nutritional Counseling	
Coordinate plan of care with health care provider, psychologist, Mrs. Cooper, and registered dietitian.	Successful nutrition care planning is a multidisciplinary approach throughout the continuum of care (DiMaria-Ghalili, 2008).
Individualize menu plans according to Mrs. Cooper's preferences.	Encourages patient to eat by incorporating her food preferences into the meal plans (DiMaria-Ghalili, 2008).
Teach Mrs. Cooper about MyPlate for Older Adults.	MyPlate for Older Adults is adapted to meet the nutritional requirements for older adults (Shelnutt et al., 2009).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

Continued

NURSING CARE PLAN

***Imbalanced Nutrition: Less Than Body Requirements*—cont'd**

Nutritional Management

Encourage Mrs. Cooper to eat small nutritious meals and snacks and increase dietary intake to help offset anorexia secondary to sertraline.	Sertraline is a selective serotonin reuptake inhibitor (SSRI) antidepressant medication, which causes diminished taste and anorexia. Frequent small nutritious meals and snacks help to reduce anorexia-associated weight loss.
Encourage fluid intake.	Older adults need eight 8-oz (240 mL) glasses per day of fluid from beverage and food sources. Concentrating intake in morning and early afternoon is acceptable to prevent nocturia (Meiner, 2011).
Encourage fiber intake.	Deters constipation, enhancing appetite.
Encourage Mrs. Cooper to eat lunch at the senior center 5 times per week.	Eating with others encourages good nutrition and promotes socialization with peers (Krondl et al., 2008; Nix, 2009).

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcome*
Monitor Mrs. Cooper monthly for weight gain, anemia, serum albumin level, and transferrin levels.	After 2 weeks Mrs. Cooper has gained 3 lbs, and her Hgb level is 12.	Mrs. Cooper is making progress with weight gain; her hemoglobin level still reflects mild anemia.
Ask Mrs. Cooper to keep a food diary for 3 days.	Food diary reflects that she ate her main meal at the senior center, has fruit and bran flakes for breakfast, and in the evening either has soup or a sandwich with fruit.	Mrs. Cooper is selecting more nutritionally rich foods, consistent with current guidelines.
Observe Mrs. Cooper's physical appearance.	At 2 weeks, her skin is less pale, and her hair appears to be in better condition and styled.	Mrs. Cooper has improved physical parameters of nutrition; still needs follow-up.
Ask Mrs. Cooper about appetite and energy level.	Mrs. Cooper responds that on days that she eats at the senior center her appetite seems better and she "wants to do more things." She notes that weekends are very lonely.	Weekday support for nutritional status appears effective; needs to increase patient's activity status and nutritional intake during weekends.

help to control their illnesses. When planning care, be aware of all factors that influence a patient's food intake. In one study patients with heart failure identified that decreased hunger, diet restrictions, fatigue, shortness of breath, anxiety, and sadness influenced their food intake (Lennie et al., 2006).

Individualized planning is essential. Explore patients' feelings about their weight and diet and help them set realistic and achievable goals (Daniels, 2006). Mutually planned goals negotiated among the patient, RD, and nurse ensure success. For the patient with heart failure described previously, an overall goal is "Patient will achieve appropriate BMI height-weight range or be within 10% of IBW." The following outcomes assist in achievement of this goal:

- Patient's daily nutritional intake meets the minimal DRIs.
- Patient's daily nutritional fat intake is less than 30%.
- Patient removes sugared beverages from diet.
- Patient refrains from eating unhealthy foods between meals and after dinner.
- Patient loses at least ½ to 1 lb (0.2 to 0.45 kg) per week.

Meeting nutritional goals requires input from the patient and the multidisciplinary team. Knowledge of the role of each discipline in providing nutrition support is necessary to maximize nutritional outcomes. For example, collaboration with an RD helps develop appropriate nutrition treatment plans. Calorie counts are frequently ordered, and assistance is necessary in obtaining accurate data. An effective plan of care requires accurate exchange of information among disciplines.

Setting Priorities. After identifying patients' nursing diagnoses, you determine priorities in order to plan timely and successful interventions. For example, managing a patient's oral pain will be a priority over the diagnosis of *imbalanced nutrition: less than body requirements* if the patient is unable to swallow and maintain adequate food intake. *Deficient knowledge* regarding diet therapy will be a priority if it is necessary to promote long-term and effective weight loss.

During acute illness or surgery the intake of food is often altered in the perioperative period. The priority of care is to provide optimal preoperative nutrition support in patients with malnutrition. The priority for the resumption of food intake after surgery depends on the return of bowel function, the extent of the surgical procedure, and the presence of any complications (see Chapter 50). For example, when patients have oral and throat surgery, they chew and swallow food in the presence of excision sites, sutures, or tissue manipulated during surgery. The priority of care is to first provide comfort and pain control. Then address nutritional priorities and plan care to maintain nutrition that does not cause pain or injury to the healing tissues.

The patient and family must collaborate with the nurse in planning care and setting priorities. This is important because food preferences, food purchases, and preparation involve the entire family. The plan of care cannot succeed without their commitment to, involvement in, and understanding of the nutritional priorities.

Teamwork and Collaboration. The care of the patient often extends beyond the acute hospital setting, requiring continued collaboration among members of the health care team. It is important that discharge planning include nutritional interventions as patients return to their homes or extended care facilities.

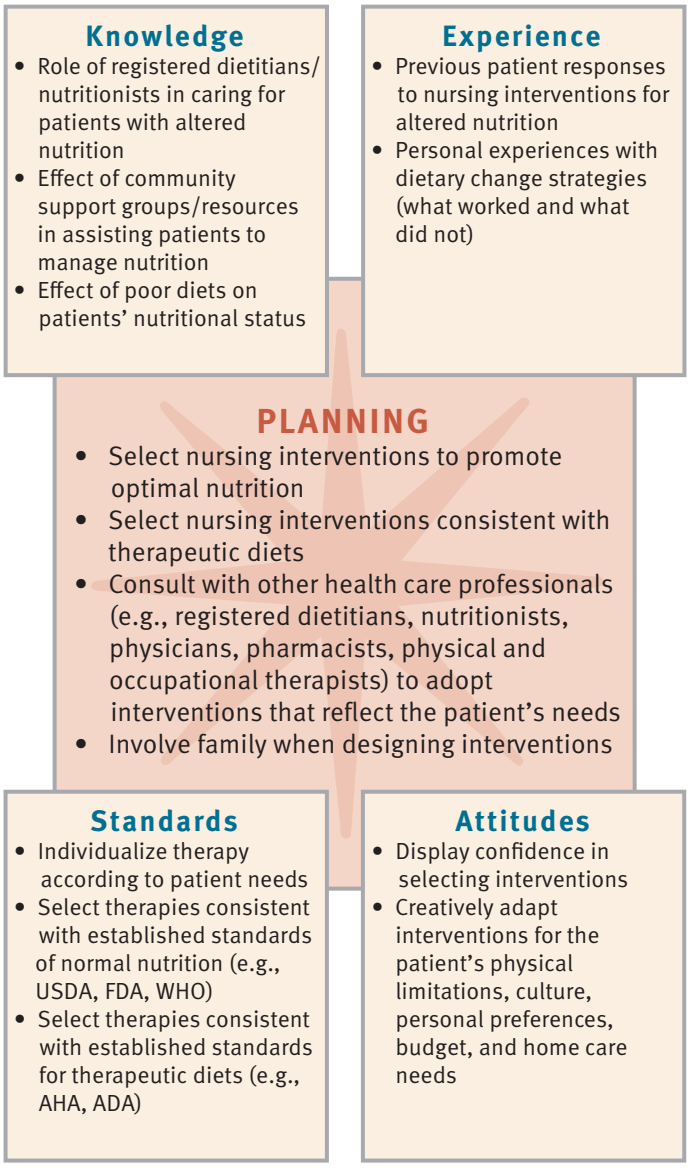

FIG. 44-6 Critical thinking model for nutrition planning. *ADA,* American Diabetes Association; *AHA,* American Heart Association; *FDA,* Food and Drug Administration; *USDA,* U.S. Department of Agriculture; *WHO,* World Health Organization.

Communicate patient goals and planned interventions to all team members to achieve expected patient outcomes. Consult with an SLP, RD, pharmacist, and/or occupational therapist when working with patients with dysphagia or who need ongoing nutritional assessment and interventions to meet their nutritional needs.

Enteral tube feedings are often administered into the stomach or intestines via a tube inserted through the nose or a percutaneous access (Skills 44-2 and 44-3 on pp. 1028-1035). These enteral feedings supplement a patient's oral nutritional intake in the home, acute care, extended care, or rehabilitation setting when they cannot meet their nutritional needs by mouth. Regardless of the setting, the RD assesses and monitors the patient's nutritional status and intake and makes recommendations for changes. RDs are expert in the choice of enteral formulas and dietary modifications required for specific disease states. Long-term management of nutritional problems is a challenge that requires collaboration among the patient, family, and health care team members.

Patients who cannot tolerate nutrition through the GI tract receive parenteral nutrition, a solution consisting of glucose, amino acids, lipids, minerals, electrolytes, trace elements, and vitamins, through an indwelling peripheral or central venous catheter (CVC) (see Chapter 41). The pharmacist is an expert who reviews medications to identify drug-nutrient interactions. Pharmacists are also experts in preparing mixtures of total parenteral nutrition (TPN).

When patients have difficulty feeding themselves, occupational therapists work with them and their families to identify assistive devices. Devices such as utensils with large handles and plates with elevated sides help a patient with self-feeding. An SLP helps a patient with swallowing exercises and techniques to reduce the risk of aspiration. Occupational therapists also help patients maintain function in the home setting by rearranging food preparation areas in an effort to maximize a patient's functional capacity.

IMPLEMENTATION

Diet therapies are numerous and are chosen on the basis of a patient's overall health status, ability to eat and digest normally, and long-term nutritional needs. The focus of health promotion is to educate patients and family caregivers about balanced nutrition and to assist them in obtaining resources to eat high-quality meals. In acute care, your role as a nurse is to manage acute conditions that alter patients' nutritional status and assist in ways to promote their appetite and ability to take in nutrients. Patients who are ill or debilitated often have poor appetites (anorexia). **Anorexia** has many causes (e.g., pain, fatigue, and the effects of medications). Help patients understand the factors that cause anorexia and use creative approaches to stimulate appetite. In the restorative care setting, you will assist patients in learning how to follow the therapeutic diets necessary for recovery and treatment of chronic health conditions.

Health Promotion. As a nurse you are in a key position to educate patients about healthy diet choices and good nutrition. Incorporating knowledge of nutrition into patients' lifestyles serves to prevent the development of many diseases. Outpatient and community-based settings are optimal locations for nursing assessment of nutritional practices and status. Early identification of potential or actual problems is the best way to avoid more serious problems. Similarly, in other health care settings patients with nutritional problems such as obesity often require assistance in menu planning and compliance strategies. Your role as educator includes educating families and providing information about community resources. Telephone numbers of an RD or nurse for follow-up questions are always a part of counseling.

Meal planning takes into account the family's budget and different preferences of family members. Choose specific foods on the basis of the dietary prescription and recommended food groups. For families on limited budgets use substitutes. For example, bean or cheese dishes often replace meat in a meal, and evaporated milk or dry skim milk is used for cooking. Have patients modify the method of preparation when it is necessary to minimize certain substances. Baking rather than frying reduces fat intake, and patients can use lemon juice or spices to add flavor to low-sodium diets.

Planning menus a week in advance has several benefits. It helps ensure good nutrition or compliance with a specific diet and helps a family stay within their allotted budget. Nurses or RDs need to check menus for content. Often a simple tip is helpful in meal planning such as avoiding grocery shopping when hungry, which can lead to spur-of-the-moment purchases of more expensive or

TABLE 44-5 Food Safety

FOODBORNE DISEASE	ORGANISM	FOOD SOURCE	SYMPTOMS*
Botulism	*Clostridium botulinum*	Improperly home-canned foods, smoked and salted fish, ham, sausage, shellfish	Symptoms varied from mild discomfort to death in 24 hours; initially nausea, vomiting, dizziness, and weakness progressing to motor (respiratory) paralysis
Escherichia coli	*E. coli*	Undercooked meat (ground beef)	Severe cramps, nausea, vomiting, diarrhea (may be bloody), renal failure; appears 1-8 days after eating; lasts 1-7 days
Listeriosis	*Listeria monocytogenes*	Soft cheese, meat (hot dogs, paté, lunch meats), unpasteurized milk, poultry, seafood	Severe diarrhea, fever, headache, pneumonia, meningitis, endocarditis; appears 3-21 days after infection
Perfringens enteritis	*Clostridium perfringens*	Cooked meats, meat dishes held at room or warm temperature	Mild diarrhea, vomiting; appears 8-24 hours after eating; lasts 1-2 days
Salmonellosis	*Salmonella* *S. typhi* *S. paratyphi*	Milk, custards, egg dishes, salad dressings, sandwich fillings, polluted shellfish	Mild-to-severe diarrhea, cramps, vomiting; appears up to 72 hours after ingestion; lasts 4-7 days
Shigellosis	*Shigella dysenteriae*	Milk, milk products, seafood, salads	Cramps, diarrhea to fatal dysentery; appears 12-50 hours after ingestion; lasts 3-14 days
Staphylococcus	*Staphylococcus aureus*	Custards, cream fillings, processed meats, ham, cheese, ice cream, potato salad, sauces, casseroles	Severe abdominal cramps, pain, vomiting, diarrhea, perspiration, headache, fever, prostration; appears 1-6 hours after ingestion; lasts 1-2 days

From Nix S: *Williams' basic nutrition and diet therapy,* ed 13, St Louis, 2009, Mosby.
*Symptoms are generally most severe for youngest and oldest age-groups.

BOX 44-9 PATIENT TEACHING

Food Safety

Objective
- Patient is able to verbalize measures to protect from foodborne illness.

Teaching Strategies
- Explain that food safety is an important public health issue. Populations particularly at risk are older and younger persons and immunosuppressed individuals.
- Instruct patients using the following four principles:
  1. CLEAN
     - Wash hands with warm, soapy water before touching or eating food.
     - Wash fresh fruits and vegetables thoroughly.
     - Clean the inside of refrigerator and microwave regularly to prevent microbial growth.
  2. SEPARATE
     - Wash cooking utensils and cutting boards with hot soapy water.
     - Wash hands after handling foods, especially meats, poultry, and eggs.
     - Clean vegetables and lettuce used in salads thoroughly.
     - Wash dishrags, towels, and sponges regularly or use paper towels
  3. COOK
     - Use a food thermometer to verify that meat, poultry, and fish are cooked properly.
     - Do not eat raw meats or unpasteurized milk.
  4. CHILL
     - Keep foods properly refrigerated at 40° F and frozen at 0° F.
     - Do not save leftovers for more than 2 days in refrigerator.

Evaluation
- Ask patient to verbalize measures to prevent foodborne illnesses.
- Observe the patient at home for safe practices if making home visit.

Data from US Department of Agriculture and US Department of Health and Human Services: *Report of the dietary guidelines advisory committee dietary guidelines for Americans 2010,* 2010, http://www.cnpp.usda.gov/dietaryguidelines.htm. Accessed November 23, 2011.

less nutritious foods that are not included in meal plans. The U.S. Department of Agriculture (USDA, 2011b) provides sample weekly meal-planning services for a range of budgets on its website.

Support individuals who are interested in losing weight. A high percentage of those who attempt to lose weight are unsuccessful, regaining lost weight over time. Diet and exercise compliance affects success with weight loss. Information on weight loss is available from multiple sources. Help patients develop a successful weight-loss plan that considers their preferences and resources and includes awareness of portion sizes and knowledge of energy content of food (Kruskall, 2006).

Food safety is an important public health issue. Foodborne bacteria can occur from improper food cleaning, preparation, or poor hygiene practices of food workers. Health care professionals not only need to be aware of the factors related to food safety but also should provide patient education to reduce the risks for foodborne illnesses (Table 44-5; Box 44-9).

Building Competency in Safety You are a nurse planning a community health program on food safety at the senior center. Develop an outline of key topics to present using the 2010 Dietary Guidelines for Americans food safety principles.

Answers to questions can be found on the Evolve website.

Acute Care. The nutritional care of acutely ill patients requires a nurse to consider a variety of factors that influence nutritional intake. Diagnostic testing and procedures in the acute care setting disrupt food intake. Often as preparation for or immediately following a diagnostic procedure, a patient is to receive nothing by mouth (NPO). Mealtimes in a health care setting are frequently interrupted, or patients have poor appetites. Patients often are too fatigued or uncomfortable to eat. It is important to continuously assess a patient's nutritional status and adopt interventions that

TABLE 44-6 Nutrition and the Immune System

IMMUNE/ PHYSIOLOGICAL COMPONENT	MALNUTRITION EFFECT	VITAL NUTRIENT
Antibodies	Decreased amount	Protein, vitamins A, B_6, B_{12}, C, folic acid, thiamin, biotin, riboflavin, niacin
GI tract	Systemic movement of bacteria	Arginine, glutamine, omega-3 fatty acids
Granulocytes and macrocytes	Longer time for phagocytosis kill time and lymphocyte activation	Protein, vitamins A, B_6, B_{12}, C, folic acid, thiamin, riboflavin, niacin, zinc, iron
Mucus	Flat microvilli in GI tract, decreased antibody secretion	Vitamins B_{12}, B_6, C, biotin
Skin	Integrity compromised, density reduced, wound healing slowed	Protein, vitamins A, B_{12}, C, niacin, copper, zinc
T-lymphocytes	Depressed T-cell distribution	Protein, arginine, iron, zinc, omega-3 fatty acids, vitamins A, B_6, B_{12}, folic acid, thiamin, riboflavin, niacin, pantothenic acid

Modified from Grodner M, Long S, DeYoung S: *Foundations and clinical applications of nutrition: a nursing approach,* ed 5, St Louis, 2012, Mosby.
GI, Gastrointestinal.

promote normal intake, digestion, and metabolism of nutrients. Patients who are NPO and receive only standard IV fluids for more than 4 to 7 days are at nutritional risk.

Advancing Diets. Acute and chronic conditions affect a patient's immune system and nutritional status. Patients with decreased immune function (e.g., from cancer, chemotherapy, human immunodeficiency virus/acquired immunodeficiency syndrome [HIV/AIDS], or organ transplants) require special diets that decrease their exposure to microorganisms and are higher in selected nutrients. Table 44-6 gives an overview of the immune system, the malnutrition impact, and which nutrients are beneficial. In addition, patients who are ill, who have had surgical procedures, or who were NPO for a period of time have specialized dietary needs. Health care providers order a gradual progression of dietary intake or therapeutic diet to manage patients' illness (Box 44-10).

Promoting Appetite. Providing an environment that promotes nutritional intake includes keeping a patient's environment free of odors, providing oral hygiene as needed to remove unpleasant tastes, and maintaining patient comfort. Offering smaller, more frequent meals often helps. In addition, certain medications affect dietary intake and nutrient use. For example, medications such as insulin, glucocorticoids, and thyroid hormones affect metabolism. Other medications such as antifungal agents frequently affect taste. Some of the psychotropic medications affect appetite, cause nausea, and also alter taste. The nurse and RD help patients to select foods that reduce the altered taste sensations or nausea. Consult with an RD regarding seasonings that may be used to improve food taste.

BOX 44-10 DIET PROGRESSION AND THERAPEUTIC DIETS

Clear Liquid
Clear fat-free broth, bouillon, coffee, tea, carbonated beverages, clear fruit juices, gelatin, fruit ices, popsicles

Full Liquid
As for clear liquid, with addition of smooth-textured dairy products (e.g., ice cream), strained or blended cream soups, custards, refined cooked cereals, vegetable juice, pureed vegetables, all fruit juices, sherbets, puddings, frozen yogurt

Pureed
As for clear and full liquid, with addition of scrambled eggs; pureed meats, vegetables, and fruits; mashed potatoes and gravy

Mechanical Soft
As for clear and full liquid and pureed, with addition of all cream soups, ground or finely diced meats, flaked fish, cottage cheese, cheese, rice, potatoes, pancakes, light breads, cooked vegetables, cooked or canned fruits, bananas, soups, peanut butter, eggs (not fried)

Soft/Low Residue
Addition of low-fiber, easily digested foods such as pastas, casseroles, moist tender meats, and canned cooked fruits and vegetables; desserts, cakes, and cookies without nuts or coconut

High Fiber
Addition of fresh uncooked fruits, steamed vegetables, bran, oatmeal, and dried fruits

Low Sodium
4-g (no added salt), 2-g, 1-g, or 500-mg sodium diets; vary from no added salt to severe sodium restriction (500-mg sodium diet), which requires selective food purchases

Low Cholesterol
300 mg/day cholesterol, in keeping with American Heart Association guidelines for serum lipid reduction

Diabetic
Nutrition recommendations by the American Diabetes Association: focus on total energy, nutrient and food distribution; include a balanced intake of carbohydrates, fats, and proteins; varied caloric recommendations to accommodate patient's metabolic demands

Regular
No restrictions, unless specified

In other situations medications need to be changed. Assessing patients for the need for pharmacological agents to stimulate appetite such as cyproheptadine (Periactin), megestrol (Megace), or dronabinol (Marinol) or to manage symptoms that interfere with nutrition requires health care provider consultation.

Mealtime is usually a social activity. If appropriate, encourage visitors to eat with the patient. When patients experience anorexia, encourage other nurses or care providers to converse and engage them in conversation. Mealtime is also an excellent opportunity for patient education. Instruct a patient about any therapeutic diets, medications, energy conservation measures, or adaptive devices to assist with independent feeding.

Assisting Patients with Oral Feeding. When a patient needs help with eating, it is important to protect his or her safety, independence, and dignity. Clear the table or over-bed tray of clutter. Assess his or her risk of aspiration (see Skill 44-1). Patients at high risk for aspiration have decreased level of alertness, decreased gag and/or cough reflexes, and difficulty managing saliva (see Assessment section of this chapter).

Patients with dysphagia are at risk for aspiration and need more assistance with feeding and swallowing. An SLP identifies patients at risk and provides recommendations for therapy (Nowlin, 2006). Provide a 30-minute rest period before eating (Palmer and Metheny, 2008). Position the patient in an upright, seated position in a chair or raise the head of the bed to 90 degrees. Have the patient flex the head slightly to a chin-down position to help prevent aspiration. If the patient has unilateral weakness, teach him or her and the caregiver to place food in the stronger side of the mouth. With the help of an SLP, determine the viscosity of foods that the patient tolerates best through the use of trials of different consistencies of foods and fluids. Thicker fluids are generally easier to swallow. The American Dietetic Association published the National Dysphagia Diet Task Force National Dysphagia Diet in 2002 to provide uniformity of diets provided to patients with dysphagia (NDDTF, 2002). There are four levels of diet: dysphagia puree, dysphagia mechanically altered, dysphagia advanced, and regular. The four levels of liquid include thin liquids (low viscosity), nectar-like liquids (medium viscosity), honey-like liquids (viscosity of honey), and spoon-thick liquids (viscosity of pudding) (NDDTF, 2002).

Feed a patient with dysphagia slowly, providing smaller-size bites. Allow him or her to chew thoroughly and swallow the bite before taking another. More frequent chewing and swallowing assessments throughout the meal are necessary. Allow the patient time to empty the mouth after each spoonful, matching the speed of feeding to the patient's readiness (see Skill 44-1). If the patient begins to cough or choke, remove the food immediately (Nowlin, 2006). Sometimes it is necessary to have oral suction equipment available at the patient's bedside.

Provide opportunities for patients to direct the order in which they want to eat the food items and how fast they wish to eat. Determine the patient's food preferences; and, unless contraindicated, try to have these items included on his or her dietary tray. Ask the patient if the food is the right temperature. These seem like small acts, but they go a long way in maintaining the patient's sense of independence.

Patients with visual deficits also need special assistance. Patients with decreased vision are able to independently feed themselves when they are given adequate information. Identify the food location on a meal plate as if it were a clock (e.g., meat at 9 o'clock and vegetable at 3 o'clock). Tell the patient where the beverages are located in relation to the plate. Be sure that other care providers set the meal tray and plate in the same manner. Patients with impaired vision and those with decreased motor skills are more independent during mealtimes with the use of large-handled adaptive utensils (Fig. 44-7). These are easier to grip and manipulate.

FIG. 44-7 Adaptive equipment. Clockwise from upper left: Two-handled cup with lid, plate with plate guard, utensils with splints, and utensils with enlarged handles.

Enteral Tube Feeding. **Enteral nutrition (EN)** provides nutrients into the GI tract. It is the preferred method of meeting nutritional needs if a patient is unable to swallow or take in nutrients orally yet has a functioning GI tract. Enteral nutrition provides physiological, safe, and economical nutritional support. Patients with enteral feedings receive formula via nasogastric, jejunal, or gastric tubes. Patients with a low risk of gastric reflux receive gastric feedings; however, if there is a risk of gastric reflux, which leads to aspiration, jejunal feeding is preferred. Box 44-11 lists indications for tube feeding. Enteral tube feedings can easily be given in the home setting by either the nurse or a family caregiver. After an enteral tube is inserted, verification of tube placement by x-ray film examination needs to occur before the patient receives the first enteral feeding (see Skill 44-2).

An enteral formula is usually one of four types. Polymeric (1 to 2 kcal/mL) includes milk-based blenderized foods prepared by hospital dietary staff or in a patient's home. The polymeric classification also includes commercially prepared whole-nutrient formulas. For this type of formula to be effective, the patient's GI tract needs to be able to absorb whole nutrients. The second type, modular formulas (3.8 to 4 kcal/mL), are single macronutrient (e.g., protein, glucose, polymers, or lipids) preparations and are not nutritionally complete. This type of formula is added to other foods to meet a patient's individual nutritional needs. The third type, elemental formulas (1 to 3 kcal/mL), contain predigested nutrients that are easier for a partially dysfunctional GI tract to absorb. Finally, specialty formulas (1 to 2 kcal/mL) are designed to meet specific nutritional needs in certain illness (e.g., liver failure, pulmonary disease, or HIV infection).

Tube feedings are typically started at full strength at slow rates (see Skill 44-3 and Box 44-12). Increase the hourly rate every 8 to 12 hours per health care provider's order if no signs of intolerance appear (high gastric residuals, nausea, cramping, vomiting, and diarrhea). Studies have demonstrated a beneficial effect of enteral feedings compared with PN. Feeding by the enteral route reduces sepsis, minimizes the hypermetabolic response to trauma, decreases hospital mortality, and maintains intestinal structure and function (Khalid et al., 2010). Enteral nutrition is successful within 24 to 48 hours after surgery or trauma to provide fluids, electrolytes, and nutritional support. Gastric ileus prevents nasogastric feedings from being given. Nasointestinal or jejunal tubes allow successful postpyloric feeding because formula is placed directly into the small intestine or jejunum or beyond the pyloric sphincter of the stomach (Bankhead et al., 2009).

A serious complication associated with enteral feedings is aspiration of formula into the tracheobronchial tree. Aspiration of enteral formula into the lungs irritates the bronchial mucosa, resulting in decreased blood supply to affected pulmonary tissue (McCance et al., 2010). This leads to necrotizing infection,

BOX 44-11 INDICATIONS FOR ENTERAL AND PARENTERAL NUTRITION

Enteral Nutrition

Cancer
- Head and neck
- Upper GI

Critical illness/trauma

Neurological and muscular disorders
- Brain neoplasm
- Cerebrovascular accident
- Dementia
- Myopathy
- Parkinson's disease

Gastrointestinal disorders
- Enterocutaneous fistula
- Inflammatory bowel disease
- Mild pancreatitis

Respiratory failure with prolonged intubation

Inadequate oral intake
- Anorexia nervosa
- Difficulty chewing, swallowing
- Severe depression

Parenteral Nutrition

Nonfunctional gastrointestinal tract
- Massive small bowel resection/GI surgery/massive GI bleed
- Paralytic ileus
- Intestinal obstruction
- Trauma to abdomen, head, or neck
- Severe malabsorption
- Intolerance to enteral feeding (established by trial)
- Chemotherapy, radiation therapy, bone marrow transplantation

Extended bowel rest
- Enterocutaneous fistula
- Inflammatory bowel disease exacerbation
- Severe diarrhea
- Moderate-to-severe pancreatitis

Preoperative total parenteral nutrition
- Preoperative bowel rest
- Treatment for co-morbid severe malnutrition in patients with nonfunctional GI tracts
- Severely catabolic patients when GI tract nonusable for more than 4 to 5 days

GI, Gastrointestinal.

BOX 44-12 ADVANCING THE RATE OF TUBE FEEDING

Protocols for advancing tube feedings are commonly institution specific. Most of these protocols are untested for validity. There does not appear to be a benefit to slow initiation of enteral nutrition over days. Most patients are able to tolerate feeding 24 to 48 hours after initiation. Do not dilute formulas with water; this increases the risk of bacterial contamination (Bankhead et al., 2009).

Intermittent

1. Start formula at full strength for isotonic formulas (300 to 400 mOsm) or at ordered concentration.
2. Infuse bolus of formula over at least 20 to 30 minutes via syringe or feeding container.
3. Begin feedings with a volume of 2.5-5 mL/kg 5 to 8 times per day. Increase by 60-120 mL per feeding every 8-12 hours to achieve needed volume and calories in four to six feedings (Bankhead et al., 2009).

Continuous

1. Start formula at full strength for isotonic formulas (300 to 400 mOsm) or at ordered concentration.
2. Begin infusion rate at designated rate typically at 10 to 40 mL/hr (Bankhead et al., 2009).
3. Advance rate slowly (e.g., 10 to 20 mL/hr every 8 to 12 hours) to target rate if tolerated (tolerance indicated by absence of nausea and diarrhea and low gastric residuals) (Bankhead et al., 2009).

pneumonia, and potential abscess formation. The high glucose content of a feeding serves as a bacterial medium for growth, promoting infection. Acute respiratory distress syndrome (ARDS) is also an outcome frequently associated with pulmonary aspiration. Some of the common conditions that increase the risk of aspiration include coughing, gastroesophageal reflux disease (GERD), nasotracheal suctioning, an artificial airway, decreased level of consciousness, and lying flat. Prokinetic medications such as metoclopramide, erythromycin, or cisapride promote gastric emptying and decrease the risk of aspiration (Bourgault et al., 2007; Metheny, 2006). Keep the head of the bed elevated a minimum of 30 degrees, preferably 45 degrees, unless medically contraindicated (Bankhead et al., 2009). Measure gastric residual volumes (GRVs) every 4 to 6 hours in patients receiving continuous feedings and immediately before the feeding in patients receiving intermittent feedings (Metheny et al., 2006). Delayed gastric emptying is a concern if 250 mL or more remains in a patient's stomach on two consecutive assessments (1 hour apart) or if a single GRV measurement exceeds 500 mL (Bankhead et al., 2009). There is a lack of consensus for recommendations for stopping feedings; decisions to stop feedings must include assessment of patient's condition (Metheny et al., 2008). The North American Summit on Aspiration in the Critically Ill Patient recommends the following: (1) stop feedings immediately if aspiration occurs; (2) withhold feedings and reassess patient tolerance to feedings if GRV is over 500 mL; (3) routinely evaluate the patient for aspiration; and (4) use nursing measures to reduce the risk of aspiration if GRV is between 250 and 500 mL (Bankhead et al., 2009).

Enteral Access Tubes. When patients are unable to ingest food but are still able to digest and absorb nutrients, enteral tube feeding is indicated. Feeding tubes are inserted through the nose (nasogastric or nasointestinal), surgically (gastrostomy or jejunostomy), or endoscopically (percutaneous endoscopic gastrostomy or jejunostomy [PEG or PEJ]). If EN therapy is for less than 4 weeks, total, nasogastric, or nasojejunal feeding tubes may be used. Surgical or endoscopically placed tubes are preferred for long-term feeding (more than 4 weeks) to reduce the discomfort of a nasal tube and provide a more secure, reliable access (Rolandelli et al., 2005). Some patients such as those with gastroparesis (decreased or absent innervation to the stomach that results in delayed gastric emptying) or esophageal reflux or with a history of aspiration pneumonia require placement of tubes beyond the stomach into the intestine (Cirgin Ellett, 2006; Metheny et al., 2007).

Most health care settings use small-bore feeding tubes because they create less discomfort for a patient (Fig. 44-8). For the adult most of these tubes are 8- to 12-Fr and 36 to 44 inches (90 to 110 cm) long. A stylet is often used during insertion of a small-bore tube to stiffen it. The stylet is removed when the correct position

FIG. 44-8 Enteral tubes, small-bore.

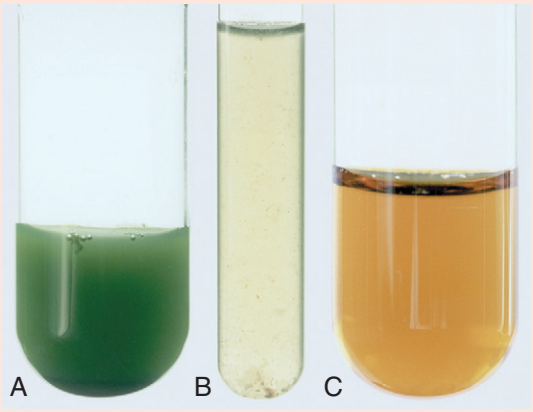
of the feeding tube is confirmed. Skill 44-3 describes the procedure for initiating beginning nasogastric, gastrostomy, and jejunostomy enteral feedings.

Historically nurses verified feeding tube placement by injecting air through the tube while auscultating the stomach for a gurgling or bubbling sound or asking the patient to speak. Auscultation has repeatedly been shown to be ineffective in detecting tubes accidentally placed in the lung (Bourgault et al., 2007). Some patients are able to speak despite placement of feeding tubes in the lung (Rolandelli et al., 2005). Furthermore, auscultation is not effective in distinguishing between gastric and intestinal placement for feeding tubes (Rauen et al., 2008). The measurement of pH of secretions withdrawn from the feeding tube helps to differentiate the location of the tube (Box 44-13). At present the most reliable

BOX 44-13 PROCEDURAL GUIDELINES

Obtaining Gastrointestinal Aspirate for pH Measurement, Large-Bore, and Small-Bore Feeding Tubes: Intermittent and Continuous Feeding

Delegation Considerations



The skill of measuring pH in gastrointestinal (GI) aspirate is not delegated to nursing assistive personnel.

Equipment

Cone-tipped or Asepto syringe, pH test paper (scale of 1.0 to 11.0 or greater), paper towel, small medication cup, clean gloves

1. Perform measures to verify placement of tube:
   a. For intermittently fed patients, test placement immediately before feeding (usually a period of at least 4 hours has elapsed since previous feeding). More frequent checking has been associated with increased clogging of small-bore tubes. To avoid clogging, flush tube with 30 mL water after aspirating for the gastric residual volume (Bourgault et al., 2007).
   b. For continuously tube-fed patients, test placement every 4 to 6 hours (Metheny, 2006). If patient is tolerating the feedings without incident and other indicators of correct location are present (i.e., the mark on the tube at the exit site has remained in its original position, and the most recent x-ray films confirm correct position of tube), it is reasonable to continue feedings. If risk of tube displacement is high, and the tube has moved, consider the need for an x-ray film to verify placement (Bankhead et al., 2009). Plan pH testing at times when feeding may be withheld (e.g., during diagnostic testing or chest physiotherapy or to avoid medication interaction).
   c. Wait at least 1 hour after medication administration by tube or mouth.
2. Perform hand hygiene and apply clean gloves.
3. Draw up 30 mL of air into syringe and attach to end of feeding tube. Flush tube with 30 mL of air before attempting to aspirate fluid. It is likely to be more difficult to aspirate fluid from the small intestine than from the stomach. Repositioning patient from side to side is helpful. More than one bolus of air through the tube is necessary in some cases. Burst of air aids in aspirating fluid more easily.
4. Draw back on syringe and obtain 5 to 10 mL of gastric aspirate. Observe appearance of aspirate (see illustration). Gently mix aspirate in syringe. Expel a few drops into a clean medicine cup. Dip the pH strip into the fluid or apply a few drops of the fluid to the strip (see illustration). Compare the color of the strip with the color on the chart provided by the manufacturer (Metheny, 2006).
   a. Gastric fluid from patient who has fasted for at least 4 hours usually has pH range of 1 to 4.
   b. Fluid from nasointestinal tube of fasting patient usually has pH greater than or equal to 6.0 (Bankhead et al., 2009).
   c. Patient with continuous tube feeding often has pH of 5.0 or higher.
   d. pH of pleural fluid from tracheobronchial tree is generally greater than 6.0.
5. Remove gloves and discard supplies. Perform hand hygiene.

CLINICAL DECISION: If after repeated attempts it is not possible to aspirate fluid from a tube that was originally established by x-ray film examination to be in desired position and (a) there are no risk factors for tube dislocation, (b) there is no change in external marked tube length, and (c) patient is not experiencing difficulty, assume that tube is correctly placed (Roberts et al., 2007).

STEP 4b Comparing pH strip with color chart.

method for verification of placement of small-bore feeding tubes is x-ray film examination (Box 44-14).

The addition of blue food coloring to enteral formula to assist with the detection of formula aspirated into the lung, presumably by staining the tracheobronchial secretions, is no longer used. The FDA issued a public health advisory reporting an association between use of Blue No. 1 food coloring and patient deaths (McClave et al., 2009).

BOX 44-14 EVIDENCE-BASED PRACTICE

Accuracy in Determining Placement of Feeding Tubes

PICO Question: In adult patients, what method determines stomach placement of enteral feeding tubes for preventing aspiration?

Evidence Summary

Two of the most frequent complications associated with tube feedings are pulmonary aspiration, potentially leading to pneumonia, and accidental placement of a nasoenteric feeding tube into the lung. Patients at highest risk for aspiration have decreased level of consciousness, confusion, uncooperativeness, agitation, presence of an endotracheal tube and absent or poor gag reflex (Metheny, 2006). Gastric residual volume has not been found to be consistently related to aspiration (Bankhead et al., 2009). A traditional bedside method used to assess for pulmonary aspiration of enteral feeding into the respiratory tract was the glucose method. The premise of the glucose method was that normal tracheal secretions contain minimal levels of glucose. Therefore, if glucose-rich enteral formula is aspirated into the airway, glucose levels of tracheal secretions increase. However, researchers have shown that the glucose levels of tracheal secretions vary widely and this method is not sufficiently sensitive or specific to be useful to detect aspiration (Metheny et al., 2007). Researchers are currently trying to develop new bedside methods for assessing for pulmonary aspiration such as using electromagnetic tracking devices and assessing for the presence of pepsin, a substance produced in the stomach in tracheal secretions (Bankhead et al., 2009).

Traditionally nurses have used the auscultatory method of assessing placement. This method has been shown to be unreliable. Auscultation does not detect when a feeding tube has inadvertently been placed into the respiratory tract and does not distinguish between placement in the stomach versus the intestine. The most accurate method for checking feeding tube placement is x-ray film examination (Bankhead et al., 2009; Kenny and Goodman, 2010). The most effective nonradiological methods include aspirating fluid from the feeding tube, measuring its pH, and describing its appearance (Bourgault et al., 2007; Bankhead et al., 2009).

Application to Nursing Practice

- X-ray film verification of feeding tube placement is the most reliable method available to confirm correct tube location. It is required in most acute care facilities after insertion of a small-bore tube.
- Verify the placement of the feeding tube every 4 to 6 hours by aspirating gastric contents, observing its appearance, and testing pH. A properly obtained pH of 0 to 4.0 is a good indication of gastric placement. A pH of 6.0 or higher likely indicates placement in the lung, intestine, or even the stomach when gastric pH is unusually high. Intestinal fluid is usually bile stained (dark golden yellow). Gastric fluid is usually grassy green, off-white to tan, or clear and colorless (Bankhead et al., 2009).
- Do not use the auscultatory method to determine tube location.
- Do not use the glucose detection method to determine if aspiration has occurred.
- Check gastric residual volumes every 4 hours in patients at high risk for aspiration (Bankhead et al., 2009).

Table 44-7 outlines major complications of EN. Of special note, patients who are severely malnourished are at risk for electrolyte disturbances from re-feeding syndrome during EN or PN therapy. In re-feeding syndrome potassium, magnesium, and phosphate move intracellularly, resulting in low serum (extracellular) levels and edema. These changes cause cardiac dysrhythmias, heart failure, respiratory distress, convulsions, coma, or death.

Parenteral Nutrition. **Parenteral nutrition (PN)** is a form of specialized nutrition support in which nutrients are provided intravenously. A basic PN formula is a combination of crystalline amino acids, hypertonic dextrose, electrolytes, vitamins, and trace elements. TPN, administered through a central line, is a 2-in-1 formula in which fat emulsions are administered separately from the protein and dextrose solution (Krzywda and Meyer, 2010). Safe administration depends on appropriate assessment of nutrition needs, meticulous management of the central venous catheter (CVC), and careful monitoring to prevent or treat metabolic complications. PN is administered in a variety of settings, including a patient's home. Regardless of the setting, adhere to principles of asepsis and infusion management to ensure safe nutrition support.

Patients who are unable to digest or absorb EN benefit from PN. Patients in highly stressed physiological states such as sepsis, head injury, or burns are candidates for PN therapy (see Box 44-11).

Clinical and laboratory monitoring by a multidisciplinary team is required throughout PN therapy. The need for continued PN is consistently reevaluated. The goal to move toward use of the GI tract is constant (McClave et al., 2009). Disuse of the GI tract has been associated with villus atrophy and generalized cell shrinkage. As a result of disuse of the GI tract, bacteria may move from the unused gut into the bloodstream, resulting in gram-negative septicemia.

Intravenous fat emulsions are sometimes added to PN to provide supplemental kilocalories, prevent essential fatty acid deficiencies, and help control hyperglycemia during periods of stress (Phillips, 2010). Administer these emulsions through a separate peripheral line, through the central line by using Y-connector tubing (see Chapter 41), or as an admixture to the PN solution. The addition of fat emulsion to a PN solution is called a *3-in-1 admixture* or *total nutrient admixture*. The patient receives it over a 24-hour period. Do not use the admixture if you observe oil droplets or an oily or creamy layer on the surface of the admixture. This observation indicates that the emulsion has broken into large lipid droplets that cause fat emboli if administered. IV fat emulsions are white and opaque. Take care to avoid confusing enteral formula with parenteral lipids.

Initiating Parenteral Nutrition. Patients with short-term nutritional needs often receive IV solutions of less than 10% dextrose via a peripheral vein in combination with amino acids and lipids. Peripheral solutions are not as calorically dense as TPN solutions and therefore are usually temporary. PN with greater than 10% dextrose requires a CVC that a health care provider places into a high-flow central vein such as the superior vena cava under sterile conditions (see Chapter 41). If you are using a CVC that has multiple lumens, use a port that is exclusively dedicated for the TPN. Label the port for TPN and do not infuse other solutions or medications through it (Krzywda and Meyer, 2010). Nurses with special training insert peripherally inserted central catheters (PICCs) that are started in a vein of the arm and threaded into the subclavian or superior vena cava vein.

TABLE 44-7 Enteral Tube Feeding Complications

PROBLEM	POSSIBLE CAUSE	INTERVENTION*
Pulmonary aspiration	Regurgitation of formula	Verify tube placement. Place patient in high Fowler's position or elevate head of bed a minimum of 30 (preferably 45) degrees during feedings and for 2 hours afterward.
	Feeding tube displaced	Reposition tube and verify tube placement.
	Deficient gag reflex	Reassess for return of normal gag reflex; until then place patient on aspiration precautions and in semi-Fowler's position.
	Delayed gastric emptying	See delayed gastric emptying that follows.
Diarrhea	Hyperosmolar formula or medications	Deliver formula continuously, lower rate, dilute, or change to isotonic enteral nutrition.
	Antibiotic therapy	Antibiotics destroy normal intestinal flora; consult with health care provider to consider changing medication; treat symptoms with antidiarrheal agents; culture stool for *Clostridium difficile.*
	Bacterial contamination	Do not hang formula longer than 4-8 hours in bag, wash bag out well when refilling, change tube feeding bags and tubing q24h and use aseptic practices. Check expiration dates.
	Malabsorption	Check for pancreatic insufficiency; use low-fat, lactose-free formula and continuous feedings.
Constipation	Lack of fiber	Consult with a dietitian to select a formula containing fiber.
	Lack of free water	Add water as needed as flushes.*
	Inactivity	Monitor patient's ability to ambulate; collaborate with health care provider and/or physical therapist for activity order.
Tube occlusion	Pulverized medications given per tube	Irrigate with 30 mL water before and after each medication per tube.* Use liquid medications when available. Completely dissolve crushed medications in liquid if liquid medication is not available.
	Sedimentation of formula	Shake cans well before administering (read label).
	Reaction of incompatible medications or formula	Read pharmacological information on compatibility of drugs and formula.
Tube displacement	Coughing, vomiting	Replace tube and confirm placement before restarting tube feeding.
	Not taped securely	With placement verification check that tape is secure (nasoenteric).
Abdominal cramping, nausea/vomiting	High osmolality of formula	Suggest an isotonic formula or dilution of current formula to health care provider.
	Rapid increase in rate/volume	Lower rate of delivery to increase tolerance. Maintain head of bed at least 30 degrees.
	Lactose intolerance	Suggest use of lactose-free formula.
	Intestinal obstruction	Stop feeding with GI obstruction.
	High-fat formula used	Use greater proportion of carbohydrate.
	Cold formula used	Warm formula to room temperature.
Delayed gastric emptying	Diabetic gastroparesis	Consult with health care provider regarding prokinetic medication for increasing gastric motility.
	Serious illnesses	Consult health care provider regarding advancing tube to intestinal placement.
	Inactivity	Monitor medications and pathological conditions that affect GI motility.
Serum electrolyte imbalance	Excess GI losses Dehydration Presence of disease states such as cirrhosis, renal insufficiency, heart failure, or diabetes mellitus	Monitor serum electrolyte levels daily. Provide free water per registered dietitian recommendation.
Fluid overload	Refeeding syndrome in malnutrition	Restrict fluids if necessary and use either a specialized formula or a diluted enteral formula at first.
	Excess free water or diluted (hypotonic) formula	Monitor levels of serum proteins and electrolytes. Use a more concentrated formula with fluid volume excess without risk of refeeding syndrome.
Hyperosmolar dehydration	Hypertonic formula with insufficient free water	Slow rate of delivery, dilute, or change to isotonic formula.

*Check first for fluid-restricted conditions that affect volume of water that can be safely given.
GI, Gastrointestinal.

TABLE 44-8 Metabolic Complications of Parenteral Nutrition

PROBLEM	SIGNS/SYMPTOMS	INTERVENTION
Electrolyte imbalance	See Chapter 41 for signs of deficiency/toxicity	Check TPN for supplemental electrolyte levels. Notify health care provider of imbalances. Maintain steady rate of infusion. Monitor intake and output.
Hypercapnia	Increased oxygen consumption, CO_2, respiratory quotient (>1), and minute ventilation	Ventilator-dependent patients are at risk; provide 30% to 60% of energy requirements per health care provider's order.
Hypoglycemia	Diaphoresis, shakiness, confusion, loss of consciousness	To prevent hypoglycemia, do not abruptly discontinue TPN but taper rate down to within 10% of infusion rate 1 to 2 hours before stopping. If you suspect hypoglycemia, test blood glucose and administer IV bolus of 50% dextrose or glucagon per order or protocol if necessary.
Hyperglycemia	Thirst, headache, lethargy, increased urination	Monitor blood glucose level every 6 hours. Initiate TPN slowly and taper up to maximal infusion rate to prevent hyperglycemia. Additional insulin may be required during therapy if problem persists or patient has diabetes mellitus.
Hyperglycemic hyperosmolar nonketotic coma (HHNKC) or hyperosmolar hyperglycemic nonketotic syndrome (HHNS)	Hyperglycemia (>500 mg/dl), glycosuria, serum osmolarity >350 mOsm/L, confusion, azotemia, headache, severe signs of dehydration (see Chapter 41), hypernatremia, metabolic acidosis, convulsions, coma	Monitor blood glucose, BUN, serum osmolarity, glucose in urine, and fluid losses; administer insulin as ordered; replace fluids as ordered; maintain constant infusion rate; and provide 30% of daily energy needs as fat. Patients at risk are those receiving steroids; older adults diagnosed with diabetes, who have impaired renal or pancreatic function or increased metabolism, or who are septic.

BUN, Blood urea nitrogen; *IV,* intravenous; *TPN,* total parenteral nutrition.

After catheter placement, wait to flush and use the catheter until the position is radiographically confirmed. The health care provider secures the CVC with a securement device and covers the site with a sterile dressing. A PICC is usually stabilized with sterile strips of tape and a sterile dressing. A chest x-ray film examination verifies catheter tip placement for a CVC or PICC before starting a PN infusion (DeChicco et al., 2007).

Before beginning any PN infusion, verify the health care provider's order and inspect the solution for particulate matter or a break in the fat emulsion. Always use an infusion pump to deliver a constant rate. The initial rate delivers no more than 50% of estimated needs for the first 24 to 48 hours. The rate is gradually increased until a patient's complete nutrition needs are supplied (National Guideline Clearinghouse, 2008). Patients receiving PN at home frequently administer the entire daily solution over 12 hours at night. This allows the patient to disconnect from the infusion each morning, flush the central line, and have independent mobility during the day. Home PN therapy often interferes with patients' normal activities, causing a poorer quality of life (Siepler, 2007).

Preventing Complications. Complications of PN include catheter-related problems and metabolic alterations (Table 44-8). Pneumothorax results from a puncture insult to the pulmonary system and involves the accumulation of air in the pleural cavity with subsequent collapse of the lung and impaired breathing. Pneumothorax is usually accompanied by symptoms of sudden sharp chest pain, dyspnea, and coughing. In relation to PN, pneumothorax most often occurs during CVC placement. Monitor a patient with a CVC for the first 24 hours for signs and symptoms of pulmonary distress.

An air embolus possibly occurs during insertion of the catheter or when changing the tubing or cap. Turn the patient into a left lateral decubitus position, and have the patient perform a Valsalva maneuver (holding the breath and "bearing down") during catheter insertion to help prevent air embolus. The increased venous pressure created by the maneuver prevents air from entering the bloodstream. Maintaining integrity of the closed IV system also helps prevent air embolus.

Catheter occlusion is present when there is sluggish or no flow through the catheter. Temporarily stop the infusion and flush with saline or heparin per protocol or orders. If this is unsuccessful, attempt to aspirate a clot. If still unsuccessful, follow institution protocol for use of a thrombolytic agent (e.g., urokinase).

Suspect catheter sepsis if a patient develops fever, chills, or glucose intolerance and has a positive blood culture. To prevent infection, change the TPN infusion tubing every 24 hours. Do not hang a single container of PN for more than 24 hours or lipids more than 12 hours. Change the administration system every 72 hours when infusing a 2-in-1 solution and every 24 hours for a 3-in-1 solution (Phillips, 2010). During CVC dressing changes, always use a sterile mask and gloves and assess insertion sites for signs and symptoms of infection (see Chapter 41). Change the CVC dressing per institution policy and anytime it becomes wet or contaminated. Use either alcohol or an alcoholic solution of chlorhexidine gluconate to clean the injection port or catheter hub 15 seconds before and after each time it is used (National Guideline Clearinghouse, 2008). Use a 1.2-micron filter for 3-in-1 formulas and an inline 0.22-micron filter for PN solutions that do not include IV fat emulsions (Task Force for the Revision of Safe Practices for Parenteral Nutrition, 2004).

PN solutions contain most of the major electrolytes, vitamins, and minerals. Patients also need supplemental vitamin K as ordered throughout therapy. Vitamin K is synthesized by microflora found in the jejunum and ileum with normal use of the GI tract; however, because PN circumvents GI use, patients need to receive exogenous vitamin K.

