FUNDAMENTALS OF NURSING

EIGHTH EDITION

POTTER ■ PERRY
STOCKERT ■ HALL

ELSEVIER

http://evolve.elsevier.com

CONTENTS

UNIT 1
Nursing and the Health Care Environment

1 Nursing Today, 1
Anne Griffin Perry, RN, EdD, FAAN

2 The Health Care Delivery System, 14
Patricia A. Stockert, RN, BSN, MS, PhD

3 Community-Based Nursing Practice, 31
Anne Griffin Perry, RN, EdD, FAAN

4 Theoretical Foundations of Nursing Practice, 40
Anne Griffin Perry, RN, EdD, FAAN

5 Evidence-Based Practice, 50
Amy M. Hall, RN, BSN, MS, PhD, CNE

UNIT 2
Caring Throughout the Life Span

6 Health and Wellness, 65
Patricia A. Stockert, RN, BSN, MS, PhD

7 Caring in Nursing Practice, 79
Anne Griffin Perry, RN, EdD, FAAN

8 Caring for the Cancer Survivor, 90
Kay E. Gaehle, PhD, RN

9 Culture and Ethnicity, 101
Jerrilee LaMar, PhD, RN, CNE

10 Caring for Families, 116
Anne Griffin Perry, RN, EdD, FAAN

11 Developmental Theories, 130
Karen Balakas, PhD, RN, CNE

12 Conception Through Adolescence, 139
Karen Balakas, PhD, RN, CNE

13 Young and Middle Adults, 157
Patsy L. Ruchala, DNSc, RN

14 Older Adults, 171
Karen Korem, RN-BC, MA

UNIT 3
Critical Thinking in Nursing Practice

15 Critical Thinking in Nursing Practice, 192
Patricia A. Potter, RN, MSN, PhD, FAAN

16 Nursing Assessment, 206
Patricia A. Potter, RN, MSN, PhD, FAAN

17 Nursing Diagnosis, 222
Patricia A. Potter, RN, MSN, PhD, FAAN

18 Planning Nursing Care, 236
Patricia A. Potter, RN, MSN, PhD, FAAN

19 Implementing Nursing Care, 253
Patricia A. Potter, RN, MSN, PhD, FAAN

20 Evaluation, 265
Patricia A. Potter, RN, MSN, PhD, FAAN

21 Managing Patient Care, 274
Patricia A. Stockert, RN, BSN, MS, PhD

Unit 4
Professional Standards in Nursing Practice

22 Ethics and Values, 286
Margaret Ecker, RN, MS

23 Legal Implications in Nursing Practice, 296
Christine R. Durbin, PhD, JD, RN

24 Communication, 309
Jeri Burger, PhD, RN

25 Patient Education, 328
Amy M. Hall, RN, BSN, MS, PhD, CNE

26 Documentation and Informatics, 348
Frank Lyerla, PhD, RN

Unit 5
Foundations for Nursing Practice

27 Patient Safety, 365
Marinetta DeMoss, RN, MSN

28 Infection Prevention and Control, 398
Ruth M. Curchoe, RN, MSN, CIC

29 Vital Signs, 441
Susan Jane Fetzer, PhD, RN, MBA

30 Health Assessment and Physical Examination, 487
Rhonda W. Comrie, PhD, RN, CNE, AE-C

31 Medication Administration, 565
Amy M. Hall, RN, BSN, MS, PhD, CNE

32 Complementary and Alternative Therapies, 643
Mary S. Koithan, PhD, RN, CNS-BS

UNIT 6
Psychosocial Basis for Nursing Practice

33 Self-Concept, 658
Victoria N. Folse, PhD, APN, PMHCNS-BC, LCPC

34 Sexuality, 674
Kathy Lever, MSN, WHNP-C

35 Spiritual Health, 691
Amy M. Hall, RN, BSN, MS, PhD, CNE

36 The Experience of Loss, Death, and Grief, 708
Valerie Yancey, PhD, RN

37 Stress and Coping, 731
Marjorie Baier, PhD, RN

UNIT 7
Physiological Basis for Nursing Practice

38 Activity and Exercise, 746
Rita Wunderlich, PhD, RN

39 Hygiene, 768
Deborah Marshall, MSN

40 Oxygenation, 821
Paulette M. Archer, RN, EdD

41 Fluid, Electrolyte, and Acid-Base Balance, 882
Linda Felver, PhD, RN

42 Sleep, 939
Patricia A. Stockert, RN, BSN, MS, PhD

43 Pain Management, 962
Linda Cason, MSN, RN-BC, NE-BC, CNRN

44 Nutrition, 996
Patricia A. Stockert, RN, BSN, MS, PhD

45 Urinary Elimination, 1042
Terry L. Wood, PhD, RN, CNE

46 Bowel Elimination, 1087
Lori Klingman, MSN, RN

47 Mobility and Immobility, 1127
Ann B. Tritak, EdD, MA, BSN, RN

48 Skin Integrity and Wound Care, 1176
Janice Colwell, RN, MS, CWOCN, FAAN

49 Sensory Alterations, 1233
Jill Parsons, RN, MSN, PCCN

50 Care of Surgical Patients, 1254
Carrie Sona, RN, MSN, CCRN, ACNS, CCNS

Glossary, 1296

Nursing Diagnoses—Definitions and Classification 2012-2014. Copyright © 2011, 2009, 2007, 2005, 2003, 2001, 1998, 1996, 1994 by NANDA International. Used by arrangement with Wiley-Blackwell Publishing, a company of John Wiley and Sons, Inc. In order to make safe and effective judgments using NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in the work.

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

The ongoing writing and review of a text requires the support of many people. I dedicate this book to the many professional colleagues who have contributed, reviewed, and critiqued our texts over the years and have always elevated the quality of our work. And I dedicate this book to my very dear friends, who offer consistent support and understanding.

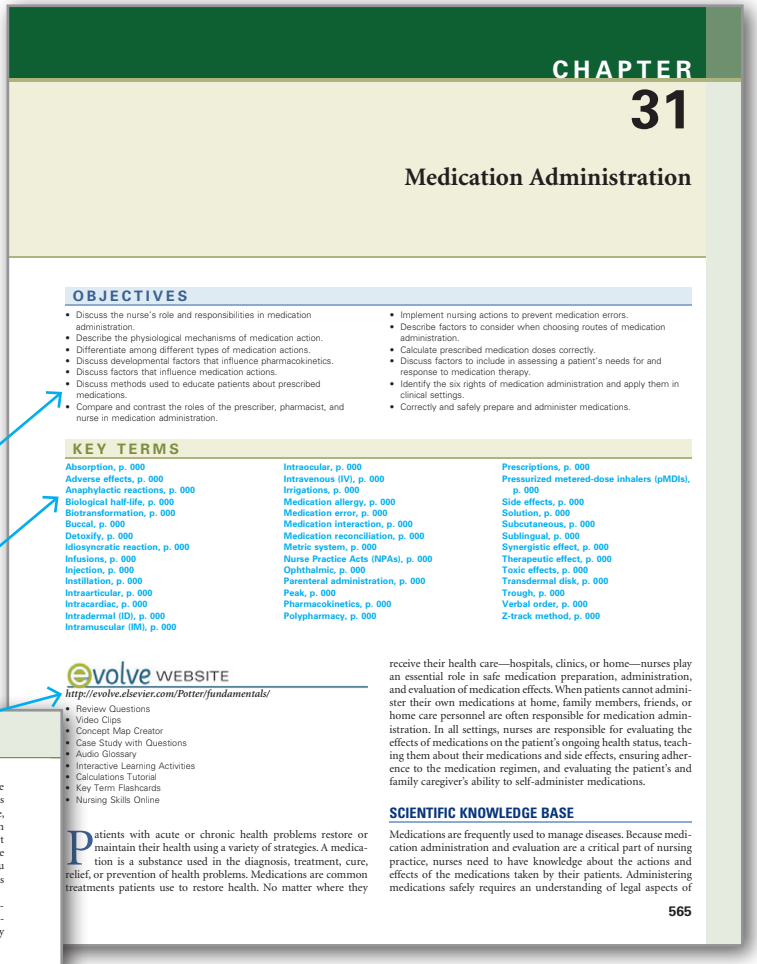
Patricia A. Potter

To the nursing faculty at Southern Illinois University Edwardsville and Saint Louis University. Your commitment to nursing and nursing education inspires us all to be the guardians of the discipline.
To my grandchildren, Cora Elizabeth Bryan, Amalie Mary Bryan, and Shepherd Charles Bryan.

Anne Griffin Perry

To my family and friends: Thank you for all your love and support as my passion for nursing has taken me on different pathways over the years. And to the faculty and staff of Saint Francis Medical Center College of Nursing: I am proud to be a part of such a great group of people who, through your caring and dedication to education and nursing, prepare excellent entry-level and advanced practice nurses for health care today and in the future.

Patricia A. Stockert



To Greg, the love of my life. Your never-ending love and support and ready supply of 4-cookbook casseroles have enabled me to achieve more than I could have ever imagined. Thank you for giving me the time to read, write, edit, travel, and think. And to the nursing faculty and staff at the University of Evansville. Your commitment to excellence in nursing education provides life-transforming experiences that are vital to shaping the nurses of the future. Thank you for your passion and most of all for your friendship. I am so blessed to have all of you in my life.

Amy M. Hall

STUDENT PREFACE

Fundamentals of Nursing provides you with all of the fundamental nursing concepts and skills you will need as a beginning nurse in a visually appealing, easy-to-use format. We know how busy you are and how precious your time is. As you begin your nursing education, it is very important that you have a resource that includes all the information you need to prepare for lectures, classroom activities, clinical assignments, and exams—and nothing more. We've written this text to meet all of those needs. This book was designed to help you succeed in this course and prepare you for more advanced study. In addition to the readable writing style and abundance of full-color photographs and drawings, we've incorporated numerous features to help you study and learn. We have made it easy for you to pull out important content. **Check out the following special learning aids:**

CHAPTER 31

Medication Administration

OBJECTIVES

- Discuss the nurse's role and responsibilities in medication administration.
- Describe the physiological mechanisms of medication action.
- Differentiate among different types of medication actions.
- Discuss developmental factors that influence pharmacokinetics.
- Discuss factors that influence medication actions.
- Discuss methods used to educate patients about prescribed medications.
- Compare and contrast the roles of the prescriber, pharmacist, and nurse in medication administration.
- Implement nursing actions to prevent medication errors.
- Describe factors to consider when choosing routes of medication administration.
- Calculate prescribed medication doses correctly.
- Discuss factors to include in assessing a patient's needs for and response to medication therapy.
- Identify the six rights of medication administration and apply them in clinical settings.
- Correctly and safely prepare and administer medications.

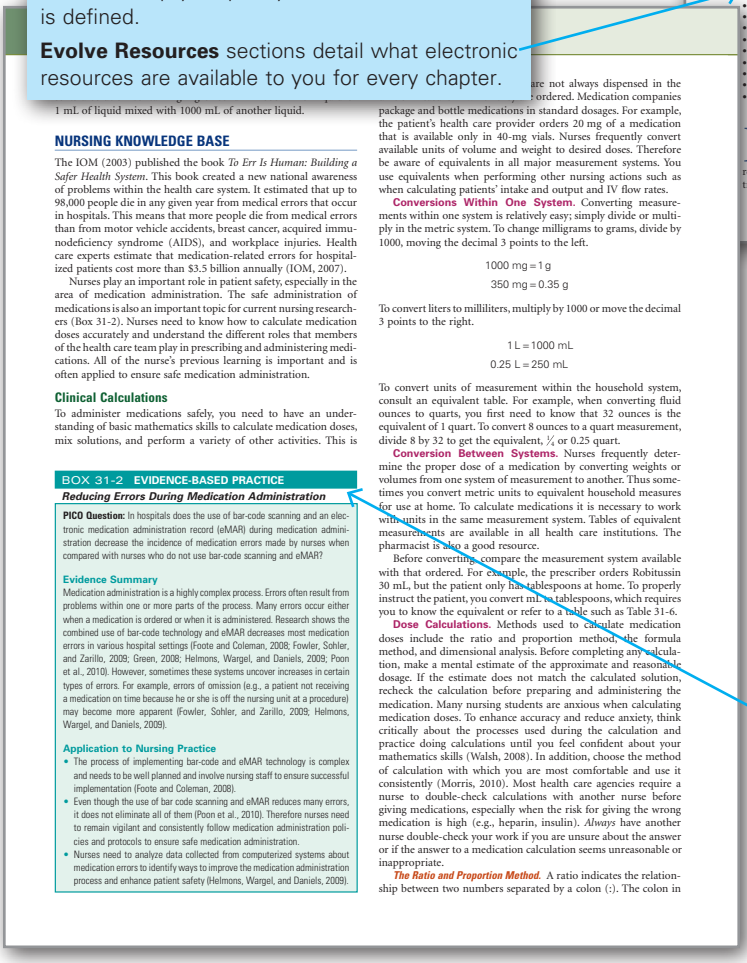
Patients with acute or chronic health problems restore or maintain their health using a variety of strategies. A medication is a substance used in the diagnosis, treatment, cure, relief, or prevention of health problems. Medications are common treatments patients use to restore health. No matter where they receive their health care—hospitals, clinics, or home—nurses play an essential role in safe medication preparation, administration, and evaluation of medication effects. When patients cannot administer their own medications at home, family members, friends, or home care personnel are often responsible for medication administration. In all settings, nurses are responsible for evaluating the effects of medications on the patient's ongoing health status, teaching them about their medications and side effects, ensuring adherence to the medication regimen, and evaluating the patient's and family caregiver's ability to self-administer medications.

SCIENTIFIC KNOWLEDGE BASE



Medications are frequently used to manage diseases. Because medication administration and evaluation are a critical part of nursing practice, nurses need to have knowledge about the actions and effects of the medications taken by their patients. Administering medications safely requires an understanding of legal aspects of

565

Learning Objectives begin each chapter to help you focus on the key information that follows.

Key Terms are listed at the beginning of each chapter and are boldfaced in the text. Page numbers help you quickly find where each term is defined.

Evolve Resources sections detail what electronic resources are available to you for every chapter.

1 mL of liquid mixed with 1000 mL of another liquid.

NURSING KNOWLEDGE BASE

The IOM (2003) published the book *To Err Is Human: Building a Safer Health System*. This book created a new national awareness of problems within the health care system. It estimated that up to 98,000 people die in any given year from medical errors that occur in hospitals. This means that more people die from medical errors than from motor vehicle accidents, breast cancer, acquired immunodeficiency syndrome (AIDS), and workplace injuries. Health care experts estimate that medication-related errors for hospitalized patients cost more than $3.5 billion annually (IOM, 2007).

Nurses play an important role in patient safety, especially in the area of medication administration. The safe administration of medications is also an important topic for current nursing researchers (Box 31-2). Nurses need to know how to calculate medication doses accurately and understand the different roles that members of the health care team play in prescribing and administering medications. All of the nurse's previous learning is important and is often applied to ensure safe medication administration.

Clinical Calculations

To administer medications safely, you need to have an understanding of basic mathematics skills to calculate medication doses, mix solutions, and perform a variety of other activities. This is

BOX 31-2 EVIDENCE-BASED PRACTICE

Reducing Errors During Medication Administration

PICO Question: In hospitals does the use of bar-code scanning and an electronic medication administration record (eMAR) during medication administration decrease the incidence of medication errors made by nurses when compared with nurses who do not use bar-code scanning and eMAR?

Evidence Summary

Medication administration is a highly complex process. Errors often result from problems within one or more parts of the process. Many errors occur either when a medication is ordered or when it is administered. Research shows the combined use of bar-code technology and eMAR decreases most medication errors in various hospital settings (Foote and Coleman, 2008; Fowler, Sohler, and Zarillo, 2009; Green, 2008; Helmons, Wargel, and Daniels, 2009; Poon et al., 2010). However, sometimes these systems uncover increases in certain types of errors. For example, errors of omission (e.g., a patient not receiving a medication on time because he or she is off the nursing unit at a procedure) may become more apparent (Fowler, Sohler, and Zarillo, 2009; Helmons, Wargel, and Daniels, 2009).

Application to Nursing Practice

- The process of implementing bar-code and eMAR technology is complex and needs to be well planned and involve nursing staff to ensure successful implementation (Foote and Coleman, 2008).
- Even though the use of bar code scanning and eMAR reduces many errors, it does not eliminate all of them (Poon et al., 2010). Therefore nurses need to remain vigilant and consistently follow medication administration policies and protocols to ensure safe medication administration.
- Nurses need to analyze data collected from computerized systems about medication errors to identify ways to improve the medication administration process and enhance patient safety (Helmons, Wargel, and Daniels, 2009).

are not always dispensed in the ordered. Medication companies package and bottle medications in standard dosages. For example, the patient's health care provider orders 20 mg of a medication that is available only in 40-mg vials. Nurses frequently convert available units of volume and weight to desired doses. Therefore be aware of equivalents in all major measurement systems. You use equivalents when performing other nursing actions such as when calculating patients' intake and output and IV flow rates.

Conversions Within One System. Converting measurements within one system is relatively easy; simply divide or multiply in the metric system. To change milligrams to grams, divide by 1000, moving the decimal 3 points to the left.

1000 mg = 1 g

350 mg = 0.35 g

To convert liters to milliliters, multiply by 1000 or move the decimal 3 points to the right.

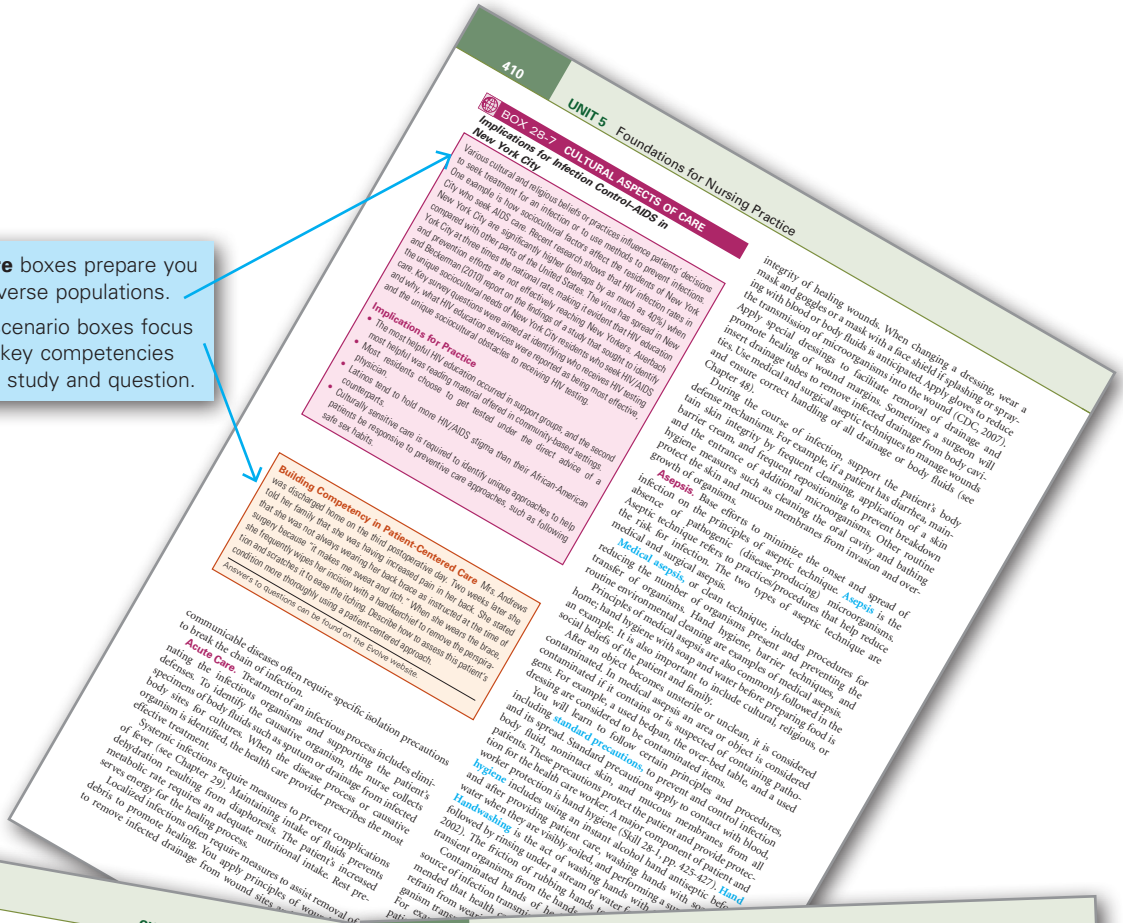
1 L = 1000 mL

0.25 L = 250 mL

To convert units of measurement within the household system, consult an equivalent table. For example, when converting fluid ounces to quarts, you first need to know that 32 ounces is the equivalent of 1 quart. To convert 8 ounces to a quart measurement, divide 8 by 32 to get the equivalent, ¼ or 0.25 quart.

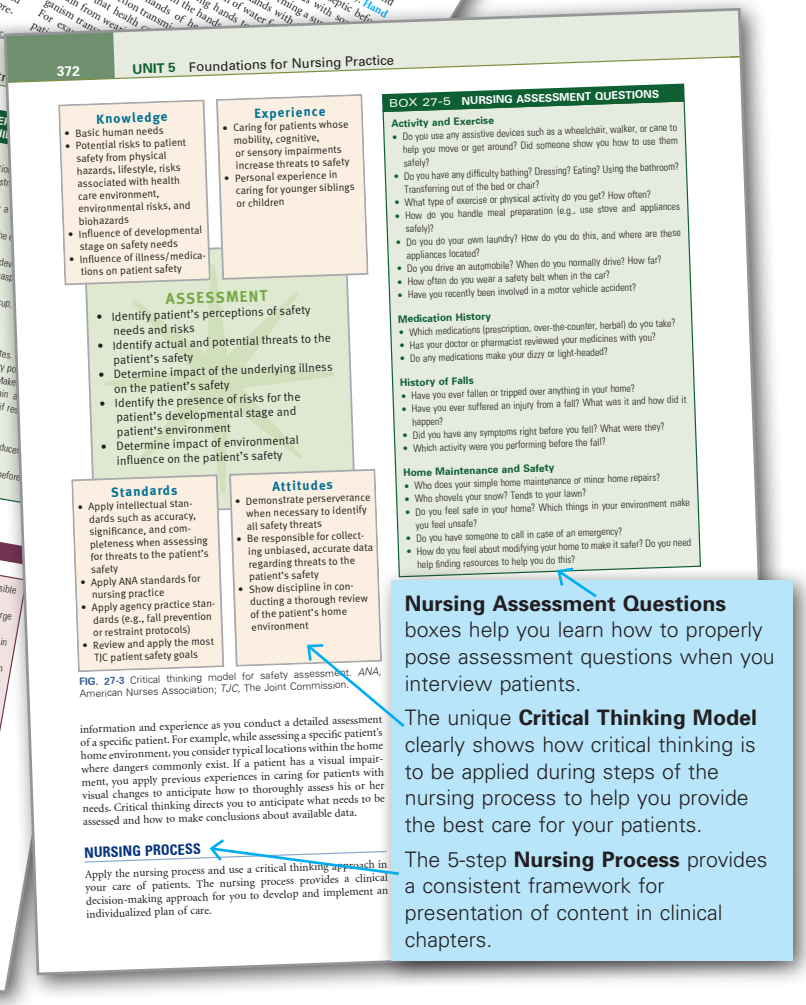
Conversion Between Systems. Nurses frequently determine the proper dose of a medication by converting weights or volumes from one system of measurement to another. Thus sometimes you convert metric units to equivalent household measures for use at home. To calculate medications it is necessary to work with units in the same measurement system. Tables of equivalent measurements are available in all health care institutions. The pharmacist is also a good resource.

Before converting, compare the measurement system available with that ordered. For example, the prescriber orders Robitussin 30 mL, but the patient only has tablespoons at home. To properly instruct the patient, you convert mL to tablespoons, which requires you to know the equivalent or refer to a table such as Table 31-6.



Dose Calculations. Methods used to calculate medication doses include the ratio and proportion method, the formula method, and dimensional analysis. Before completing any calculation, make a mental estimate of the approximate and reasonable dosage. If the estimate does not match the calculated solution, recheck the calculation before preparing and administering the medication. Many nursing students are anxious when calculating medication doses. To enhance accuracy and reduce anxiety, think critically about the processes used during the calculation and practice doing calculations until you feel confident about your mathematics skills (Walsh, 2008). In addition, choose the method of calculation with which you are most comfortable and use it consistently (Morris, 2010). Most health care agencies require a nurse to double-check calculations with another nurse before giving medications, especially when the risk for giving the wrong medication is high (e.g., heparin, insulin). *Always* have another nurse double-check your work if you are unsure about the answer or if the answer to a medication calculation seems unreasonable or inappropriate.

The Ratio and Proportion Method. A ratio indicates the relationship between two numbers separated by a colon (:). The colon in



Evidence-Based Practice boxes summarize the results of a research study and indicate how that research can be applied to nursing practice.

Cultural Aspects of Care boxes prepare you to care for patients of diverse populations.

Building Competency scenario boxes focus on one of the six QSEN key competencies and provide a short case study and question.

Focus on Older Adults boxes prepare you to address the special needs of older adults.

Nursing Assessment Questions boxes help you learn how to properly pose assessment questions when you interview patients.

The unique **Critical Thinking Model** clearly shows how critical thinking is to be applied during steps of the nursing process to help you provide the best care for your patients.

The 5-step **Nursing Process** provides a consistent framework for presentation of content in clinical chapters.

CHAPTER 28 Infection Prevention and Control 419

contamination of the hands and uniform and discard them after removal.

Respiratory Protection. Wear full-face protection (with eyes, nose, and mouth covered) when you anticipate splashing or spraying of blood or body fluid into the face. Also wear masks when working with a patient placed on airborne or droplet precautions. If the patient is on airborne precautions for TB, apply an OSHA-approved respirator-style mask. The mask protects the nurse from inhaling microorganisms and small-particle droplet nuclei that remain suspended in the air from a patient's respiratory tract. The surgical mask protects a wearer from inhaling large-particle aerosols that travel short distances (3 feet). When caring for patients on droplet or airborne precautions, apply a mask (surgical or respirator) when entering the isolation room.

At times a patient who is susceptible to infection wears a mask to prevent inhalation of pathogens. Patients on droplet or airborne precautions who are transported outside of their rooms need to wear a surgical mask to protect other patients and personnel. Masks prevent transmission of infection by direct contact with mucous membranes (CDC, 2005a). A mask discourages the wearer from touching the eyes, nose, or mouth (Box 28-13).

A properly applied mask fits snugly over the mouth and nose so pathogens and body fluids cannot enter or escape through the sides. If a person wears glasses, the top edge of the mask fits below the glasses so they do not cloud over as the person exhales. Keep talking to a minimum while wearing a mask to reduce respiratory airflow. A mask that has become moist does not provide a barrier to microorganisms and is ineffective. You need to discard it. Never reuse a disposable mask. Warn patients and family members that a mask can cause a sensation of smothering. If family members become uncomfortable, they should leave the room and discard the mask.

Specially fitted respiratory protective devices (N95 respirator masks) are required when caring for a patient with known or suspected TB (Fig. 28-3) (CDC, 2005a). The mask must have a higher filtration rating than regular surgical masks and be fitted snugly to prevent leakage around the sides. Be aware of health care facility policy regarding the type of respiratory protective device required. Special fit testing is required to establish the size and ability of the nurse to wear this type of mask (CDC, 2005a).

Eye Protection. Use either special glasses or goggles when performing procedures that generate splash or splatter. Examples of such procedures include irrigation of a large abdominal wound or insertion of an arterial catheter when the nurse assists a health care provider. A nurse who wears prescription glasses uses removable, reusable, or disposable side shields over them (OSHA 2001a, 2005). Eyewear is available in the form of plastic glasses or goggles. The eyewear needs to fit snugly around the face so fluids cannot enter between the face and the glasses.

Gloves. Gloves help to prevent the transmission of pathogens by direct and indirect contact. The CDC notes that you need to wear clean gloves when touching blood, body fluid, secretions, excretions, (except sweat), moist mucous membranes, nonintact skin, and contaminated items or surfaces. Change gloves and perform hand hygiene between tasks and procedures on the same patient after contact with material that contains a high concentration of microorganisms. Remove gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient. Perform hand hygiene immediately to avoid transfer of microorganisms to other patients or environments. Because of allergy or sensitivity to latex gloves, facilities provide nonlatex gloves to reduce the incidence of health care providers developing latex allergy or sensitivity. Most facilities are working to become latex free to protect health care providers and patients.

When full PPE is necessary, first perform hand hygiene, then apply a gown, apply mask and eyewear or goggles (as needed), and end with applying gloves. Clean gloves are easy to apply and fit either hand. Pull the cuffs of the glove up over the wrists or over the cuffs of the gown. If you notice a break or tear in a glove while providing care, change gloves. If the nurse does not plan to have more contact with the patient, reapplying gloves is unnecessary. Perform hand hygiene when gloves are removed.

Instruct family members visiting [illegible] patients on isolation precautions how to apply gloves properly [illegible] application of gloves to family members and explain how to remove gloves. Emphasize the importance of hand hygiene after removing gloves.

BOX 28-13 PROCEDURAL GUIDELINES

Applying a Surgical Type of Mask

1. Find top edge of mask (some have a thin metal strip along edge). Pliable metal fits snugly against bridge of nose. Others offer an occlusive seal that does not require an adjustment.
2. Hold mask by top two strings or loops. Secure two top ties at top of back of head (see illustration), with ties above ears. (*Alternative:* Slip loops over each ear.)

STEP 2 Securing top two ties of a tie-on mask.

3. Tie two lower ties snugly around neck with mask well under chin (see illustration).

STEP 3 Securing lower ties of a tie-on mask.

4. Gently pinch upper metal band around bridge of nose.

NOTE: Change mask if wet, moist, or contaminated.

Procedural Guidelines provide streamlined, step-by-step instructions for performing the most basic skills.

376 UNIT 5 Foundations for Nursing Practice

NURSING CARE PLAN

Risk for Falls

ASSESSMENT

Mr. Key, a visiting nurse, is seeing Ms. Cohen, an 85-year-old woman, at her home. The patient is recovering from a mild stroke affecting her left side. Ms. Cohen lives alone but receives regular assistance from her daughter Peggy and son Michael, who both live within 10 miles. Mr. Key's assessment included a discussion of Ms. Cohen's health problem and how the stroke has affected her, a pertinent physical examination, and home hazard assessment.

*Assessment Activities**	*Findings/Defining Characteristics*
Ask how the stroke has affected her mobility.	She responds, "**I bump into things**, and **I'm afraid I'm going to fall.**"
Conduct a home hazard assessment.	Cabinets in kitchen are **cluttered** and full of breakable items that could fall out. **Throw rugs** are on floors; bathroom **lighting is poor** (40-watt bulbs); bathtub **lacks safety strips** or grab bars; **home is cluttered** with furniture and small objects.
Observe gait and posture.	She has **kyphosis** and a **hesitant, uncoordinated gait**; frequently holds walls for support.
Assess muscle strength.	**Left arm and leg are weaker** than right.
Assess visual acuity with corrective lenses.	She has **trouble reading and seeing familiar objects at a distance** while wearing current glasses.

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Risk for falls related to impaired mobility, decreased visual acuity, and physical environmental hazards

PLANNING

Goal	*Expected Outcomes (NOC)†*
Home will be free of hazards within 1 month.	**Risk Control** Modifiable hazards in kitchen and hallway will be reduced in home within 1 week. Revisions to bathroom will be completed in 1 month.
Ms. Cohen and family will be knowledgeable of potential hazards for Ms. Cohen's age-group within 1 week.	**Knowledge: Personal Safety** Ms. Cohen and daughter will identify risks for falls and prevention methods to avoid falls in home at conclusion of teaching session next week.
Ms. Cohen will express greater sense of feeling safe from falling in 1 month.	**Fall Prevention Behavior** Ms. Cohen will report improved vision with the aid of new eyeglasses in 2 weeks.
Ms. Cohen will be free of injury within 1 week.	Ms. Cohen will be able to safely ambulate throughout the home within 1 week.

†Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 4, St Louis, 2008, Mosby.

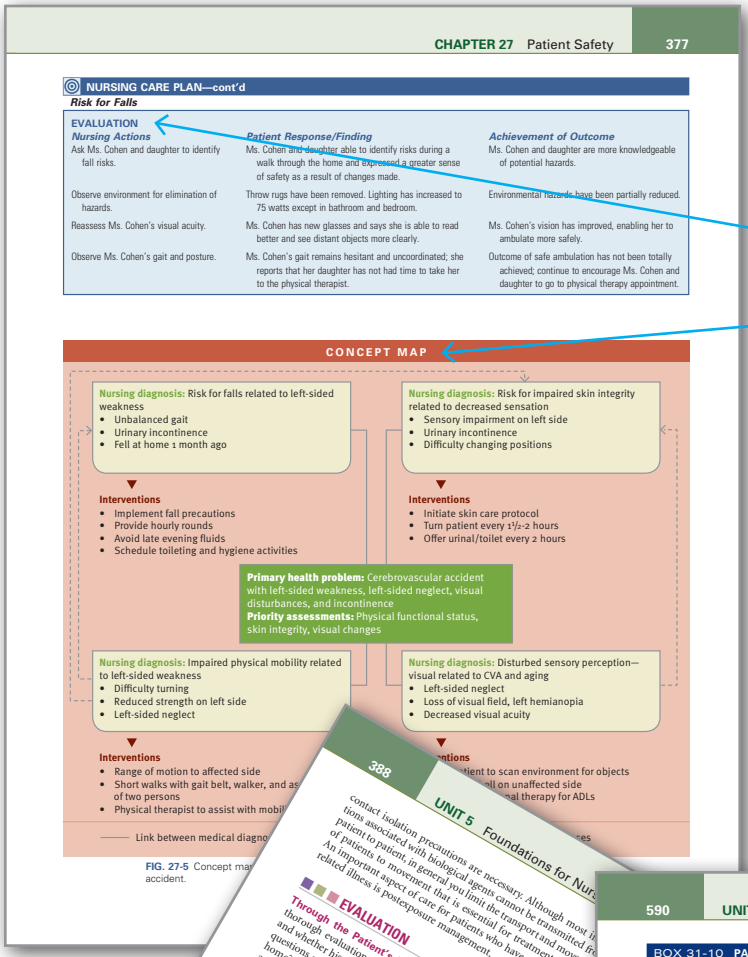
INTERVENTIONS (NIC)† ***Fall Prevention***	**RATIONALE**
Review findings from home hazard assessment with Ms. Cohen and daughter and collaborate on proposed changes.	Home hazard assessment highlights extrinsic factors that lead to falls and that can be changed.
Establish a list of priorities to modify and have Ms. Cohen's son assist in installing bathroom safety devices.	Implementing home modifications based on home assessment can decrease falls (Pynoos, 2010).
Discuss with Ms. Cohen and daughter the normal changes of aging, effects of recent stroke, associated risks for injury, and how to reduce risks.	Education regarding hazards reduces fear of falling (Banez, 2008).
Encourage daughter to schedule vision testing for new prescription within 2 to 4 weeks.	Improved visual acuity reduces incidence of falls (Edelman and Mandle, 2010).
Refer to physical therapist to assess need for strengthening and endurance training and use of assistive devices for kyphosis, left-sided weakness, and gait.	Exercise is effective in reducing falls and should include a comprehensive program combining muscle strengthening, balance, and/or endurance training for a minimum of 12 weeks (Costello, 2008)

†Intervention classification labels from Bulechek GM, Butcher HK, Dochterman JM: *Nursing interventions classification (NIC)*, ed 5, St Louis, 2008, Mosby.

Nursing Care Plans demonstrate how comprehensive a plan of care should be for a patient. Each plan helps you understand the process of assessment, the association of assessment findings with defining characteristics in the formation of nursing diagnoses, the identification of goals and outcomes, selection of nursing interventions, and the process for evaluating care.

Nursing Intervention Classification (NIC) and **Nursing Outcomes Classification (NOC)** terminologies are used in the care plans to build your knowledge of nursing concepts.

Rationales for each of the interventions in the care plans demonstrate the evidence to support nursing care approaches.



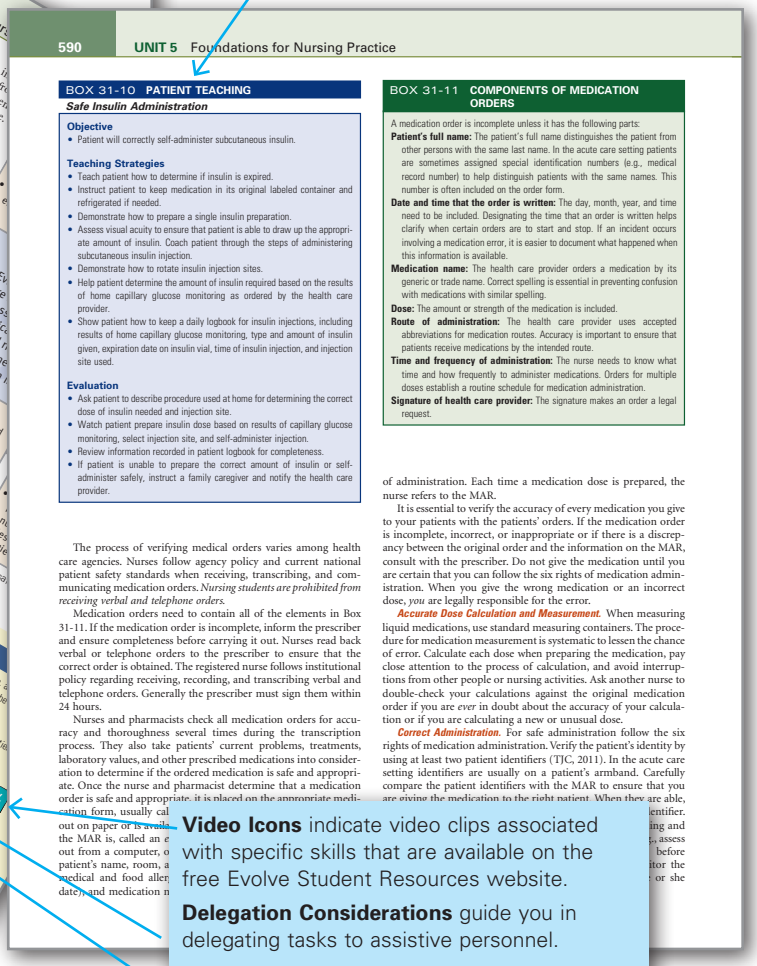


FIG. 27-5 Concept map

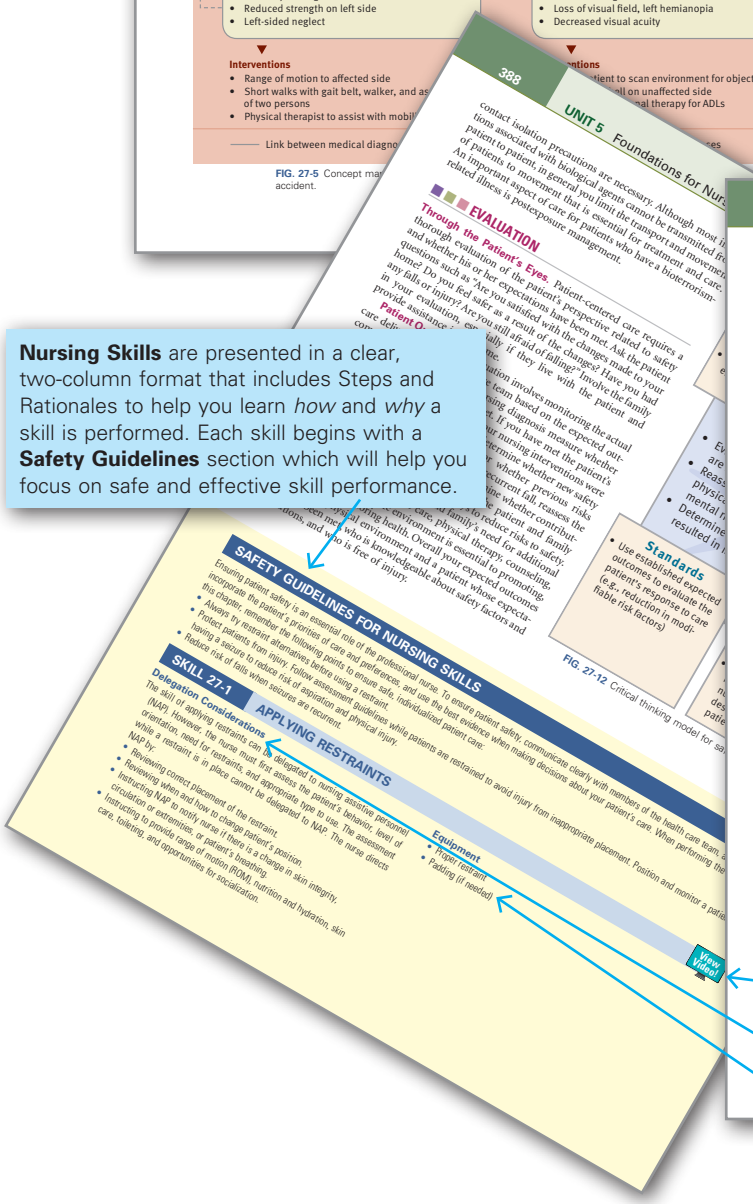
Evaluation section explains how to evaluate and determine whether patient outcomes have been achieved.

Concept Map figures help you see the connections between your patient's medical problems and your plan of care.

Patient Teaching boxes emphasize important information to teach patients.

Nursing Skills are presented in a clear, two-column format that includes Steps and Rationales to help you learn *how* and *why* a skill is performed. Each skill begins with a **Safety Guidelines** section which will help you focus on safe and effective skill performance.



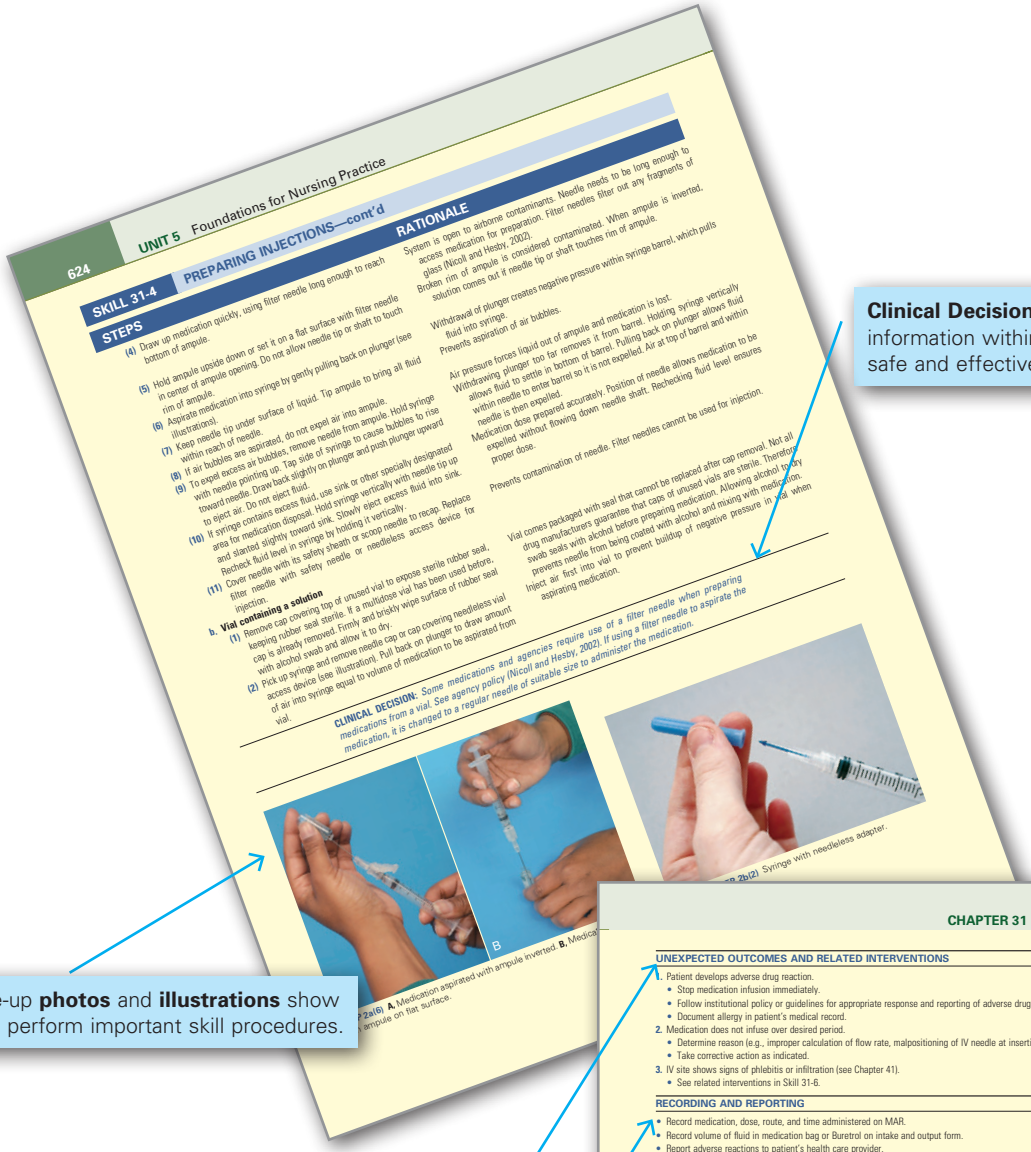


FIG. 27-12 Critical thinking model for sa

Video Icons indicate video clips associated with specific skills that are available on the free Evolve Student Resources website.

Delegation Considerations guide you in delegating tasks to assistive personnel.

Equipment lists show specific items needed for each skill.

624 UNIT 5 Foundations for Nursing Practice

SKILL 31.4 PREPARING INJECTIONS—cont'd

STEPS | RATIONALE

(4) Draw up medication quickly, using filter needle long enough to reach bottom of ampule. | System is open to airborne contaminants. Needle needs to be long enough to access medication for preparation. Filter needles filter out any fragments of glass (Nicoll and Hesby, 2002).

(5) Hold ampule upside down or set it on a flat surface with filter needle in center of ampule opening. Do not allow needle tip or shaft to touch rim of ampule. | Broken rim of ampule is considered contaminated. When ampule is inverted, solution comes out if needle tip or shaft touches rim of ampule.

(6) Aspirate medication into syringe by gently pulling back on plunger (see illustrations). | Withdrawal of plunger creates negative pressure within syringe barrel, which pulls fluid into syringe.

(7) Keep needle tip under surface of liquid. Tip ampule to bring all fluid within reach of needle. | Prevents aspiration of air bubbles.

(8) If air bubbles are aspirated, do not expel air into ampule. | Air pressure forces liquid out of ampule and medication is lost.

(9) To expel excess air bubbles, remove needle from ampule. Hold syringe with needle pointing up. Tap side of syringe to cause bubbles to rise toward needle. Draw back slightly on plunger and push plunger upward to eject air. Do not eject fluid. | Withdrawing plunger too far removes it from barrel. Pulling back on plunger allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid to enter barrel so it is not expelled. Air at top of barrel and within needle is then expelled.

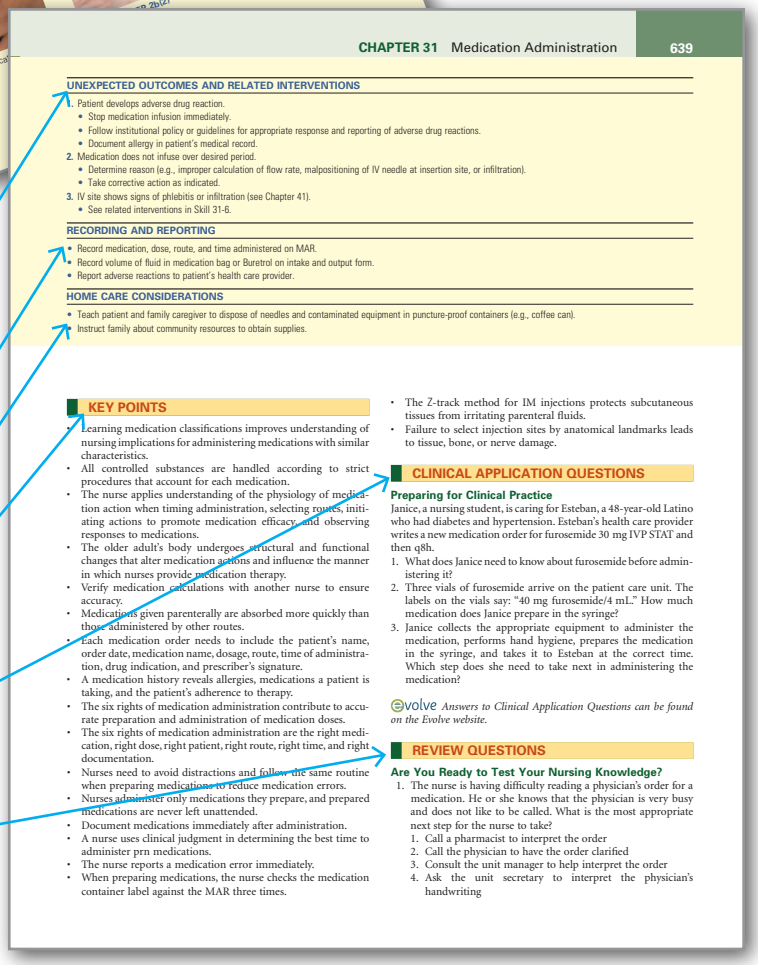
(10) If syringe contains excess fluid, use sink or other specially designated area for medication disposal. Hold syringe vertically with needle tip up and slanted slightly toward sink. Slowly eject excess fluid into sink. Recheck fluid level in syringe by holding it vertically. | Accurate positioning of needle allows medication to be prepared accurately. Rechecking fluid level ensures dose.

(11) Cover needle with its safety sheath or scoop needle to recap. Replace filter needle with safety needle or needleless access device for injection. | Medication dose prepared accurately may be expelled without flowing down needle shaft.

b. Vial containing a solution

(1) Remove cap covering top of unused vial to expose sterile rubber seal, keeping rubber seal sterile. If a multidose vial has been used before, cap is already removed. Firmly and briskly wipe surface of rubber seal with alcohol swab and allow it to dry. | Prevents contamination of needle. Filter needles cannot be used for injection.

(2) Pick up syringe and remove needle cap or cap covering needleless vial access device (see illustration). Pull back on plunger to draw amount of air into syringe equal to volume of medication to be aspirated from vial. | Vial comes packaged with seal that cannot be replaced after cap removal. Not all drug manufacturers guarantee that caps of unused vials are sterile. Therefore swab seals with alcohol before preparing medication. Allowing alcohol to dry prevents needle from being coated with alcohol and mixing with medication. Inject air first into vial to prevent buildup of negative pressure in vial when aspirating medication.



CLINICAL DECISION: *Some medications and agencies require use of a filter needle when preparing medications from a vial. See agency policy (Nicoll and Hesby, 2002). If using a filter needle to aspirate the medication, it is changed to a regular needle of suitable size to administer the medication.*

2a(6) A. Medication aspirated with ampule inverted. B. Medica... ampule on flat surface.

2b(2) Syringe with needleless adapter.

Clinical Decisions alert you to important information within a skill to consider to ensure safe and effective patient care.

Clear, close-up **photos** and **illustrations** show you how to perform important skill procedures.

CHAPTER 31 Medication Administration 639

UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS

1. Patient develops adverse drug reaction.
   - Stop medication infusion immediately.
   - Follow institutional policy or guidelines for appropriate response and reporting of adverse drug reactions.
   - Document allergy in patient's medical record.
2. Medication does not infuse over desired period.
   - Determine reason (e.g., improper calculation of flow rate, malpositioning of IV needle at insertion site, or infiltration).
   - Take corrective action as indicated.
3. IV site shows signs of phlebitis or infiltration (see Chapter 41).
   - See related interventions in Skill 31-6.

RECORDING AND REPORTING

- Record medication, dose, route, and time administered on MAR.
- Record volume of fluid in medication bag or Buretrol on intake and output form.
- Report adverse reactions to patient's health care provider.

HOME CARE CONSIDERATIONS

- Teach patient and family caregiver to dispose of needles and contaminated equipment in puncture-proof containers (e.g., coffee can).
- Instruct family about community resources to obtain supplies.

KEY POINTS

- Learning medication classifications improves understanding of nursing implications for administering medications with similar characteristics.
- All controlled substances are handled according to strict procedures that account for each medication.
- The nurse applies understanding of the physiology of medication action when timing administration, selecting routes, initiating actions to promote medication efficacy, and observing responses to medications.
- The older adult's body undergoes structural and functional changes that alter medication actions and influence the manner in which nurses provide medication therapy.
- Verify medication calculations with another nurse to ensure accuracy.
- Medications given parenterally are absorbed more quickly than those administered by other routes.
- Each medication order needs to include the patient's name, order date, medication name, dosage, route, time of administration, drug indication, and prescriber's signature.
- A medication history reveals allergies, medications a patient is taking, and the patient's adherence to therapy.
- The six rights of medication administration contribute to accurate preparation and administration of medication doses.
- The six rights of medication administration are the right medication, right dose, right patient, right route, right time, and right documentation.
- Nurses need to avoid distractions and follow the same routine when preparing medications to reduce medication errors.
- Nurses administer only medications they prepare, and prepared medications are never left unattended.
- Document medications immediately after administration.
- A nurse uses clinical judgment in determining the best time to administer prn medications.
- The nurse reports a medication error immediately.
- When preparing medications, the nurse checks the medication container label against the MAR three times.
- The Z-track method for IM injections protects subcutaneous tissues from irritating parenteral fluids.
- Failure to select injection sites by anatomical landmarks leads to tissue, bone, or nerve damage.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Janice, a nursing student, is caring for Esteban, a 48-year-old Latino who had diabetes and hypertension. Esteban's health care provider writes a new medication order for furosemide 30 mg IVP STAT and then q8h.

1. What does Janice need to know about furosemide before administering it?
2. Three vials of furosemide arrive on the patient care unit. The labels on the vials say: "40 mg furosemide/4 mL." How much medication does Janice prepare in the syringe?
3. Janice collects the appropriate equipment to administer the medication, performs hand hygiene, prepares the medication in the syringe, and takes it to Esteban at the correct time. Which step does she need to take next in administering the medication?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is having difficulty reading a physician's order for a medication. He or she knows that the physician is very busy and does not like to be called. What is the most appropriate next step for the nurse to take?
   1. Call a pharmacist to interpret the order
   2. Call the physician to have the order clarified
   3. Consult the unit manager to help interpret the order
   4. Ask the unit secretary to interpret the physician's handwriting

Unexpected Outcomes and Related Interventions identify possible undesired results and provide guidelines for appropriate nursing responses.

Recording and Reporting provides guidelines for what to chart and report with each skill.

Home Care Considerations explain how to adapt skills for the home setting.

Key Points and **Clinical Application Questions** sections help you review and apply essential content from the chapter.

The **Review Questions** at the end of each chapter, with the answer key included, help you evaluate learning and prepare for the examination.

This page intentionally left blank

PREFACE TO THE INSTRUCTOR

The nursing profession is always responding to dynamic change and continual challenges. Today nurses need a broad knowledge base from which to provide care. More important, nurses require the ability to know how to apply best evidence in practice to assure the best outcomes for their patients. The role of the nurse includes assuming the lead in preserving nursing practice and demonstrating its contribution to the health care of our nation. Nurses of tomorrow, therefore, need to become critical thinkers, patient advocates, clinical decision makers, and patient educators within a broad spectrum of care services.

The eighth edition of ***Fundamentals of Nursing*** was revised to prepare today's students for the challenges of tomorrow. This textbook is designed for beginning students in all types of professional nursing programs. The comprehensive coverage provides fundamental nursing concepts, skills, and techniques of nursing practice and a firm foundation for more advanced areas of study.

Fundamentals of Nursing provides a contemporary approach to nursing practice, discussing the entire scope of primary, acute, and restorative care. This new edition addresses a number of key current practice issues, including an emphasis on patient-centered care and evidence-based practice. Evidence-based practice is one of the most important initiatives in health care today. The increased focus on applying current evidence in skills and patient care plans helps students understand how the latest research findings should guide their clinical decision making.

KEY FEATURES

We have carefully developed this eighth edition with the student in mind. We have designed this text to welcome the new student to nursing, communicate our own love for the profession, and promote learning and understanding. Key features of the text include the following:

- Students will appreciate the **clear, engaging writing style.** The narrative actually addresses the reader, making this textbook more of an active instructional tool than a passive reference. Students will find that even complex technical and theoretical concepts are presented in a language that is easy to understand.
- **Comprehensive** coverage and readability of all fundamental nursing content.
- The **attractive, functional design** will appeal to today's visual learner. The clear, readable type and bold headings make the content easy to read and follow. Each special element is consistently color-keyed so students can readily identify important information.
- Hundreds of **large, clear, full-color photographs and drawings** reinforce and clarify key concepts and techniques.
- **Nursing process** format provides a consistent organizational framework for clinical chapters.
- **Learning aids** to help students identify, review, and apply important content in each chapter include Objectives, Key Terms, Key Points, Clinical Application Questions, and Review Questions.
- **Evolve Resources** lists detail the electronic resources available for the student at the beginning of every chapter.
- Covers **health promotion, acute and continuing care** to address today's practice in various settings.
- A **health promotion/wellness** thread is used consistently throughout the text.
- **Cultural diversity,** care of the **older adult,** and **patient teaching** are stressed throughout chapter narratives, as well as highlighted in special boxes.
- **Concept Maps** included in each clinical chapter show you the association between multiple nursing diagnoses for a patient with a selected medical diagnosis and the relationship between nursing interventions.
- **Nursing Care Plans** guide students on how to conduct an assessment and analyze the defining characteristics that indicate nursing diagnoses. The plans include NIC and NOC classifications to familiarize students with this important nomenclature. The evaluation sections of the plans show students how to evaluate and then determine the outcomes of care.
- A **critical thinking model provides a framework** for all clinical chapters, showing how elements of critical thinking, including knowledge, critical thinking attitudes, intellectual and professional standards, and experience, are integrated throughout the nursing process for making clinical decisions.
- **More than 55 nursing skills and 25 procedural guidelines** are presented. Nursing skills appear in a clear, two-column format with steps and supporting rationales that are often supported with current, evidenced-based research. Procedural guidelines boxes provide more streamlined, step-by-step instructions for performing very basic skills.
- **Delegation Considerations** guide when it is appropriate to delegate tasks to assistive personnel.
- **Unexpected Outcomes and Related Interventions** are highlighted within nursing skills to help students anticipate and appropriately respond to possible problems faced while performing skills.
- **Video Icons** indicate video clips associated with specific skills that are available on the Evolve Student Resources.
- **Printed endpapers** on the inside back cover provide information on locating specific assets in the book, including Skills, Procedure Guidelines, Nursing Care Plans, and Concept Maps.

NEW TO THIS EDITION

- **Safety Guidelines** section precedes each skill section. This helps students focus on safe and effective skill performance.
- **Skills sections** were moved to the end of the chapter for easier use, better text flow, and readability. In-text page callouts and colorful page bleeds help in locating these important sections.
- **Ongoing case studies** in each clinical chapter introduce "real-world" patients, families, and nurses. The chapter follows the same patient through the Nursing Care Plan, Concept Map, and meets them again in the Clinical Application Questions at the end of the chapter. These help students see how to apply the nursing process, along with critical thinking, to the care of patients. Cases take place in both acute and community settings, and include patients and nurses from a variety of cultural backgrounds.

- Information related to the **Quality and Safety Education for Nurses (QSEN)** initiative is highlighted by headings that coordinate with the key competencies. Building Competency scenarios for each chapter incorporate one of the six key competencies in QSEN.
- New **progressive case study** follows the same patient through each of the Nursing Process chapters (Chapters 16-20). This brings to life the framework of the process moving from Assessment, Diagnosis, Planning, Implementation, and Evaluation.
- Includes the latest **NANDA 2012-2014** diagnoses for up-to-date content.
- **New Skills** cover Blood Glucose Monitoring and Patient-Controlled Analgesia.
- **Expanded Review Questions** in each chapter resulting in an additional 250 questions. Answers are provided with questions and rationales are on Evolve.
- **Evidence-Based Practice** boxes now include a PICO question, provide a summary of nursing research evidence related to that specific topic, and then explain its implications for nursing practice. These have been updated to reflect current research topics and trends.
- Both ***Healthy People 2020*** and The Joint Commission's **2011 National Patient Safety Goals** are covered in this new edition promoting the importance of current research.
- **Chapter 41, *Fluid, Electrolyte, and Acid-Base Balance,*** has been completely rewritten and revised for better understanding of a complex topic.

LEARNING SUPPLEMENTS FOR STUDENTS

- The **Evolve Student Resources** are available online at http://evolve.elsevier.com/Potter/fundamentals/ and include the following valuable learning aids organized by chapter:
  - Chapter Review Questions from the book in an interactive format! Includes 750 questions to prepare for examinations
  - Answers and rationales to Chapter Review Questions
  - Answers and rationales to Clinical Application Questions
  - Answers and rationales to Building Competency scenario questions
  - Video clips highlight common skills
  - Animations
  - Concept Map Creator included in each clinical chapter
  - Case Study with questions
  - Audio glossary
  - Fluids & Electrolytes Tutorial
  - Interactive Learning Activities
  - Calculation Tutorial
  - Key Term Flashcards
  - Printable versions of Chapter Key Points
  - Nursing Skills Online reading assignments
  - Interactive Skills Performance Checklists are included for each skill in the text
  - Three practice quizzes cover all Fundamentals content for further study
- A thorough ***Study Guide*** by Geralyn Ochs provides an ideal supplement to help students understand and apply the content of the text. New to this edition is the inclusion of answers in the printed Study Guide. Each chapter includes multiple sections:
  - Preliminary Reading includes a chapter assignment from the text.
  - Comprehensive Understanding provides a variety of activities to reinforce the topics and main ideas from the text.
  - Review Questions are multiple-choice questions that require students to provide rationales for their answers. Answers and rationales are also provided on the Evolve site.
  - Clinical chapters include an Application of Critical Thinking Synthesis Model that expands the case study from the chapter's Care Plan and asks students to develop a step in the synthesis model based on the nurse and patient in the scenario. This helps students learn to apply both content learned and the critical thinking synthesis model.
- The handy ***Clinical Companion: Just the Facts*** complements, rather than abbreviates, the textbook. Content is presented in tabular, list, and outline format that equips your students with a concise, portable guide to all the facts and figures they'll need to know in their early clinical experiences.
- **Virtual Clinical Excursions** is an exciting workbook and CD-ROM experience that brings learning to life in a virtual hospital setting. The workbook guides students as they care for patients, providing ongoing challenges and learning opportunities. Each lesson in *Virtual Clinical Excursions* complements the textbook content and provides an environment for students to practice what they are learning. This CD/workbook is available separately or packaged at a special price with the textbook.

TEACHING SUPPLEMENTS FOR INSTRUCTORS

- The **Evolve Instructor Resources** (available online at http://evolve.elsevier.com/Potter/fundamentals) are a comprehensive collection of the most important tools instructors need, including the following:
  - **TEACH for Nurses** ties together every chapter resource you need for the most effective class presentations, with sections dedicated to objectives, teaching focus, nursing curriculum standards (including QSEN, BSN Essentials, and Concepts), instructor chapter resources, student chapter resources, answers to chapter questions, and an in-class case study discussion. Teaching strategies include content highlights, student activities, online activities, and large group activities.
  - The **Test Bank** contains a completely new set of more than 1350 questions with text page references and answers coded for NCLEX Client Needs category, nursing process, and cognitive level. Each question was involved in an instructor piloting process to ensure the best possible exam for students. The ExamView software allows instructors to create new tests; edit, add, and delete test questions; sort questions by NCLEX category, cognitive level, nursing process step, and question type; and administer/grade online tests.
  - Completely revised **PowerPoint Presentations** includes over 1500 slides for use in lectures. New to this edition are the inclusion of art within the slides and progressive case studies that include discussion questions and answers.
  - The **Image Collection** contains more than 1100 illustrations from the text for use in lectures.
  - **Simulation Learning System** is an online toolkit that helps instructors and facilitators effectively incorporate medium- to high-fidelity simulation into their nursing curriculum. Detailed patient scenarios promote and enhance the clinical decision-making skills of students at all levels. The system provides detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Each

scenario in *Simulation Learning System* complements the textbook content and helps bridge the gap between lectures and clinicals. This system provides the perfect environment for students to practice what they are learning in the text for a true-to-life, hands-on learning experience.

MULTIMEDIA SUPPLEMENTS FOR INSTRUCTORS AND STUDENTS

- **Nursing Skills Online 2.0** contains 18 modules rich with animations, videos, interactive activities, and exercises to help students prepare for their clinical lab experience. The instructionally designed lessons focus on topics that are difficult to master and pose a high risk to the patient if done incorrectly. Lesson quizzes allow students to check their learning curve and review as needed, and the module exams feed out to an instructor grade book. Modules cover Airway Management, Blood Therapy, Bowel Elimination/Ostomy Care, Chest Tubes, Enteral Nutrition, Infection Control, Injections, IV Fluid Administration, IV Fluid Therapy Management, IV Medication Administration, Nonparenteral Medication Administration, Safe Medication Administration, Safety, Specimen Collection, Urinary Catheterization, Vascular Access, Vital Signs, and Wound Care. Available alone or packaged with the text.
- **Mosby's Nursing Video Skills: Basic, Intermediate, Advanced version 3.0** provides 126 skills with overview information covering skill purpose, safety, and delegation guides; equipment lists; preparation procedures; procedure videos with printable step-by-step guidelines; appropriate follow-up care; documentation guidelines; and interactive review questions. Available online, as a student DVD set, or as a networkable DVD set for the institution.

ACKNOWLEDGMENTS

The eighth edition of *Fundamentals of Nursing* is the result of a continuing collaboration with Dr. Amy M. Hall and Dr. Patricia A. Stockert, which began with the seventh edition of *Basic Nursing*. Their insight, professionalism, attention to detail, and commitment to a quality textbook are unmatched. Their calm demeanor, sense of humor, and work ethic have made writing this textbook a pleasure.

- The editorial and production professionals at Mosby/Elsevier are supportive, creative, dedicated, and hard working. While there are many professionals involved in preparing this text, we wish to acknowledge the following persons:
  - Tamara Myers, Senior Content Strategist, for her vision, organization, professionalism, energy, and support in assisting us to develop a text that offers a state-of-the-art approach to the design, organization, and presentation of *Fundamentals of Nursing*. Her skill is in motivating and supporting a writing team so it can be creative and innovative while retaining the characteristics of a high-quality textbook.
  - Tina Kaemmerer made her maiden voyage as Content Development Specialist of *Fundamentals of Nursing*. She is an amazingly organized and talented individual who has done considerable behind-the-scenes work that has improved the accuracy and consistency in how we present content within the textbook. She, too, has limitless energy and is always willing to go the extra mile.
  - Jodi Willard, Senior Project Manager, is an accomplished production editor. Jodi approaches her work very professionally and is able to coordinate the multiple aspects of completing a well-designed finished product. She is talented and calm under pressure, and through her sense of humor and commitment to excellence guided this text to completion.
  - Mike DeFilippo, St. Louis, Missouri, for his excellent photography.
  - Goldfarb School of Nursing at Barnes-Jewish College, St. Louis, Missouri, for making their simulation lab available to us for photographs.
  - To our contributors, clinicians, and educators who share their expertise and knowledge about nursing practice in helping to create informative, accurate, and current information. Knowledge of their clinical specialties ensures we have a state-of-the-art textbook. We are fortunate to be associated with excellent nurse authors who are able to convey standards of nursing excellence.
  - To our many reviewers for their expertise, candor, knowledge of the literature, and astute comments that assist us in developing a text with high standards that reflect excellent professional nursing practice through the printed word.
  - And special recognition to our professional colleagues at Barnes-Jewish Hospital, Southern Illinois University Edwardsville, Saint Francis Medical Center College of Nursing, and the University of Evansville.

After more than 28 years of collaboration we find ourselves very fortunate and humble. *Fundamentals of Nursing* and our other textbooks allow us to contribute to nursing knowledge and help shape the practice of nursing. Nursing excellence belongs to all of us, and we are happy to have the opportunity to continue the work we love.

Patricia A. Potter
Anne Griffin Perry

CONTENTS

Any updates to this textbook can be found in the Content Updates folder on Evolve at http://evolve.elsevier.com/Potter/fundamentals/.

UNIT 1 NURSING AND THE HEALTH CARE ENVIRONMENT

1 Nursing Today, 1
Anne Griffin Perry, RN, EdD, FAAN
- Historical Highlights, 2
- Influences on Nursing, 3
- Nursing as a Profession, 4
- Nursing Education, 5
- Nursing Practice, 6
- Professional Responsibilities and Roles, 6
- Professional Nursing Organizations, 9
- Trends in Nursing, 9

2 The Health Care Delivery System, 14
Patricia A. Stockert, RN, BSN, MS, PhD
- Health Care Regulation and Competition, 15
- Emphasis on Population Wellness, 15
- Health Care Settings and Services, 16
- Issues in Health Care Delivery, 22
- The Future of Health Care, 28

3 Community-Based Nursing Practice, 31
Anne Griffin Perry, RN, EdD, FAAN
- Community-Based Health Care, 31
- Community Health Nursing, 32
- Community-Based Nursing, 33
- Community Assessment, 37
- Changing Patients' Health, 37

4 Theoretical Foundations of Nursing Practice, 40
Anne Griffin Perry, RN, EdD, FAAN
- The Domain of Nursing, 40
- Theory, 41
- Interdisciplinary Theories, 43
- Selected Nursing Theories, 44
- Link Between Theory and Knowledge Development in Nursing, 46

5 Evidence-Based Practice, 50
Amy M. Hall, RN, BSN, MS, PhD, CNE
- A Case for Evidence, 50
- Nursing Research, 56
- Research Process, 59
- Quality and Performance Improvement, 60

UNIT 2 CARING THROUGHOUT THE LIFE SPAN

6 Health and Wellness, 65
Patricia A. Stockert, RN, BSN, MS, PhD
- ***Healthy People*** Documents, 65
- Definition of Health, 66
- Models of Health and Illness, 66
- Variables Influencing Health and Health Beliefs and Practices, 68
- Health Promotion, Wellness, and Illness Prevention, 70
- Risk Factors, 71
- Risk-Factor Modification and Changing Health Behaviors, 73
- Illness, 73

7 Caring in Nursing Practice, 79
Anne Griffin Perry, RN, EdD, FAAN
- Theoretical Views on Caring, 80
- Patients' Perceptions of Caring, 82
- Ethic of Care, 83
- Caring in Nursing Practice, 83
- The Challenge of Caring, 86

8 Caring for the Cancer Survivor, 90
Kay E. Gaehle, PhD, RN
- The Effects of Cancer on Quality of Life, 91
- Cancer and Families, 94
- Implications for Nursing, 94
- Components of Survivorship Care, 97

9 Culture and Ethnicity, 101
Jerrilee LaMar, PhD, RN, CNE
- Health Disparities, 101
- Understanding Cultural Concepts, 102
- Cultural Context of Health and Caring, 103
- Culture and Life Transitions, 105
- Cultural Assessment, 107
- Caring Beliefs and Practices, 112

10 Caring for Families, 116
Anne Griffin Perry, RN, EdD, FAAN
The Family, 116
Current Trends and New Family Forms, 117
Theoretical Approaches: An Overview, 119
Attributes of Families, 120
Family Nursing, 121
Nursing Process for the Family, 123

11 Developmental Theories, 130
Karen Balakas, PhD, RN, CNE
Developmental Theories, 130

12 Conception Through Adolescence, 139
Karen Balakas, PhD, RN, CNE
Stages of Growth and Development, 139
Selecting a Developmental Framework for Nursing, 139
Intrauterine Life, 139
Transition from Intrauterine to Extrauterine Life, 140
Newborn, 141
Infant, 143
Toddler, 146
Preschoolers, 147
School-Age Children and Adolescents, 149
School-Age Children, 149
Adolescents, 151

13 Young and Middle Adults, 157
Patsy L. Ruchala, DNSc, RN
Young Adults, 157
Middle Adults, 163

14 Older Adults, 171
Karen Korem, RN-BC, MA
Variability Among Older Adults, 171
Myths and Stereotypes, 172
Nurses' Attitudes Toward Older Adults, 173
Theories of Aging, 173
Developmental Tasks for Older Adults, 173
Community-Based and Institutional Health Care Services, 174
Assessing the Needs of Older Adults, 174
Addressing the Health Concerns of Older Adults, 182
Older Adults and the Acute Care Setting, 187
Older Adults and Restorative Care, 188

UNIT 3 CRITICAL THINKING IN NURSING PRACTICE

15 Critical Thinking in Nursing Practice, 192
Patricia A. Potter, RN, MSN, PhD, FAAN
Clinical Decisions in Nursing Practice, 192
Critical Thinking Defined, 193
Levels of Critical Thinking in Nursing, 194
Critical Thinking Competencies, 195
A Critical Thinking Model for Clinical Decision Making, 198
Developing Critical Thinking Skills, 202
Critical Thinking Synthesis, 202

16 Nursing Assessment, 206
Patricia A. Potter, RN, MSN, PhD, FAAN
Critical Thinking Approach to Assessment, 207

17 Nursing Diagnosis, 222
Patricia A. Potter, RN, MSN, PhD, FAAN
History of Nursing Diagnosis, 223
Critical Thinking and the Nursing Diagnostic Process, 224
Concept Mapping Nursing Diagnoses, 230
Sources of Diagnostic Errors, 231
Nursing Diagnoses: Application to Care Planning, 233

18 Planning Nursing Care, 236
Patricia A. Potter, RN, MSN, PhD, FAAN
Establishing Priorities, 237
Critical Thinking in Setting Goals and Expected Outcomes, 238
Critical Thinking in Planning Nursing Care, 241
Systems for Planning Nursing Care, 243
Consulting Other Health Care Professionals, 249

19 Implementing Nursing Care, 253
Patricia A. Potter, RN, MSN, PhD, FAAN
Critical Thinking in Implementation, 254
Standard Nursing Interventions, 255
Implementation Process, 256
Direct Care, 259
Indirect Care, 261
Achieving Patient Goals, 262

20 Evaluation, 265
Patricia A. Potter, RN, MSN, PhD, FAAN
Standards for Evaluation, 267

21 Managing Patient Care, 274
Patricia A. Stockert, RN, BSN, MS, PhD
Building a Nursing Team, 274
Leadership Skills for Nursing Students, 279

UNIT 4 PROFESSIONAL STANDARDS IN NURSING PRACTICE

22 Ethics and Values, 286
Margaret Ecker, RN, MS
Basic Terms in Health Ethics, 286
Professional Nursing Code of Ethics, 287
Values, 288
Ethics and Philosophy, 288
Nursing Point of View, 290
Issues in Health Care Ethics, 292

23 Legal Implications in Nursing Practice, 296
Christine R. Durbin, PhD, JD, RN
Legal Limits of Nursing, 296
Federal Statutory Issues in Nursing Practice, 298
State Statutory Issues in Nursing Practice, 300
Civil and Common Law Issues in Nursing Practice, 301
Risk Management, 305

24 Communication, 309
Jeri Burger, PhD, RN
Communication and Nursing Practice, 309
Basic Elements of the Communication Process, 312
Forms of Communication, 313
Professional Nursing Relationships, 314
Elements of Professional Communication, 316
Nursing Process, 317

25 Patient Education, 328
Amy M. Hall, RN, BSN, MS, PhD, CNE
Standards for Patient Education, 328
Purposes of Patient Education, 329
Teaching and Learning, 329
Domains of Learning, 330
Basic Learning Principles, 331
Nursing Process, 335

26 Documentation and Informatics, 348
Frank Lyerla, PhD, RN
Confidentiality, 349
Standards, 349
Interdisciplinary Communication Within the Health Care Team, 349
Purposes of Records, 349
Guidelines for Quality Documentation and Reporting, 350
Methods of Documentation, 353
Common Record-Keeping Forms, 355
Home Care Documentation, 357
Long-Term Health Care Documentation, 357
Reporting, 357
Health Informatics, 359
Nursing Informatics, 359

UNIT 5 FOUNDATIONS FOR NURSING PRACTICE

27 Patient Safety, 365
Marinetta DeMoss, RN, MSN
Scientific Knowledge Base, 365
Nursing Knowledge Base, 368
Critical Thinking, 371
Nursing Process, 372
Skill 27-1 Applying Restraints, 388
Skill 27-2 Seizure Precautions, 392

28 Infection Prevention and Control, 398
Ruth M. Curchoe, RN, MSN, CIC
Scientific Knowledge Base, 399
The Infectious Process, 401
Nursing Knowledge Base, 404
Nursing Process, 405
Skill 28-1 Hand Hygiene, 425
Skill 28-2 Preparation of Sterile Field, 427
Skill 28-3 Surgical Hand Asepsis, 431
Skill 28-4 Applying a Sterile Gown and Performing Closed Gloving, 434
Skill 28-5 Open Gloving, 436

29 Vital Signs, 441
Susan Jane Fetzer, PhD, RN, MBA
Guidelines for Measuring Vital Signs, 442
Body Temperature, 442
Nursing Process, 446
Pulse, 452
Respiration, 455
Blood Pressure, 458
Health Promotion and Vital Signs, 465
Recording Vital Signs, 466
Skill 29-1 Measuring Body Temperature, 467
Skill 29-2 Assessing the Radial and Apical Pulses, 472
Skill 29-3 Assessing Respirations, 476

Skill 29-4 Measuring Oxygen Saturation (Pulse Oximetry), 478
Skill 29-5 Measuring Blood Pressure, 480

30 Health Assessment and Physical Examination, 487
Rhonda W. Comrie, PhD, RN, CNE, AE-C
Purposes of the Physical Examination, 488
Preparation for Examination, 488
Organization of the Examination, 491
Techniques of Physical Assessment, 493
General Survey, 495
Skin, Hair, and Nails, 498
Head and Neck, 507
Thorax and Lungs, 522
Heart, 527
Vascular System, 531
Breasts, 537
Abdomen, 542
Female Genitalia and Reproductive Tract, 545
Male Genitalia, 547
Rectum and Anus, 550
Musculoskeletal System, 551
Neurological System, 555
After the Examination, 560

31 Medication Administration, 565
Amy M. Hall, RN, BSN, MS, PhD, CNE
Scientific Knowledge Base, 565
Nursing Knowledge Base, 574
Critical Thinking, 584
Nursing Process, 587
Medication Administration, 593
Skill 31-1 Administering Oral Medications, 612
Skill 31-2 Administering Ophthalmic Medications, 616
Skill 31-3 Using Metered-Dose or Dry Powder Inhalers, 619
Skill 31-4 Preparing Injections, 622
Skill 31-5 Administering Injections, 626
Skill 31-6 Administering Medications by Intravenous Bolus, 631
Skill 31-7 Administering Intravenous Medications by Piggyback, Intermittent Intravenous Infusion Sets, and Mini-Infusion Pumps, 635

32 Complementary and Alternative Therapies, 643
Mary S. Koithan, PhD, RN, CNS-BS
Complementary and Alternative Approaches to Health, 643
Nursing-Accessible Therapies, 644
Training-Specific Therapies, 649
Nursing Role in Complementary and Alternative Therapies, 654

UNIT 6 PSYCHOSOCIAL BASIS FOR NURSING PRACTICE

33 Self-Concept, 658
Victoria N. Folse, PhD, APN, PMHCNS-BC, LCPC
Scientific Knowledge Base, 658
Nursing Knowledge Base, 659
Critical Thinking, 665
Nursing Process, 665

34 Sexuality, 674
Kathy Lever, MSN, WHNP-C
Scientific Knowledge Base, 674
Nursing Knowledge Base, 677
Critical Thinking, 679
Nursing Process, 680

35 Spiritual Health, 691
Amy M. Hall, RN, BSN, MS, PhD, CNE
Scientific Knowledge Base, 691
Nursing Knowledge Base, 692
Critical Thinking, 694
Nursing Process, 695

36 The Experience of Loss, Death, and Grief, 708
Valerie Yancey, PhD, RN
Scientific Knowledge Base, 709
Nursing Knowledge Base, 711
Critical Thinking, 713
Nursing Process, 713

37 Stress and Coping, 731
Marjorie Baier, PhD, RN
Scientific Knowledge Base, 731
Nursing Knowledge Base, 734
Critical Thinking, 735
Nursing Process, 736

UNIT 7 PHYSIOLOGICAL BASIS FOR NURSING PRACTICE

38 Activity and Exercise, 746
Rita Wunderlich, PhD, RN
Scientific Knowledge Base, 746
Nursing Knowledge Base, 749
Critical Thinking, 750
Nursing Process, 751

39 Hygiene, 768
Deborah Marshall, MSN
Scientific Knowledge Base, 768
Nursing Knowledge Base, 770
Critical Thinking, 772
Nursing Process, 773
Skill 39-1 Bathing and Perineal Care, 797
Skill 39-2 Performing Nail and Foot Care, 805
Skill 39-3 Providing Oral Hygiene, 808
Skill 39-4 Performing Mouth Care for an Unconscious or Debilitated Patient, 811
Skill 39-5 Making an Occupied Bed, 813

40 Oxygenation, 821
Paulette M. Archer, RN, EdD
Scientific Knowledge Base, 821
Nursing Knowledge Base, 828
Critical Thinking, 830
Nursing Process, 830
Skill 40-1 Suctioning, 855
Skill 40-2 Care of an Artificial Airway, 861
Skill 40-3 Care of Patients with Chest Tubes, 869
Skill 40-4 Applying a Nasal Cannula or Oxygen Mask, 873
Skill 40-5 Using Home Oxygen Equipment, 875

41 Fluid, Electrolyte, and Acid-Base Balance, 882
Linda Felver, PhD, RN
Scientific Knowledge Base, 883
Nursing Knowledge Base, 893
Critical Thinking, 893
Nursing Process, 895
Skill 41-1 Initiating Intravenous Therapy, 916
Skill 41-2 Regulating Intravenous Flow Rate, 925
Skill 41-3 Maintenance of Intravenous System, 929
Skill 41-4 Changing a Peripheral Intravenous Dressing, 934

42 Sleep, 939
Patricia A. Stockert, RN, BSN, MS, PhD
Scientific Knowledge Base, 939
Nursing Knowledge Base, 944
Critical Thinking, 946
Nursing Process, 947

43 Pain Management, 962
Linda Cason, MSN, RN-BC, NE-BC, CNRN
Scientific Knowledge Base, 963
Nursing Knowledge Base, 966
Critical Thinking, 969
Nursing Process, 969
Skill 43-1 Patient-Controlled Analgesia, 990

44 Nutrition, 996
Patricia A. Stockert, RN, BSN, MS, PhD
Scientific Knowledge Base, 997
Nursing Knowledge Base, 1001
Critical Thinking, 1006
Nursing Process, 1007
Skill 44-1 Aspiration Precautions, 1026
Skill 44-2 Inserting a Small-Bore Nasoenteric Tube for Enteral Feedings, 1028
Skill 44-3 Administering Enteral Feedings via Nasoenteric, Gastrostomy, or Jejunostomy Tubes, 1031
Skill 44-4 Blood Glucose Monitoring, 1036

45 Urinary Elimination, 1042
Terry L. Wood, PhD, RN, CNE
Scientific Knowledge Base, 1042
Nursing Knowledge Base, 1048
Critical Thinking, 1049
Nursing Process, 1049
Skill 45-1 Collecting Midstream (Clean-Voided) Urine Specimen, 1068
Skill 45-2 Inserting a Straight or Indwelling Catheter, 1071
Skill 45-3 Indwelling Catheter Care, 1079
Skill 45-4 Closed Catheter Irrigation, 1081

46 Bowel Elimination, 1087
Lori Klingman, MSN, RN
Scientific Knowledge Base, 1087
Nursing Knowledge Base, 1089
Critical Thinking, 1096
Nursing Process, 1096
Skill 46-1 Administering a Cleansing Enema, 1112
Skill 46-2 Inserting and Maintaining a Nasogastric Tube for Gastric Decompression, 1115
Skill 46-3 Pouching an Ostomy, 1121

47 Mobility and Immobility, 1127
Ann B. Tritak, EdD, MA, BSN, RN
Scientific Knowledge Base, 1127

Nursing Knowledge Base, 1131
Critical Thinking, 1136
Nursing Process, 1136
Skill 47-1 Moving and Positioning Patients in Bed, 1159
Skill 47-2 Using Safe and Effective Transfer Techniques, 1166

48 Skin Integrity and Wound Care, 1176
Janice Colwell, RN, MS, CWOCN, FAAN
Scientific Knowledge Base, 1176
Nursing Knowledge Base, 1184
Critical Thinking, 1186
Nursing Process, 1187
Skill 48-1 Assessment for Risk for Pressure Ulcer Development, 1213
Skill 48-2 Treating Pressure Ulcers, 1215
Skill 48-3 Applying Dry and Moist Dressings, 1218
Skill 48-4 Implementation of Negative-Pressure Wound Therapy, 1221
Skill 48-5 Performing Wound Irrigation, 1224
Skill 48-6 Applying an Abdominal Binder, 1226
Skill 48-7 Applying an Elastic Bandage, 1228

49 Sensory Alterations, 1233
Jill Parsons, RN, MSN, PCCN
Scientific Knowledge Base, 1233
Nursing Knowledge Base, 1236
Critical Thinking, 1236
Nursing Process, 1237

50 Care of Surgical Patients, 1254
Carrie Sona, RN, MSN, CCRN, ACNS, CCNS
History of Surgical Nursing, 1254
Scientific Knowledge Base, 1255
Nursing Knowledge Base, 1255
Critical Thinking, 1255
Preoperative Surgical Phase, 1256
Nursing Process, 1256
Transport to the Operating Room, 1271
Intraoperative Surgical Phase, 1271
Preoperative (Holding) Area, 1271
Admission to the Operating Room, 1271
Nursing Process, 1272
Postoperative Surgical Phase, 1274
Immediate Postoperative Recovery (Phase I), 1274
Recovery in Ambulatory Surgery (Phase II), 1275
Postoperative Convalescence, 1276
Nursing Process, 1277
Skill 50-1 Demonstrating Postoperative Exercises, 1287

Glossary, 1296

CHAPTER 1

Nursing Today

OBJECTIVES

- Discuss the development of professional nursing roles.
- Describe educational programs available for professional registered nurse education.
- Describe the roles and career opportunities for nurses.
- Discuss the influence of social, political, and economic changes on nursing practices.

KEY TERMS

Advanced practice registered nurse (APRN), p. 7
American Nurses Association (ANA), p. 1
Caregiver, p. 7
Certified nurse-midwife (CNM), p. 8
Certified registered nurse anesthetist (CRNA), p. 8
Clinical nurse specialist (CNS), p. 8
Code of ethics, p. 4
Continuing education, p. 5
Genomics, p. 10
In-service education, p. 5
International Council of Nurses (ICN), p. 9
National League for Nursing (NLN), p. 9
Nurse administrator, p. 8
Nurse educator, p. 8
Nurse practitioner (NP), p. 8
Nurse researcher, p. 8
Nursing, p. 1
Patient advocate, p. 7
Professional organization, p. 9
Quality and Safety Education for Nurses (QSEN), p. 9
Registered nurse (RN), p. 5

Nursing is an art and a science. As a professional nurse you will learn to deliver care artfully with compassion, caring, and respect for each patient's dignity and personhood. As a science nursing practice is based on a body of knowledge that is continually changing with new discoveries and innovations. When you integrate the science and art of nursing into your practice, the quality of care you provide to your patients is at a level of excellence that benefits patients and their families.

Your opportunities for a nursing career are limitless. There are a variety of career paths, including clinical practice, education, research, management, administration, and even entrepreneurship. As a student it is important for you to understand the scope of nursing practice and how nursing influences the lives of your patients.

The patient is the center of your practice. The patient includes the individual, family, and/or community. Patients have a wide variety of health care needs, experiences, vulnerabilities, and expectations; but this is what makes nursing both challenging and rewarding. Making a difference in your patients' lives is fulfilling (e.g., helping a dying patient find relief from pain, helping a young mother learn parenting skills, and finding ways for older adults to remain independent in their homes). Nursing offers personal and professional rewards every day. This chapter presents a contemporary view of the evolution of nursing and nursing practice and the historical, practical, social, and political influences on the discipline of nursing.

When giving care, it is essential to provide a specified service according to standards of practice and to follow a code of ethics (American Nurses Association [ANA], 2008, 2010b). Professional practice includes knowledge from social and behavioral sciences, biological and physiological sciences, and nursing theories. In addition, nursing practice incorporates ethical and social values, professional autonomy, and a sense of commitment and community. The **American Nurses Association (ANA)** defines **nursing** as *the protection, promotion, and optimization of health and abilities; prevention of illness and injury; alleviation of suffering through the diagnosis and treatment of human response; and advocacy in the care of individuals, families, communities, and populations* (ANA, 2010b). The International Council of Nurses (ICN, 2010) has another definition: *Nursing encompasses autonomous and collaborative care of individuals of all ages, families, groups and communities, sick or well and in all settings. Nursing includes the promotion of health; prevention of illness; and the care of ill, disabled, and dying people. Advocacy, promotion of a safe environment, research, participation in shaping health policy and in patient and health systems management, and education are also key nursing roles.* Both of these definitions support the prominence and importance that nursing holds in providing safe, patient-centered health care to the global community.

Expert clinical nursing practice is a commitment to the application of knowledge, ethics, aesthetics, and clinical experience. Your ability to interpret clinical situations and make complex decisions

is the foundation for your nursing care and the basis for the advancement of nursing practice and the development of nursing science (Benner, 1984; Benner, Tanner, and Chesla, 1997; Benner et al., 2010). Critical thinking skills are essential to nursing (see Chapter 15). When providing nursing care, you need to make clinical judgments and decisions about your patients' health care needs based on knowledge, experience, and standards of care. Use critical thinking skills and reflections to help you gain and interpret scientific knowledge, integrate knowledge from clinical experiences, and become a lifelong learner (Benner et al., 2010).

HISTORICAL HIGHLIGHTS

Nursing has responded and always will respond to the needs of its patients. In times of war the nursing response was to meet the needs of the wounded in combat zones and military hospitals in the United States and abroad. When communities face health care crises such as disease outbreaks or insufficient health care resources, nurses establish community-based immunization and screening programs, treatment clinics, and health promotion activities. Our patients are most vulnerable when they are injured, sick, or dying.

Since the beginning of the profession, nurses have studied and tested new and better ways to help their patients. A classic article described Florence Nightingale's work during the Crimean War. She studied and implemented methods to improve battlefield sanitation, which ultimately reduced illness, infection, and mortality (Cohen, 1984). Take time to reflect about Nightingale's actions centuries ago and think about the impact of her actions. She set the stage for using evidence to direct practice.

Today nurses are active in determining the best practices for skin care management, pain control, nutritional management, and care of older adults, to cite just a few examples. Nurse researchers are leaders in expanding knowledge in nursing and other health care disciplines. Their work provides evidence for practice to ensure that nurses have the best available evidence to support their practices (see Chapter 5).

Nursing is a combination of knowledge from the physical sciences, humanities, and social sciences, along with clinical competencies needed for safe, quality patient-centered care (Gugliemi, 2010). It continuously responds and adapts to new challenges. Nurses are in a unique position to refine and shape the future of health care.

Nurses are active in social policy and political arenas. Nurses and their professional organizations lobby for health care legislation to meet the needs of patients, particularly the medically underserved. For example, nurses in communities provide home visits to newborns of high-risk mothers (e.g., adolescent, poorly educated mothers or medically underserved). These visits result in fewer emergency department visits, fewer newborn infections, and reduced infant mortality (Mason et al., 2012).

Knowledge of the history of our profession increases your ability to understand the social and intellectual origins of the discipline. Although it is not practical to describe all of the historical aspects of professional nursing, some of the more significant milestones are described in the following paragraphs.

Florence Nightingale

In *Notes on Nursing: What It Is and What It Is Not*, Florence Nightingale established the first nursing philosophy based on health maintenance and restoration (Nightingale, 1860). She saw the role of nursing as having "charge of somebody's health" based on the knowledge of "how to put the body in such a state to be free of disease or to recover from disease" (Nightingale, 1860). During the same year she developed the first organized program for training nurses, the Nightingale Training School for Nurses at St. Thomas' Hospital in London.

Nightingale was the first practicing nurse epidemiologist (Cohen, 1984). Her statistical analyses connected poor sanitation with cholera and dysentery. She volunteered during the Crimean War in 1853 and traveled the battlefield hospitals at night carrying her lamp; thus she was known as the "lady with the lamp." The sanitary, nutrition, and basic facilities in the battlefield hospitals were poor at best. Eventually she was given the task to organize and improve the quality of the sanitation facilities. As a result, the mortality rate at the Barracks Hospital in Scutari, Turkey, was reduced from 42.7% to 2.2% in 6 months (Donahue, 2011).

The Civil War to the Beginning of the Twentieth Century

The Civil War (1860 to 1865) stimulated the growth of nursing in the United States. Clara Barton, founder of the American Red Cross, tended soldiers on the battlefields, cleansing their wounds, meeting their basic needs, and comforting them in death. The U.S. Congress ratified the American Red Cross in 1882 after 10 years of lobbying by Barton. Dorothea Lynde Dix, Mary Ann Ball (Mother Bickerdyke), and Harriet Tubman also influenced nursing during the Civil War (Donahue, 2011). As superintendent of the female nurses of the Union Army, Dix organized hospitals, appointed nurses, and oversaw and regulated supplies to the troops. Mother Bickerdyke organized ambulance services and walked abandoned battlefields at night, looking for wounded soldiers. Harriet Tubman was active in the Underground Railroad movement and assisted in leading over 300 slaves to freedom (Donahue, 2011).

The first professionally trained African American nurse was Mary Mahoney. She was concerned with relationships between cultures and races; and as a noted nursing leader she brought forth an awareness of cultural diversity and respect for the individual, regardless of background, race, color, or religion.

Isabel Hampton Robb helped found the Nurses' Associated Alumnae of the United States and Canada in 1896. This organization became the ANA in 1911. She authored many nursing textbooks, including *Nursing: Its Principles and Practice for Hospital and Private Use* (1894), *Nursing Ethics* (1900), and *Educational Standards for Nurses* (1907) and was one of the original founders of the *American Journal of Nursing* (AJN) (Donahue, 2011).

Nursing in hospitals expanded in the late nineteenth century. However, nursing in the community did not increase significantly until 1893, when Lillian Wald and Mary Brewster opened the Henry Street Settlement, which focused on the health needs of poor people who lived in tenements in New York City (Donahue, 2011). Nurses working in this settlement were some of the first to demonstrate autonomy in practice because they frequently encountered situations that required quick and innovative problem solving and critical thinking without the supervision or direction of a health care provider.

Twentieth Century

In the early twentieth century a movement toward developing a scientific, research-based defined body of nursing knowledge and practice was evolving. Nurses began to assume expanded and advanced practice roles. Mary Adelaide Nutting was instrumental in the affiliation of nursing education with universities. She became the first professor of nursing at Columbia University Teachers College in 1906 (Donahue, 2011). In addition, the Goldmark

Report concluded that nursing education needed increased financial support and suggested that university schools of nursing receive the money.

As nursing education developed, nursing practice also expanded, and the Army and Navy Nurse Corps were established. By the 1920s nursing specialization was developing. Graduate nurse-midwifery programs began; in the last half of the century specialty-nursing organizations were created. Examples of these specialty organizations include the American Association of Critical Care Nurses; Association of Operating Room Nurses (AORN); Emergency Nurses Association (ENA); Infusion Nurses Society (INS); Oncology Nursing Society (ONS); and Wound, Ostomy, Continence Nurses Society (WOCN).

Twenty-First Century

Nursing practice and education continue to evolve to meet the needs of society. In 1990 the ANA established the Center for Ethics and Human Rights (see Chapter 22). The Center provides a forum to address the complex ethical and human rights issues confronting nurses and designs activities and programs to increase ethical competence in nurses (ANA, 2010c).

Today the profession faces multiple challenges. Nurses and nurse educators are revising nursing practice and school curricula to meet the ever-changing needs of society, including bioterrorism, emerging infections, and disaster management. Advances in technology and informatics (see Chapter 26), the high acuity level of care of hospitalized patients, and early discharge from health care institutions require nurses in all settings to have a strong and current knowledge base from which to practice. In addition, nursing and the Robert Wood Johnson Foundation are taking a leadership role in developing standards and policies for end-of-life care through the *Last Acts Campaign* (see Chapter 36). The End-of-Life Nursing Education Consortium (ELNEC) offered collaboratively by the American Association of Colleges of Nursing (AACN) and the City of Hope Medical Center has brought end-of-life care and practices into nursing curricula and professional continuing-education programs for practicing nurses (Tilden and Thompson, 2009).

INFLUENCES ON NURSING

Multiple external forces affect nursing, including demographic changes of the population, human rights, increasing numbers of medically underserved, and the threat of bioterrorism.

Health Care Reform

Health care reform not only affects how health care is paid for but how it is delivered. There will be greater emphasis on health promotion, disease prevention, and illness management in the future. This model impacts the delivery of nursing care. More services will be in community-based care settings. As a result, more nurses will be needed to practice in community care centers, schools, and senior centers. This will require nurses to be more adept at assessing for resources, service gaps, and how the patient adapts to returning to the community. Nursing must respond to such changes by exploring new methods to provide care, changing nursing education, and revising practice standards (O'Neil, 2009).

Demographic Changes

The U.S. Census Bureau (2008a) predicts that between 2010 and 2050 there will be a steady rise in the population. This change alone requires expanded health care resources. Add to the population change a steady increase in the population of people 65 years and older (U.S. Census Bureau, 2008b). To effectively meet all the health care needs of the expanding and aging population, changes need to occur as to how care is provided, especially in the area of public health, to address health care reform and meet the needs of the changing population. The population is still shifting from rural areas to urban centers, and more people are living with chronic and long-term illness (Presley, 2010). Not only are there expansions of outpatient settings, but more and more people want to receive outpatient and community-based care and remain in their homes or community (see Chapters 2 and 3).

Medically Underserved

The rising rates of unemployment, underemployment and low-paying jobs, mental illness, and homelessness and rising health care costs all contribute to increases in the medically underserved population. Caring for the medically underserved population is a global issue; the social, political, and economic factors of a country affect both access to care and resources to provide and pay for these services (Huicho et al., 2010). In the United States some of the medically underserved population are poor and on Medicaid. Others are part of the working poor (i.e., they cannot afford their own insurance, but they make too much money to qualify for Medicaid and as a result do not receive any health care). In addition, the number of underserved patients who require home-based palliative care services is increasing. This is a group of patients whose physical status does not improve and heath care needs increase. As a result, the cost for home-based care continues to rise, to the point that some patients opt out of all palliative services because of costs (Fernandes et al., 2010). Today nurses and schools of nursing are developing partnerships to improve health outcomes in underserved communities. Nurses work in these community-based settings providing health promotion and disease prevention to the homeless, mentally ill, and others who have limited access to health care or who lack health care insurance (McCann, 2010).

Threat of Bioterrorism

The world is a changing place; the threats of bioterrorism are continuous. Many health care agencies, schools, and communities have educational programs to prepare for nuclear, chemical, or biological attack. Nurses are active in disaster preparedness. The ICN works alongside national nursing associations to determine how to best educate and prepare nurses for future disasters (Robinson, 2010). For example, public health emergency simulation exercises allow nurses and students to work with community disaster-preparedness groups and hospitals to determine what specific nursing activities are needed (Morrison and Catanzaro, 2010). These activities sometimes range from participation in vaccine research, decontamination in the event of biological attack, and triage for mass casualty to crisis response units. If a disaster were to occur, nurses would be essential in evaluating the strengths and weaknesses of any disaster plan.

Rising Health Care Costs

Skyrocketing health care costs present challenges to the profession, consumer, and the health care delivery system. As a nurse you are responsible for providing the patient with the best-quality care in an efficient and economically sound manner. The challenge is to use health care and patient resources wisely. Chapter 2 summarizes reasons for the rise in health care costs and its implications for nursing.

Nursing Shortage

There is an ongoing global nursing shortage, which results from insufficient qualified registered nurses (RNs) to fill vacant positions and the loss of qualified RNs to other professions (Flinkman et al., 2010). This shortage affects all aspects of nursing such as patient care, administration, and nursing education (Tanner and Bellack, 2010), but it also represents challenges and opportunities for the profession. Many health care dollars are invested in strategies aimed at recruiting a well-educated, critically thinking, motivated, and dedicated nursing workforce (Benner et al., 2010). There is a direct link between registered nurses' care and positive patient outcomes, reduced complication rates, and a more rapid return of the patient to an optimal functional status (Aiken, 2010; Lucero et al., 2009).

Professional nursing organizations predict that there will continue to be a diminishing pipeline of RNs in the future (AACN, 2008b; Aiken, 2010). Like it or not, the nursing shortage affects the needs of the consumer (Block and Sredl, 2006). With fewer nurses in the workplace, it is important for you to learn to use your patient contact time efficiently and professionally. Time management, therapeutic communication, patient education, and compassionate implementation of psychomotor skills are just a few of the essential skills you need. Most important, your patients leave the health care setting with a positive image of nursing and a feeling that they received quality care. In a rapid-discharge and high-tech health care environment nurses need to relate to their patients on a human, caring level (Manthey, 2008). Your patient should never feel rushed or that he or she was unimportant. If a certain aspect of patient care requires 15 minutes of contact, it will take the same time to deliver the care in an organized manner as it would in a rushed, harried manner.

NURSING AS A PROFESSION

Nursing is not simply a collection of specific skills, and you are not simply a person trained to perform specific tasks. Nursing is a profession. No one factor absolutely differentiates a job from a profession, but the difference is important in terms of how you practice. To act professionally you administer quality patient-centered care in a safe, conscientious, and knowledgeable manner. You are responsible and accountable to yourself and your patients and peers. A profession has the following primary characteristics:

- It requires a basic liberal foundation and an extended education of its members.
- It has a theoretical body of knowledge leading to defined skills, abilities, and norms.
- It provides a specific service.
- Members of a profession have autonomy in decision making and practice.
- The profession as a whole has a code of ethics for practice.

Scope and Standards of Practice

Since 1960 the ANA has engaged in documenting the scope of nursing and developing standards of practice (ANA, 2010b). Within this document are the Standards of Practice and Standards of Professional Performance. It is important that you know and apply these standards in your practice. The document is usually available in most schools of nursing and practice settings. The goal of this document is to improve the health and well-being of all individuals, communities, and populations through the significant and visible contributions of registered nursing using standard-based practice (ANA, 2010b).

BOX 1-1 ANA STANDARDS OF NURSING PRACTICE

1. **Assessment:** The registered nurse collects comprehensive data pertinent to the patient's health and/or the situation.
2. **Diagnosis:** The registered nurse analyzes the assessment data to determine the diagnoses or issues.
3. **Outcomes Identification:** The registered nurse identifies expected outcomes for a plan individualized to the patient or the situation.
4. **Planning:** The registered nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes.
5. **Implementation:** The registered nurse implements the identified plan.

5a. **Coordination of Care:** The registered nurse coordinates care delivery.

5b. **Health Teaching and Health Promotion:** The registered nurse uses strategies to promote health and a safe environment.

5c. **Consultation:** The graduate level–prepared specialty nurse or advanced practice registered nurse provides consultation to influence the identified plan, enhance the abilities of others, and effect change.

5d. **Prescriptive authority and treatment:** The advanced practice registered nurse uses prescriptive authority, procedures, referrals, treatment, and therapies in accordance with state and federal laws and regulations.

6. **Evaluation:** The registered nurse evaluates progress toward attainment of outcomes.

Standards of Practice. The Standards of Practice describe a competent level of nursing care (Box 1-1). The levels of care are demonstrated by the critical thinking model known as the nursing process: assessment, diagnosis, outcomes identification and planning, implementation, and evaluation (ANA, 2010b). The nursing process is the foundation of clinical decision making and includes all significant actions taken by nurses in providing care to patients (see Unit 3).

Standards of Professional Performance. The ANA Standards of Professional Performance (Box 1-2) describe a competent level of behavior in the professional role (ANA, 2010b). These standards provide objective guidelines for nurses to be accountable for their actions, their patients, and their peers. The standards provide a method to assure patients that they are receiving high-quality care, that the nurses know exactly what is necessary to provide nursing care, and that measures are in place to determine whether care meets the standards.

Code of Ethics. The **code of ethics** is the philosophical ideals of right and wrong that define the principles you will use to provide care to your patients. It is important for you to also incorporate your own values and ethics into your practice. As you incorporate these values, you explore what type of nurse you will be and how you will function within the discipline (ANA, 2008, 2010c). Ask yourself: how do your ethics, values, and practice compare with established standards? The ANA has a number of publications that address ethics and human rights in nursing. The *Code of Ethics for Nurses with Interpretive Statements* is a guide for carrying out nursing responsibilities that provide quality nursing care; it also outlines the ethical obligations of the profession (ANA, 2008). Chapter 22 provides a review of the nursing code of ethics and ethical principles for everyday practice.

BOX 1-2 ANA STANDARDS OF PROFESSIONAL PERFORMANCE

7. **Ethics:** The registered nurse practices ethically.
8. **Education:** The registered nurse attains knowledge and competency that reflects current nursing practice.
9. **Evidence-Based Practice and Research:** The registered nurse integrates evidence and research findings into practice.
10. **Quality of Practice:** The registered nurse contributes to quality nursing practice.
11. **Communication:** The registered nurse communicates effectively in all areas of practice.
12. **Leadership:** The registered nurse demonstrates leadership in the professional practice setting and the profession.
13. **Collaboration:** The registered nurse collaborates with health care consumer, family, and others in the conduct of nursing practice.
14. **Professional Practice Evaluation:** The registered nurse evaluates her or his own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.
15. **Resources:** The registered nurse uses appropriate resources to plan and provide nursing services that are safe, effective, and financially responsible.
16. **Environmental Health:** The registered nurse practices in an environmentally safe and healthy manner.

NURSING EDUCATION

Nursing requires a significant amount of formal education. The issues of standardization of nursing education and entry into practice remain a major controversy. In 1965 the ANA published a position paper on nursing education that emphasizes the role of education for the advancement of the science of the profession (ANA, 1965). Most nurses agree that nursing education is important to practice and that education needs to respond to changes in health care created by scientific and technological advances. There are various education preparations for an individual intending to be an RN. In addition, there is graduate nurse education and continuing and in-service education for practicing nurses.

Professional Registered Nurse Education

Currently in the United States the most frequent way to become a **registered nurse (RN)** is either through completion of an associate or baccalaureate degree program. Graduates of both programs are eligible to take the National Council Licensure Examination for Registered Nurses (NCLEX-RN®) to become RNs in the state in which they will practice.

The associate degree program in the United States is a 2-year program that is usually offered by a university or community college. This program focuses on the basic sciences and theoretical and clinical courses related to the practice of nursing.

The baccalaureate degree program usually includes 4 years of study in a college or university. The program focuses on the basic sciences; theoretical and clinical courses; and courses in the social sciences, arts, and humanities to support nursing theory. In Canada the degree of Bachelor of Science in Nursing (BScN) or Bachelor in Nursing (BN) is equivalent to the degree of Bachelor of Science in Nursing (BSN) in the United States. The *Essentials of Baccalaureate Education for Professional Nursing* (AACN, 2008a) delineates essential knowledge, practice and values, attitudes, personal qualities, and professional behavior for the baccalaureate-prepared nurse and guides faculty on the structure and evaluation of the curriculum. The National League for Nursing Accreditation Council (NLNAC) published the *NLNAC Standards and Criteria Baccalaureate Programs in Nursing—2008*. This document identifies core competencies for the professional nurse and supports the Pew Health Commission and the competencies of the Institute of Medicine (IOM) for health professionals (NLNAC, 2008). In addition, one of the IOM's recommendations is that 80% of nurses be prepared with a baccalaureate in nursing by 2020 (IOM, 2010) (see Chapter 2).

Graduate Education

After obtaining a baccalaureate degree in nursing, you can pursue graduate education leading to a master's or doctoral degree in any number of graduate fields, including nursing. A nurse completing a graduate program can receive a master's degree in nursing. The graduate degree provides the advanced clinician with strong skills in nursing science and theory, with emphasis on the basic sciences and research-based clinical practice. A master's degree in nursing is important for the roles of nurse educator and nurse administrator, and it is required for an advanced practice registered nurse (APRN).

Doctoral Preparation. Professional doctoral programs in nursing (DSN or DNSc) prepare graduates to apply research findings to clinical nursing. Other doctoral programs emphasize more basic research and theory and award the research-oriented Doctor of Philosophy (PhD) in nursing. Recently the AACN recommended the Doctor of Nursing Practice (DNP) as the terminal practice degree and required preparation for all APRNs by 2015 (Chase and Pruitt, 2006). The DNP is a practice-focused doctorate. It provides skills in obtaining expanded knowledge through the formulation and interpretations of evidence-based practice (Chism, 2010).

The need for nurses with doctoral degrees is increasing. Expanding clinical roles and continuing demand for well-educated nursing faculty, nurse administrators, and APRNs in the clinical settings and new areas of nursing specialties such as nursing informatics are just a few reasons for increasing the number of doctorally prepared nurses.

Continuing and In-Service Education

Nursing is a knowledge-based profession, and technological expertise and clinical decision making are qualities that our health care consumers demand and expect. Continuing education programs are one way to promote and maintain current nursing skills, gain new knowledge and theory, and obtain new skills reflecting the changes in the health care delivery system (Hale et al., 2010). **Continuing education** involves formal, organized educational programs offered by universities, hospitals, state nurses associations, professional nursing organizations, and educational and health care institutions. An example is a program on caring for older adults with dementia offered by a university or a program on safe medication practices offered by a hospital. Continuing education updates your knowledge about the latest research and practice developments, helps you to specialize in a particular area of practice, and teaches you new skills and techniques (Hale et al., 2010).

In-service education programs are instruction or training provided by a health care agency or institution. An in-service program is held in the institution and is designed to increase the knowledge, skills, and competencies of nurses and other health care professionals employed by the institution. Often in-service programs are focused on new technologies such as how to correctly use the

newest safety syringes. Many in-service programs are designed to fulfill required competencies of an organization. For example, a hospital might offer an in-service program on safe principles for administering chemotherapy or a program on cultural sensitivity.

NURSING PRACTICE

You will have an opportunity to practice in a variety of settings, in many roles within those settings, and with caregivers in other related health professions. Administrators in health care agencies and institutions guide the practice of nursing only in part. State and provincial Nurse Practice Acts (NPAs) establish specific legal regulations for practice, and professional organizations establish standards of practice as criteria for nursing care. The ANA is concerned with legal aspects of nursing practice, public recognition of the significance of nursing practice to health care, and implications for nursing practice regarding trends in health care. The ANA definition of nursing illustrates the consistent orientation of nurses to providing care to promote the well-being of their patients individually or in groups and communities (ANA, 2010a).

Nurse Practice Acts

In the United States the State Boards of Nursing oversee NPAs. NPAs regulate the scope of nursing practice and protect public health, safety, and welfare. This protection includes shielding the public from unqualified and unsafe nurses. Although each state defines for itself the scope of nursing practice, most have similar NPAs. The definition of nursing practice published by the ANA is representative of the scope of nursing practice as defined in most states. However, in the last decade many states have revised their NPAs to reflect the growing autonomy of nursing and the expanded roles of nurses in practice. For example, NPAs expanded their scope to include minimum education requirements, required certifications, and practice guidelines for APRNs such as nurse practitioners and certified RN anesthetists. The expansion of scope of practice includes skills unique to the advanced practice role (e.g., advanced assessment, prescriptive authority for certain medications and diagnostic procedures, and some invasive procedures).

Licensure and Certification

Licensure. In the United States RN candidates must pass the NCLEX-RN® examination administered by the individual State Boards of Nursing. Regardless of educational preparation, the examination for RN licensure is exactly the same in every state in the United States. This provides a standardized minimum knowledge base for nurses.

Certification. Beyond the NCLEX-RN®, the nurse may choose to work toward certification in a specific area of nursing practice. Minimum practice requirements are set, based on the certification the nurse seeks. National nursing organizations such as the ANA have many types of certification to enhance your career such as certification in medical surgical or geriatric nursing. After passing the initial examination, you maintain your certification by ongoing continuing education and clinical or administrative practice.

Science and Art of Nursing Practice

Because nursing is both an art and a science, nursing practice requires a blend of the most current knowledge and practice standards with an insightful and compassionate approach to patient care. Your patients' health care needs are multidimensional. Thus your care will reflect the needs and values of society and professional standards of care and performance, meet the needs of each patient, and integrate evidence-based findings to provide the highest level of care. Nursing has a specific body of knowledge; however, it is essential that you socialize within the profession and practice to fully understand and apply the nursing knowledge base and develop professional expertise. Clinical expertise takes time and commitment. According to Benner et al. (2010), an expert nurse passes through five levels of proficiency when acquiring and developing generalist or specialized nursing skills (Box 1-3).

BOX 1-3 BENNER: FROM NOVICE TO EXPERT

Novice: Beginning nursing student or any nurse entering a situation in which there is no previous level of experience (e.g., an experienced operating room nurse chooses to now practice in home health). The learner learns via a specific set of rules or procedures, which are usually stepwise and linear.

Advanced Beginner: A nurse who has had some level of experience with the situation. This experience may only be observational in nature, but the nurse is able to identify meaningful aspects or principles of nursing care.

Competent: A nurse who has been in the same clinical position for 2 to 3 years. This nurse understands the organization and specific care required by the type of patients (e.g., surgical, oncology, or orthopedic patients). This nurse is a competent practitioner who is able to anticipate nursing care and establish long-range goals. In this phase the nurse has usually had experience with all types of psychomotor skills required by this specific group of patients.

Proficient: A nurse with more than 2 to 3 years of experience in the same clinical position. This nurse perceives a patient's clinical situation as a whole, is able to assess an entire situation, and can readily transfer knowledge gained from multiple previous experiences to a situation. This nurse focuses on managing care as opposed to managing and performing skills.

Expert: A nurse with diverse experience who has an intuitive grasp of an existing or potential clinical problem. This nurse is able to zero in on the problem and focus on multiple dimensions of the situation. He or she is skilled at identifying both patient-centered problems and problems related to the health care system or perhaps the needs of the novice nurse.

Data from Benner P: *From novice to expert: excellence and power in clinical nursing practice,* Menlo Park, Calif, 1984, Addison-Wesley.

Use the competencies of critical thinking in your practice. This includes integrating knowledge from basic science and nursing knowledge bases, applying knowledge from past and present experiences, applying critical thinking attitudes to a clinical situation, and implementing intellectual and professional standards (see Chapter 15). When you provide well–thought out care with compassion and caring, you provide each of your patients the best of the science and art of nursing care (see Chapter 7).

PROFESSIONAL RESPONSIBILITIES AND ROLES

As a nurse, you are responsible for obtaining and maintaining specific knowledge and skills for a variety of professional roles and responsibilities. Nurses provide care and comfort for patients in all health care settings. Nurses' concern for meeting the patient's needs remains the same whether care focuses on health promotion and illness prevention, disease and symptom management, family support, or end-of-life care.

Autonomy and Accountability

Autonomy is an essential element of professional nursing that involves the initiation of independent nursing interventions without medical orders. For example, you independently

implement coughing and deep-breathing exercises for a patient who recently had surgery. You actively collaborate with other health professionals to pursue the best treatment plan for a patient. With increased autonomy comes greater responsibility and accountability. Accountability means that you are responsible, professionally and legally, for the type and quality of nursing care provided. You need to keep current and competent in nursing and scientific knowledge and technical skills. The nursing profession also regulates accountability through nursing audits and standards of practice.

Caregiver

As **caregiver,** you help patients maintain and regain health, manage disease and symptoms, and attain a maximal level function and independence through the healing process. You provide healing through both physical and interpersonal skills. Healing involves more than achieving improved physical well-being. You need to meet all health care needs of the patient by providing measures that restore a patient's emotional, spiritual, and social well-being. As a caregiver, you help the patient and family set goals and assist them with meeting these goals with minimal financial cost, time, and energy.

Advocate

As a **patient advocate,** you protect your patient's human and legal rights and provide assistance in asserting these rights if the need arises. As an advocate you act on behalf of your patient and secure your patient's health care rights and stand up for them (Hanks, 2010). For example, you provide additional information to help a patient decide whether or not to accept a treatment, or you find an interpreter to help family members communicate their concerns. You sometimes need to defend patients' rights in a general way by speaking out against policies or actions that put patients in danger or conflict with their rights.

Educator

As an educator you explain concepts and facts about health, describe the reason for routine care activities, demonstrate procedures such as self-care activities, reinforce learning or patient behavior, and evaluate the patient's progress in learning. Some of your patient teaching is unplanned and informal. For example, during a casual conversation you respond to questions about the reason for an intravenous infusion, a health issue such as smoking cessation, or necessary lifestyle changes. Other teaching activities are planned and more formal such as when you teach your patient to self-administer insulin injections. Always use teaching methods that match your patient's capabilities and needs and incorporate other resources such as the family in teaching plans (see Chapter 25).

Communicator

Your effectiveness as a communicator is central to the nurse-patient relationship. It allows you to know your patients, including their strengths and weaknesses, and their needs. Communication is essential for all nursing roles and activities. You will routinely communicate with patients and families, other nurses and health care professionals, resource persons, and the community. Without clear communication, it is impossible to give comfort and emotional support, give care effectively, make decisions with patients and families, protect patients from threats to well-being, coordinate and manage patient care, assist the patient in rehabilitation, or provide patient education. The quality of communication is a critical factor in meeting the needs of individuals, families, and communities (see Chapter 24).

Manager

Today's health care environment is fast paced and complex. Nurse managers need to establish an environment for collaborative patient-centered care to provide safe, quality care with positive patient outcomes. A manager coordinates the activities of members of the nursing staff in delivering nursing care and has personnel, policy, and budgetary responsibility for a specific nursing unit or agency. The manager uses appropriate leadership styles to create a nursing environment for the patients and staff that reflect the mission and values of the health care organization (see Chapter 21).

Career Development

Innovations in health care, expanding health care systems and practice settings, and the increasing needs of patients have been stimuli for new nursing roles. Today the majority of nurses practice in hospital settings, followed by community-based care, ambulatory care, and nursing homes/extended care settings.

Nursing provides an opportunity for you to commit to lifelong learning and career development to provide patients the state-of-the-art care they need. Career roles are specific employment positions or paths. Because of increasing educational opportunities for nurses, the growth of nursing as a profession, and a greater concern for job enrichment, the nursing profession offers expanded roles and different kinds of career opportunities. Your career path is limitless. You will probably switch career roles more than once. Take advantage of the different clinical practice and professional opportunities. These career opportunities include APRNs, nurse researchers, nurse risk managers, quality improvement nurses, consultants, and even business owners.

Provider of Care. Most nurses provide direct patient care in an acute care setting. As health care returns to the home care setting, there are increased opportunities for you to provide direct care in the patient's home or community. Use the nursing process and critical thinking skills to provide care that is both restorative and curative. Educate your patients and families to promote health maintenance and self-care. In collaboration with other health care team members, focus your care on returning the patient to his or her home at an optimal functional status.

In the hospital you may choose to practice in a medical-surgical setting or concentrate on a specific area of specialty practice such as pediatrics, critical care, or emergency care. Most specialty care areas require some experience as a medical-surgical nurse and additional continuing or in-service education. Many intensive care unit and emergency department nurses are required to have certification in advanced cardiac life support and critical care, emergency nursing, or trauma nursing.

Advanced Practice Registered Nurses. The **advanced practice registered nurse (APRN)** is the most independently functioning nurse. An APRN has a master's degree in nursing; advanced education in pathophysiology, pharmacology, and physical assessment; and certification and expertise in a specialized area of practice (APRN, 2008). There are four core roles for the APRN: clinical nurse specialist (CNS), certified nurse practitioner (CNP), certified nurse midwife (CNM), and certified RN anesthetist (CRNA). The educational preparation for the four roles is in at least one of the following six populations: adult-gerontology, pediatrics, neonatology, women's health/gender related, family/individual across life span, and psychiatric mental health (APRN, 2008). APRNs

FIG. 1-1 Nurse specialist consults on a difficult patient case.

function as a clinician, educator, case manager, consultant, and researcher within his or her area of practice to plan or improve the quality of nursing care for the patient and family.

Clinical Nurse Specialist. The **clinical nurse specialist (CNS)** is an APRN who is an expert clinician in a specialized area of practice (Fig. 1-1). The specialty may be identified by a population (e.g., geriatrics), a setting (e.g., critical care), a disease specialty (e.g., diabetes), a type of care (e.g., rehabilitation), or a type of problem (e.g., pain) (National CNS Competency Task Force, 2010). The CNS practice is in all health care settings.

Nurse Practitioner. The **nurse practitioner (NP)** is an APRN who provides health care to a group of patients, usually in an outpatient, ambulatory care, or community-based setting. NPs provide care for patients with complex problems and a more holistic approach than physicians. The NP provides comprehensive care, directly managing the medical care of patients who are healthy or who have chronic conditions. A significant percentage of primary care visits by patients result from health-related problems that extend beyond the boundaries of medicine and demand the expertise of a nurse. The NP is able to establish a collaborative provider-patient relationship, working with a specific group of patients or with patients of all ages and health care needs. The major NP categories are acute care, adult, family, pediatric, women's, psychiatric mental health, and geriatric. An NP has the knowledge and skills necessary to detect and manage self-limiting acute and chronic stable medical conditions such as asthma, diabetes mellitus, and hypertension.

Certified Nurse-Midwife. A **certified nurse-midwife (CNM)** is an APRN who is also educated in midwifery and is certified by the American College of Nurse-Midwives. The practice of nurse-midwifery involves providing independent care for women during normal pregnancy, labor, and delivery and care for the newborn. It includes some gynecological services such as routine Papanicolaou (Pap) smears, family planning, and treatment for minor vaginal infections. A CNM practices with a health care agency that provides medical consultation, collaborative management, and referral.

Certified Registered Nurse Anesthetist. A **certified registered nurse anesthetist (CRNA)** is an APRN with advanced education in a nurse anesthesia accredited program. Nurse anesthetists provide surgical anesthesia under the guidance and supervision of an anesthesiologist, who is a physician with advanced knowledge of surgical anesthesia.

Nurse Educator. A **nurse educator** works primarily in schools of nursing, staff development departments of health care agencies, and patient education departments. Nurse educators need experience in clinical practice to provide them with practical skills and theoretical knowledge. A faculty member in a school of nursing educates students to become professional nurses. Nursing faculty members are responsible for teaching current nursing practice, trends, theory, and necessary skills in laboratories and clinical settings. Nurse educators in schools of nursing usually have graduate degrees in nursing and additional education. Many hold doctorate or advanced degrees in nursing, education, or administration such as a master's degree in business administration (MBA). Generally they have a specific clinical, administrative, or research specialty and advanced clinical experience.

Nurse educators in staff development departments of health care institutions provide educational programs for nurses within their institution. These programs include orientation of new personnel, critical care nursing courses, assisting with clinical skill competency, safety training, and instruction about new equipment or procedures. These nursing educators often participate in the development of nursing policies and procedures.

The primary focus of the nurse educator in the patient education department of an agency is to teach patients who are ill or disabled and their families how to self-manage their illness or disability. These nurse educators are usually specialized and certified such as a certified diabetes educator (CDE) or an ostomy care nurse and see only a specific population of patients.

Nurse Administrator. A **nurse administrator** manages patient care and the delivery of specific nursing services within a health care agency. Nursing administration begins with positions such as the assistant nurse manager. Experience and additional education sometimes lead to a middle-management position such as nurse manager of a specific patient care area or house supervisor or to an upper-management position such as assistant or associate director or director of nursing services.

Nurse manager positions usually require at least a baccalaureate degree in nursing, and director and nurse executive positions generally require a master's degree. Chief nurse executive and vice president positions in large health care organizations often require preparation at the doctoral level. Nurse administrators often have advanced degrees such as an MBA or a master's degree in hospital administration (MHA), public health (MPH), or health service administration.

In today's health care organizations directors may have responsibility for more than nursing units. Often directors manage a particular service or product line such as medicine or cardiology. Management of a service line often includes directing supportive functions and the health care personnel within areas such as medicine clinics, diagnostic departments, or outpatient.

Vice presidents of nursing or chief nurse executives often have responsibilities for all clinical functions within the hospital. This may include all ancillary personnel who provide and support patient care services. The nurse administrator needs to be skilled in business and management and understand all aspects of nursing and patient care. Functions of administrators include budgeting, staffing, strategic planning of programs and services, employee evaluation, and employee development.

Nurse Researcher. The **nurse researcher** investigates problems to improve nursing care and further define and expand the scope of nursing practice (see Chapter 5). The nurse researcher

often works in an academic setting, hospital, or independent professional or community service agency. The preferred educational requirement is a doctoral degree, with at least a master's degree in nursing.

PROFESSIONAL NURSING ORGANIZATIONS

A **professional organization** deals with issues of concern to those practicing in the profession. In North America the major professional nursing organizations are the **National League for Nursing (NLN)** and the ANA. The NLN advances excellence in nursing education to prepare nurses to meet the needs of a diverse population in a changing health care environment. The NLN (2008) sets standards for excellence and innovation in nursing education.

The purpose of the ANA is to improve standards of health and the availability of health care, to foster high standards for nursing, and to promote the professional development and general and economic welfare of nurses. The ANA is part of the **International Council of Nurses (ICN).** The objectives of the ICN parallel those of the ANA: promoting national associations of nurses, improving standards of nursing practice, seeking a higher status for nurses, and providing an international power base for nurses.

The ANA is active in political, professional, and financial issues affecting health care and the nursing profession. It is a strong lobbyist in professional practice issues such as limits of overtime hours. For example, ANA extensively lobbied state legislatures to restrict the length of overtime any one nurse's shift can be extended. When nurses' shifts last longer than 12 to 16 hours, both the patient's and nurse's safety is at risk. The risk for treatment errors and nurse injury is increased when the nurse's workday is extended.

Nursing students take part in organizations such as the National Student Nurses Association (NSNA) in the United States and the Canadian Student Nurses Association (CSNA) in Canada. These organizations consider issues of importance to nursing students such as career development and preparation for licensing. The NSNA often cooperates in activities and programs with the professional organizations.

Some professional organizations focus on specific areas such as critical care, nursing administration, nursing research, or nurse-midwifery. These organizations seek to improve the standards of practice, expand nursing roles, and foster the welfare of nurses within the specialty areas. In addition, professional organizations present educational programs and publish journals.

TRENDS IN NURSING

Nursing is a dynamic profession that grows and evolves as society and lifestyles change, as health care priorities and technologies change, and as nurses themselves change. The current philosophies and definitions of nursing have a holistic focus, which addresses the needs of the whole person in all dimensions, in health and illness, and in interaction with the family and community. In addition, there continues to be an increasing awareness for patient safety in all care settings.

Quality and Safety Education for Nurses

The Robert Wood Johnson Foundation sponsored the **Quality and Safety Education for Nurses (QSEN)** initiative to respond to reports about safety and quality patient care by the IOM (Barton et al., 2009). QSEN addresses the challenge to prepare nurses with the competencies needed to continuously improve the quality of care in their work environments (Table 1-1). The QSEN initiative encompasses the competencies of: patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics (Cronenwett et al., 2007). For each competency there are targeted knowledge, skills, and attitudes

TABLE 1-1 Quality and Safety Education for Nurses

COMPETENCY	DEFINITION WITH EXAMPLES
Patient-Centered Care	Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs. ***Examples:*** *Involve family and friends in care. Elicit patient values and preferences. Provide care with respect for diversity of the human experience.*
Teamwork and Collaboration	Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care. ***Examples:*** *Recognize the contributions of other health team members and patient's family members. Discuss effective strategies for communicating and resolving conflict. Participate in designing methods to support effective teamwork.*
Evidence-Based Practice	Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care. ***Examples:*** *Demonstrate knowledge of basic scientific methods. Appreciate strengths and weaknesses of scientific bases for practice. Appreciate the importance of regularly reading relevant journals.*
Quality Improvement	Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems. ***Examples:*** *Use tools such as flow charts and diagrams to make process of care explicit. Appreciate how unwanted variation in outcomes affects care. Identify gaps between local and best practices.*
Safety	Minimize risk of harm to patients and providers through both system effectiveness and individual performance. ***Examples:*** *Examine human factors and basic safety design principles and commonly used unsafe practices. Value own role in preventing errors.*
Informatics	Use information and technology to communicate, manage knowledge, mitigate error, and support decision-making. ***Examples:*** *Navigate an electronic health record. Protect confidentiality of protected health information in electronic health records.*

BOX 1-4 EVIDENCE-BASED PRACTICE

Safety Competencies and Patient-Centered Care

PICO Question: What is the impact of communication strategies in developing competency in teamwork and collaboration in new graduates?

Evidence Summary

Patient care needs are increasingly complex, and this trend is expected to continue well into the future. The American Association of Colleges of Nursing (AACN, 2008a) endorsed a new set of guidelines, which parallel the QSEN competencies, to direct the preparation of baccalaureate nurses to provide safe, high-quality patient care (Barton et al., 2009). Collaboration and teamwork are essential competencies in delivering safe, effective patient-centered care.

Students need more than classroom and clinical experiences to understand the intricacies of effective teamwork and collaboration (Sullivan et al., 2009). They need to be able to practice teamwork in safe, clinical simulations. For teamwork and collaboration to be successful, there must be strong and clear communication between and among all health care professions. Adverse events, omission of care, and confusion are serious events in today's health care environments. Inaccurate communication among health care providers leads to serious events (Manojlovich and DeCicco, 2007). Teaching effective communication strategies across the disciplines is an effective method to help bridge this gap (Robinson et al., 2010).

Application to Nursing Practice

- Communicate with clarity and precision when designing multidisciplinary plans of care (Robinson et al., 2010).
- Seek out the skills and expertise of other disciplines.
- Develop a culture of mutual respect for all disciplines and professionals within the discipline (Manojilovich and DeCicco, 2007).
- Recognize that electronic communication may be quick, but in some situations it may not be effective (Robinson et al., 2010). When patient care issues are at stake, a focused, well-organized interdisciplinary meeting is more effective than a series of "round-robin" e-mails.
- It usually takes the same amount of time to communicate and collaborate ineffectively as it does to do it effectively.

(KSAs). The KSAs are elements that are integrated in a nursing prelicensure program (Jarzemsky et al., 2010). As you gain experience in clinical practice, you will encounter situations in which your education helps you to make a difference in improving patient care (Box 1-4).

Whether that difference in care is to provide evidence for implementing care at the bedside, identify a safety issue, or study patient data to identify trends in outcomes, each of these situations requires competence in patient-centered care, safety, or informatics. Although it is not within the scope of this textbook to present the QSEN initiative in its entirety, subsequent clinical chapters will provide you an opportunity to address how to build competencies in one or more of these areas.

Genomics

Genetics is the study of inheritance, or the way traits are passed down from one generation to another. Genes carry the instructions for making proteins, which in turn direct the activities of cells and functions of the body that influence traits such as hair and eye color. **Genomics** is a newer term that describes the study of all the genes in a person and interactions of these genes with one another and with that person's environment (CDC, 2010). Using genomic information allows health care providers to determine how genomic changes contribute to patient conditions and influence treatment decisions (Badzek et al., 2008). For example, when a family member has colon cancer before the age of 50, it is likely that other family members are at risk for developing this cancer. Knowing this information is important for family members who will need a colonoscopy before the age of 50 and repeat colonoscopies more often than the patient who is not at risk. In this case nurses are key in identifying the patients' risk factors through assessment and counseling patients about what this genomic finding means to them personally and to their family.

Public Perception of Nursing

Nursing is a pivotal health care profession. As frontline health care providers, nurses practice in all health care settings and constitute the largest number of health care professionals. They are essential to providing skilled, specialized, knowledgeable care; improving the health status of the public; and ensuring safe, effective quality care (ANA, 2010b).

Consumers of health care are more informed than ever, and with the Internet consumers have access to more health care and treatment information. This information affects the perception the public has of nursing. For example, the media frequently highlights incidents of preventable medical errors such as medication and surgical errors. Publications such as *To Err Is Human* (IOM, 2000) describe strategies for government, health care providers, industry, and consumers to reduce preventable medical errors. When you care for patients, realize how your approach to care influences public opinion. Always act in a competent professional manner.

Impact of Nursing on Politics and Health Policy

Political power or influence is known as the ability to influence or persuade an individual holding a government office to exert the power of that office to affect a desired outcome. Nurses' involvement in politics is receiving greater emphasis in nursing curricula, professional organizations, and health care settings. Professional nursing organizations have employed lobbyists to urge state legislatures and the U.S. Congress to improve the quality of health care (Mason et al., 2012).

The ANA works for the improvement of health standards and the availability of health care services for all people, fosters high standards of nursing, stimulates and promotes the professional development of nurses, and advances their economic and general welfare. The purposes are unrestricted by considerations of nationality, race, creed, lifestyle, color, gender, or age. The ANA employs RNs as lobbyists at the federal level. State nursing organizations also hire lobbyists and legislative specialists to work on state nursing issues and assist with federal efforts. Finally, lobbyists working on behalf of nursing are employed in Washington, DC, by professional organizations such as the American Federation of Teachers, the NLN, the American College of Nurse-Midwives, the American Public Health Association, and the AACN. These groups aim to remove financial barriers to health care, increase the quality of nursing care available, increase economic rewards to nurses, and expand professional nursing roles.

You can influence policy decisions at all governmental levels. One way to get involved is by participating in local and national efforts (Mason et al., 2012). This effort is critical to exerting nurses' influence early in the political process. When nurses become serious students of social needs, activists in influencing policy to meet those needs, and generous contributors of time and money

to nursing organizations and to candidates working for universal good health care, the future is bright indeed (Mason et al., 2012).

KEY POINTS

- Nursing responds to the health care needs of society, which are influenced by economic, social, and cultural variables of a specific era.
- Changes in society such as increased technology, new demographic patterns, consumerism, health promotion, and the women's and human rights movements lead to changes in nursing.
- Nursing definitions reflect changes in the practice of nursing and help bring about changes by identifying the domain of nursing practice and guiding research, practice, and education.
- Nursing standards provide the guidelines for implementing and evaluating nursing care.
- Professional nursing organizations deal with issues of concern to specialist groups within the nursing profession.
- Nurses are becoming more politically sophisticated and, as a result, are able to increase the influence of nursing on health care policy and practice.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Langman is in the hospital recovering from hip replacement surgery. Her surgery involved insertion of a new type of hip replacement prosthesis and newer postsurgical care. The advanced practice registered nurse is preparing her discharge medication and rehabilitation prescriptions. The staff nurse is preparing to transfer Mrs. Langman to a rehabilitation facility. The nurse educator is conducting bedside rounds to explain the new prosthesis and related postoperative care.

1. Identify similarities and differences in the roles of the staff nurse, advanced practice registered nurse, and nurse educator.
2. What is the educational preparation for each role?
3. Use information in this chapter to consider career objectives for yourself over the next 5 years. Obviously the first would be to complete your nursing program. But decide what you want to do as a professional nurse and then outline strategies to achieve these goals.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. You are participating in a clinical care coordination conference for a patient with terminal cancer. You talk with your colleagues about using the nursing code of ethics for professional registered nurses to guide care decisions. A nonnursing colleague asks about this code. Which of the following statements best describes this code?
   1. Improves self–health care
   2. Protects the patient's confidentiality
   3. Ensures identical care to all patients
   4. Defines the principles of right and wrong to provide patient care
2. An 18-year-old woman is in the emergency department with fever and cough. The nurse obtains her vital signs, auscultates her lung sounds, listens to her heart sounds, determines her level of comfort, and collects blood and sputum samples for analysis. Which standard of practice is performed?
   1. Diagnosis
   2. Evaluation
   3. Assessment
   4. Implementation
3. A patient in the emergency department has developed wheezing and shortness of breath. The nurse gives the ordered medicated nebulizer treatment now and in 4 hours. Which standard of practice is performed?
   1. Planning
   2. Evaluation
   3. Assessment
   4. Implementation
4. A nurse is caring for a patient with end-stage lung disease. The patient wants to go home on oxygen and be comfortable. The family wants the patient to have a new surgical procedure. The nurse explains the risk and benefits of the surgery to the family and discusses the patient's wishes with the family. The nurse is acting as the patient's:
   1. Educator
   2. Advocate
   3. Caregiver
   4. Case manager
5. Evidence-based practice is defined as:
   1. Nursing care based on tradition
   2. Scholarly inquiry of nursing and biomedical research literature
   3. A problem-solving approach that integrates best current evidence with clinical practice
   4. Quality nursing care provided in an efficient and economically sound manner
6. The examination for registered nurse licensure is exactly the same in every state in the United States. This examination:
   1. Guarantees safe nursing care for all patients
   2. Ensures standard nursing care for all patients
   3. Ensures that honest and ethical care is provided
   4. Provides a minimal standard of knowledge for a registered nurse in practice
7. Contemporary nursing requires that the nurse has knowledge and skills for a variety of professional roles and responsibilities. Which of the following are examples? (Select all that apply.)
   1. Caregiver
   2. Autonomy and accountability
   3. Patient advocate
   4. Health promotion
   5. Lobbyist
8. Advanced practice registered nurses generally:
   1. Function independently
   2. Function as unit directors
   3. Work in acute care settings
   4. Work in the university setting.
9. Health care reform will bring changes in the emphasis of care. Which of the following models is expected from health care reform?
   1. Moving from an acute illness to a health promotion, illness prevention model
   2. Moving from illness prevention to a health promotion model
   3. Moving from an acute illness to a disease management model
   4. Moving from a chronic care to an illness prevention model

10. Which of the following nursing roles may have prescriptive authority in their practice? (Select all that apply.)
    1. Critical care nurse
    2. Nurse practitioner
    3. Certified clinical nurse specialist
    4. Charge nurse
11. A critical care nurse is using a computerized decision support system to correctly position her ventilated patients to reduce pneumonia caused by accumulated respiratory secretions. This is an example of which Quality and Safety in the Education of Nurses (QSEN) competency?
    1. Patient-centered care
    2. Safety
    3. Teamwork and collaboration
    4. Informatics
12. A nurse is caring for an older-adult couple in a community-based assisted living facility. During the family assessment he notes that the couple has many expired medications and multiple medications for their respective chronic illnesses. They note that they go to two different health care providers. The nurse begins to work with the couple to determine what they know about their medications and helps them decide on one care provider rather than two. This is an example of which Quality and Safety in the Education of Nurses (QSEN) competency?
    1. Patient-centered care
    2. Safety
    3. Teamwork and collaboration
    4. Informatics
13. A nurse is working with a young childbearing family who has one child with a congenital heart disease. The parents are trying to determine the risks of a second child being born with congenital heart disease. Describe why genomics information is important in assisting the parents in this decision.
14. The nurses on an acute care medical floor notice an increase in pressure ulcer formation in their patients. A nurse consultant decides to compare two types of treatment. The first is the procedure currently used to assess for pressure ulcer risk. The second uses a new assessment instrument to identify at-risk patients. Given this information, the nurse consultant exemplifies which career?
    1. Clinical nurse specialist
    2. Nurse administrator
    3. Nurse educator
    4. Nurse researcher
15. Nurses at a community hospital are in an education program to learn how to use a new pressure-relieving device for patients at risk for pressure ulcers. This is which type of education?
    1. Continuing education
    2. Graduate education
    3. In-service education
    4. Professional Registered Nurse Education

CHAPTER

2

The Health Care Delivery System

OBJECTIVES

- Compare the various methods for financing health care.
- Explain the advantages and disadvantages of managed health care.
- Discuss the types of settings that provide various health care services.
- Discuss the role of nurses in different health care delivery settings.
- Differentiate primary care from primary health care.
- Explain the impact of quality and safety initiatives on delivery of health care.
- Discuss the implications that changes in the health care system have on nursing.
- Discuss opportunities for nursing within the changing health care delivery system.

The U.S. health care system is complex and constantly changing. A broad variety of services are available from different disciplines of health professionals, but gaining access to services is often very difficult for those with limited health care insurance. Uninsured patients present a challenge to health care and nursing because they are more likely to skip or delay treatment for acute and chronic illnesses and die prematurely (Thompson and Lee, 2007). The continuing development of new technologies and medications, which shortens length of stay (LOS), also causes health care costs to increase. Thus health care institutions are managing health care more as businesses than as service organizations. Challenges to health care leaders today include reducing health care costs while maintaining high-quality care for patients, improving access and coverage for more people, and encouraging healthy behaviors (Knickman and Kovner, 2009). Health care providers are discharging patients sooner from hospitals, resulting in more patients needing nursing homes or home care. Often families provide care for their loved ones in the home setting. Nurses face major challenges to prevent gaps in health care across health care settings so individuals remain healthy and well within their own homes and communities.

Nursing is a caring discipline. Values of the nursing profession are rooted in helping people to regain, maintain, or improve health; prevent illness; and find comfort and dignity. The health care system of the new millennium is less service oriented and more business oriented because of cost-saving initiatives, which often causes tension between the caring and business aspects of health care (Knickman and Kovner, 2009). The Institute of Medicine (IOM) (2001) calls for a health care delivery system that is safe, effective, patient centered, timely, efficient, and equitable. The National Priorities Partnership is a group of 28 organizations from a variety of health care disciplines that have joined together to work toward transforming health care (National Priorities Partnership, 2008). The group has set the following national priorities:

- Patient and Family Engagement—Providing patient-centered, effective care
- Population Health—Bringing increased focus on wellness and prevention

- Safety—Eliminating errors whenever and wherever possible
- Care Coordination—Providing patient-centered, high-value care
- Palliative Care—Providing appropriate and compassionate care for patients experiencing advanced illnesses
- Overuse—Reducing waste to achieve effective, affordable care

The Institute of Medicine and Robert Woods Johnson Foundation (2011) put forth a vision for a transformed health care delivery system. The health care system of the future makes quality care accessible to all populations, focuses on wellness and disease prevention, improves health outcomes, and provides compassionate care across the life span. Transformations in health care are changing the practice of nursing. Nursing continues to lead the way in change and retain values for patient care while meeting the challenges of new roles and responsibilities. These changes challenge the nurse to provide evidence-based, compassionate care and continue in the role as patient advocate (Singleton, 2010). According to the IOM (2011) report, nurses need to be transformed by:

- Practicing to the full extent of their education and training.
- Achieving higher levels of education and training through an improved education system that provides seamless progression.
- Becoming full partners, with physicians and other health care providers, in redesigning the health care system.
- Improving data collection and information infrastructure for effective workforce planning and policy making.

HEALTH CARE REGULATION AND COMPETITION

Through most of the twentieth century, few incentives existed for controlling health care costs. Insurers or third-party payers paid for whatever the health care providers ordered for a patient's care and treatment. As health care costs continued to rise out of control, regulatory and competitive approaches had to control health care spending. The federal government, the biggest consumer of health care, which paid for Medicare and Medicaid, created **professional standards review organizations (PSROs)** to review the quality, quantity, and cost of hospital care (Sultz and Young, 2006). Medicare-qualified hospitals had physician-supervised **utilization review (UR) committees** to review the admissions and to identify and eliminate overuse of diagnostic and treatment services ordered by physicians caring for patients on Medicare.

One of the most significant factors that influenced payment for health care was the **prospective payment system (PPS).** Established by Congress in 1983, the PPS eliminated cost-based reimbursement. Hospitals serving patients who received Medicare benefits were no longer able to charge whatever a patient's care cost. Instead, the PPS grouped inpatient hospital services for Medicare patients into **diagnosis-related groups (DRGs).** Each group has a fixed reimbursement amount with adjustments based on case severity, rural/urban/regional costs, and teaching costs. Hospitals receive a set dollar amount for each patient based on the assigned DRG, regardless of the patient's length of stay or use of services. Most health care providers (e.g., health care networks or managed care organizations) now receive capitated payments. **Capitation** means that the providers receive a fixed amount per patient or enrollee of a health care plan (Jonas et al., 2007). Capitation aims to build a payment plan for select diagnoses or surgical procedures that consists of the best standards of care at the lowest cost.

Capitation and prospective payment influences the way health care providers deliver care in all types of settings. Many now use DRGs in the rehabilitation setting, and **resource utilization groups (RUGs)** in long-term care. In all settings health care providers try to manage costs so the organizations remain profitable. For example, when patients are hospitalized for lengthy periods, hospitals have to absorb the portion of costs that are not reimbursed. This simply adds more pressure to ensure that patients are managed effectively and discharged as soon as is reasonably possible. Thus hospitals started to increase discharge planning activities, and hospital lengths of stay began to shorten. Because patients are discharged home as soon as possible, home care agencies now provide complex technological care, including mechanical ventilation and long-term parenteral nutrition.

Managed care describes health care systems in which the provider or health care system receives a predetermined capitated payment for each patient enrolled in the program. In this case the managed care organization assumes financial risk in addition to providing patient care. The focus of care of the organization shifts from individual illness care to prevention, early intervention, and outpatient care. If people stay healthy, the cost of medical care declines. Systems of managed care focus on containing or reducing costs, increasing patient satisfaction, and improving the health or functional status of individuals (Sultz and Young, 2006). Table 2-1 summarizes the most common types of health care insurance plans.

In 2006 the National Quality Forum defined a list of 28 "Never Events" that are devastating and preventable. Examples of Never Events include patient death or serious injury related to a medication error or the administration of incompatible blood products. In 2007 Medicare ruled it would no longer pay for medical costs associated with these errors. Many states now require mandatory reporting of these events when they occur (Agency for Healthcare Research and Quality Patient Safety Network, n.d.).

Major health care reform came in 2010 with the signing into law of the Patient Protection and Affordable Care Act (Public Law No. 111-148). Health care reform of this magnitude has not occurred in the United States since the 1960s when Medicare and Medicaid were signed into law. The Patient Protection and Affordable Care Act focuses on the major goals of increasing access to health care services for all, reducing health care costs, and improving health care quality. Provisions in the law include insurance industry reforms that increase insurance coverage and decrease costs, increased funding for community health centers, increased primary care services and providers, and improved coverage for children (Adashi et al., 2010; HealthReform.gov, 2010).

EMPHASIS ON POPULATION WELLNESS

The United States health care delivery system faces many issues such as rising costs, increased access to services, a growing population, and improved quality of outcomes. As a result, the emphasis of the health care industry today is shifting from managing illness to managing health of a community and the environment.

The Health Services Pyramid developed by the Core Functions Project serves as a model for improving the health care of U.S. citizens (Fig. 2-1). The pyramid shows that population-based health care services provide the basis for preventive services. These services include primary, secondary, and tertiary health care. Achievements in the lower tiers of the pyramid contribute to the improvement of health care delivered by the higher tiers. Health care in the United States is moving toward health care practices that emphasize managing health rather than managing illness. The premise is that in the long term, health promotion reduces health

TABLE 2-1 Examples of Health Care Plans

TYPE	DEFINITION	CHARACTERISTICS
Managed care organization (MCO)	Provides comprehensive preventive and treatment services to a specific group of voluntarily enrolled people. Structures include a variety of models: *Staff model:* Physicians are salaried employees of the MCO. *Group model:* MCO contracts with single group practice *Network model:* MCO contracts with multiple group practices and/or integrated organizations. **Independent practice association (IPA):** The MCO contracts with physicians who usually are not members of groups and whose practices include fee-for-service and capitated patients.	Focus is on health maintenance, primary care. All care is provided by a primary care physician. Referral is needed for access to specialist and hospitalization. It may use capitated payments.
Preferred provider organization (PPO)	Type of managed care plan that limits an enrollee's choice to a list of "preferred" hospitals, physicians, and providers. An enrollee pays more out-of-pocket expenses for using a provider not on the list.	Contractual agreement exists between a set of providers and one or more purchasers (self-insured employers or insurance plans). Comprehensive health services are at a discount to companies under contract. Focus is on health maintenance.
Medicare	A federally administrated program by the Commonwealth Fund or the Centers for Medicare and Medicaid Services (CMS); a funded national health insurance program in the United States for people 65 years and older. Part A provides basic protection for medical, surgical, and psychiatric care costs based on diagnosis-related groups (DRGs); also provides limited skilled nursing facility care, hospice, and home health care. Part B is a voluntary medical insurance; covers physician, certain other specified health professional services, and certain outpatient services. Part C is a managed care provision that provides a choice of three insurance plans. Part D is a voluntary Prescription Drug Improvement (Jonas et al, 2007).	Payment for plan is deducted from monthly individual Social Security check. It covers services of nurse practitioners. It does not pay full cost of certain services. Supplemental insurance is encouraged.
Medicaid	Federally funded, state-operated program that provides: (1) health insurance to low-income families; (2) health assistance to low-income people with long-term care (LTC) disabilities; and (3) supplemental coverage and LTC assistance to older adults and Medicare beneficiaries in nursing homes. Individual states determine eligibility and benefits.	It finances a large portion of care for poor children, their parents, pregnant women, and disabled very poor adults. It reimburses for nurse-midwifery and other advanced practice nurses (varies by state). It reimburses nursing home funding.
Private insurance	Traditional fee-for-service plan. Payment is computed after patient receives services on basis of number of services used.	Policies are typically expensive. Most policies have deductibles that patients have to meet before insurance pays.
LTC insurance	Supplemental insurance for coverage of LTC services. Policies provide a set amount of dollars for an unlimited time or for as little as 2 years.	It is very expensive. A good policy has a minimum waiting period for eligibility; payment for skilled nursing, intermediate, or custodial care and home care.
State Children's Health Insurance Programs (SCHIP)	Federally funded, state-operated program to provide health coverage for uninsured children. Individual states determine participation eligibility and benefits.	It covers children not poor enough for Medicaid.

care costs. A wellness perspective focuses on the health of populations and the communities in which they live rather than just on finding a cure for an individual's disease. Life expectancy for Americans is 77.9 years, which has shown a steady increase in the past century. Along with increased life expectancy, adult deaths related to coronary heart disease and stroke continue a long-term decreasing trend, and there is a decreasing trend in deaths of children since 1900 (Centers for Disease Control and Prevention, [CDC], 2007). The reduction in mortality rates has been credited to advancements in sanitation and prevention of infectious diseases (e.g., water, sewage, immunization, and crowded living conditions); patient teaching (e.g., dietary habits, decrease in tobacco use, and blood pressure control); and injury prevention programs (e.g., seat belt restraints, child seats, and helmet laws).

HEALTH CARE SETTINGS AND SERVICES

Currently the U.S. health care system has five levels of care for which health care providers offer services: disease prevention; health promotion; and primary, secondary, and tertiary health care. The health care settings within which the levels of care are provided include preventive, primary, secondary, tertiary, restorative, and

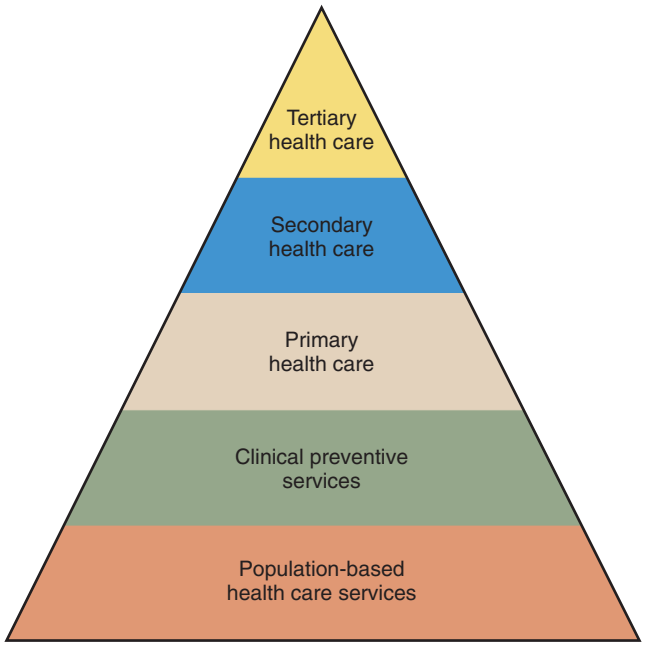

FIG. 2-1 Health services pyramid. (US Public Health Service: *The core functions project,* Washington, DC, 1994/update 2000, Office of Disease Prevention and Health Promotion. From Stanhope M, Lancaster J: *Public health nursing: population-centered health care in the community,* ed 7, St. Louis, 2008, Mosby.)

continuing care settings (Box 2-1). Larger health care systems have **integrated delivery networks (IDNs)** that include a set of providers and services organized to deliver a continuum of care to a population of patients at a capitated cost in a particular setting (Jonas et al., 2007). An integrated system reduces duplication of services across levels or settings of care to ensure that patients receive care in the most appropriate settings.

Changes unique to each setting of care have developed because of health care reform. For example, many health care providers now place greater emphasis on wellness, directing more resources toward primary and preventive care services. Nurses are especially important as patient advocates in maintaining continuity of care throughout the levels of care. They have the opportunity to provide leadership to communities and health care systems. The ability to find strategies that better address patient needs at all levels of care is critical to improving the health care delivery system.

Health care agencies seek accreditation and certification as a way to demonstrate quality and safety in the delivery of care and to evaluate the performance of the organization based on established standards. Accreditation is earned by the entire organization; specific programs or services within an organization earn certifications (The Joint Commission [TJC], 2011). The Joint Commission (formerly The Joint Commission on Accreditation of Healthcare Organizations) accredits health care organizations across the continuum of care, including hospitals and ambulatory care, long-term care, home care, and behavioral health agencies. Other accrediting agencies have a specific focus such as the Commission on Accreditation of Rehabilitation Facilities (CARF) and the Community Health Accrediting Program (CHAP). Disease-specific certifications are available in most all chronic diseases (TJC, 2011). Accreditation and certification survey processes help organizations identify problems and develop solutions to improve the safety and quality of delivered care and services.

BOX 2-1 EXAMPLES OF HEALTH CARE SERVICES

Primary Care (Health Promotion)
- Prenatal and well-baby care
- Nutrition counseling
- Family planning
- Exercise classes

Preventive Care
- Blood pressure and cancer screening
- Immunizations
- Mental health counseling and crisis prevention
- Community legislation (e.g., seat belts, air bags, bike helmets)

Secondary Acute Care
- Emergency care
- Acute medical-surgical care
- Radiological procedures for acute problems (e.g., x-rays, CT scans)

Tertiary Care
- Intensive care
- Subacute care

Restorative Care
- Cardiovascular and pulmonary rehabilitation
- Sports medicine
- Spinal cord injury programs
- Home care

Continuing Care
- Assisted living
- Psychiatric and older adult day care

Preventive and Primary Health Care

Primary health care focuses on improved health outcomes for an entire population. It includes primary care and health education, proper nutrition, maternal/child health care, family planning, immunizations, and control of diseases. Primary health care requires collaboration among health professionals, health care leaders, and community members. This collaboration needs to focus on improving health care equity, making health care systems person centered, developing reliable and accountable health care leaders, and promoting and protecting the health of communities (WHO, 2008). Successful community-based health programs take societal and environmental factors into consideration when addressing the health needs of communities (WHO, 2008). In settings in which patients receive preventive and primary care such as schools, physician's offices, occupational health clinics, community health centers, and nursing centers, health promotion is a major theme (Table 2-2). Health promotion programs lower the overall costs of health care by reducing the incidence of disease, minimizing complications, and thus reducing the need to use more expensive health care resources. In contrast, preventive care is more disease oriented and focused on reducing and controlling risk factors for disease through activities such as immunization and occupational health programs. Chapter 3 provides a more comprehensive discussion of primary health care in the community.

Secondary and Tertiary Care

In secondary and tertiary care the diagnosis and treatment of illnesses are traditionally the most common services. With the arrival of managed care, many now deliver these services in primary care

TABLE 2-2 **Preventive and Primary Care Services**

TYPE OF SERVICE	PURPOSE	AVAILABLE PROGRAMS/SERVICES
School health	These are comprehensive programs that include health promotion principles throughout a school curriculum. They emphasize program management, interdisciplinary collaboration, and community health principles.	Positive life skills Nutritional planning Health screening Counseling Communicable disease prevention Crisis intervention
Occupational health	This is a comprehensive program designed for health promotion and accident or illness prevention in the workplace setting. It aims to increase worker productivity, decrease absenteeism, and reduce use of expensive medical care	Environmental surveillance Physical assessment Health screening Health education Communicable disease control Counseling
Physicians' offices	They provide primary health care (diagnosis and treatment). Many focus on health promotion practices. Nurse practitioners often partner with a physician in managing patient population.	Routine physical examination Health screening Diagnostics Treatment of acute and chronic ailments
Nurse-managed clinics	These clinics provide nursing services with a focus on health promotion and education, chronic disease assessment management, and support for self-care and caregivers.	Day care Health risk appraisal Wellness counseling Employment readiness Acute and chronic care management
Block and parish nursing	Nurses living within a neighborhood provide services to older patients or those unable to leave their homes. It fills in gaps not available in traditional health care system.	Running errands Transportation Respite care Homemaker aides Spiritual health
Community health centers	These are outpatient clinics that provide primary care to a specific patient population (e.g., well-baby, mental health, diabetes) that lives in a specific community. They are often associated with a hospital, medical school, church, or other community organization.	Physical assessment Health screening Disease management Health education Counseling

settings. Disease management is the most common and expensive service of the health care delivery system. The acutely and chronically ill represent about 20% of the people in the United States, who consume about 80% of health care spending (CDC, 2007). Over 80% of adults 65 years of age have at least one chronic health condition that causes multiple health problems (Missouri Families, 2008).

Uninsured individuals are an increasing problem in health care. The fastest growing age-group of uninsured citizens is young adults between the ages of 19 and 34 (Billings and Cantor, 2009). Young adults turning 19 years of age from low-income families are in danger of being uninsured because of the inability to attend college and find employment with health care benefits. Coverage for young adults is important for various reasons. This age-group has a high incidence of obesity, pregnancy, and human immunodeficiency virus (HIV). People in this age-group are also less likely to see a doctor on a regular basis and follow up on a problem if they do not have health insurance. Lack of insurance rates varies by race. Statistics show that 34% of Hispanics, 19% of African Americans, and 10% of the white or Caucasian population do not have health insurance (CDC, 2010).

People who do not have health care insurance often wait longer before presenting for treatment; thus they are usually sicker and need more health care. As a result, secondary and tertiary care (also called **acute care**) is more costly. With the arrival of more advanced technology and managed care, physicians now perform simple surgeries in office surgical suites instead of in the hospital. Cost to the patient is lower in the office because the general overhead cost of the facility is lower.

Hospitals. Hospital emergency departments, urgent care centers, critical care units, and inpatient medical-surgical units provide secondary and tertiary levels of care. Quality, safe care is the focus of most acute care organizations; satisfaction with health care services is important to them. Patient satisfaction becomes a priority in a busy, stressful location such as the inpatient nursing unit. Patients expect to receive courteous and respectful treatment, and they want to be involved in daily care decisions. As a nurse, you play a key role in bringing respect and dignity to the patient (Vlasses and Smeltzer, 2007). Acute care nurses need to be responsive to learning patient needs and expectations early to form effective partnerships that ultimately enhance the level of nursing care given.

Because of managed care, the number of days patients can expect to be hospitalized is limited based on their DRGs on admission. Therefore nurses need to use resources efficiently to help patients successfully recover and return home. To contain costs, many hospitals have redesigned nursing units. Because of **work redesign,** more services are available on nursing units, thus minimizing the need to transfer and transport patients across multiple diagnostic and treatment areas.

Hospitalized patients are acutely ill and need comprehensive and specialized tertiary health care. The services provided by hospitals vary considerably. Some small rural hospitals offer only limited emergency and diagnostic services and general inpatient services. In comparison, large urban medical centers offer comprehensive, up-to-date diagnostic services, trauma and emergency care, surgical intervention, intensive care units (ICUs), inpatient services, and rehabilitation facilities. Larger hospitals also offer professional staff from a variety of specialties such as social service, respiratory therapy, physical and occupational therapy, and speech therapy. The focus in hospitals is to provide the highest quality of care possible so patients are discharged early but safely to home or another health care facility that will adequately manage remaining health care needs.

Discharge planning begins the moment a patient is admitted to a health care facility. Nurses play an important role in **discharge planning** in the hospital, where continuity of care is important. To achieve continuity of care, nurses use critical thinking skills and apply the nursing process (see Unit 3). To anticipate and identify the patient's needs, nurses work with all members of the interdisciplinary health care team. They take the lead to develop a plan of care that moves the patient from the hospital to another level of health care such as the patient's home or a nursing home. Discharge planning is a centralized, coordinated, interdisciplinary process that ensures that the patient has a plan for continuing care after leaving a health care agency.

Because patients leave hospitals as soon as their physical conditions allow, they often have continuing health care needs when they go home or to another facility. For example, a surgical patient requires wound care at home after surgery. A patient who has had a stroke requires ambulation training. Patients and families worry about how they will care for unmet needs and manage over the long term. Nurses help by anticipating and identifying patients' continuing needs before the actual time of discharge and by coordinating health care team members in achieving an appropriate discharge plan.

Some patients are more in need of discharge planning because of the risks they present (e.g., patients with limited financial resources, limited family support, and long-term disabilities or chronic illness). However, any patient who is being discharged from a health care facility with remaining functional limitations or who has to follow certain restrictions or therapies for recovery needs discharge planning. All caregivers who care for a patient with a specific health problem participate in discharge planning. The process is truly interdisciplinary. For example, patients with diabetes visiting a diabetes management center requires the group effort of a diabetes nurse educator, dietitian, and physician to ensure that they return home with the right information to manage their condition. A patient who has experienced a stroke will not be discharged from a hospital until the team has established plans with physical and occupational therapists to begin a program of rehabilitation.

Effective discharge planning often requires referrals to various health care disciplines. In many agencies a health care provider's order is necessary for a referral, especially when planning specific therapies (e.g., physical therapy). It is best to have patients and families participate in referral processes so they are involved early in any necessary decision making. Some tips on making the referral process successful include the following:

- Make a referral as soon as possible.
- Give the care provider receiving the referral as much information about the patient as possible. This avoids duplication of effort and exclusion of important information.
- Involve the patient and family in the referral process, including selecting the necessary referral. Explain the service that the referral will provide, the reason for the referral, and what to expect from the services of the referral.
- Determine what the referral discipline recommends for the patient's care and include this in the treatment plan as soon as possible.

The nurse provides resources to improve the long-term outcomes of patients with limitations. Discharge planning depends on comprehensive patient and family education (see Chapter 25). Patients need to know what to do when they get home, how to do it, and for what to observe when problems develop. Patients require the following instruction before they leave health care facilities:

- Safe and effective use of medications and medical equipment
- Instruction in potential food-drug interactions and counseling on nutrition and modified diets
- Rehabilitation techniques to support adaptation to and/or functional independence in the environment
- Access to available and appropriate community resources
- When and how to obtain further treatment
- The patient's and family's responsibilities in the patient's ongoing health care needs and the knowledge and skills needed to carry out those responsibilities
- When to notify their health care provider for changes in functioning or new symptoms

Intensive Care. An ICU or critical care unit is a hospital unit in which patients receive close monitoring and intensive medical care. ICUs have advanced technologies such as computerized cardiac monitors and mechanical ventilators. Although many of these devices are on regular nursing units, the patients hospitalized within ICUs are monitored and maintained on multiple devices. Nursing and medical staff have special knowledge about critical care principles and techniques. An ICU is the most expensive health care delivery site because each nurse usually cares for only one or two patients at a time and because of all the treatments and procedures the patients in the ICU require.

Psychiatric Facilities. Patients who suffer emotional and behavioral problems such as depression, violent behavior, and eating disorders often require special counseling and treatment in psychiatric facilities. Located in hospitals, independent outpatient clinics, or private mental health hospitals, psychiatric facilities offer inpatient and outpatient services, depending on the seriousness of the problem. Patients enter these facilities voluntarily or involuntarily. Hospitalization involves relatively short stays with the purpose of stabilizing patients before transfer to outpatient treatment centers. Patients with psychiatric problems receive a comprehensive multidisciplinary treatment plan that involves them and their families. Medicine, nursing, social work, and activity therapy work together to develop a plan of care that enables patients to return to functional states within the community. At discharge from inpatient facilities, patients usually receive a referral for follow-up care at clinics or with counselors.

Rural Hospitals. Access to health care in rural areas has been a serious problem. Most rural hospitals have experienced a severe shortage of primary care providers. Many have closed because of economic failure. In 1989 the Omnibus Budget Reconciliation Act (OBRA) directed the U.S. Department of Health and Human Services (USDHHS) to create a new health care organization, the rural primary care hospital (RPCH). The Balanced Budget Act of 1997 changed the designation for rural hospitals to Critical Access

Hospital (CAH) if certain criteria were met (American Medical Association, 2009). A CAH is located in a rural area and provides 24-hour emergency care, with no more than 25 inpatient beds for providing temporary care for 96 hours or less to patients needing stabilization before transfer to a larger hospital. Physicians, nurse practitioners, or physician assistants staff a CAH. The CAH provides inpatient care to acutely ill or injured people before transferring them to better-equipped facilities. Basic radiological and laboratory services are also available.

With health care reform, more big-city health care systems are branching out and establishing connections or mergers with rural hospitals. The rural hospitals provide a referral base to the larger tertiary care medical centers. With the development of advanced technologies such as telemedicine, rural hospitals have increased access to specialist consultations. Nurses who work in rural hospitals or clinics require competence in physical assessment, clinical decision making, and emergency care. Having a culture of evidence-based practice is important in rural hospitals so nurses practice using the best evidence to achieve optimal patient outcomes (Burns et al., 2009). Advanced practice nurses (e.g., nurse practitioners and clinical nurse specialists) use medical protocols and establish collaborative agreements with staff physicians.

Restorative Care

Patients recovering from an acute or chronic illness or disability often require additional services to return to their previous level of function or reach a new level of function limited by their illness or disability. The goals of **restorative care** are to help individuals regain maximal functional status and enhance quality of life through promotion of independence and self-care. With the emphasis on early discharge from hospitals, patients usually require some level of restorative care. For example, some patients require ongoing wound care and activity and exercise management until they have recovered enough following surgery to independently resume normal activities of daily living.

The intensity of care has increased in restorative care settings because patients leave hospitals earlier. The restorative health care team is an interdisciplinary group of health professionals and includes the patient and family or significant others. In restorative settings nurses recognize that success depends on effective and early collaboration with patients and their families. Patients and families require a clear understanding of goals for physical recovery, the rationale for any physical limitations, and the purpose and potential risks associated with therapies. Patients and families are more likely to follow treatment plans and achieve optimal functioning when they are involved in restorative care.

Home Health Care (Home Care). **Home care** is the provision of medically related professional and paraprofessional services and equipment to patients and families in their homes for health maintenance, education, illness prevention, diagnosis and treatment of disease, palliation, and rehabilitation. Nursing is one service most patients use in home care. However, home care also includes medical and social services; physical, occupational, speech, and respiratory therapy; and nutritional therapy. These services usually occur once or twice a day for as long as 7 days a week. A home care service also coordinates the access to and delivery of home health equipment, or durable medical equipment, which is any medical product adapted for home use.

Health promotion and education are traditionally the primary objectives of home care, yet at present most patients receive home care because they need nursing or medical care. Examples of home nursing care include monitoring vital signs; assessment; administering parenteral or enteral nutrition, medications, and IV or blood therapy; and wound or respiratory care. The focus is on patient and family independence. Nurses address recovery and stabilization of illness in the home and identify problems related to lifestyle, safety, environment, family dynamics, and health care practices.

Approved home care agencies usually receive reimbursement for services from the government (such as **Medicare** and **Medicaid** in the United States), private insurance, and private pay. The government has strict regulations that govern reimbursement for home care services. An agency cannot simply charge whatever it wants for a service and expect to receive full reimbursement. Government programs set the cost of reimbursement for most professional services.

Nurses in home care provide individualized care. They have a caseload and assist patients in adapting to permanent or temporary physical limitations so they are able to assume a more normal daily home routine. Home care requires a strong knowledge base in many areas such as family dynamics (see Chapter 10), cultural practices (see Chapter 9), spiritual values (see Chapter 35), and communication principles (see Chapter 24).

Rehabilitation. **Rehabilitation** restores a person to the fullest physical, mental, social, vocational, and economic potential possible. Patients require rehabilitation after a physical or mental illness, injury, or chemical addiction. Specialized rehabilitation services such as cardiovascular, neurological, musculoskeletal, pulmonary, and mental health rehabilitation programs help patients and families adjust to necessary changes in lifestyle and learn to function with the limitations of their disease. Drug rehabilitation centers help patients become free from drug dependence and return to the community.

Rehabilitation services include physical, occupational, and speech therapy and social services. Ideally rehabilitation begins the moment a patient enters a health care setting for treatment. For example, some orthopedic programs now have patients perform physical therapy exercises before major joint repair to enhance their recovery after surgery. Initially rehabilitation usually focuses on the prevention of complications related to the illness or injury. As the condition stabilizes, rehabilitation helps to maximize the patient's functioning and level of independence.

Rehabilitation occurs in many health care settings, including special rehabilitation agencies, outpatient settings, and the home. Frequently patients needing long-term rehabilitation (e.g., patients who have had strokes and spinal cord injuries) have severe disabilities affecting their ability to carry out the activities of daily living. When rehabilitation services occur in outpatient settings, patients receive treatment at specified times during the week but live at home the rest of the time. Health care providers apply specific rehabilitation strategies to the home environment. Nurses and other members of the health care team visit homes and help patients and families learn to adapt to illness or injury.

Extended Care Facilities. An **extended care facility** provides intermediate medical, nursing, or custodial care for patients recovering from acute illness or those with chronic illnesses or disabilities. Extended care facilities include intermediate care and skilled nursing facilities. Some include long-term care and assisted living facilities. At one point extended care facilities primarily cared for older adults. However, because hospitals discharge their patients sooner, there is a greater need for intermediate care settings for patients of all ages. For example, health care providers transfer a young patient who has experienced a traumatic brain injury

resulting from a car accident to an extended care facility for rehabilitative or supportive care until discharge to the home becomes a safe option.

An intermediate care or **skilled nursing facility** offers skilled care from a licensed nursing staff. This often includes administration of IV fluids, wound care, long-term ventilator management, and physical rehabilitation. Patients receive extensive supportive care until they are able to move back into the community or into residential care. Extended care facilities provide around-the-clock nursing coverage. Nurses who work in a skilled nursing facility need nursing expertise similar to that of nurses working in acute care inpatient settings, along with a background in gerontological nursing principles (see Chapter 14).

Continuing Care

Continuing care describes a variety of health, personal, and social services provided over a prolonged period. These services are for people who are disabled, who were never functionally independent, or who suffer a terminal disease. The need for continuing health care services is growing in the United States. People are living longer, and many of those with continuing health care needs have no immediate family members to care for them. A decline in the number of children families choose to have, the aging of care providers, and the increasing rates of divorce and remarriage complicate this problem. Continuing care is available within institutional settings (e.g., nursing centers or nursing homes, group homes, and retirement communities), communities (e.g., adult day care and senior centers), or the home (e.g., home care, home-delivered meals, and hospice) (Meiner, 2011).

Nursing Centers or Facilities. The language of long-term care is confusing and constantly changing. The nursing home has been the dominant setting for long-term care (Meiner, 2011). With the 1987 OBRA, the term *nursing facility* became the term for nursing homes and other facilities that provided long-term care. Now *nursing center* is the most appropriate term. A nursing center typically provides 24-hour intermediate and custodial care such as nursing, rehabilitation, dietary, recreational, social, and religious services for residents of any age with chronic or debilitating illnesses. In some cases patients stay in nursing centers for room, food, and laundry services only. Most persons living in nursing centers are older adults. A nursing center is a resident's temporary or permanent home, with surroundings made as homelike as possible (Sorrentino, 2007). The philosophy of care is to provide a planned, systematic, and interdisciplinary approach to nursing care to help residents reach and maintain their highest level of function (Resnick and Fleishell, 2002).

According to the U.S. Bureau of the Census, just over 5% of people 65 years of age and older live in nursing centers and other facilities (Missouri Families, 2008). The nursing center industry is one of the most highly regulated industries in the United States. These regulations have raised the standard of services provided (Box 2-2). One regulatory area that deserves special mention is that of resident rights. Nursing facilities have to recognize residents as active participants and decision makers in their care and life in institutional settings (Meiner, 2011). This also means that family members are active partners in the planning of residents' care.

Interdisciplinary functional assessment of residents is the cornerstone of clinical practice within nursing centers (Meiner, 2011). Government regulations require that staff comprehensively assess each resident and make care planning decisions within a prescribed period. A resident's functional ability (e.g., ability to perform activities of daily living) and long-term physical and psychosocial well-being are the focus. Staff must complete the Resident Assessment Instrument (RAI) on all residents. The RAI consists of the **Minimum Data Set (MDS)** (Box 2-3), Resident Assessment Protocols, and utilization guidelines of each state. The RAI provides a national database for nursing facilities so policy makers will better understand the health care needs of the long-term care population. The MDS is a rich resource for nurses in determining the best interventions to support the health care needs of this growing population.

Assisted Living. Assisted living is one of the fastest growing industries within the United States. There are approximately 38,000 assisted living facilities that house more than 975,000 people in the United States (National Center for Assisted Living [NCLA], 2010). **Assisted living** offers an attractive long-term care setting with an environment more like home and greater resident autonomy. Residents require some assistance with activities of daily living but remain relatively independent within a partially protective setting. A group of residents live together, but each resident has his or her own room and shares dining and social activity

BOX 2-2 MAJOR REGULATORY REQUIREMENTS DEFINED BY THE 1987 OMNIBUS BUDGET RECONCILIATION ACT

- Resident rights
- Admission, transfer, and discharge rights
- Resident behavior and facility practices
- Quality of life
- Resident assessment
- Quality of care
- Nursing services
- Dietary services
- Physician services
- Specialized rehabilitative services
- Dental services
- Pharmacy services
- Infection control
- Physical environment
- Administration

From Health Care Financing Administration, Department of Health and Human Services: *Requirements for states and long-term care facilities,* 42 CFR 483 Subpart B (483.1-75), October 1, 2004. http://ecfr.gpoaccess.gov/cgi/t/text/text-idx?c=ecfr&tpl=/ecfrbrowse/Title42/42cfr483_main_02.tpl. Accessed June 18, 2011.

BOX 2-3 MINIMUM DATA SET AND EXAMPLES OF RESIDENT ASSESSMENT PROTOCOLS

Minimum Data Set

- Resident's background
- Cognitive, communication/hearing, and vision patterns
- Physical functioning and structural problems
- Mood, behavior, and activity patterns
- Psychosocial well-being
- Bowel and bladder continence
- Health conditions
- Disease diagnoses
- Oral/nutritional and dental status
- Skin condition
- Medication use
- Special treatments and procedures

Resident Assessment Protocols (Examples)

- Delirium
- Falls
- Pressure ulcers
- Psychotropic drug use

FIG. 2-2 Providing nursing services in assisted living facilities promotes physical and psychosocial health.

areas. Usually people keep all of their personal possessions in their residences. Facilities range from hotel-like buildings with hundreds of units to modest group homes that house a handful of seniors. Assisted living provides independence, security, and privacy all at the same time (Ebersole et al., 2008). These facilities promote physical and psychosocial health (Fig. 2-2). Services in an assisted living facility include laundry, assistance with meals and personal care, 24-hour oversight, and housekeeping (NCAL, 2010). Some facilities provide assistance with medication administration. Nursing care services are not always directly available, although home care nurses can visit patients in assisted living facilities. Unfortunately most residents of assisted living facilities pay privately. The average monthly fee is $3022 for a private unit (NCAL, 2010). With no government fee caps and little regulation, assisted living is not always an option for individuals with limited financial resources.

Respite Care. The need to care for family members within the home creates great physical and emotional problems for family caregivers, especially if the people for whom they care have either physical or cognitive limitations. The family caregiver usually not only has the responsibility for providing care to a loved one but often has to maintain a full-time job, raise a family, and manage the routines of daily living as well. **Respite care** is a service that provides short-term relief or "time off" for people providing home care to an ill, disabled, or frail older adult (Meiner, 2011). Respite care is offered in the home, a day care setting, or a health care institution that provides overnight care. The family caregiver is able to leave the home for errands or some social time while a responsible person stays in the home to care for the loved one. There are few formal respite care programs in the United States because of cost. Currently Medicare does not cover respite care, and Medicaid has strict requirements for services and eligibility (Sultz and Young, 2006).

Adult Day Care Centers. **Adult day care centers** provide a variety of health and social services to specific patient populations who live alone or with family in the community. Services offered during the day allow family members to maintain their lifestyles and employment and still provide home care for their relatives (Meiner, 2011). Day care centers are associated with a hospital or nursing home or exist as independent centers. Frequently the patients need continuous health care services (e.g., physical therapy or counseling) while their families or support persons work. The centers usually operate 5 days per week during typical business hours and usually charge on a daily basis. Adult day care centers allow patients to retain more independence by living at home, thus potentially reducing the costs of health care by avoiding or delaying an older adult's admission to a nursing center. Nurses working in day care centers provide continuity between care delivered in the home and the center. For example, nurses ensure that patients continue to take prescribed medication and administer specific treatments. Knowledge of community needs and resources is essential in providing adequate patient support (Ebersole et al., 2008).

Hospice. A **hospice** is a system of family-centered care that allows patients to live and remain at home with comfort, independence, and dignity while easing the pains of terminal illness. The focus of hospice care is palliative care, not curative treatment (see Chapter 43). The interdisciplinary team in the hospice works continuously with the patient's health care provider to develop and maintain a patient-directed individualized plan of care. Many hospice programs provide respite care, which is important in maintaining the health of the primary caregiver and family.

ISSUES IN HEALTH CARE DELIVERY

The climate in health care today influences both health care professionals and consumers. Because those who provide patient care are the most qualified to make changes in the health care delivery system, nurses need to participate fully and effectively within all aspects of health care. As nursing faces issues of how to maintain health care quality while reducing costs, nurses need to acquire the knowledge, skills, and values necessary to practice competently and effectively. It will also become more important than ever before to collaborate with other health care professionals to design new approaches for patient care delivery.

Nursing Shortage

There are more than 3.1 million nurses in the United States, making nursing the largest health care profession in the country (American Association of Colleges of Nursing [AACN], 2011). Although nearly 57% of the nurses work in medical-surgical hospitals, they are involved in delivering health care at all levels, including primary and preventive care (AACN, 2011). In spite of the large number of practicing nurses, a critical shortage of nurses is projected in the United States. It is expected that this shortage will worsen with increased need for health care services by the aging baby-boomer generation (AACN, 2010). It is estimated that over 500,000 new nursing positions will be created by 2018, resulting in a 22% increase in the size of the nursing workforce (U.S. Department of Labor, 2009). The economic climate and recession had brought about an easing of the nursing shortage (Buerhaus et al., 2009). This easing is not expected to last, mainly because of the aging nursing workforce and potential retirements. The average age of nurses is projected to be 44.5 years by 2012 (AACN, 2010). One other factor contributing to the shortage is the slow growth in nursing school enrollments, often because of nursing faculty shortages, space limitations, and clinical site availability (AACN, 2010; Buerhaus et al., 2009). Buerhaus et al. (2009) estimate that by 2025 the shortage will grow to 260,000 nurses.

Competency

The Pew Health Professions Commission, a national and interdisciplinary group of health care leaders, recommended 21

BOX 2-4 INSTITUTE OF MEDICINE COMPETENCIES FOR THE TWENTY-FIRST CENTURY

Provide Patient-Centered Care
- Recognize and respect differences in patients' values, preferences, and needs.
- Relieve pain and suffering.
- Coordinate continuous care.
- Effectively communicate with and educate patients.
- Share decision making and management.
- Advocate for disease prevention and health promotion.

Work in Interdisciplinary Teams
- Cooperate, collaborate, and communicate.
- Integrate care to ensure that care is continuous and reliable.

Use Evidence-Based Practice
- Integrate best research with clinical practice and patient values.
- Participate in research activities as possible.

Apply Quality Improvement
- Identify errors and hazards in care.
- Practice using basic safety design principles.
- Measure quality in relation to structure, process, and outcomes.
- Design and test interventions to change processes.

Use Informatics
- Use information technology to communicate, manage knowledge, reduce error, and support decision-making.

Adapted from Institute of Medicine (IOM): *Crossing the quality chasm: a new health system for the 21st century,* Washington DC, 2001, National Academies Press; and Institute of Medicine: *Health professions education: a bridge to quality*, Washington, DC, 2003, National Academies Press.

BOX 2-5 TEN RULES OF PERFORMANCE IN A REDESIGNED HEALTH CARE SYSTEM

1. Care is based on continuous healing relationships.
2. Care is individualized based on patient needs and values.
3. The patient is the source of control participating in shared decision making.
4. Knowledge is shared, and information flows freely.
5. Decision making is evidence based, with care based on the best available scientific knowledge.
6. Safety is a system property and focused on reducing errors.
7. Transparency is necessary through sharing information with patients and families.
8. Patient needs are anticipated through planning.
9. Waste is continuously decreased.
10. Cooperation and communication among clinicians are priorities.

Adapted from Institute of Medicine (IOM): *Crossing the quality chasm: a new health system for the 21st century,* Washington DC, 2001, National Academies Press; and Institute of Medicine: *Health professions education: a bridge to quality*, Washington, DC, 2003, National Academies Press.

competencies for health care professionals in the twenty-first century (Pew Health Professions Commission, 1998). The competencies emphasize the importance of public service, caring for the health of communities, and developing ethically responsible behaviors. In addressing the continued challenge facing the health care system, the IOM (2001) identified five interrelated competencies that are essential for all health care workers in the twenty-first century (Box 2-4). Shifts to an emphasis on prevention and management place increased importance on the competencies of care management and coordination, patient education, public health, and transitional care (IOM, 2011). The IOM also identified 10 important rules of performance for a health care system to follow to better meet patient needs (Box 2-5) (IOM, 2003).

The health care practitioner competencies are an excellent tool for measuring how well a nurse practices nursing and serve as a guide for the development of a professional nursing career. A consumer of health care expects that the standards of nursing care and practice in any health care setting are appropriate, safe, and efficacious. Health care organizations ensure quality care by establishing policies, procedures, and protocols that are evidence based and follow national accrediting standards. A nurse's responsibility is to follow policies and procedures and know the most current practice standards. Ongoing competency is a nurse's responsibility. It is also the nurse's responsibility to obtain necessary continuing education, follow an established code of ethics, and earn certifications in specialty areas (Jordan et al., 2008). Development of a professional practice portfolio that shows learning activities and professional accomplishments is one way to show competency in nursing (Scott-Tilley, 2008).

Evidence-Based Practice

As professionals, nurses are challenged to stay familiar with new information to provide the highest quality of patient care. Nursing practice is dynamic and always changing because of new information coming from research studies, practice trends, technological development, and social issues affecting patients. Nurses need to analyze new knowledge to make sound and informed decisions about patient care (Kotzer and Arellana, 2008). Evidence-based practice is a problem-solving approach to clinical practice that involves the conscientious use of current best evidence, along with clinical expertise and patient preferences and values in making decisions about patient care (Melnyk and Fineout-Overholt, 2010). Evidence-based practice, research-based practice, and best practice are terms that are often used interchangeably. However, research-based practice refers to the use of knowledge based on the results of research studies; whereas evidence-based practice adds a nurse's clinical experience, practice trends, and patient preferences (Melnyk and Fineout-Overholt, 2010). Chapter 5 offers a thorough review of evidence-based practice.

Quality and Safety in Health Care

Nursing plays an important role in quality and safety in health care (Box 2-6). Quality health care is the "degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge" (IOM, 2001). Safety is a critical part of quality health care (Tzeng and Yin, 2007). The National Quality Forum (NQF) (2010) identified 34 health care practices, organized in seven functional areas that improve patient safety by decreasing the occurrence of adverse events. Examples of NQF practices include hand hygiene, teamwork, training, influenza prevention, catheter-associated urinary tract infection prevention, fall prevention, and medication reconciliation (NQF, 2010). Health care providers define the quality of their services by measuring health care outcomes that show how a patient's health status has changed. Examples of outcomes that are monitored are readmission rates for patients who have had surgery, functional health status of patients

BOX 2-6 EVIDENCE-BASED PRACTICE

Nursing Work Environment and Patient Safety

PICO Question: What nursing factors in the nursing work environment contribute to patient safety in hospitals?

Evidence Summary

Studies examined a variety of factors within the nursing work environment that contribute to patient safety. Nurses working in Magnet hospitals were more likely to participate in problem solving to reduce errors (Hughes et al., 2009). Environments that empowered nurses gave them control over their own practice and participation in decision making on the unit. These nurses had greater involvement in identifying patient safety issues, communicated more about safety issues, and found solutions for problems that jeopardized patient safety (Hughes et al., 2009; Spence Laschinger, 2008). Key to the development of empowering work environments were the nurse leaders and managers. Spence Laschinger (2008) found that nursing work groups that were committed to patient safety were a positive characteristic of the safety climate on the nursing unit. Research also showed that the percentage of certified registered nurses on a unit was directly related to patient safety (Kendall-Gallagher and Blegen, 2009). Greater safety compliance was also found on smaller nursing units that had less patient and work complexity (Hughes et al., 2009). Continued research is needed to validate the effect that nursing has on patient safety.

Application to Nursing Practice

- Seek out health care institutions that have empowering environments, such as shared governance, on nursing units (Spence Laschinger, 2008).
- Work toward obtaining certification in your specialty nursing area (Kendall-Gallagher and Blegen, 2009).
- Become involved in committees and decision-making processes on the unit (Spence Laschinger, 2008).
- Develop nursing work groups that are committed to patient safety (Hughes et al., 2009).
- Open channels of communication that involve the staff nurse in identifying patient safety issues (Hughes et al., 2009).

after discharge (e.g., ability and time frame for returning to work), and the rate of infection after surgery. Nurses play an important role in gathering and analyzing quality outcome data. Within a rural hospital setting, knowledge of the rural culture and connectedness to the community are unique features related to quality care (Baernholdt et al., 2010).

Pay for performance programs and public reporting of hospital quality data are designed to promote quality, effective, and safe patient care by physicians and health care organizations. These programs are quality improvement strategies that reward excellence through financial incentives to motivate change to achieve measurable improvements (Lindenauer et al., 2007). Nurses play an important role in helping hospitals meet the measure for quality, efficiency, and patient satisfaction (Lutz and Root, 2007). They are often the health care provider who ensures that performance measures occur. For example, one performance measure is the standard that any patient admitted with a possible myocardial infarction receives an aspirin. In an acute care setting a nurse is the one who obtains an order for the aspirin and ensures that the patient receives it in a timely manner (Bodrock and Mion, 2008). Research shows that financial incentives modestly increase quality improvement efforts in hospitals that do public reporting (Lindenauer et al., 2007). Some health care organizations use balanced scorecards to report data on their key performance indicators. These scorecards are reported publicly so health care consumers can use the information when choosing health care services.

More and more health care institutions are focused on improving processes as a way to improve quality and safety. Many use strategies such as Six Sigma, Lean Six Sigma, or Value Stream Analysis. Six Sigma is a data-driven approach to process improvement that reduces variation in process. It is a measure of quality (isixsigma, 2010). For example, a nursing unit sets up a project to collect data on the process of administering the first dose of an ordered chemotherapy. The audit reveals delays in getting the drug from the pharmacy to the nursing unit. Using Six Sigma, the collected data are analyzed, and unnecessary steps in the process are identified. On the basis of this analysis the process is streamlined to decrease time from ordering to administration. Lean Six Sigma and value stream analysis are two other methods that focus on improvement of processes through studying each step of a process to determine if the step adds value and reduces the health care organization's time, costs, and resources (Burger, 2008; Carey, 2010). The aim of both is to eliminate unnecessary, nonvalue-added costly steps to reduce waste.

Health plans throughout the United States rely on the Healthcare Effectiveness Data and Information Set (HEDIS) as a quality measure. The National Committee for Quality Assurance (NCQA) created HEDIS to collect various data to measure the quality of care and services provided by different health plans. It is the database of choice for the Centers for Medicare and Medicaid Services (CMS). HEDIS compares how well health plans perform on 71 measures across eight domains of care in the key areas of quality and effectiveness of care, access to care, and patient satisfaction with the health plan and doctors (NCQA, 2010). For accreditation purposes The Joint Commission requires health care organizations to determine how well an organization meets patient needs and expectations. Organizations are using outcomes such as patient satisfaction to redesign how they manage and deliver care in hopes of improving quality in the long term.

Patient Satisfaction. Every major health care organization measures certain aspects of patient satisfaction. The Hospital Consumer of Assessment of Healthcare Providers and Systems (HCAHPS) is a standardized survey developed to measure patient perceptions of their hospital experience (HCAHPS, 2010). HCAHPS was developed by the CMS and the Agency for Healthcare Research and Quality as a way for hospitals to collect and report data publicly for comparison purposes. The survey is administered to a randomly selected sample of adults who were discharged from a hospital between 48 hours and 6 weeks ago. The survey has 27 questions that ask patients to respond about communication with nurses and physicians, responsiveness of hospital staff, pain management, communication about medications, discharge planning, cleanliness and quietness of the environment, overall satisfaction, and willingness to recommend the hospital (HCAHPS, 2010). Nursing environments affect HCAHPS scores. Research found that hospitals that improved the nursing work environment and lowered nurse-patient ratios by one patient had higher patient satisfaction levels and patients who were more likely to recommend the hospital to others (Kutney-Lee et al., 2009).

The Picker Institute identified eight dimensions of **patient-centered care** (Box 2-7) that most affect patients' experiences with health care. The eight dimensions cover most of the scope of nursing practice. This is not a surprise because nurses are involved in almost every aspect of a patient's care in a hospital. A close look shows that many of the aspects reflected in patient satisfaction apply to almost any health care setting.

BOX 2-7 THE DIMENSIONS OF PATIENT-CENTERED CARE

Respect Values, Preferences, and Expressed Needs
- Patients expect to be treated with dignity, respect, and sensitivity to cultural beliefs, values, and quality-of-life issues.
- Patients want to be informed and share in decisions about their care.
- Patients' perceptions of needs should not be completely different from those identified by a care provider.

Coordination and Integration of Care
- A competent and caring staff reduces feelings of powerlessness.
- Patients look for someone to be in charge of care and communicate clearly with other health care team members.
- Patients expect to have services and care well coordinated. This includes areas of clinical care, front-line patient care, and ancillary and support services.
- Patients need to know at all times whom to call for help.

Information, Communication, and Education
- Patients expect to receive accurate and timely information about their clinical status, progress, or prognosis.
- Patients and families need to be informed of major changes in therapies or status.
- Patients need tests and procedures explained clearly in language they understand.
- Patients and family members want to know how to manage care on their own.

Physical Comfort
- Physical care needs to provide comfort for pain management.
- Nurses need to respond in a timely and effective way to any request for pain medication, explain the extent of pain patients can expect, and offer alternatives for pain management.
- Patients expect privacy and to have their cultural values respected.
- Patients often need help to complete activities of daily living.
- The health care setting environment needs to be clean and comfortable, with accessibility for visits by family.

Emotional Support and Relief of Fear and Anxiety
- Patients look to care providers to share their fears and concerns.
- Patients need to understand the impact that illness will have on their ability to care for themselves and their family.
- Patients worry about their ability to pay for their medical care. Identify staff that will help alleviate this worry.

Involvement of Family and Friends
- Care providers need to recognize, respect, and meet the needs of patients, family, and friends.
- Patients have the right to determine if family members are to be involved in decisions about their care.
- Patients expect family or friends who will provide physical support and care after discharge to be properly informed.

Transition and Continuity
- Patients want information about medications to take, physical limitations, dietary or treatment plans to follow, and danger signals for which to look after hospitalization or treatment.
- Patients expect to have their continuing health care needs met after discharge with well-coordinated services.
- Patients and family members expect access to necessary health care resources on a continuing basis.

Access to Care
- Patients want to get to hospitals, clinics, and physicians' offices easily and without hassle.
- Patients need to be able to find transportation when going to different health care settings.
- Patients want to schedule appointments at convenient times without difficulty.
- Patients want to be able to see a specialist when a referral is made.
- Patients expect to receive clear instructions on how to obtain referrals to other health care providers.

Adapted from Picker Institute: *Principles of patient-centered care,* 2011, http:pickerinstitute.org/about/picker-principles. Accessed December 28, 2011.

The survey tool from The Picker Institute measures patient satisfaction along the eight dimensions. The survey looks globally at patient perceptions of care in an attempt to understand how all hospital departments influence patient satisfaction. The program mails surveys to patients after they leave a health care setting. Many other companies have developed similar patient satisfaction surveys that are distributed in the mail to patients. Staff involved in patient care receive the satisfaction scores as feedback regarding their success in meeting patient expectations. The nursing staff is responsible for identifying unique issues that influence patient satisfaction on their unit. For example, nurses working on an oncology unit have different patient satisfaction issues around physical comfort than nurses caring for new mothers. Patient satisfaction findings become the basis for many quality improvement studies.

It is important for nurses to recognize the need to provide patient- and family-centered care. Identifying patient and family expectations, knowledge, preferences, cultural beliefs, and values is an important part of patient-centered care (Cronenwett et al., 2007; Institute for Patient- and Family-Centered Care [IPFCC], 2010). Concepts of patient-centered care include respect and dignity, sharing of information, participation in care and care decisions, and collaboration (IPFCC, 2010). By learning early what a patient expects with regard to information, comfort, and availability of family and friends, nurses are able to better plan patient care. They should ask about the patient's expectations when the patient first enters a health care setting, while care continues, and when a patient is discharged. Patient expectations are an important measure of the evaluation of nursing care. A Patient and Family Advisory Council is one strategy that is effective in obtaining patient and family feedback to develop patient- and family-centered care (Zarubi et al., 2008).

Magnet Recognition Program

The American Nurses Credentialing Center (ANCC) established the Magnet Recognition Program to recognize health care organizations that achieve excellence in nursing practice (ANCC, 2010c). In the United States approximately 6.4% of health care organizations have achieved Magnet status (ANCC, 2010b). Health care organizations that apply for Magnet status must demonstrate quality patient care, nursing excellence, and innovations in professional practice. The professional work environment must allow

BOX 2-8 MAGNET MODEL AND FORCES OF MAGNETISM

MAGNET MODEL COMPONENTS	FORCES OF MAGNETISM
Transformational Leadership—A vision for the future and the systems and resources to achieve the vision are created by nursing leaders.	• Quality of Nursing Leadership • Management Style
Structural Empowerment—Structures and processes provide an innovative environment in which staff are developed and empowered and professional practice flourishes.	• Organizational Structure • Personnel Policies and Programs • Community and the Health Organization • Image of Nursing • Professional Development
Exemplary Professional Practice—Strong professional practice is established, and accomplishments of the practice are demonstrated.	• Professional Models of Care • Consultation and Resources • Autonomy • Nurses as Teachers • Interdisciplinary Relationships
New Knowledge, Innovations, and Improvements—Contributions are made to the profession in the form of new models of care, use of existing knowledge, generation of new knowledge, and contributions to the science of nursing.	• Quality Improvement
Empirical Quality Outcomes—Focus is on structure and processes and demonstration of positive clinical, work force, and patient and organizational outcomes.	• Quality of Care

Adapted from American Nurses Credentialing Center: *A new model for ANCC's Magnet Recognition Program*, 2010a, http://www.nursecredentialing.org/Magnet/ProgramOverview/NewMagnetModel.aspx.

BOX 2-9 NURSING QUALITY INDICATORS

- Patient falls
- Patient falls with injury
- Pressure ulcers—community acquired, hospital acquired, unit acquired
- Staff mix
- Nursing hours per patient day
- Registered nurse (RN) surveys on job satisfaction and practice environment scale
- RN education and certification
- Pediatric pain assessment cycle
- Pediatric intravenous infiltration rate
- Psychiatric patient assault rate
- Restraint prevalence
- Nurse turnover
- Hospital-acquired infections of ventilator-associated pneumonia, central line–associated bloodstream infection, catheter-associated urinary tract infection

Data from National Database of Nursing Quality Indicators (NDNQI): NDNQI: transforming data into quality care, 2010, http://www.nursingquality.org. Accessed June 18, 2011.

nurses to practice with a sense of empowerment and autonomy to deliver quality nursing care. The revised Magnet model has five components that are affected by global issues that are challenging nursing today (ANCC, 2010a) (Box 2-8). The five components are Transformational Leadership; Structural Empowerment; Exemplary Professional Practice; New Knowledge, Innovation, and Improvements; and Empirical Quality Results. Institutions achieve Magnet status through an appraisal process that requires them to present evidence showing achievement of the 14 forces of magnetism (see Box 2-8). Magnet status requires nurses to collect data on specific nursing-sensitive quality indicators or outcomes and compare their outcomes against a national, state, or regional database to demonstrate quality of care.

Nursing-Sensitive Outcomes. **Nursing-sensitive outcomes** are patient outcomes and select nursing workforce characteristics that are directly related to nursing care such as changes in patients' symptom experiences, functional status, safety, psychological distress, registered nurse (RN) job satisfaction, total nursing hours per patient day, and costs. Nurses assume accountability and responsibility for achieving and accepting the consequences of these outcomes. The National Database of Nursing Quality Indicators (NDNQI) was developed by the American Nurses Association to measure and evaluate nursing-sensitive outcomes with the purpose of improving patient safety and quality care (NDNQI, 2010) (Box 2-9). The NDNQI reports quarterly results on nursing outcomes at the nursing unit level. This provides a database for individual hospitals to compare their performance against nursing performance nationally (Kurtzman and Jennings, 2008). The evaluation of patient outcomes and nursing workforce characteristics remains important to nursing and the health care delivery system. Chapter 5 describes approaches for measuring outcomes.

Because of the importance of nursing-sensitive outcomes, the Agency for Healthcare Research Quality funded several nursing research studies that looked at the relationship of nurse staffing levels to adverse patient outcomes. These studies found a connection between higher levels of staffing by registered nurses (RNs) in hospitals and fewer negative patient outcomes. For example, the incidence of hospital-acquired pneumonia was highly sensitive to RN staffing levels. Adding just 30 minutes of RN staffing per patient day greatly reduced the incidence of pneumonia in patients following surgery. These studies also found that increased levels of nurse staffing positively impacted nurse satisfaction. Future studies will examine how nurses' workloads affect patient safety and how their working conditions affect medication safety. Measuring and monitoring nursing-sensitive outcomes reveal the interventions that improve patients' outcomes. Nurses and health care facilities use nursing-sensitive outcomes to improve nurses' workloads, enhance patient safety, and develop sound policies related to nursing practice and health care.

Nursing Informatics and Technological Advancements

Quality and Safety Education for Nurses (QSEN) identified informatics as a competency for nurses (Cronenwett et al., 2007). **Nursing informatics** "uses information and technology to communicate, manage knowledge, mitigate error, and support decision-making" (Cronenwett et al., 2007). Data are individually distinct pieces of reality. Examples of data nurses collect and use to deliver safe patient care include a patient's blood pressure or the

measurement of a patient's wound. Nurses gain or use *information* when they organize, structure, or interpret data. A nurse uses information when looking at trends in a patient's blood pressure readings over the past 24 hours or when evaluating the changes in the size of a wound over the past 3 weeks. *Knowledge* develops when nurses combine and identify relationships between different pieces of information. For example, nurses know that diet plays an important role in blood pressure control and wound healing. They use this knowledge to teach patients at risk for developing high blood pressure to limit their salt intake and to teach patients who have wounds the importance of eating a well-rounded diet that includes adequate protein, vitamins, and minerals. Knowledge and skills in informatics also provides the nurse ability to access quality electronic sources of health care information to plan and coordinate patient care (Cronenwett et al., 2007). The focus of nursing informatics is not on the technology or the computer; rather, its focus is on the organization, analysis, and dissemination of information (American Nurses Association, 2008). Chapter 26 provides a thorough review of how nursing informatics improves the way nurses provide health care through use of the electronic health record.

Advances in technology are constantly evolving. People work, play, and view the world much differently because of these advances. Technological advancements also influence where and how nurses provide care to patients. Technological advances help nurses improve direct care processes, patient outcomes, and work environments (Zuzelo et al., 2008). Sophisticated equipment such as electronic IV infusion devices, cardiac telemetry (a device that monitors a patient's heart rate wherever the patient is on a nursing unit), and computerized medication dispensation systems (see Chapter 31) are just a few examples that have changed health care. In many ways, technology makes the nurse's work easier, but it does not replace nursing judgment. For example, it is the nurse's responsibility when managing a patient's IV therapy to monitor the infusion to be sure that it infuses on time and without complications. An electronic infusion device provides a constant rate of infusion, but nurses need to be sure that they calculate the rate correctly. The device sets off an alarm if the infusion slows, making it important for the nurse to respond to the alarm and troubleshoot the problem. Technology does not replace a nurse's critical eye and clinical judgment. Challenges arise for nurses when technologies create inefficient delivery systems or uses or need repairs. These problems increase the nurses' workload (Zuzelo et al., 2008).

Technology also affects the way we communicate with others. Personal computers, cell phones, and personal digital assistants (PDAs) allow us to communicate and share information or data with others in a variety of formats around the world. People expect accurate information to be delivered to them as it develops. Managing communication, information, and data is challenging in health care. Health care agencies use data to measure their outcomes and improve patient care. Accrediting bodies, insurance companies, and Medicare/Medicaid all require collection and reporting of accurate data. Furthermore, nurses need accurate, up-to-date information to make the best decisions about patient care. Therefore it is crucial that nurses help health care agencies develop an effective way to manage the collection, interpretation, and distribution of information.

Nurses need to play a role in evaluating and implementing new technological advances. They use technology and informatics to improve the effectiveness of nursing care, enhance safety, and improve patient outcomes. Most important, it is essential for nurses to remember that the focus of nursing care is not the machine or the technology; it is the patient. Therefore nurses need to constantly attend to and connect with their patients and ensure that their dignity and rights are preserved at all levels of care.

Globalization of Health Care

Globalization, the increasing connectedness of the world's economy, culture, and technology, is one of the forces reshaping the health care delivery system (Oulton, 2012). Advances in communication, primarily through the Internet, allow nurses, patients, and other health care providers to talk with others worldwide about health care issues. Improved communication, easier air travel, and easing of trade restrictions are making it easier for people to engage in "health tourism." Health tourism is the travel to other nations to seek out health care.

Many problems affect the health status of people around the world. For example, poverty is still deadlier than any disease and is the most frequent reason for death in the world today. Poverty increases the disparities in health care services among vulnerable populations (Crigger, 2008). Nations and communities that experience poverty have limited access to vaccines, clean water, and standard medical care. The growth of urbanization also currently is affecting global health. As cities become more densely populated, problems with pollution, noise, crowding, inadequate water, improper waste disposal, and other environmental hazards become more apparent. Children, women, and older adults are **vulnerable populations** most threatened by urbanization. Nurses work toward improving the health of all populations (Crigger, 2008). Although globalization of trade, travel, and culture improves the availability of health care services, the spread of communicable diseases such as tuberculosis and severe acute respiratory syndrome has become more common. Finally, the results of global environmental changes and disasters affect health. Changes in climate and natural disasters threaten food supplies and often allow infectious diseases to spread more rapidly.

Nurses need to understand how worldwide communication and globalization of health care influence nursing practice. Health care consumers demand quality and service and have become more knowledgeable. They often have searched the Internet about their health concerns and medical conditions. They also use the Internet to select their health care providers. As a result of **globalization,** health care providers have to make their services more accessible. Because of advances in communication, nurses and other health care providers practice across state and national boundaries. In response to the nursing shortage in the early 2000s, health care institutions recruited nurses from around the world to work in the United States. This was an effort to continue to provide quality, safe patient care. This trend is expected to continue to fill vacant nursing positions (Buerhaus et al., 2009). The hiring of nurses from other nations has required American hospitals to better understand and work with nurses from different cultures and with different needs.

As a leader in health care, remain aware of what is happening in the community, nation, and around the world. The International Council of Nurses (ICN), based in Switzerland, represents nursing worldwide. The purpose of the ICN is to advance the nursing profession worldwide and influence health policy (ICN, 2010). The goals of ICN are to bring nursing together, advance the nursing profession, and influence health policy worldwide (ICN, 2010). The unique focus of nursing on caring helps nurses address the issues presented by globalization. Nurses and the nursing profession are able to help overcome these issues by working together to improve nursing education throughout the world, retaining nurses

and recruiting people to be nurses, and being advocates for changes that will improve the delivery of health care. Be prepared for future health care issues. Globalization has influenced many other industries. As a leader, nursing has to take control and be proactive in developing solutions before someone outside of nursing takes control.

THE FUTURE OF HEALTH CARE

This discussion of the health care delivery system began with the issue of change. Change is often threatening, but it also opens up opportunities for improvement. The ultimate issue in designing and delivering health care is ensuring the health and welfare of the population. Health care in the United States and around the world is not perfect. Patients do not receive continuity of care when they see multiple health care providers. Often patients are uninsured or underinsured and do not have access to necessary services. However, health care organizations are trying to become better prepared to deal with the challenges in health care. Increasingly, health care organizations are changing how they provide their services, reducing unnecessary costs, improving access to care, and trying to provide high-quality patient care. Professional nursing is an important player in the future of health care delivery. The solutions necessary to improve the quality of health care depend largely on the active participation of nurses.

KEY POINTS

- Increasing costs and decreasing reimbursement are forcing health care institutions to deliver care more efficiently without sacrificing quality.
- In a managed care system the provider of care receives a predetermined capitated payment regardless of the services a patient uses.
- The Medicare prospective reimbursement system is based on payment calculated on the basis of DRG assignment.
- Levels of health care describe the range of services and settings in which health care is available to patients in all stages of health and illness.
- Health promotion occurs in home, work, and community settings.
- Nurses are facing the challenge of keeping populations healthy and well within their own homes and communities.
- Successful community-based health programs involve building relationships with the community and incorporating cultural and environmental factors.
- Hospitalized patients are acutely ill, requiring better coordination of services before discharge.
- Rehabilitation allows an individual to return to a level of normal or near-normal function after a physical or mental illness, injury, or chemical dependency.
- Home care agencies provide a wide variety of health care services with an emphasis on patient and family independence.
- Discharge planning begins at admission to a health care facility and helps in the transition of a patient's care from one environment to another.
- Health care organizations are being evaluated on the basis of outcomes such as prevention of complications, patients' functional outcomes, and patient satisfaction.
- Nurses need to remain knowledgeable and proactive about issues in the health care delivery system to provide quality patient care and positively affect health.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Community Hospital is a 400-bed urban hospital, one of six hospitals in a health care system. The system also operates a local community clinic that primarily serves a poor multicultural population. The nursing department of the hospital is considering making application to the American Nurses Credentialing Center for Magnet status. Nursing units are working on a number of projects to prepare for the Magnet application process.

1. You are a staff nurse on a medical-surgical floor at the hospital. The unit is trying to improve its culture in patient safety. How would you go about helping to improve the culture of safety on the unit?
2. Discuss three strategies that the community clinic can use to deliver patient- and family-centered care.
3. You are asked by a nurse at another hospital what it means to be a "Magnet hospital." Describe the Magnet model of nursing to answer the nurse's question.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Which of the following is an example of the principle of patient-centered care focused on continuity and transition?
   1. The nurse asks the patient who in the family should have access to patient information
   2. The nurse is teaching the patient how to change the wound dressing at home
   3. The nurse responds promptly to the patient's request for pain medication
   4. The nurse schedules the patient's diagnostic scan following the physical therapy session
2. Which activity performed by the nurse is related to maintaining competency in nursing practice?
   1. Asking another nurse about how to change the settings on a medication pump
   2. Regularly attending unit staff meetings
   3. Participating as a member of the professional nursing council
   4. Attending a review course in preparation for the certification examination
3. The patient tells the nurse that she is enrolled in a preferred provider organization (PPO) but does not understand what this is. What is the nurse's best explanation of a PPO?
   1. This health plan is for people who cannot afford their own health insurance
   2. This health plan is operated by the government to provide health care to older adults
   3. This health plan provides you with a preferred list of physicians, hospitals, and providers from which you can choose
   4. This is a fee-for-service plan in which you can choose any physician or hospital
4. Which of the following is an example of the nurse participating in primary care activities?
   1. Providing prenatal teaching on nutrition to a pregnant woman during the first trimester
   2. Working with patients in a cardiac rehabilitation program

3. Assessing a patient at an emergent care facility
4. Providing home wound care to a patient

5. Nurses on a nursing unit are discussing the processes that led up to a near-miss error on the clinical unit. They are outlining strategies that will prevent this in the future. This is an example of nurses working on what issue in the health care system?
   1. Patient safety
   2. Evidence-based practice
   3. Patient satisfaction
   4. Maintenance of competency
6. Which of the following statements is true regarding Magnet status recognition for a hospital?
   1. Nursing is run by a Magnet manager who makes decisions for the nursing units
   2. Nurses in Magnet hospitals make all of the decisions on the clinical units
   3. Magnet is a term that is used to describe hospitals that are able to hire the nurses they need
   4. Magnet is a special designation for hospitals that achieve excellence in nursing practice
7. Which statement made by the nurse is an example of applying the principle of patient-centered care while focusing on alleviation of a patient's fear and anxiety?
   1. "Let's talk about the concerns that you have about going home."
   2. "I'll get the medication prescriptions for you before discharge"
   3. "I'll be back in 30 minutes to help you get cleaned up"
   4. "I'll make a referral to the home health nurse for you"
8. Which of the following is/are characteristics of managed care systems? (Select all that apply.)
   1. Provider receives a predetermined payment for each patient in the program.
   2. Payment is based on a set fee for each service provided.
   3. System includes a voluntary prescription drug program for an additional cost.
   4. System tries to reduce costs while keeping patients healthy.
   5. Focus of care is on prevention and early intervention.
9. Which of the following nursing activities is found in a tertiary health care environment?
   1. Administering influenza immunizations at the senior independent living facility
   2. Providing well-baby care in the clinic run by the local community health department
   3. Admitting a patient following open heart surgery to the cardiovascular intensive care unit
   4. Working the triage desk in the emergency department
10. Which of the following activities performed by the nurse is/are focused on the patient-centered care principle of physical comfort? (Select all that apply.)
    1. Asking the patient what a tolerable level of pain is for him or her following surgery
    2. Providing a back rub at bedtime
    3. Offering the patient a warm washcloth for his or her hands before eating
    4. Teaching the patient about the new antihypertensive medication ordered
    5. Scheduling the patient's follow-up appointments on discharge
    6. Changing the bed linens for a patient who is experiencing diaphoresis
11. The nursing staff is developing a quality program for the floor. Which of the following are nursing-sensitive indicators from the National Database of Nursing Quality Indicators that the nurses can use to measure patient safety and quality for the unit? (Select all that apply.)
    1. Number of medication errors committed by registered nurses (RNs)
    2. Turnover rate of nurses on the unit
    3. Incidence of patient falls
    4. Number of certified RNs
    5. Number of emergency department admissions per year
12. The nurse is providing restorative care to a patient following an extended hospitalization for an acute illness. Which of the following is an appropriate goal for restorative care?
    1. Patient will be able to walk 200 feet without shortness of breath
    2. Wound will heal without signs of infection
    3. Patient will express concerns related to return to home
    4. Patient will identify strategies to improve sleep habits
13. A nurse is presenting information to a management class of nursing students on the topic of groups of inpatient hospital services that have a fixed reimbursement amount, with adjustments made on the basis of case severity and regional costs. The nurse is presenting information to the class on which topic?
    1. Utilization review committee
    2. Resource utilization group
    3. Capitation payment system
    4. Diagnosis-related groups
14. When a nurse uses information and technology to communicate, locate and use knowledge, reduce and eliminate errors, and help make decisions, the nurse is working in which area?
    1. Integrated delivery system
    2. Health care patient system
    3. Nursing informatics
    4. Computerized nursing network
15. Which of the following are examples of the principle of patient-centered care that is focused on respect, values, preferences, and expressed needs? (Select all that apply.)
    1. Administer antihypertensive medications to patient daily.
    2. Pulling the curtain around the patient bed before changing the wound dressing on the patient's leg
    3. Allowing the patient to ask questions and express his or her concern about surgery
    4. Explaining a colonoscopy procedure to the patient
    5. Working with the family to bring in ethnic foods that the patient prefers

Answers: **1.** 2; **2.** 4; **3.** 3; **4.** 1; **5.** 1; **6.** 4; **7.** 1; **8.** 1, 4, 5; **9.** 3; **10.** 1, 2, 3, 6; **11.** 2, 3, 4; **12.** 1; **13.** 4; **14.** 3; **15.** 2, 3, 5.

CHAPTER

3

Community-Based Nursing Practice

OBJECTIVES

- Explain the relationship between public health and community health nursing.
- Differentiate community health nursing from community-based nursing.
- Discuss the role of the community health nurse.
- Discuss the role of the nurse in community-based practice.
- Identify characteristics of patients from vulnerable populations that influence the community-based nurse's approach to care.
- Describe the competencies important for success in community-based nursing practice.
- Describe elements of a community assessment.

KEY TERMS

Community-based nursing, p. 33
Community health nursing, p. 32
Incident rates, p. 32
Population, p. 32
Public health nursing, p. 32
Vulnerable populations, p. 33

Community-based care focuses on health promotion, disease prevention, and restorative care. Because patients move quickly from acute care settings, there is a growing need to organize health care delivery services where people live, work, socialize, and learn (Swiadek, 2009). One way to achieve this goal is through a community-based health care model. Community-based health care is a collaborative, evidence-based model designed to meet the health care needs of a community (Downie, Ogilve, and Wichmann, 2005). A healthy community includes elements that maintain a high quality of life and productivity. For example, safety and access to health care services are elements that enable people to function productively in their community (U.S. Department of Health and Human Services [USDHHS], 2010). As community health care partnerships develop, nurses are in a strategic position to play an important role in health care delivery and improve the health of the community.

The focus of health promotion and disease prevention continues to be essential for the holistic practice of professional nursing. The history of nursing documents the roles of nurses in establishing and meeting the public health goals of their patients. Within community health settings, nurses are leaders in assessing, diagnosing, planning, implementing, and evaluating the types of public and community health services needed. Community health nursing and community-based nursing are components of a health care delivery system that improve the health of the general public.

COMMUNITY-BASED HEALTH CARE

It is important to understand the focus of community-based health care. Community-based health care is a model of care that reaches everyone in the community (including the poor and underinsured), focuses on primary rather than institutional or acute care, and provides knowledge about health and health promotion and models of care to the community. Community-based health care occurs outside traditional health care institutions such as hospitals. It provides services to individuals and families within the community for acute and chronic conditions (Stanhope and Lancaster, 2010).

Today the challenges in community-based health care are numerous. Social lifestyles, political policy, and economics all influence public health problems and subsequent health care services. Some of these problems include an increase in homeless and immigrant populations, an increase in sexually transmitted infections, underimmunization of infants and children, patients with chronic illnesses, and life-threatening diseases (e.g., patients living with human immunodeficiency virus [HIV] and other emerging infections). More than ever before, health care reform is necessary to bring attention to the health care needs of all communities.

Achieving Healthy Populations and Communities

The U.S. Department of Health and Human Services Public Health Service designed a program to improve the overall health status of people living in this country. The *Healthy People Initiative* was created to establish ongoing health care goals (see Chapter 6). The 2020 document strives to ensure that *Healthy People 2020* is relevant to diverse public health needs and seizes opportunities to achieve its goals. Since its inception, *Healthy People* has become a broad-based, public engagement initiative with thousands of citizens helping to shape it at every step along the way. The overall goals of *Healthy People 2020* are to increase life expectancy and

quality of life and eliminate health disparities through an improved delivery of health care services (USDHHS, 2010).

Improved delivery of health care occurs through assessment of health care needs of individuals, families, and communities; development and implementation of public health policies; and improved access to care. For example, assessment includes systematic data collection on the population, monitoring the health status of the population, and accessing available information about the health of the community (Stanhope and Lancaster, 2010). A comprehensive community assessment can lead to community health programs such as adolescent smoking prevention, sex education, and proper nutrition. Some examples of assessment include gathering information on **incident rates** for identifying and reporting new infections or diseases, determining adolescent pregnancy rates, and reporting the number of motor vehicle accidents by teenage drivers.

Health professionals provide leadership in developing public policies to support the health of the population (Stanhope and Lancaster, 2010). Strong policies are driven by community assessment. For example, assessing the level of lead poisoning in young children often leads to a lead cleanup program to reduce the incidence of lead poisoning. Likewise more people are choosing to remain in their homes for end-of-life care. Assessing the numbers of people in the community who need end-of-life care can lead to evidence-based practices for addressing both the needs of the nurses and the home care needs of these patients (Smith and Porock, 2009) (Box 3-1).

BOX 3-1 EVIDENCE-BASED PRACTICE

Managing Chronic Leg Ulcers in a Community Setting

PICO Question: What is the effect on quality of life (QOL) in community-dwelling patients with chronic leg ulcers who participate in leg ulcer support group compared to patients who do not participate in a support group?

Evidence Summary

Healing chronic venous leg ulcers is expensive and time consuming and impacts a patient's level of function and QOL. In addition, pain and in some cases odor are associated with the leg wound. As a result, patients and their families are socially isolated. Patients also experience depression and anxiety related to the chronic impact and the long healing process (Jones et al., 2006). Each and all of these factors impact patients' perception of QOL. When nursing resources and support groups are available in a community setting, the costs of treatment are reduced, and QOL and function and activity increase (Edwards et al., 2009; Gordon et al., 2006).

Application to Nursing Practice

- The presence of chronic wound support groups provides patients and families an opportunity to interact with individuals who experience similar situations (Edwards et al., 2009).
- Nursing wound care specialists who make home visits to patients in their community settings are able to track the healing process as the patient's level of activity and function change and offer suggestions to improve the patient's level of independence (Gordon et al., 2006).
- It is necessary to understand that some patients and family members have depression and anxiety related to the chronic nature of the wound and the slow healing process (Jones et al., 2006).
- During the early phases of healing the patient and family may report that their QOL is very low; however, let them know that, as the wound heals, their ability and desire to socialize with others may increase, the cost of care may decline, and pain may decline or resolve. All of these factors can improve the patient's QOL reports (Hareendran et al., 2005).

Improved access to care ensures that essential community-wide health services are available and accessible to the total community (Stanhope and Lancaster, 2010). Examples include prenatal care programs for the uninsured and educational programs to ensure the competency of public health professionals. Population-based public health programs focus on disease prevention, health protection, and health promotion. This focus provides the foundation for health care services at all levels (see Chapter 2).

The five-level health services pyramid is an example of how to provide community-based services within existing health care services in a community (see Fig. 2-1 on p. 17). In this population-focused health care services model, the goals of disease prevention, health protection, and health promotion provide a foundation for primary, secondary, and tertiary health care services.

A rural community often has a hospital to meet the acute care needs of its citizens. However, a community assessment might reveal that there are minimal services to meet the needs of expectant mothers, reduce teenage smoking, or provide nutritional support for older adults. Community-based programs are able to provide these services and are effective in improving the health of the community. On the other hand, when a community has the resources for providing childhood immunizations, flu vaccines, primary preventive care services are able to focus on child developmental problems and child safety.

Public health services aim at achieving a healthy environment for all individuals. Health care providers apply these principles for individuals, families, and the communities in which they live. Nursing plays a role in all levels of the health services pyramid. By using public health principles you are better able to understand the types of environments in which patients live and the types of interventions necessary to help keep patients healthy.

COMMUNITY HEALTH NURSING

Frequently the terms *community health nursing* and *public health nursing* are used interchangeably, although they are different. A **public health nursing** focus requires understanding the needs of a **population** or a collection of individuals who have one or more personal or environmental characteristics in common (Stanhope and Lancaster, 2010). Examples of populations include high-risk infants, older adults, or a cultural group such as Native Americans. A public health nurse understands factors that influence health promotion and health maintenance, the trends and patterns influencing the incidence of disease within populations, environmental factors contributing to health and illness, and the political processes used to affect public policy. For example, the nurse uses data on increased incidence of playground injuries to lobby for a policy to use shock-absorbing material rather than concrete for new public playgrounds.

Public health nursing requires preparation at the basic entry level and sometimes requires a baccalaureate degree in nursing that includes educational preparation and clinical practice in public health nursing. A specialist in public health has a graduate level education with a focus in the public health sciences (American Nurses Association [ANA], 2007).

Community health nursing is nursing practice in the community, with the primary focus on the health care of individuals, families, and groups in a community. The goal is to preserve, protect, promote, or maintain health (Stanhope and Lancaster, 2010). The emphasis of such nursing care is to improve the quality of health and life within that community. In addition, the community health nurse provides direct care services to

subpopulations within a community. These subpopulations often have a clinical focus in which the nurse has expertise. For example, a case manager follows older adults recovering from stroke and sees the need for community rehabilitation services, or a nurse practitioner gives immunizations to patients with the objective of managing communicable disease within the community. By focusing on subpopulations, the community health nurse cares for the community as a whole and considers the individual or family as only one member of a group at risk.

Competence as a community health nurse requires the ability to use interventions that include the broad social and political context of the community (Stanhope and Lancaster, 2010). The educational requirements for entry-level nurses practicing in community health nursing roles are not as clear as those for public health nurses. Not all hiring agencies require an advanced degree. However, nurses with a graduate degree in nursing who practice in community settings are considered community health nurse specialists, regardless of their public health experience (Stanhope and Lancaster, 2010).

Nursing Practice in Community Health

Community-focused nursing practice requires a unique set of skills and knowledge. In the health care delivery system nurses who become expert in community health practice usually have advanced nursing degrees, yet the baccalaureate-prepared generalist is also quite competent in formulating and applying population-focused assessments and interventions. The expert community health nurse understands the needs of a population or community through experience with individual families and working through their social and health care issues. Critical thinking is important in applying knowledge of public health principles, community health nursing, family theory, and communication in finding the best approaches in partnering with families.

Successful community health nursing practice involves building relationships with the community and being responsive to changes within the community. For example, when there is an increase in the incidence of grandparents assuming child care responsibilities, the community health nurse becomes an active part of a community by establishing an instructional program in cooperation with local schools and assists and supports grandparents in this caregiving role. The nurse knows the community members, needs, and resources and then works in collaboration with community leaders to establish effective health promotion and disease prevention programs. This requires working with highly resistant systems (e.g., welfare system) and trying to encourage them to be more responsive to the needs of a population. Skills of patient advocacy, communicating people's concerns, and designing new systems in cooperation with existing systems help to make community nursing practice effective.

COMMUNITY-BASED NURSING

Community-based nursing care takes place in community settings such as the home or a clinic, where the focus is on the needs of the individual or family. It involves the safety needs and acute and chronic care of individuals and families, enhances their capacity for self-care, and promotes autonomy in decision making (Stanhope and Lancaster, 2010). You use critical thinking and decision making for the individual patient and family—assessing health status, diagnosing health problems, planning care, implementing interventions, and evaluating outcomes of care. Because nurses provide direct care services where patients live, work, and play, it is important that nursing care remains focused on the individual and family and that the values of the individual, family, and the community are respected and incorporated (Reynolds, 2009).

FIG. 3-1 Patient and family receiving care in a community-based care center. (Courtesy Mass Communication Specialist 2nd Class Daniel Viramontes.)

Community-based nursing centers function as the first level of contact between members of a community and the health care delivery system (Fig. 3-1). Ideally health care services are provided near where patients live. This approach helps to reduce the cost of health care for the patient and the stress associated with the financial burdens of care. In addition, these centers offer direct access to nurses and patient-centered health services and readily incorporate the patient and the patient's family or friends into a plan of care. Community-based nursing centers often care for the most vulnerable of the population (Kaiser et al., 2009).

With the individual and family as the patients, the context of community-based nursing is family-centered care within the community. This focus requires a strong knowledge base in family theory (see Chapter 10), principles of communication (see Chapter 24), group dynamics, and cultural diversity (see Chapter 9). You learn to partner with your patients and families so ultimately the patient and family assume responsibility for their health care decisions.

Vulnerable Populations

In a community setting nurses care for patients from diverse cultures and backgrounds and with various health conditions. However, changes in the health care delivery system have made high-risk groups the principal patients. For example, you are not likely to visit low-risk mothers and babies. Instead, adolescent mothers or mothers with drug addiction are more likely to receive home care services. **Vulnerable populations** are groups of patients who are more likely to develop health problems as a result of excess health risks, who are limited in access to health care services, or who depend on others for care. Individuals living in poverty, older adults, people who are homeless, immigrant populations, individuals in abusive relationships, substance abusers, and people with severe mental illnesses are examples of vulnerable populations. Public and community health nursing and primary care providers share health care responsibility for health promotion, screening, and early detection and disease prevention for vulnerable populations. These patients have intense health care needs that are unmet or ignored or require more care than can be provided in outpatient or hospital settings (Kaiser et al., 2009). Vulnerable individuals and their families often belong to more than one of these

BOX 3-2 GUIDELINES FOR ASSESSING MEMBERS OF VULNERABLE POPULATION GROUPS

Setting the Stage

- Learn as much as you can about the culture of the patients with whom you work so you will understand cultural practices and values that influence their health care practices.
- Provide culturally and linguistically competent assessment by understanding the meaning of language and nonverbal behavior in a patient's culture.
- Be sensitive to the fact that the individual or family you are assessing has other priorities that are more important to them. These may include financial or legal problems. Do not provide financial or legal advice, but make sure to connect the patient with someone who will help them.

Nursing History of an Individual or Family

- You often have only one opportunity to work with a vulnerable person or family. Conduct an organized, complete history that provides all the essential information you need to help the individual or family.
- Use a modified comprehensive assessment form to focus on the special needs of the vulnerable population group.
- Include questions about social support, economic status, resources for health care, developmental issues, current health problems, medication, and how the person or family manages their health status.
- Determine if the individual has any acute, chronic, or communicable conditions.

Physical Examination or Home Assessment

- Complete a thorough physical examination (on an individual) or home assessment. Collect only useful data.
- Be alert for indications of mental and physical abuse, changes from normal physical examination findings (see Chapter 30), or substance use (e.g., underweight, being inadequately clothed).
- Observe a family's living environment. Is the environment safe and clean? Is there adequate plumbing? Are there cooking or laundry facilities? Is ventilation adequate? Is the family exposed to raw sewage or animal waste? What does the neighborhood look like?

From Sebastian JG: Vulnerability and vulnerable populations: an overview. In Stanhope M, Lancaster J: *Foundations of nursing in the community: community-oriented practice,* ed 3, St Louis, 2010, Mosby.

groups. In addition, health care vulnerability affects all age-groups (Sebastian, 2010).

Vulnerable patients often come from varied cultures, have different beliefs and values, face language and literacy barriers, and have few sources of social support. Their special needs will be a challenge for you as you care for increasingly complex acute and chronic health conditions.

To provide competent care for vulnerable populations, you need to assess these patients accurately (Box 3-2). In addition, you need to evaluate and understand a patient's and family's cultural beliefs, values, and practices to determine their specific needs and the interventions that will most likely be successful in improving their state of health (see Chapter 9). It is important not to judge or evaluate your patient's beliefs and values about health in terms of your own culture, beliefs, and values. Communication and caring practices are critical in learning a patient's perceptions of his or her problems and then planning health care strategies that will be meaningful, culturally appropriate, and successful.

Barriers to access and use of services often lead to adverse health outcomes for vulnerable populations (Rew et al., 2009). Because of these poorer outcomes, vulnerable populations have shorter life spans and higher morbidity rates. Members of vulnerable groups frequently have multiple risks, which make them more sensitive to the cumulative effects of individual risk factors. It is essential for community-based nurses to assess members of vulnerable populations by taking into account the multiple stressors that affect their patients' lives. It is also important to learn the patients' strengths and resources for coping with stressors. Complete assessment of vulnerable populations enables a community health nurse to design interventions within the context of a community (Rew et al., 2009).

Immigrant Population. Researchers predict that the immigrant population will reach a 54% majority by 2050 (U.S. Census Bureau, 2009). Immigrant populations face multiple diverse health issues that cities, counties, and states need to address. These health care needs pose significant legal and policy issues. For some immigrants access to health care is limited because of language barriers and lack of benefits, resources, and transportation. Immigrant populations often have higher rates of hypertension, diabetes mellitus, and infectious diseases; decreased outcomes of care; and shorter life expectancies (Stanhope and Lancaster, 2010).

Frequently the immigrant population practices nontraditional healing practices (see Chapter 9). Although many of these healing practices are effective and complement traditional therapies, it is important that you know and understand all of your patient's health care practices.

Certain immigrant populations left their homes as a result of oppression, war, or natural disaster (e.g., Afghans, Bosnians, and Somalis). Be sensitive to these physical and psychological stressors and consequences and identify the appropriate resources to help understand your patients and their health care needs (Stanhope and Lancaster, 2010).

Effects of Poverty and Homelessness. People who live in poverty are more likely to live in hazardous environments, work at high-risk jobs, eat less nutritious diets, have multiple stressors in their lives, and be at risk for homelessness. Patients with low income levels not only lack financial resources but also live in poor environments and face practical problems such as poor or unavailable transportation. Homeless patients have even fewer resources than the poor. They are often jobless and do not have the advantage of shelter and must continually cope with finding a place to sleep at night and finding food. Chronic health problems tend to worsen because of poor nutrition and the inability to store nutritional foods. In addition, the homeless population is usually walking the streets and neighborhoods to seek shelter, and they lack a balance of rest and activity (Schanzer et al., 2007). There is a startling increase in adolescent homelessness. The homeless adolescent is usually without a nuclear family and has greater health care risks because of immaturity, which increases the prevalence of risky behaviors (Rew et al., 2008).

Patients Who Are Abused. Physical, emotional, and sexual abuse and neglect are major public health problems affecting older adults, women, and children. Risk factors for abusive relationships include mental health problems, substance abuse, socioeconomic stressors, and dysfunctional family relationships (Landenburger and Campbell, 2010). For some, risk factors may not be present. When dealing with patients at risk for or who have suffered abuse, it is important to provide protection. Interview patients you suspect are abused at a time when the patient has privacy and the individual suspected of being the abuser is not present. Patients who are abused may fear retribution if they discuss their problems with a health care provider. Most states have abuse hot lines that nurses

TABLE 3-1 Common Health Problems in Community-Dwelling Older Adults

PROBLEM	NURSING ROLES AND INTERVENTIONS
Hypertension	Monitor blood pressure and weight; educate about nutrition and antihypertensive drugs; teach stress management techniques; promote an optimal balance between rest and activity; establish blood pressure screening programs; assess patient's current lifestyle and promote lifestyle changes; promote dietary modifications by using techniques such as a diet diary.
Cancer	Obtain health history; promote monthly breast self-examinations and annual Papanicolaou (Pap) smears and mammograms for older women; promote regular physical examinations; encourage smokers to stop smoking; correct mistaken beliefs about processes of aging; provide emotional support and quality of care during diagnostic and treatment procedures.
Arthritis	Educate adult about management of activities, correct body mechanics, availability of mechanical appliances, and adequate rest; promote stress management; counsel and assist family in improving communication, role negotiation, and use of community resources; teach adult to be cautious of false advertisements that promise a cure for arthritis.
Confusional states	Provide for a protective environment; promote activities that reinforce reality; assist with adequate personal hygiene, nutrition, and hydration; provide emotional support to the family; recommend applicable community resources such as adult day care, home care aides, and homemaker services.
Dementia	Maintain the best possible functioning, protection, and safety; foster human dignity; demonstrate to the primary family caregiver techniques to dress, feed, and toilet adult; provide frequent encouragement and emotional support to caregiver; act as an advocate for patient when dealing with respite care and support groups; protect patient's rights; provide support to maintain family members' physical and mental health; maintain family stability; recommend financial services if needed.
Medication use and abuse	Obtain drug history; educate adult about safe medication storage, the danger of polypharmacy, the risks of drug-drug and drug-food interactions, and general information about drug (e.g., drug name, purpose, side effects, dosage); instruct adult about presorting techniques (using small containers with one dose of drug that are labeled with specific administration times).

Data from Stanhope M, Lancaster J: *Foundations of nursing in the community: community-oriented practice,* ed 3, St Louis, 2010, Mosby; and Meiner S, Lueckenotte AG: *Gerontologic nursing,* ed 3, St Louis, 2006, Mosby.

and other health care providers must notify when they identify an individual as being at risk.

Patients Who Abuse Substances. *Substance abuse* is a term that describes more than the use of illegal drugs. It also includes the abuse of alcohol and prescribed medications such as antianxiety agents and opioid analgesics. A patient with substance abuse often has health and socioeconomic problems. The socioeconomic problems result from the financial strain of the cost of drugs, criminal convictions from illegal activities used to obtain drugs, communicable disease from sharing drug paraphernalia, and family breakdown. For example, health problems for cocaine users often include nasal and sinus disorders and cardiac alterations that are sometimes fatal (Decker et al., 2006; Schanzer et al., 2007). Objectively assess your patient's substance use in terms of the amount, frequency, and type of use to gain useful information to assist the patient. Frequently these patients avoid health care for fear of judgmental attitudes and concerns over being arrested by the police.

Patients with Mental Illnesses. When a patient has a severe mental illness such as schizophrenia or bipolar disorder, multiple health and socioeconomic problems need to be explored. Many patients with severe mental illnesses are homeless or live in poverty. Others lack the ability to remain employed or even to care for themselves on a daily basis (Cunningham et al., 2006). Patients suffering from mental illness often require medication therapy, counseling, housing, and vocational assistance. In addition, they are at a greater risk for abuse and assault.

Patients with mental illnesses are no longer routinely hospitalized in long-term psychiatric institutions. Instead, resources are offered within the community. Although comprehensive service networks are in every community, many patients still go untreated. Many patients are left with fewer and more fragmented services, with little skill in surviving and functioning within the community. Collaboration with multiple community resources is essential when helping patients with severe mental illness to obtain adequate health care.

Older Adults. With the increasing older-adult population, simultaneous increases in the number of patients suffering from chronic diseases and a greater demand for health care services are seen. You need to view health promotion in the older adult from a broad context. Take time to understand what health means to older-adult patients and the steps they take to maintain their own health and improve their level of function (Meiner and Leuckenotte, 2006). Thorough assessment and appropriate community-based interventions provide an opportunity to improve the lifestyle and quality of life of older adults (Table 3-1).

Competency in Community-Based Nursing

Nurses in community-based practices need a variety of skills and talents to successfully assist patients to meet their health care needs. To be successful in this setting you will be a caregiver, case manager, change agent, patient advocate, collaborator, educator, counselor, and epidemiologist (Teeley et al., 2006). These skills work together to help the patient remain in the home near his or her family and support system.

Caregiver. First and foremost is the role of caregiver. In the community setting you manage and care for the health of the community. You apply the nursing process (see Unit 3) in a

critical thinking approach to ensure appropriate, individualized nursing care for specific patients and their families. In addition, you individualize care within the context of the patient's community so long-term success is more likely. Together with the patient and family you develop a caring partnership to recognize actual and potential health care needs and identify needed community resources. As a caregiver, you also help to build a healthy community, which is one that is safe and includes elements to enable people to achieve and maintain a high quality of life and function.

Case Manager. In community-based practice, case management is an important competency (see Chapter 2). It is the ability to establish an appropriate plan of care based on assessment of patients and families and to coordinate needed resources and services for the patient's well-being across a continuum of care. Generally a community-based case manager assumes responsibility for the case management of multiple patients. The greatest challenge is coordinating the activities of multiple providers and payers in different settings throughout a patient's continuum of care. An effective case manager eventually learns the obstacles, limits, and even the opportunities that exist within the community that influence the ability to find solutions for patients' health care needs.

Change Agent. A community-based nurse is also a change agent. This involves identifying and implementing new and more effective approaches to problems. You act as a change agent within a family system or as a mediator for problems within a patient's community. You identify any number of problems (e.g., quality of community child care services, availability of older-adult day care services, or the status of neighborhood violence). As a change agent you empower individuals and their families to creatively solve problems or become instrumental in creating change within a health care agency. For example, if your patient has difficulty keeping regular health care visits, you determine why. Maybe the health clinic is too far and difficult to reach, or perhaps the hours of service are incompatible with the patient's transportation resourses. You work with the patient to solve the problem and help identify an alternative site such as a nursing clinic that is closer and has more convenient hours.

To effect change you gather and analyze facts before you implement the program. This requires you to be very familiar with the community itself. Many communities resist change, preferring to provide services in the established manner. Before analyzing facts, it is often necessary to manage conflict among the health care providers, clarify their roles, and clearly identify the needs of the patients. If the community has a history of poor problem solving, you will have to focus on developing problem-solving capabilities (Stanhope and Lancaster, 2010).

Patient Advocate. Patient advocacy is more important today in community-based practice because of the confusion surrounding access to health care services. Your patients often need someone to help them walk through the system and identify where to go for services, how to reach individuals with the appropriate authority, what services to request, and how to follow through with the information they receive. It is important to provide the information necessary for patients to make informed decisions in choosing and using services appropriately. In addition, it is important for you to support and at times defend your patients' decisions.

Collaborator. In a community-based nursing practice you need to be competent in working not only with individuals and their families but also with other related health care disciplines. Collaboration, or working in a combined effort with all those involved in care delivery, is necessary to develop a mutually acceptable plan that will achieve common goals (Stanhope and Lancaster, 2010). For example, when your patient is discharged home with terminal cancer, you collaborate with hospice staff, social workers, and pastoral care to initiate a plan to support end-of-life care for the patient and support the family. For collaboration to be effective, you will need mutual trust and respect for each professional's abilities and contributions.

Counselor. Knowing community resources is a critical factor in becoming an effective patient counselor. A counselor helps patients identify and clarify health problems and choose appropriate courses of action to solve those problems. For example, in employee assistance programs or women's shelters, a major amount of nurse-patient interaction is through counseling. As a counselor you are responsible for providing information, listening objectively, and being supportive, caring, and trustworthy. You do not make decisions but rather help your patients reach decisions that are best for them (Stanhope and Lancaster, 2010). Patients and families often require assistance in first identifying and clarifying health problems. For example, a patient who repeatedly reports a problem in following a prescribed diet is actually unable to afford nutritious foods or has family members who do not support good eating habits. You need to discuss with your patient factors that block or aid problem resolution, identify a range of solutions, and then discuss which solutions are most likely to be successful. You also encourage your patient to make decisions and express your confidence in the choice the patient makes.

Educator. In a community-based setting you have an opportunity to work with single individuals and groups of patients. Establishing relationships with community service organizations offers educational support to a wide range of patient groups. Prenatal classes, infant care, child safety, and cancer screening are just some of the health education programs provided in a community practice setting.

When the goal is to help your patients assume responsibility for their own health care, your role as an educator takes on greater importance (Stanhope and Lancaster, 2010). Patients and families must gain the skills and knowledge needed to learn how to care for themselves. Assess your patient's learning needs and readiness to learn within the context of the individual, the systems with which the individual interacts (e.g., family, business, and school), and the resources available for support. Adapt your teaching skills so you can instruct the patient within the home setting and make the learning process meaningful. In this practice setting you have the opportunity to follow patients over time. Planning for return demonstration of skills, using follow-up phone calls, and referring to community support and self-help groups give you an opportunity to provide continuity of instruction and reinforce important instructional topics (see Chapter 25).

Epidemiologist. As a community health nurse, you also apply principles of epidemiology. Your contacts with families, community groups such as schools and industries, and health care agencies place you in a unique position to initiate epidemiological activities. As an epidemiologist, you are involved in case finding, health teaching, and tracking incident rates of an illness. For example, a cafeteria worker in the local high school is diagnosed with active tuberculosis (TB). As a community health nurse, you help find new TB exposures or active disease within the worker's home, employment network, and community.

Nurse epidemiologists are responsible for community surveillance for risk factors (e.g., tracking incidence of elevated lead levels in children and identifying increased fetal and infant mortality

rates, increases in adolescent pregnancy, presence of infectious and communicable diseases, and outbreaks of head lice). Nurse epidemiologists protect the level of health of the community, develop sensitivity to changes in the health status of the community, and help identify the cause of these changes.

COMMUNITY ASSESSMENT

When practicing in a community setting, you need to learn how to assess the community at large. Community assessment is the systematic data collection on the population, monitoring the health status of the population, and making information available about the health of the community (Stanhope and Lancaster, 2010). This is the environment in which patients live and work. Without an adequate understanding of that environment, any effort to promote a patient's health and institute necessary change is unlikely to be successful. The community has three components: structure or locale, the people, and the social systems. To develop a complete community assessment, take a careful look at each of the three components to identify needs for health policy, health programs, and needed health services (Box 3-3).

When assessing the structure or locale, you travel around the neighborhood or community and observe its design, the location of services, and the locations where residents meet. You obtain the demographics of the population by accessing statistics on the community from a local public health department or public library. Acquire information about existing social systems such as schools or health care facilities by visiting various sites and learning about their services.

BOX 3-3 COMMUNITY ASSESSMENT

Structure
- Name of community or neighborhood
- Geographical boundaries
- Emergency services
- Water and sanitation
- Housing
- Economic status (e.g., average household income, number of residents on public assistance)
- Transportation

Population
- Age distribution
- Sex distribution
- Growth trends
- Density
- Education level
- Predominant ethnic groups
- Predominant religious groups

Social System
- Education system
- Government
- Communication system
- Welfare system
- Volunteer programs
- Health system

Once you have a good understanding of the community, perform all individual patient assessments against that background. For example, when assessing a patient's home for safety, you consider the following: does the patient have secure locks on doors? Are windows secure and intact? Is lighting along walkways and entryways operational? As you conduct the patient assessment, it is important to know the level of community violence and the resources available when help is necessary. Always assess an individual in the context of the community.

CHANGING PATIENTS' HEALTH

In community-based practice, nurses care for patients from diverse backgrounds and in diverse settings. It is relatively easy over time to become familiar with the available resources within a particular community practice setting. Likewise, with practice you learn how to identify the unique needs of individual patients. However, the challenge is promoting and protecting a patient's health within the context of the community. For example, can a patient with lung disease have the quality of life necessary in a community that has a serious environmental pollution problem? Similarly, nurses bring together the resources necessary to improve the continuity of care that patients receive. You are a key figure in reducing the duplication of health care services and locating the best services for a patient's needs.

Perhaps the most important theme to consider is how well you understand your patients' lives. This begins by establishing strong, caring relationships with patients and their families (see Chapter 7). As you gain experience, after being accepted by a patient's family you are able to advise, counsel, and teach effectively and understand what truly makes the patient unique. The day-to-day activities of family life are the variables that influence how you will adapt nursing interventions. The time of day a patient goes to work, the availability of the spouse and patient's parents to provide child care, and the family values that shape views about health are just a few examples of the many factors you will consider in community-based practice. Once you acquire a picture of a patient's life, you then design interventions to promote health and prevent disease within the community-based practice setting.

KEY POINTS

- Principles of public health nursing practice focus on assisting individuals and communities with achieving a healthy living environment.
- Essential public health functions include community assessment, policy development, and access to resources.
- When population-based health care services are effective, there is a greater likelihood that the higher levels of services will contribute efficiently to health improvement of the population.
- The community health nurse cares for the community as a whole and assesses the individual or family within the context of the community.
- Successful community health nursing practice involves building relationships with the community and being responsive to changes within the community.
- The community-based nurse's competence is based on decision making at the level of the individual patient.
- The special needs of vulnerable populations are a challenge that nurses face in caring for these patients' increasingly complex acute and chronic health conditions.

- A community-based nurse is competent as a caregiver, collaborator, educator, counselor, change agent, patient advocate, case manager, and epidemiologist.
- Patients are more likely to accept a change if it is more advantageous, compatible, realistic, and easy to adopt.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are managing community care for Katie, age 17, who has cerebral palsy and is severely disabled. Because of the impact of this adolescent's disability, you are also providing care to Monica, age 50, who is a single parent. Katie is the youngest of three children. Her siblings are Josh, age 22, and Marilyn, age 19. Katie attends the special education program of the local school district, and Monica works as a teachers' aide in another school in the district. Katie will remain in the special education program until she is 21. Monica does not know what will happen when Katie is 21, and she has not investigated any other community resources for Katie in the last 10 years. Both siblings are in college and live in the home and are helpful in Katie's care. Josh will graduate from college, and his mother is encouraging him to move from the home.

1. What do you need to assess in the community to identify resources that provide family support in the care of a disabled child?
2. What resources do you need to identify for the family to assist Katie's siblings in moving from the home and beginning their careers?
3. What can you do to help the family begin to envision the new family structure as Josh and Marilyn move out of the home?

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A community nurse in a diverse community is working with health care professionals to provide prenatal care for underemployed and underinsured South African women. Which overall goal of *Healthy People 2020* does this represent?
   1. Assess the health care needs of individuals, families, or communities
   2. Develop and implement public health policies and improve access to care
   3. Gather information on incident rates of certain diseases and social problems
   4. Increase life expectancy and quality of life and eliminate health disparities
2. Using *Healthy People 2020* as a guide, which of the following would improve delivery of care to a community? (Select all that apply.)
   1. Community assessment
   2. Implementing public health policies
   3. Increasing access to care
   4. Determining rates of specific illnesses
   5. Reducing the number of fast food restaurants in the community
3. A nursing student in the last semester of the baccalaureate nursing program is beginning the community health practicum and will be working in a community-based clinic with a focus on asthma and allergies. What is the focus of the community health nurse in this clinic setting? (Select all that apply.)
   1. Decreasing the incidence of asthma attacks in the community
   2. Increasing healthy food choices for school lunches
   3. Assessing for factors that contribute to asthmatic attacks in the community
   4. Providing asthma education programs for the teachers in the local schools
4. A nurse caring for a Bosnian community identifies that the children are undervaccinated and the community is unaware of resources. The nurse assesses the community and determines that there is a health clinic within a 5-mile radius. The nurse meets with the community leaders and explains the need for immunizations, the location of the clinic, and the process of accessing health care resources. Which of the following practices is the nurse providing? (Select all that apply.)
   1. Educating about community resources
   2. Teaching the community about illness prevention
   3. Promoting autonomy in decision making
   4. Improving the health care of the children in the community
5. Vulnerable populations of patients are those who are more likely to develop health problems as a result of:
   1. Chronic diseases and homelessness
   2. Poverty and acute illness
   3. Lack of transportation, ability to perform self-care but are homeless
   4. Excess health risks, limits in access to health care services, and dependency on others for care
6. Which of the following are major public health problems commonly affecting older adults? (Select all that apply.)
   1. Substance abuse
   2. Dementia
   3. Financial limitations
   4. Communicable diseases
   5. Chronic physical illnesses
7. The local health department received information from the Centers for Disease Control and Prevention that the flu was expected to be very contagious this season. The nurses set up flu vaccine clinics in local churches and senior citizen centers. This activity is an example of which level of prevention?
8. A neighborhood with old homes is undergoing a lot of restoration. Lead paint was used in the buildings. The clinic is initiating a lead screening program. This activity is an example of which level of prevention?
9. In an occupational health setting, the nurse determines that a large number of employees smoke and designs an employee assistance program for smoking cessation. This is an example of which nursing role:
   1. Educator
   2. Counselor
   3. Collaborator
   4. Case manager
10. The nurse in a community health clinic notices an increase in the number of positive tuberculosis skin tests from students in a local high school during the most recent academic year. After comparing these numbers to the previous years, a 10% increase in positive tests was found. The nurse contacts the school nurse and the director of the health department. Together they begin to expand their assessment to all students and employees of

the school district. The community health nurse is acting in which nursing role(s)? (Select all that apply.)
1. Epidemiologist
2. Counselor
3. Collaborator
4. Case manager

11. In the community clinic the nurse provides care for a 40-year-old woman who takes insulin to manage her diabetes. The patient is having increased difficulty managing her disease, and the nurse wants her to consider a new insulin pump to help her control it. Which of the following increases the likelihood that the patient will accept this new insulin pump? (Select all that apply.)
    1. Supporting the patient as she tries the insulin pump on a limited basis
    2. Identifying why the patient is reluctant to use the insulin pump
    3. Telling the patient that many other patients you know use the insulin pump successfully
    4. The patient's perception that the insulin pump is more consistent with her health care goals than insulin administration
12. The nurse in a new community-based clinic is requested to complete a community assessment. Order the steps for completing this assessment.
    1. Structure or locale
    2. Social systems
    3. Population
13. On the basis of an assessment, the nurse identifies an increase in the immigrant population group in the community. How would he or she determine some of the health needs of this population? (Select all that apply.)
    1. Identify which two health needs the immigrant population views as most important
    2. Apply information from *Healthy People 2020*
    3. Determine how the population uses available health care resources
    4. Identify perceived barriers for health care
    5. Implement an exercise program to help with weight loss
14. A patient is worried about her 76-year-old grandmother who is in very good health and wants to live at home. The patient's concerns are related to her grandmother's safety. The neighborhood does not have a lot of crime. Using this scenario, which of the following are the most relevant to assess for safety?
    1. Crime rate, locks, lighting, neighborhood traffic
    2. Lighting, locks, clutter, medications
    3. Crime rate, medications, support system, clutter
    4. Locks, lighting, neighborhood traffic, crime rate
15. The nurse is working with the county health department on a task force to fully integrate the goals of *Healthy People 2020*. How does the nurse determine which goals need to be included or updated? (Select all that apply.)
    1. Assesses the health care resources within the community
    2. Assesses the existing health care programs offered by the county health department
    3. Compares existing resources and programs with *Healthy People 2020* goals
    4. Initiates new programs to meet *Healthy People 2020* goals.

Answers: **1.** 4; **2.** 1, 2, 3, 4; **3.** 1, 2, 4; **4.** 1, 2, 4; **5.** 4; **6.** 1, 2, 3, 5; **7.** Tertiary intervention; **8.** Secondary intervention; **9.** 2; **10.** 1, 3; **11.** 1, 2, 4; **12.** 1, 3, 2; **13.** 1, 2, 3, 4; **14.** 2; **15.** 1, 2, 3.

CHAPTER

4

Theoretical Foundations of Nursing Practice

OBJECTIVES

- Explain the influence of nursing theory on a nurse's approach to practice.
- Describe types of nursing theories.
- Describe the relationship between nursing theory, the nursing process, and patient needs.
- Discuss selected theories from other disciplines.
- Discuss selected nursing theories.
- Describe theory-based nursing practice.

Providing patient-centered nursing care is an expectation for all nurses. As you progress through your curriculum, you will learn to apply knowledge from nursing science, social sciences, physical sciences, biobehavioral sciences, ethics, and health policy. To address individual and family responses to health problems, theory-based nursing practice is important for designing and implementing nursing interventions. Initially you might find nursing theory difficult to understand or appreciate. However, as you increase your knowledge about theories, you will find that they help to describe, explain, predict, and/or prescribe nursing care measures. For example, a theory about caring gives you a way to communicate with your patients and their families and individualize care to meet their needs (Watson, 2010; Sumner, 2010). The scientific work used in developing theories expands the scientific knowledge of the profession. Theories offer well-grounded rationales for how and why nurses perform specific interventions and for predicting patient behaviors and outcomes.

Expertise in nursing is a result of knowledge and clinical experience. The expertise required to interpret clinical situations and make clinical judgments is the essence of nursing care and the basis for advancing nursing practice and nursing science (Benner et al., 2010). As you progress through your courses, reflect and learn from your experiences to grow professionally and use well-developed theories as a basis for your approach to patient care.

THE DOMAIN OF NURSING

The **domain** is the perspective of a profession. It provides the subject, central concepts, values and beliefs, phenomena of interest, and central problems of a discipline. The domain of nursing provides both a practical and theoretical aspect of the discipline. It is the knowledge of nursing practice as well as the knowledge of nursing history, nursing theory, education, and research. The domain of nursing gives nurses a comprehensive perspective that allows you to identify and treat patients' health care needs at all levels and in all health care settings.

A **paradigm** is a pattern of thought that is useful in describing the domain of a discipline. A paradigm links the knowledge of science, philosophy, and theories accepted and applied by the discipline. The paradigm of nursing includes four links: the person, health, environment/situation, and nursing. The elements of the **nursing paradigm** direct the activity of the nursing profession, including knowledge development, philosophy, theory, educational experience, research, and practice (Alligood and Tomey, 2010).

Person is the recipient of nursing care, including individual patients, groups, families, and communities. The person is central to the nursing care you provide. Because each person's needs are

often complex, it is important to provide individualized patient-centered care.

Health has different meanings for each patient, the clinical setting, and the health care profession (see Chapter 6). It is dynamic and continuously changing. Your challenge as a nurse is to provide the best possible care based on the patient's level of health and health care needs at the time of care delivery.

Environment/situation includes all possible conditions affecting patients and the settings in which their health care needs occur. There is a continuous interaction between a patient and the environment. This interaction has positive and negative effects on the person's level of health and health care needs. Factors in the home, school, workplace, or community all influence a patient's level of health and health care needs. For example, an adolescent girl with type 1 diabetes needs to adapt her treatment plan to adjust for physical activities of school, the demands of a part-time job, and the timing of social events such as her prom.

Nursing is the "… diagnosis and treatment of human responses to actual or potential health problems …" (American Nurses Association, 2010). The scope of nursing is broad. For example, a nurse does not medically diagnose a patient's health condition as heart failure. However, a nurse will assess a patient's response to the decrease in activity tolerance as a result of the disease and develop nursing diagnoses of fatigue, activity intolerance, and ineffective coping. From these nursing diagnoses the nurse creates a patient-centered plan of care for each of the patient's health problems (see Unit 3). Use critical thinking skills to integrate knowledge, experience, attitudes, and standards into the individualized plan of care for each of your patients (see Chapter 15).

THEORY

Theories are designed to explain a phenomenon such as self-care or caring. For example, the nurse using Orem's self-care deficit theory helps to explain how patients meet their own therapeutic self-care demands. In this theory, nurses assist patients by acting for them or guiding necessary physical and/or psychological support (Alligood, 2010). Orem's theory contains a detailed framework of self-care concepts that are linked in such a way as to explain, describe, or predict the type of nursing care that helps patients achieve a better level of health (McEwen and Willis, 2011). A theory is a way of seeing through a "set of relatively concrete and specific concepts and the propositions that describe or link the concepts" (Fawcett, 2005).

A **nursing theory** is a conceptualization of some aspect of nursing that describes, explains, predicts, or prescribes nursing care (Meleis, 2011). For example, Orem's self-care deficit theory (2001) explains the factors within a patient's living situation that support or interfere with his or her self-care ability. As a result, a nurse who practices using this theory can anticipate such factors when designing an education plan for the patient. This theory has value in helping nursing design interventions to promote the patient's self-care in managing an illness such as asthma, heart failure, diabetes, or arthritis.

Theories constitute much of the knowledge of a discipline. Theory and scientific inquiry are vital links to one another, providing guidelines for decision making, problem solving, and nursing interventions (Selanders, 2010). Theories give us a perspective for assessing our patients' situations and organizing data and methods for analyzing and interpreting information. For example, if you use Orem's theory in practice, you assess and interpret data to determine patients' self-care needs, self-care deficits, and self-care abilities in the management of their disease. The theory then guides the design of patient-centered nursing interventions. Application of nursing theory in practice depends on the knowledge of nursing and other theoretical models, how they relate to one another, and their use in designing nursing interventions.

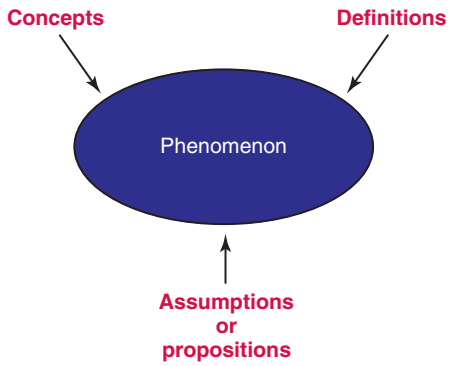

FIG. 4-1 Components of a nursing theory.

Nursing is a science and an art. Nurses need a theoretical base to demonstrate knowledge about the science and art of the profession when they promote health and wellness for their patients, whether the patient is an individual, a family, or a community (Porter, 2010). A nursing theory helps to identify the focus, means, and goals of practice. Common theories enhance communication and increase autonomy and accountability for care to our patients (Meleis, 2011).

Components of a Theory

A **theory** contains a set of concepts, definitions, and assumptions or propositions that explain a phenomenon. The theory explains how these elements are uniquely related in the phenomenon (Fig. 4-1). For example, Kristin Swanson developed her theory about the phenomenon of caring by conducting extensive interviews with patients and their professional caregivers (Swanson, 1991). Swanson's theory of caring defines five components of caring: knowing, being with, doing for, enabling, and maintaining belief (see Chapter 7). These components provide a foundation of knowledge for nurses to direct and deliver caring nursing practices. Researchers test theories, and as a result they get a clearer perspective of all parts of a phenomenon. Swanson's theory of caring is one that provides a basis for identifying and testing nurse caring behaviors to determine if caring improves patient health outcomes (Watson, 2010).

Phenomenon. Nursing theories focus on the phenomena of nursing and nursing care. A **phenomenon** is the term, description, or label given to describe an idea or responses about an event, a situation, a process, a group of events, or a group of situations (Meleis, 2011). This phenomenon may be temporary or permanent. Examples of phenomena of nursing include caring, self-care, and patient responses to stress. For example, in Neuman's systems model (2011), phenomena focus on stressors perceived by the patient or caregiver. The theoretical model is an open systems model that views nursing as being primarily concerned with nursing actions in stress-related situations. These stressors may include, but are not limited to, patient responses, internal and external environmental factors, and nursing actions.

Concepts. A theory also consists of interrelated concepts. These **concepts** can be simple or complex and relate to an object or event that comes from individual perceptual experiences (Alligood

and Tomey, 2010). Think of concepts as ideas and mental images. They help describe or label phenomena. Again, using Neuman's systems model (2011) as an example, there are concepts that affect the patient system. The patient system can be an individual, a group, a family, or a community. This system is an open structure that includes internal and external environmental factors. These concepts are physiological, psychological, sociocultural, developmental, and spiritual and may relate to health and wellness, illness prevention, stressors, and defense mechanisms (Meleis, 2011).

Definitions. The definitions within a theory communicate the general meaning of the concepts. These definitions describe the activity necessary to measure the concepts within a theory (Alligood and Tomey, 2010). For example, Neuman's model uses an open systems approach to describe how patient systems deal with stressors in their environments. A stressor is any stimuli that can produce tension and cause instability within the system. The environment includes internal and external factors that have the potential to affect the patient system. Internal factors exist within the patient system (e.g., the physiological and behavioral responses to illnesses). External factors are outside the patient system (e.g., changes in health care policy or an increase in the crime rate). It is important that nurses using Neuman's theory in practice focus their care on the system's responses to the stressors (Meleis, 2011). For example, when patients receive a new diagnosis and perceive the diagnosis to be stressful, they may react by withdrawing or eating an improper diet. In this situation the nurse focuses on both the illness process and the patient's response to the stressors and designs appropriate interventions.

Assumptions. **Assumptions** are the "taken-for-granted" statements that explain the nature of the concepts, definitions, purpose, relationships, and structure of a theory (Meleis, 2011). For example, in Neuman's systems model the assumptions include the following: patients are dynamic; the relationships between the concepts of a theory influence a patient's protective mechanisms and determine a patient's response; patients have a normal range of responses; stressors attack flexible lines of defense followed by the normal lines of defense; and the nurse's actions focus on primary, secondary, and tertiary prevention (Neuman, 2011).

Types of Theory

The general purpose of a theory is important because it specifies the context and situation in which the theory applies (Chinn and Kramer, 2011). For example, theories about pain focus on pain: its cause, effects, and alleviation measures. Theories have different purposes and are sometimes classified by levels of abstraction (grand theories versus middle-range theories) or the goals of the theory (descriptive or prescriptive). For example, a descriptive theory describes a phenomenon such as grief or caring. A predictive theory identifies conditions or factors that predict a phenomenon. A prescriptive theory details nursing interventions for a specific phenomenon and the expected outcome of the care. Box 4-1 summarizes goals of theoretical nursing models.

Grand theories are systematic and broad in scope, complex, and therefore require further specification through research. A grand theory does not provide guidance for specific nursing interventions; but it provides the structural framework for broad, abstract ideas about nursing. For example, Neuman's systems model is a grand theory that provides a comprehensive foundation for scientific nursing practice, education, and research (Walker and Avant, 2009).

Middle-range theories are more limited in scope and less abstract. They address a specific phenomenon and reflect practice (administration, clinical, or teaching). A middle-range theory tends to focus on a specific field of nursing, such as uncertainty, incontinence, social support, quality of life, and caring, rather than reflect on a wide variety of nursing care situations (Meleis, 2011). For example, Mishel's theory of uncertainty in illness (1990; 1997) focuses on patients' experiences with cancer while living with continual uncertainty. The theory provides a basis to help nurses understand how patients cope with uncertainty and the illness response.

Descriptive theories are the first level of theory development. They describe phenomena, speculate on why they occur, and describe their consequences. These theories explain, relate, and in some situations predict nursing phenomena (Meleis, 2011). For example, theories of growth and development describe the maturation processes of an individual at various ages (see Chapter 11). Descriptive theories do not direct specific nursing activities but help to explain patient assessments.

Prescriptive theories address nursing interventions for a phenomenon, describe the conditions under which the prescription (i.e., nursing interventions) occurs, and predict the consequences (Meleis, 2011). Prescriptive theories are action oriented and test the validity and predictability of a nursing intervention. These theories guide nursing research to develop and test specific nursing interventions (George, 2011). For example, Mishel's theory of uncertainty predicts that increasing the coping skills of patients with gynecological cancer assists their ability to deal with the uncertainty of the cancer diagnosis and treatment (Mishel, 1997). Thus the theory provides a framework to design interventions that support and strengthen patients' coping resources.

BOX 4-1 GOALS OF THEORETICAL NURSING MODELS

- Identify domain and goals of nursing.
- Provide knowledge to improve nursing administration, practice, education, and research.
- Guide research and expand the knowledge base of nursing.
- Identify research techniques and tools used to validate nursing interventions.
- Formulate legislation governing nursing practice, research, and education.
- Formulate regulations interpreting nurse practice acts.
- Develop curriculum plans for nursing education.
- Establish criteria for measuring quality of nursing care, education, and research.
- Guide development of a nursing care delivery system.
- Provide systematic structure and rationale for nursing activities.

Theory-Based Nursing Practice

Nursing is a practice-oriented discipline. Nursing knowledge is derived from basic and nursing sciences, experience, aesthetics, nurses' attitudes, and standards of practice. As nursing continues to grow as a profession, knowledge is needed to prescribe specific interventions to improve patient outcomes. Nursing theories and related concepts continue to evolve. Florence Nightingale spoke with firm conviction about the "nature of nursing as a profession that requires knowledge distinct from medical knowledge" (Nightingale, 1860; Selanders, 2010). The overall goal of nursing knowledge is to explain the practice of nursing as different and distinct from the practice of medicine, psychology, and other health care disciplines. Theory generates nursing knowledge for use

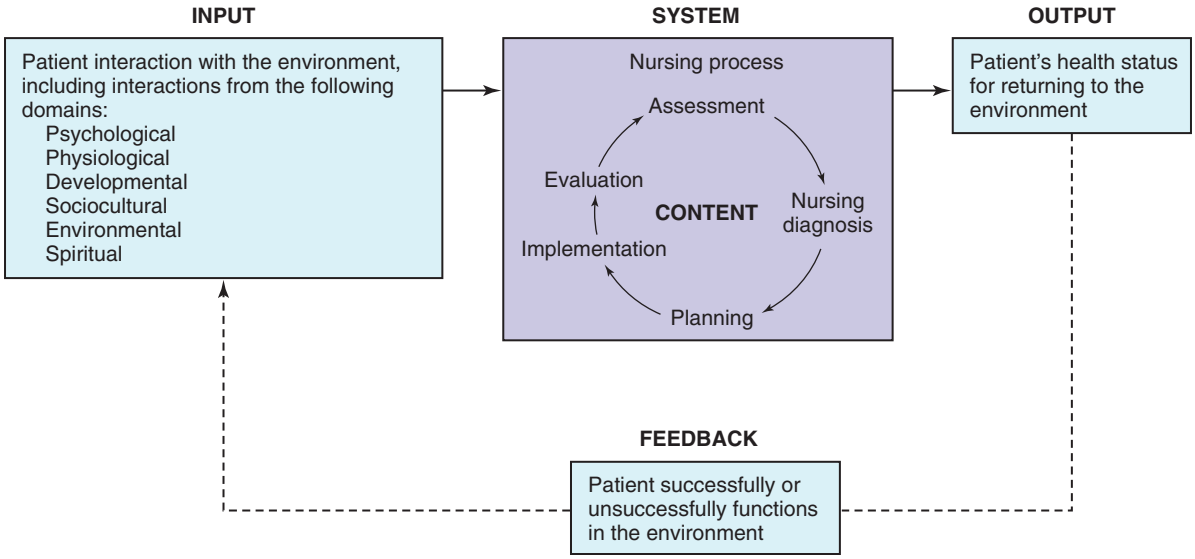

FIG. 4-2 Nursing process as a system.

in practice, thus supporting evidence-based practice. The integration of theory into practice is the basis for professional nursing (McEwen and Wills, 2011).

The nursing process is used in clinical settings to determine individual patient needs (see Unit 3). Although the nursing process is central to nursing, it is not a theory. It provides a systematic process for the delivery of nursing care, not the knowledge component of the discipline. However, a theory can direct how a nurse uses the nursing process. For example, the theory of caring influences what to assess, how to determine patient needs, how to plan care, how to select individualized nursing interventions, and how to evaluate patient outcomes.

INTERDISCIPLINARY THEORIES

To practice in today's health care systems, nurses need a strong scientific knowledge base from nursing and other disciplines such as the physical, social, and behavioral sciences. Knowledge from these other disciplines includes relevant theories that explain phenomena. An **interdisciplinary theory** explains a systematic view of a phenomenon specific to the discipline of inquiry. For example, Piaget's theory of cognitive development helps to explain how children think, reason, and perceive the world (see Chapter 11). Knowledge and use of this theory helps pediatric nurses design appropriate therapeutic play interventions for ill toddlers or school-age children.

Systems Theory

A system is composed of separate components. The components are interrelated and share a common purpose to form a whole. There are two types of systems, open and closed. An open system such as a human organism or a process such as the nursing process interacts with the environment, exchanging information between the system and the environment. Factors that change the environment also affect an open system. Neuman's systems theory (2011) defines a total-person model of wholism and an open-systems approach. A closed system such as a chemical reaction within a test tube does not interact with the environment.

Like all systems, the nursing process has a specific purpose or goal (see Unit 3). The goal of the nursing process is to organize and deliver patient-centered care. As a system the nursing process has the following components: input, output, feedback, and content (Fig. 4-2). **Input** for the nursing process is the data or information that comes from a patient's assessment (e.g., how the patient interacts with the environment and the patient's physiological function). **Output** is the end product of a system; and in the case of the nursing process it is whether the patient's health status improves, declines, or remains stable as a result of nursing care.

Feedback serves to inform a system about how it functions. For example, in the nursing process the outcomes reflect the patient's responses to nursing interventions. The outcomes are part of the feedback system to refine the plan of care. Other forms of feedback in the nursing process include responses from family members and consultation from other health care professionals.

The **content** is the product and information obtained from the system. Again, using the nursing process as an example, the content is the information about the nursing interventions for patients with specific health care problems. For example, patients with impaired bed mobility have common skin care needs and interventions (e.g., hygiene and scheduled positioning changes) that are very successful in reducing the risk for pressure ulcers.

Basic Human Needs

Maslow's hierarchy of needs is an interdisciplinary theory that is useful for designating priorities of nursing care (see Fig. 6-3, p. 69.) The hierarchy of basic human needs includes five levels of priority. The most basic, or first level, includes physiological needs such as air, water, and food. The second level includes safety and security needs, which involve physical and psychological security. The third level contains love and belonging needs, including friendship, social relationships, and sexual love. The fourth level encompasses esteem and self-esteem needs, which involve self-confidence, usefulness, achievement, and self-worth. The final level is the need for self-actualization, the state of fully achieving potential and having the ability to solve problems and cope realistically with situations of life. When using this hierarchy, basic physiological and safety needs are usually the first priority, especially when a

patient is severely dependent physically. However, you will encounter situations in which a patient has no emergent physical or safety needs. Instead, you will give high priority to the psychological, sociocultural, developmental, or spiritual needs of the patient.

Patients entering the health care system generally have unmet needs. For example, a person brought to an emergency department experiencing acute pneumonia has an unmet need for oxygen, the most basic physiological need. An older woman in a high-crime area is concerned about physical safety. A widowed homemaker whose children have moved away feels that she does not belong or is not loved. The hierarchy of needs is a way to plan for individualized patient care.

Developmental Theories

Human growth and development are orderly predictive processes that begin with conception and continue through death. A variety of well-tested theoretical models describe and predict behavior and development at various phases of the life continuum. Chapter 11 details these developmental theories, and Chapters 12 through 14 demonstrate changes in growth and development in various age-groups.

Psychosocial Theories

Nursing is a diverse discipline that strives to meet the physiological, psychological, sociocultural, developmental, and spiritual needs of patients. Theoretical models to explain and/or predict patient responses exist in each of these domains. For example, Chapter 9 discusses models for understanding cultural diversity and implementing care to meet the diverse needs of the patient. Chapter 10 describes family theory and how to meet the needs of the family when the family is the patient or when the family is the caregiver. Chapter 36 discusses several models of grieving and demonstrates how to assist patients through loss, death, and grief.

SELECTED NURSING THEORIES

Definitions and theories of nursing can help you understand the practice of nursing. The following sections describe, in chronological order of theory development, selected theories and their concepts (Table 4-1).

Nightingale's Theory

Florence Nightingale's work was an initial model for nursing. Meleis (2011) notes that Nightingale's concept of the environment was the focus of nursing care and her suggestion that nurses need not know all about the disease process differentiated nursing from medicine. The focus of nursing is caring through the environment and helping the patient deal with the symptoms and changes in function related to an illness (Selanders, 2010).

Nightingale did not view nursing as limited to the administration of medications and treatments but oriented toward providing fresh air, light, warmth, cleanliness, quiet, and adequate nutrition (Nightingale, 1860). Through observation and data collection, she linked the patient's health status with environmental factors and initiated improved hygiene and sanitary conditions during the Crimean War.

Nightingale's "descriptive theory" provides nurses with a way to think about patients and their environment. Her letters and writings direct the nurse to act on behalf of the patient. Her visionary principles included the areas of practice, research, and education. Most important, her concepts and principles shaped and defined nursing practice (Alligood and Tomey, 2010). Nightingale taught and used the nursing process, noting that "vital observation [assessment] … is not for the sake of piling up miscellaneous information or curious facts, but for the sake of saving life and increasing health and comfort (Nightingale, 1860)."

Peplau's Theory

Hildegard Peplau's theory (1952) focuses on interpersonal relations between the nurse, the patient, and the patient's family and developing the nurse-patient relationship. The patient is an individual with a need, and nursing is an interpersonal and therapeutic process. This nurse-patient relationship is influenced by both the nurse's and the patient's perceptions and preconceived ideas (George, 2011).

In developing a nurse-patient relationship, the nurse can serve as a resource person, counselor, and surrogate. For example, when the patient seeks help, the nurse and patient first discuss the nature of any problems, and the nurse explains the services available. As the nurse-patient relationship develops, the nurse and patient mutually define the problems and potential solutions. The patient gains from this relationship by using available services to meet needs, and the nurse helps the patient reduce anxiety related to the health care problems.

Peplau's theory is unique: the collaborative nurse-patient relationship creates a "maturing force" through which interpersonal effectiveness meets the patient's needs. This theory is useful in establishing effective nurse-patient communication when obtaining a nursing history, providing patient education, or counseling patients and their families (see Chapter 24). When the patient's original needs are resolved, new needs sometimes emerge. According to Peplau, the following phases characterize the nurse-patient interpersonal relationship: orientation, working phase, and termination (George, 2011).

Henderson's Theory

Virginia Henderson defines nursing as "assisting the individual, sick or well, in the performance of those activities that will contribute to health, recovery, or a peaceful death and that the individual would perform unaided if he or she had the necessary strength, will, or knowledge" (Harmer and Henderson, 1955; Henderson, 1966). Henderson organized the theory into 14 basic needs of the whole person and includes phenomena from the following domains of the patient: physiological, psychological, sociocultural, spiritual, and developmental. The interpersonal relationship between the nurse and the patient creates a caring environment to identify the patient's needs, plan the goals of care, and provide patient-centered nursing care (George, 2011). Framing nursing care around the needs of the individual allows you to use Henderson's theory for a variety of patients across the life span and in multiple settings along the health care continuum.

Orem's Theory

Dorothea Orem's self-care deficit theory (2001) focuses on the patient's self-care needs. Orem defines self-care as a learned, goal-oriented activity directed toward the self in the interest of maintaining life, health, development, and well-being. The goal of Orem's theory is to help the patient perform self-care and manage his or her health problems. Nursing care is necessary when the patient is unable to fulfill biological, psychological, developmental, or social needs. This theory works well in all steps of the nursing process (George, 2011). The nurse assesses and determines why a patient is unable to meet these needs, identifies goals to assist the

TABLE 4-1 **Summary of Nursing Theories**

THEORIST	GOAL OF NURSING	FRAMEWORK FOR PRACTICE
Nightingale—1860	Facilitate the reparative processes of the body by manipulating patient's environment	Nurse manipulates patient's environment to include appropriate noise, nutrition, hygiene, light, comfort, socialization, and hope.
Peplau—1952	Develop interaction between nurse and patient	Nursing is a significant, therapeutic, interpersonal process. Nurses participate in structuring health care systems to facilitate interpersonal relationships.
Henderson—1955	Work interdependently with other health care workers, assisting patient in gaining independence as quickly as possible; help patient gain lacking strength	Nurses help patient perform Henderson's 14 basic needs.
Orem—1971	Care for and help patient attain total self-care	Nursing care is necessary when the patient is unable to fulfill biological, psychological, developmental, or social needs.
King—1971	Use communication to help patient reestablish positive adaptation to environment	Nursing is a dynamic interpersonal process among nurse, patient, and health care system.
Neuman—1974	Help individuals, families, and groups attain and maintain maximal level of total wellness by purposeful interventions	Stress reduction is goal of systems model of nursing practice. Nursing actions are in primary, secondary, or tertiary level of prevention.
Leininger—1978	Provide care consistent with nursing's emerging science and knowledge with caring as central focus	With this transcultural care theory, caring is the central and unifying domain for nursing knowledge and practice.
Roy—1970	Identify types of demands placed on patient, assess adaptation to demands, and help patient adapt	This adaptation model is based on the physiological, psychological, sociological, and dependence-independence adaptive modes.
Watson—1979	Promote health, restore patient to health, and prevent illness	Involves the philosophy and science of caring. Caring is an interpersonal process comprising interventions to meet human needs.
Benner and Wrubel—1989	Focus on patient's need for caring as a means of coping with stressors of illness	Caring is central to the essence of nursing. It creates the possibilities for coping and enables possibilities for connecting with and concern for others.

Modified from Chinn PL, Kramer ML: *Integrated knowledge development in nursing,* ed 8, St. Louis, 2011, Mosby.

patient, intervenes to help the patient perform self-care, and evaluates how much self-care the patient is able to perform. According to Orem's theory, the goal of nursing is to increase the patient's ability to independently meet these needs (George, 2011; Orem, 2001).

Leininger's Theory

Leininger used her background in anthropology to form her theory of cultural care diversity and universality (Alligood, 2010). Human caring varies among cultures in its expressions, processes, and patterns. Social structure factors such as the patient's religion, politics, culture, and traditions are significant forces affecting care and influencing the patient's health and illness patterns. While reading the chapter on culture, think about the diversity of the patients and their nursing care needs (see Chapter 9). The major concept of Leininger's theory is cultural diversity, and the goal of nursing care is to provide the patient with culturally specific nursing care (Alligood, 2010; Leininger, 1991). To provide care to patients of unique cultures, the nurse safely integrates the patient's cultural traditions, values, and beliefs into the plan of care. Leininger's theory recognizes the importance of culture and its influence on everything that involves the patient and the providers of nursing care (George, 2011). For example, some cultures believe that the leader in the community needs to be present during health care decisions. As a result, the health care team may need to reschedule when rounds occur to include the community leader. In addition, symptom expression also differs among cultures. A person with an Irish background might be stoic and not complain about pain, whereas a person from a Middle Eastern culture might be very vocal about pain. In both cases the nurse needs to skillfully incorporate the patient's cultural practices in assessing the patient's level of pain (e.g., is the pain getting worse or remaining the same?).

Betty Neuman's Theory

The Neuman systems model is based on stress and the client's reaction to the stressor (George, 2011). In this model the client is the individual, group, family, or community. The system is composed of five concepts that interact with one another: physiological, psychological, sociocultural, developmental, and spiritual (Neuman, 2011). These concepts interact with both internal and external environmental factors and all levels of prevention (primary, secondary, and tertiary) to achieve optimal wellness (Neuman and Reed, 2007). Neuman considers any internal and external factors as stressors (Alligood, 2010) that affect the patient's stability and any or all of the five system concepts. The role of nursing is to stabilize the patient or situation. When you apply the Neuman systems model, you assess the stressor and the patient's response to the stressor, identify nursing diagnoses, plan patient-centered care, implement interventions, evaluate the patient's response, and determine if the stressor is resolved.

BOX 4-2 EVIDENCE-BASED PRACTICE

Theory-Based Practice in the Management of Heart Failure

PICO Question: What impact does applying the Roy adaptation model have on improved functional status in patients with heart failure?

Evidence Summary

The Roy adaptation model is a nursing discipline-specific theoretical model used to guide practice (Roy et al., 2009). The model is applicable in multiple settings with patients across the life span. According to this theory people adapt to changing environmental stimuli, and this adaptation is useful in assisting patients toward recovery (DeSanto-Madeya and Fawcett, 2009). An experimental study was designed to determine the effects of the Roy adaptation model on patient education, exercise, and social support systems in patients with heart failure (Bakan and Akyol, 2008). Patients were taught how medications, diet, and exercise improved their activity tolerance. They learned how to adapt their exercise prescription so they gradually increased their tolerance. In addition, the patients' support system also participated in the education and exercise program and became part of the patients' adaptation resources. The study documented that the patients in the experimental group benefited from application of the Roy adaptation model in their cardiac rehabilitation.

Application to Nursing Practice

- When using a nursing theory such as Roy's adaptation model, patients can learn techniques to improve their ability to adapt to an illness or condition.
- Involving a patient's support system increases the patient's ability to use adaptive techniques.
- Nursing theories readily support theory-based nursing practices and define the specific interventions for patients.
- Use of literature resources supports theory-based interventions.

Roy's Theory

The Roy adaptation model (Roy, 1989; Roy et al., 2009) views the patient as an adaptive system. According to Roy's model, the goal of nursing is to help the person adapt to changes in physiological needs, self-concept, role function, and interdependent relations during health and illness (Alligood and Tomey, 2010). The need for nursing care occurs when the patient cannot adapt to internal and external environmental demands. All individuals must adapt to the following demands: meeting basic physiological needs, developing a positive self-concept, performing social roles, and achieving a balance between dependence and independence.

The nurse determines which demands are causing problems for a patient and assesses how well the patient is adapting to them. Nurses direct care at helping the patient adapt to the changes (George, 2011; Alligood, 2010). For example, a patient recovering from a worsening of heart failure needs nursing interventions to assist in adapting to the resultant activity in tolerance (Box 4-2).

Watson's Theory

Jean Watson's theory of transpersonal caring (2005, 2008) defines the outcome of nursing activity in regard to the humanistic aspects of life (Alligood and Tomey, 2010). The purpose of nursing action is to understand the interrelationship among health, illness, and human behavior. Thus nursing is concerned with promoting and restoring health and preventing illness.

Watson designed the model around the caring process, assisting patients in attaining or maintaining health or dying peacefully (Watson, 2005). This caring process requires the nurse to be knowledgeable about human behavior and human responses to actual or potential health problems (see Chapter 7). The nurse also needs to know individual patient needs, how to respond to others, and strengths and limitations of the patient and family and those of the nurse. In addition, the nurse comforts and offers compassion and empathy to patients and their families. Caring represents all factors the nurse uses to deliver care to the patient (Watson, 1996).

Benner and Wrubel's Theory

The primacy of caring is a model proposed by Patricia Benner and Judith Wrubel (1989). Caring is central to nursing and creates possibilities for coping, enables possibilities for connecting with and concern for others, and allows for giving and receiving help (Chinn and Kramer, 2011). Caring means that persons, events, projects, and things matter to people. It presents a connection and represents a wide range of involvement (e.g., caring about one's family, one's friendships, and one's patients). Benner and Wrubel see the personal concern as an inherent feature of nursing practice. In caring for one's patients, nurses help patients recover by noticing interventions that are successful and that guide future caregiving.

• • •

Application of nursing theory in practice depends on nurses having knowledge of the theories and an understanding of how they relate to one another. Theories are the organizing frameworks for the science of nursing and the substantive approaches for nursing care. They provide critical thinking structures to guide clinical reasoning and problem solving.

LINK BETWEEN THEORY AND KNOWLEDGE DEVELOPMENT IN NURSING

Nursing has its own body of knowledge that is both theoretical and experiential. Theoretical knowledge includes and "reflects on the basic values, guiding principles, elements, and phases of a conception of nursing" (Meleis, 2011). The goals of theoretical knowledge stimulate thinking and create a broad understanding of the "science" and practices of the nursing discipline.

Experiential knowledge is not organized in the same manner as theoretical knowledge. This type of knowledge or the "art" of nursing is based on nurses' experience in providing care to patients. You achieve this through personal knowledge gained through reflection on care experiences, synthesis, and integration of the art and science of nursing.

Nursing theories help direct nursing practice. When using theory-based nursing practice, you apply the principles of the theory in delivering nursing interventions in your practice. Theory-based nursing practice improves nurse satisfaction and patient outcomes because the basic values, guiding principles, and elements from the foundation of a particular nursing theory give meaning to the practice and influence how patient care is provided (Veo, 2010).

Relationship Between Nursing Theory and Nursing Research

The relationship between nursing theory and nursing research builds the scientific knowledge base of nursing, which is then applied to practice. As more research is conducted, the discipline learns to what extent a given theory is useful in providing information to improve patient care. The relationships of components in a theory often help drive the research questions. For example, the

components within Orem's self-care deficit theory have led nurse researchers to test interventions for improving self-care. In one study, older hospitalized adults were able to learn their medication schedules and improve their activities of daily living before discharge, were discharged earlier, and had fewer complications (Glasson et al., 2006).

Sometimes research is used to identify new theories. Theory-generating research tries to discover and describe relationships of phenomena without imposing preconceived notions (e.g., hypotheses) of what the phenomena under study mean (George, 2011). In theory-generating research the investigator makes observations to view a phenomenon in a new way. For example, a researcher wants to understand end-of-life decision making. In this example, the researcher interviews surrogate decision makers. From these interviews he or she makes objective observations about the surrogate's decision-making process, resulting in an initial theory of surrogate decision making (Loomis, 2009).

Theory-testing research determines how accurately a theory describes a nursing phenomenon. Testing helps to develop the evidence for describing or predicting patient outcomes. The researcher has some preconceived idea as to how patients describe or respond to a phenomenon and generates research questions or hypotheses to test the assumptions of the theory. No one study tests all components of a theory; researchers test the theory through a variety of research activities. Referring to the previous example of surrogate decision making, the researcher tests elements of the theory. For example, interviews of decision makers indicated that there was a need for more knowledge about end-of-life care expectations (Loomis, 2009). The researcher then designs and tests an educational program that incorporates end-of-life expectation with one that does not to determine which is most effective for groups of surrogate caregivers. Theory-generating or theory-testing research refines the knowledge base of nursing. As a result, nurses incorporate research-based interventions into theory-based practice. As research activities continue, not only does the knowledge and science of nursing increase, but patients are the recipients of the best evidence-based nursing practice (see Chapter 5).

As an art, nursing relies on knowledge gained from practice and reflection on past experiences. As a science, nursing draws on scientifically tested knowledge applied in the practice setting (Kikuchi, Simmons, and Romyn, 1996). But it is the "expert nurse" who transports the art and science of nursing into the scientific realm of creative caring.

KEY POINTS

- A nursing theory is a conceptualization of some aspect of nursing communicated for the purpose of describing, explaining, predicting, and/or prescribing nursing care.
- Grand theories are the complex structural framework for broad, abstract ideas.
- Middle-range theories are more limited in scope and less abstract. These theories address specific phenomena or concepts and reflect practice.
- The paradigm of nursing identifies four links of interest to the profession: the person, health, environment/situation, and nursing. Nurse theorists agree that these four components are essential to the development of theory.
- Theory is the generation of nursing knowledge used for practice. Nursing process is the method for applying the theory or knowledge. The integration of theory and nursing process is the basis for professional nursing.
- Theories from nursing and other disciplines help explain how the roles and actions of nurses fit together in nursing.
- Theory-generating research tries to discover and describe relationships without imposing preconceived notions (e.g., hypotheses) of what the phenomenon under study means.
- Theory-testing research determines how accurately a theory describes nursing phenomena.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Kathy Jones and Sheri Walker are sophomores in a college program. Next week they will have their first clinical practice. Kathy will be in a community health setting, and Sheri will be in an acute health care agency. They need to prepare general assessment questions applicable to both settings using Orem's self-care deficit theory. Explain how the theory might apply for patient assessment in different health care settings.
   a. Acute care
   b. Community-based care
2. In a classroom setting you are given the following examples of questions that lead either to theory-generating or theory-testing research. Identify whether they are theory testing or theory generating and explain.
   a. Do patients who receive a prescribed exercise program wean more quickly from the mechanical ventilator?
   b. What are the perspectives of patients who are weaned from mechanical ventilation?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Which of the following are components of the paradigm of nursing?
   1. The person, health, environment, and theory
   2. Health, theory, concepts, and environment
   3. Nurses, physicians, health, and patient needs
   4. The person, health, environment/situation, and nursing
2. A theory is a set of concepts, definitions, relationships, and assumptions that:
   1. Formulate legislation.
   2. Explain a phenomenon.
   3. Measure nursing functions.
   4. Reflect the domain of nursing practice.
3. A patient with diabetes is controlling the disease with insulin and diet. The nursing health care provider is focusing efforts to teach the patient self-management. Which of the following nursing theories is useful in promoting self management?
   1. Neuman
   2. Orem
   3. Roy
   4. Peplau
4. While working in a community health clinic, it is important to obtain nursing histories and get to know the patients. Part of history taking is to develop the nurse-patient relationship. Which of the following apply to Peplau's theory when establishing the nurse-patient relationship? (Select all that apply.)
   1. An interaction between the nurse and patient must develop.
   2. The patient's needs must be clarified and described.

3. The nurse-patient relationship is influenced by patient and nurse preconceptions.
4. The nurse-patient relationship is influenced only by the nurse's preconceptions.

5. Theory-based nursing practice uses a theoretical approach for nursing care. This approach moves nursing forward as a science. This suggests that:
   1. One theory will guide nursing practice.
   2. Scientists will decide nursing decisions.
   3. Nursing will only base patient care on the practice of other sciences.
   4. Theories will be tested to describe or predict patient outcomes.
6. To practice in today's health care environment, nurses need a strong scientific knowledge base from nursing and other disciplines such as the physical, social, and behavioral sciences. This statement identifies the need for which of the following?
   1. Systems theories
   2. Developmental theories
   3. Interdisciplinary theories
   4. Health and wellness models
7. Which of the following theories describe the life processes of an older adult facing chronic illness?
   1. Systems theories
   2. Developmental theories
   3. Interdisciplinary theories
   4. Health and wellness models
8. Match the following components of systems theory with the definition of that component.

1. Feedback	A. Data entering the system
2. Input	B. End product
3. Content	C. Data related to system functioning
4. Output	D. Product and information obtained from the system

9. A patient is admitted to an acute care area. The patient is an active business man who is worried about getting back to work. He has had severe diarrhea and vomiting for the last week. He is weak, and his breathing is labored. Using Maslow's hierarchy of needs, identify this patient's immediate priority.
   1. Self-actualization
   2. Air, water, and nutrition
   3. Safety
   4. Esteem and self-esteem needs
10. Which of the following is closely aligned with Leininger's theory?
    1. Caring for patients from unique cultures
    2. Understanding the humanistic aspects of life
    3. Variables affecting a patient's response to a stressor
    4. Caring for patients who cannot adapt to internal and external environmental demands
11. Match the following theories with their definitions.

1. Grand theory	A. Addresses specific phenomena and reflect practice
2. Middle-range theory	B. First level in theory development and describes a phenomenon
3. Descriptive theory	C. Provides a structural framework for broad concepts about nursing
4. Prescriptive theory	D. Linked to outcomes (consequences of specific nursing interventions)

12. A nurse is applying Henderson's theory as a basis for theory based-nursing practice. Which other elements are important for theory-based nursing practice? (Select all that apply.)
    1. Knowledge of nursing science
    2. Knowledge of related sciences
    3. Knowledge about current health care issues
    4. Knowledge of standards of practice
13. Which of the following statements apply to theory generation? (Select all that apply.)
    1. Builds scientific knowledge base of nursing
    2. Discovers relationships of phenomena to practice
    3. Tests specific phenomena
    4. Identifies observations about a phenomenon
14. Which of the following statements about theory-based nursing practice is incorrect?
    1. Contributes to evidence-based practice
    2. Provides a systematic process for designing nursing interventions
    3. Is not linked to nursing outcomes
    4. Guides the nurse's assessment
15. As an art nursing relies on knowledge gained from practice and reflection on past experiences. As a science nursing relies on (select all that apply):
    1. Experimental research.
    2. Nonexperimental research.
    3. Research from other disciplines.
    4. Professional opinions.

Answers: **1.** 4; **2.** 2; **3.** 2; **4.** 1, 2, 3; **5.** 4; **6.** 3; **7.** 2; **8.** 1 C, 2 A, 3 D, 4 B; **9.** 2; **10.** 1; **11.** 1 C, 2 A, 3 B, 4 D; **12.** 1, 2, 4; **13.** 1, 2, 4; **14.** 3; **15.** 1, 2, 3.

CHAPTER

5

Evidence-Based Practice

OBJECTIVES

- Discuss the benefits of evidence-based practice.
- Describe the five steps of evidence-based practice.
- Develop a PICOT question.
- Explain the levels of evidence available in the literature.
- Discuss ways to apply evidence in practice.
- Explain how nursing research improves nursing practice.
- Discuss the steps of the research process.
- Discuss priorities for nursing research.
- Explain the relationship between evidence-based practice and performance improvement.
- Describe the components of a quality improvement program.

Rick has been a registered nurse (RN) on a surgical unit for over 5 years. During that time standard nursing care for patients following abdominal surgery has included getting the patient out of bed, sitting in a chair, and walking within the first postoperative day. Patients are encouraged to walk farther and more frequently each day until they begin to pass gas or have a bowel movement. Rick has noticed lately that several of his patients who have had abdominal surgery have experienced a postoperative ileus. This happens when the patient's gastrointestinal tract fails to begin moving after surgery (see Chapter 50). When patients have a postoperative ileus, they have increased pain and are in the hospital longer. Rick raises the question with the other RNs in the department, "What if we had our patients sit and rock in a rocking chair instead of sitting in a regular high-back chair after abdominal surgery? Is it possible that rocking after surgery will decrease the incidence of postoperative ileus?"

Most nurses like Rick practice nursing according to what they learn in nursing school, their experiences in practice, and the policies and procedures of their institution. Such an approach to practice does not guarantee that nursing practice is always based on up-to-date scientific information. Sometimes nursing practice is based on tradition and not on current evidence. If Rick went to the scientific literature for articles about how to prevent postoperative ileus, he would find some studies that indicate that simple changes in activity such as encouraging patients to rock in a rocking chair following surgery may help them recover more quickly. The evidence from research and the opinions of nursing experts provide a basis for Rick and his colleagues to make evidence-based changes to their care of patients following abdominal surgery. The use of evidence in practice enables clinicians like Rick to provide the highest quality of care to their patients and families.

A CASE FOR EVIDENCE

Nurses practice in an "age of accountability" in which quality and cost issues drive the direction of health care (Makadon et al., 2010; Moore et al., 2010). The general public is more informed about their own health and the incidence of medical errors within health care institutions across the country. Greater scrutiny is being given as to why certain health care approaches are used, which ones work, and which ones do not. As a result, evidence-based practice (EBP) is a guide to help nurses make effective, timely, and appropriate clinical decisions in response to the broad political, professional,

and societal forces that nurses and other health professionals are confronted with daily (Scott and McSherry, 2009).

Nurses face important clinical decisions when caring for patients (e.g., what to assess in a patient and what interventions are best to use). It is important to translate best evidence into best practices at a patient's bedside. For example, changing how patients are cared for after abdominal surgery is one way that Rick (see previous case study) can use evidence at the bedside. **Evidence-based practice (EBP)** is a problem-solving approach to clinical practice that integrates the conscientious use of best evidence in combination with a clinician's expertise and patient preferences and values in making decisions about patient care (Fig. 5-1) (Melnyk and Fineout-Overholt, 2011; Sackett et al., 2000). Today EBP is becoming a goal of all health care institutions and an expectation of professional nurses who are expected to use current evidence when caring for patients (Ingersoll et al., 2010).

Nurses find evidence in different places. A good textbook incorporates evidence into the practice guidelines and procedures it describes. However, a textbook relies on scientific literature, which is sometimes outdated by the time the book is published. Articles from nursing and the health care literature are available on almost any topic involving nursing practice in either journals or on the Internet. Although the scientific basis of nursing practice has grown, some practices are not yet "research based" (Titler et al., 2001). The challenge is to obtain the very best, most current accurate information at the right time, when you need it for patient care.

The best information is the evidence that comes from well-designed, systematically conducted research studies, mostly found in scientific journals. Unfortunately much of that evidence never reaches the bedside. Nurses in practice settings, unlike in educational settings, do not always have easy access to databases for scientific literature. Instead, they often care for patients on the basis of tradition or convenience. Another source of information comes from nonresearch evidence, including quality improvement and risk management data; international, national, and local standards; infection control data; benchmarking, retrospective, or concurrent chart reviews; and clinicians' expertise. It is important to rely more on research evidence rather than solely on nonresearch evidence. When you face a clinical problem, always ask yourself where you can find the best evidence to help you find the best solution in caring for patients.

Even when you use the best evidence available, application and outcomes will differ based on your patient's values, preferences, concerns, and/or expectations (Oncology Nursing Society [ONS], n.d.). As a nurse, you develop critical thinking skills to determine whether evidence is relevant and appropriate to your patients and to a clinical situation. For example, a single research article suggests that the use of therapeutic touch is effective in reducing abdominal incision pain. However, if your patient's cultural beliefs prevent the use of touch, you will likely need to search for a better evidence-based therapy that patients will accept. Using your clinical expertise and considering patient values and preferences ensures that you apply the evidence available in practice both safely and appropriately.

Steps of Evidence-Based Practice

EBP is a systematic approach to rational decision making that facilitates achievement of best practices. A step-by-step approach ensures that you obtain the strongest available evidence to apply in patient care (Oh et al., 2010). There are six steps of EBP (Melnyk and Fineout-Overholt, 2011):

1. Ask a clinical question.
2. Collect the most relevant and best evidence.
3. Critically appraise the evidence you gather.
4. Integrate all evidence with one's clinical expertise and patient preferences and values in making a practice decision or change.
5. Evaluate the practice decision or change.
6. Share the outcomes of EBP changes with others.

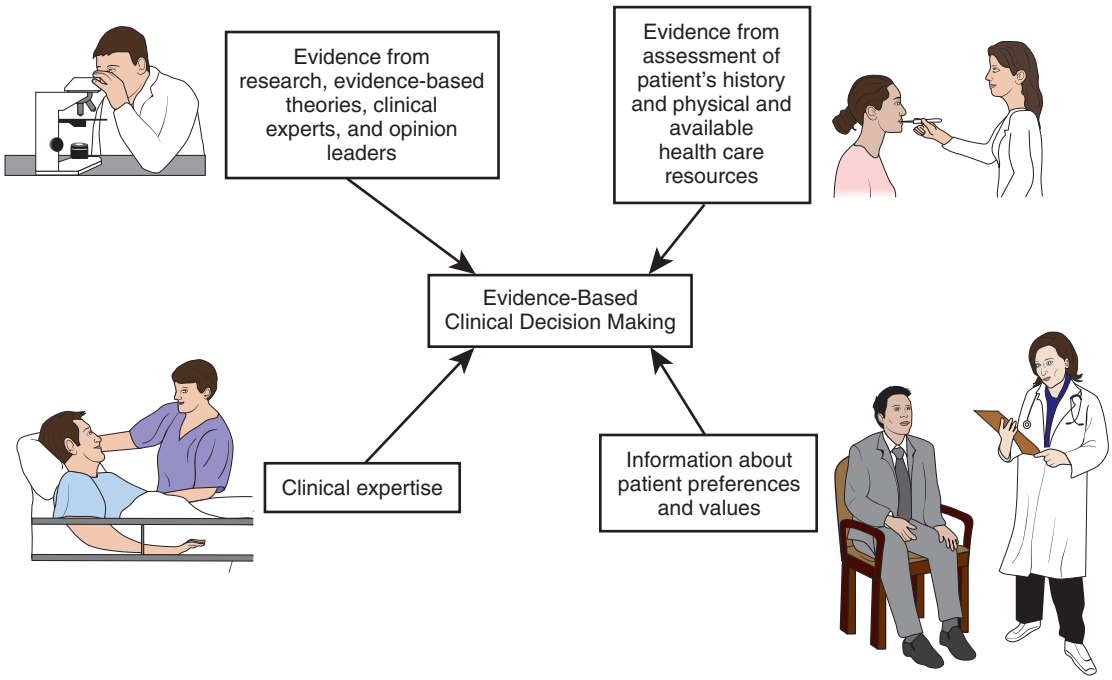

FIG. 5-1 Model for evidence-based clinical decision making.

Ask a Clinical Question. Always think about your practice when caring for patients. Question what does not make sense to you and what needs to be clarified. Think about a problem or area of interest that is time consuming, costly, or not logical (Stilwell et al., 2010). Use problem- and knowledge-focused triggers to think critically about clinical and operational nursing unit issues (Titler et al., 2001). A problem-focused trigger is one you face while caring for a patient or a trend you see on a nursing unit. For example, while Rick is caring for patients following abdominal surgery, he wonders, "If we changed our patients' activity levels after surgery, would they experience fewer episodes of postoperative ileus?" Other examples of problem-focused trends include the increasing number of patient falls or incidence of urinary tract infections on a nursing unit. Such trends lead you to ask, "How can I reduce falls on my unit?" or "What is the best way to prevent urinary tract infections in postoperative patients?"

A knowledge-focused trigger is a question regarding new information available on a topic. For example, "What is the current evidence to improve pain management in patients with migraine headaches?" Important sources of this type of information are standards and practice guidelines available from national agencies such as the Agency for Healthcare Research and Quality (AHRQ), the American Pain Society (APS), or the American Association of Critical Care Nurses (AACN). Other sources of knowledge-focused triggers include recent research publications and nurse experts within an organization.

Sometimes you use data gathered from a health care setting to examine clinical trends to develop clinical questions. For example, most hospitals keep monthly records on key quality of care or performance indicators such as medication errors or infection rates. All magnet-designated hospitals maintain the National Database of Nursing Quality Improvement (NDNQI) (see Chapter 2). The database includes information on falls, pressure ulcer incidence, and nurse satisfaction. Typically quality and risk management data do not give you evidence in finding a solution to a problem, but the data inform you about the nature or severity of problems that then allow you to form practice questions.

The questions you ask eventually lead you to the evidence for an answer. When you ask a question and then go to the scientific literature, you do not want to read 100 articles to find the handful that are most helpful. You want to be able to read the best four-to-six articles that specifically address your practice question. Melnyk and Fineout-Overholt (2011) suggest using a PICOT format to state your question. The five elements of a **PICOT question** are summarized in Box 5-1. The more focused a question you ask, the easier it becomes to search for evidence in the scientific literature. For example, Rick develops the following PICOT question: *Do patients who have had abdominal surgery (P) and who rock in a rocking chair (I) have a reduced incidence of postoperative ileus (O) during hospitalization (T) when compared with patients who receive standard nursing care following surgery (C)?* Another example is: *Is an adult patient's (P) blood pressure more accurate (O) when measuring with the patient's legs crossed (I) versus the patient's feet flat on the floor (C)?*

Proper question formatting allows you to identify key words to use when conducting your literature search. Note that a well-designed PICOT question does not have to follow the sequence of P, I, C, O, and T. In addition, intervention (I), comparison (C), and time (T) are not appropriate to be used in every question. The aim is to ask a question that contains as many of the PICOT elements as possible. For example, here is a meaningful question that contains only a *P* and *O: How do patients with cystic fibrosis (P) rate their quality of life (O)?*

BOX 5-1 DEVELOPING A PICOT QUESTION

P = Patient population of interest
Identify patients by age, gender, ethnicity, and disease or health problem.

I = Intervention of interest
Which intervention is worthwhile to use in practice (e.g., a treatment, diagnostic test, prognostic factor)?

C = Comparison of interest
What is the usual standard of care or current intervention used now in practice?

O = Outcome
What result do you wish to achieve or observe as a result of an intervention (e.g., change in patient behavior, physical finding, patient perception)?

T = Time
What amount of time is needed for an intervention to achieve an outcome (e.g., the amount of time needed to change quality of life or patient behavior)?

Inappropriately formed questions (e.g., What is the best way to reduce wandering? What is the best way to improve family's satisfaction with patient care?) are background questions that will likely lead to many irrelevant sources of information, making it difficult to find the best evidence. Sometimes a background question is needed to identify a more specific PICOT question. The PICOT format allows you to ask questions that are intervention focused. For questions that are not intervention focused, the meaning of the letter *I* can be an area of interest (Melnyk and Fineout-Overholt, 2011). For example, *What is the difference in retention (O) of new nursing graduates (P) who have previous experience as nurse assistants (I) versus those who do not (C)?*

The questions you ask using a PICOT format help to identify knowledge gaps within a clinical situation. When you raise well–thought-out questions, you should understand the evidence that is missing to guide clinical practice. Remember: do not be satisfied with clinical routines. Always question and use critical thinking to consider better ways to provide patient care.

Building Competency in Evidence-Based Practice While attending a professional nursing conference about the care of surgical patients, Rick hears a report about a research study in which nurses at one hospital had their patients chew gum following abdominal surgery. The results of the research study indicated that patients who chewed peppermint gum three times a day had reduced nausea and a return of bowel sounds sooner after surgery compared with patients who did not chew gum. Using this information, develop a PICOT question that Rick could use to further investigate this intervention. Identify each part of the PICOT question.

Answers to questions can be found on the Evolve website.

Collect the Best Evidence. Once you have a clear and concise PICOT question, you are ready to search for evidence. You can find the evidence you need in a variety of sources: agency policy and procedure manuals, quality improvement data, existing clinical practice guidelines, or computerized bibliographical databases. Do not hesitate to ask for help to find appropriate evidence. Your faculty is always a key resource. When you are assigned to a health

World Views on Evidence-Based Nursing	Electronic journal containing articles that provide a synthesis of research and an annotated bibliography for selected references

care setting, use agency experts such as advanced practice nurses, staff educators, risk managers, and infection control nurses.

When using the scientific literature for evidence, seek the assistance of a medical librarian. He or she knows the various databases that are available to you (Table 5-1). The databases contain large collections of published scientific studies, including peer-reviewed research. A **peer-reviewed** article is one reviewed by a panel of experts familiar with the topic or subject matter of the article before it was published. The librarian is available to help translate your PICOT question into the language or key words that will yield the best evidence search. When conducting a search, it is necessary to enter and manipulate different key words until you get the combination that gives you the key articles that you want to read about your question. When you enter a word to search into a database, be prepared for some confusion with the evidence you obtain. The vocabulary within published articles is often vague. The word you select sometimes has one meaning to one author and a very different meaning to another.

When Rick searches for evidence to answer his PICOT question, he asks for help from a medical librarian. The medical librarian helps him learn how to choose alternative words or terms that identify his PICOT question. During their search Rick identifies three research articles published since 1990 that address the effects of rocking in a rocking chair on return of bowel function following abdominal surgery (Massey, 2010; Moore et al., 1995; Thomas et al., 1990).

MEDLINE and the Cumulative Index of Nursing and Allied Health Literature (CINAHL) are among the best-known comprehensive databases to search for scientific knowledge in health care (Melnyk and Fineout-Overholt, 2011). Among the many databases, some are available through vendors at a cost, some are free of charge, and some offer both options. As a student you have access to an institutional subscription through a vendor purchased by your school. One of the more common vendors is OVID, which offers several different databases. Databases are also available free on the Internet. The Cochrane Database of Systematic Reviews is a valuable source of high-quality evidence. It includes the full text of regularly updated systematic reviews and protocols for reviews currently under way. Collaborative review groups prepare and maintain the reviews. The protocols provide the background, objectives, and methods for reviews in progress (Melnyk and Fineout-Overholt, 2011). The National Guidelines Clearinghouse (NGC) is a database supported by the AHRQ. It contains **clinical guidelines,** systematically developed statements about a plan of care for a specific set of clinical circumstances involving a specific patient population. Examples of clinical guidelines on NCG include care of children and adolescents with type 1 diabetes and practice guidelines for the treatment of adults with low back pain. The NGC is invaluable when developing a plan of care for a patient (see Chapter 18).

Fig. 5-2 represents the hierarchy of available evidence. The level of rigor or amount of confidence you can have in a study's findings decreases as you move down the pyramid. At this point in your nursing career, you cannot be an expert on all aspects of the types of studies conducted. But you can learn enough about the types of studies to help you know which ones have the best scientific evidence. At the top of the pyramid are systematic reviews or meta-analyses, which are state-of-the-art summaries from an individual researcher or panel of experts. Meta-analyses and systematic reviews are the perfect answers to PICOT questions because they rigorously summarize current evidence.

During either a meta-analysis or a systematic review, a researcher asks a PICOT question, reviews the highest level of evidence available (e.g., randomized controlled trials [RCTs]), summarizes what is currently known about the topic, and reports if current evidence

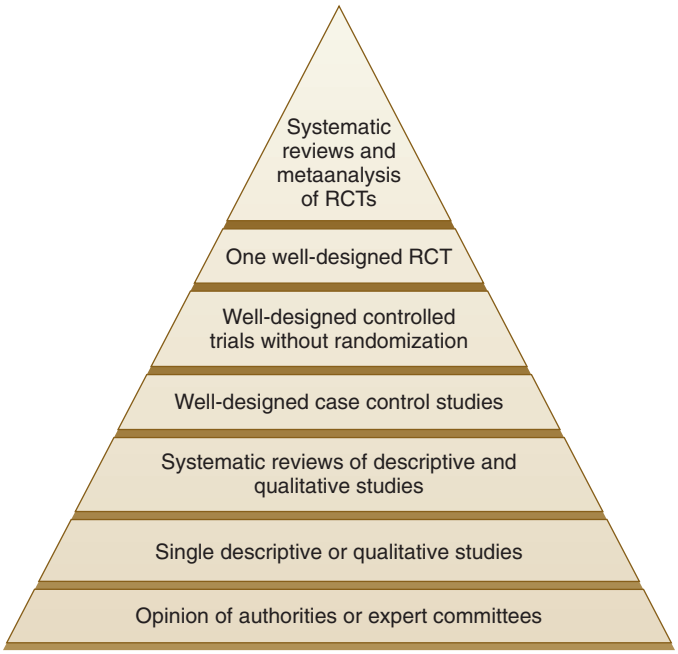

FIG. 5-2 Hierarchy of evidence. *RCTs,* Randomized controlled trials. (Modified from Guyatt G, Rennie D: *User's guide to the medical literature,* Chicago, 2002, American Medical Association; Harris RP et al: Current methods of the US Prevention Services Task Force: a review of the process, *Am J Prev Med* 20:21, 2001; Melnyk BM, Fineout-Overholt E: *Evidence-based practice in nursing and healthcare: a guide to best practice,* ed 2, Philadelphia, 2011, Lippincott Williams & Wilkins.)

supports a change in practice or if further study is needed. The main difference is that in a meta-analysis the researcher uses statistics to show the effect of an intervention on an outcome, whereas in a systematic review no statistics are used to draw conclusions about the evidence. In the Cochrane Library all entries include information on meta-analyses and systematic reviews. If you use MEDLINE or CINAHL, enter a textword such as "meta-analysis" or "systematic review" or the MeSH heading of *evidence-based medicine* to obtain scientific reviews on your PICOT question.

The RCT is the most precise form of experimental study and therefore is the gold standard for research. A single RCT is not as conclusive as a review of several RCTs on the same question. However, a single RCT that tests the intervention included in your question yields very useful evidence. If RCTs are not available, you can use results from other research studies such as descriptive or qualitative studies to help answer your PICOT question. The use of clinical experts may be at the bottom of the evidence pyramid, but do not consider clinical experts to be a poor source of evidence. Expert clinicians use evidence frequently as they build their own practice, and they are rich sources of information for clinical problems.

Critically Appraise the Evidence. Perhaps the most difficult step in the EBP process is critiquing or analyzing the available evidence. Critiquing evidence involves evaluating it, which includes determining the value, feasibility, and usefulness of evidence for making a practice change (ONS, n.d.). When critiquing evidence, first evaluate the scientific merit and clinical applicability of the findings of each study. Then with a group of studies and expert opinion determine what findings have a strong enough basis for use in practice. After critiquing the evidence you will be able to answer the following questions. Do the articles together offer evidence to explain or answer my PICOT question? Do the articles show support for the reliability and validity of the evidence? Can I use the evidence in practice?

As a student new to nursing, it takes time to acquire the skills to critique evidence like an expert. When you read an article, do not put it down and walk away because of the statistics and technical language. Know the elements of an article and use a careful approach when reviewing each one. Evidence-based articles include the following elements:

- *Abstract.* An abstract is a brief summary of the article that quickly tells you if it is research or clinically based. An abstract summarizes the purpose of the article. It also includes the major themes or findings and the implications for nursing practice.
- *Introduction.* The introduction contains more information about the purpose of the article. There is usually brief supporting evidence as to why the topic is important.

  Together the abstract and introduction help you decide if you want to continue to read the entire article. You will know if the topic of the article is similar to your PICOT question or related closely enough to provide useful information. If you decide that this article may help answer your question, continue to read the next elements of the article.
- *Literature review or background.* A good author offers a detailed background of the level of science or clinical information that exists about the topic. The literature review offers an argument about what led the author to conduct a study or report on a clinical topic. This section of an article is very valuable. Even if the article itself does not address your PICOT question the way you desire, the literature review will possibly lead you to other more useful articles. After reading a literature review, you should have a good idea of how past research led to the researcher's question. For example, a study designed to test an educational intervention for older adult family caregivers reviews literature that describes characteristics of caregivers, the type of factors influencing caregivers' ability to cope with stressors of caregiving, and any previous educational interventions used with families.
- *Manuscript narrative.* The "middle section" or narrative of an article differs according to the type of evidence-based article it is (Melnyk and Fineout-Overholt, 2011). A clinical article describes a clinical topic, which often includes a description of a patient population, the nature of a certain disease or health alteration, how patients are affected, and the appropriate nursing therapies. An author sometimes writes a clinical article to explain how to use a therapy or new technology. A research article contains several subsections within the narrative, including the following:
  - *Purpose statement:* Explains the focus or intent of a study. It includes research questions or **hypotheses**—predictions made about the relationship or difference between study **variables** (concepts, characteristics, or traits that vary within or among subjects). An example of a research question is: What environmental characteristics are common among young adults who experience frequent exacerbations of asthma?
- *Methods or design:* Explains how a research study was organized and conducted to answer the research question or test the hypothesis. This is when you learn the type of study that

was conducted (e.g., RCT, case control study, or qualitative study). You also learn how many subjects or persons were in a study. In health care studies subjects may include patients, family members, or health care staff. The language in the methods section is sometimes confusing because it explains details about how the researcher designed the study to obtain the most accurate results possible. Use your faculty member as a resource to help interpret this section.

- *Results or conclusions.* Clinical and research articles have a summary section. In a clinical article the author explains the clinical implications for the topic presented. In a research article the author details the results of the study and explains whether a hypothesis is supported or how a research question is answered. This section includes a statistical analysis if it is a quantitative research study. A qualitative study summarizes the descriptive themes and ideas that arise from the researcher's analysis of data. Do not let the statistical analysis in an article overwhelm you. Read carefully and ask these questions: Does the researcher describe the results? Were the results significant? A good author also discusses any limitations to a study in this section. The information on limitations is valuable in helping you decide if you want to use the evidence with your patients. Have a faculty member or an expert nurse help you interpret statistical results.
- *Clinical implications.* A research article includes a section that explains if the findings from the study have clinical implications. The researcher explains how to apply findings in a practice setting for the type of subjects studied.

After Rick critiques each article for his PICOT question, he combines the findings from the three articles he found about the use of rocking chairs to determine the state of the evidence. He uses critical thinking to consider the scientific rigor of the evidence and how well it answers his PICOT question. He also considers the evidence in light of his patients' concerns and preferences. As a clinician Rick judges whether to use the evidence for the group of patients for whom he normally cares on the surgical unit. Patients frequently have complex medical histories and patterns of responses (Melnyk and Fineout-Overholt, 2011). Ethically it is important for Rick to consider evidence that will benefit patients and do no harm. He needs to decide if the evidence is relevant, is easily applicable in his setting of practice, and has the potential for improving patient outcomes.

Integrate the Evidence. Once you decide that the evidence is strong and applicable to your patients and clinical situation, incorporate it into practice. Your first step is simply to apply the research in your plan of care for a patient (see Chapter 18). Use the evidence you find as a rationale for an intervention you plan to try. For instance, you learned about an approach to bathe older adults who are confused and decide to use the technique during your next clinical assignment. You use the bathing technique with your own assigned patients, or you work with a group of other students or nurses to revise a policy and procedure or develop a new clinical protocol.

The literature Rick found reveals that rocking in a rocking chair after bowel surgery usually results in a quicker return of bowel function following surgery when compared with standard nursing care (Massey, 2010; Moore et al., 1995; Thomas et al., 1990). Rick then meets with his colleagues on the unit practice committee to recommend a protocol for patients who have abdominal surgery. The protocol outlines guidelines to have patients routinely sit in rocking chairs when they get out of bed after surgery.

Evidence is integrated in a variety of ways through teaching tools, clinical practice guidelines, policies and procedures, and new assessment or documentation tools. Depending on the amount of change needed to apply evidence in practice, it becomes necessary to involve a number of staff from a given nursing unit. It is important to consider the setting where you want to apply the evidence. Is there support from all staff? Does the practice change fit with the scope of practice in the clinical setting? Are resources (time, secretarial support, and staff) available to make a change? When evidence is not strong enough to apply in practice, your next option is to conduct a pilot study to investigate your PICOT question. A pilot study is a small-scale research study or one that includes a quality or performance improvement project.

Evaluate the Practice Decision or Change. After applying evidence in your practice, your next step is to evaluate the outcome. How does the intervention work? How effective was the clinical decision for your patient or practice setting? Sometimes your evaluation is as simple as determining if the expected outcomes you set for an intervention are met (see Chapters 18 and 20). For example, after the use of a transparent intravenous (IV) dressing, does the IV dislodge, or does the patient develop the complication of phlebitis? When using a new approach to preoperative teaching, does the patient learn what to expect after surgery?

When an EBP change occurs on a larger scale, an evaluation is more formal. For example, evidence showing factors that contribute to pressure ulcers might lead a nursing unit to adopt a new skin care protocol. To evaluate the protocol, nurses track the incidence of pressure ulcers over a course of time (e.g., 6 months to a year). In addition, they collect data to describe both patients who develop ulcers and those who do not. This comparative information is valuable in determining the effects of the protocol and whether modifications are necessary.

When evaluating an EBP change, determine if the change was effective, if modifications in the change are needed, or if the change needs to be discontinued. Events or results that you do not expect may occur. For example, a hospital that implements a new method of cleaning IV line puncture sites discovers an increased rate of IV line infections and reevaluates the new cleaning method to determine why infections have increased. If the hospital does not evaluate this change in practice, more patients will develop IV site infections. *Never* implement a practice change without evaluating its effect.

In Rick's case the unit practice committee collects evaluation data after 3 months of implementing the rocking chair protocol to determine if patients experienced a lower incidence of postoperative ileus following abdominal surgery. After completing chart reviews, the committee discovers that patients who used the rocking chairs following abdominal surgery experienced fewer incidences of postoperative ileus compared with patients who did not use rockers before the protocol was implemented. The protocol patients went home 1 to 2 days sooner than the patients who did not use the rocking chairs. Patient interviews revealed that the patients were satisfied with the rocking movement and that, not only did the rocking chairs help them pass gas faster, but the patients also felt less anxious because of the rocking motion. After talking with the committee, Rick discovered that not all patients were able to use rocking chairs during this time because the unit did not have enough rocking chairs. He presented these data to his manager who approved the purchase of more rocking chairs.

Share the Outcomes with Others. After implementing an EBP change, it is important to communicate the results. If you implement an evidence-based intervention with one patient, you

and the patient determine the effectiveness of that intervention. When a practice change occurs on a nursing unit level, the first group to discuss the outcomes of the change is often the clinical staff on that unit. To enhance professional development and promote positive patient outcomes beyond the unit level, share the results with various groups of nurses or other care providers such as the nursing practice council or the research council. Clinicians enjoy and appreciate seeing the results of a practice change. In addition, the practice change will more likely be sustainable and remain in place when staff are able to see the benefits of an EBP change.

As a professional nurse it is critical to contribute to the growing knowledge of nursing practice, especially if he or she is involved in an EBP change. Nurses often communicate the outcomes of EBP changes at professional conferences and meetings. Being involved in professional organizations allows them to present EBP changes in scientific abstracts, poster presentations, or even podium presentations.

After evaluating the results of the EBP change, Rick decides to present the outcomes to the nursing research committee at his hospital. The chief nursing officer hears Rick's presentation and encourages him to submit an abstract about his EBP change to a national professional nursing conference. Rick submits his abstract for consideration as a poster presentation at the annual Midwest Nursing Research Society conference, and it is accepted. During the conference Rick tells other nurses about his EBP change and is contacted by several nurses after the conference who are thinking about implementing the use of rocking chairs on their patient care units.

NURSING RESEARCH

After completing a thorough review and critique of the scientific literature, you might not have enough strong evidence to make a practice change. Instead you may find a gap in knowledge that makes your PICOT question go unanswered. When this happens, the best way to answer your PICOT question is to conduct a research study. At this time in your career you will not be conducting research. However, it is important for you to understand the process of nursing research and how it generates new knowledge.

The International Council of Nurses (ICN) (2007) supports the need for nursing research as a means for improving the health and welfare of people. **Nursing research** is a way to identify new knowledge, improve professional education and practice, and use resources effectively. Research means to search again or to examine carefully. It is a systematic process that asks and answers questions to generate knowledge. The knowledge provides a scientific basis for nursing practice and validates the effectiveness of nursing interventions. Nursing research improves professional education and practice and helps nurses use resources effectively. The scientific knowledge base of nursing continues to grow today, thus furnishing evidence nurses can use to provide safe and effective patient care. Many professional and specialty nursing organizations support the conduct of research for advancing nursing science.

An example of how research can expand our practice can be seen in the work of Dr. Norma Metheny who has spent many years asking questions about how to prevent the aspiration of tube feeding in patients who receive feeding through nasogastric tubes (Metheny et al., 1988, 1989, 1990, 1994, 2000). Through her research she identified factors that increase the risk for aspiration and approaches to use in determining tube feeding placement. Dr. Metheny's findings are incorporated into this textbook and have changed the way nurses administer tube feedings to patients. Through research Dr. Metheny has contributed to the scientific body of knowledge that has saved patients' lives and helped to prevent the serious complication of aspiration.

Outcomes Management Research

The management of care delivery outcomes is a growing concern for nurse clinicians and researchers (Melnyk and Fineout-Overholt, 2011). Outcomes research assesses and documents the effectiveness of health care services and interventions. It responds to the increased demands from policy makers, insurers, and the public to justify care practices and systems in terms of improved patient outcomes and costs (Polit and Beck, 2007). For example, studying the effects of an outpatient education program on the ability of older adult patients to follow a nutrition and exercise program is an outcome study.

Care delivery outcomes are the observable or measurable effects of some intervention or action (Melnyk and Fineout-Overholt, 2011). As is the case with the expected outcomes you develop in a plan of care (see Chapter 18), a care delivery outcome focuses on the recipient of service (e.g., patient, family, or community) and not the provider (e.g., nurse or physician). For example, an outcome of a diabetes education program is that patients are able to self-administer insulin, not the nurses' success in instructing all patients newly diagnosed with diabetes.

A problem in outcomes research is the clear definition or selection of measurable outcomes. Components of an outcome include the outcome itself, how it is observed (the indicator), its critical characteristics (how it is measured), and its range of parameters (Melnyk and Fineout-Overholt, 2011). For example, health care settings commonly measure the outcome of patient satisfaction when they introduce new services (e.g., new care delivery model or outpatient clinic). The outcome is patient satisfaction, observed through patients' responses to a patient satisfaction instrument, including characteristics such as nursing care, physician care, support services, and the environment. Patients complete the instrument, responding to a scale (parameter) designed to measure their degree of satisfaction (e.g., scale of 1 to 5). The combined score on the instrument yields a measure of patient satisfaction, an outcome that the facility can track over time.

Although the nursing literature now addresses the identification of "nursing-sensitive outcomes" (Box 5-2), or outcomes that are sensitive to nursing practice (Ingersoll et al., 2010; Montalvo, 2007), researchers frequently choose outcomes that do not measure a true impact of care delivery, particularly nursing care delivery. For example, common outcome measures include morbidity, mortality, readmission rate, or length of stay. Although important outcomes to understand, they do not always measure the true effect of a specific nursing intervention on care delivery. For example, if a nurse researcher intends to measure the success of a nurse-initiated protocol to manage blood glucose levels in critically ill patients, the researcher will not likely measure mortality because it is too broad and susceptible to many factors (e.g., the selection of medical therapies, the patients' acuity of illness) other than the nurse-initiated protocol. Instead, he or she will have a better idea of the effects of the protocol by measuring the outcome of patients' blood glucose ranges. The nurse researcher obtains the blood glucose level of patients placed on the protocol and compares them to a desired range that represents good blood glucose control.

BOX 5-2 EXAMPLES OF NURSING-SENSITIVE OUTCOME MEASURES

- Nursing hours per patient day and skill mix
- Patient falls, with and without injury
- Pediatric pain assessment, intervention, and reassessment cycle
- Pediatric peripheral intravenous infiltration rate
- Pressure ulcer prevalence
- Psychiatric physical/sexual assault rate
- Restraint prevalence
- Registered nurse (RN) education, certification, and satisfaction
- Voluntary nurse turnover and vacancy rate
- Nosocomial infections:
  - Catheter-associated urinary tract infection (UTI)
  - Central-line catheter-associated blood stream infection (CABSI)
  - Ventilator-associated pneumonia (VAP)

Scientific Method

The **scientific method** is the foundation of research and the most reliable and objective of all methods of gaining knowledge. This method is an advanced, objective means of acquiring and testing knowledge. Aspects of the method guide you in applying research evidence in practice and in conducting research. When using research findings to change practice, you need to understand the process that a researcher uses to guide a study. For example, when Rick considered whether to have the patients on his unit use a rocking chair following abdominal surgery, he needed to know if this had been tested on similar patients and the outcomes or results. The scientific method is a systematic, step-by-step process that provides support that the findings from a study are **valid, reliable,** and **generalizable** to subjects similar to those researched.

Researchers use the scientific method to understand, explain, predict, or control a nursing phenomenon (Polit and Beck, 2007). Systematic, orderly procedures characterize this method to limit the possibility for error, although it is not without fault. The scientific method minimizes the chance that **bias** or opinion by a researcher will influence the results of research and thus the knowledge gained. The characteristics of scientific research are as follows (Polit and Beck, 2007):

- The research identifies the problem area or area of interest to study.
- The steps of planning and conducting a research study occur in a systematic and orderly way.
- Researchers try to control external factors that are not being studied but can influence a relationship between the phenomena they are studying. For example, if a nurse is studying the relationship between diet and heart disease, he or she controls other characteristics among subjects such as stress or smoking history because they are contributing factors to this disease. Patients on a study diet and those on a regular diet would both have to have similar levels of stress and smoking histories to test the true effect of the diet.
- Researchers gather **empirical data** through the use of observations and assessments and use the data to discover new knowledge.
- The goal is to understand phenomena to apply the knowledge generally to a broad group of patients.

Nursing and the Scientific Approach

In the past much of the information used in nursing practice was borrowed from other disciplines such as biology, physiology, and psychology. Often nurses applied this information to their practice without testing it. For example, nurses use several methods to help patients sleep. Interventions such as giving a patient a back rub, making sure that the bed is clean and comfortable, and preparing the environment by dimming the lights are nursing measures that are used frequently and in general are logical, commonsense approaches. However, when these measures are considered in greater depth, questions arise about their applications. For example, are they the best methods to promote sleep? Do different patients in different situations require other interventions to promote sleep?

Research provides a way to study nursing questions and problems in greater depth within the context of nursing. If nurses do not use an evidence-based approach to practice, they often rely on personal experience or the statements of nursing experts alone. If an intervention works for most patients, you may become satisfied with this success without questioning whether there might be a better way for other patients. If the intervention is not successful, you might use an approach practiced by a colleague or try a different sequence of accepted measures. Even if an intervention discovered with this approach is effective for one or more patients, it is not always appropriate for other patients in other settings. Nursing interventions must be tested through research to determine the measures that work best with specific patients.

Nursing research addresses issues important to the discipline of nursing. Some of these issues relate to the profession itself, education of nurses, patient and family needs, and issues within the health care delivery system. Once research is completed, it is important to disseminate or communicate the findings. One method of dissemination is through publication of the findings in professional journals. Nursing research uses many methods to study clinical problems (Box 5-3). There are two broad approaches to research: quantitative and qualitative methods.

Quantitative Research. **Quantitative nursing research** is the study of nursing phenomena that offers precise measurement and quantification. For example, a study dealing with pain therapies quantitatively measures pain severity. A study testing different forms of surgical dressings measures the extent of wound healing. Quantitative research is the precise, systematic, objective examination of specific concepts. It focuses on numerical data, statistical analysis, and controls to eliminate bias in findings (Polit and Beck, 2007). Although there are many quantitative methods, the following sections briefly describe experimental, nonexperimental, survey, and evaluation research.

Experimental Research. An RCT is a true **experimental study** that tightly controls conditions to eliminate bias and ensure that findings can be generalizable to similar groups of subjects. Researchers test an intervention (e.g., new drug, therapy, or education method) against the usual standard of care (Box 5-4). They randomly assign subjects to either a control or treatment group. In other words, all subjects in a study have an equal chance to be in either group. The treatment group receives the experimental intervention, and the control group receives the usual standard of care. The researchers measure both groups for the same outcomes to see if there is a difference. When an RCT is completed, the researcher will know if the intervention leads to better outcomes than the standard of care.

BOX 5-3 TYPES OF RESEARCH

Historical research: Studies designed to establish facts and relationships concerning past events. *Example:* Study examining the societal factors that led to the acceptance of advanced practice nurses by patients.

Exploratory research: Initial study designed to develop or refine the dimensions of phenomena or to develop or refine a hypothesis about the relationships among phenomena. *Example:* Pilot study testing the benefits of a new exercise program for older adults with dementia.

Evaluation research: Study that tests how well a program, practice, or policy is working. *Example:* Study measuring the outcomes of an informational campaign designed to improve parents' ability to follow immunization schedules for their children.

Descriptive research: Study that measures characteristics of persons, situations, or groups and the frequency with which certain events or characteristics occur. *Example:* Study to examine RNs' biases toward caring for obese patients.

Experimental research: Study in which the investigator controls the study variable and randomly assigns subjects to different conditions to test the variable. *Example:* RCT comparing chlorhexidine with Betadine in reducing the incidence of IV-site phlebitis.

Correlational research: Study that explores the interrelationships among variables of interest without any active intervention by the researcher. *Example:* Study examining the relationship between RNs' educational levels and their satisfaction in the nursing role.

RNs, Registered nurses; *RCT,* randomized controlled trial; *IV,* intravenous.

BOX 5-4 EXAMPLE OF A RANDOMIZED CONTROLLED TRIAL

Research question: Will the use of a formal education program for patients at risk for diabetes compared with a traditional educational pamphlet improve patient's blood glucose level and weight control?

Subjects: 130 adult patients with risk factors for diabetes who visit a local medicine clinic

Randomization: Patients are randomly assigned to one of two groups using a random numbers table.

Treatment group: 65 patients attend an 8-hour class on diabetes prevention, with group discussion, lecture, and interactive computer program use.

Control group: 65 patients receive a printed pamphlet outlining risks for diabetes and health promotion strategies.

Outcome measure: Both groups have blood glucose levels and weight measured before receiving education and every month for 3 months after receiving education.

Analysis: Statistical tests comparing the blood glucose levels and weight for the two groups will show if the treatment has the predicted effect.

Controlled trials without randomization are studies that test interventions, but researchers have not randomized the subjects into control or treatment groups. Thus there is bias in how the study is conducted. Some findings are distorted because of how the study was designed. A researcher wants to be as certain as possible when testing an intervention that the intervention is the reason for the desired outcomes. In a nonrandomized controlled trial the way in which subjects fall into the control or treatment group sometimes influences the results. This suggests that the intervention tested was not the only factor affecting the results of the study. Careful critique allows you to determine if bias were present in a study and what effect, if any, the bias had on the results of the study.

Although RCTs investigate cause and effect and are excellent for testing drug therapies or medical treatments, this approach is not always the best for testing nursing interventions. The nature of nursing care causes nurse researchers to ask questions that are not always answered best by an RCT. For example, nurses help patients with problems such as knowledge deficits and symptom management. Learning to understand how patients experience health problems cannot always be addressed through an RCT. Therefore nonexperimental descriptive studies are often used in nursing research.

Nonexperimental Research. Nonexperimental descriptive studies describe, explain, or predict phenomena such as factors that lead to an adolescent's decision to smoke cigarettes and those that lead patients with dementia to fall in a hospital setting.

A case control study is one in which researchers study one group of subjects with a certain condition (e.g., asthma) at the same time as another group of subjects who do not have the condition. A case control study determines if there is an association between one or more predictor variables and the condition (Melnyk and Fineout-Overholt, 2011). For example, is there an association between predictor variables such as family history or environmental exposure to dust and the incidence of asthma? Often a case control study is conducted retrospectively, or after the fact. Researchers look back in time and review available data about their two groups of subjects to understand what variables explain the condition. These studies involve a small number of subjects, creating a risk of bias. Sometimes the subjects in the two groups differ on certain other variables (e.g., amount of stress or history of contact allergies) that also influence the incidence of the condition, more so than the variables being studied. Correlational studies describe the relationship between two variables (e.g., the age of the adolescent and if the adolescent smokes). The researcher determines if the two variables are correlated or associated with one another and to what extent.

Many times researchers use findings from descriptive studies to develop studies that test interventions. For example, if the researcher determines that adolescents 15 years old and older tend to smoke, he or she might test if participation in a program about smoking for older adolescents is effective in helping adolescents stop smoking.

Surveys. Surveys are common in quantitative research. They obtain information from populations regarding the frequency, distribution, and interrelation of variables among subjects in the study (Polit and Beck, 2007). An example is a survey designed to measure nurses' perceptions of physicians' willingness to collaborate in practice. Surveys obtain information about practices, education, experience, opinions, and other characteristics of people. The most basic function of a survey is description. Surveys gather a large amount of data to describe the population and the topic of study. It is important in survey research that the population sampled be large enough to keep sampling error at a minimum.

Evaluation Research. **Evaluation research** is a form of quantitative research that determines how well a program, practice, procedure, or policy is working (Polit and Beck, 2007). An example is outcomes management research. Evaluation research determines why a program or some components of the program are successful or unsuccessful. When programs are unsuccessful, evaluation

TABLE 5-2 Comparison of Steps of the Nursing Process with the Research Process

NURSING PROCESS	RESEARCH PROCESS
Problem identification	Identify area of interest or clinical problem: • Review literature. • Formulate theoretical framework. • Identify study variables. • Devise research question(s)/hypotheses.
Study design	Design study protocol: • Select research design/methodology. • Identify sample population: number, recruitment, assignment to groups. • Select data collection methods. • Select instrumentation: questionnaires, physiological measures, interviews, treatments. • Formulate proposed analysis: statistical methods to answer research questions/hypotheses.
Conducting the study	Obtain necessary approvals. Recruit subjects. Implement the study protocol/collect data: • Pilot study may be done initially. • Continually assess study methodology. Is study consistently carried out? Are all investigators following study protocol?
Data analysis	Analyze results of the study: • Interpret demographics of study population. • Analyze each research question/hypothesis. • Interpret results, including conclusions, limitations.
Use of the findings	Formulate recommendations for further research. Determine implications for nursing. Disseminate the findings: presentations, publications, research use in practice.

research identifies problems with the program and opportunities for change or barriers to program implementation.

Qualitative Research. **Qualitative nursing research** is the study of phenomena that are difficult to quantify or categorize such as patients' perceptions of illness. This method describes information obtained in a nonnumerical form (e.g., data in the form of written transcripts from a series of interviews). Qualitative research offers answers when trying to understand patients' experiences with health problems and the contexts in which the experiences occur. Patients have the opportunity to tell their stories and share their experiences in these studies. The findings are in depth because patients are usually very descriptive in what they choose to share. Examples of qualitative studies include "patient's perceptions of nurses' caring in a palliative care unit," and "the perceptions of stress by family members of critically ill patients."

Qualitative research involves **inductive reasoning** to develop generalizations or theories from specific observations or interviews (Polit and Beck, 2007). For example, a nurse extensively interviews cancer survivors and then summarizes the common themes from all of the interviews to inductively determine the characteristics of cancer survivors' quality of life. Qualitative research involves the discovery and understanding of important behavioral characteristics or phenomena. An example is a qualitative research study conducted by Nixon and Narayanasamy (2010) that described the spiritual needs of patients with brain tumors and how well nurses support these needs.

There are a number of different qualitative research methods, including ethnography, phenomenology, and grounded theory. Each is based on a different philosophical or methodological view of how to collect, summarize, and analyze qualitative data.

RESEARCH PROCESS

The **research process** is an orderly series of steps that allow a researcher to move from asking the research question to finding the answer. Usually the answer to the initial research question leads to new questions and other areas of study. The research process builds knowledge for use in other similar situations. For example, a nurse researcher might seek knowledge about why a particular event happens or the best way to provide care for patients with a certain health problem. The research process provides knowledge that a nurse can apply repeatedly to a whole group or class of patients. Table 5-2 summarizes steps of the research process. Initially the researcher identifies an area of inquiry (identifying a problem), which often results from clinical practice. For example, after speaking with a researcher at a professional nursing conference, Rick decides he wants to conduct a pilot study on the nursing unit to determine if chewing peppermint gum following colon surgery prevents patients from having nausea and reduces the incidence of postoperative ileus. He reviews the relevant literature to determine what is known about chewing peppermint gum and its effect on bowel mobility and nausea following abdominal surgery. Rick notes that, although many patients report problems with nausea and return of bowel function, there is limited research on the effects of chewing gum on these two outcomes.

Following identification of the problem and review of the literature, Rick designs a study with the help of a nurse researcher. The sample includes all patients who are having elective colon resections. Subjects are excluded if they need to have surgery because of an emergency situation. Rick places each subject into one of the two groups (experimental or control) based on random assignment. The control group receives standard postoperative care. The experimental or treatment group receives standard postoperative care, and they chew gum for 5 minutes three times a day. Subjects have a 50-50 chance of being in each group. Rick selects appropriate instruments to measure postoperative nausea and decides to use patient assessment data to determine when nurses first hear bowel sounds and when patients first pass flatus and have a bowel movement after surgery.

Before conducting any study with human subjects, the researcher obtains approvals from the agency's human subjects committee or institutional review board (IRB). An IRB includes scientists and laypersons who review all studies conducted in the institution to ensure that ethical principles, including the rights of human subjects, are followed. **Informed consent** means that research subjects (1) are given full and complete information about the purpose of a study, procedures, data collection, potential harm and benefits, and alternative methods of treatment; (2) are capable of fully understanding the research and the implications of participation; (3) have the power of free choice to voluntarily consent or decline participation in the research; and (4) understand how the researcher maintains confidentiality or anonymity. **Confidentiality** guarantees that any information a subject provides will not be reported in any manner that identifies the subject and will not be accessible to people outside the research team.

Once Rick's study begins, the nurses on his unit collect data as indicated in the study protocol. The team analyzes the data from the nausea instrument and the chart review about bowel function from the two groups studied. With the help of a statistician from the hospital, a comparison of the results determines whether patients who chewed peppermint gum experienced less nausea and a quicker return of bowel function than the patients who had standard nursing care. The results from this study will advance postoperative nursing care.

In any study a researcher must consider study limitations. Limitations are factors that affect study findings such as a small sample of subjects, a unique setting where the study was conducted, or the failure of the study to include representative cultural groups or age-groups. Rick's team conducted a pilot study because little data were available about the benefits of chewing gum following abdominal surgery. The sample size only included 20 patients in each group, and it was challenging to collect all the data from the patient charts because of inconsistencies in documentation. Therefore the results of Rick's study have limited generalizability to other patients who are experiencing abdominal surgery. The limitations in this study help Rick decide how to refine or adapt it for further investigation in the future.

A researcher also addresses the implications for nursing practice. This ultimately helps fellow researchers, clinicians, educators, and administrators know how to apply findings from a study in practice. At the conclusion of Rick's study, the research team recommends that patients who have elective colon resections be offered the opportunity to chew peppermint gum following surgery. The surgeons on the unit agreed to the change in practice. The team decides to consider conducting future studies to investigate this intervention with patients who have other types of abdominal surgeries. In addition, the team suggests ways to effectively introduce the use of chewing gum into other surgical units following surgery.

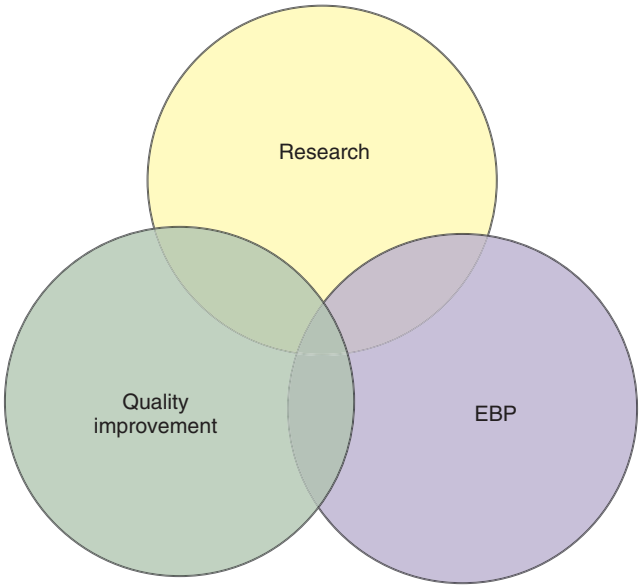

FIG. 5-3 The overlapping relationship among research, evidence-based practice, and quality improvement. *EBP,* Evidence-based practice.

QUALITY AND PERFORMANCE IMPROVEMENT

Every health care organization gathers data on a number of health outcome measures as a way to gauge its quality of care. This is the focus of outcomes management. Examples of quality data include fall rates, number of medication errors, incidence of pressure ulcers, and infection rates. Health care organizations actively promote efforts for improving patient care and outcomes, particularly with respect to reducing medical errors and enhancing patient safety. Quality data are the outcome of both quality improvement (QI) and performance improvement (PI) initiatives. The Joint Commission (TJC, 2010a) defines **quality improvement (QI)** as an approach to the continuous study and improvement of the processes of providing health care services to meet the needs of patients and others and inform health care policy. The QI program of an institution focuses on improvement of health care–related processes (e.g., medication delivery or fall prevention). Performance measurement analyzes what an institution does and how well it does it. In **performance improvement (PI)** an organization analyzes and evaluates current performance and uses the results to develop focused improvement actions. PI activities are typically clinical projects conceived in response to identified clinical problems and designed to use research findings to improve clinical practice (Melnyk and Fineout-Overholt, 2011).

EBP, research, and quality improvement are closely interrelated (Fig. 5-3). Although you use all of these in nursing practice, it is important to know the similarities and differences between them (Table 5-3). When implementing an EBP project, it is important to first review evidence from appropriate research and QI data. The information helps you better understand the extent of a problem in practice and within your organization. QI data inform you about how processes work within an organization and thus offer information about how to make EBP changes. When implementing a research project, EBP and QI can inform opportunities for research.

TABLE 5-3 Similarities and Differences Among Evidence-Based Practice, Research, and Quality Improvement

	EVIDENCE-BASED PRACTICE	RESEARCH	QUALITY IMPROVEMENT
Purpose	Use of information from research, professional experts, personal experience, and patient preferences to determine safe and effective nursing care with the goal of improving patient care and outcomes	Systematic inquiry answers questions, solves problems, and contributes to the generalizable knowledge base of nursing; it may or may not improve patient care.	Improves work processes to improve patient outcomes and efficiency of health systems
Focus	Implementation of evidence already known into practice	Evidence is generated to find answers for questions that are not known about nursing practice.	Measures effects of practice and/or practice change on specific patient population
Data sources	Multiple research studies, expert opinion, personal experience, patients	Subjects or participants have predefined characteristics that include or exclude them from the study; researcher collects and analyzes data from subjects.	Data from patient records or patients who are in a specific area such as on a patient care unit or admitted to a particular hospital
Who conducts the activity?	Practicing nurses and possibly other members of the health care team	Researchers may or may not be employed by the health care agency and usually are not a part of the clinical health care team.	Employees of a health care agency, such as nurses, physicians, pharmacists
Is activity part of regular clinical practice?	Yes	No	Yes
Is IRB approval needed?	No	Yes	Sometimes
Funding sources	Internal, from health care agency	Usually external, such as a grant	Internal, from health care agency

IRB, Institutional review board.

Rapid-cycle improvements measured through QI often identify gaps in evidence. Similarly EBP literature reviews often identify gaps in scientific evidence. Thus the two processes help to identify topics for research. When implementing a QI project, you consider information from research and EBP that aims to improve or better understand practice, thus helping to identify worthy processes to evaluate. Here is an example of how the three processes can merge to improve nursing practice. A nursing unit has an increase in the number of patient falls over the last several months. QI data identifies the type of patients who fall, time of day of falls, and possible precipitating factors (e.g., efforts to reach the bathroom, multiple medications, or patient confusion). A thorough analysis of QI data then leads clinicians to conduct a literature review and implement the best evidence available to prevent patient falls for the type of patients on the unit. Once the staff apply the evidence in a fall-prevention protocol, they implement the protocol (in this case, focusing efforts on care approaches during evening hours) and evaluate its results. Recurrent problems with falls may lead staff to conduct a research study.

Quality Improvement Programs

A well-organized QI program focuses on processes or systems that contribute to patient, staff, or system outcomes. A systematic approach ensures that all employees support a continuous QI philosophy. An organizational culture in which all staff members understand their responsibility toward maintaining and improving quality is essential. Typically in health care many individuals are involved in single processes of care. For example, medication delivery involves the nurse who prepares and administers the drugs, the health care provider who prescribes medications, the pharmacist who prepares the dosage, the secretary who communicates about new orders being written, and the transporter who delivers medications. All members of the health care team collaborate together in QI activities. As a member of the nursing team, you participate in recognizing trends in practice, identifying when recurrent problems develop, and initiating opportunities to improve the quality of care.

The QI process begins at the staff level, where problems are defined. This requires staff members to know the practice standards or guidelines that define quality. Unit QI committees review activities or services considered to be most important in providing quality care to patients. To identify the greatest opportunity for improving quality, the committees consider activities that are high-volume (greater than 50% of the activity of a unit), high-risk (potential for trauma or death), and problem areas (potential for patient, staff, or institution). TJC's annual National Patient Safety Goals provide another focus for QI committees to explore and identify problem areas (TJC, 2010b) (see Chapter 38). Sometimes the problem is presented to a committee in the form of a sentinel event (i.e., an unexpected occurrence involving death or serious physical or psychological injury). Once a committee defines the problem, it applies a formal model for exploring and resolving quality concerns. There are many models for QI and PI. One model is the PDSA cycle: plan, do, study, and act:

*P*lan—Review available data to understand existing practice conditions or problems to identify the need for change.

*D*o—Select an intervention on the basis of the data reviewed and implement the change.

*S*tudy—Study (evaluate) the results of the change.

*A*ct—If the process change is successful with positive outcomes, act on the practices by incorporating them into daily unit performance.

Six Sigma or Lean is another quality improvement model. In this model organizations carefully evaluate processes to reduce costs, enhance quality and revenue, and improve teamwork while using the talents of existing employees and the fewest resources. In a lean organization all employees are responsible and accountable for integrating quality improvement methodologies and tools into daily work (Kimsey, 2010).

Some organizations use a quality improvement model called rapid-cycle improvement or rapid-improvement event (RIE). RIEs are very intense, usually week-long events, in which a group gets together to evaluate a problem with the intent of making radical changes to current processes (Kimsey, 2010). Changes are made within a very short time. The effects of the changes are measured quickly, results are evaluated, and further changes are made when necessary. RIE is appropriate to use when a serious problem exists that greatly affects patient safety and needs to be solved quickly.

Once a QI committee makes a practice change, it is important to communicate results to staff in all appropriate organizational departments. Practice changes will likely not last when QI committees fail to report findings and results of interventions. Regular discussions of QI activities through staff meetings, newsletters, and memos are good communication strategies. Often a QI study reveals information that prompts organization-wide change. An organization must be responsible for responding to the problem with the appropriate resources. Revision of policies and procedures, modification of standards of care, and implementation of new support services are examples of ways an organization responds.

KEY POINTS

- A challenge in EBP is to obtain the very best, most current information at the right time, when you need it for patient care.
- Using your clinical expertise and considering patients' values and preferences ensures that you will apply the evidence in practice both safely and appropriately.
- The five steps of EBP provide a systematic approach to rational clinical decision making.
- The more focused a PICOT question is, the easier it will become to search for evidence in the scientific literature.
- The hierarchy of available evidence offers a guide to the types of literature or information that offer the best scientific evidence.
- A randomized controlled trial is the highest level of experimental research.
- Expert clinicians are a rich source of evidence because they use it frequently to build their own practice and solve clinical problems.
- The critique or evaluation of evidence includes determining the value, feasibility, and usefulness of evidence for making a practice change.
- After critiquing all articles for a PICOT question, synthesize or combine the findings to consider the scientific rigor of the evidence and whether it has application in practice.
- When you decide to apply evidence, consider the setting and whether there is support from staff and available resources.
- Research is a systematic process that asks and answers questions that generate knowledge, which provides a scientific basis for nursing practice.
- Outcomes research is designed to assess and document the effectiveness of health care services and interventions.
- Nursing research involves two broad approaches for conducting studies: quantitative and qualitative methods.
- The research process usually consists of the following steps: identifying the problem, designing the study, conducting the study, analyzing the data, and using the findings.
- A thorough analysis of QI data leads clinicians to understand work processes and the need to change practice.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

The nursing staff on Rick's postsurgical unit have been reviewing their patients' medical records and have seen a steady increase in the incidence of pressure ulcers over the last 3 months, especially in patients who are incontinent. Rick speaks with the wound care specialist in the hospital about this issue. The specialist recommends that the nurses try using special wipes that include an emollient to clean patients who are incontinent.

1. Rick and the nursing staff decide to approach this practice change using evidence-based practice. What would be a PICOT question for this group to ask? Identify each part of the PICOT question.
2. Rick conducts a literature search and gathers research articles about the PICOT question. He evaluates the scientific merit of each of the articles and determines that he has sufficient evidence to answer the PICOT question. Which step of the evidence-based practice process has Rick completed?
3. Rick and the staff on the postsurgical unit implemented a new skin care protocol for patients who are incontinent after surgery. The protocol has been implemented for 4 months. Rick needs to determine if this practice change has been effective. What outcome does Rick need to measure? Describe one method he could use to measure this outcome.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse researcher interviews parents of children who have diabetes and asks them to describe how they deal with their child's illness. The analysis of the interviews yields common themes and stories describing the parents' coping strategies. This is an example of which type of study?
   1. Historical
   2. Qualitative
   3. Correlational
   4. Experimental
2. A nurse who works in a newborn nursery asks, "I wonder if the moms who breastfeed their babies would be able to breastfeed more successfully if we played peaceful music while they were breastfeeding." In this example of a PICOT question, the *I* is:
   1. Breastfeeding moms.
   2. Infants.
   3. Peaceful music.
   4. The nursery.
3. A nurse researcher conducts a study that randomly assigns 100 patients who smoke and attend a wellness clinic into two groups. One group receives the standard smoking cessation handouts; the other group takes part in a new educational program that includes a smoking cessation support group. The nurse plans to compare the effectiveness of the standard

treatment with the educational program. What type of a research study is this?
1. Qualitative
2. Descriptive
3. Correlational
4. Randomized controlled trial

4. A group of nurses have implemented an evidence-based practice (EBP) change and have evaluated the effectiveness of the change. Their next step is to:
1. Conduct a literature review.
2. Share the findings with others.
3. Conduct a statistical analysis.
4. Create a well-defined PICOT question.

5. Arrange the following steps of evidence-based practice (EBP) in the appropriate order:
1. Integrate the evidence.
2. Ask the burning clinical question.
3. Evaluate the practice decision or change.
4. Share the results with others.
5. Critically appraise the evidence you gather.
6. Collect the most relevant and best evidence.

6. When recruiting subjects to participate in a study about the effects of an exercise program on balance, the researcher provides full and complete information about the purpose of the study and gives the subjects the choice to participate or not participate in the study. This is an example of:
1. Bias.
2. Anonymity.
3. Confidentiality.
4. Informed consent.

7. Nurses on a pediatric nursing unit are discussing ways to improve patient care. One nurse asks a colleague, "I wonder how best to measure pain in a child who has sickle cell disease?" This question is an example of a/an:
1. Hypothesis.
2. PICOT question.
3. Problem-focused trigger.
4. Knowledge-focused trigger.

8. The nurses on a medical unit have seen an increase in the number of pressure ulcers that develop in their patients. They decide to initiate a quality improvement project using the PDSA model. Which of the following is an example of "Do" from that model?
1. Implement the new skin care protocol on all medicine units.
2. Review the data collected on patients cared for using the protocol.
3. Review the QI reports on the six patients who developed ulcers over the last 3 months.
4. Based on findings from patients who developed ulcers, implement an evidence-based skin care protocol.

9. A nurse researcher decides to complete a study to evaluate how Florence Nightingale improved patient outcomes in the Crimean War. This is an example of what type of research?
1. Historical
2. Evaluation
3. Exploratory
4. Experimental

10. A group of nurses on the research council of a local hospital are measuring nursing-sensitive outcomes. Which of the following is a nursing-sensitive outcome that the nurses need to consider measuring?
1. Incidence of asthma among children of parents who smoke
2. Frequency of low blood sugar episodes in children at a local school
3. Number of patients who fall and experience subsequent injury on the evening shift
4. Number of sexually active adolescent girls who attend the community-based clinic for birth control

11. A group of staff nurses notice an increased incidence of medication errors on their unit. After further investigation it is determined that the nurses are not consistently identifying the patient correctly. A change is needed quickly. What type of quality improvement method would be most appropriate?
1. PDSA
2. Six Sigma
3. Rapid-improvement event
4. A randomized controlled trial

12. A nurse is providing care to a patient who is experiencing major abdominal trauma following a car accident. The patient is losing blood quickly and needs a blood transfusion. The nurse finds out that the patient is a Jehovah's Witness and cannot have blood transfusions because of religious beliefs. He or she notifies the patient's health care provider and receives an order to give the patient an alternative to blood products. This is an example of:
1. A quality improvement study.
2. An evidence-based practice change.
3. A time when calling the hospital's ethics committee is essential.
4. Considering the patient's preferences and values while providing care.

13. A group of staff educators are reading a research study together at a journal club meeting. While reviewing the study, one of the nurses states that it evaluates if newly graduated nurses progress through orientation more effectively when they participate in patient simulation exercises. Which part of the research process is reflected in this nurse's statement?
1. Introduction
2. Purpose statement
3. Methods
4. Results

14. A research study is investigating the following research question: What is the effect of the diagnosis of breast cancer on the roles of the family? In this study "the diagnosis of breast cancer" and "family roles" are examples of:
1. Surveys
2. The sample
3. Variables
4. Data collection points

15. A nurse researcher is developing a research proposal and is in the process of selecting an instrument to measure anxiety. In which part of the research process is this nurse?
1. Analyzing the data
2. Designing the study
3. Conducting the study
4. Identifying the problem

CHAPTER 6

Health and Wellness

OBJECTIVES

- List the two general *Healthy People 2020* public health goals for Americans.
- Discuss the definition of health.
- Discuss the health belief, health promotion, basic human needs, and holistic health models to understand the relationship between the patient's attitudes toward health and health practices.
- Describe variables influencing health beliefs and practices.
- Describe health promotion, wellness, and illness prevention activities.
- Discuss the three levels of preventive care.
- Describe four types of risk factors.
- Discuss risk factor modification and changing health behaviors.
- Describe variables influencing illness behavior.
- Describe the impact of illness on the patient and family.
- Discuss the nurse's role in health and illness.

In the past most individuals and societies viewed good health, or wellness, as the opposite or absence of disease. This simple attitude ignores states of health between disease and good health. Health is a multidimensional concept and is viewed from a broader perspective. An assessment of the patient's state of health is an important aspect of nursing.

Models of health offer a perspective to understand the relationships between the concepts of health, wellness, and illness. Nurses are in a unique position to help patients achieve and maintain optimal levels of health. They need to understand the challenges of today's health care system and embrace the opportunities to promote health and wellness and prevent illness. In an era of cost containment and advanced technology, nurses are a vital link to the improved health of individuals and society. They identify actual and potential risk factors that predispose a person or a group to illness. In addition, the nurse uses risk factor modification strategies to promote health and wellness and prevent illness.

Different attitudes cause people to react in different ways to illness or the illness of a family member. Medical sociologists call this reaction *illness behavior*. Nurses who understand how patients react to illness can minimize its effects and help patients and their families maintain or return to the highest level of functioning.

HEALTHY PEOPLE DOCUMENTS

Healthy People provides science-based, 10-year national objectives for promoting health and preventing disease. In 1979 an influential document, *Healthy People: the Surgeon General's Report on Health Promotion and Disease Prevention,* was published; it introduced a goal for improving the health of Americans by 1990. The report outlined priority objectives for preventive services, health protection, and health promotion that addressed improvements in health status, risk reduction, public and professional awareness of prevention, health services and protective measures, and surveillance and evaluation. The report served as a framework for the 1990s as the United States increased the focus on health promotion and disease prevention instead of illness care. The strategy announced by the Secretary of Health and Human Services required a cooperative effort by government, voluntary and professional organizations, businesses, and individuals. Widely cited by popular media, in professional journals, and at health conferences, it has inspired health promotion programs throughout the country.

Healthy People 2000: National Health Promotion and Disease Prevention Objectives, published in 1990, identified health improvement goals and objectives to be reached by the year 2000 (U.S. Department of Health and Human Services [USDHHS, Public Health Service], 1990). *Healthy People 2010,* published in 2000, served as a road map for improving the health of all people in the United States for the first decade of the twenty-first century (USDHHS, 2000). This edition emphasized the link between individual health and community health and the premise that the health of communities determines the overall health status of the nation. *Healthy People 2020* was approved in December 2010. *Healthy People 2020* promotes a society in which all people live long, healthy lives. There are four overarching goals: (1) attain high-quality, longer lives free of preventable disease, disability, injury, and premature death; (2) achieve health equity, eliminate disparities, and improve the health of all groups; (3) create social and physical environments that promote good health for all; and (4) promote quality of life, healthy development, and healthy behaviors across all life stages (USDHHS, 2011).

DEFINITION OF HEALTH

Defining health is difficult. The World Health Organization (WHO) defines **health** as a "state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity" (WHO, 1947). Many other aspects of health need to be considered. Health is a state of being that people define in relation to their own values, personality, and lifestyle. Each person has a personal concept of health. Pender, Murdaugh, and Parsons (2011) define health as the actualization of inherent and acquired human potential through goal-directed behavior, competent self-care, and satisfying relationships with others while adjustments are made as needed to maintain structural integrity and harmony with the environment.

Individuals' views of health vary among different age-groups, genders, races, and cultures (Pender, Murdaugh, and Parsons, 2011). Pender (1996) explains that "all people free of disease are not equally healthy." Views of health have broadened to include mental, social, and spiritual well-being and a focus on health at the family and community levels (Pender, Murdaugh, and Parsons, 2006).

To help patients identify and reach health goals, nurses discover and use information about their concepts of health. Pender, Murdaugh, and Parsons (2011) suggest that for many people conditions of life rather than pathological states define health. Life conditions can have positive or negative effects on health long before an illness is evident (Pender, Murdaugh, and Parsons, 2011). Life conditions include socioeconomic variables such as environment, diet, and lifestyle practices or choices and many other physiological and psychological variables.

Health and illness are defined according to individual perception. Health often includes conditions previously considered to be illness. For example, a person with epilepsy who has learned to control seizures with medication and who functions at home and work may no longer consider himself or herself ill. Nurses need to consider the total person and the environment in which the person lives to individualize nursing care and enhance meaningfulness of the patient's future health status.

MODELS OF HEALTH AND ILLNESS

A model is a theoretical way of understanding a concept or idea. Models represent different ways of approaching complex issues. Because health and illness are complex concepts, models are used to understand the relationships between these concepts and the patient's attitudes toward health and **health behaviors.**

Health beliefs are a person's ideas, convictions, and attitudes about health and illness. They may be based on factual information or misinformation, common sense or myths, or reality or false expectations. Because health beliefs usually influence health behavior, they can positively or negatively affect a patient's level of health. Positive health behaviors are activities related to maintaining, attaining, or regaining good health and preventing illness. Common positive health behaviors include immunizations, proper sleep patterns, adequate exercise, stress management, and nutrition. Negative health behaviors include practices actually or potentially harmful to health such as smoking, drug or alcohol abuse, poor diet, and refusal to take necessary medications.

Nurses developed the following health models to understand patients' attitudes and values about health and illness and to provide effective health care. These nursing models allow you to understand and predict patients' health behavior, including how they use health services and adhere to recommended therapy.

Health Belief Model

Rosenstoch's (1974) and Becker and Maiman's (1975) **health belief model** (Fig. 6-1) addresses the relationship between a person's beliefs and behaviors. The health belief model helps you understand factors influencing patients' perceptions, beliefs, and behavior to plan care that will most effectively assist patients in maintaining or restoring health and preventing illness (Box 6-1).

The first component of this model involves an individual's perception of susceptibility to an illness. For example, a patient needs to recognize the familial link for coronary artery disease. After this link is recognized, particularly when one parent and two siblings have died in their fourth decade from myocardial infarction, the patient may perceive the personal risk of heart disease.

The second component is an individual's perception of the seriousness of the illness. This perception is influenced and modified by demographic and sociopsychological variables, perceived threats of the illness, and cues to action (e.g., mass media campaigns and advice from family, friends, and medical professionals). For example, a patient may not perceive his heart disease to be serious, which may affect the way he takes care of himself.

The third component—the likelihood that a person will take preventive action—results from a person's perception of the benefits of and barriers to taking action. Preventive actions include lifestyle changes, increased adherence to medical therapies, or a search for medical advice or treatment. A patient's perception of susceptibility to disease and his or her perception of the seriousness of an illness help to determine the likelihood that the patient will or will not partake in healthy behaviors.

Health Promotion Model

The health promotion model (HPM) proposed by Pender (1982; revised, 1996) was designed to be a "complementary counterpart to models of health protection" (Fig. 6-2). It defines health as a positive, dynamic state, not merely the absence of disease (Pender, Murdaugh, and Parsons, 2011). Health promotion is directed at increasing a patient's level of well-being. The HPM describes the multidimensional nature of persons as they interact within their environment to pursue health (Pender, 1996; Pender, Murdaugh, and Parsons, 2011). The model focuses on the following three areas: (1) individual characteristics and experiences, (2) behavior-specific knowledge and affect, and (3) behavioral outcomes. The

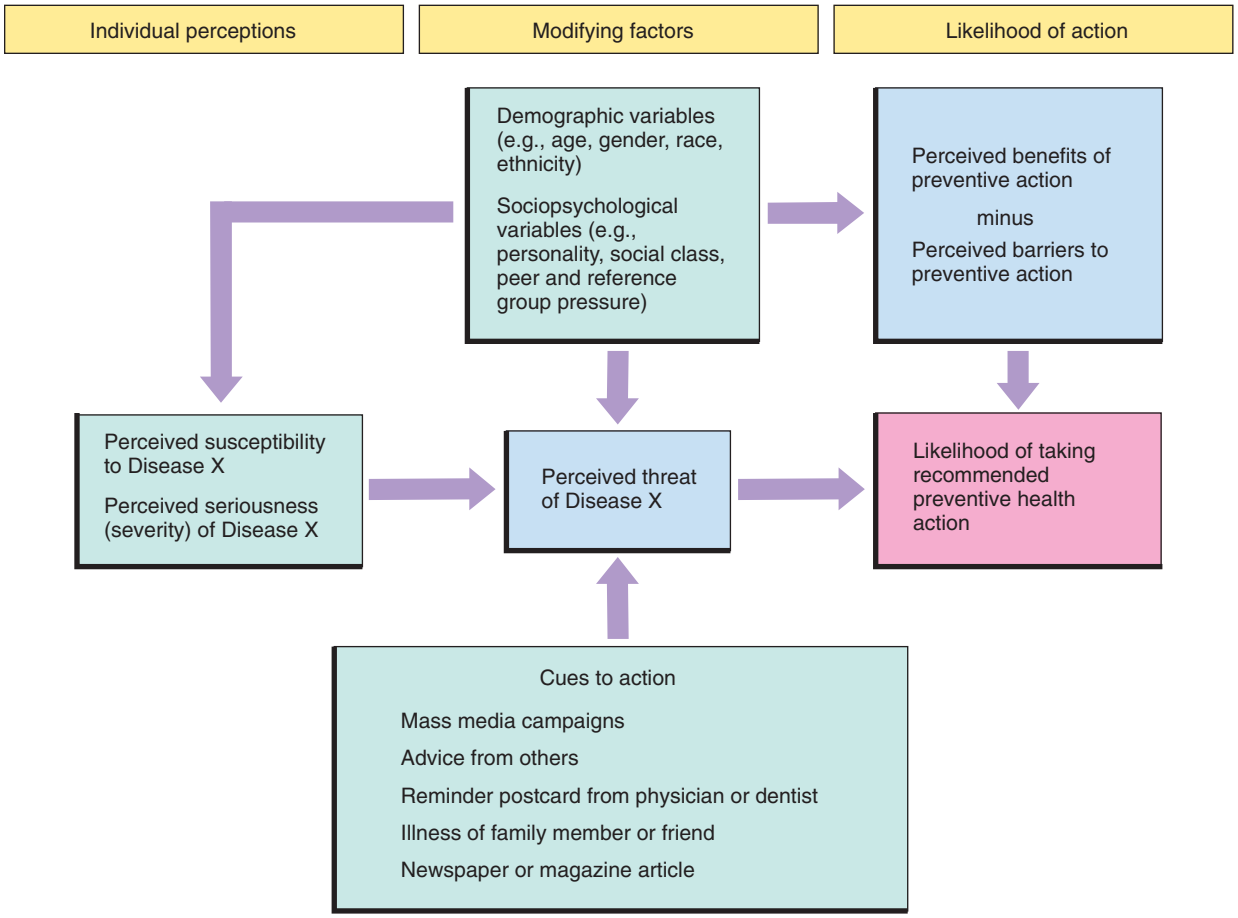

FIG. 6-1 Health belief model. (Data from Becker M, Maiman L: Sociobehavioral determinants of compliance with health and medical care recommendations, *Med Care* 13[1]:10, 1975.)

HPM notes that each person has unique personal characteristics and experiences that affect subsequent actions. The set of variables for behavioral-specific knowledge and affect have important motivational significance. These variables can be modified through nursing actions. Health-promoting behavior is the desired behavioral outcome and is the end point in the HPM. Health-promoting behaviors result in improved health, enhanced functional ability, and better quality of life at all stages of development (Pender, Murdaugh, and Parsons, 2011) (Box 6-2).

Maslow's Hierarchy of Needs

Basic human needs are elements that are necessary for human survival and health (e.g., food, water, safety, and love). Although each person has other unique needs, all people share the basic human needs, and the extent to which basic needs are met is a major factor in determining a person's level of health.

Maslow's hierarchy of needs is a model that nurses use to understand the interrelationships of basic human needs (Fig. 6-3). According to this model, certain human needs are more basic than others (i.e., some needs must be met before other needs [e.g., fulfilling the physiological needs before the needs of love and belonging]). Self-actualization is the highest expression of one's individual potential and allows for continual discovery of self. Maslow's model takes into account individual experiences, always unique to the individual (Ebersole et al., 2008).

The hierarchy of needs model provides a basis for nurses to care for patients of all ages in all health settings. However, when applying the model, the focus of care is on the patient's needs rather than on strict adherence to the hierarchy. It is unrealistic to always expect a patient's basic needs to occur in the fixed hierarchical order. In all cases an emergent physiological need takes precedence over a higher-level need. In other situations a psychological or physical safety need takes priority. For example, in a house fire fear of injury and death takes priority over self-esteem issues. Although it would seem that a patient who has just had surgery might have the strongest need for pain control in the psychosocial area, if the patient just had a mastectomy, her main need may be in the areas of love, belonging, and self-esteem. It is important not to assume the patient's needs just because other patients reacted in a certain way. Maslow's hierarchy can be very useful when applied to each patient individually. To provide the most effective care, you need to understand the relationships of different needs and the factors that determine the priorities for each patient.

Holistic Health Models

Health care has begun to take a more holistic view of health by considering emotional and spiritual well-being and other dimensions of an individual as important aspects of physical wellness. The **holistic health model** of nursing attempts to create conditions that promote optimal health. In this model, nurses using the

BOX 6-1 EVIDENCE-BASED PRACTICE

Mammography Practices in Asian-American Immigrant Women

PICO Question: What sociocultural factors affect mammography screening practices in women who are Asian-American?

Evidence Summary

Breast cancer is a leading cause of cancer deaths in women. Routine screening with mammograms is the recommended practice for early breast cancer detection. Asian women are more likely to not use mammograms for screening, to have breast cancer diagnosed at a later stage, and to have larger tumors at diagnosis (Lee et al., 2009; Lee-Lin et al., 2007; Wu and Ronis, 2009). The health belief model was used to examine the women's knowledge and perceptions about developing breast cancer and preventive actions taken such as mammography. Results showed that only approximately 50% of the women studied had a mammogram in the last year (Lee et al., 2009; Lee-Lin et al., 2007; Wu and Ronis, 2009). Findings showed that the length of time the woman lived in the United States, having a recommendation from a health care provider, and insurance coverage were significantly related to having a mammogram (Lee-Lin et al., 2007). Other factors that contributed to having a mammogram included age, education, a higher perceived benefit to having the test, and higher levels of perceived risk of cancer (Wu and Ronis, 2009). The top three identified barriers to having a mammogram were remembering to have one, a belief that a mammogram is painful, and worry about radiation exposure (Lee-Lin et al., 2007).

Application to Nursing Practice

- Assess misconceptions that women hold related to breast cancer and mammogram screening (Wu and Ronis, 2009).
- Develop culturally tailored interventions for immigrants who speak limited English (Lee et al., 2009).
- Primary health care workers need to educate women about the American Cancer Society guidelines for mammogram screening (Lee-Lin et al., 2007).
- Assess the barriers that the women identified to increase likelihood of obtaining mammograms (Lee-Lin et al., 2007).
- Develop strategies to increase screening rates for at-risk subgroups such as recent immigrants (Wu and Ronis, 2009).
- Consider the woman's perceived susceptibility to breast cancers and perceived benefit of screening when planning education (Lee et al., 2009).

BOX 6-2 FOCUS ON OLDER ADULTS

Health Promotion

- Promote healthy lifestyles by encouraging regular physical activity, accepting responsibility for one's own health, using stress management strategies, focusing on self-care abilities, and practicing relaxation (Lee and Park, 2006; Pender, Murdaugh, and Parsons, 2011).
- Consider the older adult's social environment and strengthening social support to promote health and provide access to resources (Callaghan, 2005; Ebersole et al., 2008).
- Use a holistic approach to promoting health. The focus is not on absence of disease but on achieving the highest level of health in the presence of disease (Ebersole et al., 2008).
- Injury prevention is a key strategy to promote and improve health (Ebersole et al., 2008).
- Fear of falling is a significant risk related to older adults' avoidance of physical activity. Assess for the fear and provide support, make environmental changes to help decrease falls, and provide assistive devices as needed (Bertera and Bertera, 2008).
- Factors that have been reported to affect older adults' willingness to engage in health promotion activities may include socioeconomic factors, beliefs and attitudes for patients and providers, encouragement by a health care professional, specific motivation based on efficacy beliefs, access to resources, age, number of chronic illnesses, mental and physical health, marital status, ability for self-care, gender, education, and support system presence (Byam-Williams and Salyer, 2010; Callaghan, 2005).
- Scientific evidence increasingly indicates that physical activity can extend years of active independent life, reduce disability, and improve the quality of life for older persons (Chodzko-Zajko et al., 2009).

nursing process consider patients to be the ultimate experts concerning their own health and respect patients' subjective experience as relevant in maintaining health or assisting in healing. In the holistic health model patients are involved in their healing process, thereby assuming some responsibility for health maintenance (Edelman and Mandle, 2010).

Nurses using the holistic nursing model recognize the natural healing abilities of the body and incorporate complementary and alternative interventions such as music therapy, reminiscence, relaxation therapy, therapeutic touch, and guided imagery because they are effective, economical, noninvasive, nonpharmacological complements to traditional medical care (see Chapter 32). These holistic strategies, which can be used in all stages of health and illness, are integral in the expanding role of nursing.

Nurses use holistic therapies either alone or in conjunction with conventional medicine. For example, they use reminiscence in the geriatric population to help relieve anxiety for a patient dealing with memory loss or for a cancer patient dealing with the difficult side effects of chemotherapy. Music therapy in the operating room creates a soothing environment. Relaxation therapy is frequently useful to distract a patient during a painful procedure such as a dressing change. Breathing exercises are commonly taught to help patients deal with the pain associated with labor and delivery.

VARIABLES INFLUENCING HEALTH AND HEALTH BELIEFS AND PRACTICES

Many variables influence a patient's health beliefs and practices. Internal and external variables influence how a person thinks and acts. As previously stated, health beliefs usually influence health behavior or health practices and likewise positively or negatively affect a patient's level of health. Therefore understanding the effects of these variables allows you to plan and deliver individualized care.

Internal Variables

Internal variables include a person's developmental stage, intellectual background, perception of functioning, and emotional and spiritual factors.