Electrolyte and mineral imbalances often occur. Administration of concentrated glucose is accompanied by increases in endogenous insulin production, which causes cations (potassium, magnesium, and phosphorus) to move intracellularly. Monitor blood glucose levels every 6 hours to assess for hyperglycemia

and administer supplemental insulin as needed (Phillips, 2010) (Skill 44-4 on pp. 1035-1039).

Too-rapid administration of hypertonic dextrose can result in an osmotic diuresis and dehydration (see Chapter 41). If an infusion falls behind schedule, do not increase the rate in an attempt to catch up. Sudden discontinuation of a solution can cause hypoglycemia. Usually 10% dextrose is infused when PN solution is suddenly discontinued. Patients with diabetes are more at risk.

The goal is to move patients from PN to EN and/or oral feeding. Once patients are meeting one third to one half of their kilocalorie needs per day, PN is usually decreased to half the original volume. EN feedings are then increased to meet needs. Patients who make the transition from PN to oral feedings typically have early satiety and decreased appetite. PN is gradually decreased in response to increased oral intake. If oral intake is inadequate, small frequent meals are helpful. Calorie/protein counts are recommended when patients begin taking soft foods. When 75% of needs are being met by enteral feedings or reliable dietary intake, PN therapy is usually discontinued. PN may also be discontinued if complications occur or the health care provider determines that it is not benefiting the patient (Krzywda and Meyer, 2010).

Restorative and Continuing Care. Patients discharged from a hospital with diet prescriptions often need dietary education to plan meals that meet specific therapeutic requirements. Restorative care includes both immediate postsurgical care and routine medical care and therefore includes patients in the hospital and at home. The following sections address nutritional interventions for some common disease states.

Medical Nutrition Therapy. Optimal nutrition is important in health and illness, but the specific dietary intake pattern that results in optimal nutrition is modified for patients with particular diseases. **Medical nutrition therapy (MNT)** is the use of specific nutritional therapies to treat an illness, injury, or condition. MNT is necessary to help the body metabolize certain nutrients, correct nutritional deficiencies related to the disease, and eliminate foods that may exacerbate disease symptoms. It is most effective using a team approach that promotes collaboration between the health care team and an RD (American Dietetic Association, 2010b).

Gastrointestinal Diseases. Peptic ulcers are controlled with regular meals and medications such as histamine receptor antagonists that block secretion of HCl or proton pump inhibitors. Marshall and Warren first identified *Helicobacter pylori* in 1984. *H. pylori* is a bacterium that causes up to 85% of peptic ulcers and is confirmed by laboratory tests or a biopsy during endoscopy (Nix, 2009). It is treated with antibiotics that control the bacterial infection. Stress and overproduction of gastric HCl also irritate a preexisting ulcer. Encourage patients to avoid foods that increase stomach acidity and pain such as caffeine, decaffeinated coffee, frequent milk intake, citric acid juices, and certain seasonings (hot chili peppers, chili powder, black pepper). Discourage smoking, alcohol, aspirin, and nonsteroidal antiinflammatory drugs (NSAIDs). Teach patients to eat a well-balanced, healthy diet; avoid eating large meals; and eat three regular meals (or several small meals) without snacks, especially at bedtime (Nix, 2009). Family members of the patient with a *H. pylori* infection also need to be tested and treated if indicated.

Inflammatory bowel disease includes Crohn's disease and idiopathic ulcerative colitis. Treatment of acute inflammatory bowel disease includes elemental diets (formula with the nutrients in their simplest form ready for absorption) or PN when symptoms such as diarrhea and weight loss are prevalent. In the chronic stage of the disease a regular highly-nourishing diet is appropriate. Vitamins and iron supplements are often required to correct or prevent anemia. Patients manage irritable bowel syndrome by increasing fiber, reducing fat, avoiding large meals, and avoiding lactose or sorbitol-containing foods for susceptible individuals.

The treatment of **malabsorption** syndromes such as celiac disease includes a gluten-free diet. Gluten is present in wheat, rye, barley, and oats. Short-bowel syndrome results from extensive resection of bowel, after which patients suffer from malabsorption caused by lack of intestinal surface area. These patients require lifetime feeding with either elemental enteral formulas or PN.

Diverticulitis is a condition that results from an inflammation of diverticula, which are abnormal but common pouchlike herniations that occur in the bowel lining. This condition is nutritionally treated with a moderate- or low-residue diet until the infection subsides. Afterward a high-fiber diet is generally prescribed for chronic diverticula problems.

Diabetes Mellitus. Type 1 diabetes mellitus (DM) requires both insulin and dietary restrictions for optimal control, with treatment beginning at diagnosis (ADA, 2008). By contrast, patients often control type 2 DM initially with exercise and diet therapy. If these measures prove ineffective, it is common to add oral medications. Insulin injections often follow if type 2 diabetes worsens or fails to respond to these initial interventions.

Individualize the diet according to a patient's age, build, weight, and activity level. Maintaining a prescribed carbohydrate intake is the key in diabetes management. A diet that includes carbohydrates from fruits, vegetables, whole grains, legumes, and low-fat milk is recommended (American Dietetic Association, 2010b). Monitoring carbohydrate consumption is a key strategy in achieving glycemic control (ADA, 2008). Limit saturated fat to less than 7% of the total calories and cholesterol intake to less than 200 mg/day. Also recommended are a variety of foods containing fiber. Patients are able to substitute sucrose-containing foods for carbohydrates but need to make sure to avoid excess energy intake. Sugar alcohols and non-nutritive sweeteners are able to be eaten as long as the recommended daily intake levels are followed (ADA, 2008). Patients with diabetes and normal renal function should continue to consume usual amounts of protein (15% to 20% of energy) (ADA, 2008).

The goal of MNT treatment is to have glycemic levels that are normal or as close to normal as safely possible; lipid and lipoprotein profiles that decrease the risk of microvascular (e.g., renal and eye disease), cardiovascular, neurological, and peripheral vascular complications; and blood pressure in the normal or near-normal range (ADA, 2008). Be aware of signs and symptoms of hypoglycemia and hyperglycemia.

Cardiovascular Diseases. The American Heart Association (AHA) dietary guidelines (AHA, 2010) are intended to reduce risk factors for the development of hypertension and coronary artery disease. Diet therapy for reducing the risk of cardiovascular disease includes balancing calorie intake with exercise to maintain a healthy body weight; eating a diet high in fruits, vegetables, and whole-grain high-fiber foods; eating fish at least 2 times per week; and limiting food and beverages that are high in added sugar and salt. The AHA guidelines also recommend limiting saturated fat to less than 7%, trans-fat to less than 1%, and cholesterol to less than 300 mg/day. To accomplish this goal, patients choose lean meats and vegetables, use fat-free dairy products, and limit intake of fats and sodium (Nix, 2009).

Cancer and Cancer Treatment. Malignant cells compete with normal cells for nutrients, increasing a patient's metabolic needs. Most cancer treatments cause nutritional problems. Patients with cancer often experience anorexia, nausea, vomiting, and taste distortions. The goal of nutrition therapy is to meet the increased metabolic needs of a patient (Nix, 2009). Malnutrition in cancer is associated with increased morbidity and mortality. Enhanced nutritional status often improves a patient's quality of life.

Radiation therapy destroys rapidly dividing malignant cells; however, other normal rapidly dividing cells such as the epithelial lining of the GI tract are often affected. Radiation therapy causes anorexia, stomatitis, severe diarrhea, strictures of the intestine, and pain. Radiation treatment of the head and neck region causes taste and smell disturbances, decreased salivation, and dysphagia. Nutrition management of a patient with cancer focuses on maximizing intake of nutrients and fluids. Individualize diet choices to a patient's needs, symptoms, and situation (Nix, 2009). Use creative approaches to manage alterations in taste and smell. For example, patients with altered taste often prefer chilled foods or foods that are spicy. Encourage patients to eat small frequent meals and snacks that are nutritious and easy to digest.

Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome. Patients with HIV/AIDS typically experience body wasting and severe weight loss. The wasting is related to anorexia, stomatitis, oral thrush infection, nausea, or recurrent vomiting, all resulting in inadequate intake. Factors associated with weight loss and malnutrition include severe diarrhea, GI malabsorption, and altered metabolism of nutrients. Systemic infection results in hypermetabolism from cytokine elevation. Often the medications taken to treat HIV infection cause side effects that alter nutritional status.

Restorative care of malnutrition resulting from AIDS focuses on maximizing kilocalories and nutrients. Diagnose and address each cause of nutritional depletion in the care plan. Individually tailored nutrition support progresses in stages from oral, to enteral, and finally to parenteral. Good hand hygiene and food safety are essential because of a patient's reduced resistance to infection. For example, minimization of exposure to *Cryptosporidium* in drinking water, lakes, or swimming pools is important. Small, frequent, nutrient-dense meals that limit fatty and overly sweet foods are easier to tolerate. Patients benefit from eating cold foods and drier or saltier foods with fluid in between (Nix, 2009).

EVALUATION

Through the Patient's Eyes. Patients expect competent and accurate care. If ongoing nutrition therapies do not result in successful outcomes, patients expect nurses to recognize this and alter the plan of care accordingly. Expectations and health care values held by nurses frequently differ from those held by patients. Successful interventions and outcomes require nurses to know what patients expect in addition to nursing knowledge and skill. Work closely with patients to define their expectations, and talk with them about their concerns if their expectations are not realistic. Consider the limits of their conditions and treatment, their dietary preferences, and their cultural beliefs when evaluating outcomes.

Patient Outcomes. Care plans need to reflect achievable goals and outcomes. Evaluate the actual outcomes of nursing actions and compare with expected outcomes to determine if the goals are met

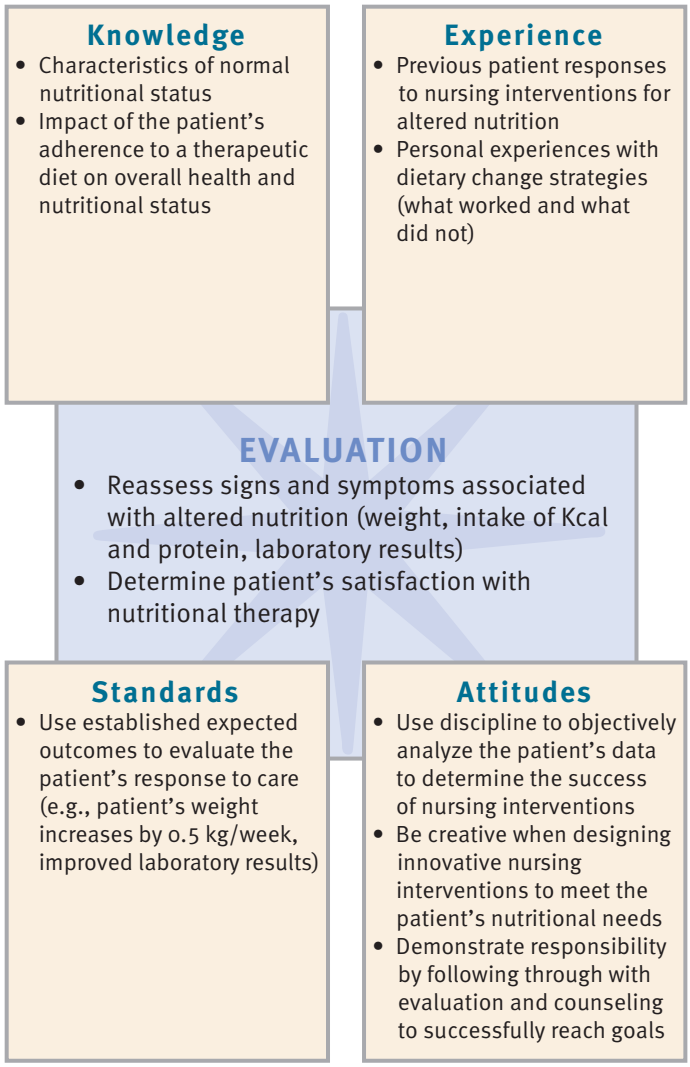

FIG. 44-9 Critical thinking model for nutrition evaluation.

(Fig. 44-9). Multidisciplinary collaboration remains essential in providing nutritional support. Nutrition therapy does not always produce rapid results. Ongoing comparisons need to be made with baseline measures of weight, serum albumin or prealbumin, and protein and kilocalorie intake. If you do not observe gradual weight gain or if weight loss continues, evaluate the dietary EN prescription and determine if the patient is experiencing any adverse effects from medications that are affecting his or her nutritional status. Changes in condition also indicate a need to change the nutritional plan of care. Consult multidisciplinary members of the health care team in an effort to better individualize this plan. The patient is an active participant whenever possible. In the end, a patient's ability to incorporate dietary changes into his or her lifestyle with the least amount of stress or disruption facilitates attainment of outcome measures. When expected outcomes are not met, revise the nursing interventions or expected outcomes based on the patient's needs or preferences. When outcomes are not met, ask questions such as "How has your appetite been?" "Have you noticed a change in your weight?" "How much would you like to weigh?" or "Have you changed your exercise pattern?"

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Use aseptic technique when preparing and delivering enteral feedings. Check agency policy for wearing gloves when handling feedings (Bankhead et al., 2009).
- Label enteral equipment with patient name, room number, formula name, rate, date and time of initiation, and nurse initials (Bankhead et al., 2009).
- Practice "right patient, right formula, right tube" by matching formula and rate to feeding order and verifying that an enteral tubing set connects formula to a feeding tube (Bankhead et al., 2009).
- Have a patient sit upright or elevate the head of the bed a minimum of 30 (preferably 45) degrees unless medically contraindicated for patients receiving enteral feedings (Bankhead et al., 2009).
- Trace all lines and tubing back to the patient to ensure that you have only enteral-to-enteral connections (Bankhead et al., 2009).
- Do not add food coloring or dye to EN. Use of dye has been linked to hypotension, metabolic acidosis, and death (Metheny et al., 2007).
- Refer to manufacturer guidelines to determine hang time for enteral feedings. Maximum hang time for formula is 8 hours in an open system and 24 to 48 hours in a closed, ready-to-hang system (if it remains closed). There is increased risk of bacterial growth in feedings that exceed the recommended hang time.
- Auscultation is not a reliable method for verification of nasogastric or nasointestinal tube placement because a tube inadvertently placed in the lungs, pharynx, or esophagus also transmits a sound similar to that of air entering the stomach (Metheny et al., 2007; Serna and McCarthy, 2006).
- Continuous enteral feedings and PN are always administered using an infusion pump.

SKILL 44-1 ASPIRATION PRECAUTIONS

View Video!

Delegation Considerations

The skill of assessing a patient's risk for aspiration cannot be delegated to nursing assistive personnel (NAP). NAP may feed patients after receiving instructions in aspiration precautions. Instruct NAP to:

- Position patient appropriately to decrease aspiration risk.
- Report any onset of coughing, gagging, or pocketing of food in the mouth.

Equipment

- Chair or electric bed (to allow patient to sit upright)
- Thickening agents as needed (rice, cereal, yogurt, gelatin, commercial thickening agent)
- Tongue blade
- Oral hygiene supplies (see Chapter 39)
- Penlight

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Perform nutrition screening.	Patients at risk for aspiration from dysphagia often alter their eating patterns or choose foods that do not provide adequate nutrition (White et al., 2008).
3 Perform dysphagia screening. Note symptoms such as cough, pharyngeal pooling, change in voice after swallowing. Use a validated screening tool (when available).	Patients at risk for dysphagia include those who have neurological or neuromuscular diseases and those who have had trauma to or surgical procedures of the oral cavity or throat.
4 Observe patient during mealtime for signs of dysphagia and allow him or her to attempt to feed self. Observe patient eat various consistencies of foods and liquids. Note at end of meal if patient becomes tired.	Helps detect abnormal eating patterns such as frequent clearing of throat or prolonged eating time. Fatigue increases risk of aspiration.
5 Ask patient and or family caregiver about any difficulties with chewing or swallowing various textures of food.	Certain types of food are more easily aspirated than others.
PLANNING	
1 Report signs and symptoms of dysphagia to the health care provider.	Signs or symptoms associated with aspiration indicate the need for further evaluation of swallowing by a radiologist or speech language pathologist such as a fluoroscopic swallow study (Ashley et al., 2006).
2 Place information on patient's medical record indicating that dysphagia is present.	Alerts the health care team to the patient's problem to help the team develop and implement an individualized plan of care (Nowlin, 2006).
3 Explain to patient why you are observing him or her while he or she eats.	Increases patient cooperation.
4 Provide a 30-minute rest period before meals.	Swallowing difficulty is less likely in a well-rested patient (Palmer and Metheny, 2008).

STEP	RATIONALE
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Perform oral hygiene, including brushing of tongue, before meals.	Risk of aspiration pneumonia is associated with poor oral hygiene (Palmer and Metheny, 2008).
3 Using penlight and tongue blade, gently inspect mouth for pockets of food.	Pockets of food in the mouth often indicate difficulty swallowing.
4 Have patient sit upright, or elevate head of patient's bed so hips are flexed at a 90-degree angle and head is flexed slightly forward or help patient to same position in a chair. Have him or her assume chin tuck position.	Chin-tuck or chin-down position helps reduce aspiration (Huang et al., 2006). A supine position increases the probability of aspiration (Palmer and Metheny, 2008).
5 Observe patient consume various consistencies of foods and liquids.	Referral to a dietitian is appropriate if a patient has difficulty with a particular consistency.
6 Add thickener to thin liquids to create the consistency of mashed potatoes or serve patient pureed foods.	Thin liquids such as water and fruit juice are difficult to control in the mouth and are more easily aspirated (White et al., 2008).
7 Place ½ to 1 teaspoon of food on unaffected side of the mouth, allowing utensil to touch the mouth or tongue.	Placement of food in the mouth varies based on the type of deficit (Palmer and Metheny, 2008).
8 Place hand on throat to gently palpate swallowing event as it occurs. Swallowing twice is often necessary to clear the pharynx.	Helps evaluate swallowing effort.
9 Provide verbal coaching while feeding patient and give positive reinforcement, as follows:	Verbal cueing keeps patient focused on swallowing. Positive reinforcement enhances patient's confidence in ability to swallow (Palmer and Metheny, 2008).
a. Open your mouth.	
b. Feel the food in your mouth.	
c. Chew and taste the food.	
d. Raise your tongue to the roof of your mouth.	
e. Think about swallowing.	
f. Close your mouth and swallow.	
g. Swallow again.	
h. Cough to clear airway.	
10 Observe for coughing, choking, gagging, and drooling food; suction airway as necessary.	These are indications that suggest dysphagia and risk for aspiration (Ashley et al., 2006).
11 Provide rest periods as necessary during meal to avoid rushed or forced feeding.	Avoiding fatigue decreases the risk of aspiration (Palmer and Metheny, 2008).
12 Ask patient to remain sitting upright for at least 30 to 60 minutes after the meal.	Requiring patients to remain upright after meals or snacks reduces the chance of aspiration by allowing food particles remaining in the pharynx to clear (Frey and Ramsberger, 2011).
13 Help patient perform hand hygiene and mouth care.	Mouth care after meals helps prevent dental caries and reduces colonization of bacteria, which reduces the risk of pneumonia (Palmer and Metheny, 2008).
14 Return patient's tray to appropriate place and perform hand hygiene.	Reduces spread of microorganisms.
EVALUATION	
1 Observe patient's ability to ingest foods of various textures and thickness.	Indicates whether aspiration risk is increased with thin liquids.
2 Monitor patient's food and fluid intake.	Patient needs to avoid certain types and textures of food that are difficult to swallow.
3 Weigh patient weekly at the same time on the same scale.	Determines if weight is stable and reflects adequate caloric level.
4 Observe patient's oral cavity after meal to detect pockets of food.	Determines patient's ability to swallow.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Patient coughs, gags, complains of food "stuck in throat," or has pockets of food in mouth.
- Patient may require a swallowing evaluation.
- Initiate consultation with a speech-language pathologist (SLP) for swallowing exercises and techniques to improve swallowing and reduce risk of aspiration.
- Notify health care provider and SLP of any symptoms that occurred during meal and which foods caused the symptoms.

2 Patient avoids certain textures of food.
- Change consistency and texture of food.

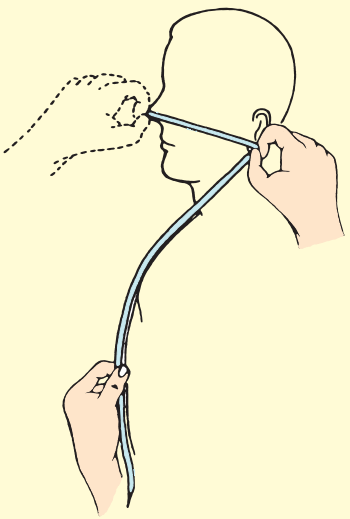
3 Patient experiences weight loss.
- Discuss findings with health care provider, SLP, and/or RD.

RECORDING AND REPORTING

- Document the following in the patient's medical record: patient's tolerance of various food textures, amount of assistance required, position during meal, absence or presence of any symptoms of dysphagia, and amount eaten.
- Report any coughing, gagging, choking, or swallowing difficulties to nurse in charge or health care provider.

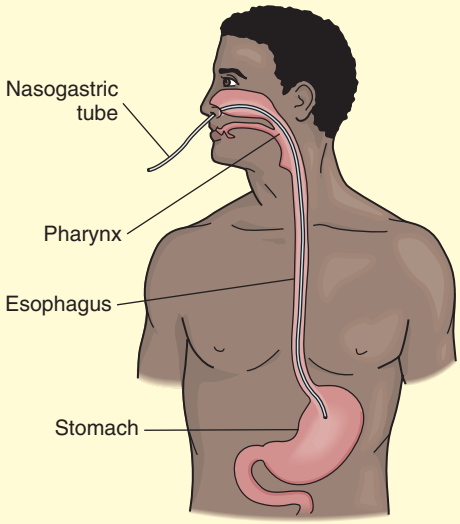
SKILL 44-2 INSERTING A SMALL-BORE NASOENTERIC TUBE FOR ENTERAL FEEDINGS

Delegation Considerations



The skill of inserting a small-bore nasoenteric tube cannot be delegated to nursing assistive personnel (NAP). The nurse guides the NAP to assist with patient positioning during tube insertion.

Equipment



- Nasogastric or nasointestinal tube (8- to 12-Fr) with guidewire or stylet
- Stethoscope
- Water-soluble lubricant
- 60-mL or larger Luer-Lok or catheter-tip syringe
- Hypoallergenic tape and tincture of benzoin or tube fixation device
- pH indicator strip (scale 1.0 to 11.0 or greater)
- Glass of water and straw
- Emesis basin
- Towel
- Facial tissues
- Clean gloves
- Suction equipment in case of aspiration
- Penlight to check placement in nasopharynx
- Tongue blade

STEP	RATIONALE
ASSESSMENT	
1 Assess patient for the need for enteral tube feeding: NPO or insufficient intake for more than 5 days, functional gastrointestinal (GI) tract, unable to ingest sufficient nutrients.	Identifying patients who need tube feedings before they become nutritionally depleted helps to prevent complications related to malnutrition.
2 Review patient's medical history for nasal problems (e.g., nosebleeds, oral facial surgery, facial trauma, past history of aspiration, anticoagulation therapy or coagulopathy).	A history of these problems may contraindicate tube placement and require you to consult with health care provider to change route of nutrition support.
3 Assess patient's mental status.	Alert patient is better able to cooperate with tube insertion. If vomiting occurs, an alert patient usually expectorates vomitus, which helps reduce the risk of aspiration.
4 Review health care provider's order for type of tube and enteral feeding schedule.	Procedure and tube feedings require a health care provider's order.
5 Perform hand hygiene. Assess patency of nares. Have patient close each nostril alternately and breathe. Examine each naris for patency and skin breakdown.	Evaluates nares for patency. Nares are often obstructed or irritated, or septal defect is present.
6 Assess for gag reflex. Place tongue blade in patient's mouth, touching uvula to induce a gag response.	Identifies ability to swallow and determines if there is a risk for aspiration.
7 Determine if health care provider wants a prokinetic agent administered before tube placement.	Prokinetic agents such as metoclopramide given before tube placement help advance the tube into the intestine (Metheny, 2006).
CLINICAL DECISION: *Patients with impaired level of consciousness often have impaired gag reflex; their risk of aspiration is increased during insertion of feeding tubes and subsequent tube feedings (Roberts et al., 2007).*	
8 Auscultate abdomen for bowel sounds.	Absence of bowel sounds indicates decreased or absent peristalsis and increased risk for aspiration and/or abdominal distention.
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure to patient, including sensations that will be felt during insertion (burning in nasal passages) and how to communicate during intubation by raising index finger to indicate gagging or discomfort.	Reduces anxiety and helps patient assist in insertion.
3 Stand on same side of bed as naris chosen for insertion and assist patient to high-Fowler's position unless contraindicated. Place pillow behind head and shoulders.	Allows easier manipulation of tube. Fowler's position reduces risk of aspiration and promotes effective swallowing.
4 Place bath towel over chest. Keep facial tissues within reach.	Prevents soiling of gown. Insertion of tube frequently produces tearing.

STEP	RATIONALE
5 Determine length of tube to be inserted and mark with tape:	
a. *Traditional method:* Measure distance from tip of nose to earlobe to xiphoid process of sternum (see illustration).	Length approximates distance from nose to stomach in 98% of patients. For duodenal or jejunal placement, an additional 20 to 30 cm (8 to 12 inches) is required.
6 Prepare nasogastric or nasointestinal tube for intubation: NOTE: Do not ice plastic tubes.	Tubes becomes stiff and inflexible, causing trauma to mucous membranes.
a. Inject 10 mL of water from 30-mL or larger Luer-Lok or catheter-tip syringe into tube.	Aids in guidewire or stylet insertion.
b. Make certain that guidewire is securely positioned against weighted tip and that both Luer-Lok connections are snugly fitted together.	Promotes smooth passage of tube into GI tract. Improperly positioned stylet induces serious trauma.
7 Cut tape 10 cm (4 inches) long, or prepare tube fixation device.	Anchors tubing following insertion.
IMPLEMENTATION	
1 Perform hand hygiene. Apply clean gloves.	Reduces transmission of microorganisms.
2 Dip tube with surface lubricant into glass of water.	Activates lubricant to facilitate passage of tube into naris to GI tract.
3 Insert tube through nostril to back of throat (posterior nasopharynx). Aim back and down toward ear (see illustration).	Natural contour facilitates passage of tube into GI tract and reduces gagging by patient.
4 Have patient flex head toward chest after tube has passed through nasopharynx.	Closes off glottis and reduces risk of tube entering trachea.
5 Encourage patient to swallow by giving small sips of water or ice chips when possible. Advance tube as patient swallows.	Swallowing facilitates passage of tube past oropharynx.
6 Emphasize need to mouth breathe and swallow during procedure.	Helps facilitate passage of tube and alleviates patient's fears during procedure.
7 When tip of tube reaches carina (about 25 cm [10 inches] in an adult), stop, hold end of tube near ear, and listen for air exchange from distal portion of tube.	If you hear air, tube is possibly in respiratory tract; remove tube and start over. *Never* use this step for tube verification (Baskin, 2006).
8 Advance tube each time patient swallows until desired length has been passed.	Reduces discomfort and trauma to patient.
CLINICAL DECISION: *Do not force the tube. If you meet resistance or patient starts to cough, choke, or become cyanotic, stop advancing the tube and pull it back.*	
9 Check for position of tube in the back of throat with penlight and tongue blade.	Tube may be coiled, kinked, or entering trachea.
10 Keep tube secure as you measure gastric pH to verify placement of tube (see Box 44-13) by obtaining gastric aspirate.	Properly obtained pH of 0 to 4 is a good indication of gastric placement (Metheny, 2006).
CLINICAL DECISION: *Auscultation is not a reliable method for verification of tube placement because a tube inadvertently placed in the lungs, pharynx, or esophagus also transmits a sound similar to that of air entering the stomach (Bankhead et al., 2009; Kenny and Goodman, 2010).*	

STEP 5a Determine length of tube to be inserted.

STEP 3 NG tube inserted through nose and esophagus into stomach.

SKILL 44-2 INSERTING A SMALL-BORE NASOENTERIC TUBE FOR ENTERAL FEEDINGS—cont'd

STEP	RATIONALE
11 After gastric aspirates are obtained, anchor tube to nose and avoid pressure on nares. Mark exit site with indelible ink. Select one of the following options.	Properly secured tube allows patient more mobility and prevents trauma to nasal mucosa.
a. Apply tape	
(1) Apply tincture of benzoin or other skin adhesive on tip of patient's nose and tube and allow it to become "tacky."	Helps tape adhere better. Protects skin.
(2) Remove gloves and split one end of tape lengthwise 5 cm (2 inches).	
(3) Place intact end of tape over bridge of patient's nose. Wrap each of the 5-cm (2-inch) strips around tube as it exits nose (see illustration).	Securing tape to nares prevents tissue necrosis.
b. Apply tube fixation device using shaped adhesive patch.	Secures tube and reduces friction on naris.
(1) Apply wide end of patch to bridge of nose (see illustration).	
(2) Slip connector around tube as it exits nose (see illustration).	
12 Fasten end of nasogastric tube to patient's gown using piece of tape (see illustration). Do not use safety pins to fasten tube to gown.	Reduces traction on naris if tube moves. Safety pins become unfastened and possibly cause injury to patient.
13 For intestinal placement, position patient on right side when possible until radiological confirmation of correct placement has been verified.	Promotes passage of tube into small intestine (duodenum or jejunum).
14 Remove gloves, perform hand hygiene, and assist patient to a comfortable position.	Prevents transmission of infection.

CLINICAL DECISION: *Leave guidewire or stylet in place until a radiologist verifies correct position by x-ray film. Never attempt to reinsert partially or fully removed guidewire or stylet while feeding tube is in place.*

15 Obtain x-ray film of chest/abdomen.	X-ray film examination is the gold standard for verifying tube placement (Bankhead et al., 2009).
16 Apply clean gloves and administer oral hygiene (see Chapter 39). Clean tubing at nostril.	Promotes patient comfort and integrity of oral mucous membranes.
17 Remove gloves, dispose of equipment, and perform hand hygiene.	Reduces transmission of microorganisms.

STEP 11a(3) Wrapping tape to anchor nasoenteral tube.

STEP 11b(1) Applying patch to bridge of nose.

STEP 11b(2) Slip connector around feeding tube.

STEP 12 Fastening feeding tube to patient's gown.

STEP	RATIONALE
EVALUATION	
1 Inspect naris and oropharynx for any irritation after insertion.	If insertion was difficult, irritation of naris or oropharynx possibly occurred.
2 Ask if patient feels comfortable.	Evaluates patient's level of comfort.
3 Observe patient for any difficulty breathing, coughing, or gagging.	Malposition of tube causes these symptoms.
4 Auscultate lung sounds.	Abnormal lung sounds are early sign of aspiration.
5 Confirm x-ray film results.	Verifies position of tube before initiating enteral feeding.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Aspiration of stomach contents into the respiratory tract
- Position patient on side.
- Suction nasotracheally and orotracheally.
- Consult health care provider immediately to order chest x-ray film examination.
- Prepare for possible initiation of antibiotics.

2 Displacement of feeding tube to another site (e.g., from duodenum to stomach, mark at exit site if tube is moved); possibly occurs when patient coughs or vomits
- Aspirate GI contents and measure pH.
- Remove displaced tube and insert and verify placement of new tube.
- If there is a question of aspiration, obtain chest x-ray film.

RECORDING AND REPORTING

- Record and report type and size of tube placed, location of distal tip of tube, patient's tolerance of procedure, pH value, and confirmation of tube position by x-ray film examination.
- If patient develops signs of aspiration, notify health care provider immediately.

SKILL 44-3 ADMINISTERING ENTERAL FEEDINGS VIA NASOENTERIC, GASTROSTOMY, OR JEJUNOSTOMY TUBES

View Video!

Delegation Considerations

The skill of administering enteral tube feeding via a nasoenteric, gastrostomy, or jejunostomy can be delegated to nursing assistive personnel (NAP) after the tube placement is verified by the nurse (refer to agency policy). The nurse is responsible for patient assessment and verification of tube placement and patency. The nurse directs the NAP to:
- Have the patient sit upright in bed/chair or elevate the head of the patient's bed at least 30 (preferably 45) degrees.
- Infuse the feeding slowly.
- Report any difficulty infusing the feeding or any discomfort voiced by the patient.
- Report any gagging, paroxysms of coughing, or choking.

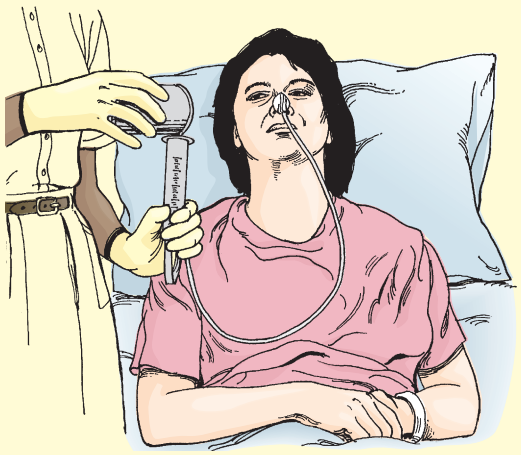
Equipment

- Disposable feeding bag and tubing or ready-to-hang system
- 30-mL or larger Luer-Lok or catheter-tip syringe
- Stethoscope
- pH indicator strip (scale 1.0 to 11.0 or greater)
- Infusion pump (required for continuous or intestinal feedings): use pump designed for tube feedings
- Prescribed enteral feedings
- Clean gloves
- Equipment to obtain blood glucose by fingerstick

STEP	RATIONALE
ASSESSMENT	
1 Assess patient's need for enteral tube feedings: impaired swallowing, decreased level of consciousness, head or neck surgery, facial trauma, surgeries of upper alimentary canal.	Identify patients who need tube feedings before they become nutritionally depleted.
2 Evaluate patient's nutritional status (see Table 44-4). Obtain baseline weight and laboratory values. Assess patient for fluid volume excess or deficit, electrolyte abnormalities, and metabolic abnormalities such as hyperglycemia.	Enteral feedings are to restore or maintain a patient's nutritional status. Provides objective data to measure effectiveness of feedings.
3 Verify health care provider's order for formula, rate, route, and frequency. Laboratory data and bedside assessments such as fingerstick blood glucose measurement are also ordered by health care provider.	Tube feedings, laboratory tests, and bedside tests must be ordered by health care provider.
4 For feedings administered through tubes placed through abdominal wall, assess tube site for breakdown, irritation, or drainage.	Infection, pressure from tube, or drainage of gastric secretions causes skin breakdown.
5 Auscultate for bowel sounds before feeding.	Absent bowel sounds indicate decreased ability of gastrointestinal (GI) tract to digest or absorb nutrients. May require holding of feeding (see agency policy).

SKILL 44-3 ADMINISTERING ENTERAL FEEDINGS VIA NASOENTERIC, GASTROSTOMY, OR JEJUNOSTOMY TUBES—cont'd

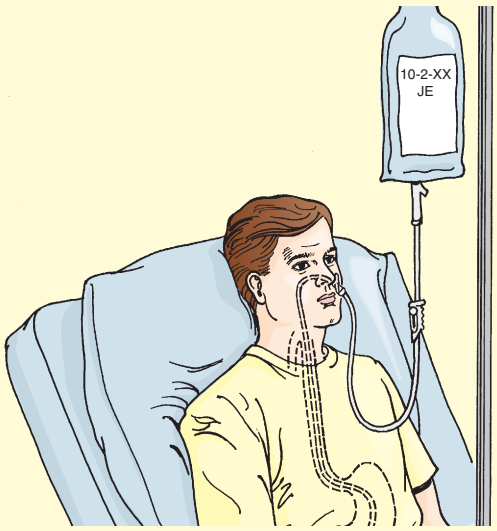
STEP	RATIONALE
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure to patient.	Well-informed patient is more cooperative and at ease.
3 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
4 Prepare feeding container and formula:	
a. Check expiration date on formula and integrity of container.	Tube feedings administered within designated shelf life from container without cracks or breaks reduces patient's risk of obtaining tube feeding–borne GI infections. In addition, a container without cracks or breaks prevents leakage of tube feeding.
b. Have tube feeding at room temperature.	Cold formula causes gastric cramping and discomfort because mouth and esophagus do not warm liquid.
c. Connect tubing to container as needed or prepare ready-to-hang container. Use aseptic technique and avoid handling feeding system or touching can tops, container openings, spike, and spike port.	Ensures that feeding system, including bag, connections, and tubing, is free of contamination to prevent bacterial growth (Bankhead et al., 2009; Matlow et al., 2006).
d. Shake formula container well. Cleanse the top of canned formula with an alcohol swab before opening it. Fill container with formula (see illustration). Open roller clamp on tubing and fill with formula to remove air. Reclamp tubing. Hang on intravenous (IV) pole.	Filling tubing with formula prevents excess air from entering GI tract.



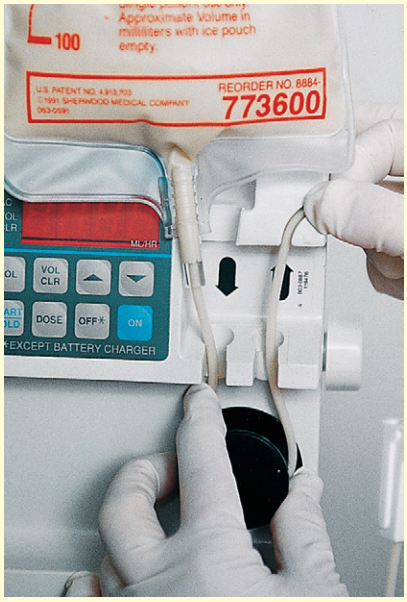
STEP 4d Pour formula into feeding container.

5 For intermittent feeding have syringe ready and be sure that formula is at room temperature.	Cold formula causes gastric cramping.
IMPLEMENTATION	
1 Place patient in high-Fowler's position or elevate head of bed at least 30 (preferably 45) degrees. For patients forced to remain supine, place in reverse Trendelenburg's position.	Elevated head helps prevent aspiration (Kenny and Goodman, 2010).
2 Verify tube placement:	
a. Nasoenteric (see Box 44-14.)	
b. *Gastrostomy tube:* Attach syringe and aspirate 5 to 10 mL of gastric secretions; observe their appearance and check pH.	Gastric fluid of patient who has fasted for at least 4 hours usually has a pH of 1 to 4, especially when patient is not receiving gastric-acid inhibitor. Continuous administration of tube feedings elevates pH (Bankhead et al., 2009).
c. *Jejunostomy tube:* Aspirate intestinal secretions, observe their appearance, and check pH.	Presence of intestinal fluid indicates that end of tube is in small intestine. If fluid tests acidic on pH test, if it looks like gastric fluid, or if residual volume is large (>10 mL), displacement of tube into stomach has possibly occurred.

STEP	RATIONALE
CLINICAL DECISION: *Auscultation is not a reliable method for verification of placement of a tube because a tube inadvertently placed in lungs, pharynx, or esophagus transmits sound similar to that of air entering the stomach (Bankhead et al., 2009; Kenny and Goodman, 2010).*	
3 Check for gastric residual volume (GRV) before each feeding for bolus and intermittent feedings and every 4 hours in critically ill patients and every 4 to 6 hours in non–critically ill patients for continuous feedings (Metheny, 2006; Bankhead et al., 2009).	Gastric residual volume (GRV) indicates if gastric emptying is delayed.
a. Draw up 10 to 30 mL of air into syringe. Connect to end of feeding tube. Flush tube with air. Pull back slowly to aspirate total amount of gastric contents (see illustration).	
b. Return aspirated contents to stomach unless volume exceeds 250 mL, then check agency policy. Some questions exist regarding the safety of returning high volumes of fluid into the stomach (Bankhead et al., 2009; Delegge, 2011).	Return of aspirate prevents fluid and electrolyte imbalance (Bankhead et al., 2009).
c. Do not administer feeding when a single GRV exceeds 500 mL or when two consecutive measurements (taken 1 hour apart) each exceed 250 mL (Metheny, 2006; Bankhead et al., 2009) (check agency policy).	Some controversy exists regarding the ability of elevated GRVs to identify risk for pulmonary aspiration. However, frequent interruptions of feeding based on GRV levels is a well-recognized reason for failure to meet nutritional goals (Metheny et al., 2008; Bankhead et al., 2009; Delegge, 2011).
4 Flush tubing with 30 mL water. Before attaching feeding administration set to feeding tube, trace tube to origin and label "Tube feeding only."	Ensures that tube is clear and patent (Bourgault et al., 2007). Usually patients receive enteral feedings continuously. Avoids misconnections (Bankhead et al., 2009). However, they often receive initial feedings by bolus to assess formula tolerance. See Box 44-12 for guidelines to advance enteral feedings.
5 Initiate feeding:	
a. Syringe for intermittent feeding	
(1) Pinch proximal end of feeding tube.	Prevents excessive air from entering patient's stomach/intestine or leaking of contents.
(2) Remove plunger from syringe and attach barrel of syringe to end of tube.	
(3) Fill syringe with measured amount of formula (see illustration). Release tube, elevate syringe to no more than 45 cm (18 inches) above insertion site, and allow it to empty gradually by gravity. Repeat Steps (1) to (3) until you have delivered prescribed amount to patient.	Height of syringe allows for safe, slow, gravity drainage of formula. This gradual emptying of tube feeding by gravity reduces risk of abdominal discomfort, vomiting, or diarrhea induced by bolus or too-rapid infusion of tube feedings.
b. Feeding bag for intermittent feeding	
CLINICAL DECISION: *Before attaching feeding administration set to a feeding tube, trace the tube to its point of origin. Label the administration set "Tube Feeding Only." This prevents misconnections between feeding set and intravenous systems or other medical tubing or devices (Bankhead et al., 2009).*	



STEP 3a Check for gastric residual (small-bore tube).



STEP 5a(3) Fill syringe with formula.

SKILL 44-3 ADMINISTERING ENTERAL FEEDINGS VIA NASOENTERIC, GASTROSTOMY, OR JEJUNOSTOMY TUBES—cont'd

STEP	RATIONALE
(1) Attach feeding bag tubing to end of feeding tube. Set rate by adjusting roller clamp on tubing or placing on feeding pump.	Reduces air introduced to stomach.
(2) Allow bag to empty gradually over 30 to 45 minutes (see illustration). Label bag with tube-feeding type, strength, and amount (include date, time, and initials). Change bag every 24 hours.	Gradual emptying of tube feeding by gravity reduces risk for abdominal discomfort, vomiting, or diarrhea induced by bolus or too-rapid infusion of tube feedings. Helps decrease bacterial colonization.
c. Continuous-drip method	
(1) Attach administration set tubing to end of feeding tube.	Continuous feeding method is designed to deliver prescribed hourly rate of feeding. This method reduces risk of abdominal discomfort.
(2) Insert tubing through infusion pump and set rate (see illustration). Use a pump designated for tube feeding and not one for intravenous fluids.	Use of an infusion pump delivers continuous feeding at a steady rate and pressure. Pump alarms for increased resistance.
6 Advance rate of tube feeding gradually as ordered (see Box 44-12).	Tube feedings are advanced gradually to prevent diarrhea and gastric intolerance to formula.
CLINICAL DECISION: *Use pump designated for tube feeding and not for intravenous fluids.*	
7 Flush with 30 mL water every 4 hours during continuous feeding, before and after an intermittent feeding. Have registered dietitian recommend total free water requirement per day and obtain a health care provider's order.	Clears tubing of formula and prevents clogging of tube (Bankhead et al., 2009). Provides patient with source of water to help maintain fluid and electrolyte balance.
CLINICAL DECISION: *Flush tube with 30 mL sterile water in immunocompromised or critically ill patients (Bankhead et al., 2009).*	
8 When tube feedings are not being administered, cap or clamp proximal end of feeding tube.	Prevents air from entering stomach between feedings.
9 Rinse bag and tubing with warm water whenever feedings are interrupted.	Clears old tube feedings and reduces bacterial growth.
10 Change bag and use a new administration set every 24 hours.	Reduces patient's exposure to bacterial growth occurring in bag and tubing.
11 Dispose of supplies, and perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Measure amount of aspirated GRV every 4 to 6 hours.	Evaluates tolerance of tube feeding.
2 Monitor fingerstick blood glucose every 6 hours until maximum administration rate is reached and maintained for 24 hours (see Skill 44-4).	Alerts nurse to patient's tolerance of glucose. Glucose testing is often continued if blood glucose levels are elevated.

STEP 5b(2) Administer feeding.

STEP 5c(2) Connect tubing through infusion pump.

STEP	RATIONALE
3 Monitor intake and output every 8 hours and calculate daily totals every 24 hours.	Intake and output are indications of fluid balance, fluid volume excess or deficit.
4 Weigh patient daily until maximum administration rate is reached and maintained for 24 hours; then weigh patient 3 times per week at same time using same scale.	Weight gain is indicator of improved nutritional status; however, sudden gain of more than 2 pounds in 24 hours usually indicates fluid retention.
5 Monitor laboratory values.	Improving laboratory values (e.g., albumin, transferrin, and prealbumin) indicate an improved nutritional status (Bankhead et al., 2009).
6 Observe patient's respiratory status.	Change in respiratory status (e.g., increased rate, declining SpO_2) may indicate aspiration of tube feeding.
7 Auscultate bowel sounds.	Assesses gastric peristalsis.
8 For tubes placed through abdominal wall, inspect insertion site for signs of impaired skin integrity.	Enteral tubes often cause pressure and excoriation at insertion site. Gastric secretions also cause irritation to skin.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS (IN ADDITION TO THOSE IN SKILL 44-1)

1 GRV exceeds 250 mL for each of two consecutive assessments (see agency policy).
- Hold feeding and notify health care provider..
- Maintain patient in upright position in chair/bed or elevate HOB at least 30 (preferably 45) degrees.
- Recheck residual in 1 hour.

2 Patient develops diarrhea 3 times or more in 24 hours.
- Notify health care provider.
- Confer with dietitian.
- Institute skin care measures.
- Consider change in antibiotics, only for patients receiving antibiotics.

3 Patient develops nausea, vomits, and aspirates formula when gastric emptying is delayed or formula is administered too rapidly and produces vomiting.
- Position patient in side-lying position.
- Suction airway.
- Notify health care provider.
- Obtain chest x-ray film.
- Check patency of tube.
- Aspirate for GRV.

RECORDING AND REPORTING

- Record amount and type of feeding instilled. Record patient's response to tube feeding, patency of tube, condition of naris or skin at tube site for tubes placed in abdominal wall, and any side effects.
- Report patient's tolerance and adverse effects.

HOME CARE CONSIDERATIONS

- Teach patient or family caregiver how to determine correct placement of feeding tube.
- Inform patient or family caregiver of signs associated with pulmonary aspiration, delayed gastric emptying.
- Reinforce signs and symptoms associated with feeding tube complications and when to call health care provider.
- Explain and demonstrate how to do skin care around gastrostomy or jejunostomy tube and explain signs and symptoms of infection at the insertion site.

SKILL 44-4 BLOOD GLUCOSE MONITORING

Delegation Considerations

The skill of measuring blood glucose level after skin puncture (capillary puncture) can be delegated to properly trained nursing assistive personnel (NAP). You must first assess the patient to determine that serum glucose monitoring is appropriate for delegation. When the patient's condition changes frequently, you should not delegate this skill to NAP. The nurse directs the NAP by:
- Explaining appropriate sites to use for puncture and when to obtain glucose levels.
- Reviewing expected levels and when to report unexpected glucose levels to the nurse.

Equipment

- Antiseptic swab
- Cotton ball
- Sterile lancet or blood-letting device
- Heel-warming device *(optional)*
- Paper towel
- Blood glucose meter (e.g., OneTouch) (Fig. 44-10)
- Blood glucose reagent strips (brand determined by meter used)
- Clean gloves

SKILL 44-4 BLOOD GLUCOSE MONITORING—cont'd

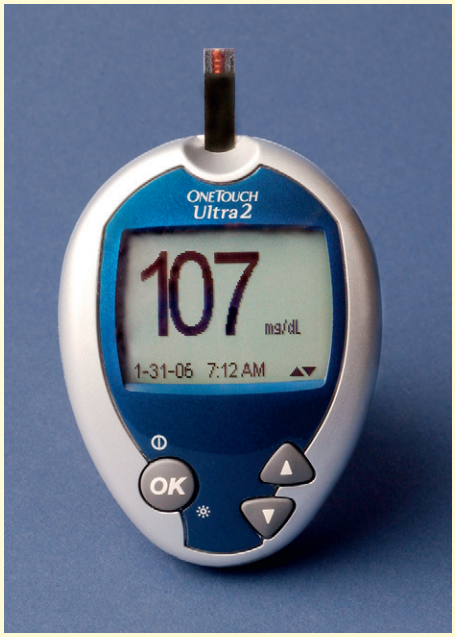


FIG. 44-10 Blood glucose monitor. (Courtesy LifeScan, Inc., Milpitas, Calif.)

STEP	RATIONALE
ASSESSMENT	
1 Assess patient's understanding of procedure and purpose of glucose monitoring. Determine if patient with diabetes mellitus performs test at home and, if so, confirm his or her competency.	Data set guidelines for nurse to develop teaching plan.
2 Determine if specific conditions need to be met before or after sample collection (e.g., with fasting, after meals, after certain medications, before insulin doses).	Dietary intake of carbohydrates and ingestion of concentrated glucose preparations alter blood glucose levels.
3 Determine if risks exist for performing skin puncture (e.g., low platelet count, anticoagulant therapy, bleeding disorders).	Abnormal clotting mechanisms increase risk for local ecchymosis and bleeding.
4 Assess area of skin that you will use as puncture site (e.g., fingers or heel). Alternative sites are palm, arm, or thigh. Avoid areas of bruising and open lesions.	Sides of fingers and heels are commonly selected because they have fewer nerve endings. Measurements from alternative sites are meter specific and may be different than those from traditional sites (Corbett, 2008). Puncture site should not be edematous, inflamed, or recently punctured because these factors cause increased interstitial fluid and blood to mix and also increase risk for infection.
5 Review health care provider's order for time of frequency of measurement.	Health care provider determines test schedule on basis of patient's physiological status and risk for glucose imbalance.
6 For patient with diabetes who performs test at home, assess ability to handle skin-puncturing device. If patient chooses, he or she may wish to continue self-testing while in hospital.	Patient's physical health may change (e.g., vision disturbance, fatigue, pain, disease process), preventing him or her from performing test.
PLANNING	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Explain procedure and purpose to patient and/or family. Offer patient and family opportunity to practice testing procedures. Provide resources/teaching aids for patient.	Promotes understanding and cooperation.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transfer of microorganisms.
2 Instruct adult to perform hand hygiene with soap and warm water if able.	Promotes skin cleaning and vasodilation at selected puncture site. Handwashing establishes practice for patient when test is performed at home.
3 Position patient comfortably in chair or in semi-Fowler's position in bed.	Ensures easy accessibility to puncture site. Patient assumes position when self-testing.