Developmental Stage. A person's thought and behavior patterns change throughout life. The nurse considers the patient's level of growth and development when using his or her health beliefs and practices as a basis for planning care. The study of development involves finding patterns or general principles that apply to most people most of the time (Murray et al., 2008). The concept of illness for a child, adolescent, or adult depends on the

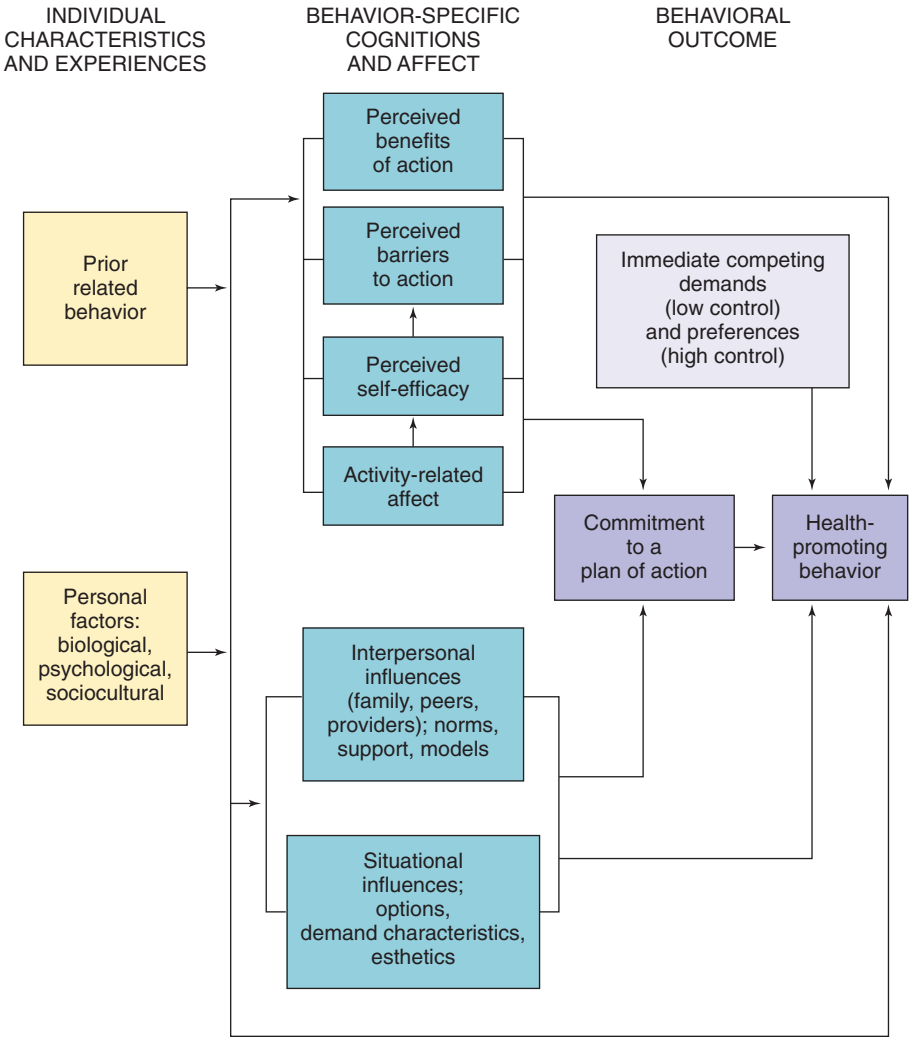

FIG. 6-2 Health promotion model (revised). (Redrawn from Pender NJ, Murdaugh CL, Parsons MA: *Health promotion in nursing practice,* ed 5, Upper Saddle River, NJ, 2006, Prentice Hall.)

individual's developmental stage. Fear and anxiety are common among ill children, especially if thoughts about illness, hospitalization, or procedures are based on lack of information or lack of clarity of information. Emotional development may also influence personal beliefs about health-related matters. For example, you use different techniques for teaching about contraception to an adolescent than you use for an adult. Knowledge of the stages of growth and development helps predict the patient's response to the present illness or the threat of future illness. Adapt the planning of nursing care to these expectations and to the patient's abilities to participate in self-care.

Intellectual Background. A person's beliefs about health are shaped in part by the person's knowledge, lack of knowledge, or incorrect information about body functions and illnesses, educational background, and past experiences. These variables influence how a patient thinks about health. In addition, cognitive abilities shape the *way* a person thinks, including the ability to understand factors involved in illness and apply knowledge of health and illness to personal health practices. Cognitive abilities also relate to a person's developmental stage. A nurse considers intellectual background so these variables can be incorporated into nursing care (Edelman and Mandle, 2010).

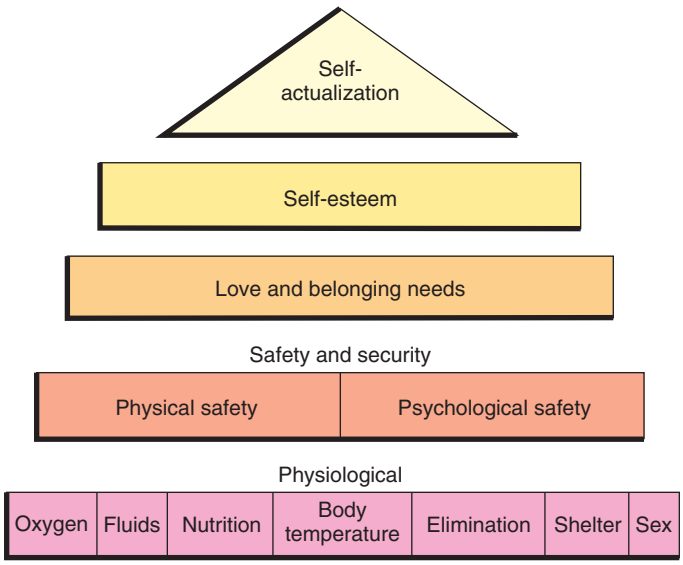

FIG. 6-3 Maslow's hierarchy of needs. (Redrawn from Maslow AH: *Motivation and personality,* ed 3, Upper Saddle River, NJ, 1970, Prentice Hall.)

Perception of Functioning. The way people perceive their physical functioning affects health beliefs and practices. When you assess a patient's level of health, gather subjective data about the way the patient perceives physical functioning such as level of fatigue, shortness of breath, or pain. Then obtain objective data about actual functioning such as blood pressure, height measurements, and lung sound assessment. This information allows you to more successfully plan and implement individualized care.

Emotional Factors. The patient's degree of stress, depression, or fear can influence health beliefs and practices. The manner in which a person handles stress throughout each phase of life influences the way he or she reacts to illness. A person who generally is very calm may have little emotional response during illness, whereas an individual unable to cope emotionally with the threat of illness may either overreact to it and assume that it is life threatening or deny the presence of symptoms and not take therapeutic action (see Chapter 37).

Spiritual Factors. Spirituality is reflected in how a person lives his or her life, including the values and beliefs exercised, the relationships established with family and friends, and the ability to find hope and meaning in life. Spirituality serves as an integrating theme in people's lives (see Chapter 35). Religious practices are one way that people exercise spirituality. Some religions restrict the use of certain forms of medical treatment. You need to understand patients' spiritual dimensions to involve patients effectively in nursing care.

External Variables

External variables influencing a person's health beliefs and practices include family practices, socioeconomic factors, and cultural background.

Family Practices. The way that patients' families use health care services generally affects their health practices. Their perceptions of the seriousness of diseases and their history of preventive care behaviors (or lack of them) influence how patients think about health. For example, if a young woman's mother never had annual gynecological examinations or Papanicolaou (Pap) smears, it is unlikely that the daughter will have annual Pap smears.

Socioeconomic Factors. Social and psychosocial factors increase the risk for illness and influence the way that a person defines and reacts to illness. Psychosocial variables include the stability of the person's marital or intimate relationship, lifestyle habits, and occupational environment. A person generally seeks approval and support from social networks (neighbors, peers, and co-workers), and this desire for approval and support affects health beliefs and practices.

Social variables partly determine how the health care system provides medical care. The organization of the health care system determines how patients can obtain care, the treatment method, the economic cost to the patient, and potential reimbursement to the health care agency or patient.

Like social variables, economic variables often affect a patient's level of health by increasing the risk for disease and influencing how or at what point the patient enters the health care system. A person's compliance with a treatment designed to maintain or improve health is also affected by economic status. A person who has high utility bills, a large family, and a low income tends to give a higher priority to food and shelter than to costly drugs or treatment or expensive foods for special diets. Some patients decide to take medications every other day rather than every day as prescribed to save money, which greatly affects the effectiveness of the medications.

BOX 6-3 CULTURAL ASPECTS OF CARE

Cultural Health Beliefs

The cultural and ethnic backgrounds of patients shape their views of health, how to treat and prevent illness, and what constitutes good care (Narayan, 2010). Health and illness beliefs often fall into magicoreligious, biomedical, and deterministic beliefs (Singleton and Krause, 2009). The magicoreligious belief is often seen in Latin American, African American, and Middle Eastern cultures. These beliefs focus on hexes (i.e., supernatural forces that cause illness) (Yeo, 2009). Illness may also be viewed as a punishment for sins, or it can focus on evil spirits or disease-bearing foreign objects. The biomedical belief system, seen in the United States, believes that health and illness are related to physical and biochemical processes, with disease being a breakdown of the processes. The belief of determinism focuses on outcomes that are externally preordained and cannot be changed (Singleton and Krause, 2009). Other examples of cultural beliefs that affect health care practices include yin/yang balance, free flow of chi, influence of humors, the importance of hexes, and spirits and soul loss (Yeo, 2009). Recognizing the patient's health beliefs helps the nurse provide holistic nursing care that considers the physical, psychological, social, emotional, and spiritual needs of each patient (Maier-Lorentz, 2008).

Implications for Practice

- Be aware of the impact of culture on a patient's view and understanding of illness.
- Focus on understanding the patient's traditions, values, and beliefs and how these dimensions may affect health, wellness, and illness.
- Do not stereotype a patient based on his or her culture and assume that they will adopt all cultural beliefs and practices (Narayan, 2010).
- When teaching patients about their illness and treatment regimens, it is important for nurses to understand that unique cultural perceptions exist regarding the cause of an illness and its treatment.
- Use a trained interpreter if possible when the patient and family do not speak English to avoid misinterpretation of information (Yeo, 2009).
- Be aware of your own cultural background and recognize prejudices that may lead to stereotyping and discrimination (Maier-Lorentz, 2008).

Cultural Background. Cultural background influences beliefs, values, and customs. It influences the approach to the health care system, personal health practices, and the nurse-patient relationship. Cultural background also influences an individual's beliefs about causes of illness and remedies or practices to restore health (Box 6-3). If you are not aware of your own cultural patterns of behavior and language, you will have difficulty recognizing and understanding your patient's behaviors and beliefs. You will also probably have difficulty interacting with patients. As with family and socioeconomic variables, you need to incorporate cultural variables into a patient's care plan (see Chapter 9).

HEALTH PROMOTION, WELLNESS, AND ILLNESS PREVENTION

Health care has become increasingly focused on health promotion, wellness, and illness prevention. The rapid rise of health care costs has motivated people to seek ways of decreasing the incidence and minimizing the results of illness or disability.

The concepts of health promotion, wellness, and illness prevention are closely related and in practice overlap to some extent. All are focused on the future; the difference among them involves motivations and goals. **Health promotion** activities such as routine

exercise and good nutrition help patients maintain or enhance their present levels of health. They motivate people to act positively to reach more stable levels of health. **Wellness** education teaches people how to care for themselves in a healthy way and includes topics such as physical awareness, stress management, and self-responsibility. Wellness strategies help people achieve new understanding and control of their lives. **Illness prevention** activities such as immunization programs protect patients from actual or potential threats to health. They motivate people to avoid declines in health or functional levels.

Nurses emphasize health promotion activities, wellness-enhancing strategies, and illness prevention activities as important forms of health care because they assist patients in maintaining and improving health. The goal of a total health program is to improve a patient's level of well-being in all dimensions, not just physical health. Total health programs are based on the belief that many factors can affect a person's level of health.

Examples of the health topics and objectives as defined by *Healthy People 2020* include physical activity, adolescent health, tobacco use, substance abuse, sexually transmitted diseases, mental health and mental disorders, injury and violence prevention, environmental health, immunization and infectious disease, and access to health care (USDHHS, 2011). A complete list of topics and objectives is available on the *Healthy People* website (www.healthypeople.gov). These objectives and topics show the importance of health promotion and illness prevention and encourage all to participate in the improvement of health.

Individual practices such as poor eating habits and little or no exercise influence health. Physical stressors such as a poor living environment, exposure to air pollutants, and an unsafe environment also affect health. Hereditary and psychological stressors such as emotional, intellectual, social, developmental, and spiritual factors influence one's level of health. Total health programs are directed at individuals' changing their lifestyles by developing habits that improve their level of health.

Other programs are aimed at specific health care problems. For example, support groups help people with human immunodeficiency virus (HIV) infection. Exercise programs encourage participants to exercise regularly to reduce their risk of cardiac disease. Stress-reduction programs teach participants to cope with stressors and reduce their risks for multiple illnesses such as infections, gastrointestinal disease, and cardiac disease.

Some health promotion, wellness education, and illness prevention programs are operated by health care agencies; others are operated independently. Many businesses have on-site health promotion activities for employees. Likewise, colleges and community centers offer health promotion and illness prevention programs. Some nurses actively participate in these programs, providing direct care, and others act as consultants or refer patients to these programs. The goal of these activities is to improve a patient's level of health through preventive health services, environmental protection, and health education.

Health care professionals who work in the field of health promotion use proactive attempts to prevent illness or disease. Health promotion activities are passive or active. With **passive strategies of health promotion,** individuals gain from the activities of others without acting themselves. The fluoridation of municipal drinking water and the fortification of homogenized milk with vitamin D are examples of passive health promotion strategies. With **active strategies of health promotion,** individuals are motivated to adopt specific health programs. Weight-reduction and smoking-cessation programs require patients to be actively involved in measures to improve their present and future levels of wellness while decreasing the risk of disease.

Health promotion is a process of helping people improve their health to reach an optimal state of physical, mental, and social well-being (WHO, 2009). An individual takes responsibility for health and wellness by making appropriate lifestyle choices. Lifestyle choices are important because they affect a person's quality of life and well-being. Making positive lifestyle choices and avoiding negative lifestyle choices also plays a role in preventing illness. In addition to improving quality of life, preventing illness has an economic impact because it decreases health care costs.

Levels of Preventive Care

Nursing care oriented to health promotion, wellness, and illness prevention is described in terms of health activities on primary, secondary, and tertiary levels (Table 6-1).

Primary Prevention. **Primary prevention** is true prevention; it precedes disease or dysfunction and is applied to patients considered physically and emotionally healthy. Primary prevention aimed at health promotion includes health education programs, immunizations, and physical and nutritional fitness activities. Primary prevention includes all health promotion efforts and wellness education activities that focus on maintaining or improving the general health of individuals, families, and communities (Edelman and Mandle, 2010). Primary prevention includes specific protection such as immunization for influenza and hearing protection in occupational settings.

Secondary Prevention. **Secondary prevention** focuses on individuals who are experiencing health problems or illnesses and are at risk for developing complications or worsening conditions. Activities are directed at diagnosis and prompt intervention, thereby reducing severity and enabling the patient to return to a normal level of health as early as possible (Edelman and Mandle, 2010). A large portion of nursing care related to secondary prevention is delivered in homes, hospitals, or skilled nursing facilities. It includes screening techniques and treating early stages of disease to limit disability by averting or delaying the consequences of advanced disease. Screening activities also become a key opportunity for health teaching as a primary prevention intervention (Edelman and Mandle, 2010).

Tertiary Prevention. **Tertiary prevention** occurs when a defect or disability is permanent and irreversible. It involves minimizing the effects of long-term disease or disability by interventions directed at preventing complications and deterioration (Edelman and Mandle, 2010). Activities are directed at rehabilitation rather than diagnosis and treatment. Care at this level helps patients achieve as high a level of functioning as possible, despite the limitations caused by illness or impairment. This level of care is called preventive care because it involves preventing further disability or reduced functioning.

RISK FACTORS

A **risk factor** is any situation, habit, social or environmental condition, physiological or psychological condition, developmental or intellectual condition, spiritual condition, or other variable that increases the vulnerability of an individual or group to an illness or accident. Risk factors, behavior, risk factor modification, and behavior modification are integral components of health promotion, wellness, and illness prevention activities. Nurses in all areas of practice often have opportunities to help patients adopt activities to promote health and decrease risks of illness.

TABLE 6-1 Three Levels of Prevention

PRIMARY PREVENTION		SECONDARY PREVENTION		TERTIARY PREVENTION
HEALTH PROMOTION	**SPECIFIC PROTECTION**	**EARLY DIAGNOSIS AND PROMPT TREATMENT**	**DISABILITY LIMITATIONS**	**RESTORATION AND REHABILITATION**
Health education Good standard of nutrition adjusted to developmental phases of life Attention to personality development Provision of adequate housing and recreation and agreeable working conditions Marriage counseling and sex education Genetic screening Periodic selective examinations	Use of specific immunizations Attention to personal hygiene Use of environmental sanitation Protection against occupational hazards Protection from accidents Use of specific nutrients Protection from carcinogens Avoidance of allergens	Case-finding measures: individual and mass screening activities Selective examinations to cure and prevent disease process, prevent spread of communicable disease, prevent complications and sequelae, and shorten period of disability	Adequate treatment to arrest disease process and prevent further complications and sequelae Provision of facilities to limit disability and prevent death	Provision of hospital and community facilities for retraining and education to maximize use of remaining capacities Education of public and industry to use rehabilitated persons to fullest possible extent Selective placement Work therapy in hospitals Use of sheltered colony

Data from Leavell H, Clark AE: *Preventive medicine for the doctors in his community,* ed 3, New York, 1965, McGraw-Hill; and modified from Edelman CL, Mandle CL: *Health promotion throughout the life span,* ed 7, St Louis, 2010, Mosby.

The presence of risk factors does not mean that a disease will develop, but risk factors increase the chances that the individual will experience a particular disease or dysfunction. Nurses and other health care professionals are concerned with risk factors, sometimes called *health hazards,* for several reasons. Risk factors play a major role in how a nurse identifies a patient's health status. They can also influence health beliefs and practices if a person is aware of their presence. Risk factors are often placed in the following interrelated categories: genetic and physiological factors, age, physical environment, and lifestyle.

Genetic and Physiological Factors

Physiological risk factors involve the physical functioning of the body. Certain physical conditions such as being pregnant or overweight place increased stress on physiological systems (e.g., the circulatory system), increasing susceptibility to illness. Heredity, or genetic predisposition to specific illness, is a major physical risk factor. For example, a person with a family history of diabetes mellitus is at risk for developing the disease later in life. Other documented genetic risk factors include family histories of cancer, heart disease, kidney disease, or mental illness.

Age

Age affects a person's susceptibility to certain illnesses. For example, premature infants and neonates are more susceptible to infections. As a person ages, the risk of heart disease and many types of cancers increases. Age risk factors are often closely associated with other risk factors such as family history and personal habits. Nurses need to educate their patients about the importance of regularly scheduled checkups for their age-group. Various professional organizations and federal agencies develop and update recommendations for health screenings, immunizations, and counseling. Access to scientific evidence, recommendations for clinical prevention services, and information on how to incorporate recommended preventive services into practice can be found at www.ahrq.gov/clinic/prevenix.htm.

Environment

Where we live and the condition of that area (its air, water, and soil) determine how we live, what we eat, the disease agents to which we are exposed, our state of health, and our ability to adapt (Murray et al., 2008). The physical environment in which a person works or lives can increase the likelihood that certain illnesses will occur. For example, some kinds of cancer and other diseases are more likely to develop when industrial workers are exposed to certain chemicals or when people live near toxic waste disposal sites. Nursing assessments extend from the individual to the family and the community in which they live (Murray et al., 2008).

Lifestyle

Many activities, habits, and practices involve risk factors. Lifestyle practices and behaviors often have positive or negative effects on health. Lifestyle choices contribute to seven of the ten leading causes of death (Table 6-2). Practices with potential negative effects are risk factors. Some habits are risk factors for specific diseases. For example, excessive sunbathing increases the risk of skin cancer; smoking increases the risk of lung diseases, including cancer; and a poor diet and being overweight increase the risk of cardiovascular disease. Because of lifestyle choices, there is an increased emphasis on preventive care. Lifestyle choices lead to health problems that cause a huge impact on the economics of the health care system. Therefore it is important to understand the effect of lifestyle behaviors on health status. Nurses educate their patients and the public on wellness-promoting lifestyle behaviors.

Stress is a lifestyle risk factor if it is severe or prolonged or if the person is unable to cope with life events adequately. Stress threatens both mental health (emotional stress) and physical well-being (physiological stress). Both play a part in the development of an illness and affect the ability to adapt to potential changes associated with the illness and survive a life-threatening illness. Stress also interferes with health promotion activities and the ability to implement needed lifestyle modifications. Some emotional stressors result from life events such as divorce, pregnancy, death of a spouse

TABLE 6-2 Causes of Death in the United States in 2007 and Contributing Lifestyle Choices

LEADING CAUSES OF DEATH	NUMBER (%)*	LIFESTYLE CHOICES
Heart disease	616,067 (25.4)	Physical inactivity, poor nutrition, use of tobacco
Cancer	562,875 (23.2)	Use of tobacco, poor nutrition, excess sun exposure, no use of preventive screenings
Stroke (cerebrovascular diseases)	135,952 (5.6)	Use of tobacco, poor nutrition, physical inactivity
Chronic lower respiratory diseases	127,924 (5.3)	Use of tobacco
Accidents (unintentional injuries)	123,706 (5.1)	Use of alcohol and drugs, no use of seat belt or motorcycle helmet
Alzheimer's disease	74,632 (3.1)	
Diabetes	71,382 (2.9)	Obesity, poor nutrition
Influenza and pneumonia	52,717 (2.2)	Use of tobacco, lack of immunizations
Nephritis, nephrotic syndrome, nephrosis	46,448 (1.9)	
Septicemia	34,828 (1.4)	

*Data from Centers for Disease Control and Prevention: *Deaths and mortality,* http://www.cdc.gov/nchs/fastats/deaths.htm. Accessed June 30, 2009.

or family member, and financial instabilities. For example, job-related stressors overtax a person's cognitive skills and decision-making ability, leading to "mental overload" or "burnout" (see Chapter 37). Stress also threatens physical well-being and is associated with illnesses such as heart disease, cancer, and gastrointestinal disorders (Pender, Murdaugh, and Parsons, 2011). Always review life stressors as part of a comprehensive risk factor analysis.

The goal of risk factor identification is to help patients visualize the areas in their life that can be modified, controlled, or even eliminated to promote wellness and prevent illness. A variety of available health risk appraisal forms can be used to estimate a person's specific health threats based on the presence of various risk factors (Edelman and Mandle, 2010). Implementation of a health risk appraisal tool needs to be linked with educational programs and other community resources if it is to result in necessary lifestyle changes and risk reduction (Pender, Murdaugh, and Parsons, 2011).

RISK-FACTOR MODIFICATION AND CHANGING HEALTH BEHAVIORS

Identifying risk factors is the first step in health promotion, wellness education, and illness prevention. Discuss health hazards with the patient following a comprehensive nursing assessment, then help the patient decide if he or she wants to maintain or improve his or her health status by taking risk-reduction actions (Edelman and Mandle, 2010). Risk-factor modification, health promotion or illness prevention activities, or any program that attempts to change unhealthy lifestyle behaviors is a wellness strategy. Emphasize wellness strategies that teach patients to care for themselves in a healthier way because they have the ability to increase the quality of life and decrease the potential high costs of unmanaged health problems.

Some attempts to change are aimed at the cessation of a health-damaging behavior (e.g., tobacco use or alcohol misuse) or the adoption of a healthy behavior (e.g., healthy diet or exercise) (Pender, Murdaugh, and Parsons, 2011). It is difficult to change health behavior, especially when the behavior is ingrained in a person's lifestyle patterns. The importance of nurses using an HPM to identify risky behaviors and implement the change process cannot be overemphasized because it is the nurse who spends the greatest amount of time in direct contact with patients. In addition, leading causes of death continue to relate to health behaviors that require a change, and nurses are able to motivate and facilitate important health behavior change when working with individuals, families, and communities (Edelman and Mandle, 2010).

Understanding the process of changing behaviors will help you support difficult **health behavior changes** in patients. It is believed that change involves movement through a series of stages. DiClemente and Prochaska (1998) describe the stages of change in the transtheoretical model of change (Table 6-3). These stages range from no intention to change (precontemplation), considering a change within the next 6 months (contemplation), making small changes (preparation), and actively engaging in strategies to change behavior (action) to maintaining a changed behavior (maintenance stage). As individuals attempt a change in behavior, relapse followed by recycling through the stages frequently occurs. When relapse occurs, the person will return to the contemplation or precontemplation stage before attempting the change again. Relapse is a learning process, and the lessons learned from relapse can be applied to the next attempt to change. It is important to understand what happens at the various stages of the change process to time the implementation of interventions (wellness strategies) adequately and provide appropriate care at each stage.

Once an individual identifies a stage of change, the change process facilitates movement through the stages. To be most effective, you choose nursing interventions that match the stage of change (DiClemente and Prochaska, 1998). Most behavior-change programs are designed for (and have a chance of success when) people are ready to take action regarding their health behavior problems. Only a minority of people are actually in this action stage (Prochaska, 1991). Changes are maintained over time only if they are integrated into an individual's overall lifestyle (Box 6-4). Maintaining healthy lifestyles can prevent hospitalizations and potentially lower the cost of health care.

ILLNESS

Illness is a state in which a person's physical, emotional, intellectual, social, developmental, or spiritual functioning is diminished or impaired. Cancer is a disease process, but one patient with leukemia who is responding to treatment may continue to function as usual, whereas another patient with breast cancer who is preparing for surgery may be affected in dimensions other than the physical. Therefore illness is not synonymous with disease. Although nurses need to be familiar with different types of diseases and their treatments, they often are concerned more with illness, which may include disease but also includes the effects on functioning and well-being in all dimensions.

TABLE 6-3 Stages of Health Behavior Change

STAGE	DEFINITION	NURSING IMPLICATIONS
Precontemplation	Not intending to make changes within the next 6 months	Patient is not interested in information about the behavior and may be defensive when confronted with it.
Contemplation	Considering a change within the next 6 months	Ambivalence may be present, but patients will more likely accept information since they are developing more belief in the value of change.
Preparation	Making small changes in preparation for a change in the next month	Patient believes that advantages outweigh disadvantages of behavior change; needs assistance in planning for the change.
Action	Actively engaged in strategies to change behavior; lasts up to 6 months	Previous habits may prevent taking action relating to new behaviors; identify barriers and facilitators of change.
Maintenance stage	Sustained change over time; begins 6 months after action has started and continues indefinitely	Changes need to be integrated into the patient's lifestyle.

Data from Prochaska JO, DiClemente CC: Stages of change in the modification of problem behaviors, *Prog Behav Modif* 28:184, 1992; and Conn VS: A staged-based approach to helping people change health behaviors, *Clin Nurs Spec* 8(4):187, 1994.

BOX 6-4 PATIENT TEACHING

Lifestyle Changes

Objective

- Patient will reduce health risks related to poor lifestyle habits (e.g., high-fat diet, sedentary lifestyle) through behavior change.

Teaching Strategies

- Practice active listening, and ask the patient how he or she prefers to learn (Cornett, 2009).
- Begin with determining what information the patient knows regarding health risks related to poor lifestyle.
- Ask which barriers the patient perceives with the planned lifestyle change.
- Assist the patient in establishing goals for change.
- In collaboration with the patient, establish time lines for modification of eating and exercise lifestyle habits.
- Reinforce the process of change.
- Use written resources at an appropriate reading level (Villaire and Mayer, 2009).
- Ensure that the education materials are culturally appropriate (Villaire and Mayer, 2009).
- Include family members to support the lifestyle change.

Evaluation

- Have the patient maintain an exercise and eating calendar to track adherence and provide positive reinforcement.
- Ask the patient to discuss success with lifestyle changes such as minutes spent in activity or actual number of fruits and vegetables eaten.

Acute and Chronic Illness

Acute and chronic illness are two general classifications of illness used in this chapter. Both acute and chronic illnesses have the potential to be life threatening. An **acute illness** is usually reversible, has a short duration, and is often severe. The symptoms appear abruptly, are intense, and often subside after a relatively short period. An acute illness may affect functioning in any dimension. A **chronic illness** persists, usually longer than 6 months, is irreversible, and affects functioning in one or more systems. Patients often fluctuate between maximal functioning and serious health relapses that may be life threatening. A person with a chronic illness is similar to a person with a disability in that both have varying degrees of functional limitations that result from either a pathological process or an injury (Larsen, 2009a). In addition, the social surroundings and physical environment in which the individual lives frequently affect the abilities, motivation, and psychological maintenance of the person with a chronic illness or disability.

Chronic illnesses and disabilities remain a leading health problem in North America for older adults and children. Issues of coping and living with a chronic illness can be complex and overwhelming. Chronic illnesses are related to four modifiable health behaviors: physical inactivity, poor nutrition, use of tobacco, and excessive alcohol consumption (CDC, 2009). A major role for nursing is to provide patient education aimed at helping patients manage their illness or disability. The goal of managing a chronic illness is to reduce the occurrence or improve the tolerance of symptoms. By enhancing wellness, nurses improve the quality of life for patients living with chronic illnesses or disabilities.

Patients with chronic diseases and their families continually adjust and adapt to their illnesses. How an individual perceives an illness influences the type of coping responses. In response to a chronic illness, an individual develops an illness career. The illness career is flexible and changes in response to changes in health, interactions with health professionals, psychological changes related to grief, and stress related to the illness (Larsen, 2009b).

Illness Behavior

People who are ill generally act in a way that medical sociologists call **illness behavior.** It involves how people monitor their bodies, define and interpret their symptoms, take remedial actions, and use the resources in the health care system (Mechanic, 1995). Personal history, social situations, social norms, and past experiences affect illness behavior (Larsen, 2009b). How people react to illness varies widely; illness behavior displayed in sickness is often used to manage life adversities (Mechanic, 1995). In other words, if people perceive themselves to be ill, illness behaviors become coping mechanisms. For example, illness behavior results in a patient being released from roles, social expectations, or responsibilities. A homemaker views the "flu" as either an added stressor or a temporary release from child care and household responsibilities.

Variables Influencing Illness and Illness Behavior

Internal and external variables influence both health and health behavior and illness and illness behavior. The influences of these variables and the patient's illness behavior often affect the likelihood of seeking health care, compliance with therapy, and health outcomes. Nurses plan individualized care based on an understanding of these variables and behaviors to help patients cope with their illness at various stages. The goal is to promote optimal functioning in all dimensions throughout an illness.

Internal Variables. Internal variables, such as patient perceptions of symptoms and the nature of the illness, influence patient behavior. If patients believe that the symptoms of their illnesses disrupt their normal routine, they are more likely to seek health care assistance than if they do not perceive the symptoms to be disruptive. Patients are also more likely to seek assistance if they believe the symptoms are serious or life threatening. Persons awakened by crushing chest pains in the middle of the night generally view this symptom as potentially serious and life threatening, and they will probably be motivated to seek assistance. However, such a perception can also have the opposite effect. Individuals may fear serious illness, react by denying it, and not seek medical assistance.

The nature of the illness, either acute or chronic, also affects a patient's illness behavior. Patients with acute illnesses are likely to seek health care and comply readily with therapy. On the other hand, a patient with a chronic illness in which symptoms are not cured but only partially relieved may not be motivated to comply with the therapy plan. Some patients who are chronically ill become less actively involved in their care, experience greater frustration, and comply less readily with care. Because nurses generally spend more time than other health care professionals with chronically ill patients, they are in the unique position of being able to help these patients overcome problems related to illness behavior. A patient's coping skills and his or her locus of control are other internal variables that affect the way the patient behaves when ill (see Chapter 37).

External Variables. External variables influencing a patient's illness behavior include the visibility of symptoms, social group, cultural background, economic variables, accessibility of the health care system, and social support. The visibility of the symptoms of an illness affects body image and illness behavior. A patient with a visible symptom is often more likely to seek assistance than a patient with no visible symptoms.

Patients' social groups either assist in recognizing the threat of illness or support the denial of potential illness. Families, friends, and co-workers all potentially influence patients' illness behavior. Patients often react positively to social support while practicing positive health behaviors. A person's cultural and ethnic background teaches the person how to be healthy, how to recognize illness, and how to be ill. The effects of disease and its interpretation vary according to cultural circumstances. Ethnic differences influence decisions about health care and the use of diagnostic and health care services. Dietary practices among ethnic groups, occupations held by certain cultural groups, and cultural beliefs are other factors that contribute to illness and the distribution of disease (Giger and Davidhizar, 2008).

Economic variables influence the way a patient reacts to illness. Because of economic constraints, some patients delay treatment and in many cases continue to carry out daily activities. Patients' access to the health care system is closely related to economic factors. The health care system is a socioeconomic system that patients enter, interact within, and exit. For many patients entry into the system is complex or confusing, and some patients seek nonemergency medical care in an emergency department because they do not know how otherwise to obtain health services or do not have access to care. The physical proximity of patients to a health care agency often influences how soon they enter the system after deciding to seek care.

Impact of Illness on the Patient and Family

Illness is never an isolated life event. The patient and family deal with changes resulting from illness and treatment. Each patient responds uniquely to illness, requiring you to individualize nursing interventions. The patient and family commonly experience behavioral and emotional changes and changes in roles, body image and self-concept, and family dynamics.

Behavioral and Emotional Changes. People react differently to illness or the threat of illness. Individual behavioral and emotional reactions depend on the nature of the illness, the patient's attitude toward it, the reaction of others to it, and the variables of illness behavior.

Short-term, nonlife-threatening illnesses evoke few behavioral changes in the functioning of the patient or family. For example, a father who has a cold lacks the energy and patience to spend time in family activities. He becomes irritable and prefers not to interact with his family. This is a behavioral change, but the change is subtle and does not last long. Some may even consider such a change a normal response to illness.

Severe illness, particularly one that is life threatening, leads to more extensive emotional and behavioral changes such as anxiety, shock, denial, anger, and withdrawal. These are common responses to the stress of illness. You can develop interventions to help the patient and family cope with and adapt to this stress when the stressor itself usually cannot be changed.

Impact on Body Image. Body image is the subjective concept of physical appearance (see Chapter 33). Some illnesses result in changes in physical appearance. Patients' and families' reactions differ and usually depend on the type of changes (e.g., loss of a limb or an organ), their adaptive capacity, the rate at which changes takes place, and the support services available.

When a change in body image such as results from a leg amputation occurs, the patient generally adjusts in the following phases: shock, withdrawal, acknowledgment, acceptance, and rehabilitation. Initially the patient is in shock because of the change or impending change. He or she depersonalizes the change and talks about it as though it were happening to someone else. As the patient and family recognize the reality of the change, they become anxious and often withdraw, refusing to discuss it. Withdrawal is an adaptive coping mechanism that helps the patient adjust. As the patient and family acknowledge the change, they move through a period of grieving. At the end of the acknowledgment phase, they accept the loss. During rehabilitation the patient is ready to learn how to adapt to the change in body image through use of prosthesis or changing lifestyles and goals.

Impact on Self-Concept. Self-concept is a mental self-image of strengths and weaknesses in all aspects of personality. Self-concept depends in part on body image and roles but also includes other aspects of psychology and spirituality (see Chapters 33 and 35). The effect of illness on the self-concepts of patients and family members is usually more complex and less readily observed than role changes.

Self-concept is important in relationships with other family members. For example, a patient whose self-concept changes

because of illness may no longer meet family expectations, leading to tension or conflict. As a result, family members change their interactions with the patient. In the course of providing care, you observe changes in the patient's self-concept (or in the self-concepts of family members) and develop a care plan to help him or her adjust to the changes resulting from the illness.

Impact on Family Roles. People have many roles in life such as wage earner, decision maker, professional, child, sibling, or parent. When an illness occurs, parents and children try to adapt to the major changes that result. Role reversal is common (see Chapter 10). If a parent of an adult becomes ill and cannot carry out usual activities, the adult child often assumes many of the parent's responsibilities and in essence becomes a parent to the parent. Such a reversal of the usual situation can lead to stress, conflicting responsibilities for the adult child, or direct conflict over decision making.

Such a change may be subtle and short term or drastic and long term. An individual and family generally adjust more easily to subtle, short-term changes. In most cases they know that the role change is temporary and will not require a prolonged adjustment. However, long-term changes require an adjustment process similar to the grief process (see Chapter 36). The patient and family often require specific counseling and guidance to help them cope with role changes.

Impact on Family Dynamics. As a result of the effects of illness on the patient and family, family dynamics often change. Family dynamics are the processes by which the family functions, makes decisions, gives support to individual members, and copes with everyday changes and challenges. When a parent in a family becomes ill, family activities and decision making often come to a halt as the other family members wait for the illness to pass, or the family members delay action because they are reluctant to assume the ill person's roles or responsibilities. Women living with spouses who have chronic illness experience a feeling of detachment from the spouse, a sense of loneliness, and a change in their relationship (Eriksson and Svedlund, 2006). The nurse views the whole family as a patient under stress, planning care to help the family regain the maximal level of functioning and well-being (see Chapter 10).

KEY POINTS

- Health and wellness are not merely the absence of disease and illness.
- A person's state of health, wellness, or illness depends on individual values, personality, and lifestyle.
- The health belief model considers the relationship between a person's health beliefs and health behaviors.
- The health promotion model highlights factors that increase individual well-being and self-actualization.
- Maslow's hierarchy of needs model emphasizes identifying a patient's individual needs, prioritizing the needs, and encouraging the patient's individual discovery of self (self-actualization).
- Holistic health models of nursing promote optimal health by incorporating active participation of patients in improving their health state.
- Health beliefs and practices are influenced by internal and external variables and should be considered when planning care.
- Health promotion activities help maintain or enhance health.
- Wellness education teaches patients how to care for themselves.
- Illness prevention activities protect against health threats and thus maintain an optimal level of health.
- Nursing incorporates health promotion activities, wellness education, and illness prevention activities rather than simply treating illness.
- The three levels of preventive care are primary, secondary, and tertiary.
- Risk factors threaten health, influence health practices, and are important considerations in illness prevention activities.
- Improvement in health may involve a change in health behaviors.
- The transtheoretical model of change describes a series of changes through which patients progress for successful behavior change rather than simply assuming that all patients are in an action stage.
- Illness behavior, like health practices, is influenced by many variables and must be considered by the nurse when planning care.
- Illness can have many effects on the patient and family, including changes in behavior and emotions, family roles and dynamics, body image, and self-concept.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Hillman is a 28-year-old divorced woman who is a single parent. She has two children, a 2-year-old boy and a 4-year-old girl. She currently does not have a job. She smokes one pack of cigarettes per day. The father of the children has limited involvement in the care of the children and gives her money when he can. Her mother lives 500 miles away, but her sister lives close by. She occasionally stops by to help with the children. Mrs. Hillman regularly takes the children to the local health clinic for care but she has not seen a health care provider since the delivery of her last child. She is experiencing a persistent cough and fatigue.

1. Identify internal and external variables that are impacting Mrs. Hillman's ability to care for herself.
2. What primary intervention activities are important for Mrs. Hillman and her family?
3. Using the transtheoretical model of change, which question could you ask Mrs. Hillman to determine how to target smoking cessation?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is participating at a health fair at the local mall giving influenza vaccines to senior citizens. What level of prevention is the nurse practicing?
   1. Primary prevention
   2. Secondary prevention
   3. Tertiary prevention
   4. Quaternary prevention
2. A patient experienced a myocardial infarction 4 weeks ago and is currently participating in the daily cardiac rehabilitation sessions at the local fitness center. In what level of prevention is the patient participating?

1. Primary prevention
2. Secondary prevention
3. Tertiary prevention
4. Quaternary prevention

3. Based on the transtheoretical model of change, what is the most appropriate response to a patient who states: "Me, exercise? I haven't done that since junior high gym class, and I hated it then!"
   1. "That's fine. Exercise is bad for you anyway."
   2. "OK. I want you to walk 3 miles 4 times a week, and I'll see you in 1 month."
   3. "I understand. Can you think of one reason why being more active would be helpful for you?"
   4. "I'd like you to ride your bike 3 times this week and eat at least four fruits and vegetables every day."
4. A patient comes to the local health clinic and states: "I've noticed how many people are out walking in my neighborhood. Is walking good for you?" What is the best response to help the patient through the stages of change for exercise?
   1. "Walking is OK. I really think running is better."
   2. "Yes, walking is great exercise. Do you think you could go for a 5-minute walk next week?"
   3. "Yes, I want you to begin walking. Walk for 30 minutes every day and start to eat more fruits and vegetables."
   4. "They probably aren't walking fast enough or far enough. You need to spend at least 45 minutes if you are going to do any good."
5. A male patient has been laid off from his construction job and has many unpaid bills. He is going through a divorce from his marriage of 15 years and has been seeing his pastor to help him through this difficult time. He does not have a primary health care provider because he has never really been sick and his parents never took him to the physician when he was a child. Which external variables influence the patient's health practices? (Select all that apply.)
   1. Difficulty paying his bills
   2. Seeing his pastor as a means of support
   3. Family practice of not routinely seeing a health care provider
   4. Stress from the divorce and the loss of a job
6. The nurse is conducting a home visit with an older adult couple. She assesses that the lighting in the home is poor and there are throw rugs throughout the home and a low footstool in the living room. She discusses removing the rugs and footstool and improving the lighting with the couple. The nurse is addressing which level of need according to Maslow?
   1. Physiological
   2. Safety and security
   3. Love and belonging
   4. Self-actualization
7. When taking care of patients, the nurse routinely asks them if they take any vitamins or herbal medications, encourages family members to bring in music that the patient likes to help the patient relax, and frequently prays with her patients if that is important to them. The nurse is practicing which model?
   1. Holistic
   2. Health belief
   3. Transtheoretical
   4. Health promotion
8. When illness occurs, different attitudes about it cause people to react in different ways. What do medical sociologists call this reaction to illness?
   1. Health belief
   2. Illness behavior
   3. Health promotion
   4. Illness prevention
9. A patient at the community clinic asks the nurse about health promotion activities that she can do because she is concerned about getting diabetes mellitus since her grandfather and father both have the disease. This statement reflects that the patient is in what stage of the health belief model?
   1. Perceived threat of the disease
   2. Likelihood of taking preventive health action
   3. Analysis of perceived benefits of preventive action
   4. Perceived susceptibility to the disease.
10. A nurse works in a special care unit for children with severe immunology problems and is caring for a 3-year-old boy from Greece. The boy's father is with him while his mother and sister are back in Greece. The nurse is having difficulty communicating with the father. What action does the nurse take?
    1. Care for the boy as she would any other patient
    2. Ask the manager to talk with the father and keep him out of the unit
    3. Have another nurse care for the boy because maybe that nurse will do better with the father
    4. Search for help with interpretation and understanding of the cultural differences by contacting someone from the local Greek community
11. A patient with a 20-year history of diabetes mellitus had a lower leg amputation. Which statement made by the patient indicates that he is experiencing a problem with body image?
    1. "I just don't have any energy to get out of bed in the morning."
    2. "I've been attending church regularly with my wife since I got out of the hospital."
    3. "My wife has taken over paying the bills since I've been in the hospital."
    4. "I don't go out very much because everyone stares at me."
12. The patient states she joined a fitness club and attends the aerobics class three nights a week. The patient is in what stage of behavioral change?
    1. Precontemplation
    2. Contemplation
    3. Preparation
    4. Action
13. The nurse is developing a health promotion program on healthy eating and exercise for high school students using the health belief model as a framework. Which statement made by a nursing student is related to the individual's perception of susceptibility to an illness?
    1. "I don't have time to exercise because I have to work after school every night."
    2. "I'm worried about becoming overweight and getting diabetes because my father has diabetes."
    3. "The statistics of how many teenagers are overweight is scary."
    4. "I've decided to start a walking club at school for interested students."
14. The nurse assesses the following risk factors for coronary artery disease (CAD) in a male patient. Which factors are classified as genetic and physiological? (Select all that apply.)

1. Sedentary lifestyle
2. Father died from CAD at age 50
3. History of hypertension
4. Eats diet high in sodium
5. Elevated cholesterol level
6. Age is 44 years

15. Which activity represents secondary prevention?
    1. A home health care nurse visits a patient's home to change a wound dressing.
    2. A 50-year-old woman with no history of disease attends the local health fair and has her blood pressure checked.
    3. The school health nurse provides a program to the first-year students on healthy eating.
    4. The patient attends cardiac rehabilitation sessions weekly.

Answers: **1.** 1; **2.** 3; **3.** 3; **4.** 2; **5.** 1, 3, 4; **6.** 2; **7.** 1; **8.** 2; **9.** 4; **10.** 4; **11.** 4; **12.** 4; **13.** 2; **14.** 2, 3, 5, 6; **15.** 1.

CHAPTER 7

Caring in Nursing Practice

OBJECTIVES

- Discuss the role that caring plays in building the nurse-patient relationship.
- Compare and contrast theories on caring.
- Discuss the evidence that exists about patients' perceptions of caring.
- Explain how an ethic of care influences nurses' decision making.
- Describe ways to express caring through presence and touch.
- Describe the therapeutic benefit of listening to patients.
- Explain the relationship between knowing a patient and clinical decision making.

KEY TERMS

Caring, p. 80
Comforting, p. 84
Ethic of care, p. 83
Presence, p. 83
Transcultural, p. 80
Transformative, p. 81

Caring is central to nursing practice, but it is even more important in today's hectic health care environment. The demands, pressure, and time constraints in the health care environment leave little room for caring practice, which results in nurses and other health professionals becoming dissatisfied with their jobs and cold and indifferent to patient needs (Watson, 2006, 2009). Increasing use of technological advances for rapid diagnosis and treatment often causes nurses and other health care providers to perceive the patient relationship as less important. Technological advances become dangerous without a context of skillful and compassionate care. Despite these challenges, more professional organizations are stressing the importance of caring in health care. *Nursing's Agenda for the Future* (ANA, 2002) states that "Nursing is the pivotal health care profession highly valued for its specialized knowledge, skill, and caring in improving the health status of the individual, family, and the community." The American Organization of Nurse Executives (AONE, 2005) describes caring and knowledge as the core of nursing, with caring being a key component of what a nurse brings to a patient experience (Fig. 7-1).

It is time to value and embrace caring practices and expert knowledge that are the heart of competent nursing practice (Benner and Wrubel, 1989; Benner et al., 2010). When you engage patients in a caring and compassionate manner, you learn that the therapeutic gain in caring makes enormous contributions to the health and well-being of your patients.

Have you ever been ill or experienced a problem requiring health care intervention? Think about that experience. Then consider the following two scenarios and select the situation that you believe most successfully demonstrates a sense of caring.

A nurse enters a patient's room, greets the patient warmly while touching him or her lightly on the shoulder, makes eye contact, sits down for a few minutes and asks about the patient's thoughts and concerns, listens to the patient's story, looks at the intravenous (IV) solution hanging in the room, briefly examines the patient, and then checks the vital sign summary on the bedside computer screen before departing the room.

A second nurse enters the patient's room, looks at the IV solution hanging in the room, checks the vital sign summary sheet on the bedside computer screen, and acknowledges the patient but never sits down or touches him or her. The nurse makes eye contact from above while the patient is lying in bed. He or she asks a few brief questions about the patient's symptoms and leaves.

There is little doubt that the first scenario presents the nurse in specific acts of caring. The nurse's calm presence, parallel eye contact, attention to the patient's concerns, and physical closeness all express a person-centered, comforting approach. In contrast, the second scenario is task-oriented and expresses a sense of indifference to patient concerns. Both of these scenarios take approximately the same amount of time but leave very different patient perceptions. It is important to remember that, during times of illness or when a person seeks the professional guidance of a nurse,

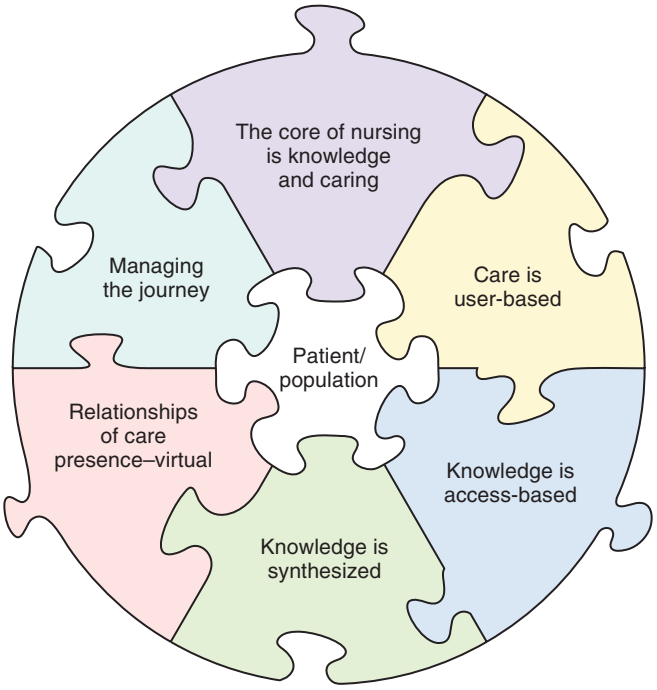

FIG. 7-1 AONE guiding principles for future care delivery. (Copyright © 2005 by the American Organization of Nurse Executives [AONE]. All rights reserved.)

caring is essential in helping the individual reach positive outcomes.

THEORETICAL VIEWS ON CARING

Caring is a universal phenomenon influencing the ways in which people think, feel, and behave in relation to one another. Since Florence Nightingale, nurses have studied caring from a variety of philosophical and ethical perspectives. A number of nursing scholars have developed theories on caring because of its importance to nursing practice. This chapter does not detail all of the theories of caring, but it is designed to help you understand how caring is at the heart of a nurse's ability to work with all patients in a respectful and therapeutic way.

Caring Is Primary

Benner offers nurses a rich, holistic understanding of nursing practice and caring through the interpretation of expert nurses' stories. After listening to nurses' stories and analyzing their meaning, she described the essence of excellent nursing practice, which is caring. The stories revealed the nurses' behaviors and decisions that expressed caring. Caring means that persons, events, projects, and things matter to people (Benner and Wrubel, 1989; Benner et al., 2010). It is a word for being connected.

Caring determines what matters to a person. It underlies a wide range of interactions, from parental love to friendship, from caring for one's work to caring for one's pet, to caring for and about one's patients. Benner and Wrubel (1989) note: "Caring creates possibility." Personal concern for another person, an event, or thing provides motivation and direction for people to care. Caring as a professional framework has practical implications for transforming nursing practice (Drenkard, 2008). Through caring, nurses help patients recover in the face of illness, give meaning to their illness, and maintain or reestablish connection. Understanding how to provide humanistic caring and compassion begins early in nursing education and continues to mature through experiential practice (Gallagher-Lepak and Kubsch, 2009).

Patients are not all the same. Each person brings a unique background of experiences, values, and cultural perspectives to a health care encounter. Caring is always specific and relational for each nurse-patient encounter. As nurses acquire more experience, they typically learn that caring helps them to focus on the patients for whom they care. Caring facilitates a nurse's ability to know a patient, allowing the nurse to recognize a patient's problems and find and implement individualized solutions.

Leininger's Transcultural Caring

From a **transcultural** perspective, Madeleine Leininger (1991) describes the concept of care as the essence and central, unifying, and dominant domain that distinguishes nursing from other health disciplines (see Chapter 4). Care is an essential human need, necessary for the health and survival of all individuals. Care, unlike cure, helps an individual or group improve a human condition. Acts of caring refer to nurturing and skillful activities, processes, and decisions to assist people in ways that are empathetic, compassionate, and supportive. An act of caring depends on the needs, problems, and values of the patient. Leininger's studies of numerous cultures around the world found that care helps protect, develop, nurture, and provide survival to people. It is needed for people of all cultures to recover from illness and to maintain healthy life practices.

Leininger (1991) stresses the importance of nurses' understanding cultural caring behaviors. Even though human caring is a universal phenomenon, the expressions, processes, and patterns of caring vary among cultures (Box 7-1). Caring is very personal; thus its expression differs for each patient. For caring to be effective, nurses need to learn culturally specific behaviors and words that reflect human caring in different cultures to identify and meet the needs of all patients (see Chapter 9).

BOX 7-1 CULTURAL ASPECTS OF CARE

Nurse Caring Behaviors

Caring includes knowing a patient's cultural values and beliefs (Suliman et al., 2009). Although the need for human caring is universal, its application is based on cultural norms. As a result, expectations may change across cultures. For example, providing time for family presence is often more valuable to traditional Asian families than a nursing presence. Using touch to convey caring sometimes crosses cultural norms. Sometimes gender-congruent caregivers or the patient's family need to provide caring touch. When listening to the patient, some cultures view eye contact as disrespectful.

Implications for Practice

- Know the patient's cultural norms for caring practices.
- Know the patient's cultural practices regarding end-of-life care. In some cultures it is considered insensitive to tell the patient that he or she is dying (Suliman et al., 2009).
- Determine if a member of the patient's family or cultural group is the best resource to use for caring practices such as providing presence or touching (Galanti, 2008).
- Know the patient's cultural practices regarding the removal of life support (Galanti, 2008).

Watson's Transpersonal Caring

Patients and their families expect a high quality of human interaction from nurses. Unfortunately many conversations between patients and their nurses are very brief and disconnected. Watson's theory of caring is a holistic model for nursing that suggests that a conscious intention to care promotes healing and wholeness (Watson, 2005, 2010). The theory integrates the human caring processes with healing environments, incorporating the life-generating and life-receiving processes of human caring and healing for nurses and their patients (Watson, 2006). The theory describes a consciousness that allows nurses to raise new questions about what it means to be a nurse, to be ill, and to be caring and healing. The transpersonal caring theory rejects the disease orientation to health care and places care before cure (Watson, 1996, 2008). The practitioner looks beyond the patient's disease and its treatment by conventional means. Instead, transpersonal caring looks for deeper sources of inner healing to protect, enhance, and preserve a person's dignity, humanity, wholeness, and inner harmony (see also Chapter 4).

In Watson's view caring becomes almost spiritual. It preserves human dignity in the technological, cure-dominated health care system (Watson, 2006). The emphasis is on the nurse-patient relationship. The focus is on the people behind the patient and nurse and the caring relationship (Table 7-1). A nurse communicates caring-healing to the patient through the consciousness of the nurse. This takes place during a single caring moment between nurse and patient. A connection forms between the one cared for and the one caring. The model is **transformative** because the relationship influences both the nurse and the patient for better or for worse (Watson, 2006, 2010). Caring-healing consciousness promotes healing. Application of Watson's caring model in practice enhances nurses' caring practices (Box 7-2).

TABLE 7-1 Watson's 10 Carative Factors (Watson, 2005, 2008)

CARATIVE FACTOR	EXAMPLE IN PRACTICE
Forming a human-altruistic value system	Use loving kindness to extend yourself. Use self-disclosure appropriately to promote a therapeutic alliance with your patient.
Instilling faith-hope	Provide a connection with the patient that offers purpose and direction when trying to find the meaning of an illness.
Cultivating a sensitivity to one's self and to others	Learn to accept yourself and others for their full potential. A caring nurse matures into becoming a self-actualized nurse.
Developing a helping, trusting, human caring relationship	Learn to develop and sustain helping, trusting, authentic, caring relationships through effective communication with your patients.
Promoting and expressing positive and negative feelings	Support and accept your patients' feelings. In connecting with your patients you show a willingness to take risks in sharing in the relationship.
Using creative problem-solving, caring processes	Apply the nursing process in systematic, scientific problem-solving decision making in providing patient-centered care.
Promoting transpersonal teaching-learning	Learn together while educating the patient to acquire self-care skills. The patient assumes responsibility for learning.
Providing for a supportive, protective, and/or corrective mental, physical, societal, and spiritual environment	Create a healing environment at all levels, physical and nonphysical. This promotes wholeness, beauty, comfort, dignity, and peace.
Meeting human needs	Assist patients with basic needs with an intentional care and caring consciousness.
Allowing for existential-phenomenological-spiritual forces	Allow spiritual forces to provide a better understanding of yourself and your patient.

Swanson's Theory of Caring

Kristen Swanson (1991) studied patients and professional caregivers in an effort to develop a theory of caring for nursing practice. This middle-range theory of caring was developed from three perinatal studies that interviewed women who miscarried, parents and health care professionals in a newborn intensive care unit, and socially at-risk mothers who received long-term public health intervention. All groups were in a perinatal (before, during, or after the birth of a child) setting or context and experienced the phenomenon of caring. Researchers asked each group questions regarding how they experienced or expressed caring in their situations (Swanson, 1999a, 1999b). After analyzing the stories and descriptions of the three groups, Swanson developed a theory of caring. The theory describes caring as consisting of five categories or processes (Table 7-2). Swanson (1991) defines caring as a nurturing way of relating to a valued other toward whom one feels a personal sense of commitment and responsibility. This theory supports the claim that caring is a central nursing phenomenon but not necessarily unique to nursing practice.

Swanson's work (1991) provides direction for how to develop useful and effective caring strategies. Each of the caring processes has definitions and subdimensions that serve as the basis for nursing interventions. Nursing care and caring are crucial in making positive differences in patients' health and well-being outcomes (Swanson, 1999a). Thus research findings develop and refine the theory and continue to guide clinical nursing practice (Andershed and Olsson, 2009). For example, Swanson (1999b) tested the effects of caring-based counseling on women's emotional well-being in the first year after miscarrying. Caring-based counseling was significant in reducing women's depression and anger, particularly for women in the first 4 months following miscarriage.

Summary of Theoretical Views

Nursing caring theories have common themes. Duffy, Hoskins, and Seifert (2007) identify these commonalities as human interaction or communication, mutuality, appreciating the uniqueness of individuals, and improving the welfare of patients and their families. Caring is highly relational. The nurse and the patient enter into a relationship that is much more than one person simply "doing tasks for" another. There is a mutual give-and-take that develops as nurse and patient begin to know and care for one another (Hudacek, 2008; Sumner, 2010). Caring theories are valuable when assessing patient perceptions of being cared for in a multicultural environment (Suliman et al., 2009). Frank (1998) described a

BOX 7-2 EVIDENCE-BASED PRACTICE

Enhancing Caring

PICO Question: Do patient satisfaction rates among hospitalized adult patients improve when carative nursing practices are used?

Evidence Summary

Patient satisfaction is an important indicator for the quality of health care. Caring facilitates healing and improves patient satisfaction with nursing care (Rush et al., 2008; Osterman et al., 2010). Researchers integrated human science caring into a professional practice model in a large health care system. This model was designed to increase nurses' presence and help them know their patients better. In turn the nurses implemented practice changes. Patient satisfaction increased, and patients indicated a willingness to return to the health care system in the event hospitalization was needed in the future (Drenkard, 2008). When using carative nursing practices, the interaction between the nurse and patient is essential and contributes to patient-centered care (Hobbs, 2009).

Application to Nursing Practice

- Setting a specific dedicated time to meet one-on-one with a patient during each nursing shift encourages the patient to be an active partner in care and helps the nurse understand the patient's perception of the need for caring (Drenkard, 2008).
- The use of caring in nursing practice encourages a more holistic approach to nursing care.
- As nurses use caring, they get to know their patients and therefore better meet their needs (Drenkard, 2008).
- The caring model involves a closeness, commitment, and involvement in the nurse-patient relationship, which contributes to patient-centered care (Hobbs, 2009).

TABLE 7-2 Swanson's Theory of Caring (Swanson, 1991)

CARING PROCESS	DEFINITIONS	SUBDIMENSIONS
Knowing	Striving to understand an event as it has meaning in the life of the other	Avoiding assumptions Centering on the one cared for Assessing thoroughly Seeking cues Engaging the self or both
Being with	Being emotionally present to the other	Being there Conveying ability Sharing feelings Not burdening
Doing for	Doing for the other as he or she would do for self if it were at all possible	Comforting Anticipating Performing skillfully Protecting Preserving dignity
Enabling	Facilitating the other's passage through life transitions (e.g., birth, death) and unfamiliar events	Informing/explaining Supporting/allowing Focusing Generating alternatives Validating/giving feedback

personal situation when he was suffering from cancer: "What I wanted when I was ill was a mutual relationship of *persons* who were also clinician and patient." It was important for Frank to be seen as one of two fellow human beings, not the dependent patient being cared for by the expert technical clinician.

Caring seems highly invisible at times when a nurse and patient enter a relationship of respect, concern, and support. The nurse's empathy and compassion become a natural part of every patient encounter. However, when caring is absent, it becomes very obvious. For example, if the nurse shows disinterest or chooses to avoid a patient's request for help, his or her inaction quickly conveys an uncaring attitude. Benner and Wrubel (1989) relate the story of a clinical nurse specialist who learned from a patient what caring is all about: "I felt that I was teaching him a lot, but actually he taught me. One day he said to me (probably after I had delivered some well-meaning technical information about his disease), 'You're doing an OK job, but I can tell that every time you walk in that door you're walking out.'" In this nurse's story the patient perceived that the nurse was simply going through the motions of teaching and showed little caring toward the patient. Patients quickly know when nurses fail to relate to them.

As you practice caring, your patient will sense your commitment and willingness to enter into a relationship that allows you to understand the patient's experience of illness. In a study of oncology patients, one patient described a nurse's caring as "putting the heart in it" and "having an investment" that makes "patients feel that you are with them" (Radwin, 2000). Thus the nurse becomes a coach and partner rather than a detached provider of care.

One aspect of caring is enabling, when a nurse and patient work together to identify alternatives in approaches to care and resources. Consider a nurse working with a patient recently diagnosed with diabetes mellitus who must learn how to administer daily insulin injections. The nurse enables the patient by providing instruction in a manner that allows the patient to successfully adapt diabetes management strategies such as self-medication, exercise, and diet to his own lifestyle.

Another common theme of caring is to understand the context of a person's life and illness. It is difficult to show caring for another individual without gaining an understanding of who the person is and his or her perception of the illness. Exploring the following questions with your patients helps you understand their perceptions of illness: How was your illness first recognized? How do you feel about the illness? How does your illness affect your daily life practices? Knowing the context of a patient's illness helps you choose and individualize interventions that will actually help the patient. This approach is more successful than simply selecting interventions on the basis of your patient's symptoms or disease process.

PATIENTS' PERCEPTIONS OF CARING

Leininger's, Watson's, and Swanson's theories provide an excellent beginning to understanding the behaviors and processes that characterize caring. Researchers explored nursing care behaviors as perceived by patients (Table 7-3). Their findings emphasize what

TABLE 7-3 Comparison of Research Studies Exploring Nurse Caring Behaviors (as Perceived by Patients)

PATIENT FALLS: ACUTE CARE NURSES' EXPERIENCES (RUSH ET AL [2008])	EXPLORATORY STUDY OF NURSES' PRESENCE IN DAILY CARE ON AN ONCOLOGY UNIT (OSTERMAN ET AL [2010])	IMPORTANCE OF KNOWING THE PATIENT IN WEANING FROM MECHANICAL VENTILATION (CROCKER AND SCHOLES [2009])
Using compassion when identifying risk factors associated with falling	Being compassionate and patient is important.	Nursing presence contributes to knowing the patient. Patients indicated that "knowing" the patient was essential to patient-centered care.
Using nursing presence to know the patient and identify patient-centered factors that promote or impede patient risk of falls	Developing patient-nurse trust and responsiveness to patient is critical to the emergence of full presence.	Maintaining a balance of continuity of care and nursing expertise. The inexperienced nurse was more likely to be away from the patient or provide care in a hurried manner.
Communicating effectively between nurses and patient/family	Maintaining presence is a way to provide emotional support to patients who are experiencing overwhelming stressors and decisions. Morning care provides an opportunity for nurses to be present with their patients.	Creating a trusting relationship between patient and nurse is important.
Incorporating patients and families into the solution		

patients expect from their caregivers and thus provide useful guidelines for your practice. Patients continue to value nurses' effectiveness in performing tasks; but clearly patients value the affective dimension of nursing care.

The study of patients' perceptions is important because health care is placing greater emphasis on patient satisfaction (see Chapter 2). Duffy, Hoskins, and Seifert (2007) developed the Caring Assessment Tool (CAT) to measure caring from a patient's perspective. This tool and other caring assessments help you, as a beginning professional, to appreciate the type of behaviors that hospitalized patients identify as caring. When patients sense that health care providers are sensitive, sympathetic, compassionate, and interested in them as people, they usually become active partners in the plan of care (Gallagher-Lepak and Kubsch, 2009). Suliman et al. (2009) studied the impact of Watson's caring theory as an assessment framework in a multicultural environment. Patients in the study indicated that they did not perceive any cultural bias when they perceived nurses to be caring. Radwin (2000) found that oncology patients associated excellent nursing care with attentiveness, partnership, individualization, rapport, and caring. As institutions look to improve patient satisfaction, creating an environment of caring is a necessary and worthwhile goal. Patient satisfaction with nursing care is an important factor in their decision to return to a hospital.

As you begin clinical practice, consider how patients perceive caring and the best approaches to provide care. Behaviors associated with caring offer an excellent starting point. It is also important to determine an individual patient's perceptions and unique expectations. Frequently patients and nurses differ in their perceptions of caring (Hudacek, 2008). For that reason focus on building a relationship that allows you to learn what is important to your patients (Gallagher-Lepak and Kubsch, 2009). For example, your patient is fearful of having an intravenous catheter inserted, and you are still a novice at catheter insertion. Instead of giving a lengthy description of the procedure to relieve anxiety, you decide that the patient will benefit more if you obtain assistance from a skilled staff member. Knowing who patients are helps you select caring approaches that are most appropriate to their needs.

ETHIC OF CARE

Caring is a moral imperative, not a commodity to be bought and sold. Caring for other human beings protects, enhances, and preserves human dignity. It is a professional, ethical covenant that nursing has with its public (Watson, 2010). Caring science provides a disciplinary foundation from which you deliver patient-centered care (Watson, 2005, 2008). Chapter 22 explores the importance of ethics in professional nursing. The term *ethics* refers to the ideals of right and wrong behavior. In any patient encounter a nurse needs to know what behavior is ethically appropriate. An ethic of care is unique so professional nurses do not make professional decisions based solely on intellectual or analytical principles. Instead, an ethic of care places caring at the center of decision making. For example, what resources should be used to care for an indigent patient? Is it caring to place a disabled relative in a long-term care facility?

An **ethic of care** is concerned with relationships between people and with a nurse's character and attitude toward others. Nurses who function from an ethic of care are sensitive to unequal relationships that lead to an abuse of one person's power over another—intentional or otherwise. In health care settings patients and families are often on unequal footing with professionals because of the patient's illness, lack of information, regression caused by pain and suffering, and unfamiliar circumstances. An ethic of care places the nurse as the patient's advocate, solving ethical dilemmas by attending to relationships and by giving priority to each patient's unique personhood.

CARING IN NURSING PRACTICE

It is impossible to prescribe ways that guarantee whether or when a nurse becomes a caring professional. Experts disagree as to whether caring is teachable or more fundamentally a way of being in the world. For those who find caring a normal part of their lives, it is a product of their culture, values, experiences, and relationships with others. Persons who do not experience care in their lives often find it difficult to act in caring ways. As you deal with health and illness in your practice, you grow in your ability to care. Caring behaviors include providing presence, offering a caring touch, and listening.

Providing Presence

Providing **presence** is a person-to-person encounter conveying a closeness and sense of caring. Fredriksson (1999) explains that presence involves "being there" and "being with." "Being there" is not only a physical presence; it also includes communication and understanding. Presence is an interpersonal process that is

characterized by sensitivity, holism, intimacy, vulnerability, and adaptation to unique circumstances. It results in improved mental well-being for nurses and patients and improved physical well-being in patients (Finfgeld-Connett, 2006). The interpersonal relationship of "being there" depends on the fact that a nurse is attentive to the patient. Presence can be translated into an actual caring art that affects the healing and well-being of both the nurse and patient. It is often used in conjunction with other nursing interventions such as establishing the nurse-patient relationship, providing comfort measures, providing patient education, and listening. The outcomes of nursing presence include alleviating suffering, decreasing a sense of isolation and vulnerability, and personal growth (Zyblock, 2010). This type of presence is something the nurse offers to the patient in achieving patient care goals.

Nursing requires being present with patients at a moment of crisis or need (Zyblock, 2010). "Being with" is also interpersonal. The nurse gives himself or herself, which means being available and at a patient's disposal. If patients accept the nurse, they will invite him or her to see, share, and touch their vulnerability and suffering. One's human presence never leaves one unaffected (Watson, 2008). The nurse then enters the patient's world. In this presence the patient is able to put words to feelings and understand himself or herself in a way that leads to identifying solutions, seeing new directions, and making choices.

When a nurse establishes presence, eye contact, body language, voice tone, listening, and a positive and encouraging attitude act together to create openness and understanding. The message conveyed is that the other's experience matters to the one caring (Swanson, 1991). Establishing presence enhances the nurse's ability to learn from the patient. This strengthens the nurse's ability to provide adequate and appropriate nursing care.

It is especially important to establish presence and caring when patients are experiencing stressful events or situations. Awaiting a physician's report of test results, preparing for an unfamiliar procedure, and planning for a return home after serious illness are just a few examples of events in the course of a person's illness that can create unpredictability and dependency on care providers. The nurse's presence and caring help to calm anxiety and fear related to stressful situations (Finfgeld-Connett, 2008a, 2008b). Giving reassurance and thorough explanations about a procedure, remaining at the patient's side, and coaching the patient through the experience all convey a presence that is invaluable to the patient's well-being.

Touch

Patients face situations that are embarrassing, frightening, and painful. Whatever the feeling or symptom, patients look to nurses to provide comfort. The use of touch is one **comforting** approach that reaches out to patients to communicate concern and support. Touch is relational and leads to a connection between nurse and patient. It involves contact and noncontact touch. Contact touch involves obvious skin-to-skin contact, whereas noncontact touch refers to eye contact. It is difficult to separate the two. Both in turn are described within three categories: task-oriented touch, caring touch, and protective touch (Fredriksson, 1999).

Nurses use task-oriented touch when performing a task or procedure. The skillful and gentle performance of a nursing procedure conveys security and a sense of competence. An expert nurse learns that any procedure is more effective when administered carefully and in consideration of any patient concern. For example, if a patient is anxious about having a procedure such as the insertion of a nasogastric tube, the nurse offers comfort through a full explanation of the procedure and what the patient will feel. Then the nurse performs the procedure safely, skillfully, and successfully. This is done as the nurse prepares the supplies, positions the patient, and gently manipulates and inserts the nasogastric tube. Throughout a procedure the nurse talks quietly with the patient to provide reassurance and support.

Caring touch is a form of nonverbal communication, which successfully influences a patient's comfort and security, enhances self-esteem, increases confidence of the caregivers, and improves mental well-being (Osterman et al, 2010). You express this in the way you hold a patient's hand, give a back massage, gently position a patient, or participate in a conversation. When using a caring touch, you connect with the patient physically and emotionally (Zyblock, 2010).

Protective touch is a form of touch that protects the nurse and/or patient (Fredriksson, 1999). The patient views it either positively or negatively. The most obvious form of protective touch is preventing an accident (e.g., holding and bracing the patient to avoid a fall). Protective touch is also a kind of touch that protects the nurse emotionally. A nurse withdraws or distances herself or himself from a patient when he or she is unable to tolerate suffering or needs to escape from a situation that is causing tension. When used in this way, protective touch elicits negative feelings in a patient (Fredriksson, 1999).

Because touch conveys many messages, use it with discretion. Touch itself is a concern when crossing cultural boundaries of either the patient or the nurse (Benner et al., 2010; Benner, 2004). The patient generally permits task-orientated touch because most individuals give nurses and physicians a license to enter their personal space to provide care (see Box 7-1, p. 80). Know and understand if patients accept touch and how they interpret your intentions.

Listening

Caring involves an interpersonal interaction that is much more than two persons simply talking back and forth (Bunkers, 2010). Listening is a critical component of nursing care and is necessary for meaningful interactions with patients (Shipley, 2010). It is a planned and deliberate act in which the listener is present and engages the patient in a nonjudgmental and accepting manner. It includes "taking in" what a patient says and interpreting and understanding what the patient is saying and then giving back that understanding to the patient (Shipley, 2010). Listening to the meaning of what a patient says helps create a mutual relationship. True listening leads to truly knowing and responding to what really matters to the patient and family.

When an individual becomes ill, he or she usually has a story to tell about the meaning of the illness. Any critical or chronic illness affects all of a patient's life choices and decisions, sometimes the individual's identity. Being able to tell that story helps the patient break the distress of illness. Thus a story needs a listener. Frank (1998) described his own feelings during his experience with cancer: "I needed a [health care professional's] gift of listening in order to make my suffering a relationship between *us,* instead of an iron cage around *me.*" He needed to be able to express what he needed when he was ill. The personal concerns that are part of a patient's illness story determine what is at stake for the patient. Caring through listening enables the nurse to be a participant in the patient's life.

To listen effectively you need to silence yourself and listen with openness (Fredriksson, 1999). Fredriksson describes silencing one's

mouth and also the mind. It is important to remain intentionally silent and concentrate on what the patient has to say. Give patients your full, focused attention as they tell their stories.

When an ill person chooses to tell his or her story, it involves reaching out to another human being. Telling the story implies a relationship that develops only if the clinician exchanges his or her stories as well. Frank (1998) argues that professionals do not routinely take seriously their own need to be known as part of a clinical relationship. Yet, unless the professional acknowledges this need, there is no reciprocal relationship, only an interaction. There is pressure on the clinician to know as much as possible about the patient, but it isolates the clinician from the patient. By contrast, in knowing and being known, each supports the other (Frank, 1998).

Through active listening you begin to truly know your patients and what is important to them (Bernick, 2004). Learning to listen to a patient is sometimes difficult. It is easy to become distracted by tasks at hand, colleagues shouting instructions, or other patients waiting to have their needs met. However, the time you take to listen effectively is worthwhile, in both the information gained and the strengthening of the nurse-patient relationship. Listening involves paying attention to the individual's words and tone of voice and entering his or her frame of reference (see Chapter 24). By observing the expressions and body language of the patient, you find cues to help the patient explore ways to achieve greater peace.

Knowing the Patient

One of the five caring processes described by Swanson (1991) is knowing the patient. Knowing the patient comprises both the nurse's understanding of a specific patient and his or her subsequent selection of interventions (Radwin, 2000). It is essential when providing patient-centered care. Two elements that facilitate knowing are continuity of care and clinical expertise. When patient care is fragmented, knowing the patient declines, and patient-centered care is compromised (Crocker and Scholes, 2009).

Knowing develops over time as a nurse learns the clinical conditions within a specialty and the behaviors and physiological responses of patients. Intimate knowing helps the nurse respond to what really matters to the patient. To know a patient means that the nurse avoids assumptions, focuses on the patient, and engages in a caring relationship with the patient that reveals information and cues that facilitate critical thinking and clinical judgments (see Chapter 15). Knowing the patient is at the core of the clinical decision-making process.

Factors that contribute to knowing the patient include time, continuity of care, team work of the nursing staff, trust, and experience. Barriers to knowing the patient are often related to the organizational structure of the organization and economic constraints. Organizational changes often result in decreasing the amount of time that registered nurses are able to spend with their patients, which in turn affects the nurse-patient relationships. Decreased length of stay also reduces the interactions' between nurses and their patients (Crocker and Scholes 2009; MacDonald, 2008).

Consequences of not knowing the patient are many. In the acute care setting, not knowing the patient contributes to risk for falls and actual falls (Rush et al., 2008). Patients and their families don't understand the complexities of treatment and their participation in care (MacDonald, 2008). Finally, patients do not adequately understand their discharge guidelines and may administer their home medications or treatments incorrectly. By establishing a caring relationship, the understanding that develops helps the nurse to better know the patient as a unique individual and choose the most appropriate and efficacious nursing therapies (Hobbs, 2009).

The caring relationships that a nurse develops over time, coupled with the nurse's growing knowledge and experience, provide a rich source of meaning when changes in a patient's clinical status occur. Expert nurses develop the ability to detect changes in patients' conditions almost effortlessly (Benner et al., 2010). Clinical decision making, perhaps the most important responsibility of the professional nurse, involves various aspects of knowing the patient: responses to therapies, routines and habits, coping resources, physical capacities and endurance, and body typology and characteristics. Experienced nurses know additional facts about their patients such as their experiences, behaviors, feelings, and perceptions (Benner et al., 2010; MacDonald, 2008). When you make clinical decisions accurately in the context of knowing a patient well, improved patient outcomes result. When a nurse bases care on knowing a patient, the patient perceives care as personalized, comforting, supportive, and healing.

The most important thing for a beginning nurse to recognize is that knowing a patient is more than simply gathering data about the patient's clinical signs and condition. Success in knowing the patient lies in the relationship you establish. To know a patient is to enter into a caring, social process, which results in a nurse-patient relationship whereby the patient comes to feel known by the nurse (Bunkers, 2010; MacDonald, 2008).

Spiritual Caring

Spiritual health occurs when a person finds a balance between his or her own life values, goals, and belief systems and those of others (see Chapter 35). Research shows a link between spirit, mind, and body. An individual's beliefs and expectations have effects on the person's physical well-being.

Establishing a caring relationship with a patient involves interconnectedness between the nurse and the patient. This interconnectedness is why Watson (2008, 2009, 2010) describes the caring relationship in a spiritual sense. Spirituality offers a sense of connectedness: intrapersonally (connected with oneself), interpersonally (connected with others and the environment), and transpersonally (connected with the unseen, God, or a higher power). In a caring relationship the patient and the nurse come to know one another so both move toward a healing relationship by (Watson, 2008):

- Mobilizing hope for the patient and the nurse.
- Finding an interpretation or understanding of illness, symptoms, or emotions that is acceptable to the patient.
- Assisting the patient in using social, emotional, or spiritual resources.
- Recognizing that caring relationships connect us human to human, spirit to spirit.

Relieving Pain and Suffering

Relieving pain and suffering is more than giving pain medications, repositioning the patient, or cleaning a wound. The relief of pain and suffering encompasses caring nursing actions that give a patient comfort, dignity, respect, and peace. Ensuring that the patient care environment is clean and pleasant and includes personal items makes the physical environment a place that soothes and heals the mind, body, and spirit (Gallagher-Lepak and Kubsch, 2009).

Through skillful and accurate assessment of a patient's level and type of pain you are able to design patient-centered care to improve the patient's level of comfort. There are multiple interventions for

FIG. 7-2 Nurse discusses patient's health care needs with the family.

BOX 7-3 NURSE CARING BEHAVIORS AS PERCEIVED BY FAMILIES

- Being honest
- Advocating for patient's care preferences
- Giving clear explanations
- Keeping family members informed
- Asking permission before doing something to a patient
- Providing comfort (e.g., offering warm blanket, rubbing a patient's back)
- Reading patient passages from religious texts, favorite book, cards, or mail
- Providing for and maintaining patient privacy
- Assuring the patient that nursing services will be available
- Helping patients do as much for themselves as possible
- Teaching the family how to keep the relative physically comfortable

Data from Brown CL et al: Caring in action: the patient care facilitator role, *Int J Hum Caring* 9(3):51, 2005; Radwin L: Oncology patients' perceptions of quality nursing care, *Res Nurs Health* 23(3):179, 2000; and Carr T: Mapping the processes and qualities of spiritual nursing care, *Qual Health Res* 18(5):686, 2008.

pain relief, but knowing about the patient and the meaning of his or her pain guides your care (see Chapter 43). Often conveying a quiet caring presence, touching a patient, or listening helps you to assess and understand the meaning of your patient's pain or discomfort. The caring presence helps you and your patient design goals for pain relief.

Human suffering is multifaceted, affecting a patient physically, emotionally, socially, and spiritually. It also affects the patient's family and friends. You may find yourself working with a young family whose newborn baby has multiple developmental challenges. Their emotional suffering encompasses anger, guilt, fear, or grief. You cannot fix it, but you can provide comfort through a listening, nonjudgmental caring presence. Patients and their families are comforted by a caring listener (Hudacek, 2008).

Family Care

People live in their worlds in an involved way. Each person experiences life through relationships with others. Thus caring for an individual cannot occur in isolation from that person's family. As a nurse it is important to know the family almost as thoroughly as you know a patient (Fig. 7-2). The family is an important resource. Success with nursing interventions often depends on their willingness to share information about the patient, their acceptance and understanding of therapies, whether the interventions fit with their daily practices, and whether they support and deliver the therapies recommended.

Families of patients with cancer perceived many nurse caring behaviors to be most helpful (Box 7-3). It is critical that the nurse ensures the patient's well-being and helps the family members to be active participants. Although specific to families of patients with cancer, these behaviors offer useful guidelines for developing a caring relationship with all families. Begin a relationship by learning who makes up the patient's family and what their roles are in the patient's life. Showing the family that you care for and are concerned about the patient creates an openness that then enables a relationship to form with the family. Caring for the family takes into consideration the context of the patient's illness and the stress it imposes on all members (see Chapter 10).

THE CHALLENGE OF CARING

Assisting individuals during a time of need is the reason many enter nursing. When nurses are able to affirm themselves as caring individuals, their lives achieve a meaning and purpose (Benner, 2004; Benner et al., 2010). Caring is a motivating force for people to become nurses, and it becomes a source of satisfaction when nurses know that they have made a difference in their patients' lives.

It is becoming more of a challenge to care in today's health care system. Being a part of the helping professions is difficult and demanding. Nurses are torn between the human caring model and the task-oriented biomedical model and institutional demands that consume their practice (Watson and Foster, 2003). Nurses have increasingly less time to spend with patients, making it much harder to know who they are. A reliance on technology and cost-effective health care strategies and efforts to standardize and refine work processes all undermine the nature of caring. Too often patients become just a number, with their real needs either overlooked or ignored.

The American Nurses Association (ANA), National League for Nursing (NLN), American Organization of Nurse Executives (AONE), and American Association of Colleges of Nursing (AACN) recommend strategies to reverse the current nursing shortage. A number of these strategies have potential for creating work environments that enable nurses to demonstrate more caring behaviors. Environmental factors promote a more artful nursing and caring presence that further enhances patient-centered care (Finfgeld-Connett, 2008a; Hobbs, 2009). Strategies include introducing greater flexibility into the work environment structure, rewarding experienced nurse mentors, improving nurse staffing, and providing nurses with autonomy over their practice (Brown et al., 2005; Watson, 2009).

If health care is to make a positive difference in their lives, patients cannot be treated like machines or robots. Instead, health care must become more holistic and humanistic. Nurses play an important role in making caring an integral part of health care delivery. This begins by making caring a part of the philosophy and environment in the workplace. Incorporating caring concepts into standards of nursing practice establishes the guidelines for professional conduct. Finally, during day-to-day practice with patients and families, nurses need to be committed to caring and willing to establish the relationships necessary for personal, competent, compassionate, and meaningful nursing care. "Consistent with the wisdom and vision of Nightingale, nursing is a lifetime journey of caring and healing, seeking to understand and preserve the wholeness of human existence and to offer compassionate, informed knowledgeable human caring …" (Watson, 2009).

KEY POINTS

- Caring is the heart of a nurse's ability to work with people in a respectful and therapeutic way.
- Caring is specific and relational for each nurse-patient encounter.
- For caring to achieve cure, nurses need to learn the culturally specific behaviors and words that reflect human caring in different cultures.
- Because illness is the human experience of loss or dysfunction, any treatment or intervention given without consideration of its meaning to the individual is likely to be worthless.
- Caring involves a mutual give and take that develops as nurse and patient begin to know and care for one another.
- It is difficult to show caring to individuals without gaining an understanding of who they are and their perception of their illness.
- Presence involves a person-to-person encounter that conveys closeness and a sense of caring that involves "being there" and "being with" patients.
- Research shows that touch, both contact and noncontact, includes task-orientated touch, caring touch, and protective touch.
- The skillful and gentle performance of a nursing procedure conveys security and a sense of competence in the nurse.
- Listening is not only "taking in" what a patient says; it also includes interpreting and understanding what the patient is saying and giving back that understanding.
- Knowing the patient is at the core of the process that nurses use to make clinical decisions.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Mrs. Lowe is a 52-year-old patient being treated for lymphoma (cancer of the lymph nodes) that occurred 6 years after a lung transplant. Mrs. Lowe is discouraged about her current health status and has a lot of what she describes as muscle pain. The unit where Mrs. Lowe is receiving care has a number of very sick patients and is short staffed.
   a. You enter her room to do a morning assessment and find Mrs. Lowe crying. How are you going to use caring practices to help her, knowing that your day has just begun and you have many nursing interventions to complete?
   b. When you listen to Mrs. Lowe, she explains that her muscle pain is very bothersome and it was worse when she was alone. Both you and Mrs. Lowe determine that an injection for her pain would be beneficial. In what way can you show caring in the way you administer the injection to Mrs. Lowe?
   c. Mrs. Lowe's day is getting better. She seems more comfortable and is crying less. You find that your day is more controlled. What else can you do for Mrs. Lowe?
2. During your next clinical practicum, select a patient to talk with for at least 15 to 20 minutes. Ask the patient to tell you about his or her illness. Review the skills of listening in this chapter and in Chapter 24. Immediately after your discussion, reflect on the discussion with the patient and determine if you have enough information about him or her to answer the following questions:
   a. What do you believe the patient was trying to tell you about his or her illness?
   b. Why was it important for the patient to share his or her story?
   c. What did you do that made it easy or difficult for the patient to talk with you? What did you do well? What could you have done better?
   d. Would you rate yourself a good listener? How can you listen better?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse hears a colleague tell a nursing student that she never touches a patient unless she is performing a procedure or doing an assessment. The nurse tells the student that from a caring perspective:
   1. She does not touch the patients either.
   2. Touch is a type of verbal communication.
   3. There is never a problem with using touch.
   4. Touch forms a connection between nurse and patient.
2. Of the five caring processes described by Swanson, which describes "knowing the patient"?
   1. Anticipating the patient's cultural preferences
   2. Determining the patient's physician preference
   3. Establishing an understanding of a specific patient
   4. Gathering task-oriented information during assessment
3. A Muslim woman enters the clinic to have a woman's health examination for the first time. Which nursing behavior applies Swanson's caring process of "knowing the patient?"
   1. Sharing feelings about the importance of having regular woman's health examinations
   2. Gaining an understanding of what a woman's health examination means to the patient
   3. Recognizing that the patient is modest; obtaining gender-congruent caregiver
   4. Explaining the risk factors for cervical cancer
4. Helping a new mother through the birthing experience demonstrates which of Swanson's five caring processes?
   1. Knowing
   2. Enabling
   3. Doing for
   4. Being with
5. A patient is fearful of upcoming surgery and a possible cancer diagnosis. He discusses his love for the Bible with his nurse, who recommends a favorite Bible verse. Another nurse tells the patient's nurse that there is no place in nursing for spiritual caring. The patient's nurse replies:
   1. "Spiritual care should be left to a professional."
   2. "You are correct, religion is a personal decision."
   3. "Nurses should not force their religious beliefs on patients."
   4. "Spiritual, mind, and body connections can affect health."
6. Which of the following is a strategy for creating work environments that enable nurses to demonstrate more caring behaviors?
   1. Increasing the working hours of the staff
   2. Increasing salary benefits of the staff
   3. Creating a setting that allows flexibility and autonomy for staff
   4. Encouraging increased input concerning nursing functions from physicians

7. When a nurse helps a patient find the meaning of cancer by supporting beliefs about life, this is an example of:
   1. Instilling hope and faith.
   2. Forming a human-altruistic value system.
   3. Cultural caring.
   4. Being with.
8. An example of a nurse caring behavior that families of acutely ill patients perceive as important to patients' well-being is:
   1. Making health care decisions for patients.
   2. Having family members provide a patient's total personal hygiene.
   3. Injecting the nurse's perceptions about the level of care provided.
   4. Asking permission before performing a procedure on a patient.
9. A nurse demonstrates caring by helping family members:
   1. Become active participants in care.
   2. Provide activities of daily living (ADLs).
   3. Remove themselves from personal care.
   4. Make health care decisions for the patient.
10. Listening is not only "taking in" what a patient says; it also includes:
    1. Incorporating the views of the physician.
    2. Correcting any errors in the patient's understanding.
    3. Injecting the nurse's personal views and statements.
    4. Interpreting and understanding what the patient means.
11. A nurse is caring for an older adult who needs to enter an assisted-living facility following discharge from the hospital. Which of the following is an example of listening that displays caring?
    1. The nurse encourages the patient to talk about his concerns while reviewing the computer screen in the room.
    2. The nurse sits at the patient's bedside, listens as he relays his fear of never seeing his home again, and then asks if he wants anything to eat.
    3. The nurse listens to the patient's story while sitting on the side of the bed and then summarizes the story.
    4. The nurse listens to the patient talk about his fears of not returning home and then tells him to think positively.
12. Presence involves a person-to-person encounter that:
    1. Enables patients to care for self.
    2. Provides personal care to a patient.
    3. Conveys a closeness and a sense of caring.
    4. Describes being in close contact with a patient.
13. A nurse enters a patient's room, arranges the supplies for a Foley catheter insertion, and explains the procedure to the patient. She tells the patient what to expect; just before inserting the catheter, she tells the patient to relax and that, once the catheter is in place, she will not feel the bladder pressure. The nurse then proceeds to skillfully insert the Foley catheter. This is an example of what type of touch?
    1. Caring touch
    2. Protective touch
    3. Task-oriented touch
    4. Interpersonal touch
14. A hospice nurse sits at the bedside of a male patient in the final stages of cancer. He and his parents made the decision that he would move home and they would help him in the final stages of his disease. The family participates in his care, but lately the nurse has increased the amount of time she spends with the family. Whenever she enters the room or approaches the patient to give care, she touches his shoulder and tells him that she is present. This is an example of what type of touch?
    1. Caring touch
    2. Protective touch
    3. Task-oriented touch
    4. Interpersonal touch
15. Match the following caring behaviors with their definitions.

1. Knowing	a. Sustaining faith in one's capacity to get through a situation
2. Being with	b. Striving to understand an event's meaning for another person
3. Doing for	c. Being emotionally there for another person
4. Maintaining belief	d. Providing for another as he or she would do for themselves.

CHAPTER

8

Caring for the Cancer Survivor

OBJECTIVES

- Discuss the concept of cancer survivorship.
- Describe the influence of cancer survivorship on patients' quality of life.
- Discuss the effects cancer has on the family.
- Explain the nursing implications related to cancer survivorship.
- Discuss the essential components of survivorship care.

KEY TERMS

Biological response modifiers (biotherapy), p. 90
Cancer-related fatigue (CRF), p. 92
Cancer survivor, p. 90
Chemotherapy, p. 90
Chemotherapy-related cognitive impairment (CRCI), p. 92
Hormone therapy, p. 90

Currently there are 16 million cancer survivors in the United States; the number of survivors will continue to grow since more than 1.5 million new cases of cancer are diagnosed each year (National Cancer Institute [NCI], 2010; American Cancer Society [ACS], 2011). Among children diagnosed with cancer, 81.46% survive for at least 5 years. Of adults diagnosed with cancer, 68% survive at least 5 years. The number of people surviving cancer will continue to increase as new cases are diagnosed and those already treated live longer. Cancer survivors' health care problems have largely been ignored or misunderstood because of the belief that health problems are over for those who receive treatment, survive, and are given a "clean bill of health." There are many different trajectories or courses for cancer survival (Box 8-1). With the advances made in early diagnosis and improved treatment, more patients are becoming long-term survivors of cancer. The major forms of cancer therapy—surgery, **chemotherapy, hormone therapy, biological response modifiers (biotherapy),** and **radiation therapy**—often create unwanted long-term effects on tissues and organ systems that impair a person's health and quality of life in many ways (Institute of Medicine [IOM], 2006). Thus cancer survivorship has enormous implications for the way these individuals monitor and manage their health throughout their lives. As a nurse, you will care for these patients when they seek care for their cancer and for other medical conditions.

The National Coalition for Cancer Survivorship (2004) offers a definition of a **cancer survivor:** "An individual is considered a cancer survivor from the time of diagnosis, through the balance of his or her life." Family members and friends are also survivors because they experience the effects that cancer has on their loved ones. Cancer truly is a life-changing event. Although progress is being made, evidence shows that there is a neglected phase of cancer care (i.e., the period following first diagnosis and initial treatment and before the development of a recurrence of the initial cancer or death) (IOM, 2006). In this phase many survivors do not have consistent health care follow-up. Once treatment is completed, contact with a cancer care provider often stops, and survivors' needs go unnoticed or untreated. Despite the incredible advances made in cancer care, many long-term survivors suffer unnecessarily and die from delayed second cancer diagnoses or treatment-related chronic disease (Curtis et al., 2006).

Nurses have the responsibility to better understand the needs of cancer survivors and provide the most current evidence-based approaches for managing late and long-term effects of cancer and cancer treatment. Evidence suggests that survivors among racial and ethnic minorities and other underserved populations have more posttreatment symptoms and poorer treatment outcomes than Caucasians (Centers for Disease Control and Prevention [CDC], 2004). The disparities in health among ethnic groups are related to a complex interplay of economic, social, and cultural factors, with poverty being a key factor (IOM, 2006). Being able to provide comprehensive care to a cancer survivor begins with recognizing the effects of cancer and its treatment and learning about the survivor's own meaning of health.

BOX 8-1 THE SEASONS OF CANCER SURVIVAL

Acute survival: Starts with the diagnosis of cancer. Diagnostic and therapeutic efforts dominate. Fear and anxiety are constant elements of this phase.

Extended survival: Period during which a patient goes into remission or has ended the basic, rigorous course of treatment and enters a phase of watchful waiting. Patient undergoes periodic examinations and/or intermittent therapy. Fear of recurrence is common. This is usually a period of physical limitations. Diminished strength, fatigue, pain, nausea, reduced tolerance for exercise, or hair loss often occurs in the acute phase; but patients now have to deal with cancer in the home, community, and workplace.

Permanent survival: This phase is roughly equated with "cure," but the experience permanently affects the survivor. Problems with employment and insurance are common. The long-term secondary effects of cancer treatment on health represent an area in which permanent survivors are at risk.

Modified from Mullan F: Seasons of survival: reflections of a physician with cancer, *N Engl J Med* 313(4):270, 1985; and Institute of Medicine and National Research Council, Hewitt M, Greenfield S, Stovall E, editors: *From cancer patient to cancer survivor: lost in transition,* Washington, DC, 2006, National Academies Press.

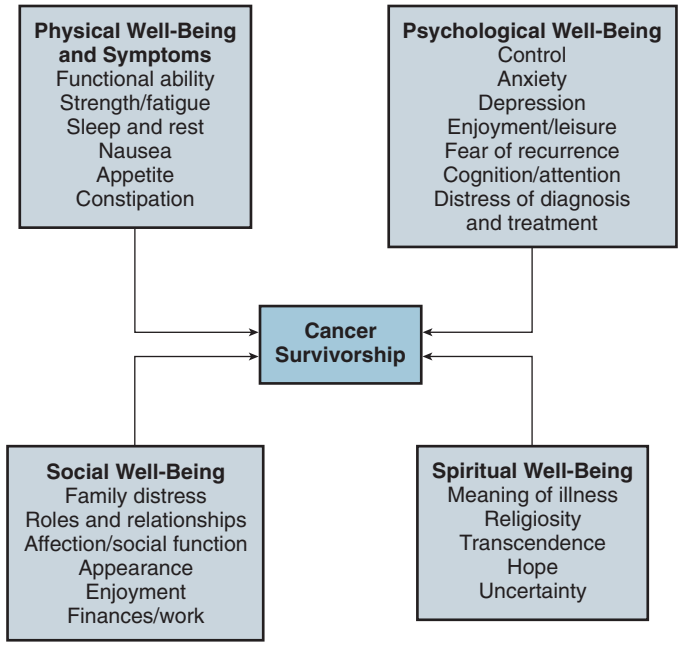

FIG. 8-1 Dimensions of quality of life affected by cancer. (From Ferrell B: *Introduction to cancer survivorship strategies for success, survivorship education for quality cancer care,* Pasadena, Calif, 2006, City of Hope National Medical Center.)

THE EFFECTS OF CANCER ON QUALITY OF LIFE

As people live longer after diagnosis and treatment for cancer, it becomes important to understand the types of distress that many survivors experience and how it affects their quality of life (Fig. 8-1). Quality of life in cancer survivorship means having a balance between the experience of increased dependence while seeking both independence and interdependence. Of course there are always exceptions in regard to the level of distress that survivors face. For some, cancer becomes an experience of self-reflection and an enhanced sense of what life is about (Box 8-2). Regardless of each survivor's journey with cancer, having cancer affects each person's physical, social, psychological, and spiritual well-being.

Physical Well-Being and Symptoms

Cancer survivors are at increased risk for cancer (either a recurrence of the cancer for which they were treated or a second cancer) and for a wide range of treatment-related problems (IOM, 2006). The increased risk for developing a second cancer is the result of cancer treatment, genetic factors or other susceptibility, or an interaction between treatment and susceptibility (Curtis et al., 2006). The risk for treatment-related problems is associated with the complexity of the cancer itself (e.g., type of tumor and stage of disease); the type, variety, and intensity of treatments used (e.g., chemotherapy and radiation combined); and the age and underlying health status of the patient. The following description shows how a cancer survivor's physical health problems can be complex and burdensome.

Susan was an Army nurse who learned 7 months after discharge from the Army that she had Hodgkin's disease. Hodgkin's is a malignancy of lymphoid tissue. Susan received an aggressive course of treatment that included surgery, 6 months of chemotherapy, and 3 months of total lymph node irradiation. It took many months for her bone marrow to heal and blood values to return to normal. After a few years she had bilateral mastectomies for treatment-related breast cancer. She also received 3 years of immunotherapy for cancer in situ

BOX 8-2 EVIDENCE-BASED PRACTICE

Cultural Aspects of Being a Cancer Survivor

PICO Question: Does the life experience of being a cancer survivor differ based on culture?

Evidence Summary

A number of different researchers have explored the cultural differences in patients who are cancer survivors. Low acculturated Hispanic cancer survivors have higher life satisfaction as compared to high acculturated Hispanic survivors because of high spirituality and positive social support (Stephens et al., 2010). Latina breast cancer survivors experience lower levels of social support and quality of life than comparable Caucasian women (Sammarco and Konecny, 2010). Mexican American female caregivers fear the cancer diagnosis, see cancer as a punishment, value maintenance of hope, believe in God and the doctor, and selectively disclose medical information (Cagle and Wolff, 2009). Older African American survivors report that social support is influenced by fears and stigma expressed by family and friends, the desire to decrease the burden and disruption on the lives of family and friends, and treatment and side effects (Hamilton et al., 2010). Some of these survivors withdrew from traditional support systems because of fear of being ostracized.

Application to Nursing Practice

- Although cancer survivors go through similar steps of cancer diagnosis and treatment, they experience cancer and the long-term impact differently based on their cultural beliefs.
- Nurses need to be aware and respect patients' cultural differences regarding the cancer experience.
- Assess patients' social support and their beliefs about cancer and incorporate these beliefs into nursing care approaches.
- Spiritual beliefs often significantly impact the patient's cancer experience.

TABLE 8-1 Examples of Late Effects of Surgery Among Adult Cancer Survivors

PROCEDURE	LATE EFFECT
Any surgical procedure	Pain, psychosocial distress, impaired wound healing
Surgery involving brain or spinal cord	Impaired cognitive function, motor sensory alterations, altered vision, swallowing, language, bowel and bladder control
Head and neck surgery	Difficulties with communication, swallowing, and breathing
Abdominal surgery	Risk of intestinal obstruction, hernia, altered bowel function
Lung resection	Difficulty breathing, fatigue, generalized weakness
Prostatectomy	Urinary incontinence, sexual dysfunction, poor body image

Modified from Institute of Medicine and National Research Council, Hewitt M, Greenfield S, Stovall E, editors: *From cancer patient to cancer survivor: lost in transition,* Washington, DC, 2006, National Academies Press.

(tumor not metastasized) of the bladder. She continues to experience many noncancer conditions: premature menopause, early osteoporosis, hypothyroidism, lung fibrosis, and atrophy of neck and upper chest muscles (Leigh, 2006).

This story is not unusual among survivors and highlights the long disease course that many cancer survivors face. A number of tissues and body systems are impaired as a result of cancer and its treatment (Table 8-1). Late effects of chemotherapy and/or radiation include osteoporosis, heart failure, diabetes, amenorrhea in women, sterility in men and women, impaired gastrointestinal motility, abnormal liver function, impaired immune function, **paresthesias,** hearing loss, and problems with thinking and memory (IOM, 2006). Some cancer treatments cause painful peripheral **neuropathy** (Pignataro and Swisher, 2010). Certain conditions resolve over time, but tissue damage causes some symptoms to persist indefinitely, especially when patients receive high-dose chemotherapy. Health care professionals do not always recognize these conditions as delayed problems. Often conditions such as osteoporosis, hearing loss, or change in memory are instead considered to be age related. It is common for patients with cancer to have multiple symptoms, and more attention is being given to the existence of symptom clusters. A symptom cluster is a group of several related and coexisting symptoms such as pain-insomnia-fatigue or pain-depression-fatigue (Kirkova et al., 2010; Xiao, 2010). Researchers are trying to better understand symptom clusters, their effects on patients, and whether clusters require a different treatment approach than current symptom management.

Cancer-related fatigue (CRF) and associated sleep disturbances are among the most frequent and disturbing complaints of people with cancer. The symptoms often last many months after chemotherapy and radiation. The National Comprehensive Cancer Network Clinical Practice Guidelines for CRF treatment includes interventions for controlling fatigue through routine physical exercise, development of good sleep habits, eating a balanced diet, and counseling for depression that often accompanies CRF. Acupuncture may also help control CRF in cancer survivors (Johnston, Xiao, and Hui, 2007; Escalante and Manzullo, 2009).

Chemotherapy-related cognitive impairment (CRCI) is estimated to occur in 17% to 75% of persons who receive standard-dose chemotherapy for cancer treatment (Myers, 2009). These cognitive changes occur during all phases of the cancer treatment, ranging from subtle symptoms such as a decreased attention span and being easily distracted to more obvious symptoms such as difficulty walking and significant behavior changes (Evans and Eschiti, 2009). There is no way to predict if a person will have CRCI. Some people who experience this symptom have difficulty working and processing information in their day-to-day lives, which affects daily functioning and the quality of their work and social life (Boykoff, Moieni, and Subramanian, 2009).

Often health care providers wrongly attribute the symptoms of cancer or the symptoms from the side effects of treatment to aging. This often leads to late diagnosis or a failure to provide aggressive and effective treatment of symptoms. Cancer is a chronic disease because of the serious consequences and the persistent nature of some of its late effects (IOM, 2006). The range of effects that patients suffer varies greatly. For example, a 46-year-old woman with early-stage melanoma on the right arm underwent successful surgery and only had an inconspicuous scar. In contrast, Susan, the Army nurse diagnosed with Hodgkin's disease, underwent intensive chemotherapy followed by an extended course of radiation. She faced serious and substantial long-term health problems from her treatment. Patients living with cancer present significant variations in the type of conditions they develop and the length of time the conditions persist.

Numerous factors contribute to survivors not receiving timely and appropriate treatment for the physical effects they suffer. Survivors often delay reporting symptoms because they fear being perceived as ungrateful for being disease free or they fear cancer recurrence (Polomano and Farrar, 2006). Survivors are not always aware that painful conditions or syndromes are common and frequently believe that pain relief is not possible (see Chapter 43). Health care providers have limited awareness of the prevalence and incidence of pain and other symptoms among survivors and frequently have limited education in symptom management. In the case of pain management, health care providers do not always acknowledge the potential for chronic pain following curative cancer therapies, or they sometimes fail to inform patients about potential long-term consequences of cancer treatment (Polomano and Farrar, 2006). Few health care settings track the health-related quality of life and symptomatology of patients over time. Researchers are beginning to recognize the need to identify the long-term patterns of symptoms most commonly associated with types of cancer and its treatment.

Psychological Well-Being

The physical effects of cancer and its treatment sometimes extend to cause serious psychological distress (see Chapter 37). Research suggests that some long-term (10-year) cancer survivors have impaired mood but also demonstrate aspects of psychological well-being compared to a cancer-free comparison group (Costanzo, Ryff, and Singer, 2009). In addition, older survivors show resilient social well-being, spirituality, and personal growth compared to younger survivors. What creates the individual response to having cancer is unclear. Research in culturally diverse long-term adult colorectal cancer survivors associates the belief in curability of the cancer with survival of over 15 years (Soler-Vilá et al., 2009). This does not mean that, just because someone believes that his or her cancer is cured, it is; however, perhaps these people had more positive coping strategies when dealing with their cancer.

Fear of cancer recurrence is common among cancer survivors (Simard, Savard, and Ivers, 2010). Use of positive coping strategies seems to help make this fear less troublesome. The levels of this fear are higher in survivors with more negative intrusive thoughts about their illness. When cancer recurs, patients and families face new challenges and distress (Vivar et al., 2009).

Another common psychological problem for survivors is **post-traumatic stress disorder (PTSD).** PTSD is a psychiatric disorder characterized by an acute emotional response to a traumatic event or situation. Approximately 3% to 4% of patients recently diagnosed with early-stage cancer experience symptoms of PTSD (e.g., grief, intrusive thoughts about the disease, nightmares, relational difficulties, or fear). This percentage increases to 35% in patients evaluated after treatment (NCI, 2009). Being unmarried or less educated or having a lower income and less social and emotional support increases the risk for PTSD (Stuber et al., 2010). The following description is an example of a cancer survivor's response to the stressors of cancer treatment:

> *The first question I asked my radiation oncologist after completing treatment for nonmetastatic breast and ovarian cancer was: "When can I go back to my job?" I remember him looking at me skeptically and replying, "Considering the work you do, I would think that 8 weeks of rest and recovery is the minimum." I left the clinic excited that my treatments were over and I could get on with my life. Eight weeks later I woke up tired after sleepless nights. I was bald and had peripheral neuropathy in my hands and feet that was crippling, and the drug I was taking made me feel like I had arthritis all over my body. Where was my energy and soft blond hair? Why couldn't I think straight? There is no way I could do my job like this. I felt like I was drowning (Bush, 2009).*

The disabling effects of chronic cancer symptoms disrupt family and personal relationships, impair individuals' work performance, and often isolate survivors from normal social activities. Such changes in lifestyle create serious implications for a survivor's psychological well-being. When cancer changes a patient's body image or alters sexual function, the survivor frequently experiences significant anxiety and depression in interpersonal relationships. In the case of breast-cancer survivors, studies show that poorer self-ratings of quality of life are associated with poor body image, coping strategies, and a lack of social support (IOM, 2006).

Some factors ease the psychological stress associated with having cancer. A survivor who sees cancer as a challenging experience and a controllable threat has less stress (Jacobsen, 2006). Patients who use problem-oriented, active, and emotionally expressive coping processes also manage stress well (see Chapter 37). Survivors who have social and emotional support systems and maintain open communication with their treatment providers will also likely have less psychological distress (Jacobsen, 2006).

Social Well-Being

Cancer affects any age-group (Fig. 8-2). The developmental effects of cancer are perhaps best seen in the social impact that occurs across the life span. For adolescents and young adults, cancer seriously alters a young person's social skills, sexual development, body image, and the ability to think about and plan for the future (see Chapter 11). Cancer interrupts their lives, causing young survivors either to feel out of touch with the interests of their peers or to perceive interests as superficial (Blum, 2006). In addition, because cancer makes them feel different, young survivors, out of fear of rejection, have problems with dating and developing new relationships. Often the course of cancer or its treatment causes young adults to delay leaving their parents. The natural separation that occurs when young adults finish school and plan to start their careers is postponed or stopped. Often a young adult then feels ill equipped to take on the real world.

FIG. 8-2 A family representing young and old. Each member could be a cancer survivor.

Adults (ages 30 to 59) who have cancer experience significant changes in their families. Once a member of the family is diagnosed with cancer, every family member's role, plans, and abilities changes (Blum, 2006). The healthy spouse often takes on added job responsibilities to provide additional income for the family. A spouse, sibling, grandparent, or child often assumes caregiving responsibilities for the patient. Patients who experience changes in sexuality, intimacy, and fertility see their marriages affected, often resulting in divorce.

A history of cancer significantly affects employment opportunities and the ability of a survivor to obtain and retain health and life insurance (IOM, 2006). Often a survivor experiences health-related work limitations that require a reduced work schedule or a complete change in employment. Between 64% and 84% of cancer survivors who worked before their diagnosis return to work (Steiner, Nowels, and Main, 2010). The most common problems reported by survivors who return to work are physical effort, heavy lifting, stooping, concentration, and keeping up with the work pace. Factors that affect a return to work include cancer site, prognosis, type of treatment, socioeconomic status, and characteristics of the work to be done. Middle-age cancer survivors have disability rates similar to those of people with chronic illnesses other than cancer (Short, Vasey, and Belue, 2008). The economic burden of cancer is enormous. If a survivor's illness affects his or her ability to work, less income goes to the individual and family. In addition, high out-of-pocket expenses for prescription drugs, medical devices and supplies and expenses for coinsurance and copayments usually increase (IOM, 2006). The problems are even greater for low-income survivors if they are uninsured or underinsured. Some Americans have health insurance that provides insurance coverage for most cancer-related care. However, approximately 42 million Americans have no health insurance at all. The uninsured do not receive the care they need, they suffer from a poorer state of health, and they are more likely to die earlier than those who have insurance (IOM, 2006).

Older adults face many social concerns as a result of cancer. The disease causes some survivors to retire prematurely or decrease work hours, thus decreasing income. The older adult faces a fixed

income and the limitations of Medicare reimbursement. Many older survivors see their retirement pensions erode away quickly. They often have to use their income for basic expenses and cancer care costs, thus limiting opportunities for social activities. Many older adults have moved to retirement residences in other states and find themselves isolated from the social support of their families. Older adults also face a high level of disability as a result of cancer and cancer treatment and report a higher incidence of limitations in activities of daily living than older adults without cancer (IOM, 2006). As a result, many older cancer survivors require ongoing caregiving support either from family members or professional caregivers.

Spiritual Well-Being

Cancer challenges a person's spiritual well-being (see Chapter 35). Key features of spiritual well-being include a harmonious interconnectedness, creative energy, and a faith in a higher power or life force (Brown-Saltzman, 2006). Cancer and its treatment create physical and psychological changes that cause survivors to question, "Why me?" and wonder if perhaps their disease is some form of punishment. They often experience a level of spiritual distress, a disruption in a person's spirit or life principle. Survivors most at risk for spiritual distress are those with energy-consuming anxiety, an inability to forgive, low self-esteem, maturational losses, and mental illness (Brown-Saltzman, 2006). Additional risk factors include poor relationships and situational losses.

Relationships with a God, a higher power, nature, family, or community are critical for survivors. Cancer threatens relationships because it makes it difficult for survivors to maintain a connection and a sense of belonging. Cancer isolates survivors from meaningful interaction and support, which then threatens their ability to maintain hope. Long-term treatment, the recurrence of cancer, and the lingering side effects of treatment all create a level of uncertainty for survivors.

CANCER AND FAMILIES

A survivor's family takes different forms: the traditional nuclear family, extended family, single-parent family, close friends, and blended families (see Chapter 10). Once cancer affects a member of the family, it affects all other members as well. Usually a member of the family becomes the patient's caregiver. Family caregiving is a stressful experience, depending on the relationship between patient and caregiver and the nature and extent of the patient's disease. Members of the "sandwich generation" (i.e., caregivers who are 30 to 50 years old) are often caught in the middle of caring for their own immediate family and a parent with cancer. The demands are many, from providing ongoing encouragement and support and assisting with household chores to providing hands-on physical care (e.g., bathing, assisting with toileting, or changing a dressing) when cancer is advanced. Caregiving also involves the psychological demands of communicating, problem solving, and decision making; social demands of remaining active in the community and work; and economic demands of meeting financial obligations.

Family Distress

Living through cancer and treatment is a stressful time for families. Many caregivers and cancer survivors attempt to hide cancer-related thoughts and concerns from one another, which increases adverse psychological outcomes (Langer, Brown, and Syrjala, 2009). Motivation for this behavior is often to protect one another from the distress that is experienced by each member of the family. Holding back emotions is sometimes a part of this effort to shield one another from true thoughts and feelings (Porter et al., 2009). Porter et al. found that, if cancer survivors and their partners participated in an educational program to teach the importance of disclosing feelings and then actually disclosed them, relationships and intimacy were improved. Encouraging honest communication within families is an important intervention for you to implement to enhance family relationships.

Families struggle to maintain core functions when one of their members is a cancer survivor. Core family functions include maintaining an emotionally and physically safe environment, interpreting and reducing the threat of stressful events (including the cancer) for family members, and nurturing and supporting the development of individual family members (Lewis, 2006). In child-rearing families, this means providing an attentive parenting environment for children and information and support to children when their sense of well-being becomes threatened. When a member of the family has cancer, these core functions become threatened. Spouses often do not know what to do to support the survivor, and they struggle with how to help. In the end family functions become fragmented, and family members develop an uncertainty about their roles.

IMPLICATIONS FOR NURSING

Cancer survivorship creates many implications for nurses who help survivors plan for optimal lifelong health. Much needs to be done to research appropriate interventions for the effects of cancer and its treatment. Nurses are in a strong position to take the lead in improving public health efforts to manage the long-term consequences of cancer. Improvement is also necessary in the education of nurses and survivors about the phenomenon of survivorship. As a nursing student, you too can make a difference. This section addresses approaches to incorporate cancer survivorship into your nursing practice.

Survivor Assessment

Knowing that there are many cancer survivors in the health care system, consider how to assess patients who report a history of cancer. It is important to assess a cancer survivor's needs as a standard part of your practice. When you are collecting a nursing history (see Chapter 30), explore with your patients their history of cancer, including the diagnosis and type of treatment they either are undergoing or have received in the past. Be aware that some patients do not always report that they have had cancer. Thus, when a patient tells you that he or she has had surgery, ask if it was cancer related. When a patient reveals a history of chemotherapy, radiation, biotherapy, or hormone therapy, you need to refer to resources to help you understand how these therapies typically affect patients in both the short and long term. Then extend your assessment to determine if these treatment effects exist for your patient. Consider not only the effects of the cancer and its treatment (such as potential symptoms) but how it will affect any other medical condition. For example, if a patient also has heart disease, how will cancer-related fatigue affect this individual?

Understanding the cancer experience comes from a patient's own story. Asking general, open-ended questions about the patient's survivor experience will help the patient reveal his or her story. For example, you might ask, "Having cancer is a journey for many. Tell me how the disease most affects you right now," or "What are the biggest problems that you are having from cancer?" or "What can

I do to help you at this point?" These types of questions focus on the area that is most important to the patient and communicate to patients your interest in their situation. Show a caring approach so patients know that their story will be accepted (see Chapter 7).

Symptom management is an ongoing problem for many cancer survivors. If cancer is their primary diagnosis, it will be natural for you to explore any presenting symptoms. Be sure to learn specifically how symptoms are affecting the patient. For example, is pain also causing fatigue, or is a neuropathy causing the patient to walk with an abnormal gait? If cancer is secondary, you do not want important symptoms to go unrecognized. Ask the patient, "Since your diagnosis of and treatment for cancer, what physical changes or symptoms have you had?" "How do these changes affect you now?" Depending on the symptoms a patient identifies, you explore each one to gain a complete picture of his or her health status (Table 8-2). Some patients are reluctant to report or discuss their symptoms. Be patient; and, once you identify a symptom, explore the extent to which the symptom is currently affecting the patient.

Because you know that cancer affects a patient's quality of life in many ways, be sure to explore the patient's psychological, social, and spiritual needs and resources. Sometimes you will not be able to conduct a thorough assessment when you perform an initial nursing history. If this is the case, incorporate your assessment into your ongoing patient care. Observe your patient's interactions with family members and friends. When you are administering care to patients, talk about their daily lives and determine the extent to which cancer has changed their lifestyle.

TABLE 8-2 Examples of Assessment Questions for Cancer Survivors

CATEGORY	EXAMPLES OF QUESTIONS
Symptoms	• Tell me about the symptoms you are having from your cancer treatment. • Describe any pain or discomfort in the area where you had surgery or radiation; discomfort, pain, or unusual sensations in your hands or feet; weakness in your legs or arms; or problems moving around. • Are you experiencing fatigue, sleeplessness, shortness of breath? If so, please describe. • Sometimes people believe that they are starting to have problems after chemotherapy such as paying attention, remembering things, or finding words. Have you noticed any changes like these?
Psychosocial problems	• How distressed are you feeling at this point on a scale of 0 to 10 with 10 being the worst distress that you could imagine? • Tell me how you think your family is doing with your cancer? • What do you see in your family members' responses to your cancer that concerns you?
Sexuality problems	• If you have had sexual changes, what strategies have you tried to make things better? Have these strategies worked? • Would you be open to a health care provider who knows how to help you? • Since your cancer, do you see yourself differently as a person?

One area that is often difficult for nurses to assess well is a patient's sexuality. Sexuality is more than simply the physical ability to perform a sex act or conceive a child. It also includes a person's body image, sexual response (e.g., interest and satisfaction), and sexual roles and relationships (see Chapter 34). Surgery for many cancers is disfiguring, and chemotherapy and radiation often alter a patient's sexual response (e.g., prostate, breast, and gynecological cancers). Cancer therapies have the potential to cause fatigue, apathy, nausea, vomiting, malaise, and sleep disturbances, all of which interfere with a patient's libido (Pelusi, 2006). It is important to simply realize that cancer often does influence the patient's sexuality. It helps to develop a comfort level in acknowledging with patients that sexual changes are common at any age level. Ask a patient, "Since your diagnosis of and treatment for cancer, has your ability or interest in sexual activity changed? If so, how?" Patients will appreciate your sensitivity and interest in their well-being. When patients begin to discuss their sexual problems, be familiar with the expert resources in your institution (e.g., psychologist or social worker) available for patient referral.

Patient Education

When you care for a cancer patient, it is important to understand whether the patient administers most of his or her own self-care or if support is required from a family caregiver. This is essential to provide the most appropriate patient education, both in the form of content and in your teaching approach. Schumacher et al. (2006) developed a conceptual model, the transactional model of cancer family caregiving skill, which describes the relationship among cancer patients and family caregivers in the performance of family caregiving skills (Fig. 8-3). The model offers a perspective on caregivers and cancer survivors both as individuals and as a team. Family caregiving skill is the ability to respond effectively and smoothly to the demands of an illness and pattern of care using multiple caregiving processes (Schumacher et al., 2006). Illness demands of cancer include dealing with symptoms, responding to illness behaviors (e.g., role changes, avoiding interaction), modifying activities for an illness situation, nutritional support, interpersonal care, use of community resources, managing acute illness episodes, and implementing treatments. The patient and caregiver follow a continuum of three patterns of care: the self-caregiving pattern (patients are mostly independent with caregivers in a standby role), the collaborative care pattern (patients and caregivers share care activities and respond together to illness demands), and the family caregiving pattern (patients are unable to perform independently and require extensive caregiver involvement) (Schumacher et al., 2006). A patient's and caregiver's response to a demand involves performing caregiving processes (e.g., monitoring [observing for problems], interpreting [identifying the problem], making decisions and adjustments, accessing resources, and providing hands-on care). In terms of providing hands-on care, family caregivers often provide complex nursing procedures in the home such as managing intravenous infusions or irrigating wounds. Knowledge about caregiving or self-care, previous experience, and emotions influence the way caregivers and survivors respond and acquire caregiving processes. Schumacher's model is a helpful resource for you to apply when initially assessing the patient and caregiver condition, identifying their learning needs, and recognizing the type of information to teach. Learn where the patient and caregiver are along the caregiving continuum and determine the information needed to support them in meeting caregiving demands and performing caregiving processes. Frequently this means that any education will involve

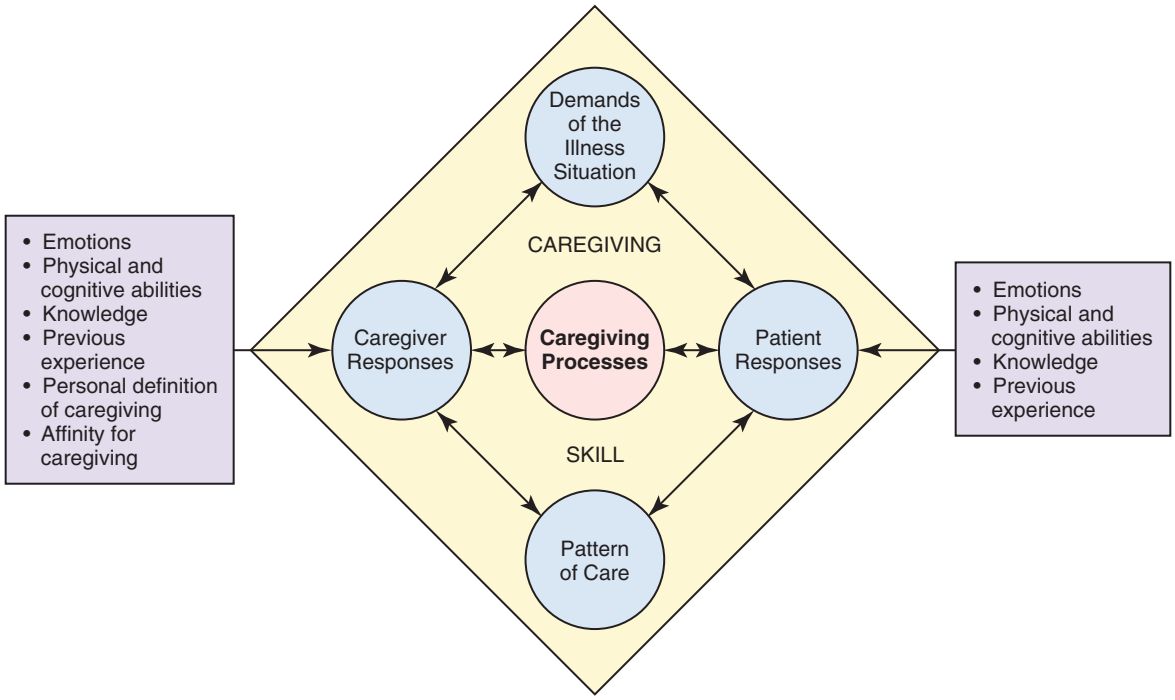

FIG. 8-3 Transactional model of cancer family caregiving skill. (From Schumacher KL et al: A transactional model of family caregiving skill, *Adv Nurs Sci* 29(3):271, 2006.)

both the patient and family caregiver together, unless the relationship is strained and the patient chooses not to have the caregiver involved.

It is a nurse's responsibility to educate cancer survivors and their families about the effects of cancer and cancer treatment. This means that, when you care for a cancer survivor, you need to understand the nature of the patient's particular disease and know the short- and long-term effects of each therapy. Cancer survivors who have an increased need for health-related information are younger and non-Caucasian, have less-than-excellent postcancer care, and have a history of other diseases (Beckford et al., 2008). When designing education that promotes self-management in caregiving, plan activities on the basis of the family caregiver's and cancer survivor's perceived disease-related problems and assist them with problem solving and gaining the self-efficacy or confidence to deal with these problems. Patient education helps survivors assume healthier lifestyle behaviors that will then give them control of aspects of their health and improve outcomes from cancer and chronic illness.

When caring for patients with an initial diagnosis of cancer, reinforce their health care provider's explanations of the risks related to their cancer and treatment, what they need to self-monitor (e.g., appetite, weight, and effects of fatigue), and what to discuss with health care providers in the future. If you teach patients and their family caregivers about the potential for treatment effects such as pain, neuropathy, or cognitive change, they are more likely to report their symptoms. It allows them to know what signs or changes to anticipate and monitor. Survivors need to learn how to manage problems related to persistent symptoms. For example, survivors with neuropathy need to learn how to protect the hands and feet, prevent falls, and avoid accidental burns.

Because survivors have an increased risk for developing a second cancer and/or chronic illness, it is important to educate them about lifestyle behaviors and the importance of participating in ongoing cancer screening and early detection practices. Lifelong cancer screening provides the opportunity to identify new cancers in early stages (Wilkins and Woodgate, 2008). When health care providers recommend follow-up screening in cancer survivors, there is a higher likelihood that the person will actually have the screening test (Mayer et al., 2007). Many survivors become interested in learning more about dietary supplements and nutritional complementary therapies to manage disease symptoms (IOM, 2006). Scientific evidence shows that several health promotion areas are of interest to cancer survivors: smoking cessation, physical activity, diet and nutrition (see Chapter 44), and the use of complementary and alternative medicine (see Chapter 32). Teach patients useful strategies to promote their health. Some health care providers wrongly attribute the symptoms of cancer or the side effects of treatment to aging. This often leads to late diagnosis or a failure to provide aggressive and effective treatment of symptoms.

Providing Resources

Numerous organizations and agencies provide resources to cancer survivors. However, many survivors do not receive timely and appropriate referrals to these resources. As a nurse, you will find that many people (e.g., friends, neighbors, and family members) come to you for advice about health care before they actually become a patient. It is important to know that cancer-related hospital and ambulatory care are not standardized. For example, when a patient with cancer is hospitalized, the availability of ancillary services for long-term care varies by care setting. Hospital-based oncologists are usually in larger hospitals and not in smaller ones. An NCI–designated cancer center offers the most comprehensive and up-to-date clinical care. NCI-designated centers also conduct important clinical trials to investigate the most current cancer therapies. Your role is to tell patients about the different resources available so they are able to make informed choices about their care. You can refer patients to the NCI website (http://www.cancer.gov/), which contains a current list of NCI-designated comprehensive cancer centers.

A wealth of cancer-related community support services is available to survivors through voluntary organizations such as the ACS (www.cancer.org), the Lance Armstrong Foundation (http://www.livestrong.org), and The National Coalition for Cancer Survivorship (NCCS) (http://www.canceradvocacy.org). Most offer their services at no cost. Many supportive services offer call centers and Internet-based information and discussion boards in addition to direct service delivery (IOM, 2006). Health care professionals are not consistent in referring patients to these valuable services. In addition, although community-based services help most survivors, there are gaps in service provision for assistance with transportation, home care, child care, and financial assistance. Become knowledgeable about the services within your community. There are several national agencies across the country, including the Cancer Support Community (http://www.thewellnesscommunity.org) and agencies targeted to racial groups such as the Sisters Network (http://www.sistersnetworkinc.org) and the Witness Program (http://www.acrc.uams.edu/patients/witness_project).

COMPONENTS OF SURVIVORSHIP CARE

Once primary cancer treatment ends, health care professionals need to develop an organized plan for survivorship care. This does not always occur because of inadequacies in the health care system, including a health care provider not assuming responsibility for coordinating care, fragmentation of care between specialists and general practitioners, and a lack of guidance on how survivors can improve their health outcomes (IOM, 2006). Patients with cancer often do not receive noncancer care (e.g., care for diabetes or heart conditions) when their cancer diagnosis shifts attention away from care that is routine but necessary. The IOM (2006) recommends four essential components of survivorship care: (1) prevention and detection of new cancers and recurrent cancer; (2) surveillance for cancer spread, recurrence, or second cancers; (3) intervention for consequences of cancer and its treatment (e.g., medical problems, symptoms, and psychological distress); and (4) coordination between specialists and primary care providers.

Survivorship Care Plan

To meet the health care needs of cancer survivors, it is essential for a "survivorship care plan" to be written by the principal provider who coordinates the patient's **oncology** treatment (Jacobsen, 2006; IOM, 2006). When the survivor is released from the oncologist, the internist and other health care providers provide and coordinate care based on knowledge of prior cancer history and treatment. The IOM (2006) also recommends that health insurance plans cover care outlined in a survivor care plan. Survivor plans are not always developed, and health insurance companies do not routinely cover this type of care. Ideally you review a survivorship care plan with a patient when he or she is formally discharged from a treatment program. The plan then becomes a guide for any future cancer or cancer-related care. Health care providers use the plan as a guide for patient education and screening for secondary cancers. Survivors use it to raise questions with health care providers to prompt appropriate care during follow-up visits. Box 8-3 highlights the components of a survivorship care plan.

Cancer organizations such as the Lance Armstrong Foundation (LiveStrong) and the Association of Cancer Online Resources (ACOR) (http://www.acor.org) provide Internet guides for the development of survivorship care plans. Several NCI-designated cancer centers and pediatric cancer centers provide survivorship care planning. Even though Internet guidelines for care plans exist, many survivors do not receive care at NCI-designated cancer centers and are discharged with no survivor plan. Thus nurses and other health care providers need to become more vigilant in recognizing cancer survivors and attempting to link them with the support and resources they require. Nurses make a difference when they consider the long-term issues that cancer survivors face after their time of diagnosis and in contributing to solutions to manage or relieve cancer-associated health problems. A strong interprofessional approach that includes nurses, oncology specialists, dietitians, social workers, pastoral care, and rehabilitation professionals is necessary. Together an interprofessional team provides a plan of care that addresses treatment-related problems and future health risks and offers a wellness focus to give patients a sense of hope as he or she enters the survivor experience.

BOX 8-3 A SURVIVORSHIP CARE PLAN

On discharge from cancer treatment, every patient and his or her primary health care provider should receive a record of all care received from the oncologist. In addition, the patient and health care provider should receive a follow-up plan incorporating available evidence-based standards of care.

Care Summary

- Diagnostic tests performed and results
- Tumor characteristics (e.g., site, stage, and grade)
- Dates when treatment started and stopped
- Surgery, chemotherapy, radiotherapy, transplant, hormone therapy, or gene therapy provided, including the specific agents used
- Psychosocial, nutritional, and other supportive services provided
- Full contact information for treating institutions and key providers
- Identification of a key point of contact and coordinator of care

Follow-up Plan

- Likely course of recovery
- Description of recommended cancer screening and other periodic testing/examinations
- Information about possible late and long-term effects of treatment and symptoms of such effects
- Information about possible signs of recurrence and second tumors
- Information about the possible effects of cancer on marital/partner relationship, sexual functioning, work, and parenting
- Information on the potential insurance, employment, and financial consequences of cancer and, as necessary, referral to counseling, legal aid, and financial assistance
- Specific recommendations for healthy behaviors
- Information about genetic counseling and testing as appropriate
- Information about known effective chemoprevention strategies for secondary prevention
- Referrals to specific follow-up care providers
- A listing of cancer-related resources and information

Modified from the President's Cancer Panel: Living beyond cancer: Finding a new balance, Bethesda, MD, 2004, National Cancer Institute; and Institute of Medicine and National Research Council, Hewitt M, Greenfield S, Stovall E, editors: *From cancer patient to cancer survivor: lost in transition,* Washington, DC, 2006, National Academies Press.

KEY POINTS

- Nurses care for cancer survivors when they seek care for their cancer and other medical conditions.
- Many cancer survivors have serious health problems that are related to their treatments.

- Cancer survivors among racial and ethnic minorities and other underserved populations have more posttreatment symptoms and poorer treatment outcomes than Caucasians.
- Survivors are often reluctant to report symptoms because of a fear of being perceived as ungrateful for being disease free or a fear of cancer recurrence.
- How well a survivor adapts to the cancer experience psychologically depends on predisposing factors, the person's current psychological status, the extent of his or her disease, and the presence of disruptive signs and symptoms.
- The disabling effects of chronic cancer symptoms disrupt family and personal relationships, impair individuals' work performance, and often isolate survivors from normal social activities.
- Adults who have cancer experience significant changes within their families, including a change in each member's role.
- Relationships among cancer survivors and family members become difficult to maintain because family members often do not know, understand, or have the skills or confidence to support the survivor's reactions to cancer.
- Because survivors are at an increased risk for developing a second cancer and/or chronic illness, it is important to educate them about lifestyle behaviors that will improve the quality of their lives.
- Once a patient's primary cancer treatment ends, health care professionals should develop an organized plan for survivorship care.
- Ideally you review a survivorship care plan with a patient when he or she is formally discharged from a treatment program, and it becomes a guide for any future cancer or cancer-related care.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Do you have a friend or family member who has cancer and is willing to talk about it? If so, ask the individual to tell you what the experience has been like and what he or she would recommend to help you provide better care for survivors.
2. Ms. Ritter is a 32-year-old woman who visits the medical outpatient clinic for her final course of chemotherapy to treat breast cancer. She is married and has one child, a daughter, who is 6 years old. She and her husband hoped to have another child in the near future but now wonder if that will be possible. She shared with the nursing staff her concerns about the future and how cancer will affect her and her family. Her case manager talks with her about a survivorship care plan before discharge from the clinic. Identify two follow-up care plan components that would be important when considering Ms. Ritter's role as a wife and parent.
3. Ms. Ritter tells her nurse, "This chemotherapy has made me feel so tired, and there are many nights I can't sleep very well. I am looking forward to this ending." What is an appropriate response the nurse might give Ms. Ritter?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. Cancer survivors are at risk for treatment-related problems. Which of the patients listed below has the greatest risk for developing such a problem?
   1. An 80-year-old woman undergoing surgery for removal of a basal cell carcinoma on the face
   2. A 71-year-old man receiving high-dose chemotherapy and radiation for an advanced-stage lymphoma
   3. A 26-year-old man receiving chemotherapy for testicular cancer that is localized to the testicle
   4. A 48-year-old woman receiving radiation for Hodgkin's disease that involves lymph nodes extending above and below the diaphragm
2. Mr. Wallace is a 34-year-old who is a 5-year survivor of Hodgkin's disease. He continues to have symptoms related to his chemotherapy treatment. Mr. Wallace is a computer expert and enjoys Internet discussion groups. What is the best resource a nurse can recommend to help him access a survivorship care plan?
   1. Association of Cancer Online Resources
   2. National Coalition for Cancer Survivorship
   3. American Cancer Society
   4. National Cancer Institute
3. A nurse reviews the medical record of a 40-year-old patient newly admitted to the medical nursing unit for evaluation of diabetes. As the nurse reviews the patient's medical history, she notices that the patient had bladder surgery 3 years ago. Which of the following assessment questions is most appropriate for the nurse to ask to determine if the patient is a cancer survivor?
   1. Determining if the patient had additional surgeries recently
   2. Assessing the patient's medication history
   3. Determining if the surgery was cancer related
   4. Assessing if the patient's parents had cancer
4. A nurse working in a medicine clinic knows that it is important to recognize cancer survivors who are most at risk for posttreatment symptoms. Which of the following patients will likely be at greatest risk for posttreatment symptoms?
   1. A 50-year-old mother of three who was diagnosed with late-stage breast cancer and has hypertension
   2. A 20-year-old male college student diagnosed with leukemia whose father had lung cancer
   3. A 32-year-old Hispanic woman who has been diagnosed with local cervical cancer and receives Medicaid
   4. A 72-year-old African American male who had colorectal cancer with surgery, radiation, and a second round of chemotherapy because of failure of initial treatment and has diabetes
5. A 41-year-old man who underwent a craniotomy for the removal of a brain tumor 6 months ago comes to the clinic for his monthly follow-up visit. In planning your assessment, you anticipate that the patient may possibly experience which of the following late effects of surgery? (Select all that apply.)
   1. Pain
   2. Fatigue
   3. Blurred vision
   4. Difficulty breathing
   5. Poor attention span
6. To successfully assess if a patient is experiencing cognitive changes as a result of cancer treatment or complications of treatment, which of the following questions by a nurse is likely most relevant?
   1. Describe for me your medication schedule.
   2. How distressed are you feeling right now on a scale of 0 to 10?

3. Tell me about when you first noticed symptoms from your chemotherapy.
4. Tell me what you notice differently in your ability to get work done at your office.

7. A support group of cancer survivors is discussing cancer-related fatigue (CRF). The survivor most likely to gain relief from CRF is the survivor who does which of the following? (Select all that apply.)
   1. Takes naps during the day and evening
   2. Drinks energy drinks daily
   3. Exercises every other day
   4. Eats a balanced diet
8. Mr. Timmons has been receiving treatment for colon cancer on and off for a year. He received multiple chemotherapy regimens and a course of radiation. The 58-year-old patient is able to perform his own hygiene but needs assistance from his wife to move about safely in the home because of ongoing fatigue and weakness. His wife assists him with dressing when he becomes excessively tired. This caregiving skill pattern is best described as which of the following?
   1. The self-caregiving pattern
   2. The collaborative care pattern
   3. The family caregiving pattern
   4. The team caregiving pattern
9. Fill in the Blank. The period during which a cancer patient goes into remission following the basic, rigorous course of chemotherapy and enters a phase of watchful waiting, is called _____.
10. A nurse in an oncology outpatient clinic has been seeing a woman and her husband since the woman was diagnosed with breast cancer. Sometimes the husband appears supportive, asking questions about his wife's care. At other times the husband seems easily distracted and uninterested. The nurse decides to reassess the psychosocial condition of the patient and her husband. Which of the following questions best elicits needed psychosocial information?
    1. "In what way does the pain you have affect you on a daily basis?"
    2. "Describe to me what you eat in a typical day."
    3. "Tell me how you think you and your husband are dealing with your cancer."
    4. "Are the two of you having any relational difficulties because of your cancer?"
11. Katie, a child in remission for leukemia, and her mother come to the pediatrician's office for a routine physical examination. The nurse asks Katie about whether she is having continued symptoms. Her mom says," I don't know why you want all of this information about Katie's cancer treatment. The leukemia is gone." The best response from the nurse in support of the child and mother would be:
    1. "The doctor likes to keep the records complete on all of her patients."
    2. "Just because Katie is in remission does not mean that it will stay that way."
    3. "It is common for children to have delayed effects from treatment, so we need to know this to plan Katie's care properly."
    4. "I understand your concern. If you don't want to provide the information, sign this release form."
12. Mr. Stewart is a 62-year-old patient diagnosed with prostate cancer who underwent surgical removal of the prostate 3 days ago. He lives with his wife at home. The nurse is planning to provide discharge instructions for the patient. What would be the most effective initial question to ask of the patient and family in determining the approach to discharge instructions?
    1. "Mr. Stewart, have you had surgery in the past?"
    2. "The doctor has ordered you to go home with a urinary catheter. Tell me how you think you can manage this."
    3. "Mrs. Stewart, do you find it difficult to look at your husband's incision? If so, tell me how you feel."
    4. "Mr. Stewart, describe for me how much your wife normally helps you at home and what you can do on your own."
13. A 62-year-old patient is being admitted to a surgical unit for a total hip replacement. The nurse reviews his medical record and learns that the patient has a history of impaired liver function and paresthesias in his feet. After assessing the patient's medical history further, the nurse is not sure what caused the liver impairment or paresthesia. To clarify, an appropriate question to ask the patient is which of the following?
    1. "Have you been treated for cancer in the past?"
    2. "What is the nature of your liver problem?"
    3. "Has the doctor discussed with you whether your liver problems will affect your recovery from surgery?"
    4. "How long have you had the numbness and tingling in your feet?"
14. Ben, a 31-year-old nursing student, is caring for Maria, a 45-year-old Latina woman who is receiving chemotherapy following surgery for breast cancer. Based on the evidence about cultural influences on cancer patients, Ben knows that which factor will likely influence this patient's ability to cope with her cancer?
    1. Transportation resources to the oncology clinic
    2. Whether the patient's physician is male or female
    3. The stigma family members place on cancer
    4. The level of social support available to the patient
15. Caring for a patient with cancer is unique because of the effects of the disease and associated treatment. An understanding of a patient's symptom experience is critical and best revealed by a nurse asking which of the following questions? (Select all that apply.)
    1. "What symptoms do you think you are having as a result of your cancer?"
    2. "Describe for me how the symptoms affect you in your daily life."
    3. "Let's focus on your pain. Tell me how it affects you."
    4. "Can you describe for me how your family provides care for your symptoms?"

Answers: **1.** 2; **2.** 1; **3.** 3; **4.** 4; **5.** 3, 5; **6.** 4; **7.** 3, 4; **8.** 2; **9.** Extended survival; **10.** 3; **11.** 3; **12.** 4; **13.** 1; **14.** 4; **15.** 1, 2, 3.

CHAPTER

9

Culture and Ethnicity

OBJECTIVES

- Describe social and cultural influences in health, illness, and caring patterns.
- Differentiate culturally congruent from culturally competent care.
- Describe steps toward developing cultural competence.
- Identify major components of cultural assessment.
- Use cultural assessment to identify significant values, beliefs, and practices critical to nursing care of individuals experiencing life transitions.
- Demonstrate nursing interventions that achieve culturally congruent care.
- Analyze outcomes of culturally congruent care.
- Apply research findings in culturally congruent care.

The demographic profile of the United States is changing dramatically as a result of immigration patterns and significant increases in culturally diverse populations already residing in the country. According to the U.S. Census Bureau, approximately 33% of the population currently belongs to a racial or ethnic minority group (Fig. 9-1). The U.S. Census also projects that this percentage will increase to 50% by the year 2050 (U.S. Census Bureau, 2010). Because it is important to care for people holistically, nurses need to integrate culturally congruent care within their nursing practice.

HEALTH DISPARITIES

Despite significant improvements in the overall health status of the U.S. population in the last few decades, disparities in health status among ethnic and racial minorities continues to be a serious local and national challenge. The Office of Minority Health and Health Disparities (2007a) reports that minority populations are more likely to have poor health and die at an earlier age because of a complex interaction among genetic differences, environmental and socioeconomic factors, and specific health behaviors such as the use of herbs to prevent or treat illnesses. Racial and ethnic minorities are more likely than white non-Hispanics to be poor or near poor. In addition, Hispanics, African Americans, and some Asian subgroups are less likely than white non-Hispanics to have a high school education. In general, racial and ethnic minorities often experience poorer access to health care and lower quality of preventive, primary, and specialty care. Eliminating such disparities in health status of people from diverse racial, ethnic, and cultural backgrounds has become one of the two most important priorities of *Healthy People 2020* (U.S. Department of Health and Human Services [USDHHS], 2010). Populations with health disparities

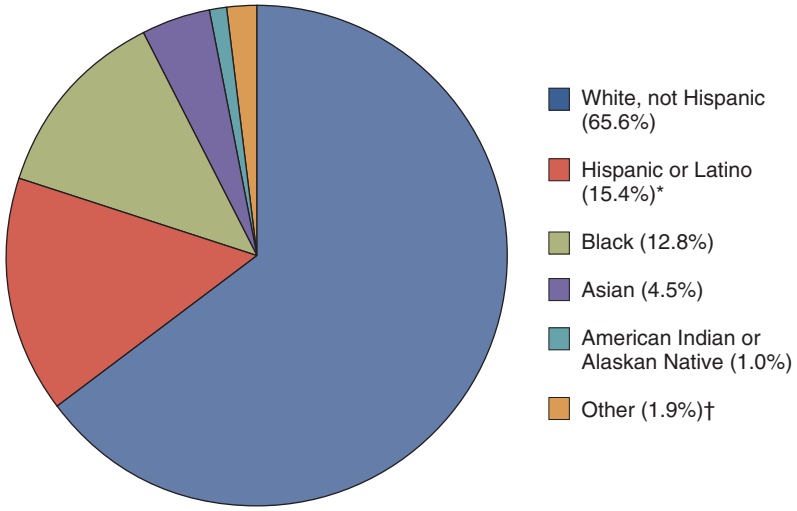

FIG. 9-1 Summary of U.S. Census Data. (Data from U.S. Census Bureau: *State and county quick facts*, 2010, http://quickfacts.census.gov/qfd/states/00000.html.) *Hispanics may be of any race, so they are also included in applicable race categories; therefore total percentages are greater than 100%. †Includes Native Hawaiian, Pacific Islander, and people reporting two or more races.

have a significantly increased incidence of diseases or increased morbidity and mortality when compared to the health status of the general population.

UNDERSTANDING CULTURAL CONCEPTS

The Office of Minority Health (OMH) (2005) describes **culture** as the thoughts, communications, actions, customs, beliefs, values, and institutions of racial, ethnic, religious, or social groups. Culture is a concept that applies to a group of people whose members share values and ways of thinking and acting that are different from those of people who are outside the group (Srivastava, 2007).

Culture has both visible (easily seen) and invisible (less observable) components. The invisible value-belief system of a particular culture is often the major driving force behind visible practices. For example, although an Apostolic Pentecostal woman can be identified by her long hair, no makeup, and the wearing of a skirt or dress, nurses cannot appreciate the meanings and beliefs associated with her appearance without further assessment. Apostolic Pentecostals believe that a woman's hair is her glory and should never be cut. Likewise, they believe that men and women need to dress differently and women need to be modest (wearing no makeup). These outward signs symbolize their belief in the scriptural definition of womanhood (United Pentecostal Church International, 2011). Cutting a woman's hair without consent of the individual or her family is sacrilegious and violates the ethnoreligious identity of the person. On the other hand, a woman of another faith who wears her hair long does not attach meaning to the length of her hair but wears it long because of a fashion preference.

In any society there is a dominant culture that exists along with other subcultures. Although subcultures have similarities with the dominant culture, they maintain their unique life patterns, values, and norms. In the United States the dominant culture is Anglo-American with origins from Western Europe. **Subcultures** such as the Appalachian and Amish cultures are examples of ethnic and religious groups with characteristics distinct from the dominant culture. Primary and secondary characteristics of culture are defined by the degree to which an individual identifies with his or her cultural group. Primary characteristics include nationality, race, gender, age, and religious beliefs. Secondary characteristics include socioeconomic and immigration status, residential patterns, personal beliefs, and political orientation.

Significant influences such as historical and social realities shape an individual's or group's worldview. Worldview is woven into the fabric of one's culture. It determines how people perceive others, how they interact and relate with reality, and how they process information (Walker et al., 2010). It is important that the nurse advocates for the patient based on the patient's worldview. Plan and provide nursing care in partnership with the patient to ensure that it is safe, effective, and culturally sensitive (McFarland and Eipperle, 2008).

Ethnicity refers to a shared identity related to social and cultural heritage such as values, language, geographical space, and racial characteristics. Members of an ethnic group feel a common sense of identity. Some declare their ethnic identity to be Irish, Vietnamese, or Brazilian. Ethnicity is different from race, which is limited to the common biological attributes shared by a group such as skin color (Dein, 2006). Examples of racial classifications include Asian and Caucasian.

Worldview refers to "the way people tend to look out upon the world or their universe to form a picture or value stance about life or the world around them" (Leininger, 2006). In any intercultural encounter there is an insider or native perspective **(emic worldview)** and an outsider perspective **(etic worldview).** For example, after giving birth, a Korean woman requests seaweed soup for her first meal. This request puzzles the nurse. Although the nurse has an emic view of professional postpartum care, as an outsider to the Korean culture he or she is not aware of the significance of the soup to the patient. Conversely, the Korean patient who has an etic view of American professional care assumes that seaweed soup is available in the hospital because it cleanses the blood and promotes healing and lactation (Edelstein, 2011). Unless the nurse seeks the patient's emic view, he or she is likely to suggest other varieties of soups available from the dietary department, disregarding the cultural meaning of the practice to the patient.

The processes of **enculturation** and **acculturation** facilitate cultural learning. Socialization into one's primary culture as a child is known as enculturation. In contrast, acculturation is a second-culture learning that occurs when the culture of a minority is gradually displaced by the culture of the dominant group in the process of **assimilation** (Cowan and Norman, 2006). When the process of assimilation occurs, members of an ethnocultural community are absorbed into another community and lose their unique characteristics such as language, customs, and ethnicity. Assimilation may be spontaneous, which is usually the case with immigrants, or forced, as is often the case of the assimilation of ethnic minority communities. **Biculturalism** (sometimes known as *multiculturalism)* occurs when an individual identifies equally with two or more cultures (Purnell and Paulanka, 2008).

It is easy for nurses to stereotype cultural groups after reading generalized information about various ethnic minority practices and beliefs (Dein, 2006). Avoid stereotypes or unwarranted generalizations about any particular group that prevents further assessment of the individual's unique characteristics. It is also important to determine how many of an individual's life patterns are consistent with his or her heritage (Armer and Radina, 2006).

Culturally Congruent Care

Leininger (2002) defines **transcultural nursing** as a comparative study of cultures to understand similarities (culture universal) and differences (culture-specific) across human groups. The goal of transcultural nursing is **culturally congruent care,** or care that fits the person's life patterns, values, and a set of meanings. Patterns and meanings are generated from people themselves rather than predetermined criteria. Culturally congruent care is sometimes different from the values and meanings of the professional health care system. Discovering patients' culture care values, meanings, beliefs, and practices as they relate to nursing and health care requires nurses to assume the role of learners and partner with patients and families in defining the characteristics of meaningful and beneficial care (Leininger and McFarland, 2002). Effective nursing care needs to integrate the cultural values and beliefs of individuals, families, and communities (Webber, 2008).

Cultural competence is the process of acquiring specific knowledge, skills, and attitudes to ensure delivery of culturally congruent care (Campinha-Bacote, 2002). This process has five interlocking components:

1. *Cultural awareness:* An in-depth self-examination of one's own background, recognizing biases, prejudices, and assumptions about other people
2. *Cultural knowledge:* Obtaining sufficient comparative knowledge of diverse groups, including their indigenous values, health beliefs, care practices, worldview, and bicultural ecology
3. *Cultural skills:* Being able to assess social, cultural, and biophysical factors influencing treatment and care of patients
4. *Cultural encounters:* Engaging in cross-cultural interactions that provide learning of other cultures and opportunities for effective intercultural communication development
5. *Cultural desire:* The motivation and commitment to caring that moves an individual to learn from others, accept the role as learner, be open and accepting of cultural differences, and build on cultural similarities

Specific knowledge, skills, and attitudes are required in the delivery of culturally congruent care to individuals and communities. Nurses who provide culturally competent care bridge cultural gaps to provide meaningful and supportive care for patients. For example, a nurse assigned to a female Egyptian patient decides to seek information about the Egyptian culture. On learning that Egyptians value female modesty and gender-congruent care, the nurse encourages female relatives to help the patient meet her needs for personal hygiene. The nurse's cultural encounter enhances understanding of the nonverbal cues of the patient's discomfort with lack of privacy.

Implementing culturally competent care requires support from health care agencies. For example, a nurse who is aware of Gypsy culture and skilled in dealing with Gypsy families is not able, as an individual, to provide for a Gypsy family's need to be present in groups near the bedside of a hospitalized family member. The nurse needs organizational support in adapting space resources to accommodate the volume of visitors who will remain with the patient for long periods.

Because patients who seek care could be from countless different world cultures, it is unlikely that a nurse could be competent in all cultures of the world. However, nurses can have general knowledge and skills to prepare them to provide culturally sensitive care, regardless of the patient's and family's culture (Purnell and Paulanka, 2008).

Cultural Conflicts

Culture provides the context for valuing, evaluating, and categorizing life experiences. Cultural groups transmit their values, morals, and norms from one generation to another, which predisposes members to **ethnocentrism,** a tendency to hold one's own way of life as superior to others. Ethnocentrism is the cause of biases and prejudices that associate negative permanent characteristics with people who are different from the valued group. When a person acts on these prejudices, discrimination occurs. For example, a nurse refuses to give prescribed pain medication to a young African male with sickle cell anemia because of the nurse's belief (stereotyped bias) that young male Africans are likely to be drug abusers. Nurses and other health care providers who have cultural ignorance or cultural blindness about differences generally resort to **cultural imposition** and use their own values and lifestyles as the absolute guide in dealing with patients and interpreting their behaviors. Thus a nurse who believes that people should bear pain quietly as a demonstration of strong moral character is annoyed when a patient insists on having pain medication and denies the patient's discomfort.

CULTURAL CONTEXT OF HEALTH AND CARING

Culture is the way in which groups of people make sense of their experiences relevant to life transitions such as birth, illness, and dying. For example, in most African groups a thin body is a sign of poor health. In some Hispanic cultures a plump baby is perceived as healthy. Traditionally in Arab culture pregnancy is not a medical condition but rather a normal life transition; thus a pregnant woman does not always go to a health care provider unless she has a problem (Purnell and Paulanka, 2008).

Table 9-1 provides a comparison of cultural contexts of health and illness in western and nonwestern cultures. Cultural beliefs highly influence what people believe to be the cause of illness. For example, many Hmong refugees (group of people who originated from the mountainous regions of Laos) believe that epilepsy is caused by the wandering of the soul. Treatment includes intervention by a shaman who performs a ritual to retrieve the patient's soul (Fadiman, 1997; Helsel et al., 2005). Their belief is distinct from the scientifically determined neurological abnormality

TABLE 9-1 Comparative Cultural Contexts of Health and Illness

	WESTERN CULTURES	NONWESTERN CULTURES
Cause of illness	Biomedical causes	Imbalance between humans and nature Supernatural Magico-religious
Method of diagnosis	Scientific, high-tech Specialty focused Organ-specific manifestations	Naturalistic, magico-religious Holistic Mixed Global, nonspecific symptomatology
Treatment	Specialty specific Pharmacological Surgery	Holistic Mixed (e.g., magico-religious, supernatural herbal, biomedical)
Practitioners/ healers	Uniform standards and qualifications for practice	May be learned through apprenticeship Criteria for practice not uniform Reputation established in community
Caring pattern	Self-care Self-determination	Caring provided by others Group reliance and interdependence

Data from Foster G: Disease etiologies in non-Western medical systems, *Am Anthropol* 78:773,1976; Kleinman A: *Patients and healers in the context of culture,* Berkeley, 1979, University of California Press; and Leininger MM, McFarland MR: *Transcultural nursing: concepts, theories, research and practice,* ed 3, New York, 2002, McGraw-Hill.

causing seizures. The biomedical orientation of western cultures emphasizing scientific investigation and reducing the human body to distinct parts is in conflict with the holistic conceptualization of health and illness in nonwestern cultures. Holism is evident in the belief in continuity between humans and nature and between human events and metaphysical and magico-religious phenomena. Therefore for the Hmong people epilepsy is connected to the magical and supernatural forces in nature. Establishing a diagnosis of epilepsy in western cultures requires scientifically proven techniques and confirmed criteria for the abnormality. Such medical criteria are meaningless to the Hmong, who believe in the global causation of the illness that goes beyond the mind and body of the person to forces in nature. A Hmong seeks a shaman, whereas a westerner seeks a neurologist. A shaman has an established reputation in the Hmong community, whose qualifications for healing are neither determined by published standardized criteria nor confined to specific bodily systems. A shaman uses rituals symbolizing the supernatural, spiritual, and naturalistic modalities of prayers, herbs, and incense burning.

The dominant value orientation in North American society is individualism and self-reliance in achieving and maintaining health. Caring approaches generally promote the patient's independence and ability for self-care. In collectivistic cultures that value group reliance and interdependence such as traditional Asians, Hispanics, and Africans, caring behaviors require actively providing physical and psychosocial support for family or community members. An adult patient is not expected to be solely responsible for his or her care and well-being; rather, family and kin are relied on to make decisions and provide care (Purnell and Paulanka, 2008). For example, a traditional older Chinese woman refuses to independently perform rehabilitation exercises after hip surgery until her daughter is present. The western health care provider interprets this as a lack of self-responsibility and motivation for her care. In contrast, the patient interprets the nurse's insistence on self-care as uncaring behavior.

Cultural Healing Modalities and Healers

Foster (1976) identified two distinct categories of healers cross-culturally. **Naturalistic practitioners** attribute illness to natural, impersonal, and biological forces that cause alteration in the equilibrium of the human body. Healing emphasizes use of naturalistic modalities, including herbs, chemicals, heat, cold, massage, and surgery. In contrast, **personalistic practitioners** believe that an external agent, which can be human (i.e., sorcerer) or nonhuman (e.g., ghosts, evil, or deity), causes health and illness. Personalistic beliefs emphasize the importance of humans' relationships with others, both living and deceased, and with their deities. For example, a voodoo priest uses modalities that combine supernatural, magical, and religious beliefs through the active facilitation of an external agent or personalistic practitioner. A Haitian woman who believes in voodoo attributes her illness to a curse placed by someone and seeks the services of a voodoo priest to remove the cause. Personalistic approaches also include naturalistic modalities such as massage, aromatherapy, and herbs (see Chapter 32). Some patients seek both types of practitioners and use a combination of modalities to achieve health and treat illness. Different cultural groups in the United States use a variety of cultural healers (Table 9-2).

Avoid making rash judgments about patients' practices when they use both healing systems at the same time. In addition, gain knowledge and understanding of remedies used by patients to prevent cultural imposition. For example, many Southeast Asian cultures practice folk remedies such as coining (rubbing a coin roughly on the skin), cupping (placing heated cups on the skin), pinching, and burning to relieve aches and pains and remove bad wind or noxious elements that cause illness. Other groups, including eastern Europeans, use cupping as treatment for respiratory ailments. These remedies leave peculiar visible markings on the skin in the form of ecchymosis, superficial burns, strap marks, or local tenderness. Cultural ignorance of these practices causes a practitioner to call authorities for suspicion of abuse.

Culture-Bound Syndrome

Human groups create their own interpretation and descriptions of biological and psychological malfunctions within their unique social and cultural context (Dein, 2006). **Culture-bound syndromes** are illnesses that are specific to one culture. They are used to explain personal and social reactions of the members of the culture. Culture-bound syndromes occur in any society. In the United States "going postal," which refers to extreme and uncontrollable anger in the workplace that may result in shooting people, is now considered a culture-bound syndrome (Flaskerud, 2009). *Hwa-byung* is a Korean culture-bound syndrome observed among middle-age, low-income women who are overwhelmed and frustrated by the burden of caregiving for their in-laws, husbands, and children. Symptoms are generally somatic manifestations consisting of insomnia, fatigue, anorexia, indigestion, feelings of an epigastric mass, palpitations, heat, panic, feelings of impending doom, and dyspnea. Women unconsciously avoid expressions of symptoms that counter the cultural ideal of females as the caretaker of older adults, husbands, and children. Symptoms reflect the cultural definition of illness as imbalance between heat (yang) and cold (yin) (Purnell and Paulanka, 2008).

TABLE 9-2 **Cultural Healers**

CULTURAL GROUP	HEALER	NATURE OF PRACTICE
Chinese and Southeast Asians	Herbalist	Combination of plant, animal, and mineral products in restoring balance based on yin/yang concepts
	Acupuncturist	Yin treatment using needles to restore balance and flow of *qi;* yang treatment using moxibustion or heat with acupuncture possibly indicated to restore yin/yang balance
	Fortune teller	Consultation to foretell outcomes of plans and seek spiritual advice to enhance good fortune and deal with misfortune
	Shaman	Combination of prayers, chanting, and herbs to treat illnesses caused by supernatural, psychological, and physical factors
Asian Indians	Ayurvedic practitioner	Combination of dietary, herbal, and other naturalistic therapies to prevent and treat illness
Native American	Shaman	Combination of prayers, chanting, and herbs to treat illnesses caused by supernatural, psychological, and physical factors
African American	Granny midwife	Consultation in diagnosing and treating common illnesses and care of women in childbirth and children
	Spiritualist	Spiritual advising, counseling, and praying to treat illness or cope with personal and psychosocial problems
	Voodoo practitioners *Hougan* (male) *Mambo* (female)	Combination of herbs, drumming, and symbolic offerings to cure illness, remove curses, and protect a person
Hispanic	*Curandero/a*	Combination of prayers, herbs, and other rituals to treat traditional illnesses, especially in children
	Parteras Lay midwives	Assistance for women in childbirth and newborn care
	Yerbero Herbalist	Consultation for herbal treatment of traditional illnesses
	Sabador Bonesetters	Massage and manipulation of bones and joints used to treat a variety of ailments, including musculoskeletal conditions
	Espiritista Spiritualist	Foretelling of future and interpretation of dreams; combination of prayers, herbs, potions, amulets, and prayers for curing illnesses, including witchcraft
	Santero/a	Combination of prayers, symbolic offerings, herbs, potions, and amulets against witchcraft and curses

Data from Hautman MA: Folk health and illness beliefs, *Nurse Pract* 4(4):23, 1976; Loustaunau MO, Sobo EJ: *The cultural context of health, illness and medicine,* Westport, Conn, 1997; Spector RE: *Cultural diversity in health and illness,* ed 6, Englewood Cliffs, NJ, 2004, Prentice Hall.

CULTURE AND LIFE TRANSITIONS

Cultures generally mark transitions to different phases of life by rituals that symbolize cultural values and meanings attached to these life passages. Van Gennep (1960) originated the concept of **rites of passage** as significant social markers of changes in a person's life. Examining the practices surrounding these life events provides a view of the cultural meanings and expressions relevant to these transitions. For example, sending flowers and get-well greetings to a sick person is a ritual showing love and care for the patient in the dominant American culture in which privacy is valued. In collectivistic groups such as the Hispanic culture, physical presence of loved ones with the patient during illness demonstrates caring.

Pregnancy

All cultures value reproduction because it promotes continuity of the family and community. Pregnancy is generally associated with caring practices that symbolize the significance of this life transition in women. Infertility in a woman is considered grounds for divorce and rejection among Arabs. Pregnancy that occurs outside of accepted societal norms is generally taboo. Among traditional Muslims pregnancy out of wedlock sometimes results in the family's imposing severe sanctions against the female member (Purnell and Paulanka, 2008).

Some cultures that subscribe to the hot and cold theory of illness such as many Asian and Hispanic cultures view pregnancy as a hot state; thus they encourage cold foods such as milk and milk products, yogurt, sour foods, and vegetables (Edelstein, 2011). They believe that hot foods such as chilies, ginger, and animal products cause miscarriage and fetal abnormality. Modesty is a strong value among Afghan (Omeri et al., 2006) and Arab women (Kulwicki et al., 2005). These women sometimes avoid or refuse to be examined by male health care providers because of embarrassment. Religious beliefs sometimes interfere with prenatal testing, as in the case of a Filipino couple refusing amniocentesis because they believe that the outcome of pregnancy is God's will and not subject to testing.

Childbirth

How individuals express pain and the expectation about how to treat suffering varies cross-culturally and in different religions. For example, Vietnamese women are often stoic regarding the pain of childbirth because their culture views childbirth pain as a normal part of life (McLachlan and Waldenstrom, 2005). Traditional Puerto Rican and Mexican women often vocalize their pain during labor and avoid breathing through their mouths because this causes the uterus to rise. Traditional Arab Americans are sometimes physically or verbally more expressive when experiencing

pain. Fear of drug addiction and the belief that pain is a form of spiritual atonement for one's past deeds motivate most Filipino mothers to tolerate pain without much complaining or asking for medication. Religious beliefs sometimes prohibit the presence of males, including husbands, from the delivery room. This often occurs among devout Muslims, Hindus, and Orthodox Jews (Purnell and Paulanka, 2008).

Health care providers other than physicians attend childbirth in some groups such as *parteras* among Mexicans, herb doctors among Appalachian and southern African Americans, and *hilots* among Filipinos (Nelms and Gorski, 2006). Known in their communities, these practitioners are affordable and accessible in remote areas. They use a combination of naturalistic, religious, and supernatural modalities combining herbs, massage, and prayers.

Newborn

The definition of newborn and how age is counted in children varies in some cultures. Among traditional Vietnamese and Koreans a newborn is 1 year old at birth. Once acculturated to the U.S. culture, they assume a bicultural view, deducting 1 year from the age of the child when speaking to an outsider. Naming ceremonies vary by culture. In the Yoruba tribes in Nigeria, the baby is named at the official naming ceremony that occurs 8 days after birth and coincides with circumcision. Many cultures around the world greatly celebrate the birth of a son, including Chinese, Asian Indians, Islamic groups, and Igbos in West Africa.

The name of the child often reflects cultural values of the group. It is typical for a Hispanic baby to have several first names followed by the surnames of the father and mother (e.g., Maria Kristina Lourdes Lopez Vega). The bilineal tracing of descent from both the mother's and father's side in Hispanic groups differs from the patrilineal system, in which the last name of the father precedes the child's first name. In the Chinese culture individuals trace descent only from the paternal side. Thus the name Chen Lu means that Lu is the daughter of Mr. Chen.

Newborns and young children are often considered vulnerable, and societies use a variety of ways to prevent harm to the child. Among the mostly Catholic Filipinos, parents keep the newborn inside the home until after the baptism to ensure the baby's health and protection. Traditional Arabs and Iranians believe that babies are vulnerable to cold and wind; thus they wrap them in blankets.

Postpartum Period

In many nonwestern cultures the postpartum period is associated with vulnerability of the mother to cold. To restore balance mothers do not shower and take sponge baths. Some groups have special dietary practices to restore balance. Cultural groups have preferences in terms of what types of foods are appropriate to restore balance in women after birth. Some Chinese mothers prefer soups, rice, rice wine, and eggs; whereas Guatemalan women avoid beans, eggs, and milk during the postpartum period (Edelstein, 2011). The length of the postpartum period is generally much longer (30 to 40 days) in nonwestern cultures to provide support for the mother and her baby (Chin et al., 2010).

Filipino, Mexicans, and Pacific Islanders use an abdominal binder to prevent air from entering the woman's uterus and to promote healing (Purnell and Paulanka, 2008). Among Orthodox Jewish, Islamic, and Hindu cultures, bleeding is associated with pollution. A woman goes into a ritual bath after bleeding stops before she is able to resume relations with her husband (Lewis, 2003). In some African cultures such as in Ghana and Sierra Leone some women do not resume sexual relations with their husbands until the baby is weaned.

Grief and Loss

Dying and death bring traditions that are meaningful to groups of people for most of their lives (see Chapter 36). When traditional medical measures fail, cultural beliefs and practices that are religious and spiritual become the focus. Societies assign different meanings to death of a child, a young person, and an older adult (Box 9-1). In western cultures with strong future time orientation and in which a child is expected to survive his or her parents, death of a young person is devastating. However, in other cultures, in which infant mortality is very high, the emotional distress over a child's death is tempered by the reality of the commonly observed risks of growing up. Thus the untimely death of an adult is sometimes mourned more deeply.

People such as devout Hindus and Buddhists who believe in the concept of reincarnation view death as a step toward rebirth. Care of the dying focuses on supporting the patient's preparation for a good death. The family prays and reads religious scriptures to the patient to improve his or her chances in the next cycle. Buddhists generally believe that life is suffering and suffering ends when a person moves beyond the earthly desires and atones for past misdeeds. When a Hindu dies, the body is bathed, massaged in oil, dressed in clean clothes, and cremated before the next sunrise to ensure that the soul passes quickly from this life to the next (Lobar et al., 2006).

BOX 9-1 EVIDENCE-BASED PRACTICE

Cultural Beliefs and Rituals Surrounding Death

PICO Question: What intervention is best when planning culturally competent care for a dying patient?

Evidence Summary

Although culture and religion are important to people who are dying and their families, practices surrounding the death of a loved one vary among cultures and religions. Many cultures and religions use their beliefs to allow them to pray, talk, and remember their loved one. Rituals often accompany ceremonies and are used to delay death, ward off evil, ensure that the dying person is remembered, and help the family cope with the death. Respect for dying family members and protection of their souls are important. Many practices that surround death are influenced by religion and culture. Those who are Hispanic and Latino often have rituals that are heavily influenced by Catholicism. African Americans and Caribbeans identify the importance of faith, hope, and prayer. Similarities exist between Hindu and Buddhist beliefs about funeral arrangements, afterlife, family customs and Karma (Lobar et al., 2006). Although preparing for death is important for many Chinese individuals, many believe that talking about death brings evil spirits, bad luck, and a premature death (Chan and Yau, 2009-2010).

Application to Nursing Practice

- Be aware of religious and cultural preferences when helping patients and families prepare for death.
- Ask families about the rituals and ceremonies they use to help them cope with the death of a loved one.
- Allow patients and families the ability to participate in planning which rituals will be performed at the patient's bedside.
- Be sensitive to cultural perceptions regarding organ donation, viewing the body, and preparing for burial.

Culture strongly influences pain expression and need for pain medication. A typical American believes that individual freedom and autonomy are synonymous with freedom from pain and suffering, but other groups accept suffering. Do not assume that all people value pain relief equally. Patients suffer **cultural pain** when health care providers disregard values or cultural beliefs (Maputle and Jali, 2006). Inability of Orthodox Jews to pray in groups at the bedside with the dying patient because of limitations in the number of visitors allowed causes cultural pain in the patient and family. Working with the family and their religious/spiritual leader facilitates culturally congruent care (Purnell and Paulanka, 2008).

Organizational policies need to be sensitive to patients' cultural life patterns, especially during times of grief and loss. The dominant values in American society of individual autonomy and self-determination are often in direct conflict with diverse groups. Advance directives, informed consent, and consent for hospice are examples of mandates that sometimes violate patients' values. Informed consent and advance directives protect the right of the individual to know and make decisions ensuring continuity of these rights, even when the individual is incapacitated. However, in some cultures the designated family members assume decision making during illness and are trusted to make the right decision for the individual. Some groups such as African Americans, Asian Americans, and Hispanics expect their families to make decisions for them; and family members prefer to protect the individual from unnecessary suffering by knowing the reality of imminent death. These cultures value group interdependence and view individual autonomy as an unnecessary burden for a loved one who is ill (Purnell and Paulanka, 2008).

The meaning and expressions of grief vary from culture to culture. The color black is not always a symbol of grief. Hindu mourners wear white. Among the usually reserved East Asians, the extent to which mourners publicly express grief reflects the social position and status of the deceased. Muslims do not encourage wailing, but crying is permitted. Muslim women are discouraged from visiting cemeteries (Lobar et al., 2006). Korean families sometimes hire people to lead the open grieving. Loud crying and screaming are common.

Religious beliefs also affect attitudes toward cremation, organ donation, and the treatment of body parts. Devout Muslims refuse an autopsy or organ donation for fear of desecrating the dead and because of their belief that one has to be whole to appear in front of the creator. Many prefer burial over cremation (Lobar et al., 2006).

CULTURAL ASSESSMENT

Cultural assessment is a systematic and comprehensive examination of the cultural care values, beliefs, and practices of individuals, families, and communities. The goal of cultural assessment is to gather significant information from the patient that enables the nurse to implement culturally congruent and safe patient care (Box 9-2). For example, it allows the nurse to gather information about which foods are culturally acceptable and whether the person practices alternative medicine and to assess pain (Maier-Lorentz, 2008). There are several models for cultural assessment, each involving different levels of skill and knowledge. Leininger's Sunrise Model (2002) in Fig. 9-2 demonstrates the inclusiveness of culture in everyday life and helps to explain why cultural assessment needs to be comprehensive. The model assumes that cultural care values, beliefs, and practices are fixed in the cultural and social structural dimensions of society, which include environmental context, language, and ethnohistory. **Ethnohistory** refers to significant historical experiences of a particular group. For example, many older Americans tend to be frugal and save everything because of their experience with the Great Depression. These patient's stories reveal the broad picture of who they are and the cultural lifestyle they embrace. Leininger's model differentiates folk care, which is caring as defined by the people, from health care, which is provided by health care professionals and based on the scientific, biomedical caring system.

Census Data

A nurse begins cultural assessment by knowing population demographic changes in the community setting of practice. Having background knowledge of a culture assists the nurse in conducting a focused assessment. Gather demographics from the local and regional census data and from the demographic breakdown of patients who come to the health care setting. Population demographics include the distribution of ethnic groups, education, occupations, and incidence of the most common illnesses. Comprehensive cultural assessment requires skill and time; preparation and anticipation of need are important.

Asking Questions

One problem in cultural assessment is failing to assess the insider or emic perspective of patients and interpret information during the assessment. Use open-ended, focused, and contrast questions. The aim is to encourage patients to describe values, beliefs, and practices that are significant to their care that health care providers will take for granted unless otherwise uncovered. Culturally oriented questions are by nature broad and require many descriptions (Box 9-3).

Establishing Relationships

In contrast to other types of interviews, cultural assessment is intrusive and time consuming and requires a trusting relationship between participants. Miscommunication commonly occurs in intercultural interactions. This is because of language and

BOX 9-2 CULTURAL ASPECTS OF CARE

Understanding Cultural Safety

It is important for nurses and other health care providers to provide culturally safe care for patients and their families. Health care disparity in minority populations is an international problem, even in multicultural societies. A large body of research has identified that the health of an ethnic group is jeopardized when their cultural identity is demeaned or disempowered. Research has identified associations between perceived racial discrimination and hypertension, low birth weight, and mental disorders (Baker, 2007).

Culturally safe care can be defined as providing an environment in which people are treated with respect for their identity and dignity for who they are and in which a shared experience of listening and learning is created (Johnstone and Kanitsaki, 2007).

Implications for Practice

- Set culture care as a priority.
- Approach patients and families in a culturally sensitive manner.
- Engage in negotiated partnerships with patients and families.
- Enable the families and social networks of patients to serve as backup support.

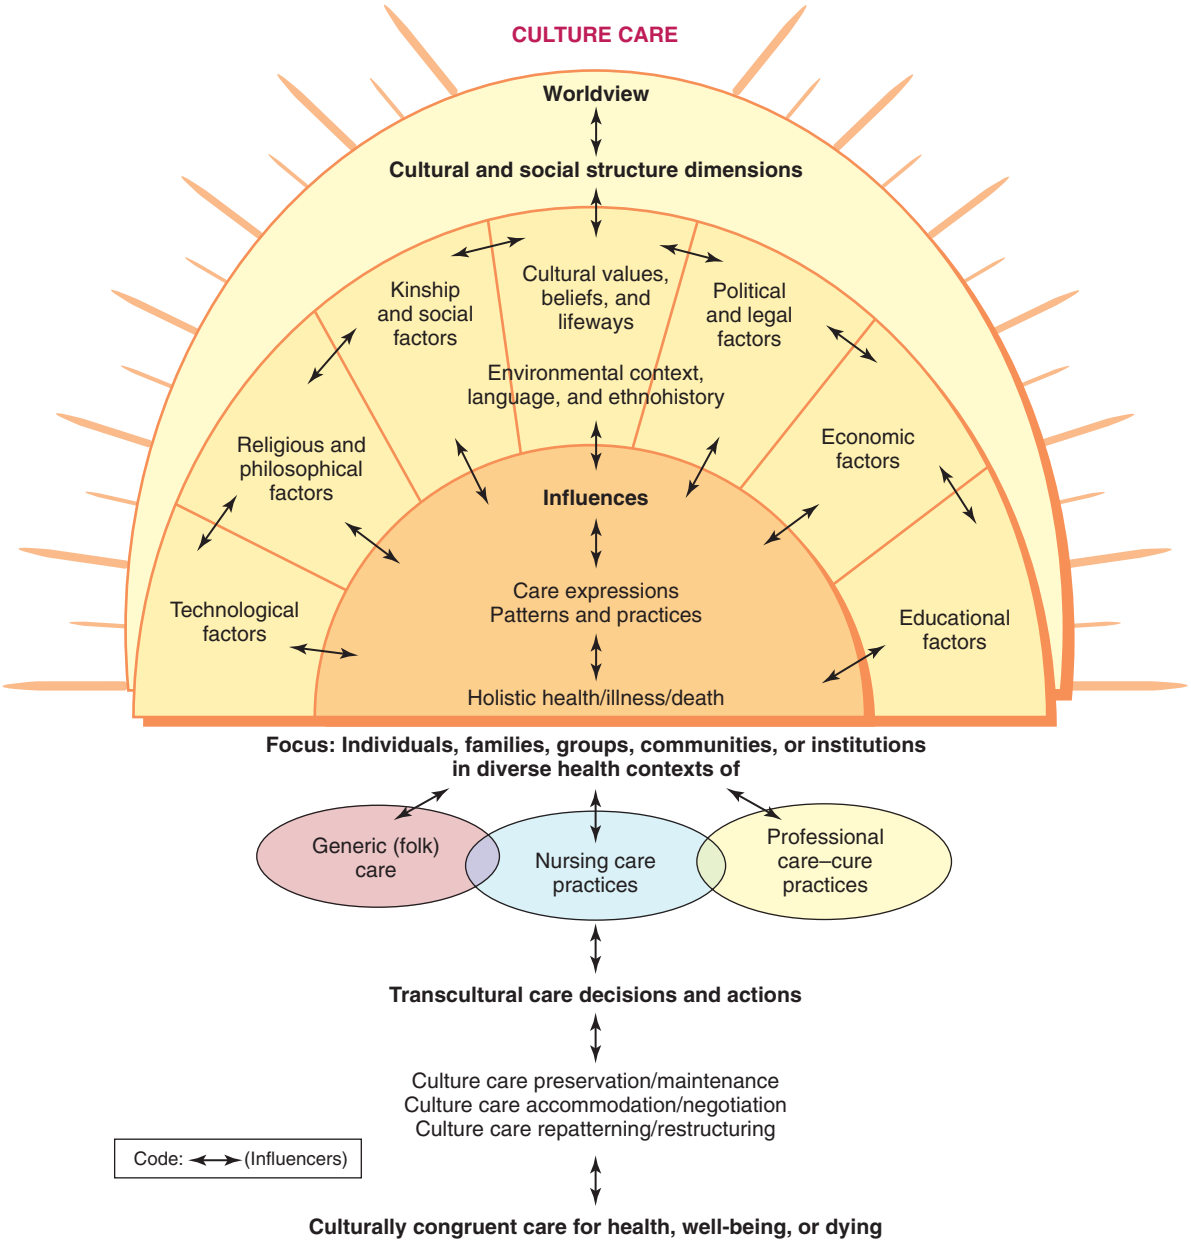

FIG. 9-2 Leininger's culture care theory and sunrise model. (Reprinted with permission from Leininger MM, McFarland MR: *Transcultural nursing: concepts, theories, research and practice,* ed 3, New York, 2002, McGraw-Hill.)

communication differences between and among participants and differences in interpreting each other's behaviors. Nurses use transcultural communication skills to interpret the patient's behavior within his or her own context of meanings and to behave in a culturally congruent way. Transcultural communication manages the impression the nurse makes on the patient to achieve desired outcomes of communication (Purnell and Paulanka, 2008). Transcultural communication requires linguistic skills, culturally congruent interpretation of behaviors of others, listening, and observation skills. In a cultural assessment the goal is to generate knowledge about the patient's values, beliefs, and practices about nursing and health care. If the nurse's behavior is offensive to the patient, he or she will not likely participate in the interaction.

To provide safe and effective patient care, you need to develop and use transcultural communication skills and be able to work with interpreters (Box 9-4). Interpreters are more effective when they have knowledge of the culture of the patient. They provide accurate accounts of what is said and, just as important, offer information regarding the cultural beliefs of the patient and family. Interpreters tactfully formulate culturally sensitive questions that provide the health care provider with needed information (Dysart-Gale, 2007). On admission nurses assess and document language(s)

BOX 9-3 NURSING ASSESSMENT QUESTIONS

Open-Ended
- What do you think caused your illness?
- How do you want us to help you with your problem?

Focused
- Did you have this problem before?
- Is there someone you want us to talk to about your care?

Contrast
- How different is this problem from the one you had previously?
- What is the difference between what we are doing and what you think we should be doing for you?

Ethnohistory
- How long have you/your parents resided in this country?
- What is your ethnic background or ancestry?
- How strongly does your culture influence you?
- Tell me why you left your homeland.

Social Organization
- Who lives with you?
- Whom do you consider members of your family?
- Where do other members of your family live?
- Who makes the decisions for you or your family?
- To whom do you go outside of your family for support?
- What expectations do you have of your family members who are males, females, old, or young?

Socioeconomic Status
- What do you do for a living?
- How different is your life here from back home?

Bicultural Ecology and Health Risks
- What caused your problem?
- How does this problem affect or how has it affected your life and your family?
- How do you treat this problem at home?
- What other problems do you have?

Language and Communication
- What language(s) do you speak at home?
- What language(s) do you use to read and write?
- How should we address you or what should we call you?
- What kinds of communication upset or offend you?

Caring Beliefs and Practices
- What do you do to keep yourself well?
- What do you do to show someone you care?
- How do you take care of sick family members?
- Which caregivers do you seek when you are sick?
- How different is what we do from what your family does for you when you are sick?

BOX 9-4 RULES OF IMPRESSION MANAGEMENT

1. Greet patients and their visitors in their own language if possible.
2. Introduce yourself. Tell patients what to call you.
3. Welcome visitors and request them to introduce themselves and explain how they are related to the patient.
4. Thank the visitors for coming.
5. Ask to talk with the patient in private and offer to accompany visitors to the waiting room.
6. Inform visitors that you will call them when you finish with the patient.
7. Tell the patient your purpose.
8. Clarify if the patient wants someone else such as a family member to be present.
9. Avoid asking the patient questions in front of the family or spouse that will put him or her at risk with this group.
10. If the patient needs an interpreter:
    a. Introduce yourself to the interpreter.
    b. Determine the qualifications of the interpreter.
        (1) Make sure that the interpreter can speak the dialect of the patient.
        (2) Ensure gender, age, and ethnic compatibility of the interpreter with the patient's preference and topic of discussion.
        (3) Watch for differences in educational and socioeconomic status between the patient and interpreter.
        (4) Orient the interpreter to your purpose and expectation (e.g., assessment of the patient's level of pain, intent to explain procedure to the patient).
    c. Clarify your questions about the interpreter's training, compatibility with the patient, and the interpreter's understanding of your expectations beforehand.
    d. Introduce the interpreter to the patient.
    e. Pace your speech slowly and allow time for back translation.
    f. Direct your questions to the patient.
    g. Request the interpreter to ask the patient for feedback and clarification at regular intervals.
    h. Observe the patient's nonverbal and verbal behaviors.
    i. Thank both the patient and interpreter.
11. Ask the patient with whom you will need to consult for major decisions and how to contact this person.
12. Observe nonverbal behavior and match the degree of distance exhibited by the patient.

patients speak and write and determine if patients need an interpreter.

Federal mandates for culturally sensitive health care delivery require accommodation for language differences. According to the Office of Minority Health and Health Disparities (2007b), national standards regarding language services include:

- Providing language assistance services free of charge to all patients with limited English at all points of contact.
- Notifying patients, both verbally and in writing, of their rights to receive language-assistance services.
- Using interpreters for patients with limited English proficiency (unless the patient requests that family or friends interpret for them).

The Joint Commission (2010) requires that informed consent materials be in the patient's language whenever possible and that an interpreter be available whenever discussing informed consent with a patient. If informed consent documents are not available in the patient's language, The Joint Commission also recommends that the health care provider obtain verbal consent from the patient via the interpreter and that this is thoroughly documented in the patient's medical record.

Nurses need to know their agencies' policies and procedures regarding these mandates. Working with interpreters and patients with little or no fluency in English requires skill development. In hospital settings use an interpreter to communicate information

BOX 9-5 LANGUAGE ACCESS SERVICES

- All health care organizations are required to offer free language assistance, including bilingual staff or interpreter services to each patient with limited English proficiency. These services must be offered in a timely manner at all hours of operation at all points of contact.
- Patients must be informed, in their preferred language, of their right to receive language assistance services both verbally and in written form.
- The competence of bilingual staff and interpreters providing language assistance must be ensured by the health care organization.
- Unless requested by the patient, family and friends should not be used to provide interpretation services.
- Interpreters are more effective when they have knowledge of the culture of the patient.
- Patient-related information and signage must be posted in the service area of the health care organization in the languages of the groups who are commonly served.

Data from Office of Minority Health US Department of Health and Human Services: A patient-centered guide to implementing language across services in healthcare organizations, 2005, http://minorityhealth.hhs.gov/Assets/pdf/Checked/HC-LSIG.pdf

about the patient's medical condition. It is not suitable for family members to translate health care information, but they can assist with ongoing interaction during the patient's care (Box 9-5).

Consider what needs to be discussed with a patient when selecting an interpreter. In some Hispanic and Asian groups a woman's breasts and genitals generally are not discussed with members of the opposite sex, including male members of one's family. In some societies, adults occupy a higher status than the young. Children in immigrant groups learn the English language faster than their parents because of their schooling experience in the new culture when they immigrate at a young age. However, assuming that children are ideal interpreters for their parents is an insult to the authority of the parent who has to take directions from a child.

Compatibility between the ethnic backgrounds of the interpreter and patient is another consideration to facilitate trust. An Israeli interpreter may cause much anxiety and distrust in a Palestinian immigrant who experienced violence from these groups in the home country. Socioeconomic and educational differences between interpreters and patients sometimes become barriers to effective interpretation. Interpreters need training not only in interpretation but also in knowing their role, which is to repeat back what the patient said without judging the content.

Selected Components of Cultural Assessment

Nurses learn various skills needed to gather an accurate and comprehensive cultural assessment. The following components of cultural assessment provide insight into the type of information that is useful in planning and delivering nursing care.

Family Structure. Integrate patients' and families' concepts of meaningful and supportive care into nursing care (see Chapter 7). Caring expressions integrate the central values of a culture. In collectivistic cultures caring means active involvement of the group, emphasizing mutual and reciprocal obligations of members to care for one another. When caring for patients from collective cultures, work with patients' families as a group, looking for ways the family can participate in basic care activities. Understand the family's social hierarchy and assume a collaborative role with patients and their families.

Culture differentiates caring roles of males and females. In many cultures caretaking tasks are the primary responsibility of women; men provide financial support and make major decisions. Age and position in the social hierarchy also influence caring roles and responsibilities. In some cultures older women are the first group consulted during illness of family members and in the care of women and children.

Ethnic Heritage and Ethnohistory. Knowledge of a patient's country of origin and its history and ecological contexts are significant to health care. For example, Haitian immigrants have linguistic and communication patterns distinct from those of Jamaicans, even though they both come from the Caribbean and have a common history of slavery. Differences come from their colonial history and intermingling with the local indigenous people. As a result of cultural differences between India and Jamaica, Hindu immigrants from Jamaica have different cultural characteristics from those originating from India. Hindu immigrants from Jamaica often have nutritional, communication, and health patterns more similar to African Jamaicans than South Asian Hindus. In caring for an Indian Hindu who grew up in Jamaica, expect the patient to interact more like a Jamaican, even though the person looks like he or she is from south India.

Immigration from one country to another occurs for various reasons. Refugees are relocated without any choice in their initial residence, in contrast to immigrants, who have options as to where they go. Refugees experience greater dislocation and deprivation than immigrants who enter a new country with specialized skills and education and have the option to return to their homeland. Age of immigration often determines the level of acculturation, with younger immigrants acculturating faster than older immigrants. Although acculturation and length of residence in the new culture are related, other factors such as education, racial characteristics, and familiarity with the language affect the extent of a person's acculturation. Ask patients about the condition or situation that brought them to the United States and how they think they are adjusting. Socioeconomic status in the new society is often not comparable to one's previous status in the country of origin. New immigrants often begin with small resources but keep the values and desires of their previous economic status. Assess for problems (such as financial hardships, becoming comfortable with the language, or understanding the routines used to set medical appointments) to make reasonable and appropriate adjustments to care. Refer patients to community resources when possible.

Bicultural Effects on Health. Identify patients' health risks related to sociocultural and biological history on admission. Some distinct health risks are the result of the ecological context of the culture. For example, immigrants originating from the region near the Nile River are generally at risk for parasitic infestations that are prevalent in that area. Immigrants from the Third World with poor sanitary conditions and water supply are at risk for infections such as hepatitis. Certain genetic disorders are also linked with specific ethnic groups such as Tay-Sachs among Ashkenazi Jews and malignant hypertension among African Americans. Lactose intolerance is frequently observed among Asians, Africans, and Hispanics (Office of Minority Health, 2005).

Social Organization. Cultural groups consist of units of organization defined by kinship, status, and appropriate roles for their members. In the dominant American society the most common unit of social organization is the nuclear family, in which married children and adults establish separate residences from their parents. Although different configurations of a family exist, the most common is the nuclear household made up of parents

and their young children (see Chapter 10). In collectivistic cultures families are made up of distant blood relatives across three generations and **fictive** or nonblood kin. Kinship extends to both the father's and mother's side of the family **(bilineal)** or is limited to the side of either father **(patrilineal)** or mother **(matrilineal)**. Patrilineally extended families exist among Chinese and Hindus, in which a woman moves into her husband's clan after marriage and minimizes ties with her own parents and siblings. Consider all options when determining a patient's next of kin. This is especially relevant to new immigrants and refugees, who often have not relocated with all members of their family. Collectivistic groups often regard members of their ethnic group as closest kin and want to consult them for health care decisions and permit them to speak on their behalf.

A patient's status within the social hierarchy is generally linked with qualities such as age, gender, and achieved status such as education and position. The dominant culture in the United States emphasizes achievement as the determinant of status, whereas most collectivistic cultures give higher priority to age and gender. The eldest male is next to his father in terms of authority in many Asian and African cultures. A Korean mother is subject to the authority of her oldest son in the absence of her husband. Sometimes an adult Hispanic woman will not sign informed consent for surgery or other medical procedures without consulting her husband, oldest son, or brothers. Older adults occupy higher status in some societies, resulting in grandparents forcing their decisions over their married children regarding the care of the grandchildren. Determine who has authority for making decisions within the family and how to communicate with the proper individuals.

Culture defines the expected roles of its members. Certain behaviors are acceptable in children but not in adults. Gender also differentiates role expectations. For example, among devout Muslims females perform the task of caregiving, whereas males are the financial providers and major decision makers. Thus nurses need to anticipate that some Muslim women insist on staying at the bedside of their children, in-laws, or husbands. However, do not assume that, just because the woman is the primary caregiver, she will make decisions independently. Determine the family social hierarchy as soon as possible to prevent offending patients and their families. Working with established family hierarchy prevents delays and achieves better patient outcomes.

Religious and Spiritual Beliefs. Religious and spiritual beliefs frequently influence the patient's worldview about health and illness, pain and suffering, and life and death. Determine the patient's religious and spiritual beliefs and their effect on health care during admission. Also understand the emic perspective of your patients. For example, to a Hmong animist spirits are dead ancestors or forces external to the person. To some Americans spirituality means an inner, personal relationship with God. Although it is sometimes difficult to find the appropriate time to discuss religion and spirituality in a hospital setting, nurses need to assess what is important to the spiritual well-being of patients and learn as much as possible about their spiritual and religious practices (see Chapter 35).

Devout Muslims pray five times daily and undergo an obligatory ritual cleansing of some parts of their body before praying. Anticipate the ritual cleansing needs of the patient and provide privacy for praying. For example, reschedule diagnostic procedures to allow Buddhist patients to participate in the festivities of their New Year. Anticipating the needs of Orthodox Jewish patients during the Sabbath, when they refrain from using electrical appliances, requires creative accommodations by the staff such as placing articles of care near the patient so he or she does not need to use the call light or telephone to get assistance. Determine how to contact the patient's next of kin who are unreachable by telephone during the Sabbath in case emergencies arise.

BOX 9-6 PATIENT TEACHING

Cultural Considerations in Healthy Food Choices

Objective

- Patient will verbalize healthy foods that are culturally appropriate.

Teaching Strategies

- Refer patient to speak with a dietitian who is familiar with cultural food choices.
- Develop a diet plan that includes patient's cultural diet preferences.
- Provide culturally sensitive teaching brochures that describe healthy food choices.
- Include people in family who help shop for and prepare food in the home.

Evaluation

- Ask patient to keep a food diary for 1 week and evaluate food choices.
- Ask patient to describe how cultural food choices will fit within his or her prescribed diet.

Religious beliefs are evident in patients' dietary practices (Box 9-6). Devout Hindus avoid beef, and many are vegetarians. Many Buddhists are vegetarians as well. *Halal* foods, which include meat, fish, fresh fruit, vegetables, eggs, milk, and cheese, are permissible for Muslims. Halal meat comes from animals slaughtered during a prayer ritual. Prohibited, or *Haram,* foods include non-Halal meat, animals with fangs, pork products, gelatin products, and alcohol (Edelstein, 2011). Muslims fast during the daylight hours for the 28 days of *Ramadan,* which occurs during the ninth lunar month. Although children and sick and frail individuals are exempt from fasting, do not assume that these individuals eat regular meals during Ramadan. Rescheduling treatments and medications is often necessary to prevent complications such as hypoglycemia.

Jewish patients who follow a kosher diet avoid meat from carnivores, pork products, and fish without scales or fins. Kosher meat comes from permissible animals that are slaughtered with the least amount of suffering. Kosher foods must not be contaminated by nonkosher foods. Thus meat is served separately from dairy, and dishes used for serving and eating these products are also separated (Edelstein, 2011).

The nursing staff needs to have background information available about major holy days and practices for commonly encountered religions. Such information prevents scheduling nonemergency treatments and procedures on major holy days such as the Jewish holidays Yom Kippur, Rosh Hashanah, or Passover. Religious mandates followed by Jehovah's Witnesses require followers to have bloodless surgery and avoid blood transfusions. Identify and contact patients' religious and spiritual leaders before problems occur and work with these leaders to mediate in times of crisis.

Life transitions are often manifested in religious and spiritual beliefs. Male circumcision occurs among Jewish and Islamic groups. Female circumcision is common among some African and Muslim groups. Anointing of the sick is a Roman Catholic sacrament. Hospitalized Catholic patients often receive daily communion. The family of a critically ill Jewish patient turns his or her head eastward or to the right side. The family of a dying Hindu remains at the bedside to place a drop of the holy water from the River Ganges on the patient's lips immediately after death to help his or her soul

to the next life. A dying Hispanic patient is not left alone so a close kin is able to hear the patient's wishes, allowing the soul to leave in peace.

Foods with Cultural Significance. Many foods have cultural significance and are adopted for traditional celebrations, medicinal purposes, and general nutritional health. For instance, in Italy it is a tradition to eat eel on Christmas Eve. It symbolizes a new beginning because eels replace their skin as they shed it. In Sweden the smorgasbord is an important part of special events such as holidays and weddings (Edelstein, 2011). Cake is a part of birthday and wedding celebrations in the United States. Russians consider honey to have healing qualities and use it to treat colds and coughs. Many Japanese follow traditional beliefs that food should be consumed as close to its natural state as possible, for instance raw fish *(sashimi)* used in making sushi.

Communication Patterns. Cultural groups have distinct linguistic and communication patterns. These patterns reflect core cultural values of a society. In the dominant American culture that supports individualism, people value assertive communication because it manifests the ideal of individual autonomy and self-determination. In collectivistic cultures the context of relationships among participants shapes communication. Promoting group harmony is a priority; thus participants interact based on their expected positions and relationships within the social hierarchy. Individuals are more likely to remain respectful and show deference to older adults or family leaders, even though they disagree on an issue. Differences in status and position, age, gender, and outsider versus insider determine the content and process of communication (Box 9-7). Among Asian cultures face-saving communication promotes harmony by indirect, ambiguous communication and conflict avoidance. In this culture spoken messages often have little to do with their meanings. Saying "no" to a superior or older person is not permissible. An affirmative response only means that "I heard you"; it is not full agreement. This type of response is likely to happen in a health care setting because a health care provider is perceived as a person of authority to some Asian, African, or Hispanic patients. Observing a patient's behavior and clarifying messages heard from a trusted insider prevents misinterpretation.

In cultural groups with distinct linear hierarchy, negotiation of conflict occurs among people within the same level of position or authority. Identifying and working with established family hierarchy prevents miscommunication. In cultures with highly differentiated gender roles some patients place more value on the advice of a man than a woman. By recognizing and working within this cultural context, nurses become more effective in achieving outcomes.

Culture also shapes nonverbal communication. It influences the distance between participants in an interaction, the degree of eye contact, the extent of touching, and how much private information the patient shares. Patients use less distance when speaking to trusted insiders and persons of the same age, gender, and position in the social hierarchy. Many ethnic groups tend to speak their own dialect with insiders for ease and privacy and as a marker of insider status. To minimize this distance when communicating with patients, nurses establish rapport and behave in a culturally congruent manner through impression management.

Time Orientation

All cultures have past, present, and future time dimensions. This information is useful in planning a day of care, setting up appointments for procedures, and helping a patient plan self-care activities in the home. The dominant American culture is future-time oriented, and people from this culture tend to schedule their time. When working with patients who are future-time oriented, it is important to plan and adhere to a schedule (Srivastava, 2007). Future-time orientation minimizes present time; thus communication tends to be direct and focused on task achievement. The rushed, hurried, and businesslike communication of a future-time oriented person may appear uncaring or disrespectful to those who are present or past-time oriented.

In some cultures time is oriented to the present, and events take place when the person arrives. Present-time orientation is in conflict with the dominant future-time orientation in health care that emphasizes punctuality and adherence to appointments. Within present-time oriented cultures it is acceptable to be late to appointments. When making appointments and referrals, explore and manage anticipated barriers to time adherence with the patient. Anticipate conflicts and make adjustments when caring for ethnic groups that value present-time orientation. African Americans, Puerto Ricans, Mexicans, Chinese, and Native Americans are some of the groups that value present-time orientation (Giger and Davidhizar, 2008). Past-time orientation is associated with adaptive cultures and populations who are exposed to situations that require immediate action such as immigrant populations (Crockett et al., 2009). Improving a patient's access to health services mandates culturally congruent time schedules that accommodate cultural patterns.

CARING BELIEFS AND PRACTICES

Obtain information about folk remedies and cultural healers that the patient uses. Assessment data yield information about the patient's beliefs about the illness and the meaning of the signs and symptoms. Focus assessment on the emic perspective of the patient. Allowing the patient to describe the meanings of care and identify caring behaviors is fundamental to culturally congruent care.

Experience with Professional Health Care

Understanding the emic perspective of the patient about professional health care is valuable in correcting misconceptions and preventing culturally offensive actions. Previous encounters with professional caregivers affect patients' adherence to therapies and continuing access of services. For example, if a patient previously

BOX 9-7 FOCUS ON OLDER ADULTS

Culturally Sensitive Communication

- Ask older adults how they like to be addressed. If in doubt, address them formally (e.g., Mr. Lin) (Meiner, 2011).
- Determine patient's preferences for touch (Meiner, 2011). For example, in the United States Americans often greet each other with a firm handshake. However, many Native Americans see this as a sign of aggression, and touch outside of marriage is sometimes forbidden in older adults from the Middle East.
- Investigate the patient's preferences for silence (Meiner, 2011). Generally Eastern cultures value silence, whereas Western cultures are uncomfortable with it.
- Be aware of the patient's beliefs about eye contact during conversation (Meiner, 2011). In European American cultures direct eye contact is a sign of honesty and truthfulness. However, eye contact with other groups such as older Native Americans is not allowed. Older Asian adults sometimes avoid eye contact with authority figures because it is considered disrespectful, and direct eye contact between genders in Middle Eastern cultures is sometimes forbidden except between spouses.

had problems with male caregivers, assign female caregivers to the patient whenever possible. If a patient perceives an essential health care resource to be inaccessible, help to find a way to connect the patient with the resource. Partnership between health care professionals and the community provides proactive and open feedback from culturally diverse patient groups. Use of comparative assessment questions gives nurses insight into patients' perceptions and reactions to different aspects of the health care system and facilitates evaluation of patient outcomes.

Culturally Congruent Care

To provide culturally congruent care it is important to identify potential conflicts between patients' health care needs and their health care practices and cultural values. Leininger (2006) identified three nursing decision and action modes to achieve culturally congruent care. All three modes of professional decisions and actions assist, support, facilitate, or enable people of particular cultures.

1. **Cultural care preservation or maintenance**—Retain and/or preserve relevant care values so patients maintain their well-being, recover from illness, or face handicaps and/or death.
2. **Cultural care accommodation or negotiation**—Adapt or negotiate with others for a beneficial or satisfying health outcome.
3. **Cultural care repatterning or restructuring**—Reorder, change, or greatly modify patients' lifestyles for a new, different, and beneficial health care pattern.

Nurses are able to use any or all of these action modes simultaneously. These actions require that nurses have knowledge of patients' culture and the willingness, commitment, and skills to work with patients and families in decision making. The intended outcome of these actions and decisions is meaningful, supportive, and facilitative care as judged by the patient.

KEY POINTS

- Culture is the context for interpreting human experiences such as health and illness and provides direction to decisions and actions.
- Culturally congruent care is meaningful, supportive, and facilitative because it fits valued life patterns of patients.
- Nurses achieve culturally congruent care through cultural assessment and the application of cultural preservation, accommodation, and repatterning.
- Culturally competent care requires knowledge, attitudes, and skills supportive of implementation of culturally congruent care.
- Cultural assessment requires a comprehensive and thorough investigation of a patient's cultural values, beliefs, and practices.
- Transcultural nursing is a comparative study and understanding of cultures to identify specific and universal caring constructs across cultures.
- Impression management facilitates culturally congruent communication and intercultural relationships.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

A 43-year-old male patient, who is an Orthodox Jew, is hospitalized following a motor vehicle accident. The nurse caring for the patient notes that he has not touched most of the food on his plate and has only eaten his bread and fruit. In reviewing the patient's intake over the past 2 days, the nurse notes that this patient has eaten very little. The nurse reviews the patient's diet order and finds that his diet orders indicate that he is to receive no pork products. The patient was served meatloaf, macaroni and cheese, green beans, a dinner roll, and a fresh peach for lunch. For dinner he was served lasagna, breadsticks, a salad, and a pear for dessert.

1. Explain possible causes for the patient's poor appetite.
2. Identify nursing interventions to help increase the patient's food intake.
3. Of the three nursing decisions and action modes described by Leininger (2006), explain which one is the most appropriate for this patient.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A 6-month-old child from Guatemala was adopted by an American family in Indiana. The child's socialization into the American midwestern culture is best described as:
   1. Assimilation.
   2. Acculturation.
   3. Biculturalism.
   4. Enculturation.
2. A 46-year-old woman from Bosnia came to the United States 6 years ago. Although she did not celebrate Christmas when she lived in Bosnia, she celebrates Christmas with her family now. This woman has experienced assimilation into the culture of the United States because she:
   1. Chose to be bicultural.
   2. Adapted to and adopted the American culture.
   3. Had an extremely negative experience with the American culture.
   4. Gave up part of her ethnic identity in favor of the American culture.
3. To enhance their cultural awareness, nursing students need to make an in-depth self-examination of their own:
   1. Motivation and commitment to caring.
   2. Social, cultural, and biophysical factors.
   3. Engagement in cross-cultural interactions.
   4. Background, recognizing personal biases and prejudices.
4. Which of the following is required in the delivery of culturally congruent care?
   1. Learning about vast cultures
   2. Motivation and commitment to caring
   3. Influencing treatment and care of patients
   4. Acquiring specific knowledge, skills, and attitudes
5. A registered nurse is admitting a patient of French heritage to the hospital. Which question asked by the nurse indicates that the nurse is stereotyping the patient?
   1. "What are your dietary preferences?"
   2. "What time do you typically go to bed?"
   3. "Do you bathe and use deodorant more than one time a week?"
   4. "Do you have any health issues that we should know about?"
6. When action is taken on one's prejudices:
   1. Discrimination occurs.
   2. Delivery of culturally congruent care is ensured.
   3. Effective intercultural communication develops.
   4. Sufficient comparative knowledge of diverse groups is obtained.

7. A nursing student is doing a community health rotation in an inner-city public health department. The student investigates sociodemographic and health data of the people served by the health department, and detects disparities in health outcomes between the rich and poor. This is an example of a(n):
   1. Illness attributed to natural and biological forces.
   2. Creation of the student's interpretation and descriptions of the data.
   3. Influence of socioeconomic factors in morbidity and mortality.
   4. Combination of naturalistic, religious, and supernatural modalities.
8. Culture strongly influences pain expression and need for pain medication. However, cultural pain is:
   1. Not expressed verbally or physically.
   2. Expressed only to others from a similar culture.
   3. Usually more intense than physical pain.
   4. Suffered by a patient whose valued way of life is disregarded by practitioners.
9. Which of the following best represents the dominant values in American society on individual autonomy and self-determination?
   1. Physician orders
   2. Advance directive
   3. Durable power of attorney
   4. Court-appointed guardian
10. The nurse at an outpatient clinic asks a patient who is Chinese American with newly diagnosed hypertension if he is limiting his sodium intake as directed. The patient does not make eye contact with the nurse but nods his head. What should the nurse do next?
    1. Ask the patient how much salt he is consuming each day
    2. Discuss the health implications of sodium and hypertension
    3. Remind the patient that many foods such as soy sauce contain "hidden" sodium
    4. Suggest some low-sodium dietary alternatives
11. A female Jamaican immigrant has been late to her last two clinic visits, which in turn had to be rescheduled. The best action that the nurse could take to prevent the patient from being late to her next appointment is:
    1. Give her a copy of the city bus schedule.
    2. Call her the day before her appointment as a reminder to be on time.
    3. Explore what has prevented her from being at the clinic in time for her appointment.
    4. Refer her to a clinic that is closer to her home.
12. A nursing student is taking postoperative vital signs in the postanesthesia care unit. She knows that some ethnic groups are more prone to genetic disorders. Which of the following patients is most at risk for developing malignant hypertension?
    1. Ashkenazi Jew
    2. Chinese American
    3. African American
    4. Filipino
13. A community health nurse is making a healthy baby visit to a new mother who recently emigrated to the United States from Ghana. When discussing contraceptives with the new mom, the mother states that she won't have to worry about getting pregnant for the time being. The nurse understands that the mom most likely made this statement because:
    1. She won't resume sexual relations until her baby is weaned.
    2. She is taking the medroxyprogesterone (Depo-Provera) shot.
    3. Her husband was recently deployed to Afghanistan.
    4. She has access to free condoms from the clinic.
14. During their clinical postconference meeting, several nursing students were discussing their patients with their instructor. One student from a middle-class family shared that her patient was homeless. This is an example of caring for a patient from a different:
    1. Ethnicity.
    2. Culture.
    3. Heritage.
    4. Religion.
15. When interviewing a Native American patient on admission to the hospital emergency department, which questions are appropriate for the nurse to ask? (Select all that apply.)
    1. Do you use any folk remedies?
    2. Do you have a family physician?
    3. Do you use a Shaman?
    4. Does your family have a history of alcohol abuse?

CHAPTER

10

Caring for Families

OBJECTIVES

- Discuss how the term family reflects family diversity.
- Explain how the relationship between family structure and patterns of functioning affects the health of individuals within the family and the family as a whole.
- Discuss the way family members influence one another's health.
- Discuss the role of families and family members as caregivers.
- Discuss factors that promote or impede family health.
- Compare family as context to family as patient and explain the way these perspectives influence nursing practice.
- Use the nursing process to provide for the health care needs of the family.

KEY TERMS

Family, p. 116
Family as context, p. 121
Family as patient, p. 121
Family as system, p. 122
Family caregiving, p. 126
Family forms, p. 117
Hardiness, p. 121
Reciprocity, p. 127
Resiliency, p. 121

THE FAMILY

The family is a central institution in American society; however, the concept, structure, and functioning of the family unit continue to change over time. Families face many challenges, including the effects of health and illness, childbearing and childrearing, changes in family structure and dynamics, and caring for older parents. Family characteristics or attributes such as durability, resiliency, and diversity help families adapt to challenges.

Family durability is the term for the intrafamilial system of support and structure that extends beyond the walls of the household. For example, the parents may remarry or the children may leave home as adults, but in the end the "family" transcends long periods and inevitable lifestyle changes.

Family resiliency is the ability of the family to cope with expected and unexpected stressors. The family's ability to adapt to role and structural changes, developmental milestones, and crises shows resilience. For example, a family is resilient when the wage earner loses a job and another member of the family takes on that role. The family survives and thrives as a result of the challenges they encounter from stressors.

Family diversity is the uniqueness of each family unit. For example, some families experience marriage for the first time and then have children in later life. Another family may include parents with young children as well as grandparents living in the home. Every person within a family unit has specific needs, strengths, and important developmental considerations.

As you care for patients and their families, you are responsible for understanding family dynamics, which include the family makeup (configuration), structure, function, problem-solving, and coping capacity. Use this knowledge to build on the family's relative strengths and resources (Duhamel, 2010). The goal of family-centered nursing care is to promote, support, and provide for the well-being and health of the family and individual family members (Astedt-Kurki et al., 2002; Joronen and Astedt-Kurki, 2005).

Concept of Family

The term *family* brings to mind a visual image of adults and children living together in a satisfying, harmonious manner (Fig. 10-1). For some this term has the opposite image. Families represent more than a set of individuals, and a family is more than a sum of its individual members (Kaakinen et al., 2010). Families are as diverse as the individuals who compose them. Patients have deeply ingrained values about their families that deserve respect. You need to understand how your patients define their family. Think of the **family** as a set of relationships that the patient identifies as family or as a network of individuals who influence one another's lives, whether or not there are actual biological or legal ties.

Definition: What Is a Family?

Defining family initially appears to be a simple undertaking. However, different definitions result in heated debates among social scientists and legislators. The definition of family is significant and affects who is included on health insurance policies, who has access to children's school records, who files joint tax returns, and who is eligible for sick-leave benefits or public assistance

FIG. 10-1 Family celebrations and traditions strengthen the role of the family.

programs. The family is defined biologically, legally, or as a social network with personally constructed ties and ideologies. For some patients family includes only persons related by marriage, birth, or adoption. To others, aunts, uncles, close friends, cohabitating persons, and even pets are family. Your personal beliefs do not have to be the same as those of your patient. Understand that families take many forms and have diverse cultural and ethnic orientations. In addition, no two families are alike. Each has its own strengths, weaknesses, resources, and challenges.

CURRENT TRENDS AND NEW FAMILY FORMS

Family forms are patterns of people considered by family members to be included in the family (Box 10-1). Although all families have some things in common, each family form has unique problems and strengths. Maintain an open mind about what makes up a family so you do not overlook potential resources and concerns.

Although the institution of the family remains strong, the family itself is changing. The "typical" family (two biological parents and children) is no longer the norm. People are marrying later, women are delaying childbirth, and couples are choosing to have fewer children or none at all. The number of people living alone is expanding rapidly and represents approximately 26% of all households. Divorce rates continue to be high; it is estimated that 54% of marriages will end in divorce (U.S. Bureau of the Census, 2008). A number of divorced adults remarry; the median interval between divorce and remarriage is about 3 years. Remarriage often results in a blended family with a complex set of relationships among stepparents, stepchildren, half brothers and sisters, and extended family members.

Marital roles are also more complex as families increasingly comprise two wage earners. The majority of women work outside the home, and about 60% of mothers are in the workforce (U.S. Bureau of the Census, 2008). Balancing employment and family life creates a variety of challenges in terms of child care and household work for both parents. The balance for working parents between child care and household duties is positive when the working parents' job and life satisfactions remain high (Hill, 2005). There is no proof that maternal employment is damaging for children (Hill, 2005; Shpancer et al., 2006). However, finding quality child care is a major issue. Managing household tasks is another challenge. Although equal division of labor receives verbal approval, most household tasks remain "women's work." There is some evidence that the father's role is changing. Fathers now participate more fully in day-to-day parenting responsibilities. Twenty-four percent of children (ages 0 to 4) have their fathers as caretakers whether or not the fathers are employed (U.S. Bureau of the Census, 2008).

The number of single-parent families, which doubled from the 1970s to the 1990s, seems to be stabilizing. Forty-one percent of children are living with mothers who have never married; many of these children are a result of an adolescent pregnancy. Although mothers head most single-parent families, father-only families are on the rise.

Adolescent pregnancy is an ever-increasing concern. The majority of adolescent mothers continue to live with their families. A teenage pregnancy has long-term consequences for the mother. For example, adolescent mothers frequently quit high school and have inadequate job skills and limited health care resources. The overwhelming task of being a parent while still being a teenager often severely stresses family relationships and resources. In addition, there is an increased risk for subsequent adolescent pregnancy, inability to obtain quality job skills, and poor lifestyles (Harper et al., 2010). Stressors are also placed on teenage fathers when their partner becomes pregnant. These young men have poorer support systems and fewer resources to teach them how to parent. In addition, adolescent fathers report early adverse family relationships such as exposure to domestic violence and parental separation or divorce and lack positive fathering role models (Biello, Sipsma, and Kershaw, 2010). As a result, both adolescent parents often struggle with the normal tasks of development and identity but must accept a parenting role that they are not ready for physically, emotionally, socially, and/or financially.

Many homosexual couples define their relationship in family terms. Approximately half of all gay male couples live together compared with three fourths of lesbian couples. These couples are more open about their sexual preferences and more vocal about their legal rights. Some homosexual families include children,

BOX 10-1 FAMILY FORMS

Nuclear Family
The nuclear family consists of husband and wife (and perhaps one or more children).

Extended Family
The extended family includes relatives (aunts, uncles, grandparents, and cousins) in addition to the nuclear family.

Single-Parent Family
The single-parent family is formed when one parent leaves the nuclear family because of death, divorce, or desertion or when a single person decides to have or adopt a child.

Blended Family
The blended family is formed when parents bring unrelated children from prior adoptive or foster parenting relationships into a new, joint living situation.

Alternative Family
Relationships include multiadult households, "skip-generation" families (grandparents caring for grandchildren), communal groups with children, "non-families" (adults living alone), cohabitating partners, and homosexual couples.

either through adoption or artificial insemination or from prior relationships.

The fastest-growing age-group in America is 65 years of age and over. For the first time in history the average American has more living parents than children, and children are more likely to have living grandparents and even great-grandparents. This "graying" of America continues to affect the family life cycle, particularly the "sandwich generation"—made up of the children of older adults (see section on restorative care). These individuals, who are usually in the middle years, have to meet their own needs along with those of their children and their aging parents. This balance of needs often occurs at the expense of their own well-being and resources. In addition, many of the family caregivers report that support from professional health professionals is lacking (Touhy and Jett, 2010). Most family caregivers are women; the average age is 46, with 13% being 65 years of age or older, and they frequently provide more than 20 hours of care per week (Schumacher, Beck, and Marren, 2006a). Caring for a frail or chronically ill relative is a primary concern for a growing number of families. It is not uncommon for people in their 60s and 70s to be the major caregivers for one another. Box 10-2 provides a list of family nursing gerontological concerns.

More grandparents are raising their grandchildren (U.S. Bureau of the Census, 2008). This new parenting responsibility is the result of a number of societal factors: the increase in the divorce rate, dual-income families, and single parenthood. Most often it is a consequence of legal intervention when parents are unfit or renounce their parental obligations.

Families face many challenges, including changing structures and roles in the changing economic status of society. In addition, social scientists identify four further trends as threats or concerns facing the family: (1) changing economic status (e.g., declining family income and lack of access to health care), (2) homelessness, (3) family violence, and (4) the presence of acute or chronic illnesses.

BOX 10-2 FOCUS ON OLDER ADULTS

Caregiver Concerns

- Assess the family for the existence of caregivers who provide daily or respite care for older adult family members. For example, determine the caregiving roles for members of the family (e.g., providing additional financial support, designating someone to obtain groceries and medications, providing hands-on physical care).
- Assess for caregiver burden such as tension in relationships between family caregivers and care recipients, changes in level of health, changes in mood, and anxiety and depression (Tamayo et al., 2010).
- Caregivers are most often spouses, who are sometimes older adults with declining physical stamina, or middle-age children, who often have other family responsibilities.
- Later-life families have a different social network than younger families because friends and same-generation family members often have died or been ill themselves. Look for social support within the community and church affiliation (Tamayo et al., 2010).
- Take time to individualize and reinforce instruction. The patient's status may change over time, and care specifics also change (Davidson, 2009).
- Abuse of older adults in families occurs across all social classes. Spouses are the most frequent abusers. Nurses need to report unexplained bruises and skin trauma to state protective agencies.

Changing Economic Status

Making ends meet is a daily concern because of the declining economic status of families. Although two-income families have become the norm, real family income has not increased since 1973. Families at the lower end of the income scale have been particularly affected, and single-parent families are especially vulnerable. Because of recent economic trends adult children are often faced with moving back home after college because they cannot find employment or in some cases lose their jobs.

The number of American children living below the poverty level continues to rise. The number of children living below poverty increased by 2 million since 2000, and 8.1 million children are uninsured (Children's Defense Fund [CDF], 2010). A majority of uninsured children have at least one parent who works but is unable to afford insurance. When caring for these families, the nurse needs to be sensitive to their desire for independence but also help them with obtaining appropriate financial and health care resources. For example, you inform the family where to go within the community to obtain assistance with energy bills, dental and health care, and assistance with school supplies.

Homelessness

Homelessness is a major public health issue. According to public health organizations, *absolute homelessness* describes people without physical shelter who sleep outdoors, in vehicles, in abandoned buildings, or in other places not intended for human habitation. *Relative homelessness* describes those who have a physical shelter, but one that does not meet the standards of health and safety (National Coalition for the Homeless, 2010).

The fastest growing section of the homeless population is families with children. This includes complete nuclear families and single-parent families. It is expected that 3.5 million people are homeless and 1.35 million are families with children. Poverty, mental and physical illness, and lack of affordable housing are primary causes of homelessness (National Coalition for the Homeless, 2010). Homelessness severely affects the functioning, health, and well-being of the family and its members. Children of homeless families are often in fair or poor health and have higher rates of asthma, ear infections, stomach problems, and mental illness (see Chapter 3). As a result, usually the only access to health care for these children is through an emergency department.

Children who are homeless face difficulties such as meeting residency requirements for public schools, inability to obtain previous enrollment records, and enrolling in and attending school. As a result, they are more likely to drop out of school and become unemployable (National Coalition for the Homeless, 2010). Homeless families and their children are at serious risk for developing long-term health, psychological, and socioeconomic problems. For example, the children are frequently underimmunized and at risk for childhood illnesses; they may fall behind in school and are at risk of dropping out; or they can develop risky behaviors.

Family Violence

The statistics regarding family violence are even more disturbing. Approximately 3.3 to 10 million children reported being abused or neglected in the period from 1991 to 2004 (Family Violence Prevention Fund, 2008a). Emotional, physical, and sexual abuse occurs toward spouses, children, and older adults and across all social classes. Factors associated with family violence are complex and include stress, poverty, social isolation, psychopathology, and learned family behavior. Other factors such as alcohol and drug

abuse, pregnancy, sexual orientation, and mental illness increase the incidence of abuse within a family (Family Violence Prevention Fund, 2008b). Although abuse sometimes ends when one leaves a specific family environment, negative long-term physical and emotional consequences are often evident. One of the consequences includes moving from one abusive situation to another. For example, an adolescent girl sees marriage as a way to leave her parents' abusive home and in turn marries a person who continues the abuse in her marriage.

Acute or Chronic Illness

Any acute or chronic illness influences the entire family economically, emotionally, socially, and functionally and affects the family's decision-making and coping resources. Hospitalization of a family member is stressful for the whole family. Hospital environments are foreign, physicians and nurses are strangers, the medical language is difficult to understand or interpret, and family members are separated from one another.

During an acute illness such as a trauma, myocardial infarction, or surgery, family members are often left in waiting rooms to anticipate information about their loved one. Communication among family members may be misdirected from fear and worry. Sometimes previous family conflicts rise to the surface, whereas others are suppressed. When implementing a patient-centered care model, patients' family members and surrogate decision makers must become active partners in decision making and care (Davidson, 2009). Understand the family's cultural beliefs and values and need for communication and support.

Chronic illnesses are a global health problem. Adaptations to chronic illnesses pose unique challenges for the family (Weinert et al., 2008). Frequently family patterns and interactions, social activities, work and household schedules, economic resources, and other family needs and functions must be reorganized around the chronic illness or disability. Despite the stressors, families also learn how to manage many aspects of their loved one's illness or disability. Astute nursing care helps the family prevent and/or manage medical crises, control symptoms, learn how to provide specific therapies, adjust to changes over the course of the illness, avoid isolation, obtain community resources, and assist in helping the family resolve conflict.

Chronic illnesses are common in a majority of family units. Chronic illness impacts a family's quality of life. Families must work at developing working partnerships with the health care delivery system to identify available health care and community resources for disease management (Weinert et al., 2008). The chronic illness continuum ranges from newly diagnosed illness to end stages of the disease. The patient's level of independence changes over time, and family members need to adapt to changing caregiving needs (Tamayo et al., 2010). Common chronic illnesses include but are not limited to asthma, diabetes, cardiovascular illnesses, renal disease, human immunodeficiency virus (HIV), and cancer.

Trauma. Trauma is a sudden unplanned event. Family members often struggle to cope with the challenges of a severe, life-threatening event, which can include the stressors associated with a family member hospitalized in an intensive care environment, loss of a family member, or an acute psychiatric illness. The powerlessness that family members experience makes them very vulnerable and less able to make important decisions about the health of the family. In caring for family members, answer their questions honestly. When you do not know the answer, find someone who does. Provide realistic assurance; giving false hope breaks the nurse-patient trust and also affects how the family can adjust to "bad news." When the victim of trauma is hospitalized, take time to make sure that the family is comfortable. You can bring them something to eat or drink, give them a blanket, or encourage them to get a meal. Sometimes telling the family that you will stay with their loved one while they are gone is all they need to feel comfortable in leaving. Most family members have a cell phone and can be reached easily if their loved one's condition changes.

End-of-Life Care. You will encounter many families with a terminally ill member. Although people equate terminal illness with cancer, many diseases have terminal aspects (e.g., heart failure, pulmonary and renal diseases, and neuromuscular diseases). Although some family members may be prepared for their loved one's death, their need for information, support, assurance, and presence is great (see Chapter 36). The more you know about your patient's family, how they interact with one another, their strengths, and their weaknesses, the better. Each family approaches and copes with end-of-life decisions differently. Give the family information about the dying process. Help the family set up home care if they desire and obtain hospice and other appropriate resources, including grief support. Make sure that the family knows what to do at the time of death. If you are present at the time of death, be sensitive to the family's needs (e.g., provide for privacy and allow sufficient time for saying good-byes).

THEORETICAL APPROACHES: AN OVERVIEW

A number of different perspectives can be applied when caring for families. It is important that you understand some of the broader perspectives for family nursing. The family health system (FHS) and developmental theories are two perspectives used in this chapter to help you provide nursing care to the family as a whole and the individuals within the family structure. These theoretical perspectives and their concepts provide the foundation for family assessment and interventions.

Family Health System

When assessing the family, it is important to use a guide such as the FHS to identify all of their needs. The FHS is a holistic model that guides the assessment and care for families (Anderson, 2000; Anderson and Friedemann, 2010). The FHS includes five realms/processes of family life: interactive, developmental, coping, integrity, and health. The FHS approach is one method for family assessment to determine areas of concern and strengths, which helps you develop a plan of care with family nursing interventions and outcomes. As with all systems, the FHS has both unspoken and spoken goals, which vary according to the stage in the family life cycle, family values, and individual concerns of the family members. When working with families, the goal of care is to improve family health or well-being, assist in family management of illness conditions or transitions, and achieve health outcomes related to the family areas of concern.

Developmental Stages

Families, like individuals, change and grow over time. Although they are far from identical to one another, they tend to go through common stages. Each developmental stage has its own challenges, needs, and resources and includes tasks that need to be completed before the family is able to successfully move on to the next stage. Societal changes and an aging population have caused changes in the stages and transitions in the family life cycle. For example, adult children are not leaving the nest as predictably or as early as in the

TABLE 10-1 **Stages of the Family Life Cycle**

FAMILY LIFE-CYCLE STAGE	EMOTIONAL PROCESS OF TRANSITION: KEY PRINCIPLES	CHANGES IN FAMILY STATUS REQUIRED TO PROCEED DEVELOPMENTALLY
Unattached young adult	Accepting parent-offspring separation	Differentiation of self in relation to family of origin Development of intimate peer relationships Establishment of self in work
Joining of families through marriage: newly married couple	Committing to new system	Formation of marital system Realignment of relationships with extended families and friends to include spouse
Family with young children	Accepting new generation of members into system	Adjusting marital system to make space for children Taking on parental roles Realignment of relationships with extended family to include parenting and grandparenting roles
Family with adolescents	Increasing flexibility of family boundaries to include children's independence	Shifting of parent-child relationships to permit adolescents to move into and out of system Refocusing on midlife material and career issues Beginning shift toward concerns for older generation
Launching children and moving on	Accepting multitude of exits from and entries into family system	Adjusting to reduction in family size Developing adult-to-adult relationships between grown children and their parents Realigning relationships to include in-laws and grandchildren Dealing with disabilities and death of parents (grandparents)
Family in later life	Accepting shifting of generational roles	Maintaining own or couple functioning and interests in the face of physiological decline; exploring new familial and social role options Making room in system for wisdom and experience of older adults; supporting older generations without overfunctioning for them Dealing with retirement Dealing with loss of spouse, siblings, and other peers and preparation for own death; a life review, in which one reviews life experiences and decisions

From Duvall EM, Miller BC: *Marriage and family development,* ed 6, Boston, 2005, Allyn & Bacon. Printed and electronically reproduced by permission of Pearson Education, Inc, Upper Saddle River, NJ.

past, and many are returning home. In addition, more people are living into their 80s and 90s. Sixty-five is now considered the "backside of middle age," and the length of the midlife stage in the family life cycle has increased, as has the later stage in family life.

McGoldrick and Carter based their 1985 classic model of family life stages on expansion, contraction, and realignment of family relationships that support the entry, exit, and development of the members (Hanson et al., 2005). This model describes the emotional aspects of lifestyle transition and the changes and tasks necessary for the family to proceed developmentally (Table 10-1). Use this model to promote family behaviors to achieve essential tasks and help families prepare for later transitions such as when helping families prepare for a new baby (see Chapter 13).

ATTRIBUTES OF FAMILIES

Structure

Families have a structure and a way of functioning. Structure and function are closely related and continually interact with one another. Structure is based on the ongoing membership of the family and the pattern of relationships, which are often numerous and complex. For example, a woman's relationships frequently include wife-husband, mother-son, mother-daughter, employee-boss, and colleague-colleague, each with different demands, roles, and expectations. Patterns of relationships form power and role structures within the family. Determine a family's structures by observing family members' behaviors and interactions.

Structure promotes or impedes the family's ability to respond to stressors. Very rigid or very flexible structures impair functioning. A rigid structure specifically dictates who is able to accomplish a task and may limit the number of persons outside the immediate family who can assume these tasks. For example, in one family the mother is the only acceptable person to provide emotional support for the children, or the husband is the only one to provide financial support. A change in the health status of the person responsible for a task places a burden on the family because no other person is available or considered acceptable to assume that task. A family must adapt its structure. For example, when a homemaker is ill, the tasks of managing the household (e.g., preparing the meals, maintaining the house, and driving school-age children to appointments and events) need to be shared. The older children may help prepare the meals, and the other parent or a family member drives the children to the events, or perhaps the events are rescheduled.

An extremely open structure also presents problems for the family. When the family structure is extremely open, consistent patterns of behavior that lead to automatic action do not exist. An example is an inconsistent parenting role. The parent sometimes is a strict authoritarian figure and at other times treats the child as a "best friend and confidant." This type of conduct causes family members to become confused about what behavior is appropriate and who is reliable for support. During a crisis or rapid change, family members do not have a defined structure to "fall back on," and family disintegration is sometimes a result.

Function

Family functioning is what the family does. Specific functional aspects include the way a family reproduces, interacts to socialize its young, cooperates to meet economic needs, and relates to the larger society. Family functioning also focuses on the processes used by the family to achieve its goals. Some processes include communication among family members, goal setting, conflict resolution, caregiving, nurturing, and use of internal and external resources. Traditional reproductive, sexual, economic, and educational goals that were once universal family goals no longer apply to all families. For example, a married couple who decides not to have children still consider themselves a family. Another example includes a blended family whose spouses bring school-age children into the new marriage. However, the spouses decide not to co-mingle their finances and have separate educational goals for their minor children. As a result, this family does not have the traditional economic patterns of a nuclear family.

Families achieve goals more successfully when communication is clear and direct. Clear communication enhances problem solving and conflict resolution, and it facilitates coping with life-changing or life-threatening stressors. Another process to facilitate goal achievement includes the ability to nurture and promote growth. For example, families might have a specific celebration for a good report card, a job well done, or specific milestones. They also nurture by helping children know right and wrong. In this situation a family might have a specific form of discipline such as "time out" or taking away privilege, and the children know why the discipline is given. Thus when a situation occurs, the child is disciplined and learns not to behave like that again.

Families need to have multiple resources available. For example, a social network is an excellent resource. Social relationships such as friends or churches within the community are important for family celebrations but also act as buffers, particularly during times of stress, and reduce a family's vulnerability.

The Family and Health

Many factors influence the health of the family (e.g., its relative position in society, economic resources, and geographical boundaries). Although American families exist within the same culture, they live in very different ways as a result of race, values, social class, and ethnicity. In some minority groups multiple generations of single-parent families live together in one home. Class and ethnicity produce differences in the access of families to the resources and rewards of society. This access creates differences in family life, most significantly in different life chances for its members.

Distribution of wealth greatly affects the capacity to maintain health. Low educational preparation, poverty, and decreased social support compound one another, magnifying their effect *on* sickness in the family, and magnifying the amount of sickness *in* the family. Economic stability increases a family's access to adequate health care, creates more opportunity for education, increases good nutrition, and decreases stress (National Coalition of the Homeless, 2010; Children's Defense Fund, 2010).

The family is the primary social context in which health promotion and disease prevention take place. The family's beliefs, values, and practices strongly influence health-promoting behaviors of its members (Epley et al., 2010). In turn the health status of each individual influences how the family unit functions and its ability to achieve goals. When the family satisfactorily functions to meet its goals, its members tend to feel positive about themselves and their family. Conversely, when they do not meet goals, families view themselves as ineffective.

Some families do not place a high value on good health. In fact, some families accept harmful practices. In some cases a family member gives mixed messages about health. For example, a parent continues to smoke while telling children that smoking is bad for them. Family environment is crucial because health behavior reinforced in early life has a strong influence on later health practices. In addition, the family environment is a crucial factor in an individual's adjustment to a crisis. Although relationships are strained when confronted with illness, research indicates that family members can have the potential to be a primary force for coping (Bluvol and Ford-Gilboe, 2004).

Attributes of Healthy Families. The family is a dynamic unit; it is exposed to threats, strengths, changes, and challenges. Some families are crisis proof, whereas others are crisis prone. The crisis-proof, or effective, family is able to combine the need for stability with the need for growth and change. This type of family has a flexible structure that allows adaptable performance of tasks and acceptance of help from outside the family system. The structure is flexible enough to allow adaptability but not so flexible that the family lacks cohesiveness and a sense of stability. The effective family has control over the environment and influences the immediate environment of home, neighborhood, and school. The ineffective, or crisis-prone, family lacks or believes it lacks control over the environments.

Health promotion research often focuses on the stress-moderating effect of **hardiness** and **resiliency** as factors that contribute to long-term health. Family hardiness is the internal strengths and durability of the family unit. A sense of control over the outcome of life, a view of change as beneficial and growth producing, and an active rather than passive orientation in adapting to stressful events characterize family hardiness (McCubbin, McCubbin, and Thompson, 1996). Family resiliency is the ability to cope with expected and unexpected stressors. It helps to evaluate healthy responses when individuals and families are experiencing stressful events. Resources and techniques that a family or individuals within the family use to maintain a balance or level of health assist in understanding a family's level of resiliency.

FAMILY NURSING

To provide compassion and caring for your patients and their families, you need a scientific knowledge base in family theory and knowledge in family nursing. A focus on the family is necessary to safely discharge patients back to the family or community settings. The members of the family may need to assume the role of primary caregiver. Family caregivers have unique nursing and caregiving needs and too often feel abandoned by the health care system (Reinhard, 2006). When a life-changing illness occurs, the family has to make major adjustments to care for a family member. Often the psychological, social, and health care needs of the caregiver go unmet (Tamayo et al., 2010).

Family nursing is based on the assumption that all people, regardless of age, are members of some type of family form, such as the traditional nuclear family or an alternate family. The goal of family nursing is to help the family and its individual members reach and maintain maximum health throughout and beyond the illness experience (Box 10-3). Family nursing is the focus of the future across all practice settings and is important in all health care environments.

There are different approaches for family nursing practice. For the purposes of this chapter, family nursing practice has three levels of approaches: (1) **family as context;** (2) **family as patient;**

BOX 10-3 EVIDENCE-BASED PRACTICE

Social Support for the Family Caregiver

PICO Question: Does strengthening social support systems improve the emotional and physical health of family caregivers?

Evidence Summary

When a family member has an illness or trauma that changes his or her physical or cognitive function, it is often a major life-changing event for the spouse, parent, family, and loved ones. Illnesses include but are not limited to strokes, cancer, Parkinson's disease, or motor vehicle and sports-related injuries. As the patient moves through acute care and rehabilitation phases, families face major changes in family dynamics, social interactions, financial commitments, and emotional support systems (Davidson, 2009; Tamayo et al., 2010). When the patient returns home, existing disabilities affect the primary caregiver and other members of the family. Families face additional changes when adjusting to the physical, emotional, and psychological consequences of the illness or trauma. The family's and caregiver's social roles and activities, health-related activities and practices, and family dynamics all change (Rosenthal et al., 2008). As a result, family members note changes in their physical and emotional health and a decline in their quality of life. Identifying social support systems and structures help the caregiver maintain a sense of hope, maintain their own health status, engage in more social activities, and have some respite from the day-to-day caregiving tasks (Duggleby et al., 2010; Weinert et al., 2008).

Application to Nursing Practice

- Focus interventions on the family's strengths (e.g., if some family members are good at helping their loved one exercise, involve them in physical rehabilitation activities [Rosenthal et al., 2008]).
- Consider the primary caregiver's experience when designing intervention (e.g., has the caregiver observed any technical nursing care? Does the caregiver have a health care background? Has he or she provided care to another person?).
- Build on the strengths of the patient and the caregivers, including their sense of hope, rather than focusing solely on any weaknesses and challenges (Duggleby et al., 2010).
- Encourage the caregiver to set a routine time for respite. The caregiver then knows when he or she can have some relaxation time or spouses can have a "date night."
- Teach older children to be part of the support system. Show them how to participate in the care of a family member. Older children, especially grandchildren, enjoy listening to the stories of the family (Bluvol and Ford-Gilboe, 2004; Tamayo et al., 2010).
- Encourage the patient, caregivers, and family members to "tell their story" (Bluvol and Ford-Gilboe, 2004; Duggleby et al., 2010).

and (3) the newest model, called **family as system,** which includes both relational and transactional concepts. If only one family member receives nursing care, it is realistic and practical to view the family as context. When all family members are involved in the daily care of one another, nursing intervention with one individual necessitates some change in the activities of the others, suggesting that family as patient is the best approach. All three approaches are useful in providing effective nursing care.

Family As Context

When you view the family as context, the primary focus is on the health and development of an individual member existing within a specific environment (i.e., the patient's family). Although the focus is on the individual's health status, assess how much the family provides the individual's basic needs. Needs vary, depending on the individual's developmental level and situation. Because families provide more than just material essentials, you will also need to consider their ability to help the patient meet psychological needs. Some family members need direct interventions themselves.

Family As Patient

When the family as patient is the approach, family processes and relationships (e.g., parenting or family caregiving) are the primary focuses of nursing care. Focus your nursing assessment on family patterns versus individual member characteristics. Concentrate on patterns and processes that are consistent with reaching and maintaining family and individual health. Plan care to meet not only the patient's needs, but also the changing needs of the family. Dealing with very complex family problems often requires an interdisciplinary approach. Always be aware of the limits of nursing practice and make referrals when appropriate.

Family As System

It is important to understand that, although you are able to make theoretical and practical distinctions between the family as context and the family as patient, they are not necessarily mutually exclusive. When you care for the family as a system, you are caring for each family member (family as context) and the family unit (family as patient), using all available environmental, social, psychological, and community resources.

The following clinical scenario illustrates three levels of approaches to family care.

You are assisting with end-of-life care for David Daniels, who is 35 years old. David and his wife, Lisa, have three school-age children. David expressed a wish to die at home and not in a hospital or extended care facility. Lisa is on family leave from her job to help David through this period. Both Lisa and David are only children. David's parents are no longer living, but Lisa's mother is committed to stay with the family to help Lisa and David.

When you view this family as *context,* you focus on the patient (David) as an individual. You assess and meet David's comfort, hygiene, and nutritional needs. You also meet David's social and emotional needs. When viewing the family as *patient,* you assess and meet David's family's comfort and nutritional needs. You determine the family's need for rest and their stage of coping. It is important to determine the demands placed on David and the family. In addition, you need to continually evaluate the family's available resources such as time, finances, coping skills, and energy level to support David through the end of life.

When viewing the family as *system,* you use elements from both of the previous perspectives, but you also assess the resources available to the family. Using the knowledge of the family as context, patient, and a system, individualize care decisions based on the family assessment and your clinical judgment. For example, based on your assessment, you determine that the family is not eating adequately. You also determine that Lisa is experiencing more stress, not sleeping well, and trying to "do it all" regarding her children's school and after-school activities. In addition, Lisa does not want to leave David's bedside when members of their church come to help. You recognize that this family is under enormous stress and that their basic needs such as meals, rest, and school activities are not adequately met. As a result, you determine that (1) the family needs assistance with meals, (2) Lisa needs time to

BOX 10-4 FIVE REALMS OF FAMILY LIFE: FAMILY HEALTH SYSTEM—FAMILY ASSESSMENT PLAN

Interactive Processes

- Family relationships—Is the family a nuclear or blended family? Is it a single-parent family?
- Family communication—How do family members share ideas, concerns?
- Family nurturing—How are family values set and communicated? How are house rules established?
- Intimacy expression—Does the family hug, touch, laugh, or cry together?
- Social support—Who in the community, school, or workplace is close to the family?
- Conflict resolution—How does conflict resolution occur? Who initiates it?
- Roles (instrumental and expressive)—What are the formal roles such as wage earner, disciplinarian, problem solver? What are the informal roles (e.g., peacekeeper)?
- Family leisure life—Vacations: what does the family do to relax? Do the parents have "date night?"

Developmental Processes

- Current family transitions—Recent death, divorces, children leaving/returning home, new births
- Family stage task completion or progression—Childbearing years, empty nesters, grandparenting
- Individual developmental issues that affect family development—Individuals in the family with social issues such as difficulty in school or legal issues who cannot participate in family development
- Development of health issue and family impact—Acute or chronic illnesses, high-risk pregnancies, delayed physical development

Coping Processes

- Problem solving—How did the family solve previous problems? Is there a single problem solver or a family resolution?
- Use of resources—Does the family use family or individual therapists, Alcoholics Anonymous, conflict resolution resources, anger management resources?
- Family life stressors and daily hassles—These include financial concerns, overscheduled children, caregiver for older adults.
- Family coping strategies and effectiveness—How do the family and individuals cope (e.g., exercise, overeating, arguing)?
- Past experiences with handling crises—This includes information about past crisis such as financial stress, illness, legal problems.
- Family resistance resources—Does the family take measures to avoid stress such as adhering to a budget, obtaining tutoring resources for their children?

Integrity Processes

- Family values—What do the family consider as their important values (e.g., health, togetherness)?
- Family beliefs—For example, ask about beliefs about health/illness, end-of-life care, advance directives.
- Family meaning—For example, ask what the family means to each member.
- Family rituals—For example, ask about celebration of holidays, birthdays, weddings; coping with death (e.g., wakes, funerals).
- Family spirituality—Ask what spirituality means. How does the family define their spirituality?
- Family culture and practices—Identify cultural customs and practice that impact health care.

Health Processes

- Family health beliefs and beliefs about health concern or problem—Does the family practice health and illness prevention or wait until a problem occurs?
- Health behaviors of the family—How does the ill family member react? How does the family react to illness? Do the family members react the same way to an ill family member, or do they react differently when a homemaker is ill versus the wage earner?
- Health patterns and health management activities—How do the family members manage their health? How do they manage care?
- Family caretaking responsibilities—When someone is ill, who is the caregiver? Is it always the same person?
- Disease conditions, treatments, and consequences for the family—Obtain current disease and treatment history for the family.
- Family illness stressors—What are these stressors (e.g., worsening of a chronic illness or when "Mom" is sick and cannot run the household)?
- Relationship with health care providers and health system access—What type of health care provider does the family have (e.g., primary care, pediatrician)? How often does the family see the providers? Any hospitalizations?

Modified from Anderson KH, Friedemann ML: Strategies to teach family assessment and intervention through an online international curriculum, *J Fam Nurs* 16(2):213, 2010; and Anderson KH: The family health system approach to family systems nursing, *J Fam Nurs* 6(2):103, 2000.

rest, and (3) the family's church is eager to help with David's day-to-day care. On the basis of these decisions, you work with Lisa, David, and the family to set up a schedule among Lisa, her mother, and two close church members to provide Lisa with some time away from David's bedside. However, David and Lisa determine when this time will be. Because of the church involvement, members of the church begin to take responsibility for groceries and all meal preparation for the family. In addition, other members of the church help with the children's school and after-school activities.

NURSING PROCESS FOR THE FAMILY

Nurses interact with families in a variety of community-based and clinical settings. The nurse uses the nursing process to care for an individual within a family (e.g., the family as context) or the entire family (e.g., the family as patient). When initiating the care of families, three factors organize the family approach to the nursing process:

1. The nurse views all individuals within their family context.
2. Families have an impact on individuals.
3. Individuals have an impact on families.

Assessing the Needs of the Family

Family assessment is a priority in order to provide adequate family care and support. You have an essential role in helping families adjust to acute and chronic illness, but first you need to understand the family unit and what a patient's illness means to the family members and family functioning. You also need to understand how the illness has affected the family structure and the support the family requires (Kaakinen et al., 2010). Although the family as a whole differs from individual members, the measure of family health is more than a summary of the health of all members. The form, structure, function, and health of the family are areas unique to family assessment. Box 10-4 includes the five areas of family life to include in an assessment.

FIG. 10-2 Nurse providing family education. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.)

During an assessment, incorporate knowledge of the patient's illness and assess the primary patient and the family. When focusing on the family, begin the family assessment by determining the patient's definition of and attitude toward the family. The concept of family is highly individualized. The patient's definition will influence how much you are able to incorporate the family into nursing care. To determine family form and membership, ask who the patient considers family or with whom the patient shares strong emotional feelings. If the patient is unable to express a concept of family, ask with whom the patient lives, spends time, and shares confidences and then ask whether the patient considers them to be family or like family. To further assess the family structure, ask questions that determine the power structure and patterning of roles and tasks (e.g., "Who decides where to go on vacation?" "How are tasks divided in your family?" "Who mows the lawn?" "Who usually prepares the meals?").

You need to assess family functions such as the ability to provide emotional support for members, the ability to cope with current health problems or situations, and the appropriateness of its goal setting and progress toward achievement of developmental tasks (Fig. 10-2). Also determine whether the family is able to provide and distribute sufficient economic resources and whether its social network is extensive enough to provide support.

Always recognize and respect the family's cultural background (see Chapter 9). Culture is an important variable when assessing the family because race and ethnicity affect structure, function, health beliefs, values, and the way the family perceives events (Box 10-5). The United States is increasingly more diverse. A large number of immigrants enter the country daily, adding to both the number and variety of the many ethnic groups that make up the population. American health care institutions tend to operate from a white, middle-class perspective; and immigrant populations have particular difficulty understanding and "fitting into" the system. Cultural assessment educators encourage the use of a "culturagram," which allows you to assess and empower culturally diverse families and encourages ethnic-sensitive practice. This tool assesses a variety of factors such as language spoken in the home; impact of crisis events; and values regarding family, education, and work.

BOX 10-5 CULTURAL ASPECTS OF CARE

Family Nursing

Families have unique perspectives and characteristics, and they have differences in values, beliefs, and philosophies. The cultural heritage of the family or member of the family affects religious practices, childrearing practices, recreational activities, and nutritional preferences. You need to be culturally sensitive and respectful when caring for multicultural patients. Incorporate individualized cultural preferences into your plan of care so it is culturally congruent. Design your care to integrate the personal values, life patterns, and beliefs of the patient and family into prescribed therapies.

Implications for Practice

- The dominant culture in the United States encourages self-care; however, collectivistic cultures such as traditional Asians, Hispanics, and Africans rely on family members to care for the ill (Giger and Davidhizar, 2008).
- In some cultures, including Gypsy, Asian, Middle Eastern, and Hispanic, males are traditionally the authority figures.
- The family structure sometimes includes multiple generations living together. For example, traditional Hispanic and Filipino families include distant blood relatives from the maternal and paternal sides of the family.
- In some cultures such as traditional Chinese or Japanese cultures, it is the custom for family members to take care of the patient's needs (Galanti, 2008).
- Intergenerational support and patterns of living arrangements are related to cultural background. For example, traditional Chinese, African American, Japanese, and Hispanic persons are more likely to live in extended family households than are their white counterparts (Giger and Davidhizar, 2008).
- In some cultures it is a sign of elder disrespect to place older adults in nursing homes, even when an older adult family member has severe dementia.
- Modesty is a strong value among Arab cultures. Many Arab women bring female family members to health care visits, and a female health care provider must examine the woman.
- In the presence of a critical or terminal illness, some cultures such as Orthodox Jews come in groups to pray together with the family at the patient's bedside (Galanti, 2008).
- Health beliefs differ among various cultures, which affect the decision of a family and its members about when and where to seek help. For example, traditional Asians rarely consider symptoms as psychological and are not likely to go to mental health clinics.

Drawing conclusions based on cultural backgrounds requires critical thinking and careful consideration. It is imperative to remember that categorical generalizations are misleading (e.g., all Asian Americans are good at mathematics). As many caution, overgeneralizations in terms of racial and ethnic group characteristics do not lead to greater understanding of the culturally diverse family. Culturally different families vary in meaningful and significant ways; however, neglecting to examine similarities leads to inaccurate assumptions and stereotyping. For example, more similarities than differences exist in parenting behaviors among white, African American, Hispanic, and Asian American parents. In addition, Asian American families use alternative therapies for illnesses and ailments. Other cultures such as Latino prefer to stay with their family members during illness (see Chapter 9). A comprehensive, culturally sensitive family assessment is critical in order for you to understand family life, the current changes within it, and the family's overall goals and expectations. These data provide the foundation for family-centered nursing care (Anderson and Friedemann, 2010).

Family-Focused Care

Use a family-focused approach to enhance your nursing care. When you establish a relationship with a patient and his or her family, it is important to identify potential and external resources. A complete patient and family assessment provides this information. Together with patients and their families, develop plans of care that all members clearly understand and mutually agree to follow. Goals that you establish need to be concrete and realistic, compatible with a family's developmental stage, and acceptable to family members.

Collaboration with family members is essential, whether the family is the patient or the context of care. Collaborate closely with all appropriate family members when determining what they hope to achieve with regard to the family's health. You base a positive collaborative relationship on mutual respect and trust. The family needs to feel "in control" as much as possible. By offering alternative actions and asking family members for their own ideas and suggestions, you help to reduce the family's feelings of powerlessness. For example, offering options for how to prepare a low-fat diet or how to rearrange the furnishings of a room to accommodate a family member's disability gives the family an opportunity to express their preferences, make choices, and ultimately feel as though they have contributed. Collaborating with other disciplines increases the likelihood of a comprehensive approach to the family's health care needs, and it ensures better continuity of care. Using other disciplines is particularly important when discharge planning from a health care facility to home or an extended care facility is necessary (Bluvol and Ford-Gilboe, 2004).

When you view the family as the patient, you need to support communication among all family members. This ensures that the family remains informed about the goals and interventions for health care. Often you participate in conflict resolution between family members so each member is able to confront and resolve problems in a healthy way. Help the family identify and use external and internal resources as necessary. For example, who in the family can run errands to get groceries while the patient is unable to drive? Are there members from the church who can come and provide respite care? Ultimately your aim is to help the family reach a point of optimal function, given the family's resources, capacities, and desire to become healthier.

Challenges for Family Nursing

If a patient has been hospitalized or is in a rehabilitation setting, discharge planning begins with the initiation of care and includes the family. You are responsible for an accurate assessment of what will be needed for care in the home at the time of discharge, along with any shortcomings in the home setting. For example, if a postoperative patient is discharged to home and the older adult husband does not feel comfortable with the dressing changes required, you need to find out if anyone else in the family or neighborhood is willing and able to do this. If not, you will need to arrange for a home care service referral. If the patient also needs exercise and strength training, you consult with the primary health care provider to recommend referral for physical therapy.

Cultural sensitivity (see Chapter 9) in family nursing requires recognizing not only the diverse ethnic, cultural, and religious backgrounds of patients but also the differences and similarities within the same family. When providing family-centered care, recognize and integrate cultural practices, religious ceremonies, and rituals. Using effective and respectful communication techniques enables you to collaborate with the family to determine how best to integrate their beliefs and practices within the prescribed health care plan. For example, traditional Asian and Mexican American cultures frequently want to remain at the bedside around the clock and provide personal care for their loved ones. Integrating the family's values and needs into the care plan involves teaching family members how to provide simple direct care measures, thus providing culturally sensitive and competent care. Together the nurse and the family blend the cultural and health care needs of the patient.

Implementing Family-Centered Care

Whether caring for a patient with the family as context, directing care to the family as patient, or providing care to the family as a system, nursing interventions aim to increase family members' abilities in certain areas, remove barriers to health care, and do things that the family is not able to do for itself. Assist the family in problem solving, provide practical services, and express a sense of acceptance and caring by listening carefully to family members' concerns and suggestions.

One of the roles you need to adopt is that of educator. Health education is a process by which the nurse and patient share information in a two-way fashion (see Chapter 25). Sometimes you recognize family/patient needs for information through direct questioning, but the methods for recognizing these needs are generally far more subtle. For example, you recognize that a new father is fearful of cleaning his newborn's umbilical cord or that an older adult woman is not using her cane or walker safely. Respectful communication is necessary. Often you find the subtle needs for information by saying, "I notice you are trying to not touch the umbilical cord; I see that a lot." Or "You use the cane the way I did before I was shown a way to keep from falling or tripping over it; do you mind if I show you?" When you are confident and skillful instead of coming across as an authority on the subject, your patient's defenses are down, making the patient more willing to listen without feeling embarrassed. You will also recognize patient and family learning needs on the basis of the patient's health condition and physical and mental limitations. Your focus as an educator may become the family caregiver, so that he or she can become prepared to manage the skills and processes needed to manage the patient's needs within the home. When educating patients and families, identify the best time to provide accurate health information about diagnosis, necessary self-care activities, and the projected course of the patient's condition. Such information helps the family caregiver to interpret behavior correctly and not to "blame" the patient (Schumacher, Beck, and Marren, 2006a).

Health Promotion. Although the family is the basic social context in which members learn health behaviors, the primary focus on health promotion has traditionally been on individuals. When implementing family nursing, health promotion interventions improve or maintain the physical, social, emotional, and spiritual well-being of the family unit and its members (Duhamel, 2010; Rosenthal et al., 2008). Health promotion behaviors need to be tied to the developmental stage of the family (e.g., adequate prenatal care for the childbearing family or adherence to immunization schedules for the childrearing family). Your interventions should be designed to enable individual members and the total family to reach their optimal levels of wellness.

One approach for meeting goals and promoting health is the use of family strengths. Families do not often look at their own system as one that has inherent, positive components. Family strengths include clear communication, adaptability, healthy childrearing practices, support and nurturing among family members, the use of crisis for growth, a commitment to one

another and the family unit, and a sense of cohesiveness and spirituality (Schumacher, Beck, and Marren, 2006a). Help the family focus on their strengths instead of on problems and weaknesses. For example, point out that a couple's 10-year marriage has endured many crises and transitions. Therefore they are likely to be able to adapt to this latest challenge. Refer families to health promotion programs aimed at enhancing these attributes as needed. For example, some communities have low-cost fitness activities for school-age children designed to reduce the risk for obesity.

Acute Care. Because the family is becoming more of a focus in nursing care, you need to emphasize family needs within the context of today's health care delivery system. Be aware of the implication of early discharge for patients and their families. Remember that increasing numbers of people within the household are now being employed outside the home. These factors are challenges in preparing family members to assist with health care or locate appropriate community resources. Often when family members assume the role of caregiver, they lose support from significant others and are at risk for caregiver role strain (Schumacher, Beck, and Marren, 2006a). You need to be sure that families are willing to assume care responsibilities.

Family nursing requires a holistic view not only of the patient but also of the family. Nursing care in the acute environment is very complex, making it a challenge for the patient to feel cared for and to keep family members involved. A helpful tool is an independent journal in which patients and family members communicate their thoughts, ideas, and reactions. The patient or family members use the journal as an open communication tool, updating entries based on their needs and observations of the acute care experience. It is also helpful for a family member to use the journal as a record of care activities. It also provides data about when the patient was turned, who visited, when the last pain medication was administered, and any special patient requests. This information helps patients and families who are trying to "keep up" with what is happening in the acute care environment.

Restorative and Continuing Care. In restorative and continuing care settings the challenge in family nursing is in trying to maintain patients' functional abilities within the context of the family. This includes having home care nurses help patients remain in their homes following acute injuries or illnesses, surgery, or exacerbation of a chronic illness. It also requires finding ways to better the lives of chronically ill and disabled individuals and their families.

Family Caregiving. One way you provide family care is through support of family caregivers. In 2007, the economic value of family caregiving was estimated at $375 billion, which exceeded the total amount of 2007 Medicaid expenditures ($311 billion) and approached the total expenditures in Medicare ($432 billion) (AARP Public Policy Institute, 2008). Research shows that millions of Americans are taking on the burden of caregiving without acknowledging the effect that it has on their lives and without realizing that relief is available. Multiple national outreach programs such as the National Family Caregivers Association (www.thefamilycaregiver.org) and the National Alliance for Caregiving (www.caregiving.org) connect family caregivers to information and services that can help improve their lives and the level of care they can offer their loved ones.

Family caregiving is a family process that occurs in response to an illness and encompasses multiple cognitive, behavioral, and interpersonal processes (Schumacher et al., 2006b). It typically involves the routine provision of services and personal care activities for a family member by spouses, siblings, friends, or parents.

BOX 10-6 PATIENT TEACHING

Family Caregiving: Caregiver Role Strain

Objective

- Patient/family will design two interventions to reduce caregiver role strain.

Teaching Strategies

- Explain to all members of the family involved in caregiving that role strain may be present when the following occur:
  - There is a change in caregiver's appetite/weight, sleeping, or leisure activities. In addition, social withdrawal, irritability, anger, or changes in the caregiver's overall level of health can occur.
  - The caregiver is fearful when learning new therapies or administering new medications to the disabled/ill family member.
  - The caregiver loses interest in his or her personal appearance.
  - Signs of caregiver role strain may intensify if the loved one's health status changes or when institutional care is considered.
- Interventions for caregiver role strain
  - Help family members set up alternating schedules to give the primary caregiver some rest.
  - Design a schedule or other methods to provide groceries, meals, and housekeeping for the caregiver and patient.
  - Identify community resources for transportation, respite care, and support groups.
- Offer an opportunity to ask questions, and when possible provide a phone number for questions and assistance.
- Provide family members with the contact information of the patient's health care provider, and instruct them to call if the caregiver has health problems, the caregiver seems overly exhausted, or they observe changes in the caregiver's interactions and attention to normal activities.

Evaluation

- Ask the family to identify two to three indicators for caregiver role strain.
- Review with the family their plan to provide groceries, meals, and occasional respite care for the caregiver and patient.
- Ask the family where they keep the contact information of the patient's health care provider and when they would call the health care provider.

Caregiving activities include finding resources, providing personal care (bathing, feeding, or grooming), monitoring for complications or side effects of an illness or treatments, providing instrumental activities of daily living (shopping or housekeeping), and the ongoing emotional support and decision making that is necessary (Schumacher, Beck, and Marren, 2006a). Family caregiving can create caregiver burden and strain. The physical and emotional demands are high, and the disease itself creates changes in the family structure and roles. Family caregivers often feel ill prepared to take on the demands of care for their loved ones (Tamayo et al., 2010). Providing education to the family caregiver helps relieve some of the stress of caregiving (Box 10-6).

Whenever an individual becomes dependent on another family member for care and assistance, significant stress affects both the caregiver and the care recipient. In addition, the caregiver needs to continue to meet the demands of his or her usual lifestyle (e.g., raising children, working full time, or dealing with personal problems or illness). In many instances adult children, the sandwich generation, are trying to take care of their parents while meeting the needs of their own family (Box 10-7). Without adequate preparation and support from health care providers, caregiving puts the family at risk for serious problems, including a decline in the health

BOX 10-7 SANDWICH GENERATION

- Usually a daughter or daughter-in-law
- Conflicting responsibilities for aging parents, children, spouse, and job
- Frequently tries to "do it all"
- May not recognize need for help or request help
- May not pursue own health care
- Potential interventions:
  - Help families establish realistic priorities
  - Suggest that family members use family leave plans or obtain some "flex time" from their employer
  - Explore resources (e.g., deliveries for meals, respite care)

of the caregiver and that of the care receiver and dysfunctional and even abusive relationships (Schumacher, Beck, and Marren, 2006a; Tamayo et al., 2010).

Despite its demands, family caregiving can be a positive and rewarding experience. It is more than simply a series of tasks and usually occurs within the context of a family. Whether it is a wife caring for a husband or a daughter caring for a mother, caregiving is an interactional process. The interpersonal dynamics among family members influence the ultimate quality of caregiving. Thus the nurse plays a key role in helping family members develop better communication and problem-solving skills to build the relationships needed for caregiving to be successful (Stajduhar et al., 2008; Tamayo et al., 2010).

Variables such as caregiver and care-recipient expectations of one another influence caregiving quality. Carruth (1996) studied the concept of **reciprocity,** acknowledging the importance of the capability of care recipients to share exchanges that contribute to a caregiver's perception of self-worth. When the caregiver knows that the care recipient appreciates his or her efforts and values the assistance provided, a healthier and more satisfying caregiving relationship exists. When a caregiver and patient solve problems together, this helps them avoid overprotection or oversolicitous behavior. Patients feel in control of their care and responsible for care decisions. The caregiver also feels very positive and enjoys the caregiving experience (Isaksen, Thuen, and Hanestad, 2003).

Providing care and support for family caregivers enhances patient safety and involves using available family and community resources. Establishing a caregiving schedule that enables all family members to participate, helping patients to identify extended family members who can share any financial burdens posed by caregiving, and having distant relatives send cards and letters communicating their support is very helpful. However, it is imperative for you to understand the relationship between potential caregivers and care recipients. If the relationship is not a supportive one, community services are often a better resource for the patient and family.

Use of community resources includes locating a service required by the family or providing respite care so the family caregiver has time away from the care recipient. Examples of services that are beneficial to families include caregiver support groups, housing and transportation services, food and nutrition services, housecleaning, legal and financial services, home care, hospice, and mental health resources. Before referring a family to a community resource, it is critical that the nurse understand the family's dynamics and know whether the family wants support. Often a family caregiver resists help, feeling obligated to be the sole source of support to the care recipient. Be sensitive to family relationships and help caregivers understand the normalcy of caregiving demands. Given the appropriate resources, caregivers are able to acquire the skills and knowledge necessary to effectively care for their loved ones within the context of the home while maintaining rich and rewarding personal relationships.

KEY POINTS

- Family structure and functions influence the lives of its individual members.
- Family members influence one another's health beliefs, practices, and status.
- The concept of family is highly individual; care focuses on the patient's attitude toward the family rather than on an inflexible definition of family.
- The family's structure, functioning, and relative position in society significantly influence its health and ability to respond to health problems.
- A nurse can view the family in three ways: as context, as the patient, or as a system.
- Measures of family health involve more than a summary of individual members' health.
- Family members as caregivers are often spouses who are either older adults themselves or adult children trying to work full-time, care for aging parents, and launch teenagers successfully.
- Cultural sensitivity is vital to family nursing. Some members have differing beliefs, traditions, and restrictions, even within the same generation.
- Family caregiving is an interactive process that occurs within the context of the relationships among its members.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Kathy is a home health nurse working with the Kline family. This is a family of four: Carol, a 45-year-old single mother; her two adolescent sons, Matt and Kent; and Sara, her 76-year-old mother, who is in the last stages of Alzheimer's disease. The mother has lived with Carol and her children for 10 years. Sara was a great support to Carol when her husband died 11 years ago. She helped Carol raise Matt and Kent. The family has decided to care for Sara in the home until she dies. Kathy is helping the family care for Sara in the home.

1. What type of assessments are important to determine family functioning and structure?
2. What should Kathy assess to determine how the family can achieve their goal of caring for Sara?
3. How does Kathy help the family determine their strengths, weaknesses, and resources?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The Collins family includes a mother, Jean; stepfather, Adam; two teenage biological daughters of the mother, Lisa and Laura; and a biological daughter of the father, 25-year-old Stacey. Stacey just moved home following the loss of her job in another city. The family is converting a study into Stacey's bedroom and is in the process of distributing household

chores. When you talk to members of the family, they all think that their family can adjust to lifestyle changes. This is an example of family:
1. Diversity.
2. Durability.
3. Resiliency.
4. Configuration.

2. The most common reason grandparents are called on to raise their grandchildren is because of:
1. Single parenthood.
2. Legal interventions.
3. Dual-income families.
4. Increased divorce rate.

3. A family's access to adequate health care, opportunity for education, sound nutrition, and decreased stress is affected by:
1. Development.
2. Family function.
3. Family structure.
4. Economic stability.

4. David Singer is a single parent of a 3-year-old boy, Kevin. Kevin has well-managed asthma and misses day care infrequently. David is in school studying to be an information technology professional. His income and time are limited, and he admits to going to fast-food restaurants frequently for dinner. However, he and his son spend a lot of time together. David receives state-supported health care for his son, but he does not have health insurance or a personal physician. He has his son enrolled in a government-assisted day care program. Which of the following are risks to this family's level of health? (Select all that apply.)
1. Economic status
2. Chronic illness
3. Underinsured
4. Government-assisted day care

5. The Cleric family, which includes a mother, stepfather, two teenage biological daughters of the mother, and a biological daughter of the father is an example of a(n):
1. Nuclear family.
2. Blended family.
3. Extended family.
4. Alternative family.

6. Which of the following are possible outcomes with clear family communication? (Select all that apply.)
1. Family goals
2. Decision making
3. Methods of discipline
4. Impaired coping

7. Communication among family members is an example of family:
1. Attributes.
2. Function.
3. Structure.
4. Development.

8. Which of the following contribute to family hardiness? (Select all that apply.)
1. Family meetings
2. Established family roles
3. Willingness to change in time of stress
4. Passive orientation to life

9. Which of the following demonstrate family resiliency? (Select all that apply.)
1. Resuming full-time work when spouse loses job
2. Arguing ways to deal with problems among siblings
3. Developing hobbies when children leave home
4. Placing blame on family members

10. When nurses view the family as context, their primary focus is on the:
1. Family members within a system.
2. Family process and relationships.
3. Family relational and transactional concepts.
4. Health needs of an individual member.

11. Diane is a hospice nurse who is caring for the Robinson family. This family is providing end-of-life care for their grandmother, who has terminal breast cancer. When Diane visits the home 3 times a week, she focuses on symptom management for the grandmother and assists the family with coping skills. Diane's approach is an example of which of the following?
1. Family as context
2. Family as patient
3. Family as system
4. Family as structure

12. Which of the following are included in a family function assessment? (Select all that apply.)
1. Cultural practices
2. Decision making
3. Rituals and celebrations
4. Neighborhood crime data

13. Karen Johnson is a single mother of a school-age daughter. Linda Brown is also a single mother of two teenage daughters. Karen and Linda are active professionals, have busy social lives, and date occasionally. Three years ago they decided to share a house and housing costs, living expenses, and child care responsibilities. The children consider one another as their family. This family form is considered a(n):
1. Diverse family relationship.
2. Blended family relationship.s
3. Extended family relationship.
4. Alternative family relationship.

14. During a visit to a family clinic the nurse teaches the mother about immunizations, car seat use, and home safety for an infant and toddler. Which type of nursing interventions are these?
1. Health promotion activities
2. Acute care activities
3. Restorative care activities
4. Growth and development–care activities

15. Which best defines family caregiving? (Select all that apply.)
1. Designing a nurturing family to raise children
2. Providing physical and emotional care for a family member
3. Establishing a safe physical environment for a family
4. Monitoring for side effects of illness and treatments

Developmental Theories

OBJECTIVES

- Discuss factors influencing growth and development.
- Describe biophysical developmental theories.
- Describe and compare the psychoanalytical/psychosocial theories proposed by Freud and Erikson.
- Describe Piaget's theory of cognitive development.
- Apply developmental theories when planning interventions in the care of patients throughout the life span.
- Discuss nursing implications for the application of developmental principles to patient care.

KEY TERMS

Biophysical development, p. 131
Conventional reasoning, p. 135
Erikson's theory of psychosocial development, p. 132
Freud's psychoanalytical model of personality development, p. 131
Kohlberg's theory of moral development, p. 135
Piaget's theory of cognitive development, p. 134
Postconventional reasoning, p. 136
Temperament, p. 133

Understanding normal growth and development helps nurses predict, prevent, and detect deviations from patients' own expected patterns. Growth encompasses the physical changes that occur from the prenatal period through older adulthood and also demonstrates both advancement and deterioration. Young children grow more quickly than older children, and by adulthood growth in height ceases. In late adulthood there is a loss of both muscle and bone, which may cause a decrease in height in some people (Santrock, 2009). Development refers to the biological, cognitive, and socioemotional changes that begin at conception and continue throughout a lifetime. Development is dynamic and includes progression. However, in some disease processes development is delayed or regresses. For example, older adults demonstrate cognitive development resulting in wisdom as they incorporate life experiences into decision making, but they do not perform as well as young adults when speed is required for information processing (Santrock, 2008).

Individuals have unique patterns of growth and development. The ability to progress through each developmental phase influences the overall health of the individual. The success or failure experienced within a phase affects the ability to complete subsequent phases. If individuals experience repeated developmental failures, inadequacies sometimes result. However, when the individual experiences repeated successes, health is promoted. For example, a child who does not walk by 20 months may demonstrate delayed gross motor ability that slows exploration and manipulation of the environment. In contrast, a child who walks by 10 months is able to explore and find stimulation in the environment.

Today nurses need to adopt a life span perspective of human development that takes into account all developmental stages of life. Traditionally development focused on childhood, but a comprehensive view of development also includes the changes that occur during the adult years. An understanding of growth and development throughout the life span assists in planning questions for health screening and health history and in health teaching for patients of all ages.

DEVELOPMENTAL THEORIES

Developmental theories provide a framework for examining, describing, and appreciating human development. For example, knowledge of Erikson's psychosocial theory of development helps caregivers understand the importance of supporting the development of basic trust in the infancy stage. Trust establishes the foundation for all future relationships. Developmental theories are also important in helping nurses assess and treat a person's response to an illness. Understanding the specific task or need of each developmental stage guides caregivers in planning appropriate individualized care for patients. Specific developmental theories that define the aging process for adults are discussed in Chapters 13 and 14.

Human development is a dynamic and complex process that cannot be explained by only one theory. This chapter presents

biophysical, psychoanalytical/psychosocial, cognitive, and moral developmental theories. Chapters 25 and 35 cover the areas of learning theory for patient teaching and spiritual development.

Biophysical Developmental Theories

Biophysical development is how our physical bodies grow and change. Health care providers are able to quantify and compare the changes that occur as a newborn infant grows into adulthood against established norms. How does the physical body age? What are the triggers that move the body from the physical characteristics of childhood, through adolescence, to the physical changes of adulthood?

Gesell's Theory of Development. Fundamental to Gesell's theory of development is that each child's pattern of growth is unique and this pattern is directed by gene activity (Gesell, 1948). Gesell found the pattern of maturation follows a fixed developmental sequence in humans. Sequential development is evident in fetuses, in which there is a specified order of organ system development. Today we know that growth in humans is both cephalocaudal and proximodistal. The cephalocaudal pattern describes the sequence in which growth is fastest at the top (head and then down); proximodistal growth starts at the center of the body and moves toward the extremities.

Genes direct the sequence of development; but environmental factors also influence development, resulting in developmental changes. For example, genes may direct the growth rate for an individual, but that growth is only maximized if environmental conditions are adequate. Poor nutrition or chronic disease often affects the growth rate and results in smaller stature, regardless of the genetic blueprint. However, adequate nutrition and the absence of disease cannot result in stature beyond that determined by heredity.

Psychoanalytical/Psychosocial Theory

Theories of psychoanalytical/psychosocial development describe human development from the perspectives of personality, thinking, and behavior (Table 11-1). Psychoanalytical theory explains development as primarily unconscious and influenced by emotion. Psychoanalytical theorists maintain that these unconscious drives influence development through universal stages experienced by all individuals (Berger, 2007).

Sigmund Freud. **Freud's psychoanalytical model of personality development** states that individuals go through five stages of psychosexual development and that each stage is characterized by sexual pleasure in parts of the body: the mouth, the anus, and the genitals. Freud believed that adult personality is the result of how an individual resolved conflicts between these sources of pleasure and the mandates of reality (Berger, 2007; Santrock, 2009).

Stage 1: Oral (Birth to 12 to 18 Months). Initially sucking and oral satisfaction are not only vital to life but also extremely pleasurable in their own rights. Late in this stage the infant begins to realize that the mother/parent is something separate from self. Disruption in the physical or emotional availability of the parent (e.g., inadequate bonding or chronic illness) could affect an infant's development.

Stage 2: Anal (12 to 18 Months to 3 Years). The focus of pleasure changes to the anal zone. Children become increasingly aware of the pleasurable sensations of this body region with interest in the products of their effort. Through the toilet-training process the child delays gratification to meet parental and societal expectations.

Stage 3: Phallic or Oedipal (3 to 6 Years). The genital organs are the focus of pleasure during this stage. The boy becomes interested in the penis; the girl becomes aware of the absence of the penis, known as *penis envy*. This is a time of exploration and imagination as the child fantasizes about the parent of the opposite sex as his or her first love interest, known as the *Oedipus* or *Electra complex*. By the end of this stage the child attempts to reduce this conflict by identifying with the parent of the same sex as a way to win recognition and acceptance.

Stage 4: Latency (6 to 12 Years). In this stage Freud believed that sexual urges from the earlier oedipal stage are repressed and channeled into productive activities that are socially acceptable. Within the educational and social worlds of the child, there is much to learn and accomplish.

Stage 5: Genital (Puberty Through Adulthood). In this final stage sexual urges reawaken and are directed to an individual outside the family circle. Unresolved prior conflicts surface during adolescence. Once the individual resolves conflicts, he or she is then capable of having a mature adult sexual relationship.

Freud believed that the components of the human personality develop in stages and regulate behavior. These components are the

TABLE 11-1 Comparison of Major Developmental Theories

DEVELOPMENTAL STAGE/AGE	FREUD (PSYCHOSEXUAL DEVELOPMENT)	ERIKSON (PSYCHOSOCIAL DEVELOPMENT)	PIAGET (COGNITIVE/ MORAL DEVELOPMENT)	KOHLBERG (DEVELOPMENT OF MORAL REASONING)
Infancy (birth to 18 months)	Oral stage	Trust vs. mistrust Ability to trust others	Sensorimotor period Progress from reflex activity to simple repetitive actions	
Early childhood/toddler (18 months to 3 years)	Anal stage	Autonomy vs. shame and doubt Self-control and independence	Preoperational period—thinking using symbols Egocentric	Preconventional level Punishment-obedience orientation
Preschool (3-5 years)	Phallic stage	Initiative vs. guilt Highly imaginative	Use of symbols Egocentric	Preconventional level Premoral Instrumental orientation
Middle childhood (6-12 years)	Latent stage	Industry vs. inferiority Engaged in tasks and activities	Concrete operations period Logical thinking	Conventional level Good boy–nice girl orientation
Adolescence (12-19 years)	Genital stage	Identity vs. role confusion Sexual maturity, "Who am I?"	Formal operations period Abstract thinking	Postconventional level Social contract orientation

id, the ego, and the superego. The id (i.e., basic instinctual impulses driven to achieve pleasure) is the most primitive part of the personality and originates in the infant. The ego represents the reality component, mediating conflicts between the environment and the forces of the id. The ego helps people judge reality accurately, regulate impulses, and make good decisions. The third component, the superego, performs regulating, restraining, and prohibiting actions. Often referred to as the conscience, the superego is influenced by the standards of outside social forces (e.g., parent or teacher).

Some of Freud's critics contend that he based his analysis of personality development on biological determinants and ignored the influence of culture and experience. Other critics think that Freud's basic assumptions such as the Oedipus complex are not applicable across different cultures. Psychoanalysts today believe that the role of conscious thought is much greater than Freud imagined (Santrock, 2008).

Erik Erikson. Freud had a strong influence on his psychoanalytical followers, including Erik Erikson (1902-1994), who constructed a theory of development that differed from Freud's in two major views. Erikson maintained that development occurred throughout the life span and that it focused on psychosocial stages rather than psychosexual stages.

According to **Erikson's theory of psychosocial development,** individuals need to accomplish a particular task before successfully mastering the stage and progressing to the next one. Each task is framed with opposing conflicts, and tasks once mastered are challenged and tested again during new situations or at times of conflict (Hockenberry and Wilson, 2011). Erikson's eight stages of life are described here.

Trust versus Mistrust (Birth to 1 Year). Establishing a basic sense of trust is essential for the development of a healthy personality. The infant's successful resolution of this stage requires a consistent caregiver who is available to meet his needs. From this basic trust in parents, the infant is able to trust in himself, in others, and in the world (Hockenberry and Wilson, 2011). The formation of trust results in faith and optimism. A nurse's use of anticipatory guidance helps parents cope with the hospitalization of an infant and the infant's behaviors when discharged to home.

Autonomy versus Sense of Shame and Doubt (1 to 3 Years). By this stage a growing child is more accomplished in some basic self-care activities, including walking, feeding, and toileting. This newfound independence is the result of maturation and imitation. The toddler develops his or her autonomy by making choices. Choices typical for the toddler age-group include activities related to relationships, desires, and playthings. There is also opportunity to learn that parents and society have expectations about these choices. Limiting choices and/or enacting harsh punishment leads to feelings of shame and doubt. The toddler who successfully masters this stage achieves self-control and willpower. The nurse models empathetic guidance that offers support for and understanding of the challenges of this stage.

Initiative versus Guilt (3 to 6 Years). Children like to pretend and try out new roles. Fantasy and imagination allow them to further explore their environment. Also at this time they are developing their superego, or conscience. Conflicts often occur between the child's desire to explore and the limits placed on his or her behavior. These conflicts sometimes lead to feelings of frustration and guilt. Guilt also occurs if the caregiver's responses are too harsh. Preschoolers are learning to maintain a sense of initiative without imposing on the freedoms of others. Successful resolution of this stage results in direction and purpose. Teaching the child impulse control and cooperative behaviors helps the family avoid the risks of altered growth and development.

Industry versus Inferiority (6 to 11 Years). School-age children are eager to apply themselves to learning socially productive skills and tools. They learn to work and play with their peers. They thrive on their accomplishments and praise. Without proper support for learning new skills or if skills are too difficult, they develop a sense of inadequacy and inferiority. Children at this age need to be able to experience real achievement to develop a sense of competency. Erikson believed that the adult's attitudes toward work are traced to successful achievement of this task (Erikson, 1963). During hospitalization it is important for the school-age child to understand the routines and participate as actively as possible in his or her treatment. For example, some children enjoy keeping a record of their intake and output.

Identity versus Role Confusion (Puberty). Dramatic physiological changes associated with sexual maturation mark this stage. There is a marked preoccupation with appearance and body image. This stage, in which identity development begins with the goal of achieving some perspective or direction, answers the question, "Who am I?" Acquiring a sense of identity is essential for making adult decisions such as choice of a vocation or marriage partner. Each adolescent moves in his or her unique way into society as an interdependent member. There are also new social demands, opportunities, and conflicts that relate to the emergent identity and separation from family. Erikson held that successful mastery of this stage resulted in devotion and fidelity to others and to their own ideals (Hockenberry and Wilson, 2011). The nurse provides education and anticipatory guidance for the parent about the changes and challenges to the adolescent. Nurses also help hospitalized adolescents deal with their illness by giving them enough information to allow them to make decisions about their treatment plan.

Intimacy versus Isolation (Young Adult). Young adults, having developed a sense of identity, deepen their capacity to love others and care for them. They search for meaningful friendships and an intimate relationship with another person. Erikson portrayed intimacy as finding the self and then losing the self in another (Santrock, 2008). If the young adult is not able to establish companionship and intimacy, isolation results because he or she fears rejection and disappointment (Berger, 2007). Nurses must understand that hospitalization increases a young adults' need for intimacy; thus young adults benefit from the support of their partner or significant other during this time.

Generativity versus Self-Absorption and Stagnation (Middle Age). Following the development of an intimate relationship, the adult focuses on supporting future generations. The ability to expand one's personal and social involvement is critical to this stage of development. Middle-age adults achieve success in this stage by contributing to future generations through parenthood, teaching, and community involvement. Achieving generativity results in caring for others as a basic strength. Inability to play a role in the development of the next generation results in stagnation (Santrock, 2008). Nurses assist physically ill adults in choosing creative ways to foster social development. Middle-age persons often find a sense of fulfillment by volunteering in a local school, hospital, or church.

Integrity versus Despair (Old Age). Many older adults review their lives with a sense of satisfaction, even with their inevitable mistakes. Others see themselves as failures, with their lives marked by despair and regret. Older adults often engage in a retrospective appraisal of their lives. They interpret their lives as a meaningful whole or experience regret because of goals not achieved (Berger, 2007). Because the aging process creates physical and social losses,

FIG. 11-1 Quilting keeps this older adult active.

some adults also suffer loss of status and function (e.g., through retirement or illness). These external struggles are also met with internal struggles such as the search for meaning in life. Meeting these challenges creates the potential for growth and the basic strength of wisdom (Fig. 11-1).

Nurses are in positions of influence within their communities to help people feel valued, appreciated, and needed. Erikson stated, "Healthy children will not fear life, if their parents have integrity enough not to fear death" (Erikson, 1963). Although Erikson believed that problems in adult life resulted from unsuccessful resolution of earlier stages, his emphasis on family relationships and culture offered a broad, life-span view of development. As a nurse, you will use this knowledge of development as you deliver care in any health care setting.

Theories Related to Temperament. Temperament is a behavioral style that affects an individual's emotional interactions with others (Santrock, 2008). Personality and temperament are often closely linked, and research shows that individuals possess some enduring characteristics into adulthood. The individual differences that children display in responding to their environment significantly influence the way others respond to them and their needs. Knowledge of temperament helps parents better understand their child (Hockenberry and Wilson, 2011).

Psychiatrists Stella Chess (1914-2007) and Alexander Thomas (1914-2003) conducted a 20-year longitudinal study that identified three basic classes of temperament:

- *The easy child*—Easygoing and even-tempered. This child is regular and predictable in his or her habits. An easy child is open and adaptable to change and displays a mild-to–moderately intense mood that is typically positive.
- *The difficult child*—Highly active, irritable, and irregular in habits. Negative withdrawal toward others is typical, and the child requires a more structured environment. A difficult child adapts slowly to new routines, people, or situations. Mood expressions are usually intense and primarily negative.
- *The slow-to–warm up child*—Typically reacts negatively and with mild intensity to new stimuli. The child adapts slowly with repeated contact unless pressured and responds with mild but passive resistance to novelty or changes in routine.

Research on temperament and its stability has continued, with an emphasis on the individual's ability to make thoughtful decisions about behavior in demanding situations. Knowledge of temperament and how it impacts the parent-child relationship is critical when providing anticipatory guidance for parents. With the birth of a second child, most parents find that the strategies that worked well with the first child no longer work at all. The nurse individualizes counseling to greatly improve the quality of interactions between parents and children (Hockenberry and Wilson, 2011).

Perspectives on Adult Development

Early study of development focused only on childhood because scholars throughout history regarded the aging process as one of inevitable and irreversible decline. However, we now know that, although the changes come more slowly, people continue to develop new abilities and adapt to shifting environments. The life span perspective suggests that understanding adult development requires multiple viewpoints. Two of the ways that researchers have studied adult development are through the stage-crisis view and the life span approach. The most well-known stage theory is the one developed by Erik Erikson that was discussed earlier. Another stage theory that contributed to understanding development throughout the life span was provided through the work of Robert Havinghurst.

Stage-Crisis Theory. Physicist, educator, and aging expert Robert Havinghurst (1900-1991) conducted extensive research and developed a theory of human development based on developmental tasks. Havinghurst's theory incorporates three primary sources for developmental tasks: tasks that surface because of physical maturation, tasks that evolve from personal values, and tasks that are a result of pressures from society. As with Erikson, Havinghurst believed that successful resolution of the developmental task was essential to successful progression throughout life. He identified six stages and six-to-ten developmental tasks for each stage: infancy and early childhood (birth to age 6), middle childhood (6 to 12 years), adolescence (13 to 18 years), early adulthood (19 to 30 years), middle adulthood (30 to 60 years), and late adulthood (60 and over). Havinghurst believed that the number of tasks differs in each age level for individuals because of the interrelationship among biology, society, and personal values. In later years Havinghurst turned his focus to the study of aging. In response to the view that older adults should gradually withdraw from society, Havinghurst proposed an *activity theory,* which states that continuing an active, involved lifestyle results in greater satisfaction and well-being in aging (see Chapter 14).

Life Span Approach. The contemporary life-events approach takes into consideration the variations that occur for each individual. This view considers the individual's personal circumstances (health and family support), how the person views and adjusts to changes, and the current social and historical context in which the individual is living (Santrock, 2009). Contemporary theorists such as Paul Baltes (1939-2006) and Laura Carstensen (1954-) have continued to study development in adulthood and proposed theories that support the need for a balance between the pursuit of active engagement and selection of activities that support personal enjoyment for successful aging. The selective optimization with compensation theory (Baltes, Freund, and Li, 2005) is based on the concept that, as individuals age, they are able to compensate for some decreases in physical or cognitive performance by developing new approaches. They are also able to optimize performance in some areas through continued practice or the use of new technology. Carstensen, Isaacowitz, and Charles (1999) developed the

socioemotional selectivity theory suggesting that, as people age, they become more selective and invest their energies in meaningful relationships, goals, and activities. Current research on successful aging is much more consistent with a life span approach that emphasizes age-related goals that are relationship and socially oriented to support continued well-being (Reichstadt et al., 2010).

Cognitive Developmental Theory

Psychoanalytical/psychosocial theories focus on an individual's unconscious thought and emotions; cognitive theories stress how people learn to think and make sense of their world. As with personality development, cognitive theorists have explored both childhood and adulthood. Some of the theories highlight qualitative changes in thinking; others expand to include social, cultural, and behavioral dimensions.

Jean Piaget. Jean Piaget (1896-1980) was most interested in the development of children's intellectual organization: how they think, reason, and perceive the world. **Piaget's theory of cognitive development** includes four periods that are related to age and demonstrate specific categories of knowing and understanding. He built his theory on years of observing children as they explored, manipulated, and tried to make sense out of the world in which they lived. Piaget believed that individuals move from one stage to the other seeking cognitive equilibrium or a state of mental balance (Santrock, 2009). Within each of these primary periods of cognitive development are specific stages (see Table 11-1).

Period I: Sensorimotor (Birth to 2 Years). Infants develop a schema or action pattern for dealing with the environment. These schemas include hitting, looking, grasping, or kicking. Schemas become self-initiated activities (e.g., the infant learning that sucking achieves a pleasing result generalizes the action to suck fingers, blanket, or clothing). Successful achievement leads to greater exploration. During this stage the child learns about himself and his environment through motor and reflex actions. He or she learns that he or she is separate from the environment and that aspects of the environment (e.g., parents or favorite toy) continue to exist even though they cannot always be seen. Piaget termed this understanding that objects continue to exist even when they cannot be seen, heard, or touched *object permanence* and considered it one of the child's most important accomplishments.

Period II: Preoperational (2 to 7 Years). During this time children learn to think with the use of symbols and mental images. They exhibit "egocentrism" in that they see objects and persons from only one point of view, their own. They believe that everyone experiences the world exactly as they do. Early in this stage children demonstrate "animism" in which they personify objects. They believe that inanimate objects have lifelike thought, wishes, and feelings. Their thinking is influenced greatly by fantasy and magical thinking. Children at this stage have difficulty conceptualizing time. Play becomes a primary means by which they foster their cognitive development and learn about the world (Fig. 11-2). Nursing interventions during this period recognize the use of play as the way the child understands the events taking place.

Period III: Concrete Operations (7 to 11 Years). Children now are able to perform mental operations. For example, the child thinks about an action that before was performed physically. Children are now able to describe a process without actually doing it. At this time they are able to coordinate two concrete perspectives in social and scientific thinking so they are able to appreciate the difference between their perspective and that of a friend. Reversibility is one of the primary characteristics of concrete operational thought. Children can now mentally picture a series of steps and reverse the steps to get back to the starting point. The ability to mentally classify objects according to their quantitative dimensions, known as *seriation,* is achieved. They are able to correctly order or sort objects by length, weight, or other characteristics. Another major accomplishment of this stage is conservation, or the ability to see objects or quantities as remaining the same despite a change in their physical appearance (Santrock, 2009).

FIG. 11-2 Play is important to a child's development.

Period IV: Formal Operations (11 Years to Adulthood). The transition from concrete to formal operational thinking occurs in stages during which there is a prevalence of egocentric thought. This egocentricity leads adolescents to demonstrate feelings and behaviors characterized by self-consciousness, a belief that their actions and appearance are constantly being scrutinized (an "imaginary audience"), that their thoughts and feelings are unique (the "personal fable"), and that they are invulnerable (Santrock, 2008). These feelings of invulnerability frequently lead to risk-taking behaviors, especially in early adolescence. As adolescents share experiences with peers, they learn that many of their thoughts and feelings are shared by almost everyone, helping them to know that they are not so different. As adolescents mature, their thinking moves to abstract and theoretical subjects. They have the capacity to reason with respect to possibilities. For Piaget this stage marked the end of cognitive development.

Piaget's work has been challenged over the years as researchers have continued to study cognitive development. For example, some aspects of objective performance emerge earlier than Piaget believed, and other cognitive abilities can surface later than he predicted. We now know that many adults may not become formal operational thinkers and others have cognitive development that goes beyond the stages that Piaget proposed (Santrock, 2009). Assessment of cognitive ability becomes critical as the nurse engages in health care teaching for patients and families.

Research in Adult Cognitive Development. Research into cognitive development in adulthood began in the 1970s and continues today. Research supports that adults do not always arrive at one answer to a problem but frequently accept several possible solutions. Adults also incorporate emotions, logic, practicality, and flexibility when making decisions. On the basis of these observations, developmentalists proposed a fifth stage of cognitive development termed *postformal thought*. Within this stage adults

BOX 11-1 EVIDENCE-BASED PRACTICE

Applying Developmental Theory to Care of Chronically Ill Older Adults

PICO Question: Among older adult patients diagnosed with heart failure (HF), does screening for depression result in improved quality of life and improved physical symptoms?

Evidence Summary

Neglect of physical health, increased symptoms from chronic illness, and forgetfulness are frequently attributed to the aging process. However, older adults do not withdraw from society or lose their cognitive abilities as part of their normal development. Depression among older adults is common, especially in those with a chronic illness such as HF. Research has found the prevalence of depression in these individuals to be as high as 58% among hospitalized patients and up to 48% in those receiving outpatient treatments (Hägglund et al., 2008). Depression often contributes to poor physical and emotional health outcomes and is a major risk factor for poor prognosis and high mortality rates in patients with HF (Cully et al., 2010). It is difficult at times to differentiate between symptoms of depression and worsening signs of HF, especially fatigue. In a study conducted with older adults who were diagnosed with HF and those without HF but who reported general fatigue and reduced activity, the researchers found no difference in the prevalence of depression (Hägglund et al., 2008). Others have noted that, since physical disorders increase with age independent of depression, the decreased diagnosis of depression in older adults is sometimes a result of confusing depression with physical symptoms and lack of screening for depression (Kessler et al., 2010).

Screening for depression as part of the overall health assessment leads to treatment that would greatly improve older adults' physical, social, and emotional functioning. It is important that nurses apply developmental theory and recognize the need to identify depression so appropriate treatment can be provided.

Application to Nursing Practice

- Be aware of the symptoms of depression such as general fatigue or insomnia since older adults and family members may attribute these signs to "old age" and not recognize the potential for treatment.
- Understanding adult development and its implications for practice is essential in providing nursing care for older adult patients.
- Understanding the older adult's concept of depression and views on treatment for mental illness helps you explain complementary and alternative treatment measures.

demonstrate the ability to recognize that answers vary from situation to situation and that solutions need to be sensible.

One of the earliest to develop a theory of adult cognition was William Perry (1913-1998), who studied college students and found that continued cognitive development involved increasing cognitive flexibility. As adolescents were able to move from a position of accepting only one answer to realizing that alternative explanations could be right, depending on one's perspective, there was a significant cognitive change. Adults change how they use knowledge, and the emphasis shifts from attaining knowledge or skills to using knowledge for goal achievement (Box 11-1).

Moral Developmental Theory

Moral development refers to the changes in a person's thoughts, emotions, and behaviors that influence beliefs about what is right or wrong. It encompasses both *interpersonal* and *intrapersonal* dimensions as it governs how we interact with others (Santrock, 2009). Although various psychosocial and cognitive theorists address moral development within their respective theories, the theories of Piaget and Kohlberg are more widely known (see Table 11-1).

Lawrence Kohlberg's Theory of Moral Development. **Kohlberg's theory of moral development** expands on Piaget's cognitive theory. Kohlberg interviewed children, adolescents, and eventually adults and found that moral reasoning develops in stages. From an examination of responses to a series of moral dilemmas, he identified six stages of moral development under three levels (Kohlberg, 1981).

Level I: Preconventional Reasoning. This is the premoral level, in which there is limited cognitive thinking and the individual's thinking is primarily egocentric. At this stage thinking is mostly based on likes and pleasures. This stage progresses toward having punishment guide behavior. The person's moral reason for acting, the "why," eventually relates to the consequences that the person believes will occur. These consequences come in the form of punishment or reward. It is at this level that children view illness as a punishment for fighting with their siblings or disobeying their parents. Nurses need to be aware of this egocentric thinking and reinforce that the child does not become ill because of wrongdoing.

Stage 1: Punishment and Obedience Orientation. In this first stage a child's response to a moral dilemma is in terms of absolute obedience to authority and rules. A child in this stage reasons, "I must follow the rules; otherwise I will be punished." Avoiding punishment or the unquestioning deference to authority is characteristic motivation to behave. Physical consequences guide right and wrong choices. If the child is caught, it must be wrong; if he or she escapes, it must be right.

Stage 2: Instrumental Relativist Orientation. In this stage the child recognizes that there is more than one right view; a teacher has one view that is different from that of the child's parent. The decision to do something morally right is based on satisfying one's own needs and occasionally the needs of others. The child perceives punishment not as proof of being wrong (as in stage 1) but as something that one wants to avoid. Children at this stage follow their parent's rule about being home in time for supper because they do not want to be confined to their room for the rest of the evening if they are late.

Level II: Conventional Reasoning. At level II, **conventional reasoning,** the person sees moral reasoning based on his or her own personal internalization of societal and others' expectations. A person wants to fulfill the expectations of the family, group, or nation and also develop a loyalty to and actively maintain, support, and justify the order. Moral decision making at this level moves from, "What's in it for me?" to "How will it affect my relationships with others?" Emphasis now is on social rules and a community-centered approach (Berger, 2007). Nurses observe this when family members make end-of-life decisions for their loved ones. Individual members often struggle with this type of moral dilemma. Grief support involves an understanding of the level of moral decision making of each family member (see Chapter 36).

Stage 3: Good Boy–Nice Girl Orientation. The individual wants to win approval and maintain the expectations of one's immediate group. "Being good" is important and defined as having good motives, showing concern for others, and keeping mutual relationships through trust, loyalty, respect, and gratitude. One earns approval by "being nice." For example, a person in this stage stays after school and does odd jobs to win the teacher's approval.

Stage 4: Society-Maintaining Orientation. Individuals expand their focus from a relationship with others to societal concerns

during stage 4. Moral decisions take into account societal perspectives. Right behavior is doing one's duty, showing respect for authority, and maintaining the social order. Adolescents choose not to attend a party where they know beer will be served, not because they are afraid of getting caught, but because they know that it is not right.

Level III: Postconventional Reasoning. The person finds a balance between basic human rights and obligations and societal rules and regulations in the level of **postconventional reasoning.** Individuals move away from moral decisions based on authority or conformity to groups to define their own moral values and principles. Individuals at this stage start to look at what an ideal society would be like. Moral principles and ideals come into prominence at this level (Berger, 2007).

Stage 5: Social Contract Orientation. Having reached stage 5, an individual follows the societal law but recognizes the possibility of changing the law to improve society. The individual also recognizes that different social groups have different values but believes that all rational people would agree on basic rights such as liberty and life. Individuals at this stage make more of an independent effort to determine what society *should* value rather than what the society as a group *would* value, as would occur in stage 4. The United States Constitution is based on this morality.

Stage 6: Universal Ethical Principle Orientation. Stage 6 defines "right" by the decision of conscience in accord with self-chosen ethical principles. These principles are abstract, like the Golden Rule, and appeal to logical comprehensiveness, universality, and consistency (Kohlberg, 1981). For example, the principle of justice requires the individual to treat everyone in an impartial manner, respecting the basic dignity of all people, and guides the individual to base decisions on an equal respect for all. Civil disobedience is one way to distinguish Stage 5 from Stage 6. Stage 5 emphasizes the basic rights, the democratic process, and following laws without question, whereas stage 6 defines the principles by which agreements will be most just. For example, a person in stage 5 follows a law, even if it is not fair to a certain racial group. An individual in stage 6 may not follow a law if it does not seem just to the racial group. For example, Martin Luther King believed that although we need laws and democratic processes, people who are committed to justice have an obligation to disobey unjust laws and accept the penalties for disobeying these laws (Crain, 1985).

Kohlberg's Critics. Kohlberg constructed a systemized way of looking at moral development and is recognized as a leader in moral developmental theory. However, critics of his work raise questions about his choice of research subjects. For example, most of Kohlberg's subjects were males raised in Western philosophical traditions. Research attempting to support Kohlberg's theory with individuals raised in the Eastern philosophies found that individuals raised in Eastern philosophies never rose above stages 3 or 4 of Kohlberg's model. To some, these findings suggest that people from Eastern philosophies have not reached higher levels of moral development, which is untrue. Others believe Kohlberg's research design did not allow a way to measure those raised within a different culture.

Kohlberg has also been criticized for age and gender bias. Carol Gilligan, an associate, criticizes Kohlberg for his gender biases. She believes that he developed his theory based on a justice perspective that focused on the rights of individuals. In contrast, Gilligan's research looked at moral development from a care perspective that viewed people in their interpersonal communications, relationships, and concern for others (Santrock, 2009). She believes that females are socialized to be nurturing and caring and thus are reluctant to make judgments based solely on justice (Berger, 2007). Other researchers have examined Gilligan's theory in studies with children and have not found evidence to support gender differences (Berger, 2007; Santrock, 2009).

Moral Reasoning and Nursing Practice. Nurses need to know their own moral reasoning level. Recognizing your own moral developmental level is essential in separating your beliefs from others when helping patients with their moral decision-making process. It is also important to recognize the level of moral reasoning used by other members of the health care team and its influence on a patient's care plan. Ideally all members of the health care team are on the same level, creating a unified outcome. This is exemplified in the following scenario: The nurse is caring for a homeless person and believes that all patients deserve the same level of care. The case manager, who is responsible for resource allocation, complains about the patient's length of stay and the amount of resources being expended on this one patient. The nurse and the case manager are in conflict because of their different levels of moral decision making within their practices. They decide to hold a health care team conference to discuss their differences and the ethical dilemma of ensuring that the patient receives an appropriate level of care.

Developmental theories help nurses to use critical thinking skills when asking how and why people respond as they do. From the diverse set of theories included in this chapter, the complexity of human development is evident. No one theory successfully describes all the intricacies of human growth and development. Today's nurse needs be knowledgeable about several theoretical perspectives when working with patients.

Your assessment of a patient requires a thorough analysis and interpretation of data to form accurate conclusions about his or her developmental needs. Accurate identification of nursing diagnoses relies on your ability to consider developmental theory in data analysis. You compare normal developmental behaviors with those projected by developmental theory. Examples of nursing diagnoses applicable to patients with developmental problems include *risk for delayed development, delayed growth and development,* and *risk for disproportionate growth.*

Growth and development, as supported by a life-span perspective, is multidimensional. The theories included are the basis for a meaningful observation of an individual's pattern of growth and development. They are important guidelines for understanding important human processes that allow nurses to begin to predict human responses and recognize deviations from the norm.

KEY POINTS

- Nurses administer care for individuals at various developmental stages. Developmental theory provides a basis for nurses to assess and understand the responses seen in their patients.
- Humans continue to develop throughout their lives. Development is not limited to childhood and adolescence; persons grow and develop throughout their life span.
- Theory is a way to account for how and why people grow up as they do. Theories provide a framework to clarify and organize existing observations to explain and try to predict human behavior.
- Growth refers to the quantitative changes that nurses measure and compare to norms.
- Development implies a progressive and continuous process of change, leading to a state of organized and specialized

functional capacity. These changes are quantitatively measurable but are more distinctly measured in qualitative changes.
- Biophysical development theory explores theories of why individuals age from a biological standpoint, why development follows a predictable sequence, and how environmental factors can influence development.
- Cognitive development focuses on the rational thinking processes that include the changes in how children, adolescents, and adults perform intellectual operations.
- Developmental tasks are age-related achievements, the success of which leads to happiness; whereas failure often leads to unhappiness, disapproval, and difficulty in achieving later tasks.
- Developmental crisis occurs when a person is having great difficulty meeting tasks of the current developmental period.
- Psychosocial theories describe human development from the perspectives of personality, thinking, and behavior with varying degrees of influence from internal biological forces and external societal/cultural forces.
- Temperament is a behavioral pattern that affects the individual's interactions with others.
- Moral development theory attempts to define how moral reasoning matures for an individual.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

1. Mrs. Banks is an 84-year-old woman who has recently been diagnosed with breast cancer. She also has severe cardiovascular disease that limits her choices of treatment. She has completed a series of radiation treatments that have left her exhausted and unable to participate in her usual activities. Her oncologist now recommends a cycle of chemotherapy treatments that her cardiologist believes would be fatal. Her family is urging her to do all that is recommended. The patient, who is in good spirits despite her diagnosis, decides against further medical treatment.
   a. How does Mrs. Banks' cognitive developmental stage impact her decision making related to her health care?
   b. Which of the psychosocial developmental theories helps explain her decision?
   c. Using your knowledge of her developmental stage, how can you help the family adjust to her choice?
2. Amanda Peters, 9 years old, was admitted to the unit yesterday with a new diagnosis of type I diabetes. Her mother has spent the night with her and is arranging the food on Amanda's breakfast tray when you enter the room to check her blood sugar and administer her insulin. Although the diabetes educator will be meeting with Amanda and her family, as part of her care today you want to begin her discharge teaching.
   a. According to Piaget's theory, how will Amanda's cognitive development direct your teaching?
   b. Using Erikson's theory as a basis, what psychosocial factors will you consider when discussing home care with Amanda and her family?
   c. Based on her developmental stage, how can Amanda's family support her active participation in care?
3. You have been assigned to care for Daniel Jackson, a 17-year-old male who was in an automobile accident several days ago and sustained a fractured pelvis. He has had a surgical repair and remains on bed rest. School is starting next month and he was scheduled to begin football practice next week. During bedside report he refuses to make eye contact with the nursing staff or respond to any questions to help direct his care.
   a. How will you incorporate your knowledge of adolescent development as you establish priorities for his care?
   b. Thinking about Erikson's theory, what psychosocial concerns do you anticipate that Daniel might experience during his hospitalization and recovery period?
   c. How will Daniel's cognitive development contribute to his future planning?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse is aware that preschoolers often display a developmental characteristic that makes them treat dolls or stuffed animals as if they have thoughts and feelings. This is an example of:
   1. Logical reasoning.
   2. Egocentrism.
   3. Concrete thinking.
   4. Animism.
2. An 18-month-old child is noted by the parents to be "angry" about any change in routine. This child's temperament is most likely to be described as:
   1. Slow to warm up.
   2. Difficult.
   3. Hyperactive.
   4. Easy.
3. Nine-year-old Brian has a difficult time making friends at school and being chosen to play on the team. He also has trouble completing his homework and, as a result, receives little positive feedback from his parents or teacher. According to Erikson's theory, failure at this stage of development results in:
   1. A sense of guilt.
   2. A poor sense of self.
   3. Feelings of inferiority.
   4. Mistrust.
4. The nurse teaches parents how to have their children learn impulse control and cooperative behaviors. This would be during which of Erickson's stages of development?
   1. Trust versus mistrust
   2. Initiative versus guilt
   3. Industry versus inferiority
   4. Autonomy versus sense of shame and doubt
5. When Ryan was 3 months old, he had a toy train; when his view of the train was blocked, he did not search for it. Now that he is 9 months old, he looks for it, reflecting the presence of:
   1. Object permanence.
   2. Sensorimotor play.
   3. Schemata.
   4. Magical thinking.
6. When preparing a 4-year-old child for a procedure, which method is developmentally most appropriate for the nurse to use?
   1. Allowing the child to watch another child undergoing the same procedure
   2. Showing the child pictures of what he or she will experience

3. Talking to the child in simple terms about what will happen
4. Preparing the child through play with a doll and toy medical equipment

7. A 35-year-old woman is speaking with you about her recent diagnosis of a chronic illness. She is concerned about her treatment options in relation to her ability to continue to care for her family. As she considers the options and alternatives, she incorporates information, her values, and emotions to decide which plan will be the best fit for her. She is using which form of cognitive development?
   1. Conventional reasoning
   2. Formal operations
   3. Integrity versus despair
   4. Postformal thought
8. You are caring for a recently retired man who appears withdrawn and says he is "bored with life." Applying the work of Havinghurst, you would help this individual find meaning in life by:
   1. Encouraging him to explore new roles.
   2. Encouraging relocation to a new city.
   3. Explaining the need to simplify life.
   4. Encouraging him to adopt a new pet.
9. Place the following stages of Freud's psychosexual development in the proper order by age progression.
   1. Oedipal
   2. Latency
   3. Oral
   4. Genital
   5. Anal
10. According to Piaget's cognitive theory, a 12-year-old child is most likely to engage in which of the following activities?
    1. Using building blocks to determine how houses are constructed
    2. Writing a story about a clown who wants to leave the circus
    3. Drawing pictures of a family using stick figures
    4. Writing an essay about patriotism
11. Allison, age 15 years, calls her best friend Laura and is crying. She has a date with John, someone she has been hoping to date for months, but now she has a pimple on her forehead. Laura firmly believes that John and everyone else will notice the blemish right away. This is an example of the:
    1. Imaginary audience.
    2. False-belief syndrome.
    3. Personal fable.
    4. Personal absorption syndrome.
12. Elizabeth, who is having unprotected sex with her boyfriend, comments to her friends, "Did you hear about Kathy? You know, she fools around so much; I heard she was pregnant. That would never happen to me!" This is an example of adolescent:
    1. Imaginary audience.
    2. False-belief syndrome.
    3. Personal fable.
    4. Sense of invulnerability.
13. Teaching an older adult how to use e-mail to communicate with a grandchild who lives in another state is an example of _____, which aids cognitive performance by using new approaches.
    1. Cognitive development
    2. Activity theory
    3. Selective optimization with compensation
    4. Formal operations
14. Dave reports being happy and satisfied with his life. What do we know about Dave?
    1. He is in one of the later developmental periods, concerned with reviewing his life.
    2. He is atypical, since most people in any of the developmental stages report significant dissatisfaction with their lives.
    3. He is in one of the earlier developmental periods, concerned with establishing a career and satisfying long-term relationships.
    4. It is difficult to determine Dave's developmental stage since most people report overall satisfaction with their lives in all stages.
15. You are working in a clinic that provides services for homeless people. The current local regulations prohibit providing a service that you believe is needed by your patients. You adhere to the regulations but at the same time are involved in influencing authorities to change the regulation. This action represents which stage of moral development?
    1. Instrumental relativist orientation
    2. Social contract orientation
    3. Society-maintaining orientation
    4. Universal ethical principle orientation

CHAPTER

12

Conception Through Adolescence

OBJECTIVES

- Discuss common physiological and psychosocial health concerns during the transition of the child from intrauterine to extrauterine life.
- Describe characteristics of physical growth of the unborn child and from birth to adolescence.
- Describe cognitive and psychosocial development from birth to adolescence.
- Explain the role of play in the development of a child.
- Discuss ways in which the nurse is able to help parents meet their children's developmental needs.

STAGES OF GROWTH AND DEVELOPMENT

Human growth and development are continuous and complex processes that are typically divided into stages organized by age-groups such as from conception to adolescence. Although this chronological division is arbitrary, it is based on the timing and sequence of developmental tasks that the child must accomplish to progress to another stage. This chapter focuses on the various physical, psychosocial, and cognitive changes and health risks and health promotion concerns during the different stages of growth and development.

SELECTING A DEVELOPMENTAL FRAMEWORK FOR NURSING

Providing developmentally appropriate nursing care is easier when you base planning on a theoretical framework (see Chapter 11). An organized, systematic approach ensures that the plan of care assesses and meets the child's and family's needs. If you deliver nursing care only as a series of isolated actions, you will possibly overlook some of the child's developmental needs. A developmental approach encourages organized care directed at the child's current level of functioning to motivate self-direction and health promotion. For example, nurses encourage toddlers to feed themselves to advance their developing independence and thus promote their sense of autonomy. Another example involves a nurse understanding an adolescent's need to be independent and thus establishing a contract about the care plan and its implementation.

INTRAUTERINE LIFE

From the moment of conception until birth, human development proceeds at a predictive and rapid rate. During gestation or the prenatal period, the **embryo** grows from a single cell to a complex, physiological being. All major organ systems develop in utero, with some functioning before birth. Development proceeds in a cephalocaudal (head-to-toe) and proximal-distal (central-to-peripheral) pattern (Santrock, 2009).

Pregnancy that reaches full term is calculated to last an average of 38 to 40 weeks and is divided into three stages or trimesters. Beginning on the day of fertilization, the first 14 days are referred to as the **preembryonic stage,** followed by the **embryonic stage** that lasts from day 15 until the eighth week. These two stages are then followed by the **fetal stage** that lasts from the end of the eighth week until birth (Davidson et al., 2008). Gestation is commonly divided into equal phases of 3 months called trimesters.

The **placenta** begins development at the third week of the embryonic stage and produces essential hormones that help maintain the pregnancy. It functions as the fetal lungs, kidneys, gastrointestinal tract, and an endocrine organ. Because the placenta is extremely porous, noxious materials such as viruses, chemicals, and drugs also pass from mother to child. These agents are called teratogens and can cause abnormal development of structures in the embryo. The effect of teratogens on the **fetus** or unborn child depends on the developmental stage in which exposure takes place, individual genetic susceptibility, and the quantity of the exposure. The embryonic stage is the most vulnerable since all body organs are formed by the eighth week. Some maternal infections can cross the placental barrier and negatively influence the health of the mother, fetus, or both. It is important to educate women about avoidable sources of teratogens and help them make healthy lifestyle choices before and during pregnancy.

Health Promotion During Pregnancy

The diet of a woman both before and during pregnancy has a significant effect on fetal development. Women who do not consume adequate nutrients and calories during pregnancy may not be able to meet the fetus' nutritional requirements. An increase in weight does not always indicate an increase in nutrients. In addition, the pattern of weight gain is important for tissue growth in a mother and fetus. For women who are at normal weight for height, the recommended weight gain is 25 to 35 pounds over three trimesters (Davidson et al., 2008). As a nurse, you are in a key position to provide women with the education they need about nutrition before conception and throughout an expectant mother's pregnancy.

Pregnancy presents a developmental challenge that includes physiological, cognitive, and emotional states that are accompanied by stress and anxiety. The expectant woman will soon adopt a parenting role; and relationships within the family will change, whether or not there is a partner involved. Pregnancy can be a period of conflict or support; family dynamics impact fetal development. Parental reactions to pregnancy change throughout the gestational period, with most couples looking forward to the birth and addition of a new family member (Davidson et al., 2008). Listen carefully to concerns expressed by a mother and her partner and offer support through each trimester.

The age of the pregnant woman sometimes plays a role in the health of the fetus and the overall pregnancy. Fetuses of older mothers are at risk for chromosomal defects, and older women may have more difficulty in becoming pregnant (Santrock, 2009). Studies indicate that pregnant adolescents often seek out less prenatal care than women in their 20s and 30s and are at higher risk for complications of pregnancy and labor. Infants of teen mothers are at increased risk for prematurity; low birth weight; and exposure to alcohol, drugs, and tobacco in utero and early childhood (Davidson et al., 2008). Adolescents who have been able to participate in prenatal classes may have improved nutrition and healthier babies.

Fetal growth and hormonal changes during pregnancy often result in discomfort for the expectant mother. Common concerns expressed include problems such as nausea and vomiting, breast tenderness, urinary frequency, heartburn, constipation, ankle edema, and backache. Always anticipate these discomforts and provide self-care education throughout the pregnancy. Discussing the physiological causes of these discomforts and offering suggestions for safe treatment can be very helpful for expectant mothers and contribute to overall health during pregnancy (Davidson et al., 2008).

Some complementary and alternative therapies such as herbal supplements can be harmful during pregnancy. Your assessment should include questions about use of these substances when providing education during pregnancy (Davidson et al., 2008). You can promote maternal and fetal health by providing accurate and complete information about health behaviors that support positive outcomes for pregnancy and childbirth.

TRANSITION FROM INTRAUTERINE TO EXTRAUTERINE LIFE

The transition from intrauterine to extrauterine life requires profound physiological changes in the newborn and occurs during the first 24 hours of life. Assessment of the newborn during this period is essential to ensure that the transition is proceeding as expected. Gestational age and development, exposure to depressant drugs before or during labor, and the newborn's own behavioral style also influence the adjustment to the external environment.

Physical Changes

An immediate assessment of the newborn's condition to determine the physiological functioning of the major organ systems occurs at birth. The most widely used assessment tool is the **Apgar score.** Heart rate, respiratory effort, muscle tone, reflex irritability, and color are rated to determine overall status of the newborn. The Apgar assessment is generally conducted at 1 and 5 minutes after birth and is sometimes repeated until the newborn's condition stabilizes. The most extreme physiological change occurs when the newborn leaves the utero circulation and develops independent circulatory and respiratory functioning.

Nursing interventions at birth include maintaining an open airway, stabilizing and maintaining body temperature, and protecting the newborn from infection. The removal of nasopharyngeal and oropharyngeal secretions with suction or a bulb syringe ensures airway patency. Newborns are susceptible to heat loss and cold stress. Because hypothermia increases oxygen needs, it is essential to stabilize and maintain the newborn's body temperature. Healthy newborns may be placed directly on the mother's abdomen and covered in warm blankets or provided warmth via a radiant warmer. Preventing infection is a major concern in the care of the newborn, whose immune system is immature. Good handwashing technique is the most important factor in protecting the newborn from infection. You can help prevent infection by instructing parents and visitors to wash their hands before touching the infant.

Psychosocial Changes

After immediate physical evaluation and application of identification bracelets, the nurse promotes the parents' and newborn's need for close physical contact. Early parent-child interaction encourages parent-child **attachment.** Merely placing the family together does not promote closeness. Most healthy newborns are awake and alert for the first half-hour after birth. This is a good time for parent-child interaction to begin. Close body contact, often including breastfeeding, is a satisfying way for most families to start bonding. If immediate contact is not possible, incorporate it into the care plan as early as possible, which means bringing the newborn to an ill parent or bringing the parents to an ill or premature child. Attachment is a process that evolves over the infant's first 24 months of life, and many psychologists believe that a secure attachment is an important foundation for psychological development in later life (Santrock, 2009).

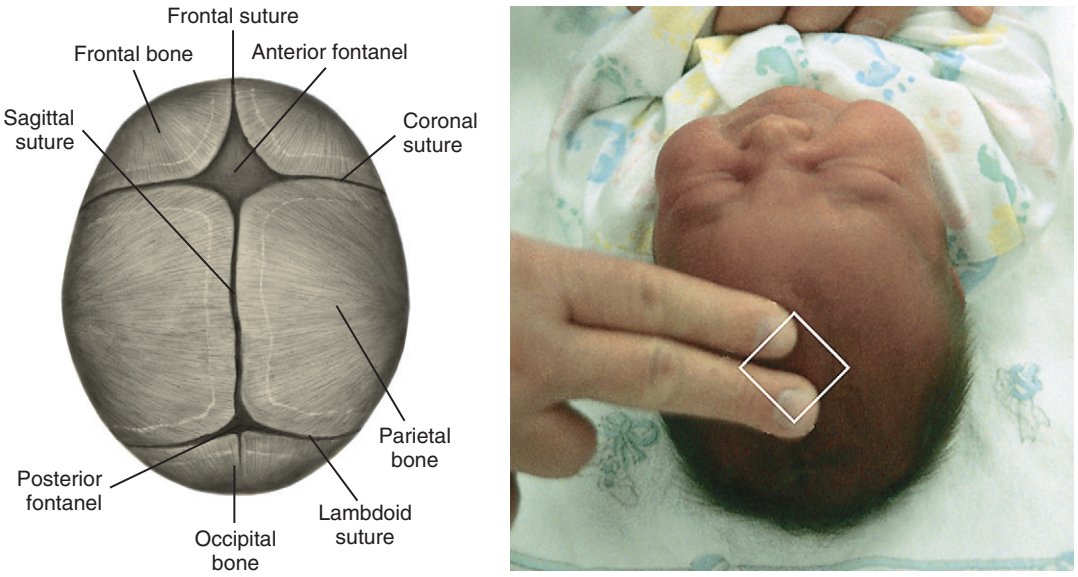

FIG. 12-1 Fontanels and suture lines. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.)

NEWBORN

The **neonatal period** is the first 28 days of life. During this stage the newborn's physical functioning is mostly reflexive, and stabilization of major organ systems is the primary task of the body. Behavior greatly influences interaction among the newborn, the environment, and caregivers. For example, the average 2-week-old smiles spontaneously and is able to look at the mother's face. The impact of these reflexive behaviors is generally a surge of maternal feelings of love that prompt the mother to cuddle the baby. You apply knowledge of this stage of growth and development to promote newborn and parental health. For example, the newborn's cry is generally a reflexive response to an unmet need (such as hunger, fatigue, or discomfort). Thus you help parents identify ways to meet these needs by counseling them to feed their baby on demand rather than on a rigid schedule.

Physical Changes

You perform a comprehensive nursing assessment as soon as the newborn's physiological functioning is stable, generally within a few hours after birth. At this time the nurse measures height, weight, head and chest circumference, temperature, pulse, and respirations and observes general appearance, body functions, sensory capabilities, reflexes, and responsiveness. Following a comprehensive physical assessment, assess gestational age and interactions between infant and parent that indicate successful attachment (Hockenberry and Wilson, 2011).

The average newborn is 2700 to 4000 g (6 to 9 pounds), 48 to 53 cm (19 to 21 inches) in length, and has a head circumference of 33 to 35 cm (13 to 14 inches). Neonates lose up to 10% of birth weight in the first few days of life, primarily through fluid losses by respiration, urination, defecation, and low fluid intake. They usually regain birth weight by the second week of life; and a gradual pattern of increase in weight, height, and head circumference is evident. Accurate measurement as soon as possible after birth provides a baseline for future comparison (Hockenberry and Wilson, 2011).

Normal physical characteristics include the continued presence of lanugo on the skin of the back; cyanosis of the hands and feet for the first 24 hours; and a soft, protuberant abdomen. Skin color varies according to racial and genetic heritage and gradually changes during infancy. **Molding,** or overlapping of the soft skull bones, allows the fetal head to adjust to various diameters of the maternal pelvis and is a common occurrence with vaginal births. The bones readjust within a few days, producing a rounded appearance to the head. The sutures and **fontanels** are usually palpable at birth. Fig. 12-1 shows the diamond shape of the anterior fontanel and the triangular shape of the posterior fontanel between the unfused bones of the skull. The anterior fontanel usually closes at 12 to 18 months, whereas the posterior fontanel closes by the end of the second or third month.

Assess neurological function by observing the newborn's level of activity, alertness, irritability, and responsiveness to stimuli and the presence and strength of reflexes. Normal reflexes include blinking in response to bright lights, startling in response to sudden loud noises or movement, sucking, rooting, grasping, yawning, coughing, sneezing, palmar grasp, swallowing, plantar grasp, Babinski, and hiccoughing. Assessment of these reflexes is vital because the newborn depends largely on reflexes for survival and in response to its environment. Fig. 12-2 shows the tonic neck reflex in the newborn.

Normal behavioral characteristics of the newborn include periods of sucking, crying, sleeping, and activity. Movements are generally sporadic, but they are symmetrical and involve all four extremities. The relatively flexed fetal position of intrauterine life continues as the newborn attempts to maintain an enclosed, secure feeling. Newborns normally watch the caregiver's face; have a nonpurposeful reflexive smile; and respond to sensory stimuli, particularly the primary caregiver's face, voice, and touch.

In accordance with the recommendations of the American Academy of Pediatrics (AAP), position infants for sleep on their backs to decrease the risk of sudden infant death syndrome (SIDS) (Hockenberry and Wilson, 2011; Santrock, 2008). Newborns establish their individual sleep-activity cycle, and parents develop sensitivity to their baby's cues. Studies have found that parents position their infants at home in the same positions they observed in the hospital setting; thus nurses must demonstrate correct positioning on the back to reduce the incidence of SIDS (Davidson et al., 2008). Co-sleeping or bed sharing has also been reported to possibly be

FIG. 12-2 Tonic neck reflex. Newborns assume this position while supine. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.)

FIG. 12-3 Siblings should be involved in newborn care. (Courtesy Elaine Polan, RNC, BSN, MS.)

associated with an increased risk for SIDS (Hockenberry and Wilson, 2011; Santrock, 2008). Safeguards include proper positioning; removing stuffed animals, soft bedding, and pillows; and avoiding overheating the infant. Individuals should avoid smoking during pregnancy and around the infant because it places the infant at greater risk for SIDS (Hockenberry and Wilson, 2011).

Cognitive Changes

Early cognitive development begins with innate behavior, reflexes, and sensory functions. Newborns initiate reflex activities, learn behaviors, and learn their desires. At birth infants are able to focus on objects about 20 to 25 cm (8 to 10 inches) from their faces and perceive forms. A preference for the human face is apparent. Teach parents about the importance of providing sensory stimulation such as talking to their babies and holding them to see their faces. This allows infants to seek or take in stimuli, thereby enhancing learning and promoting cognitive development.

For newborns crying is a means of communication to provide cues to parents. Some babies cry because their diapers are wet or they are hungry or want to be held. Others cry just to make noise or because they need a change in position or activity. The crying frustrates the parents if they cannot see an apparent cause. With the nurse's help parents learn to recognize infants' cry patterns and take appropriate action when necessary.

Psychosocial Changes

During the first month of life most parents and newborns normally develop a strong bond that grows into a deep attachment. Interactions during routine care enhance or detract from the attachment process. Feeding, hygiene, and comfort measures consume much of infants' waking time. These interactive experiences provide a foundation for the formation of deep attachments. Early on older siblings need to have opportunity to be involved in the newborn's care. Family involvement helps support growth and development and promotes nurturing (Fig. 12-3).

If parents or children experience health complications after birth, this *may* compromise the attachment process. Infants' behavioral cues are sometimes weak or absent, and caregiving is possibly less mutually satisfying. Some tired or ill parents have difficulty interpreting and responding to their infants. Preterm infants and those born with congenital anomalies are often too weak to be responsive to parental cues and require special supportive nursing care. For example, infants born with heart defects tire easily during feedings. Nurses can support parental attachment by pointing out positive qualities and responses of the newborn and acknowledging how difficult the separation can be for parents and infant.

Health Promotion

Screening. Newborn screening tests are administered before babies leave the hospital to identify serious or life-threatening conditions before symptoms begin. Results of the screening tests are sent directly to the infant's pediatrician. If a screening test suggests a problem, the baby's physician usually follows up with further testing and may refer the infant to a specialist for treatment if needed. Blood tests help determine **inborn errors of metabolism (IEMs).** These are genetic disorders caused by the absence or deficiency of a substance, usually an enzyme, essential to cellular metabolism that results in abnormal protein, carbohydrate, or fat metabolism. Although IEMs are rare, they account for a significant proportion of health problems in children. Neonatal screening is done to detect phenylketonuria (PKU), hypothyroidism, galactosemia, and other diseases to allow appropriate treatment that prevents permanent mental retardation and other health problems.

The AAP recommends universal screening of newborn hearing before discharge since studies have indicated that the incidence of hearing loss is as high as 1 to 3 per 1000 normal newborns (Davidson et al., 2008). If health care providers detect the loss before 3 months of age and intervention is initiated by 6 months, children are able to achieve normal language development that matches their cognitive development through the age of 5 (Hockenberry and Wilson, 2011).

Car Seats. An essential component of discharge teaching is the use of a federally approved car seat for transporting the infant from the hospital or birthing center to home. Automobile injuries are a leading cause of death in children in the United States. Many of these deaths occur when the child is not properly restrained

TABLE 12-1 Gross- and Fine-Motor Development in Infancy

AGE	GROSS-MOTOR SKILL	FINE-MOTOR SKILL
Birth to 1 month	Complete head lag persists No ability to sit upright Inborn reflexes are predominant	Reflexive grasp
2 to 4 months	When prone, lifts head and chest and bears weight on forearms With support able to sit erect with good head control Can turn from side to back	Holds rattle for short periods Looks at and plays with fingers Able to bring objects from hand to mouth
4 to 6 months	Turns from abdomen to back at 5 months and then back to abdomen at 6 months Can support much of own weight when pulled to stand No head lag when pulled to sit	Grasps objects at will and can drop them to pick up another object Pulls feet to mouth to explore Can hold a baby bottle
6 to 8 months	Sits alone without support Bears full weight on feet and can hold on to furniture Can move from a sitting to kneeling position	Bangs objects together Pulls a string to obtain an object Transfers objects from hand to hand
8 to 10 months	Crawls or pulls entire body along floor using arms Pulls self to standing or sitting Creeps on hands and knees	Picks up small objects Uses pincer grasp well Shows hand preference
10 to 12 months	Stands alone Walks holding onto furniture Sits down from a standing position	Can place objects into containers Able to hold a crayon or pencil and make a mark on paper

Adapted from Hockenberry M, Wilson D: *Wong's nursing care of infants and children,* ed 8, St Louis, 2007, Mosby; Santrock JW: *Life-span development,* ed 12, New York, 2008, McGraw-Hill.

(Hockenberry and Wilson, 2011). Parents need to learn how to properly fit the restraint to the infant and how to properly install the car seat. All infants and toddlers should ride in a rear-facing car safety seat until they are 2 years of age or until they reach the highest weight or height allowed by the manufacturer or their car safety seat (American Academy of Pediatrics, 2011a). Placing an infant in a rear-facing restraint in the front seat of a vehicle is extremely dangerous in any vehicle with a passenger-side air bag. Nurses are responsible for providing education on the use of a car seat before discharge from the hospital.

Cribs and Sleep. Beginning June 28, 2011, new federal safety standards prohibit the manufacture or sale of drop-side rail cribs (American Academy of Pediatrics, 2011b). New cribs sold in the United States must meet these governmental standards for safety, but some older cribs were manufactured before the newer requirements were instituted. Unsafe cribs should be disassembled and thrown away (American Academy of Pediatrics, 2011b). Parents also need to inspect an older crib to make sure the slats are no more than 6 cm (2.4 inches) apart. The crib mattress should fit snugly, and crib toys or mobiles should be attached firmly with no hanging strings or straps. Instruct parents to remove mobiles as soon as the infant is able to reach them (Hockenberry and Wilson, 2011). Also consider using a portable play yard, as long as it is not a model that has been recalled.

INFANT

During **infancy,** the period from 1 month to 1 year of age, rapid physical growth and change occur. This is the only period distinguished by such dramatic physical changes and marked development. Psychosocial developmental advances are aided by the progression from reflexive to more purposeful behavior. Interaction between infants and the environment is greater and more meaningful for the infant. During this first year of life the nurse easily observes the adaptive potential of infants because changes in growth and development occur so rapidly.

Physical Changes

Steady and proportional growth of the infant is more important than absolute growth values. Charts of normal age- and gender-related growth measurements enable the nurse to compare growth with norms for a child's age. Measurements recorded over time are the best way to monitor growth and identify problems. Size increases rapidly during the first year of life; birth weight doubles in approximately 5 months and triples by 12 months. Height increases an average of 2.5 cm (1 inch) during each of the first 6 months and about 1.2 cm (½ inch) each month until 12 months (Hockenberry and Wilson, 2011).

Throughout the first year the infant's vision and hearing continue to develop. Some infants as young as 3½ months are able to link visual and auditory stimuli (Santrock, 2009). Patterns of body function also stabilize, as evidenced by predictable sleep, elimination, and feeding routines. Some reflexes that are present in the newborn such as blinking, yawning, and coughing remain throughout life; whereas others such as grasping, rooting, sucking, and the Moro or startle reflex disappear after several months.

Gross-motor skills involve large muscle activities and are usually closely monitored by parents who easily report recently achieved milestones. Newborns can only momentarily hold their heads up, but by 4 months most infants have no head lag. The same rapid development is evident as infants learn to sit, stand, and then walk. Fine-motor skills involve small body movements and are more difficult to achieve than gross-motor skills. Maturation of eye-and-hand coordination occurs over the first 2 years of life as infants move from being able to grasp a rattle briefly at 2 months to drawing an arc with a pencil by 24 months. Development proceeds at a variable pace for each individual but usually follows the same pattern and within the same time frame (Table 12-1).

Cognitive Changes

The complex brain development during the first year is demonstrated by the infant's changing behaviors. As he or she receives stimulation through the developing senses of vision, hearing, and touch, the developing brain interprets the stimuli. Thus the infant learns by experiencing and manipulating the environment. Developing motor skills and increasing mobility expand an infant's environment and, with developing visual and auditory skills, enhance cognitive development. For these reasons Piaget (1952) named his first stage of cognitive development, which extends until around the third birthday, the sensorimotor period. Today's researchers have many more methods available to study the cognitive development of infants, and they believe that infants are far more competent than Piaget was able to discern by observation alone (Santrock, 2009) (see Chapter 11).

Infants need opportunities to develop and use their senses. Nurses need to evaluate the appropriateness and adequacy of these opportunities. For example, ill or hospitalized infants sometimes lack the energy to interact with their environment, thereby slowing their cognitive development. Infants need to be stimulated according to their temperament, energy, and age. The nurse uses stimulation strategies that maximize the development of infants while conserving their energy and orientation. An example of this is a nurse talking to and encouraging an infant to suck on a pacifier while administering the infant's tube feeding.

Language. Speech is an important aspect of cognition that develops during the first year. Infants proceed from crying, cooing, and laughing to imitating sounds, comprehending the meaning of simple commands, and repeating words with knowledge of their meaning. By 1 year infants not only recognize their own names but are able to say three to five words and understand almost 100 words (Hockenberry and Wilson, 2011). The nurse promotes language development by encouraging parents to name objects on which their infant's attention is focused. The nurse also assesses the infant's language development to identify developmental delays or potential abnormalities.

Psychosocial Changes

Separation and Individuation. During their first year infants begin to differentiate themselves from others as separate beings capable of acting on their own. Initially, infants are unaware of the boundaries of self, but through repeated experiences with the environment they learn where the self ends and the external world begins. As they determine their physical boundaries, they begin to respond to others (Fig. 12-4).

Two- and 3-month-old infants begin to smile responsively rather than reflexively. Similarly they recognize differences in people when their sensory and cognitive capabilities improve. By 8 months most infants are able to differentiate a stranger from a familiar person and respond differently to the two. Close attachment to their primary caregivers, most often parents, usually occurs by this age. Infants seek out these persons for support and comfort during times of stress. The ability to distinguish self from others allows infants to interact and socialize more within their environments. For example, by 9 months infants play simple social games such as patty-cake and peek-a-boo. More complex interactive games such as hide-and-seek involving objects are possible by age 1.

Erikson (1963) describes the psychosocial developmental crisis for the infant as trust versus mistrust. He explains that the quality of parent-infant interactions determines development of trust or mistrust. The infant learns to trust self, others, and the world through the relationship between the parent and child and the care the child receives (Hockenberry and Wilson, 2011). During infancy the child's temperament or behavioral style becomes apparent and influences the interactions between parent and child. You can help parents understand their child's temperament and determine appropriate childrearing practices (see Chapter 11).

FIG. 12-4 Smiling at and talking to an infant encourage bonding. (From Murray SS, McKinney ES: *Foundations of maternal-newborn and women's health nursing,* ed 5, St Louis, 2010, Saunders.)

Assess the availability and appropriateness of experiences contributing to psychosocial development. Hospitalized infants often have difficulty establishing physical boundaries because of repeated bodily intrusions and painful sensations. Limiting these negative experiences and providing pleasurable sensations are interventions that support early psychosocial development. Extended separations from parents complicate the attachment process and increase the number of caregivers with whom the infant must interact. Ideally the parents provide the majority of care during hospitalization. When parents are not present, either at home or in the hospital, make an attempt to limit the number of different caregivers who have contact with the infant and to follow the parents' directions for care. These interventions foster the infant's continuing development of trust.

Play. Play provides opportunities for development of cognitive, social, and motor skills. Much of infant play is exploratory as infants use their senses to observe and examine their own bodies and objects of interest in their surroundings. Adults facilitate infant learning by planning activities that promote the development of milestones and providing toys that are safe for the infant to explore with the mouth and manipulate with the hands such as rattles, wooden blocks, plastic stacking rings, squeezable stuffed animals, and busy boxes.

Health Risks

Injury Prevention. Injury from motor vehicle accidents, aspiration, suffocation, falls, or poisoning is a major cause of death in children 6 to 12 months old. An understanding of the major developmental accomplishments during this time period allows for injury-prevention planning. As the child achieves gains in motor development and becomes increasingly curious about the environment, constant watchfulness and supervision are critical for injury prevention.

Child Maltreatment. Child maltreatment includes intentional physical abuse or neglect, emotional abuse or neglect, and

BOX 12-1 WARNING SIGNS OF ABUSE

- Physical evidence of abuse or neglect, including previous injuries
- Conflicting stories about the accident/trauma
- Injury blamed on sibling or another party
- Injury inconsistent with the history such as a concussion and a broken arm from falling off the bed
- History inconsistent with the child's developmental age such as a 6-month-old burned by turning on the hot water
- An initial complaint not associated with the signs and symptoms present (e.g., bringing the child to the clinic for a cold when there is evidence of physical trauma)
- Inappropriate response of the child, especially an older child, such as not wanting to be touched, looking at caregiver before answering any questions
- Previous reports of abuse in the family
- Frequent emergency department or clinic visits

Adapted from Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 8, St Louis, 2007, Mosby.

sexual abuse (Hockenberry and Wilson, 2011). More children suffer from neglect than any other type of maltreatment. Children of any age can suffer from maltreatment, but the youngest are the most vulnerable. In addition, many children suffer from more than one type of maltreatment. No one profile fits a victim of maltreatment, and the signs and symptoms vary (Box 12-1).

A combination of signs and symptoms or a pattern of injury should arouse suspicion. It is important for the health care provider to be aware of certain disease processes and cultural practices. Lack of awareness of normal variants such as Mongolian spots causes the health care provider to assume that there is abuse. Children who are hospitalized for maltreatment have the same developmental needs as other children their age, and the nurse needs to support the child's relationship with the parents (Hockenberry and Wilson, 2011).

Health Promotion

Nutrition. The quality and quantity of nutrition profoundly influences the infant's growth and development. Many women have already selected a feeding method well before the infant's birth, yet others will have questions for the nurse later in the pregnancy. Nurses are in a unique position to help parents select and provide a nutritionally adequate diet for their infant. Understand that factors such as support, culture, role demands, and previous experiences influence feeding methods (Davidson et al., 2008).

Breastfeeding is recommended for infant nutrition because breast milk contains the essential nutrients of protein, fats, carbohydrates, and immunoglobulins that bolster the ability to resist infection. Both the AAP and the U.S. Department of Health and Human Services recommend human milk for the first year of life (Hockenberry and Wilson, 2011). However, if breastfeeding is not possible or if the parent does not desire it, an acceptable alternative is iron-fortified commercially prepared formula. Recent advances in the preparation of infant formula include the addition of nucleotides and long-chain fatty acids, which augment immune function and increase brain development. The use of whole cow's milk, 2% cow's milk, or alternate milk products before the age of 12 months is not recommended. The composition of whole cow's milk can cause intestinal bleeding, anemia, and increased incidence of allergies (Hockenberry and Wilson, 2011).

The average 1-month-old infant takes approximately 18 to 21 ounces of breast milk or formula per day. This amount increases slightly during the first 6 months and decreases after introducing solid foods. The amount of formula per feeding and the number of feedings vary among infants. The addition of solid foods is not recommended before the age of 6 months because the gastrointestinal tract is not sufficiently mature to handle these complex nutrients and infants are exposed to food antigens that produce food protein allergies. Developmentally, infants are not ready for solid food before 6 months. The extrusion (protrusion) reflex causes food to be pushed out of the mouth. The introduction of cereals, fruits, vegetables, and meats during the second 6 months of life provides iron and additional sources of vitamins. This becomes especially important when children change from breast milk or formula to whole cow's milk after the first birthday. Solid foods should be offered one new food at a time. This allows for identification if a food causes an allergic reaction. The use of fruit juices and nonnutritive drinks such as fruit-flavored drinks or soda should be avoided since these do not provide sufficient and appropriate calories during this period (Hockenberry and Wilson, 2011). Infants also tolerate well-cooked table foods by 1 year. The amount and frequency of feedings vary among infants; thus be sure to discuss differing feeding patterns with parents.

Supplementation. The need for dietary vitamin and mineral supplements depends on the infant's diet. Full-term infants are born with some iron stores. The breastfed infant absorbs adequate iron from breast milk during the first 4 to 6 months of life. After 6 months iron-fortified cereal is generally an adequate supplemental source. Because iron in formula is less readily absorbed than that in breast milk, formula-fed infants need to receive iron-fortified formula throughout the first year.

Adequate concentrations of fluoride to protect against dental caries are not available in human milk; therefore fluoridated water or supplemental fluoride is generally recommended. A recent concern is the use of complementary and alternative medical therapies in children that may or may not be safe. Inquire about the use of such products to help the parent determine whether or not the product is truly safe for the child (Hockenberry and Wilson, 2011).

Immunizations. The widespread use of immunizations has resulted in the dramatic decline of infectious diseases over the past 50 years and therefore is a most important factor in health promotion during childhood. Although most immunizations can be given to persons of any age, it is recommended that the administration of the primary series begin soon after birth and be completed during early childhood. Vaccines are among the safest and most reliable drugs used. Minor side effects sometimes occur; however, serious reactions are rare. Parents need instructions regarding the importance of immunizations and common side effects such as low-grade fever and local tenderness. The recommended schedule for immunizations changes as new vaccines are developed and advances are made in the field of immunology. Stay informed of the current policies and direct parents to the primary caregiver for their child's schedule. The AAP maintains the most current schedule on their Internet website, http://www.aap.org. Research over the past three decades has clearly indicated that infants experience pain with invasive procedures (e.g., injections) and that nurses need to be aware of measures to reduce or eliminate pain with any health care procedure (see Chapter 31).

Sleep. Sleep patterns vary among infants, with many having their days and nights reversed until 3 to 4 months of age. Thus it is common for infants to sleep during the day. By 6 months most infants are nocturnal and sleep between 9 and 11 hours at night.

Total daily sleep averages 15 hours. Most infants take one or two naps a day by the end of the first year. Many parents have concerns regarding their infant's sleep patterns, especially if there is difficulty such as sleep refusal or frequent waking during the night. Carefully assesses the individual problem before suggesting interventions to address their concern.

TODDLER

Toddlerhood ranges from the time children begin to walk independently until they walk and run with ease, which is from 12 to 36 months. The toddler has increasing independence bolstered by greater physical mobility and cognitive abilities. Toddlers are increasingly aware of their abilities to control and are pleased with successful efforts with this new skill. This success leads them to repeated attempts to control their environments. Unsuccessful attempts at control result in negative behavior and temper tantrums. These behaviors are most common when parents stop the initial independent action. Parents cite these as the most problematic behaviors during the toddler years and at times express frustration with trying to set consistent and firm limits while simultaneously encouraging independence. Nurses and parents can deal with the negativism by limiting the opportunities for a "no" answer. For example, the nurse does not ask the toddler, "Do you want to take your medicine now?" Instead, he or she tells the child that it is time to take medicine and offers a choice of water or juice to drink with it.

Physical Changes

The average toddler grows 6.2 cm (2.5 inches) in height and gains approximately 5 to 7 pounds each year (Santrock, 2009). The rapid development of motor skills allows the child to participate in self-care activities such as feeding, dressing, and toileting. In the beginning the toddler walks in an upright position with a broad stance and gait, protuberant abdomen, and arms out to the sides for balance. Soon the child begins to navigate stairs, using a rail or the wall to maintain balance while progressing upward, placing both feet on the same step before continuing. Success provides courage to attempt the upright mode for descending the stairs in the same manner. Locomotion skills soon include running, jumping, standing on one foot for several seconds, and kicking a ball. Most toddlers ride tricycles, climb ladders, and run well by their third birthday.

Fine-motor capabilities move from scribbling spontaneously to drawing circles and crosses accurately. By 3 years the child draws simple stick people and is usually able to stack a tower of small blocks. Children now hold crayons with their fingers rather than with their fists and can imitate vertical and horizontal strokes. They are able to manage feeding themselves with a spoon without rotating it and can drink well from a cup without spilling. Toddlers can turn pages of a book one at a time and can easily turn doorknobs (Hockenberry and Wilson, 2011).

Cognitive Changes

Toddlers increase their ability to remember events and begin to put thoughts into words at about 2 years of age. They recognize that they are separate beings from their mothers, but they are unable to assume the view of another. Toddlers reason based on their own experience of an event. They use symbols to represent objects, places, and persons. Children demonstrate this function as they imitate the behavior of another that they viewed earlier (e.g., pretend to shave like daddy), pretend that one object is another (e.g., use a finger as a gun), and use language to stand for absent objects (e.g., request bottle).

Language. The 18-month-old child uses approximately 10 words. The 24-month-old child has a vocabulary of up to 300 words and is generally able to speak in two-word sentences, although the ability to understand speech is much greater than the number of words acquired (Hockenberry and Wilson, 2011). "Who's that?" and "What's that?" are typical questions children ask during this period. Verbal expressions such as "me do it" and "that's mine" demonstrate the 2-year-old child's use of pronouns and desire for independence and control. By 36 months the child can use simple sentences, follow some grammatical rules, and learn to use five or six new words each day. Language development may seem to occur in early childhood, but it actually develops further into the later school years and adolescence (Santrock, 2009). Parents can facilitate language development best by talking to their children. Reading to children helps expand their vocabulary, knowledge, and imagination. Television is never used instead of parent-child interaction.

Psychosocial Changes

According to Erikson (1963) a sense of autonomy emerges during toddlerhood. Children strive for independence by using their developing muscles to do everything for themselves and become the master of their bodily functions. Their strong wills are frequently exhibited in negative behavior when caregivers attempt to direct their actions. Temper tantrums result when parental restrictions frustrate toddlers. Parents need to provide toddlers with graded independence, allowing them to do things that do not result in harm to themselves or others. For example, young toddlers who want to learn to hold their own cups often benefit from two-handled cups with spouts and plastic bibs with pockets to collect the milk that spills during the learning process.

Play. Socially toddlers remain strongly attached to their parents and fear separation from them. In their presence they feel safe, and their curiosity is evident in their exploration of the environment. The child continues to engage in solitary play during toddlerhood but also begins to participate in parallel play, which is playing *beside* rather than *with* another child. Play expands the child's cognitive and psychosocial development. It is always important to consider if toys support development of the child, along with the safety of the toy.

Health Risks

The newly developed locomotion abilities and insatiable curiosity of toddlers make them at risk for injury. Toddlers need close supervision at all times and particularly when in environments that are not childproofed (Fig. 12-5).

Poisonings occur frequently because children near 2 years of age are interested in placing any object or substance in their mouths to learn about it. The prudent parent removes or locks up all possible poisons, including plants, cleaning materials, and medications. These parental actions create a safer environment for exploratory behavior. Lead poisoning continues to be a serious health hazard in the United States, and children under the age of 6 years are most vulnerable (Hockenberry and Wilson, 2011).

Toddlers' lack of awareness regarding the danger of water and their newly developed walking skills make drowning a major cause of accidental death in this age-group. Limit setting is extremely important for toddlers' safety. Motor vehicle accidents account for half of all accidental deaths in children between the ages of 1 and 4 years. Some of these deaths are the result of unrestrained

FIG. 12-5 Safety precautions should be provided for toddlers. (Courtesy Elaine Polan, RNC, BSN, MS.)

children, and some are attributed to injuries within the car resulting from not using car seat safety guidelines (Hockenberry and Wilson, 2011). Injury prevention is best accomplished by associating various injuries with the attainment of developmental milestones.

Toddlers who become ill and require hospitalization are most stressed by the separation from their parents. Nurses encourage parents to stay with their child as much as possible and actively participate in providing care. Creating an environment that supports parents helps greatly in gaining the cooperation of the toddler. Establishing a trusting relationship with the parents often results in toddler acceptance of treatment.

Health Promotion

Nutrition. Childhood obesity and the associated chronic diseases that result are sources of concern for all health care providers. Children establish lifetime eating habits in early childhood, and there is increased emphasis on food choices. They increasingly meet nutritional needs by eating solid foods. The healthy toddler requires a balanced daily intake of bread and grains, vegetables, fruit, dairy products, and proteins. Because the consumption of more than a quart of milk per day usually decreases the child's appetite for these essential solid foods and results in inadequate iron intake, advise parents to limit milk intake to 2 to 3 cups per day (Hockenberry and Wilson, 2011). Children are usually not offered low-fat or skim milk until age 2 because they need the fat for satisfactory physical and intellectual growth.

Mealtime has psychosocial and physical significance. If the parents struggle to control toddlers' dietary intake, problem behavior and conflicts can result. Toddlers often develop "food jags," or the desire to eat one food repeatedly. Rather than becoming disturbed by this behavior, encourage parents to offer a variety of nutritious foods at meals and to provide only nutritious snacks between meals. Serving finger foods to toddlers allows them to eat by themselves and to satisfy their need for independence and control. Small, reasonable servings allow toddlers to eat all of their meals.

Toilet Training. Increased locomotion skills, the ability to undress, and development of sphincter control allow toilet training if the toddler has developed the necessary language and cognitive abilities. Parents often consult nurses for an assessment of readiness for toilet training. Recognizing the urge to urinate and or defecate is crucial in determining the child's mental readiness. The toddler must also be motivated to hold on to please the parent rather than letting go to please the self to successfully accomplish toilet training (Hockenberry and Wilson, 2011). The nurse needs to remind parents that patience, consistency, and a nonjudgmental attitude, in addition to the child's readiness, are essential to successful toilet training.

PRESCHOOLERS

The **preschool period** refers to the years between ages 3 and 5. Children refine the mastery of their bodies and eagerly await the beginning of formal education. Many people consider these the most intriguing years of parenting because children are less negative, more accurately share their thoughts, and more effectively interact and communicate. Physical development occurs at a slower pace than cognitive and psychosocial development.

Physical Changes

Several aspects of physical development continue to stabilize in the preschool years. Children gain about 5 pounds per year; the average weight at 3 years is 32 pounds; at 4 years, 37 pounds; and at 5 years about 41 pounds. Preschoolers grow 6.2 to 7.5 cm (2½ to 3 inches) per year, double their birth length around 4 years, and stand an average of 107 cm (43 inches) tall by their fifth birthday. The elongation of the legs results in more slender-appearing children. Little difference exists between the sexes, although boys are slightly larger with more muscle and less fatty tissue. Most children are completely toilet trained by the preschool years (Hockenberry and Wilson, 2011).

Large and fine muscle coordination improves. Preschoolers run well, walk up and down steps with ease, and learn to hop. By 5 years they usually skip on alternate feet, jump rope, and begin to skate and swim. Improving fine-motor skills allows intricate manipulations. They learn to copy crosses and squares. Triangles and diamonds are usually mastered between ages 5 and 6. Scribbling and drawing help to develop fine muscle skills and the eye-hand coordination needed for the printing of letters and numbers.

Children need opportunities to learn and practice new physical skills. Nursing care of healthy and ill children includes an assessment of the availability of these opportunities. Although children with acute illnesses benefit from rest and exclusion from usual daily activities, children who have chronic conditions or who have been hospitalized for long periods need ongoing exposure to developmental opportunities. The parents and nurse weave these opportunities into the children's daily experiences, depending on their abilities, needs, and energy level.

Cognitive Changes

Maturation of the brain continues, with the most rapid growth occurring in the frontal lobe areas, where planning and organizing new activities and maintaining attention to tasks are paramount. Scientific advances in the use of brain-scanning techniques have demonstrated that patterns within the brain change significantly between the ages of 3 to 15 years (Santrock, 2009).

Preschoolers demonstrate their ability to think more complexly by classifying objects according to size or color and by questioning.

Children have increased social interaction, as is illustrated by the 5-year-old child who offers a bandage to a child with a cut finger. Children become aware of cause-and-effect relationships, as illustrated by the statement, "The sun sets because people want to go to bed." Early causal thinking is also evident in preschoolers. For example, if two events are related in time or space, children link them in a causal fashion. For example, the hospitalized child reasons, "I cried last night, and that's why the nurse gave me the shot." As children near age 5, they begin to use or learn to use rules to understand causation. They then begin to reason from the general to the particular. This forms the basis for more formal logical thought. The child now reasons, "I get a shot twice a day, and that's why I got one last night." Children in this stage also believe that inanimate objects have lifelike qualities and are capable of action, as seen through comments such as, "Trees cry when their branches get broken."

Preschoolers' knowledge of the world remains closely linked to concrete (perceived by the senses) experiences. Even their rich fantasy life is grounded in their perception of reality. The mixing of the two aspects often leads to many childhood fears, and adults sometimes misinterpret it as lying when children are actually presenting reality from their perspective. Preschoolers believe that, if a rule is broken, punishment results immediately. During these years they believe that a punishment is automatically connected to an act and do not yet realize that it is socially mediated (Santrock, 2008).

The greatest fear of this age-group appears to be that of bodily harm; this is evident in children's fear of the dark, animals, thunderstorms, and medical personnel. This fear often interferes with their willingness to allow nursing interventions such as measurement of vital signs. Preschoolers cooperate if they are allowed to help the nurse measure the blood pressure of a parent or to manipulate the nurse's equipment.

Language. Preschoolers' vocabularies continue to increase rapidly; and by the age of 6 children have 8000 to 14,000 words that they use to define familiar objects, identify colors, and express their desires and frustrations (Santrock, 2008). Language is more social, and questions expand to "Why?" and "How come?" in the quest for information. Phonetically similar words such as *die* and *dye* or *wood* and *would* cause confusion in preschool children. Avoid such words when preparing them for procedures and assess comprehension of explanations.

Psychosocial Changes

The world of preschoolers expands beyond the family into the neighborhood where children meet other children and adults. Their curiosity and developing initiative lead to actively exploring the environment, developing new skills, and making new friends. Preschoolers have a surplus of energy that permits them to plan and attempt many activities that are beyond their capabilities such as pouring milk from a gallon container into their cereal bowls. Guilt arises within children when they overstep the limits of their abilities and think that they have not behaved correctly. Children who in anger wished that their sibling were dead experience guilt if that sibling becomes ill. Children need to learn that "wishing" for something to happen does not make it occur. Erikson (1963) recommends that parents help their children strike a healthy balance between initiative and guilt by allowing them to do things on their own while setting firm limits and providing guidance.

Sources of stress for preschoolers can include changes in caregiving arrangements, starting school, the birth of a sibling, parental marital distress, relocation to a new home, or an illness. During these times of stress preschoolers sometimes revert to bed wetting or thumb sucking and want the parents to feed, dress, and hold them. These dependent behaviors are often confusing and embarrassing to parents. They benefit from the nurse's reassurance that they are the child's normal coping behaviors. Provide experiences that these children are able to master. Such successes help them return to their prior level of independent functioning. As language skills develop, encourage children to talk about their feelings. Play is also an excellent way for preschoolers to vent frustration or anger and is a socially acceptable way to deal with stress.

Play. The play of preschool children becomes more social after the third birthday as it shifts from parallel to associative play. Children playing together engage in similar if not identical activity; however, there is no division of labor or rigid organization or rules. Most 3-year-old children are able to play with one other child in a cooperative manner in which they make something or play designated roles such as mother and baby. By age 4 children play in groups of two or three, and by 5 years the group has a temporary leader for each activity.

Pretend play allows children to learn to understand others' points of view, develop skills in solving social problems, and become more creative. Some children have imaginary playmates. These playmates serve many purposes. They are friends when the child is lonely, they accomplish what the child is still attempting, and they experience what the child wants to forget or remember. Imaginary playmates are a sign of health and allow the child to distinguish between reality and fantasy.

Television, videos, electronic games, and computer programs also help support development and the learning of basic skills. However, these should be only one part of the child's total play activities. The AAP (2011c) advises no more than 1 to 2 hours per day of educational, nonviolent TV programs, which should be supervised by parents or other responsible adults in the home. Limiting TV viewing will provide more time for children to read, engage in physical activity, and socialize with others (Hockenberry and Wilson, 2011).

Health Risks

As fine- and gross-motor skills develop and the child becomes more coordinated with better balance, falls become much less of a problem. Guidelines for injury prevention in the toddler also apply to the preschooler. Children need to learn about safety in the home, and parents need to continue close supervision of activities. Children at this age are great imitators; thus parental example is important. For instance, parental use of a helmet while bicycling sets an appropriate example for the preschooler.

Health Promotion

Little research has explored preschoolers' perceptions of their own health. Parental beliefs about health, children's bodily sensations, and their ability to perform usual daily activities help children develop attitudes about their health. Preschoolers are usually quite independent in washing, dressing, and feeding. Alterations in this independence influence their feelings about their own health.

Nutrition. Nutrition requirements for the preschooler vary little from those of the toddler. The average daily intake is 1800 calories. Parents often worry about the amount of food their child is consuming, and this is a relevant concern because of the problem of childhood obesity. However, the quality of the food is more important than quantity in most situations. Preschoolers consume about half of average adult portion sizes. Finicky eating habits are characteristic of the 4-year-old; however, the 5-year-old is more interested in trying new foods.

Sleep. Preschoolers average 12 hours of sleep a night and take infrequent naps. Sleep disturbances are common during these years. Disturbances range from trouble getting to sleep to nightmares to prolonging bedtime with extensive rituals. Frequently children have had an overabundance of activity and stimulation. Helping them to slow down before bedtime usually results in better sleeping habits.

Vision. Vision screening usually begins in the preschool years and needs to occur at regular intervals. One of the most important tests is to determine the presence of nonbinocular vision or strabismus. Early detection and treatment of strabismus are essential by ages 4 to 6 to prevent amblyopia, the resulting blindness from disuse (Hockenberry and Wilson, 2011).

SCHOOL-AGE CHILDREN AND ADOLESCENTS

The developmental changes between ages 6 and 18 are diverse and span all areas of growth and development. Children develop, expand, refine, and synchronize physical, psychosocial, cognitive, and moral skills so the individual is able to become an accepted and productive member of society. The environment in which the individual develops skills also expands and diversifies. Instead of the boundaries of family and close friends, the environment now includes the school, community, and church. With age-specific assessment, you need to review the appropriate developmental expectations for each age-group. You can promote health by helping children and adolescents achieve a necessary developmental balance.

SCHOOL-AGE CHILDREN

During these "middle years" of childhood, the foundation for adult roles in work, recreation, and social interaction is laid. In industrialized countries this **school-age** period begins when the child starts elementary school around the age of 6 years. Puberty, around 12 years of age, signals the end of middle childhood. Children make great developmental strides during these years as they develop competencies in physical, cognitive, and psychosocial skills.

The school or educational experience expands the child's world and is a transition from a life of relatively free play to one of structured play, learning, and work. The school and home influence growth and development, requiring adjustment by the parents and child. The child learns to cope with rules and expectations presented by the school and peers. Parents have to learn to allow their child to make decisions, accept responsibility, and learn from the experiences of life.

Physical Changes

The rate of growth during these early school years is slow and consistent, a relative calm before the growth spurt of adolescence. The school-age child appears slimmer than the preschooler as a result of changes in fat distribution and thickness (Hockenberry and Wilson, 2011). The average increase in height is 5 cm (2 inches) per year, and weight increases by 4 to 7 pounds per year. Many children double their weight during these middle childhood years, and most girls exceed boys in both height and weight by the end of the school years (Hockenberry and Wilson, 2011).

School-age children become more graceful during the school years because their large muscle coordination improves and their strength doubles. Most children practice the basic gross-motor skills of running, jumping, balancing, throwing, and catching during play, resulting in refinement of neuromuscular function and skills. Individual differences in the rate of mastering skills and ultimate skill achievement become apparent during their participation in many activities and games. Fine-motor skills improve; and, as children gain control over fingers and wrists, they become proficient in a wide range of activities.

Most 6-year-old children are able to hold a pencil adeptly and print letters and words; by age 12 the child is able to make detailed drawings and write sentences in script. Painting, drawing, playing computer games, and modeling allow children to practice and improve newly refined skills. The improved fine-motor capabilities of youngsters in middle childhood allow them to become very independent in bathing, dressing, and taking care of other personal needs. They develop strong personal preferences in the way these needs are met. Illness and hospitalization threaten children's control in these areas. Therefore it is important to allow them to participate in care and maintain as much independence as possible. Children whose care demands restriction of fluids cannot be allowed to decide the amount of fluids they will drink in 24 hours, but they can help decide the type of fluids and help keep a record of their intake.

Assessment of neurological development is often based on fine-motor coordination. Fine-motor coordination is critical to success in the typical American school, where children have to hold pencils and crayons and use scissors and rulers. The opportunity to practice these skills through schoolwork and play is essential to learning coordinated, complex behaviors.

As skeletal growth progresses, body appearance and posture change. Earlier the child's posture was stoop shouldered, with slight lordosis and a prominent abdomen. The posture of a school-age child is more erect. It is essential to evaluate children, especially girls after the age of 12 years, for scoliosis, the lateral curvature of the spine.

Eye shape alters because of skeletal growth. This improves visual acuity, and normal adult 20/20 vision is achievable. Screening for vision and hearing problems is easier, and results are more reliable because school-age children more fully understand and cooperate with the test directions. The school nurse typically assesses the growth, visual, and auditory status of school-age children and refers those with possible deviations to a health care provider such as their family practitioner or pediatrician.

Cognitive Changes

Cognitive changes provide the school-age child with the ability to think in a logical manner about the here and now and to understand the relationship between things and ideas. They are now able to use their developed thinking abilities to experience events without having to act them out (Hockenberry and Wilson, 2011). Their thoughts are no longer dominated by their perceptions; thus their ability to understand the world greatly expands.

School-age children have the ability to concentrate on more than one aspect of a situation. They begin to understand that others do not always see things as they do and even begin to understand another viewpoint. They now have the ability to recognize that the amount or quantity of a substance remains the same even when its shape or appearance changes. For instance, two balls of clay of equal size remain the same amount of clay even when one is flattened and the other remains in the shape of a ball.

The young child is able to separate objects into groups according to shape or color, whereas the school-age child understands that the same element can exist in two classes at the same time. By 7 or 8 years these children develop the ability to place objects in order according to their increasing or decreasing size (Hockenberry and

Wilson, 2011; Santrock, 2009). School-age children frequently have collections such as baseball cards or stuffed animals that demonstrate this new cognitive skill.

Language Development. Language growth is so rapid during middle childhood that it is no longer possible to match age with language achievements. Children improve their use of language and expand their structural knowledge. They become more aware of the rules of syntax, the rules for linking words into phrases and sentences. They also identify generalizations and exceptions to rules. They accept language as a means for representing the world in a subjective manner and realize that words have arbitrary rather than absolute meanings. Children begin to think about language, which enables them to appreciate jokes and riddles. They are not as likely to use a literal interpretation of a word; rather they reason about its meaning within a context (Hockenberry and Wilson, 2011).

Psychosocial Changes

Erikson (1963) identifies the developmental task for school-age children as industry versus inferiority. During this time children strive to acquire competence and skills necessary for them to function as adults. School-age children who are positively recognized for success feel a sense of worth. Those faced with failure often feel a sense of mediocrity or unworthiness, which sometimes results in withdrawal from school and peers.

School-age children begin to define themselves on the basis of their internal characteristics more than external characteristics. They begin to define their self-concept and develop self-esteem, an overall self-evaluation. Interaction with peers allows them to define their own accomplishments in relation to others as they work to develop a positive self-image (Santrock, 2008).

Peer Relationships. Group and personal achievements become important to the school-age child. Success is important in physical and cognitive activities. Play involves peers and the pursuit of group goals. Although solitary activities are not eliminated, group play overshadows them. Learning to contribute, collaborate, and work cooperatively toward a common goal becomes a measure of success (Fig. 12-6).

The school-age child prefers same-sex peers to opposite-sex peers. In general, girls and boys view the opposite sex negatively.

FIG. 12-6 School-age children gain a sense of achievement working and playing with peers. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.)

Peer influence becomes quite diverse during this stage of development. Clubs and peer groups become prominent. School-age children often develop "best friends" with whom they share secrets and with whom they look forward to interacting on a daily basis. Group identity increases as the school-age child approaches adolescence.

Sexual Identity. Freud described middle childhood as the latency period because he believed that children of this period had little interest in their sexuality. Today many researchers believe that school-age children have a great deal of curiosity about their sexuality. Some experiment, but this play is usually transitory. Children's curiosity about adult magazines or meanings of sexually explicit words is also an example of their sexual interest. This is the time for children to have exposure to sex education, including sexual maturation, reproduction, and relationships (Hockenberry and Wilson, 2011).

Stress. Today's children experience more stress than children in earlier generations. Stress comes from parental expectations; peer expectations; the school environment; or violence in the family, school, or community. Some school-age children care for themselves before or after school without adult supervision. Latchkey children sometimes feel increased stress and are at greater risk for injury and unsafe behaviors (Hockenberry and Wilson, 2011). The nurse helps the child cope with stress by helping the parents and child to identify potential stressors and designing interventions to minimize stress and the child's stress response. Deep-breathing techniques, positive imagery, and progressive relaxation of muscle groups are interventions that most children can learn (see Chapter 32). Include the parent, child, and teacher in the intervention for maximal success.

Health Risks

Accidents and injuries are a major health problem affecting school-age children. They now have more exposure to various environments and less supervision, but their developed cognitive and motor skills make them less likely to suffer from unintentional injury. Some school-age children are risk takers and attempt activities that are beyond their abilities (Hockenberry and Wilson, 2007). Motor vehicle injuries as a passenger or pedestrian and bicycle injuries are among the most common in this age-group.

Infections account for the majority of all childhood illnesses; respiratory infections are the most prevalent. The common cold remains the chief illness of childhood. Certain groups of children are more prone to disease and disability, often as a result of barriers to health care. Poverty and the prevalence of illness are highly correlated. Access to care is often very limited, and health promotion and preventive health measures are minimal.

Health Promotion

Perceptions. During the school-age years identity and self-concept become stronger and more individualized. Perception of wellness is based on readily observable facts such as presence or absence of illness and adequacy of eating or sleeping. Functional ability is the standard by which personal health and the health of others are judged. Six-year-olds are aware of their body and modest and sensitive about being exposed. Nurses need to provide for privacy and offer explanations of common procedures.

Health Education. The school-age period is crucial for the acquisition of behaviors and health practices for a healthy adult life. Because cognition is advancing during the period, effective health education must be developmentally appropriate. Promotion of good health practices is a nursing responsibility. Programs directed at health education are frequently organized

and conducted in the school. Effective health education teaches children about their bodies and how the choices they make impact their health (Hockenberry and Wilson, 2011). During these programs focus on the development of behaviors that positively affect children's health status.

Health Maintenance. Parents need to recognize the importance of annual health maintenance visits for immunizations, screenings, and dental care. When their school-age child reaches 10 years of age, parents need to begin discussions in preparation for upcoming pubertal changes. Topics include introductory information regarding menstruation, sexual intercourse, reproduction, and **sexually transmitted infections (STIs).** Human papilloma virus (HPV) is a widespread virus that will infect over 50% of males and females in their lifetime (AAP, 2010). For many individuals HPV clears spontaneously, but for others it can cause significant consequences. Females can develop cervical, vaginal, and vulvar cancers and genital warts; and males can develop genital warts. Since it is not possible to determine who or who will not develop disease from the virus, the Centers for Disease Control and Prevention (CDC) (2010a), along with the AAP, recommends routine HPV vaccination for girls ages 11 to 12 and for young women ages 13 through 26 who have not already been vaccinated. It is further recommended that HPV vaccine be given to boys and young men ages 9 to 26 years.

Safety. Because accidents such as fires and car and bicycle crashes are the leading cause of death and injury in the school-age period, safety is a priority health teaching consideration. Nurses contribute to the general health of children by educating them about safety measures to prevent accidents. At this age encourage children to take responsibility for their own safety.

Nutrition. Growth often slows during the school-age period as compared to infancy and adolescence. School-age children are developing eating patterns that are independent of parental supervision. The availability of snacks and fast-food restaurants makes it increasingly difficult for children to make healthy choices. The prevalence of obesity among children 6 to 11 years of age increased from 6.5% in 1980 to 19.6% in 2008 (CDC, 2010b). Childhood obesity has become a prominent health problem, resulting in increased risk for hypertension, diabetes, coronary heart disease, fatty liver disease, pulmonary complications such as sleep apnea, musculoskeletal problems, dyslipidemia, and potential for psychological problems. Studies have found that overweight children are teased more often, less likely to be chosen as a friend, and more likely to be thought of as lazy and sloppy by their peers (Hockenberry and Wilson, 2011). Nurses contribute to meeting national policy goals by promoting healthy lifestyle habits, including nutrition. School-age children need to participate in educational programs that enable them to plan, select, and prepare healthy meals and snacks. Children need adequate caloric intake for growth throughout childhood accompanied by activity for continued gross-motor development.

ADOLESCENTS

Adolescence is the period during which the individual makes the transition from childhood to adulthood, usually between ages 13 and 20 years. The term *adolescent* usually refers to psychological maturation of the individual, whereas **puberty** refers to the point at which reproduction becomes possible. The hormonal changes of puberty result in changes in the appearance of the young person, and cognitive development results in the ability to hypothesize and deal with abstractions. Adjustments and adaptations are necessary to cope with these simultaneous changes and the attempt to establish a mature sense of identity. In the past many referred to adolescence as a stormy and stressful period filled with inner turmoil, but today it is recognized that most teenagers successfully meet the challenges of this period.

The nurse's understanding of development provides a unique perspective for helping teenagers and parents anticipate and cope with the stresses of adolescence. Nursing activities, particularly education, promote healthy development. These activities occur in a variety of settings, and you can direct them at the adolescent, parents, or both. For example, the nurse conducts seminars in a high school to provide practical suggestions for solving problems of concern to a large group of students such as treating acne or making responsible decisions about drugs or alcohol use. Similarly a group education program for parents about how to cope with teenagers would promote parental understanding of adolescent development.

Physical Changes

Physical changes occur rapidly in adolescence. Sexual maturation occurs with the development of primary and secondary sexual characteristics. The four main focuses of the physical changes are:

1. Increased growth rate of skeleton, muscle, and viscera.
2. Sex-specific changes such as changes in shoulder and hip width.
3. Alteration in distribution of muscle and fat.
4. Development of the reproductive system and secondary sex characteristics.

Wide variation exists in the timing of physical changes associated with puberty between sexes and within the same sex. Girls tend to begin their physical changes approximately 2 years earlier than boys, usually between the ages of 11 to 14 years (Santrock, 2009). The rates of height and weight gain are usually proportional, and the sequence of pubertal growth changes is the same in most individuals.

Hormonal changes within the body create change when the hypothalamus begins to produce gonadotropin-releasing hormones that stimulate ovarian cells to produce **estrogen** and testicular cells to produce **testosterone.** These hormones contribute to the development of secondary sex characteristics such as hair growth and voice changes and play an essential role in reproduction. The changing concentrations of these hormones are also linked to acne and body odor. Understanding these hormonal changes enables you to reassure adolescents and educate them about body care needs.

Boys who mature early are more poised, relaxed, good-natured, skilled in athletic activities, and likely to be school leaders than boys who mature late. In contrast, girls who mature early are less satisfied with their figures by late adolescence. The reason for this is that early-maturing girls tend to be shorter and somewhat heavier than late-maturing girls, who tend to be taller and thinner (Santrock, 2008). Being like peers is extremely important for adolescents (Fig. 12-7). Any deviation in the timing of the physical changes is extremely difficult for adolescents to accept. Therefore provide emotional support for those undergoing early or delayed puberty. Even adolescents whose physical changes are occurring at the normal times seek confirmation of and reassurance about their normalcy.

Height and weight increases usually occur during the prepubertal growth spurt, which peaks in girls at about 12 years and in boys at about 14 years. Girls' height increases 5 to 20 cm (2 to 8 inches), and weight increases by 15 to 55 pounds. Boys' height increases

FIG. 12-7 Peer interactions help increase self-esteem during puberty. (© Petrenko Andriy.)

approximately 10 to 30 cm (4 to 12 inches), and weight increases by 15 to 65 pounds. Individuals gain the final 20% to 25% of their height and 50% of their weight during this time period (Hockenberry and Wilson, 2011).

Girls attain 90% to 95% of their adult height by **menarche** (the onset of menstruation) and reach their full height by 16 to 17 years of age, whereas boys continue to grow taller until 18 to 20 years of age. Fat is redistributed into adult proportions as height and weight increase, and gradually the adolescent torso takes on an adult appearance. Although individual and sex differences exist, growth follows a similar pattern for both sexes. Personal growth curves help the nurse assess physical development. However, the individual's sustained progression along the curve is more important than a comparison to the norm.

Cognitive Changes

The adolescent develops the ability to determine and rank possibilities, solve problems, and make decisions through logical operations. The teenager thinks abstractly and deals effectively with hypothetical problems. When confronted with a problem, the adolescent considers an infinite variety of causes and solutions. For the first time the young person moves beyond the physical or concrete properties of a situation and uses reasoning powers to understand the abstract. School-age individuals think about what is, whereas adolescents are able to imagine what might be.

Adolescents are now able to think in terms of the future rather than just current events. These newly developed abilities allow the individual to have more insight and skill in playing video, computer, and board games that require abstract thinking and deductive reasoning about many possible strategies. A teenager even solves problems requiring simultaneous manipulation of several abstract concepts. Development of this ability is important in the pursuit of an identity. For example, newly acquired cognitive skills allow the teenager to define appropriate, effective, and comfortable sex-role behaviors and to consider their impact on peers, family, and society. A higher level of cognitive functioning makes the adolescent receptive to more detailed and diverse information about sexuality and sexual behaviors. For example, sex education includes an explanation of physiological sexual changes and birth control measures.

Adolescents also develop the ability to understand how an individual's ideas or actions influence others. This complex development of thought leads them to question society and its values. Although adolescents have the capability to think as well as an adult, they do not have experiences on which to build. It is common for teenagers to consider their parents too narrow minded or too materialistic. At this time adolescents believe that they are unique and the exception, giving rise to their risk-taking behaviors. In other words, adolescents think that they are invincible. For example, an adolescent might state that he or she "is able to drive fast and not have an accident."

Language Skills. Language development is fairly complete by adolescence, although vocabulary continues to expand. The primary focus becomes communication skills that the adolescent uses effectively in various situations. Adolescents need to communicate thoughts, feelings, and facts to peers, parents, teachers, and other persons of authority. The skills used in these diverse communication situations vary. Adolescents need to select the person with whom to communicate, decide on the exact message, and choose the way to transmit the message. For example, how teenagers tell parents about failing grades is not the same as how they tell friends. Good communication skills are critical for adolescents in overcoming peer pressure and unhealthy behaviors. The following are some hints for communicating with adolescents:

- Do not avoid discussing sensitive issues. Asking questions about sex, drugs, and school opens the channels for further discussion.
- Ask open-ended questions.
- Look for the meaning behind their words or actions.
- Be alert to clues to their emotional state.
- Involve other individuals and resources when necessary.

Psychosocial Changes

The search for personal identity is the major task of adolescent psychosocial development. Teenagers establish close peer relationships or remain socially isolated. Erikson (1963) sees identity (or role) confusion as the prime danger of this stage and suggests that the cliquish behavior and intolerance of differences seen in adolescent behavior are defenses against identity confusion (Erikson, 1968). Adolescents work at becoming emotionally independent from their parents while retaining family ties. They are often described as being ambivalent. They love and hate their parents. In addition, they need to develop their own ethical systems based on personal values. They need to make choices about vocation, future education, and lifestyle. The various components of total identity evolve from these tasks and compose adult personal identity that is unique to the individual.

Sexual Identity. Physical changes of puberty enhance achievement of sexual identity. The physical evidence of maturity encourages the development of masculine and feminine behaviors. If these physical changes involve deviations, the person has more difficulty developing a comfortable sexual identity. Adolescents depend on these physical clues because they want assurance of maleness or femaleness and they do not wish to be different from peers. Without these physical characteristics, achieving sexual identity is difficult.

Group Identity. Adolescents seek a group identity because they need esteem and acceptance. Similarity in dress or speech is common in teenage groups. Peer groups provide the adolescent with a sense of belonging, approval, and the opportunity to learn acceptable behavior. Popularity with opposite-sex and same-sex peers is important. The strong need for group identity seems to

conflict at times with the search for personal identity. It is as though adolescents require close bonds with peers so they later achieve a sense of individuality.

Family Identity. The movement toward stronger peer relationships is contrasted with adolescents' movements away from parents. Although financial independence for adolescents is not the norm in American society, many work part-time, using their income to bolster independence. When they cannot have a part-time job because of studies, school-related activities, and other factors, parents can provide allowances for clothing and incidentals, which encourage them to develop decision-making and budgeting skills.

Some adolescents and families have more difficulty during these years than others. Adolescents need to make choices, act independently, and experience the consequences of their actions. Nurses help families consider appropriate ways for them to foster the independence of their adolescent while maintaining family structure.

Health Identity. Another component of personal identity is perception of health. This component is of specific interest to health care providers. Healthy adolescents evaluate their own health according to feelings of well-being, ability to function normally, and absence of symptoms (Hockenberry and Wilson, 2011). They also often include health maintenance and health promotion behaviors as important concerns.

Therefore interventions to improve health perception concentrate on the adolescent period. The rapid changes during this period make health promotion programs especially crucial. Adolescents try new roles, begin to stabilize their identity, and acquire values and behaviors from which their adult lifestyle will evolve. They are able to identify behaviors such as smoking and substance abuse as threatening to health in general terms but frequently tend to underestimate the effect of the potentially negative consequences of their own actions (Hockenberry and Wilson, 2011).

Health Risks

Accidents. Accidents remain the leading cause of death in adolescence. Motor vehicle accidents, which are the most common cause of death, resulted in 74% of all unintentional deaths among teens 10 to 19 years (Hockenberry and Wilson, 2011). Such accidents are often associated with alcohol intoxication or drug abuse. Bicycling fatalities were 4 to 7 times more likely to occur in males than females. Other frequent causes of accidental death in teenagers are drowning and the use of firearms. Feelings of being indestructible lead to risk-taking behavior. The use of alcohol precedes many injuries, and adolescents continue to be both the victims and perpetrators of violence. A proposed objective for Healthy People 2020 is to reduce the percentage of middle and public high schools with a violent incident (U.S. Department of Health and Human Services [USDHHS], 2009a).

Violence and Homicide. Homicide is the second leading cause of death in the 15- to 24-year-old age-group, and for African American teenagers it is the most likely cause of death (National Institutes of Health, 2010). Results from the Youth Risk Behavior Surveillance System show that, in 2007, 18% of high school students had carried a weapon (e.g., gun, club, or knife) at some point during the preceding 30 days (USDHHS, 2009b). Individuals 12 years of age and older are most likely to be killed by an acquaintance or gang member, most often with a firearm. Because having a gun in the home raises the risk of homicide and suicide for adolescents, include assessment of gun presence in the home when counseling families (Hockenberry and Wilson, 2011).

BOX 12-2 EVIDENCE-BASED PRACTICE

Prevention Programs for School-Based Violence

PICO Question: For middle- and high-school students, are classroom-based curricular programs that promote prosocial behaviors and attitudes compared with efforts to improve the social and interpersonal climate of a school more effective in reducing school violence?

Evidence Summary

School violence is a serious problem that encompasses everyday events such as physical assaults and fighting, threats and intimidation, sexual harassment, bullying or cyberbullying, dating violence, and stalking (Theriot, 2008). Research shows that dating violence behaviors are the most common in schools and that adolescents involved in dating violence are more likely to be involved in violent relationships as adults (Theriot, 2008). In this current era of local school accountability, health care workers and educators are charged with the responsibility of assessing the prevalence of school violence, using evidence-based programs to address the behaviors, and monitoring the effectiveness of the programs (Benbenishty et al., 2008).

Currently two different approaches are used to reduce school violence. The first approach involves the delivery of classroom-based educational programs that focus on interpersonal skills, attitudes, and emotional literacy. These programs teach students to resolve conflicts and maintain peer relationships without resorting to aggressive or violent behavior (Park-Higgerson et al., 2008). The second approach is to establish efforts to improve the social and interpersonal climate of the school. These schools focus on the relationships among students, faculty, and administrators and the policies within the school that address violent behaviors (Greene, 2008; Johnson, 2009).

The research literature indicates that school-based curricular programs can be effective but need to be implemented in schools that have a positive school climate. Programs designed to prevent school violence have largely focused on reducing student-to-student aggressive behaviors and have not fully considered interpersonal relationships between students and adults in schools, student bonding to schools, and organizational factors that comprise school climate. Reducing school violence depends on implementation of both approaches.

Application to Nursing Practice

- Ongoing school violence assessment is critical to providing a healthy school environment.
- Including dating violence and stalking at school is essential and should be a part of nursing assessment.
- School nurses can work with educators to provide an environment that promotes adolescent health.
- Successful programs are those that are tailored to a specific school.
- Although the individual is the person responsible for violent behavior, violence occurs in context so health providers and educators can work together to ensure a healthy environment.

Violence among adolescents has become a national concern (Box 12-2). Statistics now show that 63 out of every 1000 high-school students are the victims of violence at school (Johnson, 2009; Kongsuwan et al., 2009). This violence is not just limited to physical assaults and fighting, threats and intimidation, sexual harassment, or bullying. It can also include adolescent dating violence and stalking at school (Theriot, 2008). Nurses working with adolescents need to be aware of the potential for school violence and include screening questions when providing health care, regardless of the setting.

Suicide. Suicide is the third leading cause of death in adolescents 13 to 19 years of age, and in a recent study by the National Center for Health Statistics, one fifth of high-school students indicated that they had contemplated suicide in the previous 12 months (Santrock, 2008). Depression and social isolation commonly precede a suicide attempt, but suicide probably results from a combination of several factors. Nurses must be able to identify the factors associated with adolescent suicide risk and precipitating events. The following warning signs often occur for at least a month before suicide is attempted:

- Decrease in school performance
- Withdrawal
- Loss of initiative
- Loneliness, sadness, and crying
- Appetite and sleep disturbances
- Verbalization of suicidal thought

Make immediate referrals to mental health professionals when assessment suggests that adolescents are considering suicide. Guidance helps them focus on the positive aspects of life and strengthen coping abilities.