STEP	RATIONALE
4 Remove reagent strip from container; tightly seal cap. Check code on test strip vial.	Protects strips from accidental discoloration caused by exposure to air or light. Code on test strip vial must match code entered into glucose meter.
5 Turn on glucose meter if necessary.	Activates meter.
CLINICAL DECISION: *Some monitors are activated when the reagent strip is inserted and therefore do not have a specific on/off switch.*	
6 Insert strip into glucose meter (refer to manufacturer directions) and make necessary adjustments (see illustration).	Some machines must be calibrated; others require zeroing of timer. Each meter is adjusted differently.
7 Remove unused reagent strip from meter and place on paper towel or clean, dry surface with test pad facing up (see manufacturer directions). (Note that for some models of meters, strip remains in device as you apply blood to tip of strip.)	Moisture on strip can alter accuracy of final test results.
8 Apply clean gloves.	Reduces risk for contamination by blood.
9 Choose puncture site. Puncture site should be vascular. In adult select lateral side of finger; be sure to avoid central tip of finger, which has more dense nerve supply.	Ensures free flow of blood following puncture.
10 Hold finger that you will puncture in dependent position while gently massaging it toward puncture site.	Increases blood flow to area before puncture.
11 Clean site with antiseptic swab and *allow it to dry completely.*	Alcohol can cause blood to hemolyze.
12 Remove cover of lancet or blood-letting device. Hold lancet perpendicular to puncture site and pierce finger or heel quickly in one continuous motion (do not force lancet).	Cover keeps tip of lancet/needle sterile.
13 Some agencies use lancet devices with an automatic blade retraction system. This reduces the possibility of self-sticks, preventing exposure to bloodborne pathogens. Place blood-letting device firmly against side of finger and push release button, causing needle to pierce skin (see illustration).	Blood-letting devices are designed to pierce skin for specific depth, ensuring adequate blood flow. Perpendicular position ensures proper skin penetration.
14 Wipe away first droplet of blood with cotton ball. (See manufacturer directions for meter used.)	First drop of blood may contain more serous fluid than blood cells.
15 Lightly squeeze puncture site (without touching) until large droplet of blood has formed (see illustration). Repuncturing is necessary if large-enough drop does not form to ensure accurate test results. (See manufacturer directions regarding how blood is applied.)	Adequate-size droplet is needed to activate monitor and obtain accurate results. Excessive squeezing of tissues during blood sample collection may contribute to pain, bruising, scarring, and hematoma formation (Pagana and Pagana, 2009).

STEP 6 Load test strip into meter. (Courtesy of the manufacturer.)

STEP 13 Prick side of finger with lancet.

STEP 15 Squeeze puncture site until large droplet of blood is formed.

SKILL 44-4 BLOOD GLUCOSE MONITORING—cont'd

STEP	RATIONALE
CLINICAL DECISION: *Patients with diabetes frequently have peripheral vascular disease, making it difficult to produce a large drop of blood after a fingerstick. Be sure to hold finger in dependent position before puncturing to improve blood flow.*	
16 Obtain test results.	Exposure of blood to test strip for prescribed time ensures proper results.
CLINICAL DECISION: *Some meters (e.g., OneTouch [LifeScan]) require blood sample to be applied to test strip already in the meter. Once the drop of blood is applied, the meter automatically calculates the reading.*	
a. Be sure that meter is still on. Bring test strip in meter to drop of blood. The blood is wicked onto the test strip (see manufacturer's instructions).	Blood enters strip, and glucose device shows message on screen to signal that enough blood is obtained.
CLINICAL DECISION: *Do not scrape blood onto the test strips or apply it to the wrong side of the test strip. This prevents accurate glucose measurement.*	
b. Blood glucose test result appears on screen (see illustration). Some devices "beep" when completed.	

STEP 16b Results appear on meter screen. (Courtesy of the manufacturer.)

17 Turn meter off. Dispose of test strip, lancet, and gloves in proper receptacles.	Meter is battery powered. Proper disposal reduces risk for needlestick injury and spread of infection.
18 Discuss test results with patient.	Promotes participation and compliance with therapy.

EVALUATION

1 Reinspect puncture site for bleeding or tissue injury.	Site is a possible source of discomfort and infection.
2 Compare glucose meter reading with normal blood glucose levels and previous test results.	Determines if glucose level is normal.
3 Ask patient to discuss procedure.	Validates level of learning.
4 Ask patient to explain test and results.	Results of test may cause anxiety. Patient may misunderstand specific step of procedure.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Puncture site continues to bleed or is bruised.
- Apply pressure to site.
- Notify health care provider if bleeding lasts more than 5 minutes.

2 Glucose meter malfunctions.
- Repeat test, following directions.
- Follow manufacturer directions for malfunctions.

3 Blood glucose level is above or below target range.
- Continue to monitor patient.
- Follow agency protocol for laboratory confirmation testing of very high or very low results. Laboratory testing is generally considered more accurate.
- Check medical record to see if there is a medication order for deviations in glucose level; if not, notify health care provider.
- Administer insulin or carbohydrate source as ordered (depending on glucose level).
- Notify health care provider of patient's response.

RECORDING AND REPORTING

- Record glucose results on appropriate flow sheet and describe response, including presence or absence of pain or excessive oozing of blood at puncture site.
- Describe explanations or teaching provided in medical record.
- Report blood glucose levels out of target range and take appropriate action for hypoglycemia or hyperglycemia.

KEY POINTS

- Ingestion of a diet balanced with carbohydrates, fats, proteins, vitamin, and minerals provides the essential nutrients to carry out the normal physiological functioning of the body throughout the life span.
- Through digestion food is broken down into its simplest form for absorption. Digestion and absorption occur mainly in the small intestine.
- Guidelines for dietary change recommend reduced fat, saturated fat, sodium, refined sugar, and cholesterol and increased intake of complex carbohydrates and fiber.
- Because improper nutrition affects all body systems, nutritional assessment includes a review of total physical assessment.
- Enteral feedings are for patients who are unable to ingest food but are able to digest and absorb food in the gastrointestinal tract.
- EN protects intestinal structure and function and enhances immunity.
- TPN supplies essential nutrients in appropriate amounts to support life through the administration of a concentrated nutrient solution into the superior vena cava near the right atrium of the heart.
- MNT is a recognized treatment modality for both acute and chronic disease states.
- One of the most important responsibilities of a nurse administering enteral feedings is to take precautions to prevent patients from aspirating feeding formula.
- Special diets alter the composition, texture, digestibility, and residue of foods to suit the patient's particular needs.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. As part of your next visit to the senior citizens' center where Mrs. Cooper lives, you plan to present a program to the residents to help decrease their risk of cardiovascular disease. Using your knowledge of medical nutrition therapy (MNT), summarize five points that you will include in the program for the residents.
2. Six months later, Mrs. Cooper is admitted to the hospital for a viral infection. She had a recent weight loss of 6 pounds in the week before admission and lost an additional 4 pounds during the week of hospitalization. Her appetite is poor; she has frequent nausea and vomiting. Her abdomen is soft and nontender, and bowel sounds are present. The health care provider orders enteral feedings to be started.
   a. What type of tube should be selected?
   b. How is the tube placement verified?
   c. Describe the type of feeding and initiation of feedings.
   d. Which complications of tube feeding should be assessed?
3. Two years after her husband died, Mrs. Cooper suffered a stroke and developed dysphagia. Develop a plan of care for assisting Mrs. Cooper with meals to reduce the risk of aspiration.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Which statement made by an adult patient demonstrates understanding of healthy nutrition teaching?
   1. I need to stop eating red meat.
   2. I will increase the servings of fruit juice to four a day.
   3. I will make sure that I eat a balanced diet and exercise regularly.
   4. I will not eat so many dark green vegetables and eat more yellow vegetables.
2. The nurse teaches a patient who has had surgery to increase which nutrient to help with tissue repair?
   1. Fat
   2. Protein
   3. Vitamin
   4. Carbohydrate
3. The nurse is caring for a patient experiencing dysphagia. Which interventions help decrease the risk of aspiration during feeding? (Select all that apply.)
   1. Sit the patient upright in a chair.
   2. Give liquids at the end of the meal.
   3. Place food in the strong side of the mouth.
   4. Provide thin foods to make it easier to swallow.
   5. Feed the patient slowly, allowing time to chew and swallow.
   6. Encourage patient to lie down to rest for 30 minutes after eating.
4. The nurse suspects that the patient receiving parenteral nutrition (PN) through a central venous catheter (CVC) has an air embolus. What action does the nurse need to take first?
   1. Raise head of bed to 90 degrees
   2. Turn patient to left lateral decubitus position
   3. Notify health care provider immediately
   4. Have patient perform the Valsalva maneuver
5. Which action is initially taken by the nurse to verify correct position of a newly placed small-bore feeding tube?

1. Placing an order for x-ray film examination to check position
2. Confirming the distal mark on the feeding tube after taping
3. Testing the pH of the gastric contents and observing the color
4. Auscultating over the gastric area as air is injected into the tube

6. The catheter of the patient receiving parenteral nutrition (PN) becomes occluded. Place the steps for caring for the occluded catheter in the order in which the nurse would perform them.
   1. Attempt to aspirate a clot.
   2. Temporarily stop the infusion.
   3. Flush the line with saline or heparin.
   4. Use a thrombolytic agent if ordered or per protocol.
7. Based on knowledge of peptic ulcer disease (PUD), the nurse anticipates the presence of which bacteria when reviewing the laboratory data for a patient suspected of having PUD?
   1. *Micrococcus*
   2. *Staphylococcus*
   3. *Corynebacterium*
   4. *Helicobacter pylori*
8. The nurse is assessing a patient receiving enteral feedings via a small-bore nasogastric tube. Which assessment findings need further intervention?
   1. Gastric pH of 4.0 during placement check
   2. Weight gain of 1 pound over the course of a week
   3. Active bowel sounds in the four abdominal quadrants
   4. Gastric residual aspirate of 350 mL for the second consecutive time
9. The home care nurse is seeing the following patients. Which patient is at greatest risk for experiencing inadequate nutrition?
   1. A 55-year-old obese man recently diagnosed with diabetes mellitus
   2. A recently widowed 76-year-old woman recovering from a mild stroke
   3. A 22-year-old mother with a 3-year-old toddler who had tonsillectomy surgery
   4. A 46-year-old man recovering at home following coronary artery bypass surgery
10. The nurse is checking feeding tube placement. Place the steps in the proper sequence.
    1. Draw 5 to 10 mL gastric aspirate into syringe.
    2. Flush tube with 30 mL air.
    3. Mix aspirate in syringe and place in medicine cup.
    4. Observe color of gastric aspirate.
    5. Perform hand hygiene and put on clean gloves.
    6. Dip pH strip into gastric aspirate.
    7. Compare strip with color chart from manufacturer.
11. Which statement made by a patient of a 2-month-old infant requires further education?
    1. I'll continue to use formula for the baby until he is a least a year old.
    2. I'll make sure that I purchase iron-fortified formula.
    3. I'll start feeding the baby cereal at 4 months.
    4. I'm going to alternate formula with whole milk starting next month.
12. The nurse is teaching a program on healthy nutrition at the senior community center. Which points should be included in the program for older adults? (Select all that apply.)
    1. Avoid grapefruit and grapefruit juice, which impair drug absorption.
    2. Increase the amount of carbohydrates for energy.
    3. Take a multivitamin that includes vitamin D for bone health.
    4. Cheese and eggs are good sources of protein.
    5. Limit fluids to decrease the risk of edema.
13. The nurse sees the nursing assistive personnel (NAP) perform the following for a patient receiving continuous enteral feedings. What intervention does the nurse need to address immediately with the NAP? The NAP:
    1. Fastens the tube to the gown with tape.
    2. Places the patient supine while giving a bath.
    3. Performs oral care for the patient.
    4. Elevates the head of the bed 45 degrees.
14. The patient receiving total parenteral nutrition (TPN) asks the nurse why his blood glucose is being checked since he does not have diabetes. What is the best response by the nurse?
    1. TPN can cause hyperglycemia, and it is important to keep your blood glucose level in an acceptable range.
    2. The high concentration of dextrose in the TPN can give you diabetes; thus you need to be monitored closely.
    3. Monitoring your blood glucose level helps to determine the dose of insulin that you need to absorb the TPN.
    4. Checking your blood glucose level regularly helps to determine if the TPN is effective as a nutrition intervention.
15. The nurse is performing blood glucose monitoring for a patient receiving parenteral nutrition. Place the steps of the procedure in the correct sequence.
    1. Clean puncture site with antiseptic solution.
    2. Identify patient using two identifiers.
    3. Check code on test strip vial.
    4. Wick blood drop into test strip.
    5. Gently squeeze fingertip until drop of blood appears.
    6. Assess area of skin to be used as puncture site.
    7. Read results and document in medical record.

Answers: **1.** 3; **2.** 2; **3.** 1, 3, 5; **4.** 2; **5.** 1; **6.** 2, 3, 1, 4; **7.** 4; **8.** 4; **9.** 2; **10.** 5, 2, 1, 4, 3, 6, 7; **11.** 4; **12.** 1, 3, 4; **13.** 2; **14.** 1; **15.** 6, 2, 3, 1, 5, 4, 7.

CHAPTER

45

Urinary Elimination

OBJECTIVES

- Describe the process of urination.
- Identify factors that commonly influence urinary elimination.
- Compare and contrast common alterations in urinary elimination.
- Obtain a nursing history for a patient with urinary elimination problems.
- Identify nursing diagnoses appropriate for patients with alterations in urinary elimination.
- Obtain urine specimens correctly.
- Describe characteristics of normal and abnormal urine.
- Describe the nursing implications of common diagnostic tests of the urinary system.
- Discuss nursing measures to promote normal micturition and reduce episodes of incontinence.
- Insert a urinary catheter correctly.
- Discuss nursing measures to reduce urinary tract infection.
- Irrigate a urinary catheter correctly.
- Identify two modalities of renal replacement therapy.

Normal elimination of urinary wastes is a basic function that most people take for granted. When the urinary system fails to function properly, eventually all organ systems are affected. Patients with alterations in urinary elimination often suffer emotionally from body image changes. It is important to know the reasons for urinary elimination problems, find acceptable solutions, and provide understanding and sensitivity to all patients' needs.

SCIENTIFIC KNOWLEDGE BASE

Urinary elimination depends on the function of the kidneys, ureters, bladder, and urethra. Kidneys remove wastes from the blood to form urine. Ureters transport urine from the kidneys to the bladder. The bladder holds urine until the urge to urinate develops. Urine leaves the body through the urethra. All organs of the urinary system must be intact and functional for successful removal of urinary wastes. Intact efferent and afferent nerves from the bladder to the spinal cord and brain must be present (Fig. 45-1).

Kidneys

The kidneys lie on either side of the vertebral column behind the peritoneum and against the deep muscles of the back. Normally the left kidney is higher than the right because of the anatomical position of the liver.

Kidneys filter waste products of metabolism that collect in the blood. The blood reaches each kidney by a renal (kidney) artery that branches from the abdominal aorta. Approximately 20% to 25% of the cardiac output circulates each minute through the

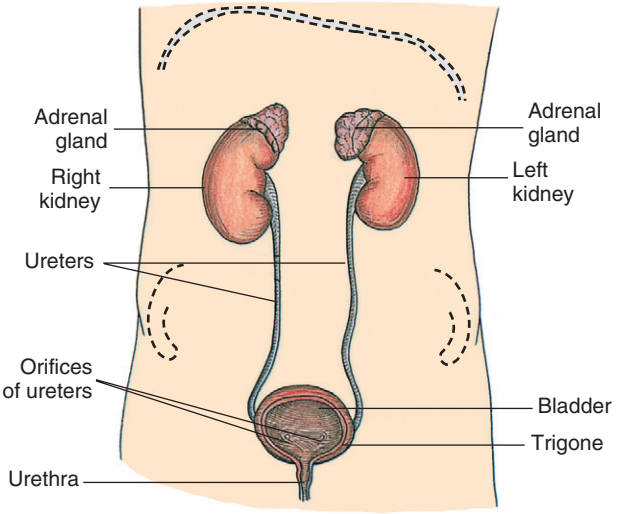

FIG. 45-1 Organs of urinary system.

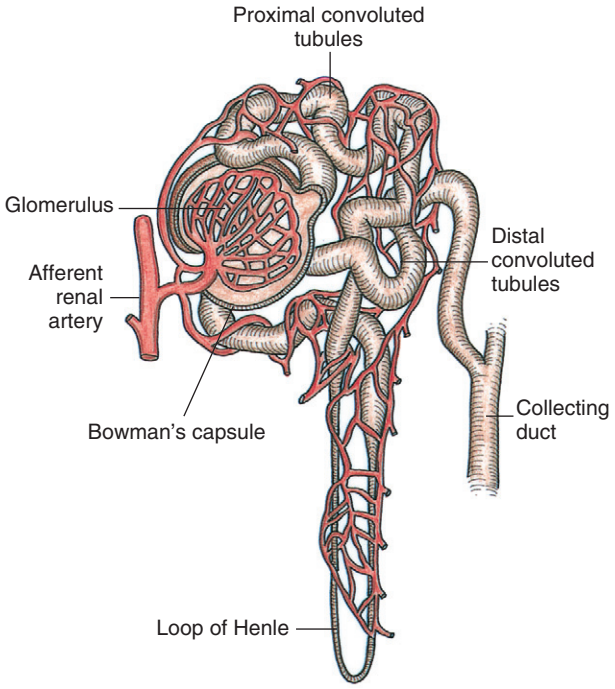

FIG. 45-2 Renal nephron.

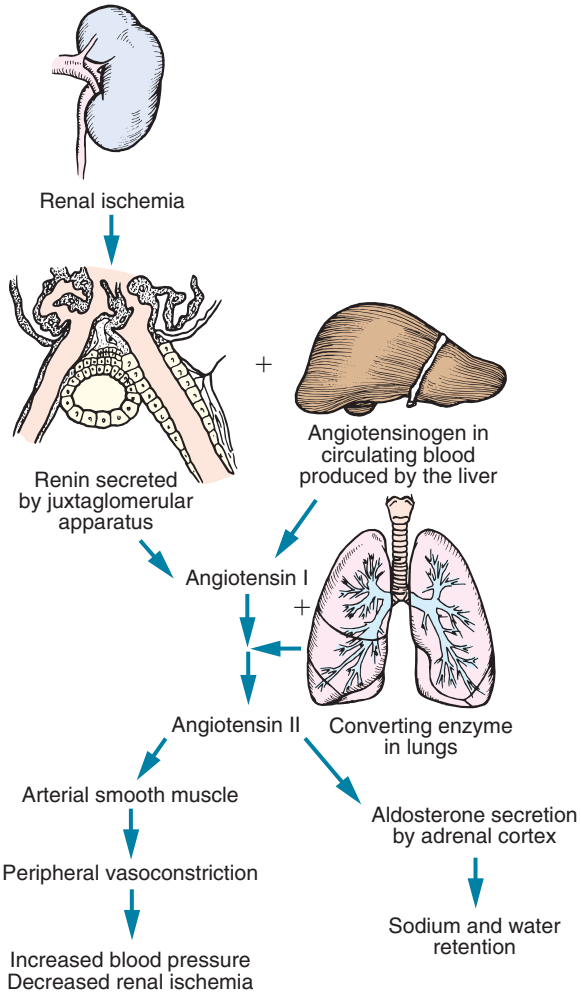

FIG. 45-3 Physiological effects of renin-angiotensin mechanism.

kidneys. The **nephron,** the functional unit of the kidney, forms the urine. It is composed of the glomerulus, Bowman's capsule, proximal convoluted tubule, loop of Henle, distal tubule, and collecting duct (Fig. 45-2).

A cluster of blood vessels forms the capillary network of the glomerulus, which is the initial site of filtration of the blood and the beginning of urine formation. The glomerular capillaries permit filtration of water, glucose, amino acids, urea, creatinine, and major electrolytes into Bowman's capsule. Large proteins and blood cells do not normally filter through the glomerulus. The presence of large proteins in the urine **(proteinuria)** is a sign of glomerular injury. The glomerulus filters approximately 125 mL of filtrate per minute.

Not all of the glomerular filtrate is excreted as urine. Approximately 99% is resorbed into the plasma, with the remaining 1% excreted as urine (Huether et al., 2008). The kidneys play a key role in fluid and electrolyte balance (see Chapter 41). Although output does depend on intake, the normal adult urine output averages 1200 to 1500 mL/day. An output of less than 30 mL/hr indicates possible circulatory, blood volume, or renal alterations.

The kidneys produce several substances vital to red blood cell (RBC) production, blood pressure, and bone mineralization. They are responsible for maintaining a normal RBC volume by producing **erythropoietin.** Erythropoietin functions within the bone marrow to stimulate RBC production and maturation and prolongs the life of mature RBCs (Huether et al., 2008). Patients with chronic kidney conditions cannot produce sufficient quantities of this hormone; therefore they are prone to anemia.

Renal hormones affect blood pressure regulation in several ways. In times of renal ischemia (decreased blood supply), **renin** is released from juxtaglomerular cells (Fig. 45-3). Renin functions as an enzyme to convert angiotensinogen (a substance synthesized by the liver) into angiotensin I. Angiotensin I is converted to angiotensin II in the lungs. Angiotensin II causes vasoconstriction and stimulates aldosterone release from the adrenal cortex. Aldosterone causes retention of water, which increases blood volume. The kidneys also produce prostaglandin E_2 and prostacyclin, which help maintain renal blood flow through vasodilation. These mechanisms increase arterial blood pressure and renal blood flow (Huether et al., 2008).

The kidneys affect calcium and phosphate regulation by producing a substance that converts vitamin D into its active form. Patients with chronic alterations in kidney function do not make sufficient amounts of the active vitamin D. They are prone to develop renal bone disease resulting from the demineralization of bone caused by impaired calcium absorption.

Ureters

The ureters are tubular structures that enter the urinary bladder. Urine draining from the ureters to the bladder is usually sterile.

Peristaltic waves cause the urine to enter the bladder in spurts. The ureters enter obliquely through the posterior bladder wall. This arrangement prevents the reflux of urine from the bladder into the ureters during the act of **micturition** by the compression of the ureter at the ureterovesical junction (the juncture of the ureters with the bladder). An obstruction within a ureter such as a kidney stone **(renal calculus)** results in strong peristaltic waves that attempt to move the obstruction into the bladder. These waves result in pain often referred to as *renal colic*.

Bladder

The urinary bladder is a hollow, distensible, muscular organ (detrusor muscle) that stores and excretes urine. When empty, the bladder lies in the pelvic cavity behind the symphysis pubis. In men the bladder lies against the anterior wall of the rectum, and in women it rests against the anterior walls of the uterus and vagina.

The bladder expands as it becomes filled with urine. Pressure within it is usually low even when partly full, a factor that protects against infection. When the bladder is full, it expands and extends above the symphysis pubis. A greatly distended bladder may reach the level of the umbilicus. In a pregnant woman the developing fetus pushes against the bladder, reducing the capacity of the bladder and causing a feeling of fullness. This effect is more likely to occur in the first and third trimesters.

The trigone (a smooth triangular area on the inner surface of the bladder) is at the base of the bladder. An opening exists at each of the three angles of the trigone. Two are for the ureters, and one is for the urethra.

Urethra

Urine exits the bladder through the urethra and passes out of the body through the urethral meatus. Normally the turbulent flow of urine through the urethra washes it free of bacteria. Mucous membrane lines the urethra, and urethral glands secrete mucus into the urethral canal. Thick layers of smooth muscle surround the urethra. In addition, it descends through a layer of skeletal muscles called the *pelvic floor muscles*. When these muscles are contracted, it is possible to prevent urine flow through the urethra (Huether et al., 2008).

In women the urethra is approximately 4 to 6.5 cm (1½ to 2½ inches) long. The external urethral sphincter, which is composed of skeletal muscle located about halfway down the urethra, permits voluntary flow of urine. However, the internal sphincter muscle is composed of smooth muscle and therefore is not under voluntary control. The short length of the urethra predisposes women and girls to infection. It is easy for bacteria to enter the urethra from the perineal area.

In men the urethra, which is both a urinary canal and a passageway for cells and secretions from reproductive organs, is about 20 cm (8 inches) long. The male urethra has three sections: prostatic, membranous, and penile.

Act of Urination

Several brain structures influence bladder function, including the cerebral cortex, thalamus, hypothalamus, and brainstem. Together they inhibit the urge to void or allow voiding. Normal voiding involves contraction of the bladder and coordinated relaxation of the urethral sphincter and pelvic floor muscles.

Bladder capacity varies with the individual but generally ranges from 600 to 1000 mL of urine (Lewis et al., 2011), and an adult normally voids every 2 to 4 hours. However, individuals are able to sense the desire to urinate when the bladder contains a smaller amount of urine (150 to 200 mL in an adult and 50 to 100 mL in a child). It is important to teach parents that children do not have enough neurological development to be toilet trained until after 24 months and some are not developed enough until 36 months. As the volume increases, the bladder walls stretch, sending sensory impulses to the micturition center in the sacral spinal cord. Impulses from the micturition center respond to or ignore this urge, thus making urination under voluntary control. If the person chooses not to void, the external urinary sphincter remains contracted, inhibiting the micturition reflex. However, when a person is ready to void, the external sphincter relaxes, the micturition reflex stimulates the detrusor muscle to contract, and efficient emptying of the bladder occurs. It is vital that nurses understand this process to be able to assess and determine which form of incontinence or bladder problem may be occurring.

Damage to the spinal cord above the sacral region causes **reflex incontinence.** This condition causes loss of voluntary control of urination; but the micturition reflex pathway often remains intact, allowing urination to occur without sensation of the need to void. If a chronic obstruction caused by neurological damage such as prostate enlargement hinders bladder emptying, over time the micturition reflex changes, causing bladder overactivity and possibly causing the bladder to not empty completely. **Overflow incontinence** occurs when a bladder is overly full and bladder pressure exceeds sphincter pressure, resulting in involuntary leakage of urine. Causes often include head injury; spinal injury; multiple sclerosis; diabetes; trauma to the urinary system; and postanesthesia sedatives/hypnotics, tricyclics, and analgesia (Lewis et al., 2011). Hyperreflexia, a life-threatening problem affecting heart rate and blood pressure, is caused by an overly full bladder. It is usually neurogenic in nature; however, it can be caused functionally by blockage.

Factors Influencing Urination. Many factors influence the volume and quality of urine and the patient's ability to urinate. Some pathophysiological conditions are acute and reversible (urinary tract infection [UTI]), whereas others are chronic and irreversible (slow, progressive development of renal dysfunction). Sociocultural factors, psychological factors, fluid balance, and surgical and diagnostic procedures affect urine and urination in several ways. In addition, medications, including anesthesia, interfere with both the production and characteristics of urine, affect the act of urination, and affect the ability to completely empty or control voiding.

Disease Conditions. Disease processes that affect urine elimination affect renal function (changes in urine volume or quality), the act of urine elimination, or both. Conditions that affect urine volume and quality are generally categorized as prerenal, renal, or postrenal in origin.

Decreased blood flow to and through the kidney (prerenal), disease conditions of the renal tissue (renal) and obstruction in the lower urinary tract that prevents urine flow from the kidneys (postrenal) sometimes alter renal function. Conditions of the lower

urinary tract, including narrowing of the urethra, altered innervation of the bladder, or weakened pelvic and/or perineal muscles, affect urinary elimination.

Diabetes mellitus and neuromuscular diseases such as multiple sclerosis cause changes in nerve functions that can lead to possible loss of bladder tone, reduced sensation of bladder fullness, or inability to inhibit bladder contractions. Older men often suffer from benign prostatic hyperplasia (BPH), which makes them prone to urinary retention and incontinence. Some patients with cognitive impairments, such as Alzheimer's disease, lose the ability to sense a full bladder or are unable to recall the procedure for voiding. Diseases that slow or hinder physical activity interfere with the ability to void. Degenerative joint disease and Parkinsonism are examples of conditions that make it difficult to reach and use toilet facilities.

Diseases that cause irreversible damage to kidney tissue result in end-stage renal disease (ESRD). Eventually the patient has symptoms resulting from **uremic syndrome.** An increase in nitrogenous wastes in the blood, marked fluid and electrolyte abnormalities, nausea, vomiting, headache, coma, and convulsions characterize this syndrome. As the uremic symptoms worsen, aggressive treatment is indicated for survival (Box 45-1). These treatments are **renal replacement therapies.**

Dialysis and organ transplantation are two methods of renal replacement. Dialysis takes one of two forms, peritoneal dialysis or hemodialysis. Patients can use both dialysis modalities for a short or long term, but they require specialized equipment and nurses with specialized education.

Peritoneal dialysis is an indirect method of cleaning the blood of waste products using osmosis and diffusion, with the peritoneum functioning as a semipermeable membrane. This method removes excess fluid and waste products from the bloodstream when a sterile electrolyte solution (dialysate) is instilled into the peritoneal cavity by gravity via a surgically placed catheter. The dialysate remains in the cavity for a prescribed time interval and then is drained out by gravity, taking accumulated wastes and excess fluid and electrolytes with it.

Hemodialysis requires a machine equipped with a semipermeable filtering membrane (artificial kidney) that removes accumulated waste products and excess fluids from the blood. In the dialysis machine dialysate fluid is pumped through one side of the filter membrane (artificial kidney) while a patient's blood passes through the other side. The processes of diffusion, osmosis, and ultrafiltration clean the patient's blood. Then the blood returns through a specially placed vascular access device (Gore-Tex graft, arteriovenous fistula, or hemodialysis catheter).

Organ transplantation is the replacement of a patient's diseased kidney with a healthy one from a living or cadaver donor of compatible blood and tissue type. The new organ is surgically implanted into the abdomen. Special medications (immunosuppressives) are administered, often for life, to prevent the body from rejecting the transplanted organ. Unlike the other treatments, successful organ transplantation offers patients the potential for restoration of normal kidney function.

Sociocultural Factors. The degree of privacy needed for urination varies with cultural norms. North Americans expect toilet facilities to be private, whereas some European cultures accept communal toilet facilities. Social expectations (e.g., school recesses) influence the time of urination.

Psychological Factors. Anxiety and emotional stress cause a sense of urgency and increased frequency of urination. Anxiety often prevents a person from being able to urinate completely; as a result, the urge to void returns shortly after voiding. Emotional tension makes it difficult to relax abdominal and perineal muscles. Attempting to void in a public restroom sometimes results in a temporary inability to void. Privacy and adequate time to urinate are usually important to most people.

Fluid Balance. The kidneys primarily maintain the balance between retention and excretion of fluids (see Chapter 41). If fluids and the concentration of electrolytes and solutes are in equilibrium, an increase in fluid intake causes an increase in urine production. This amount varies with food and fluid intake. The volume of urine formed at night is about half of the volume formed during the day because both intake and metabolism decline. **Nocturia** (awakening to void one or more times at night) is often a sign of renal alteration. In a healthy person the intake of water in food and fluids balances the output of water in urine, feces, and insensible losses in perspiration and respiration. An excessive output of urine is **polyuria.** A urine output that is decreased despite normal intake is called **oliguria.** Oliguria often occurs when fluid loss through other means (e.g., perspiration, diarrhea, or vomiting) increases. It also occurs in early kidney disease. Often in severe kidney disease no urine is produced **(anuria).**

Ingestion of certain fluids directly affects urine production and excretion. Coffee, tea, cocoa, and cola drinks that contain caffeine promote increased urine formation **(diuresis).** Alcohol inhibits the release of antidiuretic hormone (ADH), also resulting in increased water loss in urine.

Febrile conditions affect urine production. A patient with excessive perspiration loses a large amount of fluids through insensible water loss, which decreases urine production. Fever causes an increase in body metabolism and accumulation of body wastes. Although urine volume is reduced, it is highly concentrated.

Surgical Procedures. The stress of surgery initially triggers the general adaptation syndrome (see Chapter 37). Preoperative orders of nothing-by-mouth or an underlying disease condition affect fluid balance before surgery, which reduces urine output. In addition, the stress response releases an increased amount of ADH, which increases water resorption. Stress also elevates the level of aldosterone, causing retention of sodium and water. Both of these substances reduce urine output in an effort to maintain circulatory fluid volume.

Anesthetics and narcotic analgesics slow the glomerular filtration rate, reducing urine output. These pharmacological agents also impair sensory and motor impulses traveling among the bladder, spinal cord, and brain. Patients are often unable to sense bladder fullness and initiate or inhibit micturition. Spinal anesthetics, in particular, create the risk of urinary retention because of an inability to sense the need to void and a possible inability of the bladder muscles and urethral sphincters to respond (Lewis et al., 2011).

BOX 45-1 INDICATIONS FOR DIALYSIS

- Renal failure that can no longer be controlled by conservative management (i.e., dietary modifications and administration of medications to correct electrolyte abnormalities)
- Worsening of uremic syndrome associated with ESRD (i.e., nausea, vomiting, neurological changes, pericarditis)
- Severe electrolyte and/or fluid abnormalities that cannot be controlled by simpler measures (e.g., hyperkalemia, pulmonary edema)

ESRD, End-stage renal disease.

Surgery of lower abdominal and pelvic structures sometimes impairs urination because of local trauma to surrounding tissues. After returning from surgery involving the ureters, bladder, and urethra, patients routinely have urinary catheters.

Medications. Many medications directly or indirectly contribute to urinary dysfunction. Antipsychotics, antidepressants, alpha-adrenergic agonists, and calcium channel blockers can cause urinary retention and overflow incontinence. Alpha-antagonists, diuretics, sedative hypnotics, opioid analgesics, angiotensin-converting enzyme (ACE) inhibitors, and antihistamines can cause urinary incontinence. Antiparkinson medications may cause urinary urgency and subsequent incontinence. Always consider these medications as the cause of new-onset urinary incontinence, especially in older adults.

Some medications change the color of urine. For example, phenazopyridine (Pyridium) colors the urine a bright orange to rust; amitriptyline causes a green or blue discoloration, whereas levodopa discolors the urine to brown or black. Cancer chemotherapy drugs also color the urine and are often toxic to the bladder and/or kidneys. Patients with impaired kidney function require dosage adjustments in medications excreted by the kidneys.

Diagnostic Examination. Examination of the urinary system influences micturition. Some procedures such as an intravenous pyelogram (IVP) require patients to limit fluids before the test. A restriction in fluid intake commonly lowers urine output. Diagnostic examinations (e.g., cystoscopy) involving direct visualization of urinary structures cause localized edema of the urethral passageway and spasm of the bladder sphincter. After the procedure, a patient may have difficulty voiding or have red or pink urine because of trauma to the urethral or bladder mucosa.

Alterations in Urinary Elimination. Most patients with urinary problems are unable to store urine or fully empty the bladder. These disturbances result from impaired bladder function, obstruction to urine outflow, or inability to voluntarily control micturition.

Some patients may have permanent or temporary changes in the normal pathway of urinary excretion. The surgical formation of a **urinary diversion** temporarily or permanently bypasses the bladder and urethra as the exit routes for urine. Permanent urinary diversions are often necessary in the patient with cancer of the bladder. The patient with a urinary diversion has a **stoma** (artificial opening) on the abdomen to drain urine. He or she has many special needs because urine drains to the outside through a stoma.

Urinary Retention. **Urinary retention** is an accumulation of urine resulting from an inability of the bladder to empty properly. Normally urine production slowly fills the bladder and prevents activation of stretch receptors until it distends to a certain level of stretch. The micturition reflex occurs, and the bladder empties. In urinary retention the bladder is unable to respond to the micturition reflex and thus is unable to empty. Urine continues to collect in the bladder, stretching its walls and causing feelings of pressure, discomfort, tenderness over the symphysis pubis, restlessness, and diaphoresis (sweating).

As retention progresses, retention with overflow develops. Pressure in the bladder builds to a point at which the external urethral sphincter is unable to hold back urine. The sphincter temporarily opens to allow a small volume of urine (25 to 60 mL) to escape. As urine exits, the bladder pressure falls enough to allow the sphincter to regain control and close. With retention a patient may void small amounts of urine 2 or 3 times an hour with no real relief of discomfort or may continually dribble urine. Be aware of the volume and frequency of voiding to assess for urinary retention. Assess the abdomen for evidence of bladder distention and tenderness.

In acute retention key signs are bladder distention and absence of urine output over several hours. A patient under the influence of anesthetics or analgesics often feels only pressure, but the alert patient has severe pain as the bladder distends beyond its normal capacity. In severe urinary retention the bladder holds as much as 2000 to 3000 mL of urine. Retention occurs as a result of urethral obstruction, surgical or childbirth trauma, and alterations in motor and sensory innervation of the bladder such as occurs with neuropathy secondary to diabetes. It may occur after removal of an indwelling catheter. Medication side effects or anxiety may also result in urinary retention. If a patient cannot void or completely empty the bladder, he or she must be catheterized because a UTI, kidney stones, and hyperreflexia can occur.

Retained or **residual urine,** also referred to as *postvoid residual (PVR),* occurs if a patient has urinary retention or cannot empty the bladder completely. You can use a portable noninvasive bladder ultrasound device (bladder scanner) or the technique of straight/intermittent catheterization to assess for PVR. Bladder scanners are often not readily available for nurses to use in all clinical settings, and straight/intermittent catheterization may be the only means to determine bladder urine volume. Regardless of the method used to determine PVR, assess the amount of urine left in the bladder within 10 to 15 minutes after a patient voids (Altschuler and Diaz, 2006). Instruct the patient not to void again before measurement. At least two residuals should be obtained since a patient may empty well one time and not the next. Spastic bladders and some medications and problems such as using a bedpan or not sitting upright to void cause inconsistent emptying. In normal micturition or in a normal void the bladder should empty completely.

Urinary Tract Infections. UTI is the most common health care–acquired infection; 80% of these infections result from the use of an indwelling urethral catheter (Lo et al., 2009). Catheterization results in over 1 million UTIs each year in the United States (Matteucci and Walsh, 2011). Infection frequently occurs after placement of urinary catheters, and each day a catheter is in place there is a 5% increase in bacteria in the urine (Saint et al., 2009). Catheter-associated UTIs (CAUTIs) are associated with increased hospitalizations, increased morbidity and mortality, longer hospital stay, and increased hospital costs (Newman, 2007). Each episode of CAUTI and ensuing complications are estimated to cost between $600 and $2800 (Saint et al., 2009). Because a CAUTI is common, costly, and believed to be reasonably preventable, as of October 1, 2008, the Centers for Medicare and Medicaid Services (CMS) chose it as one of the complications for which hospitals no longer receive additional payment to compensate for the extra cost of treatment (Saint et al., 2009). Consequently there has been a shift in reimbursement practices from its traditional focus on early recognition and prompt treatment to one of prevention (Wilson et al., 2009).

Although several different microorganisms cause CAUTIs, the patient's own colonic flora, including *Escherichia coli,* remains the most common causative pathogen (Ksycki and Namias, 2009). **Bacteriuria** (bacteria in the urine) leads to the spread of organisms into the kidneys and possibly to **bacteremia** or **urosepsis** (bacteria in the bloodstream) (Lewis et al., 2011). Microorganisms commonly enter the urinary tract through the ascending urethral route. Bacteria inhabit the distal urethra and external genitalia in men and women and the vagina in women. Organisms enter the urethral meatus easily and travel up the inner mucosal lining to the bladder. Women are more susceptible to infection because of a short urethra and the proximity of the anus to the urethral meatus.

In men prostatic secretions containing an antibacterial substance and the length of the urethra reduce the susceptibility to UTIs. However, men are at increased risk for infection-related renal disease. Older adults and patients with progressive underlying disease or decreased immunity are also at increased risk.

In a healthy person with good bladder function, organisms are flushed out during voiding. Residual (retained) urine in the bladder becomes more alkaline and is an ideal site for microorganism growth. Any condition resulting in urinary retention such as a kinked, obstructed, or clamped catheter increases the risk of a UTI.

Poor perineal hygiene is another cause of UTIs in women. Inadequate handwashing, failure to wipe from front to back after voiding or defecating, and frequent sexual intercourse predispose women to infection.

Patients with lower UTIs have pain or burning during urination **(dysuria)** as urine flows over inflamed tissues. Fever, chills, nausea, vomiting, and malaise develop as an infection worsens. An irritated bladder **(cystitis)** causes a frequent and urgent sensation of the need to void. Irritation to bladder and urethral mucosa results in blood-tinged urine **(hematuria).** The urine appears concentrated and cloudy because of the presence of white blood cells (WBCs) or bacteria. If infection spreads to the upper urinary tract (kidneys—**pyelonephritis**), flank pain, tenderness, fever, and chills are common.

Another common cause of infection is the introduction of instruments into the urinary tract. For example, the introduction of a catheter through the urethra provides a direct route for microorganisms (Nazarko, 2008). With an indwelling catheter bacteria ascend along the outside of the catheter on the urethral wall or travel up its lumen. Local irritation to the urethra or bladder predisposes tissues to bacterial invasion.

Urinary Incontinence. **Urinary incontinence** is the involuntary leakage of urine that is sufficient to be a problem. It can be either temporary or permanent, continuous or intermittent. Urinary incontinence related to urinary causes is called either *stress* or *urge urinary incontinence* (Palmer and Newman, 2007). Urge incontinence is more common in younger women and may be caused by local irritating factors such as UTIs (Ebersole et al., 2008). Individuals sense the urge to urinate but cannot keep from urinating long enough to reach a toilet. *Stress incontinence* occurs more often in older women when intraabdominal pressure exceeds urethral resistance. Muscles around the urethra become weak; thus even a small amount of urine may leak spontaneously (Ebersole et al., 2008). Some patients may have a mixed form of incontinence that has features of both stress and urge urinary incontinence. Table 45-5 on p. 1060 describes the types of urinary incontinence, their symptoms, and treatment interventions. **Hyperactive or overactive bladder (OAB)** is associated with individuals of all ages, but older adults are more likely to have incontinence associated with it following physical and cognitive decline associated with aging and effects of medications (Stewart, 2010). OAB results from sudden, involuntary contraction of the muscles of the urinary bladder, resulting in an urge to urinate **(urge incontinence).** Common abnormalities of the nervous system that cause OAB include cerebrovascular accident (CVA) and other head injuries, spinal cord injury, and diabetic neuropathy. Other causes include UTI and anxiety.

Approximately 15% to 30% of adult women experience urinary incontinence. It is present in as many as 30% to 70% of nursing home residents and in 30% of adults living at home (Touhy and Jett, 2010). Incontinence can impair body image and often leads to a loss of independence. Clothing becomes wet with urine, and the accompanying odor adds to the embarrassment. As a result, patients with this problem often avoid social activities. They often fail to discuss this condition with health care providers or nurses, and as a result urinary incontinence is underreported and undertreated. Resources for information about continence care, patient education, and treatment are available at the following websites: the Society for Urological Nurses and Associates (http://www.suna.org), the National Association for Continence (http://www.nafc.org), and the Simon Foundation (http://www.simonfoundation.org).

Physical limitations and environmental barriers are risks for incontinence. People with restricted mobility have greater chances of being incontinent because of their inability to reach toilet facilities in time. Low-set chairs and beds raised well above the floor are obstacles for people who must get up to reach a toilet. Some patients often lack the energy to walk very far at one time. The toilet is sometimes too far away for patients with urge incontinence. Patients who have difficulty undoing buttons or manipulating zippers face another obstacle.

Continued episodes of incontinence is a risk for impaired skin integrity. The character of urine changes when it remains in contact with skin, causing skin breakdown. The immobilized patient with frequent incontinence is especially at risk for pressure ulcers (see Chapter 48). Additional health care and patient education resources are available at the websites for the American Geriatrics Society (http://www.americangeriatrics.org) or the American Urogynecologic Society (http://www.augs.org).

Urinary Diversions. Conditions such as bladder cancer, radiation injury to the bladder, or chronic urinary infections may necessitate a urinary diversion to drain urine from a diseased or dysfunctional bladder. There are two types of continent urinary diversions (Fig. 45-4, *A*). One is a continent urinary reservoir that is created from a distal portion of the ileum and proximal portion of the colon. The ureters are embedded in the reservoir. This reservoir is situated under the abdominal wall and has a narrow ileal segment brought out through the abdominal wall to form a small stoma. The ileocecal valve creates a one-way valve in the pouch through which a catheter is inserted to empty the urine from the pouch. Patients must be willing and able to catheterize the pouch 4 to 6 times a day for the rest of their lives.

The second continent urinary diversion is an orthotopic neobladder that also uses an ileal pouch to replace the bladder. Anatomically the pouch is in the same position where the bladder was before removal, allowing patients to void normally.

Incontinent urinary diversions are less commonly performed. The surgery involves connecting the ureters to a section of the intestinal ileum with formation of a stoma on the abdominal wall (Fig. 45-4, *B*). Urine drains continuously because a patient has no sensation or control over urinary output, requiring the application of a collection pouch at all times.

Some patients need urinary drainage directly from one or both kidneys. In this case a tube is placed directly into the renal pelvis. This procedure is called a **nephrostomy.**

Any urinary diversion poses threats to a patient's body image. The patient must learn how to manage the diversion, and those who do not have a continent urinary diversion must wear an artificial device at all times. However, most patients are able to wear normal clothing, engage in physical activity, travel, and have sexual relations. Care must be taken not to pull on tubing, especially in a nephrostomy, since it can be pulled out, causing tissue and organ damage and infection. Most nephrostomies are sutured into the kidney.

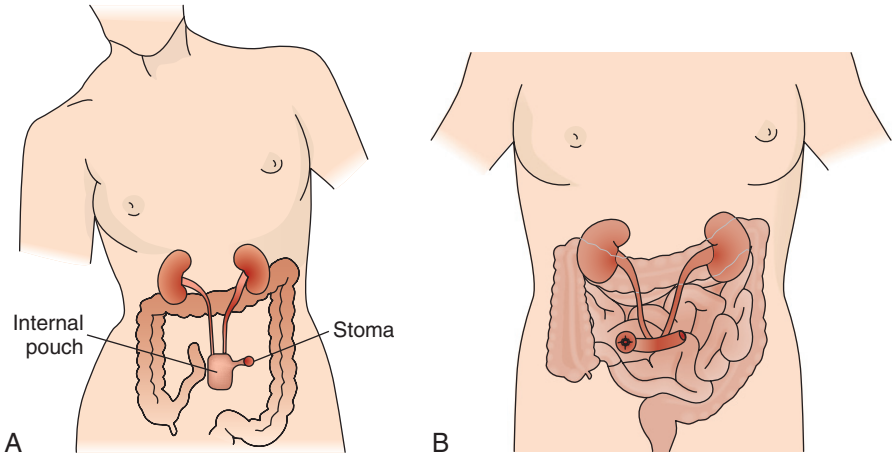

FIG. 45-4 Types of urinary diversions. **A,** Continent urinary reservoir. **B,** Urostomy (ileal conduit).

Refer patients with a urinary diversion to an ostomy nurse (a nurse with specialized education in this area). This specialist is a valuable resource for assisting a patient and family with matters pertaining to all aspects of care. The ostomy nurse often meets with the patient and family before surgery. In addition, refer the patient to the United Ostomy Associations of America (http://www.uoaa.org). This organization provides information about support groups to enhance coping and adaptation to lifestyle and body-image changes.

NURSING KNOWLEDGE BASE

Urinary elimination is a basic function and is usually a private process. Many patients need physiological and psychological assistance from the nurse. Whether a patient has an actual or potential urinary problem, be sensitive to his or her elimination needs. You need knowledge of concepts beyond the anatomy and physiology of the urinary system to give appropriate care. In addition, you need to understand and apply knowledge about infection control principles.

Infection Control and Hygiene

The urinary tract is sterile. Use infection control principles to help prevent the development and spread of UTIs and treat existing infections. *E. coli,* a common bacteria found in feces, causes many CAUTIs. Infection can occur in any location of the urinary tract. Apply knowledge of medical and surgical asepsis when providing care involving the urinary tract or external genitalia (see Chapter 28). Any invasive procedure of the urinary tract such as catheterization requires sterile technique. Procedures such as perineal care or examination of the genitalia require medical asepsis, including proper hand hygiene. Use medical asepsis by wiping off tubing with antiseptic wipes when changing from a large-volume urinary bag to a small-volume leg bag.

Factors Influencing Urination

Factors in a patient's history that normally affect urination are age, environmental factors, medication history, psychological factors, muscle tone, fluid balance, current surgical or diagnostic procedures, and presence of disease conditions. Be alert to individual needs related to normal changes of aging that predispose older adults to certain elimination problems (Box 45-2). Also assess the bowel elimination pattern because constipation often interferes with normal urine elimination (see Chapter 46). Problems with urination also stem from dehydration. Evaluate environmental barriers in the home or health care setting. Aids such as elevated toilet seats, grab bars, or a portable commode are often necessary to ensure patient safety.

BOX 45-2 FOCUS ON OLDER ADULTS

Promoting Urinary Health

- Facilitate more frequent opportunities to void. Older adults have a smaller bladder capacity than younger adults (Ebersole et al., 2008).
- Encourage older adults to empty bladder completely before and after meals and at bedtime (Touhy and Jett, 2010).
- Encourage patient to increase fluid intake to at least six to eight glasses a day unless medically contraindicated. Dilute urine discourages bacterial growth. Discourage drinking of coffee, tea, brown cola, and alcohol since these have a diuretic effect and increase urinary frequency (Touhy and Jett, 2010).
- Make fluids such as cranberry juice available as part of patient's fluid intake. Cranberry juice and vitamin C help acidify the urine to decrease bacterial infections of the bladder (Ebersole et al., 2008).
- Restricting fluid intake does not decrease urinary incontinence severity or frequency (Touhy and Jett, 2010).
- Avoid routine use of indwelling catheters. If one is necessary, use it no longer than necessary. The risk of infection increases dramatically for catheterized patients (Fernandez and Griffiths, 2006).
- Note that incontinence is not a normal part of aging and make efforts to assess incontinence and provide interventions to promote return to continence (Touhy and Jett, 2010).

Growth and Development. Growth and development factors determine a patient's ability to control the act of urination during the life span. Infants and young children cannot effectively concentrate urine. Their urine appears light yellow or clear. In relation to their small body size, infants and children excrete large volumes of urine. For example, a 6-month-old infant who weighs 13 to 18 pounds (6 to 8 kg) excretes 400 to 500 mL of urine daily.

The neurological system is not well developed until 2 to 3 years of age in a normal toddler. Until this age he or she is not able to associate the sensations of bladder filling and urination. A child must be able to recognize the feeling of bladder fullness, to hold urine for 1 to 2 hours, and to communicate the sense of urgency.

Many toddlers are then able to control the external sphincter, and toilet training begins. Daytime control of urination is easier to accomplish than nighttime control and occurs earlier in the child's development, usually by 2 to 3 years of age. Some children do not gain full control until age 4 or 5. Occasional daytime accidents or **nocturnal enuresis** (nighttime voiding without awakening) sometimes continue until age 5 (see Chapter 12).

During pregnancy urinary frequency is common, and susceptibility to UTI increases. Temporary or permanent changes resulting from repeated deliveries or hormonal changes often result in decreased perineal muscle tone, leading to urgency and stress incontinence.

Aging often impairs micturition. In men prostate enlargement usually begins during the 40s and continues throughout life, resulting in urinary frequency and possible urinary retention. In women changes in the urethral mucosa associated with loss of estrogen during and after menopause contribute to increased susceptibility to UTIs (Palmer and Newman, 2007).

Changes in kidney and bladder function also occur with aging. The ability of the kidney to concentrate urine declines. The older adult often experiences nocturia. The bladder loses muscle tone, and capacity decreases, resulting in increased **urinary frequency.** Because the bladder cannot contract effectively, an older adult often retains urine in it after voiding. These changes increase the risk for bacterial growth and development of UTIs.

Muscle Tone. Weak abdominal and pelvic floor muscles impair the ability of the urinary sphincter to maintain tone during increased abdominal pressure. Poor control of micturition or incontinence results from muscle wasting caused by prolonged immobility, muscle damage during vaginal childbirth, being overweight, caffeine use because caffeine relaxes the smooth muscle of the sphincter, muscle atrophy secondary to menopause, or other traumatic damage to pelvic nerves and muscles.

CRITICAL THINKING

Successful critical thinking requires synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to collect necessary information, analyze the data, and anticipate and make decisions regarding patient care.

During assessment consider all elements that build toward making appropriate nursing diagnoses. In the case of urinary elimination, integrate knowledge from nursing and other disciplines, previous experiences, and information gathered from patients to understand the process of urinary elimination and the impact on a patient and family. As a result, you are able to identify the unique impact of these problems on patients and families.

In addition, use critical thinking attitudes such as perseverance to find a plan of care to provide successful management of urinary elimination problems. Professional standards provide valuable directions for management. You are in a key position to serve as a patient advocate by suggesting noninvasive alternatives to catheterization use (e.g., the use of a bladder scanner to evaluate urine volume without invasive instrumentation or implementation of a voiding schedule for the incontinent patient).

When planning and implementing care for the patient with alterations in urinary elimination, also use standards developed by professional organizations such as the American Nurses Association (ANA), the International Continence Society (ICS), and the United Ostomy Associations of America as a guide for individualized patient care.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in the care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Throughout the assessment process it is important to consider the patient's frame of reference of his or her illness experience. Also consider whether the patient understands his or her health status along with his or her self-care ability. Value the patient's expertise with his or her own health and symptoms. Consider the patient's cognitive ability to understand the signs and symptoms of the illness. Remember that you are in partnership with the patient or designated surrogates in planning, implementing, and evaluating care. Always ask what he or she expects from care. Does the patient expect that the UTI will be resolved?

Make sure that your approach to a patient's elimination needs considers personal, social, and gender habits. Be sensitive and ask questions in a straightforward manner. Gender influences positioning for urination: males stand, whereas females sit. Place patients in a position of comfort. Some men who cannot stand to urinate become overly distressed. Gender differences also affect risk factors associated with urinary alterations. If a patient prefers privacy, try to prevent interruptions as he or she voids. Treat all patients with understanding and acceptance.

Be aware of your own attitudes and values about working with patients from diverse ethnic, social, and cultural backgrounds. Know that culture influences the choice of appropriate nursing interventions. In some cultures the embarrassment related to urinary elimination problems is so great that many patients, especially women, refuse to seek treatment. In some cultures patients prefer to squat over a receptacle rather than sit on one. Culture dictates when and where it is appropriate to urinate. It also determines whether it is proper for a male to care for the urinary needs of a female or if gender-congruent care is needed (see Chapter 9).

Identifying Urinary Alterations. To identify a urinary elimination problem and gather data for a care plan, use scientific and nursing knowledge, conduct a nursing history, perform a physical assessment, assess the patient's urine, and review information from diagnostic tests and examinations. Use critical thinking to synthesize this information as assessment proceeds (Fig. 45-5). Adequate assessment results in the formulation of nursing diagnoses appropriate for alterations in urinary elimination. When assessing for problems with urinary elimination, be aware of the impact of the patient's culture and language in the assessment process (Box 45-3).

Nursing History. The nursing history includes a review of a patient's elimination patterns and symptoms of urinary alterations and an assessment of other factors that possibly affect the ability to urinate normally. Use questions to help direct the patient to focus on specific urinary problems (Box 45-4).

Pattern of Urination. Ask the patient about daily voiding patterns, including frequency and times of day, normal volume at each voiding, and any recent changes. Frequency varies among individuals and with intake and other types of fluid losses. The common times for urination are on awakening, after meals, and before

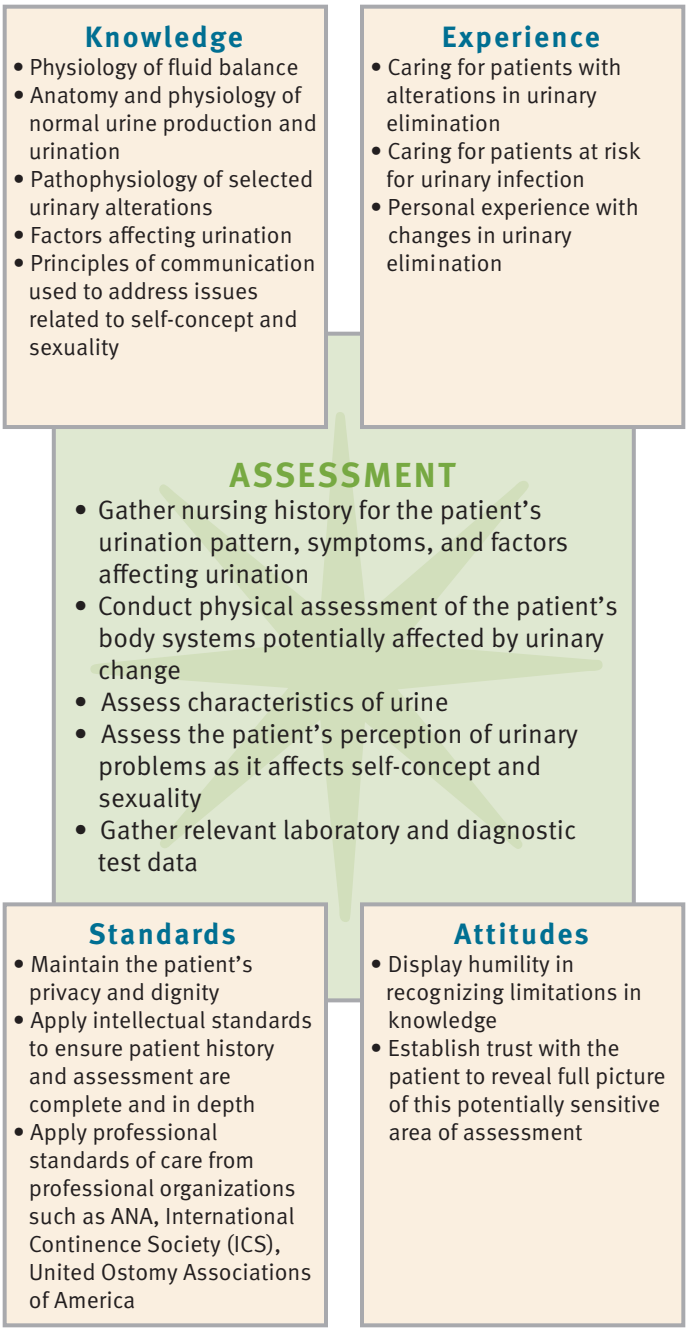

FIG. 45-5 Critical thinking model for urinary elimination assessment. *ANA,* American Nurses Association.

bedtime. Most people void an average of 5 or more times a day. Some patients who void frequently during the night may have renal disease, prostate enlargement, or cardiac disease. Information about the pattern of urination establishes a baseline for comparison.

Symptoms of Urinary Alterations. Certain symptoms specific to urinary alterations may occur in more than one type of disorder. During assessment ask the patient about any symptoms related to urination (Table 45-1). Also assess whether the patient is aware of conditions or factors that precipitate or aggravate symptoms and determine what the patient does when any of these symptoms occur.

BOX 45-3 CULTURAL ASPECTS OF CARE

Urinary Elimination

Urine elimination is a personal, private activity that individuals do not share with others. When patients have needs related to urine elimination, be aware of the intrusive nature of intervention. Because of the embarrassing nature of urinary problems such as incontinence, many women do not report symptoms (Beji et al., 2010; Gemmill and Wells, 2010). In addition, other characteristics such as a patient's culture also affect care. Although you cannot be knowledgeable about the impact of every culture on patient care, it is important to be open to and respect practices different from your own.

Implications for Practice

- When English is a second language, use simple and clear sentences in communicating with patients. Remember, speaking louder or more slowly does not always help. Learn at least a few important words in the patient's language to allow for future interchanges. In some situations an interpreter is needed (Giger and Davidhizar, 2008).
- If available, provide written materials in patient's primary language. If not, provide the English version. Some patients are able to read better than they understand the spoken word. Time to review the information also increases understanding.
- In some cultures intimate contact or discussion of urinary problems between genders is forbidden outside marriage. Urological care, whether involving questions, discussion, or contact, is usually considered intimate care. Gender-congruent caregivers are assigned to a patient from these cultures (e.g., Muslim) (Beji et al., 2010; Giger and Davidhizar, 2010).
- Cultures view disease differently. It is important to understand how the culture views the cause and treatment of the condition and how traditional Western medicine may or may not fit with that understanding. Programs to help with urinary problems need to be adapted to the cultural values of the woman seeking assistance (Bradway et al., 2010).
- Cultures allow for varied involvement of family in a patient's care. This source of strength is important to the health of the patient, and family must be included in the plan of care (Giger and Davidhizar, 2008).
- Cultural influences may affect the willingness of a patient to seek care. Be aware of topics that specific cultures may find offensive, which can make discussion of nursing interventions difficult (Giger and Davidhizar, 2008).

Note the presence of an indwelling catheter. It places a patient at risk for infection, catheter blockage, or skin-care problems. Monitor fluid balance through regular intake and output (I&O) measurements (see Chapter 41). Patients with a urinary diversion sometimes need special assistance to maintain adequate urine elimination and skin care integrity.

Physical Assessment. A physical examination (see Chapter 30) provides you with data to determine the presence and severity of urinary elimination problems. The primary structures to assess include the skin and mucosal membranes, kidneys, bladder, and urethral meatus. Fluid intake and the pattern and amounts, which are objective data, are important to assess (see Chapter 41).

Skin and Mucosal Membranes. Observe the condition of the skin and mucosal membranes. Problems with urinary elimination are frequently associated with fluid and electrolyte disturbances. By assessing skin turgor and the oral mucosa you gather data about the patient's hydration status. Urinary incontinence increases the risk for skin breakdown. Observe the perineum for rashes, blistering, irritation, and breakdown.

Kidneys. Nurses with advanced examination skills learn to palpate the kidneys during abdominal examination. The position, shape, and size of the kidneys reveal problems such as tumors;

BOX 45-4 NURSING ASSESSMENT QUESTIONS

Nature of the Problem
- What type of problems are you having with urination?
- Describe a recent day and or night when you were having urinary problems.
- Has this pattern remained constant, or do you have different patterns on different days or nights?

Signs and Symptoms
- Do you have urgency (i.e., feeling as though you have to void immediately)?
- Do you ever lose urine when you cough or sneeze?
- Does leakage occur at other times?

Onset and Duration
- When did you first notice a problem?
- How long has this problem lasted?

Severity
- How many times a day or night do you void or have leakage?
- How does this pattern compare with the pattern you last remember?
- What do you do when the symptoms occur?

Predisposing Factors
- Have you ever had a vaginal birth? More than once?
- Do you notice what you are doing at the time of urinary incidents?
- Do your symptoms increase after eating or drinking food with caffeine or alcohol?
- Which medications do you take routinely, and have any recently changed?
- Do you have a physical illness that may interfere with your usual urinary pattern?

Effect on Patient
- How have these symptoms affected your life?
- Have you had to change any of your usual activities?
- Have you sought any health care assistance with this problem?

TABLE 45-1 Common Types of Urinary Alterations

SYMPTOMS	DESCRIPTIONS	CAUSES OR ASSOCIATED FACTORS
Urgency	Feeling of need to void immediately	Full bladder, bladder irritation or inflammation from infection, overactive bladder, psychological stress
Dysuria	Painful or difficult urination	Bladder inflammation, trauma or inflammation of urethral sphincter
Frequency	Voiding at frequent intervals (less than 2 hours)	Increased fluid intake, bladder inflammation, increased pressure on bladder (pregnancy), diuretic therapy
Hesitancy	Difficulty initiating urination	Prostate enlargement, anxiety, urethral edema
Polyuria	Voiding large amounts of urine	Excess fluid intake, diabetes mellitus or insipidus, use of diuretics, postobstructive diuresis
Oliguria	Diminished urinary output relative to intake (usually 400 mL/24 hr)	Dehydration, renal failure, UTI, increased ADH secretion, heart failure
Nocturia	Voiding one or more times at night	Excessive fluid intake before bed (especially coffee or alcohol), renal disease, aging process, prostate enlargement
Dribbling	Leakage of urine despite voluntary control of urination	Stress incontinence, overflow from urinary retention (e.g., from BPH)
Incontinence	Involuntary loss of urine	Multiple factors: Unstable urethra, loss of pelvic muscle tone, fecal impaction, neurological impairment, overactive bladder
Hematuria	Blood in urine	Neoplasms of kidney or bladder, glomerular disease, infection of kidney or bladder, trauma to urinary structures, calculi, bleeding disorders
Retention	Accumulation of urine in bladder, with inability of bladder to empty fully	Urethral obstruction (stricture), decreased sensory activity, neurogenic bladder, prostate enlargement, postanesthesia effects, side effects of medications (e.g., anticholinergics, opioids)
Residual urine	Volume of urine remaining after voiding (≥100 mL)	Inflammation or irritation of bladder mucosa from infection, neurogenic bladder, prostate enlargement, trauma, or inflammation of urethra

ADH, Antidiuretic hormone; *BPH,* benign prostatic hyperplasia; *UTI,* urinary tract infection.

whereas tenderness indicates inflammation. Auscultation is sometimes performed to detect the presence of a renal artery bruit (sound resulting from turbulent blood flow through a narrowed artery).

Bladder. In adults the bladder rests below the symphysis pubis. When it is distended, it rises above the symphysis pubis at the midline of the abdomen and often extends to just below the umbilicus. On inspection you may note a swelling or convex curvature of the lower abdomen. Gently palpate the lower abdomen. The partially filled bladder normally feels smooth and rounded. Gentle palpation on a distended bladder causes the patient to feel the urge to urinate, tenderness, or even pain. Percussion of a full bladder yields a dull percussion note.

Urethral Meatus. Observe the urinary **meatus** for any discharge, inflammation, and lesions. To examine the female, a dorsal recumbent position provides full exposure of the genitalia. While wearing clean gloves, retract the labial folds to see the urethral meatus. Normally it is pink, it appears as a small slitlike opening below the

clitoris and above the vaginal orifice, and there is no discharge; if discharge is present, obtain specimens of urethral discharge before the patient voids.

Women with vaginal infections are susceptible to UTIs because it is easy for the drainage to travel to the urethral meatus. If yeast (candidiasis) is found in urine, it is important to inspect the vagina, in the groin area, under the breasts, and in the mouth for the source. It needs to be treated to keep UTI from yeast recurring. Older women may have vaginitis as a result of estrogen deficiency. Inspect the vaginal orifice carefully for signs of inflammation and describe any drainage.

A man's urethral meatus is normally a small opening at the tip of the penis. Inspect the meatus for discharge, inflammation, and lesions. It is necessary to retract the foreskin in uncircumcised men to see the meatus. Wear clean gloves when retracting the foreskin. Be sure to replace it after the examination is complete to prevent swelling of the tissue around the glans of the penis.

Assessment of Urine. Assessment of urine involves measuring patients' fluid I&O and observing characteristics of their urine.

Intake and Output. Assess the patient's average daily fluid intake. If you need an accurate measurement of fluid intake from the patient who is at home, ask him or her to estimate his or her intake by showing a measurement on a commonly used glass or cup.

In a health care setting measure a patient's fluid intake either when the health care provider orders I&O measurements or when you judge that measurement is needed (see Chapter 41). A change in urine volume is a significant indicator of fluid alterations or kidney disease. While caring for the patient, use a graduated receptacle to measure urinary output from a bedpan or urinal after each voiding. Special receptacles (urimeters) that attach between indwelling catheters and drainage bags are a convenient means of accurately measuring urine volume. A urimeter holds 100 to 200 mL of urine. After measuring urine from a urimeter, drain the cylinder into the urinary drainage bag or into a receptacle for disposal. Use urimeters when precise hourly measurements of urine are necessary.

When you measure urine from a drainage bag, the use of a separate plastic graduated measuring receptacle obtains a more precise measurement of urine output (Fig. 45-6). Each patient needs to have a graduated receptacle for his or her exclusive use to prevent potential cross-contamination. Label each container with patient name. The container needs to be rinsed after emptying, and the tubing that drains the bag securely clamped and cleaned with alcohol before putting it back in the holder.

Report any extreme increase or decrease in urine volume. An individual's daily output generally ranges from 1200 to 1500 mL of urine (Hall, 2011). An hourly output of less than 30 mL for more than 2 consecutive hours is cause for concern. Similarly, you need to report consistently high volumes of urine (polyuria) (i.e., over 2000 to 2500 mL daily).

Characteristics of Urine. Inspect the patient's urine for color, clarity, and odor.

Color. Normal urine ranges from a pale, straw color to amber, depending on its concentration. Urine is usually more concentrated in the morning or with fluid volume deficits. As a person drinks more fluids, urine becomes less concentrated.

Bleeding from the kidneys or ureters causes dark red urine; bleeding from the bladder or urethra causes bright red urine. Various medications and foods also change urine color. For example, phenazopyridine, a urinary analgesic, colors urine bright orange. Eating beets, rhubarb, or blackberries causes red urine. Special dyes used in intravenous diagnostic studies eventually discolor urine.

FIG. 45-6 Urine drainage bag.

Dark amber urine is the result of high concentrations of bilirubin caused by liver dysfunction. Document and report any abnormal color or sediment, especially if the cause is unknown.

Clarity. Normal urine appears transparent at voiding. Urine that stands in a container becomes cloudy. Freshly voided urine in patients with renal disease appears cloudy or foamy because of high protein concentrations. Urine may also appear thick and cloudy as a result of bacteria and WBCs.

Odor. Urine has a characteristic odor. The more concentrated the urine, the stronger the odor. Stagnant urine has an ammonia odor, which is common in patients who are repeatedly incontinent. A sweet or fruity odor occurs from acetone or acetoacetic acid (by-products of incomplete fat metabolism) seen with diabetes mellitus or starvation. Some food and medications can affect the odor of urine (e.g., asparagus and amoxicillin). A foul odor is often associated with a possible infection.

Urine Testing. Nurses often collect urine specimens for laboratory testing. The type of test determines the method of collection. Label all specimens with the patient's name, date, and time of collection. Transport specimens to the laboratory in a timely fashion to ensure accuracy of test results. Agency infection control policies require the adherence to standard precautions by all personnel during specimen handling (see Chapter 34).

Specimen Collection. The nurse collects random, clean-voided or midstream, sterile, and timed specimens (Table 45-2). The method of collection varies based on a patient's developmental level and the type of specimen ordered.

Urine Collection in Children. Specimen collection from infants and children is often difficult. Adolescents and school-age children are usually able to cooperate, although some are embarrassed. Preschool children and toddlers have difficulty voiding on request. It often helps to offer the child fluids 30 minutes before requesting a

TABLE 45-2 Urine Testing

COLLECTION TYPE/ USE OF SPECIMEN	NURSING CONSIDERATIONS
Random (routine urinalysis)	Collect during normal voiding or from an indwelling catheter or urinary diversion collection bag. Do not collect from an indwelling catheter drainage bag. Use a clean specimen cup.
Clean-voided or midstream (culture and sensitivity)	See Skill 45-1 on pp. 1068-1070. Use a sterile specimen cup.
Sterile specimen (culture and sensitivity)	If the patient has an indwelling catheter, collect a sterile specimen by using aseptic technique through the special sampling port (Fig. 45-7) found on the side of the catheter. Clamp the tubing below the port, allowing fresh, uncontaminated urine to collect in the tube. After wiping the port with an antimicrobial swab, insert a sterile syringe hub and withdraw at least 3 to 5 mL of urine (check agency policy). Using sterile aseptic technique, transfer the urine to a sterile container (see Chapter 28).
Timed urine specimens (for measuring levels of adrenocortical steroids or hormones, creatinine clearance, or protein quantity tests)	Time required may be 2-, 12-, or 24-hour collections. The timed period begins after the patient urinates and ends with a final voiding at the end of the time period. The patient voids into a clean receptacle, and the urine is transferred to the special collection container, which often contains special preservatives. Each specimen must be free of feces and toilet tissue. Missed specimens make the whole collection inaccurate. Check with agency policy and the laboratory for specific instructions.

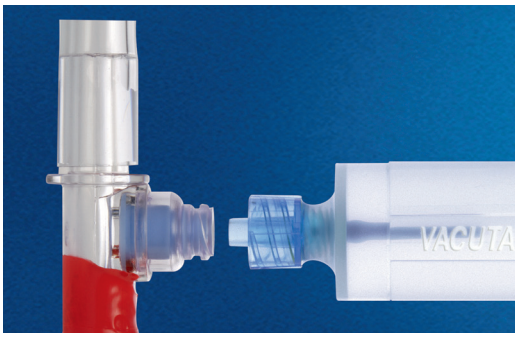

FIG. 45-7 Urine specimen collection: aspiration from a collection port in drainage tubing of indwelling catheter (needleless technique). (Courtesy and © Becton, Dickinson and Company).

FIG. 45-8 Checking results of chemical reagent strip dipped in urine.

specimen. You need to use terms for urination that the child is able understand. A young child is often reluctant to void in unfamiliar receptacles. A potty chair or specimen hat placed under the toilet seat is usually effective. You will need to use special collection devices for infants or toddlers who are not toilet trained. You can attach clear plastic, single-use bags with self-adhering material over the child's urethral meatus. Do not obtain specimens by squeezing urine from the diaper because the results will be inaccurate.

Common Urine Tests

Urinalysis. The laboratory performs a **urinalysis** on a specimen obtained by any of the previously described methods. Table 45-3 lists normal values for a urinalysis. A lab examines specimens as soon as possible, preferably within 2 hours. Make sure that it is the first voided specimen in the morning to ensure a uniform concentration of constituents. For a quick screening perform certain portions of the urinalysis with special reagent strips. Dip the strips into the urine and observe for a color change in the time interval designated on the package (Fig. 45-8).

Specific Gravity. The **specific gravity** is the weight or degree of concentration of a substance compared with an equal volume of water. Pour a urine specimen into a special clean, dry cylinder. The weighted urinometer is suspended in the cylinder of urine. The concentration of dissolved substances in the urine aids in determination of a patient's fluid balance. This measurement is always part of a complete urinalysis. Nurses in critical care units are often responsible for doing periodic measurements of urine specific gravity (see Table 45-3).

If questions regarding the accuracy of specific gravity measurements arise, obtain a urine osmolality test. Although both tests measure urine concentration, the osmolality test is more accurate because it measures the total number of particles in a solution (see Chapter 41).

Urine Culture. A urine culture requires a sterile or clean-voided sample of urine. It takes approximately 24 to 48 hours before the laboratory can report findings of bacterial growth. While awaiting results, a broad-spectrum antibiotic is sometimes ordered as soon as a culture has been obtained. The test for sensitivity determines which specific antibiotics are effective. The results (sensitivities) of a urine culture may show that another antibiotic would be more effective. In this case a new antibiotic is ordered.

Diagnostic Examinations. The urinary system is one of the few organ systems amenable to accurate diagnostic study by several

TABLE 45-3 Routine Urinalysis

View Video!

MEASUREMENT AND NORMAL VALUE	INTERPRETATION
pH (4.6-8.0)	pH of urine indicates acid-base balance. An acid pH helps protect against bacterial growth. Urine that stands for several hours becomes alkaline.
Protein (none or up to 8 mg/100 mL)	Normally protein is not present in urine. It is common in renal disease because damage to glomeruli or tubules allows it to enter urine.
Glucose (none)	Patients with diabetes mellitus often have glucose in urine as a result of inability of tubules to resorb high glucose concentrations (>180 mg/100 mL). Ingestion of high concentrations of glucose causes some glucose to appear in urine of healthy persons.
Ketones (none)	Patients whose diabetes mellitus is poorly controlled experience breakdown of fatty acids. End products of fat metabolism are ketones. Some patients with dehydration, starvation, or excessive aspirin usage also have *ketonuria.*
Blood	A positive test for occult blood occurs when intact erythrocytes, hemoglobin, or myoglobin is present. Blood in a routine urine specimen in a woman may be a result of contamination with menstrual fluid.
Specific gravity (1.0053-1.030)	Specific gravity measures concentration of particles in urine. High specific gravity reflects concentrated urine, and low specific gravity reflects diluted urine. Dehydration, reduced renal blood flow, and increased ADH secretion elevate specific gravity. Overhydration, early renal disease, and inadequate ADH secretion reduce specific gravity.
Microscopic Examination	
RBCs (up to 2)	Damage to glomeruli or tubules allows RBCs to enter the urine. Trauma, disease, or surgery of the lower urinary tract also causes blood to be present.
WBCs (0-4 per low-power field)	Greater numbers indicate urinary tract infection.
Bacteria (none)	Bacteria indicate urinary tract infection. (Patients do not always have symptoms.)
Casts (none)	Casts are cylindrical bodies the shapes of which take on likeness of objects within the renal tubule. Types include hyaline, WBCs, RBCs, granular cells, and epithelial cells. Their increased presence is always an abnormal finding and indicates renal alterations.
Crystals (none)	Crystals are the result of food metabolism. Excess crystals such as uric acid or calcium phosphate result in renal stone formation.

Data from Pagana KD, Pagana TJ: *Mosby's diagnostic and laboratory test reference,* ed 10, St Louis, 2011, Mosby.
ADH, Antidiuretic hormone; *RBCs,* red blood cells; *WBCs,* white blood cells.

radiographic techniques. The two approaches for visualization of urinary structures, direct and indirect techniques, are either quite simple or very complex, requiring extensive nursing intervention. These procedures are further subdivided into invasive or noninvasive categories (Table 45-4).

Many of the nursing responsibilities related to diagnostic examinations of the urinary tract are common to many of the studies. The common responsibilities before the study include the following:

- Obtain a signed consent (check agency policy)
- Assess patient for history of any allergies and whether they have had a previous reaction to a contrast agent (Schabelman and Witting, 2010). Allergic individuals in general (including individuals with asthma) are at mildly increased risk for developing adverse reactions to radiocontrast media (Beaty, Lieberman, and Slavin, 2008).
- Administer bowel-cleaning medications as ordered (check agency policy)
- Ensure that patient receives appropriate pretest diet (clear liquids) or nothing by mouth (NPO) as needed

The common responsibilities following the study include the following:

- Assessing I&O
- Observing characteristics of urine (color, clarity, presence of blood)
- Encouraging fluid intake, especially if using radiopaque dye

NURSING DIAGNOSIS

A thorough assessment of a patient's urinary elimination function reveals patterns of data that allow a nurse to make relevant and accurate nursing diagnoses. Use critical thinking to reflect on knowledge of previous patients, apply knowledge of urinary function and the effects of disorders, review defining characteristics, and make a specific nursing diagnosis. Data from questions about the urinary system are important in identifying nursing diagnoses. The diagnosis focuses on a specific urinary elimination alteration or an associated problem such as *impaired skin integrity related to urinary incontinence.* Identification of defining characteristics leads to selection of an appropriate diagnosis. An important part of formulating nursing diagnoses is identifying the relevant causative or related factor. You choose interventions that treat or modify the related factor for the diagnosis to be resolved. Specifying related factors for each diagnosis allows selection of individualized nursing interventions (Ackley and Ladwig, 2011). For example, *impaired skin integrity related to incontinence* requires interventions such as a toileting schedule or assisting the patient to the toilet at frequent intervals. In contrast, *impaired skin integrity related to inability to change positions* requires interventions such as placing the patient on a turning schedule. Box 45-5 provides an example of diagnostic reasoning. Some nursing diagnoses common to patients with urine elimination alterations include the following:

TABLE 45-4 Diagnostic Examinations

NAME OF PROCEDURE	PURPOSE AND METHOD OF PROCEDURE	SPECIAL NURSING CONSIDERATIONS
Noninvasive Procedures		
Abdominal roentgenogram (plain film; kidney, ureter, bladder [KUB], or flat plate)	Determine the size, shape, symmetry, and location of the kidneys.	No special preparation or precautions are required.
Computerized axial tomography (CT) scan	Obtain detailed images of structures within a selected plane of the body. The computer reconstructs cross-sectional image and thus allows the health care provider to view pathological conditions such as tumors and obstructions.	Bowel cleaning per agency or health care provider preference. Assess for shellfish (iodine) allergy if a CT scan with contrast is ordered. Prepare patient for the procedure (e.g., patient is placed into a large machine and needs to lie still; feelings of claustrophobia in some patients).
Intravenous pyelogram (IVP)	View the collecting ducts and renal pelvis and outline the ureters, bladder, and urethra. A special intravenous injection (iodine-based) that converts to a dye in urine is injected intravenously.	Bowel cleaning is completed per agency or health care provider preference. Only clear liquids are permitted until after test is completed. Assess patient for any allergies before test. After test encourage fluid intake to dilute and flush dye from patient. Observe for late symptoms of allergy (e.g., rash).
Ultrasound		
Renal	Identify gross renal structures and structural abnormalities in the kidney using high-frequency, inaudible sound waves.	No bowel cleaning needed.
Bladder	Identify structural abnormalities of bladder or lower urinary tract. It is also used to estimate the volume of urine in the bladder.	If needed, ask patient to drink fluids before the test to cause bladder distention for better results. No special care is necessary after either study.
Urodynamic testing (uroflowmetry)	Determine bladder muscle function and evaluate causes of urinary incontinence. Generally the patient urinates into a toilet equipped with a funnel and uroflowmeter. Voiding activates the uroflowmeter, and electronic data are recorded and analyzed.	The nurse explains the procedure to the patient. After the test, provide materials for perineal hygiene.
Invasive Procedures		
Endoscopy-cystoscopy	Provide direct visualization, specimen collection, and/or treatment of the interior of the bladder and urethra. Although this procedure is usually performed using local anesthesia, general anesthesia or conscious sedation is more common to avoid unnecessary anxiety and trauma for the patient. Surgery on the male prostate is also performed using a special endoscope.	Obtain signed consent. Complete a bowel cleaning if ordered. Follow agency policy for preoperative preparation and checklist (see Chapter 50). After patient's return assess the vital signs and the characteristics of urine; monitor intake and output (I&O); encourage fluids; and observe for fever, dysuria, and pain in suprapubic region.
Arteriogram (angiography)	Visualize the renal arteries and/or their branches to detect narrowing or occlusion. A catheter is placed in one of the femoral arteries and introduced up to the level of the renal arteries. Radiopaque contrast is injected through the catheter while x-ray film images are taken in rapid succession.	Obtain signed consent. Assess for any allergy. Follow agency preprocedure checklist. After the procedure monitor vital signs frequently until stable. Patient maintains bed rest for prescribed time interval. Encourage fluids to flush the contrast from the system. Also monitor the affected extremity for neurocirculatory function (pulse, skin temperature, sensation, and movement) and observe catheter site for bleeding, swelling, increased tenderness, or hematoma formation. Notify health care provider immediately of any postprocedure abnormality.

- Pain (acute, chronic)
- Risk for infection
- Toileting self-care deficit
- Impaired skin integrity
- Impaired urinary elimination
- Constipation
- Urinary retention

BOX 45-5 NURSING DIAGNOSTIC PROCESS

Stress Urinary Incontinence Related to Weakened Pelvic Musculature

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Have patient describe situations that accompany urine leakage.	Patient states that she "loses a little urine" whenever she sneezes, coughs, or laughs. Patient states she has been having problems for the past 2 years.
Observe patient behavior.	Patient wears a menstrual minipad continuously. Patient is reluctant to interact with others and tries not to cough or laugh.
Review medical history.	Patient is postmenopausal after three vaginal births.

PLANNING

During planning integrate the knowledge from assessment and information about available resources and therapies to develop an individualized plan of care (see the Nursing Care Plan). Match the patient's needs with clinical and professional standards recommended in the literature (Fig. 45-9). Building a relationship of trust with patients is important because the implementation of care involves interaction of a very personal nature.

Goals and Outcomes. The plan of care for urinary elimination alterations must include realistic and individualized goals along with relevant outcomes. The nurse and the patient need to collaborate in setting goals and outcomes and ultimately in choosing nursing interventions. A general goal is often normal urinary elimination; but sometimes the individual goal differs, depending on the problem. The goals are short or long term. For example, urinary retention following surgery requires a short-term goal: "Patient will have normal voiding with complete bladder emptying within 24 hours." Relevant expected outcomes for this goal include the following:

- Patient will void within 4 hours.
- Urinary output of 300 mL or greater will occur with each voiding.
- Patient's bladder is not distended to palpation.

Conversely, the patient with stress incontinence often has a long-term goal that depends on weeks of pelvic floor muscle exercise to achieve urinary control: "Patient will achieve full urinary continence within 8 weeks after start of exercise program (Kegel)." Make sure that goals are reasonably achievable and relevant to the patient's situation.

Setting Priorities. Urinary elimination is a personal and intimate activity. Establish a relationship with the patient that allows discussion and intervention. While you are collaborating with the patient, his or her priorities become apparent, and he or she should develop an understanding of all the goals.

When a patient has multiple nursing diagnoses (Fig. 45-10), it is important to recognize the primary health problem and its influence on other problems. In the example of the patient with chronic confusion, the resultant incontinence creates several risks. Focusing on the management of incontinence resolves more than one nursing diagnosis. Although physical needs appear to have higher priority, the psychological needs related to self-esteem or sexuality are sometimes a higher priority for the patient. Attention to the patient's perceived needs is the most satisfactory and successful approach to accomplishing all the goals. Reinforcement of good health habits that are already followed improves compliance with the care plan.

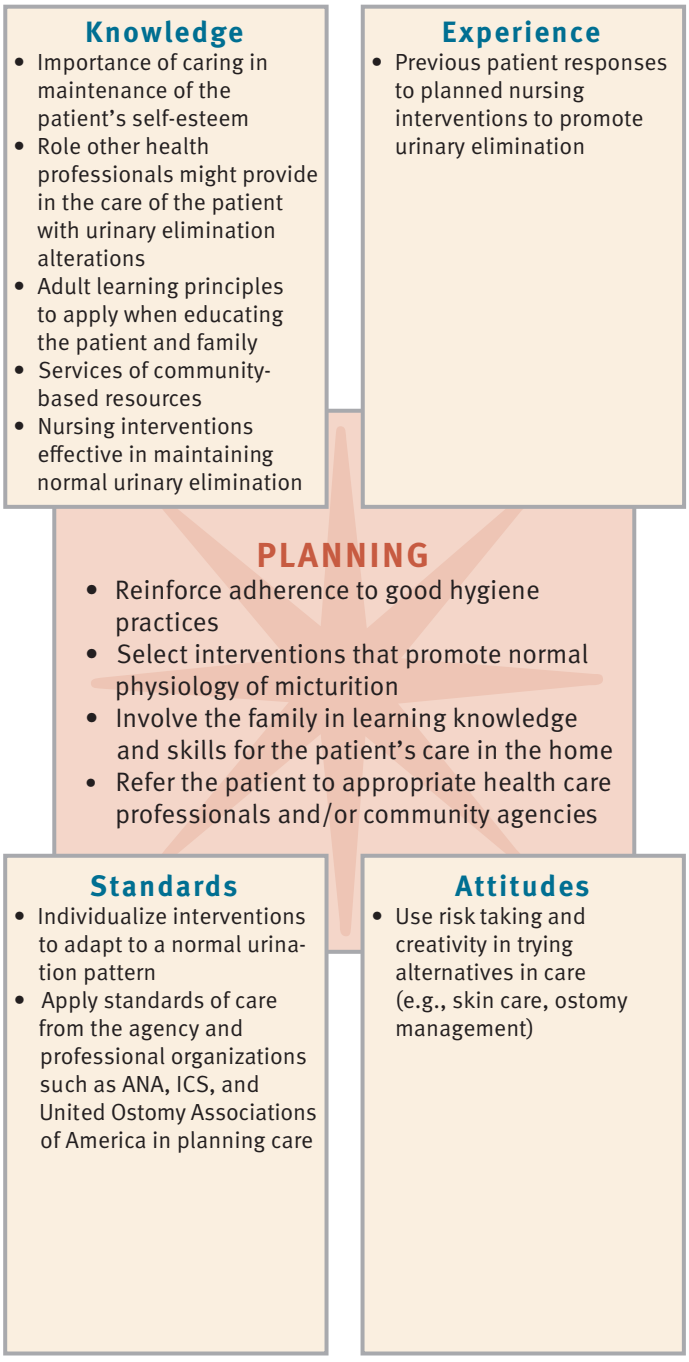

FIG. 45-9 Critical thinking model for urinary elimination planning. *ANA,* American Nurses Association; *ICS,* International Continence Society.

Teamwork and Collaboration. Incorporate individualized health promotion activities and therapeutic interventions to meet the patient's needs. Consider the patient's home environment and normal elimination routines when planning therapies. Collaborate with several health care disciplines, the patient, and the patient's family. For example, a nurse specialist in urinary continence teaches pelvic floor exercises, whereas a physical therapist designs an

NURSING CARE PLAN

Stress Urinary Incontinence

ASSESSMENT

Mrs. Kay, the nurse, is seeing Mrs. Grayson, a 55-year-old woman, for symptoms of urinary incontinence. Mrs. Grayson is postmenopausal, has a history of three vaginal births, and is "overweight." She lives with her husband, and her three grown children live nearby. Mrs. Grayson works as a secretary for a local social service agency. She confided to her gynecological practitioner that uncontrollable urine leakage has affected her life. Mrs. Kay's assessment includes a discussion of Mrs. Grayson's current health status with emphasis on her urinary concerns.

Assessment Activities	*Findings/Defining Characteristics**
Ask Mrs. Grayson about the effects of her urinary symptoms on her daily life.	She responds, "I find myself being embarrassed and frustrated for **losing control.** If my bladder is a little full, I **dribble** easily just picking something up or when I'm on my way to the bathroom. I'm afraid to laugh anymore because I **leak urine.** At work I try to avoid being close to my co-workers because I'm afraid I might have an odor."
Ask her what she has been doing about her condition.	She states that she has been wearing "one of those little pads" all the time now.
Ask Mrs. Grayson about any other effects caused by her leakage.	She begins to cry and states, "You know, I don't even like to go out to the movies or a party anymore. It's safer to stay home. I have problems being intimate with my husband because of leaking. We used to go dancing occasionally, but we don't do that anymore."
Observe Mrs. Grayson's behavior.	She appears anxious and is slowly pacing the floor.
Take a focused nursing history addressing urinary leakage and other lower urinary tract symptoms.	Mrs. Grayson's report of **urine leakage on physical exertion, sneezing, and laughing** increases the likelihood of a diagnosis of stress incontinence. Her risk factors for this condition include a **history of three pregnancies,** being **postmenopausal,** and being **overweight.** The history helps to define the proper interventions.
Have Mrs. Grayson complete a 3-day 24-hour log of urination.	The bladder log provides objective verification of urine elimination pattern and patterns of urine leakage and baseline for evaluation of effectiveness. It also demonstrates pattern of voiding that indicates more serious urinary problems related to urinary tract infections or other renal diseases (Lewis et al., 2011).

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Stress urinary incontinence related to weakened pelvic musculature

PLANNING

Goals	*Expected Outcomes (NOC)†*
Mrs. Grayson will have reduced episodes of urine leakage (incontinence) between voidings within 1 month.	**Urinary Continence** Patient will report less than two episodes of incontinence following initiation of a pattern of pelvic muscle strengthening exercises (Kegel). Patient will state increased comfort between voidings.
Mrs. Grayson will achieve and maintain an optimum urinary elimination pattern within 2 months.	**Urinary Elimination** Patient will remain free of urinary tract infection. Patient will demonstrate ability to start and stop urinary stream with no leaking between voidings. Patient will void more than 150 mL each time.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡	RATIONALE
Urinary Incontinence Care	
Assist Mrs. Grayson with supportive measures to reduce intraabdominal pressure by • Losing weight. • Avoiding heavy lifting. • Referring to urinary continence specialist if needed.	These measures reduce intraabdominal and bladder pressure, which increase leakage.

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classifications (NIC),* ed 5, St Louis, 2008, Mosby.

Continued

NURSING CARE PLAN

***Stress Urinary Incontinence*—cont'd**

Pelvic Muscle Exercise

Work with Mrs. Grayson to establish a program of pelvic muscle exercises that increase bladder control. Instruct her to tighten and then relax the ring of muscle around the urethra and anus, as if trying to prevent urination. Instruct her to work up to a total of 15 (3 sets of 5) contractions a day, ultimately holding the contraction for 10 seconds each, resting 10 seconds between each contraction, and resting 30 seconds between sets (Doughty, 2006).

Pelvic muscle rehabilitation alleviates or even cures stress incontinence for many women. Noticeable change will probably take 4 weeks, and maximum effect may take 6 weeks (Touhy and Jett, 2010).

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcomes*
Ask Mrs. Grayson about frequency of incontinence since starting pelvic muscle exercises.	She responds, "I'm dry most of the time now; and, when I do leak, it's only a few drops."	Mrs. Grayson reports increasing success with bladder control. She is satisfied that with time her success will be complete.
		Mrs. Grayson has had no symptoms of a urinary tract infection and states that she is voiding larger amounts.
Perform an ultrasound of Mrs. Grayson's bladder after voiding.	Residual volume is less than 30 mL.	Mrs. Grayson achieves improved bladder emptying.

CONCEPT MAP

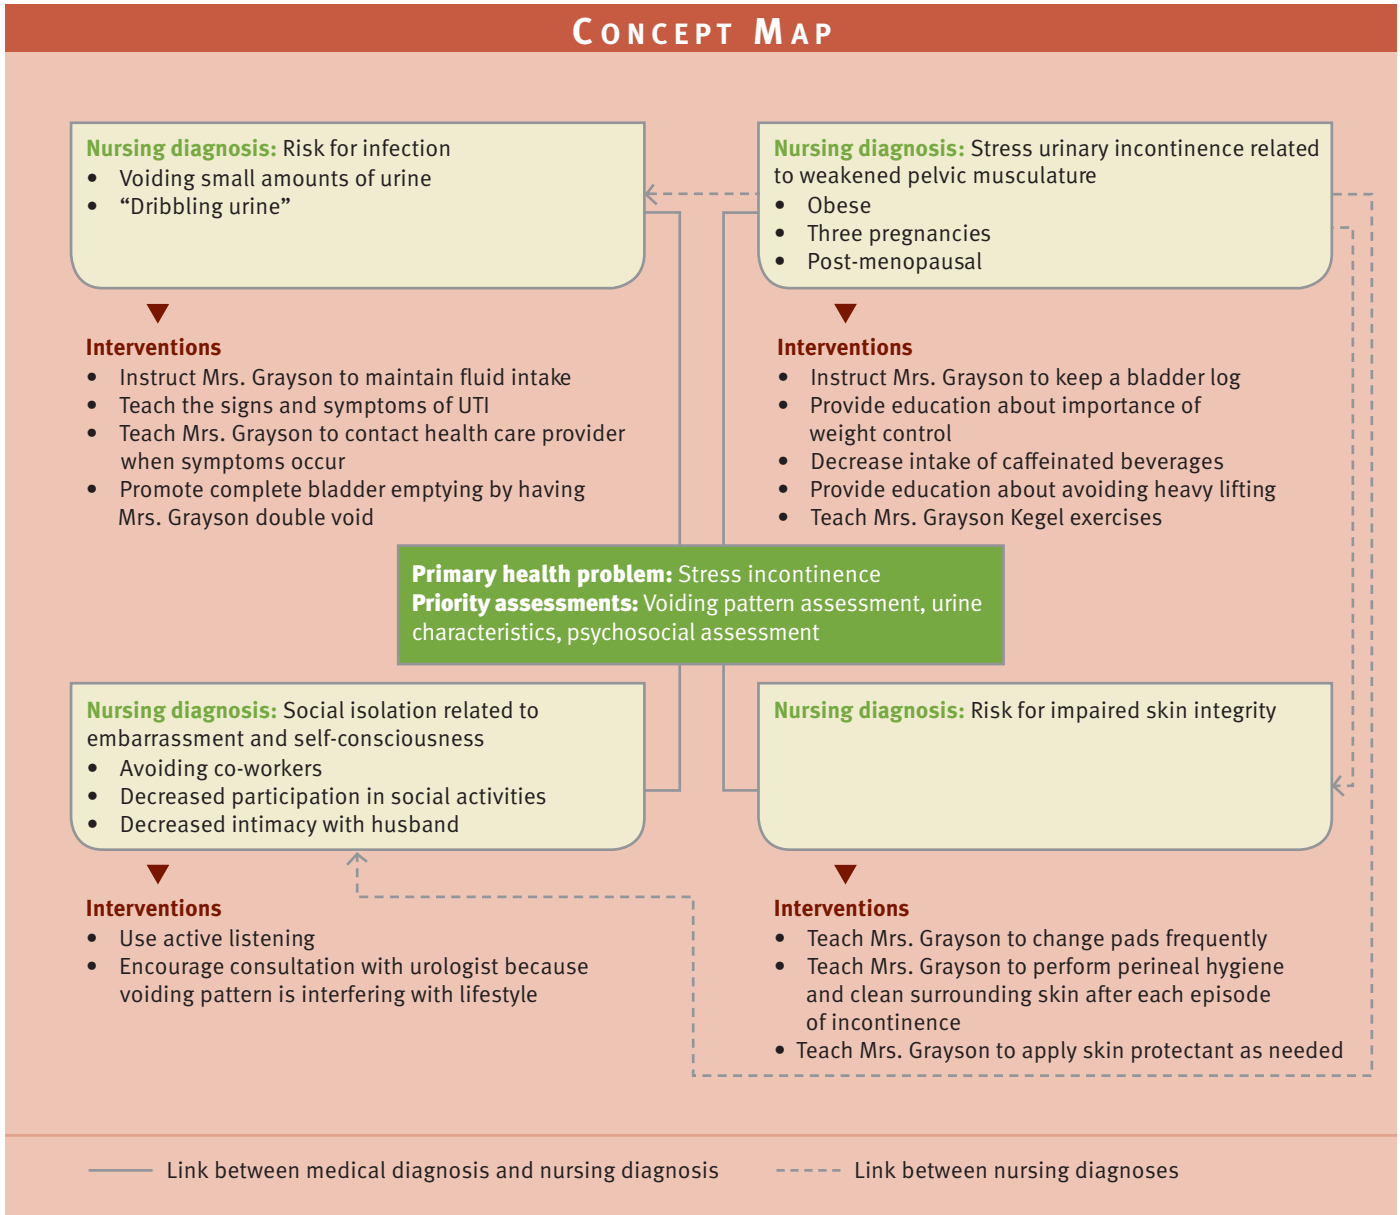

FIG. 45-10 Concept map for Mrs. Grayson. *UTI,* Urinary tract infection.

exercise plan to increase overall strength and endurance so the patient is able to ambulate to the bathroom. In addition, a health care provider prescribes an indwelling catheter. The nurse monitors the length of time that it is in place and communicates this to the health care provider. Explore the need for home care services and make the appropriate referrals. The family may need to alter the home environment to make it easier and safer for the patient to use the bathroom. The patient's plan requires multiple interventions.

IMPLEMENTATION

Complete independent and collaborative interventions to help the patient achieve the desired outcomes and goals. The independent activities are those in which nurses use their own judgment. An example of this is teaching self-care activities to the patient. Collaborative activities are those prescribed by the health care provider and carried out by the nurse such as medication administration.

Health Promotion. Health promotion assists the patient in understanding and participating in self-care practices to preserve and protect healthy urinary system function. You can achieve this focus using several means.

Patient Education. Success of therapies aimed at eliminating or minimizing urinary elimination problems depends in part on successful patient education (Box 45-6). Although many patients need to learn about all aspects of urinary elimination, first focus the teaching on their specific elimination problems. For example, patients who practice poor hygiene benefit most from learning about normal sterility of the urinary tract and how frequent handwashing and proper perineal hygiene reduce the risks for infection. Patients also learn the significance of symptoms of urinary alterations so they can initiate early preventive health care.

You can easily incorporate teaching when giving nursing care. For example, a good time to discuss the benefits of increasing fluid intake is while giving fluids with medications or meals. Often you are more successful in teaching about perineal hygiene while giving a bath or performing catheter care.

Promoting Normal Micturition. Maintaining normal urinary elimination helps to prevent many urination problems. Many nursing measures promote normal voiding in patients at risk for urination difficulties and in those with established urination problems. Some of these measures are independent nursing interventions.

Stimulating Micturition Reflex. A patient's ability to void depends on feeling the urge to urinate, being able to control the urethral sphincter, and being able to relax during voiding. Help patients learn to relax and stimulate the reflex to void by helping them assume the normal position for voiding. A woman is better able to void in a squatting or sitting position. If the patient is unable to use toilet facilities, position him or her in a squatting position on a bedpan (see Chapter 46) or bedside commode. A man voids more easily in the standing position. If the man cannot reach toilet facilities, have him stand at the bedside and void into a urinal (a metal or plastic receptacle for urine) (Fig. 45-11). At times it is necessary for one or more nurses to help a man stand.

Other measures that promote relaxation and the ability to void include sensory stimuli. The sound of running water helps many patients void through the power of suggestion. Stroking the inner aspect of the thigh stimulates sensory nerves and promotes the micturition reflex. You can also pour warm water over the patient's perineum and create the sensation to urinate. If you need to measure urine output, first measure the volume of water that you pour over the perineal area.

Maintaining Elimination Habits. Many patients follow routines to promote normal voiding. In a hospital or long-term care facility health care routines often conflict with those of patients. Integrating patients' habits into the care plan fosters normal voiding and helps prevent problems related to urination.

Maintaining Adequate Fluid Intake. A simple method of promoting normal micturition is maintaining optimal fluid intake. A patient with normal renal function who does not have heart or

BOX 45-6 PATIENT TEACHING

Urinary Elimination Problems Related to Urinary Sphincter Dysfunction

Objective

- Patient will achieve continence through increased sphincter control.

Teaching Strategies

- Have patient attempt to tighten urinary sphincter during urination to feel the sensations associated with urinary sphincter contraction.
- Teach patient progressive use of pelvic floor exercises (Kegel exercises).
  - Provide written instructions and/or audiotape for reinforcement of technique.
  - Have patient sit or stand without tensing muscles of legs, buttocks, or abdomen.
  - Have patient contract circumvaginal muscles and urinary and anal sphincters for 10 seconds and then relax for 10 seconds.
  - Have patient repeat these cycles for 30 to 100 times per day.
  - For maintenance, have patient do 1 to 2 sets per week. Patient should contract pelvic muscles and sphincters before sneezing, coughing, or lifting.
  - Maintain optimum strength through practicing hard contractions.
- Teach and monitor use of a voiding record. Inform patient that it may take 2 to 4 weeks of exercises before improvement is seen.

Evaluation

- Ask patient and caregiver about voiding record to identify changes in patterns of urinary elimination.
- Ask patient and caregiver about degree of satisfaction related to control achieved in urinary elimination.
- Ask patient and caregiver about selection and usage of incontinence control devices.

Teaching strategies modified from Bradway C, Cacchione P: Teaching strategies for assessing and managing urinary incontinence in older adults, *J Gerontol Nurs* 36(7):18, 2010; Touhy TA, Jett KF: *Ebersole and Hess' Gerontological nursing healthy aging*, ed 3, St Louis, 2010, Mosby.

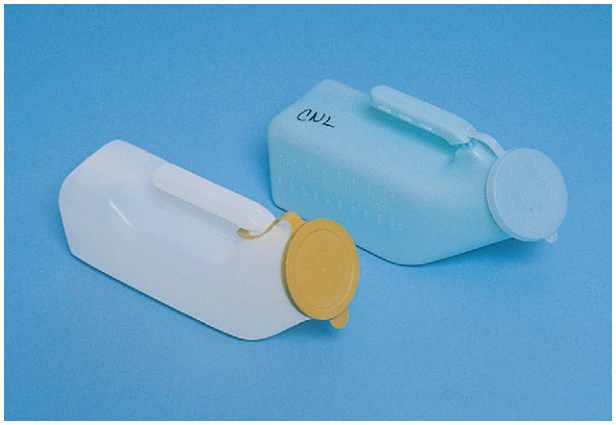

FIG. 45-11 Types of male urinals.

kidney disease needs to drink 2200 to 2700 mL of fluid daily. However, a minimal daily intake of 1200 to 1500 mL of fluids is usually adequate unless the patient has a history of UTI.

Increasing fluid intake helps flush out solutes or particles that collect in the urinary system. Because some patients are unwilling to drink 2500 mL of water daily, encourage fluids that the patient prefers. Many vegetables and fruits also have a high fluid content. At home it helps to set a schedule for drinking fluids (e.g., with meals or medications). To minimize nocturia, avoid fluids 2 hours before bedtime.