Substance Abuse. Substance abuse is a concern for all who work with adolescents. Adolescents often believe that mood-altering substances create a sense of well-being or improve level of performance. All adolescents are at risk for experimental or recreational substance use, but those who have dysfunctional families are more at risk for chronic use and physical dependency. Some adolescents believe that substance use makes them more mature. They further believe that they will look and feel better with drug usage. Current statistics show that, by the end of their high-school years, 85% of adolescents have used alcohol, 65% have tried smoking, and 49% have experimented with marijuana (Hockenberry and Wilson, 2011). Tobacco use continues to be a problem among adolescents; and, although its use is declining, 3 out of 10 adolescents are active smokers at the time of high-school graduation.

Eating Disorders. Adolescent overweight and obesity are current concerns in the United States, and most teens try dieting at some time to control weight. Unfortunately the number of eating disorders is on the rise in adolescent girls; thus the benefits of a healthy diet should be discussed with all adolescents. Routine nutritional screening should be a part of the health care provided to all adolescents. Areas to include in the assessment are past and present diet history, food records, eating habits, attitudes, health beliefs, and socioeconomic and psychosocial factors (Hockenberry and Wilson, 2011).

Anorexia nervosa and bulimia are two eating disorders that appear in adolescence. Anorexia nervosa is a clinical syndrome with both physical and psychosocial components that involves the pursuit of thinness through starvation. Persons with anorexia nervosa have an intense fear of gaining weight and refuse to maintain body weight at the minimal normal weight for their age and height. Bulimia nervosa is most identified with binge eating and behaviors to prevent weight gain. Behaviors include self-induced vomiting, misuse of laxatives and other medications, and excessive exercise. Unlike anorexia, bulimia occurs within a normal weight range; thus it is much more difficult to detect. Because adolescents rarely volunteer information about behaviors to prevent weight gain, it is important to take a thorough dietary history. If left undetected and untreated, these disorders lead to significant morbidity and mortality (Hockenberry and Wilson, 2011; Santrock, 2008).

Sexually Transmitted Infections. STIs annually affect 3 million sexually active adolescents. This high degree of incidence makes it imperative that sexually active adolescents be screened for STIs, even when they have no symptoms. The annual physical examination of a sexually active adolescent includes a thorough sexual history and a careful examination of the genitalia so STIs are not missed. Be proactive by using the interview process to identify risk factors in the adolescent and provide education to prevent STIs, including human immunodeficiency virus (HIV), HPV, and unwanted pregnancies (Hockenberry and Wilson, 2011). As discussed earlier for school-age children, immunization for HPV infection should be considered at this time if not already administered.

Pregnancy. Adolescent pregnancy continues to be a major social challenge for our nation. The United States has the highest rate of teenage pregnancy and childbearing annually compared to other industrialized nations (Hockenberry and Wilson, 2011; Santrock, 2008). Adolescent pregnancy occurs across socioeconomic classes, in public and private schools, among all ethnic and religious backgrounds, and in all parts of the country. Teenage pregnancy with early prenatal supervision is less harmful to both mother and child than earlier believed. Pregnant teens need special attention to nutrition, health supervision, and psychological support. Adolescent mothers also need help in planning for the future and obtaining competent day care for their infants.

Health Promotion

Health Education. Community and school-based health programs for adolescents focus on health promotion and illness prevention. Nurses need to be sensitive to the emotional cues from adolescents before initiating health teaching to know when the teen is ready to discuss concerns. In addition, discussions with adolescents need to be private and confidential. Adolescents define health in much the same way as adults and look for opportunities to reach their physical, mental, and emotional potential. Large numbers of school-based clinics have been developed and implemented to respond to adolescents' needs. Adolescents are much more likely to use these health care services if they encounter providers who are caring and respectful (Hockenberry and Wilson, 2011).

Nurses play an important role in preventing injuries and accidental deaths. For example, urging adolescents to discuss alternatives to driving when under the influence of drugs or alcohol prepares them to consider alternatives when such an occasion arises. As a nurse, identify adolescents at risk for abuse, provide education to prevent accidents related to substance abuse, and provide counseling to those in rehabilitation.

Minority Adolescents. By the next century estimates predict that minorities as a group will become the majority. African American, Hispanic, Latino, Asian, Native American, and Alaska Native American adolescents are the fastest-growing segment in the U.S. population. Minority adolescents experience a greater percentage of health problems and barriers to health care (Hockenberry and Wilson, 2011). Issues of concern for these adolescents living in a high-risk environment include learning or emotional difficulties, death related to violence, unintentional injuries, increased rate for adolescent pregnancy, STIs, HIV infection, and acquired immunodeficiency syndrome (AIDS). Poverty is a major factor negatively affecting the lives of minority adolescents. Limited access to health services is common. Nurses are able to make a significant contribution to improving access to appropriate health care for adolescents. With knowledge about various cultures and the means to care for minority adolescents, the nurse acts as an advocate to ensure accessibility of appropriate services.

Gay, Lesbian, and Bisexual Adolescents. Researchers have studied development of a gay or lesbian identity in adults, but there are limited studies related to adolescents. It is widely known that,

although some adolescents participate in same-gender sexual activity, they do not necessarily become homosexual as adults (Hockenberry and Wilson, 2011; Santrock, 2008). Adolescents who believe that they have a homosexual or bisexual orientation often try to keep it hidden to avoid any associated stigma. This increases their vulnerability to depression and suicide. The teens who choose to disclose a homosexual or bisexual orientation become at risk for violence, harassment, and family abuse. If a teen chooses to disclose sexual orientation to you, help the adolescent construct a safety plan before telling his or her family or friends in case the response is not supportive (Hockenberry and Wilson, 2011). One of the new additions to *Healthy People 2020* objectives is to increase the percentage of middle and high schools that prohibit harassment based on a student's sexual orientation or gender identity (USDHHS, 2009a).

KEY POINTS

- A developmental perspective helps the nurse understand commonalities and variations in each stage and the impact they have on the patient's health.
- During critical periods of development, a multitude of factors foster or hinder optimal physical, cognitive, and psychosocial development.
- Physiological, cognitive, and psychosocial development continue from conception through adolescence; thus be familiar with normal parameters to determine potential problems and identify ways to promote normal development.
- The most rapid period of growth and development occurs during infancy.
- The toddler's development of fine- and gross-motor skills support the move toward independence,
- Preschoolers interpret language literally and are unable to see another's point of view.
- Physical growth during the school years is slow and steady until the skeletal growth spurt just before puberty.
- The major psychosocial developmental task of the school-age child is the development of a sense of industry or competency.
- Adolescence begins with puberty, when primary sexual characteristics begin to develop and secondary sexual characteristics complete development.
- Adolescents are able to solve complex mental problems, which includes use of deductive reasoning.
- Accidents are the major cause of death in all age-groups.
- Sexually transmitted diseases are the most common communicable diseases among adolescents.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are caring for 12-year-old Elizabeth who has been hospitalized for an appendectomy. Her mother tells you that she is concerned about her lack of physical development compared to her peers. As a nurse you know that adolescents are preoccupied with their bodies and develop individual images of what they think they should look like. You are also aware that adolescents define health in terms of not just absence of illness but also being able to live up to one's physical, mental, and social potential.

1. What would you want to discuss concerning the onset of puberty with Elizabeth?
2. What psychosocial concerns may Elizabeth have in relation to her concerns about physical development?
3. How will Elizabeth's cognitive and psychosocial development direct your teaching?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. In an interview with a pregnant patient, the nurse discussed the three risk factors that have been cited as having a possible effect on prenatal development. They are:
   1. Nutrition, stress, and mother's age.
   2. Prematurity, stress, and mother's age.
   3. Nutrition, mother's age, and fetal infections.
   4. Fetal infections, prematurity, and placenta previa.
2. A parent has brought her 6-month-old infant in for a well-child check. Which of her statements indicates a need for further teaching?
   1. "I can start giving her whole milk at about 12 months."
   2. "I can continue to breastfeed for another 6 months."
   3. "I've started giving her plenty of fruit juice as a way to increase her vitamin intake."
   4. "I can start giving her solid food now."
3. The type of injury a child is most vulnerable to at a specific age is most closely related to which of the following?
   1. Provision of adult supervision.
   2. Educational level of the parent
   3. Physical health of the child
   4. Developmental level of the child
4. Which approach would be best for the nurse to use with a hospitalized toddler?
   1. Always give several choices.
   2. Set few limits to allow for open expression.
   3. Use noninvasive methods when possible.
   4. Gain cooperation before attempting treatment.
5. The nurse is providing information on prevention of sudden infant death syndrome (SIDS) to the mother of a young infant. Which of the following statements indicates that the mother has a good understanding? (Select all that apply.)
   1. "I won't use a pacifier to help my baby sleep."
   2. "I'll be sure my baby does not spend any time on her abdomen."
   3. "I'll place my baby on her back for sleep."
   4. "I'll be sure to keep my baby's room cold."
6. In evaluating the gross-motor development of a 5-month-old infant, which of the following would the nurse expect the infant to do?
   1. Roll from abdomen to back
   2. Move from prone to sitting unassisted
   3. Sit upright without support
   4. Turn completely over
7. Parents are concerned about their toddler's negativism and ask the nurse for guidance. Which is the most appropriate recommendation?
   1. Provide more attention.
   2. Reduce opportunities for a "no" answer.
   3. Be consistent with punishment.
   4. Provide opportunities for the toddler to make decisions.
8. When nurses are communicating with adolescents, they should:
   1. Be alert to clues to their emotional state.
   2. Ask closed-ended questions to get straight answers.

3. Avoid looking for meaning behind adolescents' words or actions.
4. Avoid discussing sensitive issues such sex and drugs.

9. Which of the following statements is most descriptive of the psychosocial development of school-age children?
   1. Boys and girls play equally with each other.
   2. Peer influence is not yet an important factor to the child.
   3. They like to play games with rigid rules.
   4. Children frequently have "best friends."
10. You are caring for a 4-year-old child who is hospitalized for an infection. He tells you that he is sick because he was "bad." Which is the most correct interpretation of his comment?
    1. Indicative of extreme stress
    2. Representative of his cognitive development
    3. Suggestive of excessive discipline at home
    4. Indicative of his developing sense of inferiority
11. At a well-child examination, the mother comments that her toddler eats little at mealtime, will only sit briefly at the table, and wants snacks all the time. Which of the following should the nurse recommend?
    1. Provide nutritious snacks.
    2. Offer rewards for eating at mealtimes.
    3. Avoid snacks so she is hungry at mealtime.
    4. Explain to her firmly why eating at mealtime is important.
12. An 8-year-old child is being admitted to the hospital from the emergency department with an injury from falling off her bicycle. Which of the following will most help her adjust to the hospital?
    1. Explain hospital routines such as meal times to her.
    2. Use terms such as "honey" and "dear" to show a caring attitude.
    3. Explain when her parents can visit and why siblings cannot come to see her.
    4. Since she is young, orient her parents to her room and hospital facility.
13. The school nurse is counseling an obese 10-year-old child. What factor would be important to consider when planning an intervention to support the child's health?
    1. Concentrate on the child only rather than the family since it is the child's responsibility.
    2. Consider the use of medications to suppress the appetite.
    3. First plan for weight loss through dieting and then add activity as tolerated.
    4. Plan food intake to allow for growth
14. You are working in an adolescent health center when a 15-year-old patient shares with you that she thinks she is pregnant and is worried that she may now have a sexually transmitted infection (STI). Her pregnancy test is negative. What is your next priority of care?
    1. Contact her parents to alert them of her need for birth control.
    2. Refer her to a primary health care provider to obtain a prescription for birth control.
    3. Counsel her on safe sex practices.
    4. Ask her to have her partner come to the clinic for STI testing.
15. While working in the high-school clinic, one of the students tells you that she is worried about her friend who has started to refuse to participate in group activities, no longer cares about how she looks at school, and is not going to all of her classes. Your assessment of these symptoms may indicate that:
    1. She has just broken up with her boyfriend and time will heal all.
    2. You will need to observe her over time to see if symptoms persist.
    3. School may be too difficult for her right now.
    4. She may be at increased risk for suicide.

CHAPTER

13

Young and Middle Adults

OBJECTIVES

- Discuss developmental theories of young and middle adults.
- List and discuss major life events of young and middle adults and the childbearing family.
- Describe developmental tasks of the young adult, the childbearing family, and the middle adult.
- Discuss the significance of family in the life of the adult.
- Describe normal physical changes in young and middle adulthood and pregnancy.
- Discuss cognitive and psychosocial changes occurring during the adult years.
- Describe health concerns of the young adult, the childbearing family, and the middle adult.

Young and middle adulthood is a period of challenges, rewards, and crises. Challenges may include the demands of working and raising families, although there are many rewards with these as well. Adults also face crises such as caring for their aging parents, the possibility of job loss in a changing economic environment, and dealing with their own developmental needs and those of their family members.

Classic works by developmental theorists such as Levinson et al (1978), Diekelmann (1976), Erikson (1963, 1982), and Havighurst (1972) attempted to describe the phases of young and middle adulthood and related developmental tasks (see Chapter 11 for an in-depth discussion of developmental theories).

Traditional masculine roles include providing and protecting. However, these roles are now shared with women. Faced with a societal structure that differs greatly from the norms of 20 or 30 years ago, both men and women are assuming different roles in today's society. Men were traditionally the primary supporter of the family. Today many women pursue careers and contribute significantly to their families' incomes. In 2006 60% of women participated in the U.S. labor force and constituted 46% of all U.S. workers in the U.S. labor force. Thirty-eight percent of employed women worked in management or professional and related occupations, 34% worked in sales and office occupations; and another 20% worked in service occupations (Business and Professional Women's Foundation, 2007). However, according to the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO) (2008) workers' union, women in the United States are paid 77.6 cents for every dollar men receive for comparable work.

Developmental theories provide nurses with a basis for understanding the life events and developmental tasks of the young and middle adult. Patients present challenges to nurses who themselves are often young or middle adults coping with the demands of their respective developmental period. Nurses need to recognize the needs of their patients even if they are not experiencing the same challenges and events.

YOUNG ADULTS

Young adulthood is the period between the late teens and the mid to late 30s (Edelman and Mandle, 2010). In recent years young adults between the ages of 18 and 29 have been referred to as part of the **millennial generation.** In 2009 young adults made up approximately 33% of the population (U.S. Census Bureau, 2009). According to the Pew Research Center (2010), today's young adults are history's first "always connected" generation, with digital technology and social media major aspects of their lives. They adapt well to new experiences, are more ethnically and racially diverse than previous generations, and are the least overtly religious American generation in modern times. Young adults increasingly move away from their families of origin, establish career goals, and decide

whether to marry or remain single and whether to begin families; however, often these goals may be delayed (e.g., because of the economic recession of recent years).

Physical Changes

The young adult usually completes physical growth by the age of 20. An exception to this is the pregnant or lactating woman. The physical, cognitive, and psychosocial changes and the health concerns of the pregnant woman and the childbearing family are extensive.

Young adults are usually quite active, experience severe illnesses less commonly than older age-groups, tend to ignore physical symptoms, and often postpone seeking health care. Physical characteristics of young adults begin to change as middle age approaches. Unless patients have illnesses, assessment findings are generally within normal limits.

Cognitive Changes

Critical thinking habits increase steadily through the young- and middle-adult years. Formal and informal educational experiences, general life experiences, and occupational opportunities dramatically increase the individual's conceptual, problem-solving, and motor skills.

Identifying an occupational direction is a major task of young adults. When people know their skills, talents, and personality characteristics, educational preparation and occupational choices are easier and more satisfying. A bachelor's or associate's degree is the most significant source of postsecondary education for 12 of the 20 fastest-growing occupations.

An understanding of how adults learn helps you to develop patient education plans (see Chapter 25). Adults enter the teaching-learning situation with a background of unique life experiences, including illness. Therefore always view adults as individuals. Their adherence to regimens such as medications, treatments, or lifestyle changes such as smoking cessation involves decision-making processes. When determining the amount of information that an individual needs to make decisions about the prescribed course of therapy, consider factors that possibly affect the individual's adherence to the regimen, including educational level, socioeconomic factors, and motivation and desire to learn.

Because young adults are continually evolving and adjusting to changes in the home, workplace, and personal lives, their decision-making processes need to be flexible. The more secure young adults are in their roles, the more flexible and open they are to change. Insecure persons tend to be more rigid in making decisions.

Psychosocial Changes

The emotional health of the young adult is related to the individual's ability to address and resolve personal and social tasks. The young adult is often caught between wanting to prolong the irresponsibility of adolescence and assume adult commitments. However, certain patterns or trends are relatively predictable. Between the ages of 23 and 28, the person refines self-perception and ability for intimacy. From 29 to 34 the person directs enormous energy toward achievement and mastery of the surrounding world. The years from 35 to 43 are a time of vigorous examination of life goals and relationships. People make changes in personal, social, and occupational areas. Often the stresses of this reexamination results in a "midlife crisis" in which marital partner, lifestyle, and occupation change.

Ethnic and gender factors have a sociological and psychological influence in an adult's life, and these factors pose a distinct challenge for nursing care. Each person holds culture-bound definitions of health and illness. Nurses and other health professionals bring with them distinct practices for the prevention and treatment of illness. Knowing too little about a patient's self-perception or beliefs regarding health and illness creates conflict between the nurse and the patient. Changes in the traditional role expectations of both men and women in young and middle adulthood also lead to greater challenges for nursing care. For example, women often continue to work during the childrearing years, and many women struggle with the enormity of balancing three careers: wife, mother, and employee. This is a potential source of stress for the adult working woman. Men are more aware of parental and household responsibilities and find themselves having more responsibilities at home while achieving their own career goals (Fortinash and Holoday Worret, 2008). An understanding of ethnicity, race, and gender differences enables a nurse to provide individualized care (see Chapter 9).

Support from a nurse, access to information, and appropriate referrals provide opportunities for achievement of a patient's potential. Health is not merely the absence of disease but involves wellness in all human dimensions. The nurse acknowledges the importance of the young adult's psychosocial needs and needs in all other dimensions. The young adult needs to make decisions concerning career, marriage, and parenthood. Although each person makes these decisions based on individual factors, a nurse needs to understand the general principles involved in these aspects of psychosocial development while assessing the young adult's psychosocial status.

Lifestyle. Family history of cardiovascular, renal, endocrine, or neoplastic disease increases a young adult's risk of illness. Your role in health promotion is to identify modifiable factors that increase the young adult's risk for health problems and provide patient education and support to reduce unhealthy lifestyle behaviors (Sanchez et al., 2009).

A personal lifestyle assessment (see Chapter 6) helps nurses and patients identify habits that increase the risk for cardiac, malignant, pulmonary, renal, or other chronic diseases. The assessment includes general life satisfaction, hobbies, and interests; habits such as diet, sleeping, exercise, sexual habits, and use of caffeine, tobacco, alcohol, and illicit drugs; home conditions and pets; economics, including type of health insurance; occupational environment, including type of work and exposure to hazardous substances; and physical or mental stress. Military records, including dates and geographical area of assignments, may also be useful in assessing the young adult for risk factors. Prolonged stress from lifestyle choices increases wear and tear on the adaptive capacities of the body. Stress-related diseases such as ulcers, emotional disorders, and infections sometimes occur (see Chapter 37).

Career. A successful vocational adjustment is important in the lives of most men and women. Successful employment not only ensures economic security, but it also leads to friendships, social activities, support, and respect from co-workers.

Two-career families are increasing. The two-career family has benefits and liabilities. In addition to increasing the family's financial base, the person who works outside the home is able to expand friendships, activities, and interests. However, stress exists in a two-career family as well. These stressors result from a transfer to a new city; increased expenditures of physical, mental, or emotional energy; child care demands; or household needs. To avoid stress in a two-career family, partners should share all responsibilities. For example, some families may decide to limit recreational expenses and instead hire someone to do routine housework. Others set up an equal division of household, shopping, and cooking duties.

FIG. 13-1 Nurse providing Lamaze class for expectant young adults.

Sexuality. The development of secondary sex characteristics occurs during the adolescent years (see Chapter 12). Physical development is accompanied by the ability to perform sex acts. The young adult usually has emotional maturity to complement the physical ability and therefore is able to develop mature sexual relationships and establish intimacy. Young adults who have failed to achieve the developmental task of personal integration sometimes develop relationships that are superficial and stereotyped (Fortinash and Holoday Worret, 2008).

Masters and Johnson (1970) contributed important information about the physiological characteristics of the adult sexual response (see Chapter 34). The psychodynamic aspect of sexual activity is as important as the type or frequency of sexual intercourse to young adults. To maintain total wellness, encourage adults to explore various aspects of their sexuality and be aware that their sexual needs and concerns change. As the rate of early initiation of sexual intercourse continues to increase, young adults are at risk for sexually transmitted infections (STIs). Consequently there is an increased need for education regarding the mode of transmission, prevention, and symptom recognition and management for STIs.

Childbearing Cycle. Conception, pregnancy, birth, and the puerperium are major phases of the childbearing cycle. The changes during these phases are complex. Education such as Lamaze classes can prepare pregnant women, their partners, and other support persons to participate in the birthing process (Fig. 13-1). A current trend in some health care agencies is to provide either professional labor support (Sauls, 2006) or a lay **doula,** a support person to be present during labor to assist women who have no other source of support (Campbell et al., 2006). The stress that many women experience after childbirth has a significant impact on postpartum women's health (Box 13-1).

Types of Families. During young adulthood most individuals experience singlehood and the opportunity to be on their own. Those who eventually marry encounter several changes as they take on new responsibilities. For example, many married couples choose to become parents (Fig. 13-2). Some young adults choose alternative lifestyles. Chapter 10 reviews forms of families.

Singlehood. Social pressure to get married is not as great as it once was, and many young adults do not marry until their late 20s or early 30s or not at all. For young adults who remain single, parents and siblings become the nucleus for a family. Some view close friends and associates as "family." One cause for the increased single population is the expanding career opportunities for women. Women enter the job market with greater career potential and have greater opportunities for financial independence. More single individuals are choosing to live together outside of marriage and become parents either biologically or through adoption. Similarly many married couples choose to separate or divorce if they find their marital situation unsatisfactory.

BOX 13-1 EVIDENCE-BASED PRACTICE

Assessing for Postpartum Depression

PICO Question: What psychosocial interventions affect a young adult woman's risk for postpartum depression (PPD)?

Evidence Summary

A woman often experiences dramatic physical and psychosocial changes during the postpartum period that impact health, with up to 85% of women experiencing some type of mood disturbance. For most women these transient symptoms are referred to as "postpartum blues" (Beck, 2006; USPSTF, 2009). Common symptoms of postpartum blues, including rapidly fluctuating mood, tearfulness, irritability, and anxiety, are generally mild (Beck, 2006; Doucet et al., 2009). A 10% to 15% group of women experience a more persistent form of PPD after the birth of a baby, and 0.1% to 0.2% of postpartum women experience postpartum psychosis (Robertson, 2010; USPSTF, 2009). The onset of postpartum psychosis carries a high risk of suicide and infanticide (murder of an infant). The onset of postpartum psychosis is abrupt and severe, with clinical manifestations of delusions, hallucinations, thoughts of harming or killing the baby, unwillingness to eat or sleep, frantic energy, risk of suicide, and severe depressive symptoms (Beacham et al., 2008).

Research findings indicate several risk factors for the development of postpartum mood disorder, including stress, fatigue, quality of relationship with the father of the baby, social support, birth of a preterm or low-birth-weight infant, and young maternal age (Akincigil et al., 2010; Bei et al., 2010). Studies also show that postpartum depression may have a negative impact on the maternal-infant relationship, infant development, and long-term child behavior (Knitzer et al., 2008; Poobalan et al., 2007). Postpartum psychosis is an extremely serious and rare postpartum mood disorder, and it is considered a psychiatric emergency.

Successful treatment of PPD depends on early identification and intervention. Clinical assessment of pregnant and postpartum women that is guided by the major predictors of PPD can help nurses identify women most at risk. Subsequently intervention can be initiated before the occurrence of depressive symptoms (Records et al., 2007).

Application to Nursing Practice

- Assess for potential postpartum stressors such as fatigue, first-time mother, previous postpartum stress, or feeling of social isolation.
- Identify sources of social support for new mothers after they are discharged from the hospital with their babies such as new-mother visits, young-mother groups, and mom's day out activities.
- Create culturally appropriate, primary prevention strategies for stressors that new mothers encounter.
- Educate new mothers and their families on the risks for and signs and symptoms of postpartum stress and depression.
- Provide new mothers with information on health care and community resources for use during the postpartum period.

FIG. 13-2 Parent-child nurturing is important in adapting to a newborn. (From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children,* ed 9, St Louis, 2011, Mosby.)

Parenthood. The availability of contraception makes it easier for today's couples to decide when and if to start a family. Social pressures may encourage a couple to have a child or influence them to limit the number of children they have. Economic considerations frequently enter into the decision-making process because of the expense of childrearing. General health status and age are also considerations in decisions about parenthood because couples are getting married later and postponing pregnancies, which often results in smaller families.

Alternative Family Structures and Parenting. Changing norms and values about family life in the United States reveal basic shifts in attitudes about family structure. The trend toward greater acceptance of cohabitation without marriage is a factor in the greater numbers of infants being born to single women. In addition, approximately 1.5 million parents are gay or lesbian. More than one third of lesbians have given birth, and one in six gay men have fathered or adopted a child. Gay and lesbian parents are raising 3% of foster children in the United States (Gates et al., 2007). The American Academy of Pediatrics (AAP), in recognizing the needs of gay and lesbian parents and their children, published a policy statement supporting adoption of children and the parenting role by same-sex parents (AAP, 2002). However, many times parents from alternative family structures still feel a lack of support and even bias from the health care system (Makadon, 2006; McManus et al., 2006).

Hallmarks of Emotional Health. Most young adults have the physical and emotional resources and support systems to meet the many challenges, tasks, and responsibilities they face. During psychosocial assessment of young adults, assess for 10 hallmarks of emotional health (Box 13-2) that indicate successful maturation in this developmental stage.

BOX 13-2 TEN HALLMARKS OF EMOTIONAL HEALTH

1. A sense of meaning and direction in life
2. Successful negotiation through transitions
3. Absence of feelings of being cheated or disappointed by life
4. Attainment of several long-term goals
5. Satisfaction with personal growth and development
6. When married, feelings of mutual love for partner; when single, satisfaction with social interactions
7. Satisfaction with friendships
8. Generally cheerful attitude
9. No sensitivity to criticism
10. No unrealistic fears

Health Risks

Health risk factors for a young adult originate in the community, lifestyle patterns, and family history. The lifestyle habits that activate the stress response (see Chapter 37) increase the risk of illness. Smoking is a well-documented risk factor for pulmonary, cardiac, and vascular diseases in smokers and the individuals who receive secondhand smoke. Inhaled cigarette pollutants increase the risk of lung cancer, emphysema, and chronic bronchitis. The nicotine in tobacco is a vasoconstrictor that acts on the coronary arteries, increasing the risk of angina, myocardial infarction, and coronary artery disease. Nicotine also causes peripheral vasoconstriction and leads to vascular problems.

Family History. A family history of a disease puts a young adult at risk for developing it in the middle or older adult years. For example, a young man whose father and paternal grandfather had myocardial infarctions (heart attacks) in their 50s has a risk for a future myocardial infarction. The presence of certain chronic illnesses such as diabetes mellitus in the family increases the family member's risk of developing a disease. Regular physical examinations and screening are necessary at this stage of development.

Personal Hygiene Habits. As in all age-groups, personal hygiene habits in the young adult are risk factors. Sharing eating utensils with a person who has a contagious illness increases the risk of illness. Poor dental hygiene increases the risk of periodontal disease. Individuals avoid gingivitis (inflammation of the gums) and periodontitis (loss of tooth support) through oral hygiene (see Chapter 39).

Violent Death and Injury. Violence is a common cause of mortality and morbidity in the young-adult population. Factors that predispose individuals to violence, injury, or death include poverty, family breakdown, child abuse and neglect, drug involvement (dealing or illegal use), repeated exposure to violence, and ready access to guns. It is important for the nurse to perform a thorough psychosocial assessment, including such factors as behavior patterns, history of physical and substance abuse, education, work history, and social support systems to detect personal and environmental risk factors for violence. Death and injury occur from physical assaults, motor vehicle or other accidents, and suicide attempts. In 2007, homicides occurred at a higher rate among men and people ages 20 to 24 years than other violent deaths (USDHHS, CDC, 2010a).

Intimate partner violence (IPV), formerly referred to as domestic violence, is a global public health problem. It exists along a continuum from a single episode of violence to ongoing battering (USDHHS, CDC, 2009a). IPV often begins with emotional or mental abuse and may progress to physical or sexual assault. Each year women in the United States experience approximately 4.8 million intimate partner–related physical assaults and rapes, and men are the victims of approximately 2.9 intimate partner–related physical assaults. Physical injuries from IPV range from minor cuts and bruises to broken bones, internal bleeding, and head trauma.

IPV is linked to such harmful health behaviors as smoking, alcohol abuse, drug use, and risky sexual activity. Risk factors for the perpetration of IPV include using drugs or alcohol, especially drinking heavily; unemployment; low self-esteem; antisocial or borderline personality traits; desire for power and control in relationships; and being a victim of physical or psychological abuse (El-Bassel et al., 2007; Gil-Gonzalez et al., 2008). The greatest risk of violence occurs during the reproductive years. A pregnant woman has a 35.6% greater risk of being a victim of IPV than a nonpregnant woman. Women experiencing IPV may be more likely to delay prenatal care and are at increased risk for multiple poor maternal and infant health outcomes such as low maternal weight gain, infections, high blood pressure, vaginal bleeding, and delivery of a preterm or low-birth-weight infant (NACCHO, 2008).

Substance Abuse. Substance abuse directly or indirectly contributes to mortality and morbidity in young adults. Intoxicated young adults are often severely injured in motor vehicle accidents, resulting in death or permanent disability to other young adults as well.

Dependence on stimulant or depressant drugs sometimes results in death. Overdose of a stimulant drug ("upper") stresses the cardiovascular and nervous systems to the extent that death occurs. The use of depressants ("downers") leads to an accidental or intentional overdose and death.

Caffeine is a naturally occurring legal stimulant that is readily available in carbonated beverages; chocolate-containing foods; coffee and tea; and over-the-counter medications such as cold tablets, allergy and analgesic preparations, and appetite suppressants. It is the most widely ingested stimulant in North America. Caffeine stimulates catecholamine release, which in turn stimulates the central nervous system; it also increases gastric acid secretion, heart rate, and basal metabolic rate. This alters blood pressure, increases diuresis, and relaxes smooth muscle. Consumption of large amounts of caffeine results in restlessness, anxiety, irritability, agitation, muscle tremor, sensory disturbances, heart palpitations, nausea or vomiting, and diarrhea in some individuals.

Substance abuse is not always diagnosable, particularly in its early stages. Nonjudgmental questions about use of legal drugs (prescribed drugs, tobacco, and alcohol), soft drugs (marijuana), and more problematic drugs (cocaine or heroin) are a routine part of any health assessment. Obtain important information by making specific inquiries about past medical problems, changes in food intake or sleep patterns, or problems of emotional lability. Reports of arrests because of driving while intoxicated, wife or child abuse, or disorderly conduct are reasons to investigate the possibility of drug abuse more carefully.

Unplanned Pregnancies. Unplanned pregnancies are a continued source of stress that may result in adverse health outcomes for the mother, infant, and family. Often young adults have educational and career goals that take precedence over family development. Interference with these goals affects future relationships and parent-child relationships.

Determination of situational factors that affect the progress and outcome of an unplanned pregnancy is important. Exploration of problems such as financial, career, and living accommodations; family support systems; potential parenting disorders; depression; and coping mechanisms is important in assessing the woman with an unplanned pregnancy.

Sexually Transmitted Infections. STIs are a major health problem in young adults. Examples of STIs include syphilis, chlamydia, gonorrhea, genital herpes, and acquired immunodeficiency syndrome (AIDS). STIs have immediate physical effects such as genital discharge, discomfort, and infection. They also lead to chronic disorders, infertility, or even death. They remain a major public health problem for sexually active people, with almost half of all new infections occurring in men and women younger than 24 years of age (USDHHS, CDC, 2009b). In 2008 20- to 24-year-old men had the highest rate of chlamydia among men (1056.1 per 100,000 population); chlamydia rates in men of this age-group increased by 12.6% from the previous year.

TABLE 13-1 Occupational Hazards/Exposures Associated with Diseases and Cancers

JOB CATEGORY	OCCUPATIONAL HAZARD/ EXPOSURE	WORK-RELATED CONDITION/ CANCER
Agricultural workers	Pesticides, infectious agents, gases, sunlight	Pesticide poisoning, "farmer's lung," skin cancer
Anesthetists	Anesthetic gases	Reproductive effects, cancer
Automobile workers	Asbestos, plastics, lead, solvents	Asbestosis, dermatitis
Carpenters	Wood dust, wood preservatives, adhesives	Nasopharyngeal cancer, dermatitis
Cement workers	Cement dust, metals	Dermatitis, bronchitis
Dry cleaners	Solvents	Liver disease, dermatitis
Dye workers	Dyestuffs, metals, solvents	Bladder cancer, dermatitis
Glass workers	Heat, solvents, metal powders	Cataracts
Hospital workers	Infectious agents, cleansers, latex gloves, radiation	Infections, latex allergies, unintentional injuries
Insulators	Asbestos, fibrous glass	Asbestosis, lung cancer, mesothelioma
Jackhammer operators	Vibration	Raynaud's phenomenon
Lathe operators	Metal dusts, cutting oils	Lung disease, cancer
Office computer workers	Repetitive wrist motion on computers; eyestrain	Tendonitis, carpal tunnel syndrome, tenosynovitis

From Stanhope M, Lancaster J: *Foundations of nursing in the community,* ed 3, St Louis, 2010, Mosby.

Environmental or Occupational Factors. A common environmental or occupational risk factor is exposure to work-related hazards or agents that cause diseases and cancer (Table 13-1). Examples include lung diseases such as silicosis from inhalation of talcum and silicon dust and emphysema from inhalation of smoke. Cancers resulting from occupational exposures may involve the lung, liver, brain, blood, or skin. Questions regarding occupational exposure to hazardous materials should be a routine part of your assessment.

Health Concerns

Health Promotion. Lifestyles (e.g., use of tobacco or alcohol) of young adults may put them at risk for illnesses or disabilities during their middle- or older-adult years. Young adults are also genetically susceptible to certain chronic diseases such as diabetes mellitus and familial hypercholesterolemia (Huether and McCance,

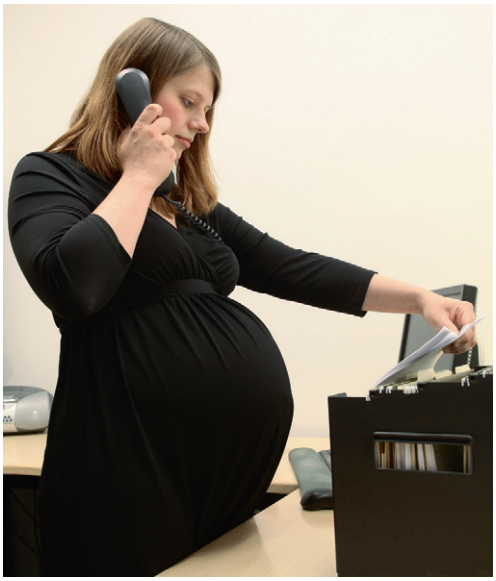

FIG. 13-3 The ability to handle day-to-day challenges at work minimizes stress.

2008). Some diseases that may appear in later years are avoidable if identified early. Encourage adults to perform monthly skin, breast, or male genital self-examination (see Chapter 30). Breast cancer is the most common major cancer among women in the United States, with a steadily increasing incidence. A nurse's role is extremely important in educating female patients about breast self-examinations (BSEs) and the current breast screening recommendations. Encourage routine assessment of the skin for recent changes in color or presence of lesions and changes in their appearance. Prolonged exposure to ultraviolet rays of the sun by adolescents and young adults increase the risk for development of skin cancer later in life. Crohn's disease, a chronic inflammatory disease of the small intestine, most commonly occurs between 15 and 35 years of age. Many young adults have misconceptions regarding transmission and treatment of STIs. Encourage partners to know one another's sexual history and practices. Be alert for STIs when patients come to clinics with complaints of urological or gynecological problems (see Chapter 34). Assess young adults for knowledge and use of safe-sex practices and genital self-examinations. Provide information on safe sex practice (e.g., use of condoms and having only one sex partner).

Psychosocial Health. The psychosocial health concerns of the young adult are often related to job and family stressors. As noted in Chapter 37, stress is valuable because it motivates a patient to change. However, if the stress is prolonged and the patient is unable to adapt to the stressor, health problems develop.

Job Stress. Job stress can occur every day or from time to time. Most young adults are able to handle day-to-day crises (Fig. 13-3). Situational job stress occurs when a new boss enters the workplace, a deadline is approaching, or the worker has new or greater numbers of responsibilities. A recent trend in today's business world and a risk factor for job stress is corporate downsizing, leading to increased responsibilities for employees with fewer positions within the corporate structure. Job stress also occurs when a person becomes dissatisfied with a job or the associated responsibilities. Because individuals perceive jobs differently, the types of job stressors vary from patient to patient. A nurse's assessment of a young adult includes a description of the usual work performed. Job assessment also includes conditions and hours, duration of employment, changes in sleep or eating habits, and evidence of increased irritability or nervousness.

Family Stress. Because of the multiplicity of changing relationships and structures in the emerging young adult family, stress is frequently high (see Chapter 10). Situational stressors occur during events such as births, deaths, illnesses, marriages, and job losses. Stress is often related to a number of variables, including the career paths of both husband and wife, and leads to dysfunction in the young adult family. This is reflected in the fact that the highest divorce rate occurs during the first 3 to 5 years of marriage for young adults under the age of 30. When a patient seeks health care and presents stress-related symptoms, the nurse needs to assess for the occurrence of a life-change event.

Each family member has certain predictable roles or jobs. These roles enable the family to function and be an effective part of society. When they change as a result of illness, a situational crisis often occurs. Assess environmental and familial factors, including support systems and coping mechanisms commonly used by family members.

Infertility. The term **infertility** refers to a prolonged time to conceive. An estimated 10% to 15% of reproductive couples are infertile, and many are young adults. However, approximately half of the couples evaluated and treated in infertility clinics become pregnant. In about 15% of infertile couples the cause is unknown. Female factors such as ovulatory dysfunction or a pelvic factor is responsible for infertility in 50% of couples, and infertility in 35% of couples is caused by a male factor such as sperm and semen abnormalities. For some infertile couples a nurse is the first resource they identify. Nursing assessment of the infertile couple includes both comprehensive histories of the male and female partners to determine factors that have affected fertility and pertinent physical findings (Lowdermilk and Perry, 2007).

Obesity. Obesity is a major health problem in young adults and is recognized as a risk factor for other health problems later in life. Obesity, influenced by poor diet and inactivity, has been linked to the development of conditions such as type 2 diabetes, hypertension, high cholesterol, asthma, joint problems, psoriatic arthritis, and poor health status (Ogdie and Gelfand, 2010; Soltani-Arabshashi et al., 2010; USDHHS, CDC, 2010b). Studies are linking time spent by young adults in sedentary behaviors such as watching television or being on the computer with increased abdominal obesity (Cleland et al, 2008). Nursing assessment of diet and physical activity of young adults is an important part of data collection. All young adults should be counseled about the benefits of a healthful diet and physical activity.

Exercise. People of all ages, both male and female, benefit from regular physical activity (USDHHS, 2002); however, young adults are spending increasingly more time with technology and less time engaged in physical activity. Exercise in young adults is important to prevent or decrease the development of chronic health conditions such as high blood pressure, obesity, and diabetes that develop later in life. Exercise improves cardiopulmonary function by decreasing blood pressure and heart rate; increases the strength and size of muscles; and decreases fatigability, insomnia, tension, and irritability. Conduct a thorough musculoskeletal assessment and exercise history to develop a realistic exercise plan. Encourage regular exercise within the patient's daily schedule.

Pregnant Woman and Childbearing Family. A developmental task for most young adult couples is the decision to begin a family. Although the physiological changes of pregnancy and childbirth occur only in the woman, cognitive and psychosocial

changes and health concerns affect the entire childbearing family, including the baby's father, siblings, and grandparents. Single-parent families and young single mothers tend to be particularly vulnerable both economically and socially.

Health Practices. Women who are anticipating pregnancy benefit from good health practices before conception; these include a balanced diet, exercise, dental checkups, avoidance of alcohol, and cessation of smoking.

Prenatal Care. **Prenatal care** is the routine examination of the pregnant woman by an obstetrician or advanced practice nurse such as a nurse practitioner or certified nurse midwife. Prenatal care includes a thorough physical assessment of the pregnant woman during regularly scheduled intervals; provision of information regarding STIs, other vaginal infections, and urinary infections that adversely affect the fetus; and counseling about exercise patterns, diet, and child care. Regular prenatal care addresses health concerns that may arise during the pregnancy.

Physiological Changes. The physiological changes and needs of the pregnant woman vary with each trimester. Be familiar with them, their causes, and implications for nursing. All women experience some physiological changes in the first trimester. For example, they commonly have morning sickness, breast enlargement and tenderness, and fatigue. During the second trimester growth of the uterus and fetus results in some of the physical signs of pregnancy. During the third trimester increases in **Braxton Hicks contractions** (irregular, short contractions), fatigue, and urinary frequency occur.

Puerperium. The **puerperium** is a period of approximately 6 weeks after delivery. During this time the woman's body reverts to its prepregnant physical status. Determine the woman's knowledge of and ability to care for both herself and for her newborn baby. Assessment of parenting skills and maternal-infant interactions is particularly important. The process of **lactation** or breastfeeding offers many advantages to both the new mother and baby. For the inexperienced mother breastfeeding can be a source of anxiety and frustration. Be alert for signs that the mother needs information and assistance (Dunn et al., 2006).

Needs for Education. The entire childbearing family needs education about pregnancy, labor, delivery, breastfeeding, and integration of the newborn into the family structure.

Psychosocial Changes. Like the physiological changes of pregnancy, psychosocial changes occur at various times during the 9 months of pregnancy and in the puerperium. Table 13-2 summarizes the major categories of psychosocial changes and implications for nursing intervention.

Health Concerns. The pregnant woman and her partner have many health questions. For example, they wonder whether the pregnancy and baby will be normal. The majority of the health needs related to pregnancy are met with proper prenatal care.

Acute Care. Young adults typically require acute care for accidents, substance abuse, exposure to environmental and occupational hazards, stress-related illnesses, respiratory infections, gastroenteritis, influenza, urinary tract infections, and minor surgery. An acute minor illness causes a disruption in life activities of young adults and increases stress in an already hectic lifestyle. Dependency and limitations posed by treatment regimens also increase frustration. To give them a sense of maintaining control of their health care choices, it is important to keep them informed about their health status and involve them in health care decisions.

Restorative and Continuing Care. Chronic conditions are not common in young adulthood, but they sometimes occur. Chronic illnesses such as hypertension, coronary artery disease, and diabetes have their onset in young adulthood but may not be recognized until later in life. Causes of chronic illness and disability in the young adult include accidents, multiple sclerosis, rheumatoid arthritis, AIDS, and cancer. Chronic illness or disability threatens a young adult's independence and results in the need to change personal, family, and career goals. Nursing interventions for the young adult faced with chronic illness or disability need to focus on problems related to sense of identity, establishing independence, reorganizing intimate relationships and family structure, and launching a chosen career (Santacroce and Lee, 2006).

TABLE 13-2 Major Psychosocial Changes During Pregnancy

CATEGORY	IMPLICATIONS FOR NURSING
Body image	Morning sickness and fatigue contribute to poor body image. Woman feels big, awkward, and unattractive during third trimester when fetus is growing more rapidly. Increase in breast size sometimes makes the woman feel more feminine and sexually appealing. Woman takes extra time with hygiene and grooming, trying new hairstyles and makeup. Woman begins to "show" during the second trimester and starts to plan maternity wardrobe. Woman has general feeling of well-being when she feels the baby move and hears the heartbeat.
Role changes	Both partners think about and have feelings of uncertainty about impending role changes. Both partners have feelings of ambivalence about becoming parents and concern about ability to be parents.
Sexuality	Woman needs reassurance that sexual activity will not harm fetus. Woman's desire for sexual activity is influenced by body image. Woman desires cuddling and holding rather than sexual intercourse.
Coping mechanisms	Woman needs reassurance that childbirth and childrearing are natural and positive experiences but are also stressful. Woman is often unable to cope with particular stressors such as finding new housing, preparing the nursery, or participating in childbirth classes.
Stresses during puerperium	Woman returns home from hospital fatigued and unfamiliar with infant care. Woman experiences physical discomfort or feelings of anxiety or depression. Woman must return to work soon after delivery with subsequent feelings of guilt, anxiety, or, possibly a sense of freedom or relief.

MIDDLE ADULTS

In 2009 39.8% of the population was middle-age adults between the ages of 35 and 64, a slight increase over the 2005 data (U.S. Census Bureau, 2010). In middle adulthood the individual makes

FIG. 13-4 Middle adults enjoy helping young people become productive and responsible adults.

lasting contributions through involvement with others. Generally the middle-adult years begin around the early to mid 30s and last through the late 60s, corresponding to Levinson's developmental phases of "settling down" and the "payoff years." During this period personal and career achievements have often already been experienced. Many middle adults find particular joy in helping their children and other young people become productive and responsible adults (Fig. 13-4). They also begin to help aging parents while being responsible for their own children, placing them in the **sandwich generation.** Using leisure time in satisfying and creative ways is a challenge that, if met satisfactorily, enables middle adults to prepare for retirement.

Although most middle adults have achieved socioeconomic stability, recent trends in corporate downsizing have left many either jobless or forced to accept lower-paying jobs. According to the U.S. Census Bureau (2009), the real median household income in the United States fell 3.6% between 2007 and 2008, and the number of people without health insurance coverage rose from 45.7 million in 2007 to 46.3 million in 2008. As a result, a greater proportion of the population became unable to afford adequate health care.

Men and women need to adjust to inevitable biological changes. As in adolescence, middle adults use considerable energy to adapt self-concept and body image to physiological realities and changes in physical appearance. High self-esteem, a favorable body image, and a positive attitude toward physiological changes occur when adults engage in physical exercise, balanced diets, adequate sleep, and good hygiene practices that promote vigorous, healthy bodies.

Physical Changes

Major physiological changes occur between 40 and 65 years of age. Because of this it is important to assess the middle adult's general health status. A comprehensive assessment offers direction for health promotion recommendations and planning and implementing any acutely needed interventions. The most visible changes during middle adulthood are graying of the hair, wrinkling of the skin, and thickening of the waist. Decreases in hearing and visual acuity are often evident during this period. Often these physiological changes during middle adulthood have an impact on self-concept and body image. Table 13-3 summarizes abnormal findings to consider when conducting a physical examination (see Chapter 30). The most significant physiological changes during middle age are menopause in women and the climacteric in men.

Perimenopause and Menopause. Menstruation and ovulation occur in a cyclical rhythm in women from adolescence into middle adulthood. Perimenopause is the period during which ovarian function declines, resulting in a diminishing number of ova and irregular menstrual cycles, and generally lasts 1 to 3 years. **Menopause** is the disruption of this cycle, primarily because of the inability of the neurohormonal system to maintain its periodic stimulation of the endocrine system. The ovaries no longer produce estrogen and progesterone, and the blood levels of these hormones drop markedly. Menopause typically occurs between 45 and 60 years of age (see Chapter 34). Approximately 10% of women have no symptoms of menopause other than cessation of menstruation, 70% to 80% are aware of other changes but have no problems, and approximately 10% experience changes severe enough to interfere with activities of daily living.

Climacteric. The **climacteric** occurs in men in their late 40s or early 50s (see Chapter 34). Decreased levels of androgens cause climacteric. Throughout this period and thereafter a man is still capable of producing fertile sperm and fathering a child. However, penile erection is less firm, ejaculation is less frequent, and the refractory period is longer.

Cognitive Changes

Changes in the cognitive function of middle adults are rare except with illness or trauma. Some middle adults enter educational or vocational programs to prepare themselves with new skills and information for entering the job market or changing jobs.

Psychosocial Changes

The psychosocial changes in the middle adult involve expected events such as children moving away from home and unexpected events such as a marital separation or the death of a close friend.

The nurse assesses major life changes occurring in any middle adult for whom he or she cares and the impact that the changes have on that person's state of health. Individual psychosocial factors such as coping mechanisms and sources of social support should also be included in the assessment.

In the middle-adult years, as children depart from the household, the family enters the postparental family stage. Time and financial demands on the parents decrease, and the couple faces the task of redefining their own relationship. It is during this period that many middle adults take on healthier lifestyles. Assessment of health promotion needs for the middle adult includes adequate rest, leisure activities, regular exercise, good nutrition, reduction or cessation in the use of tobacco or alcohol, and regular screening examinations. Assessment of the middle adult's social environment is also important, including relationship concerns; communication and relationships with children, grandchildren, and aging parents; and caregiver concerns with their own aging or disabled parents.

Career Transition. Career changes occur by choice or as a result of changes in the workplace or society. In recent decades middle adults change occupations more often for a variety of reasons, including limited upward mobility, decreasing availability of jobs, and seeking an occupation that is more challenging. In some cases downsizing, technological advances, or other changes force middle adults to seek new jobs. Such changes, particularly when unanticipated, result in stress that affects health, family relationships, self-concept, and other dimensions.

Sexuality. After the departure of their last child from the home, many couples recultivate their relationships and find increased marital and sexual satisfaction during middle age. The onset of menopause and the climacteric affect the sexual health of the middle adult. Some women may desire increased sexual activity because pregnancy is no longer possible. Menopausal women also

TABLE 13-3 Abnormal Physical Assessment Findings in the Middle Adult

BODY SYSTEM	ASSESSMENT FINDINGS
Integument	Very thin skin Rough, flaky, dry skin Lesions
Scalp and hair	Excessive generalized hair loss or patchy hair loss Excessive scaliness
Head and neck	Large, thick skull and facial bones Asymmetry in movement of head and/or neck Drooping of one side of the face
Eyes	Reduced peripheral vision Asymmetrical position of the light reflex Drooping of the upper lid (ptosis) Redness or crusting around the eyelids
Ears	Discharge of any kind Reddened, swollen ear canals
Nose, sinuses, and throat	Nasal tenderness Occlusion of nostril Swollen and pale pink or bluish-gray nasal mucosa Sinuses tender to palpation or on percussion Asymmetrical movement or loss of movement of uvula Tonsils red or enlarged
Thorax and lungs	Unequal chest expansion Unequal fremitus, hyperresonance, diminished or absent breath sounds Adventitious lung sounds such as crackles and wheezes
Heart and vascular system	Pulse inequality, weak pulses, bounding pulses, or variations in strength of pulse from beat to beat Bradycardia or tachycardia Hypertension Hypotension
Breasts—female	Recent increase in size of one breast Pigskinlike or orange-peel appearance Redness or painful breasts
Breasts—male	Soft, fatty enlargement of breast tissue
Abdomen	Bruises, areas of local discoloration; purple discoloration; pale, taut skin Generalized abdominal distention Hypoactive, hyperactive, decreased, or absent bowel sounds
Female genitalia	Asymmetrical labia Swelling, pain, or discharge from Bartholin's glands Decreased tone of vaginal musculature Cervical enlargement or projection into the vagina Reddened areas or lesions in the vagina
Male genitalia	Rashes, lesions, or lumps on skin of shaft of penis Discharge from penis Enlarged scrotal sac Bulges that appear at the external inguinal ring or femoral canal when the patient bears down
Musculoskeletal system	Uneven weight bearing Decreased range of joint motion; swollen, red, or enlarged joint; painful joints Decreased strength against resistance
Neurological system	Lethargy Inadequate motor responses Abnormal sensory system responses: inability to smell certain aromas, loss of visual fields, inability to feel and correctly identify facial stimuli, absent gag reflex

experience vaginal dryness and dyspareunia or pain during sexual intercourse (see Chapter 34).

During middle age a man may notice changes in the strength of his erection and a decrease in his ability to experience repeated orgasm. Other factors influencing sexuality during this period include work stress, diminished health of one or both partners, and the use of prescription medications. For example, antihypertensive agents have side effects that influence sexual desire or functioning. Sometimes both partners experience stresses related to sexual changes or a conflict between their sexual needs and self-perceptions and social attitudes or expectations (see Chapter 34).

Family Psychosocial Factors. Psychosocial factors involving the family include the stresses of singlehood, marital changes, transition of the family as children leave home, and the care of aging parents.

Singlehood. Many adults over 35 years of age in the United States have never been married. Many of these are college-educated people who have embraced the philosophy of choice and freedom, delayed marriage, and delayed parenthood. Some middle adults choose to remain single but also opt to become parents either biologically or through adoption. Many single middle adults have no relatives but share a family type of relationship with close friends or work associates. Consequently some single middle adults feel isolated during traditional "family" holidays such as Thanksgiving or Christmas. In times of illness middle adults who have chosen to remain single and childless have to rely on other relatives or friends, increasing caregiving demands of family members who also have other responsibilities. Nursing assessment of single middle adults needs to include a thorough assessment of psychosocial factors, including the individual's definition of family and available support systems.

Marital Changes. Marital changes occurring during middle age include death of a spouse, separation, divorce, and the choice of remarrying or remaining single. A widowed, separated, or divorced patient goes through a period of grief and loss in which it is necessary to adapt to the change in marital status. Normal grieving progresses through a series of phases, and resolution of grief often takes a year or more. You need to assess the level of coping of the middle adult to the grief and loss associated with certain life changes (see Chapter 36).

Family Transitions. The departure of the last child from the home is also a stressor. Many parents welcome freedom from child-rearing responsibilities, whereas others feel lonely or without direction. *Empty nest syndrome* is the term used to describe the sadness and loneliness that accompany children leaving home. Eventually parents need to reassess their marriage and try to resolve conflicts and plan for the future. Occasionally this readjustment phase leads to marital conflicts, separation, and divorce (see Chapter 10).

Care of Aging Parents. Increasing life spans in the United States and Canada have led to increased numbers of older adults in the population. Therefore greater numbers of middle adults need to address the personal and social issues confronting their aging parents. Many middle adults find themselves caught between the responsibilities of caring for dependent children and those of caring for aging and ailing parents. These middle adults thus find themselves in the sandwich generation, in which the challenges of caregiving can be stressful. The needs of family caregivers are being given more emphasis in the health care system.

Housing, employment, health, and economic realities have changed the traditional social expectations between generations in families. The middle adult and older-adult parent often have conflicting relationship priorities while the older adult strives to remain independent. Negotiations and compromises help to define and resolve problems. Nurses deal with middle and older adults in the community, long-term care facilities, and hospitals. Help identify the health needs of both groups and assist the multigenerational family in determining the health and community resources available to them as they make decisions and plans. Evaluate family relationships to determine family members' perceptions of responsibility and loyalty in relation to caring for older-adult members. Assessment of environmental resources (e.g., number of rooms in the house or stairwells) in relation to the complexity of health care demands for the older adult is also important.

Health Concerns

Health Promotion and Stress Reduction. Because middle adults experience physiological changes and face certain health realities, their perceptions of health and health behaviors are often important factors in maintaining health. Today's complex world makes individuals more prone to stress-related illnesses such as heart attacks, hypertension, migraine headaches, ulcers, colitis, autoimmune disease, backache, arthritis, and cancer. When adults seek health care, nurses focus on the goal of wellness and guide patients to evaluate health behaviors, lifestyle, and environment.

Throughout life people have many stressors (see Chapter 37). After identifying these stressors, work with the patient to intervene and modify the stress response. Specific interventions for stress reduction fall into three categories. First minimize the frequency of stress-producing situations. Together with the patient identify approaches to preventing stressful situations such as habituation, change avoidance, time blocking, time management, and environmental modification. Second, increase stress resistance such as increasing self-esteem, improving assertiveness, redirecting goal alternatives, and reorienting cognitive appraisal. Finally, avoid the physiological response to stress. Use relaxation techniques, imagery, and biofeedback to recondition the patient's response to stress. Chapters 36 and 37 explain these general interventions in greater detail.

Obesity. Obesity is a growing, expensive health concern for middle adults. It can reduce quality of life and increases risk for many serious chronic diseases and premature death. In 2007 no state in the United States had met the Healthy People 2010 objective to reduce obesity prevalence among adults to 15% (USDHHS, CDC, 2010b). Health consequences of obesity include such ailments as high blood pressure, high blood cholesterol, type 2 (non-insulin dependent) diabetes, coronary heart disease, osteoarthritis, and obstructive sleep apnea. Continued focus on the goal of wellness helps patients evaluate health behaviors and lifestyle that contribute to obesity during the middle adult years. Counseling related to physical activity and nutrition is an important component of the plan of care for overweight and obese patients.

Forming Positive Health Habits. A habit is a person's usual practice or manner of behavior. Frequent repetition reinforces this behavior pattern until it becomes the individual's customary way of behaving. Some habits support health such as exercise and brushing and flossing the teeth each day. Other habits involve risk factors to health such as smoking or eating foods with little or no nutritional value.

During assessment a nurse frequently obtains data indicating positive and negative health behaviors by a patient. Examples of positive health behaviors include regular exercise, adherence to good dietary habits, avoidance of excess consumption of alcohol, participation in routine screening and diagnostic tests (e.g.,

laboratory screening for serum cholesterol or mammography) for disease prevention and health promotion, and lifestyle changes to reduce stress. The nurse helps the patient maintain habits that protect health and offers healthier alternatives to poor habits.

Health teaching and counseling often focus on improving health habits. The more you understand the dynamics of behavior and habits, the more likely it is that your interventions will help patients achieve or reinforce health-promoting behaviors.

To help patients form positive health habits, you act as a teacher and facilitator. By providing information about how the body functions and how patients form and change habits, patients' levels of knowledge regarding the potential impact of behavior on health are raised. You cannot change your patients' habits. They have control of and are responsible for their own behaviors. Explain psychological principles of changing habits and offer information about health risks. Offer positive reinforcement (such as praise and rewards) for health-directed behaviors and decisions. Such reinforcement increases the likelihood that the behavior will be repeated. However, ultimately the patient decides which behaviors will become habits of daily living.

Help middle adults consider factors such as prevention of STIs, substance abuse, and accident prevention in relation to decreasing health risks. For example, provide patients with factual information on STI causes, symptoms, and transmission. Discuss methods of protection during sexual activity with a patient in an open and nonjudgmental manner and reinforce the importance of practicing safe sex (see Chapter 34). Provide counseling and support for patients seeking treatment for substance abuse. Help them recognize and alter unsafe and potential health hazards. In addition, encourage them to express their feelings so they become proficient in solving problems and recognizing risk factors themselves. Barriers to change exist (Box 13-3). Unless you minimize or eliminate these barriers, it is futile to encourage the patient to take action.

Psychosocial Health

Anxiety. Anxiety is a critical maturational phenomenon related to change, conflict, and perceived control of the environment. Adults often experience anxiety in response to the physiological and psychosocial changes of middle age. Such anxiety motivates the adult to rethink life goals and stimulates productivity. However, for some adults this anxiety precipitates psychosomatic illness and preoccupation with death. In this case the middle adult views life as being half or more over and thinks in terms of the time left to live.

Clearly a life-threatening illness, marital transition, or job stressor increases the anxiety of a patient and family. Use crisis intervention or stress-management techniques to help a patient adapt to the changes of the middle-adult years (see Chapter 37).

Depression. Depression is a mood disorder that manifests itself in many ways. Although the most frequent age of onset is between ages 25 and 44, it is common among adults in the middle years and has many causes. The risk factors for depression include being female; disappointments or losses at work, at school, or in family relationships; departure of the last child from the home; and family history. In fact, the incidence of depression in women is twice that of men. Persons experiencing mild depression describe themselves as feeling sad, blue, downcast, down in the dumps, and tearful. Other symptoms include alterations in sleep patterns such as difficulty in sleeping (insomnia) or sleeping too much (hypersomnia), irritability, feelings of social disinterest, and decreased alertness. Physical changes such as weight gain or loss, headaches, or feelings of fatigue regardless of the amount of rest are also depressive symptoms. Individuals with depression that occurs during the middle years commonly experience moderate-to-high anxiety and have physical complaints. Mood changes and depression are common occurrences during menopause. The abuse of alcohol or other substances makes depression worse. Nursing assessment of the depressed middle adult includes focused data collection regarding individual and family history of depression, mood changes, cognitive changes, behavioral and social changes, and physical changes. Collect assessment data from both the patient and the patient's family because family data are often particularly important, depending on the level of depression the middle adult is experiencing.

BOX 13-3 BARRIERS TO CHANGE

External Barriers	Internal Barriers
• Lack of facilities	• Lack of knowledge
• Lack of materials	• Insufficient skills to effect change in health habits
• Lack of social supports	
• Lack of motivation	• Undefined short- and long-term goals

Community Health Programs. Community health programs offer services to prevent illness, promote health, and detect disease in the early stages. Nurses make valuable contributions to the health of the community by taking an active part in planning screening and teaching programs and support groups for middle adults.

Family planning, birthing, and parenting skills are program topics in which adults are usually interested. Health screening for diabetes, hypertension, eye disease, and cancer is a good opportunity for the nurse to perform assessment and provide health teaching and health counseling.

Health education programs promote changes in behavior and lifestyle. As a health teacher, offer information that enables patients to make decisions about health practices within the context of health promotion for young-to-middle adults. Make sure that educational programs are culturally appropriate. Changes to more positive health practices during young and middle adulthood lead to fewer or less complicated health problems as an older adult. During health counseling, collaborate with the patient to design a plan of action that addresses the patient's health and well-being. Through objective problem solving, you can help the patient grow and change.

Acute Care. Acute illnesses and conditions experienced in middle adulthood are similar to those of young adulthood. However, injuries and acute illnesses in middle adulthood require a longer recovery period because of the slowing of healing processes. In addition, acute illnesses and injuries experienced in middle adulthood are more likely to become chronic conditions. For middle adults in the sandwich generation, stress levels also increase as he or she tries to balance responsibilities related to employment, family life, care of children, and care of aging parents while recovering from an injury or acute illness.

Restorative and Continuing Care. Chronic illnesses such as diabetes mellitus, hypertension, rheumatoid arthritis, or multiple sclerosis affect the roles and responsibilities of the middle adult. Some results of chronic illness are strained family relationships, modifications in family activities, increased health care tasks, increased financial stress, the need for housing adaptation, social isolation, medical concerns, and grieving. The degree of disability and the patient's perception of both the illness and the disability determine the extent to which lifestyle changes occur. A few examples of the problems experienced by patients who develop debilitating chronic illness during adulthood include role reversal,

changes in sexual behavior, and alterations in self-image. Along with the current health status of the chronically ill middle adult, you need to assess the knowledge base of both the patient and family. This assessment includes the medical course of the illness and the prognosis for the patient. In addition, you must determine the coping mechanisms of the patient and family; adherence to treatment and rehabilitation regimens; and the need for community and social services, along with appropriate referrals.

KEY POINTS

- Adult development involves orderly and sequential changes in characteristics and attitudes that adults experience over time.
- Many changes experienced by the young adult are related to the natural process of maturation and socialization.
- Young adults are in a stable period of physical development, except for changes related to pregnancy.
- Cognitive development continues throughout the young- and middle-adult years.
- Emotional health of young adults is correlated with the ability to address and resolve personal and social problems.
- Young adults choose a career and decide whether to remain single or marry and begin a family.
- Pregnant women need to understand physiological changes occurring in each trimester.
- Psychosocial changes and health concerns during pregnancy and the puerperium affect the parents, the siblings, and often the extended family.
- Prenatal care reduces maternal and fetal mortality and morbidity.
- Midlife transition begins when a person becomes aware that physiological and psychosocial changes signify passage to another stage in life.
- Two significant physiological changes of the middle years are menopause in women and the climacteric in men.
- Cognitive changes are rare in middle age except in cases of illness or physical trauma.
- Psychosocial changes for middle adults are often related to career transition, sexuality, marital changes, family transition, and care of aging parents.
- Health concerns of middle adults commonly involve stress-related illnesses, health assessment, and adoption of positive health habits.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

A 24-year-old female patient who smokes two packs of cigarettes per day has come to the clinic to talk with the nurse about quitting smoking. She began smoking when she was 14 years old. She complains to the nurse at the clinic, "I just can't seem to kick the habit no matter how hard I try. I am smoking more now because of increased stress from my job."

1. What information does the nurse need to know to help this patient quit smoking?
2. Which factors will have the greatest impact on health promotion related to smoking cessation in this patient?
3. What steps should the nurse take to help this patient decrease her stress?

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. With the exception of pregnant or lactating women, the young adult has usually completed physical growth by the age of:
   1. 18.
   2. 20.
   3. 25.
   4. 30.
2. The nurse is completing an assessment on a male patient, age 24. Following the assessment, the nurse notes that his physical and laboratory findings are within normal limits. Because of these findings, nursing interventions are directed toward activities related to:
   1. Instructing him to return in 2 years.
   2. Instructing him in secondary prevention.
   3. Instructing him in health promotion activities.
   4. Implementing primary prevention with vaccines.
3. When determining the amount of information that a patient needs to make decisions about the prescribed course of therapy, many factors affect the patient's compliance with the regimen, including educational level and socioeconomic factors. Which additional factor affects compliance?
   1. Gender
   2. Lifestyle
   3. Motivation
   4. Family history
4. A patient is laboring with her first baby, which is coming 2 weeks early. Her husband is in the military and might not get back in time, and both families are unable to be with her during labor. The doctor decides to call in which of the following people employed by the birthing area to be a support person to be present during labor?
   1. Nurse
   2. Midwife
   3. Assistant
   4. Lay doula
5. A single young adult female interacts with a group of close friends from college and work. They celebrate birthdays and holidays together. In addition, they help one another through many stressors. She views these individuals as:
   1. Family.
   2. Siblings.
   3. Substitute parents.
   4. Alternative family structure.
6. Sharing eating utensils with a person who has a contagious illness increases the risk of illness. This type of health risk arises from:
   1. Lifestyle.
   2. Community.
   3. Family history.
   4. Personal hygiene habits.
7. A 50-year-old woman has elevated cholesterol profile values that increase her cardiovascular risk factor. One method to control this risk factor is to identify current diet trends and describe dietary changes to reduce the risk. This nursing activity is a form of:
   1. Referral.
   2. Counseling.
   3. Health education
   4. Stress management techniques.

8. A 34-year-old female executive has a job with frequent deadlines. She notes that, when the deadlines appear, she has a tendency to eat high-fat, high-carbohydrate foods. She also explains that she gets frequent headaches and stomach pain during these deadlines. The nurse provides a number of options for the executive, and she chooses yoga. In this scenario yoga is used as a(n):
    1. Outpatient referral.
    2. Counseling technique.
    3. Health promotion activity.
    4. Stress-management technique.
9. A 50-year-old male patient is seen in the clinic. He tells the nurse that he has recently lost his job and his wife of 26 years has asked for a divorce. He has a flat affect. Family history reveals that his father committed suicide at the age of 53. The nurse should assess for the following:
    1. Cardiovascular disease
    2. Depression
    3. Sexually transmitted infection
    4. Iron deficiency anemia
10. Middle-age adults frequently find themselves trying to balance responsibilities related to employment, family life, care of children, and care of aging parents. People finding themselves in this situation are frequently referred to as being a part of:
    1. The sandwich generation.
    2. The millennial generation.
    3. Generation X.
    4. Generation Y.
11. Intimate partner violence (IPV) is linked to which of the following factors? (Select all that apply.)
    1. Alcohol abuse
    2. Pregnancy
    3. Unemployment
    4. Drug use
12. Sexually transmitted infections (STIs) continue to be a major health problem in young adults. Men ages 20 to 24 years have the highest rate of which STI?
    1. Chlamydia
    2. Syphilis
    3. Gonorrhea
    4. Herpes zoster
13. Formation of positive health habits may prevent the development of chronic illness later in life. Which of the following are examples of positive health habits? (Select all that apply.)
    1. Routine screening and diagnostic tests
    2. Unprotected sexual activity
    3. Regular exercise
    4. Excess alcohol consumption
14. Chronic illness (e.g., diabetes mellitus, hypertension, rheumatoid arthritis) may affect a person's roles and responsibilities during middle adulthood. When assessing the knowledge base of both the middle-age patient with a chronic illness and his family, the assessment should include which of the following? (Select all that apply.)
    1. The medical course of the illness
    2. The prognosis for the patient
    3. Coping mechanisms of the patient and family
    4. The need for community and social services
15. A 45-year-old obese woman tells the nurse that she wants to lose weight. After conducting a thorough assessment, the nurse concludes that which of the following may be contributing factors to the woman's obesity? (Select all that apply.)
    1. The woman works in an executive position that is very demanding.
    2. The woman works out at the corporate gym at 5 AM two mornings per week
    3. The woman says that she has little time to prepare meals at home and eats out at least four nights a week.
    4. The woman says that she tries to eat "low cholesterol" foods to help lose weight.

CHAPTER

14

Older Adults

OBJECTIVES

- Identify common myths and stereotypes about older adults.
- Identify selected biological and psychosocial theories of aging.
- Discuss common developmental tasks of older adults.
- Describe common physiological changes of aging.
- Differentiate among delirium, dementia, and depression.
- Discuss issues related to psychosocial changes of aging.
- Describe selected health concerns of older adults.
- Identify nursing interventions related to the physiological, cognitive, and psychosocial changes of aging.

Age 65 is considered to be the lower boundary for "old age" in demographics and social policy within the United States. However many older adults consider themselves to be "middle-age" well into their seventh decade. Chronological age often has little relation to the reality of aging for an older adult. Each person ages in his or her own way. Every older adult is unique, and as a nurse you need to approach each one as an individual, even though this chapter makes generalizations about the aging process and its effect on individuals.

The number of older adults in the United States is growing, both absolutely and as a proportion of the total population. In 2009 there were 39.6 million adults over age 65 in the United States, representing 12.9% of the population or one in eight Americans (Administration on Aging [AOA], 2010). This represents an increase of 4.8 million since 1998. Part of that increase is the result of extension of the average life span. Women who were age 65 in 2007 could expect to live another 19.8 years, and men another 17.1 years. According to estimates, the number of older adults will increase to 72.1 million by 2030. Factors that contribute to the projected increase in the number of older adults are the aging of the baby-boom generation and the growth of the population segment over age 85. The baby boomers are the large group of adults born between 1946 and 1964. The first baby boomers reached age 65 in 2011. As the large number of baby boomers age, the social and health care programs necessary to meet their needs must dramatically reform their services. The diversity of the population over age 65 is also increasing. In 2008 minorities (African Americans, Hispanics, Asians, American Indians/Eskimos/Aleuts, and other Pacific Islanders) made up 19.6% of the population over age 65 (AOA, 2010). Nurses need to take the cultural, ethnic, and racial diversity represented by these numbers into account as they care for older adults from these groups. The challenge is to gain new knowledge and skills to provide culturally sensitive and linguistically appropriate care. Chapter 9 provides further information on culturally competent care.

VARIABILITY AMONG OLDER ADULTS

The nursing care of older adults poses special challenges because of great variation in their physiological, cognitive, and psychosocial health. Older adults also vary widely in their levels of functional ability. Most older adults are active and involved members of their communities. A smaller number have lost the ability to care for themselves, are confused or withdrawn, and/or are unable to make decisions concerning their needs. Most older adults live in noninstitutional settings. In 2008 54.6% of older adults in noninstitutional settings lived with a spouse (41.7% of older women, 72% of older men) (AOA, 2009); 30.5% lived alone (39.5% of older women, 18.5% of older men); and only 4.1% of all older adults resided in institutions such as nursing homes or centers.

Aging does not inevitably lead to disability and dependence. Most older people remain functionally independent despite the increasing prevalence of chronic disease. Nursing assessment provides valuable clues to the effects of a disease or illness on a patient's functional status. Chronic conditions add to the complexity of assessment and care of the older adult. Most older persons have at least one chronic condition, and many have multiple conditions. The most frequently diagnosed chronic conditions occurring in 2005 to 2007 were arthritis (49%), hypertension (41%), all types of heart disease (31%), any cancer (22%), and diabetes (18%) (AOA, 2009). The physical and psychosocial aspects of aging are closely related. A reduced ability to respond to stress, the experience of multiple losses, and the physical changes associated with normal aging combine to place people at high risk for illness and functional deterioration. Although the interaction of these physical and psychosocial factors is often serious, do not assume that all older adults have signs, symptoms, or behaviors representing disease and decline or that these are the only factors you need to assess. You also need to identify the older adult's strengths and abilities during the assessment and encourage independence as an integral part of your plan of care (Kresevic, 2008).

MYTHS AND STEREOTYPES

Despite ongoing research in the field of **gerontology,** myths and stereotypes about older adults persist. These include false ideas about their physical and psychosocial characteristics and lifestyles. When health care providers hold negative stereotypes about aging, they can negatively affect the quality of patient care. Although nurses are susceptible to these myths and stereotypes, they have the responsibility to replace them with accurate information.

Some people stereotype older adults as ill, disabled, and physically unattractive. Although many older adults have chronic conditions or have at least one disability that limits their performance of activities of daily living (ADLs), most noninstitutionalized older adults (39.1%) assess their health as excellent or very good (AOA, 2009). Some people believe that older adults are forgetful, confused, rigid, bored, and unfriendly and that they are unable to understand and learn new information. Yet specialists in the field of gerontology view centenarians, the oldest of the old, as having an optimistic outlook on life, good memories, broad social contacts and interests, and tolerance for others. Although changes in vision or hearing and reduced energy and endurance sometimes affect the process of learning, older adults are lifelong learners. Use teaching techniques to compensate for sensory changes, provide additional time for remembering and responding, and present concrete rather than abstract material to facilitate learning by older adults. Other effective teaching techniques draw on the older adult's past experiences and correspond to his or her identified interests rather than to the content areas that the health care professional believes are important. Box 14-1 presents additional teaching strategies to address the special learning needs of older adults.

Stereotypes about lifestyles include mistaken ideas about living arrangements and finances. Misconceptions about their financial status range from beliefs that many are affluent to beliefs that many are poor. According to the AOA (2009), 9.7% of persons over age 65 had incomes below the poverty level, with another 6.3% classified as near poor. The median income reported was $18,337, with 87% coming from Social Security.

In a society that values attractiveness, energy, and youth, these myths and stereotypes lead to the undervaluing of older adults. Some people equate worth with productivity; therefore they think that older adults become worthless after they leave the workforce. Others consider their knowledge and experience too outdated to have any current value. These ideas demonstrate **ageism,** which is discrimination against people because of increasing age, just as people who are racists and sexists discriminate because of skin color and gender. According to experts in the field of gerontology, unopposed ageism has the potential to undermine the self-confidence of older adults, limit their access to care, and distort caregivers' understanding of the uniqueness of each older adult. Older adults who have a positive image about aging actually live 7.5 years longer than those with a negative image (Levy et al., 2002). Nursing can help promote a positive perception regarding the aging process when working with these patients.

Today laws exist that ban discrimination on the basis of age. The economic and political power of older adults challenges ageist views. Older adults are a significant proportion of the consumer economy. As voters and activists in various issues, they have major influence in the formation of public policy. Their participation adds a unique perspective on social, economic, and technological issues because they have experienced almost a century of developments. In the past 100 years our nation has progressed from riding in horse-drawn carriages to tracking the adventures of the international space station. Gaslights and steam power have been replaced by electricity and nuclear power. Computers and copier machines replace typewriters and carbon paper. Many older adults lived through or were born during the Great Depression of 1929. They also experienced two world wars and wars in Korea, Vietnam, and the Persian Gulf and are now experiencing the war on terrorism. Older adults have seen changes in health care as the era of the family physician gave way to the age of specialization. After witnessing the government initiatives establishing the Social Security system, Medicare, and Medicaid, older adults are currently living

BOX 14-1 PRINCIPLES FOR PROMOTING OLDER-ADULT LEARNING

- Make sure that the patient is ready to learn before trying to teach. Watch for clues that indicate that the patient is preoccupied or too anxious to comprehend the material.
- Is the patient physically well enough to be taught? Is he or she in pain?
- Sit facing the patient so he or she is able to watch your lip movements and facial expressions.
- Speak slowly and in a normal tone of voice.
- Present one idea or concept at a time.
- Emphasize concrete rather than abstract material.
- Give the patient enough time in which to respond because older adults process information slower than younger persons.
- Keep environmental distractions to a minimum. Provide appropriate lighting and a comfortable setting.
- Defer teaching if the patient becomes distracted or tired or cannot concentrate for other reasons.
- Invite another member of the household to join the discussion.
- Use audio, visual, and tactile cues to enhance learning and help the patient remember information.
- Ask for feedback to ensure that the patient understands the information.
- Use past experience; connect new learning to previous knowledge.

Modified from Parker P: Theories of aging. In Gilman P et al: *Nursing review and resource manual gerontological nursing,* ed 2, Silver Springs, MD, 2009, American Nurses Credentialing Center Institute for Credentialing Innovation; Ebersole et al: *Toward healthy aging: human needs and nursing response,* St Louis, 2008, Mosby.

with the changes imposed by health care reform and the uncertainty of the future of Social Security and Medicare. Living through all of these events and changes, they have stories and examples of coping with change to share.

NURSES' ATTITUDES TOWARD OLDER ADULTS

It is important for you to assess your own attitudes toward older adults; your own aging; and the aging of your family, friends, and patients. Nurses' attitudes come from personal experiences with older adults, education, employment experiences, and attitudes of co-workers and employing institutions. Given the increasing number of older adults in health care settings, forming positive attitudes toward them and gaining specialized knowledge about aging and their health care needs are priorities for all nurses. Positive attitudes are based in part on a realistic portrayal of the characteristics and health care needs of older adults. It is critical for you to learn to respect older adults and actively involve them in care decisions and activities. In the past institutional settings such as hospitals and nursing centers often treated older adults as objects rather than independent, dignified people. The time has come for nurses to recognize and address ageism by questioning prevailing negative attitudes and stereotypes and reinforcing the realities of aging as they care for older adults in all care settings.

THEORIES OF AGING

Various theories exist that describe the complex biopsychosocial processes of aging. However, there is no single, universally accepted theory that predicts and explains the complexities of the aging process. You need to be aware of the scientific attempts to explain the aging process and the concepts included in the theories. Although the theories are in various stages of development and have limitations, use them to increase your understanding of the phenomena affecting the health and well-being of older adults and to guide nursing care.

The biological theories of aging are either stochastic or nonstochastic. **Stochastic theories** view aging as the result of random cellular damage that occurs over time. The accumulated damage leads to the physical changes that are recognized as characteristic of the aging process. **Nonstochastic theories** view aging as the result of genetically programmed physiological mechanisms within the body that control the process of aging.

The psychosocial theories of aging, developed during the 1960s, explain changes in behavior, roles, and relationships that come with aging. These theories reflect the values that the theorist and society held at the time the theory was developed. A sample of theories follows. **Disengagement theory,** the oldest psychosocial theory, states that aging individuals withdraw from customary roles and engage in more introspective, self-focused activities (Cummings and Henry, 1961). The **activity theory,** unlike the disengagement theory, considers the continuation of activities performed during middle age as necessary for successful aging (Havighurst et al., 1963). **Continuity theory,** or **developmental theories,** suggests that personality remains stable and behavior becomes more predictable as people age (Neugarten, 1964). The personality and behavior patterns developed during a lifetime determine the degree of engagement and activity in older adulthood. The more recent theory of **gerotranscendence** proposes that the older adult experiences a shift in perspective with age (Wadensten, 2007). The person moves from a materialistic and national view of the world to a more cosmic and transcendent one, causing an increase in overall life satisfaction (Jett, 2008). Critics suggest that theories either fail in some measure to consider the many factors that affect an individual's response to aging or address those factors in a too-simplistic fashion. Rather, each individual ages uniquely.

BOX 14-2 DEVELOPMENTAL TASKS FOR OLDER ADULTS

- Adjusting to decreasing health and physical strength
- Adjusting to retirement and reduced or fixed income
- Adjusting to death of a spouse, children, siblings, friends
- Accepting self as aging person
- Maintaining satisfactory living arrangements
- Redefining relationships with adult children and siblings
- Finding ways to maintain quality of life

DEVELOPMENTAL TASKS FOR OLDER ADULTS

Theories of aging are closely linked to the concept of developmental tasks appropriate for distinct stages of life. Although no two individuals age in the same way, either biologically or psychosocially, researchers have developed frameworks outlining developmental tasks for older adults (Box 14-2). These developmental tasks are common to many older adults and are associated with varying degrees of change and loss. The more common losses are of health, significant others, a sense of being useful, socialization, income, and independent living. How older adults adjust to the changes of aging is highly individualized. For some adaptation and adjustment are relatively easy. For others coping with aging changes requires the assistance of family, friends, and health care professionals. Be sensitive to the effect of losses on older adults and their families and be prepared to offer support.

Older adults must adjust to the physical changes that accompany aging. The extent and timing of these changes vary from individual to individual; but, as body systems age, changes in appearance and functioning occur. These changes are not associated with a disease; they're normal. The presence of disease sometimes alters the timing of the changes or their impact on daily life. The section on physiological changes describes structural and functional changes of aging.

Some older adults, both men and women, find it difficult to accept aging. This is apparent when they understate their ages when asked, adopt younger styles of clothing, or attempt to hide physical evidence of aging with cosmetics. Others deny their aging in ways that are potentially problematic. For example, some older adults deny functional declines and refuse to ask for help with tasks that place their safety at great risk. Others avoid activities designed for their benefit such as senior citizens' centers and senior health promotion activities and thus do not receive the benefits these programs offer. Acceptance of personal aging does not mean retreat into inactivity, but it does require a realistic review of strengths and limitations.

Older adults retired from employment outside the home have to cope with the loss of a work role. Older adults who worked at home and the spouses of those who worked outside the home also face role changes. Some may welcome retirement as a time to pursue new interests and hobbies, volunteer in their community, continue their education, or start a new career. Retirement plans for others may include changing residence by moving to a different city or state or to a different type of housing within the same area.

Reasons other than retirement also lead to changes of residence. For example, physical impairments may require relocation to a smaller, single-level home or nursing center. A change in living arrangements for the older adult usually requires an extended period of adjustment, during which assistance and support from health care professionals, friends, and family members are necessary.

The majority of older adults cope with the death of a spouse. In 2008 almost half (42%) of all older women were widows, and 14% of older men were widowers (AOA, 2010). Some older adults must cope with the death of adult children and grandchildren. All experience the deaths of friends. These deaths represent both losses and reminders of personal mortality. Coming to terms with them is often difficult. By assisting older adults through the grieving process, you help them resolve the issues posed by these deaths.

The redefining of relationships with children that occurred as the children grew up and left home continues as older adults experience the challenges of aging. A variety of issues sometimes occur, including but not limited to control of decision making, dependence, conflict, guilt, and loss. How these issues surface in situations and how they are resolved depend in part on the past relationship between the older adult and their adult children. All the involved parties have past experiences and powerful emotions. When adult children become their parents' caregivers, they have to find ways to balance the demands of their own children and careers with the many challenges of family caregiving. As adult children and aging parents negotiate the aspects of changing roles, nurses are in the position to act as counselors to both the parents and the children. An aim is to help older adults find ways to maintain their quality of life. What defines quality of life is unique for each person.

COMMUNITY-BASED AND INSTITUTIONAL HEALTH CARE SERVICES

Nurses encounter older-adult patients in a wide variety of community and institutional health care settings. Outside of an acute care hospital, nurses care for older adults in private homes and apartments, retirement communities, adult day care centers, assisted-living facilities, and nursing centers (extended care, intermediate care, and skilled nursing facilities). Chapter 2 describes these settings and the services provided in detail.

Nurses help older adults and their families by providing information and answering questions as they make choices among care options. The assistance of the nurse is especially valuable when decisions about moving to a nursing center must be made. Some family caregivers consider nursing center placement when in-home care becomes increasingly difficult or when convalescence (recovery) from hospitalization requires more assistance than the family is able to provide. Although the decision to enter a nursing center is never final and a nursing center resident is sometimes discharged to home or another less-acute facility, many older adults may view the nursing center as their final residence. Results of state and federal inspections of nursing centers are available to the public at the nursing center, on-line, and at the inspectors' offices. The best way to evaluate the quality of a nursing center in a community is for the patient and family to visit that facility and inspect it personally. The Medicare website (http://www.Medicare.gov/NHcompare) is an excellent resource for you to learn about the quality rating of a nursing center based on the health inspections, staffing, and quality measures of the facility. It also offers a nursing center checklist. Box 14-3 summarizes some features to look for in a nursing center.

BOX 14-3 FOCUS ON OLDER ADULTS

Selection of a Nursing Center or Home

An important step in the process of selecting a nursing center is to visit it. A nursing home should meet these criteria (CMS, 2008; Rantz et al., 2001):

- Does not feel like a hospital. It is a home, a place where people live. Residents should be encouraged to personalize their rooms. Privacy is respected.
- Is Medicare and Medicaid certified.
- Has adequate, qualified staff members who have passed criminal background checks.
- Provides quality care, in addition to assistance with basic activities of daily living such as bathing, dressing, eating, oral hygiene, and toileting. Staff should assist residents with social and recreational activities.
- Offers quality food and mealtime choices.
- Families should be welcome when they visit the facility. Whether they wish to provide information, ask questions, participate in care planning, or assist with social activities or physical care, staff should encourage family involvement.
- Is clean. There should be no pervasive odors in the facility. The environment should be "homelike."
- Provides active communication from staff to patient and family.
- Members of the nursing home staff are attentive to resident requests and actively involved with assisting the residents. They focus on the person, not on the task.

ASSESSING THE NEEDS OF OLDER ADULTS

Gerontological nursing requires creative approaches for maximizing the potential of older adults. With comprehensive assessment information regarding strengths, limitations, and resources, the nurse and the older adult identify needs and problems. Together they select interventions to maintain the older adult's physical abilities and create an environment for psychosocial and spiritual well-being. A thorough assessment requires the nurse to actively engage older adults and provide them enough time to share important information about their health.

Nursing assessment takes into account five key points to ensure an age-specific approach: (1) the interrelation between physical and psychosocial aspects of aging, (2) the effects of disease and disability on functional status, (3) the decreased efficiency of homeostatic mechanisms, (4) the lack of standards for health and illness norms, and (5) altered presentation and response to a specific disease (Meiner, 2011). A comprehensive assessment of an older adult takes more time than the assessment of a younger adult because of the longer life and medical history and the potential complexity of the history. During the physical examination allow rest periods as needed or conduct the assessment in several sessions because of the reduced energy and limited endurance of some frail older adults. Remember to review both prescribed and over-the-counter medications carefully with the patient.

Sensory changes also affect data gathering. Your choice of communication techniques depends on visual or hearing impairments of the older adult. If older adults are unable to understand your visual or auditory cues, assessment data may be inaccurate or misleading. For example, if an older adult has difficulty hearing a nurse's questions, inappropriate responses might lead the nurse to believe that the person is confused. Chapter 49 explains in detail techniques to use when communicating with older adults who have a hearing impairment. When a person has a visual impairment, use these communication techniques:

BOX 14-4 CULTURAL ASPECTS OF CARE

Communication During Assessment

The older adult's cultural values and beliefs about health, illness, and treatment influence the quality of assessment data the nurse collects in an interview. For example, Sims (2010) found that health care providers' unfamiliarity with black women's ethnic notions can lead to misinterpretations and misunderstandings that influence their interactions. Be knowledgeable about the characteristics of an older adult's cultural group because it affects nurse-patient communication during the assessment process (Touhy and Jett, 2010).

Implications for Practice

- Use cultural interpreters when necessary,
- Use appropriate conventions of the handshake and silence during interactions (Meiner, 2011).
- Identify how the older adult wishes to be addressed; use culturally appropriate titles.
- Assess the health-related beliefs and practices of the older patient's culture group and adapt questions to obtain information on how the patient incorporates them into daily practice.
- Know beliefs and practices of the older patient's culture group regarding spatial requirements, eye contact, and touch and use them to establish rapport.
- Use a pain-rating scale for identifying and rating pain.
- Determine patient's use of folk remedies.

- Sit or stand at eye level, in front of the patient in full view.
- Face the older adult while speaking; do not cover your mouth.
- Provide diffuse, bright, nonglare lighting.
- Encourage the older adult to use his or her familiar assistive devices such as glasses or magnifiers.

Memory deficits, if present, affect the accuracy and completeness of an assessment. Information contributed by a family member or other caregiver is sometimes necessary to supplement the older adult's recollection of past medical events and information such as allergies and immunizations. Use tact when involving another person in the assessment interview. The additional person supplements the answers of the older adult with the consent of the older adult, but the older adult remains the focus of the interview.

During all aspects of the assessment you are responsible for providing culturally competent care. See Chapter 9 for a detailed description of the components of a cultural assessment. There are ways to provide culturally competent care while communicating with older adults during the assessment process (Box 14-4).

During assessment use caution when interpreting the signs and symptoms of diseases and laboratory values. Historically researchers have used younger populations to establish these signs and norms. However, the classic signs and symptoms of diseases are sometimes absent, blunted, or atypical in older adults (Gray-Miceli et al., 2010). This is especially true in the case of bacterial infection, pain, acute myocardial infarction, and heart failure. The masquerading of disease is possibly caused by age-related changes in organ systems and homeostatic mechanisms, progressive loss of physiological and functional reserves, or coexisting acute or chronic conditions. As a result the older adult with a urinary tract infection may present with confusion, incontinence, and an elevation of body temperature (within normal limits) instead of having fever, dysuria, frequency, or urgency. Some older adults with pneumonia have tachycardia, tachypnea, and confusion with decreased appetite and functioning, without the more common symptoms of fever and productive cough. Instead of crushing, substernal chest pain and diaphoresis, the older adult with a myocardial infarction experiences a sudden onset of dyspnea often accompanied by anxiety and confusion. Variations from the usual norms for laboratory values are sometimes caused by age-related changes in cardiac, pulmonary, renal, and metabolic function (Amella, 2006).

It is important to recognize early indicators of an acute illness in older adults. Note changes in mental status, occurrence and reason for falls, dehydration, decrease in appetite, loss of function, dizziness, and incontinence because these may be indicators not presented in younger adults. A key principle of providing age-appropriate nursing care is timely detection of these cardinal signs of illness so early treatment can begin (Box 14-5). Mental status

BOX 14-5 EXAMPLES OF ALTERED PRESENTATION OF ILLNESSES IN OLDER ADULTS OCCURRING IN VARIOUS HEALTH CARE SETTINGS

Hospital

- Confusion is not inevitable. Look for an acute illness, neurological events, new medication, or the presence of risk factors for delirium.
- Many hospitalized older adults suffer from chronic dehydration exacerbated by acute illness.
- Not all older adults have fevers with infection. Symptoms instead include increased respiratory rate, falls, incontinence, or confusion.

Nursing Home

- Health care providers often undertreat pain in older adults, especially those with dementia. Look for nonverbal cues or pain presence such as grimacing or resistance to care.
- Decline in functional ability (even a minor one such as the inability to sit upright in a chair) is a signal of new illness.
- Residents with less muscle mass—both the frail and the obese—are at a much higher risk for toxicity from protein-binding drugs such as phenytoin (Dilantin and others) and warfarin (Coumadin and others).
- New urinary and/or fecal incontinence is often a sign of the onset of a new illness.

Ambulatory Care

- Complaints of fatigue or decreased ability to do usual activities are signs of anemia, thyroid problems, depression, or neurological or cardiac problems.
- Severe gastrointestinal problems in older adults do not always present with the same acute symptoms seen in younger patients. Ask about constipation, cramping sensations, and changes in bowel habits.
- Older adults reporting increased dyspnea and confusion, especially those with a cardiac history, need to go to the emergency department because these are the most common manifestations of myocardial infarction in this population.
- Depression is common among older adults with chronic illnesses. Watch for lack of interest in former activities, significant personal losses, or changes in role or home life.

Home Care

- Investigate all falls, focusing on balance, gait, and neurological issues.
- Monitor older adults with late-stage heart disease for loss of appetite as an early symptom of impending failure.
- Drug-drug and drug-food interactions in older patients who are seeing more than one provider and taking multiple medications are common. Watch for signs.

Modified from Amella E: Presentation of illness in older adults, *AORN J* 83(2): 372, 377, 385, 2006.

changes commonly occur as a result of disease and psychological issues. Some mental changes are often drug related, caused by drug toxicity or adverse drug events. A fall can be a common event for an older adult and can be injury producing and costly (Ferrari et al., 2010). A fall is a complex event that needs careful investigation to find out if it was the result of environmental causes or the symptom of a new-onset illness. Problems with the cardiac, respiratory, musculoskeletal, neurological, urological, and sensory body systems can present with a fall as a chief symptom of a new-onset condition. Dehydration is common in older adults because of decreased oral intake related to a reduced thirst response and less free water as a consequence of a decrease in muscle mass. When vomiting and diarrhea accompany the onset of an acute illness, the older adult is at risk for further dehydration. Decrease in appetite is a common symptom with the onset of pneumonia, heart failure, and urinary tract infection. Loss of functional ability occurs in a subtle fashion over a period of time; or it occurs suddenly, depending on the underlying cause. Thyroid disease, infection, cardiac or pulmonary conditions, metabolic disturbances, and anemia are common causes of functional decline; thus nurses play an essential role in early identification, referral, and treatment of health problems.

Physiological Changes

Perception of well-being defines quality of life. Understanding the older adult's perceptions about health status is essential for accurate assessment and development of clinically relevant interventions. Their concepts of health generally depend on personal perceptions of functional ability. Therefore older adults engaged in ADLs usually consider themselves healthy; whereas those who have physical, emotional, or social impairments that limit their activities perceive themselves as ill.

Some frequently observed physiological changes in older adults are normal (Table 14-1). The changes are not always pathological processes in themselves, but they make older adults more vulnerable to some common clinical conditions and diseases. Some older

TABLE 14-1 Common Physiological Changes with Aging at a Glance

SYSTEM	COMMON CHANGES
Integumentary	Loss of skin elasticity with fat loss in extremities, pigmentation changes, glandular atrophy (oil, moisture, sweat glands), thinning hair, with hair turning gray-white (facial hair: decreased in men, increased in women), slower nail growth, atrophy of epidermal arterioles
Respiratory	Decreased cough reflex; decreased cilia; increased anterior-posterior chest diameter; increased chest wall rigidity; fewer alveoli, increased airway resistance; increased risk of respiratory infections
Cardiovascular	Thickening of blood vessel walls; narrowing of vessel lumen; loss of vessel elasticity; lower cardiac output; decreased number of heart muscle fibers; decreased elasticity and calcification of heart valves; decreased baroreceptor sensitivity; decreased efficiency of venous valves; increased pulmonary vascular tension; increased systolic blood pressure; decreased peripheral circulation
Gastrointestinal	Periodontal disease; decrease in saliva, gastric secretions, and pancreatic enzymes; smooth muscle changes with decreased esophageal peristalsis and small intestinal motility; gastric atrophy, decreased production of intrinsic factor, increased stomach pH, loss of smooth muscle in the stomach, hemorrhoids, anal fissures; rectal prolapse and impaired rectal sensation.
Musculoskeletal	Decreased muscle mass and strength, decalcification of bones, degenerative joint changes, dehydration of intervertebral disks
Neurological	Degeneration of nerve cells, decrease in neurotransmitters, decrease in rate of conduction of impulses
Sensory	
Eyes	Decreased accommodation to near/far vision (presbyopia), difficulty adjusting to changes from light to dark, yellowing of the lens, altered color perception, increased sensitivity to glare, smaller pupils
Ears	Loss of acuity for high-frequency tones (presbycusis), thickening of tympanic membrane, sclerosis of inner ear, buildup of earwax (cerumen)
Taste	Often diminished; often fewer taste buds
Smell	Often diminished
Touch	Decreased skin receptors
Proprioception	Decreased awareness of body positioning in space
Genitourinary	Fewer nephrons, 50% decrease in renal blood flow by age 80, decreased bladder capacity Male—enlargement of prostate Female—reduced sphincter tone
Reproductive	Male—sperm count diminishes, smaller testes, erections less firm and slow to develop Female—decreased estrogen production, degeneration of ovaries, atrophy of vagina, uterus, breasts
Endocrine	General—alterations in hormone production with decreased ability to respond to stress Thyroid—decreased secretions Cortisol, glucocorticoids—increased antiinflammatory hormone Pancreas—increased fibrosis, decreased secretion of enzymes and hormones
Immune System	Thymus involution T-cell function decreases

Modified from Touhy T, Jett K: *Ebersole and Hess' gerontological nursing and healthy aging,* ed 3, St Louis, 2010, Mosby.

adults experience all of these changes, and others experience only a few. The body changes continuously with age; and specific effects on particular older adults depend on health, lifestyle, stressors, and environmental conditions. The nurse needs to know about these normal, more common changes to provide appropriate care for older adults and assist with adaptation to the changes.

General Survey. The general survey begins during the initial nurse-patient encounter and includes a quick but careful head-to-toe scan of the older adult that the nurse writes in a brief description (see Chapter 30). An initial inspection reveals if eye contact and facial expression are appropriate to the situation and universal aging changes such as facial wrinkles, gray hair, loss of body mass in the extremities, and an increase of body mass in the trunk.

Integumentary System. With aging the skin loses resilience and moisture. The epithelial layer thins, and elastic collagen fibers shrink and become rigid. Wrinkles of the face and neck reflect lifelong patterns of muscle activity and facial expressions, the pull of gravity on tissue, and diminished elasticity. Spots and lesions are often present on the skin. Smooth, brown, irregularly shaped spots (age spots or senile lentigo) initially appear on the backs of the hands and on forearms. Small, round, red or brown cherry angiomas occur on the trunk. Seborrheic lesions or keratoses appear as irregular, round or oval, brown, watery lesions. Years of sun exposure contribute to the aging of the skin and lead to premalignant and malignant lesions. You need to rule out these three malignancies related to sun exposure when examining skin lesions: melanoma, basal cell carcinoma, and squamous cell carcinoma (see Chapter 30).

Head and Neck. The facial features of the older adult may become more pronounced from loss of subcutaneous fat and skin elasticity. Facial features appear asymmetrical because of missing teeth or improperly fitting dentures. In addition, common vocal changes include a rise in pitch and a loss of power and range.

Visual acuity declines with age. This is often the result of retinal damage, reduced pupil size, development of opacities in the lens, or loss of lens elasticity. Presbyopia, a progressive decline in the ability of the eyes to accommodate from near to far vision, is common. Ability to see in darkness and adapt to abrupt changes from dark to light areas (and the reverse) is reduced. More ambient light is necessary for tasks such as reading and other ADLs. Older adults have increased sensitivity to the effects of glare. Pupils are smaller and react slower. Objects do not appear bright, but the older adult has difficulty when coming from bright to dark environments. Changes in color vision and discoloration of the lens make it difficult to distinguish between blues and greens and among pastel shades. Dark colors such as blue and black appear the same. Diseases of the older eye include cataract, macular degeneration, diabetic retinopathy, and retinal detachment. Cataracts, a loss of the transparency of the lens, are a prevalent disorder among older adults. They normally result in blurred vision, sensitivity to glare, and gradual loss of vision. Chapter 49 outlines nursing interventions for adapting to a patient's visual changes.

Noise is the most prevalent risk factor for impaired hearing. Exposure earlier in life exacerbates hearing loss in old age. However, auditory changes are often subtle. Most of the time older adults ignore the early signs of hearing loss until friends and family members comment on compensatory attempts such as turning up the volume on televisions or avoiding social conversations. A common age-related change in auditory acuity is presbycusis. Presbycusis affects the ability to hear high-pitched sounds and sibilant consonants such as *s, sh,* and *ch.* Before the nurse assumes presbycusis, it is necessary to inspect the external auditory canal for the presence of cerumen. Impacted cerumen, a common cause of diminished hearing acuity, is easy to treat.

Salivary secretion is reduced, and taste buds atrophy and lose sensitivity. The older adult is less able to differentiate among salty, sweet, sour, and bitter tastes. The sense of smell also decreases, further reducing taste. Health conditions, treatments, and/or medications can alter taste. It is often a challenge to promote optimal nutrition in an older patient because of the loss of smell and changes in taste.

Thorax and Lungs. Because of changes in the musculoskeletal system, the configuration of the thorax sometimes changes. Respiratory muscle strength begins to decrease, and the anteroposterior diameter of the thorax increases. Vertebral changes caused by osteoporosis lead to dorsal kyphosis, the curvature of the thoracic spine. Calcification of the costal cartilage causes decreased mobility of the ribs. The chest wall gradually becomes stiffer. Lung expansion decreases, and the person is less able to cough deeply. If kyphosis or chronic obstructive lung disease is present, breath sounds become distant. With these changes the older adult is more susceptible to pneumonia and other bacterial or viral infections.

Heart and Vascular System. Decreased contractile strength of the myocardium results in decreased cardiac output. The decrease is significant when the older adult experiences anxiety, excitement, illness, or strenuous activity. The body tries to compensate for decreased cardiac output by increasing the heart rate during exercise. However, after exercise it takes longer for the older adult's rate to return to baseline. Systolic and/or diastolic blood pressures are sometimes abnormally high. Although a common chronic condition, hypertension is not a normal aging change and predisposes older adults to heart failure, stroke, renal failure, coronary heart disease, and peripheral vascular disease.

Peripheral pulses frequently are weaker, although still palpable, in the lower extremities. Older adults sometimes complain that their lower extremities are cold, particularly at night. Changes in the peripheral pulses in the upper extremities are less common.

Breasts. As estrogen production diminishes, the milk ducts of the breasts are replaced by fat, making breast tissue less firm. Decreased muscle mass, tone, and elasticity result in smaller breasts in older women. In addition, the breasts sag. Atrophy of glandular tissue, coupled with more fat deposits, results in a slightly smaller, less dense, and less nodular breast. Gynecomastia, enlarged breasts in men, is often the result of medication side effects, hormonal changes, or obesity. Both older men and women are at risk of breast cancer.

Gastrointestinal System and Abdomen. Aging leads to an increase in the amount of fatty tissue in the trunk. As a result, the abdomen increases in size. Because muscle tone and elasticity decrease, it also becomes more protuberant. Gastrointestinal function changes include a slowing of peristalsis and alterations in secretions. The older adult experiences these changes by becoming less tolerant of certain foods and having discomfort from delayed gastric emptying. Alterations in the lower gastrointestinal tract lead to constipation, flatulence, or diarrhea.

Reproductive System. Changes in the structure and function of the reproductive system occur in both sexes as the result of hormonal alterations. Female menopause is related to a reduced responsiveness of the ovaries to pituitary hormones and a resultant decrease in estrogen and progesterone levels. In men there is no definite cessation of fertility associated with aging. Spermatogenesis begins to decline during the fourth decade and continues into the ninth. However, the changes in reproductive structure and function do not affect libido; sexual desires, thoughts, and actions

continue throughout all decades of life (Wallace, 2008). Less frequent sexual activity often results from illness, death of a sexual partner, or decreased socialization.

Urinary System. Hypertrophy of the prostate gland is frequently seen in older men. This hypertrophy enlarges the gland and places pressure on the neck of the bladder. As a result, urinary retention, frequency, incontinence, and urinary tract infections occur. In addition, prostatic hypertrophy results in difficulty initiating voiding and maintaining a urinary stream. Benign prostatic hypertrophy is different from cancer of the prostate. Cancer of the prostate is the second most common cause of cancer death in men over age 50. In 2010 the American Cancer Society estimated that one in six men will be diagnosed with prostate cancer and 1 in 36 will die (American Cancer Society, 2010).

Urinary incontinence is an abnormal condition that can occur in both older men and women. Men may be afraid to discuss incontinence with their physician because of embarrassment and because they think that urinary incontinence is a "woman's disease." Older women, particularly those who have had children, experience stress incontinence, an involuntary release of urine that occurs when they cough, laugh, sneeze, or lift an object. This is a result of a weakening of the perineal and bladder muscles. Other types of urinary incontinence are urge, overflow, functional, and mixed incontinence. The risk factors for urinary incontinence include age, menopause, diabetes, hysterectomy, stroke, and obesity.

Musculoskeletal System. With aging muscle fibers become smaller. Muscle strength diminishes in proportion to the decline in muscle mass. Beginning in the 30s, bone density and bone mass decline in men and women. Older adults who exercise regularly do not lose as much bone and muscle mass or muscle tone as those who are inactive. Osteoporosis is a major public health threat. An estimated 10 million Americans already have the disease, and an additional 34 million are at risk with low bone mass (National Osteoporosis Foundation, 2010). Postmenopausal women experience a greater rate of bone demineralization than older men. Women who maintain calcium intake throughout life and into menopause have less bone demineralization than women with low calcium intake. Older men with poor nutrition and decreased mobility are also at risk for bone demineralization.

Neurological System. A decrease in the number and size of neurons in the nervous system begins in the middle of the second decade. Neurotransmitters, chemical substances that enhance or inhibit nerve impulse transmission, change with aging as a result of the decrease in neurons. All voluntary reflexes are slower, and individuals often have less of an ability to respond to multiple stimuli. In addition, older adults frequently report alterations in the quality and the quantity of sleep (see Chapter 42), including difficulty falling asleep, difficulty staying asleep, difficulty falling asleep again after waking during the night, waking too early in the morning, and excessive daytime napping. These problems are believed to be caused by age-related changes in the sleep-wake cycle.

Functional Changes

Physical function is a dynamic process. It changes as individuals interact with their environments. Functional status in older adults includes the day-to-day ADLs involving activities within physical, psychological, cognitive, and social domains. A decline in function can often be linked to illness or disease and its degree of chronicity. However, ultimately it is the complex relationship among all of these areas that influences an older adult's functional abilities and overall well-being.

Keep in mind that it may be difficult for older adults to accept the changes that occur in all areas of their lives, which in turn have a profound effect on functional status. Some deny the changes and continue to expect the same performance from themselves, regardless of age. Conversely some overemphasize them and prematurely limit their activities and involvement in life. The fear of becoming dependent is an overwhelming one for the older adult who is experiencing functional decline as a result of aging. Educate older adults to promote understanding of age-related changes, appropriate lifestyle adjustments, and effective coping. Factors that promote the highest level of function in all the areas include a healthy, well-balanced diet; paced and appropriate activity; regularly scheduled visits with a health care provider; regular participation in meaningful activities; use of stress management techniques; and avoidance of alcohol, tobacco, or illicit drugs.

Functional status in older adults refers to the capacity and safe performance of ADLs and instrumental activities of daily living (IADLs). It is a sensitive indicator of health or illness in the older adult. ADLs (such as bathing, dressing, and toileting) and IADLs (such as the ability to write a check, shop, prepare meals, or make phone calls) are essential to independent living; therefore carefully assess whether or not the older adult has changed the way he or she completes these tasks. Occupational and physical therapists are your best resources for a comprehensive assessment. A sudden change in function, as evidenced by a decline or change in the older adult's ability to perform any one or combination of ADLs, is often a sign of the onset of an acute illness (e.g., pneumonia, urinary tract infection, or electrolyte imbalance) or worsening of a chronic problem (e.g., diabetes or cardiovascular disease) (Kresevic, 2008).

Health care providers who work in a range of different settings are able to perform functional assessment. Several standardized functional assessment tools are widely available. There is an online collection of the tools used most commonly with older adults at the geriatric nursing website of the American Nurses Association (ANA), www.geronurseonline.org. When you identify a decline in a patient's function, focus your nursing interventions on maintaining, restoring, and maximizing the older adult's functional status to maintain independence while preserving dignity.

Cognitive Changes

A common misconception about aging is that cognitive impairments are widespread among older adults. Because of this misconception, older adults often fear that they are, or soon will be, cognitively impaired. Younger adults often assume that older adults will become confused and no longer able to handle their affairs. Forgetfulness as an expected consequence of aging is a myth. Some structural and physiological changes within the brain are associated with cognitive impairment. Reduction in the number of brain cells, deposition of lipofuscin and amyloid in cells, and changes in neurotransmitter levels occur in older adults both with and without cognitive impairment. Symptoms of cognitive impairment such as disorientation, loss of language skills, loss of the ability to calculate, and poor judgment *are not* normal aging changes and require you to further assess patients for underlying causes. There are standard assessment forms for determining a patient's mental status, including the Mini-Mental State Exam (MMSE), the Confusion Assessment Method (CAM) and the NEECHAM Confusion Scale (Ebersole et al., 2008).

The three common conditions affecting cognition are **delirium, dementia,** and **depression** (Table 14-2). Distinguishing among these three conditions is challenging. Complete a careful and thorough assessment of older adults with cognitive changes to

TABLE 14-2 Comparison of Clinical Features of Delirium, Dementia, and Depression

CLINICAL FEATURE	DELIRIUM	DEMENTIA	DEPRESSION
Onset	Sudden/abrupt; depends on cause	Insidious/slow and often unrecognized	Happens with major life changes; often abrupt but can be gradual
Course	Short, daily fluctuations in symptoms; worse at night, in darkness, and on awakening	Long, no diurnal effects; symptoms progressive yet relatively stable over time; some deficits with increased stress	Diurnal effects, typically worse in the morning; situational fluctuations but less than with delirium
Progression	Abrupt	Slow but uneven	Variable; rapid or slow but even
Duration	Hours to less than 1 month; longer if unrecognized and untreated	Months to years	At least 6 weeks; sometimes several months to years
Consciousness	Reduced/disturbed	Clear	Clear
Alertness	Fluctuates; lethargic or hypervigilant	Generally normal	Normal
Attention	Impaired; fluctuates; inattention; distractible	Generally normal	Minimal impairment but is easily distracted
Orientation	Generally impaired; severity varies	Generally normal to person but not to place or time	Selective disorientation
Memory	Recent and immediate impaired; forgetful; many need instructions for simple tasks one step at a time	Recent and remote impaired	Selective or "patchy" impairment; "islands" of intact memory; evaluation often difficult because of low motivation
Thinking	Disorganized, distorted, fragmented, illogical; incoherent speech, either slow or accelerated	Difficulty with abstraction; thoughts diminished; judgment impaired; words difficult to find	Intact but with themes of hopelessness, helplessness, or self-deprecation
Perception	Distorted, illusions, delusions, and hallucinations; difficulty distinguishing between reality and misperceptions	Misperceptions usually absent	Intact; delusions and hallucinations absent except in severe cases
Psychomotor behavior	Variable; hypokinetic, hyperkinetic, and mixed	Normal; some have apraxia	Variable; psychomotor retardation or agitation
Sleep/wake cycle	Disturbed; cycle reversed	Fragmented	Disturbed; usually early morning awakening
Associated features	Variable affective changes; symptoms of autonomic hyperarousal; exaggeration of personality type; associated with acute physical illness	Affect tends to be superficial, inappropriate, and labile (changing); attempts to hide deficits in intellect; personality changes, aphasia, agnosia sometimes present; lacks insight	Affect depressed; dysphoric mood; exaggerated and detailed complaints; preoccupied with personal thoughts; insight present; verbal elaboration; somatic complaints, poor hygiene, neglect of self
Assessment	Distracted from task; makes numerous errors	Failings highlighted by family, frequent "near miss" answers; struggles with test; great effort to find an appropriate reply; frequent requests for feedback on performance	Failings highlighted by individual, frequent "don't knows"; little effort; frequently gives up; indifferent toward test; does not care or attempt to find answer

Modified from Braes T et al: Assessing cognitive function. In Capezuti E et al: *Evidence-based geriatric nursing protocols for best practice,* ed 3, New York, 2008, Springer.

distinguish among them. Select appropriate nursing interventions that are specific to the cause of the cognitive impairment.

Delirium. Delirium, or acute confusional state, is potentially a reversible cognitive impairment that often has a physiological cause. Physiological causes include electrolyte imbalances; cerebral anoxia; hypoglycemia; medication effects; tumors; subdural hematomas; and cerebrovascular infection, infarction, or hemorrhage. Delirium in older adults sometimes accompanies systemic infections and is often the presenting symptom for pneumonia or urinary tract infection. Sometimes it is also caused by environmental factors such as sensory deprivation or unfamiliar surroundings or psychosocial factors such as emotional distress or pain. Sleep deprivation is another possible reason for delirium. Although it occurs in any setting, an older adult in the acute care setting is especially at risk because of predisposing factors (physiological, psychosocial, and environmental) in combination with the underlying medical condition. Dementia is an additional risk factor that greatly increases the risk for delirium, and it is possible for delirium and dementia to occur in a patient at the same time. The presence of delirium is a medical emergency and requires prompt assessment and intervention. Nurses are at the bedside 24/7 and in a position to recognize delirium development and report it. The cognitive impairment usually reverses once health care providers identify and treat the cause of delirium.

Dementia. Dementia is a generalized impairment of intellectual functioning that interferes with social and occupational

functioning. It is an umbrella term that includes Alzheimer's disease, Lewy body disease, frontal-temporal dementia, and vascular dementia. Cognitive function deterioration leads to a decline in the ability to perform basic ADLs and IADLs. Unlike delirium, a gradual, progressive, irreversible cerebral dysfunction characterizes dementia. Because of the similarity between delirium and dementia, you need to assess carefully to rule out the presence of delirium whenever you suspect dementia.

Nursing management of older adults with any form of dementia always considers the safety and physical and psychosocial needs of the older adult and the family. These needs change as the progressive nature of dementia leads to increased cognitive deterioration. To meet the needs of the older adult, individualize nursing care to enhance quality of life and maximize functional performance by improving cognition, mood, and behavior. Box 14-6 lists general nursing principles for care of older adults with cognitive changes. Support and education about Alzheimer's disease for patients, families, and professionals can be found at the Alzheimer's Association website (www.alz.org).

Depression. Approximately one third of older adults experience depressive symptoms (Mental Health America, 2011). Older adults sometimes experience late-life depression, but it is not a normal part of aging. Depression is the most common, yet most undetected and untreated, impairment in older adulthood. Co-occurring diseases may include stroke, dementia, Parkinson's disease, heart disease, cancer, and pain-provoking diseases such as arthritis. Loss of a significant loved one or a nursing center admission may precipitate depression. Clinical depression is treatable and includes medication, psychotherapy, or a combination of both. Of special note, suicide attempts in older adults are often successful. In fact, suicide in older adults comprises 20% of all suicides (Mental Health America, 2011).

BOX 14-6 NURSING CARE PRINCIPLES FOR CARE OF COGNITIVELY IMPAIRED OLDER ADULTS

- Institute medical measures to correct underlying physiological alterations.
- Maximize safe function. Keep a routine, limit choices (e.g., clothes for dressing, what to eat), allow for rest.
- Provide unconditional positive regard. Be respectful. Nonverbal communication also should be positive.
- Use behaviors to gauge activity and stimulation. Watch for facial signs of anxiety.
- Teach caregivers to listen to the behaviors that show stress (e.g., verbalizations such as repetition).
- Modify the environment.
- Promote social interaction based on abilities. Make sure that the environment is safe for mobility and promote way-finding with pictures or cues. Try to identify patients who wander and remove the cause (e.g., pain, thirst, unfamiliar surroundings, new noises).
- Compensate for any sensory deficits (e.g., hearing aids, glasses, dentures).
- Encourage fluid intake (make sure that fluids are accessible) and avoid long periods of giving nothing orally.
- Be vigilant for drug reactions or interactions; consider onset of new symptoms as an adverse reaction.
- Activate bed and chair alarms.
- Provide ongoing assistance to family caregivers; educate them in nursing care techniques and inform them about community resources.

Modified from Fletcher K: Dementia. In Capezuti et al: *Evidence-based geriatric nursing protocols for best practice,* ed 3, New York, 2008, Springer; Ebersole P et al: *Toward healthy aging: human needs and nursing response,* St Louis, 2008, Mosby.

Psychosocial Changes

The psychosocial changes occurring during aging involve life transitions and loss. The longer people live, the more transitions with which they must cope, and the more losses they experience. Life transitions, of which loss is a major component, include retirement and the associated financial changes, changes in roles and relationships, alterations in health and functional ability, changes in one's social network, and relocation. But the universal loss for older adults usually revolves around the loss of relationships through death.

It is important to assess both the nature of the psychosocial changes that occur in older adults as a result of life transitions and the loss and the adaptations to the changes. During the assessment ask how the older adult feels about self, self in relation to others, and self as one who is aging and what coping methods and skills have been beneficial. Areas to address during the assessment include family, intimate relationships, past and present role changes, finances, housing, social networks, activities, health and wellness, and spirituality. Specific topics related to these areas include retirement, social isolation, sexuality, housing and environment, and death.

Retirement. Many often mistakenly associate retirement with passivity and seclusion. In actuality it is a stage of life characterized by transitions and role changes. This transition requires letting go of certain habits and structure and developing new ones (Touhy and Jett, 2010). The psychosocial stresses of retirement are usually related to role changes with a spouse or within the family and to loss of the work role. Sometimes problems related to social isolation and finances are present. The age of retirement varies. But, whether it occurs at age 55, 65, or 75, it is one of the major turning points in life.

Preretirement planning is an important advisable task. People who plan in advance for retirement generally have a smoother transition. Preretirement planning is more than financial planning. Planning begins with consideration of the "style" of retirement desired and includes an inventory of interests, current skills, and general health. Meaningful retirement planning is critical as the population continues to age.

Retirement affects more than just the retired. It affects the spouse, adult children, and even grandchildren. When the spouse is still working, the retired person faces time alone. There may be new expectations of the retired person. For example, a working spouse might have new ideas about the amount of housework expected of the retired person. Problems develop when the plans of the retired person conflict with the work responsibilities of the working spouse. The roles of the retiree and the working spouse need clarification. Adult children may expect the retired person to always babysit for the grandchildren, forgetting that this is a time for the retired person to pursue other personal interests.

Loss of the work role has a major impact on some retired persons. When so much of life has revolved around work and the personal relationships at work, the loss of the work role can be devastating. Personal identity is often rooted in the work role, and with retirement individuals need to construct a new identity. Individuals also lose the structure imposed on daily life when they no longer have a work schedule. The social exchanges and

interpersonal support that occur in the workplace are lost. In the adjustment to retirement the older adult has to develop a personally meaningful schedule and a supportive social network.

Factors that influence the retired person's satisfaction with life are health status and sufficient income. Positive preretirement expectations also contribute to satisfaction in retirement. The nurse can help the older adult and family prepare for retirement by discussing with them several key areas, including relations with spouse and children; meaningful activities and interests; building social networks; issues related to income; health promotion and maintenance; and long-range planning, including wills and advance directives.

Social Isolation. Many older adults experience social isolation. Isolation is sometimes a choice, the result of a desire not to interact with others. It is also a response to conditions that inhibit the ability or the opportunity to interact such as the lack of access to transportation. Although some older adults choose isolation or a lifelong pattern of reduced interaction with others, older adults who experience social isolation become vulnerable to its consequences. An older adult's vulnerability increases in the absence of the support of other adults, as occurs with loss of the work role or relocation to unfamiliar surroundings. Impaired sensory function, reduced mobility, and cognitive changes all contribute to reduced interaction with others and can place the older adult at risk for isolation.

You assess patients' potential for social isolation by identifying their social network, access to transportation, and willingness and desire to interact with others. Your findings assist you in helping a lonely older adult rebuild social networks and reverse patterns of isolation. Many communities have outreach programs designed to make contact with isolated older adults such as Meals on Wheels, which provides nutritional meals. Outreach programs such as daily telephone calls by volunteers or needs for activities such as social outings also meet socialization needs. Social service agencies in most communities welcome older adults as volunteers and provide the opportunity for them to serve while meeting their socialization or other needs. Churches, colleges, community centers, and libraries offer a variety of programs for older adults that increase the opportunity to meet people with similar activities, interests, and needs.

Sexuality. All older adults, whether healthy or frail, need to express their sexual feelings. Sexuality involves love, warmth, sharing, and touching, not just the act of intercourse. Sexuality plays an important role in helping the older adult maintain self-esteem. To help an older adult achieve or maintain sexual health, you need to understand the physical changes in a person's sexual response (Chapter 34). You need to provide privacy for any discussion of sexuality and maintain a nonjudgmental attitude. Open-ended questions inviting the older adult to explain sexual activities or concerns elicit more information than a list of closed-ended questions about specific activities or symptoms. Include information about the prevention of sexually transmitted infections when appropriate. Sexuality and the need to express sexual feelings remain throughout the human life span.

When considering the older adult's need for sexual expression, do not ignore the important need to touch and be touched. Touch is an overt expression with many meanings and is an important part of intimacy (Atkinson, 2006). Touch complements traditional sexual methods or serves as an alternative sexual expression when physical intercourse is not desired or possible. Knowing an older adult's sexual needs allows you to incorporate this information into the nursing care plan.

The sexual preferences of older adults are as diverse as those of the younger population. Clearly not all older adults are heterosexual, yet little research has been done on older adult homosexuals and their health care needs. A number of emerging issues have the potential to substantially affect caregiving in the future, including the demographic changes and the overall aging of the U.S. population, shifts in the nature of families, growing economic pressures, and the societal context of caregiving (Fredriksen-Goldsen et al., 2009). Nurses often find that they are called on to help other health care professionals understand the sexual needs of older adults and advise them. Not all nurses feel comfortable counseling older adults about sexual health and intimacy-related needs. Be prepared to refer older adults to an appropriate professional counselor.

Housing and Environment. The extent of an older adult's ability to live independently influences housing choices. Changes in social roles, family responsibilities, and health status influence their living arrangements. Some choose to live with family members. Others prefer their own homes or other housing options near their families. Leisure or retirement communities provide older people with living and social opportunities in a one-generation setting. Federally subsidized housing, where available, offers apartments with communal, social, and in some cases food-service arrangements.

The goal of your assessment of a patient's environment is to consider resources that promote independence and functional ability. When assisting older adults with housing needs, assess their activity level, financial status, access to public transportation and community activities, environmental hazards, and support systems (Touhy and Jett, 2010). When helping patients consider housing choice, anticipate their future needs as much as possible. For example, a housing unit with only one floor and without exterior steps is a prudent choice for the older adult with severe arthritis who has already had lower-extremity joint replacement surgery and anticipates the need for future operations. Assessment of safety, a major component of the older adult's environment, includes risks within the environment and the older adult's ability to recognize and respond to the risks (Chapter 27). Safety risks in the home include factors leading to injury such as water heaters set at excessively hot temperatures or environmental barriers such as throw rugs or slippery floor surfaces that could cause a fall. Assess if the person has a pet that could easily move around the person's feet to cause a fall. Lighting in the home must be assessed. Is the light bright enough to see walkways and stairs, and is there a lit path to the bathroom at night? Conduct a home and environmental check with the person's family caregiver present if possible.

Housing and environment affect the health of older adults. The environment can support or hinder physical and social functioning, enhance or drain energy, and complement or tax existing physical changes such as vision and hearing. For example, furnishings with red, orange, and yellow colors are easiest for older adults to see. Shiny waxed floors may appear to be wet or have a hole in them. Older adults have difficulty distinguishing between green and blue and among pastel shades. Door frames and baseboards should be a color that contrasts with the color of the wall to improve perception of the boundaries of halls and rooms. Stairs should have a color contrast at the edge of the step so the older person knows where the stair ends. Glare from highly polished floors, metallic fixtures, and windows is difficult for the older adult to tolerate.

Furniture must be comfortable and designed for the musculoskeletal changes of older adults. Older adults need to examine it carefully for size, comfort, and function before purchasing it. It

must be easy to get into and out of and provide back support. Test dining room chairs for comfort during meals and for height in relation to the table. Armrests make it easier for patients to get in and out of a chair because they can use their arms to assist in lifting. Older adults often prefer transferring out of a wheelchair to another chair for meals because some styles of wheelchairs do not let older adults sit close enough to the table to eat comfortably. Raising the table to clear the wheelchair arms brings the table closer to the older adult but makes it too high for comfortable use. To make getting out of bed easier and safer, the height of the bed needs to allow the older adult's feet to be flat on the floor when he or she is sitting on the side of the bed.

Death. Part of one's life history is the experience of loss through the death of relatives and friends (see Chapter 36). This includes the loss of the older generations of families and sometimes, sadly, the loss of a child. However, death of a spouse is the loss that affects the lives of most older people. The death of a spouse affects older women more than men, a trend that will probably continue in the future. In spite of these experiences, it is wrong to assume that the older adult is comfortable with the idea of death. A key role of the nurse is to help older adults understand the meaning of the loss and cope with it.

Older people have a wide variety of attitudes and beliefs about death, but fear of their own death is uncommon (Friedman, 2006). Rather they are concerned with fear of being a burden, experiencing suffering, being alone, and the use of life-prolonging measures. The stereotype that the death of an older adult is a blessing does not apply to every older adult. Even as death approaches, many older adults still have unfinished business and are not prepared for it. Families and friends are not always ready to let go of him or her. The nurse is often the person to whom the older adult and family members or friends turn to for assistance. Knowledge of the grieving process (see Chapter 36), excellent communication skills; understanding of legal issues; familiarity with community resources; and awareness of one's own feelings, limitations, and strengths as they relate to care of those confronting death are critical.

ADDRESSING THE HEALTH CONCERNS OF OLDER ADULTS

As the population ages and life expectancy increases, emphasis on health promotion and disease prevention increases (see Chapter 6). The number of older adults becoming enthusiastic and motivated about these aspects of health is increasing. A number of national programs and projects address preventive practices in the older-adult population. The national initiative *Healthy People 2020* (HealthyPeople.gov), has a number of major goals affecting the older adult population, including increasing the number of older adults with one or more chronic conditions who report confidence in maintaining their conditions, reducing the proportion of older adults who have moderate-to-severe functional limitations, reducing the number of emergency department visits resulting from falls among older adults, increasing the number of older adults who live at home but have unmet long-term services and support; and increasing the proportion of older adults with reduced physical or cognitive function who engage in light, moderate, or vigorous leisure-term physical activities. Agencies that serve older adults will continue to collaborate in such efforts to promote health and prevent disease.

The challenges of health promotion and disease prevention for older adults are complex and affect health care providers as well. For the older adult, previous health care experiences, personal motivation, health beliefs, culture, and nonhealth-related factors such as transportation and finances can create barriers to participation. Barriers for health care providers include beliefs and attitudes about which services and programs to provide, their effectiveness and the lack of consistent guidelines, and absence of a coordinated approach. The nurse's role is to focus interventions on maintaining and promoting patients' function and quality of life. You can help older adults become empowered to make their own health care decisions and realize their optimum level of health, function, and quality of life (Resnick, 2006) Always be open to recognizing an older adult's concerns so you can adjust a plan of care accordingly. Although various interventions cross all three levels of care (i.e., health promotion, acute care, and restorative care), some approaches are unique to each level.

Health Promotion and Maintenance: Physiological Concerns

Older adults vary in their desire to participate in health promotion activities; therefore use an individualized approach, taking into account the person's beliefs about the importance of staying healthy and fit and remaining independent. Researchers have not fully identified the factors that lead to good health in advanced age, but three important factors seem to be genetics, good health habits, and preventive measures. Use creative approaches to incorporate health promotion activities in all health care settings.

The AOA (2009) reports that in 2008 38% of older persons had some type of disability (i.e., difficulty in hearing, vision, cognition, ambulation, self-care, or independent living). Some of these disabilities are relatively minor, but others cause people to require assistance to meet important personal needs. The incidence of disability increases with age. Limitations in ADLs limit the ability to live independently. The ADL limitations most often reported include walking, showering and bathing, getting in and out of bed and chair, dressing, toileting, and eating. There is a strong relationship between disability status and reported health status. The effect of chronic conditions on the lives of older adults varies widely, but in general chronic conditions further diminish well-being and a sense of independence. Direct nursing interventions at managing these conditions and educating family caregivers in ways to give appropriate support. It is also important to focus interventions on prevention. General preventive measures for you to recommend to older adults include:

- Participation in screening activities (e.g., blood pressure, mammography, Pap smears, depression, vision and hearing testing, colonoscopy)
- Regular exercise
- Weight reduction if overweight
- Eating a low-fat, well-balanced diet
- Moderate alcohol use
- Regular dental visits
- Smoking cessation
- Immunization for seasonal influenza, tetanus, diphtheria and pertussis, shingles, and pneumococcal disease

Those who die from influenza are predominately older adults. A debate currently centers about influenza deaths and the older adult. Do older adults die because of influenza or is the death related to worsening of a chronic illness and influenza? However, providers continue to strongly recommend annual immunization of all older adults for influenza, with special emphasis on residents of nursing homes or residential or long-term care facilities. Not all older adults are current with their booster injections, and some never

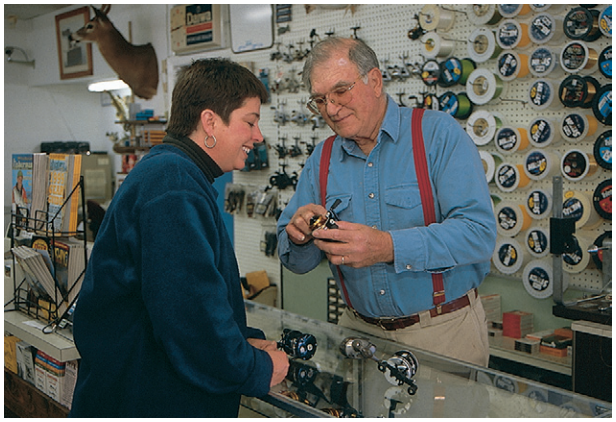

FIG. 14-1 This older adult works part time at a sporting goods store.

received the primary series of injections. Ask older adults about the current status of all immunizations, provide information about the immunizations, and make arrangements for the older adult to receive the immunizations as needed.

Most older adults are interested in their health and are capable of taking charge of their lives. They want to remain independent and prevent disability (Fig. 14-1). Initial screenings establish baseline data that you use to determine wellness, identify health needs, and design health maintenance programs. Following initial screening sessions, share with older adults information on nutrition, exercise, medications, and safety precautions. You can also provide information on specific conditions such as hypertension, arthritis, or self-care procedures such as foot and skin care. By providing information about health promotion and self-care, you significantly improve the health and well-being of older adults.

Heart Disease. Heart disease is the leading cause of death in older adults (CDC, 2010a). Common cardiovascular disorders are hypertension and coronary artery disease. Hypertension is a silent killer because often the person is unaware that his or her blood pressure is elevated (see Chapter 29). Although over half of Americans have elevated diastolic and/or systolic pressures, the fact that hypertension is common does not make it normal or harmless. Treatment of systolic pressures 160 mm Hg or higher is linked to reduced incidence of myocardial infarction, stroke, and heart failure. In coronary artery disease partial or complete blockage of one or more coronary arteries leads to myocardial ischemia and myocardial infarction. The risk factors for both hypertension and coronary artery disease include smoking, obesity, lack of exercise, and stress. Additional risk factors for coronary artery disease include hypertension, hyperlipidemia, and diabetes mellitus. Nursing interventions for hypertension and coronary artery disease address weight reduction, exercise, dietary changes, limiting salt and fat intake, stress management, and smoking cessation. Patient teaching also includes information about medication management, blood-pressure monitoring, and the symptoms indicating the need for emergency care.

Cancer. Malignant neoplasms are the second most common cause of death among older adults (CDC, 2010a). Nurses educate older adults about early detection, treatment, and cancer risk factors. Examples include smoking cessation, teaching breast self-examination (see Chapter 30), and encouraging all older adults to have annual screening for fecal occult blood with a rectal examination. It is also important to educate older adults about the signs of cancer and encourage prompt reporting of nonhealing skin lesions, unexpected bleeding, change in bowel habits, nagging cough, lump in breast or another part of body, change in a mole, difficulty swallowing, and unexplained weight loss. Cancer is difficult to detect because providers often mistake symptoms as part of the normal aging process or signs of a person's chronic disease. You need to carefully distinguish between signs of normal aging and signs of pathological conditions.

Stroke (Cerebrovascular Accident). Cerebrovascular accidents (CVAs) continue to be the third leading cause of death in the United States and occur as brain ischemia (inadequate blood supply to areas of brain caused by arterial blockage) or brain hemorrhage (subarachnoid or intercerebral bleeds) (CDC, 2010a). Risk factors for CVAs include hypertension, hyperlipidemia, diabetes mellitus, history of transient ischemic attacks, and family history of cardiovascular disease. CVAs often impair the functional abilities of older adults and lead to the inability to live independently. The scope of nursing interventions ranges from teaching older adults about risk-reduction strategies to teaching family caregivers the early warning signs of a stroke and ways to support a patient during recovery and rehabilitation.

Smoking. Cigarette smoking is a risk factor among the four most common causes of death: heart disease, cancer, stroke, and lung disease. Smoking is the most preventable cause of disease and death in the United States. As of 2009 an estimated 9.5% of people ages 65 and older smoked cigarettes (CDC, 2010b). Approximately 440,000 people die annually from smoking-related diseases, and 300,000 of those deaths occur in people ages 65 and older (CMS, 2010).

Smoking cessation is a health promotion strategy for older adults just as it is for younger adults. Older smokers still benefit from smoking cessation. In addition to reducing risk, it sometimes stabilizes existing conditions such as chronic obstructive pulmonary disease (COPD) and coronary artery disease. Smoking cessation after age 65 can add 2 to 3 years to life expectancy. Within a year of quitting, former smokers reduce their risk of coronary heart disease by 50% (National Cancer Institute, 2010). Smoking-cessation programs recommended by the CDC (2008) include individual, group, and telephone counseling and the use of nicotine (gum and patch) or nonnicotine medications. If the patient rejects smoking cessation, suggest at least a reduction in smoking. Finally, arrange with the older adult a quit or reduction date and a follow-up visit or contact to discuss the quit attempt. At follow-up visits, offer encouragement and assistance in modifying the plan as necessary.

Alcohol Abuse. Alcoholism can be found in older adults. Alcohol is inexpensive, legal, and accessible. Studies of alcohol abuse in older adults report two patterns: a lifelong pattern of heavy drinking that continues and a pattern when heavy drinking begins late in life. Frequently cited causes of excessive alcohol use are depression, loneliness, and lack of social support.

Alcohol abuse may be underidentified in older adults. The clues to creating suspicion of alcohol abuse are subtle, and coexisting dementia or depression sometimes complicates the assessment. Suspicion of alcohol abuse increases when there is a history of repeated falls and accidents, social isolation, recurring episodes of memory loss and confusion, failure to meet home and work obligations, a history of skipping meals or medications, and difficulty managing household tasks and finances. When you suspect that an older adult is abusing alcohol, realize that a variety of treatment needs are present. Treatment includes age-specific approaches that acknowledge the stresses experienced by the older adult and encourage involvement in activities that match the older adult's

interests and increase feelings of self-worth. The identification and treatment of co-existing depression are also important. The continuum of interventions can range from simple education to formalized treatment programs that include pharmacotherapy, psychotherapy, and rehabilitation.

Nutrition. Lifelong eating habits and situational factors influence how older adults meet their needs for good nutrition. Lifelong eating habits based in tradition, ethnicity, and religion influence the choice of what foods are eaten and how they are prepared. Situational factors affecting nutrition include access to grocery stores, finances, physical and cognitive capability for food preparation, and a place to store food and prepare meals. Older adults' levels of activity and clinical conditions affect their nutritional needs. Level of activity has implications for the total amount of required calories. Older adults who are sedentary usually need fewer calories than those who are more active. However, activity alone does not determine caloric requirements. Additional calories are often necessary in clinical situations such as recovery from surgery, whereas fewer calories are necessary when the older adult has diabetes or is overweight.

Good nutrition for older adults includes appropriate caloric intake and limited intake of fat, salt, refined sugars, and alcohol. The nutritional guidelines displayed in the USDA's MyPlate (see Chapter 44) are the basic recommendations for older-adult nutrition. Protein intake is sometimes lower than recommended if older adults have reduced financial resources or limited access to grocery stores. Difficulty chewing meat because of poor dentition or poor-fitting dentures also limits protein intake. Fat intake is higher than usual because of the substitution of fast-food restaurant meals for meals prepared at home or because of methods of cooking featuring fried foods and sauces using butter and cream. Some use extra salt and sugar while cooking or at the table to compensate for a diminished sense of taste.

Older adults with dementia have special nutritional needs. As their memory and functional skills decline with the progression of dementia, they lose the ability to remember when to eat, how to prepare food, and how to feed themselves. Caloric needs may increase because of the energy expended in pacing and wandering activities. When caring for older adults with dementia, routinely monitor weight and food intake, serve food that is easy to eat such as finger foods (e.g., chicken strips, sandwiches, cut-up vegetables, and fruit), provide assistance with eating, and offer food supplements that are tasty and easy to swallow.

Dental Problems. Dental problems with natural teeth and dentures are common in older adults. Dental caries, gingivitis, broken or missing teeth, and ill-fitting or missing dentures affect nutritional adequacy, cause pain, and lead to infection. Dentures are a frequent problem because the cost is not covered by Medicare and dentures tend to be quite expensive. Help prevent dental and gum disease through education about routine dental care (see Chapter 39).

Exercise. Encourage older adults to maintain physical exercise and activity. The primary benefits of exercise include maintaining and strengthening functional ability and promoting a sense of enhanced well-being. Regular daily exercise such as walking builds endurance, increases muscle tone, improves joint flexibility, strengthens bones, reduces stress, and contributes to weight loss. Other benefits include improvement of cardiovascular function, improved plasma lipoprotein profiles, increased metabolic rate, increased gastrointestinal transit time, prevention of depressive illness, and improved sleep quality. Older adults who participate in group exercise programs or physical therapy may experience improved mobility, gait, and balance, resulting in fewer falls (Michael et al., 2010).

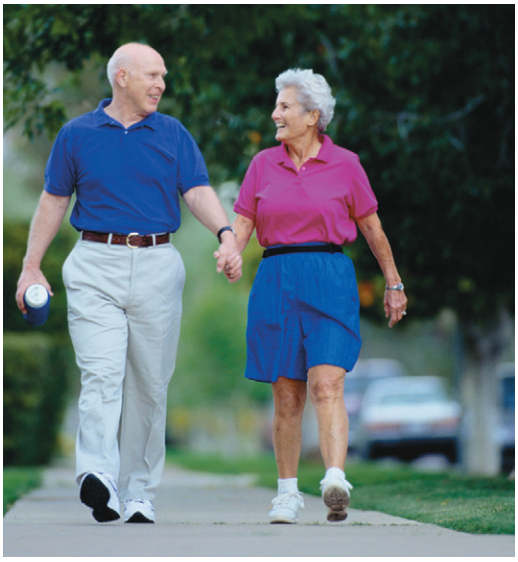

FIG.14-2 This couple enjoys walking together.

Consult with physical therapists and the patient's physician to plan an exercise program that meets physical needs and is one the patient enjoys. Consider the patient's physical limitations and encourage the older adult to stick with the exercise program. Many factors influence an individual's willingness to participate in an exercise program. These include general beliefs about benefits of exercise, past experiences with exercise, personal goals, personality, and any unpleasant sensations associated with exercise.

Walking is the preferred exercise of many older adults (Fig. 14-2). Walking and other low-impact exercises such as riding a stationary exercise bicycle or water exercises in a swimming pool protect the musculoskeletal system and joints. Other exercises can be included in the older adult's ADLs. For example, adults can perform arm and leg circles while watching television. Before beginning an exercise program, the older adult needs to have a physical examination. Exercise programs for sedentary older adults who have not been exercising regularly need to begin conservatively and progress slowly. Safety considerations include wearing good support shoes and clothing appropriate to the exercise, drinking water before and after exercising, avoiding outdoor exercise when the weather is very warm or very cold, and exercising with a partner. Instruct older adults to stop exercising and seek help if they experience chest pain or tightness, shortness of breath, dizziness or light-headedness, joint pain, or palpitations during exercise.

Falls. Falls are a safety concern of many older adults. One in three adults age 65 and older falls each year (CDC, 2010c). Fall-related injuries are often associated with a patient's preexisting medical conditions such as osteoporosis and bleeding tendencies. Hospitalization and placement in a nursing center for rehabilitation or long-term placement is sometimes necessary after a fall. In 2009 emergency departments treated 2.2 million nonfatal fall injuries among older adults; more than 582,000 of these patients had to be hospitalized (CDC, 2010c). The most common injuries in older adults include fractures of the spine, hip, forearm, leg, ankle, pelvis, upper arm, and hand. Older adults who fall may develop a fear of falling, which may in turn cause them to limit their

BOX 14-7 RISK FACTORS FOR FALLS IN OLDER ADULTS

Intrinsic Factors

- History of a previous fall
- Impaired vision
- Postural hypotension or syncope
- Conditions affecting mobility such as arthritis, muscle weakness, peripheral neuropathy, foot problems
- Conditions affecting balance and gait
- Alterations in bladder function such as frequency or urge incontinence and nocturia
- Cognitive impairment, agitation, and confusion
- Adverse medication reactions (sedatives, hypnotics, anticonvulsants, opioids)
- Slowed reaction times
- Deconditioning

Extrinsic Factors

- Environmental hazards outside and within the home such as poor lighting, slippery or wet flooring, items on floor that are easy to trip over, furniture placement and other obstacles to ambulation, and sidewalks and stairs in poor repair
- Inappropriate footwear
- Unfamiliar environment of a hospital room that contains barriers to movement (e.g., clutter, equipment, poor lighting at night)
- Improper use of assistive devices (e.g., canes, walkers, crutches)

activities, leading to reduced mobility and loss of physical fitness (CDC, 2010c). See Chapter 38 for a complete description of fall-prevention interventions. Box 14-7 summarizes both intrinsic and extrinsic risk factors leading to falls.

Sensory Impairments. Because of common sensory impairments experienced by an older adult, it is important to promote existing sensory function and to be sure that the patient lives in a safe environment. Whenever you provide care activities, make sure that the patient is wearing any assist devices such as a hearing aid or glasses so he or she can fully participate in care. Chapter 49 describes in detail the nursing interventions used to maintain and improve sensory function.

Pain. Pain is not a normal part of healthy aging. It is a symptom and a sensation of distress, alerting the person that something is wrong. It is prevalent in the older-adult population; it may be acute or chronic. The consequences of persistent pain include depression, loss of appetite, sleep difficulties, changes in gait and mobility, and decreased socialization. Many factors influence the management of pain, including cultural influences on the meaning and expression of pain for older adults, fears related to the use of analgesic medications, and the problem of pain assessment with cognitively impaired older adults. Nurses caring for older adults have to advocate for appropriate and effective pain management (see Chapter 43). Again, the goal of nursing management of pain in older adults is to maximize function and improve quality of life.

Medication Use. One of the greatest challenges for older adults is safe medication use. Although the elderly make up approximately 12% of the U.S. population, they consume 31% of the nation's prescribed drugs (Lehne, 2010). Some medication categories such as analgesics, antidepressants, antihistamines, antihypertensives, sedative-hypnotics, and muscle relaxants create a high likelihood of adverse effects in older adults. They are at risk for adverse medication effects because of age-related changes in the absorption, distribution, metabolism, and excretion of drugs, collectively referred to as the process of pharmacokinetics (see Chapter 31). Medications sometimes interact with one another, adding or negating the effect of another drug. Examples of adverse effects include confusion, impaired balance, dizziness, nausea, and vomiting. Because of these effects, some older adults are unwilling to take medications; others do not adhere to the prescribed dosing schedule, or they may try to medicate themselves with herbal and over-the-counter medications.

Polypharmacy, the concurrent use of many medications, increases the risk for adverse drug effects (Box 14-8). Although polypharmacy may reflect inappropriate prescribing, the concurrent use of multiple medications is often necessary when an older adult has multiple acute and chronic conditions. For example, it is common for a patient to take more than one medication to control hypertension. The nurse's role is to ensure the greatest therapeutic benefit with the least amount of harm by educating patients about safe medication use. Nurses must question the efficacy and safety of combinations of prescribed medications and advocate for the older adult to prevent adverse reactions. Older adults may also use over-the-counter or herbal medications. The mix of over-the-counter and herbal medications with prescription medications can also create adverse reactions.

BOX 14-8 EVIDENCE-BASED PRACTICE

Polypharmacy in Older Adults

PICO Question: What adverse outcomes does polypharmacy versus limited medication use cause in older adults who live in the community?

Evidence Summary

Polypharmacy is an important factor in causing numerous health problems for older adults, including the risk for adverse drug events (ADEs), the inappropriate use of medications, and falls (Baranzini et al., 2009; Lau et al., 2010). A study of a sample of over 4500 older adults ages 65 and over living in the community found that 44% took more than five medications (Lau et al., 2010). When patients are near death, one study found an increase in medication use, with patients averaging 7.9 prescriptions (Chen et al., 2010). Patients with dementia are also vulnerable, experiencing a higher total prescription use and greater likelihood of having inappropriate prescriptions (Lau et al., 2010). Polypharmacy regimens that include at least one established fall-increasing drug group (e.g., antiarrhythmic and antiparkinson) may be a greater problem than polypharmacy alone (Baranzini et al., 2009). Although many prescriptions may be needed for some individuals, more prudent care is needed to lessen the risks. However, decreasing the number of medications alone may not effectively improve the quality of medication use (Lau et al., 2010). Certain medications will always be critical for managing patients' health conditions.

Application to Nursing Practice

- Have patients and family caregivers be sure that one physician (or nurse practitioner) knows all medications that a patient is prescribed. This is especially important if a patient sees several physicians.
- When a patient develops a new behavior or clinical change, consider a possible ADE; consult the physician and a clinical pharmacist.
- Older adults in long-term settings should have medications reviewed routinely (e.g., monthly).
- In long-term settings prescription of certain medications (e.g., laxatives for constipation) may occur without identifying underlying causes of the condition for which they are prescribed. Nurses should be aggressive in use of nonpharmacological treatments known to be effective.

For some older adults safely managing medications is complex and often becomes overwhelming. Some older adults take their medications incorrectly because they do not understand the administration instructions, thereby complicating a nurse's assessment of effects and side effects. Medications that need to be taken more than once or twice a day are a concern because the patient may not remember to take them as scheduled. As a nurse you are in a position to assist older adult patients as they carry out this important self-care activity (see Chapter 31).

The cost of prescriptions can be prohibitive. You can advocate for patients who may need certain medications by working with pharmacies or drug companies to provide the needed medication at less cost. Often a generic medication that will provide the desired effect is available at a reduced cost.

Work collaboratively with older adults to ensure safe and appropriate use of all medications, both prescribed and over-the-counter. Teach an older adult the names of all medications that he or she is taking, when and how to take them, and desirable and undesirable effects. Explain how to avoid adverse effects and/or interactions of medications and how to establish and follow an appropriate self-administration pattern. Strategies for reducing the risk for an adverse medication effect in the older adult include reviewing the medications with the older adult at each visit; examining for potential interactions with food or other medications; simplifying and individualizing the medication regimen; taking every opportunity to inform the older adult and family about all aspects of medication use; and encouraging the older adult to question the physician, advanced practice nurse, and/or pharmacist about all prescribed medications and all over-the-counter medications.

When providers use medications to manage confusion, special care is necessary. The sedatives and tranquilizers sometimes prescribed for acutely confused older adults may cause or exacerbate confusion and increase risks for falls or other injuries. Carefully administer medications used to manage confused behaviors, taking into account age-related changes in body systems that affect pharmacokinetic activity. When confusion has a physiological cause (such as an infection), health care providers must treat the cause rather than the confused behavior. When confusion varies by time of day or is related to environmental factors, use creative, nonpharmacological measures such as making the environment more meaningful, providing adequate light, encouraging use of assistive devices, or even calling friends or family members to let older adults hear reassuring voices.

Health Promotion and Maintenance: Psychosocial Health Concerns

Interventions supporting the psychosocial health of older adults resemble those for other age-groups. However, some interventions are more crucial for older adults experiencing social isolation; cognitive impairment; or stresses related to retirement, relocation, or approaching death.

Therapeutic Communication. Therapeutic communication skills enable you to perceive and respect the older adult's uniqueness and health care expectations. Attentive nurses provide care in a timely fashion, meeting a patient's expressed or unexpressed needs. A caring nurse expresses attitudes of concern, kindness, and compassion. Knowledgeable nurses not only demonstrate procedural competence but recognize needs and relay information skillfully. Patients accept and respect nurses who meet these expectations and communicate effectively about concern for the older adult's welfare. However, you cannot simply enter an older adult's environment and immediately establish a therapeutic relationship. First you have to be knowledgeable and skilled in communication techniques (see Chapter 24).

Touch. Touch is a therapeutic tool that you use to help comfort older adults. A pilot study by Wang and Hermann (2006) showed that agitation levels were significantly lower in demented older adults who received a healing touch intervention. Touch provides sensory stimulation, induces relaxation, provides physical and emotional comfort, orients the person to reality, shows warmth, and communicates interest. It is a powerful physical expression of a relationship.

Older adults are often deprived of touching when separated from family or friends. An older adult who is isolated, dependent, or ill; who fears death; or who lacks self-esteem has a greater need for touch. You recognize touch deprivation by behaviors as simple as an older adult reaching for the nurse's hand or standing close to the nurse. Unfortunately older men are sometimes wrongly accused of sexual advances when they reach out to touch others. When you use touch, be aware of cultural variations and individual preferences (see Chapters 7 and 9). Touch should convey respect and sensitivity. Do not use it in a condescending way such as patting an older adult on the head. When you reach out to an older adult, do not be surprised if the older adult reciprocates.

Reality Orientation. **Reality orientation** is a communication technique that makes an older adult more aware of time, place, and person. The purposes of reality orientation include restoring a sense of reality; improving the level of awareness, promoting socialization; elevating independent functioning; and minimizing confusion, disorientation, and physical regression. Although you use reality orientation techniques in any health care setting, they are especially useful in the acute care setting. The older adult experiencing a change in environment, surgery, illness, or emotional stress is at risk for becoming disoriented. Environmental changes such as the bright lights, unfamiliar noises, and lack of windows in specialized units of a hospital often lead to disorientation and confusion. Absence of familiar caregivers is also disorienting. Using anesthesia, sedatives, tranquilizers, analgesics, and physical restraints with older patients increases disorientation. Anticipate and monitor for disorientation and confusion as possible consequences of hospitalization, relocation, surgery, loss, or illness and incorporate interventions based on reality orientation into the care plan.

The principles of reality orientation offer useful guidelines for communicating with acutely confused individuals. The key elements of reality orientation include frequent reminders of person, time, and place; the use of environmental aids such as clocks, calendars, and personal belongings; and stability of environment, routine, and staff. However, do not continue to reorient older adults with chronic cognitive impairment. Communication is always respectful, patient, and calm. Answer questions from the older adult simply and honestly with sensitivity and a caring attitude.

Validation Therapy. **Validation therapy** is an alternative approach to communication with a confused older adult. Whereas reality orientation insists that the confused older adult agree with our statements of time, place, and person, validation therapy accepts the description of time and place as stated by the confused older adult. Older adults with dementia are less likely to benefit and more likely to become agitated by a caregiver's insistence on the "correct" time, place, and person. In validation therapy you do not challenge or argue with statements and behaviors of the confused older adult. They represent an inner need or feeling. For example, the person might insist that the day is actually a different day because of high anxiety. The appropriate nursing intervention

is to recognize and address that inner need or feeling. Validation does not involve reinforcing the confused older adult's misperceptions; it reflects sensitivity to hidden meanings in statements and behaviors. By listening with sensitivity and validating what the patient is expressing, you convey respect, reassurance, and understanding. Validating or respecting confused older adults' feelings in the time and place that is real to them is more important than insisting on the literally correct time and place.

Reminiscence. Reminiscence is recalling the past. Many older adults enjoy sharing past experiences. As a therapy, reminiscence uses the recollection of the past to bring meaning and understanding to the present and resolve current conflicts. Looking back to positive resolutions of problems reminds the older adult of coping strategies used successfully in the past. Reminiscing is also a way to express personal identity. Reflection on past achievements supports self-esteem. For some older adults the process of looking back on past events uncovers new meanings for those events.

During the assessment process use reminiscence to assess self-esteem, cognitive function, emotional stability, unresolved conflicts, coping ability, and expectations for the future. For example, have a patient talk about a previous loss to assess coping. You can also reminisce during direct care activities. Taking time to ask questions about past experiences and listening attentively conveys to an older adult your attitudes of respect and concern.

Although many use reminiscence in a one-on-one situation, it is also used as a group therapy for cognitively impaired or depressed older adults. The nurse organizes the group and selects strategies to start a conversation. For example, the nurse asks the group to discuss family activities or childhood memories. He or she adapts the group's size, structure, process, goals, and activities to meet its members' needs.

Body-Image Interventions. The way that older adults present themselves influences body image and feelings of isolation (Chapter 33). Some physical characteristics of older adulthood such as distinguished-looking gray hair are socially desirable. Other features such as a lined face that displays character or wrinkled hands that show a lifetime of hard work are also impressive. However, too often society sees older people as incapacitated, deaf, obese, or shrunken in stature. Consequences of illness and aging that threaten the older adult's body image include invasive diagnostic procedures, pain, surgery, loss of sensation in a body part, skin changes, and incontinence. The use of devices such as dentures, hearing aids, artificial limbs, indwelling catheters, ostomy devices, and enteral feeding tubes also affects body image.

The nurse needs to consider the importance to the older adult of presenting a socially acceptable image. When older adults have acute or chronic illnesses, the related physical dependence makes it difficult for them to maintain body image. You influence the older adult's appearance by helping with grooming and hygiene. It takes little effort to help the older adult comb hair, clean dentures, shave, or change clothing. He or she does not choose to have an objectionable appearance. Be sensitive to odors in the environment. Odors created by urine and some illnesses are often present. By controlling odors you may prevent visitors from shortening their stay or not coming at all.

OLDER ADULTS AND THE ACUTE CARE SETTING

Older adults in the acute care setting need special attention to help them adjust to the acute care environment and meet their basic needs. The acute care setting poses increased risk for adverse events such as delirium, dehydration, malnutrition, health care–associated infections (HAIs), urinary incontinence, and falls. The risk for delirium increases when hospitalized older adults experience immobilization, sleep deprivation, infection, dehydration, pain, sensory impairment, drug interactions, anesthesia, and hypoxia. Nonmedical causes of delirium include placement in unfamiliar surroundings and staff, bed rest, separation from supportive family members, and stress. Impaired vision or hearing contributes to confusion and interferes with attempts to reorient the older adult. When the prevention of delirium fails, nursing management begins with identifying and treating the cause. Supportive interventions include encouraging family visits, providing memory cues (clocks, calendars, and name tags), and compensating for sensory deficits. Reality orientation techniques are also useful.

Older adults are at greater risk for dehydration and malnutrition during hospitalization because of standard procedures such as limiting food and fluids in preparation for diagnostic tests and medications that decrease appetite. The risk for dehydration and malnutrition increases when older adults are unable to reach beverages or feed themselves while in bed or connected to medical equipment. Interventions include getting the patient out of bed, providing beverages and snacks frequently, and including favorite foods and beverages in the diet plan.

The increased risk for HAIs in older adults is associated with age-related reductions in immune system responses. In a study including 47 hospitals in 14 countries across four continents, adults over 64 years of age (prevalence 12%) suffered more HAIs than others (Manyon-White, 2009). Urinary catheter–related bacteriuria in older adults is the most common type. Other HAIs in this population include infection at the surgical site, pneumonia, and bloodstream infections. Prevention begins with hand hygiene and measures to minimize the risk of infection from procedures (see Chapter 28).

Older hospitalized adults in acute care are at risk for becoming incontinent of urine (transient incontinence). Causes of incontinence include delirium, untreated urinary tract infection, medications, restricted mobility or need for assistance to get to the bathroom, and constipation or stool impaction. Interventions to decrease incontinence include individualized care planning to provide voiding opportunities and modification of the environment to improve access to the toilet. Avoid indwelling urinary catheterization and promote measures to prevent skin breakdown (see Chapter 45).

The increased risk for skin breakdown and the development of pressure ulcers is related to changes in aging skin and to situations that occur in the acute care setting such as immobility, incontinence, and malnutrition. The key points in the prevention of skin breakdown are avoiding pressure with proper positioning and use of a support surface based on risk status, reducing shear forces and friction, providing meticulous skin care and moisture management, and providing nutritional support (see Chapter 48).

Older adults in the acute care setting are at risk for falling and sustaining injuries. The cause of a fall is typically multifactorial and composed of intrinsic or extrinsic factors (see Box 14-7). Sedative and hypnotic medications increase unsteadiness. Medications causing orthostatic hypotension also increase the risk for falls because of the blood pressure drop when the older adult gets out of a bed or chair. The increase in urine output from diuretics increases the risk for falling by increasing the number of attempts to get out of bed to void. Attempts to get out of bed when physically restrained sometimes lead to injury when the older adult becomes entangled in the restraint. Equipment such as wires from monitors, intravenous tubing, urinary catheters, and other medical devices

become obstacles to safe ambulation. Impaired vision prevents the older adult from seeing tripping hazards such as trash cans. Interventions to reduce the risk for falling in a health care setting are discussed in Chapter 38.

OLDER ADULTS AND RESTORATIVE CARE

Restorative care refers to two types of ongoing care: the continuation of the recovery from acute illness or surgery that began in the acute care setting and support of chronic conditions that affect day-to-day functioning. Both types of restorative care take place in private homes and long-term care settings.

Direct interventions during convalescence from acute illness or surgery aim at regaining or improving patients' prior level of independence in ADLs. Continue interventions that began in the acute care setting and later modify them as convalescence progresses. To achieve this continuation, the discharge information provided by the acute care setting must include information on the ongoing interventions (e.g., exercise routines, wound care routines, medication schedules, and blood glucose monitoring). Interventions also need to address the restoration of interpersonal relationships and activities at either their previous level or at the level desired by the older adult. When restorative care addresses chronic conditions, the goals of care include stabilizing the chronic condition, promoting health, and promoting independence in ADLs.

Interventions to promote independence in ADLs address a person's physical ability, cognitive ability, and safety. The physical ability to perform ADLs requires strength, flexibility, and balance. You need to make accommodation for impairments of vision, hearing, and touch. The cognitive ability to perform ADLs requires the ability to recognize, judge, and remember. Cognitive impairments such as dementia interfere with safe performance of ADLs, although the older adult is still physically capable of the activities. Interventions to promote independence in ADLs should adapt these requirements to the needs and lifestyle of the older adult. You always consider safety because it is not enough just to be able to perform any of the ADLs. The older adult needs to be able to perform the ADLs with a level of risk that is acceptable to him or her.

Beyond the basic ADLs, you need to support an older adult's ability to perform IADLs such as using a telephone, doing laundry, cleaning the home or apartment, and driving an automobile. To remain living independently at home or in an apartment, older adults need to be able to perform IADLs, purchase services by outside workers, or have a supportive network of family and friends who assist with these tasks. Occupational therapists are an important resource for helping persons adapt when IADLs are difficult to perform.

Restorative care measures focus on activities to prevent, improve, reduce, or eliminate problems. You establish priorities of care and patient goals, determine expected outcomes, and select appropriate interventions. You do this with the older adult's participation so the patient understands interventions and to avoid conflicts in approaches or priorities. Consideration of the older adult's lifetime experiences and the values and sociocultural patterns developed serves as the basis for planning individual care. When the older adult's cognitive status prevents participation in health care decisions, you need to include the family. Family and friends are rich sources of data because they knew the older adult before the impairment. Frequently they provide explanations for the older adult's behaviors and suggest methods of management. Thoughtful assessment and planning lead to goals of care that consider the influence of normal aging changes, facilitate an optimal level of comfort and coping, and promote independence in self-care activities.

KEY POINTS

- Nursing care of older adults poses special challenges because of great variation in their physiological, cognitive, and psychosocial health.
- When health care providers hold negative stereotypes about aging, these stereotypes can negatively affect the quality of patient care.
- A developmental task of aging includes dealing with common losses, including loss of health, significant others, a sense of being useful, socialization, income, and independent living.
- The best way to evaluate the quality of a nursing center in a community is for the patient and family to visit that facility and inspect it personally.
- A comprehensive assessment of an older adult takes more time than the assessment of a younger adult because of the longer life and medical history and the potential complexity of the history.
- Classic signs and symptoms of diseases are sometimes absent, blunted, or atypical in older adults.
- Normal physiological changes of aging are not pathological processes, but they make older adults more vulnerable to some common clinical conditions and diseases.
- A sudden change in function, as evidenced by a decline or change in the older adult's ability to perform any one or combination of ADLs or IADLs, is often a sign of the onset of an acute illness.
- Symptoms of cognitive impairment such as disorientation, loss of language skills, and poor judgment are not normal aging changes and require you to further assess patients for underlying causes.
- Assess a patient's potential for social isolation by identifying his or her social network, access to transportation, and willingness and desire to interact with others.
- General preventive health measures for older adults include routine health screening; regular exercise; weight reduction if overweight; eating a low-fat, well-balanced diet; moderate alcohol use; regular dental visits; smoking cessation; and immunization.
- Polypharmacy, the concurrent use of many medications, increases the risk for adverse drug effects, inappropriate use of medications, and falls in older adults.
- Reminiscence uses the recollection of the past to bring meaning and understanding to the present and resolve current conflicts.
- Acute care settings place older adults at risk for delirium, dehydration, malnutrition, HAIs, and falls.
- Restorative nursing interventions stabilize chronic conditions, promote health, and promote independence in basic and instrumental activities of daily living.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Mrs. Kaven is an 81-year-old woman who is admitted to the hospital following emergency surgery for a hip pinning of a hip fracture secondary to a fall at her home. Her other medical problems are hypertension, hypothyroidism, and anxiety disorder for which

she takes a diuretic and thyroid replacement medication. She has had bilateral knee replacements in the past. Her home is "handicap" friendly. She is a retired bookkeeper, a widow living independently at her home, and usually very active. She drives, plays cards weekly with her friends, and participates in church activities twice a week. She hires help for household cleaning and yard work. She wears glasses, has uncorrected cataracts, and uses a cane.

You are assigned to care for her on her first postoperative day after the hip pinning. You learn in report that Mrs. Kaven has been receiving opioids for postoperative pain, with her last pain rating a 5 on a scale of 0 to 10. She has intravenous fluids for hydration for the first 24 hours. She has an indwelling urinary catheter. The night nurse reports that Mrs. Kaven was restless all night and slept very little and that she had even tried to get out of bed. You enter Mrs. Kaven's room and find her picking at the air and talking to herself as she tries to eat her breakfast. She is not wearing her glasses. She is oriented to self only. As you do your shift assessment, you recognize that she is delirious.

1. During your assessment what conditions prompt you to suspect that the patient has delirium? (Select all that apply.)
   1. Presence of indwelling urinary catheter
   2. Orientation status
   3. Presence of hypertension
   4. Distraction from being able to eat
2. Mrs. Kaven's good friend comes to visit. She is concerned that the patient seems confused. She asks the nurse if there is anything she can do to help the patient be less confused. The nurse's best suggestions would be to do which of the following: (Select all that apply.)
   1. Help her put on her glasses.
   2. Let her rest without the presence of a visitor.
   3. Have a conversation with her about activities of the day.
   4. Avoid giving her too many oral fluids.
3. Explain the approach that the patient's physician and other health care providers must use to reverse the patient's delirium. Give some examples of these approaches.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A student nurse is caring for a 78-year-old patient with multiple sclerosis. The patient has had an indwelling Foley catheter in for 3 days. Eight hours ago the patient's temperature was 37.1° C (98.8° F). The student reports her recent assessment to the registered nurse (RN): the patient's temperature is 37.2° C (99° F); the Foley catheter is still in place, draining dark urine; and the patient is uncertain what time of day it is. From what the RN knows about presentation of symptoms in older adults, what should he recommend first?
   1. Tell the student that temporary confusion is normal and simply requires reorientation
   2. Tell the student to increase the patient's fluid intake since the urine is concentrated
   3. Tell the student that her assessment findings are normal for an older adult
   4. Tell the student that he will notify the physician of the findings
2. A patient's family member is considering having her mother placed in a nursing center. You have talked with the family before and know that this is a difficult decision. Which of the following criteria would you recommend in choosing a nursing center? (Select all that apply.)
   1. The center should be clean, and rooms should look like a hospital room.
   2. There should be adequate staffing on all shifts.
   3. Social activities should be available for all residents.
   4. Three meals should be served daily with a set menu and serving schedule.
   5. Family involvement in care planning and assisting with physical care is necessary.
3. A nurse has conducted an assessment of a new patient who has come to the medical clinic. The patient is 82 years old and has had osteoarthritis for 10 years and diabetes mellitus for 20 years. He is alert but becomes easily distracted during the nursing history. He recently moved to a new apartment, and his pet beagle died just 2 months ago. He is most likely experiencing:
   1. Dementia.
   2. Depression.
   3. Delirium.
   4. Disengagement.
4. A major life event such as the death of a loved one, a move to a nursing home, or a cancer diagnosis could precipitate:
   1. Dementia.
   2. Delirium.
   3. Depression.
   4. Stroke.
5. Sexuality is maintained throughout our lives. Which answer below best explains sexuality in an older adult?
   1. When the sexual partner passes away, the survivor no longer feels sexual.
   2. A decrease in an older adult's libido occurs.
   3. Any outward expression of sexuality suggests that the older adult is having a developmental problem.
   4. All older adults, whether healthy or frail, need to express sexual feelings.
6. Older adults experience a change in sexual activity. Which best explains this change?
   1. The need to touch and be touched is decreased.
   2. The sexual preferences of older adults are not as diverse.
   3. Physical changes usually do not affect sexual functioning.
   4. Frequency and opportunities for sexual activity may decline.
7. You see a 76-year-old woman in the outpatient clinic. Her chief complaint is vision. She states she has really noticed glare in the lights at home. Her vision is blurred; and she is unable to play cards with her friends, read, or do her needlework. You suspect that she may have:
   1. Presbyopia.
   2. Disengagement.
   3. Cataract(s).
   4. Depression.
8. A nurse is caring for a patient preparing for discharge from the hospital the next day. The patient does not read and has a hearing loss. His family caregiver will be visiting before discharge. What can you do to facilitate the patient's understanding of his discharge instructions? (Select all that apply.)
   1. Speak loudly so the patient can hear you.
   2. Sit facing the patient so he is able to watch your lip movements and facial expressions.
   3. Present one idea or concept at a time.

4. Send a written copy of the instructions home with him and tell him to have the family review them.
5. Include the family caregiver in the teaching session.

9. Taste buds atrophy and lose sensitivity, and appetite may decrease. As a result, the older adult is less able to discern:
   1. Spicy and bland foods.
   2. Salty, sour, and bitter tastes.
   3. Hot and cold food temperatures.
   4. Moist and dry food preparations.
10. Kyphosis, a change in the musculoskeletal system, leads to:
    1. Decreased bone density in the vertebrae and hips.
    2. Increased risk for pathological stress fractures in the hips.
    3. Changes in the configuration of the spine that affect the lungs and thorax.
    4. Calcification of the bony tissues of the long bones such as in the legs and arm.
11. A 63-year-old patient is retiring from his job at an accounting firm where he was in a management role for the past 20 years. He has been with the same company for 42 years and was a dedicated employee. His wife is a homemaker. She raised their five children, babysits for her grandchildren as needed, and belongs to numerous church committees. What are your major concerns for this patient? (Select all that apply.)
    1. The loss of his work role
    2. The risk of social isolation
    3. A determination if the wife will need to start working
    4. How the wife expects household tasks to be divided in the home in retirement
    5. The age the patient chose to retire
12. During a home health visit a nurse talks with a patient and his family caregiver about the patient's medications. The patient has hypertension and renal disease. Which of the following findings places him at risk for an adverse drug event? (Select all that apply.)
    1. Taking two medications for hypertension
    2. Taking a total of eight different medications during the day.
    3. Having one physician who reviews all medications
    4. Patient's health history
    5. Involvement of the caregiver in assisting with medication administration
13. You are caring for an 80-year-old man who recently lost his wife. He shares with you that he has been drinking more than he ever did in the past and feels hopeless without his wife. He reports that he rarely sees his children and feels isolated and alone. This patient is at risk for:
    1. Dementia.
    2. Liver failure.
    3. Dehydration.
    4. Suicide.
14. You are working with an older adult after an acute hospitalization. Your goal is to help this person be more in touch with time, place, and person. What might you try?
    1. Reminiscence
    2. Validation therapy
    3. Reality orientation
    4. Body image interventions
15. A 71-year-old patient enters the emergency department after falling down stairs in the home. The nurse is conducting a fall history with the patient and his wife. They live in a one-level ranch home. He has had diabetes for over 15 years and experiences some numbness in his feet. He wears bifocal glasses. His blood pressure is stable around 130/70. The patient does not exercise regularly and complains of weakness in his legs when climbing stairs. He is alert, oriented, and able to answer questions clearly. What are the fall risk factors for this patient? (Select all that apply.)
    1. Presence of a chronic disease
    2. Impaired vision
    3. Residence design
    4. Blood pressure
    5. Leg weakness
    6. Exercise history

Answers: **1.** 4; **2.** 2, 3, 5; **3.** 2; **4.** 3; **5.** 4; **6.** 4; **7.** 3; **8.** 2, 3, 5; **9.** 2; **10.** 3; **11.** 1, 4; **12.** 2, 4; **13.** 4; **14.** 3; **15.** 2, 5, 6.

CHAPTER

15

Critical Thinking in Nursing Practice

OBJECTIVES

- Describe characteristics of a critical thinker.
- Discuss the nurse's responsibility in making clinical decisions.
- Discuss how reflection improves clinical decision making.
- Describe the components of a critical thinking model for clinical decision making.
- Discuss critical thinking skills used in nursing practice.
- Explain the relationship between clinical experience and critical thinking.
- Discuss the critical thinking attitudes used in clinical decision making.
- Explain how professional standards influence a nurse's clinical decisions.
- Discuss the relationship of the nursing process to critical thinking.

Every day you think critically without realizing it. If it's hot outside, you take off a sweater. If your DVD doesn't start, you reposition the disc. If you decide to walk the dogs, you change to a pair of walking shoes. These examples involve critical thinking as you face each day and prepare for all possibilities. As a nurse, you will face many clinical situations involving patients, family members, health care staff, and peers. In each situation it is important to try to see the big picture and think smart. To think smart you have to develop critical thinking skills to face each new experience and problem involving a patient's care with open-mindedness, creativity, confidence, and continual inquiry. When a patient develops a new set of symptoms, asks you to offer comfort, or requires a procedure, it is important to think critically and make sensible judgments so the patient receives the best nursing care possible. Critical thinking is not a simple step-by-step, linear process that you learn overnight. It is a process acquired only through experience, commitment, and an active curiosity toward learning.

CLINICAL DECISIONS IN NURSING PRACTICE

Nurses are responsible for making accurate and appropriate clinical decisions. Clinical decision making separates professional nurses from technical personnel. For example, a professional nurse observes for changes in patients, recognizes potential problems, identifies new problems as they arise, and takes immediate action when a patient's clinical condition worsens. Technical personnel simply follow direction in completing aspects of care that the professional nurse has identified as necessary. A professional nurse relies on knowledge and experience when deciding if a patient is having complications that call for notification of a health care provider or decides if a teaching plan for a patient is ineffective and needs revision. Benner (1984) describes clinical decision making as judgment that includes critical and reflective thinking and action and application of scientific and practical logic. Most patients have health care problems for which there are no clear textbook solutions. Each patient's problems are unique, a product of the patient's physical health, lifestyle, culture, relationship with family and friends, living environment, and experiences. Thus as a nurse you do not always have a clear picture of a patient's needs and the appropriate actions to take when first meeting a patient. Instead you must learn to question, wonder, and explore different perspectives and interpretations to find a solution that benefits the patient.

Because no two patients' health problems are the same, you always apply critical thinking differently. Observe patients closely, gather information about them, examine ideas and inferences about patient problems, recognize the problems, consider scientific

principles relating to the problems, and develop an approach to nursing care. With experience you learn to creatively seek new knowledge, act quickly when events change, and make quality decisions for patients' well-being. You will find nursing to be rewarding and fulfilling through the clinical decisions you make.

CRITICAL THINKING DEFINED

Mr. Jacobs is a 58-year-old patient who had a radical prostatectomy for prostate cancer yesterday. His nurse, Tonya, finds the patient lying supine in bed with arms extended along his sides but tensed. When Tonya checks the patient's surgical wound and drainage device, she notes that the patient winces when she gently places her hands to palpate around the surgical incision. She asks Mr. Jacobs when he last turned onto his side, and he responds, "Not since last night some time." Tonya asks Mr. Jacobs if he is having incisional pain, and he nods yes, saying, "It hurts too much to move." Tonya considers the information she has observed and learned from the patient to determine that he is in pain and has reduced mobility because of it. She decides that she needs to take action to relieve Mr. Jacobs' pain so she can turn him more frequently and begin to get him out of bed for his recovery.

In the case example the nurse observes the clinical situation, asks questions, considers what she knows about postoperative pain and risk for immobility, and takes action. The nurse applies **critical thinking,** a continuous process characterized by open-mindedness, continual inquiry, and perseverance, combined with a willingness to look at each unique patient situation and determine which identified assumptions are true and relevant (Heffner and Rudy, 2008). Critical thinking involves recognizing that an issue (e.g., patient problem) exists, analyzing information about the issue (e.g., clinical data about a patient), evaluating information (reviewing assumptions and evidence) and making conclusions (Settersten and Lauver, 2004). A critical thinker considers what is important in each clinical situation, imagines and explores alternatives, considers ethical principles, and makes informed decisions about the care of patients.

Critical thinking is a way of thinking about a situation that always asks "Why?", "What am I missing?", "What do I really know about this patient's situation?", and "What are my options?" (Heffner and Rudy, 2008; Paul and Heaslip, 1995). Tonya knew that pain was likely going to be a problem because the patient had extensive surgery. Her review of her observations and the patient's report of pain confirmed her knowledge that pain was a problem. Her options include giving Mr. Jacobs an analgesic and waiting until it takes effect so she is able to reposition and make him more comfortable. Once he has less acute pain, Tonya offers to teach Mr. Jacobs some relaxation exercises.

You begin to learn critical thinking early in your practice. For example, as you learn about administering baths and other hygiene measures, take time to read your textbook and the nursing literature about the concept of comfort. What are the criteria for comfort? How do patients from other cultures perceive comfort? What are the many factors that promote comfort? The use of **evidence-based knowledge,** or knowledge based on research or clinical expertise, makes you an informed critical thinker. Thinking critically and learning about the concept of comfort prepares you to better anticipate your patients' needs, identify comfort problems more quickly, and offer appropriate care. Critical thinking requires cognitive skills and the habit of asking questions, remaining well informed, being honest in facing personal biases, and always being willing to reconsider and think clearly about issues (Facione, 1990). When core critical thinking skills are applied to nursing, they show the complex nature of clinical decision making (Table 15-1). Being able to apply all of these skills takes practice. You also need to have a sound knowledge base and thoughtfully consider what you learn when caring for patients.

TABLE 15-1 Critical Thinking Skills

SKILL	NURSING PRACTICE APPLICATIONS
Interpretation	Be orderly in data collection. Look for patterns to categorize data (e.g., nursing diagnoses [see Chapter 17]). Clarify any data you are uncertain about.
Analysis	Be open-minded as you look at information about a patient. Do not make careless assumptions. Do the data reveal what you believe is true, or are there other options?
Inference	Look at the meaning and significance of findings. Are there relationships between findings? Do the data about the patient help you see that a problem exists?
Evaluation	Look at all situations objectively. Use criteria (e.g., expected outcomes, pain characteristics, learning objectives) to determine results of nursing actions. Reflect on your own behavior.
Explanation	Support your findings and conclusions. Use knowledge and experience to choose strategies to use in the care of patients.
Self-regulation	Reflect on your experiences. Identify the ways you can improve your own performance. What will make you believe that you have been successful?

Modified from Facione P: *Critical thinking: a statement of expert consensus for purposes of educational assessment and instruction. The Delphi report: research findings and recommendations prepared for the American Philosophical Association,* ERIC Doc No. ED 315, Washington, DC, 1990, ERIC.

Nurses who apply critical thinking in their work are able to see the big picture from all possible perspectives. They focus clearly on options for solving problems and making decisions rather than quickly and carelessly forming quick solutions (Kataoka-Yahiro and Saylor, 1994). Nurses who work in crisis situations such as the emergency department often act quickly when patient problems develop. However, even these nurses exercise discipline in decision making to avoid premature and inappropriate decisions. Learning to think critically helps you care for patients as their advocate, or supporter, and make better-informed choices about their care. Facione and Facione (1996) identified concepts for thinking critically (Table 15-2). Critical thinking is more than just problem solving. It is a continuous attempt to improve how to apply yourself when faced with problems in patient care.

Thinking and Learning

Learning is a lifelong process. Your intellectual and emotional growth involves learning new knowledge and refining your ability to think, problem solve, and make judgments. To learn, you have to be flexible and always open to new information. The science of nursing is growing rapidly, and there will always be new information for you to apply in practice. As you have more clinical experiences and apply the knowledge you learn, you will become better

TABLE 15-2 Concepts for a Critical Thinker

CONCEPT	CRITICAL THINKING BEHAVIOR
Truth seeking	Seek the true meaning of a situation. Be courageous, honest, and objective about asking questions.
Open-mindedness	Be tolerant of different views; be sensitive to the possibility of your own prejudices; respect the right of others to have different opinions.
Analyticity	Analyze potentially problematic situations; anticipate possible results or consequences; value reason; use evidence-based knowledge.
Systematicity	Be organized, focused; work hard in any inquiry.
Self-confidence	Trust in your own reasoning processes.
Inquisitiveness	Be eager to acquire knowledge and learn explanations even when applications of the knowledge are not immediately clear. Value learning for learning's sake.
Maturity	Multiple solutions are acceptable. Reflect on your own judgments; have cognitive maturity.

Modified from Facione N, Facione P: Externalizing the critical thinking in knowledge development and clinical judgment, *Nurs Outlook* 44(3):129, 1996.

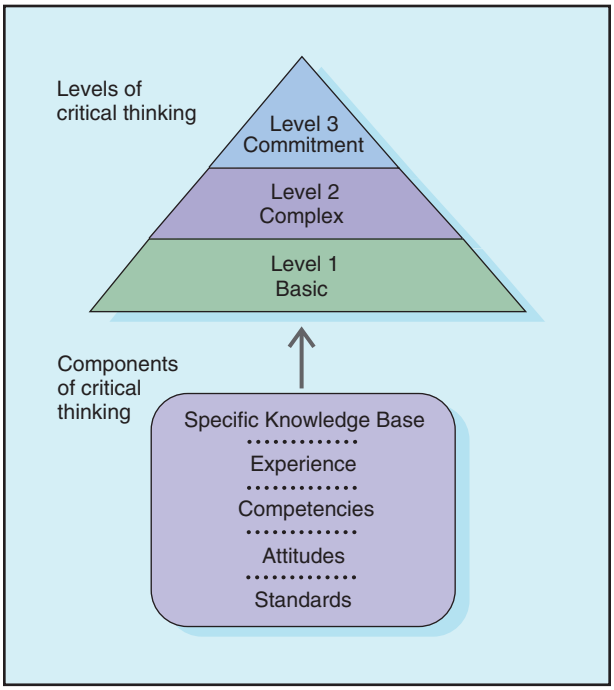

FIG. 15-1 Critical thinking model for nursing judgment. (Redrawn from Kataoka-Yahiro M, Saylor C: A critical thinking model for nursing judgment, *J Nurs Educ* 33(8):351, 1994. Modified from Glaser E: *An experiment in the development of critical thinking,* New York, 1941, Bureau of Publications, Teachers College, Columbia University; Miller M, Malcolm N: Critical thinking in the nursing curriculum, *Nurs Health Care* 11:67, 1990; Paul RW: The art of redesigning instruction. In Willsen J, Blinker AJA, editors: *Critical thinking: how to prepare students for a rapidly changing world,* Santa Rosa, Calif, 1993, Foundation for Critical Thinking; and Perry W: *Forms of intellectual and ethical development in the college years: a scheme*, New York, 1979, Holt, Rinehart, & Winston.)

at forming assumptions, presenting ideas, and making valid conclusions.

When you care for a patient, always think ahead and ask these questions: What is the patient's status now? How might it change and why? Which physiological and emotional responses do I anticipate? What do I know to improve the patient's condition? In which way will specific therapies affect the patient? What should be my first action? Do not let your thinking become routine or standardized. Instead, learn to look beyond the obvious in any clinical situation, explore the patient's unique responses to health alterations, and recognize which actions are needed to benefit the patient. With experience you are able to recognize patterns of behavior, see commonalities in signs and symptoms, and anticipate reactions to therapies. Thinking about these experiences allows you to better anticipate each new patient's needs and recognize problems when they develop.

LEVELS OF CRITICAL THINKING IN NURSING

Your ability to think critically grows as you gain new knowledge in nursing practice. Kataoka-Yahiro and Saylor (1994) developed a critical thinking model (Fig. 15-1) that includes three levels: basic, complex, and commitment. An expert nurse thinks critically almost automatically. As a beginning student you make a more conscious effort to apply critical thinking because initially you are more task oriented and trying to learn how to organize nursing care activities. At first you apply the critical thinking model at the basic level. As you advance in practice, you adopt complex critical thinking and commitment.

Basic Critical Thinking

At the basic level of critical thinking a learner trusts that experts have the right answers for every problem. Thinking is concrete and based on a set of rules or principles. For example, as a nursing student you use a hospital procedure manual to confirm how to insert a Foley catheter. You likely follow the procedure step by step without adjusting it to meet a patient's unique needs (e.g., positioning to minimize the patient's pain or mobility restrictions). You do not have enough experience to anticipate how to individualize the procedure. At this level answers to complex problems are either right or wrong (e.g., when no urine drains from the catheter, the catheter tip must not be in the bladder), and one right answer usually exists for each problem. Basic critical thinking is an early step in developing reasoning (Kataoka-Yahiro and Saylor, 1994). A basic critical thinker learns to accept the diverse opinions and values of experts (e.g., instructors and staff nurse role models). However, inexperience, weak competencies, and inflexible attitudes can restrict a person's ability to move to the next level of critical thinking.

Complex Critical Thinking

Complex critical thinkers begin to separate themselves from experts. They analyze and examine choices more independently. The person's thinking abilities and initiative to look beyond expert opinion begin to change. A nurse learns that alternative and perhaps conflicting solutions exist.

Consider the case of Mr. Rosen, a 36-year-old man who had hip surgery. The patient is having pain but is refusing his ordered analgesic. His health care provider is concerned that

the patient will not progress as planned, delaying rehabilitation. While discussing the importance of rehabilitation with Mr. Rosen, the nurse, Edwin, realizes the patient's reason for not taking pain medication. Edwin learns that the patient practices meditation at home. As a complex critical thinker, Edwin recognizes that Mr. Rosen has options for pain relief. Edwin decides to discuss meditation and other nonpharmacological interventions with the patient as pain control options and how, when combined with analgesics, these interventions can potentially enhance pain relief.

In complex critical thinking each solution has benefits and risks that you weigh before making a final decision. There are options. Thinking becomes more creative and innovative. The complex critical thinker is willing to consider different options from routine procedures when complex situations develop. You learn a variety of different approaches for the same therapy.

Commitment

The third level of critical thinking is commitment (Kataoka-Yahiro and Saylor, 1994). At this level a person anticipates when to make choices without assistance from others and accepts accountability for decisions made. As a nurse you do more than just consider the complex alternatives that a problem poses. At the commitment level you choose an action or belief based on the available alternatives and support it. Sometimes an action is to not act or to delay an action until a later time. You choose to delay as a result of your experience and knowledge. Because you take accountability for the decision, you consider the results of the decision and determine whether it was appropriate.

CRITICAL THINKING COMPETENCIES

Kataoka-Yahiro and Saylor (1994) describe critical thinking competencies as the cognitive processes a nurse uses to make judgments about the clinical care of patients. These include general critical thinking, specific critical thinking in clinical situations, and specific critical thinking in nursing. General critical thinking processes are not unique to nursing. They include the scientific method, problem solving, and decision making. Specific critical thinking competencies in clinical health care situations include diagnostic reasoning, clinical inference, and clinical decision making. The specific critical thinking competency in nursing involves use of the nursing process. Each of the competencies is discussed in the following paragraphs.

General Critical Thinking

Scientific Method. The scientific method is a way to solve problems using reasoning. It is a systematic, ordered approach to gathering data and solving problems used by nurses, physicians, and a variety of other health care professionals. This approach looks for the truth or verifies that a set of facts agrees with reality. Nurse researchers use the **scientific method** when testing research questions in nursing practice situations (see Chapter 5). The scientific method has five steps:

1. Identifying the problem
2. Collecting data
3. Formulating a question or hypothesis
4. Testing the question or hypothesis
5. Evaluating results of the test or study

Consider the following example of the scientific method in nursing practice.

A nurse caring for patients who receive large doses of chemotherapy for ovarian cancer sees a pattern of patients developing severe inflammation in the mouth (mucositis) (identifies problem). The nurse reads research articles (collects data) about mucositis and learns that there is evidence to show that having patients keep ice in their mouths (cryotherapy) during the chemotherapy infusion reduces severity of mucositis after treatment. He or she asks (forms question), "Do patients with ovarian cancer who receive chemotherapy have less severe mucositis when given cryotherapy versus standard mouth rinse in the oral cavity?" The nurse then collaborates with colleagues to develop a nursing protocol for using ice with certain chemotherapy infusions. The nurses on the oncology unit collect information that allows them to compare the incidence and severity of mucositis for a group of patients who use cryotherapy versus those who use standard-practice mouth rinse (tests the question). They analyze the results of their project and find that the use of cryotherapy reduced the frequency and severity of mucositis in their patients (evaluating the results). They decide to continue the protocol for all patients with ovarian cancer.

Problem Solving. You face problems every day such as a computer program that doesn't function properly or a close friend who has lost a favorite pet. When a problem arises, you obtain information and use it, plus what you already know, to find a solution. Patients routinely present problems in practice. For example, a home care nurse learns that a patient has difficulty taking her medications regularly. The patient is unable to describe what medications she has taken for the last 3 days. The medication bottles are labeled and filled. The nurse has to solve the problem of why the patient is not adhering to or following her medication schedule. The nurse knows that the patient was discharged from the hospital and had five medications ordered. The patient tells the nurse that she also takes two over-the-counter medications regularly. When the nurse asks her to show the medications that she takes in the morning, the nurse notices that she has difficulty reading the medication labels. The patient is able to describe the medications that she is to take but is uncertain about the times of administration. The nurse recommends having the patient's pharmacy relabel the medications in larger lettering. In addition, the nurse shows the patient examples of pill organizers that will help her sort her medications by time of day for a period of 7 days.

Effective **problem solving** also involves evaluating the solution over time to make sure that it is effective. It becomes necessary to try different options if a problem recurs. From the previous example, during a follow-up visit the nurse finds that the patient has organized her medications correctly and is able to read the labels without difficulty. The nurse obtained information that correctly clarified the cause of the patient's problem and tested a solution that proved successful. Having solved a problem in one situation adds to a nurse's experience in practice, and this allows the nurse to apply that knowledge in future patient situations.