Promoting Complete Bladder Emptying. Under normal conditions a small amount of a patient's urine remains in the bladder after voiding (residual urine). Encouraging patients to wait until urine stops flowing or to attempt to void again (double voiding) can improve bladder emptying (Table 45-5). Urinary retention care includes scheduled toileting (Lewis et al., 2011). In addition, Credé's method or manual compression of the bladder walls with each attempted void may be used (Madineh, 2008). Instruct the patient to place both hands flat on the abdomen below the umbilicus and above the symphysis pubis with the fingers pointed down toward the bladder dome. Have him or her compress the hands downward against the walls of the bladder while tightening the perineum, contracting the abdominal wall, and holding the breath. The maneuver promotes bladder emptying by relaxing the urethral sphincter.

Preventing Infection. One of the most important considerations is to prevent infection of the urinary system. Good perineal hygiene that includes cleaning the urethral meatus after each voiding or bowel movement is essential. A minimal daily fluid intake of 1200 to 1500 mL dilutes urine, promotes regular micturition, and flushes

TABLE 45-5 Urinary Incontinence and Treatment Options

TYPE	SIGNS AND SYMPTOMS	INTERVENTIONS
Functional		
Loss of urine caused by factors outside the urinary tract that interfere with the ability to respond in a socially appropriate way to the urge to void Relevant factors: Environmental barriers Sensory, cognitive, and mobility issues	Urge to void that causes loss of urine before reaching appropriate receptacle	Clothing modifications Environmental alterations Scheduled toileting Absorbent products
Stress		
Involuntary leakage of urine during increased abdominal pressure in the absence of bladder muscle contraction	Loss of urine with increased intraabdominal pressure (coughing, laughing, sneezing, or lifting with a full bladder)	Pelvic floor exercises (Kegel) Surgical interventions Biofeedback Electrical stimulation Absorbent products
Urge		
Involuntary passage of urine after a strong sense of urgency to void	Urinary urgency, often with frequency (more often than every 2 hours); bladder spasm or contraction	Antimuscarinic agents Behavioral interventions Biofeedback Bladder retraining Pelvic floor exercises Lifestyle modifications (smoking cessation, weight loss and fluid modifications) Absorbent products
Mixed		
Combination of urge and stress urinary incontinence signs and symptoms	Combination of urge and stress symptoms	Main treatments usually based on symptoms that are most bothersome to patient
Overflow Incontinence		
Involuntary loss of urine at intervals without sensation of urge to void Relevant factors: Spinal cord dysfunction—loss of cerebral awareness or impairment of reflex arc	Lack of urge to void, unawareness of bladder filling, reflex emptying when certain volume reached	Intermittent catheterization Condom catheter (male) Credé's method
Hyperactive/Overactive Bladder		
Urinary urgency that is associated with urinary frequency and nocturia	Sudden compelling desire to urinate that is difficult to deter	Pelvic floor exercises (Kegel) Intake of 1.5-2 L of fluid a day Limit carbonated and caffeinated Beverages Bladder training Biofeedback

Modified from Palmer MH, Newman DK: Urinary incontinence and estrogen, *Am J Nurs* 107(3):35, 2007; Doughty DB: *Urinary and fecal incontinence: current management concepts*, ed 3, St Louis, 2006, Mosby; and McKertich K: Urinary incontinence: Assessment in women: Stress, urge or both? *Aust Fam Physician* 37(3):112, 2008.

the urethra of microorganisms. Voiding after intercourse; not using excessive soap or taking bubble baths; wearing cotton underwear; and drinking enough fluids, especially fluids high in acid ash such as apple or cranberry juice help prevent UTI.

Acute Care

Maintaining Elimination Habits. Patients usually require time to void. Requesting a urine specimen on demand does not contribute to relaxation and normal voiding habits. Give patients at least 30 minutes to provide a specimen. Patients normally void on awakening or before meals; therefore offer the opportunity to use toilet facilities then. Also important is the need to respond to and anticipate patients' urges to urinate. For example, many older-adult falls are related to the urge to urinate. Anticipate the need and provide for scheduled bathroom visits to help reduce the fall risk in these patients.

Many patients need privacy for voiding. If a patient cannot reach the bathroom and uses a bedside commode or bedpan, make sure that the bedside curtain is closed. Patients who are debilitated and live at home often prefer using a bedside commode screened by a partition or room divider. Young children are often unable to void in the presence of persons other than their parents.

When possible encourage the continued use of special measures that the patient uses to void. Some patients are able to relax and void more easily while reading or listening to music. Having a cup or glass of fluids also promotes urination.

Medications. Drug therapy given alone or with other therapies often helps problems of incontinence or retention. The bladder is innervated by the parasympathetic nervous system. Drugs that block the muscarinic receptors suppress bladder contractions and reduce incontinence caused by bladder irritation. Examples include solifenacin (VESIcare) and oxybutynin chloride (Ditropan). These medications can cause constipation, dry mouth, and skin irritation (Lehne, 2010). Irritants present in the urine such as caffeine or alcohol may cause uncontrolled bladder contractions, and thus patients should avoid them.

When the bladder empties, the detrusor muscle contracts in response to parasympathetic stimulation. Incomplete bladder emptying results from impaired innervation or weakness of the detrusor muscle. The patient experiences retention and possible overflow incontinence. Cholinergic drugs increase contraction of the bladder and improve emptying. Bethanechol (Urecholine) stimulates parasympathetic nerves to increase bladder wall contraction and relax the sphincter. You can administer bethanechol by subcutaneous or oral routes. Cholinergic drugs often cause diarrhea as a side effect (Lehne, 2010).

The dribbling or overflow incontinence seen in men with prostatic enlargement can be treated with an alpha$_1$-adrenergic blocker such as tamsulosin (Flomax). Tamsulosin is given orally and relaxes prostatic smooth muscle, thus relieving obstructive symptoms. This drug has few side effects and does not cause transient hypotension as other alpha-adrenergic blockers do (Lehne, 2010).

Catheterization. Catheterization of the bladder involves introducing a latex or plastic tube through the urethra and into the bladder. The catheter provides a continuous flow of urine in patients unable to control micturition or those with obstructions. It also provides a means of assessing urine output in hemodynamically unstable patients. Because bladder catheterization carries the risk of UTI, blockage, and trauma to the urethra, it is preferable to rely on other measures for either specimen collection or management of incontinence.

Types of Catheterization. Intermittent and indwelling retention catheterizations are the two forms of catheter insertion. With the intermittent technique you introduce a straight single-use catheter (Fig. 45-12, *A*) long enough to drain the bladder (5 to 10 minutes). When the bladder is empty, you immediately withdraw the catheter. You can repeat intermittent catheterization as necessary, but each catheter insertion increases risk of trauma and infection. It is common for people with spinal cord injury or other neurological problems such as multiple sclerosis to perform self–intermittent catheterization up to every 4 hours daily for months or years. If done correctly with use of clean technique, they frequently do not experience more UTIs; in fact, the UTI rate is lower than for patients with long-term indwelling catheters. An indwelling or Foley catheter (Fig. 45-12, *B*) remains in place for a longer period, until a patient is able to void voluntarily or continuous accurate urine measurements are no longer needed (Box 45-7).

The straight single-use catheter has a single lumen with a small opening about 1.3 cm (½ inch) from the tip. Urine drains from the tip, through the lumen, and to a receptacle. An indwelling Foley catheter has a small inflatable balloon that encircles the catheter just above the tip. When inflated the balloon rests against the bladder outlet to anchor the catheter in place. The indwelling retention catheter often has two or three lumens within the body of the catheter (see Fig. 45-12, *B*). One lumen drains urine through the catheter to a collecting tube. A second lumen carries sterile

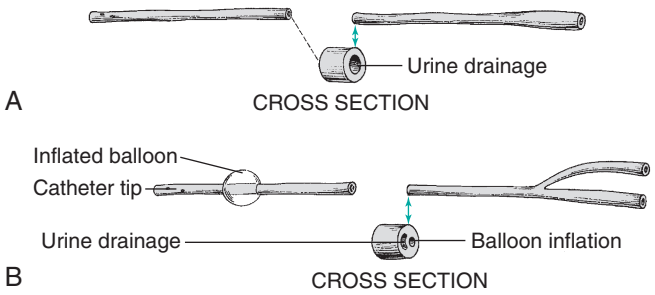

FIG. 45-12 Types of urinary catheters. **A,** Straight. **B,** Indwelling (Foley).

BOX 45-7 INDICATIONS FOR CATHETERIZATION

Intermittent Catheterization
- Relieving discomfort of bladder distention, providing decompression
- Obtaining sterile urine specimen when clean-catch specimen is unobtainable
- Assessing residual urine after urination
- Managing patients with spinal cord injuries, neuromuscular degeneration, or incompetent bladders long term

Short-Term Indwelling Catheterization
- Obstruction to urine outflow (e.g., prostate enlargement)
- Surgical repair of bladder, urethra, and surrounding structures
- Prevention of urethral obstruction from blood clots after genitourinary surgery
- Measurement of urinary output in critically ill patients
- Continuous or intermittent bladder irrigations

Long-Term Indwelling Catheterization
- Severe urinary retention with recurrent episodes of UTI
- Skin rashes, ulcers, or wounds irritated by contact with urine
- Terminal illness when bed linen changes are painful for patient

UTI, Urinary tract infection.

BOX 45-8 GUIDELINES FOR APPROPRIATE CATHETER SELECTION

- The catheter size should be determined by the size of the patient's urethral canal. When the French system is used, the larger the gauge number, the larger the catheter size. Generally children require an 8- to 10-Fr, women require a 14- to 16-Fr, and men require a 16- to 18-Fr (Gray et al., 2006). To prevent trauma, the smallest effective catheter size is preferred. Larger sizes than 18-Fr create discomfort, increase risk of blockage, and lead to urinary tract infection, urethral irritation, and erosion (Gray et al., 2006)
- The expected duration of the catheterization determines the catheter material selection.
  - Plastic catheters are suitable only for intermittent use because of their inflexibility.
  - Latex catheters are recommended for use up to 3 weeks. Be aware of allergies.
  - Pure silicon or Teflon catheters are best suited for long-term use (2 to 3 months) because of less encrustation at the urethral meatus.
- Balloon size is important in selecting an indwelling catheter. Balloon sizes range from 3 mL (pediatric) to large postoperative volumes (75 mL). In adults the 5-mL and 30-mL sizes are the most common: The 5-mL size allows for optimal drainage, whereas the 30-mL size is used after prostatectomies to provide hemostasis of the prostatic bed (Gray et al., 2006).
- Use only sterile water to inflate the balloon because saline crystallizes, resulting in incomplete deflation of the balloon at the time of removal.
- If leakage occurs around the catheter, a change in lumen size or use of antispasmodic medication is necessary.

water to and from the balloon when it is inflated or deflated. A third (optional) lumen is sometimes used to instill fluids or medications into the bladder. It is easy to determine the number of lumens by the number of drainage and injection ports at the end of the catheter.

A second type of intermittent catheter has a curved tip. A Coudé catheter is used on male patients who may have enlarged prostates that partly obstruct the urethra. It is less traumatic during insertion because it is stiffer and easier to control than the straight-tip catheter.

Catheters come in many diameters to fit the size of a patient's urethral canal. Box 45-8 provides suggestions for how to make appropriate decisions regarding catheter selection.

Catheter Insertion. Urethral catheterization requires a health care provider's order. You must use strict aseptic technique (see Chapter 28). Organizing equipment before the procedure prevents interruptions. The steps for inserting indwelling and single-use straight catheters are basically the same. The difference lies in the procedure taken to inflate the indwelling catheter balloon and secure the catheter. Skill 45-2 on pp. 1071-1079 lists steps for performing female and male urethral catheterization.

Closed Drainage Systems. After inserting an indwelling catheter, maintain a closed urinary drainage system to minimize the risk of infection. Standard urinary drainage bags are plastic and hold about 1000 to 1500 mL of urine. The bag hangs on the bed frame or wheelchair without touching the floor. Never hang the bag on the bedrail because it can accidentally be raised above the level of the bladder. In patients with indwelling catheters you can obtain specimens without opening the drainage system using a special port in the tubing (see Fig. 45-7).

An alternative to a large-volume urinary drainage bag is a small-volume leg bag. A urinary drainage bag attached to the patient's calf or thigh provides the catheterized patient with greater mobility. These drainage bags are usually worn during the day and replaced at night with a standard drainage bag.

When the patient ambulates, the nurse or patient carries the standard urinary drainage bag below the patient's waist. As with leg bags, never raise the drainage bag above the level of the patient's bladder. Urine in the bag and tubing becomes a medium for bacteria, and infection is likely to develop if urine flows back into the bladder.

Most drainage bags contain an antireflux valve to prevent urine in the bag from reentering the drainage tubing and contaminating the patient's bladder. A spigot at the base of urinary drainage bags provides a means for emptying the bag. The spigot on a leg bag is covered with a protective cap. The spigot on a standard drainage bag always needs to be clamped, except during emptying, and tucked into the protective pouch on the side of the bag (see agency policy). To keep urinary drainage systems patent so urine can flow into the drainage bag, check for kinks or bends in the tubing, avoid positioning the patient on the tubing, and observe for clots or sediment that occlude it. Patients with indwelling catheters have a number of special care needs. Direct nursing measures at preventing infection and maintaining unobstructed flow of urine through the catheter drainage system.

Perineal Hygiene. Buildup of secretions or encrustation at the catheter insertion site is a source of irritation and potential infection. Nurses provide perineal hygiene (see Chapter 39) at least 3 times daily or as needed for a patient with a retention catheter. Soap and water are effective in reducing the number of organisms around the urethra. Accidentally advancing the catheter further into the bladder during cleaning increases the risk of introducing bacteria into the bladder.

Catheter Care. In addition to routine perineal hygiene, many institutions recommend that patients with catheters receive special care 3 times a day and after defecation or bowel incontinence to help minimize discomfort and infection (Skill 45-3 on pp. 1079-1081).

Fluid Intake. All patients with catheters should have a daily intake of 2000 to 2500 mL if permitted. Patients can do this through oral intake or intravenous infusion. A high fluid intake produces a large volume of urine that flushes the bladder and keeps catheter tubing free of sediment. Cranberry, apple, and prune juices are high in acid ash and help prevent infection; conversely citrus juices such as orange, grapefruit, and pineapple should be used sparingly because they can create an environment in the bladder more prone to infection.

Preventing Infection. Maintaining a closed urinary drainage system is important in infection control. A break in the system leads to introduction of microorganisms (Box 45-9). Sites at risk are the site of catheter insertion, the drainage bag, the spigot, the tube junction, and the junction of the tube and bag (Fig. 45-13).

In addition, monitor the patency of the system to prevent pooling of urine within the tubing. Urine in the drainage bag is an excellent medium for microorganism growth. Bacteria can travel up drainage tubing to grow in pools of urine. If this urine flows back into the patient's bladder, an infection is more likely to develop. Many urine drainage systems are equipped with an antireflux valve. Suggestions for ways to prevent infections in patients with catheters are provided in Box 45-10.

Catheter Irrigations and Instillations. To maintain the patency of indwelling urinary catheters, it is sometimes necessary to irrigate or flush a catheter with sterile solution. If a catheter becomes plugged with pus or sediment, it is best to change it rather than

BOX 45-9 EVIDENCE-BASED PRACTICE

Factors to Decrease Urinary Tract Infections

PICO Question: Which factors decrease the risk of urinary tract infections (UTIs) in hospitalized patients with indwelling urinary catheters?

Evidence Summary

Urinary catheterization is a common procedure in health care settings. Nine percent of patients in hospitals acquire a health care–associated infection. UTIs account for approximately 40% of them (Parker et al., 2009). The risk of catheter-associated urinary tract infections (CAUTIs) increases by the number of days that a catheter remains in place.

Nazarko (2008) stresses that decreasing the risk for CAUTIs starts by avoiding unnecessary use of indwelling catheters and removing them as soon as medically indicated. Indications for catheterization include surgery, urinary retention, and need for accurate measurement of output (Holroyd-Leduc et al., 2007). The authors designed a study to determine the association between indwelling urinary catheterization without a specific medical indication and adverse outcomes. They found that patients older than 70 years with limited functional ability are often catheterized to facilitate their care. The results suggested that nonmedical use of indwelling catheters in older adults may result in longer hospital stays and greater risk of death resulting from the development of a UTI and subsequent development of bacteremia or urosepsis.

Urinary catheters vary in composition and design. Research related to catheter composition focuses on altering the catheter surface to slow biofilm development (adherence of microorganisms to the catheter surface). According to Parker et al. (2009), there is robust evidence supporting the insertion of a silver alloy–coated catheter to reduce the risk of CAUTIs for up to 2 weeks and an antibiotic-impregnated catheter for up to 7 days in adult patients. In addition, further research needs to be conducted on which type of catheter is effective in decreasing the risk of CAUTI for long-term use.

Many catheterizations can be avoided by using noninvasive alternatives. For example, instead of using catheterization to evaluate residual urine in the bladder, a bladder scanner can be used. When it is determined that bladder volume is normal, the invasive procedure of catheterization may not be needed (Chen et al., 2005). In addition, the incidence of CAUTI significantly decreases when nurses give the prescriber daily reminders to remove unnecessary catheters and suggest the use of alternative noninvasive treatments such as condom catheters to manage urinary elimination (Holroyd-Leduc et al., 2007; Nazarko, 2008).

Application to Nursing Practice

- Avoid the routine use of catheters; use only when clinically indicated.
- Collaborate with health care providers to remove catheters when medical indications no longer exist.
- Suggest noninvasive continent devices such as condom catheters to reduce the risk of UTI and resulting complications.
- Nurses need to be patient advocates by taking an active role in monitoring duration of treatment.

BOX 45-10 TIPS FOR PREVENTING INFECTION IN PATIENTS WITH CATHETERS

- Follow good hand hygiene techniques (see Chapter 28).
- Do not allow the spigot on the drainage system to touch a contaminated surface.
- Only use sterile technique to collect specimens from a closed drainage system.
- If the drainage tube becomes disconnected, do not touch the ends of the catheter or tubing. Wipe the end of the tubing and catheter with an antimicrobial solution before reconnecting.
- Ensure that each patient has a separate receptacle for measuring urine to prevent cross-contamination.
- Prevent pooling of urine in the tubing and reflux of urine into the bladder.
- Avoid raising the drainage bag above the level of the bladder.
- If it becomes necessary to raise the bag during transfer of the patient to a bed or stretcher, clamp the tubing or empty its contents to the drainage bag first.
- Provide for drainage of urine from the tubing to the bag by positioning the tubing.
- Before exercise or ambulation drain all urine from the tubing into the drainage bag.
- Avoid prolonged kinking or clamping of the tubing.
- Empty the drainage bag at least every 8 hours. If you note large outputs, empty more frequently.
- Encourage fluid intake (if not contraindicated).
- Remove the catheter as soon as clinically necessary (Fernandez and Griffiths, 2006).
- Tape or secure the catheter appropriately for the patient (see Skill 45-2).
- Perform routine perineal hygiene per agency policy and after defecation or bowel incontinence (see Skill 45-3).

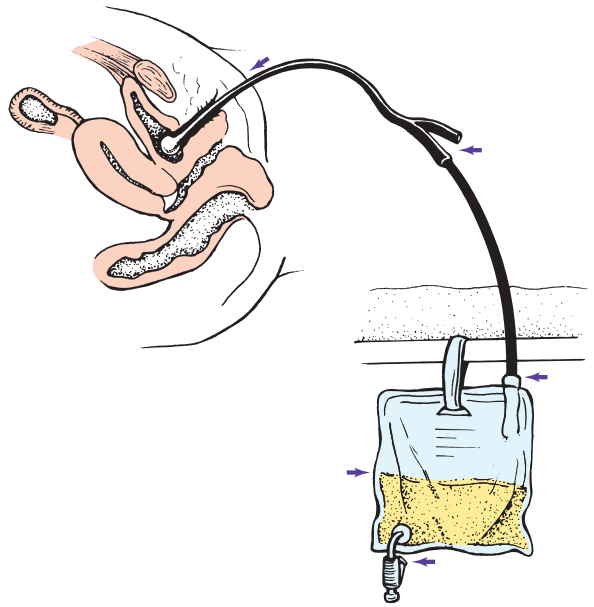

FIG. 45-13 Potential sites for introduction of infectious organisms into a urinary drainage system.

irrigate because irrigation washes the pus and sediment back into the bladder, creating a worse infection. Change the catheter as needed. It is appropriate to use irrigation after surgery for blood clots and short-term catheter use; but for long-term use irrigation can create a chronic sediment and pus problem, requiring lifelong irrigation in long-term indwelling catheters. For patients with bladder infections, a health care provider often orders antiseptic or antibiotic bladder irrigations to wash out the bladder or treat local infection. In both irrigations follow sterile aseptic technique.

Before performing irrigation assess the catheter for blockage. If the amount of urine in the drainage bag is less than the patient's intake or output during the previous shift, expect some blockage. If urine does not drain freely, milk the tubing. Milk the tube by squeezing and then releasing it, starting at a point close to the

patient and then out to the drainage bag so a clot or sediment is not forced back into the catheter. Many times this takes care of the problem without irrigation.

Maintenance of a closed system is recommended during intermittent irrigations or instillations. This technique is effective for irrigating a partially blocked catheter or for bladder instillations. One method of closed-bladder irrigation provides for frequent intermittent irrigations or continuous irrigation without disruption of the sterile catheter system through use of a three-way catheter (Skill 45-4 on pp. 1081-1084). This method is used most often in patients who have had genitourinary surgery and are at risk for blood clots and mucus fragments occluding the catheter. The other method involves accessing the closed drainage system to instill bladder irrigations (see Skill 45-4). This method is often used for unanticipated irrigation or intermittent instillations.

Removal of Indwelling Catheter. When removing an indwelling catheter, promote normal bladder function and prevent trauma to the urethra. Removing a catheter requires a clean, disposable towel; a trash receptacle; and a sterile syringe the same size as the volume of solution within the inflated balloon of the catheter. Perform hand hygiene and put on clean gloves before removing the catheter. The end of each catheter contains a label that denotes the volume of solution (5 to 30 mL) within the balloon. If a different volume was used, there should be a notation on the patient record.

Position the patient in the same position as during catheterization. Some institutions recommend collecting a sterile urine specimen at this time or sending the catheter tip for culture and sensitivity tests. After removing the tape, place the towel between a female patient's thighs or over a male patient's thighs. Insert the syringe into the balloon injection port. Most ports are self-sealing and require that only the tip of the syringe be inserted. Slowly withdraw all of the solution to deflate the balloon totally. If a portion of the solution remains, the partially inflated balloon traumatizes the urethral canal as the catheter is removed. After deflation, explain that the patient will feel a burning sensation as the catheter is withdrawn. Then pull the catheter out smoothly and slowly.

It is normal for the patient to experience some dysuria, especially if the catheter has been in place several days or weeks. Until the bladder regains full tone, some patients also experience frequency of urination or urinary retention.

Assess the patient's urinary function by noting the first voiding after catheter removal and documenting the time and amount of voiding for the next 24 hours. If amounts are small, frequent assessment of bladder for distention is necessary. If 4 hours have elapsed without voiding or the patient experiences discomfort, it often becomes necessary to reinsert the catheter.

Alternatives to Urethral Catheterization. To avoid the risks associated with urethral catheters, two alternatives are available for urinary drainage.

Suprapubic Catheterization. Suprapubic catheterization involves surgical placement of a catheter through the abdominal wall above the symphysis pubis and into the urinary bladder. A health care provider performs the procedure under local or general anesthesia. The catheter is anchored in place with sutures, a commercially prepared ring seal, or both. Urine drains into a urinary drainage bag. Maintenance of the tubing and drainage bag is the same as for an indwelling catheter. Studies comparing the use of this method of urinary drainage with indwelling catheters have shown mixed results. Infection rates may be slightly lower; however, long-term complications are similar (Doughty, 2006). Sediment, clots, or the abdominal wall itself can block the suprapubic catheter. Adequate fluid intake helps to minimize risk of blockage by increasing urine flow. The suprapubic catheter must remain patent at all times. Monitor the patient's I&O carefully, monitor the urine characteristics, and observe for signs of infection (e.g., fever and chills). Also administer skin care around the insertion site. This method may be used in men and women.

Condom Catheter. The second alternative to catheterization is the condom catheter (Box 45-11), which is suitable for incontinent or comatose men who still have complete and spontaneous bladder emptying. The condom is a soft, pliable, latex sheath that slips over the penis. Patients wear it only at night or continuously, depending on their needs. There are three general methods of securing a condom catheter. One method uses a strip of elastic tape or rubber that encircles the top of the condom to secure it in place. Another type uses a self-adhesive condom sheath. The third method uses an inflatable ring within the condom to secure placement. Take care to ensure that, whatever type or size is used, blood supply to the penis is not impaired. Never use standard adhesive tape to secure a condom catheter because it does not expand with change in penis size and is painful to remove.

The end of the condom is attached to plastic drainage tubing and a bag that you attach to the side of the bed or strap to the patient's leg. The condom catheter itself poses little risk of UTI. Infections usually result from buildup of secretions around the urethra, trauma to the urethral meatus, or buildup of pressure in the outflow tubing. If the condom catheter is made of opaque material, remove it daily to check for skin irritation. Some new condom catheters are more transparent, and you are able to observe the skin through them more easily. Change the condom catheter daily. With each catheter change clean the urethral meatus and penis thoroughly. Check the drainage tubing often for patency because twisting the condom at the drainage tube attachment irritates the skin and obstructs urine outflow. Make sure that the tip of the penis is at the end of the catheter. If there is space between the end of the penis and the catheter, urine can pool in this space and excoriate the end of the penis.

For a man with a retracted penis, maintaining a conventional condom catheter often proves difficult. Special devices are available to help alleviate this problem (Fig. 45-14). Consult manufacturer guidelines for product application.

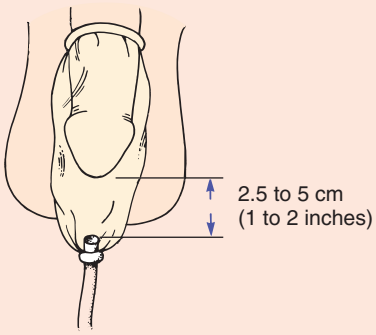
No collection devices for women are as effective as the condom catheter is for men; thus frequently the only devices used are pads and protective clothing. To maintain dignity, do not refer to pads

FIG. 45-14 Retracted penis pouch external urinary device.

BOX 45-11 PROCEDURAL GUIDELINES

Applying a Condom Catheter

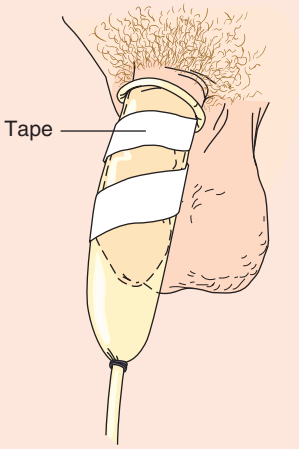
Delegation Considerations



After assessing patient for latex allergy, you can delegate the skill of applying a condom catheter to nursing assistive personnel (NAP). The nurse instructs NAP to:

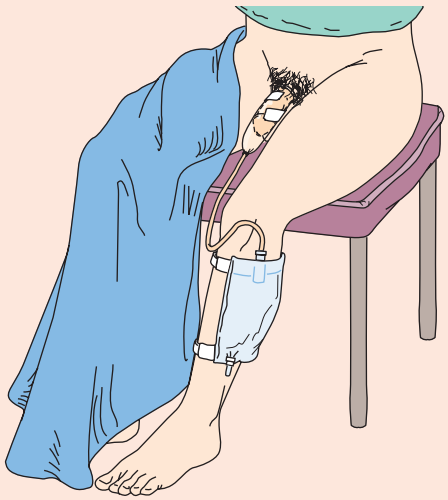
- Be sensitive to privacy needs of patients.
- Be sure that the skin of the penile shaft is intact and free from swelling, redness, or open lesions before applying the condom catheter.
- Ask for assistance if the NAP is uncertain how to apply the adhesive strip that secures the condom catheter.

Equipment



Condom catheter (sometimes comes with self-adhesive or an elastic adhesive), collection bag, skin preparation, basin with warm water, towel and washcloth, clean gloves, scissors or hair guard, bath blanket and sheet

1. Check health care provider's order. Identify patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy.
2. Perform hand hygiene.
3. Assess urinary elimination patterns, patient's ability to urinate voluntarily, and continence.
4. Assess mental status of patient and explain procedure.
5. Provide for privacy by closing room door or bedside curtain. Raise bed to working height and lower side rail on working side.
6. Prepare condom catheter and drainage bag and tubing (see manufacturer directions).
7. Assist patient to supine or sitting position. Place bath blanket over upper torso; fold sheet over lower torso so only penis is exposed.
8. Apply clean gloves, provide perineal care (see Chapter 28), and dry thoroughly. If patient is uncircumcised, return foreskin to normal position.
9. If needed, clip hair at base of penile shaft. Do not shave the pubic area. An alternative to trimming pubic hair is placing a hair guard (see manufacturer directions) over penis before applying catheter.
10. Assess condition of penis and scrotum. Use manufacturer measuring guide to measure diameter of penis in flaccid state. Penile shaft should be at least 2 cm (approximately 1 inch) in length to ensure successful application.
11. *Option:* Apply skin-cleaning preparation to penile shaft and allow to dry.
12. Hold penis along shaft in nondominant hand. With dominant hand hold condom sheath at tip of penis and smoothly roll sheath onto penis. Allow 2.5 to 5 cm (1 to 2 inches) of space between tip of penis and end of catheter (see illustration).



STEP 12 Distance between end of penis and tip of condom.

13. Secure condom catheter according to manufacturer directions.
    a. If using elastic adhesive, wrap strip of adhesive over condom to secure it in place by using spiral technique (see illustration). *Note: Never use adhesive tape.*
    b. For self-adhesive catheter, apply catheter as in Steps 11 and 12; then apply gentle pressure on penile shaft for 10 to 15 seconds to secure.
14. Connect drainage tubing to end of condom catheter. Be sure that condom is not twisted. Connect catheter to large-volume drainage bag or leg bag (see illustration). Attach large-volume drainage bag to lower bed frame. Coil excess tubing on bed.
15. Make patient comfortable, lower bed, and place side rails as appropriate.
16. Dispose of contaminated supplies, remove gloves, and perform hand hygiene.
17. Observe urinary drainage, drainage tube patency, condition of penis, and tape placement.

STEP 13a Apply elastic tape in spiral fashion to secure condom catheter to penis.

STEP 14 Attach condom catheter tubing to leg bag.

and protective clothing as adult diapers and change them frequently to control odor. Only use these products temporarily to minimize or prevent episodes of incontinence while treatment is ongoing. Monitor patients frequently and provide good skin care to prevent irritation caused by urine. Some manufacturers have developed a female urinal; however, their ease of use may be an issue.

Restorative Care. Some patients regain normal urinary voiding function through special activities such as bladder retraining, habit training, or cognitive therapy. In some cases self-catheterization may be used to restore a measure of control to the patient.

Strengthening Pelvic Floor Muscles. Patients who have stress or urge urinary incontinence and difficulty starting and stopping urination may benefit from **pelvic floor exercises.** Pelvic floor exercises, also known as **Kegel exercises,** improve the strength of pelvic floor muscles and consist of repetitive contractions of muscle groups. These exercises have demonstrated effectiveness in treating stress incontinence, OAB, and mixed cause of urinary incontinence. A patient begins these exercises during voiding to learn the technique. They are then practiced at nonvoiding times. Improvement is usually gradual. Patients need to be alert and motivated to perform the exercises. They need to continue to use them to maintain effectiveness (see Box 45-6). The exercises are noninvasive and carry a low risk of adverse effects.

Bladder Retraining. The goal of bladder retraining is to reduce the voiding frequency and perhaps the bladder capacity (Doughty, 2006). This method is a specific program for patients who have a decreased urge to void or have stress incontinence since it keeps the bladder from getting full; thus there is less dribbling. Ultimately the overall goal of this retraining is to restore a normal pattern of voiding by teaching patients to keep the patient continent. Initially patients keep a bladder diary or log noting times, volumes, fluid intake, and any other related symptoms. This provides a baseline for comparison during the retraining. For bladder retraining to be successful, patients must agree to it and be alert and physically able to follow a training program. Bladder retraining is very important in long-term care and rehabilitation facilities. Remember that keeping a patient with a severely spastic bladder from frequent toileting causes pain for the patient. Nurses should never refuse to toilet a patient. Urological consultation can be helpful; and, if treated properly, bladder capacity will increase.

Assess the patient's current pattern of urination. This information allows the nurse to plan a program that often takes 2 weeks or more to learn. Although patients may start the program in the hospital or in rehabilitation, they may need to continue it in an extended care facility or at home. Generally the patient is asked to suppress urination for each voiding and increase time by increments of 15 minutes every week. The goal is to void every 3 to 4 hours in volumes of 240 to 500 mL. If the patient has an underlying UTI, treat this at the same time.

As part of restorative and rehabilitative care, patients with different types of incontinence may benefit from specific measures that address particular continence issues. These guidelines help patients control factors that affect the number of incontinence episodes.

The following measures may help patients with stress urinary incontinence to gain control over urination:

- Learning exercises to strengthen the pelvic floor (see Box 45-6)
- Initiating a toileting schedule on awakening, at least every 2 hours during the day and evening, before getting into bed, and every 4 hours at night (individualizing time frame as needed)
- Avoiding an overfilled bladder because this increases chances of incontinence related to increased bladder pressure
- Minimizing tea, coffee, other caffeine drinks (increases urine production, frequency, and urgency) and alcohol (increases urine production)
- Taking prescribed diuretic medication early in the morning
- Following a weight-control program if obesity is a problem that is causing increased abdominal pressure

Habit Training. A patient with functional incontinence benefits from habit training, which helps patients improve voluntary control over urination. A patient establishes a flexible toileting schedule based on his or her pattern. Have the patient establish the pattern by documenting episodes of incontinence and scheduling voiding opportunities just before the urge time interval. The goal is to keep the patient dry. Help him or her to the bathroom before the urge usually occurs. Time fluids and medications to prevent interference with the toileting schedule. Patients with moderate or severe mental or physical dysfunction and those who have normal bladder function or overflow reflex incontinence benefit from habit training. When combined with positive reinforcement to reward successful voiding, this approach is also called *prompted voiding.*

Building Competency in Safety You are caring for a 70-year-old male patient who has urgency and is incontinent of urine. An indwelling catheter is prescribed for the incontinence. What is your responsibility in this situation to promote patient safety? Provide the rationales for your answer.

Answers to questions can be found on the Evolve website.

Self-Catheterization. Some patients with chronic disorders such as spinal cord injury learn to perform self-catheterization. A patient must be able to physically manipulate equipment and assume a position for successful catheterization. You teach the patient the structures of the urinary tract, clean-versus-sterile technique, the importance of adequate fluid intake, and the frequency of self-catheterization. Generally the goal is to have patients perform self-catheterization 4 to 6 times a day with volumes of 400 to 500 mL; but be sure to individualize the schedule.

Maintenance of Skin Integrity. The normal acidity of urine is irritating to skin. Urine allowed to remain in contact with the skin becomes alkaline, causing encrustations or precipitates to collect on it, fostering breakdown. Washing with mild soap and warm water is the best way to remove urine from skin. Body lotion keeps skin moisturized, and petroleum-based ointments provide a barrier to the urine. Patients who wet their clothing need to receive partial baths and dry clothing after voiding. Continuous exposure of the perineal area or skin around an ostomy leads to gradual maceration and excoriation (see Chapter 48) requiring special care.

When the skin becomes irritated or inflamed, often the health care provider prescribes a cream or spray containing steroids (e.g., Kenalog) to reduce inflammation. If fungal growth develops, the antifungal drug nystatin (Mycostatin), available in cream or powder, is effective.

Promotion of Comfort. Patients with urinary alterations become uncomfortable as a result of the symptoms of urinary problems. Frequent or unpredictable voiding, dysuria, and painful distention are sources of discomfort.

The incontinent patient gains comfort from having clean, dry clothing. When stress incontinence is the problem, a protective pad

offers protection against soiling. Wet clothing adheres to the skin and can cause rubbing and irritation.

Urinary analgesics that act on the urethral and bladder mucosa (e.g., phenazopyridine) relieve dysuria. Often you combine this drug with sulfonamide antibiotics in preparations such as Azo-Gantanol and Azo-Gantrisin. Patients taking drugs with phenazopyridine need to be aware that their urine will be orange. They must drink large amounts of fluids to prevent toxicity from the sulfonamides and maintain optimal flow through the urinary system (Lehne, 2010).

If the patient has local discomfort from an inflamed urethra, an iced sitz bath provides pain relief. The patient is often relaxed after a sitz bath; thus voiding occurs easily. Patients cannot relieve pain of distention unless they are able to empty the bladder. Interventions that stimulate micturition or intermittent catheterization may be the only sources of pain relief.

EVALUATION

Through the Patient's Eyes. The patient is the best source of evaluation of outcomes and responses to nursing care (Fig. 45-15). Note his or her responses to questions about urination. Does he or she seem hesitant or embarrassed? Psychosocial factors such as culture or sexuality sometimes influence the patient's response. Because urination is often considered a private matter, some people find it difficult to talk about their voiding habits. Remember that urinary elimination problems are not just physiological in nature. Be sensitive to any changes in self-concept and sexuality. Self-concept, which includes body image, self-esteem, roles, and identity, develops over a life span. Because the penis is an organ for both urination and sex, urinary dysfunction often greatly affects a man's self concept.

Patient Outcomes. You also evaluate the effectiveness of nursing interventions through comparisons with the outcome goals. Evaluate for changes in the patient's voiding pattern and continued presence of urinary tract alteration. Actual outcomes are compared with expected outcomes to determine success or partial success in achieving those outcomes. Examples of questions to ask for evaluation include:

- "Tell me, how frequently are you voiding now?"
- "Do you continue to have the feeling of urgency every time you void?"
- "Have the symptoms of urgency decreased since you changed your caffeine intake?
- "Do you still have burning when you pass urine?
- "Do you still feel uncomfortable over your lower abdomen?"

Evaluation of an intervention that may take weeks to accomplish such as pelvic floor exercises requires follow-up beyond the hospital or rehabilitation facility. Specific information about how well an intervention has met the need determines if you need to revise the plan of care. Continuous evaluation allows you to determine whether any new symptoms or nursing diagnoses have developed. Help the patient redefine goals when impairment in function is not likely to be altered as completely as the patient might like.

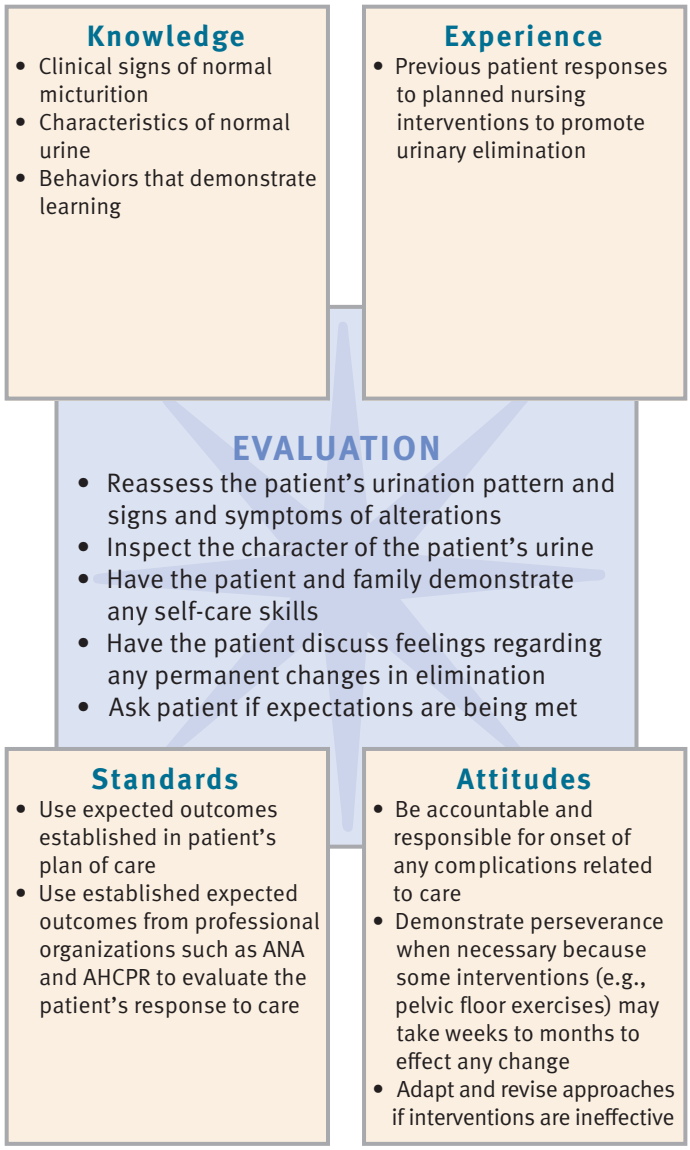


FIG. 45-15 Critical thinking model for urinary elimination evaluation. *AHCPR,* Agency for Health Care Policy and Research; *ANA,* American Nurses Association.

SAFETY GUIDELINES FOR NURSING SKILLS

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate a patient's priorities of care and preferences and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe individualized patient care.

- Follow principles of surgical and medical asepsis as indicated when performing catheterizations, handling urine specimens, or helping patients with their toileting needs.
- Identify patients at risk for latex allergies (i.e., patient history of hay fever; asthma; and allergies to certain foods such as bananas, grapes, apricots, kiwi fruit, and hazelnuts).
- Identify patients with allergies to povidone-iodine (Betadine). Provide alternatives such as chlorhexidine.

SKILL 45-1 COLLECTING MIDSTREAM (CLEAN-VOIDED) URINE SPECIMEN

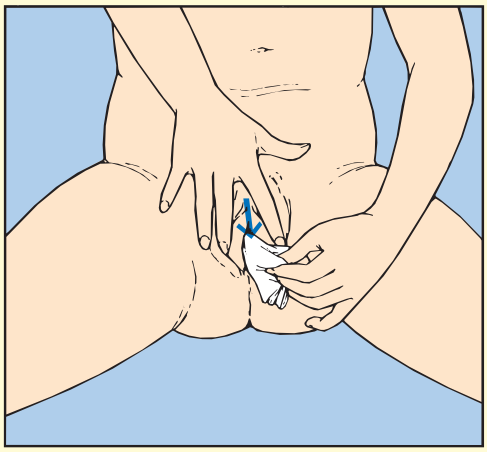
View Video!

Delegation Considerations

The skill of collecting midstream (clean-voided) urine specimens can be delegated to nursing assistive personnel (NAP). If appropriate, you can instruct an alert patient who is physically able to collect the specimen. It is the nurse's responsibility to ensure that this specimen is obtained correctly and in a timely manner. Be knowledgeable about agency policy regarding specimen collection. Direct the NAP to:

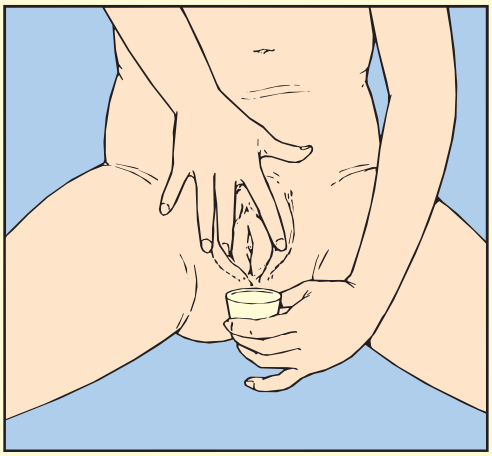
- Consider patient's mobility restrictions and inform the nurse when the specimen is obtained.
- Inform the nurse if patient is unable to initiate a stream or has pain or burning on urination.
- Inform the nurse if the collected specimen is dark, bloody, cloudy, or odorous or contains mucus.

Equipment

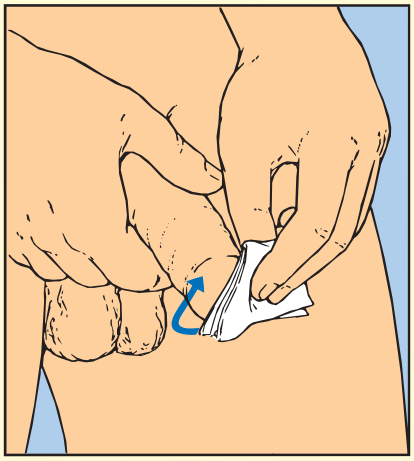


- Soap or cleaning solution, washcloth, and towel
- Commercial kit for clean-voided specimen or individual supplies as listed
  - Sterile cotton balls or sterile 2 × 2 or 4 × 4 gauze pads
  - Antiseptic solution (e.g., chlorhexidine [Hibiclens] or povidone-iodine [Betadine]); check for patient allergy to iodine (if allergic, provide alternative such as chlorhexidine)
  - Sterile water or saline
  - Sterile specimen container
- Clean gloves
- Bedpan, bedside commode, or specimen hat
- Completed specimen label with proper patient identifiers
- Completed laboratory requisition form and biohazard bag

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medical record.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
2 Assess voiding status of patient.	
a. When patient last voided	Indicates bladder fullness.
b. Level of awareness or developmental stage	Reveals patient's ability to cooperate during procedure.
c. Mobility, balance, coordination, and physical limitations	Determines level of assistance in acquiring specimen.
3 Assess for signs and symptoms of UTI.	Indicates need to screen for bacteria in urine.
4 Assess patient's understanding of purpose of test and method of collection.	Allows you to clarify misunderstandings and promotes patient cooperation.
PLANNING	
1 Provide fluids to drink ½ hour before collection unless contraindicated (i.e., fluid restriction) if patient does not feel urge to void.	Improves likelihood of patient being able to void.
2 Explain procedure to patient:	Helps patient understand procedure.
a. Reason midstream specimen is necessary	
b. Ways for patient and family to assist	
c. Ways to obtain specimen free of feces	Feces change characteristics of urine and cause abnormal values.
d. Use visual aids (if applicable) to explain procedure	Illustrations demonstrating midstream collection techniques help to clarify a complex procedure, especially with patients for whom English is a second language.
IMPLEMENTATION	
1 Perform hand hygiene.	Decreases likelihood of transfer of microorganisms.
2 Provide privacy for patient by closing door or bed curtain.	Privacy allows patient to relax and produce specimen more quickly.
3 Give patient or family member cleaning towelette or soap, washcloth, and towel to clean perineal area or assist dependent patient (wear gloves).	Patient often prefers to wash own perineal area. Cleaning prevents contamination of specimen as urine passes from urethra.
4 Assist patient who cannot ambulate onto bedpan. Raise head of bed.	Provides easy access to perineal area to collect specimen. Semi-sitting position may ease voiding.
5 Using surgical asepsis, open sterile kit (see illustration) or prepare sterile supplies.	Sterile technique is essential to maintaining sterility of equipment and specimen.
6 Apply sterile gloves (when assisting dependent patient) after opening sterile specimen cup, placing cap with sterile inside surface up; do not touch inside of container or cap (see Chapter 28).	Sterile gloves prevent introduction of microorganisms from nurse's hands to specimen. Contaminated specimen is most frequent reason for inaccurate reporting of urine cultures and sensitivities.
7 Pour antiseptic solution over cotton balls or gauze pads unless kit contains prepared gauze pads in antiseptic solution.	Use cotton balls or gauze pads to further clean the perineum.



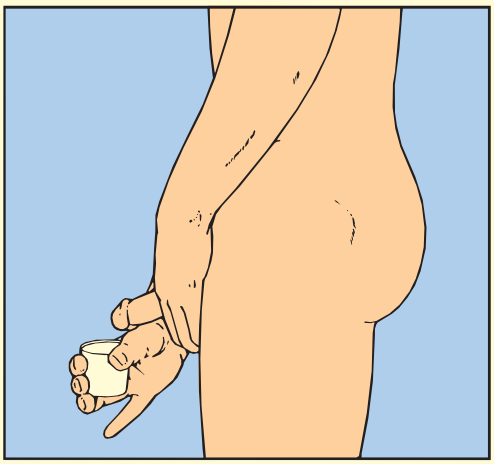
STEP	RATIONALE



STEP 5 Commercial midstream urine collection kit.

STEP 8a(2) Cleaning technique (female).

STEP 8a(4) Specimen collection (female).



STEP 8b(1) Cleaning technique (male).

8 Perform urine collection by assisting or allowing patient to independently clean perineum and collect specimen:	
a. Female	
(1) Spread labia with thumb and forefinger of nondominant hand.	Provides access to urethral meatus.
(2) Clean area with cotton ball or gauze, moving from front (above urethral orifice) to back (toward anus). Using a fresh swab each time, repeat front-to-back motion 3 times (begin with left side, then right side, then center) (see illustration).	Clean from area of least contamination to area of greatest contamination to decrease bacterial levels.
(3) If agency policy indicates, rinse area with sterile water and dry with dry cotton ball or gauze.	Prevents contamination of specimen with antiseptic solution.
(4) While continuing to hold labia apart, have patient initiate stream. After patient starts urine stream, pass container into stream and collect 30 to 60 mL (see illustration).	Initial stream flushes out microorganisms that accumulate at urethral meatus and prevents transfer into specimen.
(5) If menstruating, record this on the laboratory requisition form.	
b. Male	
(1) Hold penis with one hand and, using circular motion and antiseptic swab, clean end of penis, moving from center to outside (see illustration). In uncircumcised men retract foreskin before cleaning.	Clean from area of least contamination to area of greatest contamination to decrease bacterial levels.
(2) If agency procedure indicates, rinse area with sterile water and dry with cotton or gauze.	Prevents contamination of specimen with antiseptic solution.

SKILL 45-1 COLLECTING MIDSTREAM (CLEAN-VOIDED) URINE SPECIMEN—cont'd

STEP	RATIONALE
(3) After patient has initiated urine stream, pass specimen collection container into stream and collect 30 to 60 mL (see illustration).	Initial stream flushes out microorganisms that accumulate at urethral meatus and prevents transfer into specimen.

STEP 8b(3) Specimen collection (male).

9 Remove specimen container before flow of urine stops and before releasing labia or penis. Patient finishes voiding in bedpan or toilet.	Prevents contamination of specimen with skin flora.

CLINICAL DECISION: *If foreskin was retracted for specimen collection, replace it over the glans. If foreskin is not replaced, swelling and constriction occur, causing pain and possible obstruction to urine flow.*

10 Replace cap securely on specimen container (touch outside only).	Retains sterility of inside of container and prevents spillage of urine.
11 Clean any urine from exterior surface of container. Attach label on side of container in front of patient. Place in a plastic specimen biohazard bag as required by agency.	Prevents transfer of microorganisms to others.
12 Remove and empty bedpan (if applicable) and assist patient to comfortable position.	Promotes relaxing environment.
13 Attach laboratory requisition to specimen bag.	Prevents inaccurate identification and minimizes errors in diagnosis or treatment.
14 Remove gloves, dispose of them in proper receptacle, and perform hand hygiene.	Reduces transmission of infection.
15 Transport specimen to laboratory within 15 to 30 minutes or refrigerate immediately.	Because bacteria grow quickly in urine, urine not received by laboratory within 30 minutes should be refrigerated. However, refrigeration should not exceed 2 hours (Pagana and Pagana, 2010).

EVALUATION

1 Observe characteristics of urine and contaminants.	Contaminants prevent specimen from being used.
2 Evaluate laboratory results of urine test.	Determines presence of bacteria and kidney function.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Urine specimen is contaminated with feces or toilet paper.
- Repeat instruction to patient or assist patient in obtaining specimen.
- Obtain a new specimen.
- Request an order for using a straight catheterization to obtain specimen.

2 Specimen is accidentally discarded.
- Repeat specimen collection.

RECORDING AND REPORTING

- Record date and time urine specimen was obtained in nurses' notes.
- Notify health care provider of any significant abnormalities.

HOME CARE CONSIDERATIONS

- If patient is to collect specimen as outpatient, a clean technique may be used. Provide instruction for collection and appropriate equipment.
- Provide information about storing specimen until time for delivery to health care provider's office or hospital laboratory.

SKILL 45-2 INSERTING A STRAIGHT OR INDWELLING CATHETER

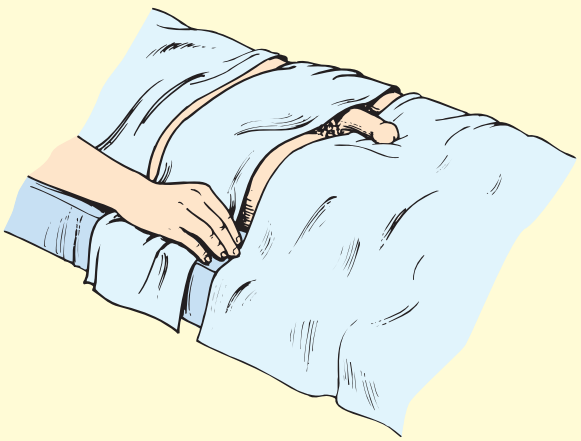
Delegation Considerations

The skill of inserting a straight or an indwelling catheter cannot be delegated. The nurse is responsible for assessing the need for and evaluation of catheterization. The nurse directs nursing assistive personnel (NAP) to:

- Assist with positioning the patient and maintaining patient privacy and comfort, emptying urine from the collection bag, and providing perineal care.
- Report patient discomfort or fever to the nurse.
- Report abnormal color, odor, and amount of urine in drainage bag to the nurse.

Equipment

- Catheterization kit containing the following sterile items:
  - Gloves (extra pair optional)
  - Drapes, one fenestrated
  - Lubricant
  - Antiseptic cleaning solution such as povidone-iodine (Betadine) or alternative chlorhexidine (Hibiclens) if allergic to iodine
  - Cotton balls
  - Forceps
  - Prefilled syringe with sterile water to inflate balloon of indwelling catheter
  - Catheter of correct size and type for procedure (i.e., intermittent or indwelling)
  - Sterile drainage tubing with collection bag and multipurpose tube holder or tape and elastic band for securing tubing to bed if patient is bed bound (for indwelling catheter)
  - Receptacle or basin (usually bottom of catheterization tray)
  - Specimen container
- Also needed
  - Clean gloves for perineal care
  - Bath blanket
  - Appropriate light source (e.g., room lighting adapted or additional lighting such as an examination lamp)

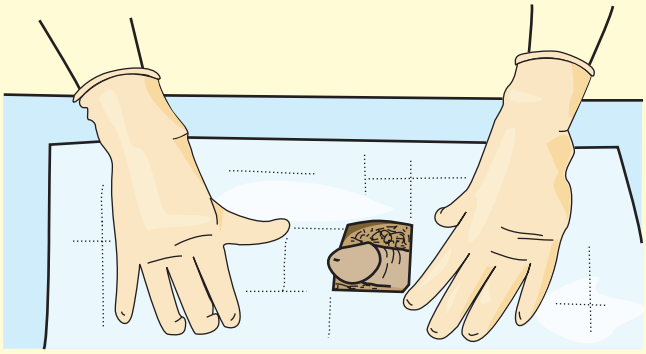


STEP	RATIONALE
ASSESSMENT	
1 Review patient's medical record, including health care provider's order and nurses' notes. When appropriate, determine previous catheterization, including catheter size.	Determines purpose of inserting catheter: preparation for surgery, urinary irrigations, collection of sterile specimens, or measurement of residual urine.
2 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
3 Assess status of patient:	
a. Last time patient urinated from intake and output (I&O) flow sheet or palpate bladder or perform bladder scan	Determine time of last voiding or potential for bladder fullness. Scanner measures presence of urine.
b. Level of awareness or developmental stage	Reveals patient's ability to cooperate and level of explanation needed.
c. Mobility and physical limitations of patient	Affect way the nurse positions patient.
d. Patient's gender and age	Determines catheter size: 5- to 6-Fr generally for an infant; 8- to 10-Fr used for children; 14- to 16-Fr recommended for most patients. Men often need a slightly larger size (such as a 16- to 18-Fr) than women. Large catheters (greater than 16-Fr can distend the urethra, permanently damage the urethra and bladder neck, and cause bladder spasms and leaking around the catheter (Hart, 2008). Use the smallest size catheter possible to minimize trauma and promote adequate drainage of the periurethral glands. This decreases the risk for infection (Hart, 2008; Senese et al., 2006a).
e. Note any pathological condition that impairs passage of catheter (e.g., enlarged prostate in men).	Obstruction prevents passage of catheter through urethra into bladder. Often requires use of Coudé catheter.
f. Perform hand hygiene. Apply clean gloves. Inspect perineum for erythema, drainage, and odor. Remove gloves following inspection and perform hand hygiene.	Reduces infection. Determines condition of perineum.
g. Allergies.	Procedure risks exposure to allergies associated with antiseptic, tape, latex, and lubricant. Allergy to povidone-iodine is common. Alternatives to povidone-iodine include chlorhexidine or Sur-Clens (Senese et al., 2006b, 2006c).
4 Assess patient's knowledge of purpose for catheterization.	Reveals need for patient instruction.

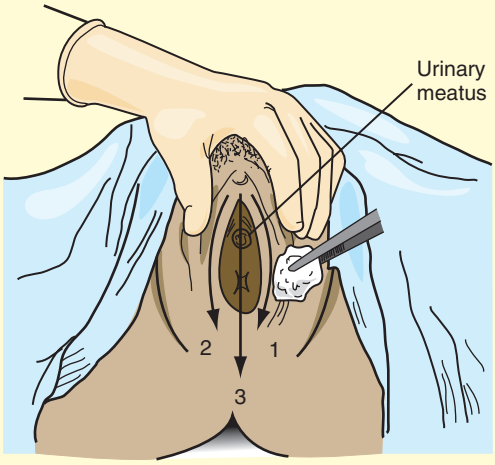
SKILL 45-2 INSERTING A STRAIGHT OR INDWELLING CATHETER—cont'd

STEP	RATIONALE
PLANNING	
1 Explain procedure to patient.	Promotes cooperation.
2 Arrange for extra nursing personnel to assist as necessary.	Some patients are unable to assume positioning for procedure.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Close curtain or door.	Offers privacy, reduces embarrassment, and aids in relaxation during procedure.
3 Raise bed to appropriate working height. Facing patient, stand on left side of bed if right-handed (on right side of bed if left-handed). Clear bedside table and arrange equipment. If side rails are in use, raise side rail on opposite side of bed and put side rail down on working side.	Promotes use of proper body mechanics. Successful catheter insertion requires nurse to assume comfortable position with all equipment easily accessible. Use of side rails in this manner promotes patient safety.
4 Place waterproof pad under patient.	Prevents soiling of bed linen.
5 Position patient.	
a. **Female patient**	
(1) Assist to dorsal recumbent position (supine with knees flexed). Ask patient to relax thighs so you can rotate hips. Support legs with pillows to reduce muscle tension and promote comfort.	Provides good visualization of perineal structures. This position is optimal because it minimizes risk for contamination by fecal material (Cochran, 2007).
(2) Position female patient in side-lying (Sims) position with upper leg flexed at hip if unable to assume dorsal recumbent position.	This alternate position is used if patient cannot abduct leg at hip joint (e.g., if patient has an arthritic joint). It is also more comfortable for patient. Support patient with pillows if necessary to maintain position.
b. **Male patient**	
(1) Assist to supine position with thighs slightly abducted.	Comfortable position for patient that aids in visualization.
6 Drape patient.	
a. **Female patient**	
(1) Drape with bath blanket. Place blanket diamond fashion over patient, with one corner at patient's midsection, side corners over each thigh and abdomen, and last corner over perineum (see illustration).	Avoids unnecessary exposure of body parts and maintains patient's comfort.
b. **Male patient**	
(1) Drape upper trunk with bath blanket and cover lower extremities with bed sheets, exposing only genitalia (see illustration).	Avoids unnecessary exposure of body parts and maintains patient's comfort.

STEP 6a(1) Draping technique (female).



STEP 6b(1) Draping technique (male).



STEP	RATIONALE
7 Wearing clean gloves, wash perineal area with soap and water as needed; dry thoroughly. Remove and discard gloves; perform hand hygiene. Position light source to illuminate perineal area. (Have an assistant hold flashlight if necessary.)	Washing ensures that area is not contaminated before catheter insertion (Leaver, 2007). It is sometimes difficult to see urinary meatus of female patient because of individual anatomical differences (Senese et al., 2006a). Permits accurate identification and good visualization of urethral meatus.
8 Open outer wrapping of the indwelling Foley catheterization kit by tearing package on paper-lined edge of plastic wrap. Place inner wrapped box on easily accessible, clean bedside table or set between patient's legs. Patient's size and positioning dictates exact placement. Place empty package (outer plastic wrap) near end of bed and use for waste disposal.	Provides easy access to supplies during catheter insertion. Maintains aseptic technique during procedure.
9 *Open sterile wrap covering box containing catheter supplies:* Using sterile technique (see Chapter 28), fold back each flap of sterile package one at a time, with last flap opened toward patient.	The tray is now open and sitting on its own sterile field.
a. Supplies in intermittent catheterization tray are contained in sterile receptacle that can be used for urine collection.	
b. Supplies in an indwelling catheter box are arranged in sequence of use.	
10 Apply waterproof sterile drape (when packed as first item in tray). Sterile gloves may be packed as first item (see Step 11).	
a. Female patient	
(1) Remove square sterile drape from the tray, touching edges (2.5 cm [1-inch] border) only. Do not touch any other item in kit (see Chapter 28).	Keeps drape and items sterile.
(2) Maintain sterility of drape and let it unfold after removing from tray. Fold top edge of drape (2.5-5 cm [1-2 inches]) away from patient to form cuff over both hands.	
(3) Have patient lift hips (if patient is unable to lift hips, get assistance).	
(4) Place sterile drape with plastic (shiny) side down under patient's buttocks.	Creates sterile field over which you work during catheterization.
(5) Apply sterile gloves and proceed to Step 12.	
b. Male patient	Creates sterile field.
(1) Use of square sterile drape is optional; you may apply fenestrated drape instead (see Step 12). Remove and unfold as with female (see Step 10a).	
(2) Apply drape over thighs just below penis (instead of under buttocks as in female).	
11 Apply sterile gloves. (When packed as first item in tray, apply and then place square drape [see Step 10].)	Apply drapes either with or without sterile gloves, depending on sequence of packaging.
12 Apply fenestrated drape:	
a. Female patient	
(1) Pick up fenestrated drape out of tray. Allow it to unfold without touching nonsterile surface. Form cuff from edges to protect sterile gloves. Apply drape over perineum, exposing labia, and be sure not to touch contaminated surface.	Creates sterile field around perineum with opening that allows you to manipulate perineum.
b. Male patient	
(1) Apply drape over thighs and below penis without completely opening it. Use this technique when you choose not to apply square sterile drape.	Either a square or fenestrated drape may be used with male patient to create sterile field.
(2) Pick up fenestrated sterile drape and allow it to unfold without touching nonsterile surface. Form cuff from edges to protect sterile gloves; drape it over penis with fenestrated slit resting over penis (see illustration).	Maintains sterility of work surface while only exposing penis.
13 Move tray/box on sterile field closer to patient. In the case of female patient, sterile wrap under tray/box and drape form a continuous field.	Prevents you from reaching over nonsterile area when manipulating sterile catheter.
a. Organize remaining items on sterile field. *Indwelling catheter:* Take top tray out of box and place it on sterile field. (Sterile catheter and drainage bag are under top tray in box.) Make sure that clamp on drainage port of bag is closed. If drainage bag is preconnected to catheter, leave bag on sterile field until catheter is inserted. If drainage bag is not connected to catheter, open package containing sterile collection bag and drainage tubing. Keep cover on tip of drainage tubing until ready to connect to catheter.	Maintains principles of surgical asepsis and organizes work area. Keeping cover on tip of sterile drainage tubing prevents contamination.

SKILL 45-2 INSERTING A STRAIGHT OR INDWELLING CATHETER—cont'd

STEP	RATIONALE

STEP 12b(2) Draping male with fenestrated drape.

STEP 16a(2) Cleaning female perineum.

b. *Intermittent catheter:* There is no drainage bag in container or specimen container.

c. Loosen lid on sterile specimen container if urine specimen is required. Otherwise discard into waste disposal bag.
Makes container accessible to receive urine from catheter if specimen is needed.

d. Open package of sterile antiseptic solution. Pour solution over sterile cotton balls. NOTE: Sometimes there are sterile antiseptic swabs instead of solution. If swabs are available, open package with "stick" ends up.

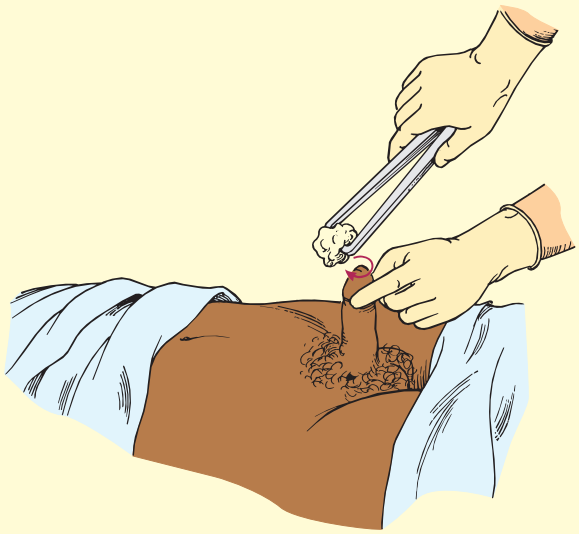
e. Open packet containing lubricant. NOTE: Lubricant is sometimes in prefilled syringe. If in prefilled syringe, remove protective cap. Spread lubricant into sterile tray.
Prepares lubricant for catheter.

14 Remove plastic covering from catheter (usually on indwelling catheter only). Take care to coil length of catheter in palm.
Do not pretest balloon.
Prevents contamination of catheter.

CLINICAL DECISION: *Pretesting balloon by injecting fluid from the prefilled sterile water syringe into the balloon port is no longer recommended. Testing the balloon may distort and stretch it and lead to damage, causing increased trauma on insertion (Smith, 2006).*

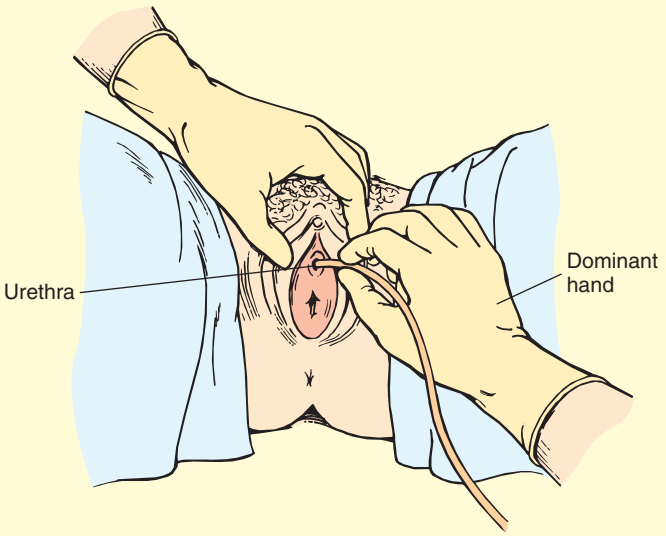
15 Place length of catheter in lubricant: Lubricate catheter 2.5-5 cm (1-2 inches) for women and 12.5-17.5 cm (5-7 inches) for men.
Lubricating catheter minimizes urethral trauma and discomfort when inserting it.

16 Clean urethral meatus:



a. Female patient

(1) With nondominant hand fully expose urethral meatus by spreading labia. Have NAP use flashlight if unable to visualize with available lighting. Maintain position of nondominant hand throughout procedure.
Optimal visualization of urethral meatus is possible. Fully spreading labia prevents contamination of urethral meatus during cleaning.
NOTE: Closure of labia during cleaning requires that cleaning procedure be repeated.

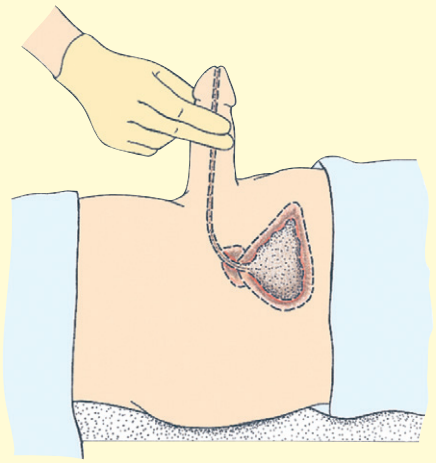


(2) Using forceps in sterile dominant hand, pick up cotton ball saturated with antiseptic solution or antiseptic swab stick and clean perineal area, wiping from front to back from clitoris toward anus. Using a new cotton ball or swab for each area you clean, wipe far labial fold, near labial fold, and directly over center of urethral meatus (see illustration).
Cleaning reduces number of microorganisms at urethral meatus.
Use of a new cotton ball for each wipe prevents transfer of microorganisms. Cleaning for each of the three areas proceeds from area of least to most contamination. Dominant hand remains sterile.

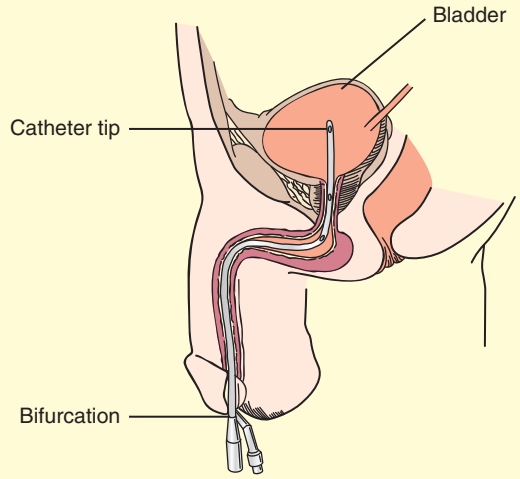
STEP	RATIONALE
b. Male patient	
(1) If patient is not circumcised, retract foreskin with nondominant hand.	Exposes urethral meatus
(a) Grasp penis at shaft just below glans.	
(b) Gently spread urethral meatus so opening is more visible. Keep nondominant hand in this position throughout procedure.	Accidental release of foreskin or dropping of penis during cleaning requires repeating process because area becomes contaminated.
(2) With dominant hand pick up antiseptic-soaked cotton ball with forceps or swab stick and clean penis. Move cotton ball or swab in circular motion from urethral meatus down to base of glans. Repeat cleaning 3 more times, using clean cotton ball/stick each time (see illustration).	Reduces number of microorganisms at urethral meatus. Follows principles of medical aseptic technique (see Chapter 28). Dominant gloved hand remains sterile.
17 Pick up catheter with gloved dominant hand 7.5-10 cm (3-4 inches) from catheter tip. Hold end of catheter loosely coiled in palm of dominant hand. Place distal end of catheter in urine tray receptacle if straight catheterization is ordered.	Prevents soiling of patient and bed with draining urine.
18 Insert catheter:	
a. Female patient	
(1) Ask patient to bear down gently as if to void and slowly insert catheter through urethral meatus (see illustration).	Relaxation of external sphincter aids in insertion of catheter.
(2) Advance catheter a total of 7.5 cm (3 inches) in adult or **until urine flows out of catheter end.** When urine appears, advance catheter another 2.5-5 cm (1-2 inches). Do not use force to insert catheter.	Female urethra is short. Appearance of urine indicates that catheter tip is in bladder or lower urethra.
(3) Release labia and hold catheter securely with nondominant hand. **Proceed to Step 20 for balloon inflation (indwelling Foley only).**	Bladder or sphincter contraction causes accidental expulsion of catheter.

CLINICAL DECISION: *If no urine appears, catheter may be in vagina. If misplaced, leave catheter in vagina as landmark indicating where not to insert and insert new sterile catheter.*

STEP 16b(2) Cleaning male urinary meatus.



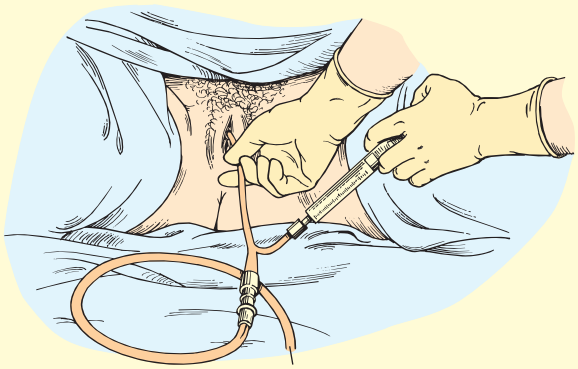
STEP 18a(1) Inserting catheter.



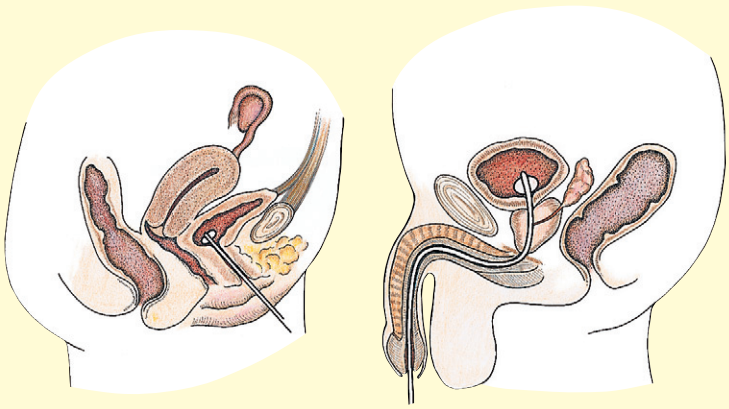
SKILL 45-2 INSERTING A STRAIGHT OR INDWELLING CATHETER—cont'd

STEP	RATIONALE
b. Male Patient	
(1) Lift penis to position perpendicular to patient's body and apply light traction (see illustration).	Straightens urethral canal to ease catheter insertion.
(2) Ask patient to bear down as if to void and slowly insert catheter through urethral meatus.	Relaxation of external sphincter aids in insertion of catheter.
(3) Advance catheter 17-22.5 cm (7-9 inches) in adult *or until urine flows out catheter.* If you feel resistance, withdraw catheter; do not force it through urethra. **If there is resistance to catheter insertion, have patient take slow deep breaths while you insert it slowly** (Senese et al., 2006c). When urine appears, advance catheter to bifurcation (see illustration).	The adult male urethra is long. It is normal to meet resistance at the prostatic sphincter. When resistance is met, hold catheter firmly against sphincter without forcing catheter. After a few seconds the sphincter relaxes, and you advance the catheter. Appearance of urine indicates that catheter tip is in bladder or urethra. Advancement of catheter to bifurcation of drainage and balloon inflation port ensures proper placement of catheter through longer urethra of male patients (Daneshgari et al., 2002; Senese et al., 2006c). Deep breathing during catheter insertion promotes relaxation (Senese et al., 2006c).
(4) Lower penis and hold catheter securely in nondominant hand. **Proceed to Step 20 for balloon inflation (indwelling Foley) only.**	Bladder or urethral contraction can accidentally expel catheter.
(5) Reduce (or reposition) foreskin if necessary.	Prevents accidental dislodgement of catheter. Paraphimosis (retraction and constriction of foreskin behind glans penis) secondary to catheterization occurs if foreskin is not reduced.
19 Collect urine specimen as needed. Fill specimen cup to correct level (20-30 mL).	Allows you to obtain sterile specimen for culture analysis.
20 Inflate balloon fully per manufacturer direction.	
a. While holding catheter with nondominant hand at urethral meatus, take end of catheter in dominant hand and place it between first two fingers of nondominant hand. Maintain secure hold on catheter with nondominant hand.	
b. With free dominant hand connect syringe to end of catheter at inflation valve and slowly inject total amount of solution. Follow manufacturer instructions regarding amount of fluid used for balloon inflation (see illustration).	Inflation of balloon anchors catheter tip in place above bladder outlet to prevent removal of catheter. Note size of balloon on catheter. Most commonly a 5-mL balloon is used and should be inflated with the amount (10 mL) supplied in the prefilled syringe to allow symmetrical expansion (Smith, 2006).
c. After inflating balloon, pull *gently* on catheter tubing until resistance is felt (see illustration).	Ensures that catheter tip is anchored.
d. Connect drainage tubing to retention catheter if it is not already preconnected. Place drainage bag below level of bladder (see illustration); do not place bag on side rails of bed.	Ensures proper drainage by gravity. Placement on side rails increases risk for tension applied to catheter, and bag can be raised above level of bladder.

CLINICAL DECISION: *If you notice resistance to inflation or if patient complains of pain, the balloon is not entirely in the bladder. Stop inflation, aspirate the fluid injected into the balloon, and advance the catheter a little more before attempting to inflate the balloon again.*



STEP 18b(1) Position penis perpendicular to body for catheter insertion.



STEP 18b(3) Male anatomy with correct catheter insertion to bifurcation.

STEP	RATIONALE

STEP 20b Inflating balloon (indwelling catheter) of drainage and balloon inflation port.

STEP 20c Placement of inflated balloon in bladder.

STEP 20d Attach drainage bag to lower bed frame.

21 Allow bladder to empty fully unless agency policy restricts maximal volume of urine to drain with each catheterization (about 500 to 800 mL).

Relieves bladder distention. There is no definitive evidence regarding whether there is benefit in limiting maximal volume drained. Retained urine serves as a reservoir for growth of microorganisms (Smith, 2006).

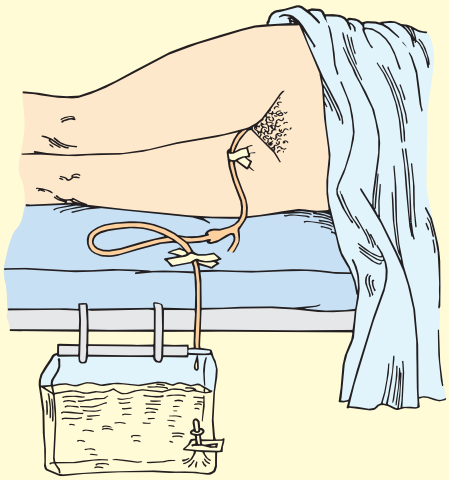
22 Anchor indwelling catheter:

a. Female patient

(1) Secure catheter tubing to inner thigh with strip of nonallergenic tape (use paper tape if allergic to silk tape or a multipurpose tube holder with a Velcro strap). Allow for slack so movement of thigh does not create tension on catheter (see illustration).

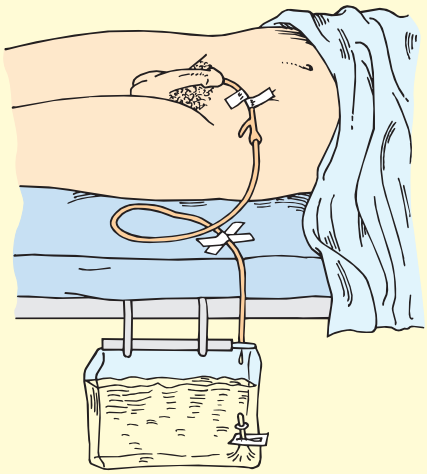
Anchoring catheter to inner thigh reduces pressure on urethra, thus reducing possibility of tissue injury (Smith, 2006).

Also minimizes risk for bleeding, trauma, meatal necrosis, and bladder spasms from pressure and traction (Senese et al., 2006a).



b. Male patient

(1) Secure catheter tubing to top of thigh or lower abdomen (with penis directed toward chest). Allow slack in catheter so movement does not create tension on catheter (see illustration).



Anchoring catheter to lower abdomen reduces pressure on urethra at junction of penis and scrotum, thus reducing possibility of tissue injury (Senese et al., 2006a).

SKILL 45-2 INSERTING A STRAIGHT OR INDWELLING CATHETER—cont'd

STEP	RATIONALE

STEP 22a(1) Tape catheter to inner thigh (female) and coil excess tubing on bed and attach to sheet.

STEP 22b(1) Tape catheter to lower abdomen (male) and coil extra tubing on bed and attach to sheet.

23 Be sure that there are no obstructions in tubing. Coil excess tubing on bed and fasten it to bottom sheet with clip from kit.	Obstructions prevent free flow of urine, leading to bladder retention.
24 Assist patient to comfortable position. Perform catheter care routinely and when secretions build up in perineum (see Skill 45-3).	Maintains comfort and security.
25 Dispose of equipment in proper receptacles, remove gloves, and perform hand hygiene.	Reduces transmission of microorganisms.
26 *For straight or intermittent catheter:* Follow Steps 1-18. Note differences identified between indwelling and straight catheter.	
a. Once catheter is in bladder, allow urine to drain out of end of catheter into sterile urine receptacle. Do not release hold on catheter.	Aim is to drain bladder fully without removing catheter too early.
b. Collect urine specimen if needed by placing end of catheter over specimen container. Collect 20-30 mL of urine.	Urine is used to test for microorganisms.
c. Gently withdraw catheter from bladder while palpating over the patient's bladder with nonsterile hand.	Allows for complete emptying of bladder.
d. Place urine in receptacle in graduated cylinder to measure. Remember to record amount in sterile specimen container as well.	Determines urinary output.
e. Complete Steps 24-25.	

EVALUATION

1 Palpate bladder for distention or perform bladder scan.	Determines if distention is relieved.
2 Ask about patient's comfort.	Determines if patient's sensation of discomfort or fullness has been relieved.
3 Observe character and amount of urine in drainage system.	Determines if urine is flowing adequately.
4 Determine that no urine is leaking from catheter or tubing connections.	Prevents injury to patient's skin.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Urethral or perineal irritation is present.
- Observe for catheter leaking; replace if necessary.
- Assess that indwelling catheter is anchored properly.
- Perform perineal hygiene and catheter care more frequently.

2 Patient has fever, and/or odor is present; or he or she experiences small frequent voiding, burning or bleeding on voiding.
- Obtain clean-voided urine specimen.
- Notify health care provider.

3 Patient experiences urinary retention and is unable to void after you remove the catheter.
- Provide adequate fluid intake and ensure patient privacy.
- If patient is unable to void 4 hours following catheter removal, notify health care provider.

RECORDING AND REPORTING

- Report and record type and size of catheter inserted, amount of fluid used to inflate the balloon, characteristics and amount of urine, reasons for catheterization, specimen collection if appropriate, and patient's response to procedure and teaching concepts.
- Initiate intake and output (I&O) record.
- If catheter is definitely in bladder and no urine is produced within an hour, immediately report absence of urine to health care provider.

HOME CARE CONSIDERATIONS

- Patients at home often use a leg bag during the day and switch to a large-volume bag at night so sleep is uninterrupted.
- Patients who catheterize themselves at home frequently use a clean technique.

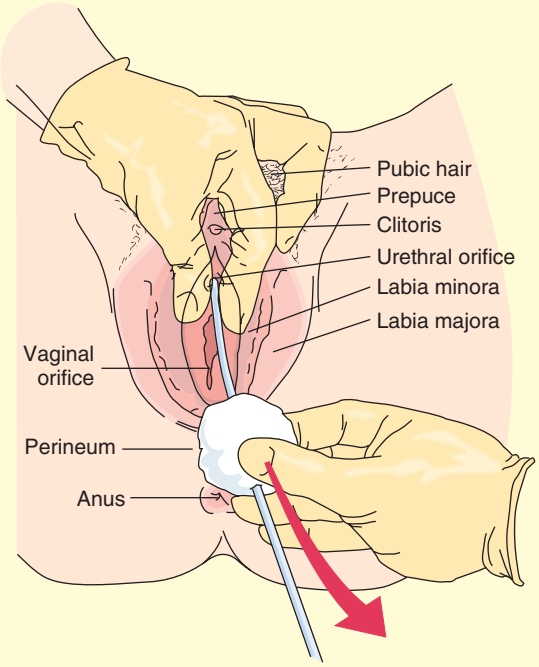
SKILL 45-3 INDWELLING CATHETER CARE

Delegation Considerations

The skill of perineal care is often part of routine hygiene care that can be delegated to nursing assistive personnel (NAP). Proper assessment and care of the perineal area is the responsibility of the nurse. If patient has had trauma or surgical procedures that involve the perineal area, do not delegate this care.

The nurse instructs the NAP to:

- Report patient discomfort and perineal pain, discharge, perineal rash, and/or odor.
- Report condition of the catheter and drainage tubing (e.g., leaks, encrustations).
- Report any discolored or foul-smelling urine.



Equipment

- Catheter care kit or individual supplies
  - Clean gloves
  - Cotton balls or large swabs
  - Clean washcloth and towel
  - Warm water and soap
- Bath blanket
- Waterproof absorbent pad

STEP	RATIONALE
ASSESSMENT	
1 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medical record.	Ensures correct patient. Complies with a recommended National Patient Safety Goal (TJC, 2011).
2 Assess for episode of bowel incontinence or patient discomfort or provide care per agency routine as part of hygiene measures (see Chapter 39).	Accumulation of secretions or feces causes irritation to perineal tissues and acts as source of bacterial growth.
3 Observe any discharge or redness around urethral meatus.	Indicates inflammatory process and possible infection.
4 Assess patient's knowledge of catheter care.	Patients who perform own catheter care may be unsure of touching catheter. Assesses patient's ability and knowledge to provide instruction as needed (Leaver, 2007).
PLANNING	
1 Explain procedure to patient. Offer opportunity to perform self-care to able patient.	Reduces anxiety and promotes cooperation. Embarrassment often motivates patient to perform own hygiene.
2 Close door or bedside curtain.	Maintains patient privacy.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of infection.
2 Position patient:	Ensures easy access and visualization of perineal tissues.
a. **Female**	
(1) Dorsal recumbent position	
b. **Male**	
(1) Supine or Fowler's position	
3 Place waterproof pad under patient.	Protects bed linens from soiling.
4 Drape bath blanket on patient so only perineal area is exposed.	Prevents unnecessary exposure of body parts.
5 Apply clean gloves.	
6 Remove anchor device to free catheter tubing.	

SKILL 45-3 INDWELLING CATHETER CARE—cont'd

STEP	RATIONALE
7 With nondominant hand:	
a. Female	
(1) Gently retract labia to fully expose urethral meatus and catheter insertion site, maintaining position of hand throughout procedure.	Provides full visualization of urethral meatus. Full retraction of labia prevents contamination of meatus during cleaning.
b. Male	
(1) Retract foreskin if not circumcised and hold penis at shaft just below glans, maintaining position throughout procedure.	Retraction of foreskin provides full visualization of urethral meatus.
8 Assess urethral meatus and surrounding tissue for inflammation, swelling, and discharge. Note amount, color, odor, and consistency of discharge. Ask patient if he or she feels any burning or discomfort.	Determines presence of local infection and status of hygiene.
9 Clean perineal tissue:	
a. Female	
(1) Use clean cloth, soap, and water. Clean around urethral meatus and catheter. Avoid getting soap into urethra. Cleaning from pubis toward anus, clean labia minora. Use clean side of cloth for each wipe. Finally clean around anus. Dry each area well.	Perineal care with soap and water is sufficient to keep area clean (Leaver, 2007). Soap entering urethra may cause urinary tract infection (UTI). Application of topical antimicrobial products is not effective in reducing meatal bacterial flora and reducing risk of UTI. Do not include them as part of routine catheter care (Leaver, 2007).
b. Male	
(1) While spreading urethral meatus, clean around catheter first and then wipe in circular motion around meatus and glans.	Cleaning moves from area of least to most contamination.
10 While stabilizing catheter with nondominant hand, clean length of catheter from meatus to tubing in circular motion. Follow agency guidelines (see illustration).	Reduces presence of secretions, drainage, and bacteria on exterior of catheter surface.

STEP 10 Cleaning catheter during catheter care. (From Sorrentino S: *Mosby's textbook for nursing assistants,* St Louis, 2007, Mosby.)

11 Reduce (or reposition) foreskin after care.	
12 Reanchor catheter tubing.	
13 Place patient in safe, comfortable position.	Promotes comfort.
14 Dispose of contaminated supplies, remove gloves, and perform hand hygiene.	Prevents spread of infection.

EVALUATION

1 Inspect condition of urethra and surrounding tissue and ask patient about discomfort.	Determines if area is cleaned properly and/or if patient has any irritation.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Urethral discharge or perineal irritation present
- Observe for leaking from around catheter; catheter may need replacing.
- Increase frequency of indwelling catheter care.
- Notify health care provider.

2 Accidental catheter dislodgement
- Notify health care provider.
- Assess for urethral trauma.
- Monitor urine output.

RECORDING AND REPORTING

- Report and record presence and characteristics of drainage, condition of perineal tissue, and any discomfort reported by patient.
- If infection is suspected, report findings to health care provider.

HOME CARE CONSIDERATIONS

- If patient is discharged with indwelling catheter, teach patient and family catheter care and signs and symptoms to report to nurse or health care provider.

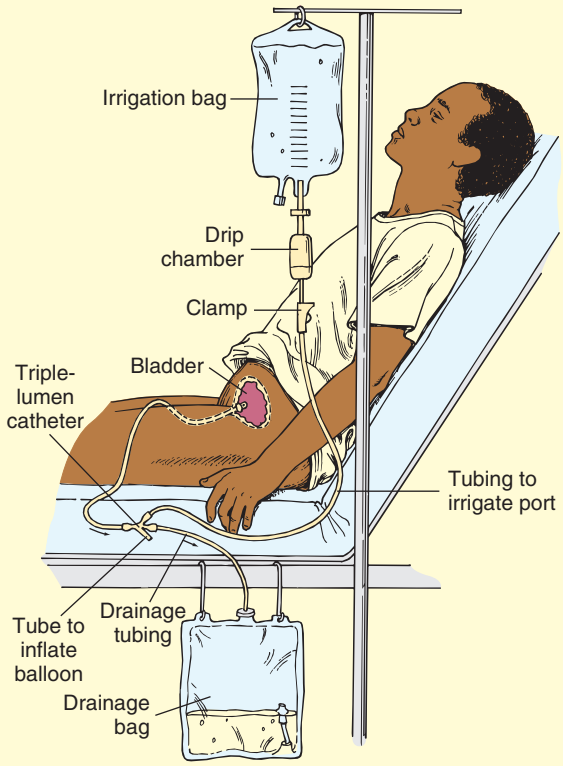
SKILL 45-4 CLOSED CATHETER IRRIGATION

Delegation Considerations

The skill of closed catheter irrigation or instillation cannot be delegated to nursing assistive personnel (NAP). The nurse is responsible for assessing the need for irrigation. Catheter irrigation is usually done in patients with complications such as urinary tract infections (UTIs) or after prostatectomy. The nurse directs NAP caring for the patient to:
- Report patient complaints of pain, discomfort, or fever and leakage of urine around catheter.
- Report the presence of blood clots or a change in color of the urine.
- Monitor and record intake and output (I&O); immediately report any decrease in urinary output.

Equipment

- Closed intermittent method for irrigation or instillation
  - Sterile irrigation or instillation solution at room temperature (unless otherwise ordered)
  - Sterile graduated container
  - Sterile 30- to 50-mL irrigation syringe (used to instill irrigant into catheter)
  - Luer-Lok syringe without needles if used for needleless access port (this varies depending on manufacturer)
  - Sterile 19- to 22-gauge 1-inch needle (if catheter access port is not needleless)
  - Clean gloves
  - Antiseptic swabs
  - Clamp for catheter or tubing
- Closed continuous method
  - Sterile irrigation solution at room temperature (unless otherwise ordered)
  - Irrigation tubing and clamp (with or without a Y connector) (Clamp regulates irrigation flow rate. Y connector allows intravenous [IV] or irrigant bags to be connected to tubing.)
  - IV pole
  - Antiseptic swab
  - Y connector (optional) (used to connect irrigation tubing to double-lumen catheter).
  - Bath blanket



STEP	RATIONALE
ASSESSMENT	
1 Assess patient's record to determine:	
a. Purpose of bladder irrigation.	Allows you to anticipate observations to make (e.g., blood or mucus in urine).
b. Prescriber's order for type and amount of irrigant (e.g., saline).	Order required to initiate therapy. Ensures that correct medication or solution and amount are administered. Amount of solution used to flush system may be a nursing judgment or indicated by prescriber or institution policy. Frequency of irrigation is based on patient's need (e.g., patient who has just had prostate gland surgery may require continuous irrigation for 24 hours).

SKILL 45-4 CLOSED CATHETER IRRIGATION—cont'd

STEP	RATIONALE
c. Type of irrigation: continuous or intermittent.	Allows for selection of proper equipment. In continuous irrigation clamp regulates slow, steady flow into bladder. Because outflow should correspond to regulated drip, patency of catheter must be checked frequently to prevent distention of bladder. For intermittent irrigation instill designated amount of irrigation solution into catheter and clamp catheter or tubing for no longer than 30 minutes. Intermittent irrigation requires close observation of catheter patency between irrigations.
d. Type of catheter used. (NOTE: Appropriate catheter should be inserted during original catheterization.) **(1)** Single lumen (single use) for open intermittent irrigation only **(2)** Double lumen (one lumen to inflate balloon, one to allow outflow of urine) **(3)** Triple lumen (one lumen to inflate balloon, one to instill irrigation solution, one to allow outflow of urine)	Indicates if it is necessary to break into closed system for irrigation.
2 Assess the following:	
a. Color of urine and presence of mucus, clots, or sediment	Indicates if patient is bleeding or sloughing tissue and determines necessity for increasing irrigation rates with continuous irrigations or increasing frequency with intermittent irrigations.
b. Bladder palpation	Determines if urine is draining freely from bladder.
c. Existing closed irrigation system	
(1) Note if fluid entering bladder and fluid draining from bladder are in approximate proportions.	Determines presence of bladder distention.
(2) Determine that drainage tubing is not kinked, clamped off incorrectly, or looped below bladder level.	Determines if system is obstructed. You would expect more output than fluid instilled because of urine production.
(3) Note amount of fluid remaining in existing irrigating solution container.	Allows you to anticipate hanging of new irrigation bag.
3 Review I&O record.	Determines baseline for prior urine output measures. All patients with continuous bladder irrigations should have I&O measurements (see Chapter 41).
4 Identify the patient using two identifiers (i.e., name and birth date or name and account number) according to facility policy. Compare identifiers with information on patient's medical record.	Ensures correct patient. Complies with recommended National Patient Safety Goal (TJC, 2011).
5 Assess patient's knowledge regarding purpose of performing catheter irrigations.	Reveals need for patient instruction.
PLANNING	
1 Explain procedure to patient.	Reduces anxiety and promotes cooperation.
IMPLEMENTATION	
1 Perform hand hygiene and apply clean gloves.	Prevents transmission of microorganisms.
2 Provide privacy by pulling bed curtains closed. Fold back covers so catheter is exposed. Cover patient's upper torso with bath blanket.	Promotes patient comfort and provides easy access to catheter.
3 Position patient in dorsal recumbent or supine position.	Promotes flow of irrigating solution into bladder.
4 *Closed intermittent irrigation or instillation with double-lumen catheter:*	
a. Pour prescribed sterile solution in sterile graduated cup.	Ensures that irrigation or instillation fluid remains sterile.
b. Clamp indwelling retention catheter just below specimen port.	Occlusion of catheter provides resistance against which nurse can forcefully instill irrigant into catheter.
c. Draw sterile solution into syringe using aseptic technique (usually 30 to 50 mL). Place sterile cap on tip of needleless syringe. Attach capped, sterile needle on end of syringe (if needleless system is not used).	Ensures sterility of irrigation fluid.
CLINICAL DECISION: *Avoid cold solution as irrigant or instillation because it results in bladder spasm and discomfort.*	
d. Using circular motion, clean injection port with antiseptic swab (same port used for specimen collection).	Reduces transmission of infection.
e. Insert tip of needleless syringe using twisting motion into irrigation port (see manufacturer instructions for possible variation). *Alternative:* Insert needle through port at 30-degree angle toward bladder.	Ensures that hub enters lumen of catheter and flow is directed into bladder.
f. Slowly inject fluid into catheter and bladder.	Slow, continuous pressure dislodges clots and sediment without traumatizing bladder wall.

STEP	RATIONALE
CLINICAL DECISION: *If catheter does not irrigate easily, the tip of the catheter is incorrectly placed in the urethra and not in the bladder. Use slow pressure when injecting fluid. Too much pressure traumatizes the urethral or bladder wall.*	
g. Withdraw syringe, remove clamp, and allow solution to drain into drainage bag. If an instillation, keep catheter clamped to allow solution to remain in bladder for ordered time, especially if irrigant is medicated per prescriber's order.	Allows drainage by gravity.
CLINICAL DECISION: *If solution is to remain in bladder, do not forget to unclamp tubing at the end of the instillation period.*	

5 *Closed continuous irrigation (see illustration):*

STEP 5 Closed continuous bladder irrigation.

a. Apply clean gloves.	Prevents entrance of microorganisms.
b. Close clamp on tubing and hang bag of solution on IV pole. Using aseptic technique, insert spike of sterile irrigation tubing into bag of sterile irrigating solution.	
c. Open clamp and allow solution to flow through tubing, keeping end of tubing sterile. Close clamp and recap end of tubing.	Removes air from tubing.
d. Use aseptic technique to wipe off irrigation port of triple-lumen catheter or attach sterile Y-connector to double-lumen catheter and then attach to irrigation tubing.	Third lumen or Y-connector provides means for irrigation solution to enter bladder. System must remain sterile.
e. Be sure that drainage bag and tubing are securely connected to drainage port of triple-lumen catheter or other arm of Y-connector.	Ensures that urine and irrigation solution drains from bladder without leaking.
f. For continuous drainage, calculate drip rate and adjust clamp on irrigation tubing accordingly. Be sure that clamp on drainage tubing is open and check volume of drainage in drainage bag. Make sure that drainage tubing is patent and avoid kinks.	Ensures continuous, even irrigation of catheter system. Prevents accumulation of solution in bladder, which causes bladder distention and possible injury.
g. For intermittent flow, clamp tubing on drainage system, open clamp on irrigation tubing, and allow prescribed amount of fluid to enter bladder (100 mL is normal for adults). Close irrigation clamp and then open drainage tubing clamp. *(Optional:* Leave clamp closed for 20 to 30 minutes if ordered.)	Fluid instills through catheter into bladder, flushing system. Fluid drains out after irrigation is completed. Do not clamp catheter for longer than 30 minutes because it can cause damage to bladder, backup to kidneys, and hyperreflexia if bladder gets too full.

SKILL 45-4 CLOSED CATHETER IRRIGATION—cont'd

STEP	RATIONALE
6 When procedure is completed, dispose of contaminated supplies, remove gloves, and perform hand hygiene.	Prevents spread of infection.

EVALUATION

1 Calculate amount of irrigation or instillation fluid and subtract from total output.	Determines accurate urinary output.
2 Assess characteristics of output: viscosity, color, clarity, odor, and presence of matter (e.g., sediment, clots, blood).	Evaluates results of irrigation or instillation and provides baseline data to judge response to therapy. Determines presence of UTI.
3 Observe for catheter patency.	Ensures that bladder is emptying freely.
4 Observe patient for signs of pain and fever.	Evaluates for presence of infection.

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1 Irrigant or instillation solution not returning; or continuous solution not flowing at prescribed rate, which indicates possible occlusion of catheter
- Examine tubing for kinks, clots, or urine sediment.
- Notify health care provider if irrigant or instillation is retained, patient complains of pain, or bladder is distended.

2 Cloudy or foul urine, fever
- Monitor fever.
- Notify health care provider.
- Obtain sterile urine specimen if ordered by health care provider.

3 Increase in bladder spasms; indicates occlusion of catheter with foreign object (e.g., blood clot)
- Notify health care provider.
- Perform intermittent irrigations until clots clear as directed.

RECORDING AND REPORTING

- Record type and amount of irrigation solution used, amount returned as drainage, and the character of drainage.
- Record and report any findings such as complaints of bladder spasms, inability to instill fluid into bladder, and/or presence of blood clots.

HOME CARE CONSIDERATIONS

- If patient is discharged with indwelling catheter and requires bladder irrigations, instruct the patient and/or the family on proper care.
- Because irrigation or instillation carries a risk of contamination, assess the level of understanding of surgical asepsis by the patient and family and provide appropriate instruction. The patient and family need guidelines for the skill and for conditions requiring a call to the health care provider.

KEY POINTS

- Voluntary control from higher brain centers and involuntary control from the spinal cord influence the act of micturition or voiding.
- Symptoms common to urinary disturbances include frequency, urgency, dysuria, polyuria, oliguria, incontinence, and difficulty in starting the urinary stream.
- When collected properly, a clean-voided urine specimen does not contain bacteria from the urethral meatus.
- Methods of promoting the micturition reflex help patients sense the urge to urinate and control urethral sphincter relaxation.
- An increased fluid intake results in increased diluted urine formation that reduces the risk of urinary tract infections.
- An indwelling urinary catheter remains in the bladder for an extended period, making the risk of infection greater than with intermittent catheterization.
- Catheter irrigation becomes necessary when the catheter becomes occluded with sediment or blood clots.
- A catheter drainage system should be a closed system positioned to allow free drainage of urine by gravity.
- Incontinence is classified as functional, overflow, stress, urge, or total. Each type has specific nursing interventions.
- Follow specific guidelines for catheter selection so the catheter does not cause harm.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Grayson is a 55-year-old woman who has had problems with stress incontinence for the past 2 years. She has not spoken to anyone about her problems because she is embarrassed. She finally confides to her health care practitioner that the problem is causing her to avoid social situations and she would like help to regain urinary control. Mrs. Grayson weighs 200 pounds, and her height is 5 feet 1 inch. She has been referred to a continence specialist. A plan of care was developed after a thorough assessment of her urinary pattern and symptoms.

1. She has recently begun Kegel exercises to attempt improvement in her urinary control. She doesn't see any improvement. She has been trying to deal with the problem by using an absorbent pad in her underwear, but she feels as though everyone knows her problem. What additional teaching does Mrs. Grayson need?
2. Two months after your first encounter with Mrs. Grayson, she has been seen by her primary health care provider for burning on urination with increased frequency and urgency. She has also noted blood in her urine for a week. What is Mrs. Grayson experiencing and what can you teach her to minimize her symptoms?
3. Mrs. Grayson says she is not satisfied with her current state of urinary control and has decided on a more permanent solution

to her stress incontinence. She opts for a minimally invasive procedure that will provide support for the urethra. She will be going home with an indwelling catheter. She asks how to care for the catheter while she is home. She does not want another urinary tract infection. What do you tell her about measures at home to remain infection free?