Decision Making. When you face a problem or situation and need to choose a course of action from several options, you are making a decision. **Decision making** is a product of critical thinking that focuses on problem resolution. Following a set of criteria helps to make a thorough and thoughtful decision. The criteria may be personal; based on an organizational policy; or, frequently in the case of nursing, a professional standard. For example,

decision making occurs when a person decides on the choice of a health care provider. To make a decision, an individual has to recognize and define the problem or situation (need for a certain type of health care provider to provide medical care) and assess all options (consider recommended health care providers or choose one whose office is close to home). The person has to weigh each option against a set of personal criteria (experience, friendliness, and reputation), test possible options (talk directly with the different health care providers), consider the consequences of the decision (examine pros and cons of selecting one health care provider over another), and make a final decision. Although the set of criteria follows a sequence of steps, decision making involves moving back and forth when considering all criteria. It leads to informed conclusions that are supported by evidence and reason. Examples of decision making in the clinical area include determining which patient care priority requires the first response, choosing a type of dressing for a patient with a surgical wound, or selecting the best teaching approach for a family caregiver who will assist a patient who is returning home after a stroke.

Specific Critical Thinking

Diagnostic Reasoning and Inference. Once you receive information about a patient in a clinical situation, **diagnostic reasoning** begins. It is the analytical process for determining a patient's health problems (Harjai and Tiwari, 2009). Accurate recognition of a patient's problems is necessary before you decide on solutions and implement action. It requires you to assign meaning to the behaviors and physical signs and symptoms presented by a patient. Diagnostic reasoning begins when you interact with a patient or make physical or behavioral observations. An expert nurse sees the context of a patient situation (e.g., a patient who is feeling light-headed with blurred vision and who has a history of diabetes is possibly experiencing a problem with blood glucose levels), observes patterns and themes (e.g., symptoms that include weakness, hunger, and visual disturbances suggest hypoglycemia), and makes decisions quickly (e.g., offers a food source containing glucose). The information a nurse collects and analyzes leads to a diagnosis of a patient's condition. Nurses do not make medical diagnoses, but they do assess and monitor patients closely and compare the patients' signs and symptoms with those that are common to a medical diagnosis. This type of diagnostic reasoning helps health care providers pinpoint the nature of a problem more quickly and select proper therapies.

Part of diagnostic reasoning is clinical **inference,** the process of drawing conclusions from related pieces of evidence and previous experience with the evidence. An inference involves forming patterns of information from data before making a diagnosis. Seeing that a patient has lost appetite and experienced weight loss over the last month, the nurse infers that there is a nutritional problem. An example of diagnostic reasoning is forming a nursing diagnosis such as *imbalanced nutrition: less than body requirements* (see Chapter 17).

In diagnostic reasoning use patient data that you gather or collect to logically recognize the problem. For example, after turning a patient you see an area of redness on the right hip. You palpate the area and note that it is warm to the touch and the patient complains of tenderness. You press over the area with your finger; after you release pressure, the area does not blanch or turn white. After thinking about what you know about normal skin integrity and the effects of pressure, you form the diagnostic conclusion that the patient has a pressure ulcer. As a student, confirm your judgments with experienced nurses. At times you possibly will be wrong, but consulting with nurse experts gives you feedback to build on future clinical situations.

Often you cannot make a precise diagnosis during your first meeting with a patient. Sometimes you sense that a problem exists but do not have enough data to make a specific diagnosis. Some patients' physical conditions limit their ability to tell you about symptoms. Some choose to not share sensitive and important information during your initial assessment. Some patients' behaviors and physical responses become observable only under conditions not present during your initial assessment. When uncertain of a diagnosis, continue data collection. You have to critically analyze changing clinical situations until you are able to determine the patient's unique situation. Diagnostic reasoning is a continuous behavior in nursing practice. Any diagnostic conclusions that you make will help the health care provider identify the nature of a problem more quickly and select appropriate medical therapies.

Clinical Decision Making. As in the case of general decision making, clinical decision making is a problem-solving activity that focuses on defining a problem and selecting an appropriate action. In clinical decision making a nurse identifies a patient's problem and selects a nursing intervention. When you approach a clinical problem such as a patient who is less mobile and develops an area of redness over the hip, you make a decision that identifies the problem (impaired skin integrity in the form of a pressure ulcer) and choose the best nursing interventions (skin care and a turning schedule). Nurses make clinical decisions all the time to improve a patient's health or maintain wellness. This means reducing the severity of the problem or resolving the problem completely. **Clinical decision making** requires careful reasoning (i.e., choosing the options for the best patient outcomes on the basis of the patient's condition and the priority of the problem).

Improve your clinical decision making by knowing your patients. Nurse researchers found that expert nurses develop a level of knowing that leads to pattern recognition of patient symptoms and responses (White, 2003). For example, an expert nurse who has worked on a general surgery unit for many years is more likely able to detect signs of internal hemorrhage (e.g., fall in blood pressure, rapid pulse, change in consciousness) than a new nurse. Over time a combination of experience, time spent in a specific clinical area, and the quality of relationships formed with patients allow expert nurses to know clinical situations and quickly anticipate and select the right course of action. Spending more time during initial patient assessments to observe patient behavior and measure physical findings is a way to improve knowledge of your patients. In addition, consistently assessing and monitoring patients as problems occur help you to see how clinical changes develop over time. The selection of nursing therapies is built on both clinical knowledge and specific patient data, including:

- The identified status and situation you assessed about the patient, including data collected by actively listening to the patient regarding his or her health care needs.
- Knowledge about the clinical variables (e.g., age, seriousness of the problem, pathology of the problem, patient's preexisting disease conditions) involved in the situation, and how the variables are linked together.
- A judgment about the likely course of events and outcome of the diagnosed problem, considering any health risks the patient has; includes knowledge about usual patterns of any diagnosed problem or prognosis.
- Any additional relevant data about requirements in the patient's daily living, functional capacity, and social resources.

- Knowledge about the nursing therapy options available and the way in which specific interventions will predictably affect the patient's situation.

Always keep the patient your center of focus as you try to solve his or her clinical problems. Making an accurate clinical decision allows you to set priorities for the interventions to implement first (see Chapter 18). Because different patients bring different variables to a situation, a certain activity is sometimes a higher priority in one situation and less of a priority in another. For example, if a patient is physically dependent, unable to eat, and incontinent of urine, you recognize skin integrity as a greater priority than if the patient was immobile but continent of urine and able to eat a normal diet. Do not assume that certain health situations produce automatic priorities. For example, a patient who has surgery is anticipated to experience a certain level of postoperative pain, which often becomes a priority for care. However, if the patient is experiencing severe anxiety that increases pain perception, it becomes necessary for you to focus on ways to relieve the anxiety before pain-relief measures will be effective.

Critical thinking and clinical decision making are complicated because nurses care for multiple patients in fast-paced and unpredictable environments. When you work in a busy setting, use criteria such as the clinical condition of the patient, Maslow's hierarchy of needs (see Chapter 6), the risks involved in treatment delays, and patients' expectations of care to determine which patients have the greatest priorities for care. For example, a patient who is having a sudden drop in blood pressure along with a change in consciousness requires your attention immediately as opposed to a patient who needs you to collect a urine specimen or a patient who needs your help to walk down the hallway. Critical thinking allows a nurse to attend to the patient whose condition is changing quickly and delegate the specimen collection and ambulation to nursing assistive personnel (Box 15-1). For you to manage the wide variety of problems associated with groups of patients, skillful, prioritized clinical decision making is critical (Box 15-2).

Nursing Process as a Competency

Nurses apply the **nursing process** as a competency when delivering patient care (Kataoka-Yahiro and Saylor, 1994). The nursing process is a five-step clinical decision-making approach: assessment, diagnosis, planning, implementation, and evaluation. The purpose of the nursing process is to diagnose and treat human responses to actual or potential health problems (American Nurses Association, 2010). Human responses include patient symptoms and physiological reactions to treatment, the need for knowledge when health care providers make a new diagnosis or treatment plan, and a patient's ability to cope with loss. Use of the process allows nurses to help patients meet agreed-on outcomes for better health (Fig. 15-2). The nursing process requires a nurse to use the general and specific critical thinking competencies described earlier to focus on a particular patient's unique needs. The format for the nursing process is unique to the discipline of nursing and provides a common language and process for nurses to "think through" patients' clinical problems (Kataoka-Yahiro and Saylor, 1994). Unit 3 describes the nursing process.

The nursing process allows for flexibility for use in all clinical settings. When using it, identify a patient's health care needs by collecting thorough information and clearly defining all nursing diagnoses or collaborative problems. You plan care by determining priorities, setting goals and expected outcomes of care, and collaborating with family and health care team members. Then you deliver nursing interventions competently and evaluate the effects of your care. When you become more competent in using the nursing process, you will be able to focus not only on a single patient problem or diagnosis but on multiple problems and diagnoses. As a nurse, always be thinking and recognizing what step of

BOX 15-1 EVIDENCE-BASED PRACTICE

Critical Thinking and Delegation

PICO Question: Do nurses in acute care apply critical thinking to delegate nursing care?

Evidence Summary

Nurses synthesize large amounts of information and think through complex and often emergent clinical situations to make decisions about patient care, including delegation. In two separate studies nurses were asked to describe the process of delegation in their clinical practice (Bittner and Gravlin, 2009; Potter et al., 2010). An important delegation issue is the right circumstances. Registered nurses (RNs) are responsible for making clinical decisions when patients' conditions change, including determining what and when to delegate. RNs in one study were able to identify when to adjust their requests of nursing assistive personnel (NAP) according to patients' needs (Potter et al., 2010). When an RN makes the clinical decision to delegate care, there is the expectation that NAP will report significant findings and that the RN will follow up on tasks that have been delegated. Delegation is ineffective if RNs fail to carry out proper supervision and evaluation of care. When delegation is ineffective, often activities such as ambulation, feedings, and turning are missed by NAP. Successful delegation depends on good communication, developing a trusting and respectful relationship, and showing initiative.

Application to Nursing Practice

- Effective communication is needed between RNs and NAP for giving feedback and clarifying tasks and patient status.
- When patients' clinical conditions change, warranting attention by RNs, clear directions are necessary to avoid missed care.
- Applying critical thinking helps RNs make the decision about when to appropriately delegate care.

BOX 15-2 CLINICAL DECISION MAKING FOR GROUPS OF PATIENTS

- Identify the nursing diagnoses and collaborative problems of each patient (see Chapter 17).
- Analyze patients' diagnoses/problems and decide which are most urgent on the basis of basic needs, the patients' changing or unstable status, and problem complexity (see Chapter 18).
- Consider the time it will take to care for patients whose problems are of high priority (e.g., do you have the time to restart a critical intravenous (IV) line when medication is due for a different patient?).
- Consider the resources you have to manage each problem, nursing assistive personnel assigned with you, other health care providers, and patients' family members.
- Consider how to involve the patients as decision makers and participants in care.
- Decide how to combine activities to resolve more than one patient problem at a time.
- Decide which, if any, nursing care procedures to delegate to assistive personnel so you are able to spend your time on activities requiring professional nursing knowledge.
- Discuss complex cases with other members of the health care team to ensure a smooth transition in care requirements.

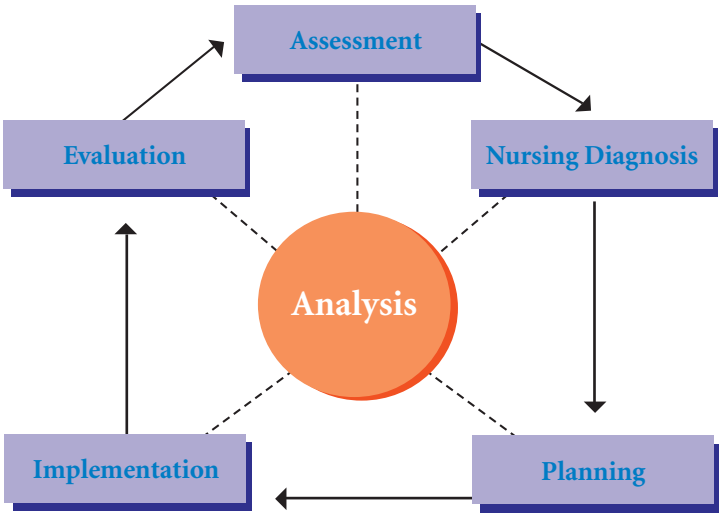

FIG. 15-2 Five-step nursing process model.

the process you are using. Within each step you apply critical thinking to provide the very best professional care to your patients.

A CRITICAL THINKING MODEL FOR CLINICAL DECISION MAKING

Thinking critically is at the core of professional nursing competence. The ability to think critically, improve clinical practice, and decrease errors in clinical judgments is the vision of nursing practice (Di Vito-Thomas, 2005). This text offers a model to help you develop critical thinking. Models help to explain concepts. Because critical thinking in nursing is complex, a model explains what is involved as you make clinical decisions and judgments about your patients. Kataoka-Yahiro and Saylor (1994) developed a model of critical thinking for nursing judgment based in part on previous work by a number of nurse scholars and researchers (Paul, 1993; Miller and Malcolm, 1990) (see Fig. 15-1). The model defines the outcome of critical thinking: nursing judgment that is relevant to nursing problems in a variety of settings. According to this model, there are five components of critical thinking: knowledge base, experience, critical thinking competencies (with emphasis on the nursing process), attitudes, and standards. The elements of the model combine to explain how nurses make clinical judgments that are necessary for safe, effective nursing care (see Box 15-2). Throughout this text the model shows you how to apply critical thinking as part of the nursing process. Graphic illustration of the critical thinking model in our clinical chapters shows you how to apply elements of critical thinking in assessing patients, planning the interventions you provide, and evaluating the results. If you learn to apply each element of this model in the way you think about patients, you will become a confident and effective professional.

Specific Knowledge Base

The first component of the critical thinking model is a nurse's specific knowledge base. Knowledge prepares you to better anticipate and identify patients' problems by understanding their origin and nature. Nurses' knowledge varies according to educational experience and includes basic nursing education, continuing education courses, and additional college degrees. In addition, it includes the initiative you show in reading the nursing literature to remain current in nursing science. A nurse's knowledge base is continually changing as science progresses (Swinny, 2010). As a nurse your knowledge base includes information and theory from the basic sciences, humanities, behavioral sciences, and nursing. Nurses use their knowledge base in a different way than other health care disciplines because they think holistically about patient problems. For example, a nurse's broad knowledge base offers a physical, psychological, social, moral, ethical, and cultural view of patients and their health care needs. The depth and extent of knowledge influence your ability to think critically about nursing problems.

Consider this scenario: Robert Perez previously earned a bachelor's degree in education and taught high school for 1 year. He is starting his third year of study in his nursing program. He has successfully completed the required courses in the sciences, health ethics, introduction to nursing concepts, and communication principles. His first clinical course is on health promotion with a clinical assignment at a general medical clinic. Although he is still new to nursing, his experiences as a teacher and his preparation and knowledge base in nursing help him know how to interview patients and begin to make clinical decisions about patients' health promotion practices.

Experience

Nursing is a practice discipline. Clinical learning experiences are necessary to acquire clinical decision-making skills. Swinny (2010) explains that knowledge itself is not necessarily related to the development of critical thinking. Instead knowledge combined with clinical expertise from experience defines critical thinking. In clinical situations you learn from observing, sensing, talking with patients and families, and reflecting actively on all experiences. Clinical experience is the laboratory for testing your nursing knowledge. You learn that "textbook" approaches form the basis for practice, but you make safe adaptations or revisions in approaches to fit the setting, the patient's unique qualities, and the experiences you have from caring for previous patients. With experience you begin to understand clinical situations, recognize cues of patients'

health patterns, and interpret cues as relevant or irrelevant. Perhaps the best lesson a new nursing student can learn is to value all patient experiences, which become stepping-stones for building new knowledge and inspiring innovative thinking.

During the previous summer Robert worked as a nurse assistant in a nursing home. This experience provided valuable time for interacting with older-adult patients and giving basic nursing care. As Robert thinks about his clinical experience at the clinic, he recognizes that he still has a lot to learn. However, each patient has provided him valuable learning experiences. Specifically he has developed good interviewing skills, understands the importance of the family in an individual's health, and has learned how nurses are patient advocates. He has also learned that older adults need more time to perform activities such as eating, bathing, and grooming; therefore he has adapted these skill techniques. His time in the physical assessment laboratory and the time he worked in the nursing home have helped him begin to be a watchful observer. Finally Robert's previous experience as a teacher helps him apply educational principles in his nursing role.

Your practice improves from what you learn personally. The opportunities you have to experience different emotions, crises, and successes in your lives and relationships with others build your experience as a nurse.

The Nursing Process Competency

Competency, specifically the nursing process, is the third component of the critical thinking model. In your practice you apply critical thinking components during each step of the nursing process. Throughout the clinical chapters of this text, the relationship of critical thinking to the nursing process is emphasized.

Attitudes for Critical Thinking

The fourth component of the critical thinking model is attitudes. Eleven attitudes define the central features of a critical thinker and how a successful critical thinker approaches a problem (Paul, 1993) (Box 15-3). For example, when a patient complains of anxiety before a diagnostic procedure, the curious nurse explores possible reasons for the patient's concerns. The nurse shows discipline in collecting a thorough assessment to find the source of the patient's anxiety. Attitudes of inquiry involve an ability to recognize that problems exist and that there is a need for evidence to support the truth in what you think is true. Critical thinking attitudes are guidelines for how to approach a problem or decision-making situation. An important part of critical thinking is interpreting, evaluating, and making judgments about the adequacy of various arguments and available data. Knowing when you need more information, knowing when information is misleading, and recognizing your own knowledge limits are examples of how critical thinking attitudes guide decision making. Table 15-3 summarizes the use of critical thinking attitudes in nursing practice.

Confidence. When you are confident, you feel certain about accomplishing a task or goal such as performing a procedure or making a diagnostic decision. Confidence grows with experience in recognizing your strengths and limitations. You shift your focus from your own needs (e.g., remembering how to perform a procedure) to the patient's needs. When you are not confident in performing a nursing skill, you become anxious about not knowing what to do. This prevents you from giving attention to the patient. Always be aware of what you know and what you do not know. If you have a question about a procedure, discuss it with your nursing instructor first before attempting it on your patient. Never attempt anything on your patient unless you have the knowledge base and feel confident. Patient safety is of the upmost importance. When you show confidence, your patients recognize it by how you communicate and the way you perform nursing care. Confidence builds trust between you and your patients.

Thinking Independently. As you gain new knowledge, you learn to consider a wide range of ideas and concepts before forming an opinion or making a judgment. This does not mean that you ignore other people's ideas. Instead you learn to consider all sides of a situation. However, a critical thinker does not accept another person's ideas without question. When thinking independently, you challenge the ways others think and look for rational and logical answers to problems. Begin to raise important questions about your practice. For example, why is one type of surgical dressing ordered over another, why do your patients not get pain relief, and what can you do to help patients with literacy problems learn about their medications? When nurses ask questions and look for the evidence behind clinical problems, they are thinking independently; this is an important step in evidence-based practice (Chapter 5). Independent thinking and reasoning are essential to the improvement and expansion of nursing practice.

Fairness. A critical thinker deals with situations justly. This means that bias or prejudice does not enter into a decision. For example, regardless of how you feel about obesity, you do not allow personal attitudes to influence the way you care for a patient who is overweight. Look at a situation objectively and consider all viewpoints to understand the situation completely before making a decision. Having a sense of imagination helps you develop an attitude of fairness. Imagining what it is like to be in your patient's situation helps you see it with new eyes and appreciate its complexity.

BOX 15-3 COMPONENTS OF CRITICAL THINKING IN NURSING

- I. Specific knowledge base in nursing
- II. Experience
- III. Critical thinking competencies
  - A. General critical thinking
  - B. Specific critical thinking
  - C. Specific critical thinking in nursing: nursing process
- IV. Attitudes for critical thinking
  - Confidence, Independence, Fairness, Responsibility, Risk taking, Discipline, Perseverance, Creativity, Curiosity, Integrity, Humility
- V. Standards for critical thinking
  - A. Intellectual standards
    - Clear, Precise, Specific, Accurate, Relevant, Plausible, Consistent, Logical, Deep, Broad, Complete, Significant, Adequate (for purpose), Fair
  - B. Professional standards
    - 1. Ethical criteria for nursing judgment
    - 2. Criteria for evaluation
    - 3. Professional responsibility

Modified from Kataoka-Yahiro M, Saylor C: A critical thinking model for nursing judgment, *J Nurs Educ* 33(8):351, 1994. Data from Paul RW: The art of redesigning instruction. In Willsen J, Blinker AJA, editors: *Critical thinking: how to prepare students for a rapidly changing world,* Santa Rosa, Calif, 1993, Foundation for Critical Thinking.

TABLE 15-3 **Critical Thinking Attitudes and Applications in Nursing Practice**

CRITICAL THINKING ATTITUDE	APPLICATION IN PRACTICE
Confidence	Learn how to introduce yourself to a patient; speak with conviction when you begin a treatment or procedure. Do not lead a patient to think that you are unable to perform care safely. Always be well prepared before performing a nursing activity. Encourage a patient to ask questions.
Thinking independently	Read the nursing literature, especially when there are different views on the same subject. Talk with other nurses and share ideas about nursing interventions.
Fairness	Listen to both sides in any discussion. If a patient or family member complains about a co-worker, listen to the story and then speak with the co-worker as well. If a staff member labels a patient uncooperative, assume the care of that patient with openness and a desire to meet that patient's needs.
Responsibility and authority	Ask for help if you are uncertain about how to perform a nursing skill. Refer to a policy and procedure manual to review steps of a skill. Report any problems immediately. Follow standards of practice in your care.
Risk taking	If your knowledge causes you to question a health care provider's order, do so. Be willing to recommend alternative approaches to nursing care when colleagues are having little success with patients.
Discipline	Be thorough in whatever you do. Use known scientific and practice-based criteria for activities such as assessment and evaluation. Take time to be thorough and manage your time effectively.
Perseverance	Be cautious of an easy answer. If co-workers give you information about a patient and some fact seems to be missing, clarify the information or talk to the patient directly. If problems of the same type continue to occur on a nursing division, bring co-workers together, look for a pattern, and find a solution.
Creativity	Look for different approaches if interventions are not working for a patient. For example, a patient in pain may need a different positioning or distraction technique. When appropriate, involve the patient's family in adapting your approaches to care methods used at home.
Curiosity	Always ask why. A clinical sign or symptom often indicates a variety of problems. Explore and learn more about the patient so as to make appropriate clinical judgments.
Integrity	Recognize when your opinions conflict with those of a patient; review your position, and decide how best to proceed to reach outcomes that will satisfy everyone. Do not compromise nursing standards or honesty in delivering nursing care.
Humility	Recognize when you need more information to make a decision. When you are new to a clinical division, ask for an orientation to the area. Ask registered nurses (RNs) regularly assigned to the area for assistance with approaches to care.

Responsibility and Accountability. When caring for patients you are responsible for correctly performing nursing care activities based on standards of practice. Standards of practice are the minimum level of performance accepted to ensure high-quality care. For example, you do not take shortcuts (e.g., failing to identify a patient, prepare medication doses for multiple patients at the same time) when administering medications. A professional nurse is competent in performing nursing therapies and making clinical decisions about patients. As a nurse you are answerable or accountable for your decisions and the outcomes of your actions. This means that you are accountable for recognizing when nursing care is ineffective and you know the limits and scope of your practice

Risk Taking. Persons often associate taking risks with danger. Driving 30 miles an hour over the speed limit is a risk that sometimes results in injury to the driver and an unlucky pedestrian. But risk taking does not always have negative outcomes. Risk taking is desirable, particularly when the result is a positive outcome. A critical thinker is willing to take risks in trying different ways to solve problems. The willingness to take risks comes from experience with similar problems. Risk taking often leads to advances in patient care. Nurses in the past have taken risks in trying different approaches to skin and wound care and pain management, to name a few. When taking a risk, consider all options; follow safety guidelines; analyze any potential dangers to a patient; and act in a well-reasoned, logical, and thoughtful manner.

Discipline. A disciplined thinker misses few details and follows an orderly or systematic approach when collecting information, making decisions, or taking action. For example, you have a patient who is in pain. Instead of only asking the patient, "How severe is your pain on a scale of 0 to 10?" you also ask more specific questions about the character of pain. For example, "What makes the pain worse? Where does it hurt? How long have you noticed it?" Being disciplined helps you identify problems more accurately and select the most appropriate interventions.

Perseverance. A critical thinker is determined to find effective solutions to patient care problems. This is especially important when problems remain unresolved or recur. Learn as much as possible about a problem and try various approaches to care. Persevering means to keep looking for more resources until you find a successful approach. For example, a patient who is unable to speak following throat surgery poses challenges for the nurse to be able to communicate effectively. Perseverance leads the nurse to try different communication approaches (e.g., message boards or alarm bells) until he or she finds a method that the patient is able to use. A critical thinker who perseveres is not satisfied with minimal effort but works to achieve the highest level of quality care.

Creativity. Creativity involves original thinking. This means that you find solutions outside of the standard routines of care while still keeping standards of practice. Creativity motivates you to think of options and unique approaches. A patient's clinical problems, social support systems, and living environment are just a few examples of factors that make the simplest nursing procedure more complicated. For example, a home care nurse has to find a way to help an older patient with arthritis have greater mobility in the home. The patient has difficulty lowering and raising herself in a chair because of pain and limited range of motion in her knees. The nurse uses wooden blocks to elevate the chair legs so the patient is able to sit and stand with little discomfort while making sure the chair is safe to use.

Curiosity. A critical thinker's favorite question is "Why?" In any clinical situation you learn a great deal of information about a patient. As you analyze patient information, data patterns appear that are not always clear. Having a sense of curiosity motivates you to inquire further (e.g., question family, consult with a physician, or review the scientific literature) and investigate a clinical situation so you get all the information you need to make a decision.

Integrity. Critical thinkers question and test their own knowledge and beliefs. Your personal integrity as a nurse builds trust from your co-workers. Nurses face many dilemmas or problems in everyday clinical practice, and everyone makes mistakes at times. A person of integrity is honest and willing to admit to mistakes or inconsistencies in his or her own behavior, ideas, and beliefs. In addition, the professional nurse always tries to follow the highest standards of practice.

Humility. It is important for you to admit to any limitations in your knowledge and skill. Critical thinkers admit what they do not know and try to find the knowledge needed to make proper decisions. It is common for a nurse to be an expert in one area of clinical practice but a novice in another. That is because the knowledge in all areas of nursing is unlimited. A patient's safety and welfare are at risk if you do not admit your inability to deal with a practice problem. You have to rethink a situation; learn more; and use the new information to form opinions, draw conclusions, and take action.

The first patient Robert meets in the clinic is a young man who has signs and symptoms of chlamydia, a sexually transmitted disease. The patient has had the symptoms for over 3 weeks and voices concern about what it means to have the disease. Robert examines the young man and finds that the patient has redness and itching on the penis with a yellowish discharge. He uses discipline to check further and asks if the patient has pain on urination. He also checks him for fever. Robert has limited knowledge about chlamydia, so he consults with the clinic nurse practitioner, who explains the nature of the infection, the risks it poses to the patient, and the usual course of treatment. Robert returns and speaks more confidently with the patient about chlamydia, the reason for his symptoms, the need to tell sex partners about the infection, and the importance of wearing a condom.

Standards for Critical Thinking

The fifth component of the critical thinking model includes intellectual and professional standards (Kataoka-Yahiro and Saylor, 1994).

Intellectual Standards. Paul (1993) identified 14 intellectual standards (see Box 15-3) universal for critical thinking. An intellectual standard is a guideline or principle for rational thought. You apply these standards when you use the nursing process. When you consider a patient problem, apply the intellectual standards such as preciseness, accuracy, and consistency to make sure that all clinical decisions are sound. A thorough use of the intellectual standards in clinical practice makes certain that you do not perform critical thinking haphazardly.

Mrs. Lamar is an 82-year-old patient who comes to the medical clinic for a follow-up following the diagnosis of a diabetic foot ulcer. Robert finds the ulcer on the patient's left foot. A quick check of the patient's medical record reveals a description of the ulcer by one of the clinic nurses from 2 weeks earlier. The patient is receiving a topical medication for the ulcer. Robert uses the same assessment criteria applied during the last clinic visit to examine the patient's ulcer (consistent). He methodically inspects the affected area of the skin, measures the size of the ulcer, and notes the appearance of any drainage (complete). He asks the patient to describe how she has been caring for the ulcer to determine if she needs health teaching (relevant). When the patient explains that she washes the ulcer, Robert asks her to describe exactly what she has used to clean the ulcer and how often (precise). He documents the wound location and appearance in the clinic record using specific anatomical terms (accurate). By applying appropriate intellectual standards, Robert is able to determine that the ulcer is healing and has improved since the last assessment.

Professional Standards. Professional standards for critical thinking refer to ethical criteria for nursing judgments, evidence-based criteria used for evaluation, and criteria for professional responsibility (Paul, 1993). Application of professional standards requires you to use critical thinking for the good of individuals or groups (Kataoka-Yahiro and Saylor, 1994). Professional standards promote the highest level of quality nursing care.

Excellent nursing practice is a reflection of ethical standards (Chapter 22). Patient care requires more than just the application of scientific knowledge. Being able to focus on a patient's values and beliefs helps you make clinical decisions that are just, faithful to the patient's choices, and beneficial to the patient's well-being. Critical thinkers maintain a sense of self-awareness through conscious awareness of their beliefs; values; feelings; and the multiple perspectives that patients, family members, and peers present in clinical situations. Critical thinking also requires the use of evidence-based criteria for making clinical judgments. These criteria are sometimes scientifically based on research findings (see Chapter 5) or practice based on standards developed by clinical experts and performance improvement initiatives of the institution. Examples are the clinical practice guidelines developed by individual clinical agencies and national organizations such as the Agency for Healthcare Research Quality (AHRQ). A clinical practice guideline includes standards for the treatment of select clinical conditions such as stroke, deep vein thrombosis, and pressure ulcers. Another example is clinical criteria used to categorize clinical conditions such as the criteria for staging pressure ulcers (see Chapter 48) and rating phlebitis (see Chapter 41). Evidence-based evaluation criteria set the minimum requirements necessary to ensure appropriate and high-quality care.

Nurses routinely use evidence-based criteria to assess patients' conditions and determine the efficacy of nursing interventions. For example, accurate assessment of symptoms such as pain includes use of assessment criteria such as the duration, severity, location,

aggravating or relieving factors, and effects on daily lifestyle (see Chapter 43). In this case assessment criteria allow you to accurately determine the nature of a patient's symptoms, select appropriate therapies, and evaluate if the therapies are effective. The standards of professional responsibility that a nurse tries to achieve are the standards cited in Nurse Practice Acts, institutional practice guidelines, and professional organizations' standards of practice (e.g., The American Nurses Association Standards of Professional Performance (see Chapter 1). These standards "raise the bar" for the responsibilities and accountabilities that a nurse assumes in guaranteeing quality health care to the public.

DEVELOPING CRITICAL THINKING SKILLS

To develop critical thinking skills, it is important to learn how to connect knowledge and theory with practice. Your ability to make sense of what you learn in the classroom, from reading, or from having dialogue with other students and then to apply it during patient care is always challenging.

Reflective Journaling

How often do you think back on a situation to consider the following: Why did that occur? How did I act? What could I have done differently? What knowledge could I have applied? **Reflection** is the process of purposefully thinking back or recalling a situation to discover its purpose or meaning. It is like rewinding a videotape. Reflection involves playing back a situation in your head and taking time to honestly review everything you remember about it. Reflective practice is a conscious process of thinking, analyzing, and learning from your work situations by way of journaling or regularly meeting with colleagues to explore work situations and self-evaluate (Cirocco, 2007). Critical thinking becomes more deliberate through reflection because it allows you to think about your previous thinking to make your future thinking better (Jackson, 2006).

Reflective journal writing is a tool for developing critical thought and reflection by clarifying concepts. Reflective writing gives you the opportunity to define and express the clinical experience in your own words (Di Vito-Thomas, 2005). By keeping a journal of each of your clinical experiences, you are able to explore personal perceptions or understanding of each experience and develop the ability to apply theory in practice. The use of a journal improves your observation and descriptive skills. Writing skills also improve through the development of conceptual clarity. The Circle of Meaning model adapted to nursing encourages concept clarification and a search for meaning in nursing practice (Bilinski, 2002). The model uses the following questions to help you journey through a clinical experience and find meaning:

1. Which experience, situation, or information in your clinical experience seems confusing, difficult, or interesting?
2. What is the meaning of the experience? What feelings did you have? What feelings did your patient have? What influenced the experience? Which guesses or questions developed with the first connection in question 1? Give examples.
3. Do the feelings, guesses, or questions remind you of any experience from the past or present or something that you think is a desirable future experience? How does it relate? What are the implications/significance?
4. What are the connections between what is being described and what you have learned about nursing science, research, and theory? What are some possible solutions? Which approach or solution would you choose and why? How is this approach effective?

Keeping a journal of your patient care experiences helps you become aware of how you make clinical decisions. Begin by recording notes after a clinical experience. Telling a story and drawing a picture are two additional ways to identify the experience on which you wish to reflect. Describe in detail what you felt, thought, and did. Analyze the experience by considering feelings, thoughts, and possible meaning. Challenge any preconceived ideas you have when you look at actual clinical situations. Describe the significance of the experience. Do not include patient identification in your journal, and refer to your journal when you care for patients in similar situations.

Meeting with Colleagues

Another way to develop critical thinking skills is regularly meeting with colleagues to discuss and examine work experiences. Having the chance to discuss anticipated and unanticipated outcomes in any clinical situation allows you to continually learn and develop your expertise and knowledge (Cirocco, 2007). When nurses have a formal means to discuss their experiences such as a staff meeting or unit practice council, the dialogue allows for questions, differing viewpoints, and sharing experiences. When they are able to discuss their practices, the process validates good practice and also offers challenges and constructive criticism. Much can be learned by drawing from others' experiences and perspectives to promote reflective critical thinking.

Concept Mapping

As a nurse you care for patients who have multiple nursing diagnoses or collaborative problems. A **concept map** is a visual representation of patient problems and interventions that shows their relationships to one another. It offers a nonlinear picture of a patient that can then be used for comprehensive care planning (Taylor and Wros, 2007). The primary purpose of concept mapping is to better synthesize relevant data about a patient, including assessment data, nursing diagnoses, health needs, nursing interventions, and evaluation measures (Hill, 2006). Through drawing a concept map, you learn to organize or connect information in a unique way so the diverse information that you have about a patient begins to form meaningful patterns and concepts. You begin to see a more holistic view of a patient. When you see the relationship between the various patient diagnoses and the data that support them, you better understand a patient's clinical situation. Concept maps become more detailed, integrated, and comprehensive as you learn more about the care of a patient and the care you provide similar patients (Ferrario, 2004). The similarities and differences that you see among patients build your decision-making skills. Unit 3 includes chapters that provide diagrams of actual concept maps and more detail on their development. Concept maps can also be found in Units 5 and 6.

CRITICAL THINKING SYNTHESIS

Critical thinking is a reasoning process by which you reflect on and analyze your own thoughts, actions, and knowledge. To be a good critical thinker requires dedication and a desire to grow intellectually. As a beginning nurse it is important to learn the steps of the nursing process and incorporate the elements of critical thinking (Fig. 15-3). The two processes go hand in hand in making quality decisions about patient care. This text provides a model to show you how important critical thinking is in nursing practice. Throughout the clinical chapters of this text, the components of

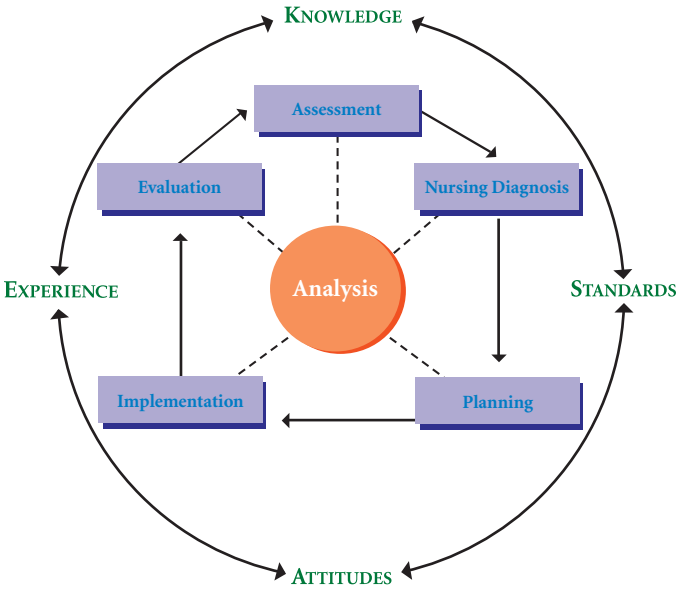

FIG. 15-3 Synthesis of critical thinking with the nursing process competency.

critical thinking are emphasized to help you better understand their relationship to the nursing process.

KEY POINTS

- Clinical decision making involves judgment that includes critical and reflective thinking and action and application of scientific and practical logic.
- Nurses who apply critical thinking in their work focus on options for solving problems and making decisions rather than rapidly and carelessly forming quick, single solutions.
- Following a procedure step by step without adjusting to a patient's unique needs is an example of basic critical thinking.
- In complex critical thinking a nurse learns that alternative and perhaps conflicting solutions exist.
- In diagnostic reasoning you collect patient data and analyze them to determine the patient's problems.
- The nursing process is a blueprint for patient care that involves both general and specific critical thinking competencies in a way that focuses on a particular patient's unique needs.
- The critical thinking model combines a nurse's knowledge base, experience, competence in the nursing process, attitudes, and standards to explain how nurses make clinical judgments that are necessary for safe, effective nursing care.
- Clinical learning experiences are necessary for you to acquire clinical decision-making skills.
- Critical thinking attitudes help you to know when more information is necessary and when it is misleading and to recognize your own knowledge limits.
- The use of intellectual standards during assessment ensures that you obtain a complete database of information.
- Professional standards for critical thinking refer to ethical criteria for nursing judgments, evidence-based criteria for evaluation, and criteria for professional responsibility.
- Meeting regularly with colleagues allows you to discuss anticipated and unanticipated outcomes in any clinical situation to continually learn and develop your expertise and knowledge.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Josh is a second-year nursing student working in a surgical clinic. He is checking Mr. Isaac's surgical wound. After removing the gauze dressing, he notes in the nurses' notes from the last visit that the wound was 3 cm long and the skin around the wound was tender when palpated. When Josh examines the wound, he measures the length and width in centimeters with a tape measure, observes the character of the tissues, looks for drainage, and palpates around the wound for tenderness and an increase in drainage. He asks Mr. Isaac if he is having discomfort from the wound and if the pain is limiting his activity.

1. Explain which intellectual standards Josh used in the wound assessment and support your answers.
2. Mr. Isaac asks Josh if the wound is going to heal soon, stating, "I thought it would have healed by now." Josh responds by saying, "What did your doctor tell you about the time it would take to heal the wound? I plan to talk with him to let him know how the wound looks so we're sure we're using the right type of dressing." In this example Josh is displaying which of the following attitudes for critical thinking during his communication:
   1. Confidence
   2. Integrity
   3. Creativity
   4. Risk taking
3. Two weeks later Mr. Isaac again comes to the clinic. The wound has not progressed, but there are no signs of infection. Josh talks with Mr. Isaac about his activities. He also has Mr. Isaac describe the type of diet he has been eating and the amount of food intake. Josh's line of questioning is an example of which critical thinking competency? Explain.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. While assessing a patient, the nurse observes that the patient's intravenous (IV) line is not infusing at the ordered rate. The nurse assesses the patient for pain at the IV site, checks the flow regulator on the tubing, looks to see if the patient is lying on the tubing, checks the point of connection between the tubing and the IV catheter, and then checks the condition of the site where the intravenous catheter enters the patient's skin. After the nurse readjusts the flow rate, the infusion begins at the correct rate. This is an example of:
   1. Inference.
   2. Diagnostic reasoning.
   3. Competency.
   4. Problem solving.
2. The nurse sits down to talk with a patient who lost her sister 2 weeks ago. The patient reports she is unable to sleep, feels very fatigued during the day, and is having trouble at work. The nurse asks her to clarify the type of trouble. The patient explains she can't concentrate or even solve simple problems. The nurse records the results of the assessment, describing the patient as having ineffective coping. This is an example of:
   1. Diagnostic reasoning.
   2. Competency.

3. Inference.
4. Problem solving.

3. A patient on a surgical unit develops sudden shortness of breath and a drop in blood pressure. The staff respond, but the patient dies 30 minutes later. The manager on the nursing unit calls the staff involved in the emergency response together. The staff discusses what occurred over the 30-minute time frame, the actions taken, and whether other steps should have been implemented. The nurses in this situation are:
   1. Problem solving.
   2. Showing humility.
   3. Conducting reflective practice.
   4. Exercising responsibility.
4. A nurse has worked on an oncology unit for 3 years. One patient has become visibly weaker and states, "I feel funny." The nurse knows how patients often have behavior changes before developing sepsis when they have cancer. The nurse asks the patient questions to assess thinking skills and notices the patient shivering. The nurse goes to the phone, calls the physician, and begins the conversation by saying, "I believe that your patient is developing sepsis. I want to report symptoms I'm seeing." What examples of critical thinking concepts does the nurse show? (Select all that apply.)
   1. Experience
   2. Ethical
   3. Analyticity
   4. Self-confidence
   5. Risk taking
5. A nurse who is working on a surgical unit is caring for four different patients. Patient A will be discharged home and is in need of instruction about wound care. Patients B and C have returned from the operating room within an hour of each other, and both require vital signs and monitoring of their intravenous (IV) lines. Patient D is resting following a visit by physical therapy. Which of the following activities by the nurse represent(s) use of clinical decision making for groups of patients? (Select all that apply.)
   1. Consider how to involve patient A in deciding whether to involve the family caregiver in wound care instruction.
   2. Think about past experience with patients who develop postoperative complications.
   3. Decide which activities can be combined for patients B and C.
   4. Carefully gather any assessment information and identify patient problems.
6. The surgical unit has initiated the use of a pain-rating scale to assess patients' pain severity during their postoperative recovery. The registered nurse (RN) looks at the pain flow sheet to see the pain scores recorded for a patient over the last 24 hours. Use of the pain scale is an example of which intellectual standard?
   1. Deep
   2. Relevant
   3. Consistent
   4. Significant
7. During a home health visit the nurse prepares to instruct a patient in how to perform range-of-motion (ROM) exercises for an injured shoulder. The nurse verifies that the patient took an analgesic 30 minutes before arrival at the patient's home. After discussing the purpose for the exercises and demonstrating each one, the nurse has the patient perform them. After two attempts with only the second of three exercises, the patient stops and says, "This hurts too much. I don't see why I have to do this so many times." The nurse applies the critical thinking attitude of integrity in which of the following actions?"
   1. "I understand your reluctance, but the exercises are necessary for you to regain function in your shoulder. Let's go a bit more slowly and try to relax."
   2. "I see that you're uncomfortable. I'll call your doctor to decide the next step."
   3. "Show me exactly where your pain is and rate it for me on a scale of 0 to 10."
   4. "Is anything else bothering you? Other than the pain, is there any other reason you might not want to do the exercises?"
8. The nurse cared for a 14-year-old with renal failure who died near the end of the work shift. The health care team tried for 45 minutes to resuscitate the child with no success. The family was devastated by the loss, and, when the nurse tried to talk with them, the mother said, "You can't make me feel better; you don't know what it's like to lose a child." Which of the following examples of journal entries might best help the nurse reflect and think about this clinical experience? (Select all that apply.)
   1. Data entry of time of day, who was present, and condition of the child
   2. Description of the efforts to restore the child's blood pressure, what was used, and questions about the child's response
   3. The meaning the experience had for the nurse with respect to her understanding of dealing with a patient's death
   4. A description of what the nurse said to the mother, the mother's response, and how the nurse might approach the situation differently in the future
9. A nurse has been working on a surgical unit for 3 weeks. A patient requires a Foley catheter to be inserted, so the nurse reads the procedure manual for the institution to review how to insert it. The level of critical thinking the nurse is using is:
   1. Commitment.
   2. Scientific method.
   3. Basic critical thinking.
   4. Complex critical thinking.
10. A patient had hip surgery 16 hours ago. During the previous shift the patient had 40 mL of drainage in the surgical drainage collection device for an 8-hour period. The nurse refers to the written plan of care, noting that the health care provider is to be notified when drainage in the device exceeds 100 mL for the day. On entering the room, the nurse looks at the device and carefully notes the amount of drainage currently in it. This is an example of:
    1. Planning.
    2. Evaluation.
    3. Intervention.
    4. Diagnosis.
11. A 67-year-old patient will be discharged from the hospital in the morning. The health care provider has ordered three new medications for her. Place the following steps of the nursing process in the correct order.
    ____ 1. The nurse returns to the patient's room and asks her to describe the medicines she will be taking at home.
    ____ 2. The nurse talks with the patient and family about who will be available if the patient has difficulty taking

medicines and considers consulting with the health care provider about a home health visit.

____ 3. The nurse asks the patient if she is in pain, feels tired, and is willing to spend the next few minutes learning about her new medicines.

____ 4. The nurse brings the containers of medicines and information leaflets to the bedside and discusses each medication with her.

____ 5. The nurse considers what she learns from the patient and identifies the patient's nursing diagnosis.

12. The nurse asks a patient how she feels about her impending surgery for breast cancer. Before the discussion the nurse reviewed the description of loss and grief and therapeutic communication principles in his textbook. The critical thinking component involved in the nurse's review of the literature is:
    1. Experience.
    2. Problem solving.
    3. Knowledge application.
    4. Clinical decision making.
13. A nurse is working with a nursing assistive personnel (NAP) on a busy oncology unit. The nurse has instructed the NAP on the tasks that need to be performed, including getting patient A out of bed, collecting a urine specimen from patient B, and checking vital signs on patient C, who is scheduled to go home. Which of the following represent(s) successful delegation? (Select all that apply.)
    1. A nurse explains to the NAP the approach to use in getting the patient up and why the patient has activity limitations.
    2. A nurse is asked by a patient to help her to the bathroom; the nurse leaves the room and directs the NAP to assist the patient instead.
    3. The nurse sees the NAP preparing to help a patient out of bed, goes to assist, and thanks the NAP for her efforts to get the patient up early.
    4. The nurse is in patient B's room to check an intravenous (IV) line and collects the urine specimen while in the room.
    5. The nurse offers support to the NAP when needed but allows her to complete patient care tasks without constant oversight.
14. Which of the following is unique to the commitment level of critical thinking?
    1. Weighs benefits and risks when making a decision.
    2. Analyzes and examine choices more independently.
    3. Concrete thinking.
    4. Anticipates when to make choices without others' assistance.
15. In which of the following examples is the nurse not applying critical thinking skills in practice?
    1. The nurse considers personnel experience in performing intravenous (IV) line insertion and ways to improve performance.
    2. The nurse uses a fall risk inventory scale to determine a patient's fall risk.
    3. The nurse observes a change in a patient's behavior and considers which problem is likely developing.
    4. The nurse explains the procedure for giving a tube feeding to a second nurse who has floated to the unit to assist with care.

Answers: **1.** 4; **2.** 1; **3.** 3; **4.** 3, 4; **5.** 1, 3; **6.** 3; **7.** 1; **8.** 2, 3, 4; **9.** 3; **10.** 2; **11.** The correct order is 3 (assessment), 5 (nursing diagnosis), 2 (planning), 4 (intervention), 1 (evaluation); **12.** 3; **13.** 1, 3, 4; **14.** 4; **15.** 4.

Nursing Assessment

OBJECTIVES

- Discuss the relationship between critical thinking and nursing assessment.
- Explain the process of data collection.
- Differentiate between subjective and objective data.
- Describe the methods of data collection.
- Discuss the process of conducting a patient-centered interview.
- Describe the components of a nursing history.
- Explain the differences among comprehensive, problem-oriented, and focused assessments.
- Explain the relationship between data interpretation and validation.
- Conduct a nursing assessment.

The **nursing process** is a critical thinking process that professional nurses use to apply the best available evidence to caregiving and promoting human functions and responses to health and illness (American Nurses Association, 2010). It is the fundamental blueprint for how to care for patients. The nursing process is also a standard of practice, which, when followed correctly, protects nurses against legal problems related to nursing care (Austin, 2008). As a nursing student, you learn the five steps of the nursing process—assessment, diagnosis, planning, implementation, and evaluation—as if they were a linear process (Fig. 16-1). However, in fact the nursing process is dynamic and continuous; and, after more experience in practice, you learn to move back and forth among the various steps (Potter et al., 2005). Consider the following scenario that was also described in Chapter 15:

Mr. Jacobs is a 58-year-old patient who had a radical prostatectomy (removal of prostate gland) for prostate cancer yesterday. He is married to Martha, who has been at his bedside most of the morning. His nurse, Tonya Moore, just started the day shift on the surgical unit and finds the patient lying flat in bed with arms tensed and extended along his sides. When Tonya checks the surgical wound and drainage device, she notes that Mr. Jacobs winces when she gently places her hands to palpate around the incisional area. She asks Mr. Jacobs when he last turned onto his side, and he responds, "Not since last night some time." Tonya asks Mr. Jacobs if he is having incisional pain, and he nods yes, saying, "It hurts too much to move." Tonya clarifies, "On a scale of 0 to 10 with 0 being no pain and 10 being the worst pain you have ever had, rate how you feel now." Mr. Jacobs states, "Oh, this is at least a 7." Tonya considers the information she has observed and learned from Mr. Jacobs to determine that he is in pain and has reduced mobility because of it. She decides that she needs to take action to relieve Mr. Jacobs' pain so she can turn him more frequently and begin to get him out of bed for his recovery.

Each time you meet a patient, you apply the nursing process, as Tonya did while caring for Mr. Jacobs, to provide appropriate and effective nursing care. The process begins with the first step, assessment, the gathering and analysis of information about the patient's health status. You then make clinical judgments from the assessment to identify the patient's response to health problems in the form of nursing diagnoses. Once you define appropriate nursing diagnoses, you create a plan of care. Planning includes setting goals and expected outcomes for your care and selecting interventions (nursing and collaborative) individualized to each of the patient's nursing diagnoses. The next step, implementation, involves performing the planned interventions. After performing

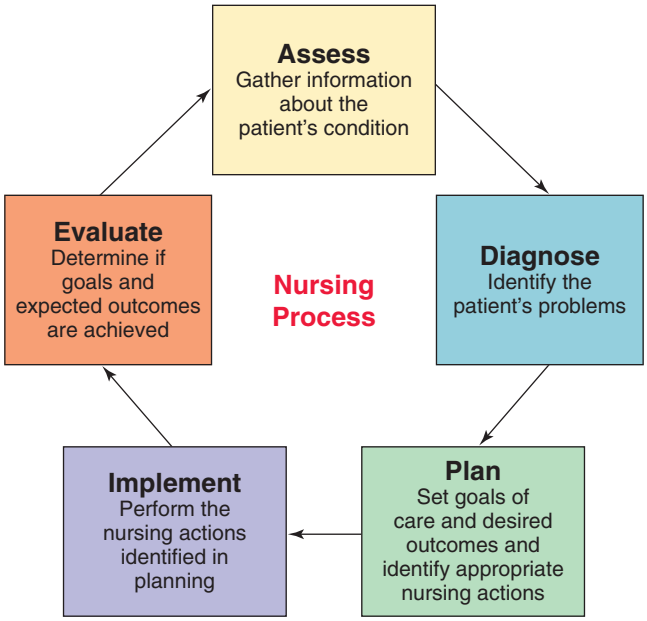

FIG. 16-1 Five-step nursing process.

interventions, you evaluate the patient's response and whether the interventions were effective. The nursing process is central to your ability to provide timely and appropriate care to your patients.

The nursing process is a variation of scientific reasoning. Practicing the five steps of the nursing process allows you to be organized and conduct your practice in a systematic way. You learn to make inferences about the meaning of a patient's response to a health problem or generalize about the patient's functional state of health. Through assessment a pattern begins to form. For example, if Mr. Jacobs is having incisional pain, the data allow Tonya to infer that his mobility is limited. Tonya gathers more information (e.g., palpating gently over the incision, having Mr. Jacobs rate the severity of discomfort, and noting that he limits movement) until an accurate classification of the patient's problem is determined such as the following nursing diagnosis: *acute pain related to trauma of incision* and the diagnosis of *impaired physical mobility related to incisional pain.* Clearly defining your patients' problems provides the basis for planning and implementing nursing interventions and evaluating the outcomes of care.

CRITICAL THINKING APPROACH TO ASSESSMENT

Assessment is the deliberate and systematic collection of information about a patient to determine his or her current and past health and functional status and his or her present and past coping patterns (Carpenito-Moyet, 2009). Nursing **assessment** includes two steps:

1. Collection of information from a primary source (the patient) and secondary sources (e.g., family members, health professionals, and medical record)
2. The interpretation and validation of data to ensure a complete database

The purpose of assessment is to establish a **database** about the patient's perceived needs, health problems, and responses to these problems. In addition, the data reveal related experiences, health practices, goals, values, and expectations about the health care system.

When a plumber comes to your home to repair a problem you describe as a "leaking faucet," the plumber checks the faucet, its attachments to the water line, and the water pressure in the system to determine the real problem. A patient presents an initial health problem to you. For example, Mr. Jacobs presents with signs of pain following surgery. You then proceed to observe his behaviors, ask questions about the nature of the problem, listen to the cues he provides, and conduct a physical examination (see Chapter 30). You also usually interview family members who are familiar with the patient's health problems and any existing medical record data. The data you collect fall into different sets or patterns of information that point to a diagnostic conclusion. Once a plumber knows the source of the leaking faucet, he is able to repair it. Once you know the nature and source of a patient's specific health problems (such as Mr. Jacob's incisional pain), you are able to provide interventions that will restore, maintain, or improve the patient's health.

Critical thinking is a vital part of assessment (see Chapter 15). It allows you to see the big picture when you form conclusions or make decisions about a patient's health condition. While gathering data about a patient, you synthesize relevant knowledge, recall prior clinical experiences, apply critical thinking standards and attitudes, and use standards of practice to direct your assessment in a meaningful and purposeful way (Fig. 16-2). Your knowledge from the physical, biological, and social sciences allows you to ask relevant questions and collect relevant history and physical assessment data related to the patient's presenting health care needs. For example, Tonya knows that Mr. Jacobs had his prostate gland removed. She reviewed her medical-surgical textbook and learned that a radical prostatectomy involves removal of a lot of tissue, including the prostate gland, seminal vesicles, part of the bladder neck, and lymph nodes. This knowledge helps her to recognize that considerable swelling can potentially create acute pain; thus she decides to inspect and palpate around Mr. Jacob's incisional area. She also questions Mr. Jacobs about how the discomfort affects his ability to turn or move in bed. Using good communication skills through interviewing and applying critical thinking intellectual standards (such as being precise and accurate in using a pain scale) enables Tonya to collect complete, accurate, and relevant data.

Prior clinical experience contributes to the skills of assessment. For example, Tonya cared for a patient with surgical incision pain in the past and knows that pain is often disabling and limits a patient's normal motion. This experience allows Tonya to thoroughly assess the extent to which pain affects the patient's ability to move and eventually get out of bed, an important step in Mr. Jacob's recovery. Validation of any abnormal assessment findings and personal observation of assessments performed by skilled professionals help you become competent in assessment. You also learn to apply standards of practice and accepted standards of "normal" for physical assessment data when assessing patients. Use of critical thinking attitudes such as curiosity, perseverance, and confidence ensure you complete a comprehensive database.

Data Collection

You perform assessment to gather information needed to make an accurate judgment about a patient's current condition (Magnan and Maklebust, 2009). Your information comes from:

- The patient, through interview, observations, and physical examination.
- Family members or significant others' reports and response to interviews.
- Other members of the health care team.

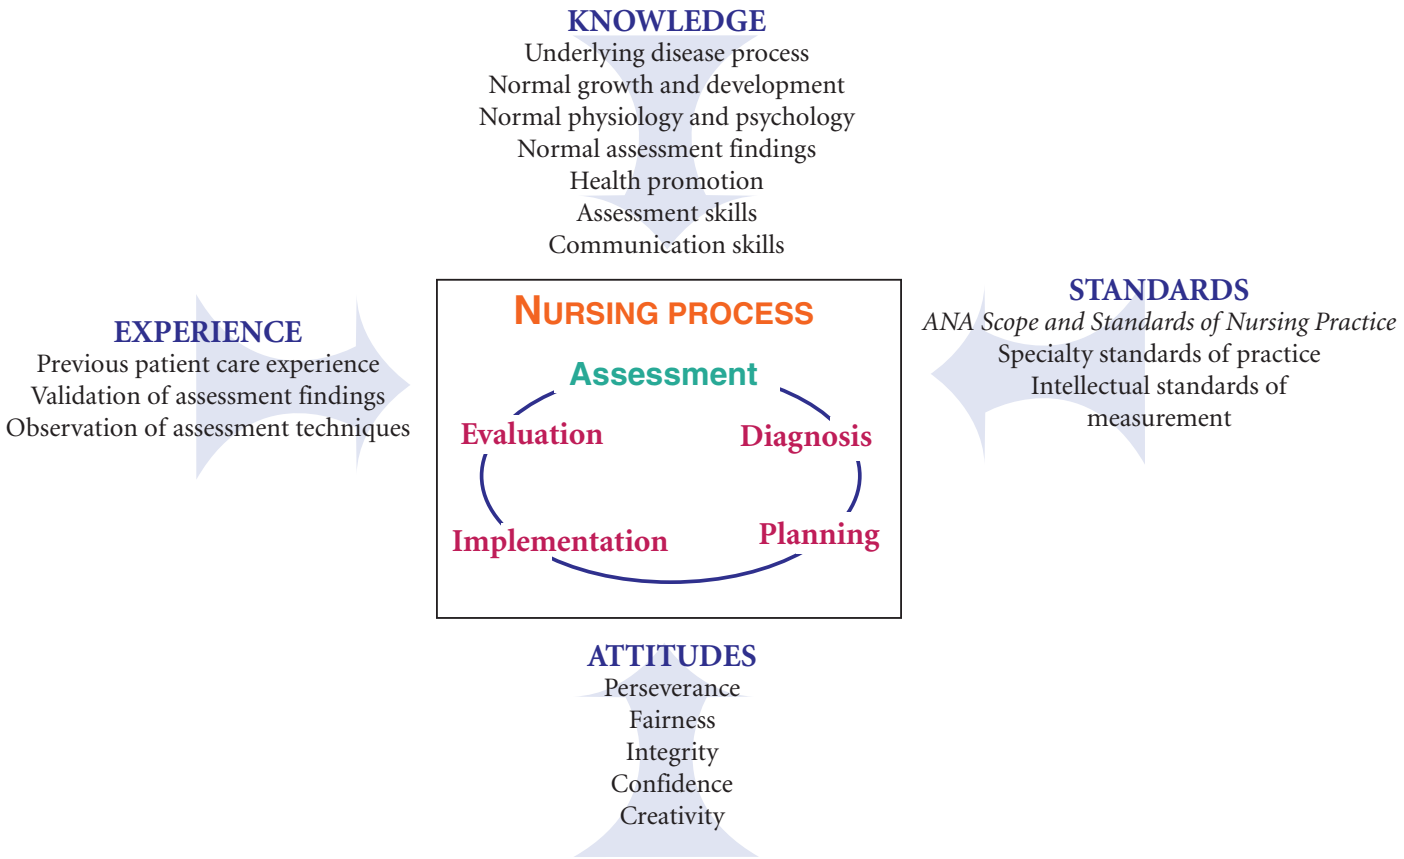

FIG. 16-2 Critical thinking and the assessment process.

- Medical record information (e.g., patient history, laboratory work, x-ray film results, multidisciplinary consultations).
- Scientific literature (evidence about assessment techniques and standards).

As you begin a patient assessment, think critically about what to assess for that specific patient. Determine which questions or measurements are appropriate based on your clinical knowledge and experience and your patient's health history and responses. When you first meet a patient, perform a quick screening. Usually your screening is based on a treatment situation. For example, a community health nurse assesses the patient's neighborhood and community; an emergency department nurse uses the ABC (airway-breathing-circulation) approach; and a surgical nurse focuses on the patient's symptoms following surgery, the expected healing response, and potential complications. For Mr. Jacobs, Tonya first focuses on the nature and severity of his pain, the risk of limited postoperative mobility, and the possibility that the wound is infected. She later expands her assessment to determine how Mr. Jacobs is adjusting emotionally to his surgery.

You learn to differentiate important data from the total data collected. A **cue** is information that you obtain through use of the senses. An **inference** is your judgment or interpretation of these cues (Fig. 16-3). For example, a patient crying is a cue that possibly implies fear or sadness. You ask the patient about any concerns and make known any nonverbal expressions you notice in an effort to direct the patient to share his or her feelings. It is possible to miss important cues when you conduct an initial overview. However, always try to interpret cues from the patient to know how in depth to make your assessment. Remember, thinking is human and imperfect. You acquire appropriate thinking processes when conducting assessments but expect to make mistakes in missing important cues (Lunney, 2006). Assessment is dynamic and allows you to freely explore relevant patient problems as you discover them.

After your observational screening, focus on the assessment cues and patterns of information that suggest problem areas. There are two approaches to a comprehensive assessment. One involves use of a structured database format, based on an accepted theoretical framework or practice standard. Gordon's model of 11 **functional health patterns** (1994) (Box 16-1) is an example. The theory or practice standard provides categories of information for you to assess. Gordon's functional health patterns model offers a holistic framework for assessment of any health problem. Tonya plans to direct her assessment of Mr. Jacobs to the cognitive-perceptual pattern to learn more about what the patient knows about the surgery and his prognosis and how he prefers to learn and make decisions about his care. Tonya is anticipating his need for education about postoperative recovery. She also plans to assess his sexuality-reproductive pattern to determine how he is accepting the potential change in sexual function resulting from surgery. A theoretical or standard-based assessment provides for a comprehensive review of a patient's health care problems.

An assessment moves from the general to the specific. For example, you assess all of Gordon's 11 functional health patterns and then determine if patterns or problems appear in your data. You then ask more focused questions about the health patterns that

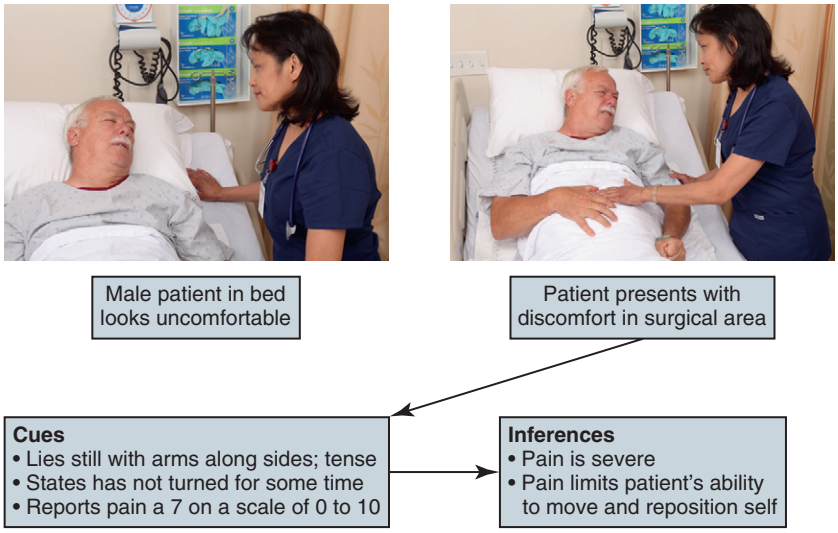

FIG. 16-3 Observational overview using cues and forming inferences.

BOX 16-1 TYPOLOGY OF 11 FUNCTIONAL HEALTH PATTERNS

Health perception–health management pattern: Describes patient's self-report of health and well-being; how patient manages health (e.g., frequency of health care provider visits, adherence to therapies at home); knowledge of preventive health practices

Nutritional-metabolic pattern: Describes patient's daily/weekly pattern of food and fluid intake (e.g., food preferences or restrictions, special diet, appetite); actual weight; weight loss or gain

Elimination pattern: Describes patterns of excretory function (bowel, bladder, and skin)

Activity-exercise pattern: Describes patterns of exercise, activity, leisure, and recreation; ability to perform activities of daily living

Sleep-rest pattern: Describes patterns of sleep, rest, and relaxation

Cognitive-perceptual pattern: Describes sensory-perceptual patterns; language adequacy, memory, decision-making ability

Self-perception–self-concept pattern: Describes patient's self-concept pattern and perceptions of self (e.g., self-concept/worth, emotional patterns, body image)

Role-relationship pattern: Describes patient's patterns of role engagements and relationships

Sexuality-reproductive pattern: Describes patient's patterns of satisfaction and dissatisfaction with sexuality pattern; patient's reproductive patterns; premenopausal and postmenopausal problems

Coping–stress tolerance pattern: Describes patient's ability to manage stress; sources of support; effectiveness of the patterns in terms of stress tolerance

Value-belief pattern: Describes patterns of values, beliefs (including spiritual practices), and goals that guide patient's choices or decisions

Data from Gordon M: *Nursing diagnosis: process and application,* ed 3, St Louis, 1994, Mosby; and Carpenito-Moyet LJ: *Nursing diagnosis: application to clinical practice,* ed 13, Philadelphia, 2009, Lippincott Williams & Wilkins.

TABLE 16-1 Example of Problem-Focused Patient Assessment: Pain

PROBLEM AND ASSOCIATED FACTORS	QUESTIONS	PHYSICAL ASSESSMENT
Nature of pain	Describe your pain for me. Place your hand over the area that hurts or is uncomfortable.	Observe nonverbal cues. Observe where patient points to pain; note if it radiates or is localized.
Precipitating factors	Do you notice if pain worsens during any activities or specific time of day? Is pain associated with movement?	Observe if patient demonstrates nonverbal signs of pain during movement, positioning, swallowing.
Severity	Rate your pain on a scale of 0 to 10.	Inspect area of discomfort; palpate for tenderness.

suggest a problem exists. You organize patterns of behavior and physiological responses that relate to a functional health category. The complete assessment of the 11 functional health patterns represents the interaction of the patient and the environment, which Gordon calls biopsychosocial integration. According to Gordon (1994), you cannot understand one health pattern without knowledge of the other patterns. Ultimately your assessment identifies functional patterns (patient strengths) and dysfunctional patterns (nursing diagnoses) that help you develop the nursing care plan.

The second approach for conducting a comprehensive assessment is the problem-oriented approach. You focus on the patient's presenting situation and begin with problematic areas such as incisional pain or limited understanding of postoperative recovery. You ask the patient follow-up questions to clarify and expand your assessment so you can understand the full nature of the problem. Later your physical examination further confirms your observations. Tonya's assessment of Mr. Jacobs ensures that she knows the type of pain he is having and the extent to which it limits his activities. Table 16-1 offers an example of a problem-focused assessment. Once you complete the assessment, thoroughly analyze the extent and nature of a patient's problem so you are able to later develop a care plan.

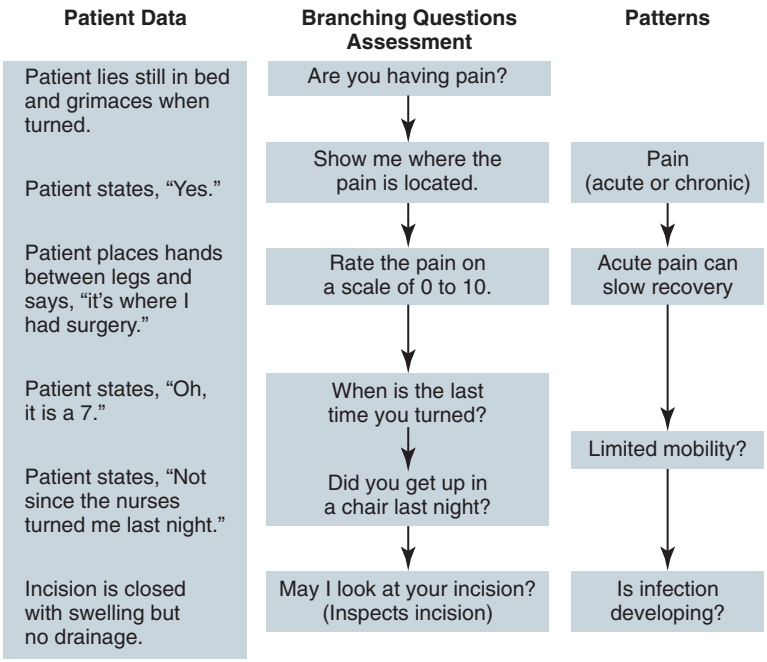

FIG. 16-4 Example of branching logic for selecting assessment questions.

Whatever approach you use to collect data, you begin to cluster cues, make inferences, and identify emerging patterns and potential problem areas. To do this well you critically anticipate, which means that you try to stay a step ahead of the assessment. Think about what the data tell you. Remember to always have supporting cues before you make an inference. Your inferences direct you to further questions. Once you ask a patient a question or make an observation, patterns form, and the information branches to an additional series of questions or observations (Fig. 16-4). Knowing how to probe and frame questions is a skill that grows with experience. You learn to decide which questions are relevant to a situation and to attend to accurate interpretations of data.

Types of Data. There are two primary sources of data: subjective and objective. **Subjective data** are your patients' verbal descriptions of their health problems. Only patients provide subjective data. For example, Mr. Jacobs's report of incision pain and his expression of concern about whether the pain means that he will not be able to go home as soon as he hoped are subjective findings. Subjective data usually include feelings, perceptions, and self-report of symptoms. Only patients provide subjective data relevant to their health condition. The data sometimes reflect physiological changes, which you further explore through objective data collection.

Objective data are observations or measurements of a patient's health status. Inspecting the condition of a surgical incision or wound, describing an observed behavior, and measuring blood pressure are examples of objective data. The measurement of objective data is based on an accepted standard such as the Fahrenheit or Celsius measure on a thermometer, inches or centimeters on a measuring tape, or known characteristics of behaviors (e.g., anxiety or fear). When you collect objective data, apply critical thinking intellectual standards (e.g., clear, precise, and consistent) so you can correctly interpret your findings.

Sources of Data. As a nurse you obtain data from a variety of sources that provide information about the patient's current level of wellness and functional status, anticipated prognosis, risk factors, health practices and goals, responses to previous treatment, and patterns of health and illness.

Patient. A patient is usually your best source of information. Patients who are conscious, alert, and able to answer questions correctly provide the most accurate information about their health care needs, lifestyle patterns, present and past illnesses, perception of symptoms, responses to treatment, and changes in activities of daily living. Always consider the setting for your assessment and your patient's condition. A patient experiencing acute symptoms in an emergency department will not offer as much information as one who comes to an outpatient clinic for a routine checkup. An older adult requires more time than someone younger, and often multiple visits are required to gather a complete database (Seidel et al., 2011) (Box 16-2). Always be attentive and show a caring presence with patients (see Chapter 7). Let a patient know you are interested in what he or she has to say. Patients are less likely to fully reveal the nature of their health care problems when nurses show little interest or are easily distracted by activities around them.

Family and Significant Others. Family members and significant others are primary sources of information for infants or children; critically ill adults; and patients who are mentally handicapped, disoriented, or unconscious. In cases of severe illness or emergency situations, families are often the only sources of information for nurses and other health care providers. The family and significant others are also important secondary sources of information. They confirm findings that a patient provides (e.g., whether he takes medications regularly at home or how well he sleeps or eats). Include the family when appropriate. Remember, a patient does not always want you to question or involve the family. You must obtain a patient's agreement to include family members or friends. Often spouses or close friends sit in during an assessment and provide their view of the patient's health problems or needs. Not only do they supply information about the patient's current health status, but they are also able to tell when changes in the patient's status occurred. Family members are often very well informed because of

BOX 16-2 FOCUS ON OLDER ADULTS

Approaches for Gathering an Older-Adult Assessment

- Listen patiently.
- Allow for pauses and time for patient to tell the story.
- Recognize normal changes associated with aging. These changes might be considered abnormal in a younger adult.
- If patient has a proxy (person who legally represents patient), gather history information from that individual.
- If patient has limited hearing or visual deficits, use nonverbal communication when conducting a patient-centered interview.
  - **Patient-directed eye gaze:** This allows the nurse or patient who is speaking to check whether information is understood. It is a signal for readiness to initiate interaction with a patient. Eye contact shows that you are interested in what the other person is saying.
  - **Affirmative head nodding:** This has an important social function. It helps to regulate an interaction (especially when alternate people speak), supports spoken language, and allows for comment on the interaction concerning the rapport and content of the communication.
  - **Smiling:** Smiling is positive and considered as a sign of good humor, warmth, and immediacy. It is most important when first establishing the nurse-patient relationship.
  - **Forward leaning:** This shows awareness, attention, and immediacy. During an interaction it also clearly suggests interest in that person.

their experiences living with the patient and observing how health problems affect daily living activities. Family and friends make important observations about the patient's needs that can affect the way care is delivered (e.g., how a patient eats a meal or how he or she makes choices).

Health Care Team. You frequently communicate with other health care team members in gathering information about patients. In the acute care setting the change-of-shift report is how nurses from one shift communicate information to nurses on the next shift (see Chapter 26). During the report you have the chance to collect the first set of information about patients assigned to your care. Researchers found that bedside rounds, also called *bedside handover,* promote patient-centered care (Chaboyer, McMurray, and Wallis, 2010). During bedside rounds, the nurse who is completing care for a shift, the patient, and the nurse assuming care for a shift share information about the patient's condition, status of problems, and treatment plan for the next shift. In some settings other health care team members participate in the rounds. When nurses, physicians, physical therapists, social workers, or other staff consult on a patient's condition, they share information about how the patient is interacting within the health care environment, the patient's reactions to treatment, and the result of diagnostic procedures or therapies. Every member of the team is a source of information for identifying and verifying information about the patient.

Medical Records. The medical record is a source for the patient's medical history, laboratory and diagnostic test results, current physical findings, and the primary health care provider's treatment plan. The record is a valuable tool for checking the consistency and similarities of your personal observations. Data in the records offer a baseline and ongoing information about the patient's response to illness and progress to date. The Health Insurance Portability and Accountability Act (HIPAA) of 1996 has a privacy rule that came into effect on April 14, 2003 to set standards for the protection of health information (USDHHS, 2003). Information in a patient's record is confidential. Each health care agency has policies governing how the patient's health information can be shared among health care providers (see Chapter 26). It is important to know organization policies for reviewing a patient's medical record for the purpose of assessment.

Other Records and the Scientific Literature. Educational, military, and employment records sometimes contain significant health care information (e.g., immunizations). If a patient received services at a community health center or different hospital, you need written permission from the patient or guardian to access the records. The HIPAA regulations protect access to patients' health information. The privacy rule allows health care providers to share protected information as long as they use reasonable safeguards. Check the policy of your agency for HIPAA guidelines.

Reviewing nursing, medical, and pharmacological literature about a patient's illness completes your assessment database. This review increases your knowledge about the patient's diagnosed problems, expected symptoms, treatment, prognosis, and established standards of therapeutic practice. The scientific literature offers evidence to direct you on how and why to conduct assessments for particular patient conditions. A knowledgeable nurse obtains relevant, accurate, and complete information for the assessment database.

Nurse's Experience. Through clinical experience a nurse observes other patients; recognizes clinical changes; and learns the types of questions to ask, choosing only the questions that will give the most useful information. A nurse's expertise develops after testing and refining inferences, questions, and principle- or standard-based expectations. For example, while caring for Mr. Jacobs, Tonya has learned what a prostatectomy incision looks like and how a patient responds to the associated discomfort. In the future Tonya will more quickly recognize the behavior of a patient in acute pain and how it affects normal mobility. Practical experience and the opportunity to make clinical decisions strengthen your critical thinking.

Methods of Data Collection

As a nurse you use patient-centered interviews, the nursing health history, physical examination, and results of laboratory and diagnostic tests to collect data for a patient's assessment database.

Patient-Centered Interview. A patient-centered *interview* is an approach for obtaining from patients the data that are needed to foster a caring nurse-patient relationship, adherence to interventions, and treatment effectiveness (Smith et al., 2006). The interview technique is the basis of a conceptual model used by nurse practitioners to form long-term therapeutic relationships with patients (Lein and Wills, 2007). However, the model has aspects that are useful to all nurses when conducting interviews for patient assessment. The partnership that forms in a patient-centered interview empowers a patient, promotes mutual decision making with the nurse, and ensures continuity of care (Dontje et al., 2004).

The expectation in a busy acute care setting such as a hospital nursing unit or clinic is for nurses to complete in a limited amount of time a patient history and nursing assessment. In the home health setting there is usually more time and fewer distractions; this allows a nurse to conduct a thorough interview. Agencies set standards for the type of information to be collected in health histories. However, there is a risk that standard assessments do not capture the patient's full story. In a patient-centered interview an organized conversation with the patient allows the patient to set the initial focus and initiate discussion about his or her chief problems or reasons for seeking health care (Lein and Wills, 2007).

A successful interview requires preparation. Collect available information about the patient before starting the interview. For example, review the information you learn during a change-of-shift report and then plan to interview the hospitalized patient as you make patient rounds and before you begin to provide ordered interventions. Create a favorable environment for the interview. A good interview environment is free of distractions, unnecessary noise, and interruptions. The patient is more likely to be open and honest if the interview is private (i.e., out of earshot of other patients, visitors, or staff). Timing is important in avoiding interruptions. If possible, set aside a 10- to 15-minute period when no other activities are planned. More time is even better but is difficult to plan when you have multiple patients. During the interview always observe your patient for signs of discomfort or fatigue and plan accordingly. Remember to let a patient decide whether to involve the family in the interview. After an initial interview, follow-up discussions allow you to learn more about a patient's situation and focus on specific problem areas. An initial patient-centered interview involves: (1) setting the stage, (2) gathering information about the patient's chief concerns or problems and setting an agenda, (3) collecting the assessment or a nursing health history, and (4) terminating the interview.

Setting the Stage. Greet the patient using his or her full name, introduce yourself and explain your role (if it is the first time you have met), and remove any barriers to privacy by closing a room curtain or shutting a door. This is the orientation phase of an interview. When you explain the reason for collecting a health history, also assure the patient that any information obtained remains confidential and is used only by health care professionals who provide his or her care. HIPAA regulations require patients to sign an authorization before you collect personal health data (USDHHS, 2003). Refer to your agency policy for the authorization process.

After giving Mr. Jacobs pain medication for his incisional pain, Tonya waits 30 minutes and decides to take the time to assess Mr. Jacobs more fully. She reviews the surgical summary in the chart and the last set of nurses' notes and enters the patient's room.

Tonya: Mr. Jacobs, I am Tonya Moore. I did not fully introduce myself earlier when you looked so uncomfortable. You look a bit more comfortable now. Can you rate your pain again for me on a scale of 0 to 10?"

Mr. Jacobs: "Yes, I think the medicine has helped. I would rate the pain a 4."

Tonya: "Good. If you're comfortable, I'd like to spend about 10 minutes to better understand what you know about your surgery and discuss it with you. Everything you share will be confidential between you and the persons providing your care. I will let nurses on the next shift know about your care."

Mr. Jacobs: "Ok, I would appreciate that."

Set an Agenda. You begin an interview by gathering information about the patient's current chief concerns or problems and setting an agenda. Remember, the best clinical interview focuses on the patient, not your agenda. Let the patient know your purpose (such as collecting an assessment or a nursing history) and ask the patient for his or her list of concerns or problems. This is the time that allows the patient to feel comfortable speaking with you and become an active partner in decisions about care. The professionalism and the competence that you show when interviewing patients strengthens the nurse-patient relationship.

Tonya: "I'm going to ask you questions about what you know about your surgery and what you need to do once you go home. But first tell me your main concerns."

Mr. Jacobs: "Concerns, you mean about the surgery?"

Tonya: "Yes, or any other health problems you would like to discuss."

Mr. Jacobs: "Well, I hope they got all of the cancer. I want to do what I need to do to get out of here as soon as I can."

Tonya: "Ok, Is there anything else?"

Mr. Jacobs: "I'm worried about my wife and me. My doctor told me that the surgery could change our ability to have sex."

Tonya: "Ok, your doctor will talk to you about your tumor. Don't be afraid to ask him questions. Which changes concern you?

Mr. Jacobs: "Well I worry that, you know, I may not be able to have intercourse."

Tonya: "It's true; that is a risk of surgery. It's important to learn from the doctor whether there was any nerve injury during surgery. It's something you need to ask him. And we can discuss it further when you know the results. Now let me ask you about your expectations after surgery so we can have a teaching plan for you. Does that sound reasonable?"

Mr. Jacobs: "Yes, I'm not sure what to expect before I get out of here."

Collect the Assessment or Nursing Health History. Start an assessment or a health history with open-ended questions that allow patients to describe more clearly their concerns and problems. For example, you can begin by having the patient explain symptoms or physical concerns, describe what he or she knows about the health problem, or ask him or her to describe health care expectations. Use attentive listening and other therapeutic communication techniques (see Chapter 24) that encourage a patient to tell his or her story. Observe verbal cues the patient expresses. Stay focused and orderly and do not rush. An initial interview (e.g., the one you conduct to collect a complete nursing history) is more extensive. You gather information about the patient's concerns and then complete all relevant sections of the nursing history (see the following dialogue). Ongoing interviews, which occur each time you interact with your patient, do not need to be as extensive. An ongoing interview allows you to update the patient's status and concerns, focus on changes previously identified, and review new problems. In the case study Tonya is gathering information to plan her postoperative teaching for Mr. Jacobs.

Tonya: "Mr. Jacobs, tell me what you expect over the next few days before you go home."

Mr. Jacobs: "Well, the doctor did tell me that I would have this catheter in my bladder after I go home. But I don't know if I have to do anything with this dressing over my stitches."

Tonya: "Un huh, go on."

Mr. Jacobs: "Will I have something to take for this pain as long as I am here, and what will I have to take at home?"

Tonya: "Yes, your doctor has ordered your pain medicine every 4 hours around the clock. You need to tell us when you begin to feel uncomfortable. You'll have a pain medicine prescribed when you go home. Do you have any other concerns or questions about your surgery?"

Mr. Jacobs: "No, I don't think so."

Tonya: "Ok. First you're right; the catheter will stay in your bladder, probably about 2 weeks. Your surgeon will have you

come to the office to have it removed. We'll talk about how you and your wife can manage the catheter, and we'll probably recommend a visit by a home health nurse. I want to look at the dressing over your incision more closely. You have a small drain in the incision to make sure fluid drains and the tissues heal well. I want to talk with you and your wife about how to observe for signs of infection."

Mr. Jacobs: "Is infection common?"

Tonya: "No, but you need to know the signs of an infection; so, if something happens once you return home, you can call your doctor quickly."

Terminating the Interview. As in the other phases of the interview, termination requires skill. You summarize your discussion with the patient and check for accuracy of the information collected. Give your patient a clue that the interview is coming to an end. For example, say, "I have just two more questions. We'll be finished in a few more minutes." This helps the patient maintain direct attention without being distracted by wondering when the interview will end. This approach also gives the patient an opportunity to ask additional questions. End the interview in a friendly manner, telling the patient when you will return to provide care.

Tonya: "Thank you, Mr. Jacobs. I am just about finished with my questions. Can I get you anything?"

Mr. Jacobs: "No, I want to rest a bit."

Tonya: You have given me a good idea of which topics we need to cover to prepare you for going home. And we'll include your wife in these discussions. Pain control is our priority right now, and we can talk further about the medicines you'll be taking when you go home. I want to go over catheter and dressing care after you rest so you feel prepared to go home. I also plan to come back and talk to you more about the surgery and its effects on your sexual function. Is there anything I can do for you now?"

Mr. Jacobs: "No, you've been helpful already."

A skillful interviewer adapts interview strategies based on the patient's responses. You successfully gather relevant health data when you are prepared for the interview and able to carry out each interview phase with minimal interruption.

Interview Techniques. How you conduct the interview is just as important as the questions you ask. Always use good communication techniques (see Chapter 24). During the interview you are responsible for directing the flow of the discussion so your patient has the opportunity to freely contribute stories about his or her health problems to enable you to get as much detailed information as possible. Some interviews are focused; others are comprehensive. Listen and consider the information shared because this helps you direct the patient to provide more detail or discuss a topic that might reveal a possible problem. Because a patient's report includes subjective information, validate data from the interview later with objective data. For example, if the patient reports difficulty breathing, this will lead you to further assess respiratory rate and lung sounds during the physical examination.

During an interview obtain information (when appropriate) about a patient's physical, developmental, emotional, intellectual, social, and spiritual dimensions. Physical and developmental information reflects normal functioning and reveals pathological changes caused by illness, trauma, or developmental crisis. Emotional information includes the patient's behavioral responses to changes in health and patterns of living. Relevant emotional information includes mood, perceptions, body image, self-concept, and attitudes about sexuality. Intellectual information includes intellectual performance, problem-solving ability, educational level, communication patterns, and attention span. Social information involves environmental, cultural, ethnic, or social patterns that affect the present or future level of wellness. You also collect information about life goals and values and religious practices, part of a patient's spirituality.

Observe the patient's nonverbal communication such as use of eye contact, body language, or tone of voice. While observing a patient's nonverbal behavior, appearance, and interaction with the environment, determine whether the data you obtain are consistent with what the patient states verbally. Your observations lead you to pursue further objective information to form accurate conclusions. Patients also obtain information during interviews. If you establish a trusting nurse-patient relationship, the patient feels comfortable asking you questions about the health care environment, planned treatments, diagnostic testing, and available resources. The patient needs this information to make decisions about goals and the plan of care.

Open-ended Questions. In a patient-centered interview you try to find out, in the patient's own words, what the health problem is and its probable cause. Remember, patients are usually the best resources in talking about their symptoms or relating their health history. Begin by asking the patient an *open-ended question* to elicit his or her story (Box 16-3). An open-ended question does not presuppose a specific answer. For example, say, "So, why did you come to the hospital today?" or "Tell me about the problems you're having." The use of **open-ended questions** prompts patients to describe a situation in more than one or two words. This technique leads to a discussion in which patients actively describe their health status. The use of open-ended questions strengthens your relationship with a patient because it shows that you want to hear the patient's thoughts and feelings. Remember to encourage and let the patient tell the entire story.

Back Channeling. Reinforce your interest in what the patient has to say through the use of good eye contact and listening skills. In addition, you may use **back channeling,** which includes active listening prompts such as "all right," "go on," or "uh-huh." These indicate that you have heard what the patient says and are interested in hearing the full story. Back channeling encourages a patient to give more details.

Probing. As a patient tells his or her story, encourage a full description without trying to control the direction the story takes. This requires you to probe with further open-ended statements

BOX 16-3 EXAMPLES OF OPEN- AND CLOSED-ENDED QUESTIONS

Open-Ended Questions

- Tell me how you are feeling.
- Tell me how your health has been.
- Describe how your wife has been helping you.
- Give me an example of how you get relief from your pain at home.

Closed-Ended Questions

- Do you think the medication is helping you?
- Who helps you at home?
- Do you understand why you are having the x-ray examination?
- Are you having pain now?
- On a scale of 0 to 10, how would you rate your pain?

such as, "Is there anything else you can tell me?" or "What else is bothering you?" Ask as many questions as it takes until the patient has nothing else to say. Remember to be observant. If the patient becomes fatigued or uncomfortable, know when to postpone an interview.

Closed-ended Questions. Once a patient finishes his or her story, use a problem-seeking interview technique. This approach takes the information provided in the patient's story and more fully describes and identifies specific problem areas. For example, a patient reports experiencing indigestion over the course of several days and acknowledges having some diarrhea and loss of appetite. The patient's explanation for the cause relates to a recent series of trips that changed his eating habits. Focus on the symptoms the patient identifies and the general indigestion problem by asking **closed-ended questions** that limit answers to one or two words such as "yes" or "no" or a number or frequency of a symptom (see Box 16-3). For example, ask, "How often does the diarrhea occur?" or "Do you have pain or cramping?" Closed-ended questions require short answers and clarify previous information or provide additional information. The questions do not encourage the patient to volunteer more information than you request. This type of questioning helps you acquire specific information about health problems such as symptoms, precipitating factors, or relief measures.

A good interviewer leaves with a complete story that contains enough details for understanding a patient's perceptions of his or her health status and the information needed to help identify nursing diagnoses and/or collaborative health problems. Always clarify or validate any information about which you are unclear.

Cultural Considerations in Assessment

As a professional nurse it is important to conduct all assessments with cultural competence. This involves a conscientious understanding of your patient's culture so you can offer better care within differing value systems and act with respect and understanding without imposing your own attitudes and beliefs (Seidel et al., 2011). To conduct an accurate and complete assessment, you need to consider a patient's cultural background. When cultural differences exist between you and a patient, respect the unfamiliar and be sensitive to a patient's uniqueness. For clarity, explain the intent of any questions you have. Avoid making stereotypes; the assumptions tied to stereotypes can lead you to collect inaccurate information. Instead draw on knowledge from your assessment and ask questions in a constructive and probing way to allow you to truly know who the patient is. You must be sure that you grasp exactly what a patient means and know exactly what a patient thinks you mean in words and actions. If you are unsure about what a patient is saying, ask for clarification to prevent making the wrong diagnostic conclusion. Do not make assumptions about a patient's cultural beliefs and behaviors without validation from the patient (Seidel et al., 2011).

Communication and culture are interrelated in the way feelings are expressed verbally and nonverbally. If you learn the variations in how people of different cultures communicate, you will gather more accurate information from patients. For example, people from Spain and France make firm eye contact when speaking. However, this is considered rude or immodest by certain Asian or Middle Eastern cultures. Americans often tend to let the eyes wander (Seidel et al., 2011). Using the right approach with eye contact shows respect for your patient and likely results in the patient sharing more information. It is easier to explore cultural differences if you allow time for thoughtful answers and ask your questions in a comfortable order. Here are examples (Seidel et al., 2011; Swartz, 2010):

- When talking about a patient's illness:
  - What do you think is wrong with you?
  - What do you call your problem?
  - What worries you the most about your sickness?
- When talking about treatments:
  - What should be done to get rid of your problem?
  - People have told me that there are ways of treating sickness that doctors and nurses don't use. Do you know any of them? Have you ever tried them?
  - Has anyone else helped you with this problem?
  - What benefit will you get from the treatment?

Nursing Health History

You gather a **nursing health history** during either your initial or an early contact with a patient. The history is a major component of assessment. Most health history forms are structured. However, based on information you gained from your patient's story (during the patient-centered interview), you learn which components of the history to explore fully and which require less detail. A good assessor learns to refine and broaden questions as needed to correctly assess the patient's unique needs. Time and patient priorities determine how complete a history will be. A comprehensive history covers all health dimensions (Fig. 16-5), allowing you to develop a complete plan of care. A nursing history usually contains the same basic components.

Biographical Information. Biographical information is factual demographic data about the patient. The patient's age, address, occupation and working status, marital status, source of health care, and types of insurance are included. Admitting office staff usually collect this information.

Reason for Seeking Health Care. This is the information you gather when you initially set an agenda during the patient-centered interview. You learn the patient's chief concerns or problems. Compare what you learn from the patient with the "chief complaint," which is often typed on the patient's admission sheet. Often you learn much more. Ask a patient why he or she is seeking health care; for example, "Tell me, Mr. Lynn, what brought you to the clinic today?" You record the patient's response in quotations to indicate the subjective response. The patient's statement is not diagnostic; instead it is his or her perception of reasons for seeking health care. Clarification of the patient's perception identifies potential needs for symptom management, education, counseling, or referral to community resources.

Patient Expectations. The assessment of patient expectations is not the same as the reason for seeking medical care, although they are often related. It is important to assess the patient's understanding of why he or she is seeking health care. Failure to identify a patient's expectations of health care providers results in poor patient satisfaction. Patient satisfaction is a standard measure of quality for all hospitals throughout the country (see Chapter 2). Patients typically have expectations of receiving information about their treatments and prognosis and a plan of care for returning home. In addition, patients expect relief of pain and other symptoms and caring expressed by health care providers. During the initial interview a patient expresses expectations when entering the health care setting. Later, as the patient interacts with health care providers, it is valuable to assess whether these expectations have changed or been met.

Present Illness or Health Concerns. If a patient presents with an illness, collect essential and relevant data about

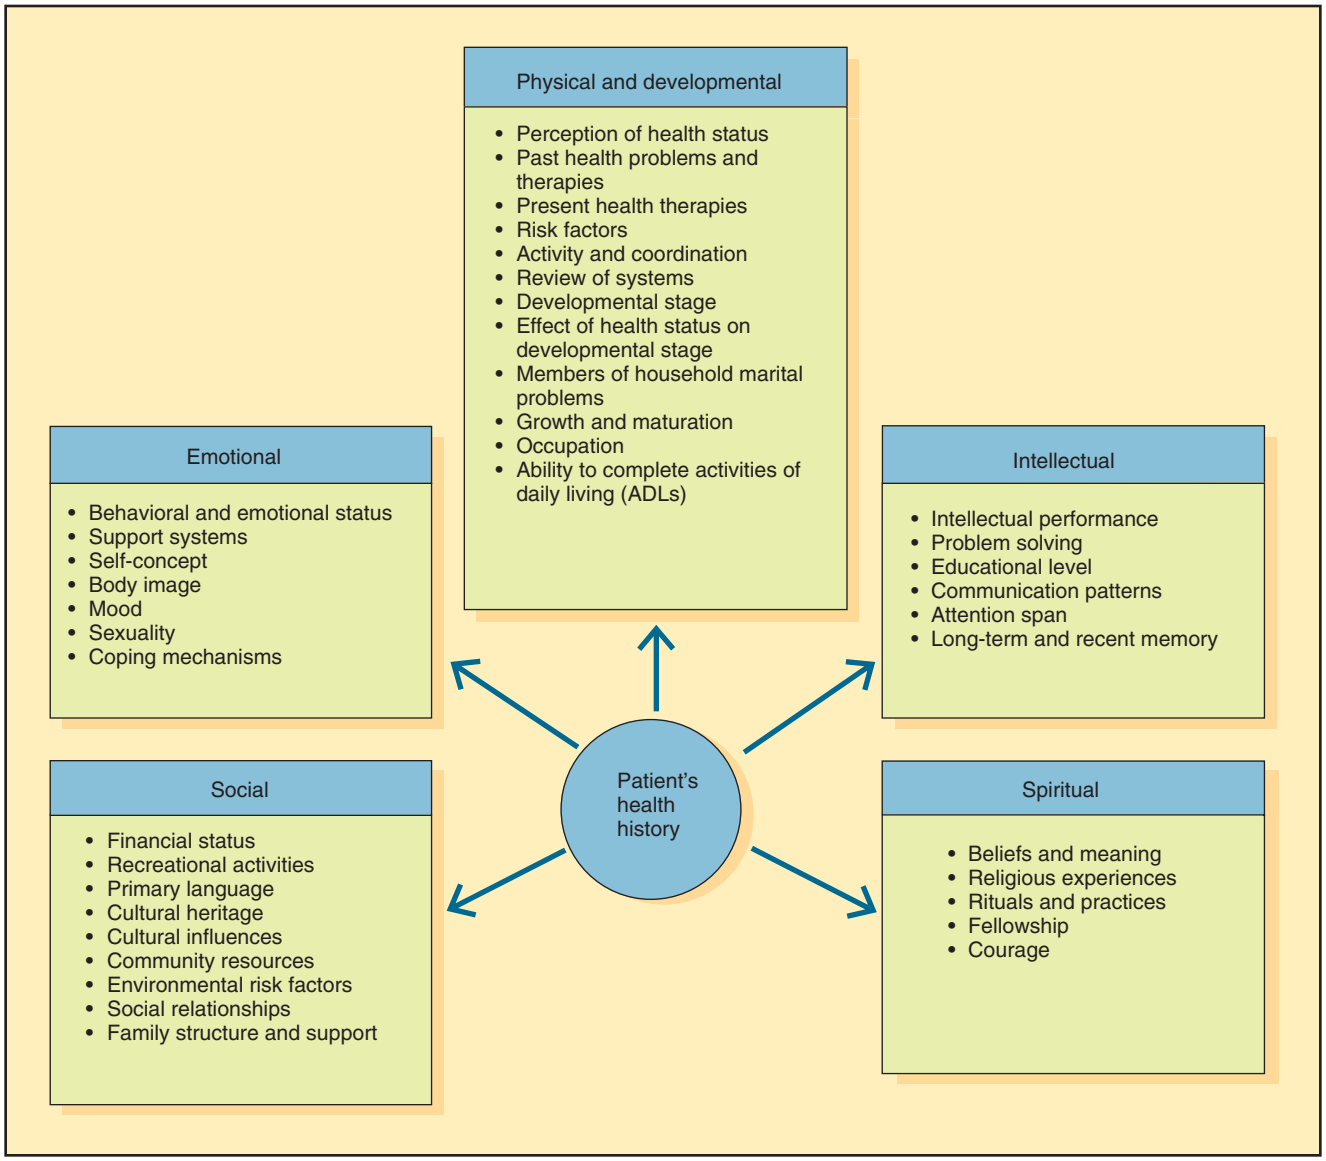

FIG. 16-5 Dimensions for gathering data for a health history.

the symptoms and their effects on the patient's health. Apply the critical thinking intellectual standards of complete and deep (see Box 15-3 on p. 199) by assessing these factors:

- Location—Where is the symptom located?
- Onset and duration—When did it start? How long has it lasted?
- Precipitating factors—What makes symptoms worse? Are there activities (e.g., exercise) that affect the symptoms?
- Relieving factors—What does the patient do to become more comfortable or relieve the symptoms?
- Quality—Have the patient describe what the symptom feels like.
- Severity—Have the patient rate the severity on a scale of 0 to 10. This gives you a baseline with which to compare in follow-up assessments.
- **Concomitant symptoms**—Does the patient experience other symptoms along with the primary symptom? For example, does nausea accompany pain?

Health History. The information in a patient's health history provides data on the patient's health care experiences and current health habits (see Fig. 16-5). Assess whether the patient has ever been hospitalized, injured, or had surgery. Include a complete medication history (including herbal and over-the-counter drugs). Also essential are descriptions of allergies, including allergic reactions to food, latex, drugs, or contact agents (e.g., soap). Asking patients if they have had problems with medications or food helps to clarify the type and amount of agent, the specific reaction, and whether the patient has required treatment. If the patient has an allergy, note the specific reaction and treatment on the assessment form.

The history also includes a description of the patient's habits and lifestyle patterns. Assessing for the use of alcohol, tobacco, caffeine, or recreational drugs (e.g., methamphetamine or cocaine) determines the patient's risk for diseases involving the liver, lungs, heart, or nervous system. Noting the type of habit and the frequency and duration of use provides essential data. Assessing

patterns of sleep (see Chapter 42), exercise (see Chapter 38), and nutrition (see Chapter 44) are also important when planning nursing care. Ultimately your aim is to match the patient's lifestyle patterns with approaches in the plan of care as much as possible.

Family History. The family history obtains data about immediate and blood relatives. The objectives are to determine whether the patient is at risk for illnesses of a genetic or familial nature and to identify areas of health promotion and illness prevention (see Chapter 6). The family history also provides information about family structure, interaction, support, and function that often is useful in planning care (see Chapter 10). For example, Tonya assesses the level of support Mrs. Jacobs is willing to provide. Mrs. Jacobs tells Tonya that the two have been married 32 years and states, "I feel I can do whatever is needed for him." Tonya's assessment shows a pattern that Mrs. Jacob is supportive and able to help her husband adjust to any initial limitations in activity when he returns home. Her assessment ultimately allows her to incorporate Mrs. Jacobs into the patient teaching portion of the patient's plan of care (see Chapter 18). If a patient's family is not supportive, it is better to not involve them in care. Stressful family relationships are sometimes a significant barrier when you try to help patients with problems involving loss, self-concept, spiritual health, and personal relationships.

Environmental History. The environmental history provides data about a patient's home and working environments with a focus on determining the patient's safety. Information about the home environment includes function of utilities, layout of rooms in the house, and the presence of any barriers or risks for injury. The history also identifies exposure to pollutants in the workplace, existence of high crime in the patient's neighborhood, and available resources that assist patients in returning to the community.

Psychosocial History. A psychosocial history reveals the patient's support system, which often includes spouse, children, other family members, and close friends. The history includes information about ways that the patient and family typically cope with stress (see Chapter 37). Behaviors patients use at home to cope with stress, such as walking, reading, or talking with a friend, can also be used as nursing interventions if the patient experiences stress while receiving health care. In addition, you need to learn if the patient has experienced any recent losses that create a sense of grief (see Chapter 36).

Spiritual Health. Life experiences and events shape a person's spirituality. The spiritual dimension represents the totality of one's being and is difficult to assess quickly (see Chapter 35). Review with patients their beliefs about life, their source for guidance in acting on beliefs, and the relationship they have with family in exercising their faith. Also assess rituals and religious practices that patients use to express their spirituality.

Review of Systems. The **review of systems (ROS)** is a systematic approach for collecting the patient's self-reported data on all body systems (see Chapter 30). You probably will not cover all of the questions in each system every time you collect a history. Nevertheless, always include some questions about each system in the nursing history, but pay close attention when a patient mentions an unexpected sign or symptom. In this case explore the system more in depth. The systems you assess depend on the patient's condition and the urgency in starting care. During the ROS ask the patient about the normal functioning of each body system and any noted changes. Such changes are subjective data because they are described as perceived by the patient. Findings from the ROS are later confirmed during the physical examination.

Documentation of History Findings. As you conduct the nursing health history, record your assessment data in a clear, concise manner using appropriate terminology. Standardized forms make it easy to enter data as the patient responds to questions. In settings that have computerized documentation, entry of assessment data becomes very easy. A clear, concise record is necessary for use by other health care professionals (see Chapter 26). Regardless of the model used in a documentation system, you need to have a thorough database that provides historical and current information about the patient's health. This information then becomes the baseline against which you evaluate any future changes.

Physical Examination

A physical examination (see Chapter 30) is an investigation of the body to determine its state of health. The examination involves use of the techniques of inspection, palpation, percussion, auscultation, and smell. A complete examination includes a patient's height, weight, vital signs, and a head-to-toe examination of all body systems. The data from a hands-on physical assessment allow you to collect valuable objective information needed to form accurate diagnostic conclusions. Always conduct an examination competently with a caring and culturally sensitive approach.

Observation of Patient Behavior

Throughout a patient-centered interview and physical examination it is important for you to closely observe a patient's verbal and nonverbal behaviors. The information adds depth to your objective database. You learn to determine if data obtained by observation matches what the patient communicates verbally. For example, if a patient expresses no concern about an upcoming diagnostic test but shows poor eye contact, shakiness, and restlessness, all suggesting anxiety, verbal and nonverbal data conflict. Observations direct you to gather additional objective information to form accurate conclusions about the patient's condition.

An important aspect of observation includes a patient's level of function: the physical, developmental, psychological, and social aspects of everyday living. Observation of level of function differs from observation you make during an interview. Observation of level of function involves watching what a patient does such as eating or making a decision about preparing a medication rather than what the patient tells you he or she can do. Observation of function often occurs in the home or in a health care setting during a return demonstration.

Diagnostic and Laboratory Data

The results of diagnostic and laboratory tests provide further explanation of alterations or problems identified during the nursing health history and physical examination. For example, during the history the patient reports having a bad cold for 6 days and at present has a productive cough with brown sputum and mild shortness of breath. On physical examination you notice an elevated temperature, increased respirations, and decreased breath sounds in the right lower lobe. You review the results of a complete blood count and note that the white blood cell count is elevated (indicating an infection). You report your results to the patient's health care provider, who orders a chest x-ray film. When the results of the x-ray film show the presence of a right lower lobe infiltrate, the health care provider makes the medical diagnosis of pneumonia. Your assessment leads to the associated nursing diagnosis of *impaired gas exchange.*

Some patients collect and monitor laboratory data in the home. For example, patients with diabetes mellitus often measure blood glucose daily. Ask patients about their routine results to determine their response to illness and information about the effects of treatment measures. Compare laboratory data with the established norms for a particular test, age-group, and gender.

Interpreting and Validating Assessment Data

Whichever clinical situation you face, assessment involves the continuous interpretation of information. This is one critical thinking aspect of assessment. The successful interpretation and validation of assessment data ensure that you have collected a complete database for your patient. Ultimately this leads you to the second step of the nursing process, in which you make clinical decisions in your patient's care. These decisions are either in the form of nursing diagnoses or collaborative problems that require treatment from several disciplines (Carpenito-Moyet, 2009) (see Chapter 17).

Interpretation. When interpreting assessment information critically, you determine the presence of abnormal findings, recognize that further observations are needed to clarify information, and begin to identify the patient's health problems. As you form a database, you begin to see patterns of data that direct you to collect more information and clarify what you have. The patterns of data reveal meaningful and usable clusters. A data cluster is a set of signs or symptoms that you group together in a logical way (Box 16-4). The clusters begin to clearly identify the patient's health problems.

Data Validation. Before you complete data interpretation, validate the collected information you have to avoid making incorrect inferences. **Validation** of assessment data is the comparison of data with another source to determine data accuracy. For example, you observe a patient crying and logically infer that it is related to hospitalization or a medical diagnosis. Making such an initial inference is not wrong, but problems result if you do not validate the inference with the patient. Instead ask, "I notice that you have been crying. Can you tell me about it?" By validating you discover the real reason for the patient's crying behavior. Ask patients to validate unclear information obtained during an interview and history. Validate findings from the physical examination and observation of patient behavior by comparing data in the medical record and consulting with other nurses or health care team members. Often family or friends can validate your assessment information.

Validation opens the door for gathering more assessment data because it involves clarifying vague or unclear data. Occasionally you need to reassess previously covered areas of the nursing history or gather further physical examination data. Continually analyze and think about a patient's database to make concise, accurate, and meaningful interpretations. Critical thinking applied to assessment enables you to fully understand the patient's problems, judge the extent of the problems carefully, and discover possible relationships between the problems.

Tonya gathered initial data about the character of Mr. Jacob's incisional pain. She applied critical thinking in her assessment as she considered what she knew about a prostatectomy and the anticipated postoperative problems that can develop. As she assessed Mr. Jacobs, she applied intellectual standards, being precise (location of pain), consistent and accurate (use of pain-rating scale), and complete (probing for factors that worsen pain). However, Mr. Jacobs was also having trouble resting, showed irritability at times when questioned, and had poor eye contact when speaking. Tonya saw the need for more information. She directed her assessment to learn more about Mr. Jacob's concerns about the success of his surgery and what to expect during recovery. Tonya asks, "Mr. Jacobs, you earlier said that you hoped they got all of the cancer. You seem uneasy. Can you tell me how you feel about your surgery?" Mr. Jacobs tells Tonya, "My friend had prostate cancer. He had surgery, but it came back. He had a long fight." Tonya could make several inferences from this information, but she applies the critical thinking attitude of discipline and stays focused to ensure that her assessment is accurate and comprehensive. She validates her inferences with Mr. Jacobs, "You sound anxious about the outcome of your surgery. Your friend had a recurrence of his cancer. Are you uncertain about what to expect?" Mr. Jacobs validates Tonya's assessment, "Yes, I'm worried. My friend and family members have died from cancer. My wife depends on me; well, we depend on one another. I'm a person who likes to have information so I can make the right decisions and know what to do." Tonya now has more complete information to help her identify Mr. Jacob's health problems and make correct diagnostic conclusions.

Data Documentation

Data documentation is the last part of a complete assessment. The timely, thorough, and accurate documentation of facts is required in recording patient data. If you do not record an assessment finding or problem interpretation, it is lost and unavailable to anyone else caring for the patient. If information is not specific, the reader is left with only general impressions. Observing and recording patient status are legal and professional responsibilities. The Nurse Practice Acts in all states and the American Nurses Association *Nursing's Social Policy Statement* (2010) require accurate data collection and recording as independent functions essential to the role of the professional nurse.

Being factual is easy after it becomes a habit. The basic rule is to record all observations succinctly. When recording data, pay attention to facts and be as descriptive as possible. Anything heard, seen, felt, or smelled should be reported exactly. Record objective information in accurate terminology (e.g., weighs 170 kg, abdomen is soft and nontender to palpation). Record subjective information from a patient in quotation marks. When entering data, do not generalize or form judgments through written communication. Conclusions about such data become nursing diagnoses and thus must be factual and accurate. As you gain experience and become familiar with clusters and patterns of signs and symptoms, you correctly conclude the existence of a problem. Review Chapter 26 for details on documentation.

BOX 16-4 RECOGNIZING DATA CLUSTERS

Interpret how data form patterns or trends.

- Patient uncomfortable: remains still in bed
  - Limits turning
  - Grimaces when moving
- Mobility limited: limits turning
  - Only out of bed once after surgery
- Knowledge about surgery: asks questions about pain control
  - Unsure about dressing care
  - Asks about risk of infection
- Appears anxious or uneasy: poor eye contact at times
  - Restless
  - Asks numerous questions

Concept Mapping

Most of the patients for whom you care present with more than one health problem. A concept map is a visual representation that allows you to graphically show the connections between a patient's many health problems. Hinck et al. (2006) showed that concept mapping is an effective learning strategy to understand the relationships that exist among patient problems (Box 16-5). Concept maps help students evaluate their thinking patterns and see the reasons for nursing care (Taylor and Wros, 2007). Your first step in concept mapping is to organize the assessment data you collect for your patient. Placing all of the cues together into the clusters that form patterns leads you to the next step of the nursing process, nursing diagnosis (see Chapter 17). Through concept mapping you obtain a holistic perspective of your patient's health care needs, which ultimately leads you to making better clinical decisions. Fig. 16-6 shows the first step in a concept map that Tonya will develop for Mr. Jacobs as a result of her nursing assessment. Tonya begins to identify patterns reflecting the problems Mr. Jacobs faces. As a result of the assessment she has noted: a mobility restriction, discomfort over incision, need for instruction about surgical postoperative care, and the patient's concern over effects that surgery will have on relationship with wife. The next step (see Chapter 17) is to identify specific nursing diagnoses so appropriate nursing interventions can be provided.

BOX 16-5 EVIDENCE-BASED PRACTICE

Using Concept Maps as a Learning Strategy

PICO Question: Is a concept map an effective strategy for nurses and nursing students to use to identify nursing concepts (nursing diagnoses)?

Evidence Summary

Concept mapping is a learning strategy used to help nursing students and staff nurses understand key nursing concepts (such as nursing diagnoses and clinical problems) and the relationship among those concepts. For example, a learner is able to view various aspects of a patient's health problems and the cause-and-effect associations to enhance critical thinking. Studies have tested the effectiveness of concept mapping on the learning of nursing students and staff nurses. Research also has investigated satisfaction with the strategy. Results show that concept mapping significantly improves students' and nurses' abilities to see patterns and relationships in concepts to plan and evaluate nursing care. Maps are effective in helping nurses learn components of new clinical protocols. Evaluation also reveals positive student and staff satisfaction (Hinck et al., 2006; Phelps et al., 2009).

Application to Nursing Practice

- A concept map organizes and links information about a patient in unique and meaningful ways.
- The relationships seen among multiple nursing diagnoses or clinical concepts allow nursing students and nurses to plan interventions that are therapeutic for more than one problem area.
- Use of concept maps helps nursing students and nurses reflect and critically think about relationships among clinical information in a way that promotes clinical decision making.

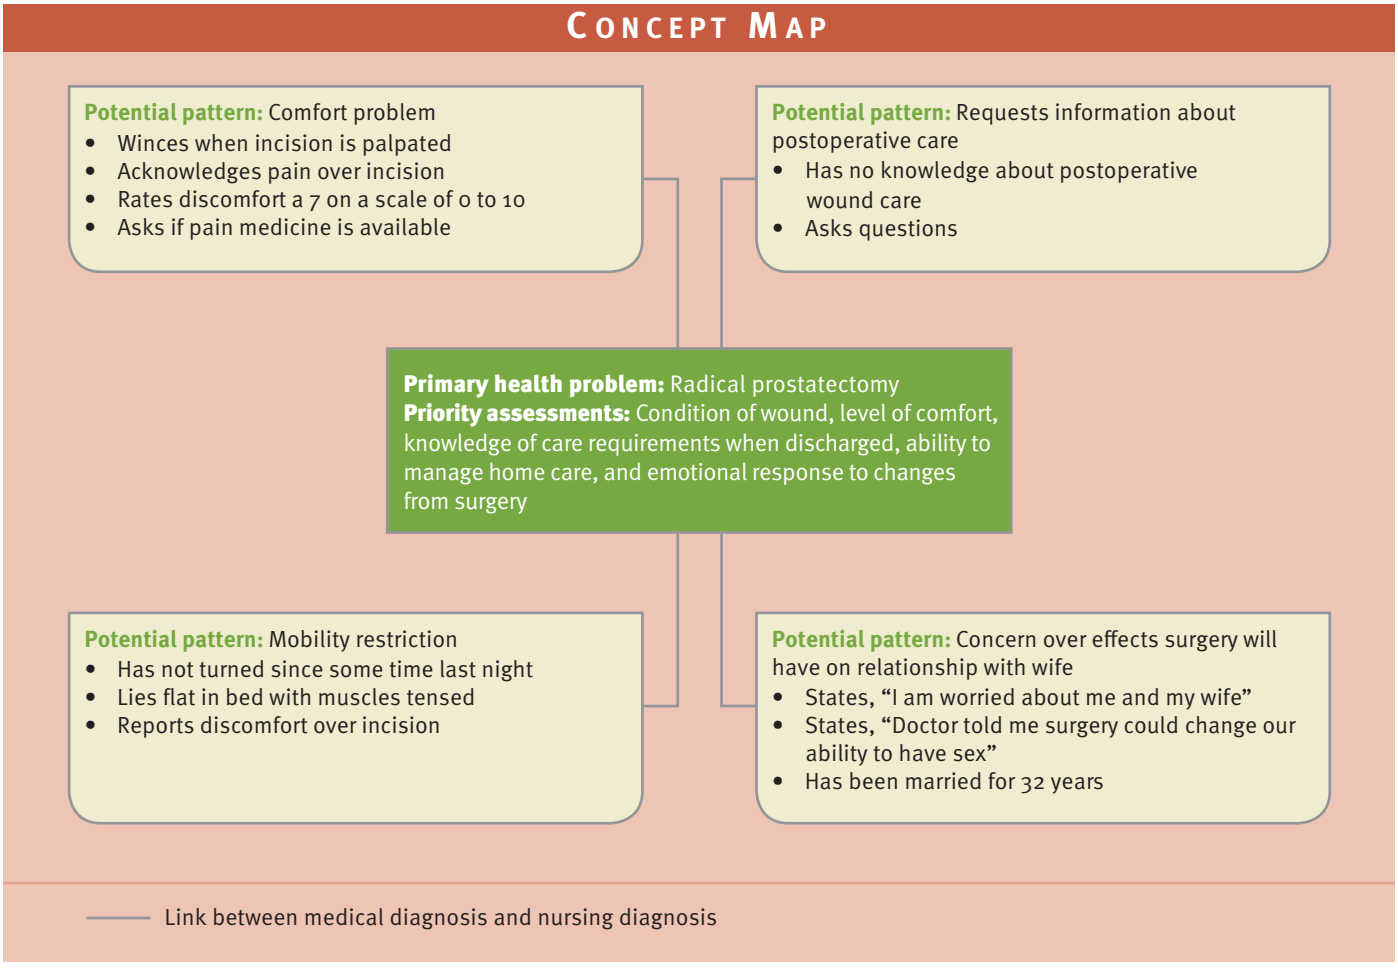

FIG. 16-6 Concept map for Mr. Jacobs: Assessment.

KEY POINTS

- The nursing process is a variation of scientific reasoning that involves five steps: assessment, nursing diagnosis, planning, implementation, and evaluation.
- Assessment involves collecting information from the patient and secondary sources (e.g., family members) along with interpreting and validating the information to form a complete database.
- There are two approaches to gathering a comprehensive assessment: use of a structured database format and use of a problem-focused approach.
- Once a patient provides subjective data, explore the findings further by collecting objective data.
- During assessment critically anticipate and use an appropriate branching set of questions or observations to collect data and cluster cues of assessment information to identify emerging patterns and problems.
- In a patient-centered interview an organized conversation with the patient allows the patient to set the initial focus and initiate discussion about his or her health problems.
- A successful interview requires preparation, including reviewing all available information about the patient, preparing the interview environment, and timing to avoid interruptions.
- An initial patient-centered interview involves: (1) setting the stage, (2) gathering information about the patient's problems and setting an agenda, (3) collecting the assessment or a nursing health history, and (4) terminating the interview.
- The best clinical interview focuses on the patient, not your own agenda.
- During an assessment interview encourage patients to tell their stories about their illnesses or health care problems.
- It is easier to explore cultural differences if you allow time for thoughtful answers and ask your questions in a comfortable order.
- When collecting a complete nursing history, let the patient's story guide you in fully exploring the components related to his or her problems.
- Successful interpretation and validation of assessment data ensure that you have collected a complete database.

CRITICAL THINKING EXERCISES

Preparing for Clinical Practice

Tonya is planning to return to Mr. Jacob's room and spend more time discussing his concerns about going home and what to expect. She knows that Mrs. Jacobs usually comes in to visit around 11 AM, just before lunchtime. Tonya believes that Mrs. Jacobs will be an important source of support in providing Mr. Jacobs any ongoing home care. The surgeon has ordered home health for Mr. Jacobs since he is going home with an indwelling catheter. Tonya's assessment will be shared with the home health agency.

1. Tonya goes to Mr. Jacob's room and asks if it is okay to include Mrs. Jacobs in the discussion about his postoperative care. Explain why Tonya has asked for Mr. Jacob's consent.
2. Tonya and Mr. Jacobs have the following interaction:
   Tonya: Mr. Jacobs, I want to know what you understand about your urinary catheter.
   Mr. Jacobs: I think it helps me to pass urine until I heal.
   Tonya: Uh huh … go on.
   Mr. Jacobs: I think the doctor said it would still be in when I go home.
   Tonya's phrase "uh huh … go on" is an example of what interviewing technique? Explain why it is useful.
3. While in Mr. Jacob's room, Tonya discusses his knowledge about surgery and performs a routine assessment of his current condition. Tonya has collected information from her assessment of Mr. Jacobs. Identify each of the items in the assessment list as either subjective or objective data.
   1. Urine output for last 4 hours is 240 mL.
   2. Mr. Jacobs rates pain severity at a level 3.
   3. Incision is 15 cm long and without drainage.
   4. Mr. Jacobs states, "I don't know when I can start to drive when I go home".

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse assesses a patient who comes to the pulmonary clinic. "I see that it's been over 6 months since you've been in, but your appointment was for every 2 months. Tell me about that. Also I see from your last visit that the doctor recommended routine exercise. Can you tell me how successful you have been following his plan?" The nurse's assessment covers which of Gordon's functional health patterns?
   1. Value-belief pattern
   2. Cognitive-perceptual pattern
   3. Coping–stress-tolerance pattern
   4. Health perception–health management pattern
2. The nurse asks a patient, "Describe for me your typical diet over a 24-hour day. What foods do you prefer? Have you noticed a change in your weight recently?" This series of questions would likely occur during which phase of a patient-centered interview?
   1. Setting the stage
   2. Gathering information about the patient's chief concerns
   3. Collecting the assessment
   4. Termination
3. What type of interview techniques does the nurse use when asking these questions, "Do you have pain or cramping?" "Does the pain get worse when you walk?" (Select all that apply.)
   1. Active listening
   2. Open-ended questioning
   3. Closed-ended questioning
   4. Problem-oriented questioning
4. What technique(s) best encourage(s) a patient to tell his or her full story? (Select all that apply.)
   1. Active listening
   2. Back channeling
   3. Validating
   4. Use of open-ended questions
   5. Use of closed-ended questions
5. A nurse gathers the following assessment data. Which of the following cues form(s) a pattern suggesting a problem? (Select all that apply.)
   1. The skin around the wound is tender to touch.
   2. Fluid intake for 8 hours is 800 mL.
   3. Patient has a heart rate of 78 and regular.
   4. Patient has drainage from surgical wound.
   5. Body temperature is 101° F (38.3° C).
   6. Patient asks, "I'm worried that I won't return to work when I planned."

6. The nurse makes the following statement during a change of shift report to another nurse. "I assessed Mr. Diaz, my 61-year-old patient from Chile. He fell at home and hurt his back 3 days ago. He has some difficulty turning in bed, and he says that he has pain that radiates down his leg. He rates his pain at a 6, but I don't think it's that severe. You know that back patients often have chronic pain. He seems fine when talking with his family. Have you cared for him before?" What does the nurse's conclusion suggest?
   1. The nurse is making an accurate clinical inference.
   2. The nurse has gathered cues to identify a potential problem area.
   3. The nurse has allowed stereotyping to influence her assessment.
   4. The nurse wants to validate her information with the other nurse.
7. A nurse checks a patient's intravenous (IV) line in his right arm and sees inflammation where the catheter enters the skin. She uses her finger to apply light pressure (i.e., palpation) just above the IV site. The patient tells her the area is tender. The nurse checks to see if the IV line is running at the correct rate. This is an example of what type of assessment?
   1. Agenda setting
   2. Problem-focused
   3. Objective
   4. Use of a structured database format
8. A patient who visits the allergy clinic tells the nurse practitioner that he is not getting relief from shortness of breath when he uses his inhaler. The nurse decides to ask the patient to explain how he uses the inhaler, when he should take a dose of medication, and what he does when he gets no relief. On the basis of Gordon's functional health patterns, which pattern does the nurse assess?
   1. Health perception–health management pattern
   2. Value-belief pattern
   3. Cognitive-perceptual pattern
   4. Coping–stress tolerance pattern
9. A nurse is conducting a patient-centered interview. Place the statements from the interview in the correct order.
   1. "You say you've lost weight. Tell me how much weight you have lost in the last month."
   2. "My name is Todd. I'll be the nurse taking care of you today. I'm going to ask you a series of questions to gather your health history."
   3. "I have no further questions. Thank you for your patience."
   4. "Tell me what brought you to the hospital."
   5. "So, to summarize, you've lost about 6 pounds in the last month, and your appetite has been poor—correct?"
10. Which of the following are examples of data validation? (Select all that apply.)
   1. The nurse assesses the patient's heart rate and compares the value with the last value entered in the medical record.
   2. The nurse asks the patient if he is having pain and then asks the patient to rate the severity.
   3. The nurse observes a patient reading a teaching booklet and asks the patient if he has questions about its content.
   4. The nurse obtains a blood pressure value that is abnormal and asks the charge nurse to repeat the measurement.
   5. The nurse asks the patient to describe a symptom by saying, "Go on."
11. A patient tells the nurse during a visit to the clinic that he has been sick to his stomach for 3 days and he vomited twice yesterday. Which of the following responses by the nurse is an example of probing?
   1. So you've had an upset stomach and began vomiting—correct?
   2. Have you taken anything for your stomach?
   3. Is anything else bothering you?
   4. Have you taken any medication for your vomiting?
12. The nurse is assessing the character of a patient's migraine headache and asks, "Do you feel nauseated when you have a headache?" The patient's response is "yes." In this case the finding of nausea is which of the following?
   1. An objective finding
   2. A clinical inference
   3. A validation
   4. A concomitant symptom
13. During the review of systems in a nursing history, a nurse learns that the patient has been coughing mucus. Which of the following nursing assessments would be best for the nurse to use to confirm a lung problem? (Select all that apply.)
   1. Family report
   2. Chest x-ray film
   3. Physical examination with auscultation of the lungs
   4. Medical record summary of x-ray film findings
14. A nurse working on a medicine nursing unit is assigned to a 78-year-old patient who just entered the hospital with symptoms of H1N1 flu. The nurse finds the patient to be short of breath with an increased respiratory rate of 30 breaths/min. He lost his wife just a month ago. The nurse's knowledge about this patient results in which of the following assessment approaches at this time? (Select all that apply.)
   1. A problem-focused approach
   2. A structured comprehensive approach
   3. Using multiple visits to gather a complete database
   4. Focusing on the functional health pattern of role-relationship
15. A 58-year-old patient with nerve deafness has come to his doctor's office for a routine examination. The patient wears two hearing aids. The advanced practice nurse who is conducting the assessment uses which of the following approaches while conducting the interview with this patient? (Select all that apply.)
   1. Maintain a neutral facial expression
   2. Lean forward when interacting with the patient
   3. Acknowledge the patient's answers through head nodding
   4. Limit direct eye contact

Answers: **1.** 4; **2.** 3; **3.** 3, 4; **4.** 1, 2, 4; **5.** 1, 4, 5; **6.** 3; **7.** 2; **8.** 1; **9.** 2, 4, 1, 5, 3; **10.** 1, 4; **11.** 3; **12.** 4; **13.** 3, 4; **14.** 1, 3; **15.** 2, 3.

Nursing Diagnosis

OBJECTIVES

- Discuss the purposes of using nursing diagnosis in practice.
- Differentiate among a nursing diagnosis, medical diagnosis, and collaborative problem.
- Discuss the relationship of critical thinking to the nursing diagnostic process.
- Describe the steps of the nursing diagnostic process.
- Explain how defining characteristics and the etiological process individualize a nursing diagnosis.
- Describe sources of diagnostic errors.
- Identify nursing diagnoses from a nursing assessment.

KEY TERMS

During the nursing assessment process (see Chapter 16) a nurse gathers the information needed to make diagnostic conclusions about patient care. A diagnosis is a clinical judgment based on information. You review information collected about a patient, see cues and patterns in the data, and identify the patient's specific health care problems. Some of the conclusions lead to identifying nursing diagnoses, whereas others do not. Diagnostic conclusions include problems treated primarily by nurses (nursing diagnoses) and those requiring treatment by several disciplines (collaborative problems). Together nursing diagnoses and collaborative problems represent the range of patient conditions that require nursing care (Carpenito-Moyet, 2009).

When physicians refer to commonly accepted medical diagnoses such as diabetes mellitus or osteoarthritis, they all know the meaning of the diagnoses and the standard approaches for treatment. A **medical diagnosis** is the identification of a disease condition based on a specific evaluation of physical signs, symptoms, the patient's medical history and the results of diagnostic tests and procedures. Physicians are licensed to treat diseases and conditions described in medical diagnostic statements.

Nursing has a similar diagnostic language. Nursing diagnosis, the second step of the nursing process (Fig. 17-1), classifies health problems within the domain of nursing. A **nursing diagnosis** such as *acute pain* or *nausea* is a clinical judgment about individual, family, or community responses to actual and potential health problems or life processes that the nurse is licensed and competent to treat (NANDA International, 2012). What makes the nursing diagnostic process unique is having patients involved, when possible, in the process.

A **collaborative problem** is an actual or potential physiological complication that nurses monitor to detect the onset of changes in a patient's status (Carpenito-Moyet, 2009). When collaborative problems develop, nurses intervene in collaboration with personnel from other health care disciplines. Nurses manage collaborative problems such as hemorrhage, infection, and paralysis using medical, nursing, and allied health (e.g., physical therapy) interventions. For example, a patient with a surgical wound is at risk for developing an infection; thus a physician prescribes antibiotics. The nurse monitors the patient for fever and other signs of infection and implements appropriate wound care measures. A dietitian recommends a therapeutic diet high in protein and nutrients to promote wound healing.

Selecting the correct nursing diagnosis on the basis of an assessment involves diagnostic expertise (i.e., being able to make quick and accurate conclusions from patient data) (Cho, Staggers, and Park, 2010). This is essential because accurate diagnosis of patient problems ensures that you select more effective and efficient nursing interventions. Diagnostic expertise improves with time. Consider the case study involving Mr. Jacobs and his nurse, Tonya Moore.

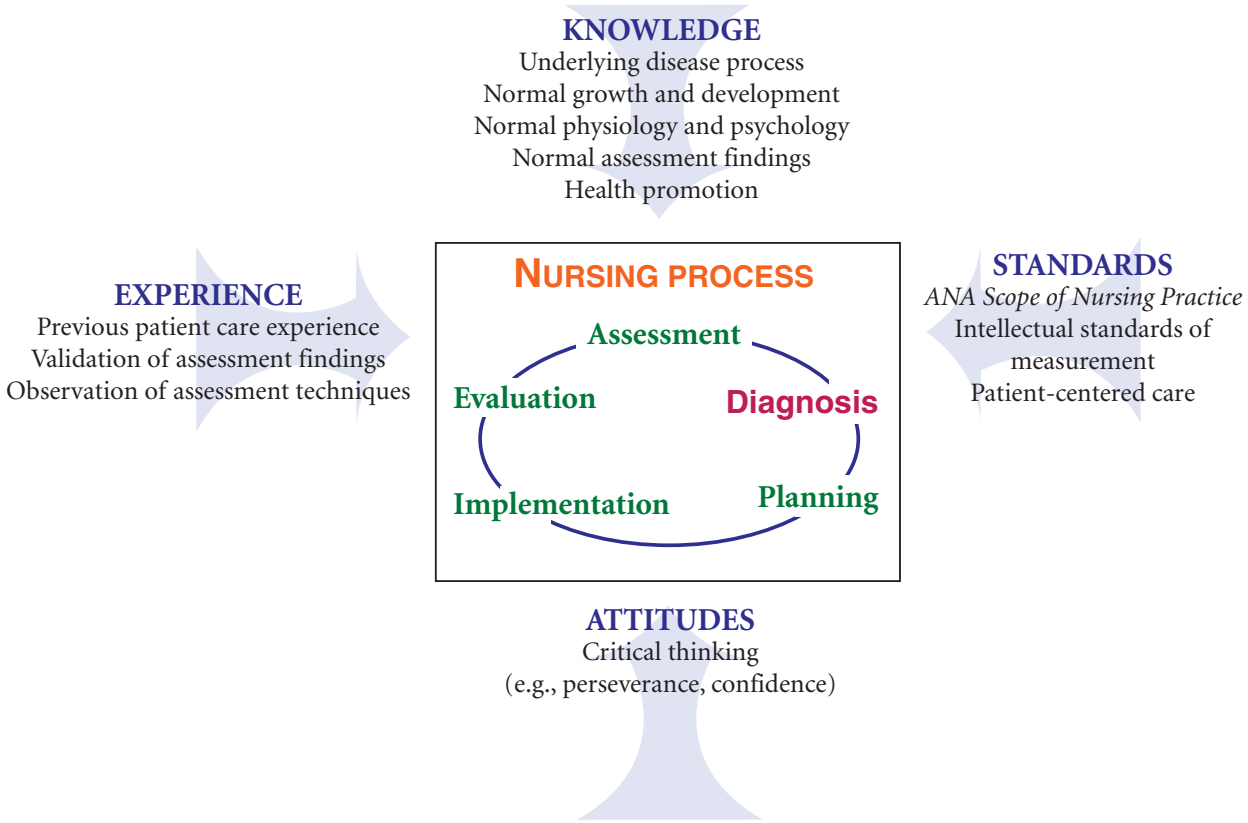

FIG. 17-1 Critical thinking and the nursing diagnostic process.

During her assessment Tonya gathers information suggesting that Mr. Jacobs possibly has a number of health problems. The data about Mr. Jacobs show patterns in four areas: comfort, requesting information about postoperative care, mobility restriction, and worries about his future and his relationship with Mrs. Jacobs. Selecting specific diagnostic labels for these problem areas allows Tonya to develop a relevant and appropriate plan of care. For example, with respect to Mr. Jacobs' request for information, there are two accepted nursing diagnostic labels for problems related to knowledge: ***deficient knowledge*** *and* ***readiness for enhanced knowledge.*** *Knowing the difference between these two diagnoses and identifying which one applies to Mr. Jacobs is key to selecting the right type of interventions for his problem. A physician needs to rule out rheumatoid arthritis versus osteoarthritis to be sure that a patient receives the right form of medical treatment. Tonya analyzes her information about Mr. Jacobs and identifies the factors that show the pattern that fits a specific diagnosis. This means that Tonya considers that the patient has no knowledge about or experience with postoperative wound care and freely asks questions. Tonya knows that these factors are defining characteristics that allow her to make an accurate nursing diagnosis.*

HISTORY OF NURSING DIAGNOSIS

Nursing diagnosis was first introduced in the nursing literature in 1950 (McFarland and McFarlane, 1989). Fry (1953) proposed the formulation of nursing diagnoses and an individualized nursing care plan to make nursing more creative. This emphasized the nurse's independent practice (e.g., patient education and symptom relief) compared with the dependent practice driven by physicians' orders (e.g., medication administration and intravenous fluids). Initially professional nursing did not support nursing diagnoses. The *Model Nurse Practice Act* of the American Nurses Association (ANA) (1955) excluded diagnosis or prescriptive therapies. As a result, few nurses used nursing diagnoses in their practice.

When Yura and Walsh (1967) developed the theory of the nursing process, it included four parts: assessment, planning, implementation, and evaluation. However, nurse leaders soon recognized that assessment data needed to be clustered into patterns and interpreted before nurses could complete the remaining steps of the process (NANDA International, 2012). You cannot plan and then intervene correctly if you do not know the problems with which you are dealing. In 1973 the first national conference to identify the interpretations of data that represent the health conditions that are of a concern to nursing was held. The first conference on nursing diagnosis identified and defined 80 nursing diagnoses (Gebbie, 1998). The list continues to grow on the basis of nursing research and the work of members of the **North American Nursing Diagnosis Association International (NANDA-I)** (NANDA International, 2012).

With use of the term *nursing diagnosis,* nurses make diagnostic conclusions and therefore the clinical decisions necessary for safe and effective nursing practice. The ANA's paper *Scope of Nursing Practice* (1987), which defined nursing as the diagnosis and treatment of human responses to health and illness, helped strengthen

BOX 17-1 EVIDENCE-BASED PRACTICE

Nursing Diagnosis Impact on Nursing Practice

PICO Question: Has the use of nursing diagnosis by nurses improved outcomes in nursing practice?

Evidence Summary

A total of 36 articles from the nursing literature were reviewed to identify the outcomes of nursing diagnosis (Muller-Staub et al., 2006). The articles included reports on the effects of nursing diagnosis on documentation of assessment, frequency, and accuracy of nursing diagnosis in practice and coherence between nursing diagnoses and selected interventions and outcomes. This systematic review found that the use of nursing diagnosis improved the quality of documented patient assessments in 14 of the studies. Coherence among nursing diagnosis and interventions improved in 8 of the studies. A total of 10 studies reported that nursing diagnosis improved identification of commonly occurring diagnoses in similar practice settings. Results varied since a total of 8 studies found no evidence that standardized electronic documentation of nursing diagnosis led to better nursing outcomes. Overall the trend shows that use of nursing diagnosis has favorable effects in nursing practice.

Application to Nursing Practice

- Develop a familiarity with agency documentation systems and the use of nursing diagnosis.
- Use of nursing diagnosis offers an approach to ensure more comprehensive nursing assessment.
- Use of nursing diagnosis can improve selection of nursing interventions by all nurses in a practice setting.

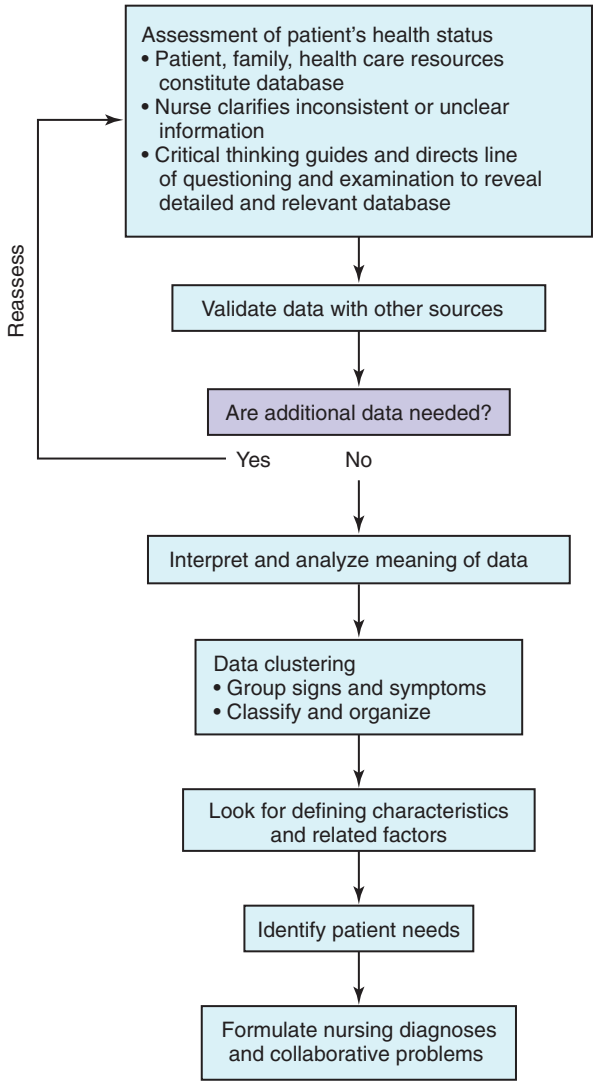

FIG. 17-2 Nursing diagnostic process.

the definition of nursing diagnosis. In 1980 and 1995 the ANA included diagnosis as a separate activity in its publication *Nursing: a Social Policy Statement* (ANA, 2003). It continues today in the ANA's most recent policy statement (ANA, 2010). As a result, most state Nurse Practice Acts include nursing diagnosis as part of the domain of nursing practice.

Research in the field of nursing diagnosis continues to grow (Box 17-1). As a result, NANDA-I continually develops and adds new diagnostic labels to the NANDA International listing (Box 17-2). The use of standard formal nursing diagnostic statements serves several purposes in nursing practice:

- Provides a precise definition of a patient's problem that gives nurses and other members of the health care team a common language for understanding the patient's needs
- Allows nurses to communicate (e.g., written and electronic) what they do among themselves with other health care professionals and the public
- Distinguishes the nurse's role from that of the physician or other health care provider
- Helps nurses focus on the scope of nursing practice
- Fosters the development of nursing knowledge
- Promotes creation of practice guidelines that reflect the essence of nursing

CRITICAL THINKING AND THE NURSING DIAGNOSTIC PROCESS

The diagnostic process requires you to use critical thinking (see Chapter 15). In the practice of nursing it is important for you to know nursing diagnoses, their definitions and the defining characteristics for making diagnoses, related factors pertinent to the diagnoses, and the interventions suited for treating the diagnoses (NANDA International, 2012). This means that you need to know how to access this information easily within the agency in which you work because the information is much too extensive for you to memorize. Sources of information about nursing diagnoses include faculty, advanced practice nurses, documentation systems, and in some settings practice guidelines or protocols. Experience also plays a role in becoming adept at nursing diagnosis. Learn from the patients for whom you care because this helps you think more carefully about your assessment information and what it means. The application of critical thinking attitudes and standards helps you to be thorough, comprehensive, and accurate when identifying nursing diagnoses that apply to your patients.

The diagnostic reasoning process involves using the assessment data you gather about a patient to logically explain a clinical judgment, in this case a nursing diagnosis. The diagnostic process flows from the assessment process and includes decision-making steps (Fig. 17-2). These steps include data clustering, identifying patient health problems, and formulating the diagnosis.

Used by arrangement with Blackwell Publishing Limited, a company of John Wiley and Sons, Inc. In order to make safe and effective judgments using NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in the work.

Data Clustering

A **data cluster** is a set of signs or symptoms gathered during assessment that you group together in a logical way. In the case of Mr. Jacobs, Tonya clustered together the signs and symptoms of "patient wincing when incision palpated," "patient acknowledges discomfort over incision," "patient rates discomfort a 7 on a scale of 0 to 10," and "pain increases with movement." Tonya analyzed these data to recognize the pattern of a comfort problem. Data clusters are patterns of data that contain **defining characteristics,** the clinical criteria that are observable and verifiable. Each **clinical criterion** is an objective or subjective sign, symptom, or risk factor that, when analyzed with other criteria, leads to a diagnostic conclusion.

BOX 17-3 EXAMPLES OF NANDA INTERNATIONAL–APPROVED NURSING DIAGNOSES WITH DEFINING CHARACTERISTICS

DIAGNOSIS: ACUTE PAIN	DIAGNOSIS: CHRONIC PAIN
Defining Characteristics	**Defining Characteristics**
Coded (scale of 0 to 10) report	Coded (scale of 0 to 10) report
Self-focus	Self-focusing
Sleep disturbance	Changes in sleep pattern
Verbal report of pain	Verbal report of pain
Protective gestures	Observed protective behavior
Guarding behavior	Guarding behavior
Change in blood pressure	Altered ability to continue previous activities
Diaphoresis	
Expressive behavior	Atrophy of involved muscle group
Positioning to avoid pain	Depression
Pupil dilation	Fatigue
	Fear of reinjury

Used by arrangement with Blackwell Publishing Limited, a company of John Wiley and Sons, Inc. In order to make safe and effective judgments using NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in the work.

Each NANDA-I–approved nursing diagnosis has an identified set of defining characteristics that support identification of a nursing diagnosis (NANDA International, 2012). You learn to recognize patterns of defining characteristics from your patient assessments and then readily select the corresponding diagnosis. Working with similar patients over a period of time helps you recognize clusters of defining characteristics, but remember that each patient is unique and requires an individualized diagnostic approach. Box 17-3 shows two examples of approved nursing diagnoses and their associated defining characteristics.

Interpretation—Identifying Health Problems

While analyzing clusters of data, you begin to consider the patient's health problems. Your interpretation of the information allows you to select among various diagnoses the ones that apply to your patient. It is critical to select the correct diagnostic label for a patient's need. Usually from assessment to diagnosis you move from general information to specific. It helps to think of the problem identification phase in assessment as the general health care problem and the formulation of the nursing diagnosis as the specific health problem. For example, after analyzing Mr. Jacob's problem with comfort, Tonya begins to identify data needed for a specific pain diagnosis.

Often a patient has defining characteristics that apply to more than one diagnosis. For example, Mr. Jacobs provided a verbal report of pain and showed protective behavior in minimizing movement while lying in bed. Both of these defining characteristics possibly indicates that the patient has either *acute pain* or *chronic pain* as nursing diagnoses. Knowing that there are similar diagnoses directs you to gather more information to clarify your interpretation. For example, Tonya checks Mr. Jacobs' blood pressure after he rates his discomfort a 7 on a 10-point rating scale. She notes that his blood pressure is elevated, a defining characteristic unique to the diagnosis of *acute pain*. When interpreting data to form a diagnosis, remember that the absence of certain defining characteristics suggests that you reject a diagnosis under consideration. Thus in the same example, if Tonya's assessment eliminates the signs of fatigue, fear of reinjury, and depression, it is less likely Mr. Jacobs' is having *chronic pain*. In addition, Tonya recognizes that the pain source is the patient's incision and not some underlying chronic problem. The correct diagnosis for Mr. Jacobs is *acute pain*. Always examine the defining characteristics in your database carefully to support or eliminate a nursing diagnosis. To be more accurate, review all characteristics, eliminate irrelevant ones, and confirm the relevant ones.

Formulating a Nursing Diagnosis

To individualize a nursing diagnosis further, you identify the associated related factor. A **related factor** is a condition, historical factor, or etiology that gives a context for the defining characteristics and shows a type of relationship with the nursing diagnosis (NANDA International, 2012). A related factor allows you to individualize a nursing diagnosis for a specific patient. For example, Mr. Jacobs has just undergone surgery and has an incision in the perineal area. This information is important in the context of the nature of his discomfort, and it is used in making a final diagnosis. Placing a diagnosis into the context of the patient's situation clarifies the nature of the patient's health problem. Tonya considers the nature of Mr. Jacobs' pain and identifies his diagnosis as *acute pain related to trauma of an incision*. When Tonya is ready to form her plan of care and select nursing interventions, this concise nursing diagnosis allows her to select therapies suited to postoperative pain management. For example, *acute pain related to trauma of an incision* is more prescriptive for Mr. Jacobs' situation than a nursing diagnosis of *acute pain related to muscular injury*.

While focusing on patterns of defining characteristics, you also compare a patient's pattern of data with data that are consistent with normal, healthful patterns. Use accepted norms as the basis for comparison and judgment. This includes using laboratory and diagnostic test values, professional standards, and normal anatomical or physiological limits. When comparing patterns, judge whether the grouped signs and symptoms are expected for the patient and whether they are within the range of healthful responses. Isolate any defining characteristics not within healthy norms to allow you to identify a specific problem.

Nursing diagnoses provide the basis for selection of nursing interventions to achieve outcomes for which you, as a nurse, are accountable (NANDA International, 2012). A nursing diagnosis focuses on a patient's actual or potential response to a health problem rather than on the physiological event, complication, or disease. A nurse cannot independently treat a medical diagnosis such as a tumor of the prostate. However, Tonya manages Mr. Jacobs' postoperative care, monitoring his postoperative progress and wound care, fluid administration, and medication therapy to prevent collaborative problems from developing. Collaborative problems occur or probably will occur in association with a specific disease, trauma, or treatment (Carpenito-Moyet, 2009). You need nursing knowledge to assess a patient's specific risk for these problems, identify the problems early, and take preventive action (Fig. 17-3). Critical thinking is necessary in identifying nursing diagnoses and collaborative problems so you appropriately individualize care for your patients.

Types of Nursing Diagnoses

NANDA-I (2012) identifies three types of nursing diagnoses: actual diagnoses, risk diagnoses, and health promotion diagnoses. An **actual nursing diagnosis** describes human responses to health conditions or life processes that exist in an individual, family, or

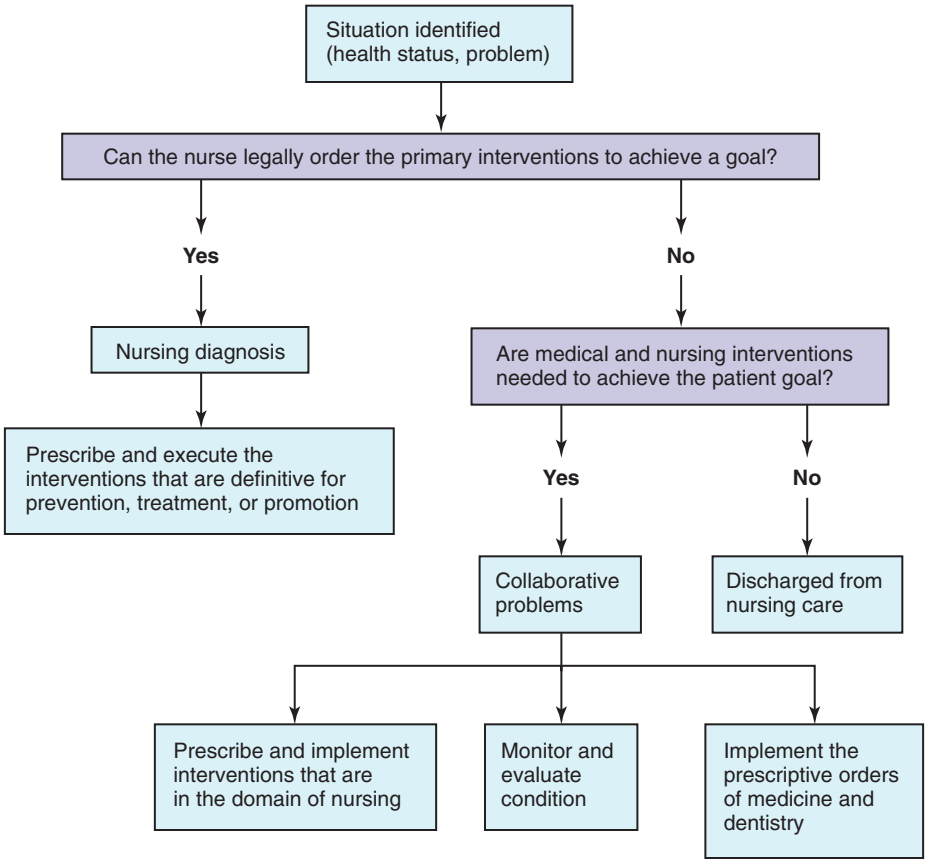

FIG. 17-3 Differentiating nursing diagnoses from collaborative problems. (©1990, 1988, 1985 Lynda Juall Carpenito. Redrawn from Carpenito LJ: *Nursing diagnosis: application to clinical practice* ed 6, Philadelphia, 1995, Lippincott.)

community. Defining characteristics support the diagnostic judgment (NANDA International, 2012). The selection of an actual diagnosis indicates that there are sufficient assessment data to establish the nursing diagnosis. Tonya assessed Mr. Jacobs as having discomfort from the prostatectomy incision with a severity rated at 7 on a 10-point rating scale. The pain increased with movement. As a result of the pain, Mr. Jacobs has limited movement in bed. *Acute pain* is an actual nursing diagnosis. Examples of other actual diagnoses include:

- Wandering
- Impaired social interaction
- Stress urinary incontinence

A **risk nursing diagnosis** describes human responses to health conditions or life processes that may develop in a vulnerable individual, family, or community (NANDA International, 2012). These diagnoses do not have related factors or defining characteristics because they have not occurred yet. Instead a risk diagnosis has risk factors. Risk factors are the environmental, physiological, psychological, genetic, or chemical elements that place a person at risk for a health problem. For example, after Mr. Jacobs' surgery, the presence of his incision, an open wound, poses a risk for a hospital-acquired infection. The key assessment for a risk diagnosis is the presence of risk factors (e.g., an incision and the hospital environment) that support a patient's vulnerability. The risk factors are the diagnostic-related factors that help in planning preventive health care measures. In Mr. Jacobs' case *risk for infection* is appropriate for his condition. Other examples of risk nursing diagnoses include:

- Risk for loneliness
- Risk for acute confusion

A **health promotion nursing diagnosis** is a clinical judgment of a person's, family's, or community's motivation, desire, and readiness to increase well-being and actualize human health potential as expressed in their readiness to enhance specific health behaviors such as nutrition and exercise. Health promotion diagnoses can be used in any health state and do not require current levels of wellness (NANDA International, 2012). A person's readiness is supported by defining characteristics. Examples of health promotion nursing diagnoses include:

- Readiness for enhanced family coping
- Readiness for enhanced nutrition

Components of a Nursing Diagnosis

When communicating a nursing diagnosis, through either discussions with health care colleagues or documentation of your care, it is important to use the language adopted within an agency. Most settings use a two-part format in labeling a nursing diagnosis: the NANDA-I diagnostic label followed by a statement of a related factor (Table 17-1). The two-part format provides a diagnosis meaning and relevance for a particular patient.

Diagnostic Label. The **diagnostic label** is the name of the nursing diagnosis as approved by NANDA International (see Box 17-2). It describes the essence of a patient's response to health conditions in as few words as possible. All NANDA-I approved diagnoses also have a definition. The definition describes the characteristics of the human response identified. You refer to

TABLE 17-1 NANDA International Two-Part Nursing Diagnosis Format

DIAGNOSTIC STATEMENT	EXAMPLES OF RELATED FACTORS
Acute pain	Biological, chemical, physical, or psychological injury agents (e.g., inflammation, edema, burn)
Anxiety	Change (economic status, environment, health status, role), familial association, maturational crisis, situational crisis, stress, threat of death, unmet needs
Impaired urinary elimination	Anatomical obstruction, urinary tract infection, sensory motor impairment)
Impaired skin integrity	Fluid retention, age extremes, hyperthermia, mechanical factors (e.g., shearing, pressure), medications, moisture, physical immobilization, impaired sensation

definitions of nursing diagnoses to assist in identifying a patient's correct diagnosis, which helps especially when selecting between two diagnoses with similar defining characteristics. The diagnostic labels include descriptors used to give additional meaning to the diagnosis. For example, the diagnosis *impaired physical mobility* includes the descriptor *impaired* to describe the nature or change in mobility that best describes the patient's response. Examples of other descriptors include *compromised, decreased, deficient, delayed, effective, imbalanced, impaired,* and *increased.*

Related Factors. The related factor is identified from the patient's assessment data and is the reason the patient is displaying the nursing diagnosis. The related factor is associated with a patient's actual or potential response to the health problem and can change by using specific nursing interventions. Related factors for NANDA-I diagnoses include four categories: pathophysiological (biological or psychological), treatment-related, situational (environmental or personal), and maturational (Carpenito-Moyet, 2009). The "related to" phrase is not a cause-and-effect statement. It indicates that the etiology contributes to or is associated with the patient's diagnosis (Fig. 17-4). The inclusion of the "related to" phrase requires you to use critical thinking to individualize the nursing diagnosis and then select nursing interventions (Table 17-2).

The **etiology** or related factor of a nursing diagnosis is always within the domain of nursing practice and a condition that responds to nursing interventions. Sometimes health care providers record medical diagnoses as the etiology of the nursing diagnosis. This is incorrect. Nursing interventions do not change a medical diagnosis. However, you direct nursing interventions at behaviors or conditions that you are able to treat or manage. For example, the nursing diagnosis *acute pain related to prostatectomy* is incorrect. Nursing actions do not affect the medical diagnosis of the surgical removal of the prostate gland. Rewording the diagnosis to read *acute pain related to trauma* of incision results in nursing interventions directed at appropriate wound care, using turning techniques to reduce stress on the suture line and offering nonpharmacological comfort measures (see Chapter 43). In the case of a risk nursing diagnosis, a risk factor is the related factor. Table 17-3 demonstrates the association between a nurse's assessment of a patient, the clustering of defining characteristics, and the formulation of nursing diagnoses. The diagnostic process results in the formation of a total diagnostic label that allows you to develop an appropriate, patient-centered plan of care. The

TABLE 17-2 Comparison of Interventions for Nursing Diagnoses with Different Related Factors

NURSING DIAGNOSES	RELATED FACTOR	INTERVENTIONS
Patient A		
Anxiety	Uncertainty over surgery	Provide detailed instructions about the surgical procedure, recovery process, and postoperative care activities. Plan formal time for patient to ask questions.
Impaired physical mobility	Acute pain	Administer analgesics 30 minutes before planned exercise. Instruct patient in technique to splint painful site during activity.
Patient B		
Anxiety	Loss of job	Consult with social worker to arrange for job counseling. Encourage patient to continue health promotion activities (e.g., exercise, routine social activities).
Impaired physical mobility	Musculoskeletal injury	Have patient perform active range-of-motion exercises to affected extremity every 2 hours. Instruct patient on use of three-point crutch gait.

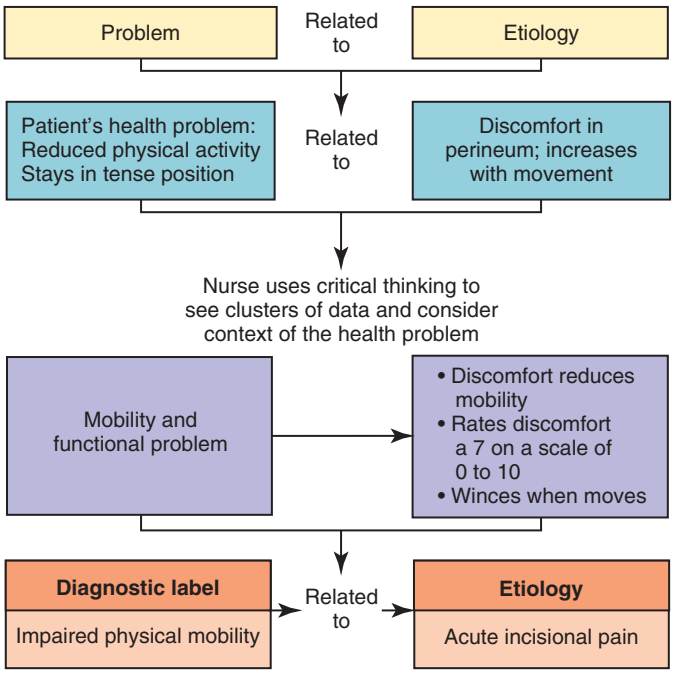

FIG. 17-4 Relationship between a diagnostic label and related factor (etiology).

defining characteristics and relevant etiologies are from NANDA International (2012).

The PES Format. Some agencies prefer a three-part nursing diagnostic label. In this case the diagnostic label consists of the NANDA-I label, the related factor, and the defining characteristics

TABLE 17-3 Developing a Two-Part Nursing Diagnosis Label

ASSESSMENT ACTIVITIES	DEFINING CHARACTERISTICS (CLUSTERING CUES)	ETIOLOGIES ("RELATED TO")	NURSING DIAGNOSIS
Ask patient to rate severity of pain on a scale from 0 to 10.	Verbal report of pain at a level of 7	Physical; swelling from incisional trauma	Acute pain related to trauma of incision
Observe patient's positioning in bed.	Lies flat, avoids turning		
Observe for any nonverbal signs of discomfort.	Winces when surgical wound is palpated		
Ask patient to describe what he knows about surgery.	Has no knowledge about postoperative wound care	Inexperience; first time to have surgery	Deficient knowledge related to inexperience with surgery
Observe his interactions.	Asks questions about pain control and what to expect.		
Question wife's role in postoperative care and her level of knowledge.	Wife to provide support within the home; no knowledge of how to manage wound		

(Ackley and Ladwig, 2011). This approach makes a diagnosis even more patient specific. The acronym PES stands for problem, etiology, and symptoms.

- **P** (problem)—NANDA-I label—Example: *impaired physical mobility*
- **E** (etiology or related factor)—Example: incisional pain
- **S** (symptoms or defining characteristics)—briefly lists defining characteristic(s) that show evidence of the health problem. Example: evidenced by restricted turning and positioning

PES diagnostic statement: *Impaired physical mobility related to incisional pain,* evidenced by restricted turning and positioning.

Cultural Relevance of Nursing Diagnoses

When you select nursing diagnoses, consider your patients' cultural diversity. This includes knowing the cultural differences that affect how a patient defines health and illness and wants to be treated (Smith, 2007). It is important to consider your own cultural competence so you are more sensitive to a patient's health care problems and the implications.

Here are examples of questions that contribute to making culturally competent nursing diagnoses (Smith, 2007):

- How has this health problem affected you and your family?
- What do you believe will help or fix the problem?
- What worries you the most about this problem?
- What do you expect from us, your nurses, to help maintain some of your cultural practices?
- What cultural practices do you do to keep yourself and your family well?
- Which practices within your culture are important to you?

When you ask questions such as these, you use a patient-centered care approach that allows you to see the patient's health situation through his or her eyes. When making a diagnosis, be sure to also consider how culture influences the related factor for your diagnostic statement. For example, *impaired verbal communication related to cultural differences* or *noncompliance related to patient value system* reflects diagnostic conclusions that consider a patient's unique cultural needs.

Your own culture potentially influences the cues and defining characteristics that you select from your assessment. In an older but still relevant study, Wieck (1996) examined how cultural differences among nurses influenced the choice of defining characteristics in making nursing diagnoses. The researchers studied the diagnosis of pain within six different cultural groups of nurses. Generally the nurses were consistent in selecting defining characteristics. However, when diagnosing pain, some of the nurses did not select restlessness or grimace as defining characteristics. The nurses were not familiar with such characteristics because they were not common to how their own culture expressed pain. Cultural awareness and sensitivity improve your accuracy in making nursing diagnoses.

CONCEPT MAPPING NURSING DIAGNOSES

When caring for a patient or groups of patients, think critically about their needs and how to prevent problems from developing. Your holistic view of a patient heightens the challenge of thinking about all patient needs and problems. Few patients have single problems. Often you care for a patient with multiple nursing diagnoses. Therefore a picture of each patient usually consists of several interconnections between sets of data, all associated with identified patient problems. A concept map diagrams the critical thinking associated with making accurate diagnoses. It is one way to graphically represent the connections between concepts (nursing diagnoses) and ideas that are related to a central subject (e.g., the patient's health problems). For each diagnosis you list defining characteristics and begin to see the connections or association among different diagnostic statements.

As you proceed in applying each step of the nursing process, your concept map expands with more detail about planned interventions (see Chapter 18). A concept map promotes critical thinking because you identify, graphically display, and link key concepts by organizing and analyzing information (Hsu and Hsieh, 2005).

Fig. 17-5 shows the next step in the development of Tonya's concept map for Mr. Jacobs. Tonya began during the assessment step of the nursing process (see Chapter 16) to gather a database for Mr. Jacobs. Her assessment included Mr. Jacobs' perspective of his health problems and the objective and subjective data she collected through observation and examination. She validated findings and added to the database as she learned new information. Data sources include physical, psychological, and sociocultural domains. Tonya applies clinical reasoning and intuition that reflect her own basic nursing knowledge, her past experiences with

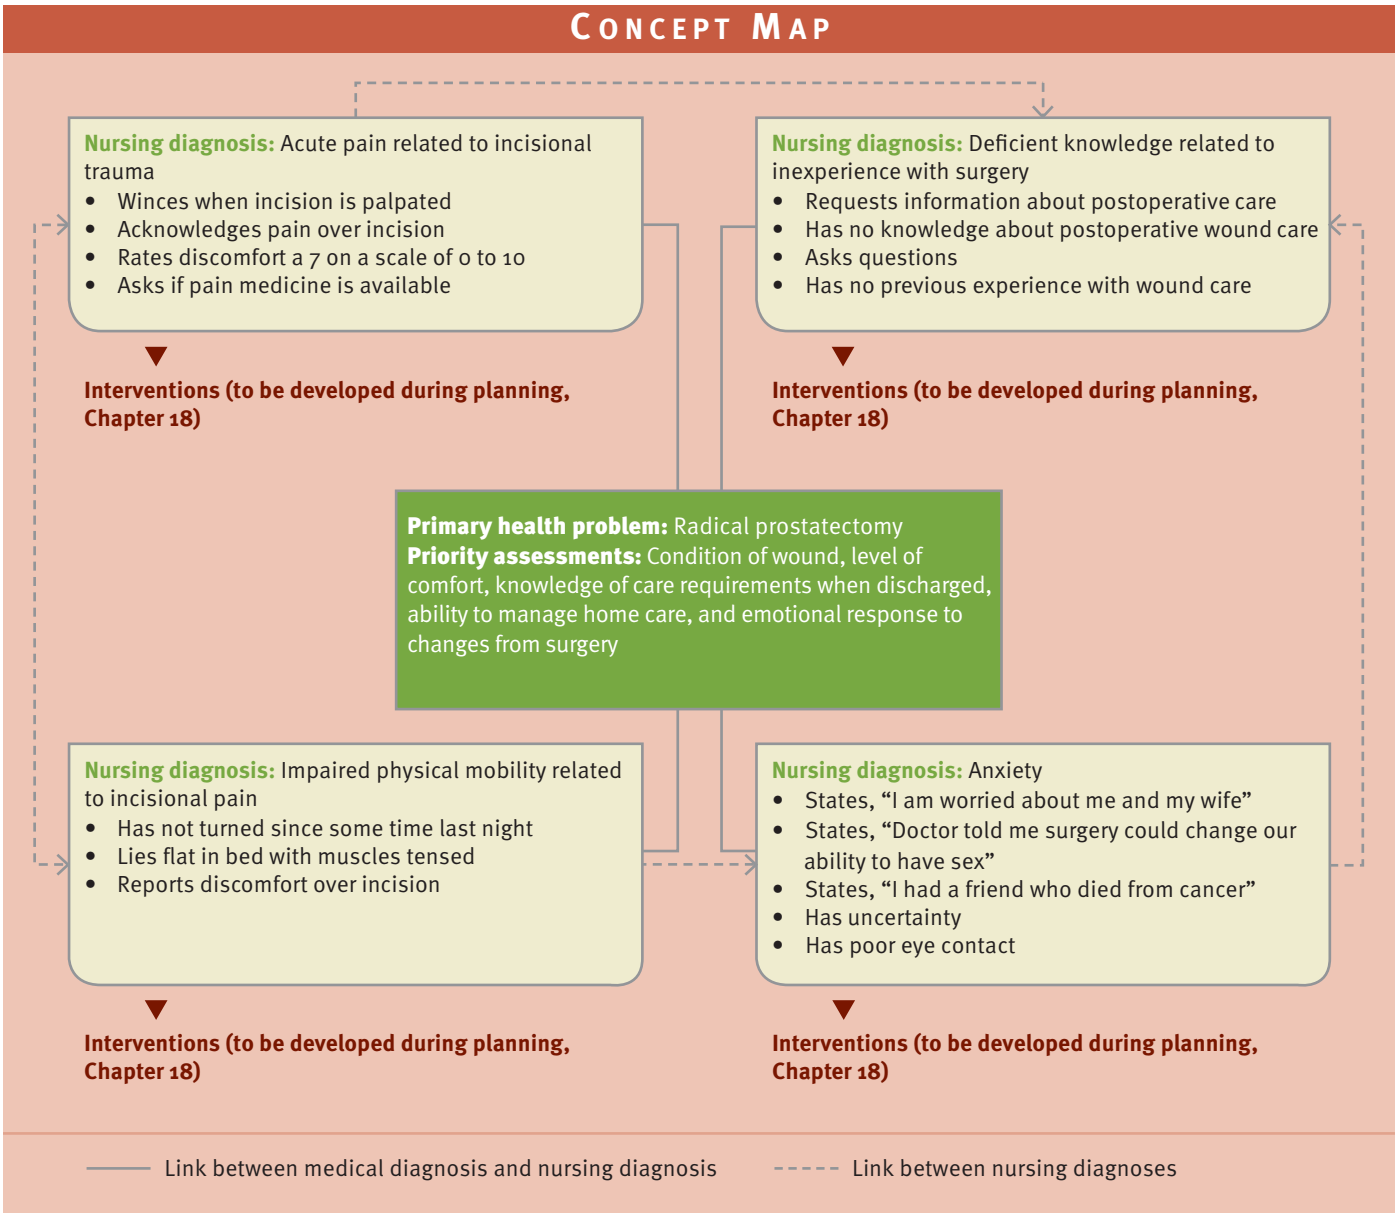

FIG. 17-5 Concept map for Mr. Jacobs: Nursing diagnoses.

patients, patterns seen in similar situations, and reference to institutional standards and procedures (e.g., pain-management policies or postoperative teaching protocols). As Tonya begins to see patterns of defining characteristics, she places labels to identify the four nursing diagnoses that apply to Mr. Jacobs. She is also able to see the relationship among the diagnoses and connects them on the concept map. If Mr. Jacobs does not receive pain relief, Tonya knows from her experience in caring for patients with pain that he will have continued problems in achieving necessary mobility for recovery. The diagnoses of *acute pain* and *impaired physical mobility* are closely related. In addition, if pain is unrelieved, it will be difficult for Mr. Jacobs' to be receptive to any patient teaching Tonya wants to provide about postoperative care, an intervention that will be later planned for *deficient knowledge*. If Mr. Jacobs' remains anxious about the outcome of his surgery and whether he can fulfill his role sexually with his wife, this *anxiety* can heighten pain perception and influence his ability to learn. Concept mapping organizes and links information to allow you to see new wholes and appreciate the complexity of patient care (Ferrario, 2004). Tonya's next step on the care map is to identify the appropriate nursing interventions for Mr. Jacobs' care (see Chapter 18).

The advantage of a concept map is its central focus on the patient rather than the patient's disease or health alteration. This encourages nursing students to concentrate on patients' specific health problems and nursing diagnoses. The focus also promotes patient participation with the eventual plan of care.

SOURCES OF DIAGNOSTIC ERRORS

Errors may occur in the nursing diagnostic process during data collection, interpretation, clustering, and labeling of the diagnosis (Box 17-4). Chapter 16 reviews how to conduct a systematic assessment so you have all of the data necessary for making accurate and timely nursing diagnoses and collaborative problems. As a nurse

BOX 17-4 SOURCES OF DIAGNOSTIC ERROR

Collecting
- Lack of knowledge or skill
- Inaccurate data
- Missing data
- Disorganization

Clustering
- Insufficient cluster of cues
- Premature or early closure
- Incorrect clustering

Interpreting
- Inaccurate interpretation of cues
- Failure to consider conflicting cues
- Using an insufficient number of cues
- Using unreliable or invalid cues
- Failure to consider cultural influences or developmental stage

Labeling
- Wrong diagnostic label selected
- Evidence that another diagnosis is more likely
- Condition a collaborative problem
- Failure to validate nursing diagnosis with patient
- Failure to seek guidance

always apply methodical critical thinking for an accurate nursing diagnostic process.

Errors in Interpretation and Analysis of Data

Following data collection, review your database to decide if it is accurate and complete. Review data to validate that measurable, objective physical findings support subjective data. For example, when a patient reports "difficulty breathing," you also want to listen to lung sounds, assess respiratory rate, and measure the patient's chest excursion. When you are not able to validate data, it signals an inaccurate match between clinical cues and the nursing diagnosis. Begin interpretation by identifying and organizing relevant assessment patterns to support the presence of patient problems. Be careful to consider conflicting cues or decide if there are insufficient cues to form a diagnosis.

Errors in Data Clustering

Errors in data clustering occur when data are clustered prematurely, incorrectly, or not at all. Premature closure of clustering occurs when you make the nursing diagnosis before grouping all data. For example, before his surgery, Mr. Jacobs experienced urinary incontinence and complained of urgency and nocturia. The nurse in the clinic clustered the available data and considered that *impaired urinary elimination* was a probable diagnosis. However, incorrect clustering occurs when you try to make a nursing diagnosis fit the signs and symptoms obtained. In this example further assessment revealed that the patient had bladder distention and dribbling and the type of incontinence was likely overflow incontinence. As a result of these findings the nurse was able to make a more accurate diagnosis, *urinary retention*. Always identify the nursing diagnosis from the data, not the reverse. An incorrect nursing diagnosis affects quality of patient care.

Errors in the Diagnostic Statement

Clinical reasoning leads to a higher quality of nursing diagnosis, which eventually leads to etiology-specific interventions and enhanced patient outcomes (Muller-Staub et al., 2008). The more competent you become in diagnostic reasoning, the more likely it is that you will correctly select diagnostic statements. This results in the appropriate selection of nursing interventions and patient outcomes during planning and implementation (see Chapters 18 and 19). Reduce errors by selecting appropriate, concise, and precise language using NANDA-I terminology. Be sure that the etiology portion of the diagnostic statement is within the scope of nursing to diagnose and treat. Additional guidelines to reduce errors in the diagnostic statement follow.

1. Identify the patient's response, not the medical diagnosis (Carpenito-Moyet, 2009). Because the medical diagnosis requires medical interventions, it is legally inadvisable to include it in the nursing diagnosis. Change the diagnosis *acute pain related to prostatectomy* to *acute pain related to trauma of an incision.*
2. Identify a NANDA-I diagnostic statement rather than the symptom. Identify nursing diagnoses from a cluster of defining characteristics and not just a single symptom. One symptom is insufficient for problem identification. For example, dyspnea alone does not definitively lead you to a diagnosis. However, the pattern of dyspnea, shortness of breath, pain on inspiration, and productive cough with thick secretions are defining characteristics that lead you to the diagnosis of *ineffective breathing pattern related to increased airway secretions.*
3. Identify a treatable etiology or risk factor rather than a clinical sign or chronic problem that is not treatable through nursing intervention. An accurate etiology allows you to select nursing interventions directed toward correcting the etiology of the problem or minimizing the patient's risk. A diagnostic test or a chronic dysfunction is not an etiology or a condition that a nursing intervention is able to treat. A patient with fractured ribs likely has pain when inhaling; impaired chest excursion; and slower, shallow respirations. An x-ray film may show atelectasis (collapse of alveolar air sacs) in the area affected. The nursing diagnosis of *ineffective breathing pattern related to shallow respirations* is an incorrect diagnostic statement. *Ineffective breathing pattern related to pain in chest* is more accurate.
4. Identify the problem caused by the treatment or diagnostic study rather than the treatment or study itself. Patients experience many responses to diagnostic tests and medical treatments. These responses are the area of nursing concern. The patient who has angina and is scheduled for a cardiac catheterization possibly has a nursing diagnosis of *anxiety related to lack of knowledge about cardiac catheterization.* An incorrect diagnosis is *anxiety related to cardiac catheterization*.
5. Identify the patient response to the equipment rather than the equipment itself. Patients are often unfamiliar with medical technology. The diagnosis of *deficient knowledge regarding the need for cardiac monitoring* is accurate compared with the statement *anxiety related to cardiac monitor*.
6. Identify the patient's problems rather than your problems with nursing care. Nursing diagnoses are always patient centered and form the basis for goal-directed care. *Potential intravenous complications related to poor vascular access* indicates a nursing problem in initiating and maintaining intravenous therapy. The diagnosis *risk for infection* properly centers attention on patient needs.
7. Identify the patient problem rather than the nursing intervention. You plan nursing interventions after identifying a nursing diagnosis. The statement, "offer bedpan frequently because of altered elimination patterns," changes to the correct diagnostic statement, *diarrhea related to food intolerance.* This corrects the misstatement and allows proper implementation of the nursing process. More appropriate interventions are selected rather than a single intervention that will not solve the problem.

8. Identify the patient problem rather than the goal of care. You establish goals during the planning step of the nursing process (see Chapter 18). Goals based on accurate identification of a patient's problems serve as a basis to determine problem resolution. Change the diagnostic statement, "Patient needs high-protein diet related to potential alteration in nutrition," to *imbalanced nutrition: less than body requirements related to inadequate protein intake.*
9. Make professional rather than prejudicial judgments. Base nursing diagnoses on subjective and objective patient data and do not include your personal beliefs and values. Remove your judgment from *impaired skin integrity related to poor hygiene habits* by changing the nursing diagnosis to read *impaired skin integrity related to inadequate knowledge about perineal care.*
10. Avoid legally inadvisable statements (Carpenito-Moyet, 2009). Statements that imply blame, negligence, or malpractice have the potential to result in a lawsuit. The statement, "recurrent angina related to insufficient medication," implies an inadequate prescription by the health care provider. Correct problem identification is *chronic pain related to improper use of medications.*
11. Identify the problem and etiology to avoid a circular statement. Circular statements are vague and give no direction to nursing care. Change the statement, "impaired breathing pattern related to shallow breathing," to identify the patient problem and cause, *ineffective breathing pattern related to incisional pain.*
12. Identify only one patient problem in the diagnostic statement. Every problem has different specific expected outcomes. Confusion during the planning step occurs when you include multiple problems in a nursing diagnosis. Restate *pain and anxiety related to difficulty in ambulating* as two nursing diagnoses such as *impaired physical mobility related to pain in right knee* and *anxiety related to difficulty in ambulating.* It is permissible to include multiple etiologies contributing to one patient problem, as in *complicated grieving related to diagnosed terminal illness and change in family role.*

Documentation and Informatics

Once you identify a patient's nursing diagnoses, enter them either on the written plan of care or in the electronic health information record of the agency. In the clinical facility list nursing diagnoses chronologically as you identify them. When initiating an original care plan, place the highest-priority nursing diagnoses first. This depends on the patient's condition and the nature of the nursing diagnosis (e.g., acute physical health problem versus a long-term chronic health management issue). Thereafter add nursing diagnoses to the list. Date a nursing diagnosis at the time of entry. When caring for a patient, review the list and identify nursing diagnoses with the greatest priority, regardless of chronological order.

In some settings data-driven computerized decision support systems are in place that allow you to be more accurate in making nursing diagnoses. A computer-based clinical decision support function involves use of the computer to bring relevant knowledge to bear for the health care of a patient (Cho, Staggers, and Park, 2010). The database within one of these systems includes diagnostic labels (e.g., NANDA-I diagnostic labels), defining characteristics, activities, and indicators for nursing. A nurse enters assessment data, and the computer helps by organizing the data into clusters that enhance the ability to select accurate diagnoses. Once diagnoses are selected, the computer system also directs the nurse to intervention options to select for a patient.

NURSING DIAGNOSES: APPLICATION TO CARE PLANNING

Nursing diagnosis is a mechanism for identifying the domain of nursing. Diagnoses direct the planning process and the selection of nursing interventions to achieve desired outcomes for patients. Just as the medical diagnosis of diabetes leads a physician to prescribe a low-carbohydrate diet and medication for blood glucose control, the nursing diagnosis of *impaired skin integrity* directs a nurse to apply certain support surfaces to a patient's bed and initiate a turning schedule. In Chapter 18 you will learn how unifying the languages of NANDA-I with the Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) facilitates the process of matching nursing diagnoses with accurate and appropriate interventions and outcomes (Dochterman and Jones, 2003). The care plan (see Chapter 18) is a map for nursing care and demonstrates your accountability for patient care. By making accurate nursing diagnoses, your subsequent care plan communicates to other professionals the patient's health care problems and ensures that you select relevant and appropriate nursing interventions.

KEY POINTS

- The diagnostic process is a clinical judgment that involves reviewing assessment information, recognizing cues and patterns in the data, and identifying the patient's specific health care problems.
- The nursing diagnostic process is unique from that of medical diagnosis in that patients become involved in the diagnostic process when possible.
- Accurate diagnosis of patient problems ensures the selection of more effective and efficient nursing interventions.
- One purpose of nursing diagnosis is that it provides a precise definition of a patient's problem that gives nurses and other members of the health care team a common language for understanding the patient's needs.
- The nursing diagnostic process includes data clustering, identifying patient needs or problems, and formulating the nursing diagnosis or collaborative problem.
- Defining characteristics are subjective and objective clinical criteria that form clusters, leading to a diagnostic conclusion.
- When an assessment reveals defining characteristics that apply to more than one nursing diagnosis, gather more information to clarify your interpretation.
- Absence of defining characteristics suggests that you reject a proposed diagnosis.
- A nursing diagnosis is usually written in a two-part format, including a diagnostic label and an etiological or related factor.
- A three-part nursing diagnosis, using a PES format, includes a diagnostic label, etiological statement, and symptoms or defining characteristics.
- The "related to" factor of the diagnostic statement helps you to individualize a patient's nursing diagnoses and provides direction for your selection of appropriate interventions.
- Risk factors serve as cues to indicate that a risk nursing diagnosis applies to a patient's condition.
- A concept map is a visual representation of a patient's nursing diagnoses and their relationship with one another.
- Nursing diagnostic errors occur by errors in data collection, interpretation and analysis of data, clustering of data, or the diagnostic statement.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya discusses the concerns Mr. Jacobs has about his sexual relationship with his wife. She knows that a radical prostatectomy can cause nerve damage that impairs a man's ability to have a normal erection. Tonya says, "You've told me that you're worried about you and your wife. Can you tell me more?" Mr. Jacobs says, "I feel uncertain about my ability to have sex. The doctor said before the surgery that there is a risk of damaging a nerve that can affect my ability to perform sexually." Tonya observes that Mr. Jacobs has poor eye contact as they talk and his voice quivers. Tonya asks, "How would you describe your relationship with Mrs. Jacobs?" The patient responds, "Oh, it's been really good. We've had our ups and downs like anyone else, but she has been so good to me. I worry that I won't be able to be the husband she wants any more." Tonya clarifies, "Has the doctor visited since surgery to discuss your concerns?" Mr. Jacobs replies, "No, he hasn't been in yet."

1. Which of the following are defining characteristics from the assessment?
   1. Quiver in Mr. Jacobs' voice
   2. Nurse's statement, "You've told me that you're worried."
   3. Uncertainty about ability to have sex
   4. Poor eye contact
   5. Nurse's question, "Can you tell me more?"
2. Tonya clusters the defining characteristics to select the diagnostic label of *anxiety*. What would you identify as the related factor for this diagnosis?
3. If Tonya identified the diagnosis as *anxiety related to risk of nerve damage during surgery,* would this be an accurate nursing diagnosis? Explain.

evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse identified that the patient has pain on a scale of 7, he winces during movement, and he expresses discomfort over the incisional area. He guards the area by resisting movement. The incision appears to be healing, but there is natural swelling. Write a three-part nursing diagnostic statement using the PES format.
2. Review the following nursing diagnoses and identify the diagnoses that are stated correctly. (Select all that apply.)
   1. Anxiety related to fear of dying
   2. Fatigue related to chronic emphysema
   3. Need for mouth care related to inflamed mucosa
   4. Risk for infection
3. A nurse reviews data gathered regarding a patient's pain symptoms. The nurse compares the defining characteristics for *acute pain* with those for *chronic pain* and in the end selects *acute pain* as the correct diagnosis. This is an example of the nurse avoiding an error in:
   1. Data collection.
   2. Data clustering.
   3. Data interpretation.
   4. Making a diagnostic statement.
4. The nursing diagnosis *readiness for enhanced communication* is an example of a(n):
   1. Risk nursing diagnosis.
   2. Actual nursing diagnosis.
   3. Health promotion nursing diagnosis
   4. Wellness nursing diagnosis.
5. In the following examples, which nurses are making nursing diagnostic errors? (Select all that apply.)
   1. The nurse who listens to lung sounds after a patient reports "difficulty breathing"
   2. The nurse who considers conflicting cues in deciding which diagnostic label to choose
   3. The nurse assessing the edema in a patient's lower leg who is unsure how to assess the severity of edema
   4. The nurse who identifies a diagnosis on the basis of a single defining characteristic
6. A nurse is reviewing a patient's list of nursing diagnoses in the medical record. The most recent nursing diagnosis is *diarrhea related to intestinal colitis.* This is an incorrectly stated diagnostic statement, best described as:
   1. Identifying the clinical sign instead of an etiology.
   2. Identifying a diagnosis based on prejudicial judgment.
   3. Identifying the diagnostic study rather than a problem caused by the diagnostic study.
   4. Identifying the medical diagnosis instead of the patient's response to the diagnosis.
7. A nurse is assigned to a new patient admitted to the nursing unit following admission through the emergency department. The nurse collects a nursing history and interviews the patient. Place the following steps for making a nursing diagnosis in the correct order.
   _____ 1. Considers context of patient's health problem and selects a related factor
   _____ 2. Reviews assessment data, noting objective and subjective clinical criteria
   _____ 3. Clusters clinical criteria that form a pattern
   _____ 4. Chooses diagnostic label
8. Match the activity on the left with the source of diagnostic error on the right:

Activity	Source of Diagnostic Error
a. Nurse listens to lungs for first time and is not sure if abnormal lung sounds are present.	__ 1. Collecting data
b. After reviewing objective data, nurse selects diagnosis of *fear* before asking patient to discuss feelings.	__ 2. Interpreting
c. Nurse identifies incorrect diagnostic label.	__ 3. Clustering
d. Nurse does not consider patient's cultural background when reviewing cues.	__ 4. Labeling
e. Nurse prepares to complete decision on diagnosis and realizes that clinical criteria are grouped incorrectly to form a pattern.	

9. Review the following list of nursing diagnoses and identify those stated incorrectly. (Select all that apply.)
   1. Acute pain related to lumbar disk repair
   2. Sleep deprivation related to difficulty falling asleep
   3. Constipation related to inadequate intake of liquids
   4. Potential nausea related to nasogastric tube insertion
10. The nurse completed the following assessment: 63-year-old female patient has had abdominal pain for 6 days. She reports

not having a bowel movement for 4 days, whereas she normally has a bowel movement every 2 to 3 days. She has not been hospitalized in the past. Her abdomen is distended. She reports being anxious about upcoming tests. Her temperature was 37° C, pulse 82 and regular, blood pressure 128/72. Which of the following data form a cluster, showing a relevant pattern? (Select all that apply.)
   1. Vital sign results
   2. Abdominal distention
   3. Age of patient
   4. Change in bowel elimination pattern
   5. Abdominal pain
   6. No past history of hospitalization

11. In question 10, which additional data do you collect to add to the cluster of information? (Short answer)
12. The nurse in a geriatric clinic collects the following information from an 82-year-old patient and her daughter, the family caregiver. The daughter explains that the patient is "always getting lost." The patient sits in the chair but gets up frequently and paces back and forth in the examination room. The daughter says, "I just don't know what to do because I worry she will fall or hurt herself." The daughter states that, when she took her mother to the store, they became separated, and the mother couldn't find the front entrance. The daughter works part time and has no one to help watch her mother. Which of the data form a cluster, showing a relevant pattern?(Select all that apply.)
   1. Daughter's concern of mother's risk for injury
   2. Pacing
   3. Patient getting lost easily
   4. Daughter working part time
   5. Getting up frequently
13. Which of the following are examples of collaborative problems? (Select all that apply.)
   1. Nausea
   2. Hemorrhage
   3. Wound infection
   4. Fear
14. Two nurses are having a discussion at the nurses' station. One nurse is a new graduate who added, "Patient needs improved bowel function related to constipation" to a patient's care plan. The nurse's colleague, the charge nurse says, "I think your diagnosis is possibly worded incorrectly. Let's go over it together." A correctly worded diagnostic statement is:
   1. Need for improved bowel function related to change in diet.
   2. Patient needs improved bowel function related to alteration in elimination.
   3. Constipation related to inadequate fluid intake.
   4. Constipation related to hard infrequent stools.
15. The following nursing diagnoses all apply to one patient. As the nurse adds these diagnoses to the care plan, which diagnoses will not include defining characteristics?
   1. Risk for aspiration
   2. Acute confusion
   3. Readiness for enhanced coping
   4. Sedentary lifestyle

Answers: **1.** P, acute pain; E, related to incisional trauma; S, evidenced by pain reported at 7, with guarding, and restricted turning and positioning; **2.** 1, 4; **3.** 3; **4.** 3; **5.** 3, 4; **6.** 4; **7.** 2, 3, 4, 1; **8.** 1 a, 2 b and d, 3 e, 4 c; **9.** 1, 2, 4; **10.** 2, 4, 5; **11.** See Evolve; **12.** 2, 3, 5; **13.** 2, 3; **14.** 3; **15.** 1.

Planning Nursing Care

OBJECTIVES

- Explain the relationship of planning to assessment and nursing diagnosis.
- Discuss criteria used in priority setting.
- Describe goal setting.
- Discuss the difference between a goal and an expected outcome.
- List the seven guidelines for writing an outcome statement.
- Develop a plan of care from a nursing assessment.
- Discuss the differences between nurse-initiated, physician-initiated, and collaborative interventions.
- Discuss the process of selecting nursing interventions during planning.
- Describe the role that communication plays in planning patient-centered care.
- Describe the consultation process.