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A female patient reports that she is experiencing burning on urination, frequency, and urgency. The nurse notes that a clean-voided urine specimen is markedly cloudy. The probable cause of these symptoms and findings is:
   1. Cystitis.
   2. Hematuria.
   3. Pyelonephritis.
   4. Dysuria.
2. A male patient returned from the operating room 6 hours ago with a cast on his right arm. He has not yet voided. Which action would be the most beneficial in assisting the patient to void?
   1. Suggest he stand at the bedside
   2. Stay with the patient
   3. Give him the urinal to use in bed
   4. Tell him that, if he doesn't urinate, he will be catheterized
3. Elimination changes that result from inability of the bladder to empty properly may cause which of the following? (Select all that apply.)
   1. Incontinence
   2. Frequency
   3. Urgency
   4. Urinary retention
   5. Urinary tract infection
4. An older male patient states that he is having problems starting and stopping his stream of urine and he feels the urgency to void. The best way to assist this patient is to:
   1. Help him stand to void.
   2. Place a condom catheter.
   3. Have him practice Credé's method.
   4. Initiate Kegel exercises.
5. Since removal of the patient's Foley catheter, the patient has voided 50 to 100 mL every 2 to 3 hours. Which action should the nurse take first?
   1. Check for bladder distention
   2. Encourage fluid intake
   3. Obtain an order to recatheterize the patient
   4. Document the amount of each voiding for 24 hours
6. To minimize the patient experiencing nocturia, the nurse would teach him or her to:
   1. Perform perineal hygiene after urinating.
   2. Set up a toileting schedule.
   3. Double void.
   4. Limit fluids before bedtime.
7. A patient with a Foley catheter carries the collection bag at waist level when ambulating. The nurse tells the patient that he or she is at risk for: (Select all that apply.)
   1. Infection.
   2. Retention.
   3. Stagnant urine.
   4. Reflux of urine.
8. The patient is incontinent, and a condom catheter is placed. The nurse should take which action?
   1. Secure the condom with adhesive tape
   2. Change the condom every 48 hours
   3. Assess the patient for skin irritation
   4. Use sterile technique for placement
9. After a transurethral prostatectomy a patient returns to his room with a triple-lumen indwelling catheter and continuous bladder irrigation. The irrigation is normal saline at 150 mL/hr. The nurse empties the drainage bag for a total of 2520 mL after an 8-hour period. How much of the total is urine output?

   _____
10. The nurse is planning to remove a Foley catheter at 1300. The nurse would check if the patient has voided by:
    1. 1400.
    2. 1600
    3. 1700.
    4. 2300.
11. The postoperative patient has difficulty voiding after surgery and is feeling "uncomfortable" in the lower abdomen. Which action should the nurse implement first?
    1. Encourage fluid intake
    2. Administer pain medication
    3. Catheterize the patient
    4. Turn on the bathroom faucet as he tries to void
12. The patient is to have an intravenous pyelogram (IVP). Which of the following apply to this procedure? (Select all that apply.)
    1. Note any allergies.
    2. Monitor intake and output.
    3. Provide for perineal hygiene.
    4. Assess vital signs.
    5. Encourage fluids after the procedure.
13. The nurse assesses that the patient has a full bladder, and the patient states that he or she is having difficulty voiding. The nurse would teach the patient to:
    1. Use the double-voiding technique.
    2. Perform Kegel exercises.
    3. Use Credé's method.
    4. Keep a voiding diary.
14. The patient states that she "loses urine" every time she laughs or coughs. The nurse teaches the patient measures to regain urinary control. The nurse recognizes the need for further teaching when the patient states:
    1. "I will perform my Kegel exercises every day."
    2. "I joined weight watchers."
    3. "I drink two glasses of wine with dinner."
    4. "I have tried urinating every 3 hours."
15. The nurse notes that the patient's Foley catheter bag has been empty for 4 hours. The priority action would be to:
    1. Irrigate the Foley.
    2. Check for kinks in the tubing.
    3. Notify the health care provider.
    4. Assess the patient's intake.

Answers: **1.** 1; **2.** 1; **3.** 1, 2, 3, 4, 5; **4.** 4; **5.** 1; **6.** 4; **7.** 1, 4; **8.** 3; **9.** 1320 mL; **10.** 3; **11.** 4; **12.** 1, 5; **13.** 3; **14.** 3; **15.** 2.

CHAPTER

46

Bowel Elimination

OBJECTIVES

- Discuss the role of gastrointestinal organs in digestion and elimination.
- Describe three functions of the large intestine.
- Explain the physiological aspects of normal defecation.
- Discuss psychological and physiological factors that influence the elimination process.
- Describe common physiological alterations in elimination.
- Assess a patient's elimination pattern.
- List nursing diagnoses related to alterations in elimination.
- Describe nursing implications for common diagnostic examinations of the gastrointestinal tract.
- List nursing interventions that promote normal elimination.
- List nursing interventions included in bowel training.
- Discuss nursing care measures required for patients with a bowel diversion.
- Use critical thinking in the provision of care to patients with alterations in bowel elimination.

Regular elimination of bowel waste products is essential for normal body functioning. Alterations in bowel elimination are often early signs or symptoms of problems within either the gastrointestinal (GI) or other body systems. Because bowel function depends on the balance of several factors, elimination patterns and habits vary among individuals.

Understanding normal bowel elimination and factors that promote, impede, or cause alterations in elimination help manage patients' elimination problems. Supportive nursing care respects the patient's privacy and emotional needs. Measures designed to promote normal elimination also need to minimize discomfort for the patient.

SCIENTIFIC KNOWLEDGE BASE

The GI tract is a series of hollow mucous membrane–lined muscular organs. These organs absorb fluid and nutrients, prepare food for absorption and use by body cells, and provide for temporary storage of feces (Fig. 46-1). The GI tract absorbs high volumes of fluids, making fluid and electrolyte balance a key function of the GI system. In addition to ingested fluids and foods, the GI tract also receives secretions from the gallbladder and pancreas.

Mouth

Digestion begins in the mouth and ends in the small intestine. The mouth mechanically and chemically breaks down nutrients into a usable size and form. The teeth masticate food, breaking it down into a size suitable for swallowing. Saliva, produced by the salivary glands in the mouth, dilutes and softens the food in the mouth for easier swallowing.

Esophagus

As food enters the upper esophagus, it passes through the upper esophageal sphincter, a circular muscle that prevents air from entering the esophagus and food from refluxing into the throat. The bolus of food travels down the esophagus and is pushed along by peristalsis, which propels it through the length of the GI tract.

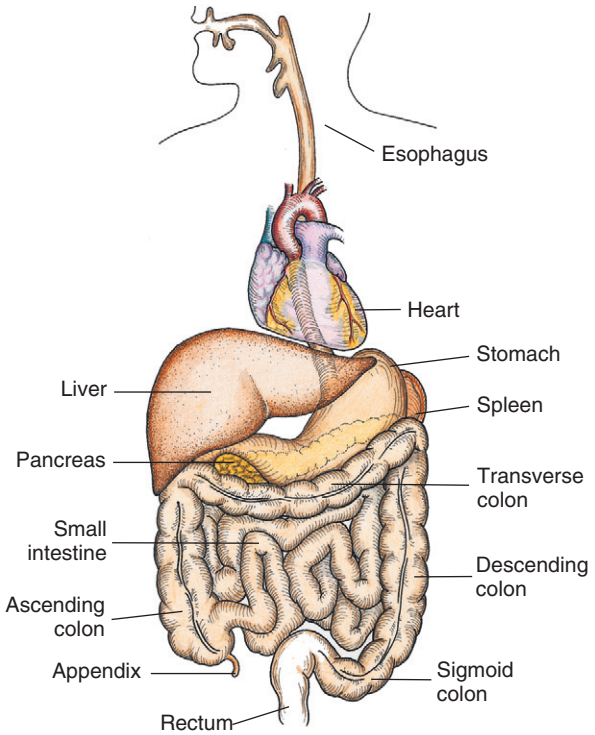

FIG. 46-1 Organs of gastrointestinal tract (with heart as reference point).

As food moves down the esophagus, it reaches the cardiac or lower esophageal sphincter, which lies between the esophagus and the upper end of the stomach. The sphincter prevents reflux of stomach contents back into the esophagus.

Stomach

The stomach performs three tasks: storing swallowed food and liquid; mixing food, liquid, and digestive juices; and emptying its contents into the small intestine. It produces and secretes hydrochloric acid (HCl), mucus, the enzyme pepsin, and the intrinsic factor. Pepsin and HCl facilitate the digestion of protein. Mucus protects the stomach mucosa from acidity and enzyme activity. The intrinsic factor is essential for the absorption of vitamin B_{12}.

Small Intestine

Segmentation and peristaltic movement in the small intestine facilitate both digestion and absorption (Fig. 46-2). Chyme mixes with digestive juices (e.g., bile and amylase). Resorption in the small intestine is so efficient that, by the time the chyme reaches the end of the small intestine, it is pastelike in consistency.

The small intestine has three sections: the duodenum, the jejunum, and the ileum. The duodenum is approximately 20 to 28 cm (8 to 11 inches) long and continues to process the chyme from the stomach. The jejunum is approximately 2.5 m (8 feet) long and absorbs carbohydrates and proteins. The ileum is approximately 3.7 m (12 feet) long and absorbs water, fats, certain vitamins, iron, and bile salts. The duodenum and jejunum absorb most of the nutrients and electrolytes. The intestinal wall also absorbs nutrients across the mucosa and into lymph fluids or blood vessels. Substances, such as plant fiber, that the small intestine cannot digest empty into the cecum at the lower right side of the abdomen. The large intestine begins at the cecum.

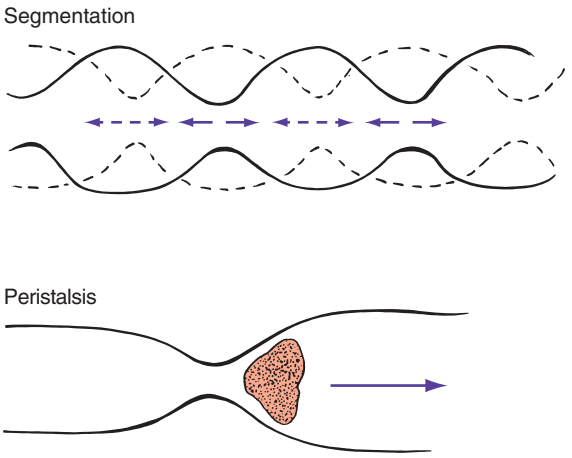

FIG. 46-2 Segmented and peristaltic waves.

Impairment of the small intestine alters the digestive process. For example, conditions such as inflammation, surgical resection, or obstruction disrupt peristalsis, reduce the area of absorption, or block the passage of chyme. Electrolyte and nutrient deficiencies then develop.

Large Intestine

The lower GI tract is called the *large intestine* (colon) because it is larger in diameter than the small intestine. The large intestine is shorter (1.5 to 1.8 m [5 to 6 feet]) but much wider than the small intestine. The large intestine is divided into the cecum, colon, and rectum (Fig. 46-3). The large intestine is the primary organ of bowel elimination. It is positioned like a question mark, partially encircling the small intestine.

Chyme enters the large intestine by waves of peristalsis through the ileocecal valve, a circular muscular layer that prevents regurgitation. The colon is divided into the ascending, transverse, descending, and sigmoid colons. The muscular tissue of the colon allows it to accommodate and eliminate large quantities of waste and gas (flatus). It has three functions: absorption, secretion, and elimination. The large intestine absorbs water, sodium, and chloride from the digested food that has passed from the small intestine. Healthy adults absorb more than a gallon of water and an ounce of salt from the colon every 4 hours. The amount of water absorbed from chyme depends on the speed at which colonic contents move. Chyme is normally a soft, formed mass. If peristalsis is abnormally fast, there is less time for water to be absorbed, and the stool is watery. If peristaltic contractions slow, water continues to be absorbed; and a hard mass of stool forms, resulting in constipation (JBI, 2008).

The secretory function of the colon aids in electrolyte balance. The colon secretes bicarbonate in exchange for chloride. The colon also excretes about 4 to 9 mEq of potassium daily. Therefore serious alterations in colon function (e.g., diarrhea) cause severe electrolyte disturbances.

Slow peristaltic contractions move contents through the colon. Intestinal content is the main stimulus for contraction. Mass peristalsis pushes undigested food toward the rectum. These mass movements occur only three or four times daily, with the strongest during the hour after mealtime.

The rectum is the final portion of the large intestine. Here bacteria convert fecal matter into its final form. Normally the rectum is empty of waste products (feces) until just before defecation. It

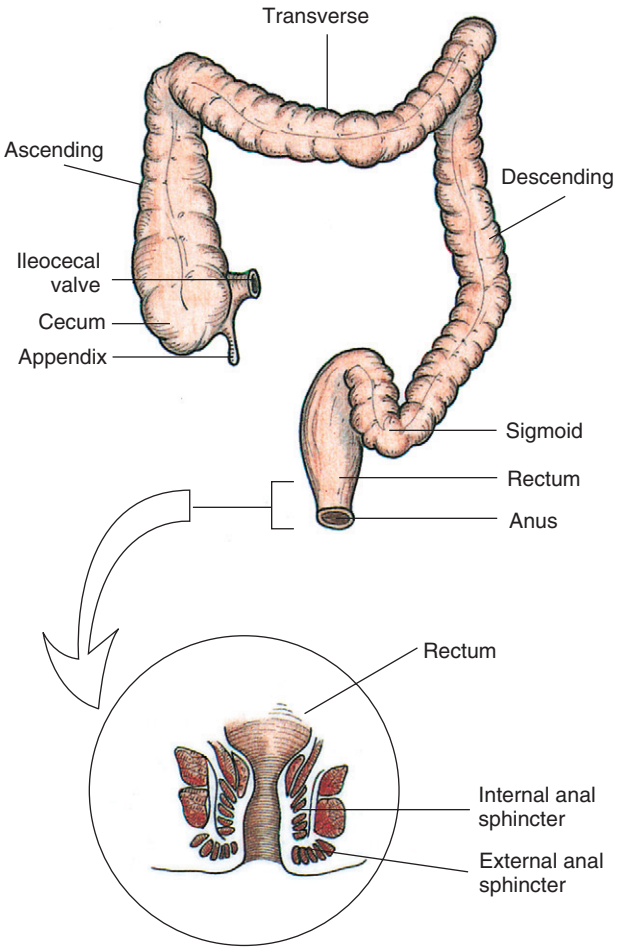

FIG. 46-3 Divisions of large intestine.

contains vertical and transverse folds of tissue that help to temporarily hold fecal contents during defecation. Each fold contains an artery and vein that can become distended from pressure during straining. This distention often results in hemorrhoid formation.

Anus

The body expels feces and flatus from the rectum through the anal canal and anus. Contraction and relaxation of the internal and external sphincters, innervated by sympathetic and parasympathetic stimuli, aid in the control of defecation. The anal canal is richly supplied with sensory nerves that help to control continence.

Defecation

The physiological factors critical to bowel function and defecation include normal GI tract function, sensory awareness of rectal distention and rectal contents, voluntary sphincter control, and adequate rectal capacity and compliance. Normal defecation begins with movement in the left colon, moving stool toward the anus. When stool reaches the rectum, the distention causes relaxation of the internal sphincter and an awareness of the need to defecate. At the time of defecation, the external sphincter relaxes, and abdominal muscles contract, increasing intrarectal pressure and forcing the stool out (Huether and McCance, 2008). Sometimes people use the **Valsalva maneuver** to assist in stool passage. The Valsalva maneuver exerts pressure to expel feces through a voluntary contraction of the abdominal muscles while maintaining forced expiration against a closed airway. Patients with cardiovascular disease, glaucoma, increased intracranial pressure, or a new surgical wound are at greater risk for cardiac dysrhythmias and elevated blood pressure with the Valsalva maneuver and need to avoid straining to pass the stool. Normal defecation is painless, resulting in passage of soft, formed stool.

NURSING KNOWLEDGE BASE

Factors Influencing Bowel Elimination

Many factors influence the process of bowel elimination. Knowledge of these factors helps to anticipate measures required to maintain a normal elimination pattern.

Age. Developmental changes affecting elimination occur throughout life. An infant has a small stomach capacity and less secretion of digestive enzymes. Food passes quickly through an infant's intestinal tract because of rapid peristalsis. The infant is unable to control defecation because of a lack of neuromuscular development. This neuromuscular development usually does not take place until 2 to 3 years of age.

Systemic changes in the function of digestion and absorption of nutrients result from changes in older patients' cardiovascular and neurological systems rather than their GI system. For example, arteriosclerosis causes decreased mesenteric blood flow, thus decreasing absorption from the small intestine (Meiner, 2011). In addition, peristalsis decreases, and esophageal emptying slows. Older adults often experience changes in the GI system that impair digestion and elimination (JBI, 2008) (Table 46-1).

Older adults also lose muscle tone in the perineal floor and anal sphincter (Holman et al., 2008). Although the integrity of the sphincter remains intact, they often have difficulty controlling bowel evacuation and are at risk for incontinence. In addition, nerve impulses to the anal region slow, causing some individuals to become less aware of the need to defecate. Older adults, especially residents in long-term care facilities, sometimes develop irregular bowel movements and an increased risk for constipation (Kyle, 2007a).

Diet. Regular daily food intake helps maintain a regular pattern of peristalsis in the colon. Fiber, the nondigestible residue in the diet, provides the bulk of fecal material. Bulk-forming foods such as whole grains, fresh fruits, and vegetables help flush the fats and waste products from the body with more efficiency (Holman et al., 2008). The bowel walls stretch, creating peristalsis and initiating the defecation reflex. With stimulation of peristalsis, bulk foods pass quickly through the intestines, keeping the stool soft. Ingestion of a high-fiber diet improves the likelihood of a normal elimination pattern if other factors are normal. Diets high in vegetables and fruits have been linked to decreased risk of colorectal cancer (ACS, 2011b).

Gas-producing foods such as onions, cauliflower, and beans also stimulate peristalsis. The gas formed distends intestinal walls and increases colon motility. Some spicy foods increase peristalsis but also cause indigestion and watery stools.

Food intolerance is not an allergy but rather a particular food that causes the body distress within a few hours of ingestion. The result is diarrhea, cramps, or flatulence. For example, people who drink cow's milk and have these symptoms are not allergic to milk but lack the enzyme needed to digest the milk sugar lactase and therefore are lactose intolerant. Another condition called *celiac disease* is a syndrome in which the patient has a hypersensitivity to protein in certain cereal grains and gluten.

TABLE 46-1 Normal Age-Related Changes in the Gastrointestinal Tract

PORTION OF GASTROINTESTINAL TRACT	FUNCTIONAL OR PHYSIOLOGICAL CHANGE	CAUSES
Mouth	Decreased chewing and salivation, including oral dryness	Degeneration of cells, medications (Gray-Vickrey, 2010; Meiner, 2011)
Esophagus	Reduced motility, especially in lower third	Degeneration of neural cells (Meiner, 2011)
Stomach	Decrease in:	
	Acid secretions	Degeneration of gastric mucosa (Banning, 2008) (Alkaline gastric medium contributes to malabsorption of iron. Although digestive enzymes are decreased, enough remain available for digestion.)
	Motor activity	Delayed gastric emptying, causing fewer hunger contractions (Gray-Vickrey, 2010)
	Mucosal thickness	Loss of parietal cells; leads to loss of intrinsic factor, which is necessary for vitamin B_{12} absorption
Small intestine	Decreased nutrient absorption	Fewer absorbing cells
Large intestine	Increase in pouches on weakened intestinal wall called *diverticulosis*	Weakened musculature Does not significantly affect absorption (Banning, 2008)
	Constipation	Decreased peristalsis (Gray-Vickrey, 2010)
	Missed defecation signal, increasing risk for fecal incontinence	Duller nerve sensations (Gray-Vickrey, 2010)
Liver	Size decreased	Reduced storage capacity and ability to synthesize protein and metabolize medications

Fluid Intake. An inadequate fluid intake or disturbances resulting in fluid loss (such as vomiting) affect the character of feces. Fluid liquefies intestinal contents, easing its passage through the colon. Reduced fluid intake slows passage of food through the intestine and results in hardening of stool contents. Unless there is a medical contraindication, an adult needs to drink at least 1100 to 1400 mL of fluid daily. An increase in fluid intake with the use of fruit juices softens stool and increases peristalsis. Poor fluid intake increases the risk of constipation because of greater resorption of fluid in the colon, resulting in hard, dry stools (Kyle, 2007a).

Physical Activity. Physical activity promotes peristalsis, whereas immobilization depresses it. Encourage early ambulation as illness begins to resolve or as soon as possible after surgery to promote maintenance of peristalsis and normal elimination. Maintaining tone of skeletal muscles used during defecation is important. Weakened abdominal and pelvic floor muscles impair the ability to increase intraabdominal pressure and control the external sphincter. Muscle tone is sometimes weakened or lost as a result of long-term illness, spinal cord injury, or neurological disease that impairs nerve transmission. As a result of these changes in the abdominal and pelvic floor muscles, there is an increased risk for constipation.

Psychological Factors. Prolonged emotional stress impairs the function of almost all body systems (see Chapter 37). During emotional stress the digestive process is accelerated, and peristalsis is increased. Side effects of increased peristalsis are diarrhea and gaseous distention. A number of diseases of the GI tract are associated with stress, including ulcerative colitis, irritable bowel syndrome, certain gastric and duodenal ulcers, and Crohn's disease. If a person becomes depressed, the autonomic nervous system slows impulses; peristalsis decreases, resulting in constipation.

Personal Habits. Personal elimination habits influence bowel function. Most people benefit from being able to use their own toilet facilities at a time that is most effective and convenient for them. A busy work schedule sometimes prevents the individual from responding appropriately to the urge to defecate, disrupting regular habits and causing possible alterations such as constipation. Individuals need to recognize the best time for elimination.

Chronically ill and hospitalized patients are not always able to maintain privacy during defecation. In a hospital or extended care setting, patients sometimes share bathroom facilities with a roommate with different hygienic habits. In addition, chronic illness limits a patient's balance, activity tolerance, or physical activity and requires the use of a bedpan or bedside commode. The sights, sounds, and odors associated with sharing toilet facilities or using bedpans are often embarrassing. This embarrassment often causes patients to ignore the urge to defecate, which begins a vicious cycle of constipation and discomfort.

Position During Defecation. Squatting is the normal position during defecation. Modern toilets facilitate this posture, allowing the person to lean forward, exert intraabdominal pressure, and contract the thigh muscles. For the patient immobilized in bed, defecation is often difficult. In a supine position it is impossible to contract the muscles used during defecation. If the patient's condition permits, raise the head of the bed to assist the patient to a more normal sitting position on a bedpan, enhancing the ability to defecate.

Pain. Normally the act of defecation is painless. However, a number of conditions such as hemorrhoids, rectal surgery, rectal fistulas, and abdominal surgery result in discomfort. In these instances the patient often suppresses the urge to defecate to avoid pain, contributing to the development of constipation.

Pregnancy. As pregnancy advances, the size of the fetus increases, and pressure is exerted on the rectum. A temporary obstruction created by the fetus impairs passage of feces. Slowing of peristalsis during the third trimester often leads to constipation. A pregnant woman's frequent straining during defecation or delivery results in formation of permanent hemorrhoids.

Surgery and Anesthesia. General anesthetic agents used during surgery cause temporary cessation of peristalsis (see Chapter 50). Inhaled anesthetic agents block parasympathetic impulses to

TABLE 46-2 Medications and the Gastrointestinal System

MEDICATIONS	ACTION
Dicyclomine HCl (Bentyl)	Suppresses peristalsis and decreases gastric emptying
Opioid analgesics	Slow peristalsis and segmental contractions, often resulting in constipation (Lehne, 2010)
Anticholinergic drugs such as atropine or glycopyrrolate (Robinul)	Inhibit gastric acid secretion and depress gastrointestinal (GI) motility (Lehne, 2010) (Although useful in treating hyperactive bowel disorders, anticholinergics cause constipation.)
Antibiotics	Produce diarrhea by disrupting the normal bacterial flora in the GI tract (An increase in the use of fluoroquinolones in recent years has provided a selective advantage for the epidemic of *Clostridium difficile*) (Vonberg et al., 2008)
Nonsteroidal antiinflammatory drugs	Cause GI irritation that increases the incidence of bleeding with serious consequences to older adults; rectal bleeding is often observed with GI irritation (Lehne, 2010)
Aspirin	Prostaglandin inhibitor; interferes with the formation and production of protective mucus and causes GI bleeding (Lehne, 2010)
Histamine$_2$ (H_2) antagonists	Suppress the secretion of hydrochloric acid and interfere with the digestion of some foods
Iron	Causes discoloration of the stool (black), nausea, vomiting, constipation (diarrhea is less commonly reported), and abdominal cramps (Lehne, 2010)

the intestinal musculature. The action of the anesthetic slows or stops peristaltic waves. The patient who receives a local or regional anesthetic is less at risk for elimination alterations because this type of anesthesia generally affects bowel activity minimally or not at all.

Any surgery that involves direct manipulation of the bowel temporarily stops peristalsis. This condition, called **paralytic ileus,** usually lasts about 24 to 48 hours. If the patient remains inactive or is unable to eat after surgery, return of normal bowel elimination is further delayed.

Medications. Some medications have certain expected actions on the bowel (e.g., there are medications to promote defecation or control diarrhea). In addition, medications prescribed for acute and chronic conditions often have secondary effects on the patient's bowel elimination patterns (Table 46-2).

Laxatives and **cathartics** soften the stool and promote peristalsis. Although similar, laxatives are milder in action than cathartics. When used correctly, laxatives and cathartics safely maintain normal elimination patterns. However, chronic use of cathartics causes the large intestine to become less responsive to stimulation by laxatives. Laxative overuse can also cause serious diarrhea, leading to dehydration and electrolyte depletion. Mineral oil, a common laxative, decreases fat-soluble vitamin absorption. Laxatives often influence the efficacy of other medications by altering the transit time (i.e., the time the medication remains in the GI tract and is available for absorption).

Diagnostic Tests. Diagnostic examinations involving visualization of GI structures often require a prescribed bowel preparation (e.g., medications, cathartics, and/or enemas) to ensure that the bowel is empty. In addition, the patient cannot eat or drink several hours before the examinations such as an **endoscopy,** colonoscopy, or other testing that requires visualization of the GI tract. Following the diagnostic procedure, changes in elimination such as increased gas or loose stools often occur until the patient resumes a normal eating pattern.

BOX 46-1 COMMON CAUSES OF CONSTIPATION

- Irregular bowel habits and ignoring the urge to defecate
- Chronic illnesses (e.g., Parkinson's disease, multiple sclerosis, rheumatoid arthritis, chronic bowel diseases, depression, diabetic neuropathy, eating disorders (McWilliams, 2010)
- Low-fiber diet high in animal fats (e.g., meats, dairy products, eggs) (McWilliams, 2010)
- Low fluid intake, which slows peristalsis (Holman et al., 2008)
- Anxiety, depression, cognitive impairment (McWilliams, 2010)
- Lengthy bed rest or lack of regular exercise (McWilliams, 2010)
- Laxative misuse (Durston, 2009)
- Slowed peristalsis, loss of abdominal muscle elasticity, and reduced intestinal mucus secretion experienced by older adults (Durston, 2009)
- Neurological conditions that block nerve impulses to the colon (e.g., spinal cord injury, tumor) (Kyle, 2007c)
- Illnesses such as hypothyroidism, hypocalcemia, or hypokalemia
- Medications such as anticholinergics, antispasmodics, anticonvulsants, antidepressants, antihistamines, antihypertensives, antiparkinsonism drugs, bile acid sequestrants, diuretics, antacids, iron supplements, calcium supplements, and opioids slow colonic action (Lehne, 2010)

Common Bowel Elimination Problems

Caring for patients who have or are at risk for elimination problems because of emotional stress (anxiety or depression), physiological changes in the GI tract such as surgical alteration of intestinal structures, inflammatory diseases, prescribed therapy, or disorders impairing defecation is common in the practice of nursing.

Constipation. **Constipation** is a symptom, not a disease (Box 46-1). Improper diet, reduced fluid intake, lack of exercise, and certain medications can cause constipation. For example, patients receiving opiates for pain after surgery often require a stool softener or laxative to prevent constipation. The signs of constipation include infrequent bowel movements (less than every 3 days), difficulty passing stools, excessive straining, inability to defecate at will, and hard feces (McWilliams, 2010). When intestinal motility slows, the fecal mass becomes exposed over time to the intestinal walls, and most of the fecal water content is absorbed. Little water is left to soften and lubricate the stool. Passage of a dry, hard stool causes rectal pain (Fig. 46-4).

Constipation is a significant health hazard. Straining during defecation causes problems for the patient with recent abdominal, gynecological, or rectal surgery. The effort to pass a stool often causes sutures to separate, reopening the wound. In addition, patients with histories of cardiovascular disease, diseases causing elevated intraocular pressure (glaucoma), and increased intracranial pressure need to prevent constipation and avoid using the Valsalva maneuver.

Impaction. Fecal **impaction** results from unrelieved constipation. It is a collection of hardened feces wedged in the rectum that a person cannot expel. In cases of severe impaction the mass extends up into the sigmoid colon. If not resolved or removed,

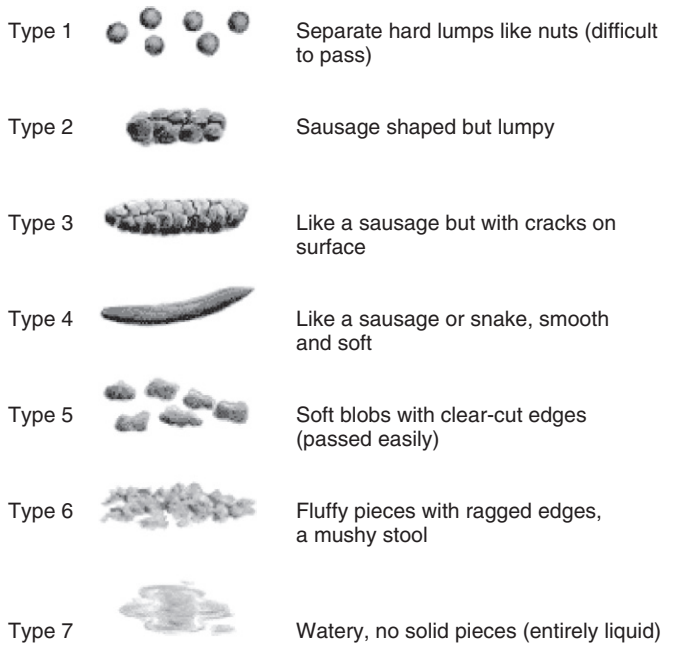

FIG. 46-4 Bristol stool form scale. (Used with permission. *Bristol Stool Form Guideline,* http://www.aboutconstipation.org/bristol.html, accessed July 31, 2006.)

severe impaction often results in intestinal obstruction. Patients who are debilitated, confused, or unconscious are most at risk for impaction. They are dehydrated or too weak or unaware of the need to defecate, and the stool becomes too hard and dry to pass.

An obvious sign of impaction is the inability to pass a stool for several days, despite the repeated urge to defecate (Chien and Bradway, 2010). You suspect impaction when a continuous oozing of diarrhea stool occurs. The liquid portion of feces located higher in the colon seeps around the impacted mass. Loss of appetite (anorexia), nausea and/or vomiting, abdominal distention and cramping, and rectal pain often accompany the condition. If an impaction is suspected, gently perform a digital examination of the rectum and palpate for the impacted mass (Steggall, 2008).

Diarrhea. Diarrhea is an increase in the number of stools and the passage of liquid, unformed feces. It is associated with disorders affecting digestion, absorption, and secretion in the GI tract. Intestinal contents pass through the small and large intestine too quickly to allow for the usual absorption of fluid and nutrients. Irritation within the colon results in increased mucus secretion. As a result, feces become watery, and the patient is unable to control the urge to defecate. Normally an anal bag is safe and effective in long-term treatment of patients with fecal incontinence at home, in hospice, or in the hospital. Fecal incontinence is expensive and a potentially dangerous condition in terms of contamination and risk of skin ulceration (Gray, 2007).

Excess loss of colonic fluid results in serious fluid and electrolyte or acid-base imbalances. Infants and older adults are particularly susceptible to associated complications (see Chapter 41). Because repeated passage of diarrhea stools also exposes the skin of the perineum and buttocks to irritating intestinal contents, meticulous skin care and containment of fecal drainage is necessary to prevent skin breakdown (see Chapter 48).

Many conditions cause diarrhea. Antibiotic use via any route of administration alters the normal flora in the GI tract (Vonberg et al., 2008). Patients receiving enteral nutrition are also at risk for diarrhea. Consult a dietitian when diarrhea occurs (Tabloski, 2009). See Chapter 44 for interventions to decrease diarrhea caused by enteral feedings. Food allergies and intolerances increase peristalsis and cause diarrhea. Surgeries or diagnostic testing of the lower GI tract also cause diarrhea. The aim of treatment is to remove precipitating conditions and slow peristalsis.

Another common causative agent of diarrhea is ***Clostridium difficile*** *(C. difficile),* in which symptoms range from mild diarrhea to severe colitis. *C. difficile* infection is acquired in one of two ways: by factors that cause an overgrowth of *C. difficile,* and by contact with the *C. difficile* organism. A new strain of *C. difficile* has been identified that is more virulent with more toxic effects (Grossman, 2010). Antibiotics (cephalosporins, ampicillin, amoxicillin, and clindamycin (Calfee, 2008), chemotherapy, and invasive bowel procedures such as surgery or colonoscopy disrupt normal bowel flora and may cause an overgrowth of *C. difficile*. Some patients acquire the organism from a health care worker's hands or direct contact with the environmental surfaces contaminated with it. Only hand hygiene with soap and water is effective to physically remove *C. difficile* spores from the hands. In addition, evidence supports the use of diluted bleach (1:10) as an environmental disinfectant to decrease the incidence of *C. difficile* (Calfee, 2008; Vonberg, 2008). The most common diagnostic test for the bacteria is the enzyme-linked immunosorbent assay (ELISA) test, which detects *C. difficile* A and B in the stool.

Communicable foodborne pathogens also cause diarrhea. Hand hygiene following the use of the bathroom, before and after preparing foods, and when cleaning and storing fresh produce and meats greatly reduces the risk of foodborne illnesses. When diarrhea is the result of a foodborne virus, the goal usually is to rid the GI system of the pathogen rather than slow peristalsis.

Incontinence. Fecal **incontinence** is the inability to control passage of feces and gas from the anus. Incontinence harms a patient's body image (see Chapter 33). In many situations the patient is mentally alert but physically unable to avoid defecation. The embarrassment of soiling clothes often leads to social isolation. Physical conditions that impair anal sphincter function or control cause incontinence. It occurs in a variety of settings. Conditions that create frequent, loose, large-volume, watery stools also predispose to incontinence. Using an anal bag or a bowel management system helps to prevent perineal skin breakdown (Fig. 46-5).

Flatulence. As gas accumulates in the lumen of the intestines, the bowel wall stretches and distends **(flatulence).** It is a common cause of abdominal fullness, pain, and cramping. Normally intestinal gas escapes through the mouth (belching) or the anus (passing of flatus). However, flatulence causes abdominal distention and severe, sharp pain if intestinal motility is reduced because of opiates, general anesthetics, abdominal surgery, or immobilization.

Hemorrhoids. **Hemorrhoids** are dilated, engorged veins in the lining of the rectum. They are either external or internal. External hemorrhoids are clearly visible as protrusions of skin. If the underlying vein is hardened, there is usually a purplish discoloration (thrombosis). This causes increased pain and often needs to be excised. Internal hemorrhoids have an outer mucous membrane. Increased venous pressure from straining at defecation, pregnancy, heart failure, and chronic liver disease causes hemorrhoids.

Bowel Diversions

Certain diseases cause conditions that prevent normal passage of feces through the rectum. The treatment for these disorders results in the need for a temporary or permanent artificial opening

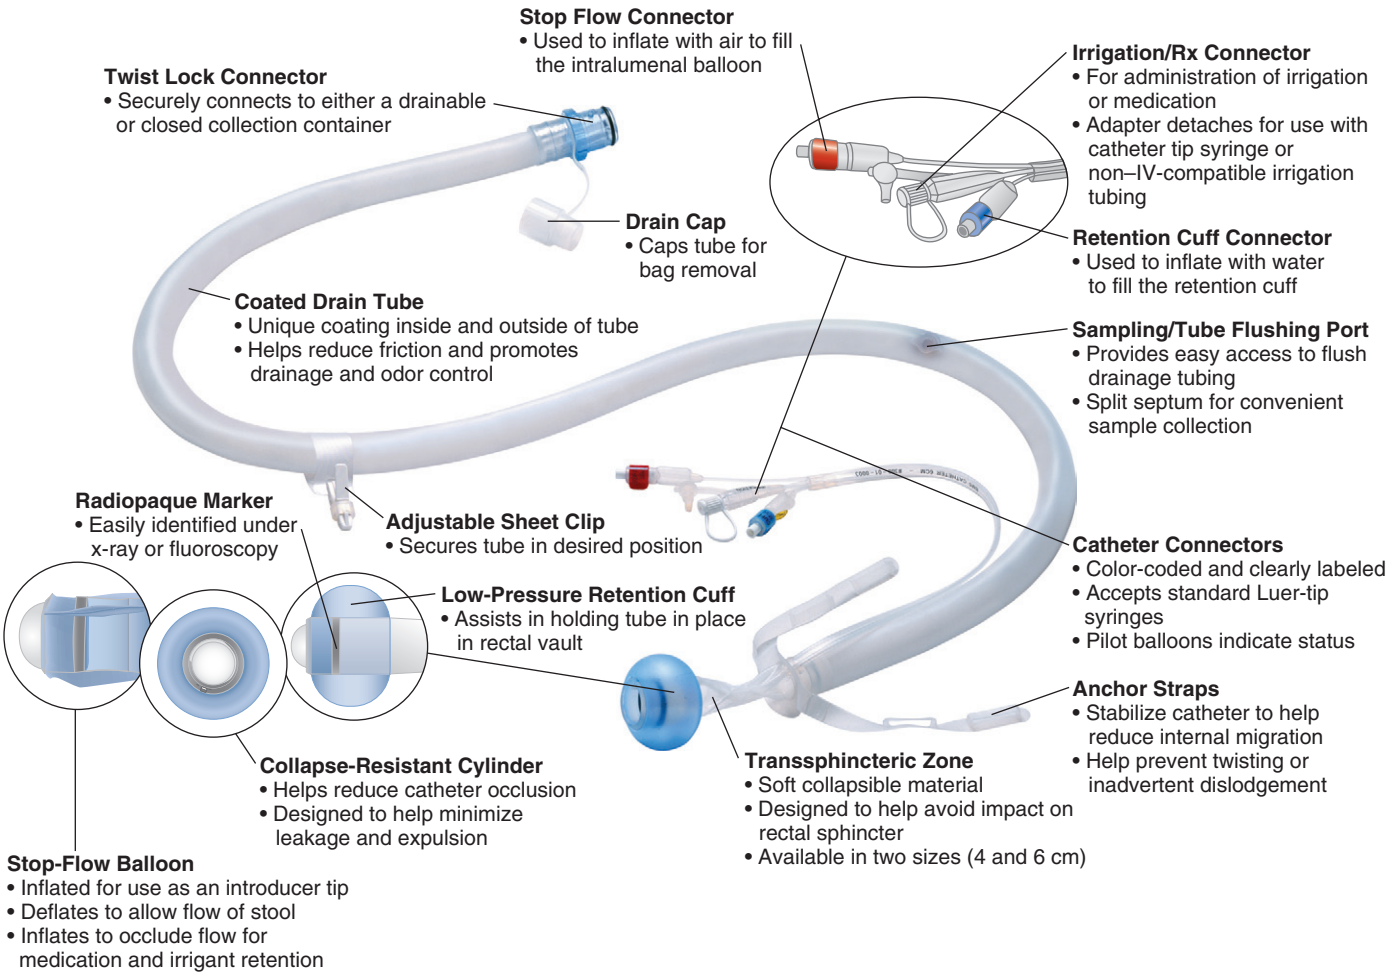

FIG. 46-5 ActiFlo™ Indwelling Bowel Catheter System. (Courtesy Hollister Incorporated, Libertyville, Ill.)

(stoma) in the abdominal wall. Surgical openings are created in the ileum (ileostomy) or colon (colostomy), with the ends of the intestine brought through the abdominal wall to create the stoma (Durston, 2009).

The standard bowel diversion creates a stoma, or the patient has reconstructive bowel surgery that uses the native sphincter for bowel continence. The reconstructive surgery includes a continent stoma procedure or the ileoanal pouch anastomosis, which is described later in the chapter.

Ostomies. The location of an ostomy determines the consistency of stool. An ileostomy bypasses the entire large intestine. As a result, stools are frequent and liquid. The same is true for a colostomy of the ascending colon. A colostomy of the transverse colon generally results in a more solid, formed stool. The sigmoid colostomy releases near-normal stool. The patient's medical problem and general condition determine the location of a colostomy. There are three types of colostomy construction: loop, end, and double-barrel.

Loop Colostomy. A loop colostomy is usually performed in a medical emergency when health care providers anticipate closure of the colostomy (Fig. 46-6). It is usually a temporary large stoma constructed in the transverse colon. The surgeon pulls a loop of bowel onto the abdomen. An external supporting device such as a plastic rod, bridge, or rubber catheter is temporarily placed under the bowel loop to keep it from slipping back. The surgeon then opens the bowel and sutures it to the skin of the abdomen. A

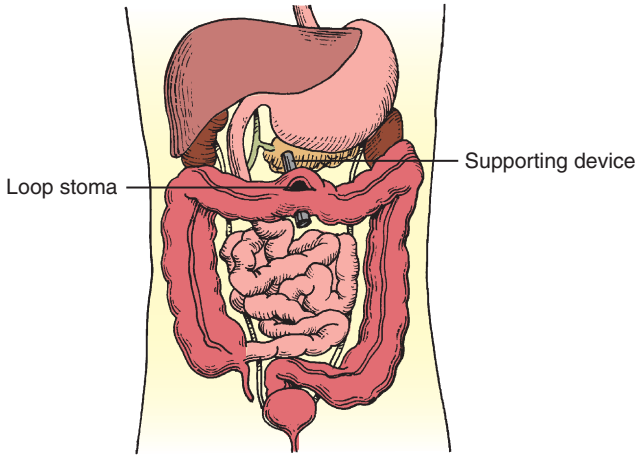

FIG. 46-6 Loop colostomy. Loop of colon is exteriorized over plastic rod for temporary fecal diversion. (Modified from Phillips N: *Berry & Kohn's operating room technique,* ed 11, St Louis, 2007, Mosby.)

communicating wall remains between the proximal and distal bowel. The loop ostomy has two openings through one stoma. The proximal end drains stool, whereas the distal portion drains mucus. Within 7 to 10 days the surgeon removes the supporting device.

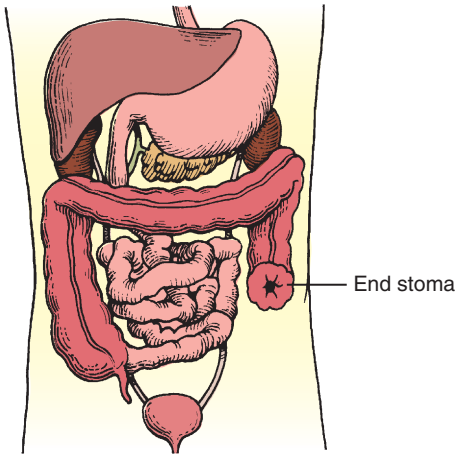

FIG. 46-7 Permanent (end) colostomy. Terminal end of descending or sigmoid colon is brought out through peritoneum and muscle and sutured to skin. (Modified from Phillips N: *Berry & Kohn's operating room technique,* ed 11, St Louis, 2007, Mosby.)

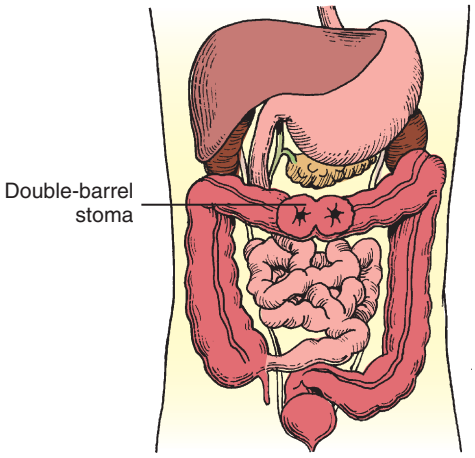

FIG. 46-8 Double-barrel colostomy. Both ends of transected colon are brought out to skin. (Modified from Phillips N: *Berry & Kohn's operating room technique,* ed 11, St Louis, 2007, Mosby.)

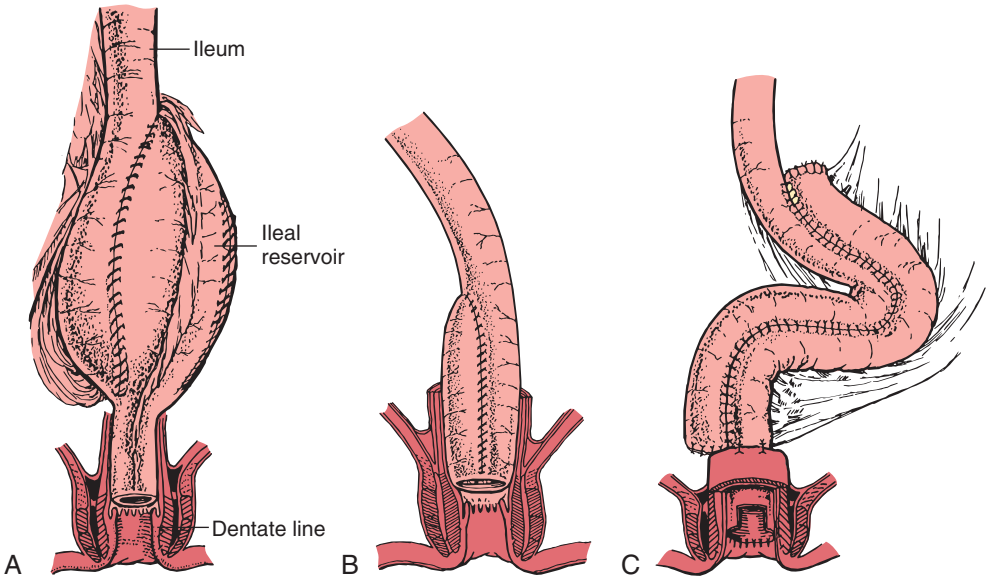

FIG. 46-9 Ileoanal reservoirs (IARs). **A,** S-shaped configuration for IAR. Three 10-cm limbs of ileum are used, antimesenteric surface of each limb is opened, and adjacent bowel walls are anastomosed. **B,** J-shaped configuration for IAR. Distal ileum is aligned in J shape, antimesenteric surface of J shape is opened, and adjacent bowel walls are anastomosed. Side-to-end anastomosis of bowel to dentate line is evident. **C,** Lateral or side-by-side ileoanal pouch configuration. (From Hampton BG, Bryant RA: *Ostomies and continent diversions: nursing management,* St Louis, 1992, Mosby.)

End Colostomy. The end colostomy consists of one stoma formed from the proximal end of the bowel, with the distal portion of the GI tract either removed or sewn closed (called *Hartmann's pouch)* and left in the abdominal cavity. For many patients end colostomies are a result of surgical treatment of colorectal cancer. In such cases the rectum is usually removed. Patients with diverticulitis who are treated surgically often have a temporary end stoma with a Hartmann's pouch (Fig. 46-7).

Double-Barrel Colostomy. Unlike the loop colostomy, the surgeon divides the intestine and brings both the proximal and distal ends through the abdominal incision to the abdominal surface when creating a double-barrel colostomy. A small incision is made in the proximal stoma for fecal drainage. The distal stoma leads to the inactive intestine and is left intact. When the intestinal injury has healed, the colostomy is reversed, and the divided ends are anastomosed to restore intestinal integrity (Fig. 46-8).

Alternative Procedures

Ileoanal Pouch Anastomosis. The ileoanal pouch anastomosis is a surgical procedure that is used in patients who need to have a colectomy for treatment of ulcerative colitis or familial polyps (Dorman, 2009). In this procedure the surgeon removes the colon, creates a pouch from the end of the small intestine, and attaches the pouch to the patient's anus (Fig. 46-9). This pouch provides for the collection of waste material, which is similar to the rectum. The patient is continent of stool because stool is evacuated via the anus.

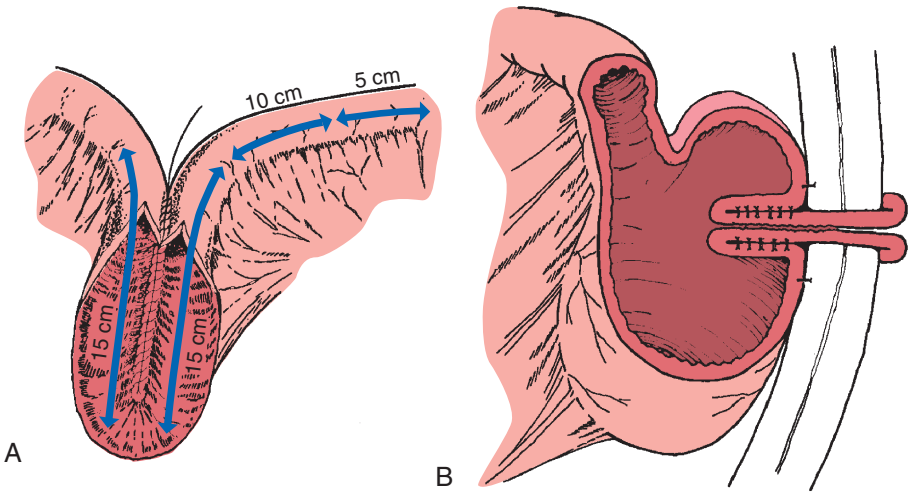

FIG. 46-10 Construction of Kock continent ileostomy—Kock pouch. **A,** Two 15-cm limbs are used to create a pouch, and one 15-cm limb is used to fashion a nipple valve and stoma. **B,** Distal limb is intussuscepted into reservoir to create one-way valve and accomplish continence. Sutures or staples, or both, are placed to stabilize and maintain intussuscepted nipple. Anterior surface of reservoir is anchored to anterior peritoneal wall. (From Hampton BG, Bryant RA: *Ostomies and continent diversions: nursing management,* St Louis, 1992, Mosby.)

When the ileal pouch is created, the patient has a temporary ileostomy to allow the anastomosis to heal.

Kock Continent Ileostomy. The Kock continent ileostomy is created using the patient's small intestine, changing its cylindrical shape into a spherical reservoir (Gordon, 2007). This procedure is occasionally used in the treatment of ulcerative colitis. The pouch has a continent stoma, a nipple type of valve that is drained with an external catheter, which the patient places intermittently in the stoma (Fig. 46-10).

Macedo-Malone Antegrade Continence Enema. The Macedo-Malone antegrade continence enema (MACE) procedure improves continence in patients with fecal soiling associated with neuropathic or structural abnormalities of the anal sphincter. This procedure isolates a 3-cm (1.2-inch) flap on the left colon. A Foley catheter placed on the surface of the flap creates a tubular passage. This produces a continence valve mechanism. The surgeon takes the distal end of the tube and makes a V shape to the skin flap (Fig. 46-11). Enema administration begins 7 to 10 days after surgery. Patients receive enemas daily. The volume of the enema varies from 250 to 800 mL and takes 45 to 60 minutes to administer. Colonic evacuation occurs within 30 to 60 minutes (Meurette et al., 2010).