KEY TERMS

Collaborative interventions, p. 242
Consultation, p. 249
Critical pathways, p. 247
Dependent nursing interventions, p. 242
Expected outcome, p. 238
Goal, p. 238
Independent nursing interventions, p. 242
Interdisciplinary care plans, p. 244
Long-term goal, p. 239
Nursing care plan, p. 244
Nursing-sensitive patient outcome, p. 240

Tonya conducted a thorough assessment of Mr. Jacobs' health status and identified four nursing diagnoses: acute pain related to incisional trauma, deficient knowledge regarding postoperative recovery related to inexperience with surgery, impaired physical mobility related to incisional pain, and anxiety related to uncertainty over course of recovery. Tonya is responsible for planning Mr. Jacobs' nursing care from the time of her initial assessment in the morning until the end of her shift. The care that she plans will continue throughout the course of Mr. Jacobs' hospital stay by the other nurses involved in Mr. Jacobs' care. If Tonya plans well, the individualized interventions that she selects will prepare the patient for a smooth transition home. Collaboration with the patient is critical for a plan of care to be successful. Using input from Mr. Jacobs, Tonya identifies the goals and expected outcomes for each of his nursing diagnoses. The goals and outcomes direct Tonya in selecting appropriate therapeutic interventions. Tonya knows that Mrs. Jacobs' must be involved in the patient's care because of the ongoing support that she provides and because she will be a key care provider once Mr. Jacobs' returns home. In addition, Mr. Jacobs has told Tonya that his wife is the one who keeps their family together. Consultation with other health care providers such as social work or home health ensures that the right resources are used in planning care. Careful planning involves seeing the relationships among a patient's problems, recognizing that certain problems take precedence over others, and proceeding with a safe and efficient approach to care.

After you identify a patient's nursing diagnoses and collaborative problems, you begin planning, the third step of the nursing process. **Planning** involves setting priorities, identifying patient-centered goals and expected outcomes, and prescribing individualized nursing interventions. Ultimately during implementation your interventions resolve the patient's problems and achieve the expected goals and outcomes (see Chapter 19). Planning requires critical thinking applied through deliberate decision making and problem solving. It also involves working closely with patients, their families, and the health care team through communication and ongoing consultation. Patients benefit most when their care represents a collaborative effort from the expertise of all health care team members. A plan of care is dynamic and changes as the patient's needs change.

ESTABLISHING PRIORITIES

Remember that a single patient often has multiple nursing diagnoses and collaborative problems. In addition, once you enter into nursing practice, you do not care for just a single patient. Eventually you care for groups of patients. Being able to carefully and wisely set priorities for a single patient or group of patients ensures the timeliest, relevant, and appropriate care.

Priority setting is the ordering of nursing diagnoses or patient problems using determinations of urgency and/or importance to establish a preferential order for nursing actions (Hendry and Walker, 2004). In other words, as you care for a patient or a group of patients, you must deal with certain aspects of care before others. By ranking a patient's nursing diagnoses in order of importance, you attend to each patient's most important needs and better organize ongoing care activities. Priorities help you to anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems. Together with your patients, you select mutually agreed-on priorities based on the urgency of the problems, the patient's safety and desires, the nature of the treatment indicated, and the relationship among the diagnoses. Establishing priorities is not a matter of numbering the nursing diagnoses on the basis of severity or physiological importance. Nurses establish priorities in relation to clinical importance, but they also prioritize on the basis of time. On a given day the demands that exist within a health care setting require you to ration your time wisely.

Classify a patient's priorities as high, intermediate, or low importance. Nursing diagnoses that, if untreated, result in harm to a patient or others (e.g., those related to airway status, circulation, safety, and pain) have the highest priorities. One way to consider diagnoses of high priority is to consider Maslow's hierarchy of needs (see Chapter 6). For example, *risk for other-directed violence, impaired gas exchange,* and *decreased cardiac output* are examples of high-priority nursing diagnoses that drive the priorities of safety, adequate oxygenation, and adequate circulation. However, it is always important to consider each patient's unique situation. High priorities are sometimes both physiological and psychological and may address other basic human needs. Avoid classifying only physiological nursing diagnoses as high priority. Consider Mr. Jacobs' case. Among his nursing diagnoses, *acute pain* and *anxiety* are of the highest priority. Tonya knows that she needs to relieve Mr. Jacobs' acute pain and lessen his anxiety so he will be responsive to discharge education and be able to participate in postoperative care activities.

Intermediate priority nursing diagnoses involve nonemergent, nonlife-threatening needs of patients. In Mr. Jacobs' case, *deficient knowledge* and *impaired physical mobility* are both intermediate diagnoses. It is important for Mr. and Mrs. Jacobs' to understand potential problems that develop following surgery, know how to recognize the problems, and be able to continue appropriate care at home. Focused and individualized instruction from all members of the health care team is necessary throughout a patient's hospitalization. The diagnosis of impaired physical mobility is not life threatening and will likely resolve once Tonya and the other nurses collaborate with the surgeon to ensure effective pain control. Relief of pain will make Mr. Jacobs' more mobile and more active in his road to recovery.

Low-priority nursing diagnoses are not always directly related to a specific illness or prognosis but affect the patient's future well-being. Many low-priority diagnoses focus on the patient's long-term health care needs. Tonya has not yet identified a nursing diagnosis related to Mr. Jacobs' concern about his sexual function. At this point the patient's anxiety over the uncertainty of the success of surgery, the risk of cancer recurrence, and his concern about his sexual function are the predominant problems. If the patient learns from the surgeon that the procedure resulted in damage to the nerves affecting his sexual performance, a diagnosis more pertinent to this health problem is appropriate.

The order of priorities changes as a patient's condition changes, sometimes within a matter of minutes. Each time you begin a sequence of care such as at the beginning of a hospital shift or a patient's clinic visit, it is important to reorder priorities. For example, when Tonya first met Mr. Jacobs, his *acute pain* was rated at a 7, and it was apparent that the administration of an analgesic was more a priority than trying to reposition or use other nonpharmacological approaches (e.g., relaxation or distraction). Later, after receiving the analgesic, Mr. Jacobs' pain lessened to a level of 4; and Tonya was able to gather more assessment information and begin to focus on his problem of *deficient knowledge*. Ongoing patient assessment is critical to determine the status of your patient's nursing diagnoses. The appropriate ordering of priorities ensures that you meet a patient's needs in a timely and effective way.

Priority setting begins at a holistic level when you identify and prioritize a patient's main diagnoses or problems (Hendry and Walker, 2004). However, you also need to prioritize the specific interventions or strategies that you will use to help a patient achieve desired goals and outcomes. For example, as Tonya considers the high-priority diagnosis of *acute pain* for Mr. Jacobs, she decides during each encounter which intervention to do first among these options: administering an analgesic, repositioning, and teaching relaxation exercises. Critical thinking helps her to prioritize. Tonya knows that a certain degree of pain relief is necessary before a patient can participate in relaxation exercises. When she is in the patient's room, she might decide to turn and reposition Mr. Jacobs first and then prepare the analgesic. However, if Mr. Jacobs expresses that pain is a high level and is too uncomfortable to turn, Tonya chooses obtaining and administering the analgesic as her first priority. Later, with Mr. Jacobs' pain more under control, she considers whether relaxation is appropriate.

Involve patients in priority setting whenever possible. Patient-centered care requires you to know a patient's preferences, values, and expressed needs. Tonya must learn what Mr. Jacobs expects with regard to pain control to have a relevant plan of care in place. In some situations a patient assigns priorities different from those you select. Resolve any conflicting values concerning health care needs and treatments with open communication, informing the patient of all options and consequences. Consulting with and knowing the patient's concerns do not relieve you of the responsibility to act in a patient's best interests. Always assign priorities on the basis of good nursing judgment.

Ethical care is a part of priority setting. When ethical issues make priorities less clear, it is important to have open dialogue with the patient, the family, and other health care providers (Holmstrom and Hoglund, 2007). For example, when you care for a patient nearing death or one newly diagnosed with a chronic long-term disabling disease, you need to be able to discuss the situation fully with the patient, know his or her expectations, know your own professional responsibility in protecting the patient from harm, know the physician's therapeutic or palliative goals, and then form a plan of care. Chapter 22 outlines strategies for choosing a course of action when facing an ethical dilemma.

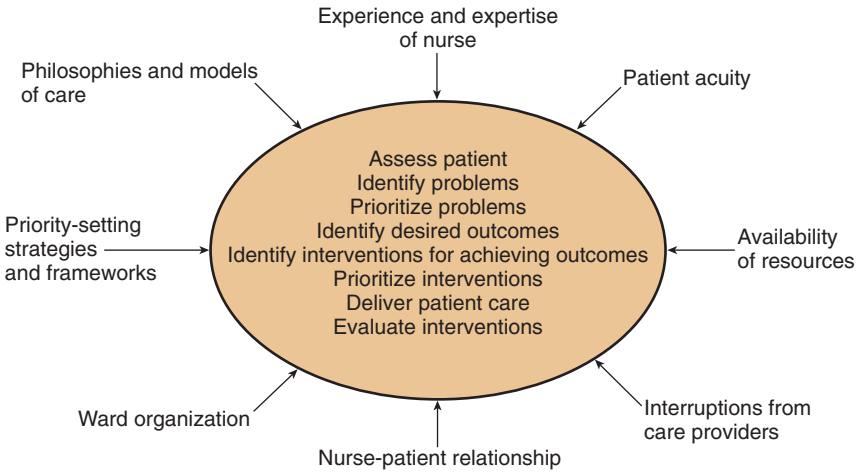

FIG. 18-1 A model for priority setting. (Modified from Hendry C, Walker A: Priority setting in clinical nursing practice, *J Adv Nurs* 47[4]:427, 2004.)

Priorities in Practice

Hendry and Walker (2004) address an important issue regarding priority setting (Fig. 18-1). Many factors within the health care environment affect your ability to set priorities. For example, in the hospital setting the model for delivering care (see Chapter 21), the organization of a nursing unit, staffing levels, and interruptions from other care providers affect the minute-by-minute determination of patient care priorities. Available resources (e.g., nurse specialists, laboratory technicians, and dietitians), policies and procedures, and supply access affect priorities as well. Finally, patients' conditions are always changing; thus priority setting is always changing.

The same factors that influence your minute-by-minute ability to prioritize nursing actions affect the ability to prioritize nursing diagnoses for groups of patients. The nature of nursing work challenges your ability to cognitively attend to a given patient's priorities when you care for more than one patient. The nursing care process is nonlinear (Potter et al., 2005). Often you complete an assessment and identify nursing diagnoses for one patient, leave the room to perform an intervention for a second patient, and move on to consult on a third patient. Nurses exercise "cognitive shifts" (i.e., shifts in attention from one patient to another during the conduct of the nursing process). This shifting of attention occurs in response to changing patient needs, new procedures being ordered, or environmental processes interacting (Potter et al., 2005). Because of these cognitive shifts, it becomes important to stay organized and know your patients' priorities. Always work from your plan of care and use your patients' priorities to organize the order for delivering interventions and organizing documentation of care.

CRITICAL THINKING IN SETTING GOALS AND EXPECTED OUTCOMES

Once you identify nursing diagnoses for a patient, ask yourself, "What is the best approach to address and resolve each problem? What do I plan to achieve?" Goals and expected outcomes are specific statements of patient behavior or physiological responses that you set to resolve a nursing diagnosis or collaborative problem. For example, Tonya chooses to administer ordered analgesics for Mr. Jacobs' *acute pain* and provide nursing measures that promote relaxation and minimize any other sources of discomfort. She hopes to achieve pain relief (goal). The specific patient behaviors or physiological responses (expected outcomes) include Mr. Jacobs' reporting pain at a level below 4, showing more freedom in movement and less grimacing, and being able to participate in education sessions.

During planning you select goals and outcomes for each nursing diagnosis to provide a clear focus for the type of interventions needed to care for your patient and to then evaluate the effectiveness of these interventions. A **goal** is a broad statement that describes a desired change in a patient's condition or behavior. Mr. Jacobs has the diagnosis of *deficient knowledge* regarding his postoperative recovery. A goal of care for this diagnosis includes, "Patient expresses understanding of postoperative risks." The goal requires making Mr. Jacobs aware of the risks associated with his type of surgery. It gives Tonya a clear focus on the topics to include in her instruction. An **expected outcome** is a measurable criterion to evaluate goal achievement. Once an outcome is met, you then know that a goal has been at least partially achieved. Sometimes several expected outcomes must be met for a single goal. Measurable outcomes for the goal of "understanding postoperative risks" include: "Patient identifies signs and symptoms of wound infection," and "Patient explains signs of urinary obstruction," both risks from a prostatectomy. After Tonya instructs Mr. Jacobs, she determines if he can identify signs and symptoms of wound infection; if so, the goal is partially met. If the patient can also explain signs of urinary obstruction, the goal is fully met.

Planning nursing care requires critical thinking (Fig. 18-2). Critically evaluate the identified nursing diagnoses, the urgency or priority of the problems, and the resources of the patient and the health care delivery system. You apply knowledge from the medical, sociobehavioral, and nursing sciences to plan patient care. The selection of goals, expected outcomes, and interventions requires consideration of your previous experience with similar patient problems and any established standards for clinical problem management. The goals and outcomes need to meet established intellectual standards by being relevant to patient needs, specific, singular, observable, measurable, and time limited. You also use critical thinking attitudes in selecting interventions with the greatest likelihood of success.

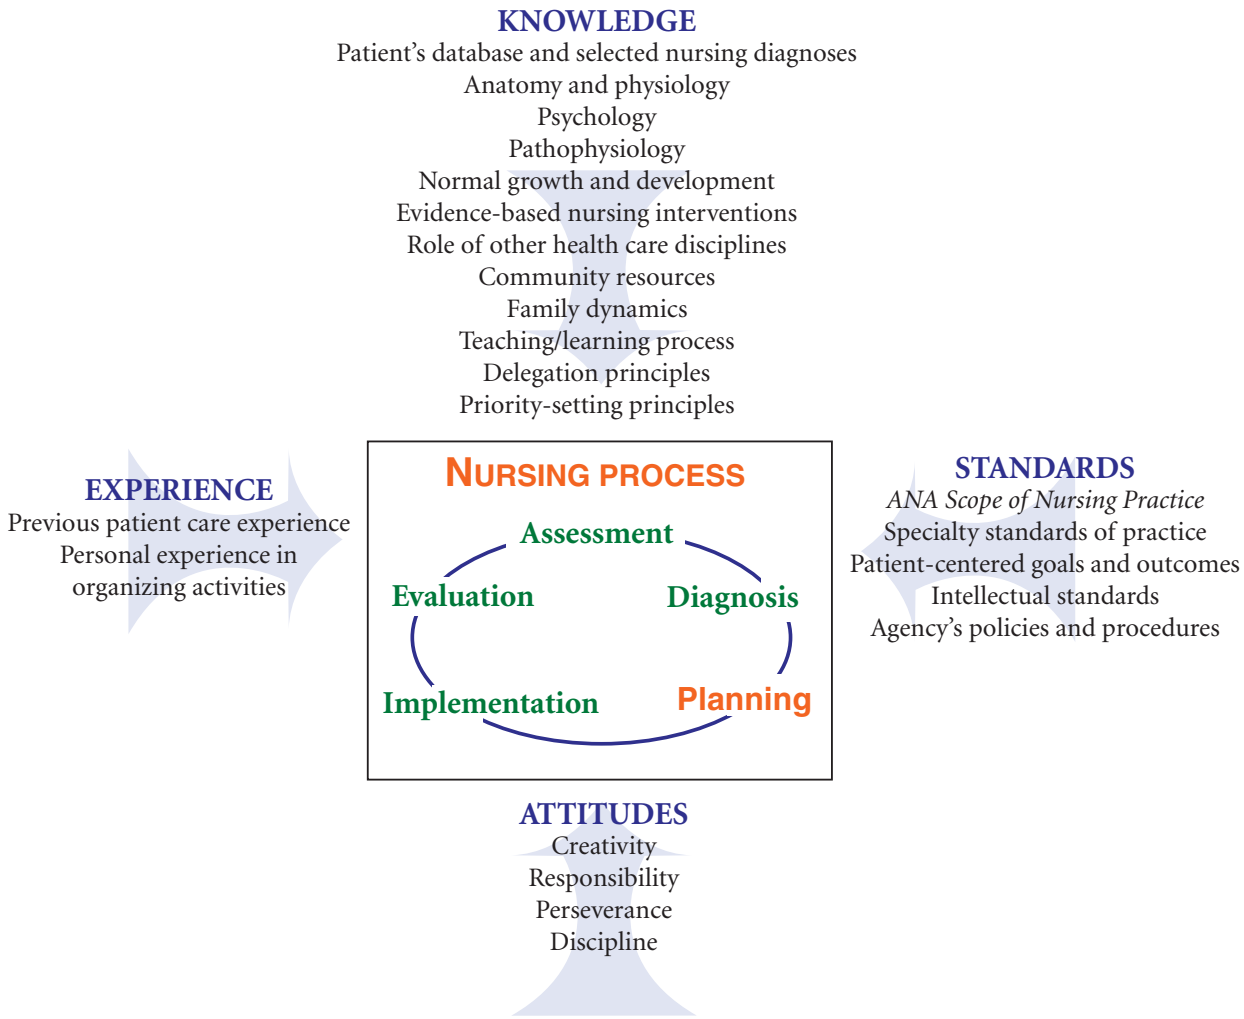

FIG. 18-2 Critical thinking and the process of planning care.

Goals of Care

A **patient-centered goal** reflects a patient's highest possible level of wellness and independence in function. It is realistic and based on patient needs and resources. For example, consider the diagnoses of *acute pain* versus *chronic pain*. A patient such as Mr. Jacobs with *acute pain* can realistically expect pain relief. In contrast, a patient with terminal bone cancer in *chronic pain* can only expect an acceptable level of pain control. A patient goal represents a predicted resolution of a diagnosis or problem, evidence of progress toward resolution, progress toward improved health status, or continued maintenance of good health or function (Carpenito-Moyet, 2009).

Each goal is time limited so the health care team has a common time frame for problem resolution. For example, the goal of "patient will achieve pain relief" for Mr. Jacobs is complete by adding the time frame "by day of discharge." With this goal in place, all efforts by the health care team are aimed at managing the patient's pain. At the time of discharge evaluation of expected outcomes (e.g., pain-rating score, signs of grimacing, level of movement) show if the goal was met. The time frame depends on the nature of the problem, etiology, overall condition of the patient, and treatment setting. A **short-term goal** is an objective behavior or response that you expect a patient to achieve in a short time, usually less than a week. In an acute care setting you often set goals for over a course of just a few hours. A **long-term goal** is an objective behavior or response that you expect a patient to achieve over a longer period, usually over several days, weeks, or months (e.g., "Patient will be tobacco free within 60 days"). Table 18-1 shows the progression from nursing diagnoses to goals and expected outcomes and the relationship to nursing interventions.

Role of the Patient in Goal Setting. Always partner with patients when setting their individualized goals. Mutual goal setting includes the patient and family (when appropriate) in prioritizing the goals of care and developing a plan of action. For patients to participate in goal setting, they need to be alert and have some degree of independence in completing activities of daily living, problem solving, and decision making. Unless goals are mutually set and there is a clear plan of action, patients fail to fully participate in the plan of care. Patients need to understand and see the value of nursing therapies, even though they are often totally dependent on you as the nurse. When setting goals, act as an advocate or support for the patient to select nursing interventions that promote his or her return to health or prevent further deterioration when possible.

TABLE 18-1 Examples of Goal Setting with Expected Outcomes for Mr. Jacobs

NURSING DIAGNOSES	GOALS	EXPECTED OUTCOMES
Acute pain related to incisional trauma	Mr. Jacobs achieves pain relief by day of discharge.	Mr. Jacobs reports pain at a level or 3 or below by discharge. Mr. Jacobs moves and turns freely in bed within 24 hours. Mr. Jacobs shows less grimacing during movement in 24 hours.
Anxiety related to uncertainty over course of recovery	Mr. Jacobs expresses acceptance of health status by day of discharge.	Mr. Jacobs discusses surgical outcomes with surgeon in 24 hours. Mr. Jacobs shares concerns with wife before discharge. Mr. Jacobs describes effects surgery will have on recovery.
Deficient knowledge regarding surgical recovery related to inexperience with surgery	Mr. Jacobs expresses understanding of postoperative risks in 24 hours.	Mr. Jacobs is able to identify signs and symptoms of wound infection in 48 hours. Mr. Jacobs or wife is able to demonstrate catheter care by discharge. Mr. Jacobs is able to identify problems to report to surgeon by discharge.
Impaired physical mobility related to incisional pain	Mr. Jacobs ambulates independently in 3 days.	Mr. Jacobs initiates turning in bed independently in 24 hours. Mr. Jacobs gets up to chair 3 times daily for next 2 days. Mr. Jacobs walks with assistance to hallway in 48 hours.

Tonya has a discussion with Mr. Jacobs and his wife together about setting the plan for the diagnosis of deficient knowledge. Tonya explains the topics that they need to discuss so the couple understands Mr. Jacobs' postoperative risks. They plan the instruction the next day just before lunch when Mrs. Jacobs' visits. Mr. Jacobs asks to have the instruction also include information on how the surgery can affect his sexual function. Tonya agrees and plans to clarify with the surgeon so the information is accurate and realistic. The surgeon has told Mr. Jacobs that there is a risk, but it is too early to know the extent of any possible nerve damage.

Expected Outcomes

An expected outcome is a specific measurable change in a patient's status that you expect to occur in response to nursing care. Outcomes as a result of Mr. Jacobs' postoperative instruction include his ability to describe signs of a surgical wound infection and identify when to call his surgeon with problems. Expected outcomes direct nursing care because they are the desired physiological, psychological, social, developmental, or spiritual responses that indicate resolution of a patient's health problems. A patient's willingness and capability to reach an expected outcome improves his or her likelihood of achieving it. Taken from both short- and long-term goals, outcomes determine when a specific patient-centered goal has been met.

Usually you develop several expected outcomes for each nursing diagnosis and goal because sometimes one nursing action is not enough to resolve a patient problem. In addition, a list of the step-by-step expected outcomes gives you practical guidance in planning interventions. Always write expected outcomes sequentially, with time frames (see Table 18-1). Time frames give you progressive steps in which to move a patient toward recovery and offer an order for nursing interventions. They also set limits for problem resolution.

Nursing Outcomes Classification. Much attention in the current health care environment is focused on measuring outcomes to gauge the quality of health care. If a chosen intervention repeatedly results in desired outcomes that benefit patients, it needs to become part of a standardized approach to a patient problem. For example, if the use of a chlorhexidine mouthwash (intervention) repeatedly results in a lower incidence of aspiration pneumonia (outcome) in critically ill patients, use of the mouthwash needs to become part of standard mouth care in critical care units.

Nursing plays an important role in monitoring and managing patient conditions and diagnosing problems that are amenable to nursing intervention. The clinical reasoning and decision making of nurses is a key part of quality health care (Moorhead et al., 2008). Thus it becomes important to identify and measure patient outcomes that are influenced by nursing care. A **nursing-sensitive patient outcome** is a measurable patient, family or community state, behavior, or perception largely influenced by and sensitive to nursing interventions (Moorhead et al., 2008). For the nursing profession to become a full participant in clinical evaluation research, policy development, and interdisciplinary work, nurses need to identify and measure patient outcomes influenced by nursing interventions. The Iowa Intervention Project has done just that. It published the Nursing Outcomes Classification (NOC) and linked the outcomes to NANDA International nursing diagnoses (Moorhead et al., 2008). For each NANDA International nursing diagnosis there are multiple NOC suggested outcomes. These outcomes have labels for describing the focus of nursing care and include indicators to use in evaluating the success with nursing interventions (Table 18-2). NOC contains outcomes for individuals, family caregivers, the family, and the community in all health care settings. Efforts to measure outcomes and capture the changes in the status of patients over time allow nurses to improve patient care quality and add to nursing knowledge (Moorhead et al., 2008). The use of a common set of outcomes allows nurses to study the effects of nursing interventions over time and across settings. The fourth edition of NOC standardizes the way to measure patient outcomes. It is an excellent resource for you to develop care plans and concept maps. NOC outcomes provide a common nursing language for continuity of care and measurement of the success of nursing interventions.

Guidelines for Writing Goals and Expected Outcomes

There are seven guidelines for writing goals and expected outcomes.

Patient-Centered. Outcomes and goals reflect patient behaviors and responses expected as a result of nursing interventions. Write a goal or outcome to reflect a patient's specific behavior, not to reflect your goals or interventions.

TABLE 18-2 Examples of NANDA International Nursing Diagnoses and Suggested NOC Linkages

NURSING DIAGNOSIS	SUGGESTED NOC OUTCOMES (EXAMPLES)	OUTCOME INDICATORS (EXAMPLES)
Deficient knowledge	Knowledge: Treatment Procedures	Description of treatment procedure
		Description of steps in procedure
	Knowledge: Disease Process	Effects of disease
		Specific disease process
Activity intolerance	Activity Tolerance	Oxygen saturation with activity
		Pulse rate with activity
		Respiratory rate with activity
	Self-Care Status	Bathes self
		Dresses self
		Prepares food and fluid for eating

NOC, Nursing Outcomes Classification.

- A correct goal statement: "Patient will ambulate independently in 3 days."
- A correct outcome statement: "Patient will ambulate in the hall 3 times a day by 4/22."
- A common error is to write an intervention: "Ambulate patient in the hall 3 times a day."

Singular Goal or Outcome. You want to be precise when you evaluate a patient's response to a nursing action. Each goal and outcome should address only one behavior or response. If an outcome reads, "Patient's lungs will be clear to auscultation, and respiratory rate will be 20 breaths per minute by 8/22," your measurement of outcomes will be complicated. When you evaluate that the lungs are clear but the respiratory rate is 28 breaths per minute, you do not know if the patient achieved the expected outcome. By splitting the statement into two parts, "Lungs will be clear to auscultation by 8/22," and "Respiratory rate will be 20 breaths per minute by 8/22," you are able to determine if and when the patient achieves each outcome. Singularity allows you to decide if there is a need to modify the plan of care.

A goal also contains only one behavior or response. The example, "Patient will administer a self-injection and demonstrate infection control measures," is incorrect because the statement includes two different behaviors, administer and demonstrate. Instead word the goal as follows, "Patient will administer a self-injection by discharge." The specific criteria you use to measure success of the goal are the singular expected outcomes. For example, "Patient will prepare medication dose correctly," and "Patient uses medical asepsis when preparing injection site."

Observable. You need to be able to observe if change takes place in a patient's status. Observable changes occur in physiological findings and in the patient's knowledge, perceptions, and behavior. You observe outcomes by directly asking patients about their condition or using assessment skills. For example, you observe the goal, "Patient will be able to self-administer insulin," through the outcome of watching, "Patient prepares insulin dosage correctly by 8/30." For the outcome, "Lungs will be clear on auscultation by 8/31," you auscultate the lungs following any therapy. The outcome statement, "Patient will appear less anxious," is not correct because there is no specific behavior observable for "will appear." A more correct outcome is, "Patient will show better eye contact during conversations."

Measurable. You learn to write goals and expected outcomes that set standards against which to measure the patient's response to nursing care. Examples such as, "Body temperature will remain 98.6° F," and, "Apical pulse will remain between 60 and 100 beats per minute," allow you to objectively measure changes in the patient's status. Do not use vague qualifiers such as "normal," "acceptable," or "stable" in an expected outcome statement. Vague terms result in guesswork in determining a patient's response to care. Terms describing quality, quantity, frequency, length, or weight allow you to evaluate outcomes precisely.

Time-Limited. The time frame for each goal and expected outcome indicates when you expect the response to occur. It is very important to collaborate with patients to set realistic and reasonable time frames. Time frames help you and the patient to determine if the patient is making progress at a reasonable rate. If not, you must revise the plan of care. Time frames also promote accountability in delivering and managing nursing care.

Mutual Factors. Mutually set goals and expected outcomes ensure that the patient and nurse agree on the direction and time limits of care. Mutual goal setting increases the patient's motivation and cooperation. As a patient advocate, apply standards of practice, evidence-based knowledge, safety principles, and basic human needs when assisting patients with setting goals. Your knowledge background helps you select goals and outcomes that should be met on the basis of typical responses to clinical interventions. Yet you must consider patients' desires to recover and their physical and psychological condition to set goals and outcomes to which they can agree.

Realistic. Set goals and expected outcomes that a patient is able to reach based on your assessment. This is a challenge when the time allotted for care is limited. But it also means that you must communicate these goals and outcomes to caregivers in other settings who will assume responsibility for patient care (e.g., home health, rehabilitation). Realistic goals provide patients a sense of hope that increases motivation and cooperation. To establish realistic goals, assess the resources of the patient, health care facility, and family. Be aware of the patient's physiological, emotional, cognitive, and sociocultural potential and the economic cost and resources available to reach expected outcomes in a timely manner.

CRITICAL THINKING IN PLANNING NURSING CARE

Part of the planning process is to select nursing interventions for meeting the patient's goals and outcomes. Once nursing diagnoses have been identified and goals and outcomes are selected, you choose interventions individualized for the patient's situation. Nursing interventions are treatments or actions based on clinical judgment and knowledge that nurses perform to meet patient outcomes (Bulechek et al., 2008). During planning you select interventions designed to help a patient move from the present level of health to the level described in the goal and measured by the expected outcomes. The actual implementation of these interventions occurs during the implementation phase of the nursing process (see Chapter 19).

Choosing suitable nursing interventions involves critical thinking and your ability to be competent in three areas: (1) knowing

the scientific rationale for the intervention, (2) possessing the necessary psychomotor and interpersonal skills, and (3) being able to function within a particular setting to use the available health care resources effectively (Bulechek et al., 2008).

Types of Interventions

There are three categories of nursing interventions: nurse-initiated, physician-initiated, and collaborative interventions. Some patients require all three categories, whereas other patients need only nurse- and physician-initiated interventions.

Nurse-initiated interventions are the **independent nursing interventions,** or actions that a nurse initiates. These do not require an order from another health care professional. As a nurse you act independently on a patient's behalf. Nurse-initiated interventions are autonomous actions based on scientific rationale. Examples include elevating an edematous extremity, instructing patients in side effects of medications, or repositioning a patient to achieve pain relief. Such interventions benefit a patient in a predicted way related to nursing diagnoses and patient goals (Bulechek et al., 2008). Nurse-initiated interventions require no supervision or direction from others. Each state within the United States has Nurse Practice Acts that define the legal scope of nursing practice (see Chapter 23). According to the Nurse Practice Acts in a majority of states, independent nursing interventions pertain to activities of daily living, health education and promotion, and counseling. For Mr. Jacobs Tonya selects anxiety-reduction interventions such as using a calm and reassuring approach, listening attentively, and providing factual information.

Physician-initiated interventions are **dependent nursing interventions,** or actions that require an order from a physician or another health care professional. The interventions are based on the physician's or health care provider's response to treat or manage a medical diagnosis. Advanced practice nurses who work under collaborative agreements with physicians or who are licensed independently by state practice acts are also able to write dependent interventions. As a nurse you intervene by carrying out the provider's written and/or verbal orders. Administering a medication, implementing an invasive procedure (e.g., inserting a Foley catheter, starting an intravenous [IV] infusion), changing a dressing, and preparing a patient for diagnostic tests are examples of physician-initiated interventions.

Each physician-initiated intervention requires specific nursing responsibilities and technical nursing knowledge. You are often the one performing the intervention, and you must know the types of observations and precautions to take for the intervention to be delivered safely and correctly. For example, when administering a medication you are responsible for not only giving the medicine correctly, but also knowing the classification of the drug, its physiological action, normal dosage, side effects, and nursing interventions related to its action or side effects (see Chapter 31). You are responsible for knowing when an invasive procedure is necessary, the clinical skills necessary to complete it, and its expected outcome and possible side effects. You are also responsible for adequate preparation of the patient and proper communication of the results. You perform dependent nursing interventions, like all nursing actions, with appropriate knowledge, clinical reasoning, and good clinical judgment.

Collaborative interventions, or interdependent interventions, are therapies that require the combined knowledge, skill, and expertise of multiple health care professionals. Typically when you plan care for a patient, you review the necessary interventions and determine if the collaboration of other health care disciplines is necessary. A patient care conference with an interdisciplinary health care team results in selection of interdependent interventions.

In the case study involving Mr. Jacobs, Tonya plans independent interventions to help calm Mr. Jacobs' anxiety and begin teaching him about postoperative care activities. Among the dependent interventions Tonya plans to implement are the administration of an analgesic and ordered wound care. Tonya's collaborative intervention involves consulting with the unit discharge coordinator, who will help Mr. and Mrs. Jacobs plan for their return home and consult with the home health department to ensure that the Jacobs have home health visits.

When preparing for physician-initiated or collaborative interventions, do not automatically implement the therapy but determine whether it is appropriate for the patient. Every nurse faces an inappropriate or incorrect order at some time. The nurse with a strong knowledge base recognizes the error and seeks to correct it. The ability to recognize incorrect therapies is particularly important when administering medications or implementing procedures. Errors occur in writing orders or transcribing them to a documentation form or computer screen. Clarifying an order is competent nursing practice, and it protects the patient and members of the health care team. When you carry out an incorrect or inappropriate intervention, it is as much your error as the person who wrote or transcribed the original order. You are legally responsible for any complications resulting from the error (see Chapter 23).

Selection of Interventions

During planning do not select interventions randomly. For example, patients with the diagnosis of *anxiety* do not always need care in the same way with the same interventions. You treat *anxiety related to the uncertainty of surgical recovery* very differently than *anxiety related to a threat to loss of family role function*. When choosing interventions, consider six important factors: (1) characteristics of the nursing diagnosis, (2) goals and expected outcomes, (3) evidence base (e.g., research or proven practice guidelines) for the interventions, (4) feasibility of the intervention, (5) acceptability to the patient, and (6) your own competency (Bulechek et al., 2008) (Box 18-1). When considering a plan of care, review resources such as the nursing literature, standard protocols or guidelines, the Nursing Interventions Classification (NIC), critical pathways, policy or procedure manuals, or textbooks. Collaboration with other health professionals is also useful. As you select interventions, review your patient's needs, priorities, and previous experiences to select the interventions that have the best potential for achieving the expected outcomes.

Nursing Interventions Classification. Just as with the standardized NOC, the Iowa Intervention Project has also developed a set of nursing interventions that provides a level of standardization to enhance communication of nursing care across all health care settings and to compare outcomes (Bulechek et al., 2008). The NIC model includes three levels: domains, classes, and interventions for ease of use. The domains are the highest level (level 1) of the model, using broad terms (e.g., safety and basic physiological) to organize the more specific classes and interventions (Table 18-3). The second level of the model includes 30 classes, which offer useful clinical categories to reference when selecting interventions. The third level of the model includes the 542 interventions, defined as any treatment based on clinical judgment and knowledge that a nurse performs to enhance patient outcomes (Bulechek et al., 2008) (Box 18-2). Each intervention then includes a variety of

BOX 18-1 CHOOSING NURSING INTERVENTIONS

Characteristics of the Nursing Diagnosis

- Interventions should alter the etiological (related to) factor or signs and symptoms associated with the diagnostic label. ***Example: Acute pain related to incisional trauma—choose interventions that relieve swelling and strain on incision site (positioning and turning measures) and lower pain reception (analgesic).***
- When an etiological factor cannot change, direct the interventions toward treating the signs and symptoms (e.g., defining characteristics for a diagnosis). ***Example: Deficient knowledge regarding surgical recovery related to inexperience—choose interventions directed toward providing information that answer patient's questions about recovery procedures and relieve anxiety.***
- For potential or high-risk diagnoses, direct interventions at altering or eliminating risk factors for the diagnosis.

Expected Outcomes

- State outcomes in terms used to evaluate the effect of an intervention. This language assists in selecting the intervention. ***Example: For the outcome "patient will perform urinary catheter care by discharge," the nurse will evaluate skills instruction by observing the patient perform catheter care.***
- Nursing Interventions Classification (NIC) is designed to show the link to Nursing Outcomes Classification (NOC) (Moorhead et al., 2008). Use these resources in developing care plans.

Research Base

- Research evidence in support of a nursing intervention will indicate the effectiveness of using the intervention with certain types of patients.
- Refer to the evidence (e.g., research articles or evidence-based practice protocols that describe the use of evidence in similar clinical situations and settings) in selecting interventions.
- When research is not available, use scientific principles (e.g., infection control) or consult a clinical expert about your patient.

Feasibility

- A specific intervention has the potential to interact with other interventions.
- Be knowledgeable about the total plan of care.
- Consider cost: Is the intervention clinically effective and cost efficient?
- Consider time: Are time and personnel resources available? ***Example: If you plan to get a patient up into a chair 3 times a day, will there be staff to assist with the transfer?***

Acceptability to the Patient

- A treatment plan needs to be acceptable to the patient and family and match the patient's goals, health care values, and culture.
- Promote informed choice; help a patient know how to participate in and anticipate the effect of interventions.

Capability of the Nurse

- Be prepared to carry out the intervention.
- Have the necessary psychosocial and psychomotor skills to complete the intervention.
- Be able to function within the specific setting and effectively and efficiently use health care resources.

BOX 18-3 EXAMPLE OF AN INTERVENTION AND ASSOCIATED NURSING ACTIVITIES

Intervention—Environmental Management: Comfort

Examples of Activities

- Create a calm and supportive environment.
- Provide a safe and clean environment.
- Adjust room temperature to that most comfortable for the individual.
- Avoid unnecessary exposure, drafts, overheating, or chilling.
- Prevent unnecessary interruptions and allow for rest period.
- Monitor skin, especially over bony prominences, for signs of pressure or irritation.
- Provide prompt attention to call bells, which should always be within reach.

From Bulechek GM et al: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

nursing activities from which to choose (Box 18-3) and which a nurse commonly uses in a plan of care. NIC interventions are also linked with NANDA International nursing diagnoses for ease of use (NANDA International, 2012). For example, if a patient has a nursing diagnosis of *acute pain,* there are 21 recommended interventions, including pain management, cutaneous stimulation, and anxiety reduction. Each of the recommended interventions has a variety of activities for nursing care. NIC is a valuable resource for selecting appropriate interventions and activities for your patient. It is evolving and practice oriented. The classification is comprehensive, including independent and collaborative interventions. It remains your decision to determine which interventions and activities best suit your patient's individualized needs and situation.

SYSTEMS FOR PLANNING NURSING CARE

In any health care setting a nurse is responsible for providing a nursing plan of care for all patients. The plan of care sometimes takes several forms (e.g., nursing Kardex, standardized care plans, and computerized plans). More hospitals today are adopting

TABLE 18-3 Nursing Interventions Classification (NIC) Taxonomy

DOMAIN 1	DOMAIN 2	DOMAIN 3
Level 1 Domains		
1. Physiological: Basic Care that supports physical functioning	**2. Physiological: Complex** Care that supports homeostatic regulation	**3. Behavioral** Care that supports psychosocial functioning and facilitates lifestyle changes
Level 2 Classes		
A Activity and Exercise Management: Interventions to organize or assist with physical activity and energy conservation and expenditure	*G Electrolyte and Acid-Base Management:* Interventions to regulate electrolyte/acid-base balance and prevent complications	*O Behavior Therapy:* Interventions to reinforce or promote desirable behaviors or alter undesirable behaviors
B Elimination Management: Interventions to establish and maintain regular bowel and urinary elimination patterns and manage complications caused by altered patterns	*H Drug Management:* Interventions to facilitate desired effects of pharmacological agents	*P Cognitive Therapy:* Interventions to reinforce or promote desirable cognitive functioning or alter undesirable cognitive functioning
C Immobility Management: Interventions to manage restricted body movement and the sequelae	*I Neurological Management:* Interventions to optimize neurological functions	*Q Communication Enhancement:* Interventions to facilitate delivering and receiving verbal and nonverbal messages
D Nutrition Support: Interventions to modify or maintain nutritional status	*J Perioperative Care:* Interventions to provide care before, during, and immediately after surgery	*R Coping Assistance:* Interventions to assist another to build on own strengths, adapt to a change in function, or achieve a higher level of function
E Physical Comfort Promotion: Interventions to promote comfort using physical techniques	*K Respiratory Management:* Interventions to promote airway patency and gas exchange	*S Patient Education:* Interventions to facilitate learning
F Self-Care Facilitation: Interventions to provide or assist with routine activities of daily living	*L Skin/Wound Management:* Interventions to maintain or restore tissue integrity	*T Psychological Comfort Promotion:* Interventions to promote comfort using psychological techniques
	M Thermoregulation: Interventions to maintain body temperature within a normal range	
	N Tissue Perfusion Management: Interventions to optimize circulation of blood and fluids to the tissue

electronic health records (EHRs) and a documentation system that includes software programs for nursing care plans (Hebda et al., 2009). Generally a **nursing care plan** includes nursing diagnoses, goals and/or expected outcomes, specific nursing interventions, and a section for evaluation findings so any nurse is able to quickly identify a patient's clinical needs and situation. Nurses revise a plan when a patient's status changes. Electronic care plans often follow a standardized format, but you can individualize each plan to a unique patient's needs (see Chapter 26). The standardized format is usually based on nursing diagnoses or select problem areas, which nurses are able to individualize for a specific patient. In hospitals and community-based settings, patients receive care from more than one nurse, physician, or allied health professional. Thus more institutions are developing **interdisciplinary care plans,** which include contributions from all disciplines involved in patient care. The interdisciplinary plan is designed to improve the coordination of all patient therapies and communication among all disciplines.

A nursing care plan reduces the risk for incomplete, incorrect, or inaccurate care. As the patient's problems and status change, so does the plan. A nursing care plan is a guideline for coordinating nursing care, promoting continuity of care, and listing outcome criteria to be used later in evaluation (see Chapter 20). The plan of care communicates nursing care priorities to nurses and other health care professionals. It also identifies and coordinates resources for delivering nursing care. For example, in a care plan you list specific supplies necessary to use in a dressing change or names of clinical nurse specialists who are providing consultation for a patient.

The nursing care plan enhances the continuity of nursing care by listing specific nursing interventions needed to achieve the goals of care. All nurses who care for a given patient carry out these nursing interventions (e.g., throughout each day during a patient's length of stay [in a hospital] or during weekly visits to the home [home health nursing]). A correctly formulated nursing care plan makes it easy to continue care from one nurse to another. The Nursing Care Plan provides an example of a care plan for Mr. Jacobs, using the format found throughout this text.

A care plan includes a patient's long-term needs. Incorporating the goals of the care plan into discharge planning is important. Thus it is beneficial to involve the family in planning care if the patient is agreeable. The family is often a resource to help the patient meet health care goals. In addition, meeting some of the family's needs will possibly improve the patient's level of wellness. Discharge planning is especially important for a patient undergoing long-term rehabilitation in the community and who will require ongoing home care. Same-day surgeries and earlier discharges from hospitals require you to begin planning discharge from the moment the patient enters the health care agency. The complete care plan is the blueprint for nursing action. It provides direction for implementation of the plan and a framework for evaluation of the patient's response to nursing actions.

Change of Shift

The change-of-shift report is the standard practice used for off-going nurses leaving a shift to communicate information about the patient's plan of care to oncoming patient care personnel. At the

DOMAIN 4	DOMAIN 5	DOMAIN 6	DOMAIN 7
4. Safety Care that supports protection against harm	**5. Family** Care that supports the family	**6. Health System** Care that supports effective use of the health care delivery system	**7. Community** Care that supports the health of the community
U Crisis Management: Interventions to provide immediate short-term help in both psychological and physiological crises	*W Childbearing Care:* Interventions to assist in understanding and coping with the psychological and physiological changes during the childbearing period	*Y Health System Mediation:* Interventions to facilitate the interface between patient/family and the health care system	*c Community Health Promotion:* Interventions that promote the health of the whole community
V Risk Management: Interventions to initiate risk-reduction activities and continue monitoring risks over time	*Z Childrearing Care:* Interventions to assist in rearing children	*a Health System Management:* Interventions to provide and enhance support services for the delivery of care	*d Community Risk Management:* Interventions that assist in detecting or preventing health risks to the whole community
	X Life Span Care: Interventions to facilitate family unit functioning and promote the health and welfare of family members throughout the life span	*b Information Management:* Interventions to facilitate communication among health care providers	

end of a shift you discuss your patients' plans of care and their overall progress with the next caregivers. Thus all nurses are able to discuss current and relevant information about each patient's plan of care. The newest term used to describe this process is *nursing handoff*. It is a critical time when nurses collaborate and share important information that ensures the continuity of care for a patient and prevents errors or delays in providing nursing interventions. In the past the change-of-shift report typically involved nurses leaving their report on an audiotape recorder, which would be heard by the oncoming nursing staff. This approach did not consistently allow staff from both shifts to share information one on one, ask questions, clarify misunderstandings, and validate the patients' priority problems. Audiotapes are often difficult to hear, and frequently nurses omit information. In some agencies, the nursing handoff process occurs during walking rounds when nurses exchange information about patients at the bedside, giving patients the opportunity to also ask questions and confirm information. Recent research identifies approaches to use for effective handoffs and barriers to their effectiveness. However, there is no evidence for one best nursing hand-off practice (Riesenberg et al., 2010) (Box 18-4). Written care plans organize information exchanged by nurses in change-of-shift reports (see Chapter 26). You learn to focus your reports on the nursing care, treatments, and expected outcomes documented in the care plans. Avoid adding personal opinions about the patient since these are not relevant and could unnecessarily influence the oncoming nurse's perception of him or her as an individual.

Student Care Plans

Student care plans are useful for learning the problem-solving technique, the nursing process, skills of written communication, and organizational skills needed for nursing care. Most important, a student care plan helps you apply knowledge gained from the nursing and medical literature and the classroom to a practice situation. Students typically write a care plan for each nursing diagnosis. The student care plan is more elaborate than a care plan used in a hospital or community agency because its purpose is to teach the process of planning care. Each school uses a different format for student care plans. Often, the format used is similar to the one used by the health care agency that provides students from that school their clinical experiences.

One example of a form of care plan developed by students is the six-column format. Starting from left to right, the six columns include: (1) assessment data relevant to corresponding diagnosis, (2) goals, (3) outcomes identified for the patient, (4) implementation for the plan of care, (5) a **scientific rationale** (the reason that you chose a specific nursing action, based on supporting evidence), and (6) a section to evaluate your care. In the implementation section you select the interventions appropriate for the patient. The following questions help you design a plan:

- *What* is the intervention?
- *When* should each intervention be implemented?
- *How* should the intervention be performed for this specific patient?
- *Who* should be involved in each aspect of intervention?

NURSING CARE PLAN

Anxiety

ASSESSMENT

Mr. Jacobs is a 58-year-old patient who had a radical prostatectomy for prostate cancer yesterday. The patient has a surgical incision in the retropubic area, which is a low midline abdominal incision. The surgery involves removal of the prostate gland, seminal vesicles, and part of the bladder neck. After the surgery there are risks of the patient having erectile dysfunction and incontinence. Before surgery Mr. Jacobs' doctor told him that the surgery could change his ability to have sex and there was also a chance of some urinary incontinence. The surgeon has not discussed this topic with Mr. Jacobs since the patient came to the surgical nursing unit. Mr. Jacobs' wife has been with the patient and is the person who will provide care and support in the home.

Assessment Activities*	***Findings/Defining Characteristics***
Ask patient what concerns he has about surgery.	Patient **states being worried** about his wife and himself and the risk of sexual dysfunction. Patient also worries because he has a friend who had cancer.
Observe patient's facial expression.	Patient shows **poor eye contact** when discussing condition.
Observe body movements.	Patient shows **tenseness** in way he **clenches hands** and in **facial expression.**

*__Defining characteristics__ are shown in bold type.

NURSING DIAGNOSIS: Anxiety related to uncertainty over course of recovery

PLANNING

Goals	***Expected Outcomes (NOC)***†
Mr. Jacobs expresses acceptance of health status by day of discharge.	**Acceptance: Health Status** Patient discusses surgical outcomes with surgeon in 24 hours. Patient shares concerns with wife before day of discharge. Patient describes effects surgery will have on recovery by day of discharge.
Mr. Jacobs expresses relief of concerns by day of discharge.	**Anxiety Level** Patient maintains eye contact during instructional discussions in 24 hours. Patient shows less facial tension during discussions in 24 hours. Patient is able to concentrate and attend to instructions in 48 hours.

†Outcomes classification labels from Moorhead S et al: *Nursing outcomes classification (NOC),* ed 4, St Louis, 2008, Mosby.

INTERVENTIONS (NIC)‡ ***Anxiety Reduction***	**RATIONALE**
Use a calm, reassuring approach in discussions	For patient to be able to express concerns, he must see nurse as being nonthreatening, reliable, and understanding (Vacarolis and Halter, 2009).
When pain is under control, have patient verbalize his perceptions, feelings, and fears.	Pain relief allows patient to attend to issues causing anxiety and discuss them more.
Encourage Mrs. Jacobs to stay with her husband as much as possible; include her in discussions.	A support system benefits a patient experiencing stress. Strong families tend to have good problem-solving skills and a commitment to one another (Schumacher et al., 2006).
Instruct Mr. Jacobs in use of progressive relaxation techniques.	Techniques teach patient how to effectively rest and reduce muscle tension, reduce symptom distress, and improve well-being (Hui et al., 2006).
Collaborate with physician to provide factual information concerning diagnosis, treatment, and prognosis.	The nurse often clarifies information provided by health care providers and is often the primary source of information needed for a patient to adjust to health problems (Bastable, 2006).

‡Intervention classification labels from Bulechek GM, Butcher HK, and Dochterman JM: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

EVALUATION

Nursing Actions	***Patient Response/Finding***	***Achievement of Outcome***
Ask Mr. Jacobs to describe what he understands about the result of his surgery and how it will affect his recovery.	Mr. Jacobs reports that his surgeon has told him the nerve affecting his ability to have sex was saved. He knows he has to have the catheter in for about a week but is not sure if incontinence is likely.	Outcomes partially met. Will discuss likelihood of incontinence more fully with surgeon. Adjust instructional plan as needed.
Observe Mr. Jacob's facial expressions.	Mr. Jacobs assumes more comfortable position in bed with less clenching of hands and a more relaxed facial expression. He maintains eye contact during discussions.	Patient's level of tension is declining.

BOX 18-4 EVIDENCE-BASED PRACTICE

Nursing Hand-Offs

PICO Question: Does the use of handoff communication compared with traditional report between nurses in acute care settings reduce errors?

Evidence Summary

A nursing handoff or change-of-shift report involves a nurse-to-nurse verbal exchange of information about patients (Athwal et al., 2009). The process involves communicating essential information to oncoming nurses, which occurs in the form of patient bedside rounds and taped or verbal reports in a conference room. Athwal et al. (2009) found that a combination of a written update along with a bedside shift report reduced the total time expended for shift report, reduced nurse overtime hours, and led to fewer times patients used call lights. In a systematic review of scientific articles discussing nursing handoffs, Riesenberg, Leisch, and Cunningham (2010) identified a number of strategies for effective handoffs and barriers to effective handoffs. However, the researchers stress that no evidence points to best nursing handoff practices and whether errors are reduced. There are risks in implementing interventions when strong evidence is lacking. Thus nurses need to carefully consider the strategies that this study found useful and decide if they fit their own institutional setting and resources.

Application to Nursing Practice

Strategies for Effective Nursing Handoffs

- Manage your time so you are prepared to give report and be concise.
- Keep report patient-centered; ask questions and clarify.
- Standardize the process using tools, forms, and checklists and be sure that essential information is consistently included.
- During walking rounds include patient and family in discussion of goals.
- Limit interruptions and distraction.

Barriers to Effective Nursing Handoffs

- Communication barriers, including omissions (missing or incomplete information), errors (incorrect, extraneous, duplicate), disorganized report or one that is routine and not individualized
- Social problems, including a culture of blame on unit that inhibits questioning
- Complexity of cases and high patient care load—increased volume of patient information and inadequate time to report

Each scientific rationale that you use to support a nursing intervention needs to include a reference, whenever possible, to document the source from the scientific literature. This reinforces the importance of evidence-based nursing practice. It is also important that each intervention be specific and unique to a patient's situation. Nonspecific nursing interventions result in incomplete or inaccurate nursing care, lack of continuity among caregivers, and poor use of resources. Common omissions that nurses make in writing nursing interventions include action, frequency, quantity, method, or person to perform them. These errors occur when nurses are unfamiliar with the planning process. Table 18-4 illustrates these types of errors by showing incorrect and correct statements of nursing interventions. The sixth column of the care plan includes a section for you to evaluate the plan of care: was each outcome fully or only partially met? Use the evaluation column to document whether the plan requires revision or when outcomes are met, thus indicating when a particular nursing diagnosis is no longer relevant to the patient's plan of care (see Chapter 20).

Care Plans for Community-Based Settings. Planning care for patients in community-based settings (e.g., clinics, community centers, or patients' homes) involves using the same principles of nursing practice. However, in these settings you need to complete a more comprehensive community, home, and family assessment. Ultimately the patient/family unit must be able to independently provide the majority of health care. You design a plan to (1) educate the patient/family about the necessary care techniques and precautions, (2) teach the patient/family how to integrate care within family activities, and (3) guide the patient/family on how to assume a greater percentage of care over time. Finally the plan includes nurses' and the patient's/family's evaluation of expected outcomes.

Critical Pathways. Critical pathways are patient care management plans that provide the multidisciplinary health care team with the activities and tasks to be put into practice sequentially (over time); their main purpose is to deliver timely care at each phase of the care process for a specific type of patient (Espinosa-Aguilar et al., 2008). A critical pathway clearly defines transition points in patient progress and draws a coordinated map of activities by which the health care team can help to make these transitions as efficient as possible. A pathway allows staff from all

TABLE 18-4 Frequent Errors in Writing Nursing Interventions

TYPE OF ERROR	INCORRECTLY STATED NURSING INTERVENTION	CORRECTLY STATED NURSING INTERVENTION
Failure to precisely or completely indicate nursing actions	Turn patient every 2 hours.	Turn patient every 2 hours, using the following schedule: 8 AM—supine 10 AM—left side; Noon—prone 2 PM—right side } Repeat at 4 PM and 2 AM
Failure to indicate frequency	Perform blood glucose measurements.	Measure blood glucose before each meal: 7 AM—11 AM—5 PM.
Failure to indicate quantity	Irrigate wound once a shift: 6 AM—2 PM—8 PM.	Irrigate wound with 100 mL normal saline until clear: 6 AM—2 PM—8 PM.
Failure to indicate method	Change patient's dressing once a shift: 6 AM—2 PM—10 PM.	Replace patient's dressing with Neosporin ointment to wound and two dry 4 × 4 dressings secured with hypoallergenic tape once a shift: 2 PM—10 PM—6 AM.

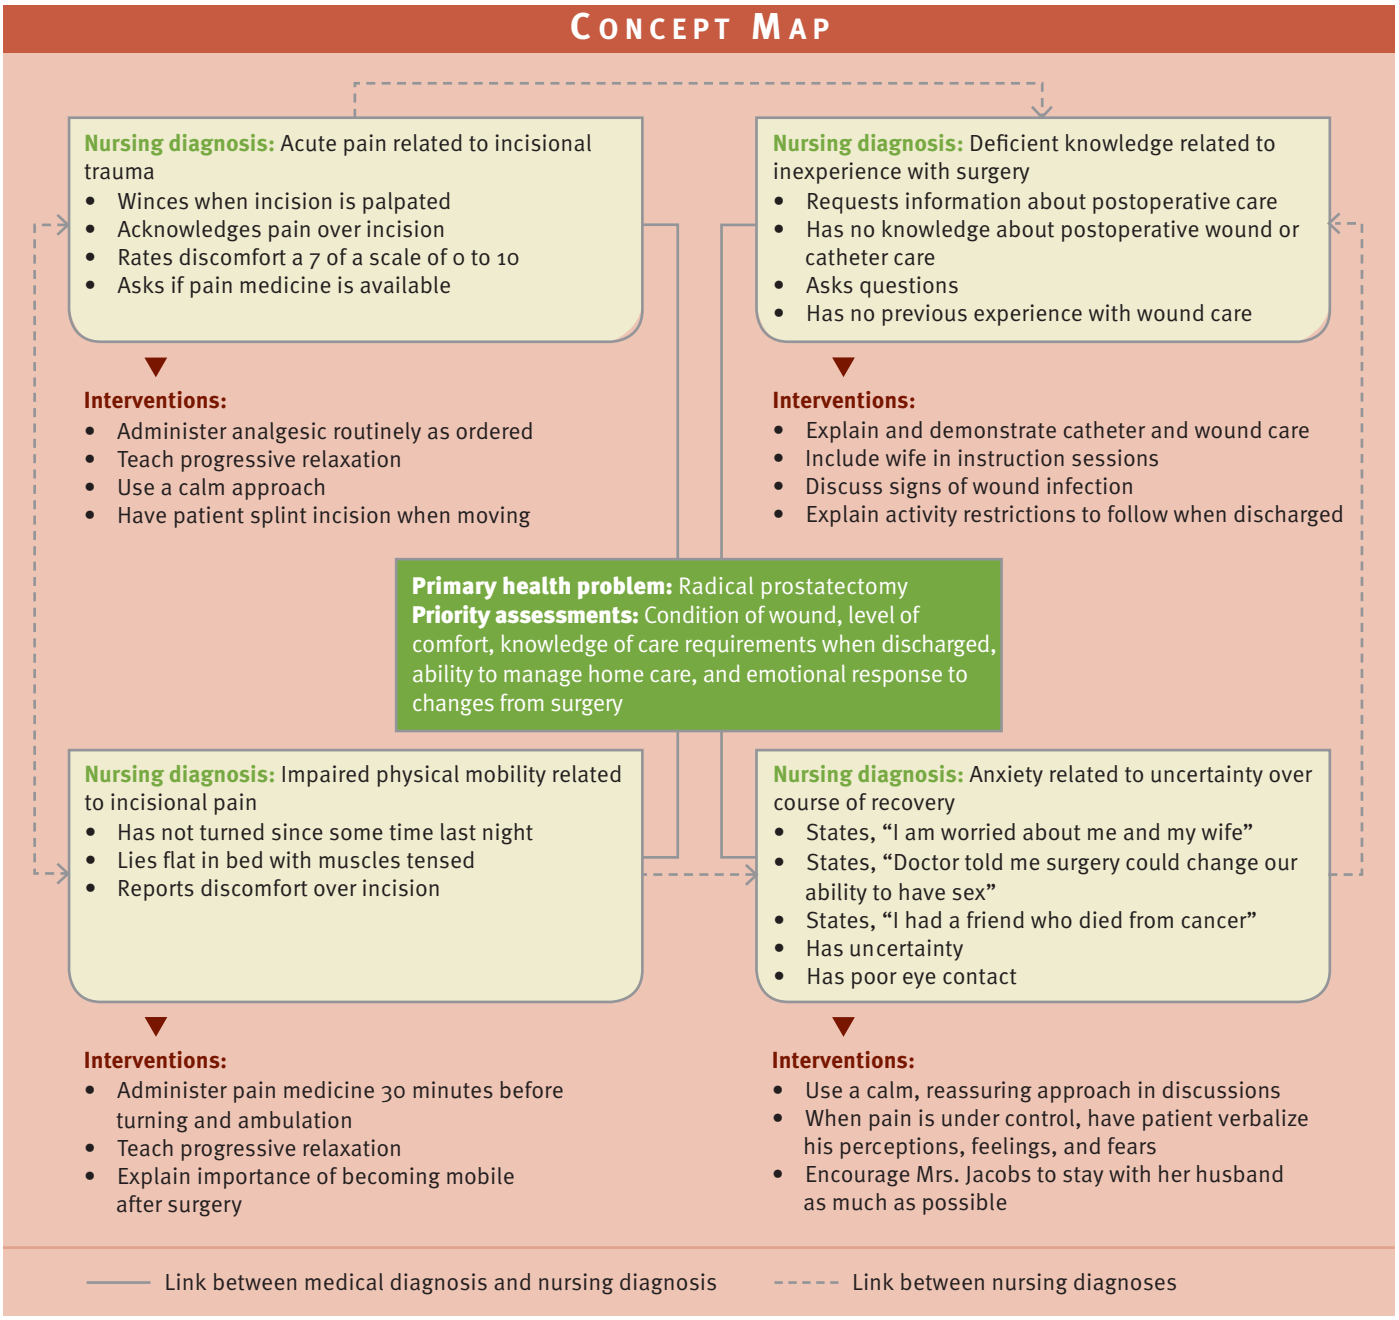

FIG. 18-3 Concept map for Mr. Jacobs: Planning.

disciplines to develop integrated care plans for a projected length of stay or number of visits. Critical pathways improve continuity of care because they clearly define the responsibility of each health care discipline. Well-developed pathways include evidence-based interventions and therapies.

Concept Maps

Chapter 16 first described concept maps and their use in care planning. Because you care for patients who present with multiple health problems and related nursing diagnoses, it is often not realistic to have a written columnar plan developed for each nursing diagnosis. In addition, the columnar plans do not contain a means to show the association between different nursing diagnoses and different nursing interventions. A concept map offers you a visual representation of all patient nursing diagnoses and allows you to diagram interventions for each. You quickly see the relationship between the diagnoses and often how a single intervention often applies to more than one health problem. Concept maps group and categorize nursing concepts to give you a holistic view of your patient's health care needs and help you make better clinical decisions in planning care.

In Chapter 17 you learned how to add nursing diagnostic labels to a concept map. When planning care for each nursing diagnosis, analyze the relationships among the diagnoses. Draw dotted lines between nursing diagnoses to indicate their relationship to one another (Fig. 18-3). It is important for you to make meaningful

associations between one concept and another. The links need to be accurate, meaningful, and complete so you can explain why nursing diagnoses are related. For example, Mr. Jacobs' *anxiety* and *acute pain* are interrelated; in addition, pain has an influence on his reduced mobility. Pain and anxiety both influence his ability to respond to instruction for his deficient knowledge.

Finally, on a separate sheet of paper or on the map itself, list nursing interventions to attain the outcomes for each nursing diagnosis. This step corresponds to the planning phase of the nursing process. While caring for the patient, use the map to write the patient's responses to each nursing activity. Also write your clinical impressions and inferences regarding the patient's progress toward expected outcomes and the effectiveness of interventions. Keep the concept map with you throughout the clinical day. As you revise the plan, take notes and add or delete nursing interventions. Use the information recorded on the map for your documentation of patient care. Critical thinkers learn by organizing and relating cognitive concepts. Concept maps help you learn the interrelationships among nursing diagnoses to create a unique meaning and organization of information.

CONSULTING OTHER HEALTH CARE PROFESSIONALS

Planning involves consultation with members of the health care team. Consultation occurs at any step in the nursing process, but you consult most often during planning and implementation. During these times you are more likely to identify a problem requiring additional knowledge, skills, or resources. This requires you to be aware of your strengths and limitations as a team member. **Consultation** is a process by which you seek the expertise of a specialist such as your nursing instructor, a physician, or a clinical nurse educator to identify ways to handle problems in patient management or the planning and implementation of therapies. The consultation process is important so all health care providers are focused on common patient goals. Always be prepared before you make a consult. Consultation is based on the problem-solving approach, and the consultant is the stimulus for change.

Often an experienced nurse is a valuable consultant when you face an unfamiliar patient care situation such as a new procedure or a patient presenting a set of symptoms that you cannot identify. In clinical nursing, consultation helps to solve problems in the delivery of nursing care. For example, a nursing student consults a clinical specialist for wound care techniques or an educator for useful teaching resources. Nurses are consulted for their clinical expertise, patient education skills, or staff education skills. Nurses also consult with other members of the health care team such as physical therapists, nutritionists, and social workers. Again, the consultation focuses on problems in providing nursing care.

When to Consult

Consultation occurs when you identify a problem that you are unable to solve using personal knowledge, skills, and resources. The process requires good intrapersonal and interprofessional collaboration. Consultation with other care providers increases your knowledge about the patient's problems and helps you learn skills and obtain resources. A good time to consult with another health care professional is when the exact problem remains unclear. An objective consultant enters a clinical situation and more clearly assesses and identifies the nature of a problem, whether it is patient, personnel, or equipment oriented. Most often you consult with health care providers who are working in your clinical area. However, sometimes you consult over the telephone (Box 18-5).

BOX 18-5 TIPS FOR MAKING PHONE CONSULTATIONS

- Have the information you need available BEFORE you make a call. At a minimum have the medical record, any medication sheets (if the consultation is about a medicine), and any notes on recent care activities.
- Assess the patient yourself before making the call. For example, when you consult with physicians, they rely heavily on your assessment so they can give appropriate advice.
- Understand why you are calling for consultation and think through some possible solutions. Your experience in caring for the patient probably allows you to make useful suggestions. This also gives you ownership of the care of patients.
- Be prepared to summarize what you think the problem is.

Data from Maison D: Effective communications are more important than ever: a physician's perspective, *J Home Care Hospice Professional* 24(3):178, 2006.

How to Consult

Begin with your own understanding of a patient's clinical problems. The first step in making a consultation is to identify the general problem area. Second, direct the consultation to the right professional such as another nurse or social worker. Third, provide the consultant with relevant information about the problem area. Include a brief summary of the problem, methods used to resolve the problem so far, and outcomes of these methods. Also share information from the patient's medical record, conversations with other nurses, and the patient's family.

Fourth, do not prejudice or influence consultants. Consultants are in the clinical setting to help identify and resolve a nursing problem, and biasing or prejudicing them blocks problem resolution. Avoid bias by not overloading consultants with subjective and emotional conclusions about the patient and the problem.

Fifth, be available to discuss the consultant's findings and recommendations. When you request a consultation, provide a private, comfortable atmosphere for the consultant and patient to meet. However, this does not mean that you leave the environment. A common mistake is turning the whole problem over to the consultant. The consultant is not there to take over the problem but to help you resolve it. When possible, request the consultation for a time when both you and the consultant are able to discuss the patient's situation with minimal interruptions or distractions. Finally, incorporate the consultant's recommendations into the care plan. The success of the advice depends on the implementation of the problem-solving techniques. Always give the consultant feedback regarding the outcome of the recommendations.

KEY POINTS

- During planning determine patient goals, set priorities, develop expected outcomes of nursing care, and select interventions for the nursing care plan.
- Priorities help you anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems.
- Goals and expected outcomes provide clear direction for the selection and use of nursing interventions and the evaluation of the effectiveness of the interventions.

- In setting goals the time frame depends on the nature of the problem, etiology, overall condition of the patient, and treatment setting.
- A patient-centered goal is singular, observable, measurable, time limited, mutual, and realistic.
- An expected outcome is an objective criterion for goal achievement.
- Nurse-initiated interventions require no order and no supervision or direction from others.
- Physician-initiated interventions require specific nursing responsibilities and technical nursing knowledge.
- During a nursing handoff nurses collaborate and share important information that ensures the continuity of care for a patient and prevents errors or delays in providing nursing interventions.
- Care plans and critical pathways increase communication among nurses and facilitate the continuity of care from one nurse to another and from one health care setting to another.
- A concept map provides a visually graphic way to show the relationship between patients' nursing diagnoses and interventions.
- The NIC taxonomy provides a standardization to help nurses select suitable interventions for patients' problems.
- Correctly written nursing interventions include actions, frequency, quantity, method, and the person to perform them.
- Consultation increases your knowledge about a patient's problem and helps in learning skills and obtaining the resources needed to solve the problem.
- When making a consultation, first identify the general problem, direct the consultation to the right professional, and provide the consultant with relevant information about the problem.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya sets out to formally plan Mr. Jacobs' care. For the nursing diagnosis of *impaired physical mobility related to incisional pain,* Tonya identifies the goal of "Patient will walk 100 yards three times a day"; and the outcome she lists is, "Patient will report pain below level of 4 and will not splint incision when moving within 48 hours." The interventions she selects for her plan include administering the ordered analgesic, progressive relaxation, and splinting the incision when the patient gets out of bed. The following three questions apply to the case study.

1. Critique the goal and outcomes that Tonya set and explain if they were written correctly.
2. Among the interventions that Tonya selected, which ones are independent, dependent, and collaborative?
3. What interventions will possibly increase the likelihood that the patient's goals of care and outcomes will be met?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse is assigned to a patient who has returned from the recovery room following surgery for a colorectal tumor. After an initial assessment the nurse anticipates the need to monitor the patient's abdominal dressing, intravenous (IV) infusion, and function of drainage tubes. The patient is in pain, reporting 6 on a scale of 0 to 10, and will not be able to eat or drink until intestinal function returns. The family has been in the waiting room for an hour, wanting to see the patient. The nurse establishes priorities first for which of the following situations? (Select all that apply.)
   1. The family comes to visit the patient.
   2. The patient expresses concern about pain control.
   3. The patient's vital signs change, showing a drop in blood pressure.
   4. The charge nurse approaches the nurse and requests a report at end of shift.
2. A patient signals the nurse by turning on the call light. The nurse enters the room and finds the patient's drainage tube disconnected, 100 mL of fluid in the intravenous (IV) line, and the patient asking to be turned. Which of the following does the nurse perform first?
   1. Reconnect the drainage tubing
   2. Inspect the condition of the IV dressing
   3. Improve the patient's comfort and turn onto her side.
   4. Obtain the next IV fluid bag from the medication room
3. A nurse assesses a 78-year-old patient who weighs 240 pounds (108.9 kg) and is partially immobilized because of a stroke. The nurse turns the patient and finds that the skin over the sacrum is very red and the patient does not feel sensation in the area. The patient has had fecal incontinence on and off for the last 2 days. The nurse identifies the nursing diagnosis of *risk for impaired skin integrity*. Which of the following goals are appropriate for the patient? (Select all that apply.)
   1. Patient will be turned every 2 hours within 24 hours.
   2. Patient will have normal bowel function within 72 hours.
   3. Patient's skin will remain intact through discharge.
   4. Patient's skin condition will improve by discharge.
4. Setting a time frame for outcomes of care serves which of the following purposes?
   1. Indicates which outcome has priority
   2. Indicates the time it takes to complete an intervention
   3. Indicates how long a nurse is scheduled to care for a patient
   4. Indicates when the patient is expected to respond in the desired manner
5. A patient has been in the hospital for 2 days because of newly diagnosed diabetes. His medical condition is unstable, and the medical staff is having difficulty controlling his blood sugar. The physician expects that the patient will remain hospitalized at least 3 more days. The nurse identifies one nursing diagnosis as *deficient knowledge regarding insulin administration related to inexperience with disease management*. Which of the following patient care goals are long term?
   1. Patient will explain relationship of insulin to blood glucose control.
   2. Patient will self-administer insulin.
   3. Patient will achieve glucose control.
   4. Patient will describe steps for preparing insulin in a syringe.
6. A patient has been in the hospital for 2 days because of newly diagnosed diabetes. His medical condition is unstable, and the medical staff is having difficulty controlling his blood sugar. The physician expects that the patient will remain hospitalized at least 3 more days. The nurse identifies one nursing diagnosis as *deficient knowledge regarding insulin administration related to inexperience with disease management*. What does the nurse

need to determine before setting the goal of "patient will self-administer insulin?" (Select all that apply.)
1. Goal within reach of the patient
2. The nurse's own competency in teaching about insulin
3. The patient's cognitive function
4. Availability of family members to assist

7. The nurse writes an expected-outcome statement in measurable terms. An example is:
1. Patient will be pain free.
2. Patient will have less pain.
3. Patient will take pain medication every 4 hours.
4. Patient will report pain acuity less than 4 on a scale of 0 to 10.

8. A patient has the nursing diagnosis of *nausea*. The nurse develops a care plan with the following interventions. Which are examples of collaborative interventions?
1. Provide frequent mouth care.
2. Maintain intravenous (IV) infusion at 100 mL/hr.
3. Administer prochlorperazine (Compazine) via rectal suppository.
4. Consult with dietitian on initial foods to offer patient.
5. Control aversive odors or unpleasant visual stimulation that triggers nausea.

9. A 72-year-old patient has come to the health clinic with symptoms of a productive cough, fever, increased respiratory rate, and shortness of breath. His respiratory distress increases when he walks. He lives alone and did not come to the clinic until his neighbor insisted. He reports not getting his pneumonia vaccine this year. Blood tests show the patient's oxygen saturation to be lower than normal. The physician diagnoses the patient as having pneumonia. Match the priority level with the nursing diagnoses identified for this patient:

Nursing Diagnoses	Priority Level
1. Impaired gas exchange _____	a. Long term
2. Risk for activity intolerance _____	b. Short term
3. Ineffective self-health management _____	c. Intermediate

10. An 82-year-old patient who resides in a nursing home has the following three nursing diagnoses: *risk for fall, impaired physical mobility related to pain,* and *wandering related to cognitive impairment.* The nursing staff identified several goals of care. Match the goals on the left with the appropriate outcome statements on the right.

Goals	Outcomes
1. Patient will ambulate independently in 3 days. _____	a. Patient will express fewer nonverbal signs of discomfort.
2. Patient will be injury free for 1 month. _____	b. Patient will follow a set care routine.
3. Patient will be less agitated. _____	c. Patient will walk correctly using a walker.
4. Patient will achieve pain relief. _____	d. Patient will exit a low bed without falling.

11. A nurse is preparing for change-of-shift rounds with the nurse who is assuming care for his patients. Which of the following statements or actions by the nurse are characteristics of ineffective handoff communication?
1. This patient is anxious about his pain after surgery; you need to review the information I gave him about how to use a patient-controlled analgesia (PCA) pump this evening.
2. The nurse refers to the electronic care plan in the electronic health record (EHR) to review interventions for the patient's care.
3. During walking rounds the nurse talks about the problem the patient care technicians created by not ambulating the patient.
4. The nurse gives her patient a pain medication before report so there is likely to be no interruption during rounding.

12. Which of the following outcome statements for the goal, "Patient will achieve a gain of 10 lbs (4.5 kg) in body weight in a month" are worded incorrectly? (Select all that apply.)
1. Patient will eat at least three fourths of each meal by 1 week.
2. Patient will verbalize relief of nausea and have no episodes of vomiting in 1 week.
3. Patient will eat foods with high-calorie content by 1 week.
4. Give patient liquid supplements 3 times a day.

13. A nurse from home health is talking with a nurse who works on an acute medical division within a hospital. The home health nurse is making a consultation. Which of the following statements describes the unique difference between a nursing care plan from a hospital versus one for home care?
1. The goals of care will always be more long term.
2. The patient and family need to be able to independently provide most of the health care.
3. The patient's goals need to be mutually set with family members who will care for him or her.
4. The expected outcomes need to address what can be influenced by interventions.

14. Which outcome allows you to measure a patient's response to care more precisely?
1. The patient's wound will appear normal within 3 days.
2. The patient's wound will have less drainage within 72 hours.
3. The patient's wound will reduce in size to less than 4 cm (1½ inches) by day 4.
4. The patient's wound will heal without redness or drainage by day 4.

15. A nurse identifies several interventions to resolve the patient's nursing diagnosis of *impaired skin integrity*. Which of the following are written in error? (Select all that apply.)
1. Turn the patient regularly from side to back to side.
2. Provide perineal care, using Dove soap and water, every shift and after each episode of urinary incontinence.
3. Apply a pressure-relief device to bed.
4. Apply transparent dressing to sacral pressure ulcer.

Answers: **1.** 2, 3; **2.** 1; **3.** 2, 3; **4.** 4; **5.** 3; **6.** 1, 3, 4; **7.** 4; **8.** 4; **9.** 1b, 2c, 3a; **10.** 1c, 2d, 3b, 4a; **11.** 3; **12.** 2, 4; **13.** 2; **14.** 3; **15.** 1, 3.

CHAPTER

19

Implementing Nursing Care

OBJECTIVES

- Explain the relationship of implementation to the nursing diagnostic process.
- Describe the association between critical thinking and selecting nursing interventions.
- Discuss the differences between protocols and standing orders.
- Identify preparatory activities to use before implementation.
- Discuss the value of the Nursing Interventions Classification system in documenting nursing care.
- Discuss the steps for revising a plan of care before performing implementation.
- Define the three implementation skills.
- Describe and compare direct and indirect nursing interventions.
- Select appropriate interventions for an assigned patient.

You first met Tonya and Mr. Jacobs in Chapter 16. The two have collaborated during the nursing process to develop a relevant and appropriate plan of care. During implementation Tonya works with fellow health care colleagues and Mr. and Mrs. Jacobs to provide the safest and most effective nursing interventions for the patient's health care problems. Implementation is circular, like all steps of the nursing process. This means that, during the course of Mr. Jacobs' hospitalization, as his clinical condition changes Tonya reassesses the status of existing nursing diagnoses, confirms that these diagnoses are still appropriate, evaluates the patient's responses to planned interventions (see Chapter 20), and continues to deliver interventions in a timely and competent manner. Critical thinking, which includes good clinical decision making, is important for the successful implementation of nursing interventions.

Implementation, the fourth step of the nursing process, formally begins after the nurse develops a plan of care. With a care plan based on clear and relevant nursing diagnoses, the nurse initiates interventions that are designed to achieve the goals and expected outcomes needed to support or improve the patient's health status. A **nursing intervention** is any treatment based on clinical judgment and knowledge that a nurse performs to enhance patient outcomes (Bulechek et al., 2008). Ideally the interventions a nurse uses are evidenced based (see Chapter 5), providing the most current, up-to-date, and effective approaches for managing patient problems. Interventions include direct and indirect care measures aimed at individuals, families, and/or the community.

Direct care interventions are treatments performed through interactions with patients (Bulechek et al., 2008). For example, a patient receives direct intervention in the form of medication administration, insertion of an intravenous (IV) infusion, or counseling during a time of grief. **Indirect care** interventions are treatments performed away from the patient but on behalf of the patient or group of patients (Bulechek et al., 2008). For example, indirect care measures include actions for managing the patient's environment (e.g., safety and infection control), documentation, and interdisciplinary collaboration. Both direct and indirect care measures fall under the intervention categories described in Chapter 18: nurse-initiated, physician-initiated, and collaborative. For example, the direct intervention of patient education is a nurse-initiated intervention. The indirect intervention of consultation is a collaborative intervention.

Benner (1984) defined the domains of nursing practice, which help to explain the nature and intent of the many ways nurses intervene for patients (Box 19-1). These domains are current today. The extent of organizational and work role competencies has

BOX 19-1 DOMAINS OF NURSING PRACTICE

- The Helping Role
- The Teaching-Coaching Function

From Benner P: *From novice to expert,* Menlo Park, Calif, 1984, Addison Wesley.

become more complex; thus it is important that the focus of implementation always be the patient. Nursing is an art and a science. It is not simply a task-based profession. Thus you learn to intervene for a patient within the context of his or her unique situation. Examples of factors to consider during intervention follow. Who is the patient? What does this illness mean to the patient and his or her family? What clinical situation requires you to intervene? How does the patient perceive the interventions that you will deliver? Will any cultural considerations influence your approach? In what way do you best support or show caring as you intervene? The answers to these questions enable you to deliver care compassionately and effectively with the best outcomes for your patients.

CRITICAL THINKING IN IMPLEMENTATION

The delivery of nursing interventions is a complex decision-making process that involves critical thinking. The context in which you deliver care to each patient and the many interventions required result in decision-making approaches for each clinical situation. Critical thinking is necessary to consider the complexity of interventions, including the number of alternative approaches and the amount of time available to act.

*Tonya indentified four relevant nursing diagnoses for Mr. Jacobs: **acute pain** related to incisional trauma, **deficient knowledge** regarding postoperative recovery related to inexperience with surgery, **impaired physical mobility** related to incisional pain, and **anxiety** related to uncertainty over the course of recovery. The diagnoses are interrelated, and sometimes a planned intervention (e.g., administering pain medication) treats or modifies more than one of the patient's health problems (pain and impaired physical mobility). Tonya applies critical thinking and uses her time with Mr. Jacobs wisely by anticipating his priorities, applying the knowledge she has about his problems and the interventions planned, and implementing care strategies skillfully.*

Before implementing a planned intervention, use critical thinking to confirm whether the intervention is correct and still appropriate for the patient's clinical situation. Even though you have planned a set of interventions for a patient, you have to exercise good judgment and decision making before actually delivering each intervention. Always think before you act. Patients' conditions often change minute to minute. You need to consider the scheduling of activities on a nursing unit, which often dictates when and how to complete an intervention. Thus many factors influence your decision on how and when to intervene. You are responsible for having the necessary knowledge and clinical competency to perform interventions for your patients safely and effectively. Some tips for making decisions during implementation follow.

- Review the set of all possible nursing interventions for the patient's problem (e.g., for Mr. Jacobs' pain Tonya considers analgesic administration, positioning and splinting, progressive relaxation, and other nonpharmacological approaches).
- Review all possible consequences associated with each possible nursing action (e.g., Tonya considers that the analgesic will either relieve pain; have little or insufficient effect; or cause an adverse reaction, including sedating the patient and increasing the risk of falling).
- Determine the probability of all possible consequences (e.g., if Mr. Jacobs' pain has decreased with analgesia and positioning in the morning and there have been no side effects, it is unlikely that adverse reactions will occur, and the intervention will be successful; however, if the patient continues to remain highly anxious, his pain may not be relieved, and Tonya needs to consider an alternative).
- Make a judgment of the value of the consequence to the patient (e.g., if the administration of an analgesic is effective, Mr. Jacobs will likely become less anxious and more responsive to postoperative instruction and counseling about his anxiety).

The selection and performance of nursing interventions for a patient are part of clinical decision making. The critical thinking model described in Chapter 15 provides a framework for how to make decisions when implementing nursing care (Fig. 19-1). You learn how to implement nursing care using appropriate knowledge. For example, as you proceed with an intervention, you consider what you know about the purpose of the intervention, the steps in performing the intervention correctly, the medical condition of the patient, and his or her expected response. It is important to prepare well before first caring for any patient. With experience you become more proficient in anticipating what to expect in a given clinical situation and how to modify your approach. As you gain clinical experience, you are able to consider which interventions worked previously, which have not, and why. It also helps to know the clinical standards of practice for your agency. For example, one hospital has a different set of standards for patient education than another. The standards of practice offer guidelines for selection of interventions and their frequency and whether you are able to delegate the procedures.

As you perform a nursing intervention, apply intellectual standards, which are the guidelines for rational thought and responsible action. For example, before Tonya begins to teach Mr. Jacobs, she considers how to make her instructions relevant, clear, logical, and complete to promote patient learning. She knows that it will be helpful to involve Mrs. Jacobs so any instruction is relevant to their home situation. Using simple, clear explanations and repeated instructions promote learning for Mr. Jacobs, who is inexperienced with postoperative recovery. Making an instructional DVD on wound care available to the family is a valuable resource for repeated viewing in the home.

As a critical thinker, apply critical thinking attitudes when you intervene. For example, show confidence in performing an intervention. When you are unsure of how to perform a procedure, be responsible in seeking assistance from others. Confidence in performing interventions builds trust with patients. Creativity and self-discipline are attitudes that guide you in reviewing, modifying, and implementing interventions. As a beginning nursing student, seek out supervision from instructors or experienced nurses to guide you in the decision-making process for implementation.

STANDARD NURSING INTERVENTIONS

Health care settings present various ways for nurses to create and individualize a patient's plan of care. Each plan of care is totally unique to that patient, with interventions individualized on the basis of his or her specific health problems. In certain situations a nurse develops the plan on the basis of personal knowledge and clinical experience. However, systems are available that provide standardized interventions for nurses to use in their plan of care. Many patients have common health care problems; thus standardized interventions for these health problems make it quicker and easier for nurses to intervene. More important, if the standards are evidence based, the nurse is more likely to deliver the most clinically effective interventions to improve patient outcomes (see Chapter 5). Standardized interventions most often set a level of clinical excellence for practice. Nurse- and physician-initiated standardized interventions are available in the form of clinical guidelines or protocols, preprinted (standing) orders, and Nursing Interventions Classification (NIC) interventions. At a professional level the American Nurses Association (ANA) defines standards of professional nursing practice, which include standards for the implementation step of the nursing process. These standards are authoritative statements of the duties that all registered nurses are expected to perform competently, regardless of role, patient population they serve, or specialty (ANA, 2010) (see Chapter 1).

Clinical Practice Guidelines and Protocols

A **clinical practice guideline** or protocol is a systematically developed set of statements that helps nurses, physicians, and other health care providers make decisions about appropriate health care for specific clinical situations (Manchikanti et al., 2010). A guideline guides interventions for specific health care problems or conditions such as low back pain, dizziness, or deep vein thrombosis. The guideline is developed on the basis of an authoritative examination of current scientific evidence (National Guideline Clearinghouse [NGC], 2010). Guidelines are now seen as key tools for improving the quality of health care and bridging the gap between the growth of research findings and actual clinical practice (Rosenbrand et al., 2008).

Clinicians within a health care agency sometimes choose to review the scientific literature and their own standard of practice to develop guidelines and protocols in an effort to improve their standard of care. For example, a hospital develops a rapid-assessment protocol to improve the identification and early treatment of patients suspected of having a stroke. However, clinical practice guidelines have already been developed by national health groups such as the National Institutes of Health and the National Guideline Clearinghouse. These guidelines are readily available to any clinician or health care institution that wishes to adopt evidence-based guidelines in the care of patients with specific health problems. One valuable source for nursing practice

guidelines is the Gerontological Nursing Interventions Research Center (GNIRC) at the University of Iowa. The center has numerous clinical guidelines, including ones for acute confusion and delirium, acute pain management, and fall prevention for older adults (GNIRC, 2010).

Advanced practice nurses who provide primary care for patients in outpatient settings frequently follow diagnostic and treatment protocols. In such a setting nurses assess the patient and identify abnormalities. The protocol outlines the conditions that nurses are permitted to treat such as controlled hypertension and the types of treatment that they are permitted to administer such as antihypertensive medications. In acute care settings it is common to find clinical protocols that outline independent nursing interventions for specific conditions. Examples include protocols for admission and discharge, pressure ulcer care, and incontinence management. Protocols are also used in interdisciplinary settings for diagnostic testing and physical, occupational, and speech therapies.

Standing Orders

A **standing order** is a preprinted document containing orders for the conduct of routine therapies, monitoring guidelines, and/or diagnostic procedures for specific patients with identified clinical problems. A standing order directs the conduct of patient care in a specific clinical setting. Licensed prescribing health care providers in charge of care at the time of implementation approve and sign standing orders. These orders are common in critical care settings and other specialized practice settings where patients' needs change rapidly and require immediate attention. An example of such a standing order is one specifying certain medications such as lidocaine or propranolol for an irregular heart rhythm. After assessing the patient and identifying the irregular rhythm, the critical care nurse gives the specified medication without first notifying the physician. The physician's initial standing order covers the nurse's action. After completing a standing order, the nurse notifies the physician. Standing orders are common in the community health setting, where the nurse faces situations that do not permit immediate contact with a health care provider. Standing orders give the nurse legal protection to intervene appropriately in the patient's best interest.

NIC Interventions

The NIC system developed by the University of Iowa helps to differentiate nursing practice from that of other health care professionals (Box 19-2). The NIC interventions offer a level of standardization to enhance communication of nursing care across settings and to compare outcomes. By using NIC nurses learn the common interventions recommended for various NANDA International nursing diagnoses. Nurses also learn the numerous care activities for each NIC intervention. Recently the NIC interventions have been used for work complexity assessment, a process that helps nurses identify interventions performed on a routine basis for their patient populations (Scherb and Weydt, 2009). Chapter 18 describes the NIC system in more detail.

Standards of Practice

The ANA Standards of Professional Nursing Practice (ANA, 2010) are to be used as evidence of the standard of care that registered nurses provide their patients (see Chapter 1). The standards are formally reviewed on a regular basis. The newest standards include competencies for establishing professional and caring relationships, using evidence-based interventions and technologies, providing holistic care across the life span to diverse groups, and using community resources and systems. In addition, the standards emphasize implementing a timely plan following patient safety goals (ANA, 2010).

BOX 19-2 PURPOSES OF THE NURSING INTERVENTIONS CLASSIFICATION

1. Standardization of the nomenclature (e.g., labeling, describing) of nursing interventions; standardizes the language nurses use to describe sets of actions in delivering patient care
2. Expanding nursing knowledge about connections among nursing diagnoses, treatments, and outcomes; connections determined through the study of actual patient care using a database that the classification generates
3. Developing nursing and health care information systems
4. Teaching decision making to nursing students; defining and classifying nursing interventions to teach beginning nurses how to determine a patient's need for care and to respond appropriately
5. Determining the cost of services provided by nurses
6. Planning for resources needed in all types of nursing practice settings
7. Language to communicate the unique functions of nursing
8. Link with the classification systems of other health care providers

From Bulechek GM et al: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

IMPLEMENTATION PROCESS

Preparation for implementation ensures efficient, safe, and effective nursing care. Five preparatory activities include reassessing the patient, reviewing and revising the existing nursing care plan, organizing resources and care delivery, anticipating and preventing complications, and implementing nursing interventions.

Tonya returns to Mr. Jacobs' room 30 minutes after administering a dose of IV morphine for his incisional pain. She notices that he is more relaxed and turning a bit on his own. She asks him to rate his pain on a scale of 0 to 10, and he responds that it is now a 3. With the pain currently under control, Tonya decides to get the patient up in a chair to begin increasing his activity level. While Mr. Jacobs is in the chair, Tonya gets the teaching booklets she wants to use to prepare the patient for wound and catheter care in the home. She knows that Mrs. Jacobs is due to arrive at any time; thus she plans to include her in the discussion. Tonya also knows that this is Mr. Jacobs' first time up in the chair; thus she anticipates monitoring him closely and judging if he is alert and comfortable enough to begin the planned instruction.

Reassessing the Patient

Assessment is a continuous process that occurs each time you interact with a patient. When you collect new data about a patient, you sometimes identify a new nursing diagnosis or determine the need to modify the care plan. During the initial phase of implementation reassess the patient. The reassessment often focuses on one primary nursing diagnosis, or one dimension of the patient such as level of comfort, or one system such as the cardiovascular system. The reassessment helps you decide if the proposed nursing actions are still appropriate for the patient's level of wellness. Reassessment is not the evaluation of care (see Chapter 20), but it is the gathering of additional information to ensure that the plan of care is appropriate. *For example, Tonya plans to talk with Mr. Jacobs*

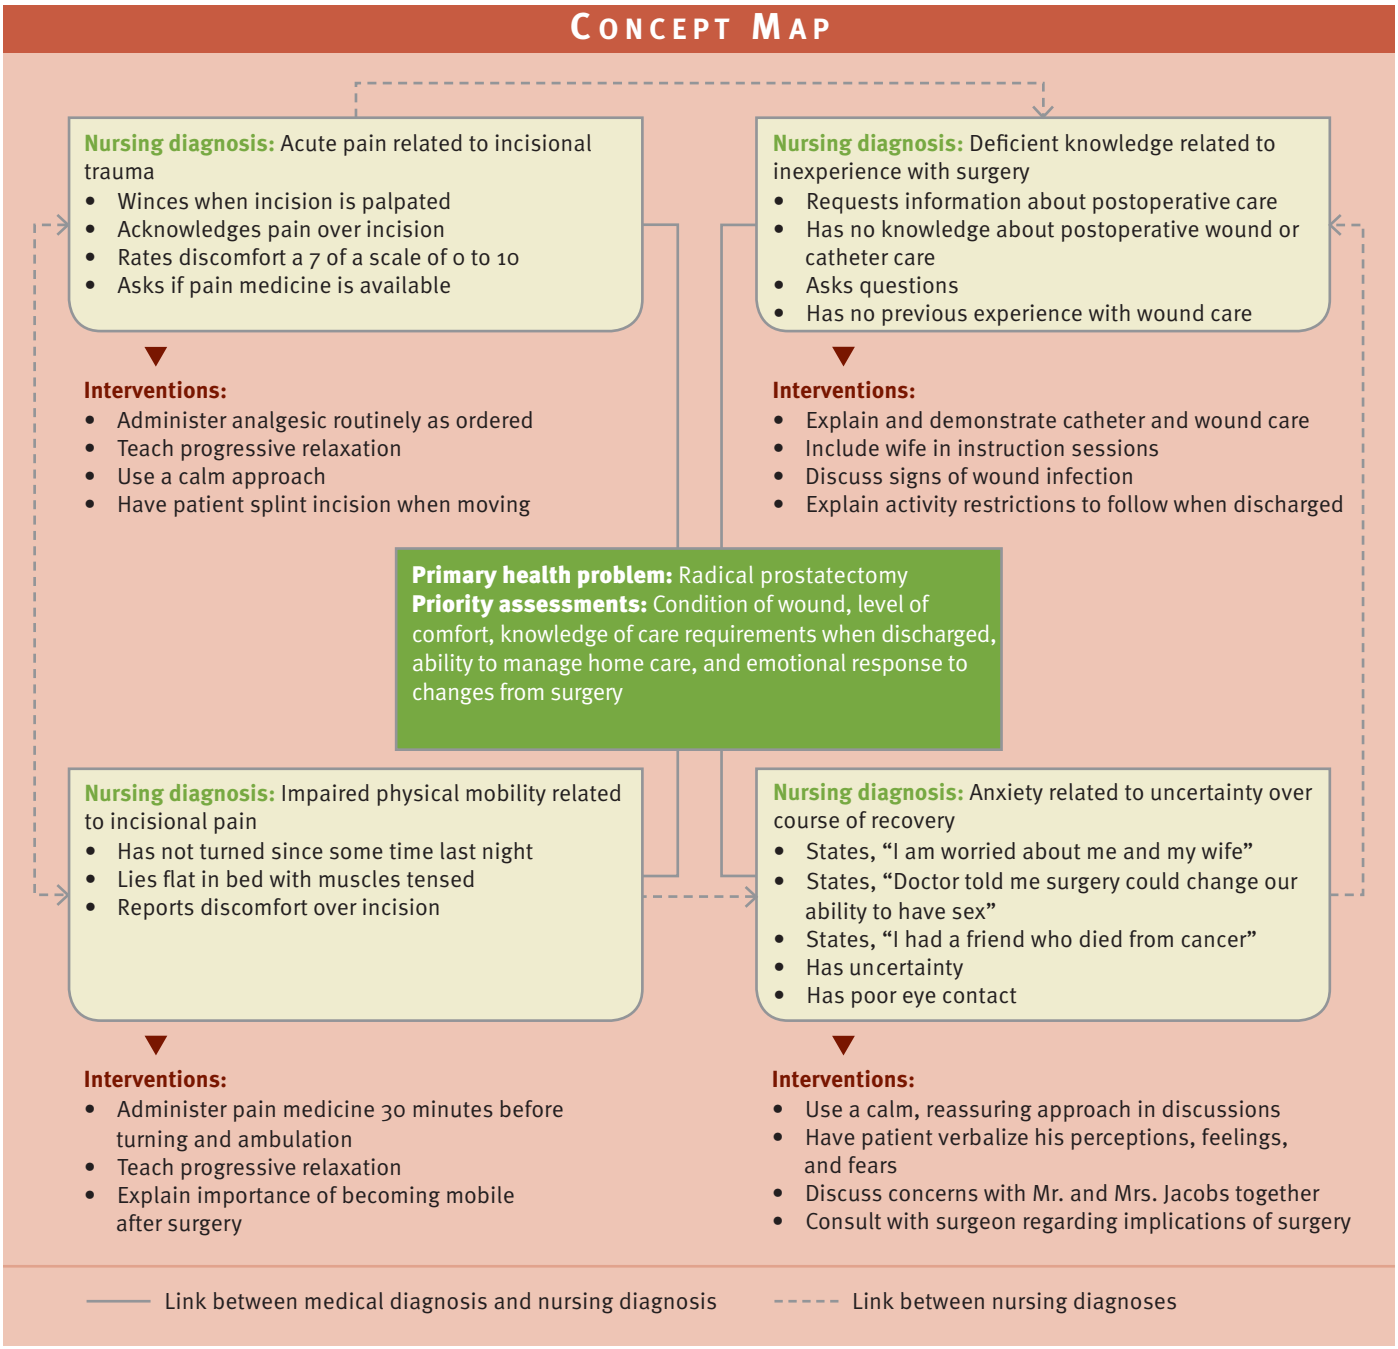

FIG. 19-2 Concept map for Mr. Jacobs: Implementation.

about surgery and what to expect during recovery. However, she learns from Mr. Jacobs that Mrs. Jacobs' visit has been delayed until lunchtime. She knows that Mrs. Jacobs is an important resource for Mr. Jacobs' recovery, but she decides to get Mr. Jacobs up in a chair and focus on how he tolerates the activity anyway. Pain control is still a priority. Tonya will help Mr. Jacobs back to bed after about 30 minutes, allow him to rest until lunchtime, and then begin her instruction.

Reviewing and Revising the Existing Nursing Care Plan

After reassessing a patient, review the care plan and compare assessment data to validate the nursing diagnoses and determine whether the nursing interventions remain the most appropriate for the clinical situation. If the patient's status has changed and the nursing diagnosis and related nursing interventions are no longer appropriate, modify the nursing care plan. An out-of-date or incorrect care plan compromises the quality of nursing care. Review and modification enable you to provide timely nursing interventions to best meet the patient's needs.

After reviewing the care plan, Tonya made a few revisions to Mr. Jacobs' concept map (Fig. 19-2). Tonya notices that eye contact with Mr. Jacobs has improved; trust is building. Mr. Jacobs' pain has also lessened. She modifies her plan for reducing anxiety by planning a discussion with Mr. and Mrs. Jacobs together and consulting with the surgeon.

Modification of an existing written care plan includes four steps:

1. Revise data in the assessment column to reflect the patient's current status. Date any new data to inform other members of the health care team of the time that the change occurred.
2. Revise the nursing diagnoses. Delete nursing diagnoses that are no longer relevant and add and date any new diagnoses. It is necessary to revise related factors and the patient's goals, outcomes, and priorities. Date any revisions.
3. Revise specific interventions that correspond to the new nursing diagnoses and goals. Revisions need to reflect the patient's present status.
4. Choose the method of evaluation for determining whether you achieved patient outcomes.

Organizing Resources and Care Delivery

The resources of a facility include equipment and skilled personnel. Organization of equipment and personnel makes timely, efficient, skilled patient care possible (see Chapter 21). It is also important to prepare the environment and patient for a nursing intervention.

Equipment. Most nursing procedures require some equipment or supplies. Before performing an intervention, decide which supplies you need and determine their availability. Is the equipment in working order to ensure safe use, and do you know how to use it? Place supplies in a convenient location to provide easy access during a procedure. Keep extra supplies available in case of errors or mishaps, but do not open them unless you need them. This controls health care costs. After a procedure return any unopened supplies to storage areas.

Personnel. Nursing care delivery models vary among facilities (see Chapter 21). The model by which nursing is organized determines how nursing personnel deliver patient care. For example, a registered nurse's (RN's) accountabilities differ in a team nursing model from those in a primary nursing model. A primary nurse is accountable for the nursing care that a patient receives during his or her length of stay or course of visits. A team nurse is accountable for the care that a patient receives for a specific shift in which the nurse works. As a nurse you are responsible for deciding whether to perform an intervention or delegate it to another member of the nursing team. Your ongoing assessment of a patient, and not the intervention alone, directs the decision about delegation.

For example, Tonya knows that nursing assistive personnel (NAP) can competently assist patients to ambulate. However, she has learned that patients who transfer to a chair or ambulate the first time after surgery are often less stable; the NAP should not be the one to assess the patient's response. She decides to personally help Mr. Jacobs get up and into a chair to evaluate his response. Tonya thus redirects the NAP to perform more suitable care activities such as helping Tonya make Mr. Jacobs' bed or assisting a different patient with oral hygiene.

Nursing staff work together as patients' needs demand it. If a patient makes a request such as use of a bedpan or assistance in feeding, help the patient if you have time rather than trying to find the NAP who is in a different room. Nursing staff respect colleagues who show initiative; collaborate together; and communicate with one another on an ongoing, reciprocal basis as patients' needs change (Potter et al., 2010). When interventions are complex or physically difficult, you probably need assistance from colleagues. For example, you and the NAP more effectively change a dressing in a large gaping wound when you apply the dressing and the NAP assists with patient positioning and handing off of supplies.

Environment. A patient's care environment needs to be safe and conducive to implementing therapies. Patient safety is your first concern. If the patient has sensory deficits, physical disabilities, or an alteration in level of consciousness, arrange the environment to prevent injury. For example, provide a patient's assist devices (e.g., walker or eyeglasses), rearrange furniture and equipment when ambulating a patient, or make sure that the water temperature is not too warm before a bath. The patient benefits most from nursing interventions when surroundings are compatible with care activities. When you need to expose a patient's body parts, do so privately by closing room doors or curtains because the patient will then be more relaxed. Ask visitors to leave as you complete care. Reduce distractions to enhance a patient's learning opportunities. Make sure that lighting is adequate to perform procedures correctly.

Patient. Before you implement interventions, make sure that the patient is as physically and psychologically comfortable as possible. For example, symptoms such as nausea, dizziness, fatigue, or pain frequently interfere with a patient's full concentration and ability to cooperate. Offer comfort measures before initiating interventions to help the patient participate more fully. If you need a patient to be alert, administer a dose of pain medication strong enough to relieve discomfort but not to impair mental faculties (e.g., ability to follow instruction, reasoning, and communication). If a patient is fatigued, delay ambulation or transfer to a chair until after he or she has had a chance to rest.

Even if symptoms are not a factor, make the patient physically comfortable during interventions. Start any intervention by controlling environmental factors, taking care of physical needs (e.g., elimination), avoiding interruptions, and positioning the patient correctly. Also consider the patient's level of endurance and plan only the amount of activity that he or she is able to tolerate comfortably.

Awareness of the patient's psychosocial needs helps you create a favorable emotional climate. Some patients feel reassured by having a significant other present to lend encouragement and moral support. Other strategies include planning sufficient time or multiple opportunities for the patient to work through and ventilate feelings and anxieties. Adequate preparation allows the patient to obtain maximal benefit from each intervention.

Anticipating and Preventing Complications

Risks to patients come from both illness and treatment. As a nurse, look for and recognize these risks, adapt your choice of interventions to the situation, evaluate the relative benefit of the treatment versus the risk, and take risk-prevention measures. Many conditions place the patient at risk for complications. For example, the patient with preexisting left-sided paralysis following a stroke 2 years earlier is at risk for developing a pressure ulcer following orthopedic surgery because it requires traction and bed rest. A patient with obesity and diabetes who has major abdominal surgery is at risk for poor wound healing and developing the complications of a fistula or dehiscence. Nurses are often the first ones to detect and document changes in a patient's condition. In her classic research Benner (1984) notes that expert nurses learn to anticipate breakdown and deterioration of patients even before confirming diagnostic signs develop.

Your knowledge of pathophysiology and experience with previous patients help in identifying the risk of complications that can occur. A thorough assessment reveals the level of a patient's current risk. The evidence or scientific rationales for how certain interventions (e.g., pressure-relief devices, repositioning, or wound care) prevent or minimize complications help you select the preventive

measures that likely are most useful. For example, if a patient who is obese has uncontrolled postoperative pain, the risk for pressure ulcer development increases because the patient is unwilling or unable to change position frequently. The nurse anticipates when the patient's pain will be aggravated, administers ordered analgesics, and then positions the patient to remove pressure on the skin and underlying tissues. If the patient continues to have difficulty turning or repositioning, the nurse selects a pressure-relief device to place on the patient's bed.

Some nursing procedures pose risks. Be aware of potential complications and take precautionary measures. For example, the patient who has a feeding tube is at risk for aspiration. Position the patient in high-Fowler's position and check the tube position before administering a feeding.

Identifying Areas of Assistance. Certain nursing situations require you to obtain assistance by seeking additional personnel, knowledge, and/or nursing skills. Before beginning care, review the plan to determine the need for assistance and the type required. Sometimes you need assistance in performing a procedure, providing comfort measures, or preparing the patient for a diagnostic test. Do not take shortcuts if assistance is not immediately available since this increases risk of injury to you and the patient. For example, when you care for a patient who is overweight and immobilized, you require additional personnel and transfer equipment to turn and position the patient safely. Be sure to determine the number of additional personnel and if you need them in advance. Discuss your need for assistance with other nurses or NAP.

You require additional knowledge and skills in situations in which you are less experienced. Because of the continual growth in health care technology, you may lack the skills to perform a procedure. When you are asked to administer a new medication, operate a new piece of equipment, or administer a procedure with which you are unfamiliar, follow these steps.

- Seek information you need to be informed about the procedure. Check the scientific literature for evidence-based information, review resource manuals and the procedure book of the agency, or consult with experts (e.g., pharmacists, clinical nurse specialists) who are familiar with the procedure.
- Collect all equipment necessary for the procedure.
- Have another nurse who has completed the procedure correctly and safely provide assistance and guidance. The assistance can come from another staff nurse, a supervisor, an educator, or a nurse specialist. Requesting assistance occurs frequently in all types of nursing practice and is a learning process that continues throughout educational experiences and into professional development. One tip is to verbalize with an instructor or staff nurse the steps you will take before actually performing the procedure to improve your confidence.

Implementation Skills

Nursing practice includes cognitive, interpersonal, and psychomotor (technical) skills. You need each type of skill to implement direct and indirect nursing interventions. You are responsible for knowing when one type of implementation skill is preferred over another and for having the necessary knowledge and skill to perform each.

Cognitive Skills. Cognitive skills involve the application of critical thinking in the nursing process. Always use good judgment and sound clinical decision making when performing any intervention. This ensures that no nursing action is automatic. Always think and anticipate so you individualize patient care appropriately. Know the rationale for therapeutic interventions and understand normal and abnormal physiological and psychological responses. In addition, know the evidence in nursing science to ensure that you deliver the most current and relevant nursing interventions. You learn to integrate different concepts and relate them to each other while recollecting facts, situations, and patients for whom you have cared previously (Di Vito-Thomas, 2005).

Tonya knows the pathophysiology of prostate cancer, the anatomy of the prostate gland and surrounding structures, and the normal mechanisms for pain. She considers each of these as she observes Mr. Jacobs, noting how the patient's movement and position either aggravate or lessen his incisional pain. Tonya focuses on relieving Mr. Jacobs' acute pain with an analgesic but then considers the noninvasive interventions needed to provide even greater pain relief so the patient can gain needed rest and relaxation.

Interpersonal Skills. Interpersonal skills are essential for effective nursing action. Develop a trusting relationship, express a level of caring, and communicate clearly with a patient and his or her family (see Chapter 24). Good interpersonal communication is critical for keeping patients informed, providing individualized patient teaching, and effectively supporting patients with challenging emotional needs. Proper use of interpersonal skills enables you to be perceptive of the patient's verbal and nonverbal communication. As a member of the health care team, communicate patient problems and needs clearly, intelligently, and in a timely manner.

Psychomotor Skills. Psychomotor skills require the integration of cognitive and motor activities. For example, when giving an injection you need to understand anatomy and pharmacology (cognitive) and use good coordination and precision to administer the injection correctly (motor). With time and practice you learn to perform skills correctly, smoothly, and confidently. This is critical in establishing patient trust. You are responsible for acquiring necessary psychomotor skills through your experience in the nursing laboratory, the use of interactive instructional technology, or actual hands-on care of patients. When attempting a new skill, always assess your level of competency and obtain the necessary resources to ensure that the patient receives safe treatment.

DIRECT CARE

Nurses provide a wide variety of direct care measures (i.e., activities that nurses perform through patient interactions). How a nurse interacts affects the success of any direct care activity. Remain sensitive to a patient's clinical condition, values and beliefs, expectations, and cultural views. All direct care measures require competent and therefore safe practice. Show a caring approach each time you provide direct care.

Activities of Daily Living

Activities of daily living (ADLs) are activities usually performed in the course of a normal day, including ambulation, eating, dressing, bathing, and grooming (see Chapter 39). A patient's need for assistance with ADLs is temporary, permanent, or rehabilitative. For example, a patient with impaired physical mobility because of bilateral arm casts has a temporary need for assistance. After the casts are removed, the patient gradually regains the strength and range of motion needed to perform ADLs. In contrast, a patient with an irreversible injury to the cervical spinal

cord is paralyzed and has a permanent need for assistance. It is unrealistic to plan rehabilitation with a goal of becoming independent with ADLs for this patient. Instead the patient learns new ways to perform ADLs independently through rehabilitation. Occupational and physical therapists play a key role in rehabilitation to restore ADL function.

When your assessment reveals that a patient is experiencing fatigue, a limitation in mobility, confusion, and pain, assistance with ADLs is likely. For example, a patient who experiences shortness of breath avoids eating because of the associated fatigue. Help the patient by setting up meals and offering to cut up food and plan for more frequent, small meals to maintain the patient's nutrition. Assistance with ADLs ranges from partial assistance to complete care. Remember to always respect the patient's wishes and determine his or her preferences. Patients from some cultures prefer receiving assistance with ADLs from family members. As long as a patient is stable and alert, it is appropriate to allow family to assist with care. Most patients want to remain independent in meeting their basic needs. Allow the patient to participate to the level that he or she is able. Involving the patient in planning the timing and types of interventions boosts the patient's self-esteem and willingness to become more independent.

Instrumental Activities of Daily Living

Illness or disability sometimes alters a patient's ability to be independent in society. **Instrumental activities of daily living (IADLs)** include such skills as shopping, preparing meals, house cleaning, writing checks, and taking medications. Nurses within the home care and community health setting frequently help patients adapt ways to perform IADLs. Occupational therapists are specially trained to know how to adapt approaches for patients to use when performing IADLs. Often family and friends are excellent resources for assisting patients. In acute care it is important for you to anticipate how a patient's illness affects the ability to perform IADLs so you can make appropriate referrals.

Physical Care Techniques

You routinely perform a variety of physical care techniques when caring for a patient. Physical care techniques involve the safe and competent administration of nursing procedures (e.g., turning and positioning, performing invasive procedures, administering medications, and providing comfort measures). The specific knowledge and skills needed to perform these procedures are in subsequent clinical chapters of this text. Common methods for administering physical care techniques appropriately include protecting you and the patient from injury, using safe patient handling techniques, using proper infection control practices, staying organized, and following applicable practice guidelines.

To carry out a procedure you need to be knowledgeable about the procedure itself, the standard frequency, the steps, and the expected outcomes. In a hospital you perform many procedures each day, often for the first time. Before conducting a new procedure, always assess the situation and your personal competencies to determine if you need assistance, new knowledge, or new skills. Benner (1984) made an important observation about physical care techniques. Nurses always need to make varied and thoughtful adaptations when administering and monitoring patient therapies. For example, when you change a complicated dressing, you can choose from many dressing materials and cleansing solutions, and the patient's size affects how to secure a dressing. Performing any procedure correctly requires critical thinking and thoughtful decision making.

Lifesaving Measures

A **lifesaving measure** is a physical care technique that you use when a patient's physiological or psychological state is threatened (see Chapter 40). The purpose of lifesaving measures is to restore physiological or psychological homeostasis. Such measures include administering emergency medications, instituting cardiopulmonary resuscitation, intervening to protect a confused or violent patient, and obtaining immediate counseling from a crisis center for a severely anxious patient. If an inexperienced nurse faces a situation requiring emergency measures, the proper nursing actions are to stay with the patient, maintain support, and have another staff member obtain an experienced professional.

Counseling

Counseling is a direct care method that helps a patient use a problem-solving process to recognize and manage stress and facilitate interpersonal relationships. As a nurse, you counsel patients to accept actual or impending changes resulting from stress (see Chapter 37). Examples include patients who are facing terminal illness or chronic disease. Counseling involves emotional, intellectual, spiritual, and psychological support. A patient and family who need nursing counseling have normal adjustment difficulties and are upset or frustrated, but they are not necessarily psychologically disabled. A good example is the stress that a young woman faces when caring for her aging mother. Family caregivers need assistance in adjusting to the physical and emotional demands of caregiving. Sometimes they need respite (i.e., a break from providing care). The recipient of care also needs assistance in adjusting to his or her disability. Patients with psychiatric diagnoses require therapy from nurses specializing in psychiatric nursing or social workers, psychiatrists, or psychologists.

Many counseling techniques foster cognitive, behavioral, developmental, experiential, and emotional growth in patients. Most of the techniques listed in Box 19-3 require additional knowledge beyond the scope of this text. Counseling encourages individuals to examine available alternatives and decide which choices are

BOX 19-3 COUNSELING STRATEGIES AND SELECTED EXAMPLES USED BY NURSES

Behavior Modification
- Encourage alternative behavior (e.g., meditation instead of smoking to relieve stress).
- Develop a chart to record and track eating habit changes.
- Use social skills training (e.g., role playing) to change behaviors (e.g., anger or aggression).

Bereavement Counseling
- Assist patient in productive reminiscing of loved one.
- Support patient in removing loved one's belongings from home.

Relaxation Exercises
- Progressive muscle relaxation exercises and guided imagery

Crisis Intervention
- Therapy designed to assist in coping with crisis
- Anticipatory guidance to recognize and avoid modifiable crises

Play Therapy
- Help children through play to cope with loss and grief.
- Help children cope with chronic illness.
- Help children become competent in self-care activities.

useful and appropriate. When patients are able to examine alternatives, they develop a sense of control and are able to better manage stress.

Teaching

Teaching is an important nursing responsibility because education is key to patient-centered care (see Chapter 25). A teaching plan is essential, especially when patients are inexperienced and being asked to manage health problems they are facing for the first time. Counseling and teaching closely align. Both involve using good interpersonal skills to create a change in the patient. However, with counseling the change results in the development of new attitudes and feelings, whereas in teaching the focus of change is intellectual growth or the acquisition of new knowledge or psychomotor skills (Redman, 2005).

When you educate patients, respect the diversity of their human experiences, know their values and preferences as to how they learn, and respect their expertise with their own health management. As an educator you present health care principles, procedures, and techniques to inform patients about their health status and help them achieve self-care within their capabilities. The types of teaching topics that you address with patients are unlimited. However, be aware that teaching is also an ongoing process of keeping patients informed. Patients want to know why you do what you do. For example, incorporate into your interventions explanations of procedures, why they are being done, what the expected outcomes are, and what the patient can expect. A simple application is informing a patient about his or her IV infusion: explain what the IV fluid bag contains, how long the bag should last, the sensations the patient will feel if the IV site becomes inflamed, the fact that a small flexible catheter is in the arm, and any potential side effects of medications in the bag.

Teaching takes place in all health care settings (Fig. 19-3). As a nurse you are accountable for the quality of education you deliver. Know your patient; be aware of the cultural and social factors that influence a patient's willingness and ability to learn. It is also important to know your patient's health literacy level. Can he or she read directions or make calculations that sometimes are necessary with self-care skills? The teaching-learning process is an interaction between you and the learner, and it offers an organizational structure and framework for successful patient education. Don't assume that patients understand their illness or disease. If they seem uneasy or refuse a treatment, simply ask what concerns them. This gives you the opportunity to provide further teaching and correct knowledge deficiencies.

FIG. 19-3 Teaching patient discharge instructions.

Controlling for Adverse Reactions

An **adverse reaction** is a harmful or unintended effect of a medication, diagnostic test, or therapeutic intervention. Adverse reactions can possibly follow any nursing intervention; thus learn to anticipate and know which adverse reactions to expect. Nursing actions that control for adverse reactions reduce or counteract the reaction. For example, when applying a moist heat compress, you want to prevent burning the patient's skin. First assess the condition of the area where you plan to place the compress. Following application of the compress, inspect the area every 5 minutes for any adverse reaction such as excessive reddening of the skin from the heat or skin maceration from the moisture. When completing a health care provider–directed intervention such as medication administration, you need to understand the potential side effects of the drug. After you administer the medication, evaluate the patient for any adverse effects. Also be aware of drugs that counteract the side effects. For example, a patient has an unknown hypersensitivity to penicillin and develops hives after three doses. You record the reaction, stop further administration of the drug, and consult with the physician. You then administer an ordered dose of diphenhydramine (Benadryl), an antihistamine and antipruritic medication, to reduce the allergic response and relieve the itching.

When caring for a patient who is undergoing a particular diagnostic test, you need to understand the test and any potential adverse effects. For example, a patient has not had a bowel movement in 24 hours after a barium enema. Because bowel impaction is a potential side effect of a barium enema, you increase fluid intake and instruct the patient to let nursing personnel know when a bowel movement occurs. Although adverse effects are not common, they do occur. It is important that you recognize the signs and symptoms of an adverse reaction and intervene in a timely manner.

Preventive Measures

Preventive nursing actions promote health and prevent illness to avoid the need for acute or rehabilitative health care (see Chapter 1). Changes in the health care system are leading to greater emphasis on health promotion and illness prevention. Primary prevention aimed at health promotion includes health education programs, immunizations, and physical and nutritional fitness activities. Secondary prevention focuses on people who are experiencing health problems or illnesses and who are at risk for developing complications or worsening conditions. It includes screening techniques and treating early stages of disease. Tertiary prevention involves minimizing the effects of long-term illness or disability, including rehabilitation measures.

INDIRECT CARE

Indirect care measures include nurse actions aimed at management of the patient care environment and interdisciplinary collaborative actions that support the effectiveness of direct care interventions (Bulechek et al., 2008). Many of the measures are managerial in nature such as emergency cart maintenance and environmental and supply management (Box 19-4). Nurses spend much time in indirect and unit management activities. Communication of information about patients (e.g., change-of-shift report and consultation) is critical, ensuring that direct care activities are planned, coordinated, and performed with the proper resources. Delegation of care to NAP is another indirect care activity (see Chapter 21). When performed correctly, delegation ensures that the right care provider performs the right tasks so the nurse and NAP work most efficiently together for the patient's benefit.

BOX 19-4 EXAMPLES OF INDIRECT CARE ACTIVITIES

- Documentation (electronic or written)
- Delegation of care activities to nursing assistive personnel
- Medical order transcription
- Infection control (e.g., proper handling and storage of supplies, use of protective isolation)
- Environmental safety management (e.g., make patient rooms safe, strategically assigning patients in a geographical proximity to a single nurse)
- Telephone consultations with physicians and other health care providers
- Change-of-shift report
- Collecting, labeling, and transporting specimens
- Transporting patients to procedural areas and other nursing units

From Bulechek GM et al: *Nursing interventions classification (NIC),* ed 5, St Louis, 2008, Mosby.

Communicating Nursing Interventions

Any intervention that you provide for a patient is communicated in a written (or electronic) and oral format. Written interventions are part of the nursing care plan (see Chapter 18) and a patient's permanent medical record. Staff in many institutions develop **interdisciplinary care plans** (i.e., plans representing the contributions of all disciplines caring for a patient). After completing any nursing interventions, you document the treatment and patient's response in the appropriate part of the record (see Chapter 26). The record entry usually includes a brief description of pertinent assessment findings, the specific intervention(s), and the patient's response. A written record validates that you performed the procedure and provides valuable information to subsequent caregivers about the approaches needed to provide successful care.

You also communicate nursing interventions verbally to other health care professionals. Unless communication is timely and accurate, caregivers can be uninformed, interventions may be duplicated needlessly, procedures may be delayed, or tasks may be left undone. Patients can quickly tell when members of the health care team communicate inconsistent messages, indicating that no one is in charge. Nurses commonly communicate orally when conferring with colleagues, during a change of shift, transferring a patient to another unit, or discharging a patient to another health care agency. Always be clear, concise, and to the point when you communicate nursing interventions.

Delegating, Supervising, and Evaluating the Work of Other Staff Members

Depending on the system of health care delivery, the nurse who develops the care plan frequently does not perform all of the nursing interventions. Some activities you coordinate and delegate to other members of the health care team (see Chapter 21). For example, an RN delegates components of care but not the nursing process itself (American Nurses Association [ANA], 2006). Noninvasive and frequently repetitive interventions such as skin care, ambulation, grooming, vital signs on stable patients, and hygiene measures are examples of care activities that you delegate to NAP such as a nurse assistant. When a nurse delegates aspects of a patient's care to another staff member, the nurse who assigns the tasks is responsible for ensuring that each task is appropriately assigned and completed according to the standard of care. You are responsible for delegating direct care interventions to personnel who are competent. Recently the ANA and the National Council of State Boards of Nursing (NCSBN) released a joint statement outlining 10 principles for delegation (Trossman, 2006). The principles are a blueprint to help RNs better understand delegation, keep patients safe, and protect their professional practice.

ACHIEVING PATIENT GOALS

Regardless of the type of interventions, you implement nursing care to achieve patient goals and outcomes. In most clinical situations multiple interventions are necessary to achieve select outcomes. In addition, patients' conditions often change minute by minute. Therefore it is important for you to apply principles of care coordination such as good time management, organizational skills, and appropriate use of resources to ensure that you deliver interventions effectively and meet desired outcomes (see Chapter 21). Priority setting is critical in successful implementation. Priorities help you to anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems (see Chapter 18).

Another way to achieve patient goals is to help them adhere to their treatment plan. **Patient adherence** means that patients and families invest time in carrying out required treatments. To ensure patients a smooth transition across different health care settings (e.g., hospital to home and clinic to home to assisted living), it becomes important to introduce interventions that patients are willing and able to follow. Adequate and timely discharge planning and education of the patient and family are the first steps in promoting a smooth transition from one health care setting to another or to the home. To be effective with discharge planning and education, you individualize your care and take into consideration the various factors that influence a patient's health beliefs. For example, for Tonya to effectively help Mr. Jacobs follow the activity limitations required after surgery, she needs to know if Mr. Jacobs understands the risks to wound healing if limitations are not followed. Chapter 6 reviews the principles of the health belief model, which influence how patients adhere to health care recommendations. You are responsible for delivering interventions in a way that reflects your understanding of a patient's health beliefs, culture, lifestyle pattern, and patterns of wellness. In addition, reinforcing successes with the treatment plan encourages the patient to follow the care plan.

KEY POINTS

- Implementation is the fourth step of the nursing process in which nurses initiate interventions that are designed to achieve the goals and expected outcomes of the patient's plan of care.
- A direct-care intervention is a treatment performed through interactions with a patient that can include nurse-initiated, physician-initiated, and collaborative approaches.
- Always think first and determine if an intervention is correct and appropriate and if you have the resources needed to implement it.
- Clinical guidelines or protocols are evidence-based documents that guide decisions and interventions for specific health care problems.
- When preparing to perform an intervention, reassess the patient, review and revise the existing nursing care plan, organize resources and care delivery approaches, anticipate and prevent complications, and implement the intervention.
- The implementation of nursing care often requires additional knowledge, nursing skills, and personnel resources.

- Before beginning to perform interventions, make sure that the patient is as physically and psychologically comfortable as possible.
- Use good judgment and sound clinical decision making when performing any intervention to ensure that no nursing action is automatic.
- To anticipate and prevent complications, identify risks to the patient, adapt interventions to the situation, evaluate the relative benefit of a treatment versus the risk, and initiate risk-prevention measures.
- Methods used to ensure that you administer physical care techniques appropriately include protecting you and the patient from injury, using proper infection control practices, staying organized, and following applicable practice guidelines.
- When you delegate aspects of a patient's care, you are responsible for ensuring that each task is assigned appropriately and completed according to the standard of care.
- To complete any nursing procedure, you need to know the procedure, its frequency, the steps, and the expected outcomes.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya is preparing to change the dressing over Mr. Jacobs' wound, and Mrs. Jacobs is present to observe. Tonya determines Mr. Jacob's level of pain to be sure that he is comfortable. She decides to include discussion of wound and urinary catheter care during her time with the family. Before beginning instruction with the Jacobs, Tonya asks Mr. Jacobs if he is ready to learn about wound and catheter care. She observes Mr. and Mrs. Jacobs' behaviors to note their receptivity to instruction. She prepares all of her supplies before the dressing change. She also assesses the condition of the dressing before she starts.

1. When Tonya asks Mr. Jacobs about his readiness for instruction, which aspect of the implementation process is she performing?
2. When changing Mr. Jacobs' dressing, Tonya cleans the wound following clinical practice guidelines for her nursing unit and checks the incision for signs of infection. Explain the benefit of cleansing the wound on the basis of practice guidelines.
3. When Tonya begins instructing the Jacobs about wound care, what implementation skill most likely ensures good outcomes, specifically that the patient is able to learn how to change his dressing correctly at home?

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The nurse enters a patient's room and finds that the patient was incontinent of liquid stool. The patient has recurrent redness in the perineal area, and there is concern that he is developing a pressure ulcer. The nurse cleanses the patient, inspects the skin, and applies a skin barrier ointment to the perineal area. She calls the ostomy and wound care specialist and asks that he visit the patient to recommend skin care measures. Which of the following describe the nurse's actions? (Select all that apply.)
   1. The application of the skin barrier is a dependent care measure.
   2. The call to the ostomy and wound care specialist is an indirect care measure.
   3. The cleansing of the skin is a direct care measure.
   4. The application of the skin barrier is a direct care measure.
2. During the implementation step of the nursing process, a nurse reviews and revises the nursing plan of care. Place the following steps of review and revision in the correct order:
   1. Review the care plan.
   2. Decide if the nursing interventions remain appropriate.
   3. Reassess the patient.
   4. Compare assessment findings to validate existing nursing diagnoses.
3. A nurse checks a physician's order and notes that a new medication was ordered. The nurse is unfamiliar with the medication. A nurse colleague explains that the medication is an anticoagulant used for postoperative patients with risk for blood clots. The nurse's best action before giving the medication is to:
   1. Have the nurse colleague check the dose with her before giving the medication.
   2. Consult with a pharmacist to obtain knowledge about the purpose of the drug, the action, and the potential side effects.
   3. Ask the nurse colleague to administer the medication to her patient.
   4. Administer the medication as prescribed and on time.
4. When does implementation begin as the fourth step of the nursing process?
   1. During the assessment phase
   2. Immediately in some critical situations
   3. After the care plan has been developed
   4. After there is mutual goal setting between nurse and patient
5. Before consulting with a physician about a patient's need for urinary catheterization, the nurse considers the fact that the patient has urinary retention and has been unable to void on her own. The nurse knows that evidence for alternative measures to promote voiding exists, but none has been effective, and that before surgery the patient was voiding normally. This scenario is an example of which implementation skill?
   1. Cognitive
   2. Interpersonal
   3. Psychomotor
   4. Consultative
6. The nurse enters a patient's room, and the patient asks if he can get out of bed and transfer to a chair. The nurse takes precautions to use safe patient handling techniques and transfers the patient. This is an example of which physical care technique?
   1. Meeting the patient's expressed wishes
   2. Indirect care measure
   3. Protecting a patient from injury
   4. Staying organized when implementing a procedure
7. In which of the following examples is a nurse applying critical thinking attitudes when preparing to insert an intravenous (IV) catheter? (Select all that apply.)
   1. Following the procedural guideline for IV insertion
   2. Seeking necessary knowledge about the steps of the procedure from a more experienced nurse
   3. Showing confidence in performing the correct IV insertion technique
   4. Being sure that the IV dressing covers the IV site completely
8. Which steps does the nurse follow when he or she is asked to perform an unfamiliar procedure? (Select all that apply.)

1. Seeks necessary knowledge
2. Reassesses the patient's condition
3. Collects all necessary equipment
4. Delegates the procedure to a more experienced staff member
5. Considers all possible consequences of the procedure

9. For each of the following interventions, note which are direct and which are indirect nursing interventions. Place a D for direct or I for indirect in the space provided
   1. A nurse checks the monthly performance improvement report on fall occurrences on a unit. _____
   2. A nurse discusses with the patient exercise restrictions to follow on return home. _____
   3. A nurse consults with a dietitian about a patient's therapeutic diet food choices. _____
   4. A nurse administers a tube feeding. _____
   5. A nurse assists a colleague in applying a complex dressing to a patient's wound. _____
10. A nurse is talking with a patient who is visiting a neighborhood health clinic. The patient came to the clinic for repeated symptoms of a sinus infection. During their discussion the nurse checks the patient's medical record and realizes that he is due for a tetanus shot. Administering the shot is an example of what type of preventive intervention?
    1. Tertiary
    2. Direct care
    3. Primary
    4. Secondary
11. A nurse is orienting a new graduate nurse to the unit. The graduate nurse asks, "Why do we have standing orders for cases when patients develop life-threatening arrhythmias? Is not each patient's situation unique?" What is the nurse's best answer?
    1. Standing orders are used to meet our physician's preferences.
    2. Standing orders ensure that we are familiar with evidence-based guidelines for care of arrhythmias.
    3. Standing orders allow us to respond quickly and safely to a rapidly changing clinical situation.
    4. Standing orders minimize the documentation we have to provide.
12. A nurse on a cancer unit is reviewing and revising the written plan of care for a patient who has the nursing diagnosis of nausea. Place the following steps in their proper order:
    1. The nurse revises approaches in the plan for controlling environmental factors that worsen nausea.
    2. The nurse enters data in the assessment column showing new information about the patient's nausea.
    3. The nurse adds the current date to show that the diagnosis of nausea is still relevant.
    4. The nurse decides to use the patient's self-report of appetite and fluid intake as evaluation measures.
13. When a nurse properly positions a patient and administers an enema solution at the correct rate for the patient's tolerance, this is an example of what type of implementation skill?
    1. Interpersonal
    2. Cognitive
    3. Collaborative
    4. Psychomotor
14. The nurse reviews a patient's medical record and sees that tube feedings are to begin after a feeding tube is inserted. In recent past experiences the nurse has seen patients on the unit develop diarrhea from tube feedings. The nurse consults with the dietitian and physician to determine the initial rate that will be ordered for the feeding to lessen the chance of diarrhea. This is an example of what type of direct care measure?
    1. Preventive
    2. Controlling for an adverse reaction
    3. Consulting
    4. Counseling
15. A nurse is starting on the evening shift and is assigned to care for a patient with a diagnosis of *impaired skin integrity related to pressure and moisture on the skin*. The patient is 72 years old and had a stroke. The patient weighs 250 pounds and is difficult to turn. As the nurse makes decisions about how to implement skin care for the patient, which of the following actions does the nurse implement? (Select all that apply.)
    1. Review the set of all possible nursing interventions for the patient's problem
    2. Review all possible consequences associated with each possible nursing action
    3. Consider own level of competency
    4. Determine the probability of all possible consequences

Answers: **1.** 2, 3, 4; **2.** 3, 1, 4, 2; **3.** 2; **4.** 3; **5.** 1; **6.** 3; **7.** 2, 3; **8.** 1, 3, 5; **9.** 1 (I), 2 (D), 3 (I) 4 (D), 5 (D); **10.** 3; **11.** 3; **12.** 2, 3, 1, 4; **13.** 4; **14.** 2; **15.** 1, 2, 4.

CHAPTER

20

Evaluation

OBJECTIVES

- Discuss the relationship between critical thinking and evaluation.
- Describe the standards of professional nursing practice for evaluation.
- Explain the relationship among goals of care, expected outcomes, and evaluative measures when evaluating nursing care.
- Give examples of evaluation measures for determining a patient's progress toward outcomes.
- Evaluate the outcomes of care for a patient.
- Describe how evaluation leads to discontinuation, revision, or modification of a plan of care.

KEY TERMS

Evaluation, p. 265
Evaluative measures, p. 268
Nursing-sensitive outcome, p. 267
Standard of care, p. 271

When a repairman comes to a home to fix a leaking faucet, he turns the faucet on to determine the problem, changes or adjusts parts, and rechecks the faucet to determine if the leak is fixed. After a patient diagnosed with pneumonia completes a course of antibiotics, the health care provider often has him or her return to the office to have a chest x-ray examination to determine if the pneumonia has cleared. When a nurse provides wound care, including application of a warm compress, several steps are involved. He or she assesses the appearance of the wound, determines its severity, applies the appropriate form of compress, and returns later to determine if the condition of the wound has improved. These three scenarios depict what ultimately occurs during the process of evaluation. The repairman rechecks the faucet, the physician orders a chest x-ray film, and the nurse reinspects the patient's wound. Evaluation involves two components: an examination of a condition or situation and a judgment as to whether change has occurred. Ideally after an intervention takes place, evaluation reveals an improvement, a desired outcome.

The previous chapters on the nursing process describe how you apply critical thinking to gather patient data, form nursing diagnoses, develop a plan of care, and implement interventions in the care plan. **Evaluation,** the final step of the nursing process, is crucial to determine whether, after application of the nursing process, the patient's condition or well-being improves. You apply all that you know about a patient and his or her condition and your experiences with previous patients to evaluate whether nursing care was effective. *You conduct evaluative measures to determine if your patients met expected outcomes, not if nursing interventions were completed.* The expected outcomes established during planning are the standards against which the nurse judges whether goals have been met and if care is successful.

In the continuing case study, Tonya has instructed Mr. Jacobs about necessary wound care. Mrs. Jacobs also participates in the education session. Tonya discusses with the family the importance of wound care in preventing infection and has Mr. and Mrs. Jacobs observe the dressing change. During the dressing change Tonya uses safe and appropriate intervention techniques to protect the integrity of the wound and minimize transmission of infection. She also discusses how physical stress such as bending and lifting strains a suture line; thus Mr. Jacobs needs to limit activity for the first few weeks after surgery. Tonya encourages the Jacobs to ask any questions they have about wound care. Tonya returns to Mr. Jacobs' room an hour later to evaluate the results of her instruction. For the nursing diagnosis of deficient knowledge, Tonya set the expected outcomes of: "Patient and wife will describe the signs and symptoms of a wound infection, explain how activity affects wound healing, and demonstrate a dressing change correctly." Mr. Jacobs is resting in bed, and Mrs. Jacobs is reading one of the instruction brochures as Tonya enters the room. Tonya says, "Mrs. Jacobs, I see that you're reviewing the booklet I gave you. Do you have any questions"? Mrs. Jacobs responds, "I guess I understand what to look for with an infection. I hope I can recognize changes." Tonya asks, "Tell me the signs of infection."

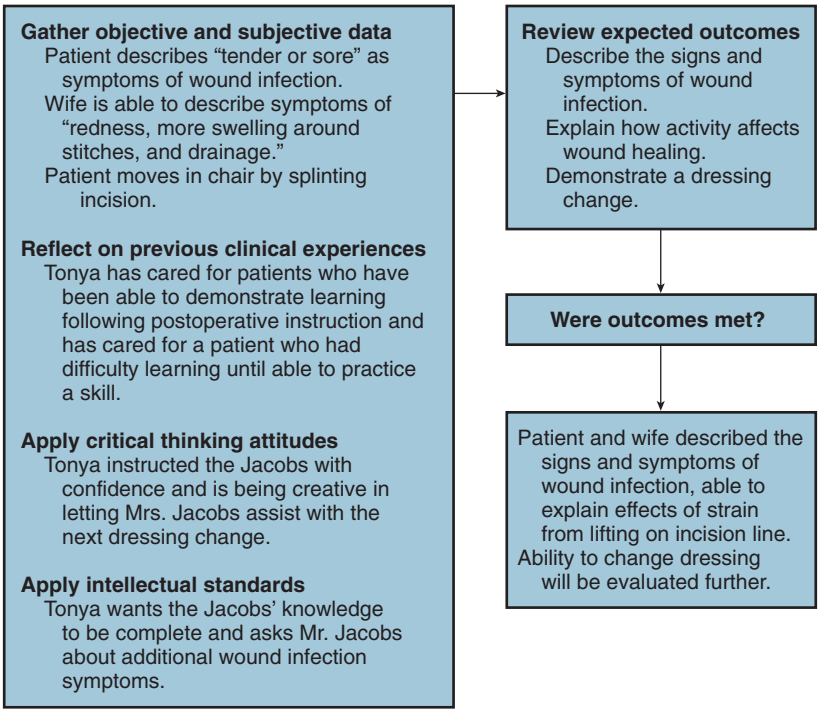

FIG. 20-1 Critical thinking and the evaluation process.

Mrs. Jacobs replies, "Redness, more swelling around the stitches, and drainage." Tonya asks Mr. Jacobs, "Are there any other signs of infection?" Mr. Jacobs responds, "You said that my incision would feel more tender or sore and that I might have a fever." "That's right," Tonya remarks. "Tell me why your doctor has limited your lifting for a month." Mr. Jacobs answers, "So I don't strain my incision and pull out the stitches." "Right again," Tonya affirms," I think that before you go home tomorrow we should let you watch one more dressing change and even let your wife help me."

Evaluation is an ongoing process that occurs whenever you have contact with a patient. Once you deliver an intervention, you gather subjective and objective data from the patient, family, and health care team members. You also review knowledge regarding the patient's current condition, treatment, resources available for recovery, and expected outcomes. By referring to previous experiences caring for similar patients, you are in a better position to know how to evaluate your patient. You can anticipate what to evaluate. Apply critical thinking attitudes and standards to determine whether outcomes of care are achieved (Fig. 20-1). If outcomes are met, the overall goals for the patient also are met. Compare patient behavior and responses that you assessed before delivering nursing interventions with behavior and responses that occur after administering nursing care. Critical thinking directs you to analyze the findings from evaluation (Fig. 20-2). Has the patient's condition improved? Is the patient able to improve, or are there physical factors preventing recovery? To what degree does this patient's motivation or willingness to pursue healthier behaviors influence responses to therapies?

During evaluation you make clinical decisions and continually redirect nursing care. For example, when Tonya evaluates the Jacobs' learning, she applies knowledge of patient education principles and postoperative wound healing to interpret whether learning has occurred and whether further instruction is needed. Tonya knows that repetition is important in learning and thus plans another instruction session with the family during a dressing change the next day. Evaluative findings determine Tonya's next course of action. In the Jacobs' case Tonya knows that this is the first time Mr. Jacobs has had major surgery. Mrs. Jacobs voiced concern about recognizing the signs of infection. To meet the outcomes of care, Tonya plans to discuss the appearance of the wound during normal healing and specifically how signs of infection present. She reinforces this explanation during the dressing change so Mr. and Mrs. Jacobs can look at the wound closely again under Tonya's instruction.

Positive evaluations occur when the patient meets desired outcomes, which leads you to conclude that the nursing intervention(s) were effective. For example, in the case study Tonya notes that Mrs. Jacobs identified three signs and symptoms of infection and Mr. Jacobs identified two. Therefore Tonya determines the expected outcome of "describing signs and symptoms of wound infection" was partially met by the patient. However, further instruction is necessary. Unmet or undesirable outcomes such as incorrect or incomplete knowledge indicate that interventions are not effective in minimizing or resolving the actual problem or avoiding an at-risk problem. An unmet outcome reveals that the patient has not responded to interventions as planned. As a result, the nurse changes the plan of care by trying different therapies or changing the frequency or approach of existing therapies.

This sequence of critically evaluating and revising therapies continues until you and the patient successfully and appropriately resolve the problems defined by nursing diagnoses. Remember that evaluation is dynamic and ever changing, depending on the patient's nursing diagnoses and conditions. As problems change, so do expected outcomes. A patient whose health status continuously changes requires more frequent evaluation. In addition, you evaluate priority diagnoses first. For example, Tonya continues to evaluate Mr. Jacobs' *acute pain* before evaluating the status of his *deficient knowledge*.

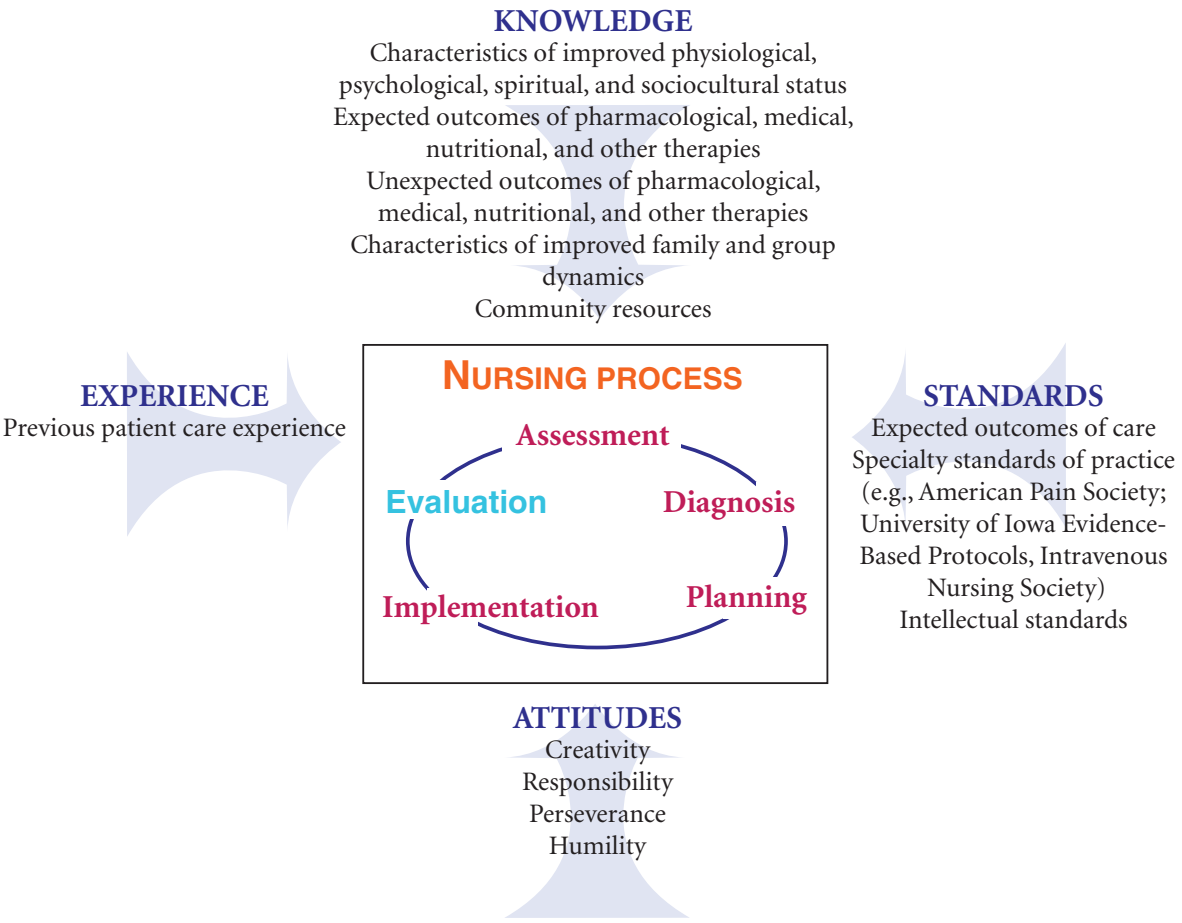

FIG. 20-2 Critical thinking and evaluation.

STANDARDS FOR EVALUATION

Nursing care helps patients resolve actual health problems, prevent the occurrence of potential problems, and maintain a healthy state. The evaluation process is an integral step to that end. The American Nurses Association (ANA) defines standards of professional nursing practice, which include standards for the evaluation step of the nursing process (see Chapter 1). The standards are authoritative statements of the duties that all registered nurses, regardless of role, patient population they serve, or specialty, are expected to perform competently (ANA, 2010). The competencies for evaluation include being systematic and using criterion-based evaluation, collaborating with patients and other professionals, using ongoing assessment data to revise the plan, and communicating results to patients and families. It is also important to ensure the responsible and appropriate use of interventions to minimize unwarranted or unwanted treatment (ANA, 2010).

Criterion-Based Evaluation

You evaluate nursing care by knowing what to look for as described in the criterion-based standards included in a patient's goals and expected outcomes. The goals and outcomes are objective criteria needed to judge a patient's response to care.

Goals. A goal is the expected behavior or response that indicates resolution of a nursing diagnosis or maintenance of a healthy state. It is a summary statement of what will be accomplished when the patient has met all expected outcomes. For Mr. Jacobs Tonya selected the goal of, "Patient expresses acceptance of health status by day of discharge" for the nursing diagnosis of *anxiety* (see Chapter 18). Successful achievement of this goal depends on Tonya delivering interventions selected from the Nursing Interventions Classification (NIC), including acceptance of health status and anxiety level (see Nursing Care Plan, Chapter 18).

Goals often are also based on standards of care or guidelines established for minimal safe practice. For example, the Infusion Nurses Society (INS) has standards of care for prevention of the intravenous (IV) complication phlebitis (INS, 2006). When a nurse cares for a patient with a peripheral IV line, the goal, "The IV site will remain free of phlebitis," is established on the basis of sound practice standards. The INS phlebitis scale contains physical criteria for determining phlebitis (see Chapter 41).

Expected Outcomes. An expected outcome is an end result that is measurable, desirable, and observable and translates into observable patient behaviors (ANA, 2010). It is a measure that tells you if the interventions applied in patient care led to successful goal achievement. When nurses apply the nursing process, a **nursing-sensitive outcome** is a measurable patient or family state, behavior, or perception largely influenced by and sensitive to nursing interventions (Moorhead et al., 2008). The interventions must be within the scope of nursing practice and integral to the processes of nursing care. Examples of nursing-sensitive outcomes include reduction in pain frequency, incidence of pressure ulcers, and incidence of falls (Box 20-1). In comparison, medical outcomes are largely influenced by medical interventions. Examples

BOX 20-1 EVIDENCE-BASED PRACTICE

Nursing-Sensitive Outcomes

PICO Question: In hospitals does the use of nursing-sensitive outcomes improve the quality of nursing care?

Evidence Summary

The current climate in health care is to increase the accountability of health care organizations for the quality of the care they provide (Loan et al., 2011). Nursing-sensitive outcomes are providing benchmarks for hospitals to gauge the quality of their care. The use of nursing-sensitive outcomes such as pressure ulcer prevalence, symptom frequency (pain, nausea, fatigue), medication administration errors, and fall and fall injury incidence offer hospitals an opportunity to compare their performance with specificity (Brown et al., 2010). In addition, these outcome measures offer a way to measure staffing effectiveness (Loan et al., 2011). Doran et al. (2006) showed that nursing-sensitive outcomes are sensitive to changes in patients' conditions and thus are a potential measure of quality of care.

Application to Nursing Practice

- Nursing care is a key factor in the outcomes of hospitalized patients.
- The collection of nursing-sensitive outcomes offers important feedback to nurses about whether nursing interventions lead to patient care improvement.
- The selection of nursing-sensitive outcomes in a plan of care makes nurses accountable for the care delivered to patients and whether there is an improvement in their health status.

include patient mortality, surgical wound infection, and hospital readmissions. Outcomes are statements of progressive, step-by-step physical, emotional, or behavioral responses that the patient needs to accomplish to achieve the goals of care. When you achieve outcomes, the related factors for a nursing diagnosis usually no longer exist. Two of the expected outcomes for Mr. Jacobs' goal of, "Patient expresses acceptance of health status by day of discharge," are "Patient describes surgical outcomes in discussion with surgeon in 24 hours," and "Patient shares concerns with wife before day of discharge." Tonya evaluates Mr. Jacobs by observing for behaviors that reflect anxiety and discussing what the patient has learned from the surgeon and discussed with his wife. The related factor of "uncertainty over recovery" no longer exists if Mr. Jacobs is able to relate surgical outcomes discussed with the surgeon and reports having had a discussion about those outcomes with his wife.

Evaluation is not a description of the achievement of an intervention. Evaluation of Mr. Jacobs *does not* involve observing his ability to perform relaxation exercises for his anxiety. Evaluation *does* involve observation of the patient's behavior (facial expression) during discussions about his recovery.

A valuable resource for selecting outcomes is the Nursing Outcomes Classification (NOC) (see Chapter 18). It offers a language for the evaluation step of the nursing process. The purposes of NOC are (1) to identify, label, validate, and classify nurse-sensitive patient outcomes; (2) to field test and validate the classification; and (3) to define and test measurement procedures for the outcomes and indicators using clinical data (Moorhead et al., 2008). Within the NOC taxonomy you can select outcomes specific for nursing interventions that relate to nursing diagnoses. The NOC project complements the work of NANDA International (NANDA-I) and the NIC project. The NOC classification offers nursing-sensitive outcomes for NANDA-I nursing diagnoses (Table 20-1).

TABLE 20-1 Linkages Between Nursing Outcomes Classification and Nursing Diagnoses

NURSING DIAGNOSIS	SUGGESTED OUTCOMES	INDICATORS (EXAMPLES)
Acute pain	Comfort level	Reports physical well-being Reports satisfaction with symptom control Expresses satisfaction with pain control
	Pain control	Recognizes pain onset Uses analgesics appropriately Reports pain controlled
	Pain level	Reports pain severity Frequency of pain Muscle tension
Deficient knowledge	Knowledge: treatment procedures	Description of treatment procedures
	Knowledge: illness care	Description of disease process Description of prescribed activity

For each outcome there are specific recommended evaluation indicators (i.e., the patient behaviors or responses that are measures of outcome achievement).

Collaborate and Evaluate Effectiveness of Interventions

An important aspect of patient-centered care and evaluation is collaboration. A nurse must respect the patient and family as a core member of the health care team, meaning that the patient and family must be actively involved in the evaluation process. When you develop patient care goals and expected outcomes with a patient, he or she becomes an important resource for being able to tell you if outcomes are being met. For example, a patient knows best if pain has lessened or if breathing is easier. The same holds true for the family, who often can recognize changes in patient behavior sooner than you can because of their familiarity with the patient. Members of the health care team who contribute to the patient's care also gather evaluative findings.

Proper evaluation determines the effectiveness of nursing interventions, allowing you to answer the following questions: What is the patient's response to nursing care? Was the therapy effective in improving the patient's physical or emotional health? It is important to evaluate whether each patient reaches a level of wellness or recovery that the health care team and patient established in the goals of care. In addition, have you met the patient's expectations of care? Ask patients about their perceptions of care such as, "Did you receive the type of pain relief you expected?" "Did you receive enough information to change your dressing when you return?" This level of evaluation determines the patient's satisfaction with care and strengthens partnering between you and the patient.

Evaluative Measures. Evaluating a patient's response to nursing care requires the use of **evaluative measures,** which are assessment skills and techniques (e.g., observations, physiological measurements, patient interview) (Fig. 20-3). In fact, evaluative measures are the same as assessment measures, but you perform them at the point of care when you make decisions about the patient's status and progress. The intent of assessment is to identify

TABLE 20-2 Evaluative Measures to Determine the Success of Goals and Expected Outcomes

GOALS	EVALUATIVE MEASURES	EXPECTED OUTCOMES
Patient's pressure ulcer will heal within 7 days.	Inspect color, condition, and location of pressure ulcer. Measure diameter of ulcer daily. Note odor and color of drainage from ulcer.	Erythema will be reduced in 2 days. Diameter of ulcer will decrease in 5 days. Ulcer will have no drainage in 2 days. Skin overlying ulcer will be closed in 7 days.
Patient will tolerate ambulation to end of hall by 11/20.	Palpate patient's radial pulse before exercise. Palpate patient's radial pulse 10 minutes after exercise. Assess respiratory rate during exercise. Observe patient for dyspnea or breathlessness during exercise.	Pulse will remain below 110 beats per minute during exercise. Pulse rate will return to resting baseline within 10 minutes after exercise. Respiratory rate will remain within two breaths of patient's baseline rate. Patient will deny feeling of breathlessness.

FIG. 20-3 Evaluative measures. **A,** Nurse evaluates patient's vital signs. **B,** Nurse evaluates patient's lung sounds.

which, if any, problems exist. The intent of evaluation is to determine if the known problems have remained the same, improved, worsened, or otherwise changed.

In many clinical situations it is important to collect evaluative measures over a period of time to determine if a pattern of improvement or change exists. A one-time observation of a pressure ulcer is insufficient to determine that the ulcer is healing. It is important to note a consistency in change. For example, over a period of 2 days is the pressure ulcer gradually decreasing in size, is the amount of drainage declining, and is the redness of inflammation resolving? Recognizing a pattern of improvement or deterioration allows you to reason and decide whether the patient's problems (expressed in nursing diagnoses) are resolved. This is very important in the home care or nursing home setting. It may take weeks or even months to determine if interventions led to a pattern of improvement. For example, when evaluating a patient's risk for falls over time, has the patient, family, or health care team successfully reduced fall risks in the home such as eliminating barriers in the home, removing factors impairing the person's vision, or providing direction for proper use of assistive devices?

Interpreting and Summarizing Findings. A patient's clinical condition often changes during an acute illness. In contrast, chronic illness results in slow, subtle changes. When you evaluate the effect of interventions, you interpret or learn to recognize relevant evidence about a patient's condition, even evidence that sometimes does not match clinical expectations. By applying your clinical knowledge and experience, you recognize complications or adverse responses to illness and treatment in addition to expected outcomes.

Careful monitoring and early detection of problems are a patient's first line of defense. Always make clinical judgments on your observations of what is occurring with a specific patient and not merely on what happens to patients in general. Frequently changes are not obvious. Evaluations are patient specific, based on a close familiarity with each patient's behavior, physical status, and reaction to caregivers. Critical thinking skills promote accurate evaluation, which leads to the appropriate revision of ineffective care plans and discontinuation of therapy that has successfully resolved a problem.

Using evidence, you make judgments about a patient's condition. To develop clinical judgment you match the results of evaluative measures with expected outcomes to determine whether or not a patient's status is improving. When interpreting findings, you compare the patient's behavioral responses and the physiological signs and symptoms you expect to see with those actually seen from your evaluation. Comparing expected and actual findings allows you to interpret and judge the patient's condition and whether predicted changes have occurred (Table 20-2). To objectively evaluate the degree of success in achieving outcomes of care, perform the following steps:

1. Examine the outcome criteria to identify the exact desired patient behavior or response.
2. Evaluate the patient's actual behavior or response.
3. Compare the established outcome criteria with the actual behavior or response.
4. Judge the degree of agreement between outcome criteria and the actual behavior or response.
5. If there is no agreement (or only partial agreement) between the outcome criteria and the actual behavior or response, what is/are the barrier(s)? Why did they not agree?

TABLE 20-3 Examples of Objective Evaluation of Goal Achievement

GOALS	OUTCOME CRITERIA	PATIENT RESPONSE	EVALUATION FINDINGS
Patient will change surgical dressing correctly by 12/18.	Patient demonstrates correct hand hygiene by 12/16. Patient describes material to use in dressing change by 12/17. Patient demonstrates dressing change by 12/18.	Patient used antiseptic hand rub correctly to wash hands. Patient applied clean gauze correctly and taped securely in place over incision.	Patient shows progression toward outcomes and achieved desired behavior.
Patient's lungs will be free of secretions by 11/30.	Coughing will be nonproductive by 11/29. Lungs will be clear to auscultation by 11/30. Respirations will be 20 per minute by 11/30.	Patient coughed frequently and productively on 11/29 following nebulization. Lungs were clear to auscultation on 11/30. Respirations were 18 per minute on 11/29.	Patient will require continued nebulizer therapy. Condition is improving.

Evaluation is easier to perform after you care for a patient over a long period. You are then able to make subtle comparisons of patient responses and behaviors. When you have not cared for a patient over an extended time, evaluation improves by referring to previous experiences or asking colleagues who are familiar with the patient to confirm evaluation findings. The accuracy of any evaluation improves when you are familiar with the patient's behavior and physiological status or have cared for more than one patient with a similar problem.

Remember to evaluate each expected outcome and its place in the sequence of care. If not, it is difficult to determine which outcome in the sequence was not met. Thus you cannot revise and redirect the plan of care at the most appropriate time. If the patient achieves the expected outcomes, you either continue the care plan to maintain a therapeutic status or discontinue interventions because the goal of care is met. If evaluation determines that the expected outcomes were not met or only partially met, you begin reassessment and revision of the care plan. If the patient's behavior begins to show changes but does not yet meet criteria set, the goal is partially met. If there is no progress, the goal is not met (Table 20-3).

Document Results

Documentation and reporting are important parts of evaluation. Accurate information needs to be present in a patient's medical record and shared during handoff communication so nurses and other health care team members know if a patient is progressing and to make ongoing clinical decisions. In settings in which the same nurse will not be providing care throughout a patient's stay, it becomes very important to have consistent, thorough documentation of the patient's progress towards expected outcomes. The use of nursing diagnostic language and the NIC and NOC is becoming more common in electronic medical records (Hendrix, 2009). The use of standardized nursing languages can improve the quality, consistency, and accuracy of what is documented by providing a broad base of nursing knowledge at the point of care (Lunney, 2006). In addition, electronic systems provide linkages to make it easier to interpret cues regarding whether interventions led to expected patient outcomes. When documenting a patient's response to your interventions, describe the interventions, the evaluative measures used, the outcomes achieved, and the continued plan of care. For example:

> 1430: Instructed patient on importance of handwashing and need to change surgical dressing if it becomes soiled, moist, or loosened. Asked patient to describe when it is necessary to change a surgical dressing. Patient was able to identify a soiled or moist dressing. Discussed further the need for a dressing to be secure. Provided pamphlet with outline of dressing change principles. Will discuss wound care with patient and wife one more time before discharge.

Your aim in documenting is to present a clear argument from the evaluative data as to whether a patient is progressing or not.

Disseminate results to patients and families. One of the ANA standards for evaluation is to share results of care with patients and their families according to federal and state regulations (ANA, 2010). Keep patients and families informed about the patients' progress. Be aware of guidelines of your agency for the type of clinical information (e.g., diagnostic findings, results of treatment) that you can communicate.

Care Plan Revision

Each time you evaluate a patient you determine if the plan of care continues or whether revisions are necessary. If your patient meets a goal successfully, discontinue that portion of the care plan. Unmet and partially met goals require you to continue intervention. It may be appropriate to modify or add nursing diagnoses for a new plan of care with appropriate goals, expected outcomes, and interventions. You must also redefine priorities. An important step in critical thinking is knowing how the patient is progressing and how problems either resolve or worsen.

Tonya's evaluation of Mr. Jacobs' interventions for deficient knowledge revealed the following: The patient and wife are able to identify signs and symptoms of wound infection, and the patient knows that strain on the suture line can affect healing. Tonya sees that the outcomes of care are partially met. She still hopes to evaluate Mr. and Mrs. Jacobs' ability to continue wound care at home through a demonstration planned for tomorrow. However, she also recognizes that, although Mr. Jacobs knows that strain on his incision can pull out the stitches, he may not realize which activities that he normally does at home would strain it. Thus she decides to modify her instructional approach by reassessing the types of activities Mr. Jacobs does at home (e.g., type of lifting, exercise, manual work) and incorporate that information into her teaching strategies.

Discontinuing a Care Plan. After you determine that expected outcomes and goals have been met, confirm this evaluation with the patient when possible. If you and the patient agree, you discontinue that portion of the care plan. Documentation of a discontinued plan ensures that other nurses will not unnecessarily continue interventions for that portion of the plan of care.

Continuity of care assumes that care provided to patients is relevant and timely. You waste much time when you do not communicate achieved goals.

Modifying a Care Plan. When goals are not met, you identify the factors that interfere with their achievement. Usually a change in the patient's condition, needs, or abilities makes alteration of the care plan necessary. For example, when teaching self-administration of insulin, a nurse discovers that the patient has developed a new problem, a tremor associated with a side effect of a medication. The patient is unable to draw medication from a syringe or inject the needle safely. As a result, the original outcomes, "Patient will correctly prepare insulin in a syringe," and "Patient will administer insulin injection independently," cannot be met. The nurse introduces new interventions (instructing a family member in insulin preparation and administration) and revises outcomes, "Family caregiver will correctly prepare insulin in syringe," and "Family caregiver will administer insulin injection correctly," to meet the goal of care.

At times a lack of goal achievement results from an error in nursing judgment or failure to follow each step of the nursing process. Patients often have multiple and complex problems. Always remember the possibility of overlooking or misjudging something. When a goal is not met, no matter what the reason, repeat the entire nursing process sequence for that nursing diagnosis to identify necessary changes to the plan. Reassess the patient, determine accuracy of the nursing diagnosis, establish new goals and expected outcomes, and select new interventions.

Reassessment. A complete reassessment of all patient factors relating to the nursing diagnosis and etiology is necessary when modifying a plan. Reassessment requires critical thinking as you compare new data about the patient's condition with previously assessed information. Knowledge from previous experiences helps you direct the reassessment process. Caring for patients and families who have had similar health problems gives you a strong background of knowledge to use for anticipating patient needs and knowing what to assess. Reassessment ensures that the database is accurate and current. It also reveals a missing link (i.e., a critical piece of new information that was overlooked and thus interfered with goal achievement). You sort, validate, and cluster all new data to analyze and interpret differences from the original database. You also document reassessment data to alert other nursing staff to the patient's status.

Redefining Diagnoses. After reassessment, determine which nursing diagnoses are accurate for the situation. Ask whether you selected the correct diagnosis and whether the diagnosis and the etiological factor are current. Then revise the problem list to reflect the patient's changed status. Sometimes you make a new diagnosis. You base your nursing care on an accurate list of nursing diagnoses. Accuracy is more important than the number of diagnoses selected. As the patient's condition changes, the diagnoses also change.

Goals and Expected Outcomes. When revising a care plan, review the goals and expected outcomes for necessary changes. In addition, examine the goals for unchanged nursing diagnoses for their appropriateness because a change in one problem sometimes affects the goals in others. Determining that each goal and expected outcome is realistic for the problem, etiology, and time frame is particularly important. Unrealistic expected outcomes and time frames make goal achievement difficult.

Clearly document goals and expected outcomes for new or revised nursing diagnoses so all team members are aware of the revised care plan. When the goal is still appropriate but has not yet been met, try changing the evaluation data to allow more time. You may also decide at this time to change interventions. For example, when a patient's pressure ulcer does not show signs of healing, you choose to use a different support surface or a different type of wound cleanser.

Interventions. The evaluation of interventions examines two factors: the appropriateness of the intervention selected and the correct application of the intervention. Appropriateness is based on the standard of care for a patient's health problem. A **standard of care** is the minimum level of care accepted to ensure high quality of care to patients. Standards of care define the types of therapies typically administered to patients with defined problems or needs. For example, if a patient who is receiving chemotherapy for leukemia has the nursing diagnosis *nausea related to pharyngeal irritation,* the standard of care established by the nursing department for this problem might include pain-control measures, mouth care guidelines, and diet therapy. The nurse reviews the standard of care to determine whether the right interventions have been chosen or whether additional ones are required.

Increasing or decreasing the frequency of interventions is another approach to ensure appropriate application of an intervention. You adjust interventions on the basis of the patient's actual response to therapy and your previous experience with similar patients. For example, if a patient continues to have congested lung sounds, you increase the frequency of coughing and deep-breathing exercises to remove secretions.

During evaluation you find that some planned interventions are designed for an inappropriate level of nursing care. If you need to change the level of care, substitute a different action verb, such as *assist* in place of *provide* or *demonstrate* in place of *instruct.* For example, assisting a patient to walk requires a nurse to be at the patient's side during ambulation, whereas providing an assistive device (e.g., a cane or walker) suggests that the patient is more independent. In addition, demonstration requires you to show a patient how a skill is performed rather than simply telling the patient how to perform it. Sometimes the level of care is appropriate, but the interventions are unsuitable because of a change in the expected outcome. In this case discontinue the interventions and plan new ones.

Make any changes in the plan of care based on the nature of the patient's unfavorable response. Consulting with other nurses often yields suggestions for improving the care delivery approach. Experienced nurses are often excellent resources. Simply changing the care plan is not enough. Implement the new plan and reevaluate the patient's response to the nursing actions. *Evaluation is continuous.*

Occasionally during evaluation you discover unmet patient needs. This is normal. The nursing process is a systematic, problem-solving approach to individualized patient care, but there are many factors affecting each patient with health care problems. Patients with the same health care problem are not treated the same way. As a result, you sometimes make errors in judgment. The systematic use of evaluation provides a way for you to catch these errors. By consistently incorporating evaluation into practice you minimize errors and ensure that the patient's plan of care is appropriate and relevant. The evaluation of nursing care is a professional responsibility, and it is a crucial component of nursing care.

KEY POINTS

- Evaluation is a step of the nursing process that includes two components: an examination of a condition or situation and a judgment as to whether change has occurred.

- During evaluation apply critical thinking to make clinical decisions and redirect nursing care to best meet patient needs.
- Positive evaluations occur when you meet desired outcomes and they lead you to conclude that your interventions were effective.
- Criterion-based standards for evaluation are the physiological, emotional, and behavioral responses that are a patient's goals and expected outcomes.
- Evaluative measures are assessment skills or techniques that you use to collect data for determining if outcomes were met.
- It sometimes becomes necessary to collect evaluative measures over time to determine if a pattern of change exists.
- When interpreting findings, you compare the patient's behavioral responses and physiological signs and symptoms that you expect to see with those actually seen from your evaluation and judge the degree of agreement.
- Documentation of evaluative findings allows all members of the health care team to know whether or not a patient is progressing.
- A patient's nursing diagnoses, priorities, and interventions sometimes change as a result of evaluation.
- Evaluation examines two factors: the appropriateness of the interventions selected and the correct application of the intervention.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

Tonya examines Mr. Jacobs' surgical incision and notices a 1.25-cm (0.5-inch) circle of yellowish drainage on the gauze dressing. On close inspection of the suture line, she also observes an area of swelling around two stitches. Mr. Jacobs notices Tonya's expression as she looks at the dressing and asks, "Is anything wrong?" Tonya responds, "A small amount of drainage is coming from your incision. Don't be alarmed." As Tonya applies mild pressure over the incision, she asks Mr. Jacobs if the area is tender. He grimaces a bit and says, "Yes, a little." Tonya says, "I'm going to let your surgeon know about this." After she consults with the physician, an intravenous (IV) antibiotic is ordered. While in Mr. Jacobs' room, Tonya notices that the patient is breathing faster and looks up to the ceiling and sighs.

1. When Tonya evaluated the surgical incision, two components of evaluation occurred. Describe each.
2. Based on this clinical scenario, how might Tonya need to modify the patient's care plan? Refer to the concept map (Fig. 19-2) on p. 257 in Chapter 19.
3. Identify two evaluative measures that Tonya used to evaluate the condition of Mr. Jacobs' wound.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse caring for a patient with pneumonia sits the patient up in bed and suctions his airway. After suctioning, the patient describes some discomfort in his abdomen. The nurse auscultates the patient's lung sounds and gives him a glass of water. Which of the following is an evaluative measure used by the nurse?
   1. Suctioning the airway
   2. Sitting patient up in bed
   3. Auscultating lung sounds
   4. Patient describing type of discomfort
2. A nurse caring for a patient with pneumonia sits the patient up in bed and suctions the patient's airway. After suctioning, the patient describes some discomfort in his abdomen. The nurse auscultates the patient's lung sounds and gives him a glass of water. Which of the following would be appropriate evaluative criteria used by the nurse? (Select all that apply.)
   1. Patient drinks contents of water glass.
   2. Patient's lungs are clear to auscultation in bases.
   3. Patient reports abdominal pain on scale of 0 to 10.
   4. Patient's rate and depth of breathing are normal with head of bed elevated.
3. The evaluation process includes interpretation of findings as one of its five elements. Which of the following is an example of interpretation?
   1. Evaluating the patient's response to selected nursing interventions
   2. Selecting an observable or measurable state or behavior that reflects goal achievement
   3. Reviewing the patient's nursing diagnoses and establishing goals and outcome statements
   4. Matching the results of evaluative measures with expected outcomes to determine patient's status
4. A goal specifies the expected behavior or response that indicates:
   1. The specific nursing action was completed.
   2. The validation of the nurse's physical assessment.
   3. The nurse has made the correct nursing diagnoses.
   4. Resolution of a nursing diagnosis or maintenance of a healthy state.
5. A patient is recovering from surgery for removal of an ovarian tumor. It is 1 day after her surgery. Because she has an abdominal incision and dressing and a history of diabetes, the nurse has selected a nursing diagnosis of *risk for infection.* Which of the following is an appropriate goal statement for the diagnosis?
   1. Patient will remain afebrile to discharge.
   2. Patient's wound will remain free of infection by discharge.
   3. Patient will receive ordered antibiotic on time over next 3 days.
   4. Patient's abdominal incision will be covered with a sterile dressing for 2 days.
6. Unmet and partially met goals require the nurse to do which of the following? (Select all that apply.)
   1. Redefine priorities
   2. Continue intervention
   3. Discontinue care plan
   4. Gather assessment data on a different nursing diagnosis
   5. Compare the patient's response with that of another patient
7. A patient comes to a medical clinic with the diagnosis of asthma. The nurse practitioner decides that the patient's obesity adds to the difficulty of breathing; the patient is 5 feet 7 inches tall and weighs 200 pounds (90.7 kg). Based on the nursing diagnosis of *imbalanced nutrition: more than body requirements,* the practitioner plans to place the patient on a therapeutic diet. Which of the following are evaluative measures for determining if the patient achieves the goal of a desired weight loss? (Select all that apply.)
   1. The patient eats 2000 calories a day.
   2. The patient is weighed during each clinic visit.

3. The patient discusses factors that increase the risk of an asthma attack.
4. The patient's food diary that tracks intake of daily meals is reviewed.

8. The nurse follows a series of steps to objectively evaluate the degree of success in achieving outcomes of care. Place the steps in the correct order.
   1. The nurse judges the extent to which the condition of the skin matches the outcome criteria.
   2. The nurse tries to determine why the outcome criteria and actual condition of skin do not agree.
   3. The nurse inspects the condition of the skin.
   4. The nurse reviews the outcome criteria to identify the desired skin condition.
   5. The nurse compares the degree of agreement between desired and actual condition of the skin.
9. The nurse checks the intravenous (IV) solution that is infusing into the patient's left arm. The IV solution of 9% NS is infusing at 100 mL/hr as ordered. The nurse reviews the nurses' notes from the previous shift to determine if the dressing over the site was changed as scheduled per standard of care. While in the room, the nurse inspects the condition of the dressing and notes the date on the dressing label. In what ways did the nurse evaluate the IV intervention? (Select all that apply.)
   1. Checked the IV infusion location in left arm
   2. Checked the type of IV solution
   3. Confirmed from nurses' notes the time of dressing change and checked label
   4. Inspected the condition of the IV dressing
10. Which of the following statements correctly describe the evaluation process? (Select all that apply.)
    1. Evaluation is an ongoing process.
    2. Evaluation usually reveals obvious changes in patients.
    3. Evaluation involves making clinical decisions.
    4. Evaluation requires the use of assessment skills.
11. A clinic nurse assesses a patient who reports a loss of appetite and a 15-pound weight loss since 2 months ago. The patient is 5 feet 10 inches tall and weighs 135 pounds (61.2 kg). She shows signs of depression and does not have a good understanding of foods to eat for proper nutrition. The nurse makes the nursing diagnosis of *imbalanced nutrition: less than body requirements related to reduced intake of food*. For the goal of, "Patient will return to baseline weight in 3 months," which of the following outcomes would be appropriate? (Select all that apply.)
    1. Patient will discuss source of depression by next clinic visit.
    2. Patient will achieve a calorie intake of 2400 daily in 2 weeks.
    3. Patient will report improvement in appetite in 1 week.
    4. Patient will identify food protein sources.
12. A patient is being discharged after abdominal surgery. The abdominal incision is healing well with no signs of redness or irritation. Following instruction, the patient has demonstrated effective care of the incision, including cleansing the wound and applying dressings correctly to the nurse. These behaviors are an example of:
    1. Evaluative measure.
    2. Expected outcome.
    3. Reassessment.
    4. Standard of care.
13. A patient has limited mobility as a result of a recent knee replacement. The nurse identifies that he has altered balance and assists him in ambulation. The patient uses a walker presently as part of his therapy. The nurse notes how far the patient is able to walk and then assists him back to his room. Which of the following is an evaluative measure?
    1. Uses walker during ambulation
    2. Presence of altered balance
    3. Limited mobility in lower extremities
    4. Observation of distance patient is able to walk
14. A patient is being discharged today. In preparation the nurse removes the intravenous (IV) line from the right arm and documents that the site was "clean and dry with no signs of redness or tenderness." On discharge the nurse reviews the care plan for goals met. Which of the following goals can be evaluated with what you know about this patient?
    1. Patient expresses acceptance of health status by day of discharge.
    2. Patient's surgical wound will remain free of infection.
    3. Patient's IV site will remain free of phlebitis.
    4. Patient understands when to call physician to report possible complications.
15. A nursing student is talking with one of the staff nurses who works on a surgical unit. The student's care plan is to include nursing-sensitive outcomes for the nursing diagnosis of *acute pain*. A nursing-sensitive outcome suitable for this diagnosis would be:
    1. Patient will achieve pain relief by discharge.
    2. Patient will be free of a surgical wound infection by discharge.
    3. Patient will report reduced pain severity in 2 days.
    4. Patient will describe purpose of pain medicine by discharge.

Answers: **1.** 3; **2.** 2, 4; **3.** 4; **4.** 4; **5.** 2; **6.** 1, 2; **7.** 2, 4; **8.** 4, 3, 5, 1, 2; **9.** 3, 4; **10.** 1, 3, 4; **11.** 2, 3; **12.** 2; **13.** 4; **14.** 3; **15.** 3.

CHAPTER

21

Managing Patient Care

OBJECTIVES

- Differentiate among the types of nursing care delivery models.
- Describe the elements of decentralized decision making.
- Discuss the ways in which a nurse manager supports staff involvement in a decentralized decision-making model.
- Discuss ways to apply clinical care coordination skills in nursing practice.
- Discuss principles to follow in the appropriate delegation of patient care activities.

KEY TERMS

Accountability, p. 277
Authority, p. 277

As a nursing student it is important for you to acquire the necessary knowledge and competencies that ultimately allow you to practice as an entry-level staff nurse. The National Council of State Boards of Nursing (NCSBN) identified competencies that registered nurses (RNs) and licensed practical/vocational nurses need on entry to practice (Kearney, 2009) (Box 21-1). Regardless of the type of setting in which you eventually choose to work as a staff nurse, you will be responsible for using organizational resources, participating in organizational routines while providing direct patient care, using time productively, collaborating with all members of the health care team, and using certain leadership characteristics to manage others on the nursing team. The delivery of nursing care within the health care system is a challenge because of the changes that influence health professionals, patients, and health care organizations (see Chapter 2). However, change offers opportunities. As you develop the knowledge and skills to become a staff nurse, you learn what it takes to effectively manage the patients for whom you care and to take the initiative in becoming a leader among your professional colleagues.

BUILDING A NURSING TEAM

Nurses are self-directed and, with proper leadership and motivation, are able to solve most complex problems. A nurse's education and commitment to practicing within established standards and guidelines ensures a rewarding professional career. As a nurse it is also important to work in an empowering environment as a member of a solid and strong nursing team. A strong nursing team works together to achieve the best outcomes for patients (Batcheller et al., 2004).

Building an **empowered** nursing team begins with the nurse executive, who is often vice president or director of nursing. The executive's position within an organization is critical in uniting the strategic direction of an organization with the philosophical values and goals of nursing. The nurse executive is both a clinical and business leader who is concerned with maximizing quality of care and cost-effectiveness while maintaining relationships and professional satisfaction of the staff. The relationship between the nurse and nurse manager contributes to job satisfaction and retention (Ulrich et al., 2005). Perhaps the most important responsibility of the nurse executive is to establish a philosophy for nursing that enables managers and staff to provide quality nursing care. In this environment staff members have high levels of productivity and make contributions to the success of the organization (Feltner et al., 2008). Box 21-2 identifies the characteristics of an effective nurse leader.

It takes an excellent nurse manager and an excellent nursing staff to make an empowering work environment. Together a manager and the nursing staff have to share a philosophy of care for their work unit. A philosophy of care includes the professional

BOX 21-1 ENTRY-LEVEL NURSE COMPETENCIES

- Possess a systems focus to see the big picture.
- Understand the environment of care.
- Manage the care of patients.
- Be able to critically think as demonstrated by assessment of problem, identification of solution, implementation of solution, evaluation of care, and follow-up of care.
- Communicate effectively with physicians and health care team members.
- Demonstrate nursing knowledge and display confidence in knowledge base.
- Work as a team member collaborating with health care team members.
- Have a patient orientation and focus with actions focused on patient and patient needs.
- Respect the rights, beliefs, wishes, and values of patients.
- Be a patient advocate.
- Recognize own limitations and see support of validation of decisions as needed.
- Demonstrate knowledge of roles, responsibilities, and functions of a nurse.

Modified from Kearney MH: *Report of the findings from the post-entry competence study,* Chicago, 2009, National Council of State Boards of Nursing; National Council of State Boards of Nursing: *2009 tuning analysis: a comparison of US and international nursing educational competences*, Chicago, 2010, National Councils State Boards of Nursing.

BOX 21-2 CHARACTERISTICS OF AN EFFECTIVE LEADER

- Is an effective communicator
- Is consistent in managing conflict
- Is knowledgeable and competent in all aspects of delivery of care
- Is a role model for staff
- Uses participatory approach in decision making
- Delegates work appropriately
- Sets objectives and guides staff
- Displays caring, understanding, and empathy for others
- Motivates others
- Is proactive and flexible

Modified from Dunham-Taylor J: Quantum leadership: love one another. In Dunham-Taylor J, Pinczak JZ*: Financial management for nurse managers*, ed 2, Boston, 2010, Jones & Bartlett Publishers; Feltner A et al: Nurses' views on the characteristics of an effective leader, *AORN J* 87(2):363, 2008.

BOX 21-3 EVIDENCE-BASED PRACTICE

Magnet Hospital Work Environment Characteristics and Outcomes

PICO Question: Do hospital work environment characteristics and outcomes differ between Magnet and non-Magnet hospitals?

Evidence Summary

The Magnet Recognition Program recognizes nursing services that build programs of excellence for the delivery of nursing care, promote quality in environments that support professional nursing practice, and promote achievement of positive patient outcomes (American Nurses Credentialing Center, 2010). Several studies examined specific work environment characteristics and outcomes to determine if they are different in Magnet versus non-Magnet hospitals. Nurses in Magnet hospitals place a high value on quality patient care, are focused on patient safety, and are more likely to communicate about errors and participate in problem solving related to errors (Hughes et al., 2009; Ulrich et al., 2009). Characteristics of Magnet hospitals were found to be positively related to climates of patient safety (Armstrong et al., 2009). Nurses in Magnet hospitals or Magnet-aspiring hospitals had higher levels of current job satisfaction, were more likely to stay with their organization, and felt empowered (Armstrong et al., 2009; Lacey et al., 2007; Lacey et al., 2009; Ulrich et al., 2009). A positive perception of support for nursing was found in Magnet hospitals or Magnet-aspiring hospitals (Lacey et al., 2007). Other identified characteristics of Magnet hospitals included increased efforts to encourage teamwork, increased recognition and reward of nurses, provision of mentoring programs for new graduates, and increased support for nursing continuing education efforts (Ulrich et al., 2009).

Application to Nursing Practice

- Seek employment in institutions that provide mentoring for new graduate nurses.
- Work on developing effective communication with peers and members of the health care team.
- Openly communicate with peers on the nursing unit related to patient safety issues.
- Develop problem-solving skills to be able to find solutions to patient safety issues.
- Participate as a member of the professional governance council of your unit or organization.
- Attend workshops and conferences to develop nursing competencies such as collaboration skills and communication.
- Seek work environments in which nursing is valued and supported.

nursing staff's values and concerns for the way they view and care for patients. For example, a philosophy addresses the purpose of the nursing unit, how staff works with patients and families, and the standards of care for the work unit. Selection of a nursing care delivery model and a management structure that supports professional nursing practice are essential to the philosophy of care.

Magnet Recognition

One way of creating an empowering work environment is through the Magnet Recognition Program (see Chapter 2). A Magnet hospital has a transformed culture with a practice environment that is dynamic, autonomous, collaborative, and positive for nurses. The culture focuses on concern for patients. Typically a Magnet hospital has clinical promotion systems and research and evidence-based practice programs. The nurses have professional autonomy over their practice and control over the practice environment (Upenieks and Sitterding, 2008). A Magnet hospital empowers the nursing team to make changes and be innovative. Professional nurse councils at the organizational and unit level are one way to create an empowerment model. An effective empowerment model leads to a staff that feels valued and has increased autonomy and a work environment that promotes job satisfaction (Gokenbach, 2007). This culture and empowerment combine to produce a strong collaborative relationship among team members and improve patient quality outcomes (Box 21-3).

Nursing Care Delivery Models

Since the time of Florence Nightingale nurses have used a variety of nursing care delivery models to provide care for patients. Ideally the philosophy that nurses establish for the quality care of patients guides the selection of a care delivery model. However, too often a lack of nursing resources and business plans from the health care organization influences the final decision. A care delivery model needs to help nurses achieve desirable outcomes for their patients, either in the way work is organized or in the way a nurse's responsibilities are defined. Important factors contributing to success of

a care delivery model are decision-making authority for nurses who provide direct care, autonomy, collaborative practice, and effective methods of communicating with colleagues, physicians, and other health care providers (Tiedeman and Lookinland, 2004). In effective nursing models, the experienced RN provides faster diagnosis and intervention, which promotes a safe patient environment (Berkow et al., 2007).

Three common models are team nursing, total patient care, and primary nursing. **Team nursing** developed in response to the severe nursing shortage following World War II. By 2000 the interdisciplinary team was a more common model (Marriner Tomey, 2009). **Total patient care** delivery was the original care delivery model developed during Florence Nightingale's time. The model disappeared in the 1930s and became popular again during the 1970s and 1980s, when the number of RNs increased (Tiedeman and Lookinland, 2004). The **primary nursing** model of care delivery was developed to place RNs at the bedside and improve the accountability of nursing for patient outcomes and the professional relationships among staff members (Marriner Tomey, 2009). The model became more popular in the 1970s and early 1980s as hospitals began to employ more RNs. Primary nursing supports a philosophy regarding nurse and patient relationships. Table 21-1 summarizes the three nursing models.

Case management is a care management approach that coordinates and links health care services to patients and their families while streamlining costs and maintaining quality (Marriner Tomey, 2009) (see Chapter 2). The Case Management Society of America (2010) defines case management as "a collaborative process of assessment, planning, facilitation, and advocacy for options and services to meet an individual's health needs through communication and available resources to promote quality cost-effective outcomes." Case management is unique because clinicians, either as individuals or as part of a collaborative group, oversee the management of patients with specific, complex health problems or are held accountable for some standard of cost management and quality.

For example, a case manager coordinates a patient's acute care in the hospital and follows up with the patient after discharge home. Case managers do not always provide direct care but instead work with and supervise the care delivered by other staff and health care team members and actively coordinate patient discharge planning. Ongoing communication with team members facilitates the patient's transition to home (Carr, 2007). In this situation the case manager helps the patient identify health needs, determine the services and resources that are available, and make cost-efficient choices (Marriner Tomey, 2009). The case manager frequently oversees a caseload of patients with complex nursing and medical problems. Often he or she is an advanced practice nurse who, through specific interventions, helps to improve patient outcomes, optimize patient safety by facilitating care transitions, decrease length of stay, and lower health care costs (Carr, 2007; Thomas, 2008).

TABLE 21-1 Nursing Care Delivery Models

NURSING MODEL	CHARACTERISTICS	ADVANTAGES	DISADVANTAGES
Team nursing	• Registered nurse (RN) leads team of other RNs, practical nurses, and unlicensed assistive personnel (UAP). • Team members provide direct patient care under supervision of RN. • Team leader develops patient care plans, coordinates care among team members, and provides care requiring complex nursing skills. • There is hierarchical communication from charge nurse to charge nurse, charge nurse to team leader, and team leader to team members.	• Care is provided through a collaborative style that encourages each member of team to work with and help the other members. • Model has a high level of autonomy for the team leader. • Decision making occurs at clinical level. • Nursing care conferences help to solve patient problems • Patient care coordinator has time to manage unit issues.	• RN team leader does not spend time with patients; thus patients may not see RN often. • Team leader needs to take time to delegate work.
Total patient care	• RN is responsible for all aspects of care for one or more patients during a shift of care. • Care can be delegated. • RN works directly with patient, family, and health care team members.	• Patient satisfaction with model is high. • RNs plan care. • There is a high degree of collaboration with other health care team members.	• Continuity of care is often a problem if RNs do not communicate patient needs to one another. • Model may not be cost effective because of high number of RNs needed to provide care.
Primary nursing	• One primary RN assumes responsibility for a caseload of patients. • When an RN is working, he or she provides care for the same patients during their stay in a facility. • RN assesses patient, develops plan of care, and delivers appropriate nursing interventions. • Communication is lateral from nurse to nurse and caregiver to caregiver.	• Model is flexible and uses a variety of staffing levels and mixes. • Model has a high level of autonomy and authority. • Model promotes collaboration with physician. • Model provides continuity of care if facilitated. • Model reduces number of errors that occur when relaying orders.	• Associate nurse cannot change care plan without discussing with primary nurse. • Model does not necessarily decrease cost of care, even with staff mix.

Modified from Marriner Tomey A: *Guide to nursing management and leadership,* ed 8, St Louis, 2009, Mosby; Tiedeman ME, Lookinland S: Traditional models of care delivery: what have we learned? *J Nurs Adm* 34(6):291, 2004.

Many organizations use critical pathways or CareMaps in a case management delivery system (see Chapter 18). These are multidisciplinary treatment plans for specific cases. The case manager, along with members of the health care team, uses the critical pathways or CareMaps to implement timely interventions in a coordinated plan of care. The plans eliminate the guesswork in patient care because all members of the health care team work from the same plan.

Decision Making

With a philosophy for nursing established, it is the manager who directs and supports staff in the realization of that philosophy. The nurse executive supports managers by establishing a structure that helps to achieve organizational goals and provide appropriate support to care delivery staff. It takes a committed nurse executive, an excellent manager, and an empowered nursing staff to create an enriching work environment in which nursing practice thrives.

Decentralized management, in which decision making is moved down to the level of staff, is very common within health care organizations. This type of management structure has the advantage of creating an environment in which managers and staff become more actively involved in shaping the identity and determining the success of a health care organization. Working in a decentralized structure has the potential for greater collaborative effort, increased competency of staff, increased staff motivation, and ultimately a greater sense of professional accomplishment and satisfaction.

Progressive organizations achieve more when employees at all levels are actively involved. As a result, the role of a nurse manager is critical in the management of effective nursing units or groups. Box 21-4 highlights the diverse responsibilities of nursing managers. To make decentralized decision making work, managers need to know how to move it down to the lowest level possible. On a nursing unit it is important for all nursing staff members (RNs, licensed practical nurses [LPNs], and licensed vocational nurses [LVNs]), nurse assistants, and unit secretaries to become involved. They need to be kept well informed. They also need to be given the opportunity by managers to participate in problem-solving activities, including opportunities in direct patient care and unit activities such as committee participation. Important elements of the decision-making process are responsibility, autonomy, authority, and accountability (Anders and Hawkins, 2006).

Responsibility refers to the duties and activities that an individual is employed to perform. A position description outlines a professional nurse's responsibilities. Nurses meet these responsibilities through participation as members of the nursing unit.

Responsibility reflects ownership. The individual who manages the employee has to distribute responsibility, and the employee has to accept it. Managers have to be sure that staff clearly understand their responsibilities, particularly in the face of change. For example, when hospitals participate in work redesign, patient care delivery models change significantly. A manager is responsible for clearly defining the RN's role within the new care delivery model. If decentralized decision making is in place, professional staff have a voice in identifying the new RN role. Each RN on the work team is responsible for knowing his or her role and how to perform that role on the busy nursing unit. For example, primary nurses are responsible for completing a nursing assessment of all assigned patients and developing a plan of care that addresses each of the patient's nursing diagnoses (see Chapters 15 to 20). As the staff delivers the plan of care, the primary nurse evaluates whether the plan is successful. This responsibility becomes a work ethic for the nurse in delivering excellent patient care.

Autonomy is freedom of choice and responsibility for the choices (Marriner Tomey, 2009). Autonomy consistent with the scope of professional nursing practice maximizes your effectiveness as a nurse (Weston, 2008). With clinical autonomy a professional nurse makes independent decisions about patient care, planning nursing care for the patient within the scope of professional nursing practice. The nurse implements independent nursing interventions (Weston, 2008) (see Chapter 18). Another type of autonomy for nurses is work autonomy. In work autonomy the nurse makes independent decisions about the work of the unit such as scheduling or unit governance (Weston, 2008). Autonomy is not an absolute; it occurs in degrees. For example, a nurse has the autonomy to develop and implement a discharge teaching plan based on specific patient needs for any hospitalized patient. He or she also provides nursing care that complements the prescribed medical therapy.