Psychological Considerations. A stoma causes serious body image changes, particularly if it is permanent. After the surgery, patients face a variety of anxieties and concerns, from learning how to manage their stoma to coping with conflicts of self-esteem and body image. Provide emotional support before and after surgery (Deitz, 2010a). Patients often perceive a stoma as invasive and disfiguring. However, a well-placed stoma usually does not interfere with the patient's activities and is concealed with clothing. Nonetheless, even though clothing conceals the ostomy, the patient feels different. Many patients have difficulty maintaining or initiating normal sexual relations (see Chapter 34) (Ramirez et al., 2009). Important factors affecting reactions to the stoma include the character of fecal secretions and the ability to control them. Foul odors, spillage, or leakage of liquid stools and inability to regulate bowel movements cause the patient to lose self-esteem (Richbourg et al., 2007). The aging process often affects the ability to manage stomas,

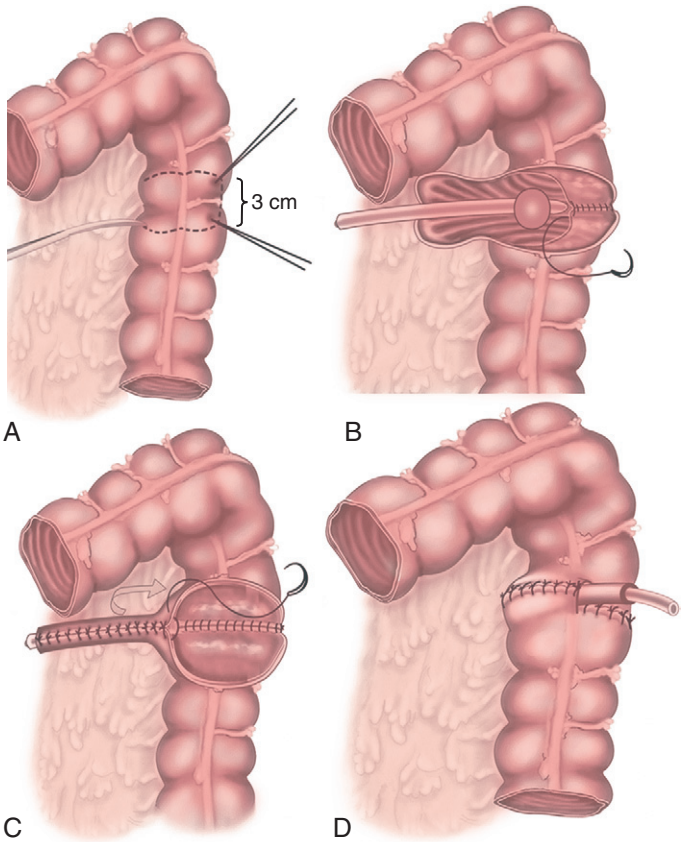

FIG. 46-11 Macedo-Malone antegrade continence enema procedure. **A,** Isolation of the flap on left colon. **B,** Foley catheters placed on mucosal surface of flap. **C,** Tubularization of plate creating efferent tubular conduit. **D,** Continence valve mechanism is created. (Used with permission. From Calado A et al: The Macedo-Malone antegrade continence enema procedure: early experience, *J Urol* 173:1340, 2005.)

even in people who have had them for years. You need to recognize and intervene when problems resulting from advanced age such as skin changes, weight loss or gain, visual impairments, or changes in diet occur (Pearson, 2010). Refer the patient to ostomy support groups such as the United Ostomy Associations of America at http://www.uoaa.org, which has discussion boards for various types of incontinent and continent diversions and networks. The Wound, Ostomy and Continence Nurses Society (http://www.wocn.org) provides information and helps patients locate a wound, ostomy continence nurse (WOCN) (Dorman, 2009).

CRITICAL THINKING

Successful critical thinking requires a synthesis of knowledge, experience, information gathered from patients, critical thinking attitudes, and intellectual and professional standards. Clinical judgments require you to anticipate the information necessary, analyze the data, and make decisions regarding patient care.

In the case of bowel elimination, integrate the knowledge from nursing and other disciplines to understand the patient's response to bowel elimination alterations. Experience in caring for patients with elimination alterations helps you provide an appropriate plan of care. Use critical thinking attitudes such as fairness, confidence, and discipline when listening to and exploring the patient's nursing history. Apply relevant standards of practice (e.g., wound care standards, quality and safety standards) when selecting nursing measures.

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

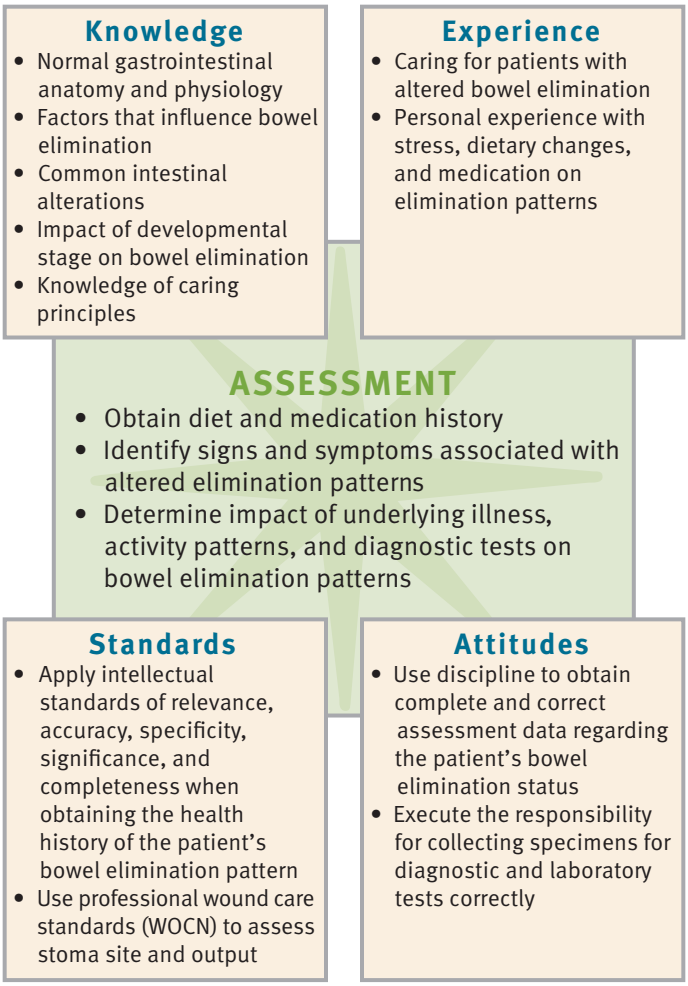

FIG. 46-12 Critical thinking model for elimination assessment. *WOCN,* Wound, Ostomy and Continence Nurses Society.

ASSESSMENT

During the assessment process, thoroughly assess each patient and critically analyze findings to ensure you make patient-centered clinical decisions required for safe nursing care. Consider all critical thinking elements that build toward making appropriate diagnoses (Fig. 46-12).

Assessment for bowel elimination patterns and abnormalities includes a nursing history, physical assessment of the abdomen, inspection of fecal characteristics, and review of relevant test results. In addition, determine the patient's medical history, pattern and types of fluid and food intake, chewing ability, medications, and recent illnesses and/or stressors.

Through the Patient's Eyes. Patients expect the nurse to answer all of their questions regarding diagnostic tests and the preparation for these tests. They are concerned about discomfort and exposure of their more personal areas. Bowel problems are often devastating for the patient and their families. Fecal incontinence in older people, most commonly caused by overflow leakage as a result of constipation, often means the breakdown of care at home, causing them to be admitted to a residential facility (Continence Care Position Statement, 2009). Some older patients who fail to recognize their elimination needs need monitoring for elimination patterns so negative consequences do not occur. Remember that each patient has a unique situation and a perception of what is "right" for him or her. Patients expect a knowledgeable nurse with the ability to teach methods of promoting and maintaining normal bowel elimination patterns. Consider the patient's cultural practices and preferences because patients of different cultures can have various expectations (Box 46-2).

Nursing History. The nursing history provides a review of the patient's usual bowel pattern and habits. What a patient describes as normal or abnormal is often different from factors and conditions that tend to promote normal elimination. Identifying normal and abnormal patterns, habits, and the patient's perception of normal and abnormal in regard to bowel elimination allows you to accurately determine a patient's problems. Organize the nursing history around factors that affect elimination (Wisniewski, 2010):

- *Determination of the usual elimination pattern:* Include frequency and time of day. Having the patient or caregiver complete a bowel elimination diary provides an accurate assessment of a patient's current bowel elimination pattern.
- *Patient's description of usual stool characteristics:* Determines whether the stool is normally watery or formed soft or hard, the typical color, and the presence of blood. Ask the patient to describe the usual shape of the stool and the number of stools per day.
- *Identification of routines followed to promote normal elimination:* Examples are drinking hot liquids, eating specific foods, or taking time to defecate during a certain part of the day.
- *Assessment of the use of artificial aids at home:* Assess whether and how often the patient uses enemas, laxatives,

BOX 46-2 CULTURAL ASPECTS OF CARE

Variables Influencing Colorectal Cancer Screening in African Americans

Biological, psychological, behavioral, and social variables influence colorectal cancer (CRC) screenings in African Americans. African Americans have a 20% higher rate of CRC and 40% higher incidence of disease-related death when compared with Caucasians (ACS, 2011b). Prevention resulting in early detection is key to finding CRC when it is often curable, but screening rates are low in African Americans.

Implications for Practice

- Lack of routine visits to a primary care provider is one of the strongest predictors for inadequate CRC screening and advanced stage at presentation (Griffin, 2009).
- Patients who do not have health insurance do not frequently seek CRC screening (Griffin, 2009).
- Patients who participate in preventive health practices (e.g., regular physical activity) often seek regular screening for CRC because these patients are often interested in promoting their own health (Griffin, 2009).
- Identification of additional social system predictors such as family support, church affiliation, and geographical access also help in receiving timely CRC screening (Griffin, 2009).
- Removing barriers of safety, quality, and cost-effectiveness improves the involvement of patients in CRC screening (Cronenwett et al., 2007).

or bulk-forming food additives before having a bowel movement.

- *Presence and status of bowel diversions:* If the patient has an ostomy, assess frequency of fecal drainage, character of feces, appearance and condition of the stoma (color, swelling, and irritation), type of fecal collection device used, and methods used to maintain the function of the ostomy.
- *Changes in appetite:* Include changes in eating patterns and a change in weight (amount of loss or gain). If a change of weight is present, ask if the patient planned it (e.g., weight loss with a diet).
- *Diet history:* Determine the patient's dietary preferences for a day. Determine the intake of fruits, vegetables, cereals, and breads and also if mealtimes are regular or irregular.
- *Description of daily fluid intake:* This includes the type and amount of fluid. The patient often estimates the amount using common household measurements.
- *History of surgery or illnesses affecting the GI tract:* This information helps explain symptoms, the potential for maintaining or restoring normal bowel elimination pattern, and whether there is a family history of GI cancer.
- *Medication history:* Ask whether the patient takes medications (e.g., laxatives, antacids, iron supplements, and analgesics) that alter defecation or fecal characteristics.
- *Emotional state:* The patient's emotions significantly alter frequency of defecation. During assessment observation of the patient's emotions, tone of voice, and mannerisms reveal significant behaviors that indicate stress.
- *History of exercise:* Ask the patient to specifically describe the type and amount of daily exercise.
- *History of pain or discomfort:* Ask the patient whether there is a history of abdominal or anal pain. The type, frequency, and location of pain help identify the source of the problem.
- *Social history:* Patients have many different living arrangements. Where patients live affects their toileting habits. If patients share living quarters, ask how many bathrooms there are. Find out if patients have their own bathroom or if they need to share bathrooms, creating a need to adjust the time they use the bathroom to accommodate others. If patients live alone, can they ambulate safely to the toilet? When patients are not independent in bowel management, determine who assists them and how.
- *Mobility and dexterity:* Evaluate patients' mobility and dexterity to determine if they need assistive devices or help from personnel.

Box 46-3 summarizes types of assessment questions to use for gathering a detailed nursing history.

Physical Assessment. Conduct a physical assessment of body systems and functions likely to be influenced by the presence of elimination problems (see Chapter 30).

Mouth. Inspect the patient's teeth, tongue, and gums. Poor dentition or poorly fitting dentures influence the ability to chew. Sores in the mouth make eating not only difficult but also painful.

Abdomen. Inspect all four abdominal quadrants for contour, shape, symmetry, and skin color. Note masses, peristaltic waves, scars, venous patterns, stomas, and lesions. Normally you do not see peristaltic waves. Observable peristalsis is often a sign of intestinal obstruction.

Abdominal distention appears as an overall outward protuberance of the abdomen. Intestinal gas, large tumors, or fluid in the peritoneal cavity cause distention. A distended abdomen feels tight like a drum; and the skin is taut and appears stretched.

Auscultate the abdomen with a stethoscope to assess bowel sounds in each quadrant (see Chapter 30). Normal bowel sounds occur every 5 to 15 seconds and last a second to several seconds. During auscultation note the character and frequency of bowel sounds. You hear an increase in pitch or a tinkling sound with abdominal distention. Absent (no auscultated bowel sounds) or hypoactive sounds (less than five sounds per minute) occur with paralytic ileus such as after abdominal surgery. High-pitched and hyperactive bowel sounds (35 or more sounds per minute) occur with small intestine obstruction and inflammatory disorders.

Percussion identifies underlying abdominal structures and detects lesions, fluid, or gas within the abdomen. Gas or flatulence creates a tympanic note. Masses, tumors, and fluid are dull to percussion (Wisniewski, 2010).

Gently palpate the abdomen for masses or areas of tenderness. It is important for the patient to relax. Tensing abdominal muscles interferes with palpating underlying organs or masses.

Rectum. Inspect the area around the anus for lesions, discoloration, inflammation, and hemorrhoids. Carefully record abnormalities.

Laboratory Tests. Laboratory and diagnostic examinations yield useful information concerning elimination problems (Table 46-3). Laboratory analysis of fecal contents detects pathological conditions such as tumors, bleeding, parasites, and infection.

Fecal Specimens. The nurse ensures that specimens are obtained accurately, labeled properly in appropriate containers, and transported to the laboratory on time. Institutions provide special containers for fecal specimens. Some tests require that specimens are placed in chemical preservatives. Use medical aseptic technique during collection of stool specimens (see Chapter 28). Because about 25% of the solid portion of a stool is bacteria from the colon, wear clean gloves when handling specimens.

Hand hygiene is necessary for anyone who comes in contact with the specimen. Often the patient is able to obtain the specimen if properly instructed. Teach the patient to avoid mixing feces with

BOX 46-3 NURSING ASSESSMENT QUESTIONS

Signs and Symptoms

Nausea or Vomiting: Onset, Duration, Associated Symptoms, Character, Exposures

- When did the nausea/vomiting start?
- Is it related to particular stimuli (odors, after eating specific food)?
- How does the emesis look (mucus type, bloody or coffee grounds, color, or undigested food)?
- Do you have other symptoms such as dizziness, headaches, abdominal pain, or weight loss?
- Do you have family members who are experiencing the same symptoms?

Indigestion: Onset, Character, Location, Associated Symptoms, Alleviating Factors

- Is the indigestion related to meals, types or quantity of food, time of day or night?
- Does the discomfort from indigestion radiate to the shoulders or arms?
- Do you feel bloated after eating?
- Do you have any other symptoms (vomiting, headaches, diarrhea, belching, flatulence, heartburn, or pain)?
- Does the indigestion respond to antacids or other self-care measures?

Diarrhea: Onset, Duration, Character, Associated Symptoms, Alleviating Factors, Exposure

- When did the diarrhea start? Was it gradual or sudden?
- How many stools do you have per day? Is it watery or explosive? What is the color and consistency?
- Have you had fever, chills, weight loss, or abdominal pain?
- Have you taken antibiotics recently?
- Have you been under stress?
- What have you used to try to alleviate the diarrhea? Was it successful?
- Have you been out of the country recently?

Constipation: Onset, Character, Symptoms, Alleviating Factors

- When was your last bowel movement? How many bowel movements do you have in a typical week?
- Is this a recent occurrence or a long-standing problem?
- Describe your bowel movements.
- Do you have to strain to have a bowel movement?
- Do you have abdominal or rectal pain when you have a bowel movement?
- Do you feel as though your bowel movements are incomplete?
- Have you recently changed your diet or fluid intake?
- Do you use stool softeners, laxatives, or enemas?
- Is it necessary to manually remove the bowel movements?

Medical History

- Do you have a previous history of gastrointestinal problems? If yes, explain.
- Have you had abdominal surgery or trauma?
- Do you have a history of major illnesses such as cancer, arthritis, respiratory disease (steroid use), kidney disease, or cardiac disease?

Effect on the Patient

- How do these symptoms affect you?
- Have you missed work or social engagements because of these symptoms?

TABLE 46-3 Laboratory and Diagnostic Tests for Bowel Function

MEASUREMENT AND NORMAL VALUES	INTERPRETATION
Laboratory Tests	
Total bilirubin: 0.3-1 mg/dL	Bilirubin is increased in hepatobiliary diseases, obstructions in bile duct, certain anemias, and following transfusion reactions (Pagana and Pagana, 2011).
Alkaline phosphatase: 30-120 units/L	Alkaline phosphatase is elevated in obstructive hepatobiliary diseases, hepatobiliary carcinomas, bone tumors, and healing fractures (Pagana and Pagana, 2011).
Amylase: 60-120 Somogyi units/dL	Amylase is elevated in abnormalities of the pancreas such as inflammation or tumors, cholecystitis, necrotic bowel, and diabetic ketoacidosis (Pagana and Pagana, 2011).
Carcinoembryonic antigen (CEA): less than 5 ng/mL	CEA is elevated in the presence of cancer or inflammation of the GI tract or hepatobiliary organs (Pagana and Pagana, 2011).
Direct Visualization	
Endoscopy, colonoscopy	Routine examination such as a colonoscopy is recommended for people after 50 years of age who have no family history of CRC. People with a personal or family history need to talk with their health care provider to determine if they need to start screening at an earlier age and recommended frequency of screening (ACS, 2011b). Normally the GI tract is free of polyps, tumors, inflammation, ulcers, hernias, obstruction, and ulcerations. If a lesion such as a polyp is identified, the health care provider removes the growth or a portion of the growth and sends it to pathology for analysis. If bleeding is present, the health care provider usually attempts to stop it at the source. In some cases the identification of an abnormality indicates the need for follow-up surgery for the patient.
Indirect Visualization	
X-ray film with contrast medium	X-ray identifies the presence of abnormalities in the GI tract. A series of x-ray films allow for indirect visualization of the entire tract (ACS, 2011b). The presence of tumors, ulcerations, inflammation, or other abnormalities indicates the need for further diagnostic testing and medical or surgical intervention.

BOX 46-4 PROCEDURAL GUIDELINES

View Video!

Performing a Guaiac Fecal Occult Blood Test

Delegation Considerations

The skill of performing a guaiac fecal occult blood test (gFOBT) can be delegated to nursing assistive personnel (NAP). However, the nurse must evaluate the significance of the findings. Instruct the NAP to

- Notify nurse immediately if frank red blood is noted or if a positive result for occult blood is found in the sample specimen.
- Have the patient void first to avoid contamination of the specimen.

Equipment

Hemoccult test paper, Hemoccult developer, and wooden applicator (Fig. 46-13)

1. Patient identification: Identify the patient using two identifiers (e.g., name and birth date or name and account number) according to facility policy. Compare identifiers with information on the patient's medical record (TJC, 2011).
2. Explain purpose of the test and ways for patient to assist. Patient can collect own specimen if possible.
3. Perform hand hygiene and apply clean disposable gloves.
4. Use tip of wooden applicator to obtain a small portion of a stool specimen. Be sure that specimen is free of tissue paper.
5. Perform Hemoccult slide test.
   a. Open flap of slide and, using the wooden applicator, thinly smear stool in the first box of the guaiac paper. Apply a second fecal specimen from a different portion of the stool to the second box of the slide (see illustration).
   b. Close slide cover and turn the packet over to the reverse side (see illustration). After waiting 3 to 5 minutes, open cardboard flap and apply 2 drops of developing solution on each smear.
   c. Interpret the color of the guaiac paper within 60 seconds. A blue color indicates a positive guaiac or presence of fecal occult blood.
   d. After determining if the patient's specimen is positive or negative, apply 1 drop of developer to the quality control section and interpret within 10 seconds.
6. Dispose of test slide in proper receptacle.
7. Wrap wooden applicator in paper towel, remove gloves, and discard in proper receptacle and perform hand hygiene.
8. Note color, changes on guaiac paper, and observe character of stool specimen.
9. Record results of test, noting any unusual fecal characteristics.

STEP 5a Application of fecal specimen on guaiac paper.

STEP 5b Application of hemoccult developing solution on guaiac paper on reverse side of test kit.

FIG. 46-13 Equipment for performing fecal occult blood testing.

urine or water. The patient defecates into a clean, dry bedpan or a special container under the toilet seat.

Tests performed by the laboratory for occult (microscopic) blood in the stool and stool cultures require only a small sample. Collect about 2.54 cm (1 inch) of formed stool or 15 to 30 mL of liquid diarrhea stool. Tests for measuring the output of fecal fat require a 3- to 5-day collection of stool. You need to save all fecal material throughout the test period.

After obtaining a specimen, label and tightly seal the container and complete all laboratory requisition forms. Record specimen collections in the patient's medical record. It is important to avoid delays in sending specimens to the laboratory. Some tests such as measurement for ova and parasites require the stool to be warm. When stool specimens remain at room temperature, bacteriological changes that alter test results occur.

A common laboratory test that patients perform at home or nurses perform at the patient's bedside is the **fecal occult blood test (FOBT),** or guaiac test, which measures microscopic amounts of blood in feces (Box 46-4). It is useful as a diagnostic screening

TABLE 46-4 Fecal Characteristics

CHARACTERISTIC	NORMAL	ABNORMAL	ABNORMAL CAUSE
Color	Infant: yellow; adult: brown	White or clay	Absence of bile
		Black or tarry (melena)	Iron ingestion or upper gastrointestinal (GI) bleeding
		Red	Lower GI bleeding, hemorrhoids
		Pale with fat	Malabsorption of fat
		Translucent mucus	Spastic constipation, colitis, excessive straining
		Bloody mucus	Blood in feces, inflammation, infection
Odor	Pungent; affected by food type	Noxious change	Blood in feces or infection
Consistency	Soft, formed	Liquid	Diarrhea, reduced absorption
		Hard	Constipation
Frequency	*Varies:* Infant 4-6 times daily (breastfed) or 1-3 times daily (bottle-fed); adult daily or 2-3 times a week	Infant more than 6 times daily or less than once every 1-2 days; adult more than 3 times a day or less than once a week	
Amount	150 g/day (adult)		Hypomotility or hypermotility
Shape	Resembles diameter of rectum	Narrow, pencil shaped	Obstruction, rapid peristalsis
Constituents	Undigested food, dead bacteria, fat, bile pigment, cells lining intestinal mucosa, water	Blood, pus, foreign bodies, mucus, worms	Internal bleeding, infection, swallowed objects, irritation, inflammation
		Excess fat	Malabsorption syndrome, enteritis, pancreatic disease, surgical resection of intestine

BOX 46-5 SCREENING FOR COLON CANCER

Risk Factors

- *Age:* Over 50 years of age
- *Family history:* Colorectal cancer
- Personal history of colorectal cancer; colorectal polyps; chronic inflammatory bowel disease (IBD), including ulcerative colitis and Crohn's disease
- *Ethnic background:* Jews of Eastern European descent
- *Race:* African Americans
- *Diet:* High intake of animal fats and low in fruits and vegetables
- Obesity and inactivity
- Smoking and alcohol intake
- Diabetes

Warning Signs

- Change in bowel habits
- Rectal bleeding
- Sensation of incomplete bowel evacuation

Beginning at age 50, men and women who are at average risk for developing colorectal cancer need to have one of the following five screening options:

- A fecal occult blood test or fecal immunochemical test (also called the iFOBT)] every year *or*
- Flexible sigmoidoscopy every 5 years *or*
- A gFOBT or iFOBT every year plus flexible sigmoidoscopy every 5 years (Of these first three options, the combination of gFOBT or iFOBT every year plus flexible sigmoidoscopy every 5 years is preferable.) *or*
- Double contrast barium enema every 5 years *or*
- Colonoscopy every 10 years

Data from The American Cancer Society (ACS): *Detailed guide: colon and rectum cancer: revised 6/17/2011,* 2011b, http://www.cancer.org/Cancer/ColonandRectumCancer/DetailedGuide/index. Accessed December 3, 2011. *gFOBT,* Guaiac fecal occult blood test; *iFOBT,* immunochemical fecal occult blood test.

tool for colon cancer (Box 46-5). The noninvasive FOBT is one of five colorectal cancer screening regimens recommended by the American Cancer Society (ACS, 2011a; 2011b). Three types of FOBT are available to date. They include the most commonly used guaiac fecal occult blood test (gFOBT), the immunochemical fecal occult blood test (iFOBT), and the stool deoxyribonucleic acid (DNA) test. One positive gFOBT result does not confirm GI bleeding. You need to repeat the test at least three times while the patient refrains from ingesting foods (e.g., some raw vegetables, red meat, poultry, fish) and medications (e.g., vitamin C, aspirin, nonsteroidal anti-inflammatory drugs) that cause false-positive results (Peters, 2008). Patients who take anticoagulants or who have a bleeding disorder or a GI disorder known to cause bleeding (e.g., intestinal tumors, bowel inflammation, or ulcerations) need regular screening for fecal occult blood.

Fecal Characteristics. Inspection of fecal characteristics (Table 46-4) reveals information about the nature of elimination alterations. Several factors influence each characteristic. Knowing whether there have been any recent changes is a key to assessment. The patient best provides this information during the nursing history.

Diagnostic Examinations. A variety of radiological and diagnostic tests are used with the patient experiencing altered bowel elimination (Box 46-6). Direct or indirect approaches are used to visualize GI structures. Many facilities use moderate sedation during these procedures. The most common types of drugs used to achieve moderate sedation include benzodiazepines and opiates. It is essential to understand the safety precautions involved concerning this form of anesthesia. In many institutions special training is required. A crash cart must be present at the bedside; and you must monitor the patient continuously with pulse oximetry and frequent vital signs, usually every 15 minutes

BOX 46-6 RADIOLOGICAL AND DIAGNOSTIC TESTS

Plain Film of Abdomen/Kidneys, Ureter, Bladder
- A simple x-ray film of the abdomen requires no preparation.

Upper Gastrointestinal/Barium Swallow
- An x-ray film examination using an opaque contrast medium (barium) examines the structure and motility of the upper gastrointestinal (GI) tract, including pharynx, esophagus, and stomach.
- Patient is ordered to have nothing by mouth (NPO) after midnight the night before the examination.
- Patient removes all jewelry or other metallic objects before the test.
- After the test patient needs to increase fluids to facilitate passage of barium.

Upper Endoscopy
- An endoscopic examination of the upper GI tract allows more direct visualization through a lighted fiber-optic tube that contains a lens, forceps, and brushes for biopsy.
- Preparation is similar to that for the upper GI.
- Light sedation is required (Herman, 2010).

Barium Enema with Air Contrast
- An x-ray film examination uses an opaque contrast medium and air that outlines the colon and rectum to examine the lower GI tract.
- Preparation includes NPO after midnight, a bowel preparation such as magnesium citrate, and in some instances enemas to empty out any remaining stool particles (ACS, 2011b).

Ultrasound
- This technique uses high-frequency sound waves to echo off body organs, creating a picture.
- Preparation depends on the organ to be visualized and includes NPO or no preparation.

Colonoscopy
- An endoscopic examination of the entire colon uses a colonoscope inserted into the rectum.
- Preparation is similar to that for barium enema: clear liquids the day before and then some form of bowel cleanser such as GoLytely. Enemas until clear are also common.
- Light sedation is required (Herman, 2010).

Flexible Sigmoidoscopy
- An examination of the interior of the sigmoid colon with a flexible or rigid lighted tube.
- Preparation is similar to that for a barium enema or colonoscopy.
- Light sedation is required (ACS, 2011b).

Computerized Tomography Scan
- An x-ray film examination of the body from many angles uses a scanner analyzed by a computer.
- Preparation is usually NPO.
- The patient needs to lie very still. If claustrophobia is a problem, use light sedation.

Magnetic Resonance Imaging
- A noninvasive examination uses magnet and radio waves to produce a picture of the inside of the body.
- Preparation is NPO 4 to 6 hours before examination.
- No metallic objects, including metal objects on clothes, are allowed in the room.

Enteroclysis
- Contrast material is introduced to jejunum, allowing entire small intestine to be studied.
- Preparation is 24 hours of clear liquid diet and colon cleansing such as GoLytely or enemas until clear.

during and immediately following the procedure (check agency policy).

NURSING DIAGNOSIS

The nursing assessment of the patient's bowel function reveals data that indicate an actual or potential elimination problem or a problem resulting from elimination alterations. In the examples discussed in the Nursing Care Plan, a patient has constipation as a result of pain medications and decreased fiber intake. Examples of diagnoses that apply to patients with elimination problems include the following:

- Bowel incontinence
- Constipation
- Risk for constipation
- Perceived constipation
- Diarrhea
- Toileting self-care deficit

Associated problems such as age, body-image changes, or skin breakdown require interventions unrelated to bowel function impairment. Ability to identify the correct diagnosis depends not only on the thoroughness of assessment but also on recognition of defining characteristics and factors that impair elimination (Box 46-7). Determine the patient's risk and institute measures to ensure maintenance of normal bowel function.

BOX 46-7 NURSING DIAGNOSTIC PROCESS

Constipation

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS
Ask patient about bowel elimination patterns.	Patient reports no bowel movement for 4 days.
Auscultate bowel sounds.	Bowel sounds are decreased in all four quadrants.
Ask patient to describe recent food and fluid intake.	Patient reports drinking six cups of coffee throughout day but no water. Eating his regular diet but no extra fiber.
Palpate abdomen.	Patient reports pain. Left lower quadrant is tender and firm.

PLANNING

When planning care, synthesize information from multiple resources (Fig. 46-14). Critical thinking ensures that the plan of care integrates everything known about the patient and the clinical problem. Rely on professional standards. The guidelines on incontinence assist in protecting the patient's skin, promoting continence, and reducing the embarrassment associated with

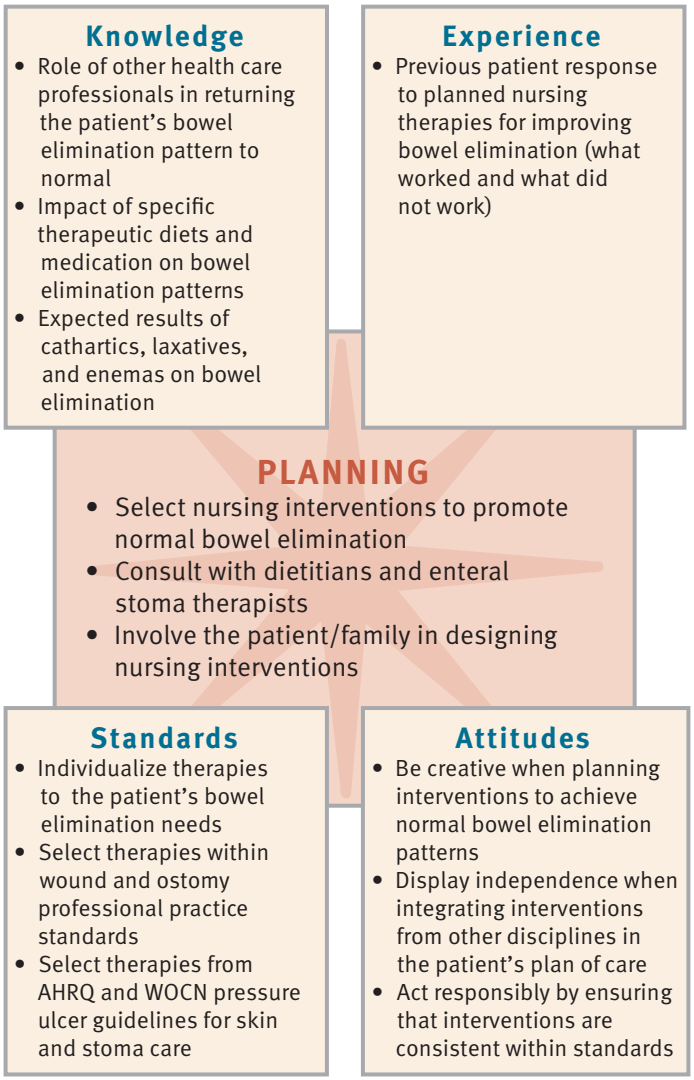

FIG. 46-14 Critical thinking model for elimination planning. *AHRQ,* Agency for Healthcare Research and Quality; *WOCN,* Wound, Ostomy and Continence Nurses Society.

incontinence. In addition, the Agency for Healthcare Research and Quality (AHRQ) provides guidelines on reduction of pressure ulcers that also help you develop a plan of care for patients with bowel incontinence (see Chapter 48).

Goals and Outcomes. Help patients establish goals and outcomes by incorporating their elimination habits or routines as much as possible and reinforcing the routines that promote health (see the Nursing Care Plan). In addition, consider preexisting health concerns. For example, if a patient is at risk for worsening heart failure, you need to individualize an outcome of increased fluid intake to accommodate cardiac function and the patient's ability to safely handle the increased fluid. In another example, if a patient's bowel habits caused the elimination problem, help the patient learn new habits. The overall goal of returning the patient to a normal bowel elimination pattern includes the following outcomes:

- Patient sets regular defecation habits.
- Patient is able to list proper fluid and food intake needed to achieve bowel elimination.
- Patient implements a regular exercise program.
- Patient reports daily passage of soft, formed brown stool.
- Patient does not report discomfort associated with defecation.

Setting Priorities. Defecation patterns vary among individuals. For this reason the nurse and patient work together closely to plan effective interventions. Patients often have multiple diagnoses. The concept map (Fig. 46-15) shows an example of how the nursing diagnosis of constipation is related to three other diagnoses and their respective interventions. A realistic time frame to establish a normal defecation pattern for one patient is sometimes very different for another. In the patient with recent abdominal surgery, the priorities of pain management and the avoidance of constipation through increasing fiber in the diet and increasing activity help in the recovery process.

Teamwork and Collaboration. When patients are disabled or debilitated by illness, you need to include the family in the plan of care. In some situations family members have the same ineffective elimination habits as the patient. Thus patient and family teaching is an important part of the care plan. Other health team members such as dietitians and WOCNs are often valuable resources. You coordinate activities of the multidisciplinary health care team.

The patient with alterations in bowel elimination requires intervention from many members of the health care team. Certain tasks such as assisting patients onto the bedpan or bedside commode are appropriate to delegate to nursing assistive personnel (NAP). It is important to remind the NAP to report any abnormal findings or difficulties encountered during the elimination process. Many of the diagnostic tests for evaluation of the GI system are performed by nonnursing personnel. Maintain ongoing communication with these caregivers to ensure that you provide safe and effective patient-centered care and address the patient's needs, wants, and concerns (Cronenwett et al., 2007).

IMPLEMENTATION

Successful nursing interventions improve the patients' and family members' understanding of bowel elimination. Teach the patient and family about proper diet, adequate fluid intake, and factors that stimulate or slow peristalsis such as emotional stress. This is often best done during the patient's mealtime. Patients also need to learn the importance of establishing regular bowel routines, regular exercise, and taking appropriate measures when elimination problems develop.

Health Promotion. One of the most important habits to teach regarding bowel habits is to take time for defecation. To establish regular bowel habits, a patient needs to know when the urge to defecate normally occurs. Advise the patient to begin establishing a routine during a time when defecation is most likely to occur, usually an hour after a meal. When patients are restricted to bed or need help to ambulate, offer a bedpan or help them reach the bathroom in a timely manner.

Many patients have established routines for defecation. In a hospital or long-term care facility make certain that treatment routines do not interfere with the patient's routine. It is important to provide privacy. When patients forced to use a bedpan share rooms with other people, pull the curtain around the area so patients are able to relax, knowing that interruptions will not occur. Always place the call light and toilet tissue within the patient's reach. When patients are at risk for falls, you stand near them or leave the door partially open so you can see them at all times.

Promotion of Normal Defecation. A number of interventions stimulate the defecation reflex, affect the character of feces, or

NURSING CARE PLAN

Constipation

ASSESSMENT

Javier, a home care nurse, is visiting Larry Johnston at his home on one of the local cattle ranches. Larry lives 20 miles from town. He is 22 years old and had surgery 6 days ago for repair of a badly broken right leg, after being thrown from a horse. Larry tells Javier that he "just doesn't feel well." His past history includes pneumonia at age 12 and a recent traumatic injury to the abdomen. The injury required emergency surgery after he was struck by a bull's horns.

Assessment Activities	*Findings/Defining Characteristics**
Ask Larry about his bowel elimination patterns over the last 5 days.	Larry tells Javier that he **has not had a bowel movement since he left the hospital 4 days ago** and that his **abdomen is tight and sore.**
Review patient's medication.	Larry says he is taking one Percocet tablet for pain, up to three tablets a day.
Review dietary and fluid intake over last day.	Diet included eggs, bacon, and toast for breakfast; soup for lunch; and chicken, rice, and corn for dinner. He drinks about six cups of coffee each day, no water, but will drink a cola.
Ask about any nausea or vomiting.	**Denies any nausea or vomiting.**
Auscultate patient's abdomen.	**Decreased bowel sounds** are auscultated throughout all four abdominal quadrants.
Palpate abdomen.	While Javier is palpating Larry's abdomen, Larry tells Javier, **"It really hurts."** On palpation **left lower quadrant is tender and firm.**

***Defining characteristics** are shown in bold type.

NURSING DIAGNOSIS: Constipation related to opiate-containing pain medication and decreased fiber intake

PLANNING

Goals	*Expected Outcomes (NOC)*†
Larry will establish normal defecation.	**Bowel Elimination** Larry will report passage of soft, formed stool without straining in next 24 hours.
Larry will make changes to his diet to prevent constipation.	**Nutritional Status: Food and Fluid Intake** Larry will drink at least 1500 mL of fluid over the next 8 hours. Larry will increase the fiber content of his diet.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡ *Constipation/Impaction Management*	RATIONALE
Encourage fluid intake of appropriate fluids, fruit juice, and water.	At least 1500 mL fluid intake daily is necessary to prevent hard, dry stool (JBI, 2008).
Encourage activity within patient's mobility regimen.	Minimal activity (such as leg lifts) increases peristalsis.
Instruct Larry to add 20g/day of wheat bran to diet.	Bran along with physical activity prevents constipation (JBI, 2008).
Provide laxative or stool softeners as ordered.	Medications soften the stool and prevent straining (Lehne, 2010).
Provide privacy during toileting.	Patients need to feel relaxed when moving bowels (Holman et al., 2008).

‡Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	*Patient Response/Finding*	*Achievement of Outcomes*
Ask Larry to identify foods high in fiber.	Able to state appropriate foods. Review of 24-hour diet diary shows Larry is selecting high-fiber, low-fat foods.	Larry is making excellent progress in introducing high-fiber and low-fat foods into his diet.
Ask Larry about physical activity.	Larry states that he has not changed his activity pattern.	Larry did not increase activity pattern and needs to continue to work on this intervention.
Observe Larry's subsequent stool for characteristics such as consistency and color.	Stools are now every 24 to 48 hours. Larry does not "feel regular." Abdomen is soft and nondistended. Stools are formed and hard, but Larry does report straining.	Larry did not achieve passage of regular, formed stool.

CONCEPT MAP

Nursing diagnosis: Insomnia related to pain
- States, "I can't get comfortable in bed"
- States, "The pain keeps me from falling asleep"
- Wakes up frequently during the night
- Reports feeling tired in the morning

Interventions:
- Encourage Larry to take a pain pill before bedtime
- Ensure environment is conducive to sleep (e.g., light, temperature, noise)
- Encourage increased activity during day as tolerated
- Teach Larry sleep hygiene measures

Nursing diagnosis: Acute pain related to physical injury
- Abdomen tight and sore
- Repair of fractured leg
- Difficulty finding a pain-free position
- States, "It really hurts"

Interventions:
- Provide pain medication as needed
- Teach Larry relaxation techniques
- Assist Larry to a comfortable position

Primary health problem: Constipation, traumatic injury, pain
Priority assessments: Bowel elimination, reports of pain, activity level, sleep pattern

Nursing diagnosis: Constipation related to effects of opioid pain medication
- Abdominal distention
- Hypoactive bowel sounds
- Last bowel movement 4 days ago
- Does not drink water during day

Interventions:
- Increase fluid intake, especially water
- Increase fiber in diet
- Use bulk-forming or stimulant laxative as needed
- Provide privacy during toileting

Nursing diagnosis: Activity intolerance related to pain
- Unable to tolerate ambulation
- Difficulty changing positions
- Experiences pain during position change
- Resistant to position changes

Interventions:
- Administer pain medication 30 minutes before activity
- Encourage activity within Larry's mobility regimen
- Assist Larry in changing position

Link between medical diagnosis and nursing diagnosis

Link between nursing diagnoses

FIG. 46-16 Types of bedpans. *From left,* Regular bedpan and fracture bedpan.

increase peristalsis to help patients evacuate bowel contents normally and without discomfort.

Sitting Position. Assist patients who have difficulty sitting because of muscular weakness and mobility problems. Place an elevated seat on the toilet when patients are unable to lower themselves to a sitting position because of joint- or muscle-wasting diseases. These seats require patients to use less effort to sit or stand.

Positioning on Bedpan. Patients restricted to bed use bedpans for defecation. Women use bedpans to pass both urine and feces, whereas men use bedpans only for defecation. Sitting on a bedpan is extremely uncomfortable. Help position patients comfortably. Two types of bedpans are available (Fig. 46-16). The regular bedpan, made of plastic, has a curved smooth upper end and a sharper-edged lower end and is about 5 cm (2 inches) deep. The

smaller fracture pan, designed for patients with lower-extremity fractures, has a shallow upper end about 1.3 cm (½ inch) deep. The shallow end of the pan fits under the buttocks toward the sacrum; the deeper end, which has a handle, goes just under the upper thighs. The pan needs to be high enough so feces enter it.

When positioning a patient, it is important to prevent muscle strain and discomfort. Never try to lift a patient onto a bedpan. Never place a patient on a bedpan and then leave with the bed flat unless activity restrictions demand it. If the bed is flat, the hips remain hyperextended.

Fig. 46-17 shows proper and improper positions on bedpans. The best method for bedpan placement is to first be sure that the patient is positioned high in bed. Then raise the patient's head about 30 degrees to prevent hyperextension of the back and provide support to the upper torso. The patient then raises the hips by bending the knees and lifting the hips upward. Place a hand palm up under the patient's sacrum, resting the elbow on the mattress and using it as a lever to help in lifting while slipping the pan under the patient. Patients who have had abdominal surgery are hesitant to exert strain on suture lines and often have difficulty positioning on a pan. Always wear gloves when handling a bedpan.

When patients are immobile or it is unsafe to allow them to raise their hips, they remain flat and roll onto the bedpan by using the following steps:

1. Lower the head of the bed flat and help the patient roll onto one side, backside toward the nurse.
2. Apply a small amount of powder to back and buttocks or cover bedpan edge with tissue to prevent skin from sticking to the pan.
3. Place the bedpan firmly against the buttocks, down into the mattress with the open rim toward the patient's feet (Fig. 46-18).
4. Keeping one hand against the bedpan, place the other around the patient's fore hip. Ask the patient to roll back onto the pan, flat in bed. Do not shove the pan under the patient.
5. With the patient positioned comfortably, raise the head of the bed 30 degrees.
6. Place a rolled towel or small pillow under the lumbar curve of the patient's back for added comfort.
7. Raise the knee gatch or ask the patient to bend the knees to assume a squatting position. Do not raise the knee gatch if contraindicated.

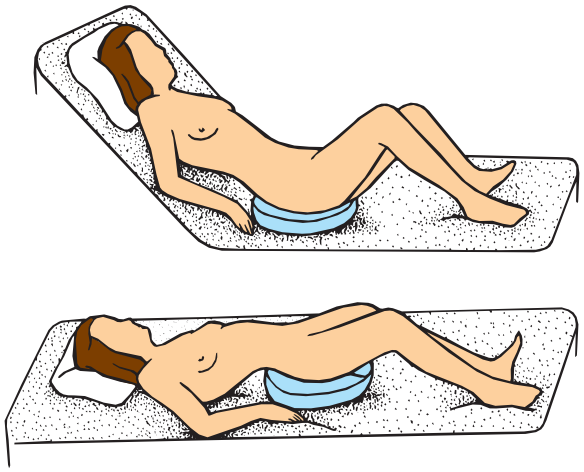

FIG. 46-17 Positions on a bedpan. *Top,* Proper position reduces patient's back strain. *Bottom,* Improper positioning of patient.

Privacy. Maintain the patient's privacy during bowel elimination. This is especially important for a patient using a bedpan. The call light and a supply of toilet paper need to be within easy reach. When the patient finishes, respond to the call signal immediately and remove the pan. The patient often requires assistance with wiping. To remove the pan, ask the patient to roll off to the side or raise the hips. While wearing gloves, hold the pan steady to avoid spilling. Avoid pulling or shoving it from under the patient's hips because this pulls the patient's skin and causes tissue injury such as shearing (see Chapter 48). Remove the pan and clean the perineum front to back.

After assessing the stool, immediately empty the contents of the bedpan into the toilet or in a special receptacle in the utility room. A spray faucet attached to most toilets allows for the ability to rinse the bedpan thoroughly. The patient uses the same bedpan each time. Finally, document the characteristics of the feces.

Offer the bedpan often. Patients will accidentally soil bedclothes if forced to wait. Many patients try to avoid using a bedpan because it is embarrassing and uncomfortable. They often try to get to the bathroom even though their conditions prohibit ambulation. Warn patients about the risk of falls or accidents.

Acute Care. With some acute illnesses the GI system becomes affected. Changes in the patient's fluid status, mobility patterns, nutrition, and sleep cycle affect regular bowel habits. Surgical interventions on the GI tract obviously affect bowel elimination. However, surgery on other systems (e.g., the musculoskeletal and cardiovascular systems) sometimes affects the patient's bowel elimination patterns. Remain sensitive to patients' elimination needs and intervene to help them maintain as normal bowel elimination habits as possible.

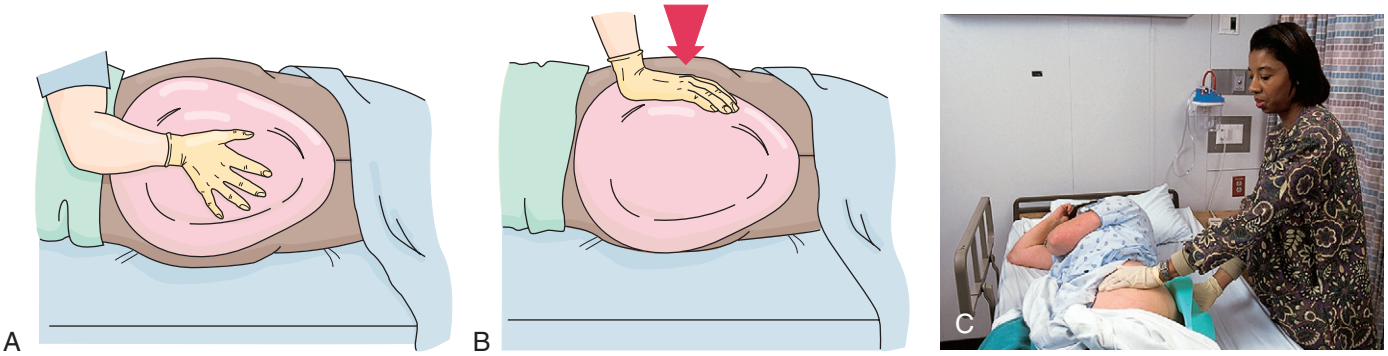

FIG. 46-18 Positioning immobilized patient on bedpan. **A,** Place bedpan firmly against buttocks. **B,** Push buttocks down into mattress with open rim toward feet. **C,** Place one hand against bedpan; place other hand around patient's fore hip.

Medications. Some medications initiate and facilitate bowel elimination. Cathartics, laxatives, and occasionally an enema are used to resolve constipation; antidiarrheal preparations help the patient to resolve diarrhea. All of these medications are available over the counter; stronger preparations are available through prescriptions. Caution patients not to use these over-the-counter medications on a prolonged basis without consulting their health care provider.

Building Competency in Patient-Centered Care You are caring for Mr. Miner, an 82-year-old male who reports experiencing constipation. He is hard of hearing and has bilateral cataracts. He admits to using laxatives and/or enemas at least on a biweekly basis. What assessment questions and teaching strategies, approaches, and tools do you use to enhance Mr. Miner's learning and ability to prevent constipation?

Answers to questions can be found on the Evolve website.

Cathartics and Laxatives. Often a patient is unable to defecate normally because of pain, constipation, or impaction. Cathartics and laxatives have the short-term action of emptying the bowel. They are prescribed for bowel evacuation for patients undergoing GI tests and abdominal surgery. Although the terms *cathartic* and *laxative* are often used interchangeably, cathartics have a stronger effect on the intestines. Five types of laxatives and cathartics are available (Table 46-5).

Cathartics and laxatives come in oral, tablet, powder, and suppository dosage forms (see Chapter 31). Although the oral route is most commonly used, suppositories are more effective because of their stimulant effect on the rectal mucosa. Cathartic suppositories such as bisacodyl (Dulcolax) act within 30 minutes. Older adults often get a strong sudden urge to defecate with Dulcolax.

Excessive use of laxatives, enemas, and/or bulk-forming agents increases the patient's risk for diarrhea and abnormal bowel elimination. It can impair the patient's normal defecation reflex. In

TABLE 46-5 Common Types of Laxatives and Cathartics

AGENT/BRAND NAME	ACTION	INDICATIONS	RISKS
Bulk Forming			
Methylcellulose (Citrucel) Psyllium (Metamucil, Naturacil) Polycarbophil (Fibercon)	High-fiber content absorbs water and increases solid intestinal bulk (JBI, 2008; Lehne, 2010). Agents stretch intestinal wall to stimulate peristalsis.	Agents are least irritating, most natural, and safest cathartics. Agents are drugs of choice for chronic constipation (e.g., pregnancy, low-residue diet). Also relieves mild diarrhea. If treating diarrhea, administer less water.	Agents that are in powder form cause obstruction if not mixed with at least 240 mL of water or juice and swallowed quickly. Caution is necessary with bulk-forming laxatives that also contain stimulants. Agents are not for patients for whom large fluid intake is contraindicated. Follow each dose with 8 oz water.
Emollient or Wetting			
Docusate sodium (Colace, Correctol, Disonate) Docusate calcium (Surfak) Docusate potassium (Dialose)	Stool softeners are detergents that lower surface tension of feces, allowing water and fat to penetrate. They increase secretion of water by intestine (Lehne, 2010).	Agents are for short-term therapy to relieve straining on defecation (e.g., hemorrhoids, perianal surgery, pregnancy, recovery from myocardial infarction).	Agents are of little value for treatment of chronic constipation.
Saline			
Magnesium citrate or citrate of magnesia Magnesium hydroxide (Milk of Magnesia) Sodium phosphate (Fleet Phospho-Soda, Fleet Enema)	Agents contain salt preparation not absorbed by intestines. Osmotic effect increases pressure in bowel to act as stimulant for peristalsis (Lehne, 2010).	Agents are only for acute emptying of bowel (e.g., endoscopic examination, suspected poisoning, acute constipation).	Agents are not for long-term management of constipation. Agents are not for patients with kidney dysfunction (toxic buildup of magnesium). Phosphate salts are not for patients on fluid restriction.
Stimulant Cathartics			
Bisacodyl (Dulcolax) Castor oil Casanthranol (Peri-Colace) Senna (Ex-Lax, Senokot)	Agents irritate intestinal mucosa to increase motility (Lehne, 2010). Agents decrease absorption in small bowel and colon (Lehne, 2010).	Agents prepare bowel for diagnostic procedures.	Agents cause severe cramping. Agents are not for long-term use. Chronic use causes fluid and electrolyte imbalances.
Lubricants			
Mineral oil (Haley's M-O, Petrogalar Plain)	Agents coat fecal contents, allowing easier passage of stool (Lehne, 2010). Agents reduce water absorption in colon.	Agents prevent straining on defecation (e.g., hemorrhoids, perianal surgery).	Agents decrease absorption of fat-soluble vitamins (A, D, E, and K). They cause dangerous form of pneumonia if aspirated into lungs. When taken with emollients, mineral oil increases risk for fat emboli.

addition, the patient develops altered absorption of nutrients, fluid and electrolyte imbalances, and generalized weakness. In chronically ill or older adult patients weakness and the frequent need to use toilet facilities result in an increased risk for falls and other injuries.