Authority refers to legitimate power to give commands and make final decisions specific to a given position (Anders and Hawkins, 2006; Marriner Tomey, 2009). For example, a primary nurse managing a caseload of patients discovers that members of the nursing team did not follow through on a discharge teaching plan for an assigned patient. The primary nurse has the authority to consult other nurses to learn why the team did not follow recommendations on the plan of care and to choose appropriate teaching strategies for the patient that all members of the team will follow. The primary nurse has the final authority in selecting the best course of action for the patient's care.

Accountability refers to individuals being answerable for their actions. It means that as a nurse you accept the commitment to provide excellent patient care and the responsibility for the outcomes of the actions in providing that care (Anders and Hawkins, 2006). A primary nurse is accountable for his or her patients' outcomes and for ensuring that each patient learns the information necessary to improve self-care. The nurse demonstrates accountability by checking on the patient and family after discharge and reviewing with the nursing team whether continuity in teaching occurred.

BOX 21-4 RESPONSIBILITIES OF THE NURSE MANAGER

- Assist staff in establishing annual goals for the unit and systems needed to accomplish goals.
- Monitor professional nursing standards of practice on the unit.
- Develop an ongoing staff development plan, including one for new employees.
- Recruit new employees (interview and hire).
- Conduct routine staff evaluations.
- Establish self as a role model for positive customer service (customers include patients, families, and other health care team members).
- Submit staffing schedules for the unit.
- Conduct regular patient rounds and problem solve patient or family complaints.
- Establish and implement a unit quality improvement plan.
- Review and recommend new equipment for the unit.
- Conduct regular staff meetings.
- Make rounds with health care providers.
- Establish and support staff and interdisciplinary committees.

FIG. 21-1 Staff collaborating on practice issues. (From Yoder-Wise P: *Leading and managing in nursing*, ed 5, St Louis, 2010, Mosby.)

A successful decentralized nursing unit supports the four elements of decision making: responsibility, autonomy, authority, and accountability. An effective manager sets the same expectations for the staff in how decisions are made. Staff routinely meet to discuss and negotiate how to maintain an equality and balance in the elements. Staff members need to feel comfortable in expressing differences of opinion and challenging ways in which the team functions while recognizing their own responsibility, autonomy, authority, and accountability. Ultimately decentralized decision making helps create the philosophy of professional nursing care for the unit.

Staff Involvement. When decentralized decision making exists on a nursing unit, all staff members actively participate in unit activities (Fig. 21-1). The influence and control that nurses have over their practice contribute to job satisfaction (Schmalenberg and Kramer, 2008). Because the work environment promotes participation, all staff members benefit from the knowledge and skills of the entire work group. If the staff learns to value knowledge and the contributions of co-workers, better patient care is an outcome. Experienced RNs provide leadership and mentoring on a nursing unit while promoting collaborative practice (Berkow et al., 2007). The nursing manager supports staff involvement through a variety of approaches:

1. *Establishing nursing practice or problem-solving committees or professional* **shared governance** *councils.* Chaired by senior clinical staff, these groups establish and maintain care standards for nursing practice on their work unit. Shared governance councils promote empowerment in staff nurses and enable them to control their nursing practice (Kramer et al., 2008, 2010). The committees review and establish standards of care, develop policy and procedures, resolve patient satisfaction issues, or develop new documentation tools. It is important for the committees to focus on patient outcomes rather than only work issues to ensure quality care on the unit. Quality of care is further improved when nurses control their own practice (Anders and Hawkins, 2006). The committee establishes methods to ensure that all staff have input or participation on practice issues. Managers do not always sit on a committee, but they receive regular reports of committee progress. The nature of work on the nursing unit determines committee membership. At times members of other disciplines (e.g., pharmacy, respiratory therapy, or clinical nutrition) participate in practice committees or shared governance councils.
2. *Nurse/physician collaborative practice.* Collaboration is a process between individuals. There is a sharing of different perspectives that are then synthesized to better understand complex problems. An outcome of collaboration is a shared solution that could not have been accomplished by a single person or organization. Nurse-physician collaboration improves patient safety and outcomes and reduces errors (Manojlovich et al., 2008; Seago, 2008). The care delivery model of the nursing unit, an environment that supports teamwork, and organizational values influence how nurses and physicians collaborate. An open communication system that fosters respect, trust, shared decision making, and teamwork among all team members is critical to achieving quality patient care (Cronenwett et al., 2007). Physicians sometimes attend practice committees when clinical problems arise and present timely in-service programs.
3. *Interdisciplinary collaboration.* The emphasis on efficiency in health care delivery brings all members of the health care team together. Teamwork decreases mistakes because team members commit to shared knowledge, skills, and attitudes (Baker et al., 2006). Interdisciplinary collaboration leads to decreased patient mortality, decreased health care costs, and increased nurse job satisfaction (Manojlovich et al., 2008). Mutual respect is a critical part of any collaborative relationship (Ulrich et al., 2005). Essential characteristics for effective teams include having a common purpose, communicating frequently, anticipating one another, trust, managing conflict well, and providing feedback to one another (Baker et al., 2006). Use your judgment to decide which problems are complex and require a collaborative process. At the patient care level, staff recognize the importance of prompt referrals and timely communication with other health professionals. Participating in interdisciplinary patient care rounds, use of protocols and critical pathways, and holding interdisciplinary training for collaboration development are strategies that promote interdisciplinary collaboration (Kramer et al., 2010). Other strategies include having representatives of the various disciplines together in practice projects, in-service programs, conferences, and staff meetings.
4. *Staff communication.* A manager's greatest challenge, especially if a work group is large, is communication with staff. It is difficult to make sure that all staff members receive the same message: the correct message. In the present health care environment, staff quickly become uneasy and distrusting if they fail to hear about planned changes on their work unit. However, a manager cannot assume total responsibility for all communication. An effective manager uses a variety of approaches to communicate quickly and accurately to all staff. For example, many managers distribute biweekly or monthly newsletters of ongoing unit or agency activities. Minutes of committee meetings are usually in an accessible location for all staff to read. When the team needs to discuss important issues regarding the operations of the unit, the manager conducts staff meetings. When the unit has practice or quality improvement committees, each committee member has the responsibility to communicate directly to a select number of staff members. Thus all staff members are contacted and given the opportunity for input.
5. *Staff education.* A professional nursing staff needs to always grow in knowledge. It is impossible to remain knowledgeable about current medical and nursing practice trends without ongoing education. The nurse manager is responsible for making learning opportunities available so staff members remain competent in their practice. This involves planning in-service programs, sending staff to continuing education classes and professional conferences, and having staff present

case studies or practice issues during staff meetings. Staff members are responsible for pursuing educational opportunities when they know that their competencies are lacking.

LEADERSHIP SKILLS FOR NURSING STUDENTS

It is important that as a nursing student you prepare yourself for leadership roles. This does not mean that you have to quickly learn how to lead a team of nursing staff. Instead first learn to become a dependable and competent provider of patient care. As a nursing student you are responsible and accountable for the care you give to your patients. Learn to become a leader by consulting with instructors and nursing staff to obtain feedback in making good clinical decisions, learning from mistakes and seeking guidance, working closely with professional nurses, and trying to improve your performance during each patient interaction. These skills require you to think critically and solve problems in the clinical setting. Thinking critically allows nurses to provide higher quality care, meet the needs of patients while considering their preferences, consider alternatives to problems, understand the rationale for performing nursing interventions, and evaluate the effectiveness of interventions (Benner et al., 2008). Clinical experiences develop these critical thinking skills (Toofany, 2008). Important leadership skills to learn include clinical care coordination, team communication, delegation, and knowledge building.

Clinical Care Coordination

You acquire necessary skills so you can deliver patient care in a timely and effective manner. In the beginning this often involves only one patient, but eventually it will involve groups of patients. Clinical care coordination includes clinical decision making, priority setting, use of organizational skills and resources, time management, and evaluation. The activities of clinical care coordination require use of critical reflection, critical reasoning, and clinical judgment (Benner et al., 2008). They are important first steps in developing a caring relationship with a patient. Use a critical thinking approach, applying previous knowledge and experience to the decision-making process (see Chapter 15).

Clinical Decisions. Your ability to make clinical decisions depends on application of the nursing process (see Chapters 16 to 20). When you begin a patient assignment, the first activity involves a focused but complete assessment of the patient's condition so you are able to make an accurate judgment about his or her nursing diagnoses and collaborative health problems (see Chapter 16). This initial contact is an important first step in developing a caring relationship with a patient. Following the identification of a patient's diagnoses and problems, you develop a plan of care, implement nursing interventions, and evaluate patient outcomes. The process requires clinical decision making, using a critical thinking approach (see Chapter 15).

If you do not make accurate clinical decisions about a patient, undesirable outcomes will probably occur. The patient's condition worsens or remains the same when you lose the potential for improvement. An important lesson in organizational skills is to be thorough. Learn to attend and listen to the patient, look for any cues (obvious or subtle) that point to a pattern of findings, and direct the assessment to explore the pattern further. Accurate clinical decision making keeps you focused on the proper course of action. Never hesitate to ask for assistance when a patient's condition changes.

Priority Setting. After forming a picture of the patient's total needs, you set priorities by deciding which patient needs or problems need attention first (see Chapter 18). It is important to prioritize in all caregiving situations because it allows you to see relationships among patient problems and avoid delays in taking action that possibly leads to serious complications for a patient (Hendry and Walker, 2004). If a patient is experiencing serious physiological or psychological problems, the priority becomes clear. You need to act immediately to stabilize his or her condition. Hendry and Walker (2004) classify patient problems in three priority levels:

- *High priority*—An immediate threat to a patient's survival or safety such as a physiological episode of obstructed airway, loss of consciousness, or a psychological episode of an anxiety attack.
- *Intermediate priority*—Nonemergency, non–life-threatening actual or potential needs that the patient and family members are experiencing. Anticipating teaching needs of patients related to a new drug and taking measures to decrease postoperative complications are examples of intermediate priorities.
- *Low priority*—Actual or potential problems that are not directly related to the patient's illness or disease. These problems are often related to developmental needs or long-term health care needs. An example of a low priority problem is a patient at admission who will eventually be discharged and needs teaching for self-care in the home.

Many patients have all three types of priorities, requiring you to make careful judgments in choosing a course of action. Obviously high-priority needs demand immediate attention. When a patient has diverse priority needs, it helps to focus on his or her basic needs. For example, a patient who is in traction reports being uncomfortable from being in the same position. The dietary assistant arrives in the room to deliver a meal tray. Instead of immediately assisting the patient with the meal, you reposition him and offer basic hygiene measures. The patient likely becomes more interested in eating after he is more comfortable. He also is more receptive to any instruction you want to provide.

Eventually you will be required to meet the priority needs of a group of patients. This means that you need to know the priority needs of each patient within the group, assessing each patient's needs as soon as possible while addressing high priorities first. To identify which patients require assessment first, rely on information from the change-of-shift report, the classification system of the agency that identifies patient acuity, and information from the medical record. Over time you learn to spontaneously rank patients' needs by priority or urgency. Priorities do not remain stable but change as a patient's condition changes. It is important to think about the resources available, be flexible in recognizing that priority needs often change, and consider how to use time wisely.

You also make priorities on the basis of patient expectations. Sometimes you have established an excellent plan of care; however, if the patient is resistant to certain therapies or disagrees with the approach, you have very little success. Working closely with the patient and showing a caring attitude are important. Share the priorities you have defined with the patient to establish a level of agreement and cooperation.

Organizational Skills. Implementing a plan of care requires you to be effective and efficient. Effective use of time means doing the right things, whereas efficient use of time means doing things right. Learn to become efficient by combining various nursing activities—in other words, doing more than one thing at a time. For example, during medication administration or while obtaining a specimen, combine therapeutic communication,

teaching interventions, and assessment and evaluation. Always try to establish and strengthen relationships with patients and use any patient contact as an opportunity to convey important information. Patient interaction gives you the chance to show caring and interest. Always attend to the patient's behaviors and responses to therapies to assess if new problems are developing and evaluate responses to interventions.

A well-organized nurse approaches any planned procedure by having all of the necessary equipment available and making sure that the patient is prepared. If the patient is comfortable and well informed, the likelihood that the procedure will go smoothly increases. Sometimes you require the assistance of colleagues to perform or complete a procedure. It is always wise to have the work area organized and preliminary steps completed before asking co-workers for assistance.

As you begin to deliver care based on established priorities, events sometimes occur within the health care setting that interfere with plans. For example, just as you begin to provide morning hygiene for a hospitalized patient, an x-ray technician enters to take a chest x-ray film. Once the technician completes the x-ray examination, a phlebotomist arrives to draw a blood sample. In this case your priorities seem to conflict with the priorities of other health care personnel. It is important to always keep the patient's needs at the center of attention. If the patient experienced symptoms earlier that required a chest x-ray film and laboratory work, it is important to be sure that the diagnostic tests are completed. In another example a patient is waiting to visit family, and a chest x-ray film is a routine order from 2 days earlier. The patient's condition has stabilized, and the x-ray technician is willing to return later to shoot the film. In this case attending to the patient's hygiene and comfort so family members can visit is more of a priority.

Use of Resources. Appropriate use of resources is an important aspect of clinical care coordination. Resources in this case include members of the health care team. In any setting the administration of patient care occurs more smoothly when staff members work together. Never hesitate to have staff assist you, especially when there is an opportunity to make a procedure or activity more comfortable and safer for the patient. For example, assistance in turning, positioning, and ambulating patients is frequently necessary when patients are unable to move. Having a staff member, such as nursing assistive personnel (NAP), assist with handling equipment and supplies during more complicated procedures such as catheter insertion or dressing change helps make procedures more efficient. In addition, you often have to recognize personal limitations and use professional resources for assistance. For example, you assess a patient and find relevant clinical signs and symptoms but are unfamiliar with the physical condition. Consulting with an RN confirms findings and ensures that you take the proper course of action for the patient. A leader knows his or her limitations and seeks professional colleagues for guidance and support.

Time Management. Changes in health care and increasing complexity of patients create stress for nurses as they work to meet patient needs (Marriner Tomey, 2009). One way to manage this stress is through the use of time management skills. These skills involve learning how, where, and when to use your time. Because you have a limited amount of time with patients, it is essential to remain goal oriented and use it wisely. You quickly learn the importance of using patient goals as a way to identify priorities. However, also learn how to establish personal goals and time frames. For example, you are caring for two patients on a busy surgical nursing unit. One had surgery the day before, and the other will be discharged the next day. Clearly the first patient's goals center on restoring physiological function impaired as a result of the stress of surgery. The second patient's goals center on adequate preparation to assume self-care at home. In reviewing the therapies required for both patients, you learn how to organize your time so the activities of care and patient goals are achieved. You need to anticipate when care will be interrupted for medication administration and diagnostic testing and when is the best time for planned therapies such as dressing changes, patient education, and patient ambulation. Delegation of tasks is another way to help improve time management.

One useful time-management skill involves making a priority to-do list (Hackworth, 2008). When you first begin working with a patient or patients, it helps to make a list that sequences the nursing activities you need to perform. The change-of-shift report helps to sequence activities based on what you learn about the patient's condition and the care provided before you arrive on the unit. It is helpful to consider activities that have specific time limits in terms of addressing patient needs such as administering a pain medication before a scheduled procedure or instructing patients before their discharge home. You also analyze the items on the list that are scheduled by agency policies or routines (e.g., medications or intravenous [IV] tubing changes). Note which activities need to be done on time and which activities you can do at your discretion. You have to administer medication within a specific schedule, but you are also able to perform other activities while in the patient's room. Finally, estimate the amount of time needed to complete the various activities. Activities requiring the assistance of other staff members usually take longer because you have to plan around their schedules.

Good time management also involves setting goals to help you complete one task before starting another (Hackworth, 2008). If possible complete the activities started with one patient before moving on to the next. Care is then less fragmented, and you are better able to focus on what you are doing for each patient. As a result, it is less likely that you will make errors. Time management requires an ability to anticipate the activities of the day and combine activities when possible. Other strategies to help you manage your time are keeping your work area clean and clutter free and trying to decrease interruptions as you are completing tasks (Pearce, 2007). Box 21-5 summarizes principles of time management.

Evaluation. Evaluation is one of the most important aspects of clinical care coordination (see Chapter 20). It is a mistake to think that evaluation occurs at the end of an activity. It is an ongoing process. Once you assess a patient's needs and begin therapies directed at a specific problem area, immediately evaluate whether therapies are effective and the patient's response. The process of evaluation compares actual patient outcomes with expected outcomes. For example, a clinic nurse assesses a foot ulcer of a patient who has diabetes to determine if healing has progressed since the last clinic visit. When expected outcomes are not met, evaluation reveals the need to continue current therapies for a longer period, revise approaches to care, or introduce new therapies. As you care for a patient throughout the day, anticipate when to return to the bedside to evaluate care (e.g., 30 minutes after a medication was administered, 15 minutes after an IV line has begun infusing, or 60 minutes after discussing discharge instructions with the patient and family).

Keeping a focus on evaluation of the patient's progress lessens the chance of becoming distracted by the tasks of care. It is common

BOX 21-5 PRINCIPLES OF TIME MANAGEMENT

Goal setting: Review the patient's goals of care for the day and any goals you have for activities such as completing documentation, attending a patient care conference, giving a staff report, or preparing medications for administration.

Time analysis: Reflect on how you use your time. While working on a clinical area, keep track of how you use your time in different activities. This provides valuable information to reveal how well organized you really are.

Priority setting: Set the priorities that you have established for patients within set time frames. For example, determine when is the best time to have teaching sessions, plan ambulation, and provide rest periods based on what you know about the patient's condition. For example, if a patient is nauseated or in pain, it is not a good time for a teaching session.

Interruption control: Everyone needs time to socialize or discuss issues with colleagues. However, do not let this interrupt important patient care activities such as medication administration. Use time during report, mealtime, or team meetings to the best of your advantage. In addition, plan time to assist fellow colleagues so it complements your patient care schedule.

Evaluation: At the end of each day take time to think and reflect about how effectively you used your time. If you are having difficulties, discuss them with an instructor or a more experienced staff member.

to assume that staying focused on planned activities ensures that you will perform care appropriately. However, task orientation does not ensure good patient outcomes. Learn that at the heart of good organizational skills is the constant inquiry into the patient's condition and progress toward an improved level of health.

Team Communication

As a part of a nursing team, you are responsible for open, professional communication. Regardless of the setting, an enriching professional environment is one in which staff members respect one another's ideas, share information, and keep one another informed. On a busy nursing unit this means keeping colleagues informed about patients with emerging problems, physicians who have been called for consultation, and unique approaches that solved a complex nursing problem. Strategies to improve your communication with physicians include addressing the physician by name, having the patient and chart available when discussing patient issues, focusing on the patient problem, and being professional and not aggressive (Nadzam, 2009). In a clinic setting it may mean sharing unusual diagnostic findings or conveying important information regarding a patient's source of family support. One way of fostering good team communication is by setting expectations of one another. A nurse treats colleagues with respect, listens to the ideas of other staff members without interruption, explores the way other staff members think, and is honest and direct while communicating. Part of good communication is clarifying what others are saying and building on the merits of co-workers' ideas (Marriner Tomey, 2009). An efficient team knows that it is able to count on all members when needs arise. Sharing expectations of what, when, and how to communicate is a step toward establishing a strong work team. Structured communication techniques that improve communication include briefings or short discussions among team members, group rounds on patients, and the use of Situation-Background-Assessment-Recommendation (SBAR) when sharing information (see Chapter 26) (Nadzam, 2009).

Delegation

The art of effective delegation is a skill you need to observe and practice to improve your own management skills. The American Nurses Association (1995) defined **delegation** as transferring responsibility for the performance of an activity or task while retaining accountability for the outcome. Delegation results in achievement of quality patient care, improved efficiency, increased productivity, empowered staff, and development of others (Huston, 2009; Marriner Tomey, 2009). Asking a staff member to obtain an ordered specimen while you attend to a patient's pain medication request effectively prevents a delay in the patient gaining pain relief and accomplishes two tasks related to the patient. Delegation also provides job enrichment. You show trust in colleagues by delegating tasks to them and showing staff members that they are important players in the delivery of care. Successful delegation is important to the quality of the RN-NAP relationship and their willingness to work together (Bittner and Gravlin, 2009; Potter et al., 2010). Never delegate a task that you dislike doing or would not do independently because this creates negative feelings and poor working relationships (Huston, 2009). For example, if you are in the room when a patient asks to be placed on a bedpan, you assist the patient rather than leave the room to find the nurse assistant. Remember that, even though the delegation of a task transfers the responsibility and authority to another person, you are accountable for the delegated task.

As a nurse you are responsible and accountable for providing care to patients and delegating care activities to NAP. However, the nurse does not delegate the steps of the nursing process of assessment, diagnosis, planning, and evaluation because these steps require nursing judgment (American Nurses Association [ANA] and National Council of State Boards of Nursing [NCSBN], 2005). Recognize that when you delegate to NAP, you delegate tasks, not patients. Do not give NAP sole responsibility for the care of patients. Instead, it is you as the professional nurse in charge of patient care who decides which activities NAP perform independently and which the RN and NAP perform in partnership. One way to accomplish this is to have the RN and technician or NAP conduct rounds together. You assess each patient as the technician helps to attend to basic patient needs. Care is delegated based on assessment findings and priority setting. As an RN, you are always responsible for the assessment of a patient's ongoing status; but if a patient is stable you delegate vital sign monitoring to NAP.

The RN is the one in most settings who decides when delegation is appropriate. The LPN directs care in many long-term care facilities. The National Council of State Boards of Nursing (1995) has provided some guidelines for delegation of tasks in accordance with an RN's legal scope of practice (Box 21-6). As the leader of the health care team, the RN gives clear instructions, effectively prioritizes patient needs and therapies, and gives staff timely and meaningful feedback. NAP respond positively when you include them as part of the nursing team.

Appropriate delegation begins with knowing which skills you are able to delegate. This requires you to be familiar with the Nurse Practice Act of the state, institutional policies and procedures, and job description for NAP provided by the institution. These standards help to define the necessary level of competency of NAP.

An institution's policies, procedures, and job description for NAP contain specific guidelines regarding which tasks or activities a nurse is able to delegate. The job description identifies any required education and the types of tasks NAP can perform, either independently or with RN direct supervision. Institutional policy defines the amount of training required of NAP while employed.

BOX 21-6 THE FIVE RIGHTS OF DELEGATION

Right Task
The right task is one that you delegate for a specific patient such as tasks that are repetitive, require little supervision, are relatively noninvasive, have results that are predictable, and have potential minimal risk.

Right Circumstances
Consider the appropriate patient setting, available resources, and other relevant factors. In an acute care setting patients' conditions often change quickly. Use good clinical decision making to determine what to delegate.

Right Person
The right person is delegating the right tasks to the right person to be performed on the right person.

Right Direction/Communication
You give a clear, concise description of the task, including its objective, limits, and expectations. Communication needs to be ongoing between the registered nurse and NAP during a shift of care.

Right Supervision/Evaluation
Provide appropriate monitoring, evaluation, intervention as needed, and feedback. NAP need to feel comfortable asking questions and seeking assistance.

Modified from National Council of State Boards of Nursing: *Delegation: concepts and decision-making process,* Chicago, 1995, The Council; National Council of State Boards of Nursing, *The five rights of delegation*, Chicago, 1997, The Council; and American Nurses Association (ANA) and National Council of State Boards of Nursing (NCSBN): *Joint statement on delegation*, http://www.ncsbn.org/pdfs/Joint_statement.pdf, 2006.

Procedures detail who is qualified to perform a given nursing procedure, whether supervision is necessary, and the type of reporting required. You need to have a means to easily access policies or have supervisory staff who inform you about NAP's job duties.

As a professional nurse you cannot simply assign NAP to tasks without considering the implications. Assess a patient and determine a plan of care before identifying which tasks someone else is able to perform. When directing NAP, determine how much supervision is necessary. Is it the first time a staff member performed the task? Does the patient present a complicating factor that makes the RN's assistance necessary? Does the staff member have prior experience with a particular type of patient in addition to having received training on skill performance? The final responsibility is to evaluate whether NAP performed a task properly and whether desired outcomes were met.

Efficient delegation requires constant communication (i.e., sending clear messages and listening so all participants understand expectations regarding patient care) (Gravlin and Bittner, 2010). Provide clear instructions when delegating tasks. These instructions initially focus on the procedure itself, what will be accomplished, and the unique needs of a patient. The RN also communicates when and what information to report such as expected observations and specific patient concerns (NCSBN, 2005). Communication is a two-way process in delegation; thus NAP need to have the chance to ask questions and have your expectations made clear (ANA and NCSBN, 2005; NCSBN, 2005). Conflict often occurs between RNs and NAP when there is little or poor communication (Potter et al., 2010). Handoff disconnects, lack of knowledge about the workload of team members, and difficulty dealing with conflict are examples of communication failures that often result in delegation ineffectiveness and omissions of nursing care (Gravlin and Bittner, 2010). As you become more familiar with a staff member's competency, trust builds, and staff need fewer instructions; but clarification of patients' specific needs is always necessary.

Another important step in delegation is evaluation of the staff member's performance, achievement of the patient's outcomes, the communication process used, and any problems or concerns that occurred (NCSBN, 2005). When an NAP performs a task correctly and does a good job, it is important to provide praise and recognition. If the staff member's performance is not satisfactory, give constructive and appropriate feedback. As a nurse, always give specific feedback regarding any mistakes that staff members make, explaining how to avoid the mistake or a better way to handle the situation. Giving feedback in private is the professional way and preserves the staff member's dignity. When giving feedback, make sure to focus on things that can be changed, choose only one issue at a time, and give specific details. Frequently when the NAP's performance does not meet expectations, it is the result of inadequate training or assignment of too many tasks. You discover the need to review a procedure with staff and offer demonstration or even recommend that additional training be scheduled with the education department. If too many tasks are being delegated, this might be a nursing practice issue. All staff need to discuss the appropriateness of delegation on their unit. Sometimes NAP need help in learning how to prioritize. In some cases you discover that you are overdelegating.

Once you delegate the task appropriately, it is important to monitor and supervise NAP in task performance. Clear directions and statement of desired outcomes increase the likelihood of successful completion of the task. If you observe a change in patient status, if the task is not being performed as directed or by agency policy and procedures, or if the NAP is having difficulty completing the task, you need to intervene and follow up as needed (ANA and NCSBN, 2005; NCSBN, 2005). It is your responsibility to complete documentation of the delegated task. Here are a few tips on appropriate delegation (Huston, 2009):

- *Assess the knowledge and skills of the delegatee:* Assess the knowledge and skills of the NAP by asking open-ended questions that elicit conversation and details about what he or she knows; for example, "How do you usually apply the cuff when you measure a blood pressure?" or "Tell me how you prepare the tubing before you give an enema."
- *Match tasks to the delegatee's skills:* Know which tasks and skills are in the scope of practice and job description for the team members to whom you delegate in your facility. Determine if personnel have learned critical thinking skills such as knowing when a patient is in harm or the difference between normal clinical findings and changes to report.
- *Communicate clearly:* Always provide clear directions by describing a task, the desired outcome, and the time period within which NAP need to complete the task. Never give instructions through another staff member. Make the person feel as though he or she is part of the team. Begin requests for help with *please* and end with *thank you*. For example, "I'd like you to please help me by getting Mr. Floyd up to ambulate before lunch. Be sure to check his blood pressure before he stands and write your finding on the graphic sheet. OK? Thanks."
- *Listen attentively:* Listen to NAP's response after you provide directions. Do they feel comfortable in asking questions or

requesting clarification? If you encourage a response, listen to what the person has to say. Be especially attentive if the staff member has a deadline to meet for another nurse. Help sort out priorities.

- *Provide feedback:* Always give NAP feedback regarding performance, regardless of outcome. Let them know of a job well done. A thank you increases the likelihood of the NAP helping in the future. If an outcome is undesirable, find a private place to discuss what occurred, any miscommunication, and how to achieve a better outcome in the future.

Knowledge Building

As a professional nurse, recognize the importance of pursuing knowledge to remain competent. You need to maintain and improve your knowledge and skills. Lifelong learning is needed to be able to continuously provide safe, effective, quality care to patients (Josiah Macy Jr. Foundation, 2008). A leader recognizes that there is always something new to learn. Opportunities for learning occur with each patient interaction, each encounter with a professional colleague, and each meeting or class session in which health care professionals meet to discuss clinical care issues. People always have different experiences and knowledge to share. Ongoing development of skills in delegation, communication, and teamwork helps maintain and build competency (Gravlin and Bittner, 2010). In-service programs, workshops, professional conferences, and collegiate courses offer innovative and current information on the rapidly changing world of health care. To become a leader, actively pursue learning opportunities, both formal and informal, and learn to share knowledge with the professional colleagues you encounter.

KEY POINTS

- A manager sets a philosophy for a work unit, ensures appropriate staffing, mobilizes staff and institutional resources to achieve objectives, motivates staff members to carry out their work, sets standards of performance, and makes decisions to achieve objectives.
- Consideration communicates mutual trust, respect, and rapport between a manager and staff members.
- Empowering staff members brings out the best in a manager and allows him or her to concentrate on effective patient care systems, support risk taking and innovation, and focus on results and rewards.
- An empowered nursing staff has decision-making authority to change how they practice.
- Nursing care delivery models vary according to the responsibility and autonomy of the RN in coordinating care delivery and the roles other staff members play in assisting with care.
- Critical to the success of decision making is making staff members aware that they have the responsibility, authority, autonomy, and accountability for the care they give and the decisions they make.
- A nurse manager encourages decentralized decision making by establishing nursing practice committees, supporting nurse-physician and interdisciplinary collaboration, setting and implementing quality improvement plans, and maintaining timely staff communication.
- Clinical care coordination involves accurate clinical decision making, establishing priorities, efficient organizational skills, appropriate use of resources and time management skills, and an ongoing evaluation of care activities.
- In an enriched professional environment, each member of a nursing work team is responsible for open, professional communication.
- Effective delegation requires the use of good communication skills.
- When done correctly, delegation improves job efficiency, productivity, and job enrichment.
- An important responsibility for the nurse who delegates nursing care is evaluation of the staff member's performance and patient outcomes.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are a staff nurse on a 32-bed cardiac step-down unit. The hospital obtained Magnet recognition last year. You are assigned as the preceptor for Tony, RN, who is a new graduate nurse, who just started his nursing career on your floor.

1. You and Tony just received morning shift report on your patients. You are assigned the following patients. Which patient do you and Tony need to see first? Explain your answer.
    1. Mr. Dodson, a 52-year-old patient who was admitted yesterday with a diagnosis of angina pectoris. He is scheduled for a cardiac stress test at 0900.
    2. Mrs. Wallace, a 60-year-old patient who was transferred out of intensive care at 0630 today. She had uncomplicated coronary artery bypass surgery yesterday.
    3. Mr. Workman, a 45-year-old patient who experienced a myocardial infarction 2 days ago. He is complaining of chest pain rated as 6 on a scale of 0 to 10.
    4. Mrs. Harris, a 76-year-old patient who had a permanent pacemaker inserted yesterday. She is complaining of incision pain rated as a 5 on a scale of 0 to 10.
2. As you work with Tony, you notice that he has trouble with organizational skills when providing patient care. What strategies will you suggest to Tony to help him improve in organizing his delivery of patient care?
3. Marianne, a NAP, is paired to work with you and Tony. You overhear Tony giving Marianne directions for what she needs to do. Tony says, "Marianne, in the next hour please assist Mrs. Harris in room 418 with her afternoon walk. She needs to walk 200 feet, which is from her room down the hall to the nurses' station and back to her room. Take her pulse before and after she walks and record it in her chart. I'll check with you when you're finished to see how she did. Do you have any questions before you walk her? Thank you for your help." Based on what you know about delegation, did Tony give appropriate or inappropriate directions to Marianne? Provide rationale for your answer.

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. After the 0700 shift report the registered nurse (RN) delegates three tasks to the nursing assistant. At 1300 the RN tells the nursing assistant that he would like to talk to her about the first task that was delegated, which was walking the patient, Mrs. Taylor, earlier that morning. The RN says, "You did a good job walking Mrs. Taylor by 0930. I saw that you recorded her pulse before and after the walk. I saw that Mrs. Taylor walked

in the hallway barefoot. For safety, the next time you walk a patient, you need to make sure that the patient wears slippers or shoes. Please walk Mrs. Taylor again by 1500." Which characteristics of good feedback did the RN use when talking to the nursing assistant? (Select all that apply.)
   1. Feedback is given immediately.
   2. Feedback focuses on one issue.
   3. Feedback offers concrete details.
   4. Feedback identifies ways to improve.
   5. Feedback focuses on changeable things.
   6. Feedback is specific about what is done incorrectly only.
2. As the nurse, you need to complete all of the following. Which task do you complete first?
   1. Administer the oral pain medication to the patient who had surgery 3 days ago
   2. Make a referral to the home care nurse for a patient who is being discharged in 2 days
   3. Complete wound care for a patient with a wound drain that has an increased amount of drainage since last shift
   4. Notify the health care provider of the decreased level of consciousness in the patient who had surgery 2 days ago
3. You are the charge nurse on a surgical unit. You are doing staff assignments for the 3-to-11 shift. Which patient do you assign to the licensed practical nurse (LPN)?
   1. The patient who transferred out of intensive care an hour ago
   2. The patient who requires teaching on new medications before discharge
   3. The patient who had a vaginal hysterectomy 2 days ago and is being discharged tomorrow
   4. The patient who is experiencing some bleeding problems following surgery earlier today
4. The type of care management approach that coordinates and links health care services to patients and their families while streamlining costs and maintaining quality is:
   1. Primary nursing.
   2. Total patient care.
   3. Functional nursing.
   4. Case management.
5. While administering medications, the nurse realizes that she has given the wrong dose of medication to a patient. She acts by completing an incident report and notifying the patient's health care provider. The nurse is exercising:
   1. Authority.
   2. Responsibility.
   3. Accountability.
   4. Decision making.
6. Your nursing manager distributes biweekly newsletters of ongoing unit or health care agency activities and posts minutes of committee meetings on a bulletin board in the staff break room. This is an example of:
   1. Staff communication.
   2. Problem-solving committees.
   3. Interdisciplinary collaboration.
   4. Nurse-physician collaborative practice.
7. The nurse asks the nursing assistant to hold the legs of a female patient during a Foley catheter insertion. This is an example of a nurse displaying:
   1. Organizational skills.
   2. Use of resources.
   3. Time management.
   4. Evaluation.
8. The nurse is assisting the patient with coughing and deep-breathing exercises following abdominal surgery. This is which priority nursing need for this patient?
   1. Low priority
   2. High priority
   3. Intermediate priority
   4. Nonemergency priority
9. The registered nurse (RN) checks on a patient who was admitted to the hospital with pneumonia. The patient is coughing profusely and requires nasotracheal suctioning. Orders include an intravenous (IV) infusion of antibiotics. The patient is febrile and asks the RN if he can have a bath because he has been perspiring profusely. Which task is appropriate to delegate to the nursing assistant?
   1. Assessing vital signs
   2. Changing IV dressing
   3. Nasotracheal suctioning
   4. Administering a bed bath
10. Which task is appropriate for a registered nurse (RN) to delegate to the nursing assistant?
   1. Explaining to the patient the preoperative preparation before the surgery in the morning
   2. Administering the ordered antibiotic to the patient before surgery
   3. Obtaining the patient's signature on the surgical informed consent
   4. Assisting the patient to the bathroom before leaving for the operating room
11. Which of the following strategies focus on improving nurse-physician collaborative practice? (Select all that apply.)
   1. Inviting the physician to attend the practice council meeting
   2. Participating in physician morning rounds
   3. Placing physician photos and names in unit newsletter
   4. Contacting physician promptly to discuss patient problems
   5. Providing a list of physician contact numbers to all staff nurses
12. The nurses on the unit developed a system for self-scheduling of work shifts. This is an example of:
   1. Responsibility.
   2. Autonomy.
   3. Accountability.
   4. Authority.
13. Which example demonstrates the nurse performing the skill of evaluation?
   1. The nurse explains the side effects of the new blood pressure medication ordered for the patient.
   2. The nurse asks the patient to rate pain on a scale of 0 to 10 before administering the pain medication.
   3. After completing the teaching, the nurse observes the patient draw up and administer an insulin injection.
   4. The nurse changes the patient's leg ulcer dressing using aseptic technique.
14. The nurse is explaining the case management model to a group of nursing students. Which characteristics best describe the model? (Select all that apply.)
   1. Case managers provide all patient care.
   2. Multidisciplinary care plans are used.
   3. Case managers coordinate discharge planning.
   4. Staffing is expensive and may not decrease care costs.
   5. Communication with health care team members is important.
   6. Model helps to improve patient safety and quality.

15. The nurse collects the supplies for the dressing change for the patient in bed 1 and signs out the capillary blood glucose monitoring equipment to test the glucose of the patient in bed 2 before walking down the hall to the room. The nurse is displaying:
    1. Organizational skills.
    2. Use of resources.
    3. Priority setting.
    4. Clinical decision making.

Answers: **1.** 2, 3, 4, 5; **2.** 4; **3.** 3; **4.** 4; **5.** 3; **6.** 1; **7.** 2; **8.** 3; **9.** 4; **10.** 4; **11.** 1, 2, 4; **12.** 2; **13.** 3; **14.** 2, 3, 5, 6; **15.** 1.

CHAPTER

22

Ethics and Values

OBJECTIVES

- Discuss the role of ethics in professional nursing.
- Discuss the role of values in the study of ethics.
- Examine and clarify personal values.
- Understand basic philosophies of health care ethics.
- Explain a nursing perspective in ethics.
- Apply critical thinking to ethical dilemmas.
- Discuss contemporary ethical issues.

KEY TERMS

Accountability, p. 287
Advocacy, p. 287
Autonomy, p. 286
Beneficence, p. 286
Code of ethics, p. 287
Confidentiality, p. 287
Consequentialism, p. 289
Deontology, p. 288
Ethics, p. 286
Ethics of care, p. 290
Fidelity, p. 287
Justice, p. 287
Nonmaleficence, p. 287
Responsibility, p. 287
Teleology, p. 289
Utilitarianism, p. 289
Value, p. 288

On your unit you are taking care of a 35-year-old female patient admitted in the final stages of her struggle with brain cancer. She is a single mother and has two young children at home. She received conventional and even experimental treatment, but the tumor has continued to grow. The medical team decides that further treatment would be futile. In an especially open discussion with you, she expresses her wish to explore a "do not resuscitate" (DNR) order. The attending physician reviews the clinical data and agrees that the patient is entering the terminal stages of her disease. However, in his opinion she is not ready to discuss end-of-life issues. He says that he has asked her about a DNR order, but she declines to discuss it. You suggest that he convene a family conference to discuss DNR options, but he dismisses the proposal at this time since his opinion is that the patient is not ready to participate.

Ethics is the study of conduct and character. It is concerned with determining what is good or valuable for individuals, for groups of individuals, and for society at large. Acts that are ethical reflect a commitment to standards beyond personal preferences (i.e., standards that individuals, professions, and societies strive to meet). However, when decisions must be made about health care, differing values and opinions among individuals can result in disagreement about the right thing to do, as the previous scenario illustrates. Understandable conflict occurs among health care providers, families, patients, friends, and people in the community about the right thing to do when ethics, values, and perceptions about health care collide. This chapter describes tools for you to use to embrace the role of ethics in your professional life and to participate and promote resolution when ethical dilemmas develop.

BASIC TERMS IN HEALTH ETHICS

For a discussion of ethics, it is helpful to establish a basic vocabulary. Your understanding of the terms common in ethical discourse helps you to shape your own thoughts about ethical issues and situations and participate thoughtfully in discussions.

Autonomy

When applied to politics or government, **autonomy** refers to freedom from external control. Similarly in health care, respect for autonomy refers to the commitment to include patients in decisions about all aspects of care as a way of acknowledging and protecting a patient's independence. For example, when a patient faces surgery, the surgeon has an obligation to review the surgical procedure, including risks and benefits, out of respect for the patient's autonomy. The consent that patients read and sign before surgery documents this respect for autonomy.

Beneficence

Beneficence refers to taking positive actions to help others. The principle of beneficence is fundamental to the practice of nursing and medicine. The agreement to act with beneficence implies that

the best interests of the patient remain more important than self-interest. It implies that nurses practice primarily as a service to others, even in the details of daily work.

Nonmaleficence

Maleficence refers to harm or hurt; thus **nonmaleficence** is the avoidance of harm or hurt. In health care, ethical practice involves not only the will to do good, but the equal commitment to do no harm. The health care professional tries to balance the risks and benefits of care while striving at the same time to do the least harm possible. A bone marrow transplant procedure may offer a chance at cure; but the process involves periods of suffering, and it may not be possible to guarantee a positive outcome. Decisions about the best course of action can be difficult and full of uncertainty, precisely because nurses agree to avoid harm at the same time as they commit to promoting benefit.

Justice

Justice refers to fairness. The term is most often used in discussions about access to health care resources, including the just distribution of resources. Discussions about health insurance, hospital locations and services, even organ transplants generally refer to issues of justice. The term *just culture* refers to the promotion of open discussion whenever mistakes occur, or nearly occur, without fear of recrimination. By fostering open discussion about errors, members of the health care team become informed participants, able to design new systems that prevent harm.

Fidelity

Fidelity refers to the agreement to keep promises. As a nurse you keep promises by following through on your actions and interventions. If you assess a patient for pain and offer a plan to manage the pain, the standard of fidelity encourages you to monitor the patient's response to the plan. Professional behavior includes revision of the plan as necessary to try to keep the promise to reduce pain. Fidelity also refers to the unwillingness to abandon patients even when care becomes controversial or complex.

PROFESSIONAL NURSING CODE OF ETHICS

A **code of ethics** is a set of guiding principles that all members of a profession accept. It is a collective statement about the group's expectations and standards of behavior. Codes serve as guidelines to assist professional groups when questions arise about correct practice or behavior. The American Nurses Association (ANA) established the first code of nursing ethics decades ago. The ANA reviews and revises the code regularly to reflect changes in practice. However, basic principles of responsibility, accountability, advocacy, and confidentiality remain constant (Box 22-1).

Advocacy

Advocacy refers to the support of a particular cause. As a nurse you advocate for the health, safety, and rights of patients, including their right to privacy. Your special relationship with patients provides you with knowledge that is specific to your role as a registered nurse and as such provides you the opportunity to make a unique contribution to understanding a patient's point of view.

Responsibility

The word **responsibility** refers to a willingness to respect one's professional obligations and follow through on promises. As a nurse you are responsible for your actions and for the actions of those to whom you delegate tasks. You strive to remain competent to practice so you are able to follow through on your responsibilities reliably.

BOX 22-1 ANA CODE OF ETHICS

A nurse, in all professional relationships, practices with compassion and respect for the inherent dignity, worth, and uniqueness of every individual, unrestricted by considerations of social or economic status, personal attributes, or the nature of health problems.

- The nurse's primary commitment is to the patient, whether an individual, family, group, or community.
- The nurse promotes, advocates for, and strives to protect the health, safety, and rights of the patient.
- The nurse is responsible and accountable for individual nursing practice and determines the appropriate delegation of tasks consistent with the nurse's obligation to provide optimum patient care.
- The nurse owes the same duties to self as to others, including the responsibility to preserve integrity and safety, to maintain competence, and to continue personal and professional growth.
- The nurse participates in establishing, maintaining, and improving health care environments and conditions of employment conducive to the provision of quality health care and consistent with the values of the profession through individual and collective action.
- The nurse participates in the advancement of the profession through contributions to practice, education, administration, and knowledge development.
- The nurse collaborates with other health professionals and the public in promoting community, national, and international efforts to meet health needs.

The profession of nursing, as represented by associations and their members, is responsible for articulating nursing values, for maintaining the integrity of the profession and its practice, and for shaping social policy.

Accountability

Accountability refers to the ability to answer for one's actions. You learn to ensure that your professional actions are explainable to your patients and your employer. Health care institutions also exercise accountability by monitoring individual and institutional compliance with national standards established by agencies such as The Joint Commission (TJC) and the ANA. Compliance officers in most health care facilities provide compliance oversight. TJC establishes national guidelines to ensure patient and workplace safety through consistent, effective nursing practices (TJC, 2011). ANA sets national standards for continuing education and curriculum development for nursing schools (ANA, 2011). TJC and ANA promote ethical decision making by requiring health care institutions to create a multidisciplinary forum, or ethics committee, for discussion of ethical issues.

Confidentiality

The concept of **confidentiality** in health care is widely respected. Federal legislation known as the Health Insurance Portability and Accountability Act of 1996 (HIPAA) mandates the protection of patients' personal health information. The legislation defines the rights and privileges of patients for protection of privacy. It establishes fines for violations (US Department of Health and Human

Services, 2011). See Chapter 26 for details on HIPAA regulations governing communication of patient information contained in medical records, both hardcopy and electronic.

VALUES

Nursing is a work of intimacy. Nursing practice requires you to be in contact with patients physically, emotionally, psychologically, and spiritually. In most other intimate relationships you choose to enter the relationship precisely because you anticipate that your values will be shared with the other person. But as a nurse you agree to provide care to your patients solely on the basis of their need for your services. As discussed previously, the ethical principles of beneficence and fidelity shape the practice of health care and distinguish it from other common human relationships.

A **value** is a personal belief about the worth of a given idea, attitude, custom, or object that sets standards that influence behavior. Inevitably you will work with patients and colleagues whose values differ from yours. To negotiate differences of opinion and value, it is important to be clear about your own values: what you value, why, and how you respect your own values even as you try to respect those of others whose values differ from yours. The values that an individual holds reflect cultural and social influences, and these values vary among people and develop and change over time. For example, in some cultures decisions about health care flow from group or family-based discussion rather than independent decisions by one person. Such a practice challenges your commitment to respect patient autonomy. Your effort to resolve differing opinions and maintain your cultural competence becomes the hallmark of your commitment to ethical practice (Box 22-2).

Value Formation

Development of values begins in childhood, shaped by experiences within the family unit. Variations in childrearing result in variations in values and behaviors as children grow. The fundamental urge to love and nurture children takes on different expressions within each of the wide variety of cultures in our world.

Schools, governments, religious traditions, and other social institutions play a role in the formation of values, reinforcing or sometimes challenging family values. Over time an individual acquires values by choosing some that the community holds strongly and perhaps discarding or transforming others.

Finally, individual experiences (i.e., the unpredictable twists and turns that occur in life) influence value formation. A person who suffers great loss early in life can grow to value things differently from someone whose life has been free from suffering.

Values Clarification

Ethical dilemmas almost always occur in the presence of conflicting values. To resolve ethical dilemmas one needs to distinguish among value, fact, and opinion. Sometimes people have such strong values that they consider them to be facts, not just opinion. Sometimes people are so passionate about their values that they provoke judgmental attitudes during conflict. Clarifying values—your own, your patients', your co-workers'—is an important and effective part of ethical discourse. In the process of values clarification, you learn to tolerate differences in a way that often (although not always) becomes the key to the resolution of ethical dilemmas.

Examine the cultural values exercise in Box 22-3. The values in the exercise conflict are in neutral terms so you can appreciate how differing values need not indicate "right" or "wrong." For example, for some people it is important to remain silent and stoic in the presence of great pain, and for others it is important to talk about it to understand and control it. Identifying values as something separate from facts can help you find tolerance for others, even when differences among you seem worlds apart.

BOX 22-2 CULTURAL ASPECTS OF CARE

Culturally Competent Care: End-of-Life Decisions

Research about end-of-life care shows that the standard of autonomous decision making is not necessarily universal. Some older-adult patients may defer to their children to make decisions for them as a sign of respect. Still others defer to a group elder to make decisions, even when the patient is competent to make them (Crawley, 2002). Although respect for autonomy has a strong presence in Western philosophy, especially in health care ethics, other cultures may express a preference for group process in making important decisions. For example, Pottinger et al. (2007) explain that "in some Asian cultures, the family is the smallest unit of identity and value is placed on interdependence as opposed to individualism . . . their strong desire to carry out this responsibility evokes equally strong feelings in Western health care providers who value autonomy in decision making."

Volker (2005) summarizes findings from several surveys of patients from different ethnic backgrounds about preferences at the end of life. The goal of the surveys was to identify cultural differences so health care providers could provide more culturally sensitive care. One survey showed that European Americans, Mexican Americans, and African Americans agreed with the concept of an advance directive. However, Mexican Americans and African Americans were "less receptive" than European Americans to the need for a written advance directive. In another survey European Americans were less likely than Mexican Americans to want life-sustaining treatments at the end of life. Korean Americans were knowledgeable about end-of-life technologies but would not choose them personally.

Implications for Practice

Volker points out that research that tries to predict behaviors based on ethnicity can be hindered by the lack of uniform definitions for various ethnic groups and by the infinite variety of human beings, even if they do seem to come from a particular ethnicity or culture. Therefore culturally competent care requires respect and patience. According to Volker, the American College of Physicians proposes the following ground rules:

- Acknowledgment of and respect for cultural differences
- A willingness to negotiate and compromise when world views differ
- Being aware of one's own values and biases
- Using communication skills that enhance empathy
- Knowing cultural practices of patient groups regularly seen
- Understanding that all patients are individuals and they may not share the same views as others within their own ethnic group

ETHICS AND PHILOSOPHY

Historically health care ethics constituted a search for fixed standards that would determine right action. Over time ethics has grown into a complex field of study, more flexible than fixed, filled with differences of opinion and deeply meaningful efforts to understand human interaction. The following review introduces to you a variety of philosophies that you may encounter during ethical discussions in health care settings.

Deontology

A traditional ethical theory, deontology proposes a system of ethics that is perhaps most familiar to health care practitioners. Its foundations come from the work of an eighteenth-century philosopher, Immanuel Kant (1724-1804). **Deontology** defines actions as right or wrong based on their "right-making characteristics" such as

BOX 22-3 CULTURAL VALUES EXERCISE

The column on the right contains statements describing an opinion; the column on the left contains statements describing the opposite opinion. Neither statement is right, nor is it wrong. These statements reflect opinion, not necessarily fact. If persons from a variety of cultures were given this questionnaire, some would strongly agree with the beliefs on the right, and others with the opinions on the left. Read each statement and reflect on your own values and opinions. Circle 1 if you strongly agree with the statement on the left, 2 if you moderately agree. Circle 4 if you strongly agreement with the statement on the right and 3 if you moderately agree.

STATEMENT	RANK	STATEMENT
Preparing for the future is an important activity and reflects maturity.	1 2 3 4	Life has a predestined course. The individual should follow that course.
Vague answers are dishonest and confusing.	1 2 3 4	Vague answers are sometimes preferred because they avoid embarrassment and confrontation.
Punctuality and efficiency are characteristics of a person who is both intelligent and concerned.	1 2 3 4	Punctuality is not as important as maintaining a relaxed atmosphere, enjoying the moment, and being with family and friends.
When in severe pain, it is important to remain strong and not to complain too much.	1 2 3 4	When in severe pain, it is better to talk about the discomfort and express frustration.
It is self-centered and unwise to accept a gift from someone you do not know well.	1 2 3 4	It is an insult to refuse a gift when it is offered.
Addressing someone by his or her first name shows friendliness.	1 2 3 4	Addressing someone by his or her first name is disrespectful.
Direct questions are usually the best way to gain information.	1 2 3 4	Direct questioning is rude and could cause embarrassment.
Direct eye contact shows interest.	1 2 3 4	Direct eye contact is intrusive.
Ultimately the independence of the individual must come before the needs of the family.	1 2 3 4	The needs of the individual are always less important than the needs of the family.

Modified from Renwick GW, Rhinesmith SH: *An exercise in cultural analysis for managers,* Chicago, 1995, Intercultural Press.

fidelity to promises, truthfulness, and justice (Beauchamp and Childress, 2008). It specifically does not look to consequences of actions to determine right or wrong. Instead it examines a situation for the existence of essential right or wrong. For example, if you try to make a decision about the ethics of a controversial medical procedure, deontology guides you to focus on how the procedure ensures fidelity to the patient, truthfulness, justice, and beneficence. You focus less on the consequences (ethically speaking). If an act is just, respects autonomy, and provides good, it will be right, and it will be ethical according to this philosophy. Deontology depends on a mutual understanding and acceptance of these principles.

Often people in ethical dilemmas have to choose between conflicting principles. For example, application of the principle of respect for autonomy is sometimes confusing when dealing with children. The health care team may recommend a certain course of treatment, but the parent disagrees or even refuses the recommendation. Whose autonomy should receive the respect—the parent's? Who should speak for the child's best interest? Communities struggle to decide who ultimately is responsible for the well-being of children. A commitment to respect the "rightness" of autonomy is a guiding principle in deontology, but adherence to the principle alone may not provide clear answers to ethical dilemmas.

Utilitarianism

A utilitarian system of ethics proposes that the value of something is determined by its usefulness. This philosophy is also known as **consequentialism** because its main emphasis is on the outcome or consequence of action. A third term associated with this philosophy is **teleology,** from the Greek word telos, meaning "end," or the study of ends or final causes. John Stuart Mill (1806-1873), a British philosopher, first proposed its philosophical foundations. The greatest good for the greatest number of people is the guiding principle for determining right action in this system. As with deontology, **utilitarianism** relies on the application of a certain principle, (i.e., measures of "good" and "greatest") (Beauchamp and Childress, 2008). The difference between utilitarianism and deontology is the focus on outcomes. Utilitarianism measures the effect that an act will have; deontology looks to the presence of principle regardless of outcome.

People have conflicting definitions of "greatest good." For example, research suggests that education about safe sex practices reduces the spread of human immunodeficiency virus (HIV). Reducing incidence of HIV is good for a great number of people. For some, education about sex is best provided within a family setting rather than in school because it promotes family values. However, for others the greater good is educating the greatest number of people in the most effective way possible; therefore sex education in the public schools would ensure the greatest good. As with deontology, utilitarianism provides guidance, but it does not guarantee agreement.

Feminist Ethics

Feminist ethics critiques conventional ethics such as deontology and utilitarianism. It looks to the nature of relationships to guide participants in making difficult decisions, especially relationships in which power is unequal or in which a point of view has become ignored or invisible (Brody, 2009). Writers with a feminist perspective tend to concentrate more on practical solutions than on theory.

Feminist ethicists propose that the natural human urge to be influenced by relationships is a positive value. Critics of feminist ethics are concerned about the lack of focus on universal principals. Without guidance from universal principals, they argue, solutions depend completely on the situation itself.

Ethics of Care

The ethics of care and feminist ethics are closely related. Both promote a philosophy that focuses on understanding relationships, especially personal narratives.

An early proponent of the ethics of care, Nel Noddings (1984), used the term *the one-caring* to identify the individual who provides care, and *the cared-for* to refer to the patient. In adopting this language Noddings hoped to emphasize the role of feelings. Contemporary writers such as Virginia Held (2005) continue to build on Noddings' foundations by making a case for a focus on the fundamental nature of relationships in understanding ethical issues. **Ethics of care** may even address issues beyond individual relationships such as ethical concerns about the structures within which individual caring occurs such as health care facilities.

Consensus in Bioethics

Bringing different points of view to agreement and harmony, or consensus, requires skill and patience. Building consensus is essentially an act of discovery, in which "collective wisdom" guides a group to the best possible decision. It encourages respect for unusual points of view while striving for agreement among all participants (Dressler, 2006). As a strategy for solving dilemmas, consensus building promotes respect and agreement rather than a particular philosophy or moral system itself. In the example of the processing of the ethical dilemma described in this chapter, the process is basically one of consensus building.

NURSING POINT OF VIEW

All patients in the health care system interact with a nurse at some point, and they interact in ways that are unique to nursing. Nurses generally engage with patients over longer periods of time than other disciplines. Because nurses are involved in intimate physical acts such as bathing, feeding, and special procedures, patients and families may feel safer or more comfortable in revealing information not always shared with physicians, health care providers, or others. Details about family life, information about coping styles, personal preferences, and details about fears and insecurities are likely to come out during the course of nursing interventions. Your ability to recognize these aspects of a patient's situation and express your professional concerns accordingly provides critical value to the discussion.

On the other hand, it is important to remember that care of any patient involves many disciplines. Managers and administrators from many different professional backgrounds contribute to ethical discourse with their knowledge of systems, distribution of resources, financial possibilities, or limits (Fig. 22-1).

Processing an Ethical Dilemma

Ethical dilemmas cause distress and controversy for both patients and caregivers. To minimize distress, you learn to process ethical issues carefully and deliberately. The process should promote the free expression of feelings and opinions. However, you do not resolve an ethical dilemma by considering only what people want and feel (Zoloth, 2010).

Resolving an ethical dilemma is similar to the nursing process in its methodical approach to a clinical issue. But it differs from the nursing process in that it requires negotiation of differences of opinion. As Zoloth (2010) suggests, the resolution of conflicting opinions works best when the following elements are part of the process: the presumption of good will on the part of all participants, strict adherence to confidentiality, patient-centered decision making, and the welcome participation of families and primary caregivers.

The process begins with gathering all pertinent information for an assessment and continues with planning, implementation, and evaluation. To distinguish an ethical problem from other kinds of problems, Curtin (2004) proposes that, if the issue is an ethical one, it entails at least one of the following:

- You are unable to resolve it solely through a review of scientific data.
- It is perplexing. You cannot easily think logically or make a decision about the problem.
- The answer to the problem will have a profound relevance for areas of human concern.

Participants begin the process with a clear statement of the ethical problem. Agreement about the nature of the problem facilitates constructive discussion. Next, listing possible courses of action helps the group explore options and identify dissent. As a group you consider and evaluate alternatives with respect for all differences of opinion. Most of the time people in an ethical conflict come to a resolution and implement a plan. Evaluation of the plan follows (Box 22-4).

If the process involves a family conference or changes in the management plan, you document the process in the medical record. Some institutions use a special ethics consultation form to structure documentation. However, if the ethical concern does not directly affect patient care, you may document the discussion in meeting minutes or in a memorandum to those involved in the discussion.

Now that we have established basic vocabulary terms and reviewed a variety of ethics philosophies, let us return to the patient care scenario at the beginning of this chapter to illustrate how methodical processing can help to resolve an ethical dilemma.

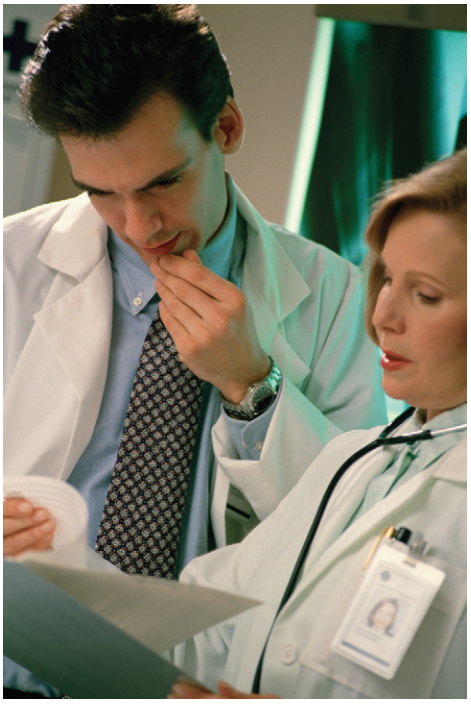

FIG. 22-1 Nurses collaborate with other professionals in making ethical decisions. (Copyright 2007 Jupiter Images Corporation.)

You are caring for a patient with a terminal illness. The patient has discussed with you her desire to explore DNR orders. However, she expresses conflicting sentiments to the admitting physician, and you are challenged with how to proceed.

BOX 22-4 KEY STEPS IN THE RESOLUTION OF AN ETHICAL DILEMMA

Step 1: Ask the question, is this an ethical dilemma? If a review of scientific data does not resolve the question, if the question is perplexing, and if the answer will have relevance for areas of human concern, an ethical dilemma probably exists.
Step 2: Gather information relevant to the case. Patient, family, institutional, and social perspectives are important sources of relevant information.
Step 3: Clarify values. Distinguish among fact, opinion, and values.
Step 4: Verbalize the problem. A clear, simple statement of the dilemma is not always easy, but it helps to ensure effectiveness in the final plan and facilitates discussion.
Step 5: Identify possible courses of action.
Step 6: Negotiate a plan. Negotiation requires a confidence in one's own point of view and a deep respect for the opinions of others.
Step 7: Evaluate the plan over time.

Step 1. Is this situation an ethical dilemma? If the question remains perplexing and the answer will have profound relevance for several areas of human concern, an ethical dilemma exists.

Your situation meets the criteria for an ethical dilemma. The disagreement does not revolve around whether the patient is in a terminally ill state; thus further clinical information will not change the basic question: Should the patient have an opportunity to discuss DNR orders at this time? The question is perplexing. Two professional team members, you and the attending physician, disagree on an assessment of a patient's readiness to confront difficult issues related to dying. The answer to the question, "Is this patient ready to discuss end of life?" has important human implications. If she is not ready, raising the issues could cause anguish and fear in the patient and her family. If she is ready and the team avoids discussion, she could suffer unnecessarily in silence. If she is very close to death, the lack of a DNR order necessitates the application of cardiopulmonary resuscitation (CPR) in a futile situation. As a nurse you know that CPR can cause pain. If applied when an extension of life is unlikely, it could prolong suffering and reduce dignity. On the other hand, if the patient or her loved ones prefer to ensure that all actions to preserve life are taken, regardless of the outcome, a DNR order would violate the patient's wishes.

Step 2. Gather as much information as possible that is relevant to the case. Because resolution of dilemmas often comes from unlikely sources, it is helpful to incorporate as much knowledge as possible. Helpful information includes laboratory and test results, the clinical state of the patient in question, and current literature about the diagnosis or condition of the patient. A patient's religious, cultural, and family situations are part of the assessment.

Since the dilemma exists because two professionals disagree about a patient's state of mind, it is helpful to reassess the patient. An independent assessment could help resolve differences of opinion. Family members or significant others in the patient's life often hold important clues to a patient's state of mind.

Step 3. Examine and determine your values about the issues. Part of the goal is to accurately identify your own opinion. An equally critical goal is to form respect for others' opinions.

Reflect on your values. You think that this patient wants a DNR order in place. But does this opinion accurately represent the patient's wishes? Let's say that your religious beliefs would allow you to obtain DNR status if you were in the patient's condition. After talking with the patient, you learn that her religion discourages acts that diminish life in any way. You realize that she may have come to view a DNR order as "giving up" or "acting like God." In addition, you understand that the attending physician has not had time to know this patient well. You continue to believe that the patient is capable of a discussion, in spite of her statements to the physician. In fact, you believe that she will benefit from a discussion, regardless of the final decision. Perhaps the combination of an unfamiliar caretaker and declining physical health has silenced her, even though her fears and concerns persist.

Step 4. Verbalize the problem. By agreeing to a statement of the problem, the group is able to conduct a focused discussion.

Is a DNR order right or wrong thing for this patient? Is she ready to discuss the options?

Step 5. Consider possible courses of action. What options are possible in this situation?

Do you initiate a discussion with the patient independent of the physician? Is this outside of your professional domain, and is it in the patient's best interest for you to facilitate a DNR order from another physician? What if your assessment of the patient is incorrect? Do you contribute to the dignity or the distress of the patient? The answers to these questions can be elusive because they depend on an understanding of patient feelings and values that are not necessarily obvious. Even if you cannot write a DNR order legally, it does not relieve you of troubling questions because the ability to influence a physician's or patient's decision regarding DNR remains.

Step 6. Negotiate the outcome. Negotiations happen informally at the bedside or in a conference room. Sometimes a formal ethics meeting is necessary. Wherever negotiations occur, the nurse has an obligation to articulate a personal point of view.

If an ethics committee meeting occurs, the discussion usually involves participants from several disciplines. A facilitator or chairperson ensures that the group examines all points of view and identifies all relevant issues. In the best circumstances participants discover a course of action that meets criteria for consensus, or acceptance by all. However, occasionally they leave the discussion disappointed or even opposed to the decision. But in a successful discussion all members will have agreed on an action.

The principles involved during the discussion include beneficence and nonmaleficence: Which plan would provide the most good for this patient, a DNR order or no order? A separate question addresses the patient's point of view and a respect for autonomy: Would a discussion with the patient promote well-being or anguish? The commitment to respect a patient's autonomy reveals that a troublesome question remains: Does the patient want something different from what she is expressing?

With several members of the health care team present, the discussion proceeds. You present your point of view. You continue to sense that the patient is ready to discuss DNR orders. But you also respect the attending physician and his perception that the patient is reluctant to talk freely about it. In the end the team proposes the following: a formal meeting with the patient in which you, the attending physician, and a respected family member are present. You support this proposal because you believe that it maximizes comfort from the patient's network of friends and family. In addition, you recognize that in a trusting environment the patient is most likely to express herself freely. You suggest that, rather than asking if the patient wants a DNR order, perhaps the team could wait for her to initiate the discussion. In this way the team would be sure of her consent and willingness to address the difficult questions about dying.

Step 7. Evaluate the action.

At the meeting the patient brings up the DNR order. She expresses relief at the chance to explore her options and feelings. The physician clarifies pain management issues that she broaches. She wants to discuss a DNR order but requests a visit from her priest before making a final decision.

Institutional Resources

Health care institutions establish ethics committees to process ethical dilemmas. Ethics committees are usually multidisciplinary and serve several purposes: education, policy recommendation, and case consultation. Any person involved in an ethical dilemma, including nurses, physicians, health care providers, patients, and family members, can request access to an ethics committee.

You also process ethical issues in settings other than a committee. Nurses provide insight about ethical problems at family conferences, staff meetings, or even in one-on-one meetings.

Many ethical problems begin when people feel misled or are not aware of their options and do not know when to speak up about their concerns. You address such concerns in a variety of constructive settings. Ethics committees serve to complement relationships within the workplace and the community and offer a valuable resource for strengthening these relationships (Box 22-5).

ISSUES IN HEALTH CARE ETHICS

You will face professional ethical issues in all kinds of settings throughout your career. Issues change as society and technologies change, but common denominators remain: the basic process used to address the issues and your responsibility to maintain skill and patience in dealing with them. The following section describes examples of current issues in which ethical concerns can occur.

Quality of Life

Quality of life represents something deeply personal. Health care researchers work to develop quality-of-life measures to define scientifically the value and benefits of certain medical interventions. Statistical analyses help scientists apply the measures in research and other settings (Walters, 2009). These measures take into account the age of the patient, the patient's ability to live independently, his or her ability to contribute to society in a gainful way, and other nuanced measures of quality. The question of quality of life is central to discussions about futile care, cancer therapy, health care provider–assisted suicide, and DNR discussions.

The population of disabled persons in the United States and elsewhere has reshaped the discussion about quality of life. The national movement to respect the abilities of the "disabled" has raised the visibility of quality-of-life issues and forced a reconsideration of the definition of quality. For example, many school districts no longer separate physically or mentally challenged children but rather integrate them into mainstream classrooms. Public places such as restaurants and buses are accessible to people who use wheelchairs. Antidiscrimination laws enhance the economic security of people with physical, mental, or emotional challenges. These changes have increased the integration of disabled persons into general society. The changes remind society, including health care workers, that definitions of quality are deeply based in individual experience.

Genetic Screening

Genetic testing can alert a patient to a condition that may not yet be evident but that is certain to develop in the future. What are the risks and benefits to individuals and to society of learning about the presence of a disease that has not yet caused symptoms or for which a cure is not yet available? The presence of Huntington's disease, an incurable disease for now, is detectable by genetic testing. Huntington's disease is a degenerative neurological disease

BOX 22-5 EVIDENCE-BASED PRACTICE

Moral Distress

PICO Question: Which ethical actions diminish distress and promote compassionate care for nurses experiencing moral distress when caring for dying patients?

Evidence Summary

Fully 45% of nurses interviewed for this study considered leaving their positions to alleviate the burden of moral distress (Hamric, 2007). Moral distress describes the anguish experienced when a person feels unable to act according to closely held core values. Evidence from interviews with nurses and physicians in 14 intensive care units (ICUs) shed light on moral distress. The interviews revealed that physicians are as capable of experiencing moral distress as are nurses. For both nurses and physicians the highest levels of distress were experienced when caregivers felt pressured to continue unwarranted aggressive treatments for patients in the ICU.

Application to Nursing Practice

- Since moral distress is a shared experience, efforts to alleviate distress are most successful when the efforts are also shared. The authors recommend:
  - Interdisciplinary ethics education, in which nurses and physicians learn together about ethical discourse.
  - Sharing stories about professional perspectives regarding difficult clinical decisions.
  - Increasing opportunities for collegial practice such as routine multidisciplinary rounds.
  - Recurrent situations of moral distress indicate underlying systemic problems of poor communication, inadequate collaboration, and perceived powerlessness must be addressed if nurses and physicians are to minimize this phenomenon in clinical settings (Ulrich, Hamric, and Grady, 2010). Willingness to speak up if they experience moral distress takes courage, but engaging in constructive conversation is key to the management of moral distress in the workplace.

that affects cognitive, emotional, and physical function. Symptoms usually do not appear until the third or fourth decade of life. If a parent or grandparent has the disease, offspring are at risk for developing it (National Institute of Neurological Disorders and Stroke, 2010). Patients may be eager to learn if they will develop the disease so they are able to make decisions about childbearing, career, and retirement planning. Others are reluctant to face the knowledge that they have the disease before symptoms begin, unwilling to compromise healthy years with anxieties about pending emotional and intellectual losses (Wexler, 2010).

Care at the End of Life

Predictions about health outcomes are not always accurate. Even when they are, opinions about the value or worth of the outcome differ. For example, patients at risk for breast cancer occasionally request a mastectomy before any symptoms of breast disease have appeared, fearful of a family history and thinking that it will prevent future suffering. Physicians may be understandably reluctant to provide this intervention, based on knowledge of risk factors and their commitment to "do no harm." On the other hand, a physician might recommend that a patient undergo a liver transplantation for end-stage liver disease even though the likelihood of a cure is uncertain. The patient may hold the opinion that the transplant is pointless: unlikely to produce benefit that justifies the suffering he or she anticipates. Agreement on what is best is often elusive.

The term *futile* refers to something that is hopeless or serves no useful purpose. In health care discussions the term refers to interventions unlikely to produce benefit for a patient. The concept is slippery when applied to clinical situations.

If a patient is dying, in a condition with little or no hope of recovery, almost any intervention beyond symptom management and comfort measures is seen as futile. In this situation an agreement to label an intervention as futile can help providers, families, and patients turn to palliative care measures as a more constructive approach to the situation (see Chapter 36).

When an aging patient is at the end of life, issues may be complicated by his or her ability to make competent decisions because of conditions such as dementia or stroke. How and when to respect the wishes of older patients whose cognitive capacities are in doubt or dispute can complicate clinical decisions and necessitate ethical discourse (Box 22-6).

BOX 22-6 FOCUS ON OLDER ADULTS

Ethical Issues and Aging

- Older people usually are not as familiar with the concept of autonomy as people from younger generations. As a result, older adults are sometimes uncomfortable disagreeing with physicians, health care providers, or nurses. They view assertiveness as a violation of trust.
- As people age, they develop clinical conditions that affect the communication process: hearing and vision deficits, memory impairments, and chronic illness. Some patients become incapacitated by stroke or disease. Most older adults take multiple medications, some of which affect cognitive skills in subtle ways. It is important to evaluate the competence of a patient to make decisions and provide assistance when necessary, especially when treatment choices conflict or ethical issues arise (Burke and Laramie, 2003).
- Consensus about medical goals for the older adult is hard to achieve. When is a person so diminished by old age that a treatment plan not only prolongs life but also prolongs suffering? Working to ensure dignity and comfort is as important as achieving medical success (Burke and Laramie, 2003).

Access to Care

The number of uninsured in the United States grew from 39 million people in 2000 to more than 46.3 million people by 2008, over 15% of the total population (US Census Bureau, 2009). Many of the uninsured are women or children. The Kaiser Family Foundation reports that young adults ages 19 to 29 have the highest uninsured rate of any age-group in the United States and represent 30% of the overall uninsured population (Schwartz and Schwartz, 2010). Although two thirds of the uninsured are poor, nearly 80% come from working families (Holahan, Cook, and Dubay, 2007). Access to care and health care reform may seem distantly related to your daily job or a specific patient care assignment. But as a nurse you will certainly deal with ethical issues related to access to care. You may care for a patient about to be discharged from the hospital when you find that he or she cannot afford to fill a prescription. Do you advocate for a delay in discharge? Do you have time to find financial resources to subsidize the prescription costs? Your involvement with issues such as these and others requires a dedication to your professional ethics, a personal commitment to continuing education, and continuing engagement.

• • •

The courage and intelligence to act as both an advocate for patients and a professional member of the health care community come from a committed effort to learn and understand ethical principles. As a professional nurse you provide a unique point of view regarding patients, the systems that support patients, and the institutions that make up the health care system. You have a duty and a privilege to articulate that point of view. Learning the language of ethical discourse is a part of the skill necessary to exercise this privilege. Review and consideration of various ethical principles helps you form personal points of view, a necessary factor in the negotiation of difficult ethical situations.

KEY POINTS

- Ethics is the study of conduct and character. It is concerned with determining what is good or valuable for individuals and society at large.
- The ANA code of ethics provides a foundation for professional nursing.
- Professional nursing promotes accountability, responsibility, advocacy, and confidentiality.
- Standards of ethics in health care include autonomy, beneficence, nonmaleficence, justice, and fidelity.
- The process of values clarification helps you to explore values and feelings and decide how to act on personal beliefs and respect values of others, even if they differ from yours.
- Ethical problems arise in the presence of differences in values, changing professional roles, technological advances, and social issues that influence quality of life.
- A process for resolving ethical dilemmas that respects differences of opinions and all participants equally helps health care providers resolve conflict about right actions.
- A nurse's point of view offers a unique voice in the resolution of ethical dilemmas.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are caring for a 17-year-old female African American patient with sickle cell disease who has been admitted for treatment of sickle cell crisis. Sickle cell disease is a genetic abnormality that

affects hemoglobin in the red blood cells. The defect is found primarily in African Americans. In a sickle cell crisis weakened red blood cells clump together and impede blood flow, causing extreme pain. To prevent stroke and manage the pain of the crisis, your patient needs aggressive fluid and comfort management. Even though she is receiving pain medication around the clock, she continues to report acute pain, a level of 10 on a scale of 0 to 10. In her distress she complains about almost everything: her roommate, the food, even the intravenous line that delivers the fluids and pain medications. Her home is far from the hospital, and neither her parents nor her friends are able to visit. She has an older brother who has been convicted of possession of illegal drugs.

1. Examine and describe your values and opinions about pain, pain management, and addiction.
2. Describe any ethical concerns you might have about this patient's autonomy.
3. How can you apply the principals of beneficence and fidelity in this situation? What about nonmaleficence?

Evolve *Answers to Clinical Application Questions can be found on the Evolve website.*

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. The patient for whom you are caring needs a liver transplant to survive. This patient has been out of work for several months and doesn't have health insurance or enough cash. What principles would be a priority in a discussion about ethics?
    1. Accountability because you as the nurse are accountable for the well-being of this patient
    2. Respect for autonomy because this patient's autonomy will be violated if he does not receive the liver transplant
    3. Ethics of care because the caring thing that a nurse could provide this patient is resources for a liver transplant
    4. Justice because the first and greatest question in this situation is how to determine the just distribution of resources
2. The point of the ethical principal to "do no harm" is an agreement to reassure the public that in all ways the health care team not only works to heal patients but agree to do this in the least painful and harmful way possible. Which principle describes this agreement?
    1. Beneficence
    2. Accountability
    3. Nonmaleficence
    4. Respect for autonomy
3. A child's immunization may cause discomfort during administration, but the benefits of protection from disease, both for the individual and society, outweigh the temporary discomforts. Which principle is involved in this situation?
    1. Fidelity
    2. Beneficence
    3. Nonmaleficence
    4. Respect for autonomy
4. When a nurse assesses a patient for pain and offers a plan to manage the pain, which principal is used to encourage the nurse to monitor the patient's response to the pain?
    1. Fidelity
    2. Beneficence
    3. Nonmaleficence
    4. Respect for autonomy
5. What is the best example of the nurse practicing patient advocacy?
    1. Seek out the nursing supervisor in conflicting procedural situations
    2. Document all clinical changes in the medical record in a timely manner
    3. Work to understand the law as it applies to an error in following standards of care
    4. Assess the patient's point of view and prepare to articulate it
6. Successful ethical discussion depends on people who have a clear sense of personal values. When a group of people share many of the same values, it may be possible to refer for guidance to philosophical principals of utilitarianism. This philosophy proposes which of the following?
    1. The value of something is determined by its usefulness to society.
    2. People's values are determined by religious leaders.
    3. The decision to perform a liver transplant depends on a measure of the moral life that the patient has led so far.
    4. The best way to determine the solution to an ethical dilemma is to refer the case to the attending physician or health care provider.
7. The philosophy sometimes called the *ethics of care* suggests that ethical dilemmas can best be solved by attention to which of the following?
    1. Patients
    2. Relationships
    3. Ethical principles
    4. Code of ethics for nurses
8. In most ethical dilemmas in health care, the solution to the dilemma requires negotiation among members of the health care team. Why is the nurse's point of view valuable?
    1. Nurses understand the principle of autonomy to guide respect for patient's self-worth.
    2. Nurses have a scope of practice that encourages their presence during ethical discussions.
    3. Nurses develop a relationship to the patient that is unique among all professional health care providers.
    4. The nurse's code of ethics recommends that a nurse be present at any ethical discussion about patient care.
9. Ethical dilemmas often arise over a conflict of opinion. What is the critical first step in negotiating the difference of opinion?
    1. Consult a professional ethicist to ensure that the steps of the process occur in full.
    2. Gather all relevant information regarding the clinical, social, and spiritual aspects of the dilemma.
    3. Ensure that the attending physician or health care provider has written an order for an ethics consultation to support the ethics process.
    4. List the ethical principles that inform the dilemma so negotiations agree on the language of the discussion.
10. The ANA code of nursing ethics articulates that the nurse "promotes, advocates for, and strives to protect the health, safety, and rights of the patient." This includes the protection of patient privacy. On the basis of this principal, if you participate in a public online social network such as Facebook, could you post images of a patient's x-ray film if you deleted all patient identifiers?
    1. Yes because patient privacy would not be violated as long as the patient identifiers were removed
    2. Yes because respect for autonomy implies that you have the autonomy to decide what constitutes privacy

3. No because, even though patient identifiers are removed, someone could identify the patient based on other comments that you make online about his or her condition and your place of work
4. No because the principal of justice requires you to allocate resources fairly

11. When an ethical dilemma occurs on your unit, can you resolve the dilemma by taking a vote?
    1. Yes because ethics is essentially a democratic process, with all participants sharing an equal voice
    2. No because an ethical dilemma involves the resolution of conflicting values and principals rather than simply the identification of what people want to do
    3. Yes because ethical dilemmas otherwise take up time and energy that is better spent at the bedside performing direct patient care
    4. No because most ethical dilemmas are resolved by deferring to the medical director of the ethics department
12. Resolution of an ethical dilemma involves discussion with the patient, the patient's family, and participants from all health care disciplines. Which of the following describes the role of the nurse in the resolution of ethical dilemmas?
    1. To articulate his or her unique point of view, including knowledge based on clinical and psychosocial observations
    2. To await new clinical orders from the physician
    3. To limit discussions about ethical principals
    4. To allow the patient and the physician to resolve the dilemma without regard to personally held values or opinions regarding the ethical issues
13. A precise definition for the word *quality* is difficult to articulate when it comes to quality of life. Why? (Select all that apply.)
    1. Quality of life is measured by potential income, and average income varies in different regions of the country.
    2. Community values are subject to change, and communities influence definitions of "quality."
    3. Individual experiences influence perceptions of quality in potentially different ways, making consensus difficult.
    4. Placing measurable value on elusive elements such as cognitive skills, ability to perform meaningful work, and relationship to family is challenging.
14. Which of the following explain how health care reform is an ethical issue? (Select all that apply.)
    1. Access to care is an issue of beneficence, a fundamental principal in health care ethics.
    2. Reforms promote the principle of beneficence, a hallmark of health care ethics.
    3. Purchasing health care insurance may become an obligation rather than a choice, a potential conflict between autonomy and beneficence.
    4. Lack of access to affordable health care causes harm, and nonmaleficence is a basic principal of health care ethics.
15. Which is the best method of negotiating or processing difficult ethical situations?
    1. Ethical issues arise between dissenting providers and can be best resolved by deference to an independent arbitrator such a chaplain.
    2. Since ethical issues usually affect policy and procedure, a legal expert is the best consultant to help resolve disputes.
    3. Institutional ethics committees help to ensure that all participants involved in the ethical dilemma get a fair hearing and an opportunity to express values, feelings, and opinions as a way to find consensus.
    4. Medical experts are best able to resolve conflicts about outcome predictions.

Answers: **1.** 4; **2.** 3; **3.** 2; **4.** 1; **5.** 4; **6.** 1; **7.** 2; **8.** 3; **9.** 2; **10.** 3; **11.** 2; **12.** 1; **13.** 2, 3, 4; **14.** 2, 3, 4; **15.** 3.

CHAPTER

23

Legal Implications in Nursing Practice

OBJECTIVES

- Explain the legal concept of standard of care.
- Discuss the nurse's role in witnessing the informed consent process.
- Describe the legal responsibilities and obligations of nurses regarding the following federal statutes: Americans with Disabilities Act (ADA), Emergency Medical Treatment and Active Labor Act (EMTALA), Health Insurance Portability and Accountability Act of 1996 (HIPAA), and the Patient Self-Determination Act (PSDA).
- List sources for standards of care for nurses.
- Describe the nurse's role regarding a "do not resuscitate" (DNR) order.
- Define legal aspects of nurse-patient, nurse–health care provider, nurse-nurse, and nurse-employer relationships.
- List the elements needed to prove negligence.
- Describe the nursing implications associated with legal issues that occur in nursing practice.

Safe nursing practice requires understanding the legal framework of health care. Understanding the legal implications of nursing practice demands critical reasoning skills to protect the patient's rights and the nurse from liability. Society expects safe health care delivery, especially from nurses who are typically perceived as the most trusted profession. As patient care practice innovations and new health care technologies emerge, the principles of negligence and malpractice liability are being applied to challenging new situations. Nurses should not fear the law but instead practice nursing armed with the judgment skills that are the outcomes of informed critical thinking.

LEGAL LIMITS OF NURSING

As a professional nurse you need to understand the legal limits influencing your practice. This, along with good judgment and sound decision making, ensures that your patients receive safe and appropriate nursing care.

Sources of Law

The legal guidelines that nurses follow come from statutory law, regulatory law, and common law. Elected legislative bodies such as state legislatures and the U.S. Congress create **statutory law.** An example of state statutes are the Nurse Practice Acts found in all 50 states (see Chapter 1). **Nurse Practice Acts** describe and define the legal boundaries of nursing practice within each state. An example of a federal statute enacted by the U.S. Congress is the Americans with Disabilities Act (ADA) (1990). The ADA protects the rights of individuals who are disabled in the workplace, in educational institutions, and throughout our society. **Regulatory law,** or **administrative law,** reflects decisions made by administrative bodies such as State Boards of Nursing when they pass rules and regulations. An example of a regulatory law is the requirement to report incompetent or unethical nursing conduct to the State

Board of Nursing. **Common law** results from judicial decisions made in courts when individual legal cases are decided. Examples of common law include informed consent, the patient's right to refuse treatment, negligence, and malpractice.

Statutory law is either civil or criminal. **Civil laws** protect the rights of individuals within our society and provide for fair and equitable treatment when civil wrongs or violations occur (Garner, 2006). The consequences of civil law violations are damages in the form of fines or specific performance of good works such as public service. An example of a civil law violation for a nurse is negligence or malpractice. **Criminal laws** protect society as a whole and provide punishment for crimes, which are defined by municipal, state, and federal legislation (Garner, 2006). There are two classifications of crimes. A **felony** is a crime of a serious nature that has a penalty of imprisonment for longer than 1 year or even death. A **misdemeanor** is a less serious crime that has a penalty of a fine or imprisonment for less than 1 year. An example of criminal conduct for nurses is misuse of a controlled substance.

Standards of Care

Standards of care are the legal requirements for nursing practice that describe minimum acceptable nursing care. Standards reflect the knowledge and skill ordinarily possessed and used by nurses actively practicing in the profession (Guido, 2010) (see Chapter 1). The American Nurses Association (ANA) (2010) develops standards for nursing practice, policy statements, and similar resolutions. These standards outline the scope, function, and role of the nurse in practice. Nursing standards of care are described in the Nurse Practice Act of every state, in the federal and state laws regulating hospitals and other health care institutions, by professional and specialty nursing organizations, and by the policies and procedures established by the health care facility where nurses work (Guido, 2010). In a malpractice lawsuit a nurse's actual conduct is compared to nursing standards of care to determine whether the nurse acted as any reasonably prudent nurse would act under the same or similar circumstances. For example, if a patient receives a burn from a warm compress application, negligence is determined by reviewing if the nurse followed the correct procedure for applying the compress. A breach of the nursing standard of care is one element that must be proven in the tort of nursing negligence or malpractice (Daller, 2010).

Nurse Practice Acts define the scope of nursing practice, distinguishing between nursing and medical practice and establishing education and licensure requirements for nurses. The rules and regulations enacted by a State Board of Nursing define the practice of nursing more specifically. For example, State Boards develop rules regarding intravenous therapy. Another example involves the use of nursing assistive personnel (NAP) (e.g., nurse assistants). Some State Boards of Nursing define the registered nurse's responsibilities specifically and develop position statements and guidelines to help licensed nurses delegate safely to NAP (National Council of State Boards of Nursing [NCSBN], 2005). All nurses are responsible for knowing the provisions of the Nurse Practice Act of the state in which they work and the rules and regulations enacted by the State Board of Nursing and other regulatory administrative bodies.

The Joint Commission (TJC) (2011a) requires accredited hospitals to have written nursing policies and procedures. These internal standards of care are specific and need to be accessible on all nursing units. For example, a policy/procedure outlining the steps to follow when changing a dressing or administering medication provides specific information about how nurses are to perform these tasks. Some hospitals are also now using commercially published procedural textbooks to reference the general policies and procedures of the institution. You need to know the policies, procedures, and protocols of your employing institution so you use the same standard of care as the other nurses in your institution. Institutional policies and procedures need to conform to state and federal laws and community standards and cannot conflict with legal guidelines that define acceptable standards of care (Guido, 2010).

In a lawsuit for malpractice or nursing negligence, a nursing expert testifies to the jury about the standards of nursing care as applied to the facts of the case (Box 23-1). A nurse may be requested

BOX 23-1 ANATOMY OF A LAWSUIT

Pleadings Phase

Petition—elements of the claim: The plaintiff outlines what the defendant nurse did wrong and how, as a result of that alleged negligence, the plaintiff was injured.

Answer: The nurse admits or denies each allegation in the petition. The prosecutor must prove anything that the nurse does not admit.

Discovery

Interrogatories: Written questions requiring answers under oath. Usual questions concern witnesses, insurance experts, and which health care providers the plaintiff has seen before and after the incident.

Medical records: The defendant obtains all of the plaintiff's relevant medical records for treatment before and after the incident.

Witnesses' depositions: Questions are posed to the witness under oath to obtain all relevant, nonprivileged information about the case.

Parties' depositions: The plaintiff and defendants (physician, nurse, hospital personnel) are almost always deposed.

Other witnesses: Factual witnesses, both neutral and biased, including family members on the plaintiff's side and other medical personnel (e.g., nurses) on the defendant's side, are deposed to obtain information and their version of the case.

Treating physicians' or health care providers' depositions: Before subsequent treating, physicians' or health care providers' depositions are taken to establish issues such as those concerning preexisting conditions, causation, the nature and extent of injuries, and permanency.

Experts: The plaintiff selects experts to establish the essential legal elements of the case against the defendant. The defendant selects experts to establish the appropriateness of the nursing care.

Trial

Following discovery phase of 1 to 3 years or longer, trial may last days to months.

Proof of Negligence

The nurse owed a duty to the patient.

The nurse did not carry out the duty or breached it (failure to use the degree of skill and learning ordinarily used under the same or similar circumstances by members of his or her profession).

The patient was injured:

- Medical bills, lost wages
- Pain and suffering
- Perinatal damages
- Wrongful death damages

The patient's injury was caused by the nurse's failure to carry out that duty ("but for" the breach of duty, the patient would not have been injured).

to give evidence in a deposition; this appearance needs to be taken seriously (Scott, 2009). The jury uses the standards of care to determine whether the nurse acted appropriately. Nurse experts base their opinions on existing standards of practice established by Nurse Practice Acts, professional organizations, institutional policies and procedures, federal and state hospital licensing laws, TJC standards, job descriptions, and current nursing research literature (Guido, 2010). Usually nurses are responsible for meeting the same standards as other nurses practicing in similar settings. Specialized nurses such as nurse anesthetists, operating room (OR) nurses, intensive care nurses, or certified nurse-midwives have specially defined standards of care and skills. Ignorance of the law or of standards of care is not a defense against malpractice. The best way for nurses to keep up with the current legal issues affecting nursing practice is to maintain familiarity with standards of care and the policies and procedures of their employing agency and to read current nursing literature in their practice area (ANA, 2010).

One of the first and most important cases to discuss a nurse's liability was *Darling v Charleston Community Memorial Hospital.* It involved an 18-year-old man with a fractured leg. The emergency department physician applied a cast with insufficient padding. The man's toes became swollen and discolored, and he developed decreased sensation. He complained to the nursing staff many times. Although the nurses recognized the symptoms as signs of impaired circulation, they failed to tell their supervisor that the physician did not respond to their calls or the patient's needs. Gangrene developed, and the man's leg was amputated. Although the physician was held liable for incorrectly applying the cast, the nursing staff was also held liable for failing to adhere to the standards of care for monitoring and reporting the patient's symptoms. Even though the nurses attempted to contact the physician, this case holds that, when the physician fails to respond, the nurse must go over the health care provider's head to make sure that he or she is appropriately treated. Almost every state uses this 1965 Illinois Supreme Court case as legal precedence.

FEDERAL STATUTORY ISSUES IN NURSING PRACTICE

Americans with Disabilities Act

The Americans with Disabilities Act (ADA) (1990) is a broad civil rights statute that protects the rights of people with physical or mental disabilities (Grohar-Murray and Langan, 2011). The ADA prohibits discrimination and ensures for persons with disabilities equal opportunities in employment, state and local government services, public accommodations, commercial facilities, and transportation. It is also the most extensive law on how employers must treat health care workers and patients infected with the human immunodeficiency virus (HIV). The Supreme Court ruled in 1998 in *Bragdon v Abbott* that even asymptomatic HIV constitutes a disability within the meaning of the ADA. This means that the ADA protects a person who is HIV positive but does not have acquired immunodeficiency syndrome (AIDS). The ADA regulations protect the privacy of infected people by giving individuals the opportunity to decide whether to disclose their disability. However, several cases have held that the health care provider has to disclose the fact that he or she has HIV. Despite these rulings, ADA protects health care workers in the workplace with disabilities such as HIV infection. Likewise, health care workers cannot discriminate against HIV-positive patients (Guido, 2010).

Emergency Medical Treatment and Active Labor Act

As a result of patients being transferred from private to public hospitals without appropriate screening and stabilization (referred to as *patient dumping)*, Congress enacted the Emergency Medical Treatment and Active Labor Act (EMTALA) (1986). This act provides that, when a patient comes to the emergency department or the hospital, an appropriate medical screening occurs within the capacity of the hospital. If an emergency condition exists, the hospital is not to discharge or transfer the patient until the condition stabilizes. Exceptions to this provision include if the patient requests transfer or discharge in writing after receiving information about the benefits and risks or if a health care provider certifies that the benefits of transfer outweigh the risks.

Mental Health Parity Act

Health insurance plans are free to eliminate coverage for certain specialties and impose limits on the amount of coverage that they will pay for certain illnesses. However, if health insurance plans provide mental health benefits, the Mental Health Parity Act of 1996 forbids health plans from placing lifetime or annual limits on mental health coverage that are less generous than those placed on medical or surgical benefits.

Admission of a patient to a mental health unit occurs involuntarily or on a voluntary basis. Involuntary detention occurs when an individual files with the court within 96 hours of the patient's initial detention. A judge may determine that the patient is a danger to self or others; then the judge will grant the involuntary detention, and the patient can be detained for 21 more days for psychiatric treatment.

Potentially suicidal patients are admitted to mental health units. If the patient's history and medical records indicate suicidal tendencies, the patient must be kept under supervision. Lawsuits result from patients' attempts at suicide within the hospital. The allegations in the lawsuits are that the health care provider failed to provide adequate supervision and safeguard the facilities. Documentation of precautions against suicide is essential.

Advance Directives

Advance directives include living wills, health care proxies, and durable powers of attorney for health care (Blais et al., 2006). They are based on values of informed consent, patient autonomy over end-of-life decisions, truth telling, and control over the dying process. The Patient Self-Determination Act (PSDA) (1991) requires health care institutions to provide written information to patients concerning their rights under state law to make decisions, including the right to refuse treatment and formulate advance directives. Under the act the patient's record needs to document whether or not the patient has signed an advance directive. For living wills or durable powers of attorney for health care to be enforceable, the patient must be legally incompetent or lack the capacity to make decisions regarding health care treatment. A judge makes the determination of legal competency, and the health care provider and family usually make the determination of decisional capacity. Decisional capacity is the ability to make right choices for oneself as they relate to medical care. Be familiar with the policies of your institution complying with the act. Likewise, check the state laws to see if a state honors an advance directive that originates in another state.

Living Wills. **Living wills** represent written documents that direct treatment in accordance with a patient's wishes in the event of a terminal illness or condition. With this legal document the patient is able to declare which medical procedures he or she wants

or does not want when terminally ill or in a persistent vegetative state. Living wills are often difficult to interpret and not clinically specific in unforeseen circumstances. Each state providing for living wills has its own requirements for executing them. If health care workers follow the directions of the living will, they should be immune from liability (Bross, 2006).

Health Care Proxies or Durable Power of Attorney for Health Care. A health care proxy or **durable power of attorney for health care (DPAHC)** is a legal document that designates a person or persons of one's choosing to make health care decisions when the patient is no longer able to make decisions on his or her own behalf. This agent makes health care treatment decisions based on the patient's wishes (Blais et al., 2006).

In addition to federal statutes, the ethical doctrine of autonomy ensures the patient the right to refuse medical treatment. Courts upheld the right to refuse medical treatment in the 1986 *Bouvia v Superior Court* case. They have also upheld the right of a legally competent patient to refuse medical treatment for religious reasons. Christian Scientists may refuse medical treatment based on religious beliefs, and Jehovah's Witnesses may accept medical treatment but may refuse blood transfusions based on personal religious beliefs. The U.S. Supreme Court stated in the *Cruzan v Director of Missouri Department of Health* case in 1990 that "we assume that the U.S. Constitution would grant a constitutionally protected competent person the right to refuse lifesaving hydration and nutrition." In cases involving the patient's right to refuse or withdraw medical treatment, the courts balance the patient's interest with the interest of the state in protecting life, preserving medical ethics, preventing suicide, and protecting innocent third parties. Children are generally the innocent third parties. Although the courts will not force adults to undergo treatment refused for religious reasons, they will grant an order allowing hospitals and health care providers to treat children of Christian Scientists or Jehovah's Witnesses who have denied consent for treatment of their minor children.

In addition to patient refusals of treatment, the nurse frequently encounters a DNR order. DNR means "do not resuscitate" or "no code." Documentation that the health care provider has consulted with the patient and/or family is required before attaching a DNR order to the patient's medical record (Guido, 2010).The health care provider needs to review DNR orders routinely in case the patient's condition demands a change. If a patient does not have a DNR order, health care providers need to make every effort to revive the patient. Some states such as Ohio offer DNR Comfort Care and DNR Comfort Care Arrest protocols. Protocols in these instances list specific actions that health care providers will take when providing cardiopulmonary resuscitation (CPR).

CPR is an emergency treatment provided without patient consent. Health care providers perform CPR on an appropriate patient unless there is a DNR order in the patient's chart. The New York law, the first adopted legislation regarding DNR, is one of the most comprehensive in the United States (New York DNR Statute, 1988). The statutes assume that all patients will be resuscitated unless there is a written DNR order in the chart. Legally competent adult patients consent to a DNR order verbally or in writing after receiving the appropriate information by the health care provider. Be familiar with the DNR protocols of your state.

Uniform Anatomical Gift Act

An individual who is at least 18 years of age has the right to make an organ donation (defined as a "donation of all or part of a human body to take effect upon or after death"). Donors need to make the gift in writing with their signature. In many states adults sign the back of their driver's license, indicating consent to organ donation.

In most states Required Request laws mandate that, at the time of admission to a hospital, a qualified health care provider has to ask each patient over age 18 whether he or she is an organ or tissue donor. If the answer is affirmative, the health care provider obtains a copy of the document. If the answer is negative, the health care provider discusses the option to make or refuse an organ donation and places such documentation in the patient's medical record. The health care provider who certifies death is not involved in the removal or transplantation of organs (see Chapter 36).

The National Organ Transplant Act of 1984 prohibits the purchase or sale of organs. The act provides civil and criminal immunity to the hospital and health care provider who performs in accordance with the act. The act also protects the donor's estate from liability for injury or damage that results from the use of the gift. Organ transplantation is extremely expensive. Patients in end-stage renal disease are eligible for Medicare coverage for a kidney transplant, but private insurance pays for other transplants. The United Network for Organ Sharing (UNOS) has a contract with the federal government and sets policies and guidelines for the procurement of organs. Patients who require organ transplantation are on a waiting list for an organ in their geographical area that gives priority to patients who demonstrate the greatest need. Be familiar with the policies and procedures of your employing institution regarding organ donation.

Health Insurance Portability and Accountability Act

The Health Insurance Portability and Accountability Act of 1996 (HIPAA) represents one of the more recent federal statutory acts affecting nursing care. This law provides rights to patients and protects employees. It protects individuals from losing their health insurance when changing jobs by providing portability. It allows employees to change jobs without losing coverage as a result of preexisting coverage exclusion as long as they have had 12 months of continuous group health insurance coverage (Carter, 2010).

In the privacy section of the HIPAA, there are standards regarding accountability in the health care setting (Carter, 2010). These rules create patient rights to consent to the use and disclosure of their protected health information, to inspect and copy one's medical record, and to amend mistaken or incomplete information. It limits who is able to access a patient's record. It establishes the basis for privacy and confidentiality concerns, viewed as two basic rights within the U.S. health care setting. **Privacy** is the right of patients to keep personal information from being disclosed. **Confidentiality** protects private patient information once it has been disclosed in health care settings. Patient confidentiality is a sacred trust. Nurses help organizations protect patients' rights to confidentiality. Although the HIPAA does not require such measures as soundproof rooms in hospitals, it does mean that nurses and all health care providers need to avoid discussing patients in public hallways and provide reasonable levels of privacy in communicating with and about patients in any manner. Message boards used in patients' hospital rooms to post daily nursing care information can no longer contain information revealing the patient's medical condition. With the increased use of technology in the health care setting such as with the use of electronic health records, nurses have a challenging task to maintain patient privacy and confidentiality. HIPAA violations have civil and criminal sanctions.

Health care information privacy is also protected by standards set by the Health Care Financing Administration (HCFA) for

hospitals and health care providers who participate in Medicare and Medicaid (Guido, 2010). These standards require that hospitals and health care providers give notice to patients of their rights to decisions about their care, grievances regarding their care management, personal freedom and safety, confidentiality, access to their own medical records, and freedom from restraints that are not clinically necessary. In addition, many state laws allow patients to access their medical records. Exceptions to the ability to access medical records apply to psychotherapy notes or when the health care provider has determined that access would result in harm to the patient or another party (Privacy Rights Clearinghouse, 2011).

Restraints

The Federal Nursing Home Reform Act (1987) gave residents in certified nursing homes the right to be free of unnecessary and inappropriate restraints. The use of physical restraints is a safety strategy that has been used in hospitals and long-term care settings to protect patients from injury. However, the Centers for Medicare and Medicaid Services (2007) and The Joint Commission (2011a) have set standards for reducing the use of restraints in health care settings and for using them only with extreme caution. The risks associated with the use of restraints are serious. A restraint-free environment is the first goal of care for all patients. *There are many alternatives to the use of restraints, and you should try all of them before using restraints.* Restraints can be used (1) only to ensure the physical safety of the resident or other residents, (2) when less restrictive interventions are not successful, and (3) only on the written order of a health care provider (TJC, 2011a). Written orders include a specific episode with start and end times. Litigation from improper restraint use is a common nursing legal issue (Evans and Cotter, 2008). Nurses are negligent for failure to initiate safety procedures when the patient condition necessitates it. Knowing when and how to use restraints correctly is key (Chapter 27). Liability for improper or unlawful restraint and for patient injury from unprotected falls lies with the nurse and the health care institution. Nurses who apply restraints in violation of state and federal regulations may be charged with abuse, battery, or false imprisonment.

STATE STATUTORY ISSUES IN NURSING PRACTICE

Licensure

A State Board of Nursing licenses all registered nurses in the state in which they practice. The requirements for licensure vary among states, but most states have minimum education requirements and require a licensure examination. All states use the National Council Licensure Examinations (NCLEX®) for registered nurse and licensed practical nurse examinations. Licensure permits people to offer special skills to the public, and it also provides legal guidelines for protection of the public.

The State Board of Nursing suspends or revokes a license if a nurse's conduct violates provisions in the licensing statute based on administrative law rules that implement and enforce the statute. For example, nurses who perform illegal acts such as selling or taking controlled substances jeopardize their license status. Because a license is a property right, the State Board has to follow due process before revoking or suspending a license. Due process means that nurses must be notified of the charges brought against them and have an opportunity to defend against them in a hearing. Hearings for suspension or revocation of a license do not occur in court. Usually a panel of professionals conducts the hearing. Some states provide administrative and judicial review of such cases after nurses have exhausted all other forms of appeal.

Good Samaritan Laws

Nurses act as Good Samaritans by providing emergency assistance at an accident scene (Good Samaritan Act, 1997). All states have Good Samaritan laws enacted to encourage health care professionals to assist in emergencies (Dachs and Elias, 2008). These laws limit liability and offer legal immunity if a nurse helps at the scene of an accident. For example, if you stop at the scene of an automobile accident and give appropriate emergency care such as applying pressure to stop hemorrhage, you are acting within accepted standards, even though proper equipment is not available. If the patient subsequently develops complications as a result of your actions, you are immune from liability as long as you acted without gross negligence (Good Samaritan Act, 1997). Although Good Samaritan laws provide immunity to the nurse who does what is reasonable to save a person's life, if you perform a procedure for which you have no training, you are liable for any injury resulting from that act. You should only provide care that is consistent with your level of expertise. In addition, once you have committed to providing emergency care to a patient, you must stay with that patient until you can safely transfer his or her care to someone who can provide needed care such as emergency medical technicians (EMTs) or emergency department staff. If you leave the patient without properly transferring or handing him or her off to a capable person, you may be liable for patient abandonment and responsible for any injury suffered after you leave him or her (Dachs, 2008). Three states (Louisiana, Minnesota, and Vermont) have enacted "failure-to-act" laws that make it a crime not to provide Good Samaritan care (Dachs and Elias, 2008).

Public Health Laws

Nurses, especially those employed in community health settings, need to understand public health laws. State legislatures enact statutes under health codes, which describe the reporting laws for communicable diseases and school immunizations and those intended to promote health and reduce health risks in communities. The Centers for Disease Control and Prevention (CDC) (http://www.CDC.gov) and the Occupational Health and Safety Act (OHSA) (http://www.osha.gov) provide guidelines on a national level for safe and healthy communities and work environments. The purposes of public health laws are protection of public health, advocating for the rights of people, regulating health care and health care financing, and ensuring professional accountability for care provided. Community and public health nurses have the legal responsibility to enforce laws enacted to protect public health (see Chapter 3). These laws include reporting suspected abuse and neglect such as child abuse, elder abuse, or domestic violence; reporting communicable diseases; ensuring that patients in the community have received required immunizations; and reporting other health-related issues enacted to protect public health. To encourage reports of suspected cases, states provide legal immunity for the reporter if the report is made in good faith. Any health care professional who does not report suspected child abuse or neglect may be liable for civil or criminal legal action.

The Uniform Determination of Death Act

Many legal issues surround the event of death, including a basic definition of the actual point at which a person is legally dead. There are essentially two standards for the determination of death. The cardiopulmonary standard requires irreversible cessation of

circulatory and respiratory functions. The whole-brain standard requires irreversible cessation of all functions of the entire brain, including the brainstem. The reason for the development of different definitions is to facilitate recovery of organs for transplantation. Even though the patient is legally "brain dead," the patient's organs are sometimes healthy for donation to other patients. Most states have adopted the Uniform Determination of Death Act (1980). It states that health care providers can use either the cardiopulmonary or the whole-brain definition to determine death. Be aware of legal definitions of death because you need to document all events that occur when the patient is in your care. Nurses have a specific legal obligation to treat the deceased person's remains with dignity (see Chapter 36). Wrongful handling of a deceased person's remains causes emotional harm to the surviving family.

Autopsy

An autopsy or postmortem examination may be requested by the patient or patient's family, as a part of an institutional policy; or it may be required by law. When a patient's death has occurred under suspicious circumstances or if the patient died within 24 hours of admission to a health care facility, the decision to conduct a postmortem examination is made by the medical examiner (Autopsy Consent, 1998). When the patient's death is not subject to a medical examiner review, consent must be obtained. The priority for giving consent is (1) the patient in writing before death; (2) durable power of attorney; (3) surviving spouse; (4) surviving child, parent, or sibling in the order named.

Physician-Assisted Suicide

Providing end-of-life care in today's world is challenging for health care professionals because people are living longer. The Oregon Death with Dignity Act (1994) was the first statute that permitted physician or health care provider–assisted suicide. The statute stated that a competent individual with a terminal disease could make an oral and written request for medication to end his or her life in a humane and dignified manner. A terminal disease is an "incurable and irreversible disease that has been medically confirmed and will, within reasonable medical judgment, produce death within 6 months."

The American Nurses Association (ANA) (2008) has held that nurses' participation in assisted suicide violates the code of ethics for nurses. The American Association of Colleges of Nursing (AACN) supports the International Council of Nurses' mandate to ensure an individual's peaceful end of life (Guido, 2010). The positions of these two national organizations are not contradictory and require nurses to approach a patient's end of life with openness to listening to the patient's expressions of fear and to attempt to control the patient's pain.

CIVIL AND COMMON LAW ISSUES IN NURSING PRACTICE

Torts

A **tort** is a civil wrong made against a person or property. Torts are classified as intentional, quasi-intentional, or unintentional. **Intentional torts** are willful acts that violate another's rights such as assault, battery, and false imprisonment. Quasi-intentional torts are acts in which intent is lacking but volitional action and direct causation occur such as in invasion of privacy and defamation of character. The third classification of tort is the unintentional tort, which includes negligence or malpractice.

Intentional Torts

Assault. **Assault** is any action that places a person in apprehension of a harmful or offensive contact without consent. No actual contact is necessary. It is an assault for a nurse to threaten to give a patient an injection or to threaten to restrain a patient for an x-ray procedure when the patient has refused consent. Likewise, it is an assault for a patient to threaten a nurse (Guido, 2010).

Battery. **Battery** is any intentional touching without consent. The contact can be harmful to the patient and cause an injury, or it can be merely offensive to the patient's personal dignity. In the example of a nurse threatening to give a patient an injection without the patient's consent, if the nurse actually gives the injection, it is battery. Battery also results if the health care provider performs a procedure that goes beyond the scope of the patient's consent. For example, if the patient gives consent for an appendectomy and the surgeon performs a tonsillectomy, battery has occurred. The key component is the patient's consent.

In some situations consent is implied. For example, if a patient gets into a wheelchair or transfers to a stretcher after receiving advice that it is time to be taken for an x-ray procedure, the patient has given implied consent to the procedure. If the patient learns that he or she will have an x-ray film of the head instead of the foot and the patient refuses to have the x-ray film taken, the consent has been revoked or withdrawn.

False Imprisonment. The tort of false imprisonment occurs with unjustified restraint of a person without legal warrant. This occurs when nurses restrain a patient in a confined area to keep the person from freedom. False imprisonment requires that the patient be aware of the confinement. An unconscious patient has not been falsely imprisoned (Guido, 2010).

Quasi-Intentional Torts

Invasion of Privacy. The tort of invasion of privacy protects the patient's right to be free from unwanted intrusion into his or her private affairs. HIPAA privacy standards have raised awareness of the need for health care professionals to provide confidentiality and privacy. Typically invasion of privacy is the release of a patient's medical information to an unauthorized person such as a member of the press, the patient's employer, or the patient's family. The information that is in a patient's medical record is a confidential communication that may be shared with health care providers for the purpose of medical treatment only.

Do not disclose the patient's confidential medical information without his or her consent. A patient must authorize the release of information and designate to whom the health care information may be released. For example, respect the wish not to inform the patient's family of a terminal illness. Similarly, do not assume that a patient's spouse or family members know all of the patient's history, particularly with respect to private issues such as mental illness, medications, pregnancy, abortion, birth control, or sexually transmitted infections. When a family asks to see a patient's medical record, you must instead establish a relationship that allows for open communication so you can discuss the family's concerns.

An individual's right to privacy sometimes conflicts with the public's right to know. In one case a television crew filmed a married couple who were participating in a hospital program. The couple had previously told no one but their immediate family that they were involved in the in vitro fertilization program and had received assurance that there would be no publicity or public exposure. After the newscast they received phone calls and embarrassing questions. The couple filed a lawsuit. The court held that the husband and wife stated a claim for invasion of privacy and that, even though the in vitro fertilization program was of public

interest, the identity of the plaintiffs was a private matter (*YG v Jewish Hospital*, 1990).

Many states, through their respective public health departments, require that hospitals report certain infectious or communicable diseases. Sometimes the patient is a public figure whose physical condition is newsworthy (Guido, 2010). There are also cases in which information about a scientific discovery or a major medical breakthrough is newsworthy, as with the first heart transplant case or the first artificial heart recipient. If an event falls into any of these categories, guide information through the public relations department of the institution to ensure that invasion of privacy does not occur. It is not the nurse's responsibility to decide independently the legality of disclosing information.

Defamation of Character. **Defamation of character** is the publication of false statements that result in damage to a person's reputation. **Slander** occurs when one speaks falsely about another. For example, if a nurse tells people erroneously that a patient has gonorrhea and the disclosure affects the patient's business, the nurse is liable for slander. **Libel** is the written defamation of character (e.g., charting false entries in a medical record).

Unintentional Torts

Negligence. **Negligence** is conduct that falls below a standard of care. The law establishes the standard of care for the protection of others against an unreasonably great risk of harm (Garner, 2006). For example, if a driver of a car acts unreasonably in failing to stop at a stop sign, it is negligence. In general, courts define negligence in car accident cases and other negligence cases as that degree of care that an ordinarily careful and prudent person would use under the same or similar circumstances. Negligent acts such as hanging the wrong intravenous solution for a patient or allowing a NAP to administer a medication often lead to disciplinary action by the state board of nursing.

Malpractice. **Malpractice** is one type of negligence and often referred to as professional negligence. When nursing care falls below a standard of care, nursing malpractice results. Certain criteria are necessary to establish nursing malpractice: (1) the nurse (defendant) owed a duty to the patient (plaintiff), (2) the nurse did not carry out that duty, (3) the patient was injured, and (4) the nurse's failure to carry out the duty caused the injury. Even though nurses do not intend to injure patients, some patients file claims of malpractice if nurses give care that does not meet the appropriate standards. Malpractice sometimes involves failing to check a patient's identification correctly before administering blood and then giving the blood to the wrong patient. It also involves administering a medication to a patient even though the medical record contains documentation that the patient has an allergy to that medication. In general, courts define nursing malpractice as the failure to use that degree of skill or learning ordinarily used under the same or similar circumstances by members of the nursing profession (Box 23-2) (Austin, 2006).

The best way for nurses to avoid malpractice is to follow standards of care, give competent health care, and communicate with other health care providers. You also avoid malpractice by developing a caring rapport with the patient and documenting assessments, interventions, and evaluations fully. Nurses need to know the current nursing literature in their areas of practice. Know and follow the policies and procedures of the institution where you work. Be sensitive to common sources of patient injury such as falls and medication errors. Finally, communicate with the patient, explain tests and treatments, document that you provided specific explanations to him or her, and listen to his or her concerns about treatments. You are accountable for reporting any significant changes in the patient's condition to the health care provider and documenting these changes in the chart (see Chapter 26). Timely and truthful documentation is important to provide the communication necessary among health care team members. Be certain that documentation is legible and signed (Austin, 2006).

BOX 23-2 COMMON NEGLIGENT ACTS

- Failure to assess and/or monitor, including making a nursing diagnosis
  - Failure to monitor in timely fashion
  - Failure to use proper equipment to monitor the patient
  - Failure to document the monitoring
- Failure to notify the health care provider of problems
- Failure to follow orders
- Failure to follow the six rights of medication administration
- Failure to convey discharge instructions
- Failure to ensure patient safety, especially patients who have a history of falling, are heavily sedated, have disequilibrium problems, are frail, are mentally impaired, get up in the night, and are uncooperative
- Failure to follow policies and procedures
- Failure to properly delegate and supervise

A number of courts have stated that, when a health care provider negligently alters or loses medical records relevant to a malpractice claim, the health care provider needs to demonstrate why these events occurred. An institution has a duty to maintain nursing records. Statutes and accreditation regulations establish these duties. Nursing notes contain substantial evidence needed to understand the care received by a patient. If records are lost or incomplete, there is a presumption that the care was negligent and therefore the cause of the patient's injuries. In addition, incomplete or illegible records make the health care provider less credible or believable.

Consent

A signed consent form is required for all routine treatment, hazardous procedures such as surgery, some treatment programs such as chemotherapy, and research involving patients (TJC, 2011a). A patient signs general consent forms when admitted to the hospital or other health care facility. The patient or his or her representative needs to sign separate special consent or treatment forms before the performance of a specialized procedure. State statutes provide the designation of individuals who are legally able to give consent to medical treatment (Medical Patient Rights Act, 1994). Nurses need to know the law in their states and be familiar with the policies and procedures of their employing institution regarding consent (Box 23-3). If a patient is deaf or illiterate or speaks a foreign language, an official interpreter must be present to explain the terms of consent. A family member or acquaintance who speaks a patient's language should not interpret health information. Make every effort to assist the patient in making an informed choice.

Informed Consent. **Informed consent** is a person's agreement to allow something to happen such as surgery or an invasive diagnostic procedure, based on a full disclosure of risks, benefits, alternatives, and consequences of refusal (Garner, 2006). Informed consent creates a legal duty for the health care provider to disclose material facts in terms the patient is able to understand to make an informed choice (Guido, 2010). Failure to obtain consent in situations other than emergencies will possibly result in a claim of battery. Without informed consent a patient may bring a lawsuit against the health care provider for negligence.

BOX 23-3 STATUTORY GUIDELINES FOR LEGAL CONSENT FOR MEDICAL TREATMENT

Those who consent to medical treatment are governed by state law but generally include the following:

I. Adults
- A. Any competent individual 18 years of age or older for himself or herself
- B. Any parent for his or her unemancipated minor
- C. Any guardian for his or her ward
- D. Any adult for the treatment of his or her minor brother or sister (if an emergency and parents are not present)
- E. Any grandparent for a minor grandchild (if an emergency and parents are not present)

II. Minors
- A. For his or her child and any child in his or her legal custody
- B. For himself or herself in the following situations:
  1. Lawfully married or a parent (emancipated)
  2. Pregnancy (excluding abortions)
  3. Venereal disease
  4. Drug or substance abuse
- C. Unemancipated minors may not consent to abortions without one of the following:
  1. Consent of one parent
  2. Self-consent granted by court order
  3. Consent specifically given by a court

Informed consent is part of the health care provider–patient relationship. It must be obtained and witnessed when the patient is not under the influence of medication such as opioids. Because nurses do not perform surgery or direct medical procedures, in most situations obtaining patients' informed consent does not fall within the nursing duty. The person responsible for performing the procedure has the responsibility to obtain the informed consent.

Key elements of responsibility for the health care provider include the following: (1) the patient receives a brief, complete explanation of the procedure or treatment; (2) the patient receives the names and qualifications of persons performing and assisting in the procedure; (3) the patient receives a description of the serious harm, including death, that may occur as a result of the procedure and anticipated pain and/or discomfort; (4) the patient receives an explanation of alternative therapies to the proposed procedure/treatment and the risks of doing nothing; (5) the patient knows that he or she has the right to refuse the procedure/treatment without discontinuing other supportive care; (6) the patient knows that he or she may refuse the procedure/treatment even after the procedure has begun.

The nurse's signature witnessing the consent means that the patient voluntarily gave consent, the patient's signature is authentic, and the patient appears to be competent to give consent (Guido, 2010). When nurses provide consent forms for patients to sign, they must ask the patients if they understand the procedure for which they are giving consent. If patients deny understanding or you suspect that they do not understand, notify the health care provider or nursing supervisor. Health care providers must inform a patient refusing surgery or other medical treatment about any harmful consequences of refusal. If the patient persists in refusing the treatment, this rejection needs to be written, signed, and witnessed. It is important to note that nursing students cannot and should not be responsible for or asked to witness consent forms because of the legal nature of the document.

Parents are usually the legal guardians of pediatric patients; therefore they typically are the persons who sign consent forms for treatment. If the parents are divorced, the parent with legal custody gives consent. Occasionally a parent or guardian refuses treatment for a child. In these cases the court sometimes intervenes on the child's behalf.

In some instances obtaining informed consent is difficult. For example, if the patient is unconscious, you must obtain consent from a person legally authorized to give it on the patient's behalf. Sometimes the patient has legally designated other surrogate decision makers through special power of attorney documents or court guardianship procedures. In emergencies, if it is impossible to obtain consent from the patient or an authorized person, a health care provider may perform a procedure required to benefit the patient or save a life without liability for failure to obtain consent. In such cases the law assumes that the patient would wish to be treated.

Patients with mental illnesses must also give consent. They retain the right to refuse treatment until a court has legally determined that they are incompetent to decide for themselves.

Abortion Issues

In 1973 in the case of *Roe v Wade,* the U.S. Supreme Court ruled that there is a fundamental right to privacy, which includes a woman's decision to have an abortion. The court ruled that during the first trimester a woman could end her pregnancy without state regulation because the risk of natural mortality from abortion is less than with normal childbirth. During the second trimester the state has an interest in protecting maternal health, and it enforces regulations regarding the person performing the abortion and the abortion facility. By the third trimester, when the fetus becomes viable, the state's interest is to protect the fetus; therefore it prohibits abortion except when necessary to save the mother.

In 1989 in the case of *Webster v Reproductive Health Services* the court substantially narrowed the *Roe v Wade* case. Some states require viability tests before conducting abortions if the fetus is over 28 weeks' gestational age. Some states also require a minor's parental consent or a judicial decision that the minor is mature and can self-consent.

Nursing Students

Nursing students are liable if their actions cause harm to patients. If a student harms a patient as a direct result of his or her actions or lack of action, the student, instructor, hospital, or health care facility and the university or educational institution generally share the liability for the incorrect action. Nursing students should never be assigned to perform tasks for which they are unprepared, and instructors should supervise them carefully as they learn new skills. Although nursing students are not employees of the hospital, the institution has a responsibility to monitor their acts. They are expected to perform as professional nurses would in providing safe patient care. Faculty members are usually responsible for instructing and observing students, but in some situations staff nurses serving as preceptors share these responsibilities. Every nursing school should provide clear definitions of preceptor and faculty responsibility.

When students work as nursing assistants or nurse's aides when not attending classes, they should not perform tasks that do not appear in a job description for a nurse's aide or assistant. For example, even if a student has learned to administer intramuscular medications in class, the student now working as a nurse's aide may not perform this task. If a staff nurse overseeing the nursing assistant or aide knowingly assigns work without regard for the person's

ability to safely conduct the task defined in the job description, the staff nurse is also liable. If someone requests students employed as nurse's aides to perform tasks that they are not prepared to complete safely, they need to bring this information to the supervisor's attention so they are able to obtain the needed help.

Malpractice Insurance

Malpractice or professional liability insurance is a contract between the nurse and the insurance company. Malpractice insurance provides for a defense when a nurse is in a lawsuit involving professional negligence or medical malpractice. As part of the insurance contract, the insurance company pays for any judgment or settlement of the case and for the attorney's fees generated in the representation of the nurse. Nurses employed by health care institutions generally are covered by insurance provided by the institution and do not need to purchase any supplemental insurance unless the nurse plans to practice nursing outside of the employing institution. However, the insurance provided by the employing institution only covers nurses while they are working within the scope of their employment. Because nurses are professionals and it is often difficult to separate their private lives from their professional skills, they need to consider purchasing individual professional liability insurance, even if the employing institution has coverage. For example, a hospital policy does not cover a nurse when neighbors and friends ask him or her to provide nursing care on a volunteer basis if the neighbor or friend files suit (Guido, 2010). Nursing students need to check with their educational institutions regarding the need for liability insurance.

Nurses need to consult their lawyers on which types of policies to purchase and which rights or duties, if any, exist under the policy. If both the employing institution and the nurse are sued in a professional liability case, even though the nurse has insurance with the hospital, he or she needs to notify his or her private insurance carrier of the lawsuit. If both the hospital policy and the private policy are considered primary and the hospital loses as a result of the nurse's acts, theoretically the hospital could sue the nurse's private insurer to recover its losses. However, most private insurance policies for nurses are excess policies and only begin covering the nurse after all of the primary (hospital) insurance coverage has been exhausted. Because hospital insurance coverage is generally much broader and has higher monetary limits than private insurance coverage, hospitals very rarely sue nurses' private insurers.

Abandonment and Assignment Issues

Short Staffing. During nursing shortages or staff downsizing periods, the issue of inadequate staffing occurs. The Community Health Accreditation Program (CHAP) and other state and federal standards require institutions to have guidelines for determining the number (staffing ratios) of nurses required to give care to a specific number of patients. Legal problems occur if there are not enough nurses to provide competent care or if nurses work excessive overtime (Box 23-4). One such example is in a class-action suit, *Spires v Hospital Corporation of America,* filed on April 10, 2006. The wife claims that there was poor patient care related to insufficient registered nurse staffing and that the poor nurse-staffing levels led to the resultant death of her husband. This suit emphasizes the potential seriousness of short staffing and the importance of nurses' asserting employee rights. In an attempt to address the short-staffing problem, 15 states and the District of Columbia have legislation to mandate fixed nurse-patient ratios for all areas of acute care nursing. The safe staffing ratio debate is occurring throughout the country and demands close attention by all nurses (ANA, 2011).

BOX 23-4 EVIDENCE-BASED PRACTICE

Consequences of Working Overtime

PICO Question: Does excess shift work by nurses have a negative effect on patient safety?

Evidence Summary

As hospitals struggle with the nurse shortage, nurses find themselves working more and longer hours and taking care of more patients. In a survey of more than 2000 nurses, 28% stated that they worked longer than 12 hours per day, including overtime; one third said that they worked more than 40 hours per week; and 23% rotated shifts (Trinkoff et al., 2006). Nurses' level of alertness changes when their work extends to off-shift work. Cognitive and psychomotor skills are impaired as indicated by delayed reaction time and decreased coordination (Berger and Hobbs, 2006). Poor patient outcomes as evidenced by increased rates of catheter-associated urinary tract infections and pressure ulcers are related to increased nursing overtime (Stone et al., 2007). As nurse staffing levels decrease, the incidence of patient falls, medication errors, and restraint application duration rate increases (Garrett, 2008).

Application to Nursing Practice

- The longer a nurse stays at work, especially if over 12.5 hours a shift, the greater is the likelihood that he or she will make an error or near error related to patient care.
- When a nurse agrees to work longer than 40 or 50 hours per week, it increases the chance of making an error affecting patient care.
- Nurses who volunteer to work overtime are subjecting themselves to potentially making medical errors.

If nurses are assigned to care for more patients than is reasonable, they need to bring this information to the attention of the nursing supervisor (Guido, 2010). If nurses have to accept unreasonable assignments, they need to make written protests to nursing administrators. Although these protests do not relieve nurses of responsibility if a patient suffers an injury because of inattention, it shows that the nurses were attempting to act reasonably. Whenever you make a written protest, keep a copy of this document in your personal file. Most administrators recognize that knowledge of a potential problem shifts some of the responsibility to the institution. Do not walk out when staffing is inadequate because you may be charged with patient abandonment. A nurse who refuses to accept an assignment may be considered insubordinate. It is important to know the policies and procedures of the institution on how to handle such reports before the situation occurs.

Floating. Nurses are sometimes required to "float" from the area in which they normally practice to other nursing units based on census load and patient acuities. In one case a nurse in obstetrics was assigned to an emergency department. A patient entered the emergency department and complained of chest pain. The patient received an incorrect dose of lidocaine by the obstetrical nurse and died after suffering irreversible brain damage and cardiac arrest. The nurse lost the malpractice lawsuit. Nurses who float need to inform the supervisor of any lack of experience in caring for the type of patients on the nursing unit. They also need to request and receive an orientation to the unit. Supervisors are liable if they give a staff nurse an assignment that he or she cannot safely handle. Before accepting employment, learn the policies of the institution regarding floating and have an understanding as to what is expected (Kane-Urrabazo, 2006).

Health Care Providers' Orders. The health care provider (physician or advanced practice nurse) is responsible for directing medical treatment. Nurses follow health care providers' orders unless they believe the orders are in error or harm patients. Therefore you need to assess all orders; if you find one to be erroneous or harmful, further clarification from the health care provider is necessary. If the health care provider confirms an order and you still believe that it is inappropriate, inform the supervising nurse or follow the established chain of command. The supervising nurse should help resolve the questionable order. A medical consultant sometimes helps clarify its appropriateness or inappropriateness. A nurse carrying out an inaccurate or inappropriate order is legally responsible for any harm the patient suffers.

In a malpractice lawsuit against a health care provider and a hospital, one of the most frequently litigated issues is whether the nurse kept the health care provider informed of the patient's condition. To inform a health care provider properly, you perform a competent nursing assessment of the patient to determine the signs and symptoms that are significant in relation to the attending health care provider's tasks of diagnosis and treatment. Be certain to document that you notified the health care provider and his or her response, your follow-up, and the patient's response.

The health care provider should write all orders. The nurse is responsible for transcribing written orders correctly. If a verbal order is necessary (e.g., during an emergency), it is signed by the health care provider as soon as possible, usually within 24 hours. Nurses verify the complete order or test results by reading verbal orders back to the health care provider. Nursing students *never* take verbal orders. Be familiar with the policy and procedures of the institution regarding verbal orders.

RISK MANAGEMENT

Risk management is an organization's system of ensuring appropriate nursing care by identifying potential hazards and eliminating them before harm occurs (Guido, 2010). The steps involved in risk management include identifying possible risks, analyzing them, acting to reduce the risks, and evaluating the steps taken. One tool used in risk management is the **occurrence report.** Occurrence reports are sometimes called *incident reports.*

Occurrence reporting provides a database for further investigation in an attempt to determine deviations from standards of care and corrective measures needed to prevent recurrence and to alert risk management to a potential claim situation. Examples of an occurrence include patient or visitor falls or injury; failure to follow health care provider orders; significant complaint by patient, family, health care provider, or other hospital department; error in technique or procedure; and malfunctioning device or product. Institutions generally have specific guidelines to direct health care providers in how to complete the occurrence report. The report is confidential and separate from the medical record. As a nurse, you are responsible for providing information in the medical record about the occurrence. *Never document in the patient's medical record that you completed an occurrence report.*

Risk management also requires complete documentation. A nurse's documentation is often the evidence of care received by a patient and serves as proof that the nurse acted reasonably and safely. When a lawsuit is filed, very often the nurses' notes are the first thing an attorney reviews (Austin, 2006). The nurse's assessments and the reporting of significant changes in the assessments are very important factors in defending a lawsuit. Therefore, it is critical for you to document the health care provider contacted, the information communicated to the health care provider, and the health care provider's response.

For nurses in practice the underlying rationale for quality improvement and risk management programs is the highest possible quality of care. Some insurance companies, medical and nursing organizations, and TJC require the use of quality improvement and risk management procedures (TJC, 2011a).

One area of potential risk is associated with the use of electronic monitoring devices. No monitor is reliable at all times; therefore do not depend on them completely. Continual assessment of a patient is necessary to help document the accuracy of electronic monitoring. There are also electrical hazards to the nurse and the patient. Biomedical engineers check equipment to ensure that it is in proper working order and that a patient will not receive an electrical shock.

All nurses need to be risk managers. For example, surgeons rely on operating room nurses to compare the consent form with the indicated and prepped surgical site for accuracy. Because of errors with patients undergoing the wrong surgery or having surgery performed on the wrong site, The Joint Commission's Universal Protocol includes guidelines for preventing such mishaps (TJC, 2011b). Implement this protocol whenever an invasive surgical procedure is to be performed, regardless of the location (hospital, ASC, or health care provider office). The three principles of the protocol include a preoperative verification that ensures all relevant documents and studies are available before the start of the procedure and are consistent with the patient's expectations; marking of the operative site with indelible ink to mark left and right distinction, multiple structures (e.g., fingers), and levels of the spine; and a "time out" just before starting the procedure for final verification of the correct patient, procedure, site, and any implants.

In the OR sponge, needle, and instrument counts are routine surgical standards to prevent patient injury and lawsuits. Health care providers rely on nurses to provide an accurate count of sponges and instruments inserted at the end of a procedure, even though it is the health care provider who inserts sponges and instruments into the surgical wound. Generally, when the chart records a correct sponge count and the patient suffers an injury because of a retained sponge, the hospital is liable because the nurse charted a correct count when it, in fact, was incorrect.

Professional Involvement

As a nurse you should stay involved in professional organizations and on committees that define the standards of care for nursing practice. If current laws, rules and regulations, or policies under which nurses practice do not reflect reality, you need to become involved as an advocate to see that the scope of nursing practice is defined accurately. Be willing to represent nursing and the patient's perspective in the community as well. The voice of nursing is powerful and effective when the organizing focus is the protection and welfare of the public entrusted to nurses' care (Blais et al., 2006).

KEY POINTS

- Registered nurses and licensed practical nurses are licensed by the state in which they practice; licensing is based on educational requirements, the passing of an examination, and other criteria.
- The civil law system is concerned with the protection of a person's private rights, and the criminal law system deals with the rights of individuals and society as defined by legislative statutes.

- A nurse is liable for malpractice if the nurse (defendant) owed a duty to the patient (plaintiff), the nurse did not carry out that duty, the patient was injured, and the nurse's failure to carry out the duty caused the patient's injury.
- All patients are entitled to confidential health care and freedom from unauthorized release of information.
- Under the law practicing nurses must follow standards of care, the guidelines of professional organizations, and the written policies and procedures of employing institutions.
- Nurses who witness consents are responsible for confirming that patients have voluntarily given informed consent for any surgery or other medical procedure before the procedure is performed.
- Nurses are responsible for performing all procedures correctly and exercising professional judgment as they carry out health care providers' orders.
- Nurses follow health care providers' orders unless they believe the orders to be in error or harmful to patients.
- Staffing standards determine the ratio of nurses to patients; if the nurse has to care for more patients than is reasonable, he or she needs to make a formal protest to the nursing administration.
- Legal issues involving death include documenting all events surrounding the death and treating a deceased person with dignity.
- All nurses need to know the laws that apply to their area of practice.
- Depending on state laws, nurses are required to report possible criminal activities such as child abuse and certain communicable diseases.
- Nurses are patient advocates and ensure quality of care through risk management and lobbying for safe nursing practice standards.
- Nurses file incident/occurrence reports for all errors even when someone is not injured.

CLINICAL APPLICATION QUESTIONS

Preparing for Clinical Practice

You are working the first shift on the hematology-oncology unit and receive report on your assigned team of four patients. You have a nursing assistive personnel assigned to help you with routine care. You make quick rounds on your patients to ensure that there are no immediate needs before you begin checking medications. Patient No. 1 is scheduled for surgery later in the morning for a biopsy and needs the surgical consent signed. Patient No. 2 is receiving blood products for an HIV complication and needs frequent vital sign monitoring. You find patient No. 3, an 83-year-old confused man, lying on the floor. He states that he needed to go to the restroom and no one was there to help. You call for help to get the patient back in bed and assess for further injuries.

1. The nurse prepares the surgical consent form for patient No. 1. What key points does he or she need to ensure that the patient received before witnessing informed consent?
2. The son of patient No. 2 calls to talk to the nurse caring for his father. The son asks questions about the reason for the blood administration. What guidelines does the nurse follow in responding to the son's questions about the father's condition? What federal statutes are involved in this scenario?
3. One week after discharge from the hospital, the hospital received a written complaint from the family of patient No. 3 about the incident related to the fall and the intent to take legal action.
   a. What must patient No. 3 establish to prove negligence against the nurse?
   b. Describe situations in which restraints may be legally applied to prevent falls.

REVIEW QUESTIONS

Are You Ready to Test Your Nursing Knowledge?

1. A nurse is caring for a patient who recently had coronary bypass surgery. Which are legal sources of standards of care the nurse uses to deliver safe health care? (Select all that apply.)
   1. Information provided by the head nurse
   2. Policies and procedures of the employing hospital
   3. State Nurse Practice Act
   4. Regulations identified in The Joint Commission's manual
   5. The American Nurses Association standards of nursing practice
2. A nurse is sued for failure to monitor a patient appropriately after a procedure. Which of the following statements are correct about this lawsuit? (Select all that apply.)
   1. The nurse represents the plaintiff.
   2. The defendant must prove injury, damage, or loss.
   3. The person filing the lawsuit has the burden of proof.
   4. The plaintiff must prove that a breach in the prevailing standard of care caused an injury.
3. A nurse stops to help in an emergency at the scene of an accident. The injured party files a suit, and the nurse's employing institution insurance does not cover the nurse. What would probably cover the nurse in this situation?
   1. The nurse's automobile insurance
   2. The nurse's homeowner's insurance
   3. The Good Samaritan laws, which grant immunity from suit if there is no gross negligence
   4. The Patient Care Partnership, which may grant immunity from suit if the injured party consents
4. A nurse is planning care for a patient going to surgery. Who is responsible for informing the patient about the surgery along with possible risks, complications, and benefits?
   1. Family member
   2. Surgeon
   3. Nurse
   4. Nurse Manager
5. A woman who is a Jehovah's Witness has severe life-threatening injuries and is hemorrhaging following a car accident. The health care provider ordered 2 units of packed red blood cells to treat the woman's anemia. The woman's husband refuses to allow the nurse to give his wife the blood. What is the nurse's responsibility?
   1. Obtain a court order to give the blood
   2. Coerce the husband into giving the blood
   3. Call security and have the husband removed from the hospital
   4. Abide by the husband's wishes and inform the health care provider
6. The nurse notes that an advance directive is on a patient's medical record. Which statement represents the best description of an advance directive guideline the nurse will follow?
   1. A living will allows an appointed person to make health care decisions when the patient is in an incapacitated state.

2. A living will is invoked only when the patient has a terminal condition or is in a persistent vegetative state.
3. The patient cannot make changes in the advance directive once admitted to the hospital.
4. A durable power of attorney for health care is invoked only when the patient has a terminal condition or is in a persistent vegetative state.

7. A nurse notes that the health care unit keeps a listing of the patient names at the front desk in easy view for health care providers to more efficiently locate the patient. The nurse talks with the nursing manager because this action is a violation of which act?
   1. Mental Health Parity Act
   2. Patient Self-Determination Act (PSDA)
   3. Health Insurance Portability and Accountability Act (HIPAA)
   4. Emergency Medical Treatment and Active Labor Act
8. Which of the following actions, if performed by a registered nurse, would result in both criminal and administrative law sanctions against the nurse? (Select all that apply.)
   1. Taking or selling controlled substances
   2. Refusing to provide health care information to a patient's child
   3. Reporting suspected abuse and neglect of children
   4. Applying physical restraints without a written physician's order
9. The nurse received a hand-off report at the change of shift in the conference room from the night shift nurse. The nursing student assigned to the nurse asks to review the medical records of the patients assigned to them. The nurse begins assessing the assigned patients and lists the nursing care information for each patient on each individual patient's message board in the patient rooms. The nurse also lists the patients' medical diagnoses on the message board. Later in the day the nurse discusses the plan of care for a patient who is dying with the patient's family. Which of these actions describes a violation of the Health Insurance Portability and Accountability Act (HIPAA)?
   1. Discussing patient conditions in the nursing report room at the change of shift
   2. Allowing nursing students to review patient charts before caring for patients to whom they are assigned
   3. Posting medical information about the patient on a message board in the patient's room
   4. Releasing patient information regarding terminal illness to family when the patient has given permission for information to be shared
10. The patient has a fractured femur that is placed in skeletal traction with a fresh plaster cast applied. The patient experiences decreased sensation and a cold feeling in the toes of the affected leg. The nurse observes that the patient's toes have become pale and cold but forgets to document this because one of the nurse's other patients experienced cardiac arrest at the same time. Two days later the patient in skeletal traction has an elevated temperature, and he is prepared for surgery to amputate the leg below the knee. Which of the following statements regarding a breach of duty apply to this situation? (Select all that apply.)
    1. Failure to document a change in assessment data
    2. Failure to provide discharge instructions
    3. Failure to follow the six rights of medication administration
    4. Failure to use proper medical equipment ordered for patient monitoring
    5. Failure to notify a health care provider about a change in the patient's condition
11. A homeless man enters the emergency department seeking health care. The health care provider indicates that the patient needs to be transferred to the City Hospital for care. This action is most likely a violation of which of the following laws?
    1. Health Insurance Portability and Accountability Act (HIPAA)
    2. Americans with Disabilities Act (ADA)
    3. Patient Self-Determination Act (PSDA)
    4. Emergency Medical Treatment and Active Labor Act (EMTALA)
12. You are the night shift nurse and are caring for a newly admitted patient who appears to be confused. The family asks to see the patient's medical record. What is the first nursing action to take?
    1. Give the family the record
    2. Give the patient the record
    3. Discuss the issues that concern the family with them
    4. Call the nursing supervisor
13. A home health nurse notices significant bruising on a 2-year-old patient's head, arms, abdomen, and legs. The patient's mother describes the patient's frequent falls. What is the best nursing action for the home health nurse to take?
    1. Document her findings and treat the patient
    2. Instruct the mother on safe handling of a 2-year-old child
    3. Contact a child abuse hotline
    4. Discuss this story with a colleague
14. A new graduate nurse is being mentored by a more experienced nurse. They are discussing the ways nurses need to remain active professionally. Which of the statements below indicates the new graduate understands ways to remain involved professionally? (Select all that apply.)
    1. "I am thinking about joining the health committee at my church."
    2. "I need to read newspapers, watch news broadcasts, and search the Internet for information related to health."
    3. "I will join nursing committees at the hospital after I have several years of experience and better understand the issues affecting nursing."
    4. "Nurses do not have very much voice in legislation in Washington, DC, because of the shortage of nurses.
15. You are floated to work on a nursing unit where you are given an assignment that is beyond your capability. What is the best nursing action to take first?
    1. Call the nursing supervisor to discuss the situation
    2. Discuss the problem with a colleague
    3. Leave the nursing unit and go home
    4. Say nothing and begin your work

Answers: **1.** 2, **2.** 3, **3.** 4; **4.** 2; **5.** 4; **6.** 2; **7.** 3; **8.** 1, 4; **9.** 3; **10.** 1, 5; **11.** 4; **12.** 3; **13.** 3; **14.** 1, 2; **15.** 1.

CHAPTER

24

Communication

OBJECTIVES

- Describe aspects of critical thinking that are important to the communication process.
- Describe the five levels of communication and their uses in nursing.
- Describe the basic elements of the communication process.
- Identify significant features and therapeutic outcomes of nurse-patient helping relationships.
- Identify a nurse's communication approaches within the four phases of a nurse-patient helping relationship.
- Identify significant features and desired outcomes of nurse–health care team member relationships.
- Describe qualities, behaviors, and communication techniques that affect professional communication.
- Discuss effective communication techniques for older patients.
- Identify patient health states that contribute to impaired communication.
- Discuss nursing care measures for patients with special communication needs.

COMMUNICATION AND NURSING PRACTICE

Communication is a lifelong learning process. Nurses make the intimate journey with patients and their families from the miracle of birth to the mystery of death. As a nurse you communicate with patients and families to collect meaningful assessment data, provide education, and interact using therapeutic communication to promote personal growth and attainment of health-related goals. Despite the complexity of technology and the multiple demands on nurses' time, it is the intimate moment of connection that makes all the difference in the quality of care and meaning for a patient and a nurse.

Communication is an essential part of patient-centered nursing care. Patient safety also requires effective communication among members of the health care team as patients move from one caregiver to another or from one care setting to another. Breakdown in communication among the health care team is a major cause of errors in the workplace and threatens professional credibility (World Health Organization, 2007). Effective team communication and collaboration skills are essential to ensure patient safety and high-quality patient care (Cronenwett et al., 2007). Competency in communication helps maintain effective relationships within the entire sphere of professional practice and meets legal, ethical, and clinical standards of care.

The qualities, behaviors, and therapeutic communication techniques described in this chapter characterize professionalism in helping relationships. Although the term *patient* is often used, the same principles apply when communicating with any person in any nursing situation.

Communication and Interpersonal Relationships

Caring relationships formed among a nurse and those affected by a nurse's practice are at the core of nursing (see Chapter 7). Communication is the means of establishing these helping-healing relationships. All behavior communicates, and all communication influences behavior. For these reasons communication is essential to the nurse-patient relationship.

Nurses with expertise in communication express caring by the following (Watson, 1985):

- Becoming sensitive to self and others
- Promoting and accepting the expression of positive and negative feelings
- Developing helping-trust relationships
- Instilling faith and hope
- Promoting interpersonal teaching and learning
- Providing a supportive environment
- Assisting with gratification of human needs
- Allowing for spiritual expression

A nurse's ability to relate to others is important for interpersonal communication. This includes the ability to take initiative in establishing and maintaining communication, to be authentic (one's self), and to respond appropriately to the other person. Effective interpersonal communication also requires a sense of mutuality, a belief that the nurse-patient relationship is a partnership and that both are equal participants. Nurses honor the fact that people are very complex and ambiguous. Often more is communicated than first meets the eye, and patient responses are not always what you expect. By giving all of your attention to a patient, you attend to the patient's needs and aid the healing process (Tavernier, 2006). Most nurses embrace the profession's view of the holistic nature of people and experience synergy in human interaction. When patients and nurses work together, much can be accomplished.

Therapeutic communication occurs within a healing relationship between a nurse and patient (Arnold and Boggs, 2011). Like any powerful therapeutic agent, the nurse's communication can result in both harm and good. Every nuance of posture, every small expression and gesture, every word chosen, every attitude held—all have the potential to hurt or heal, affecting others through the transmission of human energy. Knowing that intention and behavior directly influence health gives nurses tremendous ethical responsibility to do no harm to those entrusted to their care. Respect the potential power of communication and do not carelessly misuse communication to hurt, manipulate, or coerce others. Skilled communication empowers others and enables people to know themselves and make their own choices, an essential aspect of the healing process. Nurses have wonderful opportunities to bring about good things for themselves, their patients, and their colleagues through this kind of therapeutic communication.

Developing Communication Skills

Gaining expertise in communication requires both an understanding of the communication process and reflection about one's communication experiences as a nurse. Nurses who develop critical thinking skills make the best communicators. They draw on theoretical knowledge about communication and integrate this knowledge with knowledge previously learned through personal experience. They interpret messages received from others, analyze their content, make inferences about their meaning, evaluate their effect, explain rationale for communication techniques used, and self-examine personal communication skills (Balzer-Riley, 2007).

Critical thinking in nursing, based on established standards of nursing care and ethical standards, promotes effective communication. When you consider a patient's problems, it is important to apply critical thinking standards to ensure sound effective communication (Chitty, 2010). For example, curiosity motivates a nurse to communicate and know more about a person. Patients are more likely to communicate with nurses who express an interest in them. Perseverance and creativity are also attitudes conducive to communication because they motivate a nurse to communicate and identify innovative solutions. A self-confident attitude is important because a nurse who conveys confidence and comfort while communicating more readily establishes an interpersonal helping-trusting relationship. In addition, an independent attitude encourages a nurse to communicate with colleagues and share ideas about nursing interventions. Such an attitude often involves risk taking because colleagues sometimes question suggested nursing interventions. At the same time, an attitude of fairness goes a long way in the ability to listen to both sides in any discussion. Integrity allows nurses to recognize when their opinions conflict with those of their patients, review positions, and decide how to communicate to reach mutually beneficial decisions. It is also very important for a nurse to communicate responsibly and ask for help if uncertain or uncomfortable about an aspect of patient care. An attitude of humility is necessary to recognize and communicate the need for more information before making a decision (Paul, 1993).

It is challenging to understand human communication within interpersonal relationships. Each individual bases his or her perceptions about information received through the five senses of sight, hearing, taste, touch, and smell (Arnold and Boggs, 2011). An individual's culture and education also influence perception. Critical thinking helps nurses overcome **perceptual biases,** or human tendencies that interfere with accurately perceiving and interpreting messages from others. People often assume that others think, feel, act, react, and behave as they would in similar circumstances. They tend to distort or ignore information that goes against their expectations, preconceptions, or stereotypes (Beebe et al., 2010). By thinking critically about personal communication habits, you learn to control these tendencies and become more effective in interpersonal relationships.

As communication skills develop, competence in the nursing process also grows. You need to integrate communication skills throughout the nursing process as you collaborate with patients and health care team members to achieve goals (Box 24-1). Use communication skills to gather, analyze, and transmit information and accomplish the work of each step of the process. Assessment, diagnosis, planning, implementation, and evaluation all depend on effective communication among nurse, patient, family, and others on the health care team. Although the nursing process is a reliable framework for patient care, it does not work well unless you master the art of effective interpersonal communication.

The nature of the communication process requires you to constantly make decisions about what, when, where, why, and how to convey a message. A nurse's decision making is always contextual (i.e., the unique features of any situation influence the nature of the decisions made). For example, the explanation of the importance of following a prescribed diet to a patient with a newly diagnosed medical condition differs from the explanation to a patient who has repeatedly chosen not to follow diet restrictions. Effective communication techniques are easy to learn, but their application is more difficult. Deciding which techniques best fit each unique nursing situation is challenging. Communication about specific diagnoses such as cancer or end of life and dealing with patient and family emotions can be challenging, and some nurses struggle to cope with their own reactions and emotions (Sheldon et al., 2006).

Throughout this chapter brief clinical examples guide you in the use of effective communication techniques. Situations that challenge a nurse's decision-making skills and call for careful use of therapeutic techniques often involve the types of persons described in Box 24-2. Because the best way to acquire skill is through practice, it is useful for you to discuss and role-play these scenarios before experiencing them in the clinical setting. Consider

BOX 24-1 COMMUNICATION THROUGHOUT THE NURSING PROCESS

Assessment
- Verbal interviewing and history taking
- Visual and intuitive observation of nonverbal behavior
- Visual, tactile, and auditory data gathering during physical examination
- Written medical records, diagnostic tests, and literature review

Nursing Diagnosis
- Intrapersonal analysis of assessment findings
- Validation of health care needs and priorities via verbal discussion with patient
- Documentation of nursing diagnosis

Planning
- Interpersonal or small-group health care team planning sessions
- Interpersonal collaboration with patient and family to determine implementation methods
- Written documentation of expected outcomes
- Written or verbal referral to health care team members

Implementation
- Delegation and verbal discussion with health care team
- Verbal, visual, auditory, and tactile health teaching activities
- Provision of support via therapeutic communication techniques
- Contact with other health resources
- Written documentation of patient's progress in medical record

Evaluation
- Acquisition of verbal and nonverbal feedback
- Comparison of actual and expected outcomes
- Identification of factors affecting outcomes
- Modification and update of care plan
- Verbal and/or written explanation of revisions of care plan to patient

BOX 24-2 CHALLENGING COMMUNICATION SITUATIONS

- People who are silent, withdrawn, and have difficulty expressing feelings or needs
- People who are sad and depressed
- People with special needs
- People who are angry or confrontational and cannot listen to explanations
- People who are uncooperative and resent being asked to help others
- People who are talkative or lonely and want someone else to be with them all the time
- People who are demanding and expect others to meet their requests
- People who are frightened, anxious, and having difficulty coping
- People who have difficulty seeing or hearing
- People who are confused and disoriented
- People who speak and/or understand little English
- People who are flirtatious or sexually inappropriate

who is involved in the situation to decide which communication will be most effective.

Levels of Communication

Nurses use different levels of communication in their professional role. A competent nurse uses a variety of techniques in each level.

Intrapersonal communication is a powerful form of communication that occurs within an individual. This level of communication is also called *self-talk, self-verbalization,* or *inner thought.* People's thoughts strongly influence perceptions, feelings, behavior, and self-concept. You need to be aware of the nature and content of your own thinking. Self-talk provides a mental rehearsal for difficult tasks or situations so individuals deal with them more effectively and with increased confidence (Gibson and Foster, 2007; White, 2008). Nurses and patients use intrapersonal communication to develop self-awareness and a positive self-concept that enhances appropriate self-expression. For example, you improve your health and self-esteem through positive self-talk by replacing negative thoughts with positive assertions.

Interpersonal communication is one-on-one interaction between a nurse and another person that often occurs face to face. It is the level most frequently used in nursing situations and lies at the heart of nursing practice. It takes place within a social context and includes all the symbols and cues used to give and receive meaning. Because meaning resides in persons and not in words, messages received are sometimes different from intended messages. Nurses work with people who have different opinions, experiences, values, and belief systems; thus it is important to validate meaning or mutually negotiate it between participants. For example, use interaction to assess understanding and clarify misinterpretations when teaching a patient about a health concern. Meaningful interpersonal communication results in exchange of ideas, problem solving, expression of feelings, decision making, goal accomplishment, team building, and personal growth.

Transpersonal communication is interaction that occurs within a person's spiritual domain. Study of the influence of religion and spirituality has increased dramatically in recent years, and ongoing research helps us understand the role of nurses in addressing a patient's spiritual needs (Pesut et al., 2008). Many people use prayer, meditation, guided reflection, religious rituals, or other means to communicate with their "higher power." Nurses have a responsibility to assess a patient's spiritual needs and intervene to meet those needs (see Chapter 35).

Small-group communication is interaction that occurs when a small number of persons meet. This type of communication is usually goal directed and requires an understanding of group dynamics. When nurses work on committees, lead patient support groups, form research teams, or participate in patient care conferences, they use a small-group communication process. Small groups are most effective when they are cohesive and committed and have an appropriate meeting place with suitable seating arrangements (Arnold and Boggs, 2011). A nurse's role varies with the function of a group. He or she frequently coordinates the group, provides recognition and acceptance of the contributions of each group member, and provides encouragement and motivation to help the group meet its goals (Townsend, 2009).

Public communication is interaction with an audience. Nurses have opportunities to speak with groups of consumers about health-related topics, present scholarly work to colleagues at conferences, or lead classroom discussions with peers or students. Public communication requires special adaptations in eye contact, gestures, voice inflection, and use of media materials to communicate messages effectively. Effective public communication increases audience knowledge about health-related topics, health issues, and other issues important to the nursing profession.

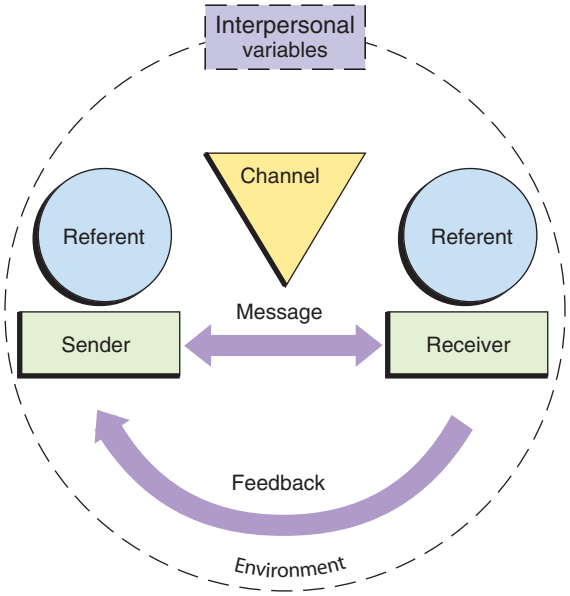

FIG. 24-1 Communication as active process between sender and receiver.

BASIC ELEMENTS OF THE COMMUNICATION PROCESS

Communication is an ongoing, dynamic, and multidimensional process. Fig. 24-1 shows the basic elements of the communication process. This simple linear model represents a very complex process with its essential components. Nursing situations have many unique aspects that influence the nature of communication and interpersonal relationships. As a professional, you will use critical thinking to focus on each aspect of communication so your interactions are purposeful and effective.

Referent

The **referent** motivates one person to communicate with another. In a health care setting sights, sounds, odors, time schedules, messages, objects, emotions, sensations, perceptions, ideas, and other cues initiate communication. Knowing which stimulus initiates communication enables you to develop and organize messages more efficiently and better perceive meaning in another's message. A patient request for help prompted by difficulty breathing brings a different nursing response than a request prompted by hunger.

Sender and Receiver

The **sender** is the person who encodes and delivers the message, and the **receiver** is the person who receives and decodes the message. The sender puts ideas or feelings into a form that is transmitted and is responsible for the accuracy of its content and emotional tone. The sender's message acts as a referent for the receiver, who is responsible for attending to, translating, and responding to the sender's message. Sender and receiver roles are fluid and change back and forth as two persons interact; sometimes sending and receiving occurs simultaneously. The more the sender and receiver have in common and the closer the relationship, the more likely they will accurately perceive one another's meaning and respond accordingly.

Messages

The **message** is the content of the communication. It contains verbal, nonverbal, and symbolic language. Personal perceptions sometimes distort the receiver's interpretation of the message. Two nurses can provide the same information yet convey very different messages because of their personal communication styles. Two persons understand the same message differently. You send effective messages by expressing clearly, directly, and in a manner familiar to the receiver. You determine the need for clarification by watching the listener for nonverbal cues that suggest confusion or misunderstanding. Communication is difficult when participants have different levels of education and experience. "Your incision is well approximated without purulent drainage" means the same as "Your wound edges are close together, and there are no signs of infection," but the latter is easier to understand. You can also send messages in writing, but make sure that patients are able to read.

Channels

Channels are means of conveying and receiving messages through visual, auditory, and tactile senses. Facial expressions send visual messages, spoken words travel through auditory channels, and touch uses tactile channels. Individuals usually understand a message more clearly when the sender uses more channels to convey it. For example, when teaching about insulin self-injection, the nurse talks about and demonstrates the technique, gives the patient printed information, and encourages hands-on practice with the vial and syringe. Nurses use verbal, nonverbal, and mediated (technological) communication channels. They send and receive information in person, by informal or formal writing, over the telephone or pager, by audiotape and videotape, through fax and electronic mail, and through interactive and informational websites.

Feedback

Feedback is the message the receiver returns. It indicates whether the receiver understood the meaning of the sender's message. Senders seek verbal and nonverbal feedback to evaluate the effectiveness of communication. The sender and receiver need to be sensitive and open to one another's messages, clarify the messages, and modify behavior accordingly. In a social relationship both persons assume equal responsibility for seeking openness and clarification, but the nurse assumes primary responsibility in the nurse-patient relationship.

Interpersonal Variables

Interpersonal variables are factors within both the sender and receiver that influence communication. Perception is one such variable that provides a uniquely personal view of reality formed by an individual's expectations and experiences. Each person senses, interprets, and understands events differently. A nurse says, "You have been very quiet since your family left. Is there something on your mind?" One patient may perceive the nurse's question as caring and concerned; another perceives the nurse as invading privacy and is less willing to talk. Other interpersonal variables include educational and developmental levels, sociocultural backgrounds, values and beliefs, emotions, gender, physical health status, and roles and relationships. Variables associated with illness such as pain, anxiety, and medication effects also affect nurse-patient communication.

Environment

The **environment** is the setting for sender-receiver interaction. For effective communication the environment needs to meet participant needs for physical and emotional comfort and safety.

Noise, temperature extremes, distractions, and lack of privacy or space create confusion, tension, and discomfort. Environmental distractions are common in health care settings and interfere with messages sent between people. You control the environment as much as possible to create favorable conditions for effective communication.

FORMS OF COMMUNICATION

Messages are conveyed verbally and nonverbally, concretely and symbolically. As people communicate, they express themselves through words, movements, voice inflection, facial expressions, and use of space. These elements work in harmony to enhance a message or conflict with one another to contradict and confuse it.

Verbal Communication

Verbal communication uses spoken or written words. Verbal language is a code that conveys specific meaning through a combination of words. The most important aspects of verbal communication are presented in the following paragraphs.

Vocabulary. Communication is unsuccessful if senders and receivers cannot translate one another's words and phrases. When a nurse cares for a patient who speaks another language, an interpreter is often necessary. Even those who speak the same language use subcultural variations of certain words (e.g., *dinner* means a noon meal to one person and the last meal of the day to another). Medical jargon (technical terminology used by health care providers) sounds like a foreign language to patients unfamiliar with the health care setting. Limiting use of medical jargon to conversations with other health care team members improves communication. Children have a more limited vocabulary than adults. They may use special words to describe bodily functions or a favorite blanket or toy. Teenagers often use words in unique ways that are unfamiliar to adults.

Denotative and Connotative Meaning. Some words have several meanings. Individuals who use a common language share the denotative meaning: *baseball* has the same meaning for everyone who speaks English, but *code* denotes cardiac arrest primarily to health care providers. The connotative meaning is the shade or interpretation of the meaning of a word influenced by the thoughts, feelings, or ideas people have about the word. For example, health care providers tell a family that a loved one is in serious condition, and they believe that death is near; but to nurses *serious* simply describes the nature of the illness. You need to carefully select words, avoiding easily misinterpreted words, especially when explaining a patient's medical condition or therapy. Even a much-used phrase such as "I'm going to take your vital signs" may be unfamiliar to an adult or frightening to a child.

Pacing. Conversation is more successful at an appropriate speed or pace. Speak slowly and enunciate clearly. Talking rapidly, using awkward pauses, or speaking slowly and deliberately conveys an unintended message. Long pauses and rapid shifts to another subject give the impression that you are hiding the truth. Think before speaking and develop an awareness of the rhythm of your speech to improve pacing.

Intonation. Tone of voice dramatically affects the meaning of a message. Depending on intonation, even a simple question or statement expresses enthusiasm, anger, concern, or indifference. Be aware of voice tone to avoid sending unintended messages. For example, a patient interprets a nurse's patronizing tone of voice as condescending, and this inhibits further communication. A patient's tone of voice often provides information about his or her emotional state or energy level.

Clarity and Brevity. Effective communication is simple, brief, and direct. Fewer words result in less confusion. Speaking slowly, enunciating clearly, and using examples to make explanations easier to understand improve clarity. Repeating important parts of a message also clarifies communication. Phrases such as "you know" or "OK?" at the end of every sentence detract from clarity. Use short sentences and words that express an idea simply and directly. "Where is your pain?" is much better than "I would like you to describe for me the location of your discomfort."

Timing and Relevance. Timing is critical in communication. Even though a message is clear, poor timing prevents it from being effective. For example, you do not begin routine teaching when a patient is in severe pain or emotional distress. Often the best time for interaction is when a patient expresses an interest in communicating. If messages are relevant or important to the situation at hand, they are more effective. When a patient is facing emergency surgery, discussing the risks of smoking is less relevant than explaining presurgical procedures.

Nonverbal Communication

Nonverbal communication includes the five senses and everything that does not involve the spoken or written word. Researchers have estimated that approximately 7% of meaning is transmitted by words, 38% is transmitted by vocal cues, and 55% is transmitted by body cues. Thus nonverbal communication is unconsciously motivated and more accurately indicates a person's intended meaning than the spoken words (Jones, 2009). When there is incongruity between verbal and nonverbal communication, the receiver usually "hears" the nonverbal message as the true message.

All kinds of nonverbal communication are important, but interpreting them is often problematic. Sociocultural background is a major influence on the meaning of nonverbal behavior. In the United States, with its diverse cultural communities, nonverbal messages between people of different cultures are easily misinterpreted. Because the meaning attached to nonverbal behavior is so subjective, it is imperative that you verify it (Stuart, 2009). Assessing nonverbal messages is an important nursing skill.

Personal Appearance. Personal appearance includes physical characteristics, facial expression, and manner of dress and grooming. These factors help communicate physical well-being, personality, social status, occupation, religion, culture, and self-concept. First impressions are largely based on appearance. Nurses learn to develop a general impression of patient health and emotional status through appearance, and patients develop a general impression of the nurse's professionalism and caring in the same way.

Posture and Gait. Posture and gait (way of walking) are forms of self-expression. The way people sit, stand, and move reflects attitudes, emotions, self-concept, and health status. For example, an erect posture and a quick, purposeful gait communicate a sense of well-being and confidence. Leaning forward conveys attention. A slumped posture and slow shuffling gait indicates depression, illness, or fatigue.

Facial Expression. The face is the most expressive part of the body. Facial expressions convey emotions such as surprise, fear, anger, happiness, and sadness. Some people have an expressionless face, or flat affect, which reveals little about what they are thinking or feeling. An inappropriate affect is a facial expression that does not match the content of a verbal message (e.g., smiling when describing a sad situation). People are sometimes unaware of the

messages their expressions convey. For example, a nurse frowns in concentration while doing a procedure, and the patient interprets this as anger or disapproval. Patients closely observe nurses. Consider the impact a nurse's facial expression has on a person who asks, "Am I going to die?" The slightest change in the eyes, lips, or facial muscles reveals the nurse's feelings. Although it is hard to control all facial expressions, try to avoid showing shock, disgust, dismay, or other distressing reactions in a patient's presence.

Eye Contact. People signal readiness to communicate through eye contact. Maintaining eye contact during conversation shows respect and willingness to listen. Eye contact also allows people to closely observe one another. Lack of eye contact may indicate anxiety, defensiveness, discomfort, or lack of confidence in communicating. However, persons from some cultures consider eye contact intrusive, threatening, or harmful and minimize or avoid its use (see Chapter 9). Always consider a person's culture when interpreting the meaning of eye contact. Eye movements communicate feelings and emotions. Looking down on a person establishes authority, whereas interacting at the same eye level indicates equality in the relationship. Rising to the same eye level as an angry person helps establish autonomy.

Gestures. Gestures emphasize, punctuate, and clarify the spoken word. Gestures alone carry specific meanings, or they create messages with other communication cues. A finger pointed toward a person communicates several meanings; but, when accompanied by a frown and stern voice, the gesture becomes an accusation or threat. Pointing to an area of pain is sometimes more accurate than describing its location.

Sounds. Sounds such as sighs, moans, groans, or sobs also communicate feelings and thoughts. Combined with other nonverbal communication, sounds help to send clear messages. They have several interpretations: moaning conveys pleasure or suffering, and crying communicates happiness, sadness, or anger. Validate nonverbal messages with the patient to interpret them accurately.

Territoriality and Personal Space. Territoriality is the need to gain, maintain, and defend one's right to space. Territory is important because it provides people with a sense of identity, security, and control. It is sometimes separated and made visible to others such as a fence around a yard or a bed in a hospital room. Personal space is invisible, individual, and travels with the person. During interpersonal interaction, people maintain varying distances between each other, depending on their culture, the nature of their relationship, and the situation. When personal space becomes threatened, people respond defensively and communicate less effectively. Situations dictate whether the interpersonal distance between nurse and patient is appropriate. Box 24-3 provides examples of nursing actions within zones of personal space and touch (Kneisl and Trigoboff, 2009; Stuart, 2009). Nurses frequently move into patients' territory and personal space because of the nature of caregiving. You need to convey confidence, gentleness, and respect for privacy, especially when your actions require intimate contact or involve a patient's vulnerable zone.

Symbolic Communication

Good communication requires awareness of **symbolic communication,** the verbal and nonverbal symbolism used by others to convey meaning. Art and music are forms of symbolic communication used by nurses to enhance understanding and promote healing. Lane (2006) found that creative expressions such as art, music, and dance have a healing effect on patients. Patients reported decreased pain and a greater sense of joy and hope.

BOX 24-3 ZONES OF PERSONAL SPACE AND TOUCH

Zones of Personal Space

Intimate Zone (0 to 18 Inches)
- Holding a crying infant
- Performing physical assessment
- Bathing, grooming, dressing, feeding, and toileting a patient
- Changing a patient's dressing

Personal Zone (18 Inches to 4 Feet)
- Sitting at a patient's bedside
- Taking a patient's nursing history
- Teaching an individual patient
- Exchanging information at change of shift

Social Zone (4 to 12 Feet)
- Making rounds with a physician
- Sitting at the head of a conference table
- Teaching a class for patients with diabetes
- Conducting a family support group

Public Zone (12 Feet and Greater)
- Speaking at a community forum
- Testifying at a legislative hearing
- Lecturing to a class of students

Zones of Touch

Social Zone (Permission not Needed)
- Hands, arms, shoulders, back

Consent Zone (Permission Needed)
- Mouth, wrists, feet

Vulnerable Zone (Special Care Needed)
- Face, neck, front of body

Intimate Zone (Great Sensitivity Needed)
- Genitalia, rectum

Metacommunication

Metacommunication is a broad term that refers to all factors that influence communication. Awareness of influencing factors helps people better understand what is communicated (Arnold and Boggs, 2011). For example, a nurse observes a young patient holding his body rigidly, and his voice is sharp as he says, "Going to surgery is no big deal." The nurse replies, "You say having surgery doesn't bother you, but you look and sound tense. I'd like to help." Awareness of the tone of the verbal response and the nonverbal behavior results in further exploration of the patient's feelings and concerns.

PROFESSIONAL NURSING RELATIONSHIPS

A nurse's application of knowledge, understanding of human behavior and communication, and commitment to ethical behavior help create professional relationships. Having a philosophy based on caring and respect for others helps you be more successful in establishing relationships of this nature.

Nurse-Patient Helping Relationships

Helping relationships are the foundation of clinical nursing practice. In such relationships you assume the role of professional helper and come to know a patient as an individual who has unique health needs, human responses, and patterns of living. Therapeutic relationships promote a psychological climate that facilitates positive change and growth. Therapeutic communication between you and your patients allows the attainment of health-related goals (Arnold and Boggs, 2011). The goals of a therapeutic relationship focus on a patient achieving optimal personal growth related to personal identity, ability to form relationships, and ability to satisfy needs and achieve personal goals (Stuart, 2009). There is an explicit time frame, a goal-directed approach, and a high expectation of confidentiality. A nurse establishes, directs,

BOX 24-4 PHASES OF THE HELPING RELATIONSHIP

Preinteraction Phase

Before meeting a patient:

- Review available data, including the medical and nursing history.
- Talk to other caregivers who have information about the patient.
- Anticipate health concerns or issues that arise.
- Identify a location and setting that fosters comfortable, private interaction.
- Plan enough time for the initial interaction.

Orientation Phase

When the nurse and patient meet and get to know one another:

- Set the tone for the relationship by adopting a warm, empathetic, caring manner.
- Recognize that the initial relationship is often superficial, uncertain, and tentative.
- Expect the patient to test your competence and commitment.
- Closely observe the patient and expect to be closely observed by the patient.
- Begin to make inferences and form judgments about patient messages and behaviors.
- Assess the patient's health status.
- Prioritize the patient's problems and identify his or her goals.
- Clarify the patient's and your roles.
- Form contracts with the patient that specify who will do what.
- Let the patient know when to expect the relationship to be terminated.

Working Phase

When the nurse and patient work together to solve problems and accomplish goals:

- Encourage and help the patient express feelings about his or her health.
- Encourage and help the patient with self-exploration.
- Provide information needed to understand and change behavior.
- Encourage and help the patient set goals.
- Take action to meet the goals set with the patient.
- Use therapeutic communication skills to facilitate successful interactions.
- Use appropriate self-disclosure and confrontation.

Termination Phase

During the ending of the relationship:

- Remind the patient that termination is near.
- Evaluate goal achievement with the patient.
- Reminisce about the relationship with the patient.
- Separate from the patient by relinquishing responsibility for his or her care.
- Achieve a smooth transition for the patient to other caregivers as needed.

and takes responsibility for the interaction; and a patient's needs take priority over a nurse's needs. Your nonjudgmental acceptance of a patient is an important characteristic of the relationship. Acceptance conveys a willingness to hear a message or acknowledge feelings. It does not mean that you always agree with the other person or approve of the patient's decisions or actions. A helping relationship between you and a patient does not just happen—you create it with care, skill, and trust.

A natural progression of four goal-directed phases characterizes the nurse-patient relationship. The relationship often begins before you meet a patient and continues until the caregiving relationship ends (Box 24-4). Even a brief interaction uses an abbreviated version of the same preinteraction, orientation, working, and termination phases (Stuart, 2009). For example, the nursing student gathers patient information to prepare in advance for caregiving, meets the patient and establishes trust, accomplishes health-related goals through use of the nursing process, and says goodbye at the end of the day.

Socializing is an important initial component of interpersonal communication. It helps people get to know one another and relax. It is easy, superficial, and not deeply personal; whereas therapeutic interactions are often more intense, difficult, and uncomfortable. A nurse often uses social conversation to lay a foundation for a closer relationship: "Hi, Mr. Simpson, I hear it's your birthday today. How old are you?" A friendly, informal, and warm communication style helps establish trust, but you have to get beyond social conversation to talk about issues or concerns affecting the patient's health. During social conversation some patients ask personal questions such as those about your family or place of residence. Students often wonder whether it is appropriate to reveal such information. The skillful nurse uses judgment about what to share and provides minimal information or deflects such questions with gentle humor and refocuses conversation back to the patient.

Creating a therapeutic environment depends on your ability to communicate, comfort, and help patients meet their needs. Comfort is a critical value inherent in the practice of nursing. Therapeutic interactions increase feelings of personal control by helping a person feel secure, informed, and valued. Optimizing personal control facilitates emotional comfort, which minimizes physical discomfort and enhances recovery activities (Williams and Irurita, 2006).

In a therapeutic relationship it is important to encourage patients to share personal stories. Sharing stories is called *narrative interaction*. Through narrative interactions you begin to understand the context of others' lives and learn what is meaningful for them from their perspective. For example, a nurse uses narratives to understand a patient's perception of risk and the meaning of risk when taking medication that increases the risk of bleeding (Andreas et al., 2010) and to explore patient experiences of dignity in care (Dawood and Gallini, 2010). It is important to listen to patient stories to better understand their concerns, experiences, and challenges. This information is not usually revealed using a standard history form that elicits short answers.

Nurse-Family Relationships

Many nursing situations, especially those in community and home care settings, require you to form helping relationships with entire families. The same principles that guide one-on-one helping relationships also apply when the patient is a family unit, although communication within families requires additional understanding of the complexities of family dynamics, needs, and relationships (see Chapter 10).

Nurse–Health Care Team Relationships

Communication with other members of the health care team affects patient safety and the work environment. Breakdown in communication is a frequent cause of serious injuries in health care settings (World Health Organization, 2007). When patients move from one nursing unit to another or from one provider to another, also known as *hand-offs*, there is a risk for miscommunication. Accurate communication is essential to prevent errors (Cronenwett et al., 2007).

Use of common language when communicating critical information helps prevent misunderstandings. SBAR is a popular

BOX 24-5 EVIDENCE-BASED PRACTICE

Safe and Effective Interprofessional Communication

PICO Question: Do hand-off communication techniques in health care team communication improve patient outcomes?

Evidence Summary

Mutual respect and trust enable clarification and unambiguous communication. Establishing a relationship and face-to-face communication are important for teamwork. Practitioners need an understanding and appreciation of unique professional roles to work together as a team, collaborating to provide patient-centered care (Robinson et al., 2010; Sutter et al., 2009). Scorning others, making others feel incompetent, linguistic and cultural barriers, and over-dependence on electronic communication systems contribute to ineffective communication (Sutter et al., 2009).

Use of communication techniques such as SBAR (Situation, Background, Assessment, Recommendation) provides a framework for a conversation among health care providers that fosters patient safety. Consistent communication practices minimize risk with hand-off communication (Amato-Vealey, Barba, and Vealey, 2008; Cronenwett et al., 2007).

Application to Nursing Practice

- Work in interdisciplinary teams to develop understanding and respect for other disciplines.
- Develop common language for critical information.
- Use a standardized SBAR format for report when patients are transferred to other units or facilities.
- Provide the opportunity for questions and confirmation of understanding of communication.

communication tool that helps standardize communication among health care providers. SBAR stands for Situation, Background, Assessment, and Recommendation (Pope et al., 2008). Research indicates that effective communication between health care providers and other members of the health care team ensures patient safety and promotes optimal patient outcomes (Amato-Vealey, Barba, and Vealey, 2008). Evidence identifies nursing actions that increase effectiveness of nurse-to-nurse interaction and interprofessional communication (Box 24-5).

Building Competency in Teamwork and Collaboration You are caring for Jane, a 78-year-old who was admitted this morning from home with pneumonia. On assessment you find that Jane has a temperature of 38.7° C (101.6° F) and an oxygen saturation of 88% on 3 L of oxygen and is confused and restless. Jane's daughter reports that Jane is usually alert and oriented, functions well, and lives alone. The health care provider has not seen Jane. Using SBAR (Situation-Background-Assessment-Recommendation), describe how you will communicate with the on-call physician to effectively address your concerns about Jane's condition.

Answers to questions can be found on the Evolve website.

Professional nursing care requires nurses to interact with members of the nursing team and interdisciplinary health care providers. Effective communication leads to a healthy work environment (Triola, 2006). Communication focuses on team building, facilitating group processes, collaborating, consulting, delegating, supervising, leading, and managing (see Chapter 21). Social, informational, and therapeutic interactions help team members build morale, accomplish goals, and strengthen working relationships. Lateral violence between colleagues sometimes occurs and includes behaviors such as withholding information, backbiting, making snide remarks, and nonverbal expressions of disapproval such as raising eyebrows or making faces. Lateral violence has an adverse effect on the work environment, leading to job dissatisfaction, poor retention of qualified nurses, nurses leaving the profession, and poor teamwork (Sheridan-Leos, 2008). It interferes with effective health care team communication and jeopardizes patient safety (Harter and Moody, 2010). Intimidation decreases the likelihood that a nurse will report a near-miss, question an order, or take action to improve the quality of patient care. There must be zero tolerance of lateral violence. Develop skill in conflict management and assertive communication to stop the spread of lateral violence in the workplace (Patterson, 2007).

Nurse-Community Relationships

Many nurses form relationships with community groups by participating in local organizations, volunteering for community service, or becoming politically active. You need to establish relationships with your community to be an effective change agent (see Chapter 3). Effective health communication requires awareness of language, nonverbal communication, and respect for contextual and cultural influences (Greef et al., 2009). Communication within the community occurs through channels such as neighborhood newsletters, health fairs, public bulletin boards, newspapers, radio, television, and electronic information sites. Use these forms of communication to share information and discuss issues important to community health.

ELEMENTS OF PROFESSIONAL COMMUNICATION

Professional appearance, demeanor, and behavior are important in establishing trustworthiness and competence. They communicate that you have assumed the professional helping role, are clinically skilled, and are focused on your patients. Nothing harms the professional image of nursing like an individual nurse's inappropriate appearance or behavior.

A professional is expected to be clean, neat, well groomed, conservatively dressed, and odor free. Visible tattoos and piercings are not acceptable in the professional setting. Professional behavior reflects warmth, friendliness, confidence, and competence. Professionals speak in a clear, well-modulated voice; use good grammar; listen to others; help and support colleagues; and communicate effectively. Being on time, organized, well prepared, and equipped for the responsibilities of the nursing role also communicate professionalism.

Courtesy

Common courtesy is part of professional communication. To practice courtesy, say hello and goodbye to patients and knock on doors before entering. State your purpose, address people by name, and say "'please" and "thank you" to team members. When a nurse is discourteous, others perceive him or her as rude or insensitive. It sets up barriers between nurse and patient and causes friction among team members.

Use of Names

Always introduce yourself. Failure to give your name and status (e.g., nursing student, registered nurse, or licensed practical nurse) or acknowledge a patient creates uncertainty about the interaction and conveys an impersonal lack of commitment or caring. Making eye contact and smiling recognizes others. Addressing people by

name conveys respect for human dignity and uniqueness. Because using last names is respectful in most cultures, nurses usually use a patient's last name in an initial interaction and then use the first name if the patient requests it. Ask how your patients and co-workers prefer to be addressed and honor their personal preferences. Using first names is appropriate for infants, young children, patients who are confused or unconscious, and close team members. Avoid terms of endearment such as "honey," "dear," "grandma," or "sweetheart." Avoid referring to patients by diagnosis, room number, or other attribute, which is demeaning and sends the message that you do not care enough to know the person as an individual.

Trustworthiness

Trust is relying on someone without doubt or question. Being trustworthy means helping others without hesitation. To foster trust, communicate warmth and demonstrate consistency, reliability, honesty, competence, and respect. Sometimes it isn't easy for a patient to ask for help. Trusting another person involves risk and vulnerability; but it also fosters open, therapeutic communication and enhances the expression of feelings, thoughts, and needs. Without trust a nurse-patient relationship rarely progresses beyond social interaction and superficial care. Avoid dishonesty at all costs. Withholding key information, lying, or distorting the truth violates both legal and ethical standards of practice. Sharing personal information or gossiping about others sends the message that you cannot be trusted and damages interpersonal relationships.

Autonomy and Responsibility

Autonomy is being self-directed and independent in accomplishing goals and advocating for others. Professional nurses make choices and accept responsibility for the outcomes of their actions (Townsend, 2009). They take initiative in problem solving and communicate in a way that reflects the importance and purpose of the therapeutic conversation (Arnold and Boggs, 2011). Professional nurses also recognize a patient's autonomy.

Assertiveness

Assertiveness allows you to express feelings and ideas without judging or hurting others. Assertive behavior includes intermittent eye contact; nonverbal communication that reflects interest, honesty, and active listening; spontaneous verbal responses with a confident voice; and culturally sensitive use of touch and space. An assertive nurse communicates self-assurance; communicates feelings; takes responsibility for choices; and is respectful of others' feelings, ideas, and choices (Stuart, 2009; Townsend, 2009). Assertive behavior increases self-esteem and self-confidence, increases the ability to develop satisfying interpersonal relationships, and increases goal attainment. Assertive individuals make decisions and control their lives more effectively than nonassertive individuals. They deal with criticism and manipulation by others, learn to say no, set limits, and resist intentionally imposed guilt. Assertive responses contain "I" messages such as "I want," "I need," "I think," or "I feel" (Townsend, 2009).

NURSING PROCESS

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. It guides care for patients who need special assistance with communication. Use therapeutic communication techniques as an intervention in an interpersonal nursing situation.

BOX 24-6 ASSESSMENT: FACTORS INFLUENCING COMMUNICATION

Psychophysiological Context

Internal factors influencing communication:

- Physiological status (e.g., pain, hunger, weakness, dyspnea)
- Emotional status (e.g., anxiety, anger, hopelessness, euphoria)
- Growth and development status (e.g., age, developmental tasks)
- Unmet needs (e.g., safety/security, love/belonging)
- Attitudes, values, and beliefs (e.g., meaning of illness experience)
- Perceptions and personality (e.g., optimist/pessimist, introvert/extrovert)
- Self-concept and self-esteem (e.g., positive or negative)

Relational Context

Nature of the relationship among participants:

- Social, helping, or working relationship
- Level of trust among participants
- Level of caring expressed
- Level of self-disclosure among participants
- Shared history of participants
- Balance of power and control

Situational Context

Reason for communication:

- Information exchange
- Goal achievement
- Problem resolution
- Expression of feelings

Environmental Context

Physical surroundings in which communication takes place:

- Privacy level
- Noise level
- Comfort and safety level
- Distraction level

Cultural Context

Sociocultural elements that affect an interaction:

- Educational level of participants
- Language and self-expression patterns
- Customs and expectations

ASSESSMENT

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes. Patient-centered care requires careful assessment of a patient's values, preferences, and cultural, ethnic, and social backgrounds (Cronenwett et al., 2007). Internal and external factors affect a patient's ability to communicate (Box 24-6). Assessing these factors keeps the focus on the patient and helps you make patient-centered decisions during the communication process.

Physical and Emotional Factors. It is especially important to assess the psychophysiological factors that influence communication. Many altered health states and human responses limit

communication. Persons with hearing or visual impairments often have difficulty receiving messages (see Chapter 49). Facial trauma, laryngeal cancer, or endotracheal intubation often prevents movement of air past vocal cords or mobility of the tongue, resulting in inability to articulate words. An extremely breathless person needs to use oxygen to breathe rather than speak. Persons with aphasia after a stroke or in late-stage Alzheimer's disease often cannot understand or form words. Some mental illnesses such as psychoses or depression cause patients to jump from one topic to another, constantly verbalize the same words or phrases, or exhibit a slowed speech pattern. Persons with high anxiety are sometimes unable to perceive environmental stimuli or hear explanations. Finally, patients who are unresponsive or heavily sedated cannot send or respond to verbal messages.

Review of a patient's medical record provides relevant information about his or her ability to communicate. The medical history and physical examination document physical barriers to speech, neurological deficits, and pathophysiology affecting hearing or vision. Reviewing a patient's medication record is also important. For example, opiates, antidepressants, neuroleptics, hypnotics, or sedatives may cause a patient to slur words or use incomplete sentences. The nursing progress notes sometimes reveal other factors that contribute to communication difficulties such as the absence of family members to provide more information about a confused patient.

Assessment includes communicating directly with patients to determine their ability to attend to, interpret, and respond to stimuli. If patients have difficulty communicating, it is important to assess the effect of the problem. Patients who cannot communicate effectively often have difficulty expressing needs and responding appropriately to the environment. Patients who are unable to speak are at risk for injury unless nurses identify an alternate communication method. If barriers exist that make it difficult to communicate directly with patients, family or friends become important sources concerning the patients' communication patterns and abilities.

Developmental Factors. Aspects of a patient's growth and development also influence nurse-patient interaction. For example, an infant's self-expression is limited to crying, body movement, and facial expression; whereas older children express their needs more directly. Adapt communication techniques to the special needs of infants and children. Communicating with children and their parents requires special consideration. Depending on the child's age, include the parents, child, or both as sources of information about the child's health. Giving a young child toys or other distractions allows parents to give you their full attention. Children are especially responsive to nonverbal messages; sudden movements, loud noises, or threatening gestures are frightening. They often prefer to make the first move in interpersonal contacts and do not like adults to stare or look down at them. A child who has received little environmental stimulation possibly is behind in language development, thus making communication more challenging.

Age alone does not determine an adult's capacity for communication. Hearing loss and visual impairments are common changes that occur during aging that contribute to communication barriers (Lubinski, 2010). Communicate with older adults on an adult level and avoid patronizing or speaking in a condescending manner. Simple measures facilitate communication with older individuals who have hearing loss (Box 24-7).

Sociocultural Factors. Culture influences thinking, feeling, behaving, and communicating. Be aware of the typical patterns of interaction that characterize various cultures. For example, European Americans are more open and willing to discuss private family matters; whereas Hispanics, African Americans, and Asian Americans are sometimes reluctant to reveal personal or family information to strangers. Hispanics and Asian Americans value a quiet demeanor and self-restraint; to be open or argumentative reflects negatively on family honor. Native Americans also value silence and are comfortable with it.

Foreign-born persons do not always speak or understand English. Those who speak English as a second language often experience difficulty with self-expression or language comprehension. To practice cultural sensitivity in communication, understand that persons of different cultures use different degrees of eye contact, personal space, gestures, loudness of voice, pace of speech, touch, silence, and meaning of language. Make a conscious effort not to interpret messages through your cultural perspective, but consider the communication within the context of the other individual's background. Avoid stereotyping, patronizing, or making fun of other cultures. Language and cultural barriers are not only frustrating but also dangerous, causing delay in care (Box 24-8).

BOX 24-7 FOCUS ON OLDER ADULTS

Tips for Improved Communication with Older Adults Who Have Hearing Loss

- Make sure the patient knows that you are talking.
- Face the patient, be sure that your face/mouth is visible to him or her, and do not chew gum or talk while chewing.
- Speak clearly but do not exaggerate lip movement or shout.
- Speak a little more slowly but not excessively slow.
- Check for hearing aids and glasses or use of adaptive equipment.
- Choose a quiet, well-lit environment with minimal distractions.
- Allow time for the patient to respond. Do not assume that patient is being uncooperative if he or she does not reply or takes a long time to reply.
- Give the patient a chance to ask questions.
- Keep communication short and to the point. Do not ramble and change subjects (Swann, 2007).

BOX 24-8 CULTURAL ASPECTS OF CARE

Communication with Non–English-Speaking Patients

Patients who speak little or no English present challenges for nurse-patient communication. Federal and state laws require that consumers of health care have access to interpreter services, but these services are costly; thus use is often limited to crucial interactions. Sometimes there is a delay in interpreter services, yet some patients require urgent care. Use of family members, children, or auxiliary personnel poses legal liabilities. Language is not the only barrier. Cultural differences also lead to misunderstanding. Developing cultural competence increases understanding (Regenstein et al., 2009; Cobb, 2010).

Implications for Practice

- Understand your own cultural values and biases.
- Assess the patient's primary language and level of fluency in English.
- Provide an interpreter for the patient and health care providers to communicate with each other.
- Speak directly to the patient even if an interpreter is present.
- Nodding or statements such as "OK" do not necessarily mean that the patient understands.
- Provide written information in English and primary language.
- Learn about other cultures, especially those commonly encountered in your work area.

Gender. Gender is another factor influencing how we think, act, feel, and communicate. Men tend to use less verbal communication but are more likely to initiate communication and address issues more directly. They are also more likely to talk about issues. Women tend to disclose more personal information and use more active listening, answering with responses that encourage the other person to continue the conversation. It is important for you to recognize a patient's gender communication pattern. Being insensitive blocks therapeutic nurse-patient relationships. Newer research questions the differences between male and female communication patterns (Arnold and Boggs, 2011). Assess communication patterns of each individual and do not make assumptions simply based on gender.

NURSING DIAGNOSIS

Most individuals experience difficulty with some aspect of communication. Patients sometimes lack skills in attending, listening, responding, and self-expression as a result of illness or the effects of treatment. You will use creative communication techniques with individuals who experience more serious impairments in communication.
